Interestingly, this is very close to the relative fuel consumption reduction that the National Academies found (25.25%) in their recent study (“Assessment of Fuel Economy Technologies for Light-Duty Vehicles.” Committee on the Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy, Board on Energy and Environmental Systems Division on Engineering and Physical Sciences, National Research Council of the National Academies, Table 5.A.1). [NHTSA-2010-0131-0213-A1, p.2]

National Academies also conclude in this report...

'...An important characteristic of CI diesel engines is that they provide reductions in fuel consumption over the entire vehicle operating range, including city driving, highway driving, hill climbing, and towing. This attribute of CI diesel engines is an advantage when compared with other technology options that in most cases provide fuel consumption benefits for only part of the vehicle operating range....' (Finding 5.3) [NHTSA-2010-0131-0213-A1, pp.2-3]

This conclusion is generally supported by a study conducted by Motor Trend Magazine in 2007 (http://www.motortrend.com/features/112_0705_alternative_fuel_technology/viewall.html), which showed that, based on its results, the diesel technology vehicle (a Mercedes-Benz E320 Bluetec) was the most fuel efficient ('work efficient') of the technologies it studied (gas-electric hybrid technology represented by a Toyota Camry Hybrid, 'E85' technology represented by a

Chrysler Sebring, and turbo-GDI technology represented by a VW Passat 2.0T), and was very close to the Camry Hybrid in 'carbon efficiency'. [NHTSA-2010-0131-0213-A1, p.3]

It should be noted that the fuel consumption gap between the European-spec BMW 535d and 535i has actually widened (from 27.4% to 28.9% for the 2012 model). On top of that, the performance gap between the 535d and 535i has increased to 0.4 seconds (0-100 km/hr) in favor of the diesel (5.5 sec vs. 5.9 sec) from 0.2 seconds (5.9 sec vs. 6.1 sec) from the previous versions, according to the manufacturer's data (http://www.bmw.co.uk/bmwuk/pricesandspecifications/0,,1156___bs-NQ%3D%3D%40bb-TEkxMA%3D%3D%40sit-bmwuk,00.html). The BMW GDI technology was specifically identified in the Draft Joint Technical Support Document supporting this proposed rule as already having advanced turbo-GDI technology (Section 3.4.1.5, Variable Valve Lift (VVL), page 3-80). [NHTSA-2010-0131-0213-A1, p.3]

It is interesting to note that the BMW 535d has lower fuel consumption (and CO_2 emissions) than the BMW 5-Series hybrid ('ActiveHybrid 5') in the combined European test cycle (NEDC), in addition to significantly better 0-100 km/hr performance based on the preceding BMW link. This, in addition to the two examples in the U.S. of diesel and hybrid technology available in the same vehicle (Mercedes-Benz S350 Bluetec/S400 Hybrid and VW Touareg TDI/Hybrid) in which the diesel versions have better fuel economy than the hybrid versions in the EPA 5-cycle, suggests that the assumption that hybrid technology is a more fuel efficient technology than diesel technology is not unequivocal. [NHTSA-2010-0131-0213-A1, p.3]

According to specification data provided in a BMW publication ('BMW Technology Day 2009 - EfficientDynamics'), the minimum brake specific fuel consumption (BSFC) of the BMW 3.0 liter, 225 kW 'TwinPower' turbo-GDI engine is 245 g/kWh, while the minimum BSFC of the previous version of the 3.0 liter, 225 kW 'TwinPower' diesel engine was 197 g/kWh (pages 28 and 34, respectively). That would equate to an efficiency gap of at least 24.3% (and gasoline contains slightly more energy per unit mass than diesel fuel according to Argonne National Laboratory's GREET model), and that efficiency advantage has apparently widened even more for the 2012, 230 kW version of the BMW 'TwinPower' diesel engine. According to the referenced spec data, the 'TwinPower' turbo-GDI gasoline engine incorporates many advanced GDI engine technologies, e.g., 'jet guided' high precision injectors, 200 bar injection pressure, variable intake valve lift adjustment ('VALVETRONIC') and infinite intake and outlet camshaft adjustment ('dual-VANOS'), and 'twin-scroll' turbocharger technology. [NHTSA-2010-0131-0213-A1, p.3]

One Automotive Industry (AID) executive describes the fuel efficiency of gasoline engines as having improved by 3.5 percent over the past few years as a result of a shift to turbo-GDI technology, but the fuel efficiency of diesel engine technology has improved by 7 percent over the same time frame (http://www.wintonsworld.com/cars/carnews/carnews-2011/Diesels-Poised.html). He also points out that turbo gasoline cars are 'remarkably thirsty' in the real world and generally do not meet their claimed fuel economy levels. [NHTSA-2010-0131-0213-A1, p.4]

Bosch has projected that the efficiency of diesel engine technology will increase even more than gasoline engine technology (Climate and Transportation Solutions: Findings from the 2009

Asilomar Conference on Transportation and Energy Policy, Chapter 10: 'The Case for Diesel Cars To Reduce Greenhouse Gas Emissions.' by Johannes-Joerg Rueger; 'The internal-combustion engine of the future: Excellent economy and high power despite smaller size.' Dr. Rolf Leonhard, Executive Vice President Engineering, Diesel Systems, Presentation at the 59th International Automotive Press Briefing, Boxberg, June 2009). This appears reasonable since FEV has identified the potential for extremely high power density for diesel technology (>100 kW/liter - http://www.greencarcongress.com/2011/04/fev-20100405.html#more) which may allow as aggressive of downsizing as is assumed for advanced turbo-GDI in the proposed rule. [NHTSA-2010-0131-0213-A1, p.4]

Whether advanced turbo-GDI technology can close the fuel consumption gap on advanced diesel technology as much as estimated in the proposed rule seems very optimistic and speculative. Furthermore, if diesel technology is capable of improving as much as Bosch estimates, it will rival the other technologies considered in terms of fuel economy, especially if combined with hybrid technology. [NHTSA-2010-0131-0213-A1, p.4]

EPA officials have reportedly stated that a diesel penetration of just 33% could reduce U.S. fuel consumption enough to eliminate the need to import the amount of crude oil currently imported from Saudi Arabia (http://www.businessweek.com/magazine/content/06_08/b3972138.htm). This penetration appears possible based on recent U.S. sales data showing that diesel 'take rates' are 39% in vehicles which offer diesel engines in addition to conventional gasoline engines, while hybrid vehicles have a 'take rate' of only about 5% in vehicles in which hybrid technology is offered in addition to conventional gasoline engines (http://www.cleandieseldelivers.com/upload/CleanDieselDelivers_White_Paper.pdf - page 13). In the few vehicles in the U.S. that are currently offered with all three of these technologies (gasoline, diesel and hybrid technology - the Mercedes-Benz S-class and the VW Touareg SUV), the diesel versions are easily outselling the hybrid versions (http://www.hybridcars.com/news/december-2011-dashboard-sales-still-climbing-35093.html) and in the case of the Touareg, the diesel model has recently been outselling the hybrid and gasoline versions combined. It should be noted that this sales mix occurred in a month (December 2011) in which the price gap between regular gasoline and diesel fuel increased to over $0.50/gallon (national average per EIA). [NHTSA-2010-0131-0213-A1, p.4]

Many alternate diesel fuels ('synthetic' diesel fuels) are nearly carbon neutral when produced from biomass. According to Argonne National Laboratory's latest version of the GREET model released in October 2011 (GREET1_2011 - http://greet.es.anl.gov/), dimethyl ether (DME) produced from biomass would generate about 11 grams/mile well-to-wheel (WTW) net GHG emissions in the default diesel vehicle assumed in GREET, compared to 451 g/mi for the baseline gasoline vehicle, 333 g/mi for an equivalent electric vehicle (EV) based on the assumed U.S. electricity mix in GREET, and 253 g/mi for a fuel cell vehicle (FCV) using gaseous hydrogen. Renewable diesel fuel produced from biomass using the Fischer-Tropsch process (BTL) is not far behind DME at about 36 g/mi net WTW GHG emissions. BTL renewable diesel fuel is a direct 'drop-in' replacement for petroleum diesel fuel, is infinitely miscible with petroleum diesel fuel, and precludes the need to adopt an entirely new fuel distribution system. Even the diesel vehicle using first-generation biodiesel (B20) produced from virgin soybean oil generates lower net WTW GHG emissions than EV per GREET (~329 g/mi). [NHTSA-2010-0131-0213-A1, p.5]

California also has identified biodiesel from 'Conversion of corn oil, extracted from distillers grains prior to the drying process, to biodiesel' as having the lowest 'carbon intensity' of all of the fuel pathways it has identified in its latest 'carbon intensity lookup table', much lower than either the assumed electricity mix in California or any of the hydrogen fuels. This implies that the WTW GHG emissions from this source of biodiesel would be significantly lower than EV/PHEV/FCV, even taking the much higher 'fuel mileage' of those technologies into account. [NHTSA-2010-0131-0213-A1, p.6]

GREET1_2011 shows that for most fuel pathways identified in GREET, WTW emissions of criteria pollutants are generally lower for diesel technology/diesel fuel pathways than other vehicle technology/fuel pathways, through at least 2020. Furthermore, GREET1_2011 projects that DME produced from biomass produces the best overall well-to-wheels energy efficiency (of the biomass-based fuels - D. Kittelson et al, “Performance and Emissions of a Second Generation Biofuel – DME.” (2010), http://www.me.umn.edu/centers/cdr/reports/E3_Kittelson.pdf), petroleum and fossil fuel consumption reductions, GHG emission reductions, and arguably the greatest across-the-board criteria pollutant emission reductions of any other combination of fuel pathways and vehicle technologies identified in GREET through at least 2020, including any of the 'advanced vehicle technologies' identified in the proposed rule as receiving special incentives. Again, BTL is very close to DME with respect to aforementioned reductions. Diesel engine technologies will be required to take advantage of these advanced biofuels, and should be encouraged to the greatest extent possible. [NHTSA-2010-0131-0213-A1, p.6]

Diesel vehicles have substantially lower hydrocarbon emissions than gasoline vehicles, both directly and indirectly. EPA has mentioned in previous reports that diesel technology has '...near-zero evaporative hydrocarbon emissions due to the extremely low vapor pressure of diesel fuel....' (e.g., 'Progress Report on Clean and Efficient Automotive Technologies Under Development at EPA - Interim Technical Report.' January 2004, page 19). This appears to be a very important characteristic in light of the DOE/NREL 'weekend ozone effect' studies which suggest that hydrocarbon emissions are a more important factor in the accumulation of ground-level ozone than NO_x emissions in urban locations. Many studies (e.g., Eric Fujita et al, 'Weekend/Weekday Ozone Study in the South Coast Air Basin.' Proceedings of the 2002 DEER Conference; John G. Watson et al, “Review of volatile organic compound source apportionment by chemical mass balance.” Atmospheric Environment, Volume 35, Issue 9, March 2001, Pages 1567-1584; Heidi Hellén et al, “Determination of source contributions of NMHCs in Helsinki (60°N, 25°E) using chemical mass balance and the Unmix multivariate receptor models.” Atmospheric Environment, Volume 37, Issue 11, April 2003, Pages 1413-1424; Steven G. Brown et al, “Source apportionment of VOCs in the Los Angeles area using positive matrix factorization.” Atmospheric Environment, Volume 41, Issue 2, January 2007, Pages 227-237) have shown that gasoline exhaust and evaporative emissions from gasoline fuel (with evaporative emissions being implicated as an increasingly more important source in latter studies) account for a majority of hydrocarbon emissions in metropolitan areas where ground-level ozone is most problematic. Diesel technology along with EV and FCV technology could have a dramatic impact on improving air quality in metropolitan areas. [NHTSA-2010-0131-0213-A1, p.6]

Associated with this property of gasoline (relatively high evaporation rate) is the utter waste of a very valuable resource (petroleum) through evaporation, which would be mitigated by at least a partial switch of the U.S. light-duty fleet to diesel technology. Based on Table 4-12 (page 4-42) of the Draft Joint Technical Support Document supporting this proposed rule, 'Conventional Gasoline' produces about 5.70 grams of VOC per gallon well-to-pump (WTP), while 'Low Sulfur Diesel' produces about 0.95 grams of VOC per gallon WTP, using the GREET default BTU/gallon values for gasoline and low sulfur diesel fuel. According to EIA (http://www.eia.gov/energyexplained/index.cfm?page=oil_home#tab2), 378 million gallons/day of gasoline are consumer in the U.S. Assuming most of this consumption is by motor vehicles, that's about 138,000,000,000 gallons of gasoline consumed by the U.S. vehicle fleet per year. 138,000,000,000 gallons X 5.70 g/gal = 867,063 tons of VOC WTP per year from the fuel gasoline. Switching just 33% of the light-duty vehicles in the U.S. to diesel could reduce WTP VOC emissions to (0.67 X 138,000,000,000 gallons X 5.70 g/gal) + (0.33 X 138,000,000,000 gallons X 0.95 g/gal) = 628,621 tons. 867,063 tons - 628,621 tons = 238,442 tons or almost 80,000,000 gallons of gasoline not evaporated as VOC. This does not take into account the typically much lower fuel consumption of diesel vehicles, so assuming gasoline-hybrid technology and diesel technology achieve roughly the same fuel economy on average in the real world, as has been addressed previously, 80,000,000 gallons of gasoline/year would not only not be wasted, but would not contribute to ozone formation in VOC-limited areas, even in the case of gasoline-hybrid technology vehicles, for which special incentives are being proposed in this proposed rule. This also does not take into account the demonstrably higher VOC emissions of gasoline vehicles during vehicle refueling, diurnal + hot soak, and running loss. [NHTSA-2010-0131-0213-A1, p.7]

If the goal of the proposed rule is to increase fuel economy and reduce greenhouse gas emissions (and not increase emissions of some criteria pollutants in the process), diesel technology is a more effective strategy than GDI, and as potentially 'game-changing' a technology as gasoline-hybrid, and even EV, PHEV and FCV technology, possibly even more so in some cases. There is no logical reason that diesel technology shouldn't be afforded the same consideration as any other of the 'advanced technologies'. Preferably, no artificial incentives should be given to any of the technologies considered and all should just stand on their own merits. I urge EPA/NHTSA to reconsider the special incentives proposed for EV/PHEV/FCV/gasoline-hybrids, or at least put diesel technology on a level playing field with these technologies. [NHTSA-2010-0131-0213-A1, p.9]

As a disclaimer, I am in no way associated with the auto industry or any support industries to the auto industry, including diesel engine manufacturers. [NHTSA-2010-0131-0213-A1, p.9]

Organization: Plant Oil Powered Diesel Fuel Systems, Inc.

2. The Proposed GHG Standards are arbitrary and capricious because their exclusive consideration of tailpipe GHG emissions fails to take into account the relative life cycle contribution to GHG emissions of various engine technologies and the energy sources that make them run. The analysis of the wells-to-wheels energy inputs associated with various technologies and fuels set forth herein demonstrates that the Proposed Regulations' apportionment of GHG credits to various technologies and fuels is irrational because it considers only tailpipe emissions. [EPA-HQ-OAR-2010-0799-10337-A2, p. 2]

c. re-do the weight the Agencies give to various alternative technologies and fuels according to a wells-to-wheels approach that corresponds more accurately with their relative contribution to and mitigation of atmospheric greenhouse gas accumulation; [EPA-HQ-OAR-2010-0799-10337-A2, pp. 2-3]

Although the Renewable Fuel Standard provides incentives for the use of fuels covered by it, such as biodiesel, which may have a lower life cycle emissions of carbon than petroleum, such as biodiesel, pure plant oil is not eligible for the RFS. Therefore, the Proposed Regulations do not provide any incentive for the use of 100 percent plant oil or an engine specially equipped to run on this fuel. [EPA-HQ-OAR-2010-0799-10337-A2, p. 6]

In considering only tailpipe emissions, rather than the full life cycle GHG emissions of a technology and fuel that would result from a wells-to-wheels analysis, the Proposed Regulations arbitrarily favor and disfavor some alternatives over others. The net effect is that the Proposed Regulations are not rationally related to their purpose of reducing or slowing global warming. Following is factual analysis of the wells-to-wheels attributes of the relevant alternative technologies and fuels, pointing to the idiosyncratic and counter-productive values that the Proposed Regulations assign to them insofar as they mitigate GHG emissions. [EPA-HQ-OAR-2010-0799-10337-A2, p. 6]

Organization: U.S. Coalition for Advanced Diesel Cars

A national policy that favors specific technologies will prevent America from achieving dramatic petroleum reduction in the near- and medium-term. By favoring leap-ahead technologies that will not see significant market penetration even by the end of this proposed rule's term, the Administration is choosing a revolutionary path based on assumptions and uncertainties instead of an evolutionary path that will achieve similarly dramatic petroleum and emission reductions TODAY at a comparatively minimal cost to the consumer and avoid tremendous infrastructure costs. [NHTSA-2010-0131-0246-A1, p.1]

Focusing on Fuel Savings, Not Market Challenges: The NPRM goes on to state that diesel engines are not "advanced technology" per se" (FR 25454). In reality, diesel is the number one selling advanced CO_2 reduction technology sold in the world and is responsible for billions of gallons saved annually. Diesel technology combines high consumer acceptance – both in the United States and abroad - high residual values, high demand among used vehicle buyers and real-world fuel saving performance that is aligned with consumer expectations. [NHTSA-2010-0131-0246-A1, p.6]

In 2006, EPA confirmed the benefit of clean diesel vehicles when it stated that if 33% of America's vehicles were diesel-powered cars, the nation's fuel savings would be equal to the amount of fuel America imports from Saudi Arabia. Yet, the NPRM's analysis and commentary discount the role clean diesel vehicles are already playing to reduce national emissions and fuel consumption. [NHTSA-2010-0131-0246-A1, pp.6-7]

CAFE credits offered in the NPRM will bring some of these future technologies to market, but will not meet the Administration's expectations in changing the American vehicle fleet for several decades. [NHTSA-2010-0131-0246-A1, p.14]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 238-239.]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 240.]

To ensure that we spur not only innovation but broad innovation that will include multiple technology paths, public policies, regulations and incentive plans must be technology neutral. Government should set the goals, even aggressive goals, that inspire the freedom to innovate, and then get out of the way. State, federal and public officials and regulators must resist the temptation to pick winners and losers; to let politics and fads enter the debate or to engage in centralized planning in a highly complex industry.

Organization: Volkswagen Group of America

Volkswagen anticipates that some stakeholders will propose to include hybridization technologies as applied to all vehicles. Building upon this, Volkswagen proposes that the agencies adopt the following:

- Credits for deployment of advanced technology compression ignition engines as applied to both passenger cars and light duty trucks

- Credits for vehicles capable of operating on advance bio-fuels such as B20 (Biodiesel)

- Credits to promote combinations of expensive high-investment technologies such as electrification of vehicles incorporating advanced compression ignition or bio-fuel capable engines

Many technologies which deserve crediting may serve as 'bridging technologies' capable of providing near- and mid-term CO_2 reductions until such time as technologies and market demand for other more effective concepts mature. [EPA-HQ-OAR-2010-0799-9569-A1, p. 28]

Response:

EPA OMEGA Model does not project significant diesel market penetration

Comments from BMW and Loren Marz suggest that EPA's OMEGA model was pessimistic in its projections of diesel market penetration and that this is inconsistent with increasing consumer acceptance and market share for diesel vehicles. EPA emphasizes that the OMEGA model is designed to project the most cost effective way, not to mandate a compliance pathway, for automakers to meet the EPA GHG emissions standards. It is not designed to account for all of the complex elements that, in the aggregate, will determine future market share for any individual technology, whether conventional gasoline vehicles, electric vehicles, or diesel vehicles. Manufacturers remain free to choose any means of compliance, which of course includes use of diesel vehicles. For more discussion of diesel technology issues, see Section 12.2.

No incentive multiplier for diesel vehicles

Volkswagen, the U.S. Coalition for Advanced Diesel Cars, and Loren Marz suggested that diesel vehicles be provided the same incentives as EV/PHEV/FCV/CNG vehicles, such as the incentive multipliers. EPA believes it is not appropriate to adopt incentive multipliers in this rule for manufacturers of diesel vehicles. One, diesel technology is not a vehicle GHG emissions game-changer—the tailpipe GHG emissions of diesel vehicles are typically 10-20% lower than GHG emissions from conventional vehicles (of course, those lower values would be accounted for in EPA compliance calculations), while EV/PHEV/FCVs all have the potential for much larger game-changing GHG emissions reductions. Two, diesel vehicles do not face the same consumer barriers as EV/PHEV/FCV/CNG vehicles—diesel technology has been in the market for a long time, diesel fuel is available at a large number of fueling stations, and diesel vehicle range is higher than that of gasoline vehicles.

The related comments regarding technology neutrality and "government picking winners and losers" are addressed in Section 4.

No accounting of potential upstream GHG emissions benefits due to biodiesel (B20)

Volkswagen and Loren Marz suggested that credits should be available for vehicles that can operate on biodiesel blends, such as B20, since the biofuel portion of B20 has the potential to yield large lifecycle GHG emissions benefits due to the CO_2 uptake during plant growth. Likewise, Plant Oil Powered (POP) Diesel Fuel Systems criticized the proposal for considering only tailpipe GHG emissions and not accounting for lifecycle GHG emissions. The use of biofuels with lower lifecycle GHG emissions is already required under the Renewable Fuel Standard (RFS) program, which has been in place since 2006 and is designed to achieve GHG emissions benefits through the required use of renewable transportation fuels that have better lifecycle GHG emissions performance than the gasoline or diesel fuel that they displace. EPA has already quantified the GHG emissions benefits associated with the RFS program. Providing an additional incentive in the MYs 2017-2025 GHG program, which is focused on vehicle tailpipe emissions and not lifecycle emissions, would not achieve any greater use of renewable fuels than is already required under the RFS program, and thus would not achieve any greater emissions reductions from the use of such fuel. Thus, providing an additional incentive would reduce the emissions benefits of the MYs 2017-2025 light-duty vehicle GHG emissions program. Given that biofuel fuel use is already required by and accounted for under the RFS program, it therefore would be inappropriate to provide additional incentives in the MYs 2017-2025 program.

Finally, as noted in earlier responses, although the plant oil-based fuel produced by POP Diesel Fuel Systems is not currently identified as an acceptable renewable fuel under the RFS program, EPA is currently considering the company's petition seeking approval of its product under the RFS program. The RFS program established by Congress is the appropriate mechanism for evaluating the full lifecycle emissions impact of this type of biofuel use, rather than a program focused principally on vehicle tailpipe emissions.

6.5. Comments Regarding Other Alternative Fuels

Organizations Included in this Section

Alliance of Automobile Manufacturers
Association of Global Automakers, Inc. (Global Automakers)
Environmental Consultants of Michigan
Ford Motor Company
Manufacturers of Emission Controls Association (MECA)
Plant Oil Powered Diesel Fuel Systems, Inc.
St. Clair-Detroit River Sturgeon for Tomorrow

Organization: Alliance of Automobile Manufacturers

Credits for Other Alternative Fuel Vehicles [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

In the effort to continue the development of advanced technology vehicles, the Alliance would like to show support of the following technologies, which will help drive our country down the road toward energy independence. [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

Dual-Fuel CNG and LPG Gasoline Vehicles [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

CNG and LPG vehicles are another option that our country has to diversify the vehicle fleet and use a domestically available energy source. The Alliance supports the development of a utility factor approach very similar to the SAE standard mentioned above for PHEVs. The Alliance is also in favor of the option to allow manufacturers to use the proposed utility factor-based methodology as a "pull-ahead" option for MYs 2012-2015. [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

Based on the added cost of the vehicle technology and the cost advantage of using CNG and LPG fuel relative to gasoline, customers that purchase a dual-fuel CNG or LPG vehicle will, to the extent possible, use the intended alternative fuel. [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

Many companies may leverage global designs in developing dual-fuel CNG and LPG vehicles for the U.S. market. It is important that the variety of global design features available be allowed into the U.S. market. Rather than making specific design requirements in the rules, a better approach would be have these design features be factors in the calculation of the CNG and LPG utility factors. The Alliance would like to propose a work group to discuss the constraints mentioned in the NPRM for dual-fuel CNG and LPG vehicles. [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

In the NPRM, EPA specifically requested comments on the merits of providing sales multiplier (similar to the EV/PHEV incentives) for dedicated and/or dual-fuel compressed natural gas vehicles. The Alliance believes CNG and LPG technology also deserve multipliers. [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

The Alliance also supports EPA's proposal to continue use of the 0.15 divisor for gaseous and liquid alternative fuels and the petroleum equivalency factor for electricity. As noted by the Agencies, this approach will maintain consistency between dedicated and dual fuel vehicle calculations and will continue to encourage manufacturers to build vehicles capable of operating on fuels other than petroleum. [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

Organization: Association of Global Automakers, Inc. (Global Automakers)

Furthermore, Global Automakers supports the extension of multiplier incentives to other alternative fuels as well, such as liquid petroleum gas (LPG) or biodiesel. With regard to dual fueled vehicles in general, we urge the agencies to reconsider the treatment of these vehicles as part of the planned mid-term review of the standards, at which point the need for particular incentives would be clearer. Whatever approach is adopted, we urge that EPA and NHTSA agree on a single, harmonized set of incentives. [EPA-HQ-OAR-2010-0799-9466-A1, p. 7]

Organization: Environmental Consultants of Michigan

The Department of Energy lifecycle model demonstrates that switching to a renewable fuel using the Fischer-Thropsch process can achieve carbon neutrality without any change to the vehicle fleet. The Fischer-Thropsch 8 process has been used around the world since the 1920s to produce a very high quality diesel that can be used in existing vehicles. It can also be used to produce a high quality gasoline. The technology exists to produce fuels profitably at any crude oil price in excess of $17 per barrel of crude oil. This leaves sufficient room for a profitable switch to a renewable feedstock at today's oil prices. [NHTSA-2010-0131-0166-A1, p. 4]

---

8 This is not an ethanol fuel but a true, high quality gasoline and diesel product

Organization: Ford Motor Company

EPA further requested comment on the merits of providing similar multipliers for dedicated and/or dual fuel compressed natural gas vehicles. Ford supports providing multipliers for natural gas fueled vehicle, and further requests that the same multiplier be provided for dedicated and/or dual fuel liquefied petroleum gas vehicles. Both gaseous fuels provide substantial reductions in greenhouse gas emissions, as well as support the diversification of our energy supply, providing greater energy security. However, the vehicle technologies required to allow operation on these fuels is expensive, and the market availability of the fuel, similar to the availability of public charging stations for electric vehicles, remains very limited. Therefore, we believe that the multiplier is appropriate to encourage the investment in these technologies for broader new vehicles applications, and drive the volumes that will encourage greater investment in the necessary re-fueling infrastructure. We further recommend that the credit values for dedicated and bi-fuel gaseous vehicles be aligned with those provided for dedicated and bi-fuel electricity fueled vehicles. [EPA-HQ-OAR-2010-0799-9463-A1, p. 18]

Organization: Manufacturers of Emission Controls Association (MECA)

Emission controls for gasoline and diesel engines are also generally compatible with low carbon, alternative fuels (e.g., gasoline blends with renewable ethanol or biodiesel blends) that can provide additional reductions in mobile source greenhouse gas emissions. Engine operating strategies and emission control catalyst formulations, however, often need to be optimized depending on fuel composition to ensure that criteria pollutant emission standards are met. It is also important that specifications associated with any low carbon fuel should be compatible with the use of available exhaust emission control technologies. [EPA-HQ-OAR-2010-0799-9452-A3, p.3]

Organization: Plant Oil Powered Diesel Fuel Systems, Inc.

3. The Proposed GHG Standards are both inconsistent with law and arbitrary and capricious because they, and other EPA Regulations they incorporate by reference, fail to take into account in any respect the feasibility of equipping light duty engines to operate on 100 percent untransesterified plant oil. If EPA took such feasibility into account, an effective way to regulate GHG emissions would be to impose strict manufacturer GHG emissions averages that are independent of the corporate average fuel economy standards already in place for light duty vehicles. [EPA-HQ-OAR-2010-0799-10337-A2, p. 2]

d. recognize 100 percent plant oil as a viable renewable diesel engine fuel eligible to receive Renewable Identification Number (“RIN”) credits under the Renewable Fuels 2 standard (“RFS 2”);

e. grant POP DieselTM’s application, submitted separately, for a RIN pathway for 100 percent plant oil fuel; and [EPA-HQ-OAR-2010-0799-10337-A2, p. 3]

f. impose strict corporate fleet averages for GHG emissions on all classes of manufacturers as the most effective way to ramp down such emissions across the light duty market. [EPA-HQ-OAR-2010-0799-10337-A2, p. 3]

As set forth below, the Proposed Regulations’ treatment of the alternatives to fossil fuel petroleum in light duty vehicles will not have the effect of mitigating greenhouse gasses. As a result, even if the Proposed Regulations took into account the full scope of the rebound effect arising from reliance on improvements in fuel economy, which they do not do, they fail to establish a framework of incentives to "slow or reduce" Global Warming. Massachusetts v. EPA, 549 U.S. at 525, 127 S. Ct. at 1457. [EPA-HQ-OAR-2010-0799-10337-A2, p. 5]

Although the Renewable Fuel Standard provides incentives for the use of fuels covered by it, such as biodiesel, which may have a lower life cycle emissions of carbon than petroleum, such as biodiesel, pure plant oil is not eligible for the RFS. Therefore, the Proposed Regulations do not provide any incentive for the use of 100 percent plant oil or an engine specially equipped to run on this fuel. [EPA-HQ-OAR-2010-0799-10337-A2, p. 6]

In considering only tailpipe emissions, rather than the full life cycle GHG emissions of a technology and fuel that would result from a wells-to-wheels analysis, the Proposed Regulations arbitrarily favor and disfavor some alternatives over others. The net effect is that the Proposed Regulations are not rationally related to their purpose of reducing or slowing global warming. Following is factual analysis of the wells-to-wheels attributes of the relevant alternative technologies and fuels, pointing to the idiosyncratic and counter-productive values that the Proposed Regulations assign to them insofar as they mitigate GHG emissions. [EPA-HQ-OAR-2010-0799-10337-A2, p. 6]

E Biodiesel

The International Council on Clean Transportation ("ICCT") has determined that based on reliable analyses of the carbon intensity involved in manufacturing biodiesel, "replacing fossil diesel with biodiesel would not help to mitigate climate change, unless biodiesel could be produced entirely from wastes with no other use, crops grown on low value land [,] or some other policy could be put in place to substantially improve performance on emissions." ICCT Briefing: Biodiesel Carbon Intensity, Sustainability and Effects on Vehicles and Emissions (2012), at 5 ("ICCT Briefing") (Exhibit 5). The following ICCT chart depicting Biodiesel Total Emissions shows that the life cycle emissions of biodiesel derived from the most common triglyceride feedstocks are higher than they are for fossil fuel petroleum. [See chart on p. 11 of Docket number EPA-HQ-OAR-2010-0799-10337-A2] [EPA-HQ-OAR-2010-0799-10337-A2, p. 10]

Source: ICCT Briefing, at 5 (Exhibit 5).

High level officials in the diesel engine and petroleum industries agree that the manufacture of 100 percent plant oil fuel requires less energy input than biodiesel. Deposition testimony of the organizational representative of the Engine Manufacturers Association, Roger Gault (Exhibit 7) ("EMA by Gault testimony"), at 170, lines 12-16) ("[T[here's a relative cost between raw vegetable oil and biodiesel where biodiesel will by its nature be more expensive than raw vegetable oil because the raw vegetable oil is a component of the biodiesel that's produced"); declaration of Andrew L. Pickard, Ph.D., P. Chem. ("Pickard decl."), para. 3.6 (Exhibit 9)("An obvious advantage of using triglycerides (such as 'raw' vegetable oil) directly as fuel for diesel engines is that no energy is spent to convert the 'raw' feedstock into an alternative fuel such as biodiesel, and there are no by-products or waste products for disposal"). [EPA-HQ-OAR-2010-0799-10337-A2, p. 11]

The means to avoid the counter-productive carbon intensity of manufacturing biodiesel is to leave the triglyceride feedstock as Nature made it, 100 percent plant oil, and to run it through a diesel engine that is properly equipped to handle it. The only way that GHG Proposed Regulations for mobile sources will slow or reduce Global Warming is if they take into account the wells-to-wheels carbon intensity of all of the alternatives and reward or penalize them accordingly. Since the Proposed Regulations, instead, expressly reward technologies and fuels on the basis only of tailpipe emissions and they rely on other irrational assumptions, they fail accomplish the underlying objective. They are, therefore, arbitrary and capricious. [EPA-HQ-OAR-2010-0799-10337-A2, p. 12]

F. 100 Percent Plant Oil

The POP Diesel Fuel SystemTM, patented in 2011, may be installed after-market on any diesel engine to permit it to operate on 100 percent untransesterified plant oil. The engine starts and shuts down on No. 2 diesel drawn from the original tank, but in the interim, it runs on 100 percent plant oil coming from the auxiliary tank. This approach safeguards engine performance and preserves the cleanliness of the crankcase oil, obviating the need for any alteration to service intervals, other than monitoring of the plant oil fuel filter. The plant oil fuel is heated prior to injection to reduce its viscosity and better assure a finely atomized spray pattern and clean and efficient burn. [EPA-HQ-OAR-2010-0799-10337-A2, p. 12]

Aftertreatment equipment may even function better on plant oil fuel than No. 2 diesel, if biodiesel is any indication. A. William, S. Black, and R.L. McCormick, “Biodiesel Fuel Property Effects on Particulate Matter Reactivity,” DOE, National Renewable Energy Laboratory (“NREL”) (biofuel enhances diesel particulate filter function). [EPA-HQ-OAR-2010-0799-10337-A2, pp. 12-13]

POP DieselTM’s experience in installing its equipment on thirty experimental diesel engines of all stripes and sizes demonstrates that this solution can work on any engine. The feasibility of POP DieselTM’s basic plant oil technology is proven. Rudolph Diesel himself observed in 2012:

The use of vegetable oils for engine fuels may seem insignificant today. But such oils may become in course of time as important as the petroleum and the coal tar products of the present time. [EPA-HQ-OAR-2010-0799-10337-A2, p. 13]

A.K. Babu and G. Devaradjane, “Vegetable Oils and Their Derivatives as Fuels for CI Engines: An Overview, section 2, SAE 2003-01-0767 (Exhibit 8), at 0605. [EPA-HQ-OAR-2010-0799-10337-A2, p. 13]

1. Exclusion of Untransesterified Plant Oil from Eligibility for the RFS 2

Because the RFS does not apply to untransesterified plant oil fuel, POP DieselTM cannot formally petition for a pathway that would entitle its fuel to a RIN and to earn GHG-reducing, RIN credits. Therefore, the Proposed Regulations do not afford POP DieselTM the RIN credits benefit they contemplate for other biofuels that do qualify for the RFS and RFS 2. In this regard, the Proposed Regulations are arbitrary and capricious. POP DieselTM’s separate application for a RIN contains the life cycle information necessary for EPA to designate a pathway under RFS 2. [EPA-HQ-OAR-2010-0799-10337-A2, p. 13]

2. Institutional Barriers to Introduction of Plant Oil Fuel [EPA-HQ-OAR-2010-0799-10337-A2, p. 13]

Any plant oil consisting of triglycerides will work in a diesel engine equipped by POP DieselTM. Just as, depending on source, there are a variety of crude petroleum oils, there are a variety of plant oils that each have slightly different physical properties. “There is no question that” all of these plant oils are capable of powering a diesel engine. Sam Jones, and Charles Peterson, “Using Unmodified Vegetable Oils as a Diesel Fuel Extender,” U. Of Idaho (Exhibit 8, documents 0571 -0578). All of them will deliver undiminished engine performance and emissions comparable to No. 2 diesel in any diesel engine equipped by POP DieselTM. [EPA-HQ-OAR-2010-0799-10337-A2, pp. 13-14]

However, imprudent or illogical development of a standard for triglyceride fuel might unreasonably restrict the scope of feedstock qualifying for plant oil fuel. For this reason, POP DieselTM has opposed adoption of the first triglyceride standard specification by ASTM International, to govern this fuel’s use in commercial and industrial burners. An exposition of the unreasonable and unjustified barriers this standard erects to the use of triglyceride fuel in the diesel fuel market is beyond the scope of this petition. An antitrust lawsuit filed by POP DieselTM has, thus far, prevented ASTM from publishing this standard, which event would automatically make it, by law, the quality standard for triglyceride burner fuel in most states. Plant Oil Powered Diesel Fuel Systems, Inc. v. ExxonMobil, et al. (D.N.M. No. 1:11-cv-00103-JB-LFG) (filed Feb. 1, 2012) (see all versions of the complaint for enumeration of the Standard’s unreasonable and unjustified restrictions on triglyceride diesel fuel). [EPA-HQ-OAR-2010-0799-10337-A2, p. 14]

The gist of the antitrust allegations are as follows. The National Biodiesel Board (“NBB”) instigated the drafting of the ASTM triglyceride burner fuel standard to purposefully restrict the competing biofuel from undercutting its market. ExxonMobil used its dominance of ASTM’s Petroleum Products Committee, by expressly making a threat to vote against any triglyceride standard that did not include the unreasonable restrictions, to enforce this arrangement. (The biodiesel industry enjoys preferred status with the petroleum industry by virtue of the 5 percent blending of biodiesel with No. 2 diesel authorized by ASTM D-975, Standard Specification for Diesel Fuel Oils. This arrangement allows the petroleum industry to say to the public that it supports renewable energy.) ASTM’s Petroleum Products Committee approved the triglyceride burner fuel standard without subjecting any of the test methods applied therein to ASTM’s validation procedure that would normally apply to a new fuel. Pickard decl., para. 3.12 (Exhibit 9). [EPA-HQ-OAR-2010-0799-10337-A2, pp. 14-15]

An example of the problems that arise with applying test methods developed for No. 2 diesel to triglyceride fuel appears in the lab report that is Exhibit 10 (Confidential Business Information).1 ASTM Test Method D-1160 distillation “could not be completed beyond” 40 percent recovery “after 449 degrees C due to the sample forming a gel that stopped the distillation.” Id., footnote (Exhibit 10) (Confidential Business Information). This example calls into question the precision of all other ASTM petroleum and biodiesel test methods for use with triglyceride fuel, none of which have ever been validated for triglyceride fuel via an ASTM interlaboratory study (“ILS”), a comprehensive study involving replicate testing done at between six and nine laboratories. See Pickard decl., para. 3.12 (Exhibit 9). [EPA-HQ-OAR-2010-0799-10337-A2, p. 15]

The fact that there have not been any ILS’s conducted, much less successfully concluded, for any test methods for triglyceride fuel may make it premature for EPA to designate this fuel for registration under 40 C.F.R. part 79. See supra. In the absence of test methods validated for triglyceride fuel, a triglyceride fuel manufacturer, such as POP DieselTM, would not have benchmarks for determining if its fuel submitted for EPA registration was within specifications and EPA would lack rational means to evaluate the same question. [EPA-HQ-OAR-2010-0799-10337-A2, p. 15]

The antitrust allegations are, further, that the conspirators used deception to orchestrate ASTM’s development and passage of the triglyceride burner fuel standard. These allegations are that the NBB had a surrogate, Ralph Turner, who had previously served as the owner’s representative and managing agent of a 45 million gallon per year biodiesel facility, one of the largest in the United States, propose to ASTM the drafting of a triglyceride standard. On the pretext that Mr. Turner’s ostensibly having used around 4,000 gallons per year of raw vegetable oil to heat greenhouses on his farm gave him experience with triglyceride fuel, ASTM appointed him to serve as Technical Contact for the ASTM Subcommittee that undertook to draft the standard. The result has the primary effects of enshrining false shibboleths and unnecessarily crimping restraints into a precedent-setting ASTM triglyceride fuel standard, the laws of most states and possibly, federal law. [EPA-HQ-OAR-2010-0799-10337-A2, p. 16]

The federal district judge in New Mexico dismissed the antitrust lawsuit in July 2011 but conducted a three-hour hearing on POP DieselTM’s motion to reconsider in mid-December 2011. He has not issued his ruling yet on whether to reinstate this suit. [EPA-HQ-OAR-2010-0799-10337-A2, p. 16]

3. Overcoming Prejudice Against POP DieselTM’s Use of 100 Percent Plant Oil.

Two organizations, the Engine Manufacturers Association and the National Renewable Energy Laboratory, have issued public statements arguing against the use of vegetable oil as fuel in a diesel engine. As set forth below, both of these statements are unjustified and based on outdated data. [EPA-HQ-OAR-2010-0799-10337-A2, p. 16]

i. Engine Manufacturers Association Statement [EPA-HQ-OAR-2010-0799-10337-A2, p. 16]

Research on the use of raw vegetable oil running in a diesel engine dating to the 1970's and early 1980's found that it caused carbon deposits and other problems. EMA by Gault testimony (Exhibit 7) (referring to numbered documents that constitute Exhibit 8). As is evident from the testimony of the Engine Manufacturers Association’s representative Mr. Gault, this research, and nothing more recent than that, was the primary basis for EMA to adopt a statement in 2006 condemning the use of raw vegetable oil in a diesel engine. EMA statement (Exhibit 8, document 0566). [EPA-HQ-OAR-2010-0799-10337-A2, pp. 16-17]

Based on documents kept in the EMA's file concerning development of its position statement, the NBB's Steve Howell ("Mr. Howell") seemed to be the instigator of this statement. EMA by Gault testimony, at 171, lines 18-22 (Exhibit 7) (referring to Exhibit 8, documents numbered 0569, 0579, 0582, 0603 and 0604). As other documents in the same file indicate, Mr. Howell, on behalf of the biodiesel industry, also took the lead in agitating for EPA to impose additional restrictions on the use of 100 percent plant oil in a diesel engine. Exhibit 8, document 0582 (Mr. Gault's notes of teleconference organized in December 2005 by Mr. Howell with EPA officials Jim Caldwell, Dave Kortum and Joseph Sopata); document 0603 (text of email by Mr. Howell to EPA officials seeking meeting "on the subject of EPA registration of Straight Vegetable Oil or Raw Vegetable Oil"). [EPA-HQ-OAR-2010-0799-10337-A2, p. 17]

POP DieselTM does not advocate, in fact it shuns, the methods of use of plant oil in the failed research studies from the 1970's and early 1980's: either blending the vegetable oil with No. 2 diesel in a single tank, or else, using it at 100 percent concentration, but without the safeguards that POP DieselTM has learned are necessary. These necessary safeguards include: [EPA-HQ-OAR-2010-0799-10337-A2, p. 17]

1. Always starting the engine on 100 percent No. 2 diesel drawn from its own fuel tank, so as to prevent excessive blow-by of plant oil fuel past the cold piston rings into the engine crankcase, where it will polymerize and gum up the engine; [EPA-HQ-OAR-2010-0799-10337-A2, pp. 17-18]

2. Always shutting down the engine on 100 percent No. 2 diesel drawn from its own fuel tank, so that the plant oil fuel does not remain on the hot metal parts of the fuel injection system to sizzle and plasticize and so that, in cooler weather, the plant oil fuel does not congeal upon engine cool-down and then cause difficulty on engine start-up; and [EPA-HQ-OAR-2010-0799-10337-A2, p. 18]

3. Always flushing the engine and fuel system with 100 percent No. 2 diesel drawn from its own fuel tank prior to engine shut-down, to take advantage of this fuel's excellent properties as a solvent in removing plant oil from the internal fuel passages of the engine, where it may eventually gel. [EPA-HQ-OAR-2010-0799-10337-A2, p. 18]

In fact, more recent studies than the ones from the 1970's and early 1980's speak favorably of plant oil fuel. Jones, S. and Peterson, C., "Using Unmodified Vegetable Oils as a Diesel Fuel Extender," U. of Idaho (Exhibit 8, at 0575 (citing Nag et al. (1995) and Sapaum et al. (1996))). POP DieselTM has overcome the technical hurdles to warrant that the use of 100 percent plant oil in a diesel engine is absolutely feasible. [EPA-HQ-OAR-2010-0799-10337-A2, p. 18]The EMA position statement on the use of raw vegetable oil in a diesel engine is further suspect because the final draft omitted language included in earlier drafts that seemed to approve of a dual tank fuel system like POP DieselTM's: "Vehicles may be modified to achieve compatibility between raw vegetable oil and animal fats with the fuel delivery system (e.g., by heating the fuel system to reduce the fuel's viscosity)." Exhibit 8, document 0596. [EPA-HQ-OAR-2010-0799-10337-A2, p. 18]

ii. National Renewable Energy Laboratory Statement [EPA-HQ-OAR-2010-0799-10337-A2, p. 18]

Three sentences buried in NREL's Biodiesel Handling and Use Guide ("NREL statement"), at page 8, advise avoiding the use of untransesterified plant oil as diesel fuel. NREL statement (Dec. 2009) (Exhibit 11). Both the NREL and EMA statements turn on the conclusion that "the[] problems [with plant oil fuel] are caused mostly by the greater viscosity, or thickness, of the raw oils." NREL statement, at 8 (Exhibit 11). [EPA-HQ-OAR-2010-0799-10337-A2, pp. 18-19]

However, the fuel injection equipment manufacturer Bosch states that in contemporary, pressure-regulated common rail fuel systems, the higher viscosity of vegetable oil fuel does not exceed design thresholds for component strength. Dr. Jorge Ullmann and Dr. Heinz Stutzemberger, "Biofuels of the Future – Injection System Requirements in Terms of Quality," section 2.1, Robert Bosch GmbH (Nov. 2007) (Exhibit 12-A); deposition testimony of the organizational representative of Bosch, Tom Livingston, at page 74, lines 5-8 and 21-24 (Exhibit 12-B). [EPA-HQ-OAR-2010-0799-10337-A2, p. 19]

The NREL statement does not refer to any evidentiary source to justify its advisory against the use of plant oil fuel. NREL statement, at page 8 (Exhibit 11). The EMA statement refers as its only source to the conclusory NREL statement. EMA statement (Exhibit 8, document 0504). The organizational representative of the EMA, trying to justify the sweep of EMA's statement, could only cite to a single example of an engine that suffered a catastrophic – meaning sudden and disabling – engine failure, allegedly due to use of untranesterified plant oil in the engine. EMA by Gault testimony, at page 202, line 12 - page 203, line 4 (Exhibit 7). [EPA-HQ-OAR-2010-0799-10337-A2, p. 19]

The close ties that the NBB's Mr. Howell has with Robert McCormick, the director of NREL's Center for Transportation Technologies and Systems, are evident in the EMA's background file on the development of its statement. Mr. McCormick keeps Mr. Howell apprized of his communications with EPA on the subject of vegetable oil fuel. Exhibit 8, document 0569. The reader is left to speculate whether Mr. Howell asked Mr. McCormick to speak negatively to EPA about this fuel, as Mr. McCormick appears to have done in December 2005. Exhibit 8, document 0570 (Joe Sopata of EPA to Mr. McCormick: "You mentioned to me during the diesel subcommittee meeting that using vegetable oil at any level in a diesel engine would render the diesel engine inoperable within one year. Do you have any data on this issue?"). Mr. McCormick forwards to Mr. Howell research papers on the topic of plant oil fuel. Exhibit 8, document 0604. Mr. Howell uses Mr. McCormick's intelligence feed in the NBB's campaigns to get EMA and EPA to take action to inhibit the use of plant oil fuel. [EPA-HQ-OAR-2010-0799-10337-A2, pp. 19-20]

All of the foregoing communications occur, and the EMA and NREL adopted their statements condemning the use of raw vegetable oil as fuel based on, old, faulty evidence. [EPA-HQ-OAR-2010-0799-10337-A2, p. 20]

POP DieselTM agrees that the improper management of plant oil fuel may cause longer term problems in a diesel engine. This is no different from the fact that petroleum diesel fuel functioned less than optimally in compression ignition engines for years, until its properties and their behavior in the engine came to be better understood. ASTM D-975, Standard Specification for [Petroleum] Diesel Fuel Oils, was not adopted until 1948, four decades after the diesel engine came into wide usage on petroleum diesel fuel. Pickard decl., para. 2.9 (Exhibit 9). [EPA-HQ-OAR-2010-0799-10337-A2, p. 20]

Plant oil fuel is in its infancy, but POP DieselTM has shown that the technology to run it at 100 percent concentration is feasible and practical. Moreover, given life cycle GHG emissions that are better than the alternatives, plant oil fuel is particularly effective at reducing or slowing global warming. The Proposed Regulations ought to embrace this solution, rather than ignore it. The best way to embrace it would be for EPA to impose strict corporate fleet averages for GHG emissions that are divorced from fuel efficiency considerations and that take into account the full embodied energy and life cycle emissions inherent in the various engine technologies and fuels. This approach would allow EPA to fulfill its duty to ramp down GHG emissions with a certainty that is lost in the Agencies' false trust in fuel economy and myopic focus on tailpipe emissions, as embodied in the Proposed GHG Standards. [EPA-HQ-OAR-2010-0799-10337-A2, pp. 20-21]

1The fuel sample of jatropha plant oil used in this study had relatively high levels of phosphorous and sulfur. Normally, virgin plant oils have negligible quantities of these elements in them. The high levels got into the fuel sample through the use of fertilizer, herbicide or pesticide. The grower will alter its cultivation method to eliminate the presence of these elements in his extracted oil.

Organization: St. Clair-Detroit River Sturgeon for Tomorrow

We understand that smaller and lighter vehicles will be part of the equation to accomplish future fuel economy standards, however many of us drive larger, heavier vehicles used to tow boats, snowmobiles and travel trailers. We support the further development of alternative fuel sources such as bio-diesel which as renewable energy sources will help to reduce dependence on oil, will reduce emissions and will still allow us to drive vehicle suitable for towing and hauling. We are glad to see the plan is designed to ensure that we will still have a full range of vehicle choices. The development of alternative fuels will also help to control costs due to increasing global demand for diminishing fossil fuel resources. [EPA-HQ-OAR-2010-0799-4151, p. 1]

Response:

The Alliance of Automobile Manufacturers, Association of Global Automakers, and Ford recommended that incentive multipliers be available for manufacturers of liquefied petroleum gas (LPG) vehicles. EPA is not adopting incentive multipliers for LPG vehicles because the Agency does not believe that LPG vehicles promote the commercialization of technologies that have, or technologies whose commercialization can be critical facilitators of next-generation technologies that have, the potential to transform the light-duty vehicle sector by achieving zero or near-zero GHG emissions and oil consumption.

POP Diesel's comments regarding the merits of its product, and the (asserted) obstacles it has faced from competitive interests and others, is beyond the scope of this rulemaking. However, the comment that EPA should base compliance on fleet wide averaging is misplaced since this is precisely how compliance is measured for all manufacturers.

6.6 Comments Regarding Issues Relevant to Multiple Fuels

Alliance of Automobile Manufacturers (AAM)
American Petroleum Institute (API)
Bosch
Motor & Equipment Manufacturers Association (MEMA)
Nissan North America, Inc.
Plant Oil Powered Diesel Fuel Systems, Inc.
Securing America's Future Energy (SAFE)

Organization: Alliance of Automobile Manufacturers

The Alliance also supports EPA's proposal to continue use of the 0.15 divisor for gaseous and liquid alternative fuels and the petroleum equivalency factor for electricity. As noted by the Agencies, this approach will maintain consistency between dedicated and dual fuel vehicle calculations and will continue to encourage manufacturers to build vehicles capable of operating on fuels other than petroleum. [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

Organization: American Petroleum Institute (API)

EPA and NHTSA Should Not Contravene the Will of Congress by Allowing an Unlimited Fleet Fuel Economy Credit for MY 2020 and Later Dual-Fueled Vehicles

EPA and NHTSA also are requesting comment on whether to continue to use the 0.15 divisor for CNG and ethanol, and the petroleum equivalency factor for electricity, both of which the statute requires to be used through MY 2019, for model years 2020 and later dual-fueled vehicles. The use of these factors in conjunction with the utility factor approach discussed above artificially and substantially inflates the fuel economy of dual-fueled vehicles and thus provides an incentive to the automakers to produce these for CAFE compliance purposes regardless of other consequences. In essence, the agencies are proposing that automakers may "…increase their calculated fleet fuel economy for dual-fueled vehicles by an unlimited amount using these flexibilities."16 However, Section 32906 of the Energy Independence and Security Act of 2007 (EISA 2007) phased-out the maximum fuel economy credit attributable to dual-fuel vehicles (except electric vehicles) that could be taken by manufacturers of those vehicles such that the credit was reduced from 1.2 mpg in model year 2014 (and previous model years) to 0.2 mpg in model year 2019 to "0 miles per gallon for model years after 2019" (Section 32906(a)(7)). Clearly, the EPA and NHTSA proposed treatment of model year 2020 and later dual-fueled natural gas vehicles is overly generous and inconsistent with the intent and will of Congress. It should be set aside. [EPA-HQ-OAR-2010-0799-9469-A1, p. 7]

It is also useful to note that for the many years that this CAFE credit incentive has been in place, dual-fueled vehicles (particularly those using natural gas) have continued to remain a negligible fraction of the fleet. In other words, the presence of the incentive has not contributed to the influx of dual-fueled CNG vehicles. (In fact, there are no OEM dual-fuel CNG vehicles offered today; only a few after-market conversion models.) [EPA-HQ-OAR-2010-0799-9469-A1, p. 7]

Organization: Bosch

EPA has proposed two options for the calculation for CAFE for alternative fuel vehicles in MY2020 and beyond (after expiration of the calculation specified in 49 U.S.C. 32905). The treatment of E85 FFV, CNG and electricity is called out specifically in the NPRM, however there are a number of other alternative fuels, such as renewable diesel, in the market today and under development. Bosch recommends, regardless of which calculation option the EPA should decide on, clarification that all types of alternative fuels, not only E85, CNG and electricity, are included and treated in an equivalent manner in the calculation. This recommendation applies to treatment of dedicated alternative fuel vehicles as well. [EPA-HQ-OAR-2010-0799-9462-A1, p. 4]

Organization: Motor & Equipment Manufacturers Association (MEMA)

All alternative fuels, such as biodiesel, must be considered equally and not limited to just E85, CNG and electricity. Dedicated alternative fuel vehicles should be treated equally, regardless of fuel type. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

Regardless of which option EPA decides to adopt for MY2020 and beyond, MEMA recommends that the agency clarify that all types of alternative fuels, such as biodiesel, are considered and treated equivalently in this CAFE calculation, and not only limit it to E85, CNG and electricity. In addition, MEMA believes that the treatment of dedicated alternative fuel vehicles should also be equivalent regardless of the alternative fuel type. [EPA-HQ-OAR-2010-0799-9478-A1, p.12]

All alternative fuels should be considered equally and not limited to just E85, CNG and electricity. [EPA-HQ-OAR-2010-0799-9478-A1, p.13]

Organization: Nissan North America, Inc.

Nissan Supports Continued Use of the Petroleum Equivalency Factor for CAFE Calculations in MYs 2020-2025 [EPA-HQ-OAR-2010-0799-9471-A1 p.24]

EPA proposes to continue to use the petroleum equivalency factor for MYs 2020 and later. Proposed Rule at 75,019. Nissan supports EPA's proposal to continue to use the petroleum equivalency factor for electricity in MYs 2020-2025, which is consistent with the purpose of the CAFE program-to reduce our country's dependence on foreign oil. See 65 Fed. Reg. 36,986, 36,986 (June 12, 2000) (establishing the petroleum equivalency factor). Not only is such an approach consistent with the purpose of the CAFE Program, continued use of the petroleum equivalency factor will incentivize manufacturers to invest in EVs and PHEVs, thereby increasing the rate of adoption of these technologies. [EPA-HQ-OAR-2010-0799-9471-A1 p.24]

Organization: Plant Oil Powered Diesel Fuel Systems, Inc.

b. de-couple fuel efficiency policy from GHG emissions policy, since they are distinct and the former is not a surrogate for the latter; [EPA-HQ-OAR-2010-0799-10337-A2, p. 2]

c. re-do the weight the Agencies give to various alternative technologies and fuels according to a wells-to-wheels approach that corresponds more accurately with their relative contribution to and mitigation of atmospheric greenhouse gas accumulation; [EPA-HQ-OAR-2010-0799-10337-A2, pp. 2-3]

Organization: Securing America's Future Energy (SAFE)

Use of Miles Per Gallon as Appropriate Metric: To calculate fuel economy across vehicles that rely on an increasingly diverse portfolio of fuels, NHTSA relies on an alternative fuel vehicle's "miles per gallon equivalent" (MPGe) as a representation of its fuel economy. Doing so, however, measures the performance of alternative fuel vehicles in a manner that is not particularly meaningful (miles per 115,000 BTU of energy) and is inconsistent with the original intent of the CAFE program. But virtually no one understands the meaning of miles per BTU of energy, and even if they did it is not particularly meaningful. Most importantly, however, it fails to account for the very real value that most alternative fuels provide to the nation by reducing our use of oil, helping to delink our economy from the global market, and reducing the economic and national security consequence of that dependence. [EPA-HQ-OAR-2010-0799-9518-A1, p. 16]

The MPG metric was really developed to serve as a surrogate for operating costs. That made sense when we relied on a single fuel, whose price was volatile. It allowed owners to compare the relative efficiency of vehicles so that we could quickly compare their relative operating costs. The use of MPG also allowed us to report a common measure of efficiency that isolated the effects of fuel price volatility. [EPA-HQ-OAR-2010-0799-9518-A1, p. 16]

Calculating fuel economy on the basis of MPGe is perhaps simple but flawed. In essence, the calculation upon which NHTSA relies is intended to promote efficiency for efficiency's sake. SAFE believes, however, that NHTSA should consider whether it makes more sense for its calculation to seek to optimize the primary goal of fuel economy regulations, which is to reduce oil consumption, which is overconsumed because it is underpriced. [EPA-HQ-OAR-2010-0799-9518-A1, p. 16]

A revised method of calculating fuel economy is warranted because using oil to fuel vehicles is different than the consumption of other fuels; the unique manner in which oil dependence undermines our nation's energy, economic and national security is different than other fuels. Nearly every fuel used in the United States other than those derived from crude oil, including the fuels used to generate electricity, is produced in North America. Their production supports American jobs and does increase the trade deficit, and their prices are less volatile than the price of oil. It was, in fact, concern about our consumption of oil that led to the first fuel economy standards, which were required by the Energy Policy and Conservation Act of 1975. Moreover, even as the United States established national policies to reduce our consumption of oil, we also established national policies, and spent tens of billions of dollars to promote the production and use of other fuels because of their merits relative to oil. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 16-17]

While several commenters at the public hearings concerning this regulation stated their desire for “technology neutral” regulations, SAFE believes that different treatment is justified for alternative fuels because their use does not have the same economic or security consequences as using oil. In fact, given the importance, and statutory goal, of reducing petroleum consumption, SAFE believes that vehicles that do not consume oil should be treated as such in the development of these regulatory programs. Such calculations are not possible when fuel economy is calculated on the basis of miles per gallon which is calculated as miles traveled divided by gallons of fuel consumed, because they do not consume any gallons of fuel and the denominator in the MPG calculation cannot be zero. They are, however, possible when fuel consumption is calculated on the basis of gallons per mile (or per 100 miles) which is calculated as gallons consumed divided by miles travelled, because the numerator in the equation can be zero. [EPA-HQ-OAR-2010-0799-9518-A1, p. 17]

As demonstrated in Table 2,[39] calculating the fleet average fuel consumption while treating alternative fuel vehicles as requiring no oil is a simple calculation that accurately reflects their contribution to our national goal of reducing oil consumption. Column 2 represents a vehicle’s fuel economy measure in miles per gallon, which is calculated by dividing miles travelled per gallons of gasoline consumed. Column 3 represents the gallons of fuel consumed by the vehicle per 100 miles travelled, which is calculated by dividing 100 by a vehicle’s MPGe. Column 4 reflects the numbers in column 3 taking into account that that vehicles 8 and 9 were natural gas vehicle and electric vehicles that consumed no oil and vehicle 10 was a PHEV that consumed less oil than reflected in its MPGe rating. [Table 2 can be found on p. 18 of Docket number EPA-HQ-OAR-2010-0799-9518-A1] [EPA-HQ-OAR-2010-0799-9518-A1, p. 17]

SAFE believes that calculating fuel economy as demonstrated in this table is more consistent with the original intent of the statute, in that properly emphasizes the goal of reducing petroleum consumption, and acknowledges that certain vehicles consume less or no petroleum products. SAFE recognizes that the current calculation, which is based in a vehicle’s MPGe, may be required by statute at this point in time. SAFE nevertheless encourages NHTSA to evaluate calculating fuel economy based on a gallons-per-mile metric, bring this issue to Congress’ attention at some point in the near future, and recommend that Congress amend the statute as appropriate. This is the first period of time over which NHTSA is likely to be regulating large the fuel economy of substantial numbers of electric drive vehicles. It is important to get the regulatory approach right at the earliest possible time. [EPA-HQ-OAR-2010-0799-9518-A1, p. 18]

39 The calculation of fuel consumption for a PHEV assumed calculation over a 100 mile trip without charging, a combined MPGe of 73, an MPGe in charge depleting mode of 93 MPGe, an MPG of 37 in charge sustaining mode, and a utility factor of 0.65.

Response:

Rejecting use of the 0.15 factor for GHG emissions compliance for all fuels

Many comments recommended that EPA use the 0.15 divisor, which has long been used for CAFE credits for alternative fuel vehicles, as an incentive for GHG emissions compliance for a variety of alternative fuels. Boyden Gray and Associates went so far as to argue that EPA is legally compelled to do so because the divisor is included in the 2007 EISA legislation, issued after the Supreme Court's decision in Massachusetts v. EPA. The argument goes that EISA and the CAA are in conflict on this point, and since EISA is the later-enacted statute, it must take precedence over both the CAA and the Supreme Court's opinion. EPA does not accept this argument. There is no suggestion in either the EISA text establishing the divisor (or elsewhere in EISA), or in the legislative history, of any Congressional intent to de facto amend the emission-standard setting provisions of the Clean Air Act, or to restrict the scope of the Supreme Court's holding that greenhouse gases are pollutants under the Clean Air Act (and therefore potentially subject to all Clean Air Act provisions for "pollutants"). Nor are the statutes in such dramatic conflict as the commenter would have it. The statutory divisor disappears for dual fuel CNG (and other alternative fuel) vehicles after MY 2019, and the statutory divisor is of little practical benefit to any CNG vehicles before then. This is because of a different limitation in EISA on the upper limit on credit use under CAFE, and because all available credits are being utilized by FFVs. See, e.g., comments of Encana and NGV America (alluding to this practical limitation). Moreover, the EPCA/EISA statutory criteria for eligibility for dual fuel CNG incentives are more restrictive than under the GHG rule. Under EPCA, dual-fuel CNG vehicles are required to have a CNG-only range of at least 200 miles to qualify for the CAFE credit - a requirement equivalent to a 95.4% natural gas usage rate according to the utility factor methodology. As commenter VNG pointed out, this effectively results in vehicles expected to fuel on natural gas a large majority of the time being treated as dedicated gasoline vehicles. Thus, had EPA adhered to strict harmonization with EPCA/EISA, the GHG rule would be more restrictive with respect to the use of utility factors for dual fuel CNG vehicles.

EPA thus does not accept that it is legally compelled to offer the 0.15 divisor as an incentive under the GHG rules. EPA also rejects this approach for policy reasons. Congress provided the 0.15 divisor for CAFE compliance because a vehicle that operates on a non-petroleum fuel consumes zero or near-zero petroleum, and petroleum conservation is a primary objective of the CAFE program. But the tailpipe GHG emissions from most alternative fuel vehicles are not zero or near-zero, and in any case EPA believes that GHG emissions compliance should simply be based on GHG emissions performance. The primary focus of the GHG standards must be GHG emissions performance. Cf. Massachusetts v. EPA, 549 U.S. at 528 ("But that DOT sets mileage standards in no way licenses EPA to shirk its environmental responsibilities. EPA has been charged with protecting the public's 'health' and 'welfare' [citing CAA section 202 (a)], a statutory obligation wholly independent of DOT's mandate to promote energy efficiency.") Adopting the 0.15 factor for GHG emissions compliance for vehicles with substantial tailpipe GHG emissions could yield a significant reduction of GHG programmatic benefits that is not warranted by these vehicles. We also disagree with those commenters who argued that EPA must adopt the 0.15 factor in order to not "negate the Congressional mandate" for CAFE credits. The Congressional mandate still applies for CAFE purposes. EPA's GHG program and NHTSA's CAFE program are harmonized in numerous ways, but there are a number of instances where the programs diverge with respect to incentives and flexibilities. See Preamble Section I.B.4. Here, EPA believes that the paramount emission reduction goals of the CAA warrant the difference in approach.

Adopting use of the 0.15 factor for CAFE compliance beginning in MY 2020

With one exception, commenters supported the proposal to continue to use the 0.15 divisor for CAFE compliance beginning in MY 2020. Nissan summarized the most common argument for retaining the 0.15 divisor for CAFE compliance, stating that the 0.15 divisor "is consistent with the purpose of the CAFE program—to reduce our country's dependence on foreign oil." The Alliance of Automobile Manufacturers argued that "this approach will maintain consistency between dedicated and dual fuel vehicle calculations and will continue to encourage manufacturers to build vehicles capable of operating on fuels other than petroleum." There was also support for retaining the 0.15 divisor for the CAFE program from other automakers, natural gas advocacy groups, and ethanol/renewable fuel groups. The one comment against retaining the 0.15 divisor was the American Petroleum Institute. It argued: "Section 32906 of the Energy Independence and Security Act of 2007 phased-out the maximum fuel economy credit attributable to dual fuel vehicles (except electric vehicles) that could be taken by manufacturers of those vehicles such that the credit was reduced from 1.2 mpg in model year 2014 (and previous model years) to 0.2 mpg in model year 2019 to '0 miles per gallon for model years after 2019.' Clearly, the EPA and NHTSA proposed treatment of model year 2020 and later dual fueled natural gas vehicles is overly generous and inconsistent with the intent and will of Congress. It should be set aside."

EPA, pursuant to its EPCA authority, is finalizing the CAFE compliance treatment for MY 2020 and later, as proposed, with one change being the addition of eligibility requirements for dual fuel CNG vehicles to be able to use the utility factor approach, as discussed in RTC Section 6.2. EPA is adopting the same approaches for weighting the fuel economy compliance values for dual fuel vehicles for CAFE compliance as we have done for GHG emissions compliance: using utility factors for PHEVs and dual fuel CNG vehicles (the latter must meet the eligibility requirements), and providing manufacturers the option of using projected national average E85 usage data, manufacturer-specific E85 usage data, or a 100% gasoline default value for ethanol FFVs. EPA is adopting the 0.15 divisor, and petroleum equivalency factor for PHEVs, for dual fuel vehicle CAFE compliance in MY 2020 and later, for two reasons. One, this approach is directionally consistent with the overall petroleum reduction goals of EPCA/EISA and the CAFE program, because it reflects the much lower or zero petroleum content of alternative fuels and continues to encourage manufacturers to build vehicles capable of operating on fuels other than petroleum. Two, the 0.15 divisor and petroleum equivalency factor (PEF) are used under EPCA to calculate CAFE compliance values for dedicated alternative fuel vehicles, and retaining this approach for dual fuel vehicles maintains consistency, for MY 2020 and later, between the approaches for dedicated alternative fuel vehicles and for the alternative fuel portion of dual fuel vehicle operation.

In response to the comment from the American Petroleum Institute, EPA recognizes that use of the 0.15 divisor, and petroleum equivalency factor for PHEVs, will continue to provide a large increase in CAFE compliance values for the vehicles previously covered by the special calculation procedures in 49 U.S.C. 32905, and that Congress chose both to end the specific calculation procedures in that section and over time to reduce the benefit for CAFE purposes of the increase in fuel economy mandated by those special calculation procedures. However, the MY 2020 and later methodology differs significantly in important ways from the special calculation provisions mandated by EPCA. Most importantly, the MY 2020 and later methodology reflects actual usage rates of the alternative fuel and does not use the artificial 50/50 weighting previously mandated by 49 U.S.C. 32905. In practice this means the primary vehicles to benefit from the MY 2020 and later methodology will be PHEVs and dual-fuel CNG vehicles, and not ethanol FFVs, while the primary source of benefit to manufacturers under the statutory provisions came from ethanol FFVs. Changing the weighting to better reflect real world usage is a major change from that mandated by 49 U.S.C. 32905, and it orients the calculation procedure more to the real world impact on petroleum usage, consistent with the statute's overarching purpose of petroleum conservation. In addition, as noted above, Congress maintained the 0.15 divisor in the calculation procedures for dedicated alternative fuel vehicles that result in increased fuel economy values. Finalizing the 0.15 divisor for dual fuel vehicles is consistent with this, as it uses the same approach for calculating fuel economy on the alternative fuel when there is real world usage of the alternative fuel. Since the MY 2020 and later methodology is quite different in effect from the specified provisions in 49 U.S.C. 32905, and is consistent with the calculation procedures for dedicated vehicles that use the same alternative fuel, EPA believes this methodology is an appropriate exercise of discretion under the general authority provided in 49 U.S.C. 32904.

Equivalent treatment of all alternative fuels under CAFE beginning in MY 2020

Bosch and the Motor and Equipment Manufacturers Association commented that all types of alternative fuels, including biodiesel, should be treated "equivalently" under the CAFE program. EPA agrees with these comments, and all dedicated alternative fuel vehicles will use the 0.15 divisor in CAFE calculations for MY 2020 and later. In addition, vehicles capable of operating on diesel containing at least 85% biodiesel (B85), will also use the 0.15 divisor in CAFE calculations for MY2020 and later. While B85 may not be considered an alternative fuel under EPCA at this time, 20% biodiesel (B20) is recognized by Congress for purposes of section 32905, and B85 exhibits the same or better petroleum replacement benefits as the 85% alcohol blend alternative fuels currently used in FFVs. Several commenters recommended that utility factors be used for CAFE calculations prior to 2020. EPA is rejecting this recommendation, as EPCA requires the Agency to assume 50% use of the conventional fuel and 50% use of the alternative fuel for CAFE calculations through MY 2019. Finally, VNG.Co suggested that the agencies consider possible ways to provide CAFE credits, in the pre-2020 timeframe, for duel fuel CNG vehicles that have a CNG range of less than 200 miles. EPA is rejecting this recommendation as well, as the 200-mile minimum range requirement is required under 49 U.S.C. 32901(c).

Finally, Plant Oil Powered Diesel Fuel Systems argued that EPA should re-evaluate the weight given to various alternative technologies and fuels according to a life-cycle approach, and to decouple fuel efficiency policy from GHG emissions policy. In setting these emissions standards, EPA reasonably chose to consider the impact on GHG emissions of the fuels used by the different types of vehicles by measuring the tailpipe emissions of vehicles, including alternative fuel vehicles (which normally emit less GHG emissions than gasoline or diesel-powered vehicles). POP Diesel's statement that the rules arbitrarily assign zero emissions and zero fuel consumption to electric vehicles is also misplaced. Electric vehicles have zero GHG emissions measured at the tailpipe. POP Diesel states further that the standards are arbitrary in the GHG-reducing weight given to some alternative technologies and fuels. POP Diesel's complaint that the rule provides incentives for use of certain advanced technologies such as hybrid electrification and hydrogen fuel cells questions legitimate policy choices unrelated to the issue of fuel use. See also responses in RTC Section 4 above.

In the separate, congressionally mandated, Renewable Fuel Standard program, there are strong incentives for use of renewable diesel fuels (the commenter's specific interest). This program is specifically designed to mandate increasing volumes of renewable fuel use in transportation fuels. The definition of renewable fuel includes thresholds for reductions in lifecycle greenhouse gas emissions, compared to petroleum fuel. For example, specified volumes of biomass-based diesel fuel must be used in the diesel transportation sector, and biomass-based diesel is defined in part as a diesel fuel that achieves a 50% reduction in life-cycle greenhouse emissions compared to baseline petroleum diesel fuel.

7. Off-Cycle Technology Credits

The Alliance Supports the Credits for Off-Cycle GHG Emission Reductions And Fuel Economy Improvements. [EPA-HQ-OAR-2010-0799-9487-A1, p.10]

The overall GHG emission reductions proposed in the NPRM are a formidable challenge that requires new, creative approaches to emission reduction and energy efficiency. Continuing the off-cycle credit program provides an incentive to manufacturers to introduce new technologies that produce concrete environmental and fuel consumption benefits, provides flexibility toward meeting the increasingly stringent standards and encourages investment in technologies that will pay off over the longer term. [EPA-HQ-OAR-2010-0799-9487-A1, p.10]

The program flexibilities in the NPRM will help manufacturers introduce new technologies that produce concrete environmental and fuel consumption benefits. [EPA-HQ-OAR-2010-0799-9487-A1, p.10]

The proposed rules properly include various provisions offering manufacturers some flexibility in developing their plans to comply with the CAFE and GHG standards. Some of these provisions enable manufacturers to earn credits that can be used to satisfy part of their compliance obligations. While some may think the term 'credits,' as used here, connotes reduced stringency or even 'loopholes,' that is not the case. The objective of the CAFE and GHG standards is to reduce actual fuel consumption and actual GHG emissions from vehicles driven on American roads. In some cases, however, the laboratory testing used by the agencies to measure fuel economy and GHG emissions may not fully reflect the improvements built into a vehicle by the manufacturer, due to limitations of laboratory-based tests. And improvements to reduce MAC system refrigerant loss can reduce GHG emissions from vehicles while having little or no impact on fuel economy. It is important for the rules to properly account for such factors. Otherwise, manufacturers would be encouraged to focus solely on the test procedures, and opportunities for real-world GHG reduction and fuel economy improvement would be lost. The Alliance believes that the various credit provisions proposed by EPA and NHTSA are essential elements of the rulemaking package. Below we offer our specific comments on the details of these provisions. [EPA-HQ-OAR-2010-0799-9487-A1, p.10] [[This comment can also be found in Outline Heading 3.]]

Substantial GHG improvements should be achievable in off-cycle conditions using new technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

While there are substantial emission reductions that can be achieved through off-cycle technologies, it will be essential that the off-cycle program function effectively if the overall emission reduction goals are to be achieved. [EPA-HQ-OAR-2010-0799-9487-A1, p.26]

Organization: American Honda Motor Co., Inc.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 121.]

The addition of a thoughtful and reasonable approach to off-cycle credits is exciting to us and we believe will result in the introduction of many new and innovative technologies.

Organization: Association of Global Automakers, Inc. (Global Automakers)

The off-cycle credits provide incentives for manufacturers to pursue technologies that produce benefits in actual on-road driving but are not measured using the Federal Test Procedure (FTP). [EPA-HQ-OAR-2010-0799-9466-A1, p. 1]

Global Automakers supports the availability of credits for technologies that provide on-road efficiency and emissions benefits but whose benefits are not fully measured using the current city-highway test. [EPA-HQ-OAR-2010-0799-9466-A1, p. 5]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 66.]

Off-cycle credits provide incentives for manufacturers to pursue technologies that produce benefits in actual on-road driving but are not measured using the FTP.

Organization: BMW of North America, LLC

BMW supports both approaches - predefined list and individual OEM applications; furthermore, we welcome the proposed extension of the scope for off-cycle technologies. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 1]

Organization: Borg Warner, Inc.

BorgWarner supports the inclusion of “off-cycle credits” that attempt to give manufacturers the proper motivation for implementing technologies that achieve real world results that are not seen on the official rating test cycles. While we support this type of thinking, a more robust solution would be to employ updated testing methods that more accurately measure real world results seen by the consumer. [EPA-HQ-OAR-2010-0799-9320-A1, p. 2]

Organization: Center for Biological Diversity

3. Off-cycle credits in general

The concept of allowing credit for the installation of new and energy efficient technology that is early in the compliance cycle, or that cannot be measured by existing testing mechanisms, is sound, as long as the duration of the credit period is brief and provides no disincentive to the implementation of other available features. However, all such credits must be carefully vetted to ensure that there is no double counting. Any technologies already required to be implemented cannot also generate credits, and there must be verified data showing that actual efficiency gains equal to the credits are being achieved. [EPA-HQ-OAR-2010-0799-9479-A1, p. 22]

We disagree with the Agencies’ suggestion that even more off-cycle credits should be allowed, without any rulemaking, if some unspecified data supports them. That the Agencies perceive a need for this request simply points out the fact that technological innovation will race far ahead of the weak standards the Agencies are here proposing, and that the Agencies are aware of this fact. Instead, the Agencies must design much stronger standards, rather than requesting the right to “catch up” with clearly foreseeable improvements without the requisite notice and comment rulemaking process. [EPA-HQ-OAR-2010-0799-9479-A1, p. 22]

Organization: Chrysler Group LLC

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 54.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 61.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 26.]

Secondly, Chrysler supports the additional detail proposed for catching off-cycle fuel economy and greenhouse gas improvements. The agency's built on this facet of the 2012 through '16 model year regulation that recognizes improvements in fuel economy and greenhouse gases that are not captured in laboratory tests but do have real-world reductions.

Organization: Delphi Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 108.]

We support the existing credit options

In addition, existing credit options and additional flexibility for off-cycle credits provide an incentive for the industry to look across the entire automobile for solutions. [This comment can also be found in section 7 of this comment summary.]

We applaud the agencies' efforts to extend additional flexibility for off-cycle credits.

In addition, existing credit options and additional flexibility for off-cycle credits provide an incentive for the industry to look across the entire automobile for solutions. [This comment can also be found in section 10.1 of this comment summary.]

Organization: EcoMotors International, Inc.

Several significant changes are being proposed to the off-cycle credits program, including some modifications to the existing MYs 2012-2016 program. These changes include establishment of a list of pre-approved off-cycle technologies with pre-defined CO_2 credits, commencing in MY2017; removing the requirement that off-cycle technologies must be 'new, innovative, and not widespread', and that the benefits of these technologies must not be 'significantly measurable over the 2-cycle test'; clarifying several requirements of the current two-tiered process for demonstrating the CO_2 reductions of off-cycle technologies and instituting this testing methodology for MYs 2012-2016 credits as well; establishing a four-step process for reviewing and providing a decisions on credits; and starting with MY2017, allowing manufacturers to generate 'fuel consumption improvement values' equivalent to CO_2 off-cycle credits for use in the CAFE program. [EPA-HQ-OAR-2010-0799-9594-A2, pp. 12-13]

The concept of providing credits as a way to further incentivize technology development in key areas is a good one. EcoMotors generally supports the changes made to the off-cycle credit program to provide manufacturers with more certainty with regard to credit application and testing. [EPA-HQ-OAR-2010-0799-9594-A2, p. 13]

- Specific Recommendation: EcoMotors generally supports continuation of the off-cycle credit program with the changes proposed to the current program, as well as the enhancements proposed for the future. [EPA-HQ-OAR-2010-0799-9594-A2, p. 13]

Organization: Fisker Automotive, Inc.

- Encourage application of the pre-approved list for earlier model years [EPA-HQ-OAR-2010-0799-9266-A1, p. 5]

Organization: Ford Motor Company

Ford strongly supports many of the updates that the agencies have proposed to the off-cycle technology program, as detailed in the comments provided by the Alliance. [EPA-HQ-OAR-2010-0799-9463-A1, p. 15]

Organization: General Motors Company

GM supports the proposal for an updated off-cycle technology framework. Significant detailed technical information on off-cycle technologies and the off-cycle framework is contained in the Alliance comments. GM recommends that the off-cycle program be fully examined in the mid-term review, and updated as appropriate. [EPA-HQ-OAR-2010-0799-9465-A1, p. 3]

Organization: Hyundai America Technical Center

Hyundai supports the proposed improvements in accounting for technologies whose benefits are not realized on the city and highway cycles. Hyundai believes off-cycle technology is an area that is ripe for innovation and can provide important gains in real world fuel economy. However, we do have several suggestions for improvements to the off-cycle credit processes. [EPA-HQ-OAR-2010-0799-9547-A1, pp.4-5]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 172.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 22.]

We support the credit and banking provisions and continued application of off-cycle credits for technology whose benefits cannot be accounted for on the city and highway test cycles.

Hyundai believes that off-cycle technology is an area that is ripe for innovation, and can provide important gains in real world fuel economy and greenhouse gas reductions.

Organization: International Council on Clean Transportation (ICCT)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 197.]

ICCT supports the concept of off-cycle credits. However, we will provide detailed written suggestions on how to better implement them so that they are valid and avoid double counting.

Organization: Johnson Controls, Inc.

Rewarding various innovative off-cycle technologies encourages rapid adoption and increases deployment into the fleet. [NHTSA-2010-0131-0253-A1, p. 4]

Organization: Mazda North American Operations

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 63-64.]

Mazda fully supports the proposed extension of the availability of off-cycle credits for model years 2017 to 2025. We agree that continuing the off-cycle credit program provides an incentive to manufacturers to introduce new technologies that produce concrete environmental and fuel consumption benefits, provides flexibility toward meeting the increasingly stringent standards, and encourages investment into technologies that will have a payoff over the longer term.

Organization: Mercedes-Benz USA, LLC

DAG supports the effort to include off-cycle credits that reduce CO_2 in ways not measured by the fuel economy test cycles. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-2]

Organization: Motor & Equipment Manufacturers Association (MEMA)

Taken as a whole, MEMA supports the proposal to provide off-cycle credits for any technologies that demonstrate significant, incremental off-cycle CO_2 reductions and the corresponding fuel consumption improvement values. [EPA-HQ-OAR-2010-0799-9478-A1, p.7]

Organization: National Wildlife Federation (NWF)

In principle, we also support incentives for plug-in hybrid electric and electric vehicle technology and for real off-cycle CO_2 reductions, and we look forward to continuing to work with automakers, the agencies and consumers to maximize the effectiveness of these credits and other measures which enable rapid adoption of new technology, and to optimize short and long term emissions impacts. [EPA-HQ-OAR-2010-0799-9887-A2, p. 4] [[This comment can also be found in Outline Headings 4. and 5.]]

Organization: Natural Resources Defense Council (NRDC)

5. Off-cycle credits: Off-Cycle Technology Credits Should Only Be Awarded for Real and Verifiable GHG Reductions

While NRDC appreciates EPA's efforts to evaluate GHG reduction technologies that are not identified under current compliance tests and to encourage continued innovation in this area, EPA should only provide credits if such technologies can be verified as providing real and enforceable GHG reductions. As GHG reductions are indentified and evaluated, EPA should consider the widespread adoption of these technologies when setting the stringency of future standards. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

Organization: Porsche Cars North America, Inc. (PCNA)

Porsche strongly supports provisions for off-cycle credits, which encourage creative approaches to emission reduction and energy efficiency, provide compliance flexibility amid increasingly stringent standards, and encourage investment in technologies for long term benefit. [EPA-HQ-OAR-2010-0799-9264-A1, p. 5]

Organization: United Automobile Workers (UAW)

Off-cycle credits also recognize real-world emission reductions that are not accounted for in the current official test procedures to measure vehicle emissions. [EPA-HQ-OAR-2010-0799-9563-A2, p.3]

Organization: Volkswagen Group of America

Volkswagen contributed to and supports the comments submitted by the Alliance of Automobile Manufacturers (Alliance) regarding off-cycle technology credits. Volkswagen continues to make significant investments in deploying an array of innovative, fuel saving off-cycle technologies for our consumers. [EPA-HQ-OAR-2010-0799-9569-A1, p. 32]

Organization: Volvo Car Corporation (VCC)

Off-cycle credits are a good opportunity for manufacturers to get credits for technology that does not appear on the normal cycle but favors the overall fuel economy. [EPA-HQ-OAR-2010-0799-9551-A2, p. 6]

Response:

EPA received widespread support for continuing the off-cycle credits program beyond MY 2016. Several manufacturers noted that the program provides additional flexibility and encourages the development of technologies that provide real world emissions reductions not captured on the 2-cycle test procedure. EPA concurs with these comments and is extending the off-cycle credit program to MY 2017 and later. The National Wildlife Federation and Natural Resources Defense Council (NRDC) also supported the off-cycle credits program in principle as long as credits can be verified as providing real and enforceable GHG reductions. Center for Biological Diversity also raised the issue that EPA must ensure that there is no double counting of credits. As discussed in Section III.C.5.b., EPA believes that the program has been designed to ensure credits are real and verifiable and to prevent double counting. Several commenters provided comments on the various aspects of the proposed design of the off-cycle credits program. These comments are summarized and addressed in this section below.

NRDC commented that as GHG reductions are indentified and evaluated, EPA should consider the widespread adoption of these technologies when setting the stringency of future standards. In response, EPA plans to closely monitor the use of the off-cycle credits program and expects that it will be one of the factors considered in the mid-term evaluation. In addition, EPA notes that the 2017-2025 model year standard stringencies in fact reflect the use of direct and indirect air conditioning improvements, as well as the two cycle benefits of stop start and active aero dynamic technologies.

ICCT comments in public hearing testimony that they support the concept of off-cycle credits and will provide detailed written suggestions on how to better implement them so that they are valid and avoid double counting. As discussed in RTC section 7.2 below, ICCT provided detailed written comments regarding the proposed off-cycle credit technology list and the issue of double counting.

16) Off-Cycle Credits

ICCT general comment on off-cycle credits and testing

ICCT strongly supports credits for off-cycle reductions in concept. Such credits can reduce the cost to manufacturers for compliance in the short run and can create cost-effective pathways for greater fuel consumption and GHG emission reductions in the long run. [EPA-HQ-OAR-2010-0799-9512-A1, p. 36]

However, it is extremely important that the credits properly reflect actual in-use reductions, do not duplicate on-cycle benefits, and can be validated. Credits that are artificial and do not directly result in comparable in-use reductions can severely undermine the effectiveness and credibility of the standards. [EPA-HQ-OAR-2010-0799-9512-A1, p. 36]

The same principle applies to default off-cycle credits. In theory they are a good idea that can create incentives for manufacturers to invest in off-cycle technologies, but if not assessed properly they create windfall credits that reduce fuel consumption and GHG emissions benefits of the program. [EPA-HQ-OAR-2010-0799-9512-A1, p. 36]

The ICCT recommends that EPA establish procedures to quantify and validate off-cycle benefits before granting a specific default off-cycle credit value. Absent a solid case for default off-cycle credit values, traditional case-by-case testing is needed to properly access off-cycle credits. Any default credits should be based on: [EPA-HQ-OAR-2010-0799-9512-A1, pp. 36-37]

1. Robust data showing real and quantifiable reductions that are not double counted on the regulatory test cycles, and [EPA-HQ-OAR-2010-0799-9512-A1, p. 37]

2. Effective performance benchmarks and verification that ensure vehicles receiving these credits will achieve the potential emission reductions in the real world. [EPA-HQ-OAR-2010-0799-9512-A1, p. 37]

The off-cycle approval procedures adopted by EPA for the 2012-2016 final rule provide accurate and appropriate guidelines for approval of off-cycle credits. These procedures should be followed both for granting specific approvals to manufacturers for off-cycle credits and for establishing default off-cycle credit values. [EPA-HQ-OAR-2010-0799-9512-A1, p. 37]

Given the importance of maintaining the benefits of this rulemaking and the ability to make additions to the default lists later as additional data is generated, technologies that do not clearly meet these requirements should be dropped from the default list during this rulemaking. [EPA-HQ-OAR-2010-0799-9512-A1, p. 37]

Solar Reflective Paint and Window Glazings

We agree with the criteria used for this category of off-cycle credits. US EPA has determined that it will achieve real reductions that are not counted in the regulatory test cycle through detailed technical studies including the CARB regulatory development process (these off-cycle credits are in lieu of CARB regulation). Specific benchmarks in the draft TSD are based on well-established principles of solar gain and OEMs must meet performance criteria to verify the emission reductions. Thus, these credits meet the general principle of being verifiable and additive off-cycle benefits. [EPA-HQ-OAR-2010-0799-9512-A1, p. 38]

As noted earlier, the off-cycle credits for solar reflective paint and window glazings must be combined with other load reductions and A/C system efficiency in a multiplicative manner in cases where an OEM wishes to claim both types of credits. [EPA-HQ-OAR-2010-0799-9512-A1, p. 39]

Active or Passive Ventilation

Vehicle active or passive ventilation may have the technical potential to reduce air conditioning load, but they do not meet the general criteria discussed above for default credits. The NREL report on these technologies was developed based on limited data and states that further evaluation is needed.[67] The NREL report also notes that floor-level ventilation could allow dust, animals, and/or exhaust to enter the vehicles.[68] Thus drivers (or dealers) may be motivated to close them off. Similarly, the driver's response to ventilated seats is unclear at this time. [EPA-HQ-OAR-2010-0799-9512-A1, p. 39]

These ventilation technologies could also compete with glazings and paints, which have been more thoroughly evaluated, for solar load reduction credits. Default credits for active or passive ventilation should be deferred. They can be reconsidered later if there is further study to verify real-world performance and if a performance benchmark for verification is developed. [EPA-HQ-OAR-2010-0799-9512-A1, p. 39]

Should credits be granted, the method of combining AC system efficiency and any such credits in cases where an OEM wishes to claim both types of credits must be used, as noted above. [EPA-HQ-OAR-2010-0799-9512-A1, p. 39]

General Credit Calculation for Reducing or Offsetting Vehicle Load

The draft TSD bases the 'off-cycle' benefits of reducing engine load by 100 W on the simulated values provided in table 5-18 of the draft TSD. The benefits calculated on FTP/HWY cycle are appropriate. However, the calculations of the 5-cycle benefits of a 100 w load reduction were inappropriately applied, as they used a g/mile offset instead of a percentage offset. [EPA-HQ-OAR-2010-0799-9512-A1, p. 42]

Table 10 compares the benefits of a 100 w load reduction on the FTP/HWY to the benefits on the 5-cycle. For each vehicle, the benefits on the 5-cycle are less then than the 2-cycle testing benefits in terms of percentage CO_2 reduction. While the g/mi reductions for 5-cycle testing is greater in terms of g/mi that on the 2-cycle testing, this is only because the baseline CO_2 is much higher on the 5-cycle. The benefits of reducing or offsetting vehicle load on the 5-cycle are actually proportionally less than they are on the FTP/HWY. It is not appropriate to apply 5-cycle gCO_2/mi reductions to FTP/HWY baseline gCO_2/mi values. This is mixing apples and oranges. [Table 10 can be found on p. 43 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, pp. 42-43]

The last row in the table illustrates that using the 5-cycle g/mi instead of the percent benefit produces a percentage benefit that is larger than the benefit on either the FTP/HWY or the U506. This is artificial and unwarranted. The FTP/HWY percentage benefits must be used for any electrical load reduction that does not occur on the test cycles (for instance headlights) and no additional credits should be given for any electrical load reduction that occurs on the test cycle (for instance thermoelectric generation). [EPA-HQ-OAR-2010-0799-9512-A1, p. 43]

LED Lighting

We agree that this technology has the potential to reduce emissions that are not captured on FTP/highway testing cycles. However, as discussed above, the off-cycle credits must be based upon the FTP/HWY percent and g/mile reductions and not on the 5-cycle g/mile reductions. As a result the credit value should be 0.8 grams per mile rather than 1.1 g/mile, or 0.9 g/mile with headlights, based on actual load reduction scaled to the potential benefits that US EPA modeled for FTP/highway testing cycle as shown in Table 11 and Table 12. [Tables 11 and 12 can be found on p. 44 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 43]

Thermoelectric and Solar Electrical Generation

Thermoelectric and solar electrical generation could reduce vehicle consumption of energy generated by the engine by recharging the battery pack in hybrids or electric vehicles. However, the premise that engine load reduction is undercounted on the FTP/HWY is incorrect, as noted above. [EPA-HQ-OAR-2010-0799-9512-A1, p. 44]

In addition, the benefits of these technologies would be difficult to quantify and verify. An NREL study indicates that potential thermoelectric output changes dramatically based on temperature conditions.76 A rating based on theoretical peak output may not reflect real world conditions with rapidly varying engine loads, competition for exhaust heat, high thermal stress, etc. Similarly, the tailpipe benefits of vehicle rooftop solar electrical generation are highly variable. A plug-in Prius may see little solar availability during early and late commute hours, and displace grid electricity if parked at a vehicle charger during the day while a delivery vehicle in use all day may get more benefits. Solar availability also varies hourly, seasonally and geographically. [EPA-HQ-OAR-2010-0799-9512-A1, p. 45]

Appropriate in-use data would be necessary to quantify and verify any proposed off-cycle credit. Further any credit, including default credit, granted should be based on the FTP/HWY results in Table 5-18, as discussed above. [EPA-HQ-OAR-2010-0799-9512-A1, p. 45]

Engine Heat Recovery

The off-cycle benefits for engine heat recovery are entirely based upon the erroneous assumption that there are larger benefits off-cycle than on cycle for electricity generation or load reduction, as discussed above. The benefits of electricity generation are larger on-cycle than on the 5-cycle test. Thus, the proposed default off-cycle credits for engine heat recovery are not appropriate. [EPA-HQ-OAR-2010-0799-9512-A1, p. 45]

There is some reason to believe that high vehicle loads will cause engine heat recovery systems to operate more efficiently. However, there are at least three different ways to recover exhaust heat as electricity; Rankine cycle devices, turbo-compounding, and thermo-electric generators. Each operates very differently and has a different profile of energy captured. Thus, credits could be appropriate, but only if a performance benchmark for verification is developed and valid data is generated. [EPA-HQ-OAR-2010-0799-9512-A1, p. 45]

Active Transmission Warm-Up and Active Engine Warm-Up

The proposed off-cycle credits for active transmission and engine warm-up are highly questionable. The primary problem is that EPA assumed no benefit from an active transmissions/engine warm-up during the FTP. [EPA-HQ-OAR-2010-0799-9512-A1, p. 45]

However, normal engine operating temperatures are about 180°F. This is about 105°F above the FTP test temperature and about 160°F above the 20°F test temperature. Thus, the benefit of active engine warm-up on the FTP should be about two-thirds of the benefit at 20°F and the proportional benefit will be even closer. [EPA-HQ-OAR-2010-0799-9512-A1, p. 45]

The statement about transmission warm-up is similarly incorrect:

'In cold temperatures, the exhaust heat warms the transmission fluid much more quickly than if the vehicle relies on passive heating alone.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 45]

In reality, the exhaust heat will warm the transmission fluid much more quickly than if the vehicle relies on passive heating alone at all ambient temperatures. Thus, most of the benefit of the warm-up systems will occur on-cycle during 2-cycle testing. [EPA-HQ-OAR-2010-0799-9512-A1, p. 46]

Another concern is the statement about the benefits of active warm-up:

'The Ricardo data indicates that there is a potential to improve GHG emissions by 7% at 20°F if the vehicle is fully warm.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 46]

The ICCT has thoroughly read the Ricardo report and all references to the Ricardo report in the draft TSD. There is no reference of any kind to any modeling, detailed or otherwise, on active transmission warm-up or accelerating powertrain warm-up from 20°F. More importantly, no data is presented by the agencies to show what the improvement in GHG emissions would be at 75°F if the vehicle is fully warm, as would also occur with active warm-up. Only if the percentage improvement in GHG emissions at 20°F is larger than the percentage improvement at 75°F would off-cycle credits be warranted - and even in this case the benefit would only be the difference in the percentage improvement, averaged over the annual temperature distribution. [EPA-HQ-OAR-2010-0799-9512-A1, p. 46]

Performance benchmarks need to be established and valid data generated before granting credits for active engine and transmission warmup. As a minimum, the effect of active warmup needs to be evaluated at both 20°F and at 75°F on the 2-cycle and the 5-cycle procedures, and evaluations at intermediate temperatures would be helpful. Most vehicles are equipped with engine temperature sensors, and usually also transmission temperature sensors, which could be helpful in evaluating the length of the warm-up time, but efficiency data associated with warm-up time and ambient temperatures is also needed. [EPA-HQ-OAR-2010-0799-9512-A1, p. 46]

The ICCT agrees that there may be some incremental off-cycle benefits from active warmup systems, but most of the benefit will occur on cycle and it is important to properly evaluate the incremental benefits before granting default credits. [EPA-HQ-OAR-2010-0799-9512-A1, p. 46]

Active Aerodynamics

Active aerodynamic devices may have real benefits beyond what is measured on the regulatory test cycles, but such devices would also improve efficiency on the 2-cycle tests. Thus, additional verification is needed to determine whether active aerodynamics would show incremental improvement. Benchmarks would also be necessary to quantify any benefits for active aerodynamics above and beyond the test cycle. [EPA-HQ-OAR-2010-0799-9512-A1, p. 46]

Coast-down testing for regulatory compliance could either understate or overstate the benefits of active aerodynamics. Grill shutters could activate at higher speeds than tested, while on the other hand the technology may be more active during the test cycle than when encountering real world conditions, such as AC load and deactivation when there is a risk of freezing. 77 In addition, quantification and verification would be necessary for any technologies that are not 'active' or fully 'active' on the test cycle. For instance, the draft TSD notes that the potential benefits range from 0-5%. Thus, we strongly encourage US EPA to develop performance criteria before granting any off-cycle credits for active aerodynamics. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 46-47]

Start-Stop Technology

We agree with US EPA and NHTSA's principle that technologies inherent to the vehicle (mass, tire rolling resistance, etc) are not appropriate for off-cycle credits. This principle also applies to start stop technology. [EPA-HQ-OAR-2010-0799-9512-A1, p. 47]

The draft TSD states that real world vehicle stop times and start-stop emission benefits are higher than reflected on the regulatory test cycle. However, this is based upon two erroneous assumptions. [EPA-HQ-OAR-2010-0799-9512-A1, p. 47]

First, the idle rate during the FTP is listed at 16% in Table 5-23 of the draft TSD. This is incorrect. Prior EPA documentation lists a 19% idle rate79 and a simple accounting of the LA finds a 19.1% idle rate (1372 total seconds with 262 seconds at zero speed). A smaller error is that the highway cycle was considered to have zero idle, while a simple accounting shows a 0.5% idle rate (764 total seconds with 4 seconds at zero speed). Weighted 55% for the FTP and 45% for the highway cycle, this yields an idle rate of 10.7%, not the 9% listed in the table. [EPA-HQ-OAR-2010-0799-9512-A1, p. 47]

Second, and more important, the draft TSD improperly accounts for the reduction in idle off operation at cold temperatures. The TSD assumes that the engine will continue to run 25% of the time to provide cabin heating at cold ambient temperatures (vehicles that reduce this percentage can apply for a separate credit). If the engine is also needed to power the air conditioner during start stop then further adjustment will be needed. However, the draft TSD first calculates the idle-off benefits assuming 100% idle-off time, then applies the 25% reduction only to the calculated benefit. This is not appropriate. The proper accounting should reflect the fact that the total idle-off time has been reduced by 25% and should apply the 25% reduction to the total in-use idle-off time. The total in-use idle-off time is estimated to be 13.5%, so the actual amount of idle-off time in-use is 10.1% (13.5% times 75%). [EPA-HQ-OAR-2010-0799-9512-A1, p. 47]

To the extent that air conditioning use further causes the engine to stay on at idle, in-use idle time will be even lower. Accounting for both heating and air conditioning use, the in use idle-off time could be as low as 6%. (This is assuming that the idle-off time from MOVES is accurate. No documentation of the source of the 13.5% estimate is presented.) [EPA-HQ-OAR-2010-0799-9512-A1, p. 47]

The amount of idle-off time in-use is significantly less that the idle-off time on the FTP-HWY cycles. Thus, the FTP-HWY overstates the benefit of idle-off and no off-cycle credit is warranted for idle-off systems. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 47-48]

Electric Heater Circulation Pumps

We agree that electric heater circulation pumps have the potential for increment benefits for start-stop and that further evaluation will help better quantify those benefits. As the base engine-off time was not calculated properly, the assessment of the benefit of electric heater circulation pumps needs to be redone as well with the proper assumptions about engine-off time. [EPA-HQ-OAR-2010-0799-9512-A1, p. 48]

In addition, it is reasonable to reflect the entire idle period when calculating the engine-off time on the FTP test cycle, since cabin heating is not active and not captured during FTP under any circumstances (which is different than start-stop as noted in our comments on start-stop). However, a downward adjustment is needed at colder ambient temperatures to account for some idle conditions where the engine may be operated, such as for warm-up purposes and for defroster use. Also, the amount of water pump electrical consumption needs to be accounted for in calculating the emissions benefit of this technology. [EPA-HQ-OAR-2010-0799-9512-A1, p. 48]

Finally, off-cycle credits should be granted only if the total amount of engine-off time is less than occurs on the 2-cycle tests and only for the amount of this reduction. [EPA-HQ-OAR-2010-0799-9512-A1, p. 48]

Performance criteria need to be developed and valid data generated to quantify the potential incremental improvement, including consideration of total engine-off time versus that on the 2-cycle test, before granting off-cycle credits for electric heater water circulation pumps. [EPA-HQ-OAR-2010-0799-9512-A1, p. 48]

Response:

We appreciate the extensive comments from the International Council on Clean Transportation (ICCT) and the effort that went into generating them. We agree with ICCT that the off-cycle credit program will “reduce the cost to manufacturers for compliance in the short run and can create cost-effective pathways for greater fuel consumption and GHG emission reductions in the long run.” In addition, we agree that it is “extremely important that the credits properly reflect actual in-use reductions, do not duplicate on-cycle benefits, and can be validated.” Lastly, we agree with ICCT “that EPA establish procedures to quantify and validate off-cycle benefits” and that any off-cycle credits should be based on “robust data showing real and quantifiable reductions that are not double counted on the regulatory test cycles” and “Effective performance benchmarks and verification that ensure vehicles receiving these credits will achieve the potential emission reductions in the real world.” We believe the off-cycle credit program provisions we are finalizing today achieve this.

Accordingly, we carefully considered the comments from ICCT on the off-cycle credit program and technologies on the off-cycle technology menu. This consideration and our responses are reflected throughout the Off-Cycle Program discussion in Section 5.2 of TSD Chapter 5 for this final rule. In some cases, we felt that ICCT's comments had merit and either revised the underlying credit analysis and credit value (e.g., engine idle start-stop) or are finalizing the credit values as proposed (e.g., solar reflective paint, glazing) after considering and responding to the comment in that part of the Joint TSD. In other cases (e.g., active aerodynamics, waste heat recovery (formerly engine heat recovery), active and passive cabin ventilation, vehicle load reduction offset estimate, electric heater circulation pump, active transmission and engine warm-up, high efficiency exterior lights, solar and thermal electrical generation), we disagreed with the comments from ICCT. Further, the supplemental comments from the Alliance addressed ICCT's concerns and (as explained specifically in the technology-by-technology discussion in section 5.2 of the Joint TSD) presented data that supported the proposed credit values and represented "robust data showing real and quantifiable reductions."

Therefore, we are finalizing the off-cycle credit program and the off-cycle technology menu as discussed on 5.2 of TSD Chapter 5 and Preamble II.F.2. addressing many of the concerns expressed by ICCT.

Organization: Alliance of Automobile Manufacturers

The off-cycle technology credit menu is a necessary addition to the off-cycle program to avoid administrative delays and burdensome credit application requirements. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

The procedures for earning off-cycle credits need to be kept simple. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

The pre-defined list will incentivize automakers to apply technologies earlier than they might have otherwise. It also offers manufacturers certainty about how much credit they will earn if they choose to apply one or more of the technologies on the list. The Alliance welcomes the agencies' willingness to add further technologies to the list as additional information becomes available. [EPA-HQ-OAR-2010-0799-9487-A1, p.26]

The proposed off-cycle credit menu is therefore a great addition to the GHG reduction and corporate fuel economy programs, as the experience thus far with separately testing and applying for off-cycle credits on each model has shown that the administrative obstacles inherent in this approach prohibit an effective program. [EPA-HQ-OAR-2010-0799-9487-A1, p.26]

The Alliance supports establishment of credits for all of the proposed technologies, but, in a few cases, recommends revisions to the proposed credit amounts. [EPA-HQ-OAR-2010-0799-9487-A1, p.26]

High Efficiency Exterior Lighting [EPA-HQ-OAR-2010-0799-9487-A1, p.26]

The Alliance supports this proposed off-cycle credit, but with modifications. EPA's calculation of the feasibility of a 60 watt total reduction threshold to qualify for this credit contains flaws in the calculation. Because of these flaws, achieving a full 60 watt improvement from the lights impacted by the credit may not be realistic. [EPA-HQ-OAR-2010-0799-9487-A1, p.26]

The 60 watt calculation included benefits from high efficiency low beam and high beam headlights, even though these lights are not covered by the credit provision. Due to their high wattage, the net benefits from these two high efficiency sets of lights are approximately 9 watts of the estimated 60 watt improvement. Creating such an unrealistically high improvement threshold for this technology could render the credit provision ineffective. In order to make the incentive to implement this technology more functional, this improvement threshold should be reduced to no more than 50 watts for the listed package of exterior lights, assuming no other changes are made to this provision. The credit amount for this package of lights would need to be adjusted accordingly. Also, Center High-Mount Stop Lamps (CHMSL) and brake lights impact the two-cycle fuel economy test, and high efficiency CHMSL and brake lights should not be a requirement to qualify for this off-cycle credit. [EPA-HQ-OAR-2010-0799-9487-A1, p.26]

In support of our above analysis, we recommend that the definition of "high efficiency exterior lighting" be updated to: [EPA-HQ-OAR-2010-0799-9487-A1, p.26]

High efficiency exterior lighting means a lighting technology that, when installed on the vehicle, is expected to reduce the total electrical demand of the exterior lighting system when compared to conventional lighting systems. LED lights specifically qualify. Separate credit values may be earned for high efficiency lighting installed in the following components: parking/position, tail lights, license plate lights, low beam lights and daytime running lights. Credits may also be earned for a high efficiency lighting bundle that is installed in the following components: front and rear side markers, and backup/reverse lights. [EPA-HQ-OAR-2010-0799-9487-A1, pp.26-27]

Additional changes to this credit provision are also attractive. Roll-out implementation may be speeded if portions of the credit were available for separate, individual lights, rather than requiring that all exterior lights feature high efficiency before a credit can be gained. This would allow each light to be swapped at the earliest possible time, in order to gain credits as quickly as possible. The most attractive candidates for individual credits are the largest three savings opportunities on the EPA/NHTSA list: parking/position lights, tail lights and license plate lights. Scaling the 1.1 gCO_2/mile credit proposed in the NPRM to the proportional benefits of these individual lights would indicate that individual credits are warranted of 0.2 gCO_2/mile for substitution of each of these lights individually (i.e., 0.2 gCO_2/mile for the parking/position lights, 0.2 gCO_2/mile for the tail lights and 0.2 gCO_2/mile for the license plate lights). The remaining 0.5 gCO_2/mile could then be earned by applying the package of all the remaining listed smaller lights in the NPRM. [EPA-HQ-OAR-2010-0799-9487-A1, pp.26-27]

Because of their low usage and corresponding low energy consumption, we do not feel that it is warranted to include the requirement for more costly high efficiency turn signals in this package in order to qualify for the high efficiency lighting off-cycle credit. [EPA-HQ-OAR-2010-0799-9487-A1, p.27]

Our experience indicates that an off-cycle credit for low beam lights would also be beneficial. The source used by EPA showed potential LED low beam benefits of only a few watts, whereas automakers' recent development experience has identified potential low beam savings opportunities of at least 60 watts. Based on EPA's usage calculations, a low beam savings of 60 watts should justify an off-cycle credit of 1.1 gCO_2/mile. We therefore recommend that a 1.1 gCO_2/mile off-cycle credit be offered on the menu for low beam lights that achieve power levels consistent with a savings of 60 watts below the baseline halogen technology. [EPA-HQ-OAR-2010-0799-9487-A1, p.27]

Beneficial emission reductions can also be achieved if a credit is offered for high efficiency Daytime Running Lights (DRLs). Based on the calculation below, we estimate a credit of 0.6 gCO_2/mile is justified for application of LED DRLs. Although DRLs are not mandatory, the reality is that they are often implemented as standard equipment by many manufacturers to improve highway safety. Due to their safety impact, they are a socially beneficial technology that has been encouraged by public policies at both EPA and NHTSA. Given that they are widely used, and that more efficient LED DRLs are often prohibitively expensive, it makes sense to offer an off-cycle credit as an incentive for LED DRLs. More widespread use of LED DRLs will result in real-world energy savings and GHG reductions. Because they are illuminated such a large portion of the time, they are the single most important exterior light to target for an off-cycle credit. [EPA-HQ-OAR-2010-0799-9487-A1, p.27]

Engine Heat Recovery

The Alliance supports EPA's analysis for this credit. This technology is not yet available for commercial implementation. Offering a credit is appropriate and could play an important role in bringing this technology into commercial use. However, we believe that the credit amounts should be determined by a scalable application of the metric that EPA proposed, rather than a step-wise function that awards credits only in increments of 100 watt capacities. Further we believe that it is appropriate to award credits for recovered heat that is converted to either electrical or mechanical energy to meet vehicle requirements. To simplify implementation and fairly reward each application, the credit should be made a linear function, based on the wattage generated. [EPA-HQ-OAR-2010-0799-9487-A1, p.29]

We recommend that the definition be updated to: [EPA-HQ-OAR-2010-0799-9487-A1, p.29]

Engine heat recovery means a system that captures heat that would otherwise be lost through the exhaust system or through the radiator and converting that heat to electrical or mechanical energy to meet the requirements of the vehicle. Systems obtain credits according to the following formula: [EPA-HQ-OAR-2010-0799-9487-A1, p.29]

Credit (gCO_2/mile) = (System watt Capacity / 100) * 0.7 [EPA-HQ-OAR-2010-0799-9487-A1, p.29]

Solar Panels

The Alliance supports EPA's analysis for this credit. Based on rough theoretical calculations and experimental data, offering a credit as proposed for each 50 watt unit of electricity generation is appropriate. Because there is a wide range of potential sizes for these panels, this credit should be scalable to reward panels that are smaller or larger than 50W. Also, the credit should not be confined to panels installed on the roof, since they may be installed elsewhere on the vehicle. This credit should be available for all vehicles, not only for electric-propulsion vehicles, since all vehicles can benefit from the additional battery charging to power accessories, even where it is not used for propulsion. [EPA-HQ-OAR-2010-0799-9487-A1, p.29]

Therefore, we suggest the following update to the proposed technology name and definition: [EPA-HQ-OAR-2010-0799-9487-A1, p.29]

Solar Panels means the installation of solar panels on a vehicle to capture and provide energy to the vehicle (e.g., provide energy to an electric drive system via battery charging or provide power to an electric motor or 12V battery trickle charging or cabin ventilation, etc.). Credit levels are granted according to the following formula: [EPA-HQ-OAR-2010-0799-9487-A1, p.29]

Credit (gCO_2/mile) = (Equivalent watt Output / 50) * 3.0 [EPA-HQ-OAR-2010-0799-9487-A1, p.29]

Active Aerodynamic Improvements

The Alliance supports EPA's analysis for this credit. Active aerodynamic technologies hold great promise and are already entering commercial usage. Offering sizable off-cycle credits will be very helpful to stimulate faster adoption. The tables on p. 5-64 of the Draft Joint Technical Support Document (TSD) show the relationship between aerodynamic improvement and credit amounts. The credits offered by EPA in the credit menu should be scalable, based on the lines in this table, rather than simply using one point on the table. Application of multiple active aerodynamic technologies can result in a Cd improvement of over 3%, whereas the proposed credit amounts are based on a 3% improvement. Therefore, to maintain an incentive to maximize the use of these technologies (e.g., active grille shutters plus active air dams), higher credit amounts should be allowed on the menu for aerodynamic improvements above 3%. EPA acknowledges in the TSD that larger aerodynamic improvements are possible, but suggests using model-by-model testing and applications to EPA for situations where greater credit is sought for these larger aerodynamic improvements. Case-by-case testing and applications are overly burdensome, and it would be much simpler to amend the credit menu to use the tables below, from p. 5-64 of the TSD, to award appropriate credit for higher levels of aerodynamic improvement. [EPA-HQ-OAR-2010-0799-9487-A1, p.30] [For table referenced, please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.30]

In practice, drivers often operate vehicles at sustained, steady-state, high speeds. This condition is barely represented in the drive cycles and weighting system used in the 5-cycle fuel economy calculations. For a Cd improvement of 3%, this actually warrants a credit in excess of the proposed 0.6 gCO_2/mile for cars and 1.0 gCO_2/mile for trucks. Therefore, EPA should consider the lines on p. 5-64 of the TSD as minimum possible credit amounts for these technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.31]

We recommend the definition be updated as follows: [EPA-HQ-OAR-2010-0799-9487-A1, p.31]

Active aerodynamic improvements means technologies that are actively controlled to improve aerodynamic efficiency. Credits are awarded according to the following formulas: [EPA-HQ-OAR-2010-0799-9487-A1, p.31]

Car: Credit (gCO_2/mile) = (Percent Reduction in Aero Drag, Cd) * 0.2 [EPA-HQ-OAR-2010-0799-9487-A1, p.31]

Truck: Credit (gCO_2/mile) = (Percent Reduction in Aero Drag, Cd) * 0.33 [EPA-HQ-OAR-2010-0799-9487-A1, p.31]

Engine Stop-Start

The Alliance supports the creation of a substantial off-cycle credit for this important technology. The proposed potential credit of 2.9 gCO_2/mile for cars and 4.5 gCO_2/mile for trucks, as proposed in the NPRM, is a major concern. We believe a credit of 5.5 gCO_2/mile is warranted; credits for this technology below 2.9/4.5 gCO_2/mile could substantially undermine the ability of the industry to achieve the overall GHG targets. [EPA-HQ-OAR-2010-0799-9487-A1, p.31]
Occupant Thermal Comfort Technologies (e.g., Electric Heater Circulation Pump) [EPA-HQ-OAR-2010-0799-9487-A1, p.32]

In 2011, based on actual vehicle tests and 5-cycle calculations, EPA awarded General Motors (GM) credits of 1.8 gCO_2/mile for GM's 2009-2012 full-size truck hybrids and 1.5 gCO_2/mile for its 2012 Buick Lacrosse© and Regal© hybrids. These vehicles use the auxiliary coolant pump to keep the stop/start feature working in cold weather, while continuing to provide heat to the passenger cabin. In contrast, the proposed credits for this technology are only 1.0 gCO_2/mile for cars and 1.5 gCO_2/mile for trucks. [EPA-HQ-OAR-2010-0799-9487-A1, p.32] Using the 5-cycle methodology, the technology simply provides continued operation of the stop/start feature during the idle portions of the cold weather test, and the amount of fuel savings should be fairly consistent between applications. The differential between the proposed credit and the actual test results is sufficiently large that automobile manufacturers may independently file separate credit applications for the larger credit amount justified by actual vehicle testing of each application using the 5-cycle provisions of the regulation. This would be a large and unnecessary testing and administrative burden for the automobile manufacturers as well as the regulatory agencies. We recommend that EPA avoid this unattractive situation by making the menu credit for this technology more consistent with actual test values. A menu credit of at least 1.5 gCO_2/mile for cars and 1.8 gCO_2/mile for trucks is justified. [EPA-HQ-OAR-2010-0799-9487-A1, p.32]

We recommend that the definition be modified slightly to: [EPA-HQ-OAR-2010-0799-9487-A1, p.31]

Engine stop-start means a technology which enables a vehicle to automatically turn off the engine when the vehicle comes to rest and to restart the engine with driver action (e.g., applying pressure to the accelerator or releasing the brake). Off-cycle engine stop-start credits will only be allowed if the Administrator has made a determination under the testing and calculation provisions in 40 C.F.R. part 600 that engine stop-start is the predominant operating mode. [EPA-HQ-OAR-2010-0799-9487-A1, p.31]

Various studies and agency literature suggest longer periods are spent at idle than would be indicated by the FTP cycle, and support a high off-cycle credit for the stop-start technology. [EPA-HQ-OAR-2010-0799-9487-A1, p.31]

To encourage additional technologies that provide similar benefits, the Alliance also recommends that the proposed definition be broadened to include other methods of maintaining occupant thermal comfort during off-engine periods. Specifically, we propose the following technology name and definition updates: [EPA-HQ-OAR-2010-0799-9487-A1, p.32]

Occupant thermal comfort technologies means technologies or strategies that maintain occupant thermal comfort during off-engine periods in a stop-start equipped vehicle or in a hybrid electric vehicle or plug-in hybrid electric vehicle (e.g., PTC heater or electric heater circulation pump). [EPA-HQ-OAR-2010-0799-9487-A1, p.32]

Active Drivetrain Warm-Up (e.g., Active Transmission Warm-Up)

The Alliance supports EPA’s analysis for the active transmission warm-up off-cycle credit of at least 1.8 gCO_2/mi. EPA’s proposed definitions for credits for these technologies should, however, be broadened to allow the inclusion other methods of driveline fluid warm-up as well as other sources of waste heat (perhaps using different credit amounts for other variations of this technology). For example, credits should explicitly be allowed for systems that use a coolant loop to transfer the heat from the exhaust system to the transmission and/or engine, since this may be more practical than directly heating engine oil or transmission oil in a heat exchanger in the exhaust system. Also, the performance of the system is not significantly changed by the use or non-use of coolant in the heat exchange process. [EPA-HQ-OAR-2010-0799-9487-A1, p.32]

Provisions should also be made to provide similar credits for other technologies that hasten transmission warm-up and viscosity management (perhaps without using exhaust gases). Some of these technologies are discussed in the next section of our comments, including quantification of potential credit amounts. [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

In addition, we recommend the following updates to the proposed technology name and definition: [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

Active drivetrain warm-up means a system that uses waste heat or waste energy to warm-up driveline fluids quickly and reduces parasitic drivetrain (transmission, axles, PTUs, t-cases) system losses related to friction and fluid viscosity. In this category, active transmission warm-up would receive credit of at least 1.8gCO_2/mi. [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

As mentioned in on p. 5-68 of the TSD, it is not necessary to heat the differential in rear-wheel-drive vehicles in order to qualify for this credit. However, we believe that heating the rear differential in these vehicles for viscosity management might provide an attractive additional credit opportunity, and urge EPA to re-examine this possibility. [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

Active Engine Warm-Up

Our research supports the 1.8 gCO_2/mile off-cycle credit proposed by EPA for this technology. However, EPA's definitions for earning this credit should be broadened such that a coolant loop may be used to transfer the heat. Provisions should be made to provide similar credits for any other technologies that hasten engine warm-up to provide similar benefits. [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

We recommend the following updates to the proposed definition: [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

Active engine warm-up means a system that uses waste heat, thermal storage, or waste energy to warm up targeted sub-systems of the engine such that frictional losses are reduced. It would allow a faster transition from colder operation to warm operation, decreasing CO_2 emissions and increasing fuel economy. In this category, active engine warm-up would receive credit of at least 1.8 gCO_2/mi. [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

Thermal Control [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

Substantial benefits are available from thermal management technologies, and we support establishing off-cycle credits for these technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

Glazing [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

The Alliance supports including glazing as an available off-cycle credit. However, the most effective of these technologies (solar reflective) have relatively high cost, weight and functional impact hurdles that must be overcome to integrate these technologies into the vehicle. For simplicity and clarity, the Alliance recommends that EPA state that the glazing area to be used in the calculation is the total glazing surface area. Also, credit should be granted for all vehicles that utilize glazing better than 62% Tts (except roof lights), regardless of whether the improved glass is marketed as the standard glazing or an optional upgrade. [EPA-HQ-OAR-2010-0799-9487-A1, p.33]

In addition, we ask that EPA and NHTSA consider the input of suppliers of alternative glazing technologies on amendments or additions to the proposed rule. Consideration of a broader range of technologies will provide the necessary flexibility to achieve the desirable air conditioning-related emission reductions, for example, based on reduced glazing thermal conductivity. [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

Active Seat Ventilation [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

The Alliance supports EPA's analysis for this credit. As a practical matter, only the front seats need to be ventilated to qualify for this credit, and this should be stated in the final regulation. The analysis EPA uses to quantify the credit is based on two ventilated front seats. Rear seats are used much less than front seats, and the cost attractiveness of this credit opportunity would fall dramatically if it were required that more than the front seats be ventilated. Also, EPA's definitions should specify that this credit can be earned for systems that either pull air into the seat or push air out. The impacts on occupant comfort and energy consumption are the same, and both approaches are used. This could be accomplished by making the following minor modifications to the proposed definition: [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

Active seat ventilation means a device which draws (or pushes) air or transfers heat/energy from the seating surface which is in contact with the occupant and exhausts (or pushes) it to a location away from the seat. [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

Solar Reflective Paint [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

The Alliance supports this credit while noting that, as with glazings, the analysis of energy benefits may be optimistic because of the "worst case" test conditions used in the studies by the National Renewable Energy Laboratory. [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

The draft EPA definitions for both active and passive ventilation satisfy that objective, since the definitions allow for many ventilation techniques. [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

Active Cabin Ventilation

Cabin ventilation can be attractive for reducing air conditioner energy consumption and improving comfort upon vehicle entry. Research on ventilation technologies has confirmed that interior breath level temperatures can be reduced to the levels that EPA used in its analyses for both active and passive ventilation. [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

There are many approaches that can be used, such as ventilating through slightly open windows or sunroofs, existing air conditioner ducts, or new air flow passages with dedicated fans. The ventilation may also be continuous or pulsed. Since such a wide range of approaches can be applied, the definitions used for this technology should not be overly prescriptive. [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

Also, we have found that it is very difficult to physically measure air flow through the vehicle to a tight margin, so it is not practical to set air flow thresholds in order to qualify for these ventilation credits. [EPA-HQ-OAR-2010-0799-9487-A1, p.34]

The cost of these technologies can be high. For example, active ventilation fans may need to be coupled to a photovoltaic panel which powers the fans, so that the system does not drain the battery if the vehicle is parked for long periods. The system used in EPA's analysis featured a unique sunroof with several small fans to pull hot air out of the cabin. Because are all very costly items, the credit offered for these technologies needs to be ample in order to make the business case for their implementation attractive. [EPA-HQ-OAR-2010-0799-9487-A1, p.35]

The Alliance therefore supports the definition of “active cabin ventilation” as proposed. [EPA-HQ-OAR-2010-0799-9487-A1, p.35]

Passive Cabin Ventilation

As previously stated in the discussion of active ventilation, cabin ventilation can be attractive for reducing air conditioner energy consumption. Research on ventilation technologies has confirmed that interior breath level temperatures can be reduced to the levels that EPA used in its analyses for passive ventilation. All of our other comments relative to active ventilation also apply to passive ventilation. For example, the system analyzed by EPA employed automatic sunroof features together with eight new floor vents in the vehicle. These are significant hardware changes to the vehicle which would require a significant credit in order to make an adequate business case for implementation. [EPA-HQ-OAR-2010-0799-9487-A1, p.35]

We propose to broaden the definition of Passive Cabin Ventilation slightly as follows: [EPA-HQ-OAR-2010-0799-9487-A1, p.35]

Passive cabin ventilation means ducts, devices or methods that utilize convective airflow to move heated air from the cabin interior to the exterior of the vehicle. [EPA-HQ-OAR-2010-0799-9487-A1, p.35]

High Efficiency Alternator [EPA-HQ-OAR-2010-0799-9487-A1, p.35]

This was a good recommendation on EPA’s initial off-cycle technology list, as contained in the EPA/NHTSA July 2011 Supplemental Notice of Intent. However, this technology subsequently did not appear in the proposed credit menu contained in the NPRM. We recommend that it be added back to the menu. [EPA-HQ-OAR-2010-0799-9487-A1, p.35]

The standard 2-cycle fuel economy test is performed with accessories “off,” and even the 5-cycle tests only activate some accessories, such as the air conditioner on the SCO3 test. In contrast, real-world driving has higher average electrical loads from a variety of accessories such as radios, lights, rear-seat entertainment systems, wipers, power window motors, etc. Conservatively, we estimate that at least a 20 amp average electric load differential exists in actual real-world driving over the typical 20 amp load during the 2-cycle test. High efficiency alternators provide fuel consumption benefits for this extra 20 amp real-world-driving differential which are not captured on the 2-cycle test, and so these benefits should be eligible for an off-cycle credit. [EPA-HQ-OAR-2010-0799-9487-A1, pp.35-36]

A traditional baseline alternator might have had an efficiency rating under the Verband der Automobilindustrie (VDA, the trade association represent German automobile manufacturers) test procedure of 60% to 64%, with high efficiency models having ratings above 68% VDA. To translate these differences into a GHG-equivalent, GM ran simulations of three different alternators on a range of four different vehicles using the NEDC drive cycle. The alternators were the Valeo SG11 (61% VDA), Bosch E6 (69% VDA) and Denso DSO (70% VDA). [EPA-HQ-OAR-2010-0799-9487-A1, p.36]

Each of these was simulated using the GM Unified Models for the Cadillac SRX, Chevrolet Sonic, Chevrolet Cruze, and the new GM Alpha platform. Actual performance curves for each of the alternators were used for one set of simulations. To simplify the comparisons, another set of simulations was done for the high efficiency Bosch and Denso alternators, wherein the actual performance curves were compared to alternator performance curves set to be exactly 10% lower than the actual curves. Also, a very simple set of simulations was done to compare a flat 70% efficiency alternator to a 60% efficiency alternator. [EPA-HQ-OAR-2010-0799-9487-A1, p.36]

The following chart shows the efficiency curves for the Bosch and Valeo alternators, and also shows the curve for the Bosch alternator modified to be exactly 10% below the actual Bosch data: [EPA-HQ-OAR-2010-0799-9487-A1, p.36] [For the chart please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.36]

Using this approach, the following CO_2 savings were estimated for the extra 20 amps typical of real word driving, compared to the 2-cycle test's 20 amp load: [EPA-HQ-OAR-2010-0799-9487-A1, p.37] [For the chart please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.37]

As would be expected, the complexity of vehicle operations results in a spread in results from this exercise. However, there are consistently CO_2 savings, with a representative savings appearing to be approximately 1.0 gCO_2/mile. We therefore recommend that an off-cycle credit of 1.0 gCO_2/mile be established for vehicles that use an alternator rated at 68% VDA or better. Alternator loads are rising as more electric features are used in vehicles; this credit amount is conservative in that it does not account for this trend of increasing vehicle-generated electricity usage. [EPA-HQ-OAR-2010-0799-9487-A1, p.38]

HVAC Eco-Mode

We appreciate the agencies' willingness to recognize the real-world fuel economy and GHG improvements from driver-selectable technologies. We understand that expected usage data will be required as a basis for adding these technologies to the menu. Since 2011, GM has featured an "eco button" on the Chevrolet Equinox® that allows drivers to select a driving mode which adjusts powertrain operation to achieve an improvement of approximately one mpg in combined city/highway driving. This has proven to be a popular feature with many customers, and GM has collected substantial data that documents high customer usage of this driving mode. In a two-week survey of 3,500 owners of the 2011 Equinox conducted through OnStar® technology, the following usage information was collected: [EPA-HQ-OAR-2010-0799-9487-A1, p.38]

50.3% of customers were using the eco mode for in excess of 90% of their driving, [EPA-HQ-OAR-2010-0799-9487-A1, p.38]

57.4% of customers were using the eco mode in excess of 50% of the time, and [EPA-HQ-OAR-2010-0799-9487-A1, p.38]

34% had never activated their eco mode. [EPA-HQ-OAR-2010-0799-9487-A1, p.38] While the fuel economy benefits of the powertrain eco settings appear in the city and highway fuel economy tests, the benefits of the new HVAC eco settings do not. These HVAC eco features should therefore be candidates for off-cycle GHG emissions credits. [EPA-HQ-OAR-2010-0799-9487-A1, p.38]

The driver selectable HVAC eco mode initiates alternative air conditioner settings, such as reduced blower speeds and evaporator core temperatures, both of which reduce load on the compressor. During cold weather, the blower speed is also reduced, which reduces blower energy consumption while also improving powertrain warm-up. Below are tables presenting test data from six SCO3 tests and two Cold CO tests on a 2013 Equinox. This data clearly shows the different, energy-saving operating characteristics from normal mode to eco mode. [EPA-HQ-OAR-2010-0799-9487-A1, p.38]

Based on GM 5-cycle testing on the 2013 Equinox, GM calculated that the HVAC energy savings for the eco button are 1.8 g CO_2/mile. Based on GM OnStar usage data, 50% usage is an appropriate adjustment for this credit, since at least 50% of the drivers are using it at least 90% of the time, with another 7% of drivers using it between 50% and 90% of the time, and 13% of drivers using it between 0% and 50% of the time. Multiplying 50% usage by GM's tested 5-cycle improvement of 1.8 gCO_2/mile yields a credit of 0.9 gCO_2/mile. The Alliance therefore recommends that a 0.9 gCO_2/mile credit for an HVAC eco button be established on the EPA menu. [EPA-HQ-OAR-2010-0799-9487-A1, pp.38-39] [For the figure please refer EPA-HQ-OAR-2010-0799-9487-A1, p.39]

Bypass Valve for Transmission Oil Cooler

This is an alternative approach to faster transmission warm-up and viscosity management, without using exhaust gases. Many vehicles, especially large trucks, feature transmission oil coolers that provide increased functionality to operate under heavy loads. One drawback, however, of the traditional transmission oil cooler is that it continuously cools the oil, even under circumstances when it would be advantageous for fuel economy to have the transmission oil gaining heat more rapidly. Adding a bypass valve for the transmission oil cooler allows the oil flow to be controlled to provide maximum fuel economy under a wide variety of operating conditions such as cold weather. However, bypass valves are not currently commonly used with transmission oil coolers. [EPA-HQ-OAR-2010-0799-9487-A1, p.39]

The Alliance recommends that an off-cycle credit of 0.3 gCO_2/mile be established for vehicles that have a transmission oil cooler with a bypass valve. This 0.3 gram proposed credit is proportional to the 1.8 gram benefit observed for active transmission warm-up using exhaust gases, based on the benefits observed during GM engineering development work with these technologies. Also, the bypass valve is additive, and even synergistic to the benefits of using exhaust gases for faster transmission warm-up, so both of these active transmission warm-up credits should be available on a vehicle. For example, a transmission with an oil cooler, combined with the bypass valve and exhaust gas-assisted warm-up, allows fine tuning of viscosity management, since accelerated heating or cooling of the oil can both be accomplished, depending on operating conditions. [EPA-HQ-OAR-2010-0799-9487-A1, p.39]

Electronic Thermostat and Electric Water Pump

This technology provides both faster engine warm-up and tighter continuous control of engine block temperature. The variable electric water pump only performs as much work as is demanded of it at any given time, based on instructions coming from the thermostat. This allows the water pump to work less immediately after startup, thereby warming the engine faster, since less heat is taken from the engine by its cooling system. This is especially valuable on the cold CO test cycle. The pump also works less under other operating conditions, thereby reducing the parasitic drag on the engine when compared to a conventional mechanical belt driven pump. This provides for tighter control of the engine temperature to its ideal (which optimizes fuel economy), with less energy spent on engine cooling. In an analysis using a conservative 3% on FTP City combined cycle, the improvement from a mechanically driven water pump and a conventional thermostat produces a 1 gram CO_2/ benefit using the 5-cycle calculation method. The vehicle used for this analysis was a 2.4L four cylinder SUV. [EPA-HQ-OAR-2010-0799-9487-A1, p.40]

As noted above, we also recommend the following updates to the off-cycle technology definitions: [EPA-HQ-OAR-2010-0799-9487-A1, p.41] [For the figures 'above' please refer to EPA-HQ-OAR-2010-0799-9487-A1, pp.40-41]

High efficiency exterior lighting means a lighting technology that, when installed on the vehicle, is expected to reduce the total electrical demand of the exterior lighting system when compared to conventional lighting systems. LED lights specifically qualify. Separate credit values may be earned for high efficiency lighting installed in the following components: parking/position, tail lights, license plate lights, low beam lights, and daytime running lights. Credits may also be earned for a high efficiency lighting bundle that is installed in the following components: front and rear side markers, and backup/reverse lights. [EPA-HQ-OAR-2010-0799-9487-A1, p.41]

Engine heat recovery means a system that captures heat that would otherwise be lost through the exhaust system or through the radiator and converting that heat to electrical or mechanical energy to meet the requirements of the vehicle. Systems obtain credits according to the following formula: [EPA-HQ-OAR-2010-0799-9487-A1, p.41]

Credit (gCO_2/mile) = (System watt Capacity / 100) * 0.7 [EPA-HQ-OAR-2010-0799-9487-A1, p.41]

Solar Panels means the installation of solar panels on a vehicle to capture and provide energy to the vehicle (e.g., provide energy to an electric drive system via battery charging or provide power to an electric motor or 12V battery trickle charging or cabin ventilation, etc.). Credit levels are granted according to the following formula: [EPA-HQ-OAR-2010-0799-9487-A1, p.41]

Credit (gCO_2/mile) = (Equivalent watt Output / 50) * 3.0 [EPA-HQ-OAR-2010-0799-9487-A1, p.41]

Active aerodynamic improvements means technologies that are actively controlled to improve aerodynamic efficiency. Credits are awarded according to the following formulas: [EPA-HQ-OAR-2010-0799-9487-A1, p.41]

Car: Credit (gCO_2/mile) = (Percent Reduction in Aero Drag, Cd) * 0.2 [EPA-HQ-OAR-2010-0799-9487-A1, p.41]

Truck: Credit (gCO_2/mile) = (Percent Reduction in Aero Drag, Cd) * 0.33 [EPA-HQ-OAR-2010-0799-9487-A1, p.41]

Engine stop-start means a technology which enables a vehicle to automatically turn off the engine when the vehicle comes to rest and restart the engine with driver action (e.g., applies pressure to the accelerator or releases the brake). Off-cycle engine stop-start credits will only be allowed if the Administrator has made a determination under the testing and calculation provisions in 40 C.F.R. part 600 that engine stop-start is the predominant operating mode. [EPA-HQ-OAR-2010-0799-9487-A1, p.42]

Occupant thermal comfort technologies means technologies or strategies that maintain occupant thermal comfort during off-engine periods in a stop-start equipped vehicle or in a hybrid electric vehicle or plug-in hybrid electric vehicle (e.g., PTC heater or electric heater circulation pump). [EPA-HQ-OAR-2010-0799-9487-A1, p.42]

Active drivetrain warm-up means a system that uses waste heat or waste energy to warm-up driveline fluids quickly and reduces parasitic drivetrain (transmission, axles, PTUs, t-cases) system losses, related to friction and fluid viscosity. In this category, active transmission warm-up would receive credit of at least 1.8 gCO_2/mi. [EPA-HQ-OAR-2010-0799-9487-A1, p.42]

Active engine warm-up means a system that uses waste heat, thermal storage, or waste energy to warm up targeted sub-systems of the engine such that frictional losses are reduced. It would allow a faster transition from colder operation to warm operation, decreasing CO_2 emissions, and increasing fuel economy. In this category, active engine warm-up would receive credit of at least 1.8 gCO_2/mi. [EPA-HQ-OAR-2010-0799-9487-A1, p.42]

Active seat ventilation means a device which draws (or pushes) air or transfers heat/energy from the seating surface which is in contact with the occupant and exhausts (or pushes) it to a location away from the seat. [EPA-HQ-OAR-2010-0799-9487-A1, p.42]

Passive cabin ventilation means ducts, devices or methods that utilize convective airflow to move heated air from the cabin interior to the exterior of the vehicle. [EPA-HQ-OAR-2010-0799-9487-A1, p.42]

Finally, opportunities exist to streamline traffic flow, reduce congestion and reduce emissions through better driving. For example, there are technologies that provide the driver or the vehicle with information for improved routing, or that provide the driver or the vehicle with information for more efficient vehicle operation. GPS technology can play a role in improving both driver behavior and vehicle operation. The opportunities for improvements through these eco driving technologies are not sufficiently defined for the Alliance to propose specific credit definitions and criteria at this time, but the industry hopes that it can work with the agencies in the future to create off-cycle credits for these technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.44]

The following supplemental comments address the comments of the International Council on Clean Transportation (ICCT). While ICCT purports to support the proposed rule, it advocates eliminating or rendering de minimis many of the proposed flexibility mechanisms. [EPA-HQ-OAR-2010-0799-11790-A1, p.2]

1. ICCT's Approach Would Delay Important Program Flexibilities Needed to Encourage Experimentation and Early Adoption of Innovative Technologies.

The mechanisms under attack by ICCT are a key feature of the proposed regulation, and have helped this rulemaking to proceed on an expedited timeline compared to similar major EPA and NHTSA rulemaking processes. Many of ICCT's comments call for further study before compliance credits are granted under the flexibility provisions. There will, in fact, be further study of the effectiveness of these technologies, but the timing for establishing the flexibility mechanisms cannot be separated from the expedited timing for the overall regulation. With this in mind, we encourage EPA to move forward with establishing a broad array of credit opportunities in the flexibility provisions of their regulation, to encourage early experimentation and early adoption of innovative new technologies. As the Agencies gain experience with the new approaches, they can refine the flexibility mechanisms appropriately. [EPA-HQ-OAR-2010-0799-11790-A1, p.2]

2. ICCT's Approach Would Make It Impossible for Automakers to Achieve the Level of Off-Cycle Credits that EPA Included in Setting the Stringency of the Overall GHG Regulations.

Although ICCT states that it "strongly supports" credits for off-cycle emission reductions (ICCT Comments, p. 1), the net effect of its specific recommendations would almost completely eliminate the off-cycle improvement program. [EPA-HQ-OAR-2010-0799-11790-A1,p.2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 98.]

Finally, manufacturers should be encouraged through flexibilities and incentives to implement verifiable innovations that enhance vehicle safety, that explore new technology applications and reduce CO_2 emissions.

The following supplemental comments address the comments of the International Council on Clean Transportation (ICCT). While ICCT purports to support the proposed rule, it advocates eliminating or rendering de minimis many of the proposed flexibility mechanisms. [EPA-HQ-OAR-2010-0799-11790-A1, p.2]

For most technologies in EPA's proposal, ICCT either entirely opposes credits (e.g., stop-start, active engine and transmission warm-up, ventilated seats and active and passive ventilation), or requests further study (e.g., engine heat recovery, solar panels, active aerodynamic improvements, and electric heater circulation pumps). Only three technologies would remain; for these, ICCT recommends reducing the credit amounts to levels well below the credit levels proposed in the NPRM. The remaining credits that ICCT recommends would be LED lights (at 0.8 gCO_2/mile) and solar reflective paint and glazing (jointly capped at 1.8 gCO_2/mile for cars and 2.6 gCO_2/mile for trucks, following a recommended 40% reduction for expected MAC efficiency improvements). Based on these ICCT recommendations, the maximum potential off-cycle credits for any car would be 2.6 gCO_2/mile and the maximum truck off-cycle credit would be 3.4 gCO_2/mile. [EPA-HQ-OAR-2010-0799-11790-A1, p.2]

In contrast, EPA included off-cycle credits for widespread implementation of start-stop and active aerodynamic technologies in setting the stringency of the overall GHG standards. The combined off-cycle credits for these two technologies are proposed to be 3.5 gCO_2/mile for cars and 5.5 gCO_2/mile for trucks (76 Fed. Reg. 74854, 75022 (Dec. 1, 2011)). Thus, if ICCT recommendations were fully implemented, it would be impossible to achieve the level of off-cycle credits that EPA included in setting the stringency of the overall greenhouse gas regulations. [EPA-HQ-OAR-2010-0799-11790-A1, p.3]

1. ICCT's Approach Would Delay Important Program Flexibilities Needed to Encourage Experimentation and Early Adoption of Innovative Technologies.

The mechanisms under attack by ICCT are a key feature of the proposed regulation, and have helped this rulemaking to proceed on an expedited timeline compared to similar major EPA and NHTSA rulemaking processes. Many of ICCT's comments call for further study before compliance credits are granted under the flexibility provisions. There will, in fact, be further study of the effectiveness of these technologies, but the timing for establishing the flexibility mechanisms cannot be separated from the expedited timing for the overall regulation. With this in mind, we encourage EPA to move forward with establishing a broad array of credit opportunities in the flexibility provisions of their regulation, to encourage early experimentation and early adoption of innovative new technologies. As the Agencies gain experience with the new approaches, they can refine the flexibility mechanisms appropriately. [EPA-HQ-OAR-2010-0799-11790-A1, p.2]

2. ICCT's Approach Would Make It Impossible for Automakers to Achieve the Level of Off-Cycle Credits that EPA Included in Setting the Stringency of the Overall GHG Regulations.

Although ICCT states that it "strongly supports" credits for off-cycle emission reductions (ICCT Comments, p. 1), the net effect of its specific recommendations would almost completely eliminate the off-cycle improvement program. [EPA-HQ-OAR-2010-0799-11790-A1,p.2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 98.]

Finally, manufacturers should be encouraged through flexibilities and incentives to implement verifiable innovations that enhance vehicle safety, that explore new technology applications and reduce CO_2 emissions.

3. Credit Calculation for Specific Off-Cycle Technologies

a. General Credit Calculation for Reducing Vehicle Load

EPA states a goal of matching off-cycle credits to real world emission reductions, and ICCT endorses the principle that “the credits properly reflect actual in-use reductions” (ICCT Comments, p. 36). However, ICCT then states that credits for reductions in electrical load should be based on the (lower) electrical loads on the two-cycle FTP/HWY tests, rather than the (higher) loads on the five-cycle tests. Yet it is the higher electrical loads on the five-cycle test that are more representative of “actual in-use reductions,” since some accessories such as the air conditioner are activated in the five-cycle tests, the fuel pump works harder at higher speeds, etc. In fact, since there are electrical features such as radios, phones, etc. not activated on the five-cycle procedures, the real world benefits are probably even higher. Despite ICCT’s comments to the contrary, there is no reason that grams per mile of CO_2 calculated using the five-cycle procedure, or any other more “real world” basis, cannot be subtracted from baseline emissions measured on the two-cycle tests. Doing so is consistent with the principle of providing off-cycle credits that reflect actual in-use reductions. [EPA-HQ-OAR-2010-0799-11790-A1, p.3]

b. High Efficiency Exterior Lighting

ICCT supports off-cycle credits for this technology, although it proposes changes in the calculation methodology to base it on the 2-cycle drive cycles, rather than 5-cycle calculations. As discussed above, this change would go against the goal of the program to grant credit based on real world emission reductions. The 5-cycle procedures are intended to be more representative of real world conditions. [EPA-HQ-OAR-2010-0799-11790-A1, p.3]

ICCT does not note the two most important changes that are needed to the exterior lighting credit, which are to offer credit for LED low beam and daytime running lights. These two sets of lights offer the greatest potential emissions reductions in the exterior lighting category. [EPA-HQ-OAR-2010-0799-11790-A1, p.3]

c. Electric Heater Circulation Pump

The Alliance recommendation for these credits was based on actual vehicle testing, quantifying the credit as the incremental 5-cycle test benefit over the 2-cycle benefit (although the 2-cycle benefit is zero, since the heater would never be “on” for 2-cycle test temperatures). The Alliance recommendation should fit ICCT criteria for a credit. All of the ICCT criticisms of EPA’s calculations for this technology become moot if the actual vehicle test data are used (e.g., time at idle, electricity to run the pump, and any engine warm-up at idle). [EPA-HQ-OAR-2010-0799-11790-A1, p.4]

d. Active Aerodynamic Technologies

Active aerodynamic features have been in production for some time, and the performance is reliable and well understood. The factors that ICCT notes do not create a significant deterioration or uncertainty in the benefits. For example, when there is a risk of freezing, active grill shutters are typically “deactivated” by placing them in the closed position, which maximizes the aerodynamic benefits while also hastening powertrain warm-up. This “ice mode” for active grill shutters is typically activated for all temperatures below approximately 40-45oF (vehicle temperature sensors typically indicate slightly warmer temperatures than the true ambient, so an indicated temperature in this range is chosen since the true ambient may be close to the temperature for ice formation). The shutters are kept shut, even as the temperature warms, for a sufficient time for any ice to melt. So a significant portion of real world vehicle operation is conducted in cold weather where the benefits of active grill shutters are actually higher than would be measured on the standard FTP/HWY test cycles. [EPA-HQ-OAR-2010-0799-11790-A1, p.4]

For ambient temperatures above approximately 80oF, active grill shutters are typically kept open to provide ample air flow for both the powertrain and the air conditioner. Opening the shutters in this condition actually saves fuel compared to the alternative of making the air conditioner and engine cooling fan work harder. For mild ambients - between approximately 45-80 oF - active grill shutter operation is typically controlled in accordance with the engine cooling fan, so the control system is fairly sophisticated in maximizing fuel economy while providing adequate air flow. We do not know how EPA simulations for this technology included these various modes, but it can be easily seen that this technology provides higher benefits in certain off-cycle conditions, such as high speeds and cold weather, and is therefore suitable for an off-cycle credit. Further, the conditions where the system is “deactivated” do not uniformly reduce the benefit, but would be expected, on balance, to actually increase the net real world benefit, given the large proportion of time spent with the shutters closed in “ice mode.” Active air dams operate similarly. Adjustable ride height is comparatively simple in operation, with straightforward high speed benefits. [EPA-HQ-OAR-2010-0799-11790-A1, p.4]

As recommended by the Alliance, a good performance criterion for these credits is the coefficient of drag (Cd) of the vehicle when the active aero features are deployed. A close relationship exists between Cd and the overall greenhouse gas savings, which can be the basis for granting credits based on Cd, thereby encouraging the maximum possible implementation of these technologies. It is not realistic to require case-by-case vehicle testing for these technologies, which would be prohibitively burdensome, thereby greatly slowing progress in this promising area. [EPA-HQ-OAR-2010-0799-11790-A1, p.5]

e. Active Engine and Drivetrain Warm-up

ICCT makes the case that off-cycle credits for active engine and transmission warm-up are “highly questionable,” since “most of the benefit of the warm-up systems will occur on-cycle during 2-cycle testing” (ICCT Comments, p. 46). ICCT bases this on an assertion that the amount of warm-up on the FTP, measured in degrees of engine temperature, is about two-thirds of the warm-up on the 20oF cold cycle:

However, normal engine operating temperatures are about 180oF. This is about 105oF above the FTP test temperature and about 160oF above the 20oF test temperature. Thus, the benefit of active engine warm-up on the FTP should be about two-thirds of the benefit at 20oF and the proportional benefit will be even closer. (ICCT Comments, p. 45). [EPA-HQ-OAR-2010-0799-11790-A1, p.5]

This analysis is grossly incorrect, since it omits the viscosity behavior of fluids such as engine oil and transmission fluid at low temperatures. Viscosity is the measure of a fluid’s resistance to flow, or fluid friction, and is therefore strongly related to powertrain and driveline efficiency. Kinematic viscosity increases exponentially as temperature falls, such that the viscosity of engine oil and transmission fluid is many times higher at the start of the cold test compared to the FTP. The graph below shows this for some common engine oils. At the starting temperature for the cold test (which at 20oF is actually -6.7oC, well below the starting point for this graph), viscosity would be above 600 centistokes (cSt). In contrast, at the start of the FTP, around 24oC, viscosity is around 125 cSt. Therefore, engine friction could be reduced several times by warming the temperature of the engine oil rapidly into the range of the FTP. Transmissions and transmission fluids behave similarly, as do rear differentials, etc. That is why accelerated warm-up of these components produces significant off-cycle benefits in cold weather. Improvements in engine oil viscosity taper off above 50oC, to the normal engine operating temperatures above 80oC, so most of the benefits of these technologies occur off-cycle and not on the two-cycle tests. [EPA-HQ-OAR-2010-0799-11790-A1, p.5]

f. Ventilated Seats and Other Ventilation Technologies

ICCT suggests that credits for ventilation technologies are not appropriate because they are based on “limited data”, and the driver response is “unclear” (ICCT Comments, p. 39). However, there are additional supporting studies and data beyond the series of National Renewable Energy Laboratory (NREL) studies that were cited in the EPA analysis. For example, studies of thermal comfort from heated and cooled seats were performed at the Technical University of Denmark, resulting in technical publications such as the summary in the journal “Ergonomics” in 2007 by Zhang, Dyon, Fang and Melikov (Vol. 50, Issue 4, pp. 586-600, “The Influence of Heated or Cooled Seats on the Acceptable Ambient Temperature Range”). [EPA-HQ-OAR-2010-0799-11790-A1, p.6]

Quoting the abstract of this study:

In 11 climate chamber experiments at air temperatures ranging from 15 to 45 degrees C, a total of 24 subjects, dressed in appropriate clothing for entering a vehicle at these temperatures, were each exposed to four different seat temperatures, ranging from cool to warm. In one simulated summer series, subjects were preconditioned to be too hot, while in other series they were preconditioned to be thermally neutral. They reported their thermal sensations, overall thermal acceptability and comfort on visual analogue scales at regular intervals. Instantaneous heat flow to the seat was measured continuously. At each ambient room temperature, the percentage dissatisfied was found to be a second-order polynomial function of local heat flow. Zero heat flow was preferred at an air temperature of 22 degrees C and the heat flow that minimized the percentage dissatisfied was found to be a single linear function of air temperature in all conditions. The analysis indicates that providing optimal seat temperature would extend the conventional 80% acceptable range of air temperature for drivers and passengers in vehicle cabins by 9.3 degrees C downwards and by 6.4 degrees C upwards. [EPA-HQ-OAR-2010-0799-11790-A1, p.7]

Only 20% of occupants were dissatisfied by the cabin temperature in the range from 10.8o to 34oC when the seat was heated or cooled optimally, according to a simple control strategy that changed seat heat flux as a linear function of ambient temperature. Regarding the potential for lower air conditioner usage in hot weather, it was concluded that 80% of occupants would be satisfied by seats that were cooled even if the cabin temperature was raised by up to 6.4oC. Note that this is more than the cabin temperature increases used in the NREL studies as the basis for their calculations of the fuel savings from reduced air conditioner usage due to ventilated seats. Making a rough estimate based the EPA factors for translating cabin temperature reductions to CO_2 reductions (Draft Joint Technical Support Document (TSD), p. 5-73), that 6.4oC temperature change would equal a 1.9 gCO_2/mile credit for cars and a 2.6 gCO_2/mile credit for trucks. The proposed off-cycle credits of 1.0 gCO_2/mile for cars and 1.3 gCO_2/mile for trucks, based on the NREL study, are modest in comparison. [EPA-HQ-OAR-2010-0799-11790-A1, p.7]

Also, the seat heat flux of 60 W/m2 in the NREL study (Figure 11) equals the optimal flux in the Zhang study at about 37oC (Figure 8). Thus, the actual seat heat transfer performance of the production seats in the Cadillac STS used in the NREL study is more than sufficient to achieve the results seen from the laboratory set-up used by Zhang et al, at least through ambient temperatures up to 37oC. Therefore, the comfort results quantified by Zhang et al can be achieved using actual ventilated seat components that are already in the market. Moreover, the air conditioner energy savings attributed to ventilated seats by NREL are not excessive compared to similar estimates for related thermal technologies in the TSD and elsewhere. [EPA-HQ-OAR-2010-0799-11790-A1, p.7]

This Technical University of Denmark data and the resulting polynomial function are summarized in the chart below. [EPA-HQ-OAR-2010-0799-11790-A1, p.7] [[See Docket Number EPA-HQ-OAR-2010-0799-11790-A1, p.8 for the chart.]]

Ventilated seats are a popular feature on luxury vehicles, despite the typically high price. Therefore, if the feature becomes more widespread as a result of the off-cycle credit program, it can be expected that the “driver response” will be to learn to appreciate and use this luxury feature, which provides quicker cool-down, as well as fuel savings. When the ventilated seats are in use, it can be reasonably expected that the air conditioner would be turned down to maintain comfort levels, providing the energy savings and emission reductions estimated in these analyses. [EPA-HQ-OAR-2010-0799-11790-A1, p.8]

g. Active and Passive Ventilation

As with ventilated seats, more research data and field experience is available for active and passive ventilation than was cited in the EPA TSD. Several manufacturers already offer active or passive ventilation technologies on production vehicles. The 2010 Toyota Prius began offering options of a solar panel ventilation system and a remote air conditioning controls system, both designed to reduce cabin temperature when the vehicle is parked in hot ambient conditions. Data has been provided by Toyota to the EPA on the performance of the Prius solar panel ventilation, corroborating the NREL report which EPA used as the basis for its proposed active ventilation off-cycle credit. Furthermore, market experience has already shown these features to be quite popular, as the projected installation rate of 3% has been actually running at 12% - which equates to about 50,000 units sold. Given the popularity of the solar panel ventilation system and the potential for expanding this technology to provide additional electrical energy to power the vehicle, it would be prudent for EPA to encourage development via off-cycle credits, rather than defer credits as ICCT suggests. [EPA-HQ-OAR-2010-0799-11790-A1, pp.8-9]

In addition, General Motors commissioned NREL in 2008-2009 to analyze over a dozen variations of active and passive ventilation, as well as additional combinations of ventilation technologies with solar reflective technologies, with the goals of identifying the most effective combinations, as well as validating a comprehensive range of improved thermal modeling methods. [EPA-HQ-OAR-2010-0799-11790-A1, p.9]

The ventilation technologies used the existing HVAC blower or additional fans at various power levels to provide either continuous or pulsed exchanges of fresh air into the vehicle. Based on a standardized solar load of 800 W/m2, among the variations using solely active ventilation, five out of twelve applications produced average interior temperature reductions during solar soaks in excess of the 6.9oC reduction measured in the older NREL study which was used as the basis for the proposed off-cycle credit. The biggest reduction was 11.4oC. Moreover, six of the lowest performing active ventilation applications were simply low-wattage versions of a system that achieved a 7.2oC average interior temperature reduction in its seventh, most high-powered application. Since each version of this system would cost the same, regardless of the wattage, the low-performance versions of this system can be disregarded as not commercially attractive when compared to the version that achieved a 7.2oC reduction at the same cost. If these low-powered systems are disregarded, only one application achieved an interior temperature reduction of less than 6.9oC, while five systems surpassed the 6.9oC reduction level. [EPA-HQ-OAR-2010-0799-11790-A1, p.9]

In comparison, a very simple passive system that opened the windows 2 cm achieved an average interior temperature reduction of 3.5oC, and also provided an additional improvement of approximately 1.5oC when combined with one of the active ventilation technologies. While this system was not as sophisticated as the one evaluated by EPA as the basis for the passive ventilation credit, it shows that there is significant potential for low cost emission reductions from this passive ventilation approach. [EPA-HQ-OAR-2010-0799-11790-A1, p.9]

In summary, the early experience with active and passive ventilation technologies has been promising, and the interior temperature data from these experiences supports the levels of off-cycle credit proposed by EPA. We therefore urge EPA to offer the proposed credits to encourage further progress in implementing and improving these technologies. [EPA-HQ-OAR-2010-0799-11790-A1, p.9]

Response:

The EPA agrees with the comments from the Alliance that the "off-cycle technology credit menu is a necessary addition to the off-cycle program" and appreciates the accolade that it is a "great addition to the GHG reduction and corporate fuel economy programs." As a result we are finalizing this rule with the off-cycle technology credit menu.

Regarding the Alliance comments that "recommend[ed] revisions to the proposed credit amounts", the EPA responded to the comments regarding each of these technologies in greater detail in Chapter 5.2 of the TSD and Preamble II.F of this final rule. Specifically, our responses for each of the technologies on the off-cycle technology menu can be found in TSD Chapter 5 as follows: High Efficiency Exterior Lighting (5.2.3), Waste Heat Recovery (5.2.2; formerly termed "Engine Heat Recovery"), Solar Panels (5.2.4), Active Aerodynamic Improvements (5.2.6), Active Drivetrain Warm-Up (e.g., Active Transmission Warm-Up; 5.2.8.3), Active Engine Warm-Up (5.2.8.4), Thermal Control Technologies (5.2.9) including Glazing (5.2.10), Solar Reflective Paint (5.2.12), Active Seat Ventilation (5.2.11), Active Cabin Ventilation (5.2.13), and Passive Cabin Ventilation (5.2.13). In addition, our responses regarding additional technologies that the Alliance recommended we consider adding to the off-cycle technology credit menu or allowing credit for including: High Efficiency Alternator, HVAC Eco-Mode, Bypass Valve for Transmission Oil Cooler, and Electronic Thermostat and Electric Water Pump; are discussed in Section II.F.2. of the preamble for this final rule. Finally, our responses to the comments from the Alliance regarding clarifying the technology definitions are included in TSD Chapter 5 and the definitions for specific off-cycle technologies can be found in 5.2.5, 5.2.7., 5.2.8.5, and 5.2.15.

The EPA also agrees with and appreciates the supplemental comments from the Alliance. The EPA sought to ensure that the off-cycle credits for technologies on the off-cycle technology menu were verifiable and supported by data. This supporting information from the Alliance was helpful to support the basis for the credit values that we are finalizing in this rule.

Organization: Association of Global Automakers, Inc. (Global Automakers)

Global Automakers supports the availability of credits for technologies that provide on-road efficiency and emissions benefits but whose benefits are not fully measured using the current city-highway test. In a number of cases, these technologies are currently known, as indicated by the "menu" of credits developed by the agencies for the proposed rule. However, given the long time-frame for the proposed standards, it is very possible that additional technologies will be identified which should qualify for off-cycle credits, and the characteristics of these technologies cannot currently be predicted. In order to provide an incentive for manufacturers to pursue the implementation of these technologies and realize the resulting benefits, it is important that the agencies provide maximum flexibility to manufacturers to obtain credits. For these reasons, we urge the agencies to avoid imposing unnecessary restrictions on qualification for off-cycle credits. The proposed rule establishes numerous restrictions on the use of off-cycle credits which appear to be arbitrary and unnecessary to the effective functioning of the GHG and CAFE programs. [EPA-HQ-OAR-2010-0799-9466-A1, p. 5]

(1) The pre-approved technology "menu." Global Automakers supports the inclusion of the menu in the regulations as a default list of pre-approved technologies, with manufacturers being authorized to petition for larger credit or credits for additional technologies, based on credible data. [EPA-HQ-OAR-2010-0799-9466-A1, p. 5]

The agencies should also update the menu list from time-to-time, as they receive information on additional technologies that provide off-cycle benefits. Inclusion of technologies on the pre-approved menu provides a significant incentive for manufacturers to implement those technologies, so the menu should be as comprehensive as possible. One example of such a technology that is mentioned in the comments on the proposed standards is high efficiency alternators. This technology provides benefits greater than those measured in 2-cycle testing, since its efficiency advantage is applied to the electrical loads of equipment that is operated during typical on-road driving but that is not operated during 2-cycle tests (e.g., lighting, radio, etc.). [EPA-HQ-OAR-2010-0799-9466-A1, pp. 5-6]

EPA should not maintain any of the restrictions on off-cycle credits in the absence of a strong showing of need for the restriction. Additionally, we believe that the agencies should update the off-cycle credits menu in the mid-term review. [EPA-HQ-OAR-2010-0799-9466-A1, p. 7]

Response:

The EPA agrees with the comments from the Global Automakers that it is important to "provide an incentive for manufacturers to pursue the implementation of these technologies and realize the resulting benefits" and we believe the off-cycle program achieves this.

In contrast, the EPA disagrees with statements from the Global Automakers that all of the eligibility criteria to receive off-cycle credits are "arbitrary and unnecessary to the effective functioning of the GHG and CAFE." We did revise the criteria for receiving off-cycle credit menu default values by eliminating the requirement for 10% market penetration for the technologies on the off-cycle technology menu (see Preamble III.C.5.b.i.). However, other criteria such as the 10 g/mile total cap for menu-based credits have been retained since these criteria "balanc[e] the goal of providing a streamlined pathway to encourage significant introduction of innovative off-cycle technologies with the uncertainty inherent with the estimated level of credits being provided" (see Preamble III.C.5.b.i.). Therefore, other than the 10% market penetration rate requirement, we believe that the eligibility criteria for the default credit values in the menu are appropriate. Manufacturers may, of course, seek credits in greater amounts for the technologies on the menu using the case-by-case demonstration procedures.

The EPA agrees with the comments from the Global Automakers that we should review the list of technologies and consider additions to the off-cycle technology menu. EPA will continue to closely watch new technologies and evaluate applications for new off cycle credits as they come in.

Finally, the comments from the Global Automaker regarding high efficiency alternators are discussed in greater detail in Section II.F.2. of the preamble for this final rule.

Organization: Bosch

The agencies have recognized certain technologies, while having a measurable impact on CO_2 and fuel economy on the 2-cycle test, have an even greater impact off-cycle and as such the agencies have included these technologies on the pre-approved off-cycle technology credit list. Bosch commends the agencies for the inclusion of stop/start and active aerodynamics on this off-cycle list. In response to the agencies' request for input regarding the off-cycle credit list, Bosch is proposing the addition of brushless technology for engine cooling fans and high efficiency alternators to the pre-approved off-cycle technology credit list. [EPA-HQ-OAR-2010-0799-9462-A1, p. 2]

Brushless technology (EC) for Engine Cooling Fans – This high efficiency technology for electrical motors / drives should be added to the pre-approved list of technologies for off-cycle credits. Most of today's vehicles utilize brushed motors (DC) in a series-parallel dual fan configuration, which allows for only three fan power levels. In a typical high-power system, these levels could equate to 0 watts (OFF), 170 watts (Low Speed), and 660 watts (High Speed). Transitioning from series-parallel brushed motors to advanced brushless motor technology reduces average vehicle electrical power consumption by 81 watts (Appendix A) – resulting in a direct fuel economy improvement of 0.27 mpg assuming standard measurements and calculations that form a general rule that reducing vehicle electrical consumption by 30 watts will result in a fuel economy improvement of 0.1 mpg. Field data at major OEMs have proven this relationship over a number of years for both passenger cars and light duty pickups. [EPA-HQ-OAR-2010-0799-9462-A1, pp. 2-3]

High Efficiency Alternators – While Bosch recognizes high efficiency alternators were included as an integral technology in the setting of the standards, and are thus precluded from off-cycle credits, the fuel savings and CO_2 reduction attributable to high efficiency alternators are greater in the 5-cycle versus the 2-cycle tests. Alternator efficiency plays an even greater role in real life applications and drive cycles where a higher, more realistic vehicle load is encountered. The base alternator efficiency assumed in the NPRM is approximately 65%. Increases in alternator efficiency to 75% and up to 82% can be realized using a combination of existing and new technologies respectively. Alternators with increased efficiency are a drop-in replacement with no other changes needed to the vehicle architecture. Bosch therefore recommends the addition of high efficiency alternators to the pre-approved off-cycle technology list. [EPA-HQ-OAR-2010-0799-9462-A1, p. 3]

An example demonstrating the effect of a high efficiency alternator is provided in Appendix B. In tests on a GM 2.4L 4 cylinder gasoline engine, an increase in alternator efficiency of 10% resulted in 1.23% improvement in fuel economy on the 2-cycle test and 1.93% improvement on the 5-cycle test. Typical vehicle electrical loads are included in the appendix. At higher, more real world electrical loads, this off-cycle benefit would have an even greater impact on fuel consumption. Upon request, additional calculations using the MOVES model as well as additional 5-cycle test data can be provided. [EPA-HQ-OAR-2010-0799-9462-A1, p. 3]

Response:

We appreciate the comments from Bosch and the supporting information that the company supplied. However, we disagree with Bosch that high-efficiency alternators and brushless technology for engine cooling fans should be added to the off-cycle technology menu.

Our detailed responses to the comments from Bosch on additional technologies for the off-cycle technology menu are in Section II.F.2. of the preamble for this final rule. To summarize, we are not adding high efficiency alternators and brushless technology for engine cooling fans to the off-cycle credit menu due to the variability in implementation strategy and electrical loads for the systems and related components. This makes it difficult to pinpoint a single, default value for the off-cycle technology menu. Therefore, we feel that these technologies are better suited for off-cycle credit consideration using the alternate case-by-case approval process for technologies not on the off-cycle technology menu. As a result, manufacturers may seek off-cycle credit for high efficiency alternators and brushless technology for engine cooling fans but must make an individualized demonstration in order to obtain such credits.

Organization: Chrysler Group LLC

The Agencies have established separate credits for off-cycle technologies which are expected to have different greenhouse gas and fuel consumption benefits for passenger cars and light-duty truck. Similar to many of the other off-cycle technologies, active engine and transmission warm-up technologies are expected to yield a greater absolute benefit for light-duty trucks. [EPA-HQ-OAR-2010-0799-9495-A1, p. 6]

Recommend improvements to the process for qualifying additional off-cycle technologies; [EPA-HQ-OAR-2010-0799-9495-A1, p. 9]

And provide numerous other technical comments and recommendations on off-cycle technologies. [EPA-HQ-OAR-2010-0799-9495-A1, p. 9]

Support the establishment of a table of pre-approved off-cycle technologies with defined greenhouse gas and fuel consumption benefits; [EPA-HQ-OAR-2010-0799-9495-A1, p. 9]

Support expansion of the pre-approved off-cycle technology list; [EPA-HQ-OAR-2010-0799-9495-A1, p. 9]

The Agencies propose a pre-approved table of greenhouse gas and fuel consumption improvement values for GHG and CAFE compliance applicable to the 2017-2025 MYs. The Agencies note that this “Off-Cycle Technology Table” would “significantly streamline and simplify the [off-cycle credit] program for manufacturers choosing to use it and would provide manufacturers with certainty that credits may be generated through the use of pre-approved technologies.” EPA further notes that the values in the Off- Cycle Technology Table were developed using “a combination of available activity data from the MOVES model, vehicle and test data, and EPA’s vehicle simulation tool to estimate a proposed credit value EPA believes to be appropriate.” The approach of the Off-Cycle Technology Table makes sense. By providing manufacturers certainty that their efforts to improve real-world greenhouse gas emissions and fuel economy will be taken into account for compliance purposes, the Agencies encourage the adoption of these technologies. [EPA-HQ-OAR-2010-0799-9495-A1, p. 9]

Chrysler recommends that the Agencies define separate passenger car- and light-duty truck-specific credits for active engine and transmission warm-up technologies. [EPA-HQ-OAR-2010-0799-9495-A1, p. 10]

EPA is proposing to establish a list of pre-defined and pre-approved off-cycle technologies. This list contains three basic technology types according to the Agencies’ Draft Joint Technical Support Document7 (“DJTSD”): technologies which reduce or offset electrical loads; active aerodynamic improvement technologies; and advanced load reduction technologies. [EPA-HQ-OAR-2010-0799-9495-A1, p. 10]

The advanced load reduction technologies proposed for inclusion in the pre-defined and pre-approved list are engine start-stop (idle off), electric heater circulation pump, active transmission warm-up, active engine warm-up, and thermal/solar control technologies. All of these advanced load reduction technologies, except for active transmission and active engine warm-up, have passenger car and light-duty truck-specific credits derived for them based on their relative benefit for cars and trucks. In the case of active transmission and engine warm-up, EPA based the estimated benefits on a mid-size car only. EPA should treat all advanced load reduction technologies in a similar manner by estimating passenger car and light-duty truck-specific credits for active transmission and engine warm-up technologies. [EPA-HQ-OAR-2010-0799-9495-A1, p. 10]

If additional technologies are added to the pre-defined and pre-approved off-cycle technology list, Chrysler supports passenger car and light-duty truck specific credits where such technologies affect vehicle greenhouse gas emission and fuel consumption in a similar manner to advanced load reduction technologies. [EPA-HQ-OAR-2010-0799-9495-A1, p. 10]

Response:

We appreciate the comments from Chrysler Group LLC and agree with the comments on establishing a table of pre-approved off-cycle technologies and credit values, and improvements to the process for qualifying additional off-cycle technologies.

Regarding the comments from Chrysler for separate passenger car and light-duty truck-specific credits for active transmission and engine warm-up technologies, we reviewed our estimates for active transmission warm-up and active engine warm-up and revised the default credit amount as discussed in Section 5.2.8.3 and 5.2.8.4, respectively of Joint TSD Chapter 5 and Section II.F.2. of the preamble for this final rule.

Based on our revised estimates, we agree with Chrysler that there is a clear difference in the benefit of active transmission and engine warm-up technologies between passenger cars and light-duty trucks. Therefore, we are including separate car and truck credits on the off-cycle technology menu for active transmission and engine warm-up of 1.5 grams/mi for cars and 3.2 grams/mi for trucks.

Organization: Denso International America, Inc.

DENSO has developed high efficiency alternators for use in light vehicles and, as a result, has significant expertise in this technology. These alternators have a higher degree of effectiveness in reducing real-world CO_2 emissions than is measured using the Federal Test Procedure/Highway Fuel Economy Test 2-cycle procedure. This difference in performance levels is similar to that of stop-start systems and active grill shutters, which are included in the pre-defined technology "menu" list in section 86.1866-12(d)(1)(i) of the agencies' proposed 2017-25 rule. Therefore, we request that EPA and NHTSA add high efficiency alternators to the off-cycle menu list along with the other technologies that have similar performance characteristics. [EPA-HQ-OAR-2010-0799-9269-A1, p. 1]

We would be pleased to work with EPA and NHTSA to develop any data or other information that EPA and NHTSA need in order to make a determination regarding the appropriateness of adding high efficiency alternators to add the pre-defined list. [EPA-HQ-OAR-2010-0799-9269-A1, p. 1]

I. Background.

EPA and NHTSA published on August 9, 2011 a Supplemental Notice of Intent announcing plans to propose stringent federal greenhouse gas and fuel economy standards for model year (MY) 2017-2025 light-duty vehicles (hereinafter referred to as the SNOI). The SNOI described high efficiency alternators as one of candidates for the off-cycle credits. However, the high efficiency alternator was not included in an applicable technology list of § 86.1866–12(d)(1) of the proposed rule. Therefore, the proposed off-cycle credit program does not allow manufacturers to obtain credits of the high efficiency alternator without EPA prior approval. Inclusion of the technology in the off-cycle menu is important, since it provides an assurance to vehicle manufacturers that they will receive a specified credit for use of the technology, significantly improving the marketability of the technology. In this way, the emissions and energy benefits of the technology will be maximized. [EPA-HQ-OAR-2010-0799-9269-A1, p. 1]

II. Electrical load over 2 cycle (FTP/HFET) test and real world condition.

High efficiency alternators supply electrical power to vehicle electrical equipment with less required engine power than normal efficiency alternators. The reduction of required engine power by the high efficiency alternators yields a corresponding reduction of CO_2 emissions. [EPA-HQ-OAR-2010-0799-9269-A1, p. 1]

The benefit of the high efficiency alternators over real world condition cannot be sufficiently captured by the 2 cycle (FTP/HFET) test procedure, however. This is because the electrical load over the 2 cycle test condition is much less than the load over real world condition. [EPA-HQ-OAR-2010-0799-9269-A1, p. 2]

DENSO estimates that the electrical load of vehicles over 2 cycle test conditions and real world conditions are as shown in Table 1. We estimate the electrical load over 2 cycle test conditions is 240W and over real world condition is 750W. If the electrical load of optional equipment which may be selected by the driver is considered, the real world electrical load is increased to 1470W. This means that the CO_2 reduction benefit by the high efficiency alternator, which we project to be 510W (750W – 240W) at minimum, is not captured by the 2 cycle test. Therefore, we believe that the high efficiency alternator is qualified as an off-cycle technology. [See Table 1 on page 2 of Docket number EPA-HQ-OAR-2010-0799-9269-A1] [EPA-HQ-OAR-2010-0799-9269-A1, p. 2]

According to the Draft Technical Support Document (TSD) for the NPRM, section 5.2.1, EPA and NHTSA estimate that a reduction of required engine power of 100W yields 3.0g/mi CO_2

emission reduction over the 2 cycle test and 3.7g/mi CO_2 emission reduction over the 5 cycle test. Table 2 shows our brief simulation of CO_2 reduction benefit by improving the alternator efficiency from an average 65% to average 75% and using the EPA and NHTSA study in the TSD and our estimation of vehicle electrical load. Based on this simulation, we can estimate that a 2.8 g/mi CO_2 reduction is available by improving of the alternator efficiency. This constitutes a substantial real world CO_2 emission reduction. Therefore, the high efficiency alternator should be included in the menu list of off-cycle credits to promote the introduction of the technology. [See Table 2 on page 3 of Docket number EPA-HQ-OAR-2010-0799-9269-A1] [EPA-HQ-OAR-2010-0799-9269-A1, pp. 2-3]

III. Off-cycle credit for high efficiency alternators in passenger car CO_2 emission regulation in Europe.

The European Union (EU) has adopted CO_2 emission reduction regulations for passenger cars effective in 2012, through their Regulation (EC) No. 443/2009. Regulation (EC) No. 443/2009 provides “eco-innovation” credits, which are similar to the U.S. proposed off-cycle credits. The eco-innovation credits are available for technologies whose CO_2 reduction benefit cannot be fully measured using the EU CO_2 emission test methodology (New European Driving Cycle, “NEDC”). [EPA-HQ-OAR-2010-0799-9269-A1, p. 3]

On July 25, 2011, the EU published a regulation (Commission Regulation (EU) No. 725/2011) and a technical guideline document to establish type approval procedures for eco-innovation credits. The technical guideline document describes the high efficiency alternator as one of the technologies that qualifies for eco-innovation credits, and establishes the credit calculation methodology for such alternators. This methodology should be considered by EPA and NHTSA as a reference for developing an off-cycle credit for high efficiency alternators in the U.S. final rule. According to the guideline, because the electrical load of the vehicle over real world conditions is larger than the load over NEDC test, the CO_2 reduction benefit of the high efficiency alternator cannot be sufficiently measured using the NEDC test. Therefore, EU determined the high efficiency alternator as one of technologies that qualifies for eco-innovation credits. See the technical guideline at http://ec.europa.eu/clima/policies/transport/vehicles/cars/docs/guidelines_en.pdf [EPA-HQ-OAR-2010-0799-9269-A1, p. 3]

The eco-innovation credit calculation methodology for the high efficiency alternator is described in paragraph 8.4 of the EU technical guideline. The credit of the alternator is calculated as follows. [See the calculation on page 4 of Docket number EPA-HQ-OAR-2010-0799-9269-A1] [EPA-HQ-OAR-2010-0799-9269-A1, p. 4]

Response:

We appreciate the comments from Denso International America, Inc. and the supporting information that they supplied. However, we disagree with Denso that high-efficiency alternators should be added to the off-cycle technology menu.

Our detailed responses to the comments from Denso on the addition of high-efficiency alternators to the off-cycle technology menu are in Section II.F.2. of the preamble for this final rule. To summarize, we are not adding high efficiency alternators to the off-cycle technology menu due to variability in implementation strategy and electrical loads for the systems and related components. This makes it difficult to pinpoint a single, default value for the off-cycle technology menu. Therefore, we feel that this technology is better suited for off-cycle credit consideration using the alternate method approval process for technologies not on the off-cycle technology menu. As a result, manufacturers seeking off-cycle credit for high efficiency alternators must pursue this path.

Organization: EcoMotors International, Inc.

It is vital that EPA continue to evaluate off-cycle technologies and consider adding technologies to the pre-approved list even after the Final Rule's adoption. Similarly, manufacturers should always have the ability to provide data for pre-approved technologies to demonstrate a credit value greater than that assigned on the EPA pre-approved list. EcoMotors encourages EPA to continue to provide as much guidance and certainty to OEMs as possible (via guidance letters or other mechanisms), as this program continues to evolve and as new technologies emerge and are developed. [EPA-HQ-OAR-2010-0799-9594-A2, p. 13]

Response:

The EPA agrees with the comments from EcoMotors International, Inc. The alternate method approval process for technologies not on the off-cycle technology menu is a pathway for manufacturers to “provide data for pre-approved technologies to demonstrate a credit value greater than that assigned on the EPA pre-approved list.” Therefore, we believe the provisions for the off-cycle credit program in this final rule address the comments from EcoMotors International, Inc.

Organization: Ford Motor Company

Further, we believe that there is opportunity to expand the menu beyond the currently proposed list to capture other fuel-saving technologies such as high efficiency alternators, HVAC Eco-Mode, transmission oil cooler bypass valves, and electronic thermostats and electric water pumps. The inclusion of these items to the list may encourage more widespread implementation of these technologies. The list of technologies (currently proposed and new) and credit levels, as proposed by the Alliance and supported by Ford, is shown below: [The list can be found on p. 16 of Docket number EPA-HQ-OAR-2010-0799-9463-A1] [EPA-HQ-OAR-2010-0799-9463-A1, p. 15]

The addition of the predefined technology menu is extremely beneficial to manufacturers as it provides a clear methodology to achieve credits for technologies that provide real world fuel economy benefits that are not reflected in the regulated test procedures. To improve this method even further, Ford agrees that several of the menu technology definitions should be revised to improve clarity or to broaden their scope of applicability. We also propose that some of the credits should be adjusted to higher levels, based on industry data, as detailed in the Alliance comments. [EPA-HQ-OAR-2010-0799-9463-A1, p. 15]

In addition to the technologies discussed and listed above, we anticipate working with EPA to establish the correct methodologies to account for benefits of in-vehicle systems that provide tools for more efficient driving. Driver coaching or feedback systems, such as Ford EcoMode, can result in more fuel efficient driver behavior (e.g., less aggressive acceleration or braking, more efficient shifting, etc.) and have already deployed successfully in our hybrid electric vehicles and the new Ford Focus. Similarly, vehicle maintenance alerts and reminders can help drivers ensure that their vehicles are operating efficiently; for example, Ford's Crew Chief program, offered to fleet customers, currently helps drive fleet efficiency through improved vehicle maintenance by communicating oil life and low tire pressure to the fleet manager. Opportunities to expand these capabilities could provide significant real world fuel savings across our customer fleet. Finally, route planning tools can assist drivers in finding the best route as well as avoiding (and thus reducing) congestion. Real world benefits to both greenhouse gas emissions and fuel economy can be achieved through these technologies, and while quantifying the benefit is an acknowledged challenge, we look forward to further discussion with the agencies. [EPA-HQ-OAR-2010-0799-9463-A1, p. 16]

While the pre-approved technology list is only proposed to apply for 2017 and later MYs, Ford would support an allowance to also use it for 2012-2016 MY vehicles. If the same technologies are used prior to 2017, we believe they should be eligible for the same benefits. Such an extension of the menu would help to encourage earlier implementation of these technologies. [EPA-HQ-OAR-2010-0799-9463-A1, p. 17]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 44-47.]

Further, we anticipate working together to establish the correct methodologies to account for the benefits of driver-activated technologies. For example, coaching systems result in more fuel-efficient driver behavior as well as eco-route planning tools can provide a significant improvement in real-world fuel economy.

Response:

The EPA agrees with the comments from Ford Motor Company that "the predefined technology menu is extremely beneficial to manufacturers as it provides a clear methodology to achieve credits for technologies that provide real world fuel economy benefits."

Our responses to the comments from Ford Motor Company on additional technologies for the off-cycle technology credit menu including High Efficiency Alternators, HVAC Eco-Mode, Bypass Valves for Transmission Oil Cooler, and Electronic Thermostat and Electric Water Pump are discussed in Section II.F.2. of the preamble for this final rule. In summary, we are not adding these technologies to the off-cycle technology menu but credit for these technologies may be requested using the alternate method approval process for technologies not on the off-cycle technology menu. Responses to comments regarding off-cycle credit eligibility for crash avoidance and driver interactive technologies are likewise discussed in preamble section II.F 2.

Organization: Hyundai America Technical Center

1) Modifications to the Off-Cycle Menu: Hyundai supports the menu format for off-cycle technologies which will allow for a less burdensome path of accounting for the performance of several well-accepted technologies. [EPA-HQ-OAR-2010-0799-9547-A1, p.5]

2) Update of Off-Cycle Technology Menu: Hyundai recommends that the agencies conduct an annual update of the existing menu technologies to ensure that improvements in the technologies, which are likely to occur over the extended time period of the rule, are properly reflected in the menu. In addition, Hyundai strongly requests that the menu list be updated annually with new technologies that have been approved by the agencies. Hyundai believes it is unnecessary for manufacturers to generate burdensome confirmatory data of off-cycle technology benefits if the data is already available. Additionally, this has the potential of reducing the agencies' burden in reviewing redundant technologies and reducing the time and number of public review requests. [EPA-HQ-OAR-2010-0799-9547-A1, p.5]

Response:

We agree with the comments from Hyundai America Technical Center that the off-cycle technology menu "will allow for a less burdensome path of accounting for the performance of several well-accepted technologies." However, we disagree with the comments from Hyundai that the agencies should "conduct an annual update of the existing menu technologies to ensure that improvements are properly reflected in the menu."

The off-cycle technology menu was adopted to add a certain level of stability to the off-cycle credit program. Continually updating the off-cycle technology menu on an annual basis has the complete opposite effect. Further, the menu is part of the rule and can only be amended through notice-and-comment rulemaking proceedings.

In addition, the alternate demonstration methods for technologies not on the off-cycle technology menu offers a pathway for manufacturers to demonstrate benefits and request credit beyond the technologies (or the amounts) offered in the off-cycle technology menu. The off-cycle technology menu credit values are based on existing technology and currently available information using conservative estimates. As individual manufacturers develop specific technology that achieves greater benefits (than those listed on the menu), it would be imprudent to reflect this on annual basis in the off-cycle technology menu since not all vehicles are not expected to have identical technology effectiveness and implementation. Thus, credit values are expected to vary. Therefore, the alternate demonstration method process is better suited for case-by-case evaluations where there is insufficient data to support a default credit or where the level of credit may depend on a specific manufacturer's design.

Finally, regarding the Hyundai comments on burden, it should be noted that the information used in the alternate demonstration method process can be used as long as the off-cycle technology and the vehicle application remain unchanged. In this manner, this data can be carried over on an annual basis, provided no changes have occurred, thus reducing the burden for requesting and approving credit. Further, as Hyundai points out in their comments, if the data is already available to the manufacturer, there is no need to "generate burdensome confirmatory data of off-cycle technology benefits."

Organization: Mercedes-Benz USA, LLC

DAG supports credits to encourage vehicle technologies that reduce CO_2 emissions by reducing collisions resulting in fuel consuming traffic congestion. Below DAG suggests a package menu approach with conservatively-based credit opportunities that will encourage the deployment of these technologies and considerably reduce CO_2 emissions. [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

With regard to particular off-cycle credits, DAG supports the Alliance proposal for calculating the potential for High Efficiency Light Savings. However, in the event that the agencies do not adopt the Alliance proposal, DAG suggests that the agencies adopt EPA's methodology, as described in the draft Joint Technical Support Document (TSD § 5.2.1.1). DAG believes that all cars equipped with LED lighting systems should be eligible for an off-cycle credit, even if LED lighting is not used on all lamps throughout the vehicle. DAG proposes both that the credit be premised on the real power consumption of the LED-light systems actually incorporated into the vehicle, and further that both low and high beam LED light systems be eligible. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-3]

The process DAG envisions to account for this off-cycle credit would be that the manufacturer supply the agencies with electric power consumption of each LED light system on the vehicle. Using that data, the off-cycle credit can be derived according to the methodology described in Table 5.21 in the draft TSD, with the exception that the electric power consumption of the high efficiency LED system supplied by the manufacturer be used rather than the values in the table. This change in the methodology will not limit the off-cycle credit to vehicles fully equipped with high efficiency LED lighting; it will instead allow vehicles partially equipped with high efficiency LED lighting to also be eligible for the off-cycle credit. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-3]

As the agencies began to construct a CO_2 program complementing the traditional fuel economy program, EPA and NHTSA recognized that the traditional definition of 'fuel economy' is restrictive and that significant additional reductions in emissions and fuel consumption can be attained by encouraging the advent of vehicle-based technologies that reduce fuel consumption in ways that are not reflected in the federal test procedures. As a result, the agencies have included within their assessments CO_2 and fuel consumption reductions associated with enhanced air conditioning efficiencies and reduced refrigerant leakage. The agencies have also created an off-cycle CO_2 and fuel consumption improvement program to encourage the proliferation of technologies capturing these additional benefits. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-6-A-7]

Similar to off-cycle technologies are technologies that lead directly to CO_2 and fuel consumptions reductions by avoiding crashes and the associated traffic congestion they cause. Crash avoidance technologies serve not only to promote motor vehicle safety, but also to ease the flow of traffic and to mitigate traffic congestion that is associated with motor vehicle collisions. The real world CO_2 and fuel economy benefits of these technologies, when they are not mandated through regulation, should be recognized and their widespread deployment encouraged within the context of the GHG and fuel economy programs.[13] [EPA-HQ-OAR-2010-0799-9483-A1, p. A-7]

Below DAG sets forth the analytic foundation and the suggested elements of a program to encourage and to acknowledge the significant CO_2 and fuel consumption benefits associated with the potential for these technologies to reduce crash-induced congestion. While these benefits are derived independently of NHTSA's safety mission, promoting vehicle-based technologies that avoid crashes in order to reduce fuel consumption and CO_2 emissions is entirely consistent with that mission. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-7]

Significantly, in the context of saving fuel and reducing CO_2 emissions, the relevant linkage in terms of any technology's effectiveness is whether the agencies can link the technology to crash avoidance and enhanced traffic flow, not whether the agencies can link the technology to reduced fatalities and injuries. As a result, the technologies encouraged within the GHG and CAFE programs need not be premised on technologies already approved by NHTSA within the New Car Assessment Program or other safety programs linked to fatalities and injuries. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-7]

DAG acknowledges the inherent limitations in trying to quantify specific levels of CO_2 reductions to particular features. There is clear data, however, relating unnecessary fuel consumption to traffic congestion and traffic congestion to collisions. There is also data showing the effectiveness of certain crash avoidance technologies. The agencies have linked crash-induced congestion to excess fuel consumption and CO_2 emissions. With the CO_2 benefits of crash mitigation clear, the agencies have an opportunity to encourage significant additional emissions benefits through promoting crash avoidance technologies, and can do so through a process utilizing conservative assumptions. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-7]

The fact that crash avoidance technologies are a primary countermeasure within NHTSA's safety program should not preclude the agencies from gaining the substantial CO_2 and fuel consumption benefits associated avoiding crashes and enhancing the efficiency of the transportation system. The agencies need not limit their authority to advance the fundamental policies embedded in each empowering statute by focusing too narrowly on the specific type of regulatory action each has traditionally issued. The National Program in particular represents a regulatory transformation. Three government bodies are working together under a historic program to harmonize regulatory programs all aimed at common theme; and the historically separate considerations of emissions and safety have converged. This convergence is an opportunity to improve emissions reductions and fuel economy within the GHG and CAFE program with the corollary effect of also advancing motor vehicle safety. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-7]

The Clean Air Act obligates EPA to redress endangerments to public health and welfare arising as the result of the emission of air pollutants. The concept of welfare, in particular, is broad and encompasses a wide array of potential dangers. As set forth in more detail below, EPA has determined that traffic congestion is a substantial contributor endangering public health and welfare due to the excessively unnecessary amounts of fuel consumed, and also that climate change is leading to more weather-related traffic accidents and delays. Having already linked traffic accidents, congestion, climate change and the endangerment to public health and welfare, EPA is well within its authority under the Clean Air Act to redress the endangerment posed by undue CO_2 emissions caused by traffic crashes by encouraging the deployment of crash avoidance technologies. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-7-A-8]

Similarly, the CAFE program has long promoted the convergence of safety and fuel economy considerations. Not only has NHTSA long taken into account any potentially adverse safety implications that might arise from mass reduction, but also NHTSA has affirmatively designed the CAFE program with the explicit aim of addressing safety. Specifically, while it is widely acknowledged that weight is more closely aligned with fuel economy, the agency chose footprint as the attribute upon which to base the CAFE program. The decision to base the fuel economy program on a footprint attribute was expressly linked to the fact that doing so promoted motor vehicle safety in addition to fuel economy. NHTSA, therefore, has already inexorably linked the CAFE program with advancing its safety mission. The provision of congestion mitigation credits based on crash avoidance technologies is simply a further extension of the well-received policy decisions the agency has previously made. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-8]

EPA has also confirmed the correlation between reducing congestion from motor vehicle crashes and reducing emissions. In a recent report aimed at providing information to local governments on effective Transportation Control Measures, the agency noted that 'efforts to improve the efficiency of transportation ... help reduce air pollution and GHG emissions, improve energy security and independence, and save money. One of the specific measures suggested by EPA is to: [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-9-A-10]

Enhance incident management systems. Incident management systems focus on quickly clearing roadways of accidents and stalled vehicles. These systems typically include roving tow or service vehicles, motorist aid call boxes, contingency planning, and other means for quickly responding to incidents (U.S. EPA, 1998b). Traffic incidents account for about one-quarter of all congestion on U.S. roadways, and for every minute that a freeway travel lane is blocked during a peak travel period, four minutes of travel delay results after the incident is cleared (National Traffic Incident Management Coalition, Undated). Since traffic incident management helps to minimize and prevent congestion, these systems can reduce fuel consumption by more than I percent annually and save 2,600-7,700 gallons of gasoline per incident, thereby reducing associated vehicle emissions [U.S. DOT, Undated(d)]. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-10]

NHTSA's most recent Vehicle Safety and Fuel Economy Rulemaking and Research Priority Plan for 2011-2013 identifies the potential for crash avoidance technologies to reduce these congestion-causing collisions:

From the crash avoidance perspective, NHTSA looks at types of crashes that might be mitigated by new technologies. Based on the General Estimates System (GES) and the Fatality Analysis Reporting System (FARS), four types of crashes total 85 percent of all crashes. These include Run-Off-Road (23%), Rear-End (28%), Lane Change (9%), and Crossing Path (25%). [EPA-HQ-OAR-2010-0799-9483-A1, p. A-10]

Longitudinal assistance, lateral assistance, and driver attention monitoring can alleviate a significant number of these collisions. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-10]

The Agencies can Reasonably Estimate the Fuel Savings Associated with Crash Avoidance Technologies

Certain crash avoidance technologies have had enough exposure the market to establish that they have a statistically significant impact on reducing collisions. Data from the German insurance institute GDV/UDV shows that Advanced Driver Assistance Systems have significantly reduced collisions. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-10]

With 25% of the congestion in the United States due to traffic incidents, and an overall fuel loss from congestion of approximately 38 million tons, about 9.5 million tons of CO_2 loss annually is associated with traffic incidents. Scaling this loss to vehicle miles traveled results in approximately 6 grams CO_2 per vehicle per mile if all accidents could be avoided. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-10]

The longitudinal assistance technologies Forward Collision Warning and Adaptive Brake Assist have already been proven effective in real world field data. Scaling the GDV/UDV field experience to U.S. crash data, DAG estimates up to 15% of crashes could be avoided by deploying such a Primary Longitudinal Assistance Package. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-10-A-11]

Adding to the proven effectiveness of primary longitudinal assistance technology is a more Advanced Longitudinal Assistance Package incorporating Autonomous Emergency Braking and Adaptive Cruise Control. DAG estimates that such a system could potentially avoid up to 18% of crashes. This package provides the most advanced longitudinal anti-collision technology and is currently cost-effective only on high priced luxury vehicles. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-11]

There are other technologies where effectiveness estimates are more difficult to attain but where data suggests that the technology will have a significant positive impact on avoiding traffic collisions. NHTSA has already recognized lane departure warning as an effective crash avoidance technology (along with forward collision warning). Active Lane Keeping Assist combined with Blind Spot Assist provides a Lane Tracking Package that offers significant potential to reduce CO_2 both by averting up to 5% of crashes and by maintaining the flow of traffic by averting 'near misses.' [EPA-HQ-OAR-2010-0799-9483-A1, p. A-11]

Driver Attention Monitor is another promising technology. A survey of owners who have had the attention assistance feature in Mercedes vehicles for about a year found that the system was effective in helping drivers to avoid fatigue. Sixty-eight percent of those surveyed indicated that they took a break from driving when the attention assistance alerted them to the fact that their driving behavior had become more erratic.[20] Fatigue, in turn is a significant factor in traffic collisions.[21] [EPA-HQ-OAR-2010-0799-9483-A1, p. A-11]

Adaptive Forward Lighting systems provide enhanced visibility in a variety of driving conditions which enhance the driver's ability to safely operate their vehicle. Emerging field experience suggests these systems may be highly effective in reducing crashes. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-11]

There are currently accepted technical understandings regarding the definitional and/or performance criteria for many of the technologies listed below. Brake Assist systems are defined in ECE regulations (UN-R-13H, Annex 9, Part B). NHTSA's NCAP program already includes performance specifications for Forward Collision Warning and Lane Departure Warning, and the agency is working towards performance specifications for Dynamic Brake Support and Collision Imminent Braking systems. Adaptive Cruise Control and Lane Keeping Assist are subject to various ISO definitions which could be applied as appropriate. For those technologies where NHTSA is currently working, we would anticipate that the work would be complete well before Model Year 20 I7 and further that NHTSA or other standards organizations will address additional technologies, such as Attention Assist or Adaptive Forward Lighting. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-11]

Regulation to mandate new technology and/or to link technology directly to fatalities or injuries necessitates specific definitions and performance criteria to determine compliance or eligibility. DAG understands that NHTSA, SAE, ISO, and others are working towards concrete and performance based definitions applicable to ensuring that these features will result in reduced fatalities and injuries. However, the level of stringency needed to develop and validate functional definitions and objective test procedures for collision avoidance safety systems is necessarily causing this process to take a considerable amount of time. In the context of gaining the emissions and fuel economy benefits of reducing collision-induced congestion, there is no need to link the definitions and performance criteria to reduced fatalities and injuries; instead, technologies are appropriate if they can reasonably be shown to avoid accidents, and thereby reduce congestion and its associated fuel consumption and CO_2 emissions. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-11-A-12]

The chart below summarizes a proposed credit methodology with technology packages and suggested credit opportunities. DAG proposes that NHTSA allow a manufacturer to submit to the agency data specific to its product offerings showing that its technology is effective in reducing vehicles collisions. NHTSA may approve the application and determine the amount of the credit and would be assured that the technology is robust and effective in terms of crash avoidance and the consequent fuel savings.[22] [EPA-HQ-OAR-2010-0799-9483-A1, p. A-12]

DAG conducted an extensive review of the available literature, including published OEM studies by, for example, Honda and Bosch, and the German Insurance Institute GDV/UDV quantification of brake assist benefits for all crashes (including non-injury crashes) based on POL insurance data (20022006) case-by-case simulation. Consistent with DAG's suggestion that each company present its package, the benefits may be adjusted slightly to account for which features are included. For example, the GDV study finds that an emergency brake assist (EBA2) system with Forward Collision Warning and Adaptive Brake Assist results in an approximate 12% reduction in all passenger vehicle crashes in all crash types with all crash partners within the German study. Adaptive Brake Assist with Autonomous Emergency Braking (EBA2+) results in an approximate 13.9% reduction in all passenger vehicle crash types with all partners within the German study. Adjusting for the percentage of crashes that are rear-end crashes (22.2% in GDV vs. 28% in US) renders an effectiveness rate between 15.3% and 17.5% for these longitudinal assistance packages. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-12]

With regard to the Lane Keeping Package, NHTSA has estimated effectiveness of approximately 6%. This includes an assumption of 55% availability. Taking a more conservative approach, for this purpose it is reasonable to assume a 5% effectiveness rate in reducing crashes. The remaining technologies listed below will produce effectiveness data before and through the rulemaking model years and should be considered for inclusion in a congestion reduction credit program as they are becoming offered in the light duty fleet. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-12]

Individually and collectively these technologies will measurably diminish traffic incidents, and therefore fuel consumption. In light of the significant amount of fuel wasted every year in collision-induced congestion, applying maximum credit opportunities of 1 g/m or less per package places a conservative value on proliferating these technologies throughout the fleet. Manufacturers should be encouraged to incorporate all fuel saving and emissions reducing technologies into their offerings, whether those features reduce CO_2 emissions on a per vehicle basis or whether they reduce CO_2 emissions through technologies proven to be effective in reducing a significant cause of fuel-consuming congestion. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-13]

The Agencies Have Ample Legal Authority to Provide Congestion Mitigation Credits

Both EPA and NHTSA have ample legal authority to provide credits for fuel consumption improvements that lead directly to CO_2 reductions. In reviewing this authority, it is important to consider that providing credits for technologies that reduce fuel consuming congestion due to traffic congestion involves no policy trade-offs. To the contrary, the credits would promote each of the policies that both agencies are charged with promoting: environmental protection, fuel economy, public health and welfare and motor vehicle safety. As such, the suggested credit program is fully consistent with the public objectives underlying each of the agencies' enabling statutes and would be fully harmonious with all statutory provisions. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-13-A-14]

First, the legal authority for congestion reduction credits is similar to that utilized by the agencies to establish off-cycle and fuel consumption improvement credits for technologies that reduce CO_2 in ways that are not measured in the applicable and traditional fuel economy tests. There has been no dispute that EPA has the authority to promote further CO_2 reductions under the Clean Air Act. As the agencies have recognized, the authority to apply such credits under EPCA is based on EPA's authority to define the methodology to calculate fuel economy for purposes of determining compliance. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-14]

Second, the congestion reduction credits are wholly consistent with EPA's obligation to address the endangerment to public health and welfare identified as arising from the air pollutant at issue. In this case, EPA has found that part of the endangerment to public and welfare arising from climate change is a potential increase in traffic incidents. The agency concluded, for example, that 'the increase in heavy precipitation will cause increases in weather-related accidents, delays, and traffic disruptions in a network that is already being challenged by increasing congestion. Traffic congestion leads to excess CO_2 emissions and CO_2 emissions lead to more traffic congestion - creating a circle of endangerment and effect that can be diminished through the advent of technologies that help to avert the cause of the emissions and the resulting additional endangerment. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-14]

Third, a credit program that achieves CO_2 reductions while also advancing safety is also consistent with both the Clean Air Act and with EPCA. EPA has long considered any adverse safety impacts from mandating a particular emissions control technology. The agency, moreover, has construed 'effects on welfare' broadly to encompass an array of considerations that may result from the consequences of air pollution. The courts have also long upheld NHTSA's consideration of safety impacts when determining maximum feasible fuel economy standards. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-14]

Indeed, the agencies have embedded considerations of safety into the fabric of the regulatory program by taking safety considerations into account in deciding upon footprint as the attribute and in deciding on the structure of the curves. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-14]

The agencies need not base the legal authority to establish congestion reduction credits on the advancement of safety. The credits are independently justified by the fuel consumption and CO_2 reductions they create. Significantly, however, there is robust precedent for linking together the GHG program with advancing motor vehicle safety and promoting both CO_2 reductions and motor vehicle safety. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-14-A-15]

---

13 As with off-cycle credits, the fuel consumption reductions associated with these technologies need not be specifically accounted for when establishing the CO_2 and CAFE standards. These technologies represent another area where significant gains can be made if the agencies incentivize the widespread deployment of these technologies.

20 The attention assist operates by analyzing steering wheel movements for the driver and providing an alert when steering inputs deviate from that driver's normal pattern. Attention assist not only helps alert drivers to the need to rest when fatigued, but also can help alert drivers who have become distracted.

21 A NHTSA study showed that 80% of accidents and 65% of near-accidents are caused by the inattentiveness of the driver, including drowsiness. See NHTSA, The Impact of Driver

Inattention on Near-Crash/Crash Risk: An Analysis Using the 100-Car Naturalistic Driving Study Data, DOT HS 810 594 (Apr. 2006). Various studies have estimated that between 10 and 25% of severe traffic accidents can be attributed to driver drowsiness. NHTSA has reported that annually about 100,000 crashes in the U.S., with 40,000 persons injured and 1,550 killed, are the result of driver sleepiness. NHTSA, Research on Drowsy Driving, http://www.nhtsa.gov/Driving+Safety/Distracted+Driving/Research+on+Drowsy+Driving.

22 DAG does not believe that this process would overwhelm the agency. Agency personnel are already familiar with the technologies and much of the data relating to these technologies. This process would put the onus on each manufacturer to develop robust data regarding its technologies and to present that information in a clear and concise manner to enable the agency to make a determination as to whether the credit should be applicable. Manufacturers may be required to submit this data with their pre-model year report and/or in their EPA certification applications. This process is similar to applying for air conditioning credits and DAG believes it can be implemented efficiently and without the need for substantial agency resources to be devoted to an additional task.

Response:

We appreciate the comments from Mercedes-Benz USA, LLC and agree with the comments on high efficiency exterior lighting. As discussed in greater detail in Section 5.2.3 of TSD Chapter 5, we are allowing manufacturers to receive off-cycle credit for partial lighting elements and agree that the approach suggested by Mercedes-Benz makes sense. In addition, we are allowing scaling of the lighting elements if the benefits achieved exceed those set forth in Table 5-21, Section 5.2.3 of TSD Chapter 5.

However, we disagree with the comments from Mercedes-Benz regarding eligibility of crash avoidance technologies for off-cycle credits. This issue is discussed further in Section II.F.2. of the preamble for this final rule. As stated there, the agencies do not believe that a "calculable relationship between congestion mitigation and fuel/CO_2 savings directly attributable to individual vehicles produced by a manufacturer, or even to a manufacturer's fleet of vehicles" and that "for a technology to be "counted" under the credit provisions, it must make direct improvements to the performance of the specific vehicle to which it is applied." In addition, and importantly, in the agencies' judgment, evaluation of crash avoidance technologies is better addressed under NHTSA's vehicle safety authority than under a case-by-case off-cycle credit process.

Therefore, we are finalizing today that crash avoidance technologies are not eligible for off-cycle credit under any off-cycle credit pathway (e.g., off-cycle technology menu, alternate method demonstration process).

Organization: Motor & Equipment Manufacturers Association (MEMA)

In response to the agencies' request for input on off-cycle technologies and the "Pre-Defined Credit List," MEMA has a few proposals. [EPA-HQ-OAR-2010-0799-9478-A1, p.7]

Second, collectively, the MEMA supports the technologies, emissions and fuel consumption estimates in the NPRM's proposed Pre-Defined Credit List. The estimates presented in the NPRM tables are relatively on par, and, in some cases may even be on the conservative side. Also, MEMA believes there are other technologies currently in the field with proven off-cycle benefits that were not in the NPRM (some examples include high efficiency alternators and brushless motor technology for engine cooling fans). These and other technologies, as appropriate, should be considered for inclusion on the list. Since MEMA represents a wide variety of motor vehicle parts manufacturers that make a huge range of various products, components and systems, we fully expect individual member companies to submit comments and specific remarks not only about the Pre-Defined technologies list and their corresponding ranges in the NPRM, but also about adding to the agencies' "menu" of technology choices for the final rule. MEMA asks that the agencies consider and fully evaluate those requests that have comprehensive, valid and confirmed data demonstrating the real-world, off-cycle benefits for revision to or inclusion in the final rule's Pre-Defined Credit List. [EPA-HQ-OAR-2010-0799-9478-A1, p.7]

Fourth, with respect to the "engine heat recovery" technology credit in the tables and in the proposed regulatory text definition, MEMA finds the term not very descriptive and confusing; also, it is inadvertently interchanged in the NPRM with "exhaust heat recovery" (also see our comment in Section IX). The engine heat recovery technology mentioned in the agencies' Technical Support Document (thermoelectric) can, in fact, be used to recover exhaust heat or any other source of heat. The industry, academia, and the Department of Energy have called the group of technologies that fall under the rulemaking nomenclature of "engine and exhaust heat" as "waste heat recovery" (WHR) technologies. Utilizing recovered heat and repurposing for other vehicle tasks, increases efficiencies for all types of vehicles – internal combustion engines and hybrids, alike. In some cases, the WHR system generates electricity and in other cases it can be used to expedite the warm-up of engines, transmissions, rear axles, and even the passenger compartment, to reduce ancillary loads and, for hybrid vehicles, to speed up the transition to all-electric mode. The source of the waste heat – whether the exhaust stream, engine coolant EGR cooler, or other – is all dependent on numerous criteria selected by the OEM to produce the most cost-effective solution. [EPA-HQ-OAR-2010-0799-9478-A1, p.8]

In keeping with our technology-neutral thesis, MEMA recommends that all these technologies be classified as WHR and the credits be listed separately as has been proposed in the NPRM. If the technology converts waste heat into 100W of electrical power, regardless of the technology, then a 0.7 g/mi credit is applied. If the technology uses waste heat for active transmission or engine warm-up, then the 1.8 g/mi credit would be applied. Due to its significant benefit, a credit for using waste heat to warm the passenger compartment in hybrid vehicles should be considered. [EPA-HQ-OAR-2010-0799-9478-A1, p.8]

Furthermore, MEMA believes that essentially any WHR technology, beyond those listed in the proposal (such as, thermal control of electronics and vehicle cabin climate control) that achieves the significant improvements, efficiencies and goals of the Program, should be considered for credit. If the EPA and NHTSA desire to have separate nomenclature, then we recommend that they be more descriptive (but technology-neutral) and be consistent throughout the rule, rather than “engine” or “exhaust” heat recovery. For example, engine heat recovery could be labeled as “eWHR” for electric WHR. [EPA-HQ-OAR-2010-0799-9478-A1, p.8]

There are special cases where even off-cycle technologies are difficult to evaluate using traditional test methods (e.g., dynamometer testing, etc.). Advances being made in vehicle telematics can very directly influence driving behavior – but it requires active driver inputs. By providing information that will aid the driver to drive more efficiently, we propose that there are considerations made in the decision-making process to allow technologies that cannot be quantified literally, but rather could be argued to have a positive impact on fuel consumption reduction and improved emissions. For example, the use of real-time traffic information to avoid congestion has been demonstrated to significantly reduce CO_2 emissions. Since historical testing methodologies cannot accurately quantify these benefits, new test methodologies that currently do not exist must be developed. MEMA encourages the agencies to form a working “partnership” to develop new test methodologies. The use of existing statistical traffic data should be used as much as possible in analytically modeling and quantifying the benefits. Instrumented vehicles and road tests would be required to statistically validate the results of any analytical models. There is precedent for providing CAFE credits based on a projected usage factor of a fuel saving device. Since the actual real-world usage of a traffic avoidance system cannot be guaranteed for 100 percent of the time, a similar percentage credit should be applied based on the anticipated usage rate. In addition to real-time traffic technologies, the agencies should be open to consider other automatic and driver-initiated location content-based technologies that have been shown to reduce fuel consumption. [EPA-HQ-OAR-2010-0799-9478-A1, p.9]

Under the Pre-Defined Credit List and related tables, MEMA points out some needed clarifications. First, the term “engine heat recovery” – which is used in Tables II-11, III-17 and III-18, in the proposed regulatory text (§ 86.1866–12 at page 75383), and in the TSD (at page 5-62) – is contrary to the NPRM text at page 75023 in Columns 2 and 3, which uses the term “exhaust heat recovery” (emphasis added). MEMA believes the unwitting interchange of “engine” with “exhaust” in this instance was an error. Therefore, for clarification purposes, MEMA asks that as the agencies develop the final rule, they ensure the nomenclature used to describe “engine heat recovery” is consistent with the term’s application in the Tables and in the regulatory text and is not interchanged with the term “exhaust heat recovery.” (Please refer to Section VI.B.2. for more information.) [EPA-HQ-OAR-2010-0799-9478-A1, p.12]

Response:

The EPA agrees with the comments from the Motor & Equipment Manufacturers Association (MEMA) regarding the terminology and range of technologies considered for waste heat recovery. This is reflected in our responses in 5.2.2 and 5.2.5 (i.e., definitions) of Joint TSD Chapter 5.

Regarding the comments from MEMA on interactive, driver-based technologies, our responses on this topic are discussed in Section II.F.2., III.C and III.E.11. of the preamble for this final rule. As stated, we believe that there is a high burden of proof from the OEMs that off-cycle credits could be justified for these interactive, driver based technologies but manufacturers may pursue this using the alternate demonstration methods for technologies not on the off-cycle technology menu if they choose.

Organization: Natural Resources Defense Council (NRDC)

EPA should only provide credits for off-cycle technologies if such technologies can be verified as providing real and enforceable GHG reductions. Based on data in the Draft Joint Technical Support Document, some technologies on the pre-defined list do not meet these criteria. EPA needs to scale-back the technologies provided on the pre-defined list until sufficient evidence of verifiable real world GHG reductions is available to the public. [EPA-HQ-OAR-2010-0799-9472-A2, p. 3]

In general, NRDC believes EPA should only allow off-cycle credits for measures that meet the following conditions: [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

The agency has verified that the GHG reductions are real through actual testing and real-world, in-use testing data from a statistically representative fleet of vehicles. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

The magnitude of the credits offered per vehicle should account for any degradation (including potential for failure and operator misuse) in the off-cycle technology over the life of the vehicle and not base the credits solely on performance during the test or from simulation modeling. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

The credits must not double count reductions with that are partially captured over the 2-cycle tests. In some cases, technologies will also produce some measurable reductions in the 2-cycle test. EPA acknowledges that off-cycle credits are intended for technologies that provide benefits that are not fully captured on the 2-cycle test but may be partially captured. It is critical that credits awarded for off-cycle operations only account for the portion not captured on the 2-cycle test. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

EPA should ensure that the benefits of the technology can be verified and enforced in use. The agency should require the manufacturers to collect and provide real-world data on an ongoing basis. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

Additionally, test procedures should be subjected to periodic review to keep up with the latest technology advancements both in the off-cycle technologies and the other vehicle characteristics as each may impact the level of GHG reductions that should be attributed to the off-cycle technology. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

Meeting the above criteria is especially critical for technologies on the pre-defined list. In addition, EPA must ensure the following:

The pre-defined list should require actual, publically available representative test data and not just be based on computer simulation or limited data, which appears to be the case for many of the technologies on the pre-defined list. The agencies should also require the manufacturers to collect and provide real-world measurement data on an ongoing basis to validate the model and credit levels going forward. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

EPA must verify that there is no double-counting of benefits due to the interaction between multiple off-cycle technologies a manufacturer chooses to use. For example, credits for solar load reduction through glazing must account for improvements to the A/C system. A vehicle with a very efficient, low leak A/C system may only generate very small or insignificant benefits from the addition of glazing. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

NRDC does not support the full range of off-cycle credit opportunities in the pre-defined menu because some fail to meet criteria for verifiable real world GHG reductions based on data presented in the Draft Joint TSD. EPA itself acknowledges that the proposed credits "…were largely determined from research, analysis and simulations, rather from full vehicle testing…" [EPA-HQ-OAR-2010-0799-9472-A2, p. 15]

Active grill shutters is an example of a proposed credit that does not appear to be well supported by data. It is unclear how EPA developed its assumption of 3 percent improvement in aerodynamics, given that it does not provide the underlying manufacturing data that it relies upon and does not justify its assumption that the 3 percent improvement can apply over the entire drive cycle.40 The 5-cycle benefits are clearly dependent on how the manufacturer chooses to design its system and its durability. NRDC believes that the active grill shutters menu credits should not be provided at this time until further data is provided and put into the public domain. [EPA-HQ-OAR-2010-0799-9472-A2, p. 15]

The same general concerns apply to many of the other technologies on the pre-defined list. Before finalizing the pre-defined list, EPA should provide in the public domain much more data that it proposes to use to justify credit levels. [EPA-HQ-OAR-2010-0799-9472-A2, p. 15]

---

40 EPA and NHSTA. Draft Joint TSD. Page 5-65. [EPA-HQ-OAR-2010-0799-9472-A2, p. 15]

Response:

The EPA welcomes the comments from Natural Resources Defense Council (NRDC) and agrees with NRDC that off-cycle technology benefits must "be verified as providing real and enforceable GHG reductions." In addition, we agree that it is important that the credits be based on actual data, do not duplicate on-cycle benefits, and that "test procedures [for determining credits] should be subjected to periodic review to keep up with the latest technology advancements." We believe the off-cycle credit program provisions we are finalizing today achieve this and satisfy NRDC's concerns.

Regarding the NRDC comments that "[t]he magnitude of the credits offered per vehicle should account for any degradation (including potential for failure and operator misuse) in the off-cycle technology over the life of the vehicle," we believe such a dynamic approach would make administering the off-cycle program nearly untenable since it would require individual manufacturer' vehicle-specific failure rates, deterioration curves and failure modes for every off-cycle technology, and overlay this onto the off-cycle technology menu. In lieu of this complexity, we believe that the certification durability requirements used for other emissions components and applied to off-cycle technologies will provide similar results in a less complex fashion.

For the comments from NRDC that "EPA must verify that there is no double-counting of benefits due to the interaction between multiple off-cycle technologies a manufacturer chooses to use," EPA is finalizing the rule with the provisions for the 10 g/mi cap on off-cycle technology menu credits. In addition, we have revised certain technologies as discussed in TSD Chapter 5 (e.g., engine idle start-stop and electric heater circulation pump, solar panels and active cabin ventilation) to account for synergistic affects. Therefore, we believe that these measures will account for the interaction between multiple off-cycle technologies and prevent benefits from being double counted, where appropriate.

Next, NRDC stated in their comments that: "Active grill shutters is an example of a proposed credit that does not appear to be well supported by data. It is unclear how EPA developed its assumption of 3 percent improvement in aerodynamics, given that it does not provide the underlying manufacturing data that it relies upon and does not justify its assumption that the 3 percent improvement can apply over the entire drive cycle. The 5-cycle benefits are clearly dependent on how the manufacturer chooses to design its system and its durability. NRDC believes that the active grill shutters menu credits should not be provided at this time until further data is provided and put into the public domain." We believe that NRDC has misinterpreted this information and would like to clarify this below.

In the TSD to the proposal, Section 5.2.2, we stated that "the EPA conducted an analysis of the reduction in emissions corresponding to a general reduction of aerodynamic drag on a vehicle. Using EPA's full vehicle simulation tool described in EPA's draft RIA, the agency evaluated the change in fuel consumption for increasing reductions in aerodynamic drag." Later in this same section, EPA stated "Based on manufacturer data, active grill shutters provide a reduction in aerodynamic drag (Cd) from 0 to 5% when deployed. EPA expects that most other active aerodynamic technologies will provide a reduction of drag in the same range as active grill shutters. EPA also expects that active aerodynamic technologies may not always be available during all operating conditions. Active grill shutters, for example, may not be usable in very cold temperatures due to concerns that they could freeze in place and cause overheating. Control and calibration issues, temperature limitations, air conditioning usage, and other factors may limit the usage of grill shutters and other active aerodynamic technologies. Therefore, EPA is proposing to provide a credit for active aerodynamic technologies that any of these technologies will achieve an aerodynamic drag of at least 3% improvement."

Therefore, EPA used the simulation tool to develop a correlation between aerodynamic efficiency and CO2 reduction, as shown in Table 5-26 and Figure 5-11, Section 5.2.6 of TSD Chapter 5 for this rule, and simply referenced the manufacturer's data as validation of this correlation and to select credit value for active aerodynamics, not to develop the credit. As a result, EPA has documented the 3% value for the active aerodynamics credit. Subsequent to this rulemaking, the ALPHA (Advanced Light-Duty Powertrain and Hybrid Analysis Tool) that EPA used to perform this simulation will be available to the public and we encourage NRDC to examine its potential.

Finally, NRDC made the comments that “Before finalizing the pre-defined list, EPA should provide in the public domain much more data that it proposes to use to justify credit levels,” and “[t]he pre-defined list should require actual, publically available representative test data and not just be based on computer simulation or limited data.”

In response, we disagree with NRDC since EPA used currently available, public data to support the development of the off-cycle technology menu credits. In addition, any additional materials used as the basis for the off-cycle credit values are available in the public docket for this final rule (see EPA docket #EPA-HQ-OAR-2010-0799). The Alliance also submitted supplemental comments in response to the detailed comments from ICCT as discussed in TSD Chapter 5 for this rule regarding supporting data (see EPA docket #EPA-HQ-OAR-2010-0799) citing actual manufacturer test data to support the credit values they suggested. Much of the Alliance test data and proposed credit values aligned with EPA’s off-cycle credit values and serve to bolster the off-cycle technology menu credits that EPA determined. Consequently, the EPA feels there is sufficient information in the public domain to justify the credit values we are finalizing today.

Regarding the NRDC comments that we based the credits solely on vehicle simulation, the EPA light-duty vehicle simulation tool, Advanced Light-Duty Powertrain and Hybrid Analysis Tool or ALPHA, is discussed in greater detail in the RIA Chapter 2 of this final rule. For all of the off-cycle credits other than solar and thermal control technologies, a mix of actual vehicle data and vehicle simulation was used to develop the off-cycle credits. The ALPHA model depends on actual vehicle data (e.g., engine torque curves) to provide a reasonable (though not absolute) prediction of the fuel economy and GHG emissions of specific vehicles produced in the future. Therefore, none of the credit values are based solely on vehicle simulation or actual vehicle data since the vehicle simulation depends on actual vehicle data to function. Finally, in order to ensure transparency of the models and free public access, EPA has developed the tool in MATLAB/Simulink environment with a completely open source code. Subsequent to this final rule, this open source code will be made available to the public and we encourage NRDC to take advantage of this ability to evaluate the ALPHA tool.

Organization: Porsche Cars North America, Inc. (PCNA)

• Porsche supports the Alliance's comments on inclusion of additional technologies in the table of default off-cycle credits. However, our analysis shows that the potential GHG benefit for high efficiency alternators is on the order of 2.0 grams/mile. We therefore request that the Agencies allow a default credit of 1.6 grams/mile for this technology. In addition, our analysis shows that the potential GHG benefit for electronic thermostat can be realized in configurations which do not include an electric water pump. We therefore request that the Agencies not limit this off-cycle credit to such configurations, but to instead allow the electronic thermostat credit to stand alone regardless of any other cooling system specifics. [EPA-HQ-OAR-2010-0799-9264-A1, pp. 5-6]

Response:

The EPA would like to thank Porsche for their comments. Our responses on high efficiency alternators are discussed in Section II.F.2. of the preamble for this final rule. To summarize, we are not adding high efficiency alternators to the off-cycle credit menu due to the variability in implementation strategy and electrical loads for the systems and related components. This makes it difficult to pinpoint a single, default value for the off-cycle technology menu. Therefore, we feel that high efficiency alternators are better suited for off-cycle credit consideration using the alternate case-by-case approval process for technologies not on the off-cycle technology menu.

As a result, Porsche may seek off-cycle credit for high efficiency alternators but must make an individualized demonstration in order to obtain such credits. Porsche did not submit the underlying data that was used to develop their estimates of benefits for high efficiency alternators in their comments. However, the underlying data that Porsche seemingly has can be used in this process to request the level of credit they proposed.

Organization: Toyota Motor North America

Second, EPA has added a list of off-cycle technologies in §86.1866-12(d)(l) that awards pre-determined credit values to all vehicles and manufacturers employing those technologies. Toyota generally supports the proposed changes to EPA's off-cycle regulations, subject to specific comments below. [EPA-HQ-OAR-2010-0799-9586-A1, p.10]

Off-Cycle Credits: Pre-Determined Credit List [EPA-HQ-OAR-2010-0799-9586-A1, p.11]

EPA has proposed a list of off-cycle technologies with pre-determined levels of credit for each technology on a per vehicle basis. The manufacturer would only need to demonstrate in its application for certification that a technology meets EPA's proposed definition for that technology. However, EPA has proposed to limit the amount of credits that can be earned in a given model year to 10 g/mi on a fleet-wide basis. Further, several technologies require a 10 percent minimum market penetration (combined car and truck production) before credits can be generated.[3] [EPA-HQ-OAR-2010-0799-9586-A1, p.11]

Toyota supports the proposed pre-determined list of off-cycle technologies. The predetermined list provides a level playing field for all manufacturers and uses a conservative per-vehicle credit value and an overall 10 g/mi cap that will protect against concerns of unwarranted credit generation. Toyota also supports expanding the predetermined list to include additional technologies as discussed in more detail in the Alliance comments. [EPA-HQ-OAR-2010-0799-9586-A1, p.11]

3 - Because NHTSA has proposed to accept EPA's approval of off-cycle credits for CAFE, EPA's proposed restrictions also impact credit generation for CAFE purposes. [EPA-HQ-OAR-2010-0799-9586-A1, p.11]

Response:

The EPA appreciates the comments from Toyota for their support of the off-cycle technology menu and the accompanying 10 g/mi cap and 10% market penetration requirements on credits.

The full discussion on comments concerning the 10 g/mi cap and 10% market penetration is provided in section III.C.5.b.i and II.F. of the preamble. Briefly, we are retaining the 10 g/mi cap and finalizing those provisions in this final rule. However, we are finalizing the off-cycle credit program without the 10% threshold requirement due to adverse comments that this requirement would be counterproductive and no favorable comments to the contrary. Accordingly, we are eliminating the 10% sales threshold to qualify for off-cycle credit for the applicable technologies on the off-cycle technology menu.

Finally, regarding Toyota's support for the Alliance comments for expanding the list of technologies on the off-cycle technology menu, our responses to these comments are discussed in Section II.F.2. of the preamble for this final rule.

Organization: United Automobile Workers (UAW)

The UAW applauds EPA for proposing a pre-approved list of off-cycle technologies. [EPA-HQ-OAR-2010-0799-9563-A2, p.3]

Response:

The EPA would like to thank the UAW for their support of the off-cycle technology menu and their continued support for the rule in general. We are finalizing the off-cycle technology menu and believe this will sufficiently address the UAW comments.

Organization: Volkswagen Group of America

Volkswagen is supportive of the agencies proposal for a list of technologies being made available with pre-determined off-cycle credit levels. Based on experience from the European Union, having a manageable procedure offers incentives to include CO_2 reducing technologies earlier and shows real world benefit for consumers. [EPA-HQ-OAR-2010-0799-9569-A1, p. 32]

Volkswagen understands that the intention is for the list of technologies to be a 'living document' and that additional technology may be added over time. Volkswagen further understands that the process for how this list will be updated may be fluid as the industry seeks to add new technologies. We look forward to a transparent process which will be based on testing and technical evidence. Volkswagen supports adding new technologies to the pre-determined credit list once benefits have been established under either of the other two pathways. This will help reduce redundant testing and further streamline this flexibility. [EPA-HQ-OAR-2010-0799-9569-A1, p. 32]

HIGH EFFICIENT LIGHTING

The Volkswagen Group remains an innovator in advanced, power-saving, lighting technology. Audi has been involved in the development of off-cycle credits related to lighting within the European Commission 'Eco-Innovations' regulatory system. Volkswagen offers the following information based on Audi's application regarding EU eco-innovation. [See Table APP-1 on p. 33 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 33]

Although significant focus has been made with regards to LED lights, Volkswagen suggests that several other technologies including Xenon and OLED (Organic LED) will be capable of similar savings. Volkswagen offers the following proposal for the High Efficiency Lighting definition to clarify the baseline from which improvements are measured (building upon the proposal from the Alliance): [EPA-HQ-OAR-2010-0799-9569-A1, p. 33]

'High efficiency exterior lighting means a lighting technology that, when installed on the vehicle, is expected to reduce the total electrical demand of the exterior lighting system when compared to conventional lighting systems employing halogen bulb technology. LED lights specifically qualify. Separate credit values may be earned for high efficiency lighting installed in the following components: parking/position, tail lights, license plate lights, low beam lights, and daytime running lights. Credits may also be earned for a high efficiency lighting bundle that is installed in the following components: front and rear side markers, and backup/reverse lights.' [EPA-HQ-OAR-2010-0799-9569-A1, p. 33]

ENGINE HEAT RECOVERY

Volkswagen proposes that the definition for Engine Heat Recovery be broadened to include applications which may convert recovered energy into cooling. Building upon the definition proposed by the Alliance:

'… converting that heat to electrical, mechanical energy or other thermal energy …' [EPA-HQ-OAR-2010-0799-9569-A1, p. 33]

ACTIVE DRIVETRAIN WARM UP

Volkswagen proposes that the definition be broadened to include indirect drivetrain warm-up such as could be accomplished via secondary water loop.

'.. uses waste heat or waste energy to directly or indirectly warm-up driveline fluids…' [EPA-HQ-OAR-2010-0799-9569-A1, p. 33]

HIGH EFFICIENCY ALTERNATOR

Volkswagen supports the proposal by the Alliance to include High Efficiency Alternators as an off-cycle option. Volkswagen believes that these components have promising potential for CO_2 reductions and will continue to evaluate their potential through technical analysis. [EPA-HQ-OAR-2010-0799-9569-A1, p. 34]

Response:

We appreciate the comments from Volkswagen and their support for the off-cycle technology menu. We provided detailed responses in TSD Chapter 5 on many of the technologies that Volkswagen mentioned in their comments as follows: High Efficiency Exterior Lighting (5.2.3), Waste Heat Recovery (5.2.2; formerly termed "Engine Heat Recovery"), Active Drivetrain Warm-Up (e.g., Active Transmission Warm-Up; 5.2.8.3); and High Efficiency Alternators in Section II.F.2. of the preamble for this final rule. In addition, the technology definitions we are finalizing for specific off-cycle technologies can be found in 5.2.5, 5.2.7., 5.2.8.5, and 5.2.15 of TSD Chapter 5.

In short, we agreed with Volkswagen's comments on expanding the definition for waste heat recovery (formerly engine heat recovery) and active drivetrain warm-up. For high efficiency exterior lighting, we are allowing credits for separate lighting elements as suggested by Volkswagen and others, and expanded the high efficiency exterior lighting definition in a similar, but not exact, fashion to Volkswagen's suggestion. Finally, we agree with Volkswagen that the off-cycle credit program will be "a transparent process which will be based on testing and technical evidence," and over time will consider whether or not technologies should be added to the off-cycle technology menu.

In contrast, we disagree with Volkswagen on the inclusion of high efficiency alternators on the off-cycle technology menu. The variability in implementation strategy and electrical loads for the systems and related components makes it difficult to pinpoint a single, default value for the off-cycle technology menu. Therefore, we feel that high efficiency alternators are better suited for off-cycle credit consideration using the alternate case-by-case approval process for technologies not on the off-cycle technology menu and are not adding this technology to the off-cycle technology menu at this time.

Organization: Volvo Car Corporation (VCC)

VCC strongly supports the pre-defined list. This is a simple effective way to advance innovations and enable manufacturers to take steps that traditionally would not be taken in an early stage of development. The proposed regulation will be a challenge for VCC and for small manufacturers, because new technology is directly linked to high development costs which limit the choice to embark upon an unlimited innovation path. Introducing a new technology, even in small volume, is both costly and risky for manufacturers. If customers do not choose the option in sufficient volumes, the manufacturers will suffer both from the resulting lack of return of investment and a lack of contribution to the fleet's regulatory targets. [EPA-HQ-OAR-2010-0799-9551-A2, p. 6]

• Substantial greenhouse gas improvements can be achieved in off-cycle conditions using new technologies. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

• The off-cycle technology credit menu is a necessary addition to the off-cycle program to avoid administrative delays and burdensome credit application requirements. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

A manufacturer that has completed this extensive testing and is first to complete the approval process will be first out in utilizing the credits once accepted; off-cycle credits should be accessible to applicants without the need to retest the technology. After the technology has been approved for one manufacturer, it should become part of the pre-defined list for other manufacturers to utilize. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

• If a manufacturer applies and is granted off-cycle credits by EPA for a new technology for one model year, this technology should eventually be added to the off-cycle predefined technology list within a reasonable timeframe after the approval giving the introducing manufacturers opportunities to do their initial introduction. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

• Criteria for a proven CO_2-case should be reasonable and kept at a same level for all technologies; enormous testing burdens might be an obstacle which may hinder the development toward positive GHG actions rather than evolving them. [EPA-HQ-OAR-2010-0799-9551-A2, p. 8]

Response:

The EPA would like to thank Volvo for their support of the off-cycle technology menu and agrees with Volvo's comments that it is "is a simple effective way to advance innovations and enable manufacturers to take steps that traditionally would not be taken in an early stage of development."

However, we disagree with the comments from Volvo regarding a technology being added to the list a year after approval is granted. First, the off-cycle technology menu was adopted to add a certain level of stability to the off-cycle credit program. Continually updating the off-cycle technology menu on an annual basis has the complete opposite effect. Further, the menu is part of the rule and can only be amended through notice-and-comment rulemaking proceedings.

Second, the off-cycle technology menu credit values we are finalizing today are based on existing technology and currently available information using conservative estimates. In contrast, the alternate demonstration methods for technologies not on the off-cycle technology menu offers a pathway for manufacturers to demonstrate benefits and request credit beyond the technologies (or the amounts) offered in the off-cycle technology menu. As individual manufacturers develop specific technology that achieves greater benefits (than those listed on the menu), it would be imprudent to reflect this on an annual basis in the off-cycle technology menu since not all vehicles are not expected to have identical technology effectiveness and implementation. Thus, credit values are expected to vary. In this case, the alternate demonstration method process is better suited for case-by-case evaluations where there is insufficient data to support a default credit or where the level of credit may depend on a specific manufacturer's design.

Therefore, we believe a better approach is to address technology improvements that may achieve greater benefits than the default values in the off-cycle technology menu on a case-by-case basis using the alternate demonstration method process until this technology, or associated level of benefit achieved, is common across the industry.

Finally, regarding the comments from Volvo that "If customers do not choose the option in sufficient volumes, the manufacturers will suffer both from the resulting lack of return of investment and a lack of contribution to the fleet's regulatory targets.", we are eliminating the 10% sales threshold to qualify for off-cycle credit for the applicable technologies on the off-cycle technology menu. This should provide Volvo and other manufacturers the necessary flexibility to request credits in the off-cycle credit program.

Organization: American Chemistry Council (ACC)

(5) The final rule should extend the proposed off-cycle credit for thermal control to recognize the benefits of glazing materials with superior insulation performance

In addition to lightweighting, polycarbonate (PC) glazing delivers insulating benefits, which reduce the demand on a vehicle's air conditioning (A/C) system. PC glazing's thermal conductivity is approximately five times lower than glass. In simple terms, PC glazing better insulates the passenger cabin, thereby reducing the load on the air conditioning associated with maintaining a comfortable cabin temperature. The result is an off-cycle benefit analogous to that in the proposed credit calculation for glazing reducing solar transmittance into the cabin. [EPA-HQ-OAR-2010-0799-9517-A2, p. 5]

Certain technologies that reduce A/C demand are not fully captured by current drive test cycles. For this reason, the agencies have proposed off-cycle credits for various technologies that provide this benefit. Unfortunately, the proposed off-cycle credit for glazing does not explicitly recognize the thermal insulation benefits of advanced automotive glazing exemplified by PC. The NPRM discusses the benefits of certain types of glazing, exemplified primarily by infrared (IR) reflective glass, in reducing solar energy transmission into a parked vehicle. In contrast, while PC glazing provides some solar control in relation to the agency's proposed baseline, it generally provides a greater benefit by inhibiting the transfer of heat from warmer outside air into a cooler cabin. As such, insulation benefits accrue in a broader range of scenarios including those where solar radiation is absent or diminished -- for example, at nighttime and on overcast days. [EPA-HQ-OAR-2010-0799-9517-A2, pp. 5-6]

ACC urges the agencies to make clear that the "Glass" or "Glazing" category for these credits includes reduced thermal conductivity, and include within the final rule a calculation to quantify credits related to this effect. The intent of the agencies to address benefits such as thermal conductivity is clear from the administrative record. The Joint Technical Support Document, for example, discusses incentivizing technologies that "reduce the amount of solar energy which enters the vehicle's cabin area, reduce the amount of heat energy build-up within the cabin when the vehicle is parked, and/or reduce the amount of cooling/heating energy required through measures which improve passenger comfort. [EPA-HQ-OAR-2010-0799-9517-A2, p. 6]

While glazing with superior insulation value responds to the agencies' stated intent, the NPRM and associated documents neglect to provide a methodology for quantifying thermal conductivity benefits. Modifying the existing credit to include appropriate references and a calculation to cover RTC benefits is consistent with the scope of the rulemaking and the intent of the agencies in the area of thermal control. As such, ACC believes that the agencies can accomplish this in the present rulemaking, and that a separate petition process is not necessary. [EPA-HQ-OAR-2010-0799-9517-A2, p. 6]

We support and incorporate by reference the detailed written comments separately submitted by a member company of ACC's Plastics Division, SABIC Innovative Plastics, with respect to this issue. We believe the methodology proposed by SABIC is sound and will provide the agencies with a tool to recognize fully the thermal control benefits of advanced glazing. [EPA-HQ-OAR-2010-0799-9517-A2, p. 6]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 267-268.]

The proposed rule contains an option for off-cycle technology credit but, unfortunately, the off-cycle credit in the proposed rule does not recognize the thermal control benefits of polycarbonate in automotive glazing. The formula does recognize the benefits of certain types of glass in controlling solar radiation in parked vehicles, but in contrast, while polycarbonate glazing provides some solar control in relation to engaging this proposed baseline, the benefits accrue in a broader range of scenarios in which the effect of solar radiation is absent or less pronounced. These include nighttime and overcast days as well as those times when the vehicle is in motion. More detailed comments will be presented by other colleagues later today, but we do urge that this will make and consider a parallel credit that fully recognizes thermal control benefits of polycarbonate in glazing applications.

Organization: Bayer MaterialScience

The Final Rule Should Expand the Off-Cycle Credit to Account for Thermal Benefits

Bayer MaterialScience is dedicated to developing innovative high performance materials that will give automakers a choice of materials when it comes to meeting the CAFE requirements. Bayer MaterialScience produces polycarbonate in the United States, thus giving auto manufacturers a domestically-made alternative to glass. The off-cycle credit in the proposed rule fails to take into account the thermal control benefits of polycarbonate glazing. The final rule should take this benefit into account by expanding the off-cycle credit when polycarbonate glazing is used. Polycarbonate would help automakers to meet CAFE requirements and reduce greenhouse gases by providing increased insulation benefits, contributing to net weight reduction of the vehicle, offering more aerodynamic styling options to the manufacturer (and thus increasing fuel efficiency) and lowering CO_2 emissions over the lifecycle of polycarbonate. As a result, for purposes of the current rulemaking, Bayer MaterialScience feels it is appropriate to include the additional methodology for calculating thermal conductivity benefits within the Final Rule, and that a separate petition process for this rule is not needed. [EPA-HQ-OAR-2010-0799-9198-A2, pp. 1-2]

Using polycarbonate as a glazing material will contribute to lower thermal conductivity. This benefit of polycarbonate will contribute to better energy efficiency in all vehicle types. Thus, we reiterate our support for an expansion of the off-cycle credit to account for this benefit or the addition of a new corresponding credit. [EPA-HQ-OAR-2010-0799-9198-A2, p. 2]

Polycarbonate Glazing has Additional Benefits for Automakers and the Environment

For years automotive manufacturers have used polycarbonates and polycarbonates composites in the manufacture of their vehicles. Polycarbonate glazing allows for integration of parts that was previously not possible (exhibit 1). [See exhibit 1 in Docket number EPA-HQ-OAR-2010-0799-9198-A2, p. 5.] This can contribute to vehicles being lighter in weight without compromising the structural integrity of the vehicle. For example, it is now possible to manufacture a clear view roof module and window pane or rear side window and window pane using a two-shot injection molding process. This injection molding process also allows the manufacturer to functionally integrate brackets, ribs and attachment points into the backlight assembly. And, of course, polycarbonate can be used for better insulation benefits, which can reduce demand on the vehicle's battery and HVAC units, thereby reducing greenhouse gases. [EPA-HQ-OAR-2010-0799-9198-A2, p. 2]

Polycarbonate has an extensive history of serial applications in the automotive glazing industry. In fact, the first commercial application was in 1998 with a rear quarter window on the Smart ForTwo vehicle. The number of applications has steadily grown through the years as automakers have seen the many benefits that polycarbonate can provide. These applications now include rear side windows, sun roof systems, panoramic roof systems and transparent rear body parts. I have included two slides with the handouts that show the progression of applications since 1998 (exhibit 2). [See exhibit 2 in Docket number EPA-HQ-OAR-2010-0799-9198-A2, pp. 6-7.] Polycarbonate is also recognized as a suitable glazing material by authorities around the world, including the United Nations Economic Commission for Europe. [EPA-HQ-OAR-2010-0799-9198-A2, p. 2]

Bayer MaterialScience has developed innovative and sustainable material solutions using polycarbonate and polycarbonate composites for glazing applications. These materials enable weight reductions of up to 50 percent compared to glass, as already demonstrated by the use of polycarbonate in panoramic roofs and fixed side windows already in commercial production (BayerNews, October 7, 2011). The density of polycarbonate is less than half the density of glass (1200 Kg/m3 for polycarbonate vs. 2500 Kg/m3 for glass) and contributes to the weight reduction of up to 50 percent versus glass. This weight reduction contributes to CO_2 emissions being cut by up to 728 pounds per vehicle over a vehicle's service life of 95,000 miles compared to cases where glass is used. [EPA-HQ-OAR-2010-0799-9198-A2, p. 3]

With polycarbonate enabling weight reductions of up to 50 percent compared to glass, automakers can achieve better fuel efficiency and greater stability by lowering the vehicle's center of gravity. Use of polycarbonate in a panoramic roof, for example, can help to significantly lower the vehicle's center of gravity and improve handling (exhibit 4). [See exhibit 4 in Docket number EPA-HQ-OAR-2010-0799-9198-A2, pp. 24-32.] [EPA-HQ-OAR-2010-0799-9198-A2, p. 3]

Bayer MaterialScience has developed transparent tinted colors specifically for polycarbonate glazing that filter out a large proportion of the sun's infrared (IR) rays. As a result, the vehicle interior does not heat up as much under the effects of sunshine. Appropriately treated glazing made of IR grade polycarbonate enables IR light and energy transmission values for dark colors that are at least as low as commercial thermal insulation pigments for glass. Polycarbonate glazing also offers benefits in terms of thermal insulation thanks to the plastic's thermal conductivity, which is roughly five times lower than that of glass. In cold weather conditions, this increases the temperature of the internal surfaces of the polycarbonate glazing inside the vehicle significantly, which in turn cuts the energy needed to heat the vehicle and also improves comfort. This feature, too, can help boost the travel range of electric vehicles. [EPA-HQ-OAR-2010-0799-9198-A2, p. 3]

The wide choice of styling options with polycarbonate is testing conventional assumptions of automotive window design and creating whole new opportunities for advanced vehicle styling. This design flexibility of windows can contribute to better aerodynamics for vehicle manufacturers, which of course leads to lighter weight vehicles and better fuel economy. The ability to add colors to glazing parts, along with sharp corners, smooth corner radii and complex three dimensional shapes are among the many other benefits associated with these styling options by using polycarbonate. [EPA-HQ-OAR-2010-0799-9198-A2, p. 3]

Polycarbonate Glazing Reduces Life-Cycle Greenhouse Gas Emissions Compared to Glass

An independent study from a renowned Europe-based company indicates that when studying polycarbonate vs. glass over the life of the product, which would be from initial production to usage of the product to the waste phase, polycarbonate can help to substantially lower CO_2 emissions (Exhibit 3). [See exhibit 3 in Docket number EPA-HQ-OAR-2010-0799-9198-A2, pp. 8-23.] 1 KG (2.2046 lbs.) of polycarbonate saves 14-22 KG (30.85-48.50 lbs.) of CO_2 emission over the lifecycle of the material. If all of a car's windows with the exception of the windshield were made of polycarbonate (a total of 33 pounds of the plastic), the lower fuel consumption could cut CO_2 emissions by up to 728 pounds per vehicle over a vehicle's service life of 95,000 miles compared to cases where glass is used. [EPA-HQ-OAR-2010-0799-9198-A2, p. 4]

Polycarbonate Glazing Enhances Vehicle Safety

You don't need to start smashing windows to know that polycarbonate has a significant impact strength advantage over glass. With polycarbonate's superior impact resistance it can contribute to safety by improving passenger retention in the event of a crash. [EPA-HQ-OAR-2010-0799-9198-A2, p. 4]

In closing, we would like to express our support for the expansion of the off-cycle credit to account for the thermal control benefits that polycarbonate glazing can provide for automotive manufacturers looking to contribute to the reduction of harmful greenhouse gases. The benefits of a material like polycarbonate, such as weight reduction, reduced CO_2 emissions and safety improvements, would give automotive manufacturers a valuable alternative to consider when trying to achieve these valuable CAFE requirements. [EPA-HQ-OAR-2010-0799-9198-A2, p. 4]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 271-274.]

Organization: California Air Resources Board (CARB)

During the public comment period on the notice of proposed rulemaking for the '2017 and Later Model Year Light-Duty Vehicle, Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards,' U.S. EPA received numerous comments on the proposed off-cycle credits for advanced solar load reduction technologies. Unfortunately, several of these comments contained inaccuracies with regard to the California Air Resources Board's (CARB or Board) prior work on 'the 2009 proposed Cool Gars regulation. I welcome this opportunity to make you aware of these inaccuracies and set the record straight. [EPA-HQ-OAR-2010-0799-11799-A2, p.1]

The primary inaccuracy was that CARB ceased work on the Cool Cars regulation due to the belief that the metallic glazing used to comply with the rule interferes with radio signals, thus jeopardizing public safety. While these concerns were brought to the attention of CARB, they were not the basis of the decision to cease-work on the regulation. In fact, the decision to cease work stemmed from a June 2009 Board hearing during which the Board directed staff to revise the proposed regulation and subsequently return with a proposal for a performance-based option, which, would have increased the stringency of the rule while also providing greater flexibility in achieving the greenhouse gas (GHG) benefits. It was this increase in stringency that could have resulted in greater use of metallic glazing, which spurred concerns of public safety advocates. Due to the inability to achieve consensus on the best path forward during the timeframe required, staff ceased work on the regulation. Instead, it was determined that the direction of the Board would be best implemented by folding the objectives of Cool Cars into the Advanced Clean Cars regulation. [EPA-HQ-OAR-2010-0799-11799-A2, pp.1-2]

As you know, staff from ARB and U.S. EPA worked together to craft the off-cycle credit option for solar control and thermal load. reduction technologies. Contrary to the comments received, this credit option provides increased flexibility to manufacturers to achieve their fleet GHG targets. The solar control off-cycle credits are not proscriptive in any way and manufacturers may use any glazing technology on the market in order to receive credits, as long as the performance of the glazing is better than baseline glass. To date, there are multiple technology options available to manufacturers, including solar absorbing (non-metallic) and solar reflective (both metallic and nonmetallic) glazing. In addition, there is at least one company with a new non-metallic, non-radio interfering reflective product in development that is expected to be in production by 2014. Ultimately, a manufacturer may choose not to use solar control glazing and achieve their GHG targets through any other means, including mass reduction or improved aerodynamics, both of which can be aided by the use of polycarbonate glazing. [EPA-HQ-OAR-2010-0799-11799-A2, p.2]

It is important to note that many manufacturers are already using some level of solar control product on their vehicles today. These products are safe, and testing conducted by ARB indicated that there were no statistically significant effects pf metallic reflective glazing on the operation of GPS ankle bracelets or cell phone operation in an urban environment. Although there may be adverse effects of metallic glazing on cell phone connectivity in a rural environment, which was not tested by ARB, it is worth repeating that metallic glazing is used today on many vehicles in the United States and Europe, both as a manufacturer-installed option and as an aftermarket film, without any known public safety impacts. [EPA-HQ-OAR-2010-0799-11799-A2,p.2]

The reason that solar control products are widely used is because of their ability to improve occupant comfort and, by extension, reduce GHG emissions and fuel use due to reduced loads on the air conditioning system. The analysis conducted by ARB for Cool Cars, and subsequently applied by both U.S. EPA and ARB to determine the off cycle credit calculations, demonstrates a benefit of solar control glazing of up to three grams per mile for a passenger car. Contrary to the comments received by U.S. EPA suggesting that this methodology is 'flawed,' the benefit calculations were based on several peer-reviewed reports and refined through consultation with industry experts. [EPA-HQ-OAR-2010-0799-11799-A2, p.2]

We therefore maintain that the three gram per mile benefit for passenger cars is an accurate, and likely conservative estimate of the true benefit of solar control glazing. [EPA-HQ-OAR-2010-0799-11799-A2, p.3]

In closing, I urge U.S. EPA to retain the structure of the off-cycle credits for solar control technologies. Doing so will properly credit the benefits of a wide range of solar load reduction products, while still providing manufacturers 'with the flexibility to use any available engine or vehicle technology to achieve their fleet GHG targets. It will also appropriately reward the early adopters of advanced solar control materials and continue to spur innovation in the glazing industry. [EPA-HQ-OAR-2010-0799-11799-A2, p.3]

Organization: California Manufacturers & Technology Association (CMTA)

CMTA understands that the joint USEPA-National Highway Transportation and Safety Administration (NHTSA) notice of proposed rulemaking for fuel economy and greenhouse gas emission regulations for model year 2017-2025 light-duty vehicles, dated December 1, 2011, includes options under which auto manufacturers may obtain “off-cycle” greenhouse gas emission reduction credits. In 2010, we were involved in a similar proposal put forth by the California Air Resources Board (CARB) which CARB eventually dropped. The savings in fuel was exceptionally small (under 4-1/2 gallons year for the average vehicle) for the amount of possible complications that would have occurred. [EPA-HQ-OAR-2010-0799-9536-A2, p.1]

While the CARB regulation would have mandated the use of a reflective glazing material in car windshields and windows, it would have had a significant negative impact on radio frequency transmissions of cell telephones, garage door openers, global positioning system (GPS) equipment, toll tag transponders (Fast Track), emergency equipments signals (police, fire, ambulance), and even parolee ankle bracelets. While we understand that the decision to choose a particular technology to obtain an off-cycle credit will be voluntary, it is reasonable to assume that auto manufacturers seeking to maximize credits under the proposed rule would be inclined toward use of metallicized reflective materials in the glass. [EPA-HQ-OAR-2010-0799-9536-A2, pp.1-2]

In addition, this approach will benefit reflective glass technologies, but fails to recognize other technologies which can achieve similar results. For example, off-cycle reduction in air conditioning load can also be achieved through use of polycarbonate glazing technologies that reduce thermal conductivity, helping to maintain a more comfortable interior temperature. Such technologies should also be accommodated in the final federal rule so that vehicle manufacturers have greater flexibility in meeting the stringent emission limits contemplated in the draft regulation. [EPA-HQ-OAR-2010-0799-9536-A2, p.2]

For the above reasons, we believe these incentives need to be more thoroughly evaluated. [EPA-HQ-OAR-2010-0799-9536-A2, p.2]

Organization: California State Sheriffs' Association (CSSA), California Police Chiefs Association (CPCA), California Narcotic Officers' Association (CNOA)

On behalf of the California State Sheriffs' Association (CSSA), California Narcotic Officers' Association (CNOA) and the California Police Chiefs Association (CPCA), we write to express our concern regarding the joint United States Environmental Protection Agency (USEPA) and National Highway Traffic Safety Administration (NHTSA) proposed rule making for fuel economy and greenhouse gas (GHG) emissions for model year 2017-2025 light-duty vehicles of December 1, 2011. [EPA-HQ-OAR-2010-0799-9488-A1, p. 1]

While we support the intended goals of establishing certain GHG emission reduction credits and appreciate that this federal proposal takes a voluntary approach relative to ARB's Cool Cars proposal, we remain concerned that the proposal will incentivize the use of metallic reflective window technology. There are a number of implications that this regulation will have on GPS technology for ankle bracelets used to monitor offenders and the ability of law enforcement, parole agents, and probation officers to monitor and track offenders accurately as well as Enhanced 9-1-1. [EPA-HQ-OAR-2010-0799-9488-A1, pp. 1-2]

Over the last year California has made significant changes to the delivery of criminal justice services to address its prison overcrowding crisis. This has led the state to take measures to reduce the prison population, one of which is to place more offenders on GPS or electronic monitoring. The use of metallic reflective window technology presents the potential for unintended, and very adverse, consequences associated with RF device interference. ARB's own analysis illustrated a doubling of dropped GPS signals under varying circumstances. Even a slight drop or deviance in connectivity and the ability to locate an offender as a result of metallic glazing is problematic and concerning, especially in light of the availability of alternative solutions that achieve energy savings while not presenting the same public safety impacts. [EPA-HQ-OAR-2010-0799-9488-A1, p. 2]

In addition to concerns relative to GPS monitoring, we are concerned that use of metallic reflective window technologies can increase the likelihood of interference with reliable operation of cell phones and Enhanced 9-1-1 capabilities for PSAP's. This concern is magnified in emergency situations where a caller may need to place an emergency 9-1-1 call and where signal strength may already be lessened such as in rural areas. Further, in may impact the ability of PSAPs to locate a caller via Enhanced 9-1-1. [EPA-HQ-OAR-2010-0799-9488-A1, p. 2]

We appreciate the opportunity to comment on this regulation and for your consideration of our comments. We would be remiss if we did not share these concerns with you and the implications of this regulation on public safety. For reasons stated, we ask that you consider reworking the current proposal and specifically removing the off-cycle credit that incentivizes the use of metallic reflective window technology. [EPA-HQ-OAR-2010-0799-9488-A1, p. 2]

Organization: Crime Victims United of California (CVUC)

On behalf of Crime Victims United, of California(CVUC),I am writing to convey serious concerns regarding the joint United States Environmental Protection Agency (USEPA) and National Highway Traffic Safety Administration (NHTSA) proposed rulemaking for fuel economy and greenhouse gas (GHG) emissions for model year 2017-2025 light-duty vehicles of December 1, 2011. [EPA-HQ-OAR-2010-0799-9883-A1, p. 1]

CVUC is a nonprofit organization that uses education, legislative advocacy and political action to enhance public safety, promote effective crime-reduction measures and strengthen the rights of crime victims. [EPA-HQ-OAR-2010-0799-9883-A1, p. 1]

As you may be aware, California is facing a prison overcrowding crisis. Such crisis has led the state to take measures to reduce the prison population, one of which is to place more offenders on GPS or electronic monitoring. CVUC understands local law enforcement's need for alternative custody options and has been generally supportive of providing these alternative options; however, our position on the use of this technology is dramatically altered in light of the potential consequences of this joint regulatory proposal. [EPA-HQ-OAR-2010-0799-9883-A1, p. 1]

As you may know, in 2010 California's Air Resources Board (ARB) proposed a regulation known as 'Cool Cars' that would have effectively mandated the use of metallic reflective window technology. CVUC adamantly opposed this proposal due to the serious implications for RF signal interference and the associated potential for public safety consequences. As a result of CVUC and other stakeholders' concerns, California's ARB ultimately abandoned the Cool Cars regulation in recognition of the fact theft the emission reduction benefit calculations were based on flawed methodology and that use of this technology presented the potential for unintended adverse consequences associated with RF device interference. Despite this history, EPA and NHTSA appear to be using the same methodology in this proposed regulation for establishing certain GHG emission reduction credits. While we understand that this joint federal proposal takes a voluntary approach relative to ARB's Cool Cars proposal, we remain concerned that it will incentivize use of metallic reflective window technology, giving rise to the same RF interference and public safety concerns at issue under the Cool Cars proposal. [EPA-HQ-OAR-2010-0799-9883-A1, pp. 1-2]

ARB's own analysis illustrated a doubling of dropped GPS signals under varying circumstances. While this is significant, it is also important to note that the testing was done in an urban area where signal strength was very strong. What about in areas where signal strength is not strong (i.e. rural areas where our prison facilities are located or foothill/mountain communities where signals are lost in canyons)? [EPA-HQ-OAR-2010-0799-9883-A1, p. 2]

Given the difficulty in adequately monitoring the prison, jail and parolee population in California as it is, CVUC feels strongly that the approach under the federal regulation should be reworked to address the potential problems for the state in monitoring its GPS population. In these grave times of prison overcrowding, the early release of inmates, and more, such an approach to global warming is unacceptable and has crime victims in California highly concerned. In our discussions with other stakeholders and the ARB in 2010, we came to learn that there are other options to achieve GHG emission reductions that do not have to compromise signal strength that could ultimately impact the ability to monitor offenders' activities through GPS. [EPA-HQ-OAR-2010-0799-9883-A1, p. 2]

In addition to concerns relative to GPS monitoring, we are concerned that use of metallic reflective window technologies as contemplated in the joint rulemaking - even under limited circumstances -can increase the likelihood of interference with reliable operation of cell phones. This would be particularly problematic in troubling emergency situations where a motorist might need to place an emergency 911 call - especially in rural locations where signal strength may already be lessened. [EPA-HQ-OAR-2010-0799-9883-A1, p. 2]

While increased fuel efficiency and lower greenhouse gas emissions are both laudable goals, under the proposed rule these goals could be achieved at the expense of significant potential adverse impacts on the ability of consumers, emergency workers and law enforcement personnel to contact help in an emergency, communicate life-saving instructions, and track prisoners released under electronic surveillance. [EPA-HQ-OAR-2010-0799-9883-A1, p. 2]

For these reasons, we ask EPA and NHTSA to consider reworking the current proposal and specifically removing the off-cycle credit that effectively incentivizes use of metallic reflective window technology. [EPA-HQ-OAR-2010-0799-9883-A1, p. 2]

Organization: CTIA - The Wireless Association

On behalf of CTIA-The Wireless Association®, the international trade association representing wireless carriers, equipment manufacturers, and Internet service providers, I write to express the wireless industry's concerns regarding potential regulations which would reward "off-cycle" GHG credits for the use of a single type of technology for window glazing. [EPA-HQ-OAR-2010-0799-11759-A2, p.1]

The current draft of the regulations would create incentives for the use of metallic films for glazing in automobiles. Metallic films can interfere with electronic devices that depend on radio frequency (RF) transmissions, such as cellular telephones, GPS systems, and other devices. [EPA-HQ-OAR-2010-0799-11759-A2, p.1]

While we support lowering greenhouse gas emissions and increasing fuel efficiency, that should not be done at the risk of interfering with wireless devices, which are frequently used to communicate during emergencies and to provide location assistance for drivers. [EPA-HQ-OAR-2010-0799-11759-A2, p.1]

There are other glazing technologies that offer similar emission reduction benefits without compromising the performance of wireless devices or other technologies that rely on RF transmissions. One example is polycarbonate glazing which can help reduce air conditioning load through superior insulating properties. [EPA-HQ-OAR-2010-0799-11759-A2, p.1]

We ask EPA and NHTSA to consider alternatives that do not encourage solar reflective glazing only. We would ask you to consider credits for other types of glazing technologies that are less obstructive to wireless devices. [EPA-HQ-OAR-2010-0799-11759-A2, p.1]

Organization: Enhanced Protective Glass Automotive Association (EPGAA)

Member companies of the EPGAA provide glazing products to the automotive market. These products include solar control glazing, which include technologies that reduce the solar heat load in a vehicle. The reduction of the solar heat load results in lower air conditioning load, which in turn results in lower fuel consumed and reduced greenhouse gas emissions. Since the cabin comfort requirements are indifferent to the powertrain technology, the solar glazing impact is just as valid on Internal Combustion Engine vehicles as it is on Hybrid-Electric or fully electric vehicles. Since the glazing technology is a passive technology for the consumer, in that it does not require any consumer interface, the benefits to the consumer and to the environment are independent of consumer behavior. Finally, the solar control glazing technologies are designed to meet or exceed the safety, security, health, and other benefits of glass that are either required by regulations or expected by the customers. [EPA-HQ-OAR-2010-0799-9301-A1, p. 1]

EPGAA supports the proposed rule for the off-cycle credits for technologies whose impact on fuel consumption and emissions cannot be measured in the test cycles. The calculation proposed by the EPA on the off-cycle credit for solar glazing provides a simplified model for defining the impact of glazing on the heat load reduction and the emissions. EPGAA supports the general concept but recommend that the following changes be considered: [EPA-HQ-OAR-2010-0799-9301-A1, p. 1]

1. There should be a method to account for the total glass surface in a vehicle. The credit calculation as defined in the NPRM treats all vehicles in a class as being similar in the amount of heat load coming through the glass. There has been a trend in the market to have larger size glass, which would lead to higher heat load and therefore higher emissions. Therefore, we recommend that there be an accounting for the total glass surface. A simple multiplier could be applied. See below for an example:

Base line glass surface = 4 sq.m.

Actual glass surface = 4.4 sq.m.

Therefore, total impact = 4.4/4.0 = 1.1 times the baseline impact. Thus the total impact of glazing on the emissions would be 110% of the baseline vehicle. [EPA-HQ-OAR-2010-0799-9301-A1, p. 2]

2. The impact captured by the formula as defined in the NPRM was based on several studies of internal combustion engine vehicles in drive cycles and modeling studies that the EPGAA supports. However, the introduction of technologies such as start/stop, hybrid, electric, etc. would provide additional benefits from the use of solar glazing. Additionally, the formula does not capture the benefits of solar glazing during the times when the cabin temperature in the vehicle may only increase marginally above setpoint due to heat load. In such instances, the use of heat load reduction technologies may completely eliminate the need for air conditioning by keeping the cabin temperature below setpoint. These benefits have not been captured in the formula and EPGAA recommends that further analysis be done to quantify these benefits and include them in the regulation at the time of the mid-term evaluation. [EPA-HQ-OAR-2010-0799-9301-A1, p. 2]

3. The NPRM puts a maximum limit on the credit from thermal control technologies at 3 g/mi for passenger automobiles and 4.3 g/mi for light trucks. The credit for glazing is also limited to 3.0 g/mi for passenger automobiles and to 4.3 g/mi for light trucks. Since the data used for the calculations has been based on currently known technologies, it would be difficult to predict the actual savings from the solar glazing in the higher efficiency vehicles. EPGAA recommends that the impact of solar glazing on (higher efficiency) vehicles should not be capped. EPGAA believes that regulation should promote innovation and is concerned that such a cap could potentially stifle innovation in solar glazing rather than promote continued advancement of the technology. [EPA-HQ-OAR-2010-0799-9301-A1, p. 2]

5. EPGAA supports the use of the off-cycle credits as provided in these regulations and urges the Agency to adopt them in the final rule. EPGAA also recommends that these regulations be adopted for the MY 2012-2016 without the formal review process as currently required. Allowing these credits earlier would encourage the use of the technologies that provide the benefits sooner. [EPA-HQ-OAR-2010-0799-9301-A1, p. 3]

In conclusion, the EPGAA supports the agencies in considering the off-cycle technologies and specifically the solar glazing technologies. [EPA-HQ-OAR-2010-0799-9301-A1, p. 3]

Organization: Garmin International Inc.

The first area of concern is that the proposed rule would reward (with Thermal Control 'off-cycle' GHG credits) only the automobile manufacturers who select a single type of technology for window glazing. This is a fundamentally flawed approach because it limits choices, thereby stifling innovation and artificially raising prices due to lessened competition. [EPA-HQ-OAR-2010-0799-9508-A1, p.1]

Since 2009, it has been commonly accepted that metallicized reflective glazing that reflects the solar rays also attenuates radio frequency (RF) signals. This reflection of RF signals is one of the factors that caused California to reject this technology. The lack of flexibility in window materials technology that vehicle manufacturers are given by the NPRM--to achieve GHG credits--will negatively affect consumers, emergency responders, RF-signal-dependent device manufacturers (GPS ankle bracelets and transponders for parolees, mobile phones, GPS devices, toll tags, to name a few) and their service providers. [EPA-HQ-OAR-2010-0799-9508-A1, p. 2]

The proposed rule also provides a disincentive for any manufacturer to utilize off-cycle design technologies that are very beneficial in terms of air emissions and exceed (together or separately) the 109/mi. threshold imposed by (d)(1) of the 'CO_2 fleet average credit and incentive programs' section. We view the threshold as a defacto limit on the investments you will see in off-cycle environmental technologies, because some beneficial technologies may not be able to be adequately demonstrated using the EPA 5-cycle methodology described by section (d)(2), and there is no guarantee the manufacturer will receive the required permission from the EPA, per section (d)(3) to perform a technology demonstration using an alternative EPA-approved methodology. In addition, the technology demonstrations per (d)(2) and (d)(3) must be performed, documented, submitted to, and approved by, the EPA. To follow this regimen for several models in the fleet would be prohibitive in terms of time, resources, cost and uncertainty. For manufacturers who wish to move forward quickly to improve the CO_2 emissions of their fleet, we ask that you provide ways to validate a CO_2 credit for a technology being adopted in many models without having to go through the (d)(2) or (d)(3) demonstration process for every model. [EPA-HQ-OAR-2010-0799-9508-A1, pp.2-3]

Strategic development plans and roadmaps for numerous models in the fleet can hardly withstand this degree of uncertainty over the lengthy research and development cycles that precede the rollout of a car or light truck model. This disincentive that the rule has constructed may reduce the investment in breakthrough CO_2-reducing technologies that would otherwise be deployed in the US automobile market. This brings to light the importance of NHTSA and USEPA (1) working with industry to frequently test, validate and add other CO_2-reducing technologies to the off-cycle technology table, and giving serious consideration to removing the 109/mi. threshold. We are not in favor of limiting the credits manufacturers' rightly receive for innovative, environmentally responsible design features. [EPA-HQ-OAR-2010-0799-9508-A1, p.3]

Research has shown that metallicized reflective glazing will cause significant adverse effects on the reception and transmission of E911, mobile phone and GPS navigation signals. Two years ago, Garmin and a broad coalition of interested parties field-tested the impact of the 'Cool Cars' regulations that were being promoted by the California Air Resources Board (CARB) under AB 32 (the Global Climate Change regulations). At that time, CARB was pursuing a vehicle glass requirement which would have required a layer of metallic reflective material in the windshield to reflect solar rays. CARB had similar goals as described in the U.S. EPA NPRM, but forcing car and light truck manufacturers to use this type of glazing could have been very counterproductive. If 10% of drivers quit using GPS because of signal interruptions caused by metallicized reflective glazing, the increased GHG emissions from these vehicles more than cancels out all GHG reduction benefits of metallicized glazing. Put another way, for every theoretical 1 ton decrease of GHG emissions from metallicized glazing, vehicles send 2 extra tons of GHG emissions into the atmosphere. [EPA-HQ-OAR-2010-0799-9508-A1, p. 3]

We see no reason why lower-weight and lower-cost alternative solutions such as non-metallic polycarbonate materials are not listed as options in the NPRM. An advanced insulating or solar absorbent technology with solar transmittance (Tts) properties of 54% is equally as effective as metallic reflective (50% Tts with 10% deletion windows) in blocking the sun's rays from the auto interior and has none of the negative shortcomings as far as attenuating signals. We respectfully ask EPA and NHTSA to include an off-cycle credit that recognizes the relative benefit of insulating glazing for reducing GHG emissions without harming systems such as E911. [EPA-HQ-OAR-2010-0799-9508-A1, p. 3]

We would be happy to share the results of the coalition's testing and discuss this matter with you in greater detail. Our nation's cellular networks and global positioning system are national assets in which US taxpayers have invested billions. These systems support our economic growth, as well as our personal and public safety. [EPA-HQ-OAR-2010-0799-9508-A1, p. 3]

Garmin's second area of concern is that the proposed rule does not give vehicle manufacturers the opportunity to generate a defined minimum off-cycle credit for some verifiable real-world fuel saving and CO_2-reducing technologies. These would include in-dash GPS navigation and in-dash GPS navigation with traffic avoidance. We respectfully ask that the current literature and research be thoroughly explored and reviewed with the goal of facilitating the generation of CO_2 credits for these additional technologies in some standardized way. We would be happy to discuss this with you. [EPA-HQ-OAR-2010-0799-9508-A1, p. 3]

In order to assist manufacturers in meeting their 2025 targets ahead of schedule, Garmin believes these companies should have no regulatory disincentives to fully utilize every kind of smart driving CO_2-reducing technology that they are willing to invest in. [EPA-HQ-OAR-2010-0799-9508-A1, p.3]

We look forward to working with you towards getting credits placed on the off-cycle technology menu for in-dash GPS navigation technologies. [EPA-HQ-OAR-2010-0799-9508-A1, p.3]

Organization: Guardian Automotive Products, Inc.

Guardian commends NHTSA and EPA for recognizing through off cycle credits a variety of technologies which can significantly improve fuel economy and emissions, yet were previously excluded due to the short falls of the current vehicle test cycles. [EPA-HQ-OAR-2010-0799-9299-A1, p. 1]

Thermal Control and Glazing

Guardian recommends that the formula for solar glazing credits be adjusted to include a factor that accounts for the overall surface area of glazing in the vehicle. The proposed formula accounts for the incremental area contribution of each glazing aperture with respect to the total, but ultimately provides the same potential credit for a vehicle with a small glazing area and no sunroof as it does for a vehicle with a large glazing area and large sunroof. [EPA-HQ-OAR-2010-0799-9299-A1, pp. 1-2]

While the 2012-2016 GHG regulation permits an OEM to apply for glazing or heat load reduction credit, the glazing credit formula in the 2017 and later regulation should improve and simplify this process and be made available for OEMs to use immediately. [EPA-HQ-OAR-2010-0799-9299-A1, p. 2]

Solar Roof Panels

Guardian applauds NHTSA's and EPA's recognition of the potential benefits photovoltaics can offer, especially as the popularity of hybrids and EV's grows. [EPA-HQ-OAR-2010-0799-9299-A1, p. 3]

This technology is rapidly evolving to the point that the 50 Watt threshold required in the proposed regulation is likely to be significantly surpassed by the time the regulation takes effect in 2017. In fact, there are examples today which already significantly surpass this value. For instance, the Fisker Karma today employs a photovoltaic roof panel which produces in excess of 100 Watts at standard conditions. As a result, Guardian urges NHTSA and EPA to adopt a formula based credit for this technology in order to fully recognize future benefits and to encourage the development and use of higher power systems. Presuming that the same logic the agencies used to arrive at the credit listed for the 50 Watt threshold holds for higher power, is this first equation simply a linear relationship based on this value? Guardian acknowledges that while it is fairly simple to determine output of any PV panel at any given conditions of direct normal solar irradiance combined with angle and temperature, it is not so evident today to predict exactly what total benefit will be achievable based on average vehicle use and driving as well as parking conditions. We suggest for this reason that at this time a simple equation for credit is appropriate, and as systems increase in popularity there will be more data available to refine the credit, perhaps at the mid term review. However, given the long timeframe of the proposed regulation and the pace of innovation in the photovoltaic industry, it seems imperative that such a credit not be simply a fixed value if the true objective is to incentivize further advancement in output, and hence potential reduction in GHG emissions and fuel consumption. [EPA-HQ-OAR-2010-0799-9299-A1, p. 3]

As the primary goal of the regulation is to generate significant improvements to emissions and fuel economy (and the associated economic and societal benefits), Guardian also urges that the credit for solar roof panels be made available prior to 2017. [EPA-HQ-OAR-2010-0799-9299-A1, p. 3]

Moreover, as a clarification point, Guardian recommends that the proposed credit be allowed for any solar panel with appropriate output and not be limited to roof mounted panels, as suggested by the term 'solar roof panel'. [EPA-HQ-OAR-2010-0799-9299-A1, p. 4]

Guardian also requests that the test conditions to establish panel power with respect to the proposed rule be defined as part of the rule. For instance, in the photovoltaic industry it is common to provide output values at STC (Standard Test Conditions) which are most commonly a direct normal solar irradiance of 1000 W/m2 and a panel temperature of 25°C± 2°C. [EPA-HQ-OAR-2010-0799-9299-A1, p. 4]

Conclusion

In summary, Guardian applauds the efforts of EPA and NHTSA with respect to the treatment of off cycle credits in the proposed regulation. These credits will encourage innovation and technological advancements as well as corresponding improvements in fuel economy and emissions. We hope the agencies find the above comments useful and relevant, and will draw upon them to further improve the regulation and drive incentives to maximize benefits offered by such technologies. [EPA-HQ-OAR-2010-0799-9299-A1, p. 4]

Organization: Pittsburgh Glass Works (PGW)

Pittsburgh Glass Works (PGW) supports the proposed rule's provisions for providing credit for off-cycle technologies. The benefits of solar glazing, for example, are not measured in any current test cycle, but have been proven to reduce emissions and improve fuel efficiency. Solar glazing has been proven to reduce interior cabin temperatures by as much as 10 deg C and thus reduce the work load of the air conditioning system. Solar glazing technologies provide additional benefits to the consumer, such as improved noise reduction, UV protection, better security, etc. beside the emissions reduction. [EPA-HQ-OAR-2010-0799-9300-A1, p. 1]

PGW would like to provide the following suggestions for the agencies' consideration:

1. The off-cycle credit for glazing is calculated using a formula that correlates the benefit to the glass properties. PGW supports the general concept of the formula used, but would like to offer a recommendation to improve the methodology to enable a more accurate accounting of the contribution of solar glazing. The formula, as defined in the NPRM, calculates the temperature reduction from the glass where the contribution of each piece of glass is measured as a percentage of the total glass area. However, there is no accounting for the fact that the total glass area in the vehicle is in itself a very large contributor to the heat load in a vehicle. There is a general trend of increasing glass size in the vehicles, and the larger amount of glass would actually contribute a larger proportion of heat load that would be affected by the kind of glazing. Therefore, it is PGW's recommendation that the agencies introduce a factor that accounts for the total glass area in the vehicle. For example, if the average glass surface in a car is 4.0 sq.m., then if the glass usage is greater than 4.0 sq.m. the contribution of the solar glazing should be proportionately larger. Therefore, the revised equation would be as follows: [EPA-HQ-OAR-2010-0799-9300-A1, p. 2]

Baseline glass size = 4.0 sq.m.

Actual glass used = 5.0 sq.m.

Contribution of glass in actual vehicle = 5.0/4.0 = 125% of baseline glass. [EPA-HQ-OAR-2010-0799-9300-A1, p. 2]

2. The off-cycle credit for thermal load reduction technologies is capped at 3.0 g/mile for cars and 4.3 g/mile for light-duty trucks. The credit for glazing technologies is also subject to the same limitations. The data to support the benefits of the glazing technologies and heat load reduction technologies has been gathered from analysis of current technologies. There are likely to be innovations in the technologies before and during the time frame of the regulations that might surpass the performance of existing technologies. Therefore, applying the limits to the benefits could inhibit innovation. PGW urges the agencies to remove these maximum limits so that technology innovation is encouraged. [EPA-HQ-OAR-2010-0799-9300-A1, p. 2]

4. The data used for the credit calculation has been based on testing and modeling of existing technologies primarily on internal combustion engine vehicles. The benefit of the solar glazing technologies would be compounded with other technologies such as start/stop, hybrid, electric, etc. Therefore, PGW recommends that the agencies continue to consider the full benefit of the solar glazing technologies and refine the model at the mid-term review of the regulations. [EPA-HQ-OAR-2010-0799-9300-A1, p. 3]

5. Finally, PGW strongly urges that the credit be made available in the MY2012-2016 regulations without the burdensome review process as currently stipulated. This will enable earlier implementation of the technologies and the benefits could be accrued much sooner. [EPA-HQ-OAR-2010-0799-9300-A1, p. 3]

PGW support the agencies' consideration of off-cycle credits in general, and the impact of solar glazing in particular. If there is any further information that can be provided, please do not hesitate to contact us. [EPA-HQ-OAR-2010-0799-9300-A1, p. 3]

Organization: SABIC Innovative Plastics US LLC

These comments focus on the proposed off-cycle and fuel consumption improvement credits for Thermal Control Technologies. Specifically, SABIC-IP requests that the agencies make clear that the "Glass or Glazing" category for these credits includes reduced thermal conductivity benefits ("RTC" benefits or credits) as well as reduced solar transmittance benefits ("RTts" benefits or credits), and further that the agencies include within the regulatory text a calculation to quantify credits associated with the RTC benefits. A modification of the proposed credit to encompass thermal conductivity benefits is within the scope of the NRPM, and can therefore be accomplished during the next stage of this rulemaking. As such, a separate petition process to achieve this result is not necessary. The Alliance of Automobile Manufacturers, the American Chemistry Council, Bayer MaterialScience and the Society of the Plastics Industry support this request. [EPA-HQ-OAR-2010-0799-9467-A1, pp.1-2]

Modifying the existing credit to recognize the additional benefits of other glass or glazing technologies generally, and RTC glazing specifically, is consistent with the intent to promote advanced energy management within the passenger compartment, or cabin, to reduce air conditioning (A/C) loads. Accounting for the RTC benefits also promotes continued innovation in glazing technologies. Finally, placing RTC-based technologies on an even footing with RTts-based technologies ensures that all glass and glazing technologies will be treated similarly within the regulatory program and will remain available in the marketplace. [EPA-HQ-OAR-2010-0799-9467-A1, p.2]

In addition to a calculation to quantify RTC benefits, SABIC-IP presents test data measuring the fuel economy benefits of lightweight materials and confirming the traditional estimates that vehicle weight reductions of 10% result in approximately 6-7% better fuel economy. Finally, SABIC-IP presents information regarding how additional GHG emissions and fuel economy benefits from improved aerodynamics and other factors can result from the integration of engineering thermoplastics into the front six inches and most of the rear six inches of a light duty motor vehicle. [EPA-HQ-OAR-2010-0799-9467-A1, p.2]

In sum, engineering thermoplastics offer three-fold emissions and fuel economy benefits: (1) polycarbonate glazing reduces air conditioning load by substantially reducing window thermal conductivity relative to traditional glass; (2) engineering thermoplastics offer significant mass reduction opportunities throughout the vehicle; and (3) engineering thermoplastics offer aerodynamic design opportunities that further reduce GHG emissions and fuel consumption. [EPA-HQ-OAR-2010-0799-9467-A1, p.2]

The agencies propose off-cycle GHG and fuel consumption improvement credits for advanced glass or glazing technology and specify a calculation to quantify this benefit based on the ability to reduce the amount of solar energy entering the passenger cabin of the vehicle, relative to a baseline glazing.1 This technology decreases the “total solar transmittance,” or “Tts”, of the glazing and, as a result, lowers the “soak” temperature in the cabin of a “standing” vehicle under hot sunny conditions.2 By lowering soak temperature, reduced Tts glass or glazing reduces the subsequent demand on the A/C system to cool the cabin air to a comfortable temperature. [EPA-HQ-OAR-2010-0799-9467-A1, p.3]

SABIC-IP endorses off-cycle credits for reduced Tts glass or glazing as long as the regulatory structure remains technology neutral and does not advantage a particular glazing technology.3 SABIC-IP therefore requests that the agencies also include a calculation to quantify reduced thermal conductivity credits for glazing that provides similar GHG reduction benefits. These benefits are independent of those resulting from reductions in Tts. Moreover, RTts and RTC benefits can coexist not only within the same vehicle but also within the same window application when both Tts and thermal conductivity are reduced below the respective baselines for solar transmittance and thermal conductivity. [EPA-HQ-OAR-2010-0799-9467-A1, p.3]

To support this request, SABIC-IP sets forth below a detailed methodology to account for and quantify the RTC benefits associated with advanced glass or glazing. This methodology tracks the methodology in the proposed rule for quantifying RTts benefits, adopting the same standards and analytical steps applied by the agencies for the RTts credit. The result is an off-cycle credit formulation for RTC benefits analogous to that in the proposed rule for RTts benefits. [EPA-HQ-OAR-2010-0799-9467-A1, p.3]

Reducing window thermal conductivity inhibits heat transfer between the ambient air outside the vehicle and the passenger cabin. Thus, the amount of heat transfer into the cabin is reduced. This reduction in heat transfer can be identified with a reduction in A/C load, 4 which in turn yields a reduction of the A/C related GHG emissions associated with maintenance of a comfortable cabin temperature. PC glazing can provide this benefit because it offers an inherent thermal conductivity five times lower than glass, thereby offering a significantly greater insulating capacity. [EPA-HQ-OAR-2010-0799-9467-A1, p.4]

The purpose of the proposed off-cycle credits for Thermal Control Technologies5 is to encourage innovations that “reduce the amount of solar energy which enters the vehicle’s cabin area, reduce the amount of heat energy build-up within the cabin when the vehicle is parked, and/or reduce the amount of cooling/heating energy required through measures which improve passenger comfort.” [EPA-HQ-OAR-2010-0799-9467-A1, p.4]

Throughout the process of developing the proposal, EPA and NHTSA sought industry guidance regarding a broad category of thermal control technologies. At the outset, the agencies met with OEMs to assess major technology areas, including “thermal management technologies.” The proposed list of Thermal Control Technologies is indicative of this approach and includes a varied list of features that rely on many distinct technological innovations to achieve GHG and fuel economy benefits. [EPA-HQ-OAR-2010-0799-9467-A1, p.4]

The proposed regulatory text furthers this intent by referring to the off-cycle credits for Thermal Control Technologies as applicable to “Glass or Glazing,” and this reference is repeated in the TSD. [EPA-HQ-OAR-2010-0799-9467-A1, pp.4-5]

However, when setting forth the calculation to quantify the credits, the agencies refer only to a single glazing attribute, Tts, and do not include thermal conductivity values. Consequently, although RTC benefits fall squarely within the stated intent and the scope of the credits as expressed in the proposal, the regulation fails to encompass the full range of benefits and credits associated with Glass or Glazing Thermal Control Technologies. Extending the existing credit to include appropriate references and a calculation to cover RTC benefits is clearly within the scope of the proposed rule and a logical extension of the proposed regulatory text. As a result, for purposes of the current rulemaking, SABIC-IP believes it is appropriate to include the additional methodology for calculating thermal conductivity benefits within the final rule, and that a separate petition process is not necessary. [EPA-HQ-OAR-2010-0799-9467-A1, p.5]

The comparison in the following table of the mechanisms underlying the RTts and RTC benefits illustrates why both should be included on the off-cycle credit menu. The RTts benefit recognizes the role of solar energy transmission in generating high soak temperatures in parked unoccupied vehicles. RTC glazing insulates the passenger cabin from the effects of higher outside air temperatures and reduces the demand on the A/C system to maintain a comfortable cabin temperature. Both technologies inhibit energy transfers that tend to increase the cabin temperature. Both technologies reduce the amount of fuel required by operation of the A/C system, during cool down from the soak state in one case and while maintaining a comfortable cabin temperature in the other. The two technologies through different mechanisms provide similar benefits in terms of A/C related fuel use and GHG emissions. [EPA-HQ-OAR-2010-0799-9467-A1, p.5] [For the associated table please refer to EPA-HQ-OAR-2010-0799-9467-A1, p.6]

Significantly, RTC glazing does not appreciably influence soak temperature or negatively offset the GHG and CAFE benefits estimated for RTts glazing. Thus, because RTC and RTts operate through independent, but not mutually exclusive mechanisms, the benefits from RTts glazing and RTC glazing are independent and entirely additive. [EPA-HQ-OAR-2010-0799-9467-A1, p.6]

The agencies’ proposed methodology for RTts-based credits may be applied simultaneously with the methodology for the RTC-based credits presented below. The methodology for quantifying RTC credits is closely modeled after the approach in the proposed rule for quantifying the RTts credits. [EPA-HQ-OAR-2010-0799-9467-A1, p.6]

Quantifying the Benefits of Reduced Tts and Reduced Thermal Conductivity [EPA-HQ-OAR-2010-0799-9467-A1, p.6]

The RTts credit methodology in the proposal provides a common structure for quantifying the GHG reduction benefits of both reduced solar transmission and reduced thermal conductivity. [EPA-HQ-OAR-2010-0799-9467-A1, p.6]

The proposed RTts credit calculations rely on National Renewable Energy Laboratory (NREL) studies that evaluated technologies to reduce soak temperature for climate control purposes. Based on NREL's finding that reduced Tts glazing decreases the cabin temperature gain when a car is left parked in the sun, the proposal calculates GHG reductions based on window Tts values relative to location-specific window baseline values. The agencies have proposed an off-cycle credit opportunity for glazing of up to 2.9 g/mi for passenger vehicles and 3.9 g/mi for light trucks to recognize this benefit.12 [EPA-HQ-OAR-2010-0799-9467-A1, pp.6-7]

Vehicles equipped with both RTts glazing and RTC glazing would be entitled to separate and cumulative off-cycle credits for each technology, as long as their combined cumulative credit is no more than 2.9 g/mi for cars and 3.9 g/mi for trucks. [EPA-HQ-OAR-2010-0799-9467-A1, p.7]

Summary of the Proposed Calculation for Reduced Tts [EPA-HQ-OAR-2010-0799-9467-A1, p.7]

The existing glass or glazing credit uses Tts as the measurable attribute to quantify the GHG reduction and off-cycle credit amount. This arises from the theory that limiting the amount of solar energy transmitted into the passenger cabin during a solar soak will decrease the amount of fuel required to subsequently cool the cabin. Tts describes the percentage of the incoming solar energy transmitted through the automobile glazing. [EPA-HQ-OAR-2010-0799-9467-A1, p.7]

The first step in the proposed RTts-based calculation is to quantify the connection between Tts reductions and the reduction in cabin temperature during a standing car's prolonged sun exposure (i.e. the "soak" temperature). Working from NREL data that pairs Tts values with soak temperature reductions, the draft Joint TSD assumes a linear correlation to find a relationship between Tts and temperature reduction. The equation developed in this step can be used to calculate an expected temperature reduction from window Tts values. [EPA-HQ-OAR-2010-0799-9467-A1, p.7]

The draft Joint TSD uses a weighted average to combine individual window contributions into a temperature reduction average for the entire vehicle.13 This accounts for differences in area and Tts values across windows. The proposed methodology, as set forth in the draft Joint TSD and the regulatory text, uses each window's Tts value to calculate an individual window contribution to temperature reduction via the relationship between Tts and cabin soak temperature. The draft Joint TSD assumes that each window's contribution to the reduction in soak temperature is proportional to its area independent of window orientation. [EPA-HQ-OAR-2010-0799-9467-A1, pp.7-8]

The second analytical step of the proposed Tts analysis quantifies the connection between reduced cabin temperature and reduced A/C related fuel use. The draft Joint TSD quotes NREL's published result, based on simulation data, that a 12 degree centigrade reduction in cabin soak temperature results in a 26% reduction in A/C fuel consumption. This corresponds to a 2.2% reduction in A/C fuel consumption for every 1 degree centigrade reduction in the soak temperature.14 [EPA-HQ-OAR-2010-0799-9467-A1, p.8]

The third and final step connects the decrease in A/C fuel use, expressed in terms of the Tts glazing attribute, to a GHG reduction. Working from agency assumptions about the CO_2 impact of A/C systems (13.8 g/mi for cars and 17.2 g/mi for trucks), the draft Joint TSD calculates a CO_2 reduction of 0.3 g/mi (cars) and 0.4 g/mi (trucks) for each degree centigrade reduction in air cabin temperature. [EPA-HQ-OAR-2010-0799-9467-A1, p.8]

The proposed Tts methodology allows the agencies to calculate a vehicle GHG reduction based on a set of vehicle window areas and Tts values. Below, we present a methodology using the same analytical steps to calculate GHG reductions from the thermal conductivity and thickness of a reduced thermal conductivity glazing. [EPA-HQ-OAR-2010-0799-9467-A1, p.8]

Calculating the CO_2 Benefits of Reduced Thermal Conductivity [EPA-HQ-OAR-2010-0799-9467-A1, p.8]

SABIC-IP proposes a calculation to quantify the benefits of RTC glazing that is similar to the calculations included in the proposal for RTts glazing. The RTC approach set forth below is analytically premised on two peer-reviewed SAE papers demonstrating how PC glazing, with its lower thermal conductivity as compared to glass, reduces the A/C load required to maintain cabin temperature and the lack of any adverse practical impact on the cabin soak temperature when PC glazing is used. The RTC credit analysis parallels the proposal's methodology for the RTts credits.17 [EPA-HQ-OAR-2010-0799-9467-A1, p.8]

After we describe the measurable glazing attribute that underlies the RTC off-cycle glass or glazing benefit (here, thermal conductivity normalized to window thickness rather than Tts), the RTC credit calculation proceeds in three steps: (1) quantification of the cabin response as a function of the measured window attribute (for the RTts credit, the agencies related soak temperature reduction to Tts reduction; here, we relate a reduction in the heat transfer into a cabin to a reduction in window thermal conductivity normalized to window thickness); (2) relating the cabin response to a reduction in A/C fuel use; and (3) relating the reduction in A/C fuel use to GHG emission reduction. The net result is a set of equations that match the RTts credit's form and methodology, but which relate the GHG emission reduction to a reduction in window thermal conductivity rather than to a reduction in Tts.18 The full calculation is described in identical steps and in more detail in the attached Annex A. [EPA-HQ-OAR-2010-0799-9467-A1, p.9]

RTC glazing's GHG benefits are derived from a lower thermal conductivity (relative to glass) that inhibits heat transfer between the vehicle cabin and the outside air. In the governing physical relationships, the glazing thermal conductivity (k) appears with glazing thickness (d) as a reciprocal factor (k/d). For example, at a given window location, insulation performance can be enhanced by lowering thermal conductivity and/or increasing window thickness. Accordingly, to calculate the off-cycle credit for a car with RTC technology, the thermal conductivity normalized to window thickness (k/d) is selected as the glazing attribute. This parallels the adoption of Tts as the measurable vehicle attribute for the RTts credit calculation. Though thermal conductivity is intrinsic to a given material, the typical window thickness generally varies from location to location and across different car models.19 [EPA-HQ-OAR-2010-0799-9467-A1, p.9]

Step 1: Express the Cabin Response (a change in heat transfer) In Terms of the Attribute [EPA-HQ-OAR-2010-0799-9467-A1, p.10]

As in the RTts case, the proposed methodology is based on a linear relationship between the cabin response and a change in window attribute. Thus, the cabin response to RTC glazing, namely the reduction in steady state heat transfer (in Watts), is related to the change in window thermal conductivity normalized to window thickness (k/d). The area-weighting used in the RTts credit calculation to account for variations in window size is also used here to account for similar variations as well as the selective application of PC glazing to the rooflite and backlite positions in the prototype case. This case, studied in the underlying SAE papers, nevertheless provides the basis for a general result applicable to other glazing configurations. [EPA-HQ-OAR-2010-0799-9467-A1, p.10]

Data from the relevant SAE paper is used to calculate the relationship between (k/d) and the heat transfer into the cabin. This data can be found within Annex A as well as in the table below. [EPA-HQ-OAR-2010-0799-9467-A1, p.10] [For the table please refer to EPA-HQ-OAR-2010-0799-9467-A1, p.10]

The above table summarizes glazing parameters for two comparison vehicles. The baseline vehicle has standard glass windows at all positions and provides the baseline values for calculating the RTC credit. The other vehicle has PC glazing at the backlite and rooflite positions and glass windows at all remaining positions. Thermal conductivity (k), thickness (d), and (k/d) are listed for each vehicle's window position. "Change" represents the difference in (k/d) values for each window where glass glazing is replaced with PC glazing. Since there is no change in the windshield or side window from the baseline vehicle, the corresponding "change" value for those positions is zero. [EPA-HQ-OAR-2010-0799-9467-A1, p.10]

Applying parameters presented above and following the reduced Tts approach to account for individual window contributions, the area-weighted change in thermal conductivity normalized to thickness is 118.6 W/m2-K. Again following the SAE paper's results which show a heat transfer reduction of 107 Watts for the window configuration in the above table, and adopting the same linear relationship assumed for the reduced Tts credit, implies a response constant of 0.9021. Therefore, the following equation quantifies the heat transfer reduction (cabin response) due to a change in (k/d):[EPA-HQ-OAR-2010-0799-9467-A1, pp.10-11] [For the equation please refer to EPA-HQ-OAR-2010-0799-9467-A1, p.11]

The external temperature and solar radiation data used to generate this result incorporate a range meant to reflect real-world variations. The data represent mid-day August conditions in Phoenix, Arizona averaged over all Augusts from 1991-2005. As such, the data are not limited to a single sky condition but represent clear sunny days as well as the actual range of cloud cover configurations. [EPA-HQ-OAR-2010-0799-9467-A1, p.11]

Step 2: Use the Cabin Response to Calculate the Resulting Reduction in A/C Fuel Use [EPA-HQ-OAR-2010-0799-9467-A1, p.11]

For vehicles with RTC glazing technology installed at the backlite and rooflite window positions and with cabin air recirculating so that the A/C load reduction can be identified with the reduction of heat transfer through the glazing, the SAE study demonstrated a decrease in the steady state air conditioning load of 107 Watts, or 6.4%. This allows us to use the equation developed in Step 1 to calculate individual window contributions to a reduced A/C load. [EPA-HQ-OAR-2010-0799-9467-A1, p.11]

A/C load reduction can be related to A/C fuel use reduction by following the NREL methodology used for the reduced Tts credit. The RTts credits derived in the proposal rely on two separate NREL computer simulations that model, respectively, how a decrease in soak temperature reduces the A/C load for subsequent cool down and how, in turn, a decrease in A/C load reduces fuel consumption. A/C load was simulated to show a decrease of 29.8% for a 12 degree centigrade reduction in soak temperature (the latter generated in part by differences from the baseline vehicle other than the glazing). Fuel use was simulated to show a 26% decrease for this reduction in A/C load. [EPA-HQ-OAR-2010-0799-9467-A1, p.11]

Adapting these two NREL simulation results (i.e. using the ratio of 26% to 29.8%) to calculate fuel reductions attributable to RTC shows a 5.6% percent decrease in fuel use for a 107 Watt decrease in air conditioning load. 21 This corresponds to a 0.052% A/C fuel use reduction for each Watt reduction in the air conditioning load. [EPA-HQ-OAR-2010-0799-9467-A1, p.11]

Step 3: Relate Fuel Use Reductions to CO_2 Reductions [EPA-HQ-OAR-2010-0799-9467-A1, p.12]

In order to arrive at a final credit amount, the RTC reduction in A/C fuel use must be related to a reduction in GHG emissions expressed in grams of CO_2 per mile. The proposed calculation for a reduced Tts Solar Control credit does this by multiplying the area-weighted average of individual window contributions (Step 1) by a conversion factor Z. This conversion factor can be calculated by using the relationship between A/C load reduction and fuel use found in Step 2 (a 0.052% decrease in A/C/ fuel use for each Watt reduction in A/C load). [EPA-HQ-OAR-2010-0799-9467-A1, p.12]

Applying the same air conditioning CO_2 emissions data used in the agencies' RTts-based credit calculation (13.8 g/mi for cars and 17.2 g/mi for trucks), Z values applicable to RTC are derived: 0.0072 (g/mi)/Watt for cars and 0.0090 (g/mi)/Watt for trucks. [EPA-HQ-OAR-2010-0799-9467-A1, p.12]

Example: RTC-Based Credit Calculation for a Car with PC Glazing [EPA-HQ-OAR-2010-0799-9467-A1, p.12]

Again working from the above table of glazing parameters, this example calculates a representative off-cycle credit for a car22 where half of the glass window area is replaced with PC. We chose a value of 220 as a reasonable midpoint between the change values for thermal conductivity divided by window thickness in the table above. Since we have chosen an example where one-half of the vehicle windows remain unchanged, this introduces a factor of one-half via the area-weighted average. Thus, the calculated RTC credit for a car with half of the glass window area replaced by PC is: [EPA-HQ-OAR-2010-0799-9467-A1, p.12] [For the equation please refer to EPA-HQ-OAR-2010-0799-9467-A1, p.12]

This calculated value falls within the range of proposed values on the off-cycle credit menu. It is greater than the 0.4 g/mi proposed for solar reflective paint, another Thermal Control Technology credit, and close to the proposed credit for active aerodynamics (0.6 g/mi), a credit on the general Off-Cycle Technology menu. [EPA-HQ-OAR-2010-0799-9467-A1, p.12]

Summary [EPA-HQ-OAR-2010-0799-9467-A1, p.12]

Linking the above steps leads to an RTC off-cycle credit that is consistent with the RTts credit. It uses similar factors in the same methodology to calculate an off-cycle credit for RTC glazing. Following from the structure and placement of the RTts credit, we propose that the summary below be added to the Code of Federal Regulations at 40 C.F.R. 86.1866-12(d)(1)(i)(D) to calculate an off-cycle credit (CTC) for RTC glazing as follows: [EPA-HQ-OAR-2010-0799-9467-A1, p.12] [For the associated figure please refer to EPA-HQ-OAR-2010-0799-9467-A1, p.13]

Where ZTC = 0.0072 for passenger automobiles and 0.0090 for light trucks; Gi = the measured area of window i, in square meters and rounded to the nearest tenth; G = the total window area of the vehicle in square meters and rounded to the nearest tenth; Qi = the steady state load reduction for window i, determined by using the following formula: [EPA-HQ-OAR-2010-0799-9467-A1, p.13] [For the associated figure please refer to EPA-HQ-OAR-2010-0799-9467-A1, p.13]

Where (k/d)new,i, = the thermal conductivity of window i normalized to thickness d; (k/d)base,i = the thermal conductivity for a standard glass window in i’s position normalized to thickness (k/d)base,i = 312 for the backlite location, 260 for the rooflite location, and 200 for the windshield, side-front, side-rear, and rear quarter locations. [EPA-HQ-OAR-2010-0799-9467-A1, p.13] [For the associated figure please refer to EPA-HQ-OAR-2010-0799-9467-A1, p.13]

The methodology proposed here for RTC credits closely tracks the methodology proposed in the regulation for calculating RTts credits. Adding a calculation applicable to reduced thermal conductivity benefits expands the off-cycle credit menu in a way that furthers the express intent of the credit program to capture the full range of Thermal Control Technologies, including Glass or Glazing able to achieve and/or maintain comfortable cabin temperatures with reduced load on the A/C system. SABIC-IP believes it is appropriate to include the additional methodology for calculating thermal conductivity benefits within the final rule, and that a separate petition process to accomplish this is not necessary. [EPA-HQ-OAR-2010-0799-9467-A1, p.13]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 283-286.]

1 - We use the term “off-cycle” credit as a general reference encompassing the “off-cycle” credits provided in EPA’s greenhouse gas program as well as the corollary “fuel consumption improvement” credits in the CAFE program. See, e.g., 76 Fed. Reg. 75,021. [EPA-HQ-OAR-2010-0799-9467-A1, p.3]

2 - A “standing” vehicle for this purpose is one promoting the maximum soak temperature for a given glazing type: the A/C off, the windows closed, no ventilation and no shading. The term “standing” is used throughout these comments with the same meaning. [EPA-HQ-OAR-2010-0799-9467-A1, p.3]

3 - When regulating products, “the overriding principle of fairness is always the same: the government must govern with an even hand.” U.S. v. Undetermined Quantities of an Article of Drug Labeled as Exachol, 716 F. Supp. 787, 795 (S.D.N.Y. 1989) (holding that the FDA applied an “uneven regulatory policy” by not treating one product like similar situated other product). It is well-established that an agency cannot treat similarly situated parties differently without a reasoned basis for doing so. See, e.g., Burlington Northern and Santa Fe Ry. Co. v. Surface Transp. Bd., 403 F.3d 771, 776-777 (D.C. Cir. 2005) (“Where an agency applies different standards to similarly situated entities and fails to support this disparate treatment with a reasoned explanation and substantial evidence in the record, its action is arbitrary and capricious and cannot be upheld.”). [EPA-HQ-OAR-2010-0799-9467-A1, p.3]

4 - For a vehicle equipped with PC glazing technology rather than traditional glass in the backlite and rooflite windows, research has demonstrated a 107 Watt or 6.4% reduction in the A/C load required to maintain a comfortable cabin temperature for particular solar and temperature conditions and with air recirculating. See Reduced Steady State Heating and Air Conditioning Loads via Reduced Glazing Thermal Conductivity, SAE Technical Paper 2011-01-0126, 2011. Although the benefits of air recirculation and RTC are synergistic, the latter is an independent incremental benefit over and above the benefit of recirculation previously recognized by the agencies. [EPA-HQ-OAR-2010-0799-9467-A1, p.4]

5 - The Proposed Rule and supporting documents inconsistently categorize some of the proposed off-cycle credits as both Thermal and Solar Control technologies. For example, when the category is introduced within the draft Joint Technical Support Document (TSD), it is proposed as “Thermal (and Solar) Control Technologies.” p.5-69 (Section 5.2.3.5). This categorization is consistently applied through that Section. However, the draft Joint TSD later abandons reference to the Thermal Control Technologies when it summarizes the proposed off-cycle credits, referring only to Solar Control. See draft Joint TSD at 5-74 (table 5-26). Because Solar Control fails to accurately characterize all of the technologies listed in the Thermal Control category, the terminology should be revised in the final Joint TSD. This would also align it with the proposed regulatory language at 76 Fed. Reg. 75,381-2 where Thermal Control is used. [EPA-HQ-OAR-2010-0799-9467-A1, p.4]

12 - The proposed regulatory language for 40 C.F.R. § 86.1866-12(d)(1)(i)(B) appears to mistakenly set the "glass or glazing" credit caps at 3.0 g/mi for passenger automobiles and 4.3 g/mi for light trucks. See 76 Fed. Reg. 75,382. Conflicting "Glass or glazing" caps of 2.9 g/mi (cars) and 3.9 g/mi (trucks) are indicated in the Thermal Control Technology Table on the same page of the Federal Register and within the draft Joint TSD. See Draft Joint TSD at 5-73 (Table 5-25). This seems to arise from an accidental substitution of the categorical Thermal Control Technology caps for the specific glass or glazing limit. [EPA-HQ-OAR-2010-0799-9467-A1, p.7]

13 - Although the draft Joint TSD does not explicitly use area weighting until a later step of its analysis, we summarize it here to parallel the RTC calculation discussion. Area-weighting serves to preserve the analogy between RTts, where 100% of the glazing area is modified in the prototype case from which the off-cycle credit is derived, and RTC, where only 50% of the glazing area is modified in the prototype case. The resulting analogous expressions for the incremental cabin response to a change in attribute at one window (subject to area weighting) are labeled as the "General Case" in the attached Annex A. [EPA-HQ-OAR-2010-0799-9467-A1, p.7]

14 - The origin of this result and its reliance on computer simulations is explained in more detail below when the RTC-based credit calculation is presented. [EPA-HQ-OAR-2010-0799-9467-A1, p.8]

17 - The agencies have not specified any particular approach to calculating off-cycle or fuel consumption improvement benefits, and recognize that the demonstration of such benefits may involve "on-road testing, modeling, or some other analytic approach," Instead, the agencies require that, regardless of approach, the demonstration must be "robust, verifiable, and capable of demonstrating the real-world emissions benefit of the technology with strong statistical significance." 76 Fed. Reg. 75,021; Draft Joint TSD at 5-56 (Section 5.2) ("The estimates of these credits were largely determined from research, analysis and simulations, rather than from full vehicle testing, which would have been cost and time prohibitive.") To that end, we propose a method of demonstrating the real world benefits associated with the thermal control properties of PC glazing that tracks the methodology proposed with regard to Tts technology. As noted above, the PC glazing approach is also supported by published peer-reviewed SAE papers. In addition, the proposed methodology employs the applicable assumptions in the 2007 NREL paper cited frequently in the proposal and the TSD. See Reduction in Vehicle Temperatures and Fuel Use from Cabin Ventilation, Solar-Reflective Paint, and New Solar-Reflective Glazing, SAE Technical Paper 2007-01-1194. [EPA-HQ-OAR-2010-0799-9467-A1, pp.8-9]

18 - The agencies have recognized in the context of the proposed Tts methodology that an analytic approach is necessary to calculate the benefits for thermal and solar technologies. The same is true for RTC glazing. The SC03 test cycle does not capture PC glazing's benefits which are most pronounced when the A/C is maintaining a cabin air temperature much cooler than the outside air and the A/C is allowed to run for long periods. The SC03 cycle in the 5-cycle test, though it imposes an outside air temperature 12.8 C higher than the cabin temperature automatically targeted by the A/C, has a much smaller average temperature difference over the test duration because the cycle, only 10 minutes long, immediately follows a soak phase. This is

too short to attain and simulate the steady state cabin conditions (common in the real world) where RTC glazing's benefits are most pronounced. Instead, the SC03 cycle simulates cabin cool down from a solar soak state where RTC glazing provides practically no net effect. An analytic methodology is therefore appropriate. [EPA-HQ-OAR-2010-0799-9467-A1, p.9]

19 - An example of how these variations are treated in practice can be seen in the PC glazing credit calculation below. [EPA-HQ-OAR-2010-0799-9467-A1, p.9]

21 - See Annex A for a complete description of how the NREL results are applied to calculate the RTC fuel use reduction. [EPA-HQ-OAR-2010-0799-9467-A1, p.11]

22 - See id. for a calculation of a representative truck RTC credit value. [EPA-HQ-OAR-2010-0799-9467-A1, p.12]

Organization: Society of the Plastics Industry, Inc. (SPI)

We respectfully request modification of the proposed off-cycle credit addressing thermal control technology to specifically recognize the insulation benefits of innovative glazing technologies such as polycarbonate (PC) glazing, in order to employ a technology neutral approach. This can be achieved by clarifying that the "glass or glazing" category includes both reduced thermal conductivity benefits (for which a calculation for corresponding credits should be included within the regulatory text) and reduced solar transmittance benefits. [EPA-HQ-OAR-2010-0799-9492-A1, p.2]

The Agencies Should Clarify that Glazing with Reduced Thermal Conductivity is Eligible for the Proposed Off-Cycle Credit (OCC) for Thermal Control, and Include a Methodology for Quantifying This Benefit [EPA-HQ-OAR-2010-0799-9492-A1, p.6]

SPI supports the inclusion of an off-cycle credit (OCC) for thermal control. As the agencies are aware, the performance of technologies that reduce air conditioning demand are not captured on test drive cycles, and are therefore appropriate for recognition under the OCC program. As proposed, the credit appears focused on solar control technologies.[29] This phenomenon would be relevant to some PC glazing products, including those that filters a proportion of infrared rays. However, we note that the proposed glazing credit formulation is inadequate to capture other qualities of advanced glazing that reduce A/C load and associated emissions. [EPA-HQ-OAR-2010-0799-9492-A1, p.6-7]

In particular, SPI respectfully requests consideration for modification of the proposed off-cycle credit for thermal control to employ a technology neutral approach, and include the full range of glazing with reduced thermal control properties. With a thermal conductivity approximately five times lower than glass, PC glazing helps to maintain a comfortable temperature with less air conditioning use. The substantial off-cycle reduction on the air conditioning (A/C) load is expected to result in improved energy efficiency regardless of vehicle type or power train. [EPA-HQ-OAR-2010-0799-9492-A1, p.7]

The administrative record makes clear the agencies' intent to encourage innovations that: "reduce the amount of solar energy which enters the vehicle's cabin area, reduce the amount of heat energy build-up within the cabin when the vehicle is parked, and/or reduce the amount of cooling/heating energy required through measures which improve passenger comfort." [EPA-HQ-OAR-2010-0799-9492-A1, p.7]

This intent is also reflected in the regulatory text and the Technical Support Document, both of which refer to thermal control technologies applicable to "glass or glazing." While glazing with superior insulation value clearly responds to the agencies' stated intent, the NPRM and associated documents neglect to provide a methodology for quantifying thermal conductivity benefits. Modifying the existing credit to include appropriate references and a calculation to cover reduced thermal conductivity benefits is consistent with the scope and intent of the agencies in the area of thermal control. As such, SPI believes that providing such a methodology can be accomplished in the present rulemaking, and that a separate petition process is not necessary. [EPA-HQ-OAR-2010-0799-9492-A1, p.7]

SPI understands that comments to be submitted by SABIC Innovative Plastics will provide details for quantifying the off-cycle benefits from reduced thermal conductivity, and we urge the agencies carefully consider modifying the OCC to incorporate such a calculation. An amended credit is appropriate in assuring vehicle manufacturers are provided with appropriate flexibility to meet standards. Recognition in an OCC of thermal benefits and other technologies would be consistent with agencies' planned mid-term evaluation, and would not favor a particular material or technology over another. [EPA-HQ-OAR-2010-0799-9492-A1, p.7]

SPI again expresses its appreciation for the opportunity to comment, in support for the inclusion of thermal control benefits in an off-cycle credit for automotive manufacturers. [EPA-HQ-OAR-2010-0799-9492-A1, p.8]

---

29 - The equation at 76 FR 75382 includes Tts for total solar transmittance

Organization: TechAmerica

We would like to bring to your attention a concern we have identified in the proposal as it relates to the available options through which auto manufacturers may obtain "off-cycle" greenhouse gas emission reduction credits. One of the options included in the proposed rule involves window glazing technologies to reduce heat buildup in parked cars, which can reduce fuel consumption associated with air conditioning use. [EPA-HQ-OAR-2010-0799-9470-A1, p.1]

To the best of our knowledge, the most effective of these technologies is glass treated with metallicized reflective materials. While we understand that the decision to choose a particular technology to obtain an off-cycle credit will be voluntary, it is reasonable to assume that auto manufacturers seeking to maximize credits under the proposed rule would be inclined toward use of the metallicized reflective materials in glass. [EPA-HQ-OAR-2010-0799-9470-A1, p.1]

This incentive is of great concern because metallic films are known to interfere with electronic devices that depend on radio frequency (RF) transmissions, such as global positioning systems, toll tag transponders and cellular telephones. Even limited use of metallicized reflective technology (e.g. only in windshields) can increase the likelihood of interference with reliable operation of these devices. The potential for cell phone interference or dropped calls is especially troubling in emergency situations. [EPA-HQ-OAR-2010-0799-9470-A1, p.1]

While increased fuel efficiency and lower greenhouse gas emissions are both laudable goals, under the proposed rule these goals would be achieved at the expense of significant adverse impacts on the ability of consumers, emergency workers and law enforcement personnel to contact help in an emergency, communicate life-saving instructions, determine the most direct route to a destination, and track prisoners released under electronic surveillance. For these reasons, we ask EPA and NHTSA to consider removing the off-cycle credit that effectively incentivizes metallicized reflective glazing. [EPA-HQ-OAR-2010-0799-9470-A1, p.2]

We also request that the EPA and NHTSA consider the impact of adding metallic film on the cost of recycling mass produced windows. With this proposal’s implementation, the EPA and NHTSA would need to consider providing recyclers a list of benign metals (similar to the SNAP list) that manufacturers can use as a reference for materials that do not need to be recovered. [EPA-HQ-OAR-2010-0799-9470-A1, p.2]

There are also safety considerations that go beyond the interference with RF transmission due to the metallic glazing of driver’s windows. This concern is evident in some local laws in North America such as in British Columbia that requires that no film is permitted on the driver’s compartment right or left. Such legislation indicates a tint of any kind may be considered a means to increase the risk of an accident. [EPA-HQ-OAR-2010-0799-9470-A1, p.2]

As an industry, we have dealt with this issue most recently at the state level in California. In March of 2010, the California Air Resources Board (CARB) abandoned a regulatory proposal to mandate use of this technology in recognition of the fact that the emission reduction benefit calculations were based on flawed methodology and that use of this technology presented the potential for unintended adverse consequences associated with RF device interference. The California Legislature subsequently passed SB 1328 (Lowenthal, 2010), which requires CARB to consider the following factors when adopting or amending regulations to reduce motor vehicle cabin temperature in order to reduce greenhouse gas emissions: [EPA-HQ-OAR-2010-0799-9470-A1, p.2]

(a) Potential reductions in air-conditioning use that can be achieved while a motor vehicle is moving, in addition to reductions in air-conditioning use when a motor vehicle is parked. [EPA-HQ-OAR-2010-0799-9470-A1, p.2]

(b) Potential conflicts between, and relative benefits of, motor vehicle cabin temperature reduction requirements and technologies that provide motor vehicle greenhouse gas emission reductions through various means. [EPA-HQ-OAR-2010-0799-9470-A1, p.2]

(c) The flexibility necessary to achieve overall maximum greenhouse gas emission reductions from motor vehicles. [EPA-HQ-OAR-2010-0799-9470-A1, p.2]

In light of this history, it is not clear why USEPA is now effectively promoting future use of a technology rejected by California because it is known to interfere with RF transmissions. At a minimum, we ask that USEPA consider the same factors before adopting any regulation that purports to reduce vehicle cabin temperature as a means of achieving greenhouse gas emission reductions. [EPA-HQ-OAR-2010-0799-9470-A1, p.2]

Response:

We appreciate all of the comments on the off-cycle credit for glazing from all of the commenters. The range of comments fell into three main areas: 1) accounting for the overall glazing surface area in the calculations and a minimum level of solar transmittance, 2) concerns regarding metallic glazing and incentivizing this technology, and 3) granting of credit for polycarbonate (PC) glazing technology. EPA responds to the comments on PC glazing in greater detail in Chapter 5 of the TSD for this final rule (See 5.2.10). In addition, we will briefly summarize those responses here.

For the comments from the EPGAA, Guardian and PGW regarding accounting for the total glass surface in a vehicle, this is discussed further in Section 5.2.10 of TSD Chapter 5. In summary, the equation that was included for calculating the glazing benefits includes a variable for the total glazing surface area when accounting for each location where glazing is applied. Further, the comments advocate for proportional scaling based on data larger glass area. We believe that this scaling provides a perverse incentive to increase glass area on vehicles even more than levels seen today, which would in turn have deleterious environmental impacts, as the interior cabin would experience greater heat loads. Therefore, we are finalizing the format for the glazing credit formula as proposed.

Regarding the comments on metallic glazing and incentivizing this technology, this is discussed in greater detail in Section 5.2.10 of TSD Chapter 5 and Section II.F.2. of the preamble for this final rule. To briefly summarize, we met with the Enhanced Protective Glass Automotive Association, which represents the automotive glass manufacturers and suppliers, and representatives from the automotive glass industry including PGW, Guardian, and AGC to discuss the concerns with metallic glazing and the potential for signal interference and/or radio frequency (RF) attenuation (details of this meeting are available in EPA docket # EPA-HQ-OAR-2010-0799 and NHTSA docket #NHTSA-2010-0131). Based on their feedback and supporting data supplied, there was no statistically-significant increase in signal interference or RF attenuation when reflective (or metallic) glazing was used. They also supplied a list of vehicles that currently use metallic glazing was supplied but there have been no wide scale reports of signal interference or RF attenuation on these vehicles.

In addition, we received comments from the California Air Resources Board (CARB) in response to the comments on concerns with metallic glazing and it's affect on the Cool Cars Regulation, and supporting the information from automotive glass industry. CARB stated that the reason they did not finalize a mandate for metallic glazing in the Cool Cars Regulation was primarily the timing for when the signal interference and RF attenuation concerns were raised.

They also clarified that they were not requiring a specific type of glazing and that the performance-based approach ultimately adopted in the Advanced Clean Cars Regulation accomplished the same objectives as proposed under the Cool Cars Regulation. Finally, CARB also performed testing of signal interference and RF attenuation (see test results in EPA docket #EPA-HQ-OAR-2010-0799-41752) echoing the findings of the automotive glass industry that there is "[n]o effect of reflective glazing observed on monitoring ankle bracelets or cell phones" and that any "[e]ffects on GPS navigation devices [are] completely mitigated by use of [the] deletion window" placing either the device or the external antennae in this area. CARB urged EPA to finalize the proposed credit values for glass and glazing as proposed. Based on these statements, the primary reason for CARB ceasing work on the regulation was not due to concerns raised regarding reflective/metallic glazing as many of the commenters asserted.

Based on the information supplied by the automotive glass industry and CARB, there is no evidence to support the commenters' claims of significant adverse effects on signal interference and RF attenuation. However, to allay the commenters' concerns, we will emphasize that manufacturers strongly consider and evaluate the potential for signal interference and RF attenuation in their vehicle design and glazing technology when requesting the solar control glazing credit.

Regarding the comments on PC glazing, several commenters (American Chemistry Council or ACC, Bayer Material Science, California Manufacturers and Technology Association, CTIA-The Wireless Association, Garmin, SABIC Innovative Plastics, and the Society of Plastics Industry) touted the benefits of polycarbonate (PC) glazing (e.g., reduced thermal conductivity compared to glass reduced weight of PC glazing compared to other materials) and suggested that the glazing credit not be restricted to metallic glazing and, further, recommended that a separate PC glazing credit should be established. In addition, SABIC Innovative Plastics supplied an equation for calculating the thermal conductivity benefits from PC glazing similar to the equation for glazing credit in Section 5.2.10 in TSD Chapter 5.

In response, we believe it is important to note that we are not mandating a particular technology to qualify for the off-cycle glazing credit. The off-cycle glazing credit is technology neutral and performance based with manufacturers able to select the glazing technologies and designs based on desired heat rejection performance and considering signal interference or RF attenuation (if any), as discussed above. Therefore, we believe that a separate PC glazing credit is not necessary since this credit covers all types of glazing technologies.

Second, the formula we referenced in Section 5.2.10 of TSD Chapter 5 for solar transmittance is an established ISO procedure (ISO 13837) that can be used and referenced to ensure a consistent basis for information supporting the credit request. To offer a separate credit for PC glazing on the off-cycle technology menu, we would need to have a similar, established set of procedures to validate the equations, and substantiate a credit for PC glazing. Therefore, we are not including the specific equations used to calculate the benefits of thermal conductivity from PC glazing. If manufacturers believe that there is some additional benefit, they may apply for additional glazing credit using the demonstration methods for technologies not on the defined technology list. See preamble section II.E.5.

Therefore, we agree with the comments from CARB "to retain the structure of the off-cycle credits for solar control technologies." Accordingly, we are finalizing the off-cycle provisions for solar and thermal control technologies, including glazing, as proposed in this final rule. More detailed discussion on the solar and thermal technologies can be found in Section 5.2.9 of TSD Chapter 5 and Section II.F.2. of the preamble for this final rule.

The EPA also agrees with the comments from the Enhanced Protective Glass Automotive Association (EPGAA) that the off-cycle credit for solar glazing "provides simplified model for defining the impact of glazing on the heat load reduction and the emissions." and Pittsburgh Glass Works (PGW) that "the benefits of solar glazing…have been proven to reduce emissions and improve fuel efficiency."

Regarding the comments from EPGAA and PGW on capturing the additional benefits of glazing in conjunction with other advanced technologies, we encourage EPGAA, PGW and other member companies to develop measurement standards to capture these benefits. If a method for demonstrating these benefits can be developed, this process may be used for the alternate demonstration methods for technologies not on the off-cycle technology menu.

For the comments from EPGAA and PGW on the 3.0 g/mi for passenger automobiles and to 4.3 g/mi for light trucks limit for solar and thermal control technologies, the alternate method approval process for technologies not on the off-cycle technology menu is a pathway for manufacturers to demonstrate benefits and request credit above and beyond these limits. The default values in the off-cycle technology menu were developed based on available information. However, it is possible a manufacturer may have data specific to their design that exceeds the default values in the off-cycle technology menu. Therefore, the alternate method approval process would be the arena to present this information and receive credit beyond the imposed solar and thermal control technology limits.

For the comments from EPGAA and PGW regarding extension of the off-cycle technology menu to the MY2012-2016 GHG Program are discussed in Section III.C.5 of the preamble for this final rule, as well as EPA's decision to do so under the circumstances described in the preamble.

Regarding the comments from Garmin relating to a defined minimum off-cycle credit for some technologies such as in-dash GPS navigation traffic avoidance, our response to this is discussed in greater detail in Section II.F.2 of the preamble for this final rule. In summary, these technologies face a high hurdle in quantifiable associated benefit and demonstrated real-world activity. These factors make it difficult to develop a pre-defined minimum off-cycle credit and we believe that the technologies are more relevant to a more flexible, open process such as the alternate demonstration methods for technologies. As such, EPA is not including these "driver selectable" off-cycle technologies on the final rule off cycle menu.

We agree with the comments from Guardian on solar roof panels and the changes they recommended as explained in Section 5.2.4 of TSD Chapter 5. In summary, we now use the term "Solar Panels" to describe this credit and the definition in 5.2.5 of TSD Chapter 5 reflects this revised terminology. In addition, the definition also explicitly states that this credit is available for “horizontally-oriented” surfaces, not just the roof, and that the rated power for the solar panel be determined using standardized test conditions as suggested by Guardian. Finally, we agree with Guardian regarding the need to account for different panel power ratings. We received similar comments from other commenters advocating for scaling of the solar panel credit since panel power may vary. In response to their comments, we developed a formula that can be scaled according to the rated solar panel power and takes into account various environmental factors such as on average vehicle use and driving and parking conditions. These revisions are being finalized in today’s action.

In general, we believe the off-cycle technology menu will provide some certainty to requesting off-cycle credits. In addition, the technologies on the off-cycle technology menu and associated credit values are based on robust data and verifiable methods and produce real-world benefits. For technologies not on the off-cycle technology menu, we believe one of the alternate methods for approval provides manufacturers the necessary flexibility to have the agency consider other technologies.

We believe that the technologies in the off-cycle program also will be durable in-use. As noted in section III.C. 5 of the preamble to the final rule, EPA requires off-cycle components to be durable in-use and continues to believe that this is an important aspect of the program. See 86.1866-12 (d)(1)(iii). The technologies upon which the credits are based are subject to full useful life compliance provisions, as with other emissions controls. Unless the manufacturer can demonstrate that the technology would not be subject to in-use deterioration over the useful life of the vehicle, the manufacturer must account for deterioration in the estimation of the credits in order to ensure that the credits are based on real in-use emissions reductions over the life of the vehicle. In-use requirements apply to technologies generating credits based on the pre-defined list as well as to those based on a manufacturer’s demonstration. In addition, the data we used to support the credit values is based on actual, real world vehicle data, where available, and represents the durability that can be expected on future vehicle applications.

In conclusion, we believe that all of the comments were helpful to improving the off-cycle credit program and we are finalizing the off-cycle credit program with the revisions based on the comments above in this final rule.

7.3. Comments Regarding Using Pre-Approved List in MYs 2012-2016

Organization: Alliance of Automobile Manufacturers

The improved off-cycle technology framework for MY 2017 and later years should be made available for MYs 2012-16. The Alliance supports the additional detail and improved processes proposed for capturing off-cycle fuel economy and GHG improvements. This facet of the MY 2012-16 regulation recognizes improvements in fuel economy and GHGs that are not captured in current laboratory tests but do have real-world benefits. Recognizing the real-world improvements that these technologies achieve and how challenging it will be to place these technologies in the market, the agencies should allow automakers to apply all aspects of the revised off-cycle framework to MYs 2012-2016. [EPA-HQ-OAR-2010-0799-9487-A1, p.4]

The improved off-cycle technology framework for MY 2017 and later years should be made available for MYs 2012-16. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

The Alliance urges the agencies to allow manufacturers to utilize the off-cycle pre-defined technology list and values for MYs 2012-2016. Providing this program feature in the earlier years improves the usefulness of the credit program and encourages manufacturers to introduce the listed technologies sooner, in lieu of postponing them to MY 2017 and beyond. There is every reason to incentivize early adoption of these technologies, since this would result in real CO_2 emissions reductions. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

Additionally, such action would provide manufacturers with the same planning certainty regarding available credits as will be provided in 2017 and beyond. This in turn would help encourage earlier investments in off-cycle technologies. The alternative that an OEM faces (pathway 2 or 3) otherwise would be to make the investment without the certainty provided by the list, which may result in postponing investment until 2017. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

Off-cycle technologies will have to compete with resource demands for other vehicle technologies, and knowing that the same credit for the technology available in MY 2017 would be available starting in MY 2012 would help the business case for earlier deployment. The result could be earlier availability of GHG-reducing technologies for consumers to buy. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

Organization: American Honda Motor Co., Inc.

7. Off-cycle Credits:

- Off-cycle Credit Menu for Model Years 2012 – 2016. Honda believes that the off-cycle credits identified in the menu represent real, environmentally-beneficial reductions in greenhouse gases. Therefore, Honda proposes to allow the applicability of the off-cycle credit menu to models prior to model year 2017. Real, effective greenhouse gas reductions can be achieved by off-cycle technologies implemented before model year 2017, and their credits should be recognized. This is good public policy as it is certain that earlier, effective environmental benefits are better for society. In the preamble, EPA states: "As noted above, EPA proposes to make the list available for credit generation starting in MY 2017. Prior to MY 2017, manufacturers would need to demonstrate off-cycle emissions reductions in order to generate credits for off-cycle technologies, including those on the list." This has the potential to create significant problems and discrepancies. If EPA awards credits higher or lower than the credit menu, it will create unfairness. EPA is already modifying the 2012 -2016 requirements by removing the language requiring off-cycle technologies to be "new, innovative, and not widespread." The best approach is to allow the inclusion of the off-cycle credit menu in the 2012 – 2016 standards. [EPA-HQ-OAR-2010-0799-9489-A1, p. 5]

Organization: Association of Global Automakers, Inc. (Global Automakers)

Global Automakers supports the availability of credits for technologies that provide on-road efficiency and emissions benefits but whose benefits are not fully measured using the current city-highway test. In a number of cases, these technologies are currently known, as indicated by the "menu" of credits developed by the agencies for the proposed rule. However, given the long time-frame for the proposed standards, it is very possible that additional technologies will be identified which should qualify for off-cycle credits, and the characteristics of these technologies cannot currently be predicted. In order to provide an incentive for manufacturers to pursue the implementation of these technologies and realize the resulting benefits, it is important that the agencies provide maximum flexibility to manufacturers to obtain credits. For these reasons, we urge the agencies to avoid imposing unnecessary restrictions on qualification for off-cycle credits. The proposed rule establishes numerous restrictions on the use of off-cycle credits which appear to be arbitrary and unnecessary to the effective functioning of the GHG and CAFE programs. [EPA-HQ-OAR-2010-0799-9466-A1, p. 5]

(1) The pre-approved technology "menu." Global Automakers supports the inclusion of the menu in the regulations as a default list of pre-approved technologies, with manufacturers being authorized to petition for larger credit or credits for additional technologies, based on credible data. EPA characterizes the menu credits as being conservative estimates of actual on-road benefits, so we see no reason to limit the availability of the menu credits to MY 2017 and thereafter. Therefore, we request that EPA revise section 86.1866-12(d)(1) to make the menu credits also available in MYs 2012-16. [EPA-HQ-OAR-2010-0799-9466-A1, p. 5]

Organization: BMW of North America, LLC

As many of these technologies will be introduced in the timeframe before 2017, we would appreciate the ability to use the predefined list as soon as possible. That would avoid unnecessary workload on both sides. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 1]

Organization: Chrysler Group LLC

Recommend establishing the list of pre-approved off-cycle technologies for the 2012-2016 rule; [EPA-HQ-OAR-2010-0799-9495-A1, p. 9]

Organization: Fisker Automotive, Inc.

Support the off-cycle technology credits as proposed

Fisker supports the design-based or "menu" approach to accounting for emissions reductions benefits from off-cycle technologies proposed to start in model year 2017. This approach is simpler and imposes less of a testing burden on automakers than the approach currently in place, so we would encourage the implementation of the new approach before model year 2017. [EPA-HQ-OAR-2010-0799-9266-A1, p. 5]

Organization: General Motors Company

To help foster these technologies, we urge the agencies to also make all aspects of the updated off-cycle framework available for the 2012-2016 model years. [EPA-HQ-OAR-2010-0799-9465-A1, p. 3]

Organization: Hyundai America Technical Center

Additionally, Hyundai asks that EPA and NHTSA allow the menu technologies to be used to comply with the MY 2012-2016 regulations. [EPA-HQ-OAR-2010-0799-9547-A1, p.5]

[This comment was also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 22.]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 172.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 22-23.]

Now that the agencies have quantified the value of off-cycle technologies in a menu format, Hyundai asks that EPA and NHTSA allow the menu technologies to be used in the 2012 through 2016 model years.

Organization: Johnson Controls, Inc.

Additionally, since the 2012-2016 joint rule on CAFE and CO_2 allowed for the usage of off-cycle credits to contribute towards compliance, Johnson Controls recommends that any credits defined through the NPRM process for 2017-2025 is applied retroactively to the 2012-2016 MY regulatory timeframe. [NHTSA-2010-0131-0253-A1, p. 4]

Organization: Motor & Equipment Manufacturers Association (MEMA)

First, MEMA recommends the agencies consider making available the off-cycle credits for MY2012-2016 to encourage early implementation of these technologies without the formal review process required under the MY2012-2016 National Program rule. [EPA-HQ-OAR-2010-0799-9478-A1, pp.9-10]

Organization: Porsche Cars North America, Inc. (PCNA)

Substantial greenhouse gas improvements should be achievable in off-cycle conditions using new technologies, but procedures for earning credits must be simplified. Porsche submits the following comments on the program: [EPA-HQ-OAR-2010-0799-9264-A1, p. 5]

• The concept of a pre-defined off-cycle technology credit menu is a valuable addition, which will prevent administrative delays and eliminate the need for burdensome analyses and credit applications. However, we believe that this simplified program should be extended retroactively to the 2012-2016 program in order to accelerate innovation during these early years. [EPA-HQ-OAR-2010-0799-9264-A1, p. 5]

Organization: Toyota Motor North America

Off-Cycle Credits: Availability to 2012-2016 Model Years [EPA-HQ-OAR-2010-0799-9586-A1, p.12]

Toyota requests EPA and NHTSA revise the 2012-2016 model year regulations to allow off-cycle credits to be generated using the proposed pre-determined credit list. Such a revision of the existing regulations would promote earlier development and deployment of off-cycle technologies, which in turn could accelerate real world CO_2 reduction and fuel savings by as much as five model years. It would also provide further harmonization of the EPA and NHTSA regulations for 2012-2016 model years. In addition, the certainty of pre-determined credits for the 2012-2016 model year regulations would further minimize the need for the arbitrary sales volume threshold proposed for 2017-2025 model years. Finally, this approach is consistent with the agency's proposal to make both the revised 5-cycle and non-5-cycle demonstration methods discussed below retroactive to the 2012-2016 model year regulations. [EPA-HQ-OAR-2010-0799-9586-A1, p.12]

Organization: Volkswagen Group of America

Volkswagen supports the proposal made by the Alliance to make the credited list of technologies available for use in the 2012-2016MY regulatory program. [EPA-HQ-OAR-2010-0799-9569-A1, p. 32]

Organization: Volvo Car Corporation (VCC)

VCC also wants to emphasize that the pre-defined list from the proposal for 2017-2025 be standard for the MY 2012-2016. The purpose of granting off-cycle credits is to enable early introduction of advanced technology, so it is a reasonable strategy to incentivize early adoption of these technologies, since this would result in real CO_2 emissions reductions. [EPA-HQ-OAR-2010-0799-9551-A2, p. 6]

The off-cycle credit program in 2012-2016 is difficult for industry to utilize. Since EPA intends to maintain and also enhance the off-cycle credit program for 2017-2025, it would be helpful to strengthen the overall program by making it available for the entire 2012-2025 period. [EPA-HQ-OAR-2010-0799-9551-A2, p. 6]

• The off-cycle program should be made available for the entire 2012-2025 period. [EPA-HQ-OAR-2010-0799-9551-A2, p. 8]

Response:

There is broad support in the comments submitted by manufacturers to allow the use of the pre-defined list in MYs 2012-2016. In response to these comments, EPA is allowing manufacturers to use the pre-defined list beginning in MY 2014. EPA's full response and discussion of the topic of using the pre-defined list prior to MY 2017 is provided in Section III.C.5.b.i.

7.4. Comments Regarding Credit Cap and Sales Thresholds Proposed for Pre-Approved List

Organization: Alliance of Automobile Manufacturers

The proposed fleet penetration requirements and credit cap could slow new technology implementation and should therefore be removed. Throughout the NPRM, the agencies suggest that an automaker be required to apply advanced technologies to a minimum percentage of its fleet before receiving any level of credit. That would be the case even when the addition of an advanced technology to a single vehicle results in measurable, real-world GHG emission reductions. We propose that all actions be recognized, as they historically have been, on a per-vehicle-so-equipped basis. This is an equitable and efficient approach, under which every vehicle built with the required technology for our customers receives credit. The prerequisite of specific penetration rates and imposition of a credit cap are economically inefficient and inconsistent with the goals of the rulemaking and may well have the unintended consequence of delaying the introduction of these technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.4]

However, the 10% minimum penetration threshold and the credit cap are barriers to the success of this feature and could result in the level of credits being out of sync with the level of GHG reductions that is actually achieved. [EPA-HQ-OAR-2010-0799-9487-A1, p.10]

It is counterproductive and unfair to create a 10% sales threshold during the initial phase-in period before some technologies can begin earning off-cycle credits. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

It is counterproductive to cap off-cycle credit attainment at 10 grams of carbon dioxide (gCO_2)/mile. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

The proposed fleet penetration requirements and credit cap could slow new technology implementation and should therefore be removed. [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

While the Alliance strongly supports the concept of a pre-defined list, two proposed limitations -- the 10% minimum penetration rate and the 10 g/mi cap -- will constrain its ability to incentivize technology application. The public policy goal of maximizing early introduction of these technologies is at odds with both of these limitations and the NPRM fails to provide a compelling justification for either restriction. [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

Further, the 10% threshold and 10 g/mi cap add an element of planning uncertainty that discourages use of the off-cycle program. The threshold also unfairly withholds credit for actual, real-world emission reductions that are achieved in the early stages of technology roll-out, before a 10% penetration can be achieved. [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

New, innovative technologies are customarily initially introduced at low volumes in order to demonstrate the benefits, reduce costs and work through technology problems before the technology is rolled out in larger volumes. To minimize warranty concerns and expense, automakers always try to phase-in new technology at a measured pace across their fleets (often during the course of major vehicle redesigns). Requiring large step changes to get widespread penetration – i.e., above a 10% penetration - is unlikely even with these off-cycle incentives. [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

Requiring a minimum penetration rate would discourage companies from offering a new technology on a limited basis to test the technology and gauge consumer acceptance before launching it more broadly. [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

The 10% minimum penetration threshold – or any other minimum penetration rate − may also have the unintended consequence of delaying investment in some technologies, at least until they can be applied to higher-volume models. Similarly, the 10 g/mi cap on credits would discourage maximum adoption of the pre-defined off-cycle technologies. Manufacturers would have less incentive to introduce technologies that would take them beyond the cap, leaving untapped GHG emissions reductions on the table. We think it would be productive to have further dialogue with the agencies regarding these issues. [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

Organization: American Honda Motor Co., Inc.

Minimum Fleet Percentages. EPA requested comment on applying a minimum threshold of 10 percent for several of the listed technologies, and the proposed treatment of HEV/PHEV/EV specific technologies and exhaust heat recovery (see Table III-17). Honda believes that the minimum threshold concept is unnecessarily restrictive. New, expensive technologies often are applied first on more expensive, lower volume models. This process has the salutary affect of lowering a manufacturer's risk. Consumer feedback on lower volume cars can provide: a) important consumer feedback, and b) production experience prior to much higher volumes which can help lower costs. Additionally, the "minimum fleet percentages" can have the unintended consequence of slowing the introduction of new technologies into the market. Honda currently has about sixteen models in our U.S. line-up, only three of which account for 10% or more of our sales in a given year. If an off-cycle credit technology is ready for market introduction at a time when it is not convenient to add it to one of the three models that exceed 10% of sales, there would be no credit allowed for adding it to any one of the other thirteen models that Honda sells in the U.S. The fact that the credits are weighted to U.S. sales means that there is no windfall for an automaker who only manages to apply one of these technologies to less than 10% of its sales. We believe that EPA is unnecessarily complicating and constraining the introduction of off-cycle credit technologies. [EPA-HQ-OAR-2010-0799-9489-A1, pp. 5-6]

Organization: Association of Global Automakers, Inc. (Global Automakers)

(2) Cap on off-cycle credits. EPA proposes several caps on off-cycle credits. Under section 86.1866(d)(1)(i)(B), EPA establishes maximum allowed credits for thermal control technologies and advanced glazing. A cap on menu credits of 10 grams per mile is also established (paragraph (d)(1)(ii)). Manufacturers may exceed the 10 gram cap by demonstrating the benefits using 5-cycle testing or analysis. See preamble page 75023. However, since EPA characterizes the menu credits as being based on conservative estimates of benefits, we see no reason to require testing when the menu values exceed the 10 gram limit. [EPA-HQ-OAR-2010-0799-9466-A1, p. 6]

The basis for these maximum credits is not clear. EPA should either provide an explanation for the need for these caps or eliminate them. [EPA-HQ-OAR-2010-0799-9466-A1, p. 6]

(5) Minimum market penetration to qualify for credit. EPA proposes minimum market penetration rates of 10 percent of the manufacturer's combined car-truck fleet for most of the off-cycle menu technologies, in order to qualify for credits. The minimum penetration rate creates an unnecessary impediment to the introduction of new technologies. The off-cycle technologies may be relatively new items, and consumers may not be familiar with these items. Implementation of these technologies at low levels may, if successful, lead to substantial benefits in the future, and manufacturers should be encouraged to pursue such technologies. A smaller penetration rate would create a correspondingly smaller credit, so we see no problem being created at lower penetration levels. EPA has failed to demonstrate a clear need for the minimum penetration restriction. [EPA-HQ-OAR-2010-0799-9466-A1, p. 7]

Organization: Borg Warner, Inc.

However, we also believe there should not be a double standard of requiring a 10% market penetration threshold for non hybrid-based technologies and no market penetration requirement for hybrid-based technologies in order to receive the off-cycle credit. There are technologies that are much less proven than hybrids and this threshold could unnecessarily complicate and discourage the introduction of new, higher risk, technologies. Credit would only be given for those vehicles with the technology, so a lower penetration rate has no artificial benefit.[EPA-HQ-OAR-2010-0799-9320-A1, p. 2]

Organization: Chrysler Group LLC

Oppose minimum penetration rates for all technologies and the 10 g/mi maximum cap for using the credit table as unnecessary restrictions; [EPA-HQ-OAR-2010-0799-9495-A1, p. 9]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 54-55.]

And, finally, there are references to minimum penetration levels in various aspects of the proposed rule. These thresholds are unnecessary in our opinion and serve as potential disincentives to invest in new technologies. We propose that all actions be recognized as they had historically been on a per-vehicle-so-equipped basis. This is an equitable approach where every vehicle built with the required technology for our customers is acknowledged. If a minimum penetration rate is required, a manufacturer may be discouraged from pursuing innovative technologies with uncertain acceptance and possibly no credit or payback.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 61-62.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 26-27.]

And finally, there are references to minimum penetration levels in various aspects of the proposed rule. These thresholds are unnecessary and will serve as potential disincentives to investing in new technologies. We propose that all actions be recognized, as they have been historically, on a per-vehicle-so-equipped basis. This is an equitable approach where every vehicle built with the required technology for our customers is acknowledged.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 62.]

If a minimum penetration rate is required, the manufacturer will be discouraged from pursuing innovative technologies with uncertain acceptance and possibly no credit or pay backs.

Organization: EcoMotors International, Inc.

Except for technologies specific to HEVs/PHEVs/EVs (e.g., solar roof panels) and exhaust heat recovery, EPA is proposing to require minimum penetration rates for the pre-approved off-cycle technologies - 10% of a manufacturer's combined car and light truck production. Again, EcoMotors encourages the agencies to remove the market penetration requirements established for the credits, to better reflect historic market penetration issues facing new technologies. As discussed above, new technologies typically take years to prove themselves and attain significant market penetration. Thus, 10% is likely too high a threshold for these technologies during the time period in question. [EPA-HQ-OAR-2010-0799-9594-A2, p. 13]

However, EcoMotors encourages the agencies to remove the market penetration requirements established for some of the off-cycle credits in order to better reflect historic market penetration issues facing new technologies. [EPA-HQ-OAR-2010-0799-9594-A2, p. 13]

Organization: Ferrari

It is also necessary to eliminate the minimum market penetration requirement for such technologies. If a vehicle is fitted with one or more of such technologies it can reduce the GHG emissions, and therefore it make sense to account that, even if only a small percentage of the manufacturer fleet is equipped. [EPA-HQ-OAR-2010-0799-9535-A2, p.14]

Organization: Ford Motor Company

Ford is not in favor of the proposed minimum penetration thresholds that have been proposed for the menu technologies. As new technologies are developed, they are often introduced on certain models or trim levels, as opposed to making them widely available across the entire fleet. The gradual introduction of new technologies reflect product cycle plan cadence, the need to gain in-use experience and familiarity with a new technology, and customer acceptance and/or interest in a new feature or option. Generally, we anticipate that the technologies will become more widespread over time. However, requiring a minimum sales threshold does not incentivize the introduction of these technologies, which typically require extensive development at significant cost. Instead, manufacturers may choose not to implement new technologies, or to delay introduction based on the fact that they cannot know with certainty if they will be able to meet the proposed penetration rates. In fact, we find ourselves aligned with the agencies when they state that "…for most of these technologies the agencies have no data on what the rates of penetration of these technologies would be during the rule timeframe" (76 Fed. Reg. 74941). The business cases for some of these new technologies will be based on the ability to achieve expected credit amounts. If the credit is contingent upon a volume threshold, which in turn is contingent upon marketplace factors beyond our control, manufacturers may find it difficult to justify the incorporation of the technology. Ford therefore recommends that the agencies award credits on a per-vehicle-so-equipped basis, or alternatively consider some flexibility in the minimum penetration rates, such as a phase-in over time. We would like the opportunity to explore this issue further with the agencies in the future. [EPA-HQ-OAR-2010-0799-9463-A1, p. 17]

For similar reasons, Ford also does not support the proposed 10 g/mile fleet-based cap on credits earned from using technologies from the pre-approved menu as it may discourage manufacturers from maximum adoption of the pre-defined technologies. [EPA-HQ-OAR-2010-0799-9463-A1, p. 17]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 35-36.]

In order to pave the way for such technologies, manufacturers must have confidence that their efforts and investment will be evaluated fairly and given appropriate credit.

We also strongly encourage that the agencies to reconsider the production volume thresholds that have been established in order to reflect new technology introductions in our compliance strategy.

Setting high thresholds, which are entirely dependent on consumer acceptance, may actually serve a hindrance to the investment of these new technologies.

Organization: Hyundai America Technical Center

3) Market Penetration Requirement: EPA has proposed that credits for most off-cycle menu technologies will only be available if an automaker achieves a minimum market penetration rate of 10% of its combined fleet. Hyundai believes that if the agency wants to encourage new technology, such a hurdle should not be included. EPA notes that the 10% threshold does not apply to hybrids or electric vehicles because EPA does not want to impede the introduction of these technologies. The same should hold true for off-cycle technologies. Often times, off-cycle technologies are only introduced in limited production initially until they are proven in the marketplace. Yet, there are still benefits available even if a technology is not widely adopted. We ask that EPA encourage the introduction of innovative and efficient technologies by eliminating minimum penetration levels. [EPA-HQ-OAR-2010-0799-9547-A1, p.5]

EPA plans to implement a 10 gram cap on the menu credits for off-cycle technologies because they are based on limited data. However, EPA notes that these credits are conservative and Hyundai agrees. For this reason, and because it is possible to exceed 10 grams using the menu technologies, we do not believe a cap is necessary and urge the agency to remove it. The industry should receive credits for all applications that provide real world benefits without requiring additional testing. [EPA-HQ-OAR-2010-0799-9547-A1, p.5]

[This comment was also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 22.]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 172-174.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 23.]

We recommend also that the agencies eliminate the ten-gram cap on the menu technology.

EPA planned the cap because the menu technology credits are based on limited data. However, Hyundai agrees with the agency that the credits offered are conservative and thus a cap is not necessary.

Organization: International Council on Clean Transportation (ICCT)

Because some uncertainty is inherent even in a well-designed process the ICCT also supports the proposed 10 g/mile cap. ICCT's comments on specific off-cycle credits below are designed to make the off-cycle credit system as accurate as possible and to maximize the overall benefits of the rule. The NPRM and draft TSD show that some of the technologies meet ICCT's recommended criteria for off-cycle credits, such as some of the proposed AC system credits, while other proposed off-cycle credits do not. We note that excluding the later category will not affect the very favorable benefit-cost ratio for this rule because the draft TSD did not consider these technologies in that analysis. [EPA-HQ-OAR-2010-0799-9512-A1, p. 37]

Organization: Mazda North American Operations

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 64.]

While we strongly support the concept of a predefined list of off-cycle technologies, we urge the agencies to eliminate the proposed 10 percent minimum penetration rate. Requiring a minimum penetration rate would discourage companies from offering a new technology on a limited basis to test the technology and gauge consumer acceptance before launching it more broadly.

Moreover, new technologies are typically added when a model is redesigned or updated. To give a specific example, adding one of the off-cycle technologies on the predefined list to either the Mazda2, Mazda5 or the Miata models would result in no credit because they each account for less than 10 percent of our fleet. The 10 percent minimum penetration threshold or any other minimum penetration rate may well have the unintended consequence of encouraging manufacturers to postpone technology application until a model that accounts for the acquired percentage is redesigned rather than installing it earlier on a lower volume model.

Organization: Mercedes-Benz USA, LLC

The off-cycle credits are necessary to continue to provide an incentive for these technologies to assure their continued implementation. Incorporating these technologies into vehicles with lower price points and smaller volumes remains challenging from a cost perspective, and the ability to do so may require longer lead times before certain technologies proliferate through the fleets. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-2]

The agencies should gain the maximum benefit from off-cycle technologies by applying the credits on a vehicle basis, rather than requiring threshold penetrations before the credits can be applied. A threshold requirement deters incremental investment, especially on lower volume model lines, and may detract from overall, real world CO_2 emissions reductions. Manufacturers should be recognized for applying off-cycle technologies in all vehicles. Similarly, since off-cycle credits must meet demonstrated performance criteria linking them to real world CO_2 reductions, imposing caps on the off-cycle credits would be inconsistent with the real world benefits and a detraction from the incentive that the agencies are intending to provide. Accordingly, DAG urges the agencies to apply off-cycle credits on a per vehicle basis without threshold penetration rates and without artificial caps. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-2]

Organization: Motor & Equipment Manufacturers Association (MEMA)

However, the current cap on credits is ultimately limiting. Removing the cap would reward the full lot of vehicles/technologies that achieve or exceed the National Program goals of reduced emissions and improved fuel consumption. Thus, MEMA urges the agencies to remove the cap on credits. [EPA-HQ-OAR-2010-0799-9478-A1, p.5]

First, regarding the off-cycle technologies' credits, MEMA believes the agencies' minimum penetration requirement of 10 percent of manufacturer's overall combined car and light truck production (with the HEV, PHEV and EV exceptions) is not only a significant hurdle for OEMs to meet, but also an undue influence of the market pushing the "preferred vehicle technologies" that we discussed earlier in our comments. Therefore, MEMA requests that the penetration rates for off-cycle technologies should be eliminated entirely, so that the marketplace can determine "winners and losers." [EPA-HQ-OAR-2010-0799-9478-A1, p.7]

Penetration rate requirements and caps on credits should be eliminated. [EPA-HQ-OAR-2010-0799-9478-A1, p.13]

Organization: Natural Resources Defense Council (NRDC)

While NRDC strongly supports the use of a cap per manufacturer for off-cycle credits, NRDC believes it is critical that EPA fully evaluate the adequacy of the 10 g/mi cap level, given the uncertainties in real, verifiable emissions reduction. EPA should adopt a lower cap if necessary. [EPA-HQ-OAR-2010-0799-9472-A2, p. 14]

Organization: Porsche Cars North America, Inc. (PCNA)

• Imposing an arbitrary 10 grams/mile cap for total off-cycle credit has no basis in real world accounting, and is counterproductive to innovation. The Agencies should encourage maximum adoption of all GHG improvements by providing unlimited additive credits. [EPA-HQ-OAR-2010-0799-9264-A1, p. 5]

• It is counterproductive and unjust to impose a 10% sales threshold before some technologies can earn off-cycle credits. Every gram of GHG improvement is just as valuable as any other. In addition, gradual introduction of new technologies is often necessary, and should not be penalized. Sensible sales weighting would provide more reasonable credit accounting. [EPA-HQ-OAR-2010-0799-9264-A1, p. 5]

However, there is no engineering justification for setting arbitrary limits and thresholds for credit availability. To be a meaningful feature of the program, the level of off-cycle credit must be in sync with the level of actual GHG reductions. Worse, such limits and thresholds are potentially a perverse disincentive to introduce valuable innovations or to maximize penetration of known technologies. Ironically, it is likely that such disincentives will thus unnecessarily increase actual GHG emissions. [EPA-HQ-OAR-2010-0799-9264-A1, p. 5]

Organization: Toyota Motor North America

Off-Cycle Credits: Pre-Determined Credit List (10 Percent Sales Volume Threshold) [EPA-HQ-OAR-2010-0799-9586-A1, p.11]

EPA's intent is for the 10 percent minimum sales threshold is to encourage companies to more rapidly adopt off-cycle technologies for larger volume vehicle models and bring these technologies into the mainstream. Toyota opposes a minimum sales volume threshold for generating off-cycle credits and we believe a threshold will be counterproductive to achieving EPA's goal. [EPA-HQ-OAR-2010-0799-9586-A1, p.11]

If the agencies expand the list of technologies on the pre-determined list in the future and/or as more performance data on off-cycle technologies becomes available, Toyota requests that the 10 g/mi cap be revisited. This could be done as part of the mid-term review. [EPA-HQ-OAR-2010-0799-9586-A1, p.11]

First, GHG benefits are realized for each and every vehicle purchased with a given off-cycle technology. The accumulation of benefits does not somehow begin when an arbitrary sales threshold is met. As such, manufacturers should earn credits for each and every vehicle sold with a given off-cycle technology. Second, an arbitrary sales threshold does not recognize the potential for high deployment rates on low sales volume vehicles. As proposed, a manufacturer could introduce an off-cycle technology over an entire model or configuration, but not be eligible for credits if that model or configuration does not make up at least 10 percent of the manufacturer's fleet. Third, absent market demand, the arbitrary 10 percent sales threshold will do nothing to speed deployment due to significant risks to the manufacturer. Despite the motivation for a rapid return on investment, new technologies typically enter the market at a slow pace. It is common practice for new automotive technologies to be introduced on a single model, or even single configuration within a model. This low production trial period allows manufacturers to monitor technology performance and reliability, gauge consumer acceptance, and make necessary adjustments before expanding the technology to other models. Technology is typically integrated into those other models during a redesign, which typically occurs every five to seven years. Achieving a 10 percent sales threshold could literally take years to achieve depending on the technology. Appendix I shows actual penetration rates for various automotive technologies, and while consumer uptake rates vary, achieving a 10 percent market penetration can take a decade or more for certain technologies. Finally, the proposed sales threshold could actually create a disincentive for manufacturers to deploy off-cycle technologies. The risk of forcing off-cycle technology on consumers beyond natural market demand and then falling short of the 10 percent threshold provides a substantial disincentive for even trying, unless the manufacturer is extremely confident the threshold can be reached. [EPA-HQ-OAR-2010-0799-9586-A1, pp.11-12]

Organization: Volkswagen Group of America

Further, the max fleet improvement, commonly referred to as the 'credit cap', of 10g/mi should be increased on a regular basis as new technologies are added to the list. The will further improve the value of this flexibility and provided added planning certainty as newer technologies are added to the list. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 32-33]

Volkswagen supports the comments of the Alliance that the penetration threshold should be removed and that credits are awarded on a per-vehicle equipped basis. We echo the concerns raised by the Alliance regarding fleet phase-in trends for new technologies and agree that the high threshold may inadvertently create a disincentive to delay new technology. [EPA-HQ-OAR-2010-0799-9569-A1, p. 33]

Organization: Volvo Car Corporation (VCC)

In the NPRM, the proposed penetration requirements of 10% risk hobbling the entire proposal and the program may fail to work in practice. The 10% sales threshold may limit a smaller manufacturer from introducing new innovative, but uncertain, technology. VCC supports the approach taken in Europe of one car one credit. However, any threshold should start at 0% in order to expedite advanced technologies. [EPA-HQ-OAR-2010-0799-9551-A2, p. 6]

• It is counterproductive to create a 10% sales threshold during the initial phase-in period. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

• The 10% sales threshold may limit the small manufacturer from introducing new technology due to the uncertainty around the possible credit situation. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

Response:

10 Percent Penetration Threshold

EPA received many adverse comments from manufacturers regarding the proposed 10% production threshold for the pre-defined list and no comments in favor of the proposal. As discussed in section III.C.5.b.i of the preamble, EPA understands and agrees with the concerns raised by commenters that the proposed requirement could well be counterproductive, and is therefore finalizing the off-cycle credits program without the 10% threshold requirement.

10 g/mile Credit Cap

EPA received several comments from manufacturers recommending that EPA eliminate the 10 g/mile fleetwide cap on credits that could be generated using the predefined list. EPA also received comments from ICCT and NRDC supporting the proposed 10 g/mile cap. Further, some commenters commented that the pre-defined list should be revisited and updated on regular intervals. EPA is retaining the 10 g/mile cap as proposed. The full discussion on comments is provided in section III.C.5.b.i and II.F. of the preamble. As there explained, the cap is only on the amount of default credits under the menu. Manufacturers remain free to provide data to demonstrate on a case-specific basis through the 5-cycle testing or public review pathways that additional credit values are warranted for their technology, even though that technology is included on the menu.

7.5. Step-by-Step Process and Test Procedures

Organizations Included in this Section

Alliance of Automobile Manufacturers
Association of Global Automakers, Inc. (Global Automakers)
Ford Motor Company
Hyundai America Technical Center
Motor & Equipment Manufacturers Association (MEMA)
Toyota Motor North America
United Automobile Workers (UAW)
Volvo Car Corporation (VCC)

Organization: Alliance of Automobile Manufacturers

Regarding the EPA approval process for technologies not included in the pre-defined list, the Alliance welcomes the efforts to provide a step-by-step process and 60-day timeline for approval of new technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.10]

The process changes outlined below would further streamline the program and provide more certainty to manufacturers irrespective of which approval process is used. [EPA-HQ-OAR-2010-0799-9487-A1, p.10]

Process for Qualifying Off-Cycle Credits from New Technologies [EPA-HQ-OAR-2010-0799-9487-A1, p.42]

EPA originally adopted this program for model years MYs 2012-2016 as an optional credit opportunity for new and innovative technologies that reduce vehicle CO_2 emissions, but for which CO_2 reduction benefits are not significantly captured over the 2-cycle test procedure. The agency adopted the off-cycle credit option to provide an incentive to accelerate the introduction of these types of technologies that result in concrete reductions in CO_2 emissions. However well-meaning this program, its actual use has been undermined by uncertainties over which technologies would be deemed eligible, how much credit would be provided, and the risks and burdens on manufacturers inherent in a cumbersome case-by-case approval process. [EPA-HQ-OAR-2010-0799-9487-A1, p.42]

The NPRM would require three complete sets of 5-cycle tests (with technology “on” and technology “off”) for relatively large impacts of over 3% GHG reduction. For technologies with less than a 3% impact, manufacturers would be required to run five complete 5-cycle tests (with technology “on” and technology “off”), plus complete an analysis using EPA’s Vehicle Simulation Tool. It can be expected that almost all of the off-cycle technologies will individually yield emission reductions of less than 3%, making mandatory the completion of five full test series and the simulation analysis. [EPA-HQ-OAR-2010-0799-9487-A1, pp.42-43]

While an extensive off-cycle credit menu will result in the largest portion of off-cycle emission reductions, the regulatory agencies also need to have an open system for submitting and evaluating new off-cycle technologies, since an ongoing flow of new technologies can be expected. In this regard, simplicity and openness should be the goals, since the program benefits from bringing in new approaches that can be developed into future credit menu items for widespread implementation. As currently proposed, the provisions for off-cycle credit applications require very extensive vehicle testing and modeling. These proposed requirements lean towards a very high level of accuracy and proof, but would also serve to hinder the flow of new technologies by setting such a high administrative burden. [EPA-HQ-OAR-2010-0799-9487-A1, p.43]

Our expectation is that the vast majority of credits would be pursued through the menu, and that the process for alternative individual applications will represent a small amount of total credit. It may be counterproductive to require a high test and analysis burden, in return for small credits, since manufacturers may choose simply not to undertake such unattractive projects. This may discourage efforts which, if undertaken, could eventually grow beyond the initial low-volume stage into widespread usage, with corresponding broad emission benefits. This was, after all, the original goal of the MY 2012-2016 off-cycle program. [EPA-HQ-OAR-2010-0799-9487-A1, p.43]

The Alliance proposes some simplifications to these provisions. Based on our members’ experiences over the past year evaluating technologies for off-cycle credit in the MY 2012-2016 timeframe, we would expect that the credit menu would be used almost universally to gain credit for any technologies that are listed on the menu, rather than testing and quantifying slightly larger credits for each model under this section of the regulation. The overwhelming majority of credits would be expected to flow from the menu, and the relatively small amount of credits arising through this alternative section of the regulation does not warrant the proposed very high level of accuracy and documentation through repeat testing and modeling. [EPA-HQ-OAR-2010-0799-9487-A1, p.43]

In order to encourage development of new technologies under this section of the regulation, the Alliance recommends that only three five-cycle tests be required for all applications, with no requirement to use the EPA Vehicle Simulation Tool. This retains a high level of accuracy, but with lower administrative obstacles. We expect the mechanism for energy savings to be easily explained and, if documented through actual vehicle testing, do not see the need to also conduct simulations. Although we have no experience with this particular tool, we anticipate that any single simulation tool may not be compatible or easily adaptable to analyze specific, unusual technologies, especially technologies which address the proliferation of very diverse sources of off-cycle energy losses. [EPA-HQ-OAR-2010-0799-9487-A1, p.43]

We also recommend that EPA retain discretion to approve applications which forego some of the 5-cycle tests if such testing is deemed unnecessary. In many cases, technologies would reasonably be expected to have no impact on certain test cycles. For example, cold weather technologies might be expected to have no impact on the SCO3 cycle. In these cases, it would be wasteful to require multiple tests for cycles which do not impact the credits. [EPA-HQ-OAR-2010-0799-9487-A1, p.44]

Organization: Association of Global Automakers, Inc. (Global Automakers)

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 51.]

Second, the agencies should carefully consider the relationship between the creation of incentives under the new standards and the development of alternative test procedures to assess the incentivized technologies. Global Automakers strongly supports incentivizing technologies whose potential benefits are not fully measured under the 1975 CAFE test procedure. Air conditioning efficiency, off-cycle, and advanced technology incentives are justified based on their potential long term, real world benefits. Such incentives will typically take the form of compliance credits that are assessed using alternative test procedures. In developing incentives for the final rule, the agencies need to carefully consider how to reconcile these incentives with the testing procedures required by law. [EPA-HQ-OAR-2010-0799-9466-A1, p.2]

[[This comment can also be found in Outline Heading 3.2.1.]]

Organization: Ford Motor Company

Beyond the pre-defined list of off-cycle methods, Ford supports the allowance of alternative pathways for achieving off-cycle technology benefits and the efforts the agencies have taken to attempt to streamline the process, as compared to the previous method finalized in the 2012-2016 MY rule. We agree with the Alliance recommendations on how to further refine that process and avoid unnecessary test burden. Related specifically to the technology demonstration pathway using the EPA 5-cycle methodology, we believe that the proposal to demonstrate at least a three percent off-cycle benefit in order to claim credits amounts under 40 CFR § 86.1866-12(d)(2)(iii) is too high. EPA suggests a 3% threshold based upon historical test speed vs. time tolerance data for chassis dynamometer testing. Given the +/- 1.5% drive cycle energy tolerances outlined in 40 CFR § 1066.425(c)(1) and described in detail in SAE J2951, future test to test variability will be substantially reduced. As such, a tolerance of 1.5% is recommended in lieu of the proposed 3%. [EPA-HQ-OAR-2010-0799-9463-A1, p. 17]

Organization: Hyundai America Technical Center

4) Durability Demonstration: EPA states that 'manufacturers may demonstrate in-use emissions durability at the time of certification by submitting an engineering analysis. This demonstration may also include component durability testing or whole vehicle aging if the manufacturer has such data. The demonstration would be subject to EPA approval prior to credits being awarded. Since credits are not actually generated until the final CAFE and GHG reports after the end of the model year, Hyundai requests that EPA provide manufacturers additional time to generate the durability data, if necessary (e.g. six months after certification). [EPA-HQ-OAR-2010-0799-9547-A1, pp.5-6]

5) Public Notice of New Technologies: The agency proposes that credits for new off-cycle technologies benefit from a public comment period. Hyundai supports a process to provide transparency for the off-cycle credit approval process. However, it is unclear from the proposal language whether the approval process will be completed and credits will be available in the same year the automaker provides data and requests approval for new off-cycle technologies. Hyundai recommends that the agencies create a standardized and streamlined process to ensure that credits are available in the year requested. [EPA-HQ-OAR-2010-0799-9547-A1, p.6]

Organization: Motor & Equipment Manufacturers Association (MEMA)

Lastly, in cases where the technologies are not yet fully developed, but are expected to be in the future, MEMA agrees that the step-by-step process the agencies outline in the NPRM is an appropriate and transparent process. This way, future technologies can be reviewed, vetted and considered for approval in a straight-forward and timely process. MEMA believes this is another important component to the long-term success of the National Program, to allow for the inclusion of and credits for yet-to-be-seen evolutions in off-cycle technologies and related efficiency benefits. [EPA-HQ-OAR-2010-0799-9478-A1, p.7]

Organization: Toyota Motor North America

Third, EPA has proposed changes in §86.1866-12(d)(2) and (3) in order to streamline and clarify the demonstration process to promote greater manufacturer participation and encourage greater deployment of off-cycle technologies.[EPA-HQ-OAR-2010-0799-9586-A1, p.10]

Off-Cycle Credits: EPA 2012-2016 Model Year Regulations [EPA-HQ-OAR-2010-0799-9586-A1, p.10]

For the 2012-2016 model year GHG standards, EPA's regulations provide credits for technologies that reduce CO_2 in real world operation that are not well represented on the test procedure used to determine a vehicle's fuel economy or tailpipe GHG emissions. The 2012-2016 model year provisions are limited to new and innovative technologies, and manufacturers can demonstrate the benefits of such technologies using a two-tiered process. First, a manufacturer can demonstrate benefits through EPA's 5-cycle method used for determining fuel economy label values. If the 5-cycle method is inadequate for demonstrating benefits, the manufacturer can work with EPA to develop a test plan customized for a specific technology. EPA approval of both the test plan and demonstrated off-cycle benefits are made on a case-by-case basis. In implementing the current off-cycle provisions, EPA has discovered that manufacturers have been discouraged from applying for off-cycle credits because of the uncertainty and potential testing burden associated with the current provisions. [EPA-HQ-OAR-2010-0799-9586-A1, p.10]

Revised 5-Cycle Demonstration Program [EPA-HQ-OAR-2010-0799-9586-A1, p.12]

For credits not generated by the pre-determined list, but rather through 5-cycle testing, EPA has proposed measures to more precisely define both the manufacturer's testing requirements and EPA's approval. The proposal involves up to three iterations of demonstration. [EPA-HQ-OAR-2010-0799-9586-A1, p.12]

First, a manufacturer must conduct three complete sets of 5-cycle tests, once with the technology 'off' and once with the technology 'on'. If that testing shows less than three percent improvement, two additional 5-cycle tests (with the technology 'on') are required. If at least a 3 percent improvement still cannot be demonstrated, EPA's Vehicle Simulation Tool is used to determine the technology's benefits. We have several concerns with this approach. Toyota anticipates that most off-cycle technologies will individually yield emission reductions of less than three percent, as none of the technologies on the pre-determined list alone would meet the three percent criteria. This means the full set of five-cycle tests and the simulation analysis would essentially become the de facto procedure. This full level of demonstration would require over 40 tests per vehicle model. Bundling technologies could reduce test burden, but we assume those technologies would then need to be bundled for sale, which could be prohibitively expensive. [EPA-HQ-OAR-2010-0799-9586-A1, p.12]

Toyota appreciates that EPA has made the 5-cycle demonstration procedure clearer. However, in doing so, the procedure has become is too burdensome to be practical. We request the agency consider alternatives to reduce the burden. For example, the second iteration of 5-cycle testing seems unlikely to yield significantly different results than the initial testing and should be eliminated. We also request EPA consider dropping components of the 5-cycle test if good engineering practice suggests that test element is not a factor in demonstrating the benefits for a given technology. For example, if it is clear that an active warm up technology does not affect greenhouse gas emissions or fuel economy performance over the US06, the US06 should not be required. Finally, EPA has not made the simulation tool available; therefore Toyota has no basis upon which to comment on this method of verification. If simulation ultimately proves a viable method for quantifying off-cycle credits, EPA should allow it to be used in lieu of 5-cycle testing. [EPA-HQ-OAR-2010-0799-9586-A1, p.13]

Demonstration Not Based on 5-Cycle Testing or Simulation [EPA-HQ-OAR-2010-0799-9586-A1, p.13]

EPA proposes to continue allowing manufacturers to request demonstration of off-cycle credit levels using methods other than 5-cycle testing or EPA's simulation method. While the proposal to establish an agency decision deadline and agency report provides more transparency in EPA's decision making process, what constitutes an acceptable testing program still remains unclear in the current proposal. The inherent uncertainty in manufacturer-proposed demonstration makes it less appealing to Toyota and reiterates the need for a more inclusive pre-determined technology list that is retroactive to the 20122016 model year standards. [EPA-HQ-OAR-2010-0799-9586-A1, p.13]

Organization: United Automobile Workers (UAW)

We also applaud the EPA's recognition that other technologies not listed could prove beneficial in the future, or that the actual reductions achieved from the listed technologies could exceed EPA's original assessment of them, and proposing that manufacturers may gain additional credits by supplying credible and verifiable data about improvements from any particular technology. [EPA-HQ-OAR-2010-0799-9563-A2, p.3]

Organization: Volvo Car Corporation (VCC)

VCC supports simplifying the verification requirements for off-cycle credits. [EPA-HQ-OAR-2010-0799-9551-A2, p. 6]

The proposal is requiring three complete sets of 5-cycle tests, with and without the technology for CO_2 impacts of over 3% GHG reduction. For technologies with less than a 3% impact, manufacturers are required to run five complete 5-cycle tests with and without the technology, plus complete an analysis using EPA's Vehicle Simulation Tool. The requirement of 3% is a large number for a CO_2 effect and most technologies will be around 0.5-1.5 %. This will mean that extensive testing will be necessary in order to request off-cycle credits. This extensive testing would impact smaller manufacturers disproportionately since the cost per vehicle would be higher. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

To encourage development, the EPA-simulation tool should not be the only permitted means of presenting simulations; other simulation for applicable pre-confirming data should be permitted if they are reasonably accurate. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

To confirm the application, either the EPA Vehicle Simulation Tool or only three five-cycle tests should be required. This would ease the burdens on manufacturers by keeping testing to a minimum, while maintaining accuracy at a good level. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

• The procedures for earning off-cycle credits need to be kept simple. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

• Once a technology has been approved by an agency it should be applicable for all agencies - both EPA and CARB. [EPA-HQ-OAR-2010-0799-9551-A2, p. 7]

Response:

EPA received generally supportive comments regarding its proposal to adopt a streamlined step-by-step process for credits not based on the pre-defined list. EPA received comments that the 5-cycle testing requirements should not include additional testing or vehicle simulation beyond the initial three sets of tests. EPA also received comments that manufacturers should not be required to run test cycles where the off-cycle technology is known not to provide emissions reductions. EPA concurs with these comments. In response to the points raised by commenters, EPA will not make additional testing and vehicle simulations mandatory. Rather, EPA will have discretion to request additional testing in cases where the agency determines that the additional test would provide useful data in verifying credit levels. Further, EPA is not requiring manufacturers to use the EPA simulation tool, but EPA may use the simulation tool as a check to help verify the level of credits as part of the credit approval process. Also, EPA will allow manufacturers to avoid unnecessary testing by instead submitting an engineering analysis demonstrating that the technology has no effect (either positive or negative) on emissions for one or more of the 5-cycle tests. These comments and provisions are discussed further in preamble Section III.C.5.b.iii.

EPA received a mix of comments from manufacturers regarding the use of vehicle simulations. The Alliance and Toyota opposed incorporating the EPA Vehicle Simulation Tool into the 5-cycle approval process. Volvo supported the use of EPA's simulation tool (and others) and suggested that it should be allowed to be use in lieu of vehicle 5-cycle testing. As noted above, EPA is not requiring the use of the vehicle simulation tool but may use it to further confirm test results. At this point, EPA is also not prepared to accept vehicle simulation results from manufacturers in lieu of 5-cycle testing as the basis for credits not derived from the pre-defined list. EPA is taking a more conservative approach of requiring 5-cycle testing and using vehicle simulations as a tool to further confirm the appropriateness of the credit value. EPA notes that vehicle simulations may be part of the methodology for credits based on the public process (for credits not based on 5-cycle testing or the pre-defined list).

In response to Hyundai's concerns regarding the timing of data submittal, EPA is clarifying these provisions as discussed in preamble sections III.C.5.b.iv and Section III.C.5.b.v.

7.6. Comments Regarding Technology Eligibility Criteria

Organizations Included in this Section

Alliance of Automobile Manufacturers

Motor & Equipment Manufacturers Association (MEMA)
Toyota Motor North America

Organization: Alliance of Automobile Manufacturers

Finally, opportunities exist to streamline traffic flow, reduce congestion and reduce emissions through better driving. For example, there are technologies that provide the driver or the vehicle with information for improved routing, or that provide the driver or the vehicle with information for more efficient vehicle operation. GPS technology can play a role in improving both driver behavior and vehicle operation. The opportunities for improvements through these eco driving technologies are not sufficiently defined for the Alliance to propose specific credit definitions and criteria at this time, but the industry hopes that it can work with the agencies in the future to create off-cycle credits for these technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.11]

The minor proposed changes in terminology are directionally correct but do not alleviate the overwhelming need to streamline the process by incorporating the pre-defined technology list for MYs 2012-2016 as well as the later model years. [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

Organization: American Honda Motor Co., Inc.

Dealer-Installed Options. Furthermore, some off-cycle technologies can be installed at the dealership. Honda proposes that off-cycle credit technologies that are installed on a vehicle prior to its first retail sale, whether at the factory or at a dealership, can be included in the minimum percentage calculation and in an OEM’s credit calculation. For example, engine-block heaters are sold in cold-weather states as a dealer-installed option. Engine-block heaters keep engine oil warm, reducing friction and improving fuel economy and lowering CO_2. (Honda recognizes that an engine-block heater might not itself qualify for off-cycle credits, it is illustrative of market-specific, dealer-installed options that could increase marketability of the kinds of technologies EPA wants to endorse). [EPA-HQ-OAR-2010-0799-9489-A1, p. 6]

Organization: Association of Global Automakers, Inc. (Global Automakers).

(3) Credits for “integral” technologies. EPA proposes that technologies that are integral to the basic vehicle design, including engine transmission, mass reduction, passive aerodynamic design, and base tires, are ineligible for credits. See 76 FR 75024. In other words, the credits would only be available for “add-on” technologies. EPA imposes this restriction based on its belief that it would be difficult to establish the credit by making a clear comparison of the vehicle’s performance using baseline and advanced forms of the technology in question. In our view, the difficulty of making a credible demonstration of the benefits of an off-cycle technology should not be judged in advance of any data that might be developed by a manufacturer. It may well be that making a credible demonstration of benefits for some of these integral technologies will be difficult, but that is no reason to deny manufacturers the opportunity to make such a demonstration. If EPA finds such a demonstration to lack credibility, it would of course be able to deny the manufacturer’s credit request. [EPA-HQ-OAR-2010-0799-9466-A1, p. 6]

(4) Credits for technologies that are included in the agencies’ standard-setting analysis. EPA states in the preamble to the proposal (76 FR 75023) that technologies that are included in the agencies’ standard-setting analysis may not generate off-cycle credits (with the exception of active aerodynamic devices and engine stop-start systems). EPA states that allowing such credits for these technologies would amount to “double-counting” of benefits. However, there may emerge by 2025 advanced levels for current technologies that are capable of achieving greater

benefits than current systems. If a manufacturer can demonstrate that an advanced version of one of the technologies that is included in the standard-setting analysis can achieve greater benefits than projected by the agencies, and those benefits are not captured with the current test procedure, there is no justification for excluding these technologies from the off-cycle credit program. [EPA-HQ-OAR-2010-0799-9466-A1, p. 6]

Organization: BMW of North America, LLC

More specifically, we support EPA's proposal to delete the 'not significantly measureable over the 2-cycle test' and to delete the 'new, innovative, not widespread use' as criteria. These new approaches make the application for credits for off-cycle technologies more attractive and therefore can be seen as a driver for innovation. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 1]

Organization: Ferrari

Regarding off-cycle technologies, we agree with EPA to remove the criteria in the 2012- 2016 rule that off-cycle technologies must be “new, innovative, and not widespread” because these terms are imprecise and could create implementation issues and uncertainty in the program. [EPA-HQ-OAR-2010-0799-9535-A2, p.14]

Organization: Ford Motor Company

The three methods outlined in the NPRM to quantity real world fuel consumption benefits are helpful and we anticipate they will encourage invention and introduction of new fuel saving technologies. One important class of fuel saving technologies to consider are those that are impossible to turn-off or disable because they are highly integrated into the system. Examples of these technology could be advanced combustion concepts, cam-less engines, variable compression ratio engines, air/hydraulic micro hybrids/launch assist devices, advanced transmissions, new aftertreatment concepts and other yet to be invented concepts. The proposed methods may not adequately cover demonstration of these technologies. As such, we encourage the agencies to consider other alternatives, such as an optional pathway that would allow manufacturers to demonstrate the off-cycle benefit by simply comparing the 5-cycle results to the 2-cycle results with the new technology operating, or perhaps using other analytical methods. We look forward to working with the agencies to develop these methodologies. [EPA-HQ-OAR-2010-0799-9463-A1, p. 18]

Organization: Motor & Equipment Manufacturers Association (MEMA)

Also, we support the agencies’ decision to remove the criteria initiated under the MY2012-2016 program (“new, innovative, not widespread use”) for the reasons stated in the NPRM. MEMA further supports the option to make eligible for credit those technologies that may only register small reductions on the 2-cycle test, but have more significant (and verifiable) off-cycle gains. MEMA also supports the agencies’ decision not to sunset the availability of these credits during the 2017-2025 timeframe for all of the same reasons stated in the NPRM. Again, overall MEMA is supportive of the direction the agencies are taking with respect to off-cycle credits. There are some key issue areas, however, where either changes or clarifications are needed; these are discussed below. [EPA-HQ-OAR-2010-0799-9478-A1, p.7]

MEMA further proposes any technology resulting in significant, quantifiable benefit off-cycle – regardless of 2-cycle benefit – should receive credit reflecting the real-world benefit of such technology. There will very likely be future technologies – in addition to Stop/Start and Active Aerodynamics – that could result in both significant on-cycle and off-cycle benefits. MEMA believes that these dual-benefit technologies should not be precluded from consideration. For example, if any of the technologies that are considered in setting the standard (in other words, baseline technologies for the Program), there could come a time when an on-cycle technology may evolve and provide a significant off-cycle benefit. Under this scenario, would EPA preclude it from consideration under their step-by-step approval process to be added to the approved list of technologies? MEMA recognizes the agency's concern about potential 'double counting.' However, we would point out that since off-cycle credits are recognized in the rule – and particularly if they were expanded to include any technology that has both on- and off-cycle benefit – then the potential unintended consequence of pushing "preferred technologies" and "winners and losers" diminishes somewhat. [EPA-HQ-OAR-2010-0799-9478-A1, pp.8-9]

Organization: Toyota Motor North America

Off-Cycle Credits: New Innovative Technology Criterion [EPA-HQ-OAR-2010-0799-9586-A1, p.10]

Toyota supports the agencies' decision to drop the requirement that off-cycle technologies must be new, innovative, or not wide spread. We agree that this requirement is confusing and has no relevance for technologies that deliver real world benefits regardless of when they are implemented or how prevalent they are in the fleet. For the same reason, we support the agencies' intent to clarify that the eligibility of approved technologies and credits generated will not sunset in the future. [EPA-HQ-OAR-2010-0799-9586-A1, p.10]

Response:

Commenters were supportive of EPA's proposal to eliminate the "new, innovative, and not in widespread use" as a criteria for eligibility for off-cycle credits, and EPA is finalizing these changes as proposed. Comments regarding potential off-cycle credits for integral technologies or 2-cycle technologies considered in establishing the standards are discussed in section III.C.5.b.ii of the preamble. EPA continues to believe that it would not be appropriate to provide off-cycle credits for integral technologies or technologies projected to be used to meet the 2-cycle standards, with the exception of stop-start and active aerodynamics which are on the pre-defined list and whose two cycle benefits were considered in determining the stringency of the standards.

Honda suggests that credits should be available for technologies installed at the dealership prior to initial sale. In response, only original equipment may be approved and eligible for credits as off-cycle credits are available only to OEMs. The manufacturer is responsible for the emissions performance of the vehicle and also all of the tracking to ensure that credit reporting to EPA is accurate. The standards and other program requirements apply to manufacturers and do not apply to dealerships or other (aftermarket) parties. Installations that might occur under some type of contractual arrangement with dealerships prior to the sale of the vehicle would not be transparent to EPA (i.e., EPA would not be monitoring these activities). EPA should note that there are a large number of aftermarket technologies that have a deleterious effect on fuel economy and end up in higher GHG emissions. These might include, remote starters, lights, powerful stereo systems, rooftop luggage racks and other devices that increase weight, aerodynamic, rolling, friction, or electrical load. By this reasoning, EPA might then consider taking credits away from manufacturers, for vehicles that have such technologies added. Clearly this becomes impractical.

However, the manufacturer is solely responsible for the accurate reporting of credits in the end of model year credit report. The manufacturer would need to be able to demonstrate, upon request from EPA, that the credits they are claiming are based on technology installed on the vehicles. This would likely be a much more straightforward proposition for the manufacturer if the technology is installed during vehicle assembly. The burden of proof falls solely on the manufacturer and EPA would expect manufacturers to be able to provide a detailed accounting of the vehicles on which they are claiming credits so that EPA could verify the validity of the credits. Credits that are claimed by the manufacturer and then later found not to be supported by evidence or found to be invalid could lead to noncompliance and enforcement action against the manufacturer.

8. A/C, Off-Cycle, and “Game Changing” Technology Fuel Consumption Improvement Values in CAFE Program

CAFE Fuel Consumption Improvement Values for MAC Efficiency Improvements and Off-Cycle Technologies [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

In the GHG portion of the joint rulemaking, EPA is proposing to allow manufacturers to generate credits for improvements to MAC systems that reduce GHG emissions. EPA is also proposing to allow manufacturers to generate credits for implementing off-cycle technologies that result in real-world GHG reductions not fully accounted for under the existing test procedures. [EPA-HQ-OAR-2010-0799-9487-A1, p.12]

In the CAFE portion of the joint rulemaking, EPA, in coordination with NHTSA, is proposing to allow fuel consumption reductions (also called “fuel consumption improvement values”) equivalent to the GHG credits allowed by EPA. These would apply for the credit menus provided for MAC efficiency and the use of off-cycle technologies. The proposal makes it clear that in the CAFE program manufacturers would only get credit for improvements that lead to better real-world fuel economy; improvements that are aimed at other GHG reductions such as reducing or eliminating MAC refrigerant leakage are not tied to fuel economy and would not qualify for CAFE program incentives. The expected generation of these MAC credits is accounted for by both agencies in setting the level of the overall GHG and CAFE standards they propose, but the ability to generate off-cycle credits and fuel consumption reductions is not accounted for in the standards. The agencies seek comment on the proposals to allow manufacturers to estimate fuel consumption reductions from MAC improvements and off-cycle technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.13]

While the Alliance has some suggestions for modifying the details of the above-described proposals, we firmly believe that the proposals in general are both appropriate and necessary. As noted by the agencies in the preamble to the proposed rule, President Obama's Memorandum of May 21, 2010 requested that NHTSA and EPA work together to develop "...a coordinated national program under the [Clean Air Act] and the [Energy Independence and Security Act of 2007] to improve fuel efficiency and to reduce greenhouse gas emissions of passenger cars and light-duty trucks of model years 2017-2025.'9 As the President directed, and as all stakeholders recognize, a primary benefit of the single National Program approach is that it provides for harmonized EPA and NHTSA regulations so that manufacturers can build one fleet of vehicles that complies with both sets of rules. In keeping with that directive, it is important for EPA and NHTSA to include common provisions in both sets of rules to the maximum extent possible. [EPA-HQ-OAR-2010-0799-9487-A1, p.13]

The Alliance has already expressed its support for the inclusion of provisions allowing for MAC credits and off-cycle credits in the context of EPA's GHG rules, and we have explained why the inclusion of such provisions will further the goals of the program. In the interests of promoting harmonization, it only makes sense for the agencies to include comparable provisions in the CAFE rules. This applies to MAC and off-cycle improvements, as well as to the implementation of "game changing-technologies" in full-size pickup trucks and other credits. Failure to do so would only lead to increased disparities between the rules, giving rise to the possibility that manufacturers would need to undertake different actions to comply with the GHG rule on one hand, and the CAFE rule on the other. Of course, in developing these provisions, the agencies must be mindful of differences in the statutes underlying the two regulatory programs. Here, the agencies are being careful to ensure that the CAFE adjustments are limited to the demonstrated fuel economy benefits of the MAC and off-cycle improvements, which is entirely appropriate given the scope of the CAFE program. [EPA-HQ-OAR-2010-0799-9487-A1, p.13]

In light of the above, the Alliance believes that the agencies should proceed to include provisions accounting for the fuel economy benefits of MAC improvements and off-cycle technologies in the CAFE program, providing equivalent fuel consumption and CO_2 credit values toward both the GHG and CAFE programs. This step will help to further harmonize one of the many remaining differences between the two regulations. [EPA-HQ-OAR-2010-0799-9487-A1, p.14]

Organization: Arkema Inc.

The NPRM currently provides an opportunity for auto manufacturers to receive consumption improvement values for air conditioning efficiency and off-cycle technologies. [EPA-HQ-OAR-2010-0799-9468-A1, p.3]

Organization: Association of Global Automakers, Inc. (Global Automakers)

These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 51.]

We urge the agencies to consider two factors in developing compliance incentives under the GHG and CAFE standards. First, it is important that the agencies harmonize flexibility mechanisms between the GHG and CAFE programs to the maximum possible extent, consistent with the goals of the National Program. This principle of harmonization does not apply, however, to the measurement of GHG emissions that are not efficiency-related, such as air conditioning refrigerant leakage. [EPA-HQ-OAR-2010-0799-9466-A1, p.2]

Organization: EcoMotors International, Inc.

EPA is proposing CO_2 credits for manufacturers that hybridize a significant quantity of their full-size pickup trucks, and the agencies are also proposing that manufacturers be able to include 'fuel consumption improvement values' equivalent to EPA CO_2 credits in the CAFE program. Access to the incentives is conditioned on a minimum penetration of mild and strong hybrid electric vehicle (HEV) technologies in an OEM's full-size pickup truck fleet. [This comment can also be found in section 5 of this comment summary.] [EPA-HQ-OAR-2010-0799-9594-A2, p. 8]

Organization: Electric Drive Transportation Association

Third, EDTA opposes NHTSA's determination that it lacks authority to include a multiplier as part of its CAFE standards under EPCA and EISA. While these statutes do provide for certain incentives, they do not preclude NHTSA from establishing additional incentives, such as a multiplier. Adoption of a multiplier in NHTSA's rule would promote the fundamental policy of developing a harmonized national system in which EPA and NHTSA establish consistent regulatory requirements. [EPA-HQ-OAR-2010-0799-9449-A1, p. 2]

Organization: Environmental Defense Fund

C. Constraints on NHTSA's Authority

In contrast to EPA's expansive authority under Section 202 of the Clean Air Act, EPCA as amended by EISA includes limitations on NHTSA's authority to regulate fuel economy. NHTSA's authority is focused on fuel economy and not air pollution, and as a result, NHTSA is constrained in regulating direct discharges of N20, CH4, and HFC emissions from automobiles. 76 Fed. Reg. at 74,902. [EPA-HQ-OAR-2010-0799-9519-A1, p. 6]

Within its focus on fuel economy, EPCA contains additional, limitations on NHTSA's discretion to establish CAFE standards including the nexus to fuel efficiency. And, of particular importance, any proposed expansion of NHTSA's fuel economy analysis must be consistent with EPA's statutorily-mandated procedures to test fuel economy. [EPA-HQ-OAR-2010-0799-9519-A1, p. 6]

EPCA directs the Secretary of Transportation to prescribe CAFE standards, which "shall be the maximum feasible average fuel economy level that the Secretary decides the manufacturers can achieve in that model year." 49 U.S.C. § 32902; see also § 32902(f) (directing the Secretary to consider statutorily-enumerated factors in making this determination). While NHTSA has discretion in standard setting, under EPCA, EPA alone has the authority to measure fuel economy and to calculate CAFE values, 49 U.S.C. § 32904(a). In doing so, EPA "shall use the same procedures for passenger automobiles the Administrator used for model year 1975 . . . or procedures that give comparable results." Id. at 32904(c). The D.C. Circuit has concluded that, to produce "comparable results," "[t]he critical fact is that a procedure . . . was available for MY1975 testing, and those manufacturers, however few in number, that found it advantageous to do so, employed that procedure." Center for Auto Safety v. EPA, 806 F.2d 1071, 1077 (D.C. Cir. 1986). [EPA-HQ-OAR-2010-0799-9519-A1, p. 6]

In a previous rulemaking, the agencies concluded that this statutory structure did not allow for incorporation of air-conditioning efficiency improvement and off-cycle technology credits into NHTSA's fuel economy analysis. 75 Fed. Reg. at 25,544 ("The CAFE standards and compliance testing cannot capture all of the real world CO2 emissions, because EPCA currently requires EPA to use the 1975 passenger car test procedures under which vehicle air conditioners are not turned on during fuel economy testing."); 25,663 (requesting comment on including air conditioning credits in light-truck testing requirements but emphasizing "that modernizing the passenger car test procedures as well would not be possible under EPCA as currently written."). [EPA-HQ-OAR-2010-0799-9519-A1, p. 6]

In this proposal, however, the agencies forward different legal rationales, id. at 74,998, which they characterize as "major changes" from past practice, id., that would allow them to incorporate air-conditioning efficiency and off-cycle technology improvements into NHTSA standard setting. Both the agencies themselves, supra, and regulated industry have raised questions regarding this conclusion. See EPA Doc. No. OAR-2009- 0472-7123.1 at 17 (Comments of Association of International Automakers on LDV Phase I) (noting that the Association "does not support fundamentally changing the fuel economy/greenhouse gas test procedures at this time"); see also EPA Doc. No. EPA-HQOAR- 2003-0214-0208 at 10 (Comments of the Alliance of Automobile Manufacturers) (noting that any change in test procedures would require EPA "to develop a complex set of test procedure adjustment factors to ensure that the new procedures 'give comparable results' to the existing ones"). [EPA-HQ-OAR-2010-0799-9519-A1, pp. 6-7]

Organization: Ferrari

Ferrari strongly supports the proposal to allow manufacturers to generate fuel consumption improvement values for purposes of CAFE compliance based on the use of A/C efficiency technologies. [EPA-HQ-OAR-2010-0799-9535-A2, p.13]

Finally, we support to allow these credits to be counted for the CAFE compliance calculations. [EPA-HQ-OAR-2010-0799-9535-A2, p.14]

Ferrari appreciates the proposal to gain credits for high efficiency A/C systems and offcycle technologies to be used for fuel consumption improvement and CAFE compliance. [EPA-HQ-OAR-2010-0799-9535-A2, p.15]

Organization: Ford Motor Company

In order to provide equivalent fuel consumption benefits for these fuel saving technologies, Ford also supports the inclusion of off-cycle credits as part of the NHTSA CAFE program. This allowance helps to coordinate the EPA and NHTSA programs in the efforts of harmonization. [EPA-HQ-OAR-2010-0799-9463-A1, p. 18]

NHTSA Incentives for Electric Vehicles, Plug-in Hybrids, and Fuel Cell Vehicles

NHTSA has also expressed the view that it lacks authority to establish an incentive multiplier for EVs, PHEVs, and FCVs, comparable to the one proposed by EPA, in the fuel economy regulations under EPCA and EISA. In this case, we disagree with NHTSA's interpretation of EPCA and EISA. In our view, the law does not address this issue, either directly or indirectly. Moreover, the President has directed EPA and NHTSA to coordinate and harmonize their regulations as much as possible. Consistent with that directive, the agencies should interpret statutes so as to optimize the degree of harmonization between the GHG program and the CAFE program. Thus, if one agency incorporates a program flexibility into its rules, the other agency should adopted a corresponding program flexibility unless expressly prohibited by law. We refer the agencies to the comments of EDTA on this point, which we support and incorporate by reference. [EPA-HQ-OAR-2010-0799-9463-A1, p. 21]

Organization: Johnson Controls, Inc.

Specifically, we support the inclusion of fuel consumption reductions resulting from air conditioning improvements and the application of off-cycle credits and equivalent fuel consumption improvements in NHTSA's CAFE compliance calculations. [NHTSA-2010-0131-0253-A1, p. 2]

Organization: Mazda North American Operations

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 63-64.]

Additionally, we support providing equivalent fuel consumption and CO_2 credit values towards both the greenhouse gas and CAFE programs, helping to further harmonize one of the many remaining differences between the two regulations.

Organization: Mercedes-Benz USA, LLC

DAG also supports the agencies' decision to provide the analogous fuel consumption improvement credits within the CAFE program.[4] As set forth in DAG's comments to the MY 2012-2016 rulemaking, EPA has broad discretion to determine how to calculate fuel economy for purposes of the CAFE program and should utilize that discretion as necessary to harmonize the CAFE and GHG programs. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-2]

Organization: Motor & Equipment Manufacturers Association (MEMA)

Specifically, we support the agencies' decision to parallel the efficiency credits and fuel consumption improvement values for compliance calculations for their respective GHG emissions and CAFE standards programs (for example, the air conditioning and off-cycle emissions improvements and its equivalent fuel consumption improvement). [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

Particularly, MEMA supports the agencies proposal to align EPA credits with NHTSA's CAFE compliance by allowing manufacturers to generate fuel consumption improvement values for air conditioning (A/C) technologies and off-cycle technologies. These technologies are not otherwise "captured" on traditional test cycles, but they still provide contributing real-world benefits that improve vehicle efficiencies. Therefore, rewarding various A/C and innovative off-cycle technologies under both components of the rule will encourage faster adoption and increase deployment into the fleet. [EPA-HQ-OAR-2010-0799-9478-A1, p.5]

In the NPRM, Tables II-11, II-18 and IV-117 show a 0.000778 gal/mi consumption improvement value for engine heat recovery. We believe the agencies actually intended this to be a value of 0.0000788 as stated in the Technical Support Document on Table 5-26, page 5-75, where it was rounded up to 0.000079. [EPA-HQ-OAR-2010-0799-9478-A1, p.12]

Organization: Porsche Cars North America, Inc. (PCNA)

It is widely understood that GHG improvements are equivalent to fuel economy improvements. Therefore, we believe it is appropriate to extend all credit provisions in the GHG program to equivalent credit in the CAFE program. This additional CAFE credit would also provide additional incentive for further advances in efficiency improvement. [EPA-HQ-OAR-2010-0799-9264-A1, p. 6]

Organization: Toyota Motor North America

The agencies have proposed significant changes to EPA's existing off-cycle credit regulations. First, NHTSA has proposed to adopt off-cycle credits for the 2017-2025 model years. While EPA will continue to administer the program, NHTSA has proposed to award a corresponding level of CAFE credit for any EPA-approved off-cycle technologies. Toyota supports NHTSA's proposed adoption of off-cycle credits as a necessary step towards further harmonizing the federal regulations. [EPA-HQ-OAR-2010-0799-9586-A1, p.10]

Response:

EPA received several comments supporting EPA's inclusion of fuel economy improvement values under CAFE testing and calculations procedures that are equivalent to EPA credits for A/C efficiency improvements, off-cycle, and full-size pick-ups. Commenters note that these provisions help to further harmonize the programs. EPA is finalizing fuel consumption improvement value approach under its EPCA authority as proposed. This is discussed in more detail in section III.B.10 of the preamble. EPA appreciates MEMA comments noting an error for one of the fuel consumption improvement values in the proposal and EPA has corrected this error.

Regarding Porsche comments that all GHG credits have a corresponding fuel consumption improvement and should receive equivalent credits under CAFE, EPA disagrees. A/C credits based on reduced refrigerant leakage and alternative refrigerant use are based on reducing HFCs rather than CO_2 and therefore do not have a corresponding fuel consumption improvement. With regard to incentives under CAFE for EVs, PHEVs, and FCVs, this involves NHTSA's interpretation of its authority under EPCA/EISA. As noted in the NPRM (see 76 FR 74878) and discussed in NHTSA's Preamble Section IV addresses this, NHTSA currently interprets EPCA and EISA as precluding the agency from offering additional incentives for these vehicles except as specified by statute.

9. Certification, Compliance, and Enforcement

Organizations Included in this Section

Ford Motor Company

Organization: Ford Motor Company

We support NHTSA's efforts to receive and retain CAFE projections and related data in electronic format. We recommend that NHTSA does not create a new database with new requirements, but rather NHTSA should use a database format the same as EPA's Verify system. Manufacturers have spent significant time and money updating our databases to conform to EPA's new requirements commencing with the 2009 MY. (76 Fed. Reg. 75340) [EPA-HQ-OAR-2010-0799-9463-A1, p. 25]

In fact, the government of Canada is creating a new database for their new GHG requirements, and their system will be based on EPA's Verify format rather than retaining their current online xml reporting system. Their previous fuel consumption database is being converted over to the new Verify like format, recognizing the need for consistency among systems. [EPA-HQ-OAR-2010-0799-9463-A1, p. 26]

There are no GHG reductions or benefits to be gained by manufacturers spending time and resources reformatting complex data. An important aspect of a single, harmonized fuel economy and greenhouse gas program is communized reporting formats. [EPA-HQ-OAR-2010-0799-9463-A1, p. 26]

We support NHTSA's proposal to move to all electronic reporting. We support emailing data in Excel format as long as current manufacturer format is acceptable, and support moving to xml as long as Verify format is followed (76 Fed. Reg. 75350). [EPA-HQ-OAR-2010-0799-9463-A1, p. 26]

We do not support NHTSA's proposed change to 49 CFR § 537.7(c)(4) which moves credit reporting to a configuration level. For example, air conditioning efficiency credits are not going to vary by fuel economy configuration (basic engine / transmission class / IWC / transmission configuration / axle ratio / calibration); they may only vary by vehicle line. This type of vehicle characteristic should not be attempted as an overlay on a very specific fuel economy structure. Manufacturers should be allowed to delineate the credit applicability specifically, as needed, but for cases where credits apply across a much broader section of vehicles, manufacturers should be allowed to report on that level. EPA has already developed a credit spreadsheet for tracking credits and volumes that provides for accurate credit reporting. This spreadsheet should be allowed by NHTSA as well. In the future, should EPA move credit reporting to their Verify database, NHTSA's reporting requirements should be flexible enough to allow manufacturers to fulfill data and formatting requirements for both agencies simultaneously. (76 Fed. Reg. 75351-2) [EPA-HQ-OAR-2010-0799-9463-A1, p. 26]

Similarly, for 49 CFR § 537.7(c)(5) requesting light truck classification data, we support NHTSA's desire to consolidate all truck classification data to one location. We do note that requiring cargo-carrying volumes in the truck classification section (5) and also in the configuration information (4) is duplicitous. Requiring the same data in multiple places is either wasteful or inviting error. We also suggest that this overload of data actually makes it more difficult for NHTSA to use manufacturers' reports due to the unnecessary complexity and added length. We recommend that NHTSA's reporting regulations allow manufacturers to streamline reporting, as long as all the data required to confirm CAFE calculations, fleet classification, and NHTSA's fleet analyses are present and easily identified. [EPA-HQ-OAR-2010-0799-9463-A1, p. 26]

Response:

These comments are directed at the NHTSA program, and as such do not require a response from EPA.

9.1. Base Tire Definition

Organizations Included in this Section

Alliance of Automobile Manufacturers
Association of Global Automakers, Inc. (Global Automakers)
Ford Motor Company
General Motors Company
Hyundai America Technical Center
Toyota Motor North America

Organization: Alliance of Automobile Manufacturers

Base Tire Definition [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

EPA invites comment on whether changes to the base tire definition are warranted to "ensure a more uniform application across manufacturers." The Alliance recommends that changes to the definition of base tire be deferred. [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

In 40 C.F.R. §600.002, EPA currently defines base tire as follows: [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

Base tire means the tire specified as standard equipment by the manufacturer. [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

In 49 C.F.R. §523.2, NHTSA currently defines base tire as follows: [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

Base tire for passenger automobiles, light trucks and medium-duty passenger vehicles means the tire specified as standard equipment by a manufacturer on each vehicle configuration of a model type. [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

Although EPA has not proposed specific language to replace its definition, NHTSA has proposed to change its definition to the following: [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

Base tire (for passenger automobiles, light trucks and medium duty passenger vehicles) means the tire that has the highest production sales volume that is installed by the vehicle manufacturer on each vehicle configuration of a model type. [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

The Alliance does not support the proposed change to the NHTSA definition of base tire. NHTSA's proposed definition of base tire ties the footprint to high sales points within the fuel economy hierarchy. This can and does change throughout the model year based on many factors beyond a manufacturer's control or foresight. EPA's definition allows manufacturers to retain the direct link between footprint and the physical dimensions of the vehicles. All vehicles should be included in the fleet average using a representative footprint based on the physical vehicle, not a footprint based on a moving target of sales. [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

Additionally, NHTSA's current definition lends to the confusion by overlaying footprint on the fuel economy hierarchy through the inclusion of the defined fuel economy term 'configuration' in the base tire definition. Footprint is a function of the vehicle's dimensions. This is not related to any fuel economy 'configuration.' The footprint fuel economy target is simply a function of the production volume and its associated footprint. [EPA-HQ-OAR-2010-0799-9487-A1, p.84]

Under the current regulations, the base tire definition has a direct effect on footprint values and footprint has a direct effect on a manufacturer's targets. Therefore, any changes to the definition of base tire will have an effect on the stringency of a manufacturer's CAFE and CO_2 targets. This effect may vary from manufacturer to manufacturer. Nevertheless, each manufacturer has analyzed many scenarios and made long-range projections regarding its own ability to meet CAFE and CO_2 standards within a product segment. All of these projections have assumed that the base tire and footprint definitions would remain the same and would continue into the future. To change any of these definitions at this point in time would render any previous analyses regarding projected CAFE and GHG capabilities null and void. [EPA-HQ-OAR-2010-0799-9487-A1, p.84]

Therefore, we recommend that changes to any fundamental definitions that could effectively increase the stringency of the GHG and CAFE standards be deferred to a separate, future rulemaking and that both agencies engage in a joint dialogue with automakers to understand the complex technical issues involved. Further, any fundamental changes that could potentially increase the stringency of the standards should not be applied retroactively to past model years and should only go into effect starting with a future model year. Finally, in order to avoid future confusion and misinterpretation, we suggest that EPA and NHTSA endeavor to maintain identical definitions wherever possible. [EPA-HQ-OAR-2010-0799-9487-A1, p.84]

Organization: Association of Global Automakers, Inc. (Global Automakers)

NHTSA also invites comment on its proposed modification to its definition of “base tire,” which affects the determination of footprint size in determining compliance with standards. This change is proposed due to NHTSA’s concern that the current definition lacks specificity, leading to differing interpretations by manufacturers. Global Automakers supports clarification of the definition. We also urge that NHTSA and EPA adopt the same definitions of “base tire,” in order to increase the harmonization of standards under the national standards program. [EPA-HQ-OAR-2010-0799-9466-A1, p. 9]

Organization: Ford Motor Company

Base Tire

Ford does not support the proposed change to the NHTSA definition of base tire. We believe that NHTSA's current definition lends to the confusion by overlaying footprint on the fuel economy hierarchy through the inclusion of the defined fuel economy term 'configuration' in the base tire definition. Footprint is a function of the vehicle's dimensions. This is not related to any fuel economy 'configuration'. The footprint fuel economy target is simply a function of the production volume and its associated footprint. We recommend that NHTSA adopt EPA’s definition, and hence help maintain the development of a One National Program moving forward. [EPA-HQ-OAR-2010-0799-9463-A1, p. 25]

Organization: General Motors Company

GM supports further analysis and discussion with industry, EPA and NHTSA, regarding the complex task of defining “base tire”. We recommend that changes to the definition of base tire be deferred – and taken up potentially as part of one of the mid-term review “check-ins” - to minimize the potential for unnecessary complications and unintended consequences. [EPA-HQ-OAR-2010-0799-9465-A1, p. 4]

Organization: Hyundai America Technical Center

Base Tire Definition [EPA-HQ-OAR-2010-0799-9547-A1, p.7]

The agencies have asked whether the definition of base tire should be revised. We agree that there should be a definition which would require all automakers to consistently calculate their vehicle footprints. NHTSA has proposed the definition of 'tire installed by the vehicle manufacturer that is used on the highest production sales volume of vehicles within the configuration'. We agree that the tires installed on the vehicle most commonly sold within a vehicle configuration should become the basis for setting a manufacturer's fuel economy standards. This is a fair and a workable definition. [EPA-HQ-OAR-2010-0799-9547-A1, p.7]

Organization: Toyota Motor North America

Base Tire Definition [EPA-HQ-OAR-2010-0799-9586-A1, p.21]

Under existing and proposed attribute standards, base tire is used to define vehicle footprint, which in turn determines a vehicle's fuel economy and CO_2 targets. Existing EPA and NHTSA definitions of base tire are similar, but differ in their level of specificity.[5] In the preamble for the 2017-2025 model year proposal, NHTSA expresses concern that the current definition of base tire is insufficiently descriptive and open to interpretation. In response, NHTSA has proposed redefining base tire to be the tire with highest sales within a vehicle configuration. EPA requests comment on whether changes to the EPA base tire definition are warranted to 'ensure a more uniform application across manufacturers', but does not propose a revised definition. [EPA-HQ-OAR-2010-0799-9586-A1, p.21]

Toyota shares the concern that different interpretations of base tire could potentially lead to different calculated attribute targets for the different vehicles that otherwise should have the same attribute targets. This could create an un-level playing field among manufacturers. Any change in definitions that affects vehicle footprint has the potential to impact the stringency of the standards. The magnitude of that impact is currently unknown and could vary by manufacturer. However, we do not believe enough analysis has been performed to date to suggest exactly how the definition should be revised. Further, the comment period for this rulemaking does not provide adequate time to carefully explore alternatives to address the agencies' concerns. [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

As a result, Toyota requests that NHTSA and EPA study this issue further and take appropriate action in a future rulemaking to clarify this issue. Any change in regulatory definitions should be adopted by both agencies to further the objective of regulatory harmonization. [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

---

5 - NHTSA currently defines base tire as the tire specified as standard equipment by a manufacturer on each vehicle configuration of a model type (49 C.F.R. §600.2). EPA defines base tire as the tire specified as standard equipment by the manufacturer (49 C.F.R. §523.2). [EPA-HQ-OAR-2010-0799-9586-A1, p.21]

<u>Response:</u>

One of the factors in a manufacturer's calculation of vehicle footprint is the base tire. Footprint is based on a vehicle's wheel base and track width, and track width in turn is "the lateral distance between the centerlines of the base tires at ground, including the camber angle."[17] EPA's current definition of base tire is the "tire specified as standard equipment by the manufacturer."[18] NHTSA proposed a specific change to the base tire definition for the CAFE program (see Section IV.I.5.g, and proposed 49 CFR 523.2), and EPA requested comment on

[17] See 40 CFR 86.1803-01

[18] See 40 CFR 86.1803-01, and 40 CFR 600.002. Standard equipment means those features or equipment which are marketed on a vehicle over which the purchaser can exercise no choice.

whether the base tire definition should be clarified to ensure a more uniform application across manufacturers (76 FR 75088, December 1, 2011).

Vehicle manufacturers were the only parties providing comments on this issue, and they were essentially unanimous in stating a desire for a level playing field, while reiterating that the issue is complex. Several manufacturers pointed out that the proposed NHTSA definition, which includes a connection to a vehicle configuration, may not be workable because the definition of a configuration is independent of vehicle size, or footprint. Several manufacturers suggested that EPA, NHTSA, and the auto companies should postpone action on this issue in this rule and work together to ensure a consistent and complete understanding of the issue. Others agreed that the definition could benefit from some clarification. After consideration of the comments, and a recognition of the importance that the footprint calculation (and therefore all the elements that comprise the footprint calculation) be harmonized across EPA and NHTSA, EPA is finalizing a revised definition in this final rule, which is consistent with the definition being finalized by NHTSA. The revised definition is as follows:

> *Base tire* means the tire size specified as standard equipment by the manufacturer on each unique combination of a vehicle's footprint and model type. Standard equipment is defined in 40 CFR 86.1803-01.

This definition appropriately removes the link to vehicle configuration that was in NHTSA's proposal, and improves upon EPA's existing definition with additional specificity that is consistent with the goal of a footprint-based program, which, as stated by the Alliance of Automobile Manufacturers, is that "All vehicles should be included…using a representative footprint based on the physical vehicle…" EPA agrees with this broadly stated goal, and we believe that the revised definition offers reasonable clarification that should help ensure a consistent application of the footprint-based standards across manufacturers. This new definition, which is harmonized with the definition being finalized by NHTSA, is also consistent with existing regulatory language that specifies how EPA intends that footprint-based standards be implemented. For example, EPA regulations currently state that "Each CO_2 target value, which represents a unique combination of model type and footprint value, shall be multiplied by the total production of that model type/footprint combination for the appropriate model year" (see 40 CFR 86.1818-12(c)(2)).

9.2. Car-Truck Definitions

Ford Motor Company
Toyota Motor North America
Union of Concerned Scientists (UCS)

Organization: Alliance of Automobile Manufacturers

The agencies must maintain the current car and truck vehicle classification framework. The standards (i.e., footprint curves) that have been established, and the goals that have been placed are all based upon the current and known set of harmonized definitions. Any changes to the definitions during MYs 2017-2025 necessarily would require a reevaluation of the appropriate level of stringency, cost, necessary flexibilities and final standards for any and all years in which a change would apply. [EPA-HQ-OAR-2010-0799-9487-A1, p.4]

The Agencies Must Maintain the Current Car and Truck Vehicle Classification Framework. [EPA-HQ-OAR-2010-0799-9487-A1, p.8]

In section IV.H. of the NPRM, NHTSA discusses the existing regulations governing the classification of cars and trucks. The agency states, “NHTSA continues to believe that the definitions as they currently exist are consistent with the text of [the Energy Independence and Security Act of 2007 (EISA)] and with Congress' original intent.'8 Nevertheless, NHTSA requests comment on the possibility of changing the vehicle classification definitions, citing the long time frame of the rulemaking. [EPA-HQ-OAR-2010-0799-9487-A1, p.8]

First, we agree with NHTSA’s assessment that the existing definitions for classifying vehicles are consistent with EISA and the original intent of Congress in EPCA. In past rulemakings, NHTSA has made some adjustments to the classification rules and clarified its interpretation of certain aspects of the rules. These efforts have accomplished their intended objectives by clearing up ambiguities and leveling the playing field. The Alliance is not aware of any further systemic problems with respect to the interpretation of the rules, and we do not believe any further changes need to be made. [EPA-HQ-OAR-2010-0799-9487-A1, p.8]

NHTSA requests comment on whether the current definitions might create an incentive to manufacturers to “game” vehicle designs in a way that would reduce potential fuel savings in the future. We consider this risk to be minimal because vehicle designs are evaluated primarily based upon an assessment of consumer acceptance. In other words, the key issue for manufacturers is whether potential purchasers would find the design useful and appealing, not how the vehicle would be classified under various regulatory programs. Moreover, the advent of 'Reformed CAFE' has reduced the incentives for manufacturers to attempt to reclassify vehicles from one fleet to another, given the fact that even larger vehicles can be 'CAFE-positive' based on their status relative to their footprint target. Finally, the existing definitions simply do not lend themselves to gamesmanship, a testament to NHTSA's efforts over the years to improve and refine the classification rules. [EPA-HQ-OAR-2010-0799-9487-A1, p.9]

Having developed a robust set of classification rules, NHTSA's priority should be preserving the stability of those rules, rather than engaging in continual modification and experimentation. Changes to the classification rules could have unintended consequences. For example, they could create new ambiguities or open up new opportunities for gamesmanship. If the changes are overly restrictive, they could have the effect of discouraging the production of vehicles that American consumers want to buy. [EPA-HQ-OAR-2010-0799-9487-A1, p.9]

A decision to change the classification rules at this point would create other problems. The classification rules represent a fundamental building block of the single National Program, and any attempt to change the car/truck definitions would have far-reaching consequences. All of the analyses of the proposed standards that manufacturers have conducted to date have been based on the assumption that the existing car/truck definitions would be retained. If the definitions applicable to MYs 2017-2025 were changed, it would require a complete reevaluation of virtually all other aspects of the proposed rules, including the stringency of the standards, the cost of compliance and the adequacy of the program flexibilities. Such a reevaluation would be essential because, as a practical matter, a change to the classification definitions can be equivalent to a major change to the standards themselves. An amendment to the car/truck definitions could easily mean the difference between compliance and non-compliance for many manufacturers. Therefore, amendments to the classification rules would necessitate a brand new, top-to-bottom reanalysis of the standards by all manufacturers as well as NHTSA and EPA. And it is highly probable that large portions of the rulemaking package would need significant readjustment as a result of that exercise. [EPA-HQ-OAR-2010-0799-9487-A1, p.9

In light of the above, the agencies must maintain the current car and truck vehicle classification framework. The standards (i.e., footprint curves) that have been established and the goals that have been placed are all based upon the current and known set of harmonized definitions. Any changes to the definitions during MYs MY 2017-2025 necessarily would require a reevaluation of the appropriate level of stringency, cost, necessary flexibilities and final standards for any and all years that a change would apply. [EPA-HQ-OAR-2010-0799-9487-A1, p.9]

Organization: Association of Global Automakers, Inc. (Global Automakers)

NHTSA invites comment on the reclassification of vehicles with a third row of seats that are currently classified as light trucks under NHTSA regulations in title 49 U.S.C. 523.5(a). Global Automakers agrees with NHTSA's conclusion that there would be no clear energy savings benefit from reclassifying these vehicles to be passenger automobiles, and we urge the agency to maintain the current classification system. Shifting these vehicles into the passenger automobile category would likely necessitate changes to the auto standards to make the standards less stringent to accommodate these vehicles, potentially reducing fuel savings. Such a shift would also impose significant compliance costs on manufacturers as the stringency of both the auto and truck standards would change. We also reject the argument presented in the proposal that the third row of seats is installed in some crossover vehicles as a gaming strategy, in order to shift vehicles into the truck category. There are substantial cost and weight penalties associated with the addition of third row seats, so installing these seats cannot be justified in the absence of consumer demand for them. [EPA-HQ-OAR-2010-0799-9466-A1, pp.8-9]

Organization: Ford Motor Company

Clarification of the Interpretation of 'Running Clearance'

As explained in more detail in the Alliance comments, NHTSA should not change the existing framework for vehicle classification. However, NHTSA could assist light truck manufacturers in the production of more fuel-efficient light trucks by providing a small clarification with respect to the minimum running clearance criterion applicable to vehicles classified as light trucks by virtue of their off-highway capability. [EPA-HQ-OAR-2010-0799-9463-A1, p.28]

Many SUVs and some crossover vehicles are classified as light trucks because they are 'capable of off-highway operation' as defined in 49 CFR § 523.5(b). Such vehicles need either have 4-wheel drive or be over 6,000 pounds GVWR, and they need to meet four out of five dimensional criteria. One of the five criteria is a running clearance of 20 cm; the others relate to approach angle, breakover angle, departure angle, and axle clearance. The key terms used in § 523.5(b) are defined in 49 CFR § 523.2. 'Running clearance' is defined as 'the distance from the surface on which an automobile is standing to the lowest point on the automobile, excluding unsprung weight.' [EPA-HQ-OAR-2010-0799-9463-A1, p.28]

Our concern has to do with the interpretation of the running clearance criterion, and its effect on our efforts to make our light trucks as fuel-efficient as possible. As a motor vehicle is driven down the highway, the movement of air past the wheels and tires contributes to the aerodynamic drag of the vehicle, tending to reduce fuel economy. This aerodynamic drag can be reduced by the installation of flexible plastic components in front of the tire and wheel. Ford calls these components tire aero deflectors. They help to deflect oncoming air around the tire/wheel assembly, reducing aerodynamic drag and improving fuel economy. The fuel economy benefit of tire aero deflectors is primarily apparent in real-world highway driving. [EPA-HQ-OAR-2010-0799-9463-A1, p.28]

The optimal design of a tire aero deflector can vary from vehicle to vehicle, depending on the vehicle's design. For some vehicles, the bottom edge of the deflector may need to be less than 20 cm from the ground (when the vehicle is parked on a flat surface) in order to provide the desired deflection of air around the wheels and tires. This raises the issue: if a vehicle that a manufacturer intends to classify as a light truck needs to meet the running clearance criterion in order to meet the '4-out-of-5' requirement in 49 CFR § 523.5(b)(2); and if the manufacturer wishes to install a tire aero deflector that hangs below the 20 cm running clearance line; should the installation of such a component prevent the vehicle from being classified as a light truck? Another manufacturer raised a similar issue in its comments on the MY 2012-2016 rules. In response, NHTSA indicated that it needed further information and would defer consideration of the issue to another time. (75 Fed. Reg 25662) [EPA-HQ-OAR-2010-0799-9463-A1, pp.28-29]

As noted previously, the optimal design for a tire aero deflector may be such that the bottom of the deflector may be less than 20 cm away from the road surface. A tire aero deflector is not connected to the vehicle's suspension, so it is not considered 'unsprung weight.' Therefore, under a literal reading of the rule, a tire aero deflector whose bottom edge is less than 20 cm from the road surface might be considered to infringe upon the 20 cm running clearance criterion. If the rule is interpreted in this fashion, it would mean that if a manufacturer installs tire aero deflectors on a vehicle that does not meet the approach angle criterion of 28 degrees, the manufacturer would be compelled to reclassify the vehicle as a passenger car because the vehicle would not be able to meet four of the five dimensional criteria specified 49 CFR 523.5(b). [EPA-HQ-OAR-2010-0799-9463-A1, p.29]

In reality, if tire aero deflectors whose bottom edge is less than 20 cm from the road surface are considered to violate the running clearance criterion, manufacturers simply will not install them on the affected light trucks. Typically, whatever fuel economy benefit the deflectors may provide will be outweighed by the disadvantages to the manufacturer of reclassifying the vehicle as a passenger car. Reclassifying the vehicle as a passenger car would mean that the vehicle would become subject to the passenger car 'curve,' resulting in a more stringent fuel economy and GHG 'target' for the vehicle. This could have the effect of hurting the manufacturer's ability to meet both the car standards and the truck standards for a given model year. As a result, manufacturers will leave the tire aero deflectors off of the vehicles, and the classification rules would end up discouraging manufacturers from installing components that help to improve real-world fuel efficiency. [EPA-HQ-OAR-2010-0799-9463-A1, p.29]

One might suggest that the interpretation issue can be avoided if the manufacturer simply concedes the running clearance criterion and plans to meet the other four dimensional criteria in 49 CFR 523.5(b). However, it is not that simple in the real world, particularly for vehicle manufacturers concerned with producing fuel-efficient products. One of the other five criteria for 'off-highway capable' truck classification is an approach angle of not less than 28 degrees. Many SUVs and crossovers built today do not meet this criterion. An approach angle of 28 degrees means that a vehicle will have a high front fascia. In general, a high front fascia tends to create more aerodynamic drag, which is not conducive to better fuel economy and reduced GHG emissions. A lower front fascia allows a vehicle to have better aerodynamic characteristics. In this era of increasingly stringent CAFE and GHG standards, many manufacturers, including Ford, disfavor vehicle designs that would feature a high front fascia. If a manufacturer elects to design a SUV or crossover with a lower front fascia for better fuel economy, it must then plan to meet all of the remaining four dimensional criteria for off-highway capability in 49 CFR 523.5(b)(2) in order to classify the vehicle as a light truck. This means that the vehicle would need to have a running clearance of at least 20 cm. [EPA-HQ-OAR-2010-0799-9463-A1, p.29]

Ford designs its tire aero deflectors to be flexible enough to bend without breaking when encountering a 20 cm high solid object at relatively low speeds (i.e., off-road driving speeds). In our view, this is fully consistent with the spirit and intent of the off-highway-capable criteria. In other words, even with the deflectors present, our customers would continue to be able to engage in the same kinds of off-highway driving envisioned by the current rules, without damaging their vehicles. [EPA-HQ-OAR-2010-0799-9463-A1, pp.29-30]

In light of the above, we believe that NHTSA can promote improved fuel economy and reduced GHG emissions, without compromising other objectives, by issuing an interpretation clarifying that the installation of flexible tire aero deflectors whose bottom edge is less than 20 cm from the road surface would not compromise compliance with the running clearance criterion in 49 CFR 523.5(b)(2). We therefore requests that in the final rule, NHTSA either provide a regulatory interpretation in the preamble to the rule, or modify the regulatory language in 49 CFR Part 523, to provide the following clarification: [EPA-HQ-OAR-2010-0799-9463-A1, p.30]

A flexible component (or components) attached to the undercarriage of a vehicle shall not be considered in determining compliance with the running clearance measurement found in 49 CFR 523.5(b)(2)(iv), provided as follows:

1. The component(s) is/are installed in front of, and in close proximity to, the wheels, tires, and associated suspension components that create aerodynamic drag.

2. The component(s) will flex without damage when a solid obstacle of 20 cm in height is passed underneath the component(s) when the vehicle is parked on a flat surface. [EPA-HQ-OAR-2010-0799-9463-A1, p.30]

Organization: Toyota Motor North America

Vehicle Classification Definitions [EPA-HQ-OAR-2010-0799-9586-A1, p.21]

NHTSA is concerned that manufacturers have an incentive to classify passenger cars as light-duty trucks to secure an easier CAFE target. Given the 2017-2025 model year standards are being set so far in advance, NHTSA is also concerned that the definitions could eventually lose their relevance as the market evolves. [EPA-HQ-OAR-2010-0799-9586-A1, p.21]

Toyota believes that changes to the current vehicle classification definitions are unnecessary. First, NHTSA itself states that the current definitions are consistent with the text of EISA and Congress' original intent. Toyota agrees with NHTSA. Second, there has been no evidence to substantiate speculation that §523.5(a)(5) is being 'gamed' by manufacturers through addition of 3rd row seating. Third, NHTSA's own evaluation concludes that eliminating §523.5(a)(5) may actually be counterproductive. NHTSA reports that during the 2012-2016 model year rulemaking it evaluated the impact of moving all two-wheel drive SUYs from the truck fleet to the passenger car fleet and concluded that such a move would result in lower fuel savings, increased costs, and significant disruption to the industry. In the year since the 2012-2016 model year standards were finalized, Toyota is unaware of new information that would change this conclusion. Finally, the proposed attribute curves are based on extensive analysis of maximum feasible target curves and standards using current classification definitions. Any revision to the vehicle classification definitions for standards finalized in this rulemaking would change the shape of the footprint curves and the stringency of the proposed standards and would necessitate re-proposal of those standards. To the extent NHTSA is concerned about whether the classification definitions can keep pace with evolving market through the 2017-2025 model year period, we suggest the issue be revisited during the mid-term review. [EPA-HQ-OAR-2010-0799-9586-A1, p.21]

Organization: Union of Concerned Scientists (UCS)

(b) Loss in Benefits from Increased Vehicle Size and Car/Truck Reclassification

Another helpful improvement would be to modify the definition of light trucks, adding new criteria to better differentiate non-passenger vehicles with true off-road capability from passenger vehicles designed to carry individuals. In addition to the current differentiating list, a requirement to meet new criteria – a majority subset of the following 5 items: limited slip center differential, limited slip rear differential, locking axles, skid plates, and 2-speed transfer cases – could be added. [EPA-HQ-OAR-2010-0799-9567-A2, p. 8]

29 CARB, Initial Statement of Reasons for Proposed Rulemaking, Public Hearing to Consider the “LEV III” Amendments to the California Greenhouse Gas and Criteria Pollutant Exhaust and

Evaporative Emission Standards and Test Procedures and to the On-Board Diagnostic System Requirements for Passenger Cars, Light-Duty Trucks, and Medium-Duty Vehicles, and to the Evaporative Emission Requirements for Heavy-Duty Vehicles, p. 159. [EPA-HQ-OAR-2010-0799-9567-A2, p. 7]

30 http://www.cal-span.org/cgi-bin/media.pl?folder=CARB, January 26, 2012, at approx. time marker 5:21. Accessed February 3, 2012. [EPA-HQ-OAR-2010-0799-9567-A2, p. 7]

Response:

These comments are generally directed at NHTSA's request in the proposed rule regarding the definitions of "passenger automobile" and "light truck" (or "non-passenger automobile"), and thus EPA is not responding to these comments. Although EPA's rules incorporate the definitions used in the CAFE program (see 40 CFR 86.1818-12(b)), EPA adopted these definitions in the MYs 2012-2016 rulemaking in order to harmonize the GHG rules with the CAFE program. EPA did not raise the possibility of revising these definitions in the present rulemaking, or otherwise reconsider or reassess its approach of using the harmonized definitions in the GHG rules. Consequently, EPA is not responding to these comments here, and views them as addressed exclusively to the CAFE program.

9.3. Compliance Data Transparency

Organizations Included in this Section

Natural Resources Defense Council (NRDC)
Union of Concerned Scientists (UCS)

Organization: Natural Resources Defense Council (NRDC)

EPA and NHTSA should create greater public transparency by annually publishing data on each manufacturer's credit status and technology penetration, thus ensuring greater public confidence in the program's effectiveness. [EPA-HQ-OAR-2010-0799-9472-A2, p. 3]

C. Automaker Credit Balance and Technology Application Should be Transparently Reported Annually to Allow for Public Evaluation of Program Effectiveness

Effective public support for the National Program is dependent on transparent data that proves that the program is working effectively. To enable the public to evaluate the effectiveness of the program, EPA should publish an annual public report that includes at minimum the following quantitative information on credits (in megagrams or metric tons and mpg) for each manufacturer's car and light truck fleets: [EPA-HQ-OAR-2010-0799-9472-A2, p. 15]

The amount of cumulative credits or deficits;

The amount of credit transfers made by a manufacturer between its car and light truck fleets (if any);

The amount of credits traded between manufacturers including which manufacturers were involved and the car/truck credit origination and destination; and [EPA-HQ-OAR-2010-0799-9472-A2, p. 15]

The amount of credits generated, for each manufacturer's car and truck fleet, from the additional credit opportunities including:

air conditioning related credits;

multipliers for electric vehicles, plug-in hybrid electric vehicles and fuel cell vehicles;

full-size pick-up truck hybrid and performance-based incentive credits;

CAFE credits associated with flex fuel vehicles and alternative fuel vehicles and the fuel usage assessment that factored into CAFE and GHG calculations; and

off-cycle technology credits. [EPA-HQ-OAR-2010-0799-9472-A2, p. 16]

For each of the five additional credit opportunities above, EPA should specify the basis for calculating the credits and indicate how many credits were awarded for each mechanism. For example, EPA should indicate how many plug-in hybrid electric vehicles earned advanced technology multiplier credits for a manufacturer's car fleet and how EPA calculated the credit per vehicle type. For off-cycle technology credits, EPA should specify what technologies earned the credit. [EPA-HQ-OAR-2010-0799-9472-A2, p. 16]

The EPA should also enhance technology descriptions to the annual Fuel Economy Trends Report and/or Fuel Economy Guide and associated on-line database. Included in the reports should be the following:

Footprint per model and manufacturer;

Sales per model;

Car or truck classifications by model and manufacturer; and

Penetrations of efficiency and emission reduction technologies by vehicle class and manufacturer to understand what portions of vehicles have which technologies. [EPA-HQ-OAR-2010-0799-9472-A2, p. 16]

Organization: Union of Concerned Scientists (UCS)

(e) Transparency and Compliance Accounting

UCS commends the agencies in general on their noticeable efforts to provide high levels of transparency throughout the 2012-2016 and 2017-2025 rulemaking processes. All three agencies—EPA, NHTSA, and CARB—have embraced an approach to base findings not upon confidential business information, but rather upon well-documented, proven, and transparent information. [EPA-HQ-OAR-2010-0799-9567-A2, p. 11]

The agencies could further improve transparency by having a clear public accounting of credits and program compliance. Over the years, it has been exceedingly difficult to independently verify whether manufacturers are complaint with their CAFE obligations, and as noted in previous comment submissions, we have concerns that the same will hold true with manufacturers' vehicle greenhouse gas obligations. Given the numerous compliance flexibility mechanisms being proposed by the agencies – as well as a multitude of opportunities for trading, transferring, banking, and borrowing of credits – it is critical that manufacturers' compliance ledgers be documented, publicly available, and sufficiently granular to assess by which measures companies are complying with the regulations. [EPA-HQ-OAR-2010-0799-9567-A2, p. 11]

For example, for each model year, this may include (but not be limited to) each manufacturer's: car average greenhouse gas emissions performance; light truck average greenhouse gas emissions performance; amount of credits (on at least car and light-truck fleet average basis) accrued through advanced technology vehicle credits, early credits, A/C credits, off-cycle technology credits, flex fuel vehicle credits, and (in the case of MYs 2012-2016) use of temporary lead-time allowance alternative standards; amount of total banks/debits accrued in each year; and a running balance of banks/debits. We urge the agencies to undertake an effort to provide clear public accounting of credits and program compliance. [EPA-HQ-OAR-2010-0799-9567-A2, p. 11]

Further, in order for UCS and other public interest groups to effectively assess industry compliance and behavior, we request that the agencies expand the public availability and quality of disaggregated vehicle data. Because of the new attribute-based standards, it is critical that sub-model level data be regularly published that includes not only fuel economy and greenhouse gas emissions performance specifications, but at a minimum, finalized sales, vehicle footprint, and regulatory vehicle classification. In order to improve the quality of public interest group assessments, we request that the following data be regularly published at the sub-model level: [EPA-HQ-OAR-2010-0799-9567-A2, p. 11]

- Model Year
- Make
- Model/Nameplate
- Engine Family
- Transmission Type
- Criteria Pollutant Emission Certification Level(s)
- Number of Cylinders
- Fuel Type
- Drive Type (Fwd/Rwd/4wd)
- Vehicle Weight (ITW, ETW, curb)
- Regulatory Vehicle Classification (Passenger Car, LDT1, LDT2, etc.)
- Horsepower
- Footprint (or wheelbase and front/rear track width)
- Test Greenhouse Gas Emissions – city, highway, and combined

- Greenhouse Gas Emissions Adjusted for Upstream – city, highway, and combined
- Unadjusted (CAFE) Test Fuel Economy – city, highway, and combined
- Unadjusted (CAFE) Credited Fuel Economy – city, highway, and combined
- Window Label Fuel Economy (for vehicle identification purposes)
- Sales Volume (finalized sales) [EPA-HQ-OAR-2010-0799-9567-A2, p. 11]
- Sales Origin (domestic passenger, import passenger, non-passenger)
- Market Classification
- EPA Classification
- Identification of whether the vehicle applies under Temporary Lead-time Allowance Alternative Standards [EPA-HQ-OAR-2010-0799-9567-A2, p. 12]

UCS requests that the data set include all makes and models covered under EPA and NHTSA greenhouse gas and fuel economy regulations, with no exceptions. As this is a request for the most recent complete model year of data -- not projected sales, or even existing mid-year sales – any automaker confidentiality claims on these data are unwarranted. [EPA-HQ-OAR-2010-0799-9567-A2, p. 12]

Finally, UCS suggests that EPA expand its Light-Duty Automotive Technology, Carbon Dioxide Emissions, and Fuel Economy Trends report to include annual assessments of car/truck designations and vehicle size (by footprint). Doing so will allow the agencies to better track whether manufacturers are complying with the standards by deploying clean, fuel-efficient technologies in their fleets, or whether they are doing so by upsizing, by reclassifying cars as light trucks, or by other regulatory gaming methods. [EPA-HQ-OAR-2010-0799-9567-A2, p. 12]

Response:

As was the case in the MYs 2012-2016 regulation, EPA received several comments about the need for transparency in its implementation of the greenhouse gas program and specifically about the need for public access to information about Agency compliance determinations. NRDC argued that EPA and NHTSA should publish data on each manufacturer's credit status and technology penetration on an annual basis. They suggested specific data that should be disclosed, by car and truck fleets, including the amount of cumulative credits or debits, the within-manufacturer credit transfers between car and truck fleets, air conditioning credits, use of multipliers for EVs, PHEVs, and FCVs, full size pick-up truck HEV and performance-based credits, and off-cycle technology credits. They further suggested that the Fuel Economy Trends Report and the Fuel Economy Guide and associated online database could be enhanced to include additional vehicle and technology information, by model and manufacturer. The Union of Concerned Scientists (UCS) reiterated these comments, noting that EPA should have a "clear public accounting of credits and program compliance." They specifically request that data at the "sub-model level" be published regularly, and that such data include the following: model year, make, model/nameplate, engine family, transmission type, criteria pollutant certification levels, number of cylinders, fuel type, drive type, horsepower, footprint, GHG emissions and fuel economy test results, window label fuel economy, sales volume, sales origin, market classification, EPA classification, and whether a vehicle is using the TLAAS program standards. Like NRDC, UCS also requested enhancements to the Light-Duty Automotive Technology, Carbon Dioxide Emissions, and Fuel Economy Trends report by adding information on car/truck designations and vehicle size/footprint.

EPA remains committed to the principle of transparency and to disseminating as much information as we are reasonably and legally able to provide. Indeed, as explained in section II.F of the preamble, one reason the agencies have rejected off-cycle credits for crash avoidance technologies are difficulties in quantifying GHG emissions/fuel economy improvements attributable to the technology, which would raise issues of transparency and verifiability. Not surprisingly, manufacturers have also commented about the need to protect confidential business information, a practice to which we also remain committed. As stated in the MYs 2012-2016 final rule, and in section III.E of the preamble to the final rule, EPA expects that the dissemination of GHG program data will possibly take place through the annual Fuel Economy Trends report, the annual Compliance Report, or through other means, such as online distribution through fueleconomy.gov or other EPA websites, new GHG-specific reports, or through some combination of all of these. Given that the data will be released well after the conclusion of a given model year, certain information is clearly no longer confidential business information. For example, vehicle production volumes by model type are unlikely to be treated as confidential given that essentially the same information can be purchased from sources like WardsAuto. But production volumes at a finer level of detail, such as at the subconfiguration or configuration level, could potentially be considered confidential because those volumes, which are not available elsewhere, may potentially reveal something about a manufacturer's long-term strategies. These are issues and questions that EPA expects to be addressing as we move forward with publishing our compliance data.

EPA already releases a considerable amount of information regarding fuel economy, emissions, and vehicle characteristics, both at the test level and at the model type level.[19] The downloadable model type data available at fueleconomy.gov will soon have CO_2 emissions values (adjusted label values and unadjusted values, similar to the MPG reporting) in addition to the 127 columns of data we already provide for each model type. However, we plan to expand what we release publicly such that more information is available regarding GHG program compliance, For example, EPA intends to publish the applicable fleet average standards (for cars and for trucks) and the actual fleet performance for each manufacturer, and the resulting credits or debits (in Megagrams, or metric tons). In addition, EPA anticipates publishing the amount of credits generated by each manufacturer (separately for each of the car and truck fleets) under the optional credit programs, and the associated volumes of vehicles to which those credits apply. EPA will also likely publish various credit transactions (transfers among fleets within a manufacturer and trades between manufacturers), as well as the total credits or debits accumulated in a model year and the resulting overall credit or debit balance, taking into account the credit and debit carry-forward provisions. EPA anticipates that the data publication will evolve over time, both as the program progresses and as our data systems adapt to the new requirements and are able to manage and report data accurately and effectively. For example, our first public release of information is likely to be a summary of the early credits generated in the 2009-2011 model years that, at least initially, may not be as comprehensive as the reporting that

[19] See http://www.epa.gov/otaq/tcldata.htm and http://www.fueleconomy.gov/.

follows the 2012 model year.[20] EPA is currently assessing how to best release these data (both the content and the mechanism), but expects that publication will occur later this year.

9.4. Harmonization with CAFE

Organizations Included in this Section

Alliance of Automobile Manufacturers
Ford Motor Company

Organization: Alliance of Automobile Manufacturers

The Agencies Should Insure that the NHTSA Requirements are Fully Harmonized with the EPA Requirements. [EPA-HQ-OAR-2010-0799-9487-A1, p.14]

EPA and NHTSA mention several times in the NPRM that they have worked to develop “strong and coordinated” Federal GHG and CAFE standards so that manufacturers can build a single fleet of vehicles to satisfy requirements under both programs as well as under the California program. As the agencies explain, this helps to reduce costs and regulatory complexity while achieving significant energy security and environmental benefits. While we appreciate the agencies' efforts to harmonize the two programs, more work needs to be done in this area. Specifically, NHTSA should modify its CAFE program for MY 2017-2025 to better harmonize with EPA's GHG program. [EPA-HQ-OAR-2010-0799-9487-A1, p.14]

NHTSA's proposed CAFE standards account for many of the same factors that EPA considers in setting its proposed GHG standards. However, the proposed CAFE program does not include all of the program flexibilities built into the GHG program. NHTSA's program does not account for some of the EPA flexibilities, including off-cycle technology benefits, mobile air conditioning benefits, and benefits for hybridizing large work trucks. However, there are other important flexibilities that are present in the GHG program, but not the CAFE program. These include the advanced technology volume multiplier, the difference in quantification for advanced technologies with respect to the treatment of electricity, natural gas fuel utility factors, unlimited credit transfers between fleets and the one-time carry forward of previous credits through MY 2021. [EPA-HQ-OAR-2010-0799-10153-A2, p.1]

By MY 2025, the difference between the EPA's proposed fleet average standard and NHTSA's proposed fleet average standard equates to about 4.9 mpg. However, this difference is not large enough to offset the benefits of the additional flexible mechanisms included in EPA's program. In order to bring the two programs into better alignment, NHTSA needs to either increase the program flexibilities offered under the CAFE program or modify its curves to better reflect the other differences between the two programs. While the impact of the program differences is relatively small in the early years of the program, it will increase with the passage of time, particularly as manufacturers rely more and more on vehicle electrification in order to comply

[20] Reporting of these credits was due from manufacturers at the end of March, 2012, and EPA is currently evaluating the data to ensure compliance with regulatory requirements.

with the standards. Unless this imbalance is corrected, it will result in significant disharmony in the middle and later years of the time period covered by this proposal. [EPA-HQ-OAR-2010-0799-9487-A1, p.14]

The Alliance recognizes that, with respect to program flexibilities, EPCA and EISA impose some restraints on NHTSA that the Clean Air Act does not impose on EPA. Nevertheless, the Alliance believes that increased harmonization between the two programs is both possible and necessary. The Alliance strongly recommends that NHTSA undertake further study of its ability to include additional, appropriate program flexibilities to provide for equivalent stringency between the proposed CAFE standards and the proposed GHG standards.[10] To the extent that NHTSA cannot fully provide for equivalent stringency through the addition of program flexibilities, NHTSA should adjust the proposed CAFE standards themselves to fully account for the differences in the two programs. Such an adjustment is necessary to ensure that the President's goal of coordinated, harmonized CAFE and GHG programs is realized, and to avoid potential future problems due to disparities in the stringency of the two programs. [EPA-HQ-OAR-2010-0799-9487-A1, pp.14-15]

---

10 - Please note that the term 'program flexibilities' does not refer to the enforcement provisions of the two programs, such as the payment of fines. The agencies' harmonization efforts should focus on achieving equivalent stringency in the CAFE and GHG standards, regardless of any differences in the enforcement mechanisms for the two programs.

Organization: Ford Motor Company

Consistent Geographical Fleets for the CAFE and GHG Programs

As noted repeatedly by the agencies, a key objective of One National Program is harmonization of the GHG and CAFE requirements to the greatest extent possible. In that regard, the agencies should strive to harmonize the fleets that are used to calculate the GHG and CAFE fleet averages, respectively. [EPA-HQ-OAR-2010-0799-9463-A1, p.26]

In its comments on the MY 2012-2016 One National Program regulations, Ford raised an issue related to GHG-CAFE harmonization. The issue is that there is a geographical discrepancy between vehicles covered under the CAFE program and those covered under the Clean Air Act (CAA). Under NHTSA's regulations, CAFE compliance is based on vehicles delivered for sale in the 50 states, the District of Columbia, and Puerto Rico. (49 CFR § 525.4(a)(5)) However, under Section 302(d) of the CAA, the term 'State' is defined to include vehicles delivered to those locations, plus the Virgin Islands, Guam, American Samoa, and the Commonwealth of Northern Mariana Islands. The result is that, under the existing rules, manufacturers have to use different databases of vehicles to calculate their CAFE fleet average and their GHG fleet average, respectively. In Ford's case, the additional territories included under the CAA definition means that the GHG database has about 1,000 more vehicles than the CAFE database. [EPA-HQ-OAR-2010-0799-9463-A1, pp.26-27]

Given the size of Ford's fleet, the impact of an additional 1,000 vehicles in the GHG database is negligible from a fleet average standpoint. However, the administrative burden caused by the need to maintain two databases, and to chase down the relevant information for the vehicles in the additional territories covered by the CAA, is not negligible. The additional vehicles are not easily identified on a model type, base level, configuration, or subconfiguration level, and it represents a significant effort to gather all of this information for the GHG database. In short, the geographic discrepancy between the GHG fleet and the CAFE fleet adds administrative burden for no real benefit. [EPA-HQ-OAR-2010-0799-9463-A1, p.27]

In our comments on the MY 2012-2016 rules, Ford suggested that EPA could amend its regulations to clarify that, for purposes of emissions compliance reporting and fleet averaging only, the fleet is composed of vehicles for the 50 states, the District of Columbia and Puerto Rico. In promulgating the final MY 2012-2016 rules, EPA responded to this comment as follows:

The comment stated that EPA has the discretion under the CAA to align the sales area location of production vehicles for the greenhouse gas fleet with the sales area location for the CAFE fleet and recommended that EPA amend the definitions in 40 CFR 86.1803 accordingly. This would exclude from greenhouse gas requirements production vehicles that are introduced into commerce in the Virgin Islands, Guam, American Samoa, and the Commonwealth of the Northern Mariana. [EPA-HQ-OAR-2010-0799-9463-A1, p.27]

Although EPA has tried to harmonize greenhouse gas and CAFE requirements in this rule to the extent possible, EPA believes that the approach suggested in comment would be contrary to the requirements of the Act. EPA does not believe that the Agency has discretion under the CAA to exclude from greenhouse gas requirements production vehicles introduced into commerce in the Virgin Islands, Guam, American Samoa, and the Commonwealth of the Northern Mariana Islands. In addition, this change would introduce an undesirable level of complexity into the certification process and result in confusion due to vehicles intended for commerce in separate geographical locations being covered under a single certificate. For these reasons, EPA will retain the proposed greenhouse gas production vehicle sales area location as defined in the CAA. (75 Fed. Reg. 25484) [EPA-HQ-OAR-2010-0799-9463-A1, p.27]

Based on EPA's response, it is apparent that Ford's original comment was unclear. It was never Ford's intention to exclude vehicles delivered to the Virgin Islands, Guam, American Samoa, or the Commonwealth of the Northern Mariana Islands from any certification requirements, or to otherwise introduce any complexity or confusion into the certification process. Under our concept, the certification process would not change; all vehicles delivered to those locations would be fully certified to all applicable standards, just as they are today. The only proposed change is that, solely for purposes of calculating and reporting a manufacturer's GHG fleet average, the rules would give manufacturers the option not to include the vehicles delivered to the specified locations, thereby enabling the manufacturers to harmonize their GHG fleet with their CAFE fleet. Such a change would have no adverse environmental consequences; as noted above, it would not alter the vehicles sent to the territories in question, and the small number of vehicles at issue is not significant enough to affect a manufacturer's fleet average. Meanwhile, this change would be very beneficial from the standpoint of promoting harmonization and reducing unnecessary administrative burdens. [EPA-HQ-OAR-2010-0799-9463-A1, pp.27-28]

There may be a number of ways to accomplish this goal through amendments to the regulatory language, but here is our suggestion. After 40 CFR § 86.1865-12 (a)(2), add the following:

(3) As used in this section, the term 'delivered for sale' refers to new passenger automobiles and light trucks transported to dealerships for the purpose of retail sales to consumers in the United States (including the District of Columbia), Puerto Rico, the Virgin Islands, Guam, American Samoa, and the Commonwealth of Northern Mariana Islands. For purposes of this section only, manufacturers may elect not to include vehicles delivered for sale in the Virgin Islands, Guam, American Samoa, and the Commonwealth of Northern Mariana Islands their computation of fleet average carbon-related exhaust emissions by notifying EPA of this election in the annual report required pursuant to subsection (l)(2)(vi) of this section. [EPA-HQ-OAR-2010-0799-9463-A1, p.28]

This language helps to clarify the universe of vehicles subject to the fleet average carbon-related exhaust emission calculation in subsection (h)(3)(1) of § 86.1865-12, and it also provides manufacturers with the ability to harmonize this GHG fleet with the fleet of vehicles subject to CAFE reporting under EPCA and EISA. We encourage EPA to adopt this amendment in the interests of promoting harmonization and minimizing the burden on manufacturers. [EPA-HQ-OAR-2010-0799-9463-A1, p.28]

Response:

With regard to the comment from the Alliance of Automobile Manufacturers, EPA finds that it is directed towards the NHTSA program, and as such, no EPA response is needed.

With regard to the comment from Ford, EPA appreciates the company’s willingness to continue to certify these non-mainland vehicles. However, it would still be the case that these vehicles are not included in the manufacturers’ fleet average for the GHG standard, which is not a desirable result. Nor does EPA understand why the associated administrative burden is so great. Presumably Ford (and any other manufacturer) would have already identified whatever extra-territorial vehicles it sells for purposes of CAFÉ. That is, manufacturers would need to know how many and what these vehicles are in order to keep them out of their CAFÉ calculations. Given that this information is already being gathered, EPA does not perceive why applying that same already-at-hand information to determine the GHG fleet average would add significant additional administrative burden.

9.5. Durability Procedures for Diesel Vehicles

Organization:	Alliance of Automobile Manufacturers

Treatment of Diesel-Fueled Vehicles Under Emissions Durability Demonstration Test Procedures [EPA-HQ-OAR-2010-0799-9487-A1, p91]

All technologies should be treated fairly under the exhaust emission durability demonstration procedures at 40 CFR 86.1823-08. Within these procedures, however, diesel-fueled vehicles are specifically disallowed from making use of bench-aging durability procedures, (40 CFR 86.1823-08(d)), adding significant and unnecessary expense to the durability demonstration for such vehicles. Diesel technology offers a greenhouse gas and fuel consumption reduction opportunity and should be allowed similar flexibility to other fuel technologies under the durability demonstration procedures. Therefore, the Alliance requests that EPA work with manufacturers to develop a bench-aging durability procedure for diesel-fueled vehicles for proposal in a future rulemaking. [EPA-HQ-OAR-2010-0799-9487-A1, p91]

Organization:	Chrysler Group LLC

We urge the agencies to treat diesel vehicles fairly under the EPA durability demonstration procedures, as described in depth in the comments from the Alliance.

Organization:	Mercedes-Benz USA, LLC

All technologies should be treated fairly under the exhaust emission durability demonstration procedures at 40 CFR 86.1823-08. The procedures, however, specifically disallow the use of bench-aging durability procedures for diesel-fueled vehicles. This adds significant and unnecessary expense to the durability demonstration for diesel vehicles. Diesel technology offers a greenhouse gas and fuel consumption reduction opportunity and should be allowed similar flexibility to other fuel technologies under the durability demonstration procedures. DAG therefore agrees with others in the industry in the request that EPA work with manufacturers to develop a bench-aging durability procedure for diesel fueled vehicles for proposal in a future rulemaking. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-5]

Response:

Commenters regarding this issue appear to be aware that the issue they are raising cannot be resolved in this final rule. EPA did not propose any changes to the exhaust emission durability demonstration provisions, and thus is not finalizing any related changes to the regulations. In general, EPA strives for emission standards that are applied equitably across technologies, and as such, we are willing to consider future discussions regarding this issue, and, if appropriate, a future rulemaking action.

Driver Selectable Modes [EPA-HQ-OAR-2010-0799-9487-A1, p.90]

EPA has requested comment on "…whether there is a need to clarify in the regulations how EPA treats driver-selectable modes…" We believe that EPA should continue to use its current methods for dealing with driver-selectable modes and that no additional regulatory clarification is necessary. [EPA-HQ-OAR-2010-0799-9487-A1, p.90]

The current regulations and guidance, administered at the national level, allow common driver-selectable modes to be dealt with in a consistent manner while still allowing flexibility in dealing with any new and unusual modes that may develop. EPA should continue to monitor the use and application of its driver-selectable mode policies and update or refine its guidance as necessary. [EPA-HQ-OAR-2010-0799-9487-A1, p.90]

U.S. Production [EPA-HQ-OAR-2010-0799-9487-A1, p.90]

There are provisions in the proposed regulations that reference U.S. production as a component of applicability or eligibility for that provision. For example, in describing the minimum sales volume threshold for the list of predetermined off-cycle technologies, §86.1866-12(d)(1)(i) states 'The manufacturer may generate a CO_2/g credit ... provided that each technology is applied to the minimum percentage of the manufacturer's U.S. production of passenger automobiles ... for which credit is claimed.' Similarly, the provisions for advanced technology vehicles in §86.1866-12(a)(1) states, "Electric vehicles, plug-in hybrid electric vehicles, and fuel cell vehicles … that are certified, produced, and delivered for sale in the United States … may use a value of zero (0) grams/mile of CO_2 …" [EPA-HQ-OAR-2010-0799-9487-A1, p.90]

A reasonable interpretation of the provisions above could imply they are applicable only to vehicles produced in the U.S. It is the understanding of the Alliance that the agencies do not intend for the applicability or eligibility of the proposed regulations to depend on a vehicle's origin. [EPA-HQ-OAR-2010-0799-9487-A1, p.90]

The Alliance requests that the agencies clarify that the eligibility and applicability of the provisions being proposed are not contingent on a manufacturer producing vehicles in the U.S. We suggest that where the agencies currently reference "U.S. production" in a provision, that language be revised to instead use the term "production for U.S. sale," which is consistent with the intent of the provisions in both the Clean Air Act and the Energy Policy and Conservation Act of 2005, as amended by the Energy Independence and Security Act of 2007. [EPA-HQ-OAR-2010-0799-9487-A1, p.90]

Credits for Aftermarket Sales of Alternative Fuel Systems

Organization: Clean Energy

Currently only original equipment manufacturers (OEM) are required to meet fuel economy regulations. However, a number of aftermarket conversions to natural gas continue to be performed each year. The effect is that a significant supply of potential fuel economy credits for dedicated and dual-fuel NGVs are lost to the OEMs. Since most aftermarket systems also are exempt for the GHG regulations these credits are also lost to the OEMs. To address this situation, EPA and NHTSA should establish procedures to reward the OEMs for aftermarket conversions. [EPA-HQ-OAR-2010-0799-9511-A1, pp.4-5]

Organization: NGV America

Currently only original equipment manufacturers (OEM) are required to meet fuel economy regulations. However, a number of aftermarket conversions to natural gas continue to be performed each year. The effect is that a significant supply of potential fuel economy credits for dedicated and dual-fuel NGVs are lost to the OEMs. Since most aftermarket systems also are exempt for the GHG regulations these credits are also lost to the OEMs. To address this situation, EPA and NHTSA should establish procedures to reward the OEMs for aftermarket conversions. We propose that converters be able to collect and trade FE and GHG credits with the underlying OEM. At each fuel economy reporting interval, the OEM would substitute FE data for the base vehicle with that for the converted NGV. For example, a dedicated vehicle achieving 18 mpg in gasoline mode would be substituted with an NGV achieving 18/0.15= 120 mpg. For purposes of compliance, the OEM would be treated as if they were the manufacturer of record (MOR) for the converted vehicle. To facilitate this, the converter would have to report to the OEM and NHTSA/EPA the number of vehicles sold each reporting period. [EPA-HQ-OAR-2010-0799-9461-A1, p. 12]

Organization: Ferrari

In-use standards and durability

EPA proposes in-use CO_2 standards that would apply throughout a vehicle's useful life, with the standard determined by adding a 10 percent adjustment factor to the model-level emission results. We agree to keep the 10% higher CO_2 standards to take into account the variability involved, such as: [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

• Normal variability in test results. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

• Variability in the production for the same vehicle configuration. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

• Differences in the equipments with different optional items that can affect CO_2 emissions (curb weight, wheels, tires, engine lubricant, and state of maintenance). [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

We agree that manufacturers may demonstrate in-use emissions durability of off-cycle technologies at time of certification, by submitting an engineering analysis describing why the technology is durable and expected to last for the full useful life of the vehicle. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

OBD monitoring of GHG-emissions

We support EPA that is not proposing any OBD requirements regarding CO_2, CH4, and N2O emissions, because these GHG emissions should not deteriorate over the full vehicle life. We appreciate that EPA does not propose at this time OBD monitoring for off-cycle technologies. [EPA-HQ-OAR-2010-0799-9535-A2, pp.12-13]

Applicability of high altitude provisions to greenhouse gases

We agree with EPA that is proposing to retain its current high altitude regulations so manufacturers would not normally be required to submit vehicle CO_2, CH4, and N2O test data for high altitude. Instead, they would submit an engineering evaluation indicating that common calibrations will be utilized at high altitude, and therefore the compliance is assured also in these conditions. [EPA-HQ-OAR-2010-0799-9535-A2, p.13]

The main benefit is to reduce the number of emissions tests to be performed (in labs located at high altitude or with the capability to simulate such conditions) during vehicles certification, especially relevant for small-volume manufacturers. This approach is useful to streamline the emission certification procedure in U.S.A. [EPA-HQ-OAR-2010-0799-9535-A2, p.13]

Civil penalties

Ferrari opposes any increase in civil penalties for CAFE because it will not result in substantial energy conservation and could have a negative impact mainly on small businesses. Increasing the penalty up to 10.00 $ per tenth-mpg per vehicle will increase the burden mainly on few vehicle manufacturers (which already pay a lot of money in fines and/or penalties) which cannot change their products because are typical and identify the uniqueness of the makes. For example, Ferrari traditionally manufactures high-performance sports vehicles. [EPA-HQ-OAR-2010-0799-9535-A2, p.15]

We believe that higher penalties are not an effective method to increase the CAFE in U.S.A. Historically; the penalties have been paid mainly by foreign manufacturers responsible of a relatively limited number of vehicles. [EPA-HQ-OAR-2010-0799-9535-A2, p.15]

Organization: Manufacturers of Emission Controls Association (MECA)

MECA believes that further reductions of hydrocarbon and NO_x emissions from the existing light-duty vehicle fleet can be achieved by revising the current EPA aftermarket converter performance requirements. California has revised their aftermarket converter requirements for light-duty, gasoline vehicles by requiring a higher level of emission performance and longer durability standards. ARB’s regulation eliminates the sale of older aftermarket converter products that have modest performance standards and a limited 25,000 mile warranty, and requires that higher performance and more durable OBD-compliant aftermarket converter products be used on both non-OBD and OBD-equipped vehicles (ARB implemented their revised aftermarket converter requirements in January 2009). These ARB approved OBD-compliant aftermarket converters are warranted for 50,000 miles based on the use of a more aggressive, high temperature, accelerated engine-aging protocol compared to the vehicle durability demonstration currently required by EPA for approved aftermarket converter products. EPA has not updated its aftermarket converter requirements since 1986 and with more than three million aftermarket converters sold per year across the U.S. (based on surveys completed by MECA with aftermarket converter manufacturers), significant additional reductions of hydrocarbon emissions, including toxic hydrocarbon emissions, and NO_x emissions could be achieved with a national aftermarket converter policy that made use of the same higher performance OBD-compliant aftermarket converters available in California. [EPA-HQ-OAR-2010-0799-9452-A3, p.5]

Response:

Driver-Selectable Modes

EPA requested comments on whether there is a need to clarify in the regulations how EPA treats driver-selectable modes (such as multi-mode transmissions and other user-selectable buttons or switches) that may impact fuel economy and GHG emissions in certification testing. See 76 FR 75089. EPA addresses those comments here. The issue of whether user-selectable technologies may be eligible for off-cycle credits is addressed in preamble section II.F and in section 7 of this RTC document. Note also that this discussion pertains specifically to implementing the testing required on the Federal Test Procedure and the Highway Fuel Economy Test as used to generate combined City/Highway GHG and MPG values for each model type for use in calculating fleet average GHG and MPG values. For the purpose of assigning off-cycle credit values that may be based on a driver-selectable technology (see preamble section II.F), where determination of an accurate real-world benefit of the technology is a fundamental goal, the policy described here and in current EPA guidance may not be appropriate.

New technologies continue to arrive on the market, with increasing complexity and an increasing array of ways a driver can make choices that affect the fuel economy and greenhouse gas emissions. For example, some start-stop systems may offer the driver the option of choosing whether or not the system is enabled. Similarly, vehicles with ride height adjustment or grill shutters may allow drivers to override those features. Under the current regulations, EPA draws a distinction between vehicles tested for purposes of CO_2 emissions performance and fuel economy and vehicles tested for non-CO_2 emissions performance. When testing emission data vehicles for certification under Part 86 for non-CO_2 emissions standards, a vehicle that has multiple operating modes must meet the applicable emission standards in all modes, and on all fuels. Sometimes testing may occur in all modes, but more frequently the worst-case mode is selected for testing to represent the emission test group. For example, a vehicle that allows the user to disengage the start-stop capability must meet the standards with and without the start-stop system operating. Similarly, a plug-in hybrid electric vehicle is tested in charge-sustaining (i.e., gasoline-only) operation. Current regulations require the reporting of CO_2 emissions from certification tests conducted under Part 86, but EPA regulations also recognize that these values, from emission data vehicles that represent a test group, are ultimately not the values that are used to establish in-use CO_2 standards (which are established on much more detailed sub-configuration-specific level) or the model type CO_2 and fuel economy values used for fleet averaging under Part 600.

When EPA tests vehicles for fuel economy and CO_2 emissions performance, user-selectable modes are treated somewhat differently, where the goals are different and where worst-case operation may not be the appropriate choice for testing. For example, EPA does not believe that the fuel economy and CO_2 emissions value for a PHEV should ignore the use of grid electricity, or that other dual fuel vehicles should ignore the real-world use of alternative fuels that reduce GHG emissions. For PHEVs and dual fuel CNG vehicles, where the consumer pays an up-front premium for the vehicle but can recoup that investment by using a less expensive fuel, the regulations allow the use of utility factors to weight the CO_2 performance on the conventional fuel and the alternative fuel. Similarly, non-CO_2 emission certification testing may be done in a transmission mode that is not likely to be the predominant mode used by consumers. Testing under Part 600 must determine a single fuel economy value for each model type for the CAFE program and a single CO_2 value for each model type for EPA's program. With respect to transmissions, Part 600 refers to 40 CFR 86.128, which states the following:

> "All test conditions, except as noted, shall be run according to the manufacturer's recommendations to the ultimate purchaser, *Provided*, That: Such recommendations are representative of what may reasonably be expected to be followed by the ultimate purchaser under in-use conditions."

For multi-mode transmissions EPA relies on guidance letter CISD-09-19 (December 3, 2009) to guide the determination of what is "representative of what may reasonably be expected to be followed by the ultimate purchaser under in-use conditions." If EPA can make a determination that a certain mode is the "predominant" mode (meaning nearly total usage), then testing may be done in that mode. However, if EPA cannot be convinced that a single mode is predominant, then fuel economy and GHG results from each mode are typically averaged with equal weighting. There are also detailed provisions that explain how a manufacturer may conduct surveys to support a statement that a given mode is predominant. However, CISD-09-19 only addresses transmissions, and states the following regarding other technologies:

> "Please contact EPA in advance to request guidance for vehicles equipped with future technologies not covered by this document, unusual default strategies or driver selectable features, e.g., hybrid electric vehicles where the multimode button or switch disables or modifies any fuel saving features of the vehicle (such as the stop-start feature, air conditioning compressor operation, electric-only operation, etc.)."

The unique operating characteristics of these technologies often requires that EPA determine fuel economy and CO_2 testing and calculations on a case-by-case basis. Because the CAFE and CO_2 programs require a single value to represent a model type, EPA must make a decision regarding how to account for multiple modes of operation. When a manufacturer brings such a technology to us for consideration, we will evaluate the technology (including possibly requiring that the manufacturer give us a vehicle to test) and provide the manufacturer with instructions on how to determine fuel economy and CO_2 emissions. In general we will evaluate these technologies in the same way and following the same principles we use to evaluate transmissions under CISD-09-19, making a determination as to whether a given operating mode is predominant or not (using the criteria for predominance described in CISD-09-19). These instructions are provided to the manufacturer under the authority for special test procedures described in 40 CFR 600.111-08. EPA would apply the same approach to testing for compliance with the in-use CO_2 standard, so testing for the CO_2 fleet average and testing for compliance with the in-use CO_2 standard would be consistent.

EPA requested comment on whether the current approach and regulatory provisions are sufficient, or whether additional regulations or guidance should be developed to describe EPA's process. Manufacturers, who were the only commenters on this issue, commented that the current case-by-case approach is adequate, and EPA agrees. We recognize that no regulation can anticipate all options, devices, and operator controls that may arrive in the future, and adequate flexibility to address future situations is an important attribute for fuel economy and CO_2 emissions testing. We believe it would be difficult at this time to construct regulations that adequately and generically address the use of multiple modes in GHG/MPG testing.

U.S. Production

EPA agrees that requirements are not limited to vehicles produced in the U.S., and are not contingent on a manufacturer producing vehicles in the U.S. EPA has revised the regulatory language where appropriate to be consistent with the commenter's suggestion.

Credits for Aftermarket Sales of Alternative Fuel Systems

EPA discusses the applicability of GHG standards to aftermarket conversions in the preamble to the final rule in section III.E.7. One of the relevant points is that credits are generated based on the determination of a fleet average GHG value, and fleet average standards are generally not appropriate for aftermarket conversions. This is because the vehicles that are converted have already been included in the fleet calculations for the OEM. It is possible that at some point EPA and NHTSA could develop a methodology to appropriately account for the emissions impact of aftermarket conversions, but there are a number of other issues that have to be resolved and that EPA was not prepared to address in this rulemaking. For example, it is not immediately clear how the agencies would account for vehicle conversions that take place mid-way through a vehicle's useful life. Given the complexities involved, and the fact that we did not propose a credit program for aftermarket conversions, EPA is not finalizing such a program in this action.

In-use Standards and Durability

EPA agrees with the commenter. The 10% adjustment used to create the in-use emission standard was finalized in the MY 2012-2016 program, and EPA did not propose to change it in this rulemaking. Thus it is being maintained for the MY 2017-2025 program.

OBD Monitoring of GHG Emissions

EPA agrees with the commenter. The MY 2012-2016 program was finalized such that OBD monitoring is not required for CO_2 ,N_2O, and CH_4 emissions, and EPA did not propose to change these provisions for the 2017 and later model years. Consequently, the exclusion of these emission constituents from OBD monitoring continues to be part of the MY 2017 and later program.

Applicability of High Altitude Provisions to Greenhouse Gases

EPA agrees with the commenter. Under the current program, vehicles would be required to meet the CO2, N2O, and CH4 standards at high altitude, but would not normally be required to submit vehicle test data at high altitude. Instead, manufacturers may submit an engineering analysis indicating that common calibration approaches will be used at high altitude. EPA did not propose to change these provisions for the 2017 and later model years, or otherwise reconsider or reassess those provisions. Consequently, the provisions supported by the commenter will continue to be part of the MY 2017 and later program.

Civil Penalties

EPA will not respond to the comments that are directed towards the civil penalties that apply under NHTSA's CAFE program.

Aftermarket Catalysts

EPA finds that the comment from MECA regarding EPA's aftermarket catalyst program is not relevant to the proposed program, and thus a response is not warranted.

We support the credit approach taken by the agencies.

Organization: Association of Global Automakers, Inc. (Global Automakers)

We also support the flexibility mechanisms and credits that the agencies propose to make available. These provisions enhance the ability of manufacturers to meet market demand, while maintaining the emissions and energy security benefits of the program. They also provide another means of dealing with the uncertainty associated with the out year standards. The various credits work in different ways, all of which are important. [EPA-HQ-OAR-2010-0799-9466-A1, p.1]

The credit banking and trading system provides an incentive for manufacturers to implement advanced technologies at early dates. [EPA-HQ-OAR-2010-0799-9466-A1, p. 1]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 66.]

Organization: BMW of North America, LLC

BMW supports the proposed flexibilities such as averaging, credit banking, extended approach for off-cycle technologies as well as retaining the approach for A/C credits. These flexibilities are needed in order for manufacturers to achieve overall regulatory compliance in a cost effective manner. [EPA-HQ-OAR-2010-0799-9579-A1, p.5]

BMW supports the continuation of the credit banking scheme as proposed. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 1]

Organization: Chrysler Group LLC

To provide these levels of improvement in the most cost-effective and customer acceptable manner, manufacturers need maximum flexibility. The proposals by the agencies to continue and improve flexibility mechanisms and to offer incentives to encourage early adoption of advanced technologies are helpful and will be an integral part to meeting the National Program goals. [EPA-HQ-OAR-2010-0799-9495-A1, p.2]

Organization: Eaton Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 186-187.]

Eaton believes it is vital that the rule maintains the flexibility to adapt the solutions that can be rapidly adopted by OEMs and accepted by consumers. An example is the increased use of supercharged and mild hybrid technologies that provide fuel savings and performance with return on investments that is acceptable to the average consumer.

The proposed rule provides regulatory incentives that foster innovation and technology deployment. We believe that many of the technologies needed to achieve the proposed standards are available. Some are already in use, while others will benefit from the new paradigm these proposed regulations will provide. Working with our OEM partners, Eaton looks forward to providing high performance and cost-effective fuel efficient technologies.

Organization: Ecology Center

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 190.]

The Ecology Center would also like to express support for the flexibility mechanisms in the proposed standards.

Organization: Ford Motor Company

Program Flexibilities: Finally, it is important for the rules to include program flexibilities that provide manufacturers with compliance options, and that provide appropriate incentives for the deployment of technologies offering real-world fuel economy and GHG benefits not reflected in the test procedures. The proposal for model years 2017 through 2025 retains and enhances the flexibilities of the earlier rulemaking. Opportunities to acknowledge the environmental impact of more efficient air-conditioning technologies, new refrigerants, real-world fuel economy benefits from non-traditional technologies, and the acceleration of more advanced technologies, will encourage the adoption and penetration of the innovations needed to achieve our aggressive national goals. [EPA-HQ-OAR-2010-0799-9463-A1, p.2]

Ford applauds the efforts of EPA and NHTSA to incorporate a range of compliance mechanisms into the proposed rules. These include credits for innovations such as off-cycle technologies, improvements in air-conditioning systems designed to minimize refrigerant leakage, and the promotion of advanced technologies that operate on a variety of alternatives to traditional gasoline. These compliance mechanisms are fully consistent with the goals of the One National Program, and they also provide manufacturers with needed flexibility to comply with a demanding set of standards. The agencies have recognized that automobile manufacturers come to these regulations with varying product line-ups, different marketing strategies, and a range of capabilities with respect to fuel economy technologies. In this context, a one-size-fits-all regulatory program would be very problematic. Appropriately, the proposed rule offers manufacturers flexibility by enabling them to earn and apply credits for various actions tied to the real-world benefit these technologies provide in regard to both fuel efficiency and greenhouse gas reduction. [EPA-HQ-OAR-2010-0799-9463-A1, p.10]

Organization: General Motors Company

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 36.]

Moving into my second comment, General Motors fully supports the flexibilities in this proposal. Some may criticize them, but the flexibilities included go directly towards real CO_2 reduction and the furthering of advanced technologies.

The flexibilities do provide some compliance opportunity for the manufacturers in the future, but importantly these are already assumed in both of the agencies' assessment of the future of fuel economy levels that are anticipated under this proposal. As a result they are absolutely necessary for us to achieve the equivalent compliance levels anticipated.

Organization: Hyundai America Technical Center

While we believe the standards are achievable, doing so will not be easy and it will depend on additional technology breakthroughs and consumer acceptance. Therefore, Hyundai finds the flexibilities and incentives included in the proposal to be important. Furthermore, we prefer that the incentives be technology-neutral and performance-based so that all OEMs have an equal opportunity to develop technology and achieve the standards. [EPA-HQ-OAR-2010-0799-9547-A1, p.2]

Hyundai appreciates that there are a number of flexibilities in the proposal that address automaker's differing strategies for creating a fuel efficient fleet. For example, some manufacturers are focusing resources on electric vehicles and will receive credit multipliers for expanding that market. Others will improve the fuel efficiency of cargo-carrying full-size pick-up trucks and the agency is providing additional incentives for that improvement. Some makers plan to focus on fuel efficiency leadership with gasoline vehicles, and CARB has adopted a provision to allow those automakers to offset part of the zero emission vehicle mandates for a limited time if it is possible to over-comply with these challenging GHG and CAFE standards. Should it be possible that automakers are capable of significantly over-complying with the EPA and NHTSA requirements; this will be important information to the agencies at the time of the mid-term review regarding the feasibility of achieving the standards. We appreciate and support the government's recognition of varying automaker strategies by providing a variety of incentives to maximize performance in each area. However, we have several comments on areas where we believe modifications to the credit methodologies could improve the program. [EPA-HQ-OAR-2010-0799-9547-A1, pp.3-4]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 172-173.]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 22-24.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 21-23.]

Organization: Johnson Controls, Inc.

Credits are an important tool which can be positively applied and provide the industry necessary options to achieve future standards. [NHTSA-2010-0131-0253-A1, p. 2]

Continuing the use of credits and regulatory flexibilities, as proposed, is necessary and appropriate, but require some revisions. [NHTSA-2010-0131-0253-A1, p. 4]

Organization: Motor & Equipment Manufacturers Association (MEMA)

Continuing the use of credits and regulatory flexibilities, as proposed, is necessary and appropriate, but require some revisions. MEMA provides some proposals for the agencies' consideration. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

Continuing the use of credits and regulatory flexibilities, as proposed, is necessary and appropriate. Generally, MEMA believes that the agencies have provided adequate program flexibilities. [EPA-HQ-OAR-2010-0799-9478-A1, p.5]

Credits are an important tool and can be positively applied and provide the industry necessary options to achieve future standards. [EPA-HQ-OAR-2010-0799-9478-A1, p.7]

Continuing the use of credits and regulatory flexibilities is necessary and appropriate, but does require some revisions. [EPA-HQ-OAR-2010-0799-9478-A1, p.13]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 71-72.]

The NESCAUM states support inclusion of flexibility mechanisms in the proposed rule providing manufacturers with pathways to compliance and a range of technologies efficient to meet the goal of the program.

Organization: Toyota Motor North America

The agencies have proposed a variety of credit programs and compliance flexibilities, which Toyota generally supports. These credits and flexibilities are an import aspect of the proposed standards because they allow manufacturers to better manage technology investment and deployment while achieving overall environmental and energy goals. Specific comments about the programs are provided below. [EPA-HQ-OAR-2010-0799-9586-A1, p.9]

Organization: United Automobile Workers (UAW)

Fourth, the UAW appreciates and supports the proposed inclusion by EPA of program flexibilities that will help automakers comply with the tougher standards at a lower cost. These features of the proposal are important for their recognition of the long product cycles of the automotive industry and the inherently “clunky” nature of technology upgrades timed to coincide with major updates of existing models or the introduction of completely new models. [EPA-HQ-OAR-2010-0799-9563-A2, p.2]

The UAW supports the credit averaging, trading and banking provisions proposed separately by NHTSA and EPA, which are a continuation of the comprehensive program established for 2012–2016. NHTSA’s proposal is in line with the dictates of EISA, while EPA has taken advantage of the provisions of the Clean Air Act to propose banking and trading provisions that allow more flexibility but still maintain the features necessary for a harmonized common system of regulation with NHTSA’s proposed rule. The UAW believes that EPA’s proposal is sensible and recognizes the real benefits of early over-compliance by manufacturers. [EPA-HQ-OAR-2010-0799-9563-A2, p.2]

Response:

The commenters above express support for credits programs and flexibilities in general and EPA concurs that these are important aspects of the program. As noted by some commenters, these provisions allow manufacturers to better manage technology deployment, allowing for a smoother implementation of standards. In addition to comments generally supporting flexibilities, many commenters also provided specific comments on the proposed flexibilities, which are addressed in other sections of this Response to Comments document, including; off-cycle credits in Section 7, incentives for EVs, PHEVs, and FCVs in Section 4, and game changing technologies for full size pick-up trucks in Section 5. Specific comments regarding averaging, banking, and trading are addressed in this section below.

10.1.1. Carry-Forward and Carry-Back of Credits

Organizations Included in this Section

Center for Biological Diversity

General Motors Company
Motor & Equipment Manufacturers Association (MEMA)
Northeast States for Coordinated Air Use Management (NESCAUM)
Toyota Motor North America
Volkswagen Group of America

Organization: Center for Biological Diversity

The credit loophole would be made even larger were the Agencies to implement their "one time" proposal to extend the credit carry-forward provision even beyond the five-year period Congress has permitted.66 In essence, this provision would allow manufacturers to carry forward credits earned as early as two years ago, in 2010, all the way through 2021, or for more than a decade. It is self-evident that allowing manufacturers to evade increasing fuel efficiency for this long is directly contrary to Congressional intent. Nothing in the statute and nothing in the record justifies any such extension. To the contrary, the fact that Congress specifically limited the time period for carry-forward credits to five years plainly speaks against this industry give-away. We request that the Agencies abandon this proposal. Similarly, the Agencies may not increase the availability of credit transfers between the two fleets, passenger vehicles and light trucks. The existence of statutory caps for these transfers67 is a strong indication of Congressional disapproval of extending them further, and the Clean Air Act's silence on that issue does not override EISA's statutory restriction. [EPA-HQ-OAR-2010-0799-9479-A1, pp. 13-14]

---

66 NPRM, 76 Fed. Reg. at 74,877. The "justification" for this give-away is ludicrous. Nothing is needed to "facilitate the transition to the increasingly more stringent standards" for light trucks: these standards are already egregiously lax and will in any event not begin until 2017. *See* NPRM, 76 Fed. Reg. 74877. [EPA-HQ-OAR-2010-0799-9479-A1, p. 13]

67 49 U.S.C. § 32903(g)(3). [EPA-HQ-OAR-2010-0799-9479-A1, p. 14]

Organization: Ferrari

7) Credits

Ferrari supports all the credit provisions set forth in the present EPA proposal including a one-time carry-forward of any credits generated in MY 2010-2016 to be used anytime through

MY2021. This would provide greater flexibility for manufacturers in using the credits they have generated. [EPA-HQ-OAR-2010-0799-9535-A2, p.13]

Organization: Fisker Automotive, Inc.

Support the proposal to carry over MY 2010-2015 credits through MY 2021. This proposal would provide added utility to credits generated early in the program, which helps to incentivize early adoption of fuel saving technologies. [EPA-HQ-OAR-2010-0799-9266-A1, p. 4]

Organization: Ford Motor Company

Credit Carry-forward

We support EPA's proposal to provide a one-time carry-forward of greenhouse gas reduction credits through the 2021 model year, thus rewarding early investment and providing better flexibility to account for market conditions that may impact year-over-year compliance. We concur with the agency's assessment (76 Fed. Reg. 74968) that, "provisions are not expected to change the emissions reductions achieved by the standards, but should significantly reduce the cost of achieving those reductions." While we acknowledge that NHTSA is legislatively bound to restrict fuel economy credit carry-forward to only 5 years, it must be noted that this is disconnect between the two programs, and may unfortunately drive product strategies for one program that would not otherwise be required by the other. We encourage NHTSA to consider other alternatives that may enable the agency to offset this difference between the GHG and CAFE programs. [EPA-HQ-OAR-2010-0799-9463-A1, p. 21]

Organization: General Motors Company

GM supports the proposed EPA provision to allow credit carry forward beyond 5 years, such that any credits generated from model year 2010 through model year 2016 will be able to be used any time through model year 2021. [EPA-HQ-OAR-2010-0799-9465-A1, p. 3]

Organization: Motor & Equipment Manufacturers Association (MEMA)

The NPRM clearly states the agencies will allow for carry-back/carry-forward credits, as per their respective statutes' stated limitations. [EPA-HQ-OAR-2010-0799-9478-A1, pp.9-10]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

Flexibility Mechanisms & Credits

NESCAUM supports EPA's proposal to include flexibility mechanisms to provide manufacturers with the means to incorporate a range of technologies to meet the requirements of the proposed standards. Allowing credit transfers between a manufacturer's passenger car and light truck fleet will likewise facilitate compliance without reducing the GHG benefits of the program, as do provisions for carry-forward and carry-back of generated credits. [EPA-HQ-OAR-2010-0799-9476-A1, p. 2

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 72.]

Organization: Toyota Motor North America

Carry-forward and Carry-back Credits [EPA-HQ-OAR-2010-0799-9586-A1, p.9]

EPA and NHTSA propose to continue allowing credits earned by a manufacturer to be applied for a period of up to five model years after the model year in which they were earned. Further, the agencies propose to continue to offer the flexibility to 'borrow' credits up three years into the future to address potential compliance shortfalls in a given model year. [EPA-HQ-OAR-2010-0799-9586-A1, p.9]

These 5-year 'carry-forward' and 3-year 'carry-back' provisions are subject to certain adjustments and limits which differ between NHTSA's CAFE regulations and EPA's GHG regulations. Toyota supports the 5-year carry-forward and 3-year carry-back proposals. [EPA-HQ-OAR-2010-0799-9586-A1, p.10]

Organization: Volkswagen Group of America

3.3. FIVE YEAR DEBIT CARRY-BACK

Volkswagen proposes that EPA and NHTSA amend the NPRM to provide for 5 year carry back of debits. [EPA-HQ-OAR-2010-0799-9569-A1, p. 28]

Response:

EPA is retaining the credit carry-forward and carry-back credit provisions as proposed. Section III.B.4 of the preamble provides EPA's response to the comments regarding credit carry-forward, including both the one-time credit carry-forward of MY 2010-2016 credit to MY 2021, VW's comment regarding five year credit carry-back, and Center for Biological Diversity comments regarding unlimited credit transfers in EPA's program. In addition to the discussion in the preamble, we add the following in response to the comments of the Center for Biological Diversity. The ABT program does not create a "credit loophole", as CBD would have it, but provides needed flexibility and lead time allowing EPA to adopt standards which are more stringent than otherwise would be possible, and reasonably encourages earlier introduction of control technology into the fleet. See 76 FR 57127-129. When credits generated under that program are carried forward to later model years, the carry forward reflects real-world emission reductions, not perpetuation of a loophole. The commenter also argues that, because the Clean Air Act is silent on the issue of credit carry forward, the GHG rules cannot extend that period beyond what is allowed under EISA. The argument that EPA's Clean Air Act authority is constrained by EPCA/EISA was rejected by the Supreme Court in State of Massachusetts v.

EPA, 549 U.S. at 531-32, and more recently by the D.C. Circuit in Coalition for Responsible Regulation v. EPA. See No. 09-1322 (D.C. Cir. June 26, 2012) slip op. pp. 41-42.

10.1.2. Credit Transfers between Cars and Trucks and Credit Trading between Manufacturers

Organizations Included in this Section

Ferrari
Mercedes-Benz USA, LLC
Northeast States for Coordinated Air Use Management (NESCAUM)
Tesla Motors, Inc.
United Automobile Workers (UAW)
Volkswagen Group of America

Organization: Ferrari

We think that there should not be a cap in the amount of credit transferred or traded, in order to give manufacturers the greatest flexibility to comply with the CAFE standards and to harmonize with the corresponding EPA GHG credit provisions. [EPA-HQ-OAR-2010-0799-9535-A2, p.15]

Organization: Mercedes-Benz USA, LLC

DAG also supports the overall structure of the attribute-based program and the provisions for transferring and trading credits. [This comment can also be found in section 2.1 of this comment summary.] [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

DAG supports allowing credits for Class 2b vehicles earned in the medium duty program to be applied in the light duty truck programs as well. The medium duty category is similar in approach to the light duty program, utilizes similar testing methodology and requires significant achievement to reach the requirements. The similarities between the programs support allowing for the flexibility of trading credits between them. [EPA-HQ-OAR-2010-0799-9483-A1, p. 3]

Credits for Class 2b Medium Duty Trucks and Vans

EPA and NHTSA recently established new programs aimed at reducing GHG emissions from medium and heavy duty trucks and van. The program covers MYs 2014-2018. NHTSA's standards are voluntary for MYs 2014-2015, but NHTSA has indicated that it will begin tracking credits when a manufacturer opts into the program. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-16]

The agencies purposely structured the medium/heavy duty truck and van program to be akin to the light duty program. The program is attribute based with the standards set pursuant to a mathematical function. While the agencies added elements to the footprint based attribute to account for the functionality of these vehicles, the agencies also made clear that the measured performance values for CO_2 will generally be equivalent to fuel consumption. The compliance with the light duty and medium duty standards will be measured through similar dynamometer testing. Indeed, the same engine and after treatment technologies that will be used to comply with the Class 2b vehicles in the medium duty program will also be used to comply with the light truck program. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-16]

DAG considers the standards established for medium duty trucks and vans to be challenging and aggressive. For example, as shown in the illustration below, compliance will require that many 6 cylinder diesel engines be downsized to 4 cylinder diesel engines. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-16]

There is ample legal authority to apply medium duty truck and van credits within the light duty programs. EPA has broad discretion under the Clean Air Act to structure programs to ensure that it promotes public health and welfare with cost-effective technology feasibly applied. The agency has often created Average, Banking and Trading (ABT) programs as part of its emissions regulations. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-17]

In the medium and heavy duty rule, the agencies effectively created three separate programs: One for tractor/trailers; one for vocational vehicles; and one for medium and heavy duty trucks and vans. The former two programs are similar and involve vehicles where emissions regulation has in the past been focused exclusively on engines. In those programs, EPA designed a computer model to generate data relating to the vehicle-portion of those regulations. The latter program, on the other hand, is vehicle based - just as with the light duty GHG program - and in fact involves vehicles in the same weight range but subject to different use. Vehicles that meet certain criteria designed to identify 'work trucks' are placed within the medium duty truck and van program; while vehicles meeting certain criteria designed to identify 'medium duty passenger vehicles' are placed within the light duty program. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-17]

The agency initially proposed to restrict each ABT program to its own category within the heavy duty rule, but in the final rule relaxed this restriction and instead defined three heavy duty averaging sets and decided to allow credits to be used within those averaging sets. The first set of Light Heavy Duty vehicles is comprised of trucks within Classes 2b-5. While the agency stated in that rule that credits could be transferred across the heavy duty averaging sets but not between the heavy duty groupings and light trucks, we believe the agency should reconsider that statement as applied to Class 2b vehicles. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-17]

Allowing credit transfers in this Class between the light duty and light heavy duty vehicle fleets is consistent with the agency's general structure to treat like vehicles alike. The basic programs categorize vehicles by general type, construction and use. The ABT program recognizes that similarly weighted vehicles are likely to utilize the same engine and after-treatment technologies to reach and exceed compliance. EPA established a system whereby similar vehicles using similar technologies could share credits across the various programs. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-17]

The same reason allowing credits earned on Class 2b vehicles to be applied within other heavy duty categories applies even more strongly with regard to the light duty fleet. Many vehicles within the light duty fleet are essentially the same or similar to many of the Class 2b vehicles - they are either 'work trucks' or 'medium duty passenger vehicles' depending on their particular configuration. The same engine, transmission and after-treatment technology will be applied to Class 2b vehicles, whether they are in the light duty or the medium and heavy duty program. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-17]

Nothing in the Clean Air Act prohibits the agency from using its discretion to harmonize and promote its greenhouse gas program across similar vehicles and to promote more broadly the application of emissions reducing technology. The agency should exercise this discretion in a limited fashion to allow credits earned on Class 2b vehicles in the medium truck and van program to be applied in the light duty program as well. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-17]

NHTSA also has the legal authority to apply credits developed in its Medium and Heavy Duty Fuel Consumption Program. As noted above, although NHTSA's program is voluntary for MYs 2014-2015, the agency has made clear that it will begin to track credits beginning with a company's decision to opt into the program. Although the legislation mandating NHTSA's program did not expressly authorize a credit program, NHTSA nonetheless exercised its discretion to adopt one and to remain harmonious with the EPA program. NHTSA also noted in the medium and heavy duty fuel consumption program that it has considerably more leeway within the medium and heavy duty program to establish flexibilities and to include consideration of credits within its standard setting than it does under the light duty program. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-17-A-18]

The fact that EPCA's credit provisions at 49 U.S.C. § 32903 do not expressly refer to credits earned in the fuel consumption program promulgated under § 32022(k) does not preclude NHTSA from exercising this authority. Applying the credits for Class 2b vehicles in the medium duty program to the light duty program is an extension of the same discretion that led and authorized NHTSA to develop the medium duty credit program initially. NHTSA has long construed the EPCA provisions to be limitations on its authority rather than restrictive contours of its authority. NHTSA should use this same authority to extend the credits in a limited fashion, and along the same lines as EPA, to allow credits generated on Class 2b medium duty trucks and vans to be applied in the light duty CAFE program. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-18]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

Allowing credit transfers between a manufacturer’s passenger car and light truck fleet will likewise facilitate compliance without reducing the GHG benefits of the program [EPA-HQ-OAR-2010-0799-9476-A1, p. 2]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 72.]

Organization: Tesla Motors, Inc.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 94.]

We applaud the use of inter-tradability of credits. They support very critically the rollout of first-generation technology.

Organization: United Automobile Workers (UAW)

The proposal also contains limits on credit trading and transfers that prohibit the use of trading and transfers to satisfy the alternative minimum standard for domestically produced passenger cars. This accurately and effectively implements the provisions Congress included in EISA. [EPA-HQ-OAR-2010-0799-9563-A2, p.2]

Organization: Volkswagen Group of America

The transfer of credits is unlimited under EPA's GHG program. Volkswagen recognizes that the transfer from trucks to cars is limited under NHTSA's CAFE program. However, there is no limit for transfer within the truck compliance fleet, meaning unlimited transfer from larger trucks to smaller trucks or SUVs. [EPA-HQ-OAR-2010-0799-9569-A1, p. 25]

In light of this, Volkswagen is proposing:

Any credits earned by larger trucks and full-size pick-ups due to either the reduced stringency 8 or the unique full-size truck credit program should remain available only amongst large trucks and not be transferable or bankable for use in other segments or compliance fleets. [EPA-HQ-OAR-2010-0799-9569-A1, p. 27]

Volkswagen expects no reasonable protest from stakeholders to limiting transferability since according to EPA's prediction there would be no need to transfer credits away from non-compliant or debit stricken full-size trucks. Should stakeholders protest and claim that this somehow infringes on a flexibility that could be valuable to their future corporate compliance strategy, Volkswagen would then suggest that EPA reconsider the expected burden on full-size trucks. [EPA-HQ-OAR-2010-0799-9569-A1, p. 27]

An alternative would be to provide lower annual reduction percentages and 'game-changing' credits available to a broader range of vehicles, including other trucks and even passenger cars. [EPA-HQ-OAR-2010-0799-9569-A1, p. 27]

[See Figure 3-1 on p. 28 of Docket number EPA-HQ-OAR-2010-0799-9569-A1]

Volkswagen suggests the agency consider a broader range of vehicle capabilities which may require additional flexibility in establishing an achievable standard such as cargo volume, seating capacity, off-road or all-weather capability, or any other attribute which may preclude the adoption of certain fuel saving technologies. This is equally true for trucks of all sizes, minivans, and even some passenger cars. [EPA-HQ-OAR-2010-0799-9569-A1, p. 28]

8 Credits earned from the reduced percent stringency relative to what the larger trucks target would have been had it been subjected to the fleetwide truck percent reduction for that model year.

Response:

While EPA agrees with DAG that transfers between heavy-duty vehicles and light-duty vehicles is not precluded by the CAA, EPA does not agree that such trading should be allowed at this time. Section III.B.4 of the preamble addresses DAG comments regarding the use of heavy-duty vehicle GHG credits in the light-duty vehicle program. In addition, we note that DAG further refined its comments in a meeting with EPA Staff on July 18, 2012. The company further suggested that a medium heavy duty engine could generate credits which could be used in the light duty sector if a 4 cylinder engine is used which engine is also used in light duty applications and the total amount of credits is capped. For the reasons stated in preamble section III.B.4, this comment still remains outside the scope of the proposal. Among other things, acting on it would necessitate amending the heavy duty GHG standards, which allow averaging only between specified averaging sets. There was no notice that the agencies might amend the heavy duty GHG standards as part of this rulemaking.

EPA does not agree with VW's comments that transfers of truck credits to the passenger car category should be restricted. VW's comments regarding truck credits are addressed in Section II.F.3 of the preamble and also III.D.6 where the credits program is discussed in the context of the stringency of the truck standards.

10.1.3. Over Compliance Credits for Use in the California ZEV Program

Organizations Included in this Section

Chrysler Group LLC
Hyundai America Technical Center
Mitsubishi Motors R&D of America, Inc. (MRDA)
Union of Concerned Scientists (UCS)

Organization: Chrysler Group LLC

Chrysler also provides comment on California's 2017-2021MY ZEV Program greenhouse gas over-compliance credit provision, the sales projections utilized by the agencies for this proposed rule, and treatment of diesel vehicles. [EPA-HQ-OAR-2010-0799-9495-A1, p.6]

The California Air Resources Board ("ARB") has approved new Zero Emission Vehicle ("ZEV") regulations for MYs 2018-2021 that, when finalized, will include a provision providing that over-compliance with the federal GHG standards in the prior MY may be used to reduce a manufacturer's ZEV obligation in the next MY (the "ZEV Over-Compliance Provision"). The proposed federal GHG program does not account for or address the potential impacts of the ZEV Over-Compliance Provision on the federal GHG standards. EPA should clarify that the ZEV

Over-Compliance Provision interferes with the EPA standards and is preempted. [EPA-HQ-OAR-2010-0799-9495-A1, p.20]

Section 202(a)(1) of the Clean Air Act provides EPA with general authority to establish emissions standards for motor vehicles and engines. Section 202(a)(2) requires that the EPA standards take effect after such period as EPA finds necessary for the development and application of the requisite technology, considering cost of compliance within that period. [EPA-HQ-OAR-2010-0799-9495-A1, p.20]

EPA has explained both in the MY 2012-2016 rule and the proposal for MY 2017-2025 its approach to the statutory factors in setting standards under Section 202(a)(1). In the MY 2017-2025 proposal, EPA identifies the relevant factors, including availability of technology, cost (including impacts on the industry and consumers), energy impacts, and safety. *See* 76 Fed. Reg. at 74,901, 74,903 and 74,905 (MY 2017- 2025 proposal preamble). In both the MY 2012-2016 final rule and the MY 2017-25 proposal, EPA expressed confidence that the standards at issue strike a reasonable balance considering these factors. For MY 2012-16, EPA explained that it adopted standards it considers feasible and that “there are compelling reasons not to adopt more stringent standards, based on reasonable weight of the statutory factors, including available technology, its cost, and the lead time necessary to permit its development and application.” 75 Fed. Reg. 25,324, 25,468 (May 7, 2010). In the MY 2017-25 proposal, EPA explained that it is “confident that the standards are an appropriate balance of the factors to consider under section 202(a).” 76 Fed. Reg. at 74,975. [EPA-HQ-OAR-2010-0799-9495-A1, p.20]

Chrysler agrees that the proposed standards strike an appropriate balance of the statutory factors as described by EPA in the preamble to the proposal. However, California’s ZEV Over-Compliance Provision will make the national standards more difficult to achieve. This is because National Program greenhouse gas credits used to reduce ZEV obligations would have to be *retired*,33 and accordingly not be available to offset manufacturer-specific under-compliance in the federal program.34 As a result, we would expect overall GHG emissions necessarily to be lower (more stringent) than that which would occur absent the California ZEV Over-Compliance Provision. Removing over-compliance credits from the federal GHG program makes those credits unavailable in the federal GHG “emissions credit market” for automaker’s use in complying with the federal standards. This diversion of federal GHG over-compliance credits for another purpose makes compliance more difficult because there are fewer credits to use, effectively increasing the stringency of the federal GHG standards. As a result, California’s 2018-2025 MY ZEV Program standards, as promulgated with the ZEV Over-Compliance Provision, do impose an additional burden on manufacturers, not accounted for in the balance of relevant statutory factors EPA struck to support the federal MY 2017-25 GHG standards. In short, the California ZEV Over-Compliance Provision disturbs EPA’s careful balance in setting the federal standards, and indeed interferes with that balance. [EPA-HQ-OAR-2010-0799-9495-A1, pp.20-21]

EPA should address in this rulemaking the effect of the California ZEV Over-compliance Provision. Because the EPA standards as proposed, (which Chrysler supports, subject to the comments herein), strike an appropriate balance of the statutory factors under Section 202(a), EPA should explain that in doing so EPA is effectively precluding the validity of California’s

ZEV Over-Compliance Provision. Specifically, the California ZEV Program, as revised to add this provision, would be preempted under Section 209(a) of the Clean Air Act unless granted a waiver (or found to be within the scope of an existing waiver) under Section 209(b). Section 209(b) specifies that no such waiver shall be granted if California's standards "are not consistent with section [202(a)]." The California standards, if revised in final to include the ZEV Over-Compliance Provision, would impose an additional burden on standards that EPA already set at a level that is appropriate based on the statutory factors under Section 202(a). Accordingly, such California standards would interfere and be inconsistent with the federal standards. Thus, EPA may not grant a waiver to a California program that contains this component, and the California program with that component would remain preempted. [EPA-HQ-OAR-2010-0799-9495-A1, p.21]

Were EPA not to conclude that the California Over-Compliance Provision is preempted, EPA would theoretically have to relax the federal standards once California adopts its provision to apply to the 2017- 2025 federal program, to account for the effective increase in stringency that California's provision would cause. In this manner, EPA might theoretically take into account the California provision in setting standards and thereby re-strikes the balance of the Section 202(a) factors. Chrysler doubts this approach would be lawful, however. In determining its proposed standards, EPA did not identify California's ZEV Over-Compliance Provision as a relevant statutory factor. Section 202(a) (and indeed none of the Section 202 provisions), identify California regulations as a relevant statutory factor in setting federal standards. 35 We are not aware of any time that EPA has set standards under Section 202(a) to account for the impact of such a California provision that so directly affects the stringency of the federal program. EPA should make clear that the interference that California would cause through its provision is preempted. [EPA-HQ-OAR-2010-0799-9495-A1, p.21]

The impact of California's proposal should not be underestimated, as the ARB anticipates manufacturers accounting for sales up to 50 percent of total California sales to utilize the ZEV Over-Compliance Provision. Chrysler reiterates its support of a single national GHG program and encourages the EPA to take into account the potential impact of California's ZEV over-compliance provision and deny any waiver request made by California for its ZEV Program insofar as it contains the ZEV Over-Compliance Provision. [EPA-HQ-OAR-2010-0799-9495-A1, p.21]

---

33 In addition, by allowing manufacturers to substitute federal GHG program over-compliance for compliance with the ZEV program, California would effectively be foregoing a portion of the environmental benefits upon which their Clean Air Act waiver for the ZEV Program is premised. [EPA-HQ-OAR-2010-0799-9495-A1, p.20]

34 By modeling all light-duty vehicle manufacturers as a single fleet to establish the 2017-2025 MY federal GHG standards, EPA has implicitly assumed that debits incurred by some companies unable to meet the standards would be satisfied by credits earned by other companies that over-comply with the standards. This implicit assumption is explicitly noted in the 2012-2016 National Program, where in describing the feasibility of the final standards EPA notes that a

company unable to meet the standard could comply by buying credits from another manufacturer. 75 Fed. Reg. 25463 (May 7, 2010) Similarly, EPA requires manufacturers to make good-faith efforts to purchase credits from other manufacturers prior to qualifying for temporary lead-time alternative standards (40 CFR 86.1818-12(e)(3)). [EPA-HQ-OAR-2010-0799-9495-A1, p.20]

35 Chrysler further notes that if EPA were to identify the California ZEV Program as a relevant statutory factor, the ZEV Program requirements for manufacturers to build specific volumes of zero emission and plug-in hybrid electric vehicles would need to be included in EPA's modeling of the technology penetration rates required to meet the National Program standards, thereby increasing the costs associated with the National Program with no additional environmental benefit. [EPA-HQ-OAR-2010-0799-9495-A1, p.21]

Organization: Hyundai America Technical Center

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 173.]

The California Air Resources Board is proposing to allow those OEMs to offset part of the zero emission vehicle mandate for a limited time through over-compliance in challenging GHG/CAFE standards.

Organization: Mitsubishi Motors R&D of America, Inc. (MRDA)

Mitsubishi Motors proposes that GHG credits should be available to those manufacturers who over-comply with the California ZEV Mandate on a NATIONAL BASIS. Mitsubishi Motors supports compliance with one harmonized national fuel economy and GHG program. However, Mitsubishi Motors must also plan to comply with the ZEV mandate. National and California programs regulating vehicle GHG emissions reflect overlapping standards upon a manufacturer's single ZEV fleet. In recognition of these overlapping programs and OEMs' efforts to deploy capital-intensive ZEVs, California allows manufacturers to earn ZEV credits by over-compliance with EPA's GHG standard starting in MY 2018. Similarly, in order to be consistent with the CA ZEV Mandate, Mitsubishi Motors recommends that EPA allow manufacturers to gain credits by over-compliance with the California ZEV mandate nationwide starting in MY 2018. The mid-term evaluation also offers an opportunity for EPA to consider an option to offer manufacturers, who demonstrate plans to over-comply with the ZEV Mandate for the entire MY 2022 through 2025 timeframe, a 2 grams per mile GHG credit. This will allow manufacturers to keep their conventional technology fleets in compliance, while introducing and selling advanced ZEV technologies nationally. Mitsubishi Motors' proposal will contribute to reducing GHG emissions while providing customers reasonably-priced vehicle choices. [EPA-HQ-OAR-2010-0799-9507-A1, p.5]

Organization: Union of Concerned Scientists (UCS)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 139.]

This is why policies like California's Zero-Emission Vehicle program are an important complement to the proposed greenhouse gas and fuel economy standards being discussed here today. The Zero-Emission Vehicle program helps ensure that investments in research, development and deployment of advanced vehicle technologies continue.

Response:

In response to Chrysler's comments, issues of whether a California state provision should be preempted are not part of this proceeding, and EPA therefore declines to address this comment here. The commenter may resubmit this comment if and when the issue should be presented directly to EPA, potentially in a request by the State of California for a waiver pursuant to section 209 (b) or in some other direct context. EPA disagrees with Chrysler's assertion that the feasibility of the standards hinge on the availability of credits through banking or trading. EPA has shown that the standards being finalized are feasible at reasonable cost without assuming carry-forward of banked credits or credit trading between manufacturers. See discussion in preamble III.D.6 and RIA Chapter 3 footnote 2. Further, EPA's requirement that SVMs make a good faith effort to seek out credits as part of the MY 2012-2016 SVM exemption eligibility provisions does not require SVMs to buy credits unless they are reasonably available from other manufacturers. If EPA determines that the SVM has made a good faith effort to purchase credit but that credits are not available, the SVM is exempt from meeting CO_2 standards with no obligation to purchase credits.

In response to Mitsubishi's comments regarding additional credits for over-compliance with the California ZEV program, EPA is already adopting multiplier incentives for PHEVs, EVs and FCVs which we believe are appropriate (see preamble section III.C.2.c.ii). EPA does not believe that it is necessary at this time to introduce an additional type of credit for these vehicles or tie the availability of incentives for these vehicles to a manufacturer's performance in the California ZEV program. Also, EPA did not seek comments on using over compliance with the ZEV program as the basis for an EPA GHG credit. Mitsubishi comments that California allows manufacturers to earn ZEV credits by over-compliance with EPA's GHG standard starting in MY 2018, and in order to be consistent with the CA ZEV Mandate, EPA should allow manufacturers to gain credits by over-compliance with the California ZEV mandate nationwide starting in MY 2018. EPA does not agree that this type of credit is a matter of making the programs consistent. The California provision to allow GHG credits to be used in the ZEV program would presumably reduce the number of ZEVs that a manufacturer would be required to produce. The commenter does not explain how a 2 g/mile credit for ZEV over compliance is needed to make the two programs consistent. The commenter also does not offer a basis for why 2 g/mile is an appropriate credit. Further, the California ZEV provision is limited and only available for essentially the same model years as the EPA multiplier incentives for these vehicles. Manufacturers will already be effectively receiving credits under the EPA program for the same types of vehicles covered by the ZEV program, as noted above. EPA believes the additional credit suggested by the commenter would be redundant and is unnecessary.

10.2. Nitrous Oxide (N_2O) and Methane (CH_4) Standard

10.2.1. Flexibility for Compliance with N_2O and CH_4 Standard

CO_2-Equivalent Option

AGA and ANGA support EPA's decision, first announced in the preamble to the Heavy Duty Rule (76 FR 57123) to include the CO_2 -Equivalent Option as part of the light-duty regulations through MY 2016, to allow for the Option to be used on a test-group basis instead of having to apply a manufacturer's entire fleet. EPA should now extend the Option through MY 2025, and continue the policy of allowing CO_2 -equivalent compliance on a test-group basis, which would enable manufacturers who offer NGVs to avoid requiring all of their vehicles to be subject to the CO_2-Equivalent Option. [EPA-HQ-OAR-2010-0799-9548-A1, p. 8]

However, if the agency adopts its proposal to require that the Option be applied to a manufacturer's entire fleet, we support EPA's additional proposal to include an offsetting "equivalence option adjustment factor", so that "manufacturers do not have to offset the typical N_2O and CH_4 vehicle emissions, while holding manufacturers responsible for higher than average N_2O and CH_4 emissions levels." [EPA-HQ-OAR-2010-0799-9548-A1, pp. 8-9]

Organization: Association of Global Automakers, Inc. (Global Automakers)

With regard to the standards for nitrous oxide and methane, we support the credit-based compliance option for the nitrous oxide and methane standards, as well as the new "upward adjustment" approach to allow these emissions to be included with carbon dioxide emissions. However, we see no need for the limitation on the use of methodologies under 40 Code of Federal Regulations (CFR) Section 86.1818-12(f) for nitrous oxide and methane, finalized under the MYs 2012-2016 standards and carried over for MYs 2017-2025. We would like to see an allowance to use different compliance options for methane and/or nitrous oxide and also for passenger car and light truck fleets in the same model year, without the need for prior EPA approval. This restriction limits manufacturers' compliance options but with no clear environmental benefit. We urge EPA to eliminate this restriction in the final rule. [EPA-HQ-OAR-2010-0799-9466-A1, pp. 2-3]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 67.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 51.]

We also support the credit-based compliance option for methane and nitrous oxide standards, as well as the new upward adjustment approach to allow these standards to be included with carbon dioxide emissions. However, we would like to see more flexible -- more flexible compliance options and will be addressing that in more detail in our written comments.

Organization: BMW of North America, LLC

BMW supports the option to convert measured N_2O and CH_4 emissions that are above the applicable standards into CO_2 -equivalent emissions for compliance purposes. The calculation of emission debits on this basis allows them to be offset by other GHG reduction measures. While leading to the same overall GHG reduction impact, this option provides flexibility and still gives an incentive to further work on the reduction of N_2O and CH_4 emissions. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 4]

Organization: Ferrari

We agree with the option proposed by EPA in this rulemaking to use CO_2 credits to comply with the CH_4 and N_2O standards, because this measure is consistent with the compliance option to add these emissions to those of CO_2 (instead to meet specific standards), and increases the flexibility to comply. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

Organization: General Motors Company

In the NPRM, EPA requests comments on "establishing an adjustment to the CO_2 - equivalent standard for manufacturers selecting the CO_2 -equivalent option established in the model year 2012–2016 rulemaking." (p. 74993). GM disagrees with establishing a blanket adjustment to the CO_2 -equivalent standard. EPA has gone to great lengths to establish CO_2 emission targets based on individual manufacturer fleets. Using the average value of all passenger cars and light trucks to establish an adjustment factor will inherently and unduly lessen the stringency for some manufacturers while increasing the stringency for others. [EPA-HQ-OAR-2010-0799-9465-A1, p. 5]

In order to appropriately incorporate a CO_2 -equivalent approach into the standard, EPA would have to return to the baseline data and develop CO_2 target value equations based on CO_2 - equivalent data. [EPA-HQ-OAR-2010-0799-9465-A1, p. 5]

A second approach would be to modify the CO_2 -equivalent equations instead of adjusting the CO_2 standard. Under the current regulations, if a manufacturer meets the N_2O and CH_4 emission standards, they are not required to include N_2O or CH_4 emissions in their carbon related exhaust emission (CREE) calculations (i.e., the impact of N_2O and CH_4 emissions on the CREE value is zero). If a manufacturer chooses the option to use the CO_2 -equivalent CREE equations, it has to include all CH_4 and N_2O emissions which would result in an increase of up to approximately 3 g/mile for vehicles that would have otherwise been able to meet the N_2O and CH_4 emission standards. So, in order to make the CO_2 -equivalent option more appealing, EPA would have to modify the CO_2 -equivalent equations in such a fashion as to not penalize a manufacturer for meeting the current CH_4 and N_2O emission standards while still including a mechanism that would allow a manufacturer to account for exceedances of the standards. [EPA-HQ-OAR-2010-0799-9465-A1, p. 5]

What follows is a suggested modified equation for EPA to consider:

Change the CREE equation from:

$CREE = [(CWF/0.273)xNMHC]+(1.571xCO)+CO_2 +(298xN_2O)+(25xCH_4)$

To:

$CREE = [(CWF/0.273)xNMHC]+(1.571xCO)+CO_2 +[298x(N_2O-0.010)]+[25x(CH_4-0.030)]$

And:

Include requirements that negative values for N_2O or CH_4 contribution shall be set to zero. (An allowance would have to be made such that manufacturers could set N_2O equal to 0.010 until a practical and accurate method of measuring N_2O is established.) [EPA-HQ-OAR-2010-0799-9465-A1, p. 5]

By subtracting the N_2O and CH_4 emission standards from their respective emission values and setting any negative result to zero, the manufacturer would be required to account for emissions in exceedance of the standards and would not benefit from performing at levels lower than the emission standards (does not affect the stringency of the fleet-average standard). [EPA-HQ-OAR-2010-0799-9465-A1, p. 5]

Organization: Toyota Motor North America

Standards and Flexibility - As part of the recently completed heavy-duty GHG rulemaking, EPA finalized provisions allowing manufacturers to use CO_2 credits, on a CO_2- equivalent basis, to meet the light-duty N_2O and CH_4 standards. Toyota appreciates, having the option of using CO_2 credits to meet N_2O and CH_4 standards on a test group basis as needed for 2012-2016 model years and supports EPA's current proposal to extend this flexibility through the 2025 model year. [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

Organization: VNG Co. (VNG)

Recently-revised alternative compliance options for the methane standard are extended and made permanent by this NPRM, which will benefit NGVs whose slightly elevated methane emissions compared to gasoline vehicles are more than outweighed by reductions in CO_2 emissions. [EPA-HQ-OAR-2010-0799-7941-A2, p. 6]

Methane Standard Compliance Flexibility

VNG strongly supports the Agencies' decision to allow automakers the same flexible options for meeting methane (CH_4) standards for light-duty vehicles as are now allowed for heavy-duty vehicles. Under these flexible rules, automakers and conversion manufacturers may convert CO_2 over-compliance into CO_2 equivalents of CH_4 (or N_2O) that can be used to facilitate compliance with these standards. As it is the total global warming potential ('GWP') of all GHGs that is important, and not the emissions of any specific pollutant, this flexibility is appropriate and in line with EPA's regulatory goal. [EPA-HQ-OAR-2010-0799-7941-A2, p. 10]

This flexibility may be useful for manufacturers of NGVs, particularly converters that will be important in developing the market in the early years. Because small quantities of unburned natural gas from NGV engines may be emitted as methane, NGVs may have slightly higher emissions of this GHG than petroleum-fueled ICE vehicles. However, due to much greater reductions of CO_2 emissions, NGVs still yield net GHG emission reductions of approximately 24 percent. These flexible compliance rules will ensure that net GHG reductions are accounted for properly, and automakers are not penalized so long as slight increases in methane emissions are offset by CO_2 over-compliance. [EPA-HQ-OAR-2010-0799-7941-A2, p. 10]

Organization: Volkswagen Group of America

EPA seeks comment in the NPRM regarding additional flexibility when complying with the N_2O standards. Volkswagen supports EPA’s proposal to allow the option of using CO_2 credits to comply with the N_2O standards and Volkswagen also supports the option of meeting these standards on a test group basis. Furthermore, Volkswagen supports the NPRM proposal to extend theses options through all models years of the regulation beyond 2016. Volkswagen also supports the concept of an adjustment factor to the CO_2 equivalent standard for manufacturers selecting the CO_2 equivalent option the pathway to compliance with both CH_4 and N_2O. Volkswagen pledges to work with EPA in the future to generate the proper data such that an appropriate adjustment factor can be determined. [EPA-HQ-OAR-2010-0799-9569-A1, p. 34]

Response:

EPA received only supportive comments regarding the proposal to permanently allow CO_2 credits to be used on a CO_2-equivalent basis to meet the CH_4 and N_2O standards and EPA is finalizing this provision as proposed. EPA concurs that this provision provides an important flexibility to manufacturers while not undermining the overall GHG reductions of the program. Additional discussion regarding CO2-equivalent options and comments, including GM’s comments, is provided in preamble section III.B.9.a.

Organization: Alliance of Automobile Manufacturers

Additional time is needed for development of a method for measuring nitrous oxide (N_2O). EPA has recognized the difficulties and complexities of evaluating, procuring and installing the equipment that would be needed to measure N_2O. But, as our comments explain, EPA still has not provided sufficient time for manufacturers to incorporate accurate and robust N_2O measurement capabilities into their test sites. The deadline for measuring N_2O should be extended until the N_2O measurement issues are resolved, and N_2O measurement capabilities should be reevaluated during the mid-term and interim evaluations. By so doing, EPA would be providing manufacturers with sufficient time to evaluate appropriate test equipment and would be aligning possible N_2O regulatory changes with possible subsequent changes to other light-duty GHG regulations. [EPA-HQ-OAR-2010-0799-9487-A1, p.5]

Nitrous Oxide (N_2O) Measurement [EPA-HQ-OAR-2010-0799-9487-A1, p.71]

EPA has recognized the difficulties and complexities of evaluating, procuring and installing the equipment that would be needed to measure N_2O and has proposed that manufacturers be permitted to use compliance statements in lieu of test data through MY 2016. However, as explained below, EPA has not provided sufficient time for manufacturers to incorporate accurate and robust N_2O measurement capabilities into their test sites. We propose that the deadline for measuring N_2O be extended until the measurement issues are resolved. The N_2O measurement capabilities should be reevaluated during both the mid-term evaluation of standards and the "check-ins" occurring prior to the mid-term. By so doing, EPA would be providing manufacturers sufficient time to evaluate appropriate test equipment and would be aligning possible N_2O regulatory changes with possible subsequent changes to other light duty GHG regulations. [EPA-HQ-OAR-2010-0799-9487-A1, p.71]

The first issue with regard to N_2O measurement timing is that there is currently no accurate measurement technology available that is suitable for high-volume testing. As one example, the gas chromatograph electron capture detector (GC-ECD) is not suitable for high-volume testing since it includes an off-line multi-hour long analysis and has robustness issues. [EPA-HQ-OAR-2010-0799-9487-A1, p.71]

EPA provided a technical study of the capabilities of currently available and potentially available future measurement technologies as a separate memorandum to the docket. The study compares instruments by analyzing ambient air and diluted vehicle exhaust samples on a number of different vehicles and schedules (FTP and HFET). The EPA technical study highlights the continuing difficulties of the currently available measurement technologies to accurately measure N_2O. [EPA-HQ-OAR-2010-0799-9487-A1, p.71]

In the study, EPA compared the Fourier Transform Infrared Spectrometer (FTIR) to the GC-ECD and concluded that the "FTIR compared very well to GC-ECD, which is considered the gold standard," but the accompanying data actually demonstrates the opposite. The data shows significant differences and variability between these two instruments on the order of approximately -17 to +25 ppb N_2O equivalent for ambient air analysis and approximately -27 to +85 ppb N_2O equivalent for vehicle exhaust testing. These differences represent a significant error at an N_2O standard level of 0.010 g/mi. [EPA-HQ-OAR-2010-0799-9487-A1, p.71]

In addition, in comparing the FTIR to the Non-Dispersive Infrared (NDIR) analyzer, the study states "Both the NDIR and FTIR analyzers performed well, however some questions regarding performance remain." The accompanying data, however, shows significant interferences with both analyzers, results which are similar to those of the previously supplied Alliance Technical Study (June 2011). [EPA-HQ-OAR-2010-0799-9487-A1, p.71]

The study also highlights a potentially promising new N_2O measurement technology that is based on laser spectroscopy and is made by a few manufacturers. However, N_2O analysis is so new that most of these instruments are still in the development stages and hence are prototypes. Although these instruments show promise for N_2O analysis, questions remain as to their accuracy and robustness (i.e., reliability) at such low N_2O standards. [EPA-HQ-OAR-2010-0799-9487-A1, p.72]

The study contains evaluations of two such laser instruments based on simulated exhaust gas (water, carbon monoxide (CO), CO_2 and N_2O). In comparison to NDIR and FTIR, the data for the first laser instrument shows interference errors that were typically lower, ranging from -29 to +10 ppb N_2O equivalent. Although the errors appear to be reduced, they still represent a significant portion of the 10 mg/mi N_2O standard. CO and CO_2 measurements were likewise affected by interference gases but in the opposite direction, i.e., higher levels than that observed with N_2O. [EPA-HQ-OAR-2010-0799-9487-A1, p.72]

For the first laser instrument the study concludes that the instrument "…performed very well and does not appear to show any susceptibility to CO, CO_2, or water interference…" and "Based on CO and CO_2 measurement error, we believe that the bulk of the associated N_2O measurement error is due to bag blending error." It would seem that if the N_2O errors were due to gas blending errors, then CO and CO_2 would be likewise affected, but the data generally shows an underreporting of N_2O and an over reporting of CO and CO_2. Looking at this limited data, the Alliance believes that although the instrument shows promise, it still demonstrates significant measurement errors which have not yet been accounted for. [EPA-HQ-OAR-2010-0799-9487-A1, p.72]

The second laser instrument evaluation showed similar N_2O measurement errors in the presence of interference gases but this was attributed to "…the inability to properly zero/span the instrument after the initial zero/span at the start of the testing." In the conclusions it is stated that

"EPA intends to re-evaluate this instrument after the manufacturer has resolved issues…" [EPA-HQ-OAR-2010-0799-9487-A1, p.72]

Suffice it to say that until more studies are conducted by multiple facilities, including correlation vehicle testing between facilities, the true accuracy of laser based instruments is still to be determined. [EPA-HQ-OAR-2010-0799-9487-A1, p.72]

The second issue with regard to N_2O measurement is emission development and certification timing. Taking all things into account, we estimate that it will take approximately 4.5 years to properly install a new N_2O analyzer into a single test site. Below is a graphical representation of the estimated timeline for instrument procurement and installation. [EPA-HQ-OAR-2010-0799-9487-A1, p.72] [For the 'graphical representation', please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.73]

Included in the above graph are the generic timelines for emission development and certification for the individual model years. We estimate that the first test site with N_2O measurement capabilities would not be available until midway through the emission development process for MY 2019. We estimate that the earliest that a manufacturer could certify a limited portion of its product line with measured N_2O data would be mid-MY 2019. Please note that a manufacturer's ability to certify in MY 2019 will still be limited by the number of available test sites (i.e., it would be impossible to certify a full-line manufacturer's entire product line in the MY 2019 utilizing only one test site). [EPA-HQ-OAR-2010-0799-9487-A1, p.74] [For the 'graph', please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.73]

N_2O Data [EPA-HQ-OAR-2010-0799-9487-A1, p.74]

EPA has requested "…city and highway cycle N_2O data on current Tier 2 vehicles…" 1 However, supplying N_2O data will not be possible at this time due to lack of accurate and robust N_2O measurement instrumentation and insufficient lead time to install this instrumentation into certification quality test laboratories. As mentioned above, it will take several years to get even rudimentary measurement capability that is proven to be both accurate and robust. [EPA-HQ-OAR-2010-0799-9487-A1, p.74]

N_2O Certification [EPA-HQ-OAR-2010-0799-9487-A1, p.74]

In paragraphs 40 CFR §86.1823-08(m)(2)(iii) and §86.1829-01(b)(1)(iii)(G) of the proposed rule, EPA proposes the extension of the use of alternative N_2O deterioration factors (DF's) and N_2O compliance statements, respectively, through the MY 2016. While the Alliance appreciates the extension of these deadlines, setting these deadlines is essentially precluding a manufacturer from utilizing the concept of carryover which is critical to the successful implementation of emission certification programs. Therefore, the Alliance recommends that the use of alternate N_2O DFs and compliance statements be further extended and that the requirement to measure N_2O only be applied to new emission certification programs that are implemented after the establishment of proper N_2O measurement instrumentation and procedures. [EPA-HQ-OAR-2010-0799-9487-A1, p.74]

In order to balance emission testing burden and certification workload, manufacturers routinely "carryover" emission certification and durability data. Carryover essentially means that representative emission data that was generated in a previous model year is re-used in the new model year in lieu of repeating the same emission tests. Lacking certification quality N_2O data in early model years means that the emission data will not be viable for carryover into a model year that requires actual N_2O data. That means that all emission data generated during these years will not qualify for carryover into a model year for which actual N_2O data is required. Therefore, assuming that N_2O measurement capabilities are not available until the MY 2017, manufacturers would be forced to rerun all of their emission durability and certification testing in one model year. This would be an unnecessary and unwarranted certification burden for that particular model year. [EPA-HQ-OAR-2010-0799-9487-A1, pp.74-75]

In-Use N_2O [EPA-HQ-OAR-2010-0799-9487-A1, p.75]

Although EPA did not propose any changes to in-use testing requirements, the Alliance requests that EPA exclude N_2O measurement and reporting from in-use testing (IUVP and IUCP) for all model years and test groups that certify to the N_2O standards via a compliance statement. Because accurate N_2O measurement technology is not readily available, manufacturers have been forced to rely on theoretical information and/or possibly inaccurate data in order to make N_2O compliance statements. EPA should not hold the manufacturers accountable for measuring N_2O utilizing a method that will have been established subsequent to certification, nor should EPA hold a manufacturer responsible for meeting a standard for which accurate measurement methods were not available at the time of certification. [EPA-HQ-OAR-2010-0799-9487-A1, p.75]

Heavy Duty N_2O [EPA-HQ-OAR-2010-0799-9487-A1, p.75]

Although EPA has not proposed modifications to the heavy-duty GHG regulations, the Alliance requests that EPA also modify the heavy-duty GHG N_2O measurement requirements to coincide with the timing of the light-duty requirements. Heavy-duty chassis GHG testing will be performed on the same test sites that are utilized by light-duty and will therefore have the same N_2O measurement issues. Providing N_2O measurement relief solely for the light-duty vehicles does not fully address the issue. [EPA-HQ-OAR-2010-0799-9487-A1, p.75]

Organization: Association of Global Automakers, Inc. (Global Automakers)

With regard to the proposed requirement for testing to measure nitrous oxide emissions beginning in MY 2017, we urge EPA to reconsider the cost-effectiveness of this requirement. The quantity of these emissions is quite low, and we see no indication that they will become an important factor in climate change in the future. Testing for this substance will require expensive new analyzers, whose performance remains to be determined. We support the comment of one manufacturer at the Detroit public hearing, which noted that the proposed test method for nitrous oxides is neither proven nor developed and that the Non-Dispersive Infrared Analyzer (NDIR) and Fourier Transform Infrared (FTIR) bag analysis methods currently have repeatability, durability and/or practicality concerns. [EPA-HQ-OAR-2010-0799-9466-A1, p. 3]

We urge the agency to allow manufacturers to continue to demonstrate compliance using the pre-MY 2017 analysis-based methodology in 2017 and thereafter. EPA should monitor these emissions and the development of testing analyzers and adopt new test-based requirements in the future should the emissions grow in significance or when the testing technology is ready. For instance, it would be appropriate to review the testing technology as part of the mid-term review and then determine whether testing as part of the regulations should be finalized following the mid-term review. [EPA-HQ-OAR-2010-0799-9466-A1, p. 3]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 67-68.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 51-52.]

Organization: Ferrari

EPA intends to extend the ability for manufacturers to use compliance statements for N_2O standard based on good engineering judgment in lieu of test data through MY 2016. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

It is fine, but we request EPA to delete the requirement to actually measure N_2O emissions for the following reasons: [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

The quantity of these emissions is quite low, and they should remain a minimal contribution over the total GHG inventory in the future. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

The related burdens (laboratory update, testing, reporting) is relevant. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

There are some concerns on the accuracy of the measurement. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

At least small-volume manufacturers should be exempted to carry out the N_2O measurement. [EPA-HQ-OAR-2010-0799-9535-A2, p.12]

Organization: Ford Motor Company

As noted in the NPRM and support documents, EPA understands that N_2O measurement complexity remains an important issue to be addressed for both 2012-2016 MY as well as 2017 MY and beyond. Due to these measurement difficulties, EPA has granted some flexibilities through previous rulemakings and is now proposing to extend the timing for requiring N_2O measurement to the 2017 MY. While Ford acknowledges these allowances, we do not believe they sufficiently address all of the concerns related to N_2O. We agree with the Alliance comments that recommend that N_2O measurement requirements be delayed until those measurement issues are fully resolved. A number of instruments have been studied with varying levels of success. Variability remains a key concern, but we believe that some of these technologies show promise. However, much additional work remains to identify viable solutions, conduct correlation studies, and upgrade facilities for certification level testing. Until that time, there should be no requirement to measure N_2O or comply with a standard that cannot be accurately assessed. [EPA-HQ-OAR-2010-0799-9463-A1, p. 24]

Ford is in the process of collecting data to further evaluate the capability of N_2O measurement technologies. Once that information is available, we will review it with EPA to provide additional basis for 2012 – 2016 MY interim containment actions and additional flexibilities on N_2O requirements. Going forward, we look forward to continued data-driven dialogue with EPA to resolve the current manufacturer concerns with N_2O compliance, beyond the allowances outlined in the current proposal. [EPA-HQ-OAR-2010-0799-9463-A1, p. 25]

Organization: General Motors Company

GM supports the deferral for N_2O measurement until MY2017. As mentioned in the Alliance comments, since additional time and evaluation are necessary to develop accurate and repeatable N_2O measurement capabilities, we recommend that work continue expeditiously – and progress be evaluated as part of one of the mid-term review "check-ins." [EPA-HQ-OAR-2010-0799-9465-A1, p. 4]

Organization: Hyundai America Technical Center

Testing for N_2O [EPA-HQ-OAR-2010-0799-9547-A1, p.7]

EPA has proposed a new requirement to measure N_2O emissions starting in MY 2017. Based on research we have conducted, Hyundai believes the measurement methods suggested by the agencies are not fully proven or developed, and are very expensive as they require new analyzers. [EPA-HQ-OAR-2010-0799-9547-A1, p.7]

Hyundai prefers a bag analysis method of measurement to minimize decreased testing throughput. The NDIR, FTIR and GC bag analysis methods for N_2O currently have repeatability or practicality concerns. Therefore, while Hyundai supports the bag methodology for measurement, we recommend that the testing issue be revisited at such time when there is a proven, accurate and efficient means of measurement. [EPA-HQ-OAR-2010-0799-9547-A1, p.7]

Organization: Kia Motors

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 101.]

Sort of the technical side, based on research that we have conducted, Kia believes the methods suggested by the agencies for nitrous oxide which must be measured starting in 2013 are not fully proven and developed. Kia prefers the bag method analysis of measurement to minimize reduction of testing throughout. However, the NDIR and FTIR bag analysis methods currently have repeatability and practicality concerns. We support the measurement but recommend that it be revisited in a time when there is improved and accurate and more efficient means available.

Organization: Toyota Motor North America

N_2O Measurement - Toyota remains concerned that EPA has not provided sufficient time for manufacturers to incorporate accurate and robust N_2O measurement capabilities into their test sites. N_2O measurement currently has no accurate measurement technology available that is suitable for high-volume testing at this time. Toyota fully supports the comments and recommendations submitted by the Alliance on this matter. [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

In the proposed regulation paragraphs 40 CFR §86.1823-08(m)(2)(iii) and §86.182901(b)(I)(iii)(G), EPA proposes to extend the use of alternative N_2O deterioration factors (DF's) and N_2O compliance statements, respectively, through the 2016 model year. Toyota appreciates EPA's consideration in extending these deadlines, and supports the Alliance recommendation that the use of alternate N_2O DFs and compliance statements be further extended until the establishment of proper N_2O measurement instrumentation and procedures. Furthermore, because accurate N_2O measurement technology is not readily available, Toyota requests that EPA extend the N_2O compliance statement beyond the 2016 model year, up until the establishment of proper N_2O measurement instrumentation and procedures has been demonstrated. [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

Due to the fact that accurate N_2O measurement technology is not readily available, Toyota requests that EPA should exclude N_2O measurement and reporting from in-use testing for all model years and test groups that certify to the N_2O standards via a compliance statement. We support the Alliance comments on this matter. [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

Organization: Volvo Car Corporation (VCC)

'EPA is also finalizing standards that will cap tailpipe nitrous oxide (N_2O) and methane (CH_4) emissions at 0.010 and 0.030 grams per mile, respectively. Even after adjusting for the higher relative global warming potencies of these two compounds, nitrous oxide and methane emissions represent less than one percent of overall vehicle greenhouse gas emissions from new vehicles. Accordingly, the goal of these two standards is to limit any potential increases of tailpipe emissions of these compounds in the future but not to force reductions relative to today's low levels.' [EPA-HQ-OAR-2010-0799-9551-A2, p. 11]

In the final Rule, EPA focuses on four important aspects of N_2O and CH_4:

• EPA wants a cap

• N_2O and CH_4 are two strong GHG emissions

• EPA wants to ensure that N_2O and CH_4 do not increase as a consequence of the introduction of new technologies.

• N_2O and CH_4 represent less than 1% of the GHG gases from the vehicle [EPA-HQ-OAR-2010-0799-9551-A2, p. 11]

To monitor these potent greenhouse gases against a given value is reasonable when it is not possible to predict the consequences that new technology can generate. However, it is a significant difference, via a statement providing a declaration of compliance in accordance with the standard instead of conducting a full certification and the subsequent protocol. [EPA-HQ-OAR-2010-0799-9551-A2, p. 11]

It also should be considered that, as noted above, N_2O and CH_4 represent only 1% of the guarded carbonaceous compounds that make up a manufacturer CREE value. [EPA-HQ-OAR-2010-0799-9551-A2, p. 11]

Currently, there is no equipment on the market that can measure according to proper certifying standard, using 'bag measurement' for N_2O with a relevant repeatability. During 2012-2013, new technology will be introduced to the market, but this technology is still in the research stage, and it would be premature to commit to its use as a certification tool at this time. VCC is concerned about technology readiness, instrument availability, measurement accuracy, and implementation lead time, including verifying that the instrument is robust enough for certification testing. [EPA-HQ-OAR-2010-0799-9551-A2, p. 11]

VCC would like to ask EPA, in collaboration with CARB, to consider continuing the practice used today (fulfillment of CAP through a written statement). VCC does not think manufacturers should have to certify N_2O in accordance with procedures similar as those of Criteria Emission. [EPA-HQ-OAR-2010-0799-9551-A2, p. 11]

The above-required instrumentation to be able to measure N_2O in certification facility (bag measurement) at the level of 10 mg/mi with a adequate accuracy, is not available on the market today. It will probably be possible to order it during 2012. After the order is completed, the installation process will take place somewhere in 2013 and method development will be initiated which will require some development work for 1-2 years at least. [EPA-HQ-OAR-2010-0799-9551-A2, pp. 11-12]

Response:

EPA is finalizing the additional lead-time for N_2O testing essentially as proposed. In response to Alliance comments, EPA is temporarily (for MYs 2017 and 2018) allowing manufacturers to continue to use compliance statements for test groups certified using carry-over data. EPA is also clarifying, in response to Alliance comments, that manufacturers will not be required to conduct in-use testing for vehicle test groups certified using a compliance statement. Section III.B.9.b of the preamble provides EPA's response to the comments received regarding N_2O measurement timing and issues.

Ferrari commented that small volume manufacturers should not be required to measure N_2O. Ferrari raises issues that are essentially the same as those raised by large volume manufacturers, which EPA has addressed in the preamble as noted above. Ferrari does not provide any rationale why the sales volume of a manufacturer would be relevant to the manufacturer's ability to measure N_2O with the lead time being provided. Also, EPA did not receive similar comments from manufacturers that are currently SVMs in the GHG program. EPA does not know of any reason, nor did Ferrari provide one, why SVMs, which are large companies with limited sales in the U.S., would not be able to measure N_2O in the same time-frame as the large volume manufacturers and therefore is not differentiating between large and small volume manufacturers with regard to N_2O measurement.

In response to Alliance comments regarding N_2O testing for heavy-duty vehicles, EPA did not propose or request comment on heavy-duty vehicle issues in this rulemaking and therefore making changes to the heavy-duty vehicle requirements is beyond the scope of this rule. However, EPA understands the issue raised by the Alliance and plans to consider heavy-duty vehicle N_2O testing as part of a future action.

Methane Global Warming Potential

Citing the IPCC Fourth Assessment Report, EPA's uses a Global Warming Potential ("GWP") factor of 25 for the Proposed LD Rule's methane emissions standards: "CH_4 has a 100-year GWP of 25 according to the 2007 IPCC AR4." 76 FR 74993, n.236. [EPA-HQ-OAR-2010-0799-9548-A1, p. 9]

However, while EPA uses the 25 GWP for mobile sources, the rest of EPA's Office of Air and Radiation uses a GWP of 21 for stationary source methane emission standards. See, e.g., the Prevention of Significant Deterioration and Title V Greenhouse Gas Tailoring Rule, 75 FR 31519, 31522, June 3, 2010 ("CH_4 has a GWP of 21"); PSD Permit Number PSD-TX-1244-GHG, issued November 10, 2011 by EPA Region VI for the Lower Colorado River Authority Thomas Ferguson Power Plant, p. 7 (mass-based methane emissions limits of 16.8 and 16.2 tons per year are each multiplied by 21 to establish CO_2 -equivalent emissions limits of 353.3 and 327.2 tpy; attached as Exhibit 6.) [EPA-HQ-OAR-2010-0799-9548-A1, p. 9]

In other words, the proposed LD Rule arbitrarily deems vehicle methane emissions as having 19% greater heat-trapping characteristics than the chemically identical molecules emitted from stationary sources. Unless EPA can explain the scientific basis for this, light duty vehicle methane emissions should be regulated with the same GWP as all other U.S. methane sources. [EPA-HQ-OAR-2010-0799-9548-A1, p. 9]

Organization: Ferrari

Ferrari supports the EPA proposal not to increase the stringency of the CH_4 and N_2O standards set forth in the MYs 2012-16 GHG final rule. [EPA-HQ-OAR-2010-0799-9535-A2, p.2]

Organization: Manufacturers of Emission Controls Association (MECA)

Tightening of hydrocarbon and CO_2 emission standards over time with the parallel introduction of more effective emission control systems have resulted in lower emissions of N_2O and CH_4 from today's vehicles compared to older vehicles certified to less stringent hydrocarbon and CO_2 standards. The performance of advanced emission control technologies for advanced diesel, gasoline, and natural gas-fueled powertrains can also be optimized to minimize N_2O and CH_4 emissions from future light-duty vehicles consistent with the limits EPA set for these important greenhouse gas emissions in their first round of light-duty vehicle greenhouse gas emission standards. [EPA-HQ-OAR-2010-0799-9452-A3, p.3]

Organization: Vehicle Production Group LLC (VPG)

Methane emissions

In order for the industry to achieve expanded use of CNG as an automotive fuel, in VPG's opinion, the methane standard must be revisited relative to CNG fuel usage and emissions from CNG fueled engines. We do not believe that the methane emissions standards advised in III.6. are in line with methane emissions from vehicles running on natural gas. Table 2 details the emissions for two dedicated CNG fueled vehicles as well as VPG's gasoline fueled MV-1 as a reference point. [See Table 2. Methane emissions from one gasoline and two CNG certification tests in Docket number EPA-HQ-OAR-2010-0799-7985-A2, p. 4] [EPA-HQ-OAR-2010-0799-7985-A2, p. 3]

VPG notes that, as can be expected, gasoline emissions of methane are significantly less than the new standard. More significantly though, VPG's MV-1 is certified as a LDT 4 light duty truck, and has a curb weight of 5250 pounds, yet it is certified at the bin 2 level. Even at this clean certification level, the MV- 1 is does not meet the methane standard. [EPA-HQ-OAR-2010-0799-7985-A2, p. 4]

Additional methane emissions data do not appear to be available in certificate summary information reports for CNG fueled vehicles accessed through the EPA Document Index System (DIS). One of the better known OEM vehicles certified for dedicated CNG use is the Honda Civic. The methane results for this vehicle however (test group BHNXV01.8BDT) are not available from the DIS on the EPA website. [EPA-HQ-OAR-2010-0799-7985-A2, p. 4]

Our evidence indicates that a there are technological feasibility issues with methane standards at the current level for CNG fueled vehicles with engines of a displacement similar to VPG's. VPG requests a review of the CH_4 standard as applied to dedicated CNG fueled vehicles. [EPA-HQ-OAR-2010-0799-7985-A2, p. 4]

Finally, VPG recommends a review of the methane emissions standards as applied to CNG fueled vehicles. [EPA-HQ-OAR-2010-0799-7985-A2, p. 4]

Response:

In response to AGA and ANGA comments concerning the global warming potential (GWP of CH_4, the GWPs used in this rule are consistent with the 100-year time frame values in the 2007 Intergovernmental Panel on Climate Change (IPCC) Fourth Assessment Report (AR4). These AR4 values are based on latest science from the IPCC, they are consistent with the values used in the MYs 2012-2016 LD and MYs 2014-2018 HD rulemakings, and we consider them to be the most appropriate values for this rule. At this time, the 100-year GWP values from the 1995 IPCC Second Assessment Report (SAR) are used in the official U.S. GHG inventory submission to the United Nations Framework Convention on Climate Change (UNFCCC) per the reporting requirements under that international convention. As the commenters note, some EPA programs use SAR values since they have deemed consistency with the national GHG inventory and other relevant programs to be appropriate for their purposes. For example, the GWP of 21 was used in a recent oil and gas rulemaking in order to maintain consistency with the SAR GWP values used in the national GHG inventory and in the US Greenhouse Gas Reporting Program, which collects data from emitters in that sector. The UNFCCC recently agreed on revisions to the national GHG inventory reporting requirements, and will begin using the 100-year GWP values from AR4 for inventory submissions in the future.

Commenters generally supported EPA's proposal not to change the CH_4 standards and supported the flexibilities discussed in section 10.2.1 above. VPG commented that the CH_4 standard established in the MY 2012-2016 rule should be revisited for CNG vehicles. VPG mentions not being able to find the CH_4 data for the Honda dedicated CNG vehicle in the certification data. In response, EPA believes that CH_4 can be controlled through emissions systems optimization and continues to believe that the CH_4 standard previously established is feasible and appropriate. As noted in comments submitted by the Manufacturers of Emission Controls Association (MECA), the performance of advanced emission control technologies for advanced diesel, gasoline, and natural gas-fueled powertrains can also be optimized to minimize N_2O and CH_4 emissions from future light-duty vehicles consistent with the limits EPA has set. The Honda dedicated CNG vehicle provides an example of the potential for CH_4 emissions control, with a certification value of 0.015 compared to a CH_4 standard of 0.03 g/mile.[21]

In addition, EPA is providing the flexibility to use CO_2 credits on a CO_2-equivalent basis to address excess CH4 emissions. Several commenters from the natural gas industry commented in support of these provisions (see 10.2.1, above). VNG Co commented that "the flexibility may be useful for manufacturers of NGVs, particularly converters that will be important in developing the market in the early years. Because small quantities of unburned natural gas from NGV engines may be emitted as methane, NGVs may have slightly higher emissions of this GHG than petroleum-fueled ICE vehicles. However, due to much greater reductions of CO_2 emissions, NGVs still yield net GHG emission reductions of approximately 24 percent. These flexible compliance rules will ensure that net GHG reductions are accounted for properly, and automakers are not penalized so long as slight increases in methane emissions are offset by CO_2 over-compliance." America's Natural Gas Alliance (ANGA) and American Gas Association (AGA) also commented in support of this flexibility. EPA concurs with these comments.

[21] MY 2012 certification data is available at: http://www.epa.gov/otaq/crttst.htm.

EPA notes further that manufacturers that are small businesses remain exempt from meeting the N_2O and CH_4 standards as well as the CO_2 standards under the MY2017-2025 program, as with the MY 2012-2016 program. It is EPA's understanding that VPG currently qualifies as a small business.

Comments regarding CH_4 and N_2O standards as they apply to police and emergency vehicles are addressed in section 10.5 below.

10.3. Alternative CO_2 Standards for Small Volume Manufacturers with U.S. Sales below 5,000 Vehicles

Organizations Included in this Section

Association of Global Automakers, Inc. (Global Automakers)
Aston Martin Lagonda Limited, Lotus Cars Limited and McLaren Automotive
Ferrari
Ferrari & Maserati of Seattle
Ferrari of Houston, Texas and Ferrari of Austin, Texas
Miller Motorcars
Penske Corporation
Volkswagen Group of America
Wide World Ferrari, Wide World of Cars, LLC

Organization: Association of Global Automakers, Inc. (Global Automakers)

Global Automakers supports the approach proposed by EPA to establish small volume manufacturer standards on a company-specific basis. The approach provides the compliance flexibility that this small segment of the industry needs while also contributing to the control of GHG emissions. This approach would be most efficiently administered if manufacturers may petition for, and EPA grants, alternative standards for multiple model years in a single proceeding. Such standards should be issued at least 18 months prior to the first affected model year. We also urge EPA and NHTSA to work cooperatively to harmonize CAFE and GHG standards for these small companies. [EPA-HQ-OAR-2010-0799-9466-A1, p. 8]

Also with regard to the issue of small volume manufacturers, Global Automakers strongly supports including regulatory language in the final rules that would amend the existing 40 CFR 86.1838(b) regarding small volume manufacturers to include the criteria set forth in the preamble to this regulatory package at 76 FR 74992 (middle column). These criteria would allow a manufacturer to retain SVM status if it can demonstrate that it is 'operationally independent' from another manufacturer that may have an ownership interest in that manufacturer. [EPA-HQ-OAR-2010-0799-9466-A1, p. 8]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 52.]

Additionally, Global Automakers supports the case-by-case small-volume manufacturers' approach as well as harmonization of the definitions for small-volume manufacturers. The case-by-case approach allows the flexibility that this small segment of the industry needs while maintaining requirements necessary to control greenhouse emissions.

Inclusion of the criteria included in the above referenced preamble text would provide necessary flexibility for historically independent small manufacturers, while the criteria are sufficiently stringent (e.g., strict limits on the total vehicles sold in the US, no joint ownership of intellectual property by the manufacturers, separate R&D, testing, and development facilities, independent verification, etc) so that there would be virtually no ability to abuse this provision. In addition, any manufacturer that meets the criteria set forth in the preamble would still need to comply with the provisions applicable to all SVMs. [EPA-HQ-OAR-2010-0799-9466-A1, p. 8]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 68.]

And, finally, Global Automakers supports the case-by-case small volume manufacturers approach. It allows the flexibility that this small segment of the industry needs while also mandating requirements necessary to control greenhouse gases. We also support the harmonization of the definition of small volume manufacturers.

Organization: Aston Martin Lagonda Limited, Lotus Cars Limited and McLaren Automotive

This comment is submitted on behalf of Aston Martin Lagonda Limited, Lotus Cars Limited and McLaren Automotive Limited. Each of these companies is classified as a “small volume manufacturer” (SVM) under EPA regulations and is a manufacturer of a very limited number of high performance sports cars. See www.astonmartin.com; www.lotuscars.com; www.mclarenautomotive.com. [EPA-HQ-OAR-2010-0799-5387-A2, p. 1]

We present here the viewpoint of SVMs as regards EPA’s proposal to establish MY 2017-2025 GHG standards for light-duty vehicles.2 All three manufacturers understand the need to control CO_2 and support the regulatory efforts of EPA and NHTSA. The three companies further believe that small manufacturers must do their fair share to reduce GHGs. [EPA-HQ-OAR-2010-0799-5387-A2, p. 1]

SVMs agree with both the rationale and goal behind the NPRM’s SVM provisions and urge EPA to promulgate the proposed mechanism to set SVM GHG standards on an SVM-by-SVM basis. [EPA-HQ-OAR-2010-0799-5387-A2, p. 3]

As recognized by EPA, the case-by-case SVM approach is already found in the CAFÉ law (49 USC 32902), the EU small volume manufacturer CO_2 derogation, and both the California existing GHG provision (13 CCR 1961.1) as well as in the recently proposed Advanced Clean Car rule. Adopting the case-by-case SVM GHG mechanism would thus align EPA’s approach with that of NHTSA, the EU, and CARB, furthering the desirable objective of harmonization. [EPA-HQ-OAR-2010-0799-5387-A2, p. 3]

EPA has requested comments on allowing SVMs to apply for a case by case standard for model years prior to MY 2017. We fully support the idea of allowing optional application for a case-by-case standard starting with MY 2015 (with application being made no later than July 2013). [EPA-HQ-OAR-2010-0799-5387-A2, p. 3]

CONCLUSION: The proposed case-by-case SVM mechanism is fair and equitable and also meets the necessary goal of appropriate control of GHG. The SVM provisions should be promulgated as proposed with optional early opt in starting in MY 2015.

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 118-119.]

---

2 The three companies submitting this comment take no position on the issue of expanding the GHG SVM rule to small manufacturers that are part of larger groups and are operationally independent.

Organization: Ferrari

Ferrari fully supports EPA's proposal to establish a method for a vehicle manufacturer to demonstrate "operational independence" if, under EPA regulations, the manufacturer's sales otherwise would have to be aggregated with those of another vehicle manufacturer. Finalizing this provision will benefit truly small, historically independent vehicle manufacturers while still protecting the environment and minimizing vehicle greenhouse gas ("GHG") emissions. As proposed, the proposed criteria enumerated at 76 Fed. Reg, 74,992 (middle column) are fully sufficient to prevent vehicle manufacturers from "gaming" the system, yet still offer necessary flexibility for individual vehicle manufacturers with unique ownership and operational structures. [EPA-HQ-OAR-2010-0799-9535-A2, pp.1-2]

Despite the Ownership Structure, Ferrari is Uniquely Positioned as an Operationally Independent Vehicle Manufacturer. [EPA-HQ-OAR-2010-0799-9535-A2, p.2]

The existing 40 CFR § 86.1838(b), which governs small volume manufacturer ("SVM") certification procedures, includes a provision regarding "aggregation" of sales which is based on the percentage ownership of the SVM by another vehicle manufacturer. Sales of the two manufacturers are aggregated when another manufacturer owns more than 10% of the smaller manufacturer. At the present time Fiat SpA) owns 90i% of Ferrari SpA. Due to the transactions that occurred in 2009 regarding Fiat, the U.S. government and Chrysler Group LLC [[EPA-HQ-OAR-2010-0799-10037-A2]], a unit of Fiat SpA now owns more than 10% of Chrysler. As an unintended consequence of these transactions, Ferrari could lose its status as an SVM, which it has historically held. If that were to occur, the result would be devastating to Ferrari since it would need to immediately change its certification, durability testing, as well as making it part of a large volume manufacturer for purposes of the GHG rules. This consequence could severely limit Ferrari in the U.S. market, despite aggressive efforts to reduce GHG emissions from vehicles sold in the U.S. It also would ignore the reality of how Ferrari and Fiat operate. For the 60 years of Ferrari's existence, the company has always operated independently of any parent company or other ownership structure. [EPA-HQ-OAR-2010-0799-9535-A2, p.2]

Specifically, Ferrari has complete design autonomy from Fiat and every other company in the Fiat Automobiles group, including Chrysler. Overall vehicle and powertrain design is overseen from the Ferrari Maranello facility; no Fiat personnel are involved in any way with this operation. Ferrari is exclusively in charge of all Ferrari research and development, with no participation or assistance from Fiat. Ferrari's budget for R&D is set by Ferrari and is independent of any R&D budget for Fiat. Ferrari parts design and procurement are completely independent of Fiat Automotive's procurement operations. Ferrari engine and transmission design, machining and production, as well as body, paint, interior and final assembly are all performed at the Maranello facility— again, completely independent of Fiat design, machining, production, and assembly. All Ferrari vehicle testing, evaluation, emission certification and documentation are all performed at Maranello, completely independent of Fiat testing, certification, and other operations. Marketing, competitive racing and other actions to promote the Ferrari brand are all handled by exclusively by Ferrari without control by Fiat. Overall management of Ferrari is independent from Fiat. While there are a small number of individuals from Fiat SpA who are on Ferrari's Board of Directors, these individuals (separately or combined) are not able to exercise exclusive management control over Ferrari or Fiat. In sum, despite the ownership of stock, Ferrari operates on a day-to-day and model year-to-model year basis as an entity that is entirely separate from Fiat. [EPA-HQ-OAR-2010-0799-9535-A2, p.2]

Furthermore, EPA states in the proposal: [EPA-HQ-OAR-2010-0799-9535-A2, p.3]

[A] small manufacturer under the umbrella of a large manufacturer is fundamentally different from other SVMs because the large manufacturer has several options under the GHG program to bring the smaller subsidiary into compliance, including the use of averaging or credit transfer provisions, purchasing credits from another manufacturer, or providing technical and financial assistance to the smaller subsidiary. [EPA-HQ-OAR-2010-0799-9535-A2, p.3]

While this may be true in other circumstances, the ownership structure between Fiat and Ferrari provides Ferrari with little, if any, preferential access to any credits generated by Fiat. As explained above, under the long-standing arrangement between the two companies, Fiat does not provide financial or technical assistance to Ferrari. Any such transactions between the two companies would be at arms-length and no different than if the two companies had no common ownership. Ferrari therefore obtains no preference or benefits through its association with Fiat that would advantage Ferrari compared to other SVMs. [EPA-HQ-OAR-2010-0799-9535-A2, p.3]

Establishing an "Operational Independence" Option Would Be Consistent with Past EPA and California Air Resources Board Practice. [EPA-HQ-OAR-2010-0799-9535-A2, p.3]

Over the past ten years in determinations under the existing EPA SVM regulations, the Highway Safety Act, and the California Air Resources Board ("CARB") regulations, Ferrari has consistently been determined to be an independent SVM. Even in the early 2000s, when General

Motors owned 20% of Fiat, EPA determined under the then existing SVM regulations, which are comparable to the current SVM certification provision that Ferrari was an independent SVM. The National Highway Traffic Safety Administration ("NHTSA") has made similar determinations under the Safety Act. CARB has also considered Ferrari an independent SVM for purposes of their vehicle tailpipe emissions and on-board diagnostic ("OBD") programs. Thus, establishing criteria by which a manufacturer can demonstrate that it is operationally independent would be fully consistent with past EPA, NHTSA, and CARB practice. [EPA-HQ-OAR-2010-0799-9535-A2, p.3]

The Proposed Criteria Are Stringent And Will Not Encourage "Gaming" of the System. [EPA-HQ-OAR-2010-0799-9535-A2, p.3]

EPA requested comment on the agency's concern that some manufacturers could "change their corporate structure to take advantage of such provisions (that is, gaming)." Ferrari supports the proposed criteria for establishing operational independence and believes that they are sufficiently stringent to prevent some manufacturer from attempting to "game" the system. In order to attempt to restructure an existing corporate situation, Ferrari believes the cost of separating all, R&D, production and testing facilities from the parent company, along with the expense of developing completely new powertrains and platforms, would be prohibitively expensive. The cost of purchasing any jointly-held patents also could be astronomical. Depending on the company, separating all business, administration, legal, purchasing, sales, and marketing functions also could be complicated and cost prohibitive. [EPA-HQ-OAR-2010-0799-9535-A2, pp.3-4]

Finally, the "new" manufacturer would have to maintain this status for two full years prior to applying for operational independence SVM status. During this time, the new manufacturer presumably would have to comply with the applicable GHG emission standards without any support from the manufacturer from which it is newly separated. The new manufacturer would not be eligible to apply for and comply with the more flexible case-by-case SVM standards that EPA has proposed. Given that there would be little benefit to a large manufacturer to spin off and separate a model line that over-complies with the applicable GHG standard, the new manufacturer would likely not be in compliance with the GHG standards during this two-year period. Even with the credit carry-forward/carry-back options, it would be exceedingly difficult for a new manufacturer to make up this credit deficit if and when it is deemed an operationally-independent SVM without purchasing credits (which may be a very difficult task, given the stringency of the proposed GHG standards for these MYs). In addition, if the newly-created SVM applied for case-by-case standards, EPA intends to establish such standards at a "challenging but less stringent" level; thus, the SVM would not be generating large numbers of credits for each model year that could make up for two years of likely credit deficits. [EPA-HQ-OAR-2010-0799-9535-A2, p.4]

Overall, there do not appear to be any scenarios where it would make financial or operating sense for a large manufacturer to try to take advantage of the operational independence criteria to "spin-off" fewer than 5000 vehicles per year. EPA also has the authority to deny an application for operational independent SVM status and can address any concerns about gaming during the application and approval process. Because we believe that opportunities for gaming the system are minimal at best, and that EPA will be able to adequately identify such circumstances, Ferrari recommends that EPA finalize the operational independence criteria with only one small revision. [EPA-HQ-OAR-2010-0799-9535-A2, p.4]

In order to eliminate any confusion regarding the meaning of the requirement, Ferrari recommends that EPA revise the proposed 40 CFR § 86.1838-01(b)(4)(a)(iii) as follows: [EPA-HQ-OAR-2010-0799-9535-A2, p.4]

(iii) ~~related manufacturers~~ the applicant does not use any vehicle powertrains or platforms developed or produced by related manufacturers. [EPA-HQ-OAR-2010-0799-9535-A2, p.4]

This minor change will clarify that the applicant for operationally independent SVM status does not rely on other, related manufacturers for powertrains or other vehicle platforms. However, the revision would enable the applicant to sell, consistent with (i) and (vii), parts and components to a related manufacturer through an open market process at competitive pricing. [EPA-HQ-OAR-2010-0799-9535-A2, pp.4-5]

An Operational Independence Option Will Have Little Overall Effect on Vehicle GHG Emissions. [EPA-HQ-OAR-2010-0799-9535-A2, p.5]

EPA's proposal to allow an operationally-independent manufacturer to be considered an SVM for purposes of the GHG program will have very little overall effect on vehicle GHG emissions. As noted above, Ferrari sells approximately 1500-1800 vehicles in the U.S. each year. Under the MY 2012-2016 rules, Ferrari would need to make the requisite showing in 40 CFR § 1801-12(k), and under the proposal for MY 2017-2025, as an SVM, Ferrari could seek alternative, case-by-case standards for its fleet. EPA explained in the preamble that the SVM case-by-case standards are still intended to be challenging, will still require innovation and development of new technologies, and will still require the SVM to do its "fair share" of reducing emissions.5 As proposed, the process of obtaining SVM-specific standards includes a comprehensive evaluation of all aspects of the SVM's fleet, use of technology, and projections of sales and introduction of new models covering up to five model years. This process will enable EPA and the manufacturer to develop SVM-specific standards that are protective of the environment and require technological innovation while reflecting the unique characteristics of the SVM's fleet of vehicles. Ferrari supports the approach EPA has proposed and notes that it is consistent in concept with the system used in the European Union. [EPA-HQ-OAR-2010-0799-9535-A2, p.5]

The Provision on "Attest Engagements" Should Mirror the Provision Contained in EPA's Regulations on Fuel and Fuel Additives. [EPA-HQ-OAR-2010-0799-9535-A2, p.5]

EPA requested comments on whether to require a manufacturer seeking operationally independent SVM status to provide an "attest engagement" from an independent auditor, verifying the accuracy of the information contained in the manufacturer's application. Ferrari supports this concept and recommends that EPA adopt a provision that is comparable to the provision in the agency's Fuel and Fuel Additive regulations in 40 C.F.R. Part 80. In those regulations, EPA requires refiners and fuel importers subject to Subpart F of 40 C.F.R. Part 80 to engage an outside auditor to verify information. Section 80.125 specifies that the CPA shall perform the attest engagement in accordance with the Statements on Standards for Attestation Engagements, which is incorporated by reference, and allows the assistance of internal auditors who are employees or agents of the regulated company, as long as such assistance is consistent with the guidelines contained in the Statements on Standards for Attestation Engagements. This provision further allows the attest engagement to be completed by an auditor who is an employee of the regulated company, provided that the employee is an internal auditor certified by the Institute of Internal Auditors and completes the internal audits in accordance with the Codification of Standards for the Professional Practice of Internal Auditing. Adopting these requirements into the process for demonstrating operational independence will allow some measure of flexibility for the manufacturer while ensuring the accuracy of the information and the independence of the auditor. Furthermore, Ferrari recommends that EPA clarify in the final rule that the auditor performing the attest engagement does not have to be a new auditor hired solely for the purposes of conducting this audit. Rather, EPA should allow a manufacturer to continue to use a CPA or other auditor who has previously performed similar functions for the company, as long as the auditor meets the requirements discussed above. Finally, since a number of the criteria listed in the preamble involve engineering issues, Ferrari suggests that the entity performing the Attest Engagement be allowed to use personnel from outside its organization as necessary to assist in this effort. [EPA-HQ-OAR-2010-0799-9535-A2, pp.5-6]

EPA Should Allow a Time Period for Adjustment If a Manufacturer's Situation Changes. [EPA-HQ-OAR-2010-0799-9535-A2, p.6]

EPA has asked for comment on what should occur in the event a manufacturer who is an SVM has changed circumstances that would no longer make it eligible for this status. While Ferrari does not anticipate this occurring, if its status or other SVM's status should change, EPA should provide at least a three-year transition period to allow the manufacturer to develop the additional testing facilities and time for durability testing, as well as for software, hardware development and installation. Such a period will be needed, since it is highly unlikely that any SVM would be able to immediately transition from this status to that of a full-line manufacturer. [EPA-HQ-OAR-2010-0799-9535-A2, p.6]

Inclusion of a revision to 40 CFR § 86.1838(b) to provide for "operational independence" in this package of rules is critically important to Ferrari. As such, Ferrari strongly supports including such a provision in the final rule. Attached is proposed text of such a revision. [EPA-HQ-OAR-2010-0799-9535-A2, p.6]

Ferrari agrees with many parts and principles of the proposed regulations, including the specific provisions for small-volume manufacturers contained in the EPA GHG proposal. We deem that the proposed approach to define specific standards for each single SVM is the best solution, because it is possible to take into account the potential technical and economic capabilities of each small-volume manufacturer. Moreover, this method is consistent with both the already existing CAFE regulation that allows small manufacturers to petition NHTSA for alternative fuel economy standards, and also the corresponding European Union Regulation 443/2009/EC on CO_2. [EPA-HQ-OAR-2010-0799-9535-A2, p.10]

As noted in the main comments, we strongly recommend introducing the concept of "operational independence" for small-volume manufacturers, so that the specific standards reserved to SVMs can also be used by this sub-category of small-volume manufacturers that operate independently from any other companies, in spite of ownership interests. [EPA-HQ-OAR-2010-0799-9535-A2, p.10]

NHTSA's proposed standards will require passenger cars to meet an estimated average of 49.6 mpg in MY 2025. This represents an average annual increase of 5 percent from the 34.4 mpg average for 2016 MY. [EPA-HQ-OAR-2010-0799-9535-A2, p.14]

With reference to the final 2010 MY Ferrari CAFE of 18.3 mpg (the best ever so far) we would need to increase our CAFE by approximately 108 % in MY 2017 up to 191 % in MY 2025. We are confident to achieve remarkable improvements in the fuel economy and reductions of CO_2 emissions with new models which will benefit of further improvements and other technologies in the future, but we cannot satisfy the proposed targets and percentages. [EPA-HQ-OAR-2010-0799-9535-A2, p.14]

Organization: Ferrari & Maserati of Seattle

We therefore urge EPA to finalize the criteria that would enable a very small volume manufacturer (SVM), such as Ferrari, to demonstrate that it is operationally independent from related manufacturers and comply with company-specific fleet average greenhouse gas (GHG) emission standards. [EPA-HQ-OAR-2010-0799-9197-A2, p. 1]

Existing EPA regulations require sales to be aggregated when one vehicle manufacturer holds more than a 10% interest in another manufacturer. In the proposed rule, EPA included a list of criteria that a SVM could satisfy in order to demonstrate that it is operationally independent, despite the ownership structure that would otherwise require sales aggregation. See pages 74,991-92 of the proposed rule. These criteria are stringent enough to prevent gaming of the system, yet would provide a manufacturer like Ferrari with the necessary flexibility to comply with case-by-case GHG emission standards. Given the very low number of Ferraris sold in the U.S. each year, the proposal would have only negligible effects on overall vehicle GHG emissions. If EPA does not finalize the operational independence criteria and Ferrari's sales must be aggregated with sales of Fiat in the U.S., sales of Ferrari may be reduced. This would have a devastating effect on our business and our employees. [EPA-HQ-OAR-2010-0799-9197-A2, p. 1]

Organization: Ferrari of Houston, Texas and Ferrari of Austin, Texas

In the December 2011 proposal EPA proposed criteria that would allow a vehicle manufacturer to demonstrate that it is 'operationally independent' from other related vehicle manufacturers (see pages 74,991-92). EPA Regulations currently require sales to be aggregated if a vehicle manufacturer owns a 10% or greater share in another manufacturer. The operational independence criteria would allow a qualifying manufacturer to be treated as a small volume manufacturer (SVM) for the purposes of GHG regulations, including compliance with challenging case-by-case emission standards instead of the fleet average standards that would otherwise apply. Ferrari of Houston and Ferrari of Austin urge EPA to finalize this option. [EPA-HQ-OAR-2010-0799-9230-A2, p.1]

EPA's proposal would establish a rigorous process to ensure that a manufacturer applying to be treated as an operationally-independent SVM is truly an independent entity. [EPA-HQ-OAR-2010-0799-9230-A2, p.1]

Opportunities to game the system would be limited and, given the very small number of vehicles that Ferrari sells each year in the U.S., the effect on the overall vehicle GHG emissions would be miniscule. [EPA-HQ-OAR-2010-0799-9230-A2, p.2]

However, without this option, the U.S. sales of Ferrari and Fiat would have to be aggregated. Aggregation would restrict Ferrari's ability to sell vehicles in the U.S., which would be harmful to our business, our employees, and our vendors and suppliers. EPA should therefore finalize the operational independence criteria and provide necessary flexibility to SVMs that can demonstrate independence from any related manufacturers. [EPA-HQ-OAR-2010-0799-9230-A2, p.2]

Organization: Miller Motorcars

EPA has proposed to allow a manufacturer to comply with the small volume manufacturer (SVM) GHG emission standards if the manufacturer can show that it is 'operationally independent' from other related manufacturers. Under current EPA regulations, sales of two related vehicle manufacturers must be aggregated if there is common ownership of 10% or more. The EPA proposal would suspend the aggregation requirement if specific, stringent criteria can be satisfied. The proposal would provide needed flexibility for very small manufacturers, like Ferrari, that are fully independent from any related companies. No environmental harm would ensue since the SVM would have to comply with case-by-case GHG emission standards that EPA intends to be challenging yet achievable. At the same time, EPA has proposed criteria that are difficult to satisfy and which will prevent companies from trying to take advantage of the provision or game the system. Without this option, Ferrari may be forced to reduce or limit U.S. vehicle sales, which would adversely affect our business and our employees. Miller Motorcars therefore urges EPA to finalize this option. [EPA-HQ-OAR-2010-0799-8141-A2, p. 1]

Organization: Penske Corporation

Ferrari of Scottsdale, Ferrari of Central Jersey, and Ferrari of Las Vegas support EPA's proposal to allow a manufacturer to demonstrate that it is 'operationally independent' from the other automobile manufacturers with which its sales would otherwise have to be aggregated under existing EPA regulations. As a small volume manufacturer (SVM), the manufacturer would then be able to apply for and comply with case-by-case GHG emission standards that reflect the degree of GHG emissions reduction that is challenging but still achievable for the manufacturer's fleet. This option would provide necessary flexibility for those small volume manufacturers that are truly independent from other automobile manufacturers in their operations and ensure that Ferrari's ability to sell vehicles in the U.S. is preserved. [EPA-HQ-OAR-2010-0799-9187-A2, p. 1]

If Ferrari does not obtain SVM status and the sale of Ferraris is restricted, then our Ferrari business could suffer greatly. Even a modest reduction in the number of vehicles that Ferrari is able to sell in the U.S. in a given model year could have a substantial impact on these Ferrari dealers and the number of employees we are able to sustain. [EPA-HQ-OAR-2010-0799-9187-A2, p. 2]

Thus, Ferrari of Scottsdale, Ferrari of Central Jersey, and Ferrari of Las Vegas urge EPA to finalize the option described on page 74,992 of the proposal to demonstrate operational independence. EPA has proposed stringent criteria that will ensure that a manufacturer seeking to establish operational independence is truly independent. As proposed, the criteria and application process would make it extraordinarily difficult for a manufacturer to change its existing business operation in order to take advantage of the flexibility granted to SVMs. The proposal also would be protective of the environment, as the agency would set case-by-case GHG emissions standards for a SVM that would be challenging yet achievable. [EPA-HQ-OAR-2010-0799-9187-A2, p. 2]

Organization: Volkswagen Group of America

In the NPRM the agencies seek comment on the concept of operational independence for Small Volume Manufacturers (SVM), whereby a captured small volume brand that is more than 10% owned by another company could petition the agencies for SVM status based on an attestation and demonstration of operational independence. As an operationally independent small volume manufacturer, a company would then have the option to petition the agencies for a negotiated CO_2 and fuel economy standard. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 28-29]

Volkswagen supports the concept of allowing a captured brand with less than 5,000 annual vehicle sales to have the flexibility to petition for SVM status. However, Volkswagen is concerned that the operational independence criteria listed in the NPRM is too prescriptive and difficult to apply across all circumstances of captured small volume brands. For example, while it may be common for a small volume brand to use a common platform or engine from a parent company, in many cases these systems are altered to accommodate separate features or performance characteristics. In addition, such major components would be part of a business contract and not merely provided gratis to different brands within a group. As such Volkswagen requests that EPA and NHTSA allow this flexibility for demonstration of operational independence in the final regulation but requests that the agencies consider the operational independence of each manufacturer on an individual basis during the petition process. As such the degree of independence could be part of the negotiation process for setting standards for a particular SVM. [EPA-HQ-OAR-2010-0799-9569-A1, p. 29]

Organization: Wide World Ferrari, Wide World of Cars, LLC

The proposed language would allow a manufacturer to qualify as a small volume manufacturer (SVM) on the basis of its own sales if it can show that it is 'operationally independent' from related manufacturers with which its sales would otherwise be aggregated (see pages 75,991-92 of the proposal). Ferrari of West Palm Beach and Wide World of Cars support EPA’s proposal to allow an operationally-independent manufacturer to be considered a SVM for purposes of the greenhouse gas (GHG) program. The proposed federal regulatory language contains stringent criteria that would ensure strong environmental protections and minimize gaming opportunities, while still allowing flexibility for SVMs like Ferrari that cannot offset emissions of their low volume high performance vehicles with higher volume, lower emission vehicles in the larger fleet. [EPA-HQ-OAR-2010-0799-8142-A2, p. 1]

The proposed language would provide flexibility for small volume manufacturers like Ferrari that are truly independent from other automobile manufacturers in the ownership structure. It also would preserve Ferrari's ability to sell vehicles in the U.S. Our business could suffer if Ferrari does not obtain SVM status and the sale of Ferraris is restricted. A small change in the number of vehicles that Ferrari is able to sell in the U.S. in a given model year could have a substantial impact on our bottom line and number of employees. [EPA-HQ-OAR-2010-0799-8142-A2, p. 2]

EPA's proposal would have very little overall effect on vehicle GHG emissions, because the vehicles sold by SVMs would still have to comply with challenging case-by-case GHG emission standards. The proposed regulatory language also contains stringent criteria and an application process that would make it exceedingly difficult for a manufacturer to alter its existing business in order to take advantage of the flexibility granted to SVMs. [EPA-HQ-OAR-2010-0799-8142-A1, p. 2]

Thus, Ferrari of West Palm Beach and Wide World of Cars urge EPA to finalize the option to demonstrate operational independence. [EPA-HQ-OAR-2010-0799-8142-A2, p. 2]

Response:

EPA received only supportive comments for the proposed case-by-case alternative standards approach for SVMs. In addition, EPA received only supportive comments on allowing manufacturers able to demonstrate operational independence from a parent company to also be eligible for SVM provisions under the GHG program. Responses to comments regarding the SVM alternative standards are provided in section III.B.5.b and comments regarding operational independence are addressed in III.B.5.e.

With regard to Ferrari's suggestion regarding regulatory text pertaining to the applicant's use of any vehicle powertrains or platforms developed or produced by related manufacturers, EPA concurs with the comment and the final regulatory text is consistent with Ferrari's suggestion.

Ferrari recommends that "EPA clarify in the final rule that the auditor performing the attest engagement does not have to be a new auditor hired solely for the purposes of conducting this audit. Rather, EPA should allow a manufacturer to continue to use a CPA or other auditor who has previously performed similar functions for the company, as long as the auditor meets the requirements discussed above. Finally, since a number of the criteria listed in the preamble involve engineering issues, Ferrari suggests that the entity performing the Attest Engagement be allowed to use personnel from outside its organization as necessary to assist in this effort." EPA believes these recommendations are reasonable and has adopted Ferrari's suggestions regarding the attest engagement.

Ferrari commented that EPA should provide at least a three-year transition period to allow the manufacturer to develop the additional testing facilities and time for durability testing, as well as for software, hardware development and installation. EPA is providing 2 full model years after the model year in which a manufacturer's status as operationally independent has changed. In total this will provide the manufacturer with 2 to 3 years to comply with the primary program depending on the timing of the change. EPA believes that this will be sufficient as the parent company and manufacturer would likely have some control over the timing of the change in their status.

10.4. Exemption for Small Businesses

Organizations Included in this Section

AMP Electric Vehicles
Fisker Automotive, Inc.
Vehicle Production Group LLC (VPG)

Organization: AMP Electric Vehicles

The purpose of this letter is to state our support for the provision in the proposed 2017 Light-Duty Vehicle Greenhouse Gas rules that allows small business the opportunity of voluntarily opting-in to the GHG standards. Further, it is our contention that the voluntary opt-in option should be extended to EV converters and alterers. [EPA-HQ-OAR-2010-0799-7984-A1, p. 1]

As you are aware, in the MY 2012-2016 rule regarding greenhouse gas, EPA exempted entities from the emissions standard, "if the entity met the Small Business Administration (SBA) size criteria of a small business as described in 13 CFR 121.201." As we researched this issue, we learned that the intent of the exemption was to assist small OEMs that might not have the resources necessary to address the CO_2 standards in the regulation. An unintended consequence of this small business exclusion is that start up companies, such as AMP, are not be able to accumulate CO_2 credits for converting high emitting internal combustion engine SUVs to emission free EVs. [EPA-HQ-OAR-2010-0799-7984-A1, p. 1]

In the recently published "2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards Rules" an "opt-in" provision allowing small businesses to voluntarily waive their small entity exemption to the GHG standards is proposed. AMP Electric Vehicles unequivocally supports this proposed rule, request that it be made effective immediately and that it be made applicable to converters and alterers. [EPA-HQ-OAR-2010-0799-7984-A1, p. 1]

Passage of the 2017 GHG opt-in provision would allow AMP the ability to accumulate greenhouse gas credits and market them to larger OEMs. Our intent is to exchange these credits with large OEM's in return for distribution assistance through their dealer networks. This would greatly enhance our ability to sell greater volumes of EV's than we would otherwise. In our preliminary discussion with large OEMs in need of credits this concept has received favorable consideration. [EPA-HQ-OAR-2010-0799-7984-A1, p. 1]

Additionally, approval of the opt-in provision would allow AMP the opportunity to generate greater revenue to offset our technology investments and free up capital to invest in additional innovative automotive green technologies. [EPA-HQ-OAR-2010-0799-7984-A1, p. 1]

Further, the provision will afford larger OEM seeking credits a better opportunity to meet their compliance obligations. [EPA-HQ-OAR-2010-0799-7984-A1, p. 2]

Finally, and very importantly, the net result of the passage of 2017 Green House Gas Small Business Opt-In provision is that it would increase the percentage of low and emission free vehicles on America's roads consistent with the intent of this legislation. [EPA-HQ-OAR-2010-0799-7984-A1, p. 2]

AMP recognizes that by choosing to opt-in, our company would be subject to all of the requirements that would otherwise be applicable under this legislation. However, the net effect of its passage would greatly benefit our company and our goal of producing a significant quantity of zero emission vehicles allowing us to contribute to our mutual goal of cleaning up our country's environment. [EPA-HQ-OAR-2010-0799-7984-A1, p. 2]

Organization: Fisker Automotive, Inc.

2) Discuss modifications to the optional compliance provision for small entities

Fisker Automotive is a start-up automobile manufacturer employing fewer than 1,000 people, which qualifies our company as a small entity under Small Business Administration guidelines. The final rule for model years 2012-2016 exempted and excluded small entities from the fleet greenhouse gas standards. Without the ability to opt-in to the rule, we would miss an important opportunity to market the credits generated by this rule to other manufacturers. [EPA-HQ-OAR-2010-0799-9266-A1, p. 2]

Fisker greatly appreciates the proposed optional compliance provision for small entities included in the current proposed rule. We fully agree with the rationale stated in the preamble: [EPA-HQ-OAR-2010-0799-9266-A1, p. 2]

EPA believes that there could be several benefits to this approach, as it would allow small businesses an opportunity to generate revenue to offset their technology investments and encourage commercialization of the innovative technology, and it would benefit any manufacturer seeking those credits to meet their compliance obligations.” [EPA-HQ-OAR-2010-0799-9266-A1, p. 2]

As proposed, the provision would make the opt-in available starting in model year 2014. While this provision would indeed allow Fisker to access the credits it would have generated for model years 2012 and 2013 if it were a large manufacturer, these credits would not be accessible until 90 days after the end of model year 2014, when final compliance for the model year is established. [EPA-HQ-OAR-2010-0799-9266-A1, p. 2]

We view the timing required by this proposal as problematic. Fisker would not be able to complete a transfer on its earned credits until late in calendar year 2014 at the earliest, or nearly three years from today. This would significantly diminish the revenue generating benefit of these credits, particularly during the critical early years of our company when they are most beneficial. [EPA-HQ-OAR-2010-0799-9266-A1, p. 2]

For this reason, we highly encourage EPA to modify the language of this provision such that a small entity would be allowed to fully demonstrate compliance beginning with the 2012 model year. [EPA-HQ-OAR-2010-0799-9266-A1, p. 2]

We believe optional compliance would be feasible beginning with model year 2012 for the following reasons: [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

1) The proposed rule is expected to go into effect by October of this year (60 days after final publication in August). Fisker anticipates its model year 2012 to end around the same time. Final compliance for a given model year is demonstrated with an end-of-year report due 90 days after the end of the model year. There is sufficient time after the rule takes effect for Fisker to demonstrate compliance with its end-of-year report for model year 2012 [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

2) The Fisker Karma sedan is already EPA-certified for model year 2012 under Federal Tier 2 exhaust emission standards, and has been issued a certificate of conformity to this effect [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

3) Fisker Automotive has a strong working relationship with EPA’s compliance division [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

4) Fisker is already subject to the CAFE regulation for model year 2012 [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

5) Since the GHG program “will not impose additional timing or testing requirements on manufacturers beyond that required by the CAFE program,” the only additional work required to comply with the GHG program would be limited to reporting [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

6) Fisker already adheres to the existing practice under Tier 2 to provide EPA with a compliance plan; for the GHG element of this plan, Fisker’s compliance is trivial since our fleet consists only of a vehicle that significantly over-complies with its GHG standard [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

Encourage enforcement of the requirement that manufacturers must make a good faith effort to secure credits from other manufacturers before becoming exempt from standards or becoming eligible for alternative standards As part of establishing eligibility for exemption from the CO_2 standards under the greenhouse gas (GHG) program for MY 2012-2016, Small Volume Manufacturers (SVMs) “must make a good faith effort to secure credits from other manufacturers, if they are reasonably available, to cover the emissions reductions they would have otherwise had to achieve under applicable standards." Fisker Automotive strongly encourages EPA to hold to the spirit of these provisions. As the only entity with complete knowledge of every automaker's credits and deficits, it is incumbent upon EPA to ensure that this provision is fairly enforced. [EPA-HQ-OAR-2010-0799-9266-A1, p. 4]

Organization: Vehicle Production Group LLC (VPG)

Limited Line Manufacturer

Among the first decisions in the development of the business model, was the powertrain selection. The option for VPG to manufacture its own powertrain was determined not to be practical for reasons of cost related to the development of base algorithms for engine controls and on-board diagnostics. Following that determination, a study of powertrains which were offered for sale was undertaken, which ultimately resulted in VPG securing a supply agreement with Ford Motor Company through the Ford Component Sales Division for the supply of powertrains and associated emissions equipment. Ford offered to VPG the V-8, 4.6 liter 16 valve engine, based upon VPG's power requirements, structural architecture, CNG compatibility as well as the production capacity of Ford's engine manufacturing operations. VPG's ability to provide wheelchair users with a superior alternative is dependent upon the production capacity and offerings of the engine manufacturer. [EPA-HQ-OAR-2010-0799-7985-A2, p. 1]

VPG's place in the automotive market is that we are the OEM manufacturer of vehicles which are accessible to wheelchairs. VPG's vehicle design encompasses ADA guidelines for ingress and egress, as well as wheelchair positioning and restraint inside the vehicle. This necessarily puts VPG in the role of a limited line manufacturer. [EPA-HQ-OAR-2010-0799-7985-A2, p. 2]

VPG's fuel economy performance is dependent upon the use of one powertrain. While VPG does have the benefit of offering a fueling option in CNG, the public acceptance of this fueling option is limited and focused, mostly for reasons of infrastructure. The customer base for the CNG option remains the fleet market, where driving patterns are routed near CNG filling stations, although this option offers the potential to raise VPG's CAFE. [EPA-HQ-OAR-2010-0799-7985-A2, p. 2]

As EPA advises in the NPRM, there are high risks for limited line manufacturers in implementing new technologies. In VPG's case, access to the technologies are limited or out of reach for reasons of market offerings, lead time, or feasibility. For example, EPA counts among other technologies, turbocharging as a technology which can be implemented after production decisions have been undertaken. However, such technologies are available to VPG only if the powertrain supplier offers the technology for sale to VPG. The alternative of VPG implementing a technology like turbocharging under the assumption it were added to the engines as a retrofit is not feasible. From the standpoint of development of controls and diagnostics algorithms, a limited line manufacturer such as VPG would not have the financial resources or expertise to implement these technologies with the requisite reliability, durability and timing. [EPA-HQ-OAR-2010-0799-7985-A2, p. 2]

We point out that the limited line nature of manufacturers has been used in the regulatory environment to differentiate the impact of regulations on smaller entities. Therefore, VPG requests institution of exemption from the greenhouse gas regulations based on the limited line manufacturer status. VPG suggests a review of the appropriate vehicle line threshold, with 3 lines or less being a reasonable place to visit this subject. [EPA-HQ-OAR-2010-0799-7985-A2, p. 2]

VPG notes that on page 75161 of this NPRM, potentially affected small entities are discussed in terms of three models: 1) small volume manufacturers (SVMs), 2) independent commercial importers, (ICIs), and 3) alternative fuel vehicle converters. We believe that the limited line manufacturer should be added to this list of types of small entities affected, and that allowances should be made for manufacturers in this list. [EPA-HQ-OAR-2010-0799-7985-A2, p. 2]

VPG requests exemption from this GHG regulation for small entities, limited line manufacturers. [EPA-HQ-OAR-2010-0799-7985-A2, p. 4]

Response:

EPA is finalizing its proposal to exempt small businesses from the MY 2017-2025 standards. EPA is also finalizing its proposal to allow small businesses manufacturers to waive their small entity exemption and opt-in to the primary GHG standards. Commenters generally supported both the exemption and the opt-in provisions. The opt-in will allow small business manufacturers to earn CO_2 credits under the program. The small business would have to meet the primary standard for its fleet (that is, the small business would be allowed to opt-in to the primary program standard, but not to the small volume manufacturer standards. Fisker's comments regarding the timing of the opt-in and credit generation are discussed in section III.B.7 of the preamble. VPGs comments regarding limited line manufacturers are also addressed in III.B.7.

In response to AMP's comments that small business alternative fuel converters should be allowed to generate credits, EPA does not view this as a small business issue but as an issue with the way alternative fuel conversions are addressed under EPA's fleet average standards. Alternative fuel converters are not required to meet fleet average standards but instead must comply with anti-tampering regulations by demonstrating that the conversion does not increase emissions. Fleet average standards are not generally appropriate for fuel conversion manufacturers because the ''fleet'' of vehicles to which a conversion system may be applied has already been accounted for under the OEM's fleet average standard. Alternative fuel converters are not manufacturing new vehicles, but are converting existing vehicles that have already been certified by the OEM. Converters must qualify for a tampering exemption under 40 CFR subpart F and fleet average standards do not apply. CO_2 credits are available to OEMs based on fleet emissions performance compared to the fleet average standards and therefore conversions are not eligible for these credits. A small business alternative fuel convertor may opt into the GHG program and thus be required to make a showing that they are in compliance with requirements of 40 CFR subpart F, but these vehicles would not be subject to the fleet average standards and therefore would remain ineligible for credits.

10.5. Exemption for Emergency and Police Vehicles

Organizations Included in this Section

Alliance of Automobile Manufacturers
Ford Motor Company
General Motors Company
Pennsylvania Department of Environmental Protection
Vehicle Production Group LLC (VPG)

Organization: Alliance of Automobile Manufacturers

Police and Emergency Vehicles [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

The Alliance agrees with EPA's proposal for the option to exclude police and emergency vehicles from fleet-average CO_2 standards.10 However, in order to harmonize with the CAFE regulations and fully exclude any influence that emergency vehicles may have on fleet average CO_2, EPA must exempt emergency vehicles from the methane (CH_4) and N_2O standards as well. [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

Per the current regulations, if any vehicle were to exceed the CH_4 and/or N_2O standards, a manufacturer would be required to either include the CH_4 and N_2O emission values for all vehicles in its fleet average calculation or account for the exceedance(s) using CO_2 credits. Therefore, if a police or emergency vehicle were to be the only vehicle to exceed either of these standards, the manufacturer would be incurring an increase in fleet-average CO_2 or a decrease in CO_2 credits solely due to the influence of the emergency vehicle. [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

The Alliance recommends that the following paragraph be added to 40 C.F.R. §86.1818-12(f): [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

Emergency vehicles. Emergency vehicles that have been excluded from fleet average CO_2 exhaust emission standards under paragraph (c)(4) of this section are exempt from the N_2O and CH_4 standards of this paragraph (f). [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

Organization: Ford Motor Company

Emergency Vehicles

EPA has proposed to exclude emergency vehicles, from the greenhouse gas requirement effective with the 2012 model year, consistent with the exclusion of emergency vehicles from CAFE standards. In our comments on the 2012-2016 rules, Ford urged EPA to exclude emergency vehicles from the GHG regulations; we stand by those comments and incorporate them herein by reference. Those comments are fully consistent with EPA's determination that the exclusion of these vehicles is appropriate,

"…because of the unique features of vehicles designed specifically for law enforcement and emergency purposes, which have the effect of raising their GHG emissions and calling into question the ability of manufacturers to sufficiently reduce the emissions from these vehicles without compromising necessary vehicle features or dropping vehicles from their fleets. (76 Fed. Reg. 74880) [EPA-HQ-OAR-2010-0799-9463-A1, p. 25]

Section 202(a) of the CAA allows EPA to prescribe standards 'applicable to the emission of any air pollutant from any class or classes of new motor vehicles…' The language 'class or classes' indicates that EPA may apply its standards to particular types or categories of vehicles, and likewise make exclude particular types or categories of vehicles when there is reason to do so. This language gives EPA the authority to incorporate regulatory provisions excluding emergency vehicles from the fleet average requirement. The exclusion of emergency vehicles makes sense as a matter of policy, and it also promotes the goals of One National Program by harmonizing the GHG and CAFE rules on this point. [EPA-HQ-OAR-2010-0799-9463-A1, p. 25]

Organization: General Motors Company

GM supports EPA's efforts to further harmonize with the NHTSA program with regard to the exclusion of emergency and police vehicles, and joins with the Alliance in suggesting modifications to section 40 C.F.R. §86.1818-12(f). [EPA-HQ-OAR-2010-0799-9465-A1, p. 4]

Organization: Pennsylvania Department of Environmental Protection

The Agencies Should Ensure that the Fleet Averages Reflect Real-World Conditions.

The agencies should, at minimum, include police and emergency vehicles in calculations of GHG fleet average standards. The EPA-led advisory committee presents a good case for new technologies to generate more horsepower. This extra horsepower can be used to downsize a vehicle's engine. No logical reason seems to exist as to why this new technology cannot be used for police and emergency vehicles in order to gain fuel efficiency without loss of power. Police and emergency vehicles constitute a large fleet in the United States; not including them so they can benefit from the same GHG-reducing technology would be unfortunate. If manufacturers are not being tasked to develop more fuel-efficient police and emergency vehicles, then at the very least, emissions of emergency vehicles should be included in the overall targeted standards. Including emissions produced by emergency vehicles would lower the overall emission standard of the proposed rulemaking, but would make for a more accurate accounting of the impact of the program. [EPA-HQ-OAR-2010-0799-7821-A1, p. 4]

Organization: Vehicle Production Group LLC (VPG)

Vehicles Used for the Public Good

EPA advises in III.B.9. that police and emergency response vehicles will be exempted from the regulation. This is in following with past regulations and U.S. code which have exempted vehicles manufactured "for the public good". While that exact stipulation is generally phased out, the spirit and intent is still a part of the regulatory backdrop. VPG suggests that a vehicle manufactured for the specific purpose of transporting wheelchair users is indeed for the public good; and in fact VPG's vehicle is a unique and robust solution to the needs of the disabled community as well as several legal actions relating to wheelchair accessibility of federally funded transportation services – most notably in New York City. It is VPG's proposal to extend this exemption beyond police and ambulance vehicles to vehicles whose intended use is for the public good. [EPA-HQ-OAR-2010-0799-7985-A2, p. 2]

VPG also proposed that vehicles used for the public good not be subject to this regulation. [EPA-HQ-OAR-2010-0799-7985-A2, p. 4]

Response:

EPA is finalizing its proposal to exempt police and other emergency vehicles from the GHG standards starting in MY2012. Emergency vehicles are also exempt from the N_2O and CH_4 standards. Thus emergency vehicles are not included in the National Program at this time. Comments, including those from Pennsylvania DEP and the Vehicle Production Group, are addressed in preamble section III.B.8.

11. Gasoline Fuel Quality

11.1. Need for Octane

Some commenters have advocated for a required increase in gasoline octane levels to improve vehicle efficiency and reduce greenhouse gas emissions, particularly if it would enable future vehicles to be designed with higher compression ratios.

Organizations contained in this section

Comments:

Organization: Boyden Gray & Associates PLLC

Why the industry's interest in octane? The proposed rule preamble devotes considerable discussion to technology improvements for spark ignition engines, but the agencies do not explain in any detail why they have requested comment on whether higher octane fuels are needed to comply with increasingly stringent fuel economy standards. [EPA-HQ-OAR-2010-0799-9506-A1, p. 6]

Organization: Boyden Gray & Associates PLLC

The issue of octane is worth much more than the few words provided by the agencies out of hundreds of pages of proposed rule. Octane has a major impact on both the efficiency gains the car companies can provide as well as the traditional pollution benefits that the agencies can achieve. These improvements, in turn, have a significant impact on the cost-benefit ratios the agencies must consider. [EPA-HQ-OAR-2010-0799-9506-A1, p. 6]

Organization: Pennsylvania Department of Environmental Protection

The agencies should re-evaluate the rulemaking, the Draft Joint Technical Support Document (TSD) and the Regulatory Impact Analysis (RIA) in order to assess the future consumer demand for higher octane gasoline that will be needed to adequately power technologies that EPA believes will be used to meet the GHG emission standards. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Organization: Pennsylvania Department of Environmental Protection

EPA predicts that the burden of meeting these standards will fall on gasoline vehicles since diesel vehicles will not penetrate the light-duty fleet significantly and all alternative-fueled vehicles will amount to no more than 10 percent of the fleet. EPA believes automobile manufacturers will rely heavily on new engine designs that use eight-speed, high-compression, turbocharged engines, but typically manufacturers recommend that engines of this type be refueled with higher octane gasoline (91- to 93-octane) to avoid potentially damaging engine knocking. EPA indicated that using the combination of turbocharging and other technology improvements will eliminate the need to use high octane gas and will allow the consumer to use 87-octane gasoline. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Organization: Pennsylvania Department of Environmental Protection

In addition to examining the air quality effects of the factors above [see section 18.2 of this comment summary], the increase in volatile organic compounds (VOC) emissions needs to be estimated due to the possible increase in Reid vapor pressure in gasoline from the increased use of higher octane gasoline. Higher emissions of VOC can lead to increased ground-level ozone concentrations. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

AFPM supports the Administration’s decision not to include gasoline octane rating in this rulemaking. [EPA-HQ-OAR-2010-0799-9485-A1, p.9]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

Automakers have recommended increasing the minimum gasoline octane rating to help meet future GHG emissions requirements (see Oct. 6, 2011 letter from the Alliance of Automobile Manufacturers to Lisa Jackson). The cost implications of such a change are enormous and would have serious impacts on U.S. refinery operations. Evidently, the Administration shares our belief that an increase in gasoline octane is not necessary and is unsubstantiated. [EPA-HQ-OAR-2010-0799-9485-A1, p.9]

Organization: Alliance of Automobile Manufacturers

These improvements will better support several technologies and allow introduction of some options, like stratified lean burn engines, which otherwise might not be available for U.S. consumers. Reduced sulfur will also optimize emission control systems and reduce emissions in existing vehicles. Higher octane grades in market fuels would enable optimization of combustion/thermal efficiency, for example in certain high compression or turbocharged engines. Other fuel-related characteristics to assure timely compatibility with advanced technology vehicles may also need to be addressed during the period covered by this rulemaking. [EPA-HQ-OAR-2010-0799-9487-A1, p.85]

Organization: Ford Motor Company

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 44-47.]
Also, market fuel quality, particularly octane level, can have a significant positive impact on all on-road vehicles and should, therefore, be a key part of our national strategy to improve energy security.

Organization: Volvo Car Corporation (VCC)

Higher octane fuel would enable manufacturers to pursue strategies that better support development and introduction of advance vehicle technologies, and a consequent reduction in greenhouse gases and criteria emissions. To optimize engine fuel efficiency and minimize emissions, transitioning to higher octane regular and premium grade market gasoline may be necessary. VCC would support establishment of a minimum blend stock octane. In this way, adding ethanol would raise fuel octane without risk that blenders would make corresponding reductions in base blend stock octane, thereby undoing the octane benefit of ethanol addition. We recommend that EPA assess the environmental benefits of higher octane gasoline. [EPA-HQ-OAR-2010-0799-9551-A2, p.15]

Organization: Clean Fuels Development Coalition (CFDC)

THE CRITICAL IMPORTANCE OF OCTANE. For SI gasoline-powered engines, octane is an extremely important fuel property to help the OEMs achieve both efficiency improvement and pollution reduction. NHTSA requested comment on whether higher octane fuels “may be necessary if certain advanced fuel economy-improving technologies are required by stringent CAFE standards” (p. 75335). [EPA-HQ-OAR-2010-0799-9574-A3, p. 3]

Organization: Clean Fuels Development Coalition (CFDC)

In a recent letter to EPA Administrator Jackson, the Alliance of Automobile Manufacturers has suggested increasing gasoline octane levels: “…[T]o help achieve future requirements for the reduction of greenhouse gas emissions, we also recommend increasing the minimum market gasoline octane rating, commensurate with increased use of ethanol.” [See Attachment A in Docket number EPA-HQ-OAR-2010-0799-9574-A4] The Auto Alliance also has recently stressed how important it is for regulators to recognize the differences between the various octane sources and the importance of ensuring fuel quality, in addition to controlling vehicle hardware and calibration effects. In comments submitted in September 2010 to California EPA on its LEV III certification fuel hearing, the Alliance noted that, “[a] Total Aromatics limit alone in the cert fuel spec does not preclude the blending of relatively high molecular weight aromatics that can lead to increased HC and PM emissions.” [See Attachment C in Docket number EPA-HQ-OAR-2010-0799-9574-A6] [EPA-HQ-OAR-2010-0799-9574-A3, p. 3]

Organization: Clean Fuels Development Coalition (CFDC)

While EPA did not specifically request comment on the matter of octane, it is our understanding that EPA assumes that the standard for SI engine fuel will be 87 octane (R + M/2), and that engine compression will be capped at 10.5:1. We believe this assumption unnecessarily inhibits fuel quality and engine design improvements that could be made available by both fuel providers and the OEMs, and that it could adversely impact the nation‘s petroleum dependence, carbon footprint, and health and welfare goals. Today, Aromatic Group Compounds constitute approximately 25% of an average gallon of U.S. gasoline, which refiners synthesize from crude oil to increase octane ratings. They are the most toxic, energy inefficient, carbon-intensive, and costly components in gasoline, and we believe that the goals of this rulemaking cannot be fully and efficiently met unless they are steadily reduced over time. As will be discussed further below, it is entirely realistic to reduce Aromatic Group Compounds in the U.S. gasoline pool while simultaneously increasing average octane levels over the life of this rulemaking. [EPA-HQ-OAR-2010-0799-9574-A3, p. 4]

Organization: Renewable Fuels Association (RFA)

EPA/NHTSA should consider what fuel properties and characteristics, such as minimum octane levels, will be necessary to achieve the proposed CAFE/GHG standards. EPA should be mindful of these properties and characteristics as it considers both the final CAFE/GHG standards and the elements of the upcoming Tier 3 rulemaking. [EPA-HQ-OAR-2010-0799-9490-A1, p.2 and 7]

Organization: Renewable Fuels Association (RFA)

Similarly, in a letter dated October 6, 2011, to EPA Administrator Jackson, the Alliance of Automobile Manufacturers stated, "…to help achieve future requirements for the reduction of greenhouse gas emissions, we also recommend increasing the minimum market gasoline octane rating, commensurate with increased use of ethanol. Adding ethanol to gasoline increases its octane rating" (Attachment B). We agree that EPA should consider including an increased minimum octane rating when contemplating changes to the certification test fuel. We fully understand that changes to fuel requirements will be primarily undertaken as part of the Tier 3 rulemaking, and not as part of the CAFE/GHG rule. However, as stated earlier, we believe the two rules are tightly connected, and as such, the fuel properties and characteristics needed to achieve the 2017-2025 CAFE/GHG requirements must be closely examined as both rulemakings are advanced. [EPA-HQ-OAR-2010-0799-9490-A1, pp.7-8] [For attachment B please refer to EPA-HQ-OAR-2010-0799-9490-A1, pp.55-57]

Organization: Pennsylvania Department of Environmental Protection

However, at this point, no mechanical approach seems to have solved the problem of engine knock in a high compression turbocharged engine, and manufacturers are still advising owners to use the higher octane fuel. Consumers will most likely follow a manufacturer's recommendation or risk a forced reduction in performance, increased maintenance costs, or engine damage. We believe that a greater volume of higher octane gasoline will be required to mix with regular high compression engines to achieve the GHG standards. This will mean that either higher volumes of ethanol, an oxygenate, will need to be added by gasoline distributors to boost octane levels or the refiner will need to supply higher octane base stock gasoline. A higher octane base stock may require additional chemical additives like alkylates to be produced and used at the refinery. The agencies have not adequately addressed these problems in any of the documentation in the public docket for this rulemaking. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Organization: Pennsylvania Department of Environmental Protection

The Agencies Should Evaluate Fuel Costs, Availability, and Impacts of Higher Octane Gasoline.

The agencies should re-evaluate the costs in the proposed rulemaking's RIA to account for the increased cost to the consumer to purchase higher octane gasoline. The agencies should also examine the likely future availability of ethanol or alkylates needed to meet the standards in the proposed rulemaking and the potential for adverse environmental consequences due to increased production of higher octane gasoline. The agencies need to examine the ability of refiners to supply, and the ability of fuel distribution system to transport, higher octane gasoline. We ask that the agencies expand the consideration of costs and air quality impacts. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Costs and Life-Cycle Costs. The extra cost for higher octane gasoline should be used to estimate the costs for this rulemaking. It appears that EPA used the cost of regular gasoline in their RIA (p. 3-15) for this rulemaking. Also, the increased performance that EPA is expecting to achieve from turbocharging and other technologies seems to be based on the vehicle using higher octane fuel. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

All potential costs and environmental impacts must be considered such as supply chain burdens, transportation availability, market transition costs, capital investments for higher octane gasoline and/or for production of additional ethanol or alkylates and the possibility of shortages in some areas of the country. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Nevertheless, we are concerned that much of the nation’s gasoline supply will require higher octane levels to meet these GHG standards and that EPA has not considered the implications. EPA either needs to address (in the face of manufacturers’ current recommendations) why more mid-grade gasoline will not be needed to run turbocharged, high-compression engines or the implications of greater use of higher octane gasoline should be fully evaluated. [EPA-HQ-OAR-2010-0799-7821-A1, p. 5]

Organization: ICM Inc.

Octane. Health and Environmental Impacts. [EPA-HQ-OAR-2010-0799-9541-A2, p.2]
The question was posed in the NPRM as to what other health and environmental impacts associated with advancements in vehicle GHG reduction technologies should be considered. To the extent that those GHG reduction strategies involve smaller but higher compression engines that require higher octane fuels, the impacts could be considerable. [EPA-HQ-OAR-2010-0799-9541-A2, p.2]

Organization: ICM Inc.

Octane. Health and Environmental Impacts. [EPA-HQ-OAR-2010-0799-9541-A2, p.2]

In addition to our work in developing food and fuel technologies, ICM has been directly engaged in cooperative research with the auto industry, and we have focused much of our effort on maximizing the octane value of ethanol. In our ongoing work and discussions with automakers, it has become clear there are only a few avenues available to them that would enable them to meet the aggressive fuel economy and carbon reduction requirements of this Rule. Foremost among them is the likelihood of downsized engines that would have higher compression and require higher octane. These smaller engines operating on premium grade fuels can achieve significantly greater efficiency. [EPA-HQ-OAR-2010-0799-9541-A2, p.2]

Organization: Growth Energy

As explained in Attachment 3 [pp. 22-41 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] to this letter, there are strong policy reasons for EPA to establish regulations for a new gasoline certification fuel at 94 octane (AKI), and to provide for the general commercial availability of such a fuel for vehicles produced in or after MY 2017, in the same manner that "regular" gasoline at a lower octane level is now currently sold. [EPA-HQ-OAR-2010-0799-9505-A1, p. 5]

Organization: Growth Energy

Growth Energy recommends enforceable requirements for the gasoline marketing industry in the U.S. that will ensure the commercial availability of gasolines that have an octane value of 94, for use in optimizing the GHG performance of new vehicles certified to the proposed GHG emission standards. [EPA-HQ-OAR-2010-0799-9505-A1, p. 22]

Organization: Boyden Gray & Associates PLLC

In sum, 87-octane fuel is a potentially significant limitation on technology improvement. Moreover, clean higher-octane components are lower in CO_2 than the current principal source of octane in gasoline, as well as lower in traditional pollutants. It is clear that toxic-free premium fuel is in fact necessitated by the rule, since the rule relies on advanced technologies that can only function on higher-octane fuel, and this fuel must be clean burning in order to avoid PM increases. [EPA-HQ-OAR-2010-0799-9506-A1, p. 7]

Organization: Alliance of Automobile Manufacturers

Two key fuel properties of concern to Alliance members for market fuel gasoline and gasoline blends are: (1) the need for continued reductions to minimize sulfur content, and (2) the need to transition to higher octane grades (most likely commensurate with higher ethanol or other bio-based fuel blend content), and related issues about renewable fuel and base gasoline contributions. [EPA-HQ-OAR-2010-0799-9487-A1, p.84]

Organization: Boyden Gray & Associates PLLC

Another provision of the 1990 CAAA—the mobile source air toxics (MSAT) provision—requires EPA to reduce toxics as far as technology will permit. EPA has not enforced this section except to reduce benzene by modest amounts in 2007, notwithstanding the fact that the U.S. is drowning in non-toxic alternatives to gasoline and diesel (i.e., all of the non-petroleum alternatives like alcohols, natural gas, electricity, etc.). There were indications that EPA intended to address the issue of aromatics and octane in the Tier III rulemaking, but this may apparently longer be the case—hence the letter from the auto companies to EPA referred to above. But if EPA is not going to address octane in Tier III, it must do so now in order to allow the car companies more flexibility. [EPA-HQ-OAR-2010-0799-9506-A1, p. 7]

Organization: Boyden Gray & Associates PLLC

Alternative fuels all have two important characteristics in common. They are all essentially free of air toxics, which are the principal source of unhealthy particulate matter (PM). Both air toxics and PM are dangerous pollutants that are regulated under the CAA. Alternative fuels also have significantly higher octane ratings, which would enable higher compression. This, as the Ricardo study notes, allows for "increased thermodynamic efficiency" when used in connection with some direct injection technologies."18 Yet the review does not appear to include a simple stand-alone compression increase as a proposed advance. The proposed rules provide no explanation for this omission. The Ricardo study indicates that the analysis is based throughout on a 10.5:1 compression ratio,19 and further that the octane of the fuel used for evaluating all new technology is 87.20 If the octane available to the auto manufacturers is capped at 87, then they cannot seek efficiency gains from compression higher than the ratio identified above. Moreover, they may not be able to take advantage of other technologies such as direct fuel injection without increasing tailpipe pollution.21 Finally, they will not be able to take advantage of high-octane fuels such as alcohols and natural gas, which produce lower levels of both traditional pollutants and CO_2 than gasoline and diesel. [EPA-HQ-OAR-2010-0799-9506-A1, pp. 6-7]

Response:

As evidenced by the analysis supporting this final action, we believe that the LD GHG standards being finalized today are entirely feasible and cost effective without the need for increasing the octane of gasoline. . Nor do we agree that higher octane fuel will be necessary for turbocharged and downsized engines to prevent the onset of combustion knock. EPA assumed no change in the octane of certification or in-use gasoline within its analysis and the effectiveness values used for the high BMEP engines reflect that fact. The current Ford EcoBoost turbocharged GDI engines do not require the use of premium fuel, although those engines are not operating at BMEP levels as high as those expected under our rule. Importantly, a combination of both intake charge dilution (e.g., cooled EGR) and in-cylinder evaporative fuel cooling (e.g., direct injection) are expected to allow higher BMEP GDI engines to operate on regular grade gasoline. All packages at 27 bar BMEP analyzed by EPA included cooled EGR to allow higher BMEP operation and prevent the onset of combustion knock on current certification or in-use fuels. See Joint TSD p. 3-88 ("Use of GDI systems with turbocharged engines and air-to-air charge air cooling also reduces the fuel octane requirements for knock limited combustion and allows the use of higher compression ratios.") See also Joint TSD at p. 3-91 ("Use of GDI systems with turbocharged engines and air-to-air charge air cooling also reduces the fuel octane requirements for knock limited combustion and allows the use of higher compression ratios. Ford's "Ecoboost" downsized, turbocharged GDI engines introduced on MY 2010 vehicles allow the replacement of V8 engines with V6 engines with improved in 0-60 mph acceleration and with fuel economy improvements of up to 12 percent.")

Consequently, we do not believe any regulatory action is warranted at this time to increase the octane level of all gasoline. Furthermore, any benefits of higher octane gasoline are already possible. Were manufacturers to design their vehicles to take advantage of higher octane fuel, such fuel - premium gasoline - is already available nationwide for those consumers who purchase such vehicles, and production of higher octane gasoline could easily rise to respond to market demand. There is not a compelling need to require consumers whose vehicles will not benefit appreciably from higher octane gasoline to pay for it.

11.2. Aromatics

The commenters highlight a number of potential health concerns with respect to the aromatic content of gasoline.

Comments:

Organization: Clean Fuels Development Coalition (CFDC)

It is especially important to note that, in order to provide an accurate picture of the final rule‘s health and welfare impacts, the Agencies cannot evaluate emissions results based only on certification fuels and laboratory testing procedures such as the FTP and US06 methods. When real-world fuels containing on average 25% Aromatic Group Compounds are combusted under real-world driving conditions (e.g., stop-start, acceleration and high speeds, heavy loads, etc.), tailpipe emissions of harmful ambient particulate matter increase significantly, as the Aromatic Group Compounds‘ extraordinary resistance to complete combustion ultimately stymies the best efforts of the vehicles‘ catalytic converter. Even more worrisome is the fact that some of the more important new advanced engine technologies (e.g., gasoline direct injection) will make these emissions even worse if fuel quality is not improved. [EPA-HQ-OAR-2010-0799-9574-A3, p. 2]

Organization: American Council on Renewable Energy (ACORE) and Biomass Coordinating Council (BCC)

3. Reducing the level of aromatics (BTX) in gasoline to limit emissions of highly health-damaging particulate matter, especially ultrafine particulates. [EPA-HQ-OAR-2010-0799-9593-A2, p. 5]

Organization: American Council on Renewable Energy (ACORE) and Biomass Coordinating Council (BCC)

The continued use of BTX as octane enhancers represents a serious health threat according to existing data. BTX group compounds that do not completely combust remain in the air and form fine (known as $PM_{2.5}$, or particulate matter smaller than 2.5 microns in diameter) and ultrafine particulate matter (UFP). There is extensive evidence linking $PM_{2.5}$ and UFP to numerous diseases and conditions, including [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]

- Respiratory diseases such as asthma [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]
- Cardiovascular illness and heart diseases [EPA-HQ-OAR-2010-0799-9593-A2, p. 3]
- A wide range of cancers [EPA-HQ-OAR-2010-0799-9593-A2, p. 3]
- Infant mortality and premature birth [EPA-HQ-OAR-2010-0799-9593-A2, p. 3]

Organization: ICM Inc.

Octane. Health and Environmental Impacts. [EPA-HQ-OAR-2010-0799-9541-A2, p.2]
Given the documented position of automakers as to their need for increased octane, it would be completely consistent to the Rule if a cap on aromatics was imposed, recognizing a failure to do so could, in fact, lead to significant increase in overall aromatic content and corresponding adverse health impacts as previously described. [EPA-HQ-OAR-2010-0799-9541-A2, p.4]

Organization: ICM Inc.

Octane. Health and Environmental Impacts. [EPA-HQ-OAR-2010-0799-9541-A2, p.2]
Replacing petroleum derived aromatics with 'clean octane,' i.e., ethanol, achieves both a petroleum reduction and the energy, economic, and health benefits that result from such a reduction, as well as a carbon reduction for the purposes of greenhouse gas mitigation and climate change. The cost of ethanol, as compared to current aromatic compounds used in gasoline, would favor consumers. As of late January, toluene, the most popular aromatic compound sold for octane purposes, was selling for $3.20 per gallon (Gulf Coast) while ethanol-with a higher blending octane value--was selling for $ 2.32 (Gulf Coast). This is a historical spread that has remained constant over several years (Fig 1). [EPA-HQ-OAR-2010-0799-9541-A2, p.3] [For the associated figure please refer to EPA-HQ-OAR-2010-0799-9541-A2, p.3]

Organization: ICM Inc.

Octane. Health and Environmental Impacts. [EPA-HQ-OAR-2010-0799-9541-A2, p.2]
EPA needs to consider the source of that octane, given the increasing body of evidence suggesting the relationship between octane, aromatics and particulates. The Agency has long documented the relationship of air toxics and particulate matter to various respiratory ailments and other health risks. As EPA is well aware from its modeling in the MSAT Rule, ethanol is an

excellent source of octane and, of course, has considerably lower carbon content than gasoline, even with full lifecycle penalties applied. Conversely, aromatic compounds, such as benzene, toluene, and xylene, are classified as air toxics, and benzene is a known carcinogen. It would appear to be in the public's best interest in terms of health and the environment to do everything possible to limit the aromatic content in gasoline so that the public is not subjected to these harmful compounds. Strictly from a carbon reduction standpoint, aromatic compounds can be 20% more carbon intensive than gasoline itself. Ethanol can reduce base gasoline by 20%. When used to replace an aromatic compound, it would result in a potential total 40% carbon reduction. [EPA-HQ-OAR-2010-0799-9541-A2, pp.2-3]

Organization: ICM Inc.

Octane. Health and Environmental Impacts. [EPA-HQ-OAR-2010-0799-9541-A2, p.2]
We believe the critical health impacts need to be considered as a result of higher octane fuels center around the under-regulated subset ofpm1iculates which are ultra-fine particulates (UFPs). They are produced as a result of the fuel combustion process and are not controlled via current vehicle technology, nor are they likely to be. Long thought to be a diesel or stationary source problem, increasing data suggests PM does have a relationship to gasoline, specifically UFPs, which are considerably smaller than the regulatory benchmark of$PM_{2.5}$. They may actually be produced in the combustion process as a result of the higher aromatic content in gasoline, according to recent research by Honda.1 These UFPs are suspected of being a much more significant health threat as they can essentially bypass the lungs as a filter system and enter the bloodstream. [EPA-HQ-OAR-2010-0799-9541-A2, p.3]

Organization: ICM Inc.

1) The likelihood of increased octane needs of the auto industry resulting in higher aromatics; [EPA-HQ-OAR-2010-0799-9541-A2, p.1]

Organization: ICM Inc.

2) The negative health and environmental impacts of increasing octane from aromatics, the relationship of air toxics and aromatics to particulate formation, and the growing body of evidence showing aromatics to be precursors to ultra-fine particulates; [EPA-HQ-OAR-2010-0799-9541-A2, p.1]

Organization: Growth Energy

Attachment 3 also explains why examination of the potential increases in emissions that EPA has regulated for many years (more specifically, fine particulate matter) in the current rulemaking is important even if EPA decides that it cannot take regulatory action under section 211 as the statute currently exists. The Agencies' cost-benefit analysis of the standards in the Joint NPRM assumes reductions in fine particulate matter. If, as explained in Attachment 3 [pp. 22-41 of Docket number EPA-HQ-OAR-2010-0799-9505-A1], those standards would have the unintended effect of increasing engine PM emissions, then the cost-benefit analysis mandated by governing Executive Orders must be revised. [EPA-HQ-OAR-2010-0799-9505-A1, p. 6]

Organization: Growth Energy

Among the fuel-related mitigation methods, further regulation of the composition of gasoline should be considered since there is evidence that the heavier components of gasoline, i.e., the aromatics, contribute substantially to PM emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 40]

Organization: Governors' Biofuels Coalition

Petroleum refiners produce aromatics, also known as the BTX (benzene, toluene, xylene) Group, from crude oil. The BTX Group is the most toxic, energy inefficient, and expensive gasoline component. As crude oil costs escalate, BTX Group costs increase the price of gasoline disproportionately and affect the nation's economic growth. Lower cost, clean octane alternatives to the BTX Group include the use of intermediate ethanol blends and a greater reliance on natural gas vehicles and electric vehicles. [EPA-HQ-OAR-2010-0799-9570-A1, p. 2]

Organization: Governors' Biofuels Coalition

A final rule that fails to improve U.S. transportation fuel standards by reducing BTX Group compounds is the wrong policy for America. On behalf of the Coalition, I respectfully urge you to modify the proposed rule so as to provide market-based incentives and encourage the cost effective substitution of domestic clean octane alternatives for toxic BTX Group compounds derived largely from imported crude oil. [EPA-HQ-OAR-2010-0799-9570-A1, pp. 2-3]

Organization: Governors' Biofuels Coalition

The Wall Street Journal reported on November 8, 2011 that emerging science points to an alarming but largely hidden trend: 'As roadways choke on traffic, researchers suspect that the tailpipe exhaust from cars and trucks - especially tiny carbon particles already implicated in heart disease, cancer and respiratory ailments - may also injure brain cells and synapses key to learning.' The article specifically noted the threat to expectant mothers who live near high-traffic areas, whose babies' DNA may be significantly harmed by 'prenatal exposure to high levels of polycyclic aromatic hydrocarbons in exhaust.' [EPA-HQ-OAR-2010-0799-9570-A1, p. 2]

Organization: Governors' Biofuels Coalition

The Health Effects Institute has also warned that '[u]ltrafine particles' ...small size and high surface area might make [them] especially toxic when inhaled. Many researchers have pointed to gasoline octane enhancers - known as aromatics - as the primary source of the urban ultrafine particles emissions and the toxic derivatives that coat them. Concern has heightened recently, given evidence that emissions of ultrafine particles might increase with greater use of gasoline direct-injection engines and other changes in fuels and technology.' For these reasons, European regulators have already announced their intention to regulate not only diesel, but also spark ignition and particle number emissions, which recent studies have shown are directly linked to aromatics. [EPA-HQ-OAR-2010-0799-9570-A1, p. 2]

Organization: Clean Fuels Development Coalition (CFDC)

In its 2007 MSAT Final Rule, EPA observed that "[t]here may be compelling reasons to consider aromatics control in the future, especially regarding reduction in secondary $PM_{2.5}$ emissions, to the extent that evidence supports a role for aromatics in secondary $PM_{2.5}$ emissions."20 In a 2010 study, EPA Office of Research and Development experts confirmed that anthropogenic pollution, especially mobile source primary carbonaceous particulate matter and NO_x emissions, "facilitate transformation of naturally emitted VOCs to the particle phase." EPA's modeling predicted that reducing mobile source emissions could help to reduce biogenic SOA emissions in the eastern U.S. by as much as 50% or more.21 This rulemaking provides EPA an opportunity to recognize the significant role played by gasoline exhaust, not just diesel exhaust, and the dominant role that Aromatic Group Compounds play in gasoline emissions. A May 2010 UCLA study noted that "several polycyclic aromatic hydrocarbons (PAHs) are toxic to living organisms, and engine exhaust emissions constitute a major source in urban areas…We focus this report on our estimates of vapor-phase naphthalene (NAP) from gasoline and diesel engines emissions…taking into consideration that SI engines constitute 96% of the estimated 28 million California vehicle fleet, and that the NAP content in regular and premium gasoline ranges from 69 up to 2,600 ppm since 1999, reduction of NAP from SI fuels may constitute an effective means of reducing the emissions of a major SOA-forming precursor to the atmosphere of large urban centers."22 [EPA-HQ-OAR-2010-0799-9574-A3, pp. 5-6]

Organization: Clean Fuels Development Coalition (CFDC)

P. 75104, ULTRAFINE PARTICLES' PM AND AIR TOXIC HEALTH EFFECTS. We believe it is critically important for the Agencies to recognize the direct connection between the UFP fraction of $PM_{2.5}$ and the deadly toxics that coat them: the polycyclic aromatic hydrocarbons + quinones (PAHQs). Two of the nation's leading UFP authorities released a 2009 study finding that "[u]rban UFP contain a higher content per unit mass of polycyclic aromatic hydrocarbons, which are relevant organic constituents since they can induce oxidative stress…in human tissues after conversion to quinones…"25 Over the past decade, advancing science and measurement techniques have established that the PAHQs—which experts say are carcinogenic, cytotoxic, and genotoxic—"hitchhike" on the tiny particles, which carry them to the bloodstream and throughout the body to the organs.26 [EPA-HQ-OAR-2010-0799-9574-A3, p. 7]

Organization: Clean Fuels Development Coalition (CFDC)

P. 75112, OTHER HEALTH AND ENVIRONMENTAL IMPACTS ASSOCIATED WITH ADVANCEMENTS IN VEHICLE GHG REDUCTION TECHNOLOGIES. We strongly urge the Agencies to recognize the substantial body of evidence that links gasoline Aromatic Group Compounds to increasing levels of urban PM ($PM_{2.5}$, which includes the UFPs), which are coated with highly toxic polycyclic aromatic hydrocarbons and quinones (PAHQs). Attachment E summarizes and provides cites for just a few of the leading epidemiological and related studies that provide alarming evidence linking gasoline Aromatic Group Compound combustion products to premature births and infant mortality, a wide range of cancers, asthma and other respiratory diseases, cardiovascular and heart conditions, and even brain disorders and autism.

Many of the same PAHs found in secondhand cigarette smoke are found in gasoline exhaust (see cites 10, 11, and 12 of Attachment E), and for the tens of millions of Americans who live within 300 – 2,500 meters of congested roadways, there is no escape from the particle-bound toxics that originate from incomplete combustion of Aromatic Group Compounds.23 [Attachment E can be found in Docket number EPA-HQ-OAR-2010-0799-9574-A8] [EPA-HQ-OAR-2010-0799-9574-A3, p. 7]

Organization: Clean Fuels Development Coalition (CFDC)

In short, Aromatic Group Compounds are expensive to manufacture, and their costs escalate as crude oil prices rise. Aromatic Group Compounds would be even less cost competitive compared to Clean Octane alternatives if appropriate actions were taken to level the playing field, and Aromatic Group Compounds‘ true social costs were fully considered (under current policy, these costs are not borne by petroleum refiners as they should be, but rather by taxpayers and other industries in the form of higher health care spending and lost productivity, etc.). This is true even though budgetary pressures are forcing an end to tax incentives and other forms of public sector support for alternative fuel technologies. Examples of commercially available and cost-competitive Clean Octane alternatives to the Aromatic Group Compounds include: [EPA-HQ-OAR-2010-0799-9574-A3, pp. 4-5]

- Compressed natural gas (CNG), especially in centrally fueled fleets
- Biofuels, especially intermediate ethanol blends (e.g., E30+) [See Attachment B in Docket number EPA-HQ-OAR-2010-0799-9574-A5] [EPA-HQ-OAR-2010-0799-9574-A3, p. 5]

Organization: Clean Fuels Development Coalition (CFDC)

Consider the many shortcomings of Aromatic Group Compounds:

- Gasoline and finished product yield losses at the refinery due to the energy intensive requirements of the catalytic reformer
- High cost component which escalates as crude oil prices increase
- High carbon intensity component
- Incomplete combustion properties exacerbate wide range of tailpipe emissions
- Primary source of urban ambient particulate matter 9
- Primary source of urban polycyclic aromatic hydrocarbons (PAHs) and quinones (oxidative derivatives of Aromatic Group Compounds)10 that coat the UFP particles in $PM_{2.5}$
- Major culprit in combustion chamber deposits , which over time reduce vehicle efficiency and increase carbon and other harmful tailpipe emissions [EPA-HQ-OAR-2010-0799-9574-A3, p. 4]

Organization: Clean Fuels Development Coalition (CFDC)

Congress most certainly did not intend for EPA to reduce one non-health pollutant (CO_2) while inadvertently increasing emissions of one of the nation‘s more dangerous health pollutants (PM 2.5). As will be demonstrated below, extensive scientific evidence provides ample basis to “reasonably anticipate” that particulate emissions from Aromatic Group Compounds represent a serious health threat today, and one that is almost certain to get worse unless new fuel quality standards that complement new engine technologies are imposed. [EPA-HQ-OAR-2010-0799-9574-A3, p. 3]

Organization: Clean Fuels Development Coalition (CDFC)

ESTIMATED COST AND ECONOMIC BENEFITS. As referenced in Attachment B [see Docket number EPA-HQ-OAR-2010-0799-9574-A5], the 2008 – 2011 cost comparison of USGC spot toluene prices (a reference marker for Aromatic Group Compound pricing in general) and USGC ethanol prices shows that toluene prices have exceeded ethanol prices by an average of approximately $.70/ gallon over the three-year period, and more than $.80 per gallon over the past two years. (Q3 and Q4 in 2008 saw a precipitous drop in crude oil prices, from approximately $140 per barrel at its peak to $70+ per barrel at year-end. This global recession-induced plunge in oil prices had a direct, and aberrational, price depression effect on Aromatic Group Compounds.) As a March 2010 United Kingdom Department for Environment, Food, and Rural Affairs report confirmed, world corn prices also dropped precipitously during this period, in line with oil and other raw commodities, even though U.S. ethanol production actually increased, a relationship that clearly refutes the much-publicized but fallacious "food vs. fuel" attacks.30 The cost advantages of ethanol‘s Clean Octane compared to the Aromatic Group Compound‘s Dirty Octane, while impressive enough, pales in comparison to the enormous health benefits as well as reduced petroleum and carbon footprint benefits that would be achieved. Attachment F [see Docket number EPA-HQ-OAR-2010-0799-9574-A10] explains the basis of the table that extrapolates from EPA and Energy Future Coalition sources, and suggests that a gradual phase-down in Aromatic Group Compounds could save the public and private sectors more than $400 billion per year by 2025. [See Attachment G in Docket number EPA-HQ-OAR-2010-0799-9574-A11] In the final rule, we strongly urge the Agencies to take all of its these critically important cost-benefit factors into account, especially as the EPA reassesses its $PM_{2.5}$ SOA apportionment due to mobile sources based upon its new CMAQ modeling results. [EPA-HQ-OAR-2010-0799-9574-A3, pp. 8-9]

Organization: Boyden Gray & Associates PLLC

These factors suggest how EPA can avoid the impermissible side effect of this rulemaking that will increase traditional and life endangering PM pollution as the price for reducing CO_2. Rather than relying on the uncertain possibility of finalizing a future rulemaking to impose tailpipe PM restrictions, which may not in fact eliminate the secondary atmospheric reactions that cause most fine particle harm, EPA should use fuel efficiency concerns that ARE the subject of this proposal to solve this problem. This would involve the obvious step of reducing the most carbon intensive fuel components— aromatics—which would have positive outcome of reducing CO_2, eliminating the impermissible traditional pollutant increases, and providing needed octane, all at the same time. This could and should be done in this proceeding, which, as discussed above, needs in any event to make available the statutory incentives for the non-petroleum alternatives (which are also substitutes for toxic aromatics and the key to increasing clean octane—a necessary precursor to innovation in fuel-efficient internal combustion). [EPA-HQ-OAR-2010-0799-9506-A1, pp. 10-11]

Organization: Boyden Gray & Associates PLLC

Ozone and CO_2 itself are also implicated. Reducing aromatics reduces ozone as well as PM, since aromatics are highly reactive photochemically even if not highly volatile. Restriction of aromatics thus contributes more to ozone reduction than Reid vapor pressure (RVP) controls that address only the so-called “light-ends” like butane and pentane, since these are highly volatile but virtually unreactive.35 But EPA discourages this shift not only by blocking state VOC regulation and capping the effects of the multiplier for purposed of curbing oil imports, but also by penalizing ethanol and methanol by not making allowance for their air quality and other benefits. In fact, aromatics are 20% more carbon-intensive than gasoline, meaning that direct octane substitutes like ethanol and methanol, which are less carbon intensive, provide in fact as much as a 50% improvement over gasoline in CO_2, in addition to the PM, ozone and mileage improvements. [EPA-HQ-OAR-2010-0799-9506-A1, p. 10]

Organization: Boyden Gray & Associates PLLC

Finally, it is important to note that aromatics are more wasteful and, therefore, more expensive than gasoline, ethanol and methanol. The rule of thumb is that every point of octane generated by the reformers’ production of aromatics uses 1% percent of crude. In part as a result, the BTX group costs nearly one dollar more per gallon than regular gasoline. Therefore, EPA and DOE are incorrect to calculate ethanol’s or methanol’s fuel equivalency solely on the basis of BTU content, since upstream fuel consumption and accompanying pollution increases are relevant factors along with the increased efficiency allowed by the high octane of ethanol, methanol, and CNG. [EPA-HQ-OAR-2010-0799-9506-A1, p. 10]

Organization: Boyden Gray & Associates PLLC

EPA’s failure to address the issue of octane, aromatics and air toxics is curious in light of the Presidential directive to do so in Section 3 of the Presidential Memorandum of September 2010. Moreover, EPA acknowledges on page 6-32 of its DRIA that it “is important to quantify the health and environmental impacts associated with the proposed standard, because a failure to adequately consider these ancillary co-pollutant impacts could lead to an incorrect assessment of their net costs and benefits.” But the proposed rule itself is silent on the question. [EPA-HQ-OAR-2010-0799-9506-A1, p. 7]

Response:

In response to comments (most from Boyden Gray and Associates) that EPA should reduce the amount of aromatics in vehicular fuels to reduce secondary PM and photochemical ozone formation, those issues are beyond the scope of this proceeding. Furthermore, the innuendo that EPA is trading CO2 reduction for increases in PM and air toxics under this rule is not correct.

The rule does not result in increases to either the PM, ozone, or air toxics inventories, but rather to reductions. For PM, the results indicate that in 2030, a population weighted average reduction of approximately 0.01 ug/m3 can be expected (see RIA Chapter 6.3.1). For ozone, we estimate that in 2030, on a population-weighted basis, there is virtually no change in ambient concentrations in ozone.

In terms of health impacts, however, it is clear that upstream reductions in emissions related to ambient concentrations of both direct and indirect PM outweigh the slight emission increases associated with rebound driving (and none associated with fuel content, contrary to the commenter's statements). In terms of PM-related health impacts, we estimate that in 2030, emission reductions associated with the rule will result in between 110 to 280 fewer premature mortalities across the U.S. Compared to the estimate of 1 to 3 additional ozone-related premature mortalities associated with rebound-related emission increases, it is clear that upstream emission reductions outweigh the slight downstream emission increases and in fact improve health on a national basis.

EPA estimates the full range of pollution impacts from the standards, including emissions at the tailpipe and emissions from "upstream" sources such as power plants, refineries, and fuel transportation and distribution. Please refer to Preamble Section III.G.1 and RIA Chapter 4 for a complete description of the emissions impacts of the rulemaking and the estimation methodology. This includes both upstream and tailpipe VOC emissions associated with the final standards. We use these non-GHG inventories to estimate the changes in ambient concentrations of PM, ozone, and selected air toxics. Please refer to Chapter 6 of the RIA for a description of both the air quality modeling and health impact analyses. Taken together, the non-GHG emission changes yield a net reduction in human health risk and contribute to the overall benefits of the standards.

Furthermore, as ethanol use in gasoline has continued to rise in response to market forces and RFS, the additional octane provided by ethanol has been used by refiners to reduce the concentration of aromatics (another source of octane) in the gasoline they supply. As shown below in figure below, there has been a 15 percent decrease in aromatics with the rise in ethanol use over the past decade. With the increased use of ethanol, not only have the aromatic levels in gasoline been declining, but we project that they will continue to decline. The average level of aromatics in gasoline today is around 22 percent, although it ranges from 3 to 47 percent on a batch basis, and 10 to 40 percent on a refinery average basis due to the wide variation in refinery configuration, crude oil source, and available product markets.

Comments:

Organization: American Petroleum Institute (API)

Changes to the Test Fuel Used for Emissions and Fuel Economy Certification
EPA suggests that it may in the future consider changing the property specifications of the test fuel used to certify the emissions and fuel economy performance of new vehicles vis-à-vis the standards, and it specifically indicates that the fuel may include some unspecified amount of ethanol. API's fundamental position on the ethanol content of federal gasoline certification test

fuel remains unchanged from that conveyed in earlier comments on the MY 2012-2016 CAFE/GHG rule for light-duty vehicles: “The ethanol concentration of the certification reference fuel should match the fuel that vehicles are expected to use.”20 [EPA-HQ-OAR-2010-0799-9469-A1, p 9]

Organization: American Petroleum Institute (API)

Changes to the Test Fuel Used for Emissions and Fuel Economy Certification
EPA suggests that it may in the future consider changing the property specifications of the test fuel used to certify the emissions and fuel economy performance of new vehicles vis-à-vis the standards, and it specifically indicates that the fuel may include some unspecified amount of ethanol. API’s fundamental position on the ethanol content of federal gasoline certification test fuel remains unchanged from that conveyed in earlier comments on the MY 2012-2016 CAFE/GHG rule for light-duty vehicles: “The ethanol concentration of the certification reference fuel should match the fuel that vehicles are expected to use.”20 [EPA-HQ-OAR-2010-0799-9469-A1, p 9]

Organization: Pennsylvania Department of Environmental Protection

We believe that EPA should change the test fuel used for certifying emission standards of passenger cars and light-duty vehicles in the laboratory. For years, EPA has been using a gasoline for emissions testing that is never used by motorists to determine if a vehicle meets emission standards. We believe this leads to an unrealistic estimate of emissions and fuel efficiency. EPA needs to follow CARB’s lead and use a fuel for emissions testing that is more representative of what the nation's consumers use, such as a fuel that contains 10 percent ethanol. A representative fuel will produce more realistic emissions testing results and promote a firmer understanding of what emissions are produced in the mobile sector. [EPA-HQ-OAR-2010-0799-7821-A1, p. 4]

Organization: Mercedes-Benz USA, LLC

The National Program recognizes the importance of harmonizing regulatory programs. Reducing greenhouse gas emissions and enhancing energy independence depends upon coordinating the regulation of tailpipe emissions with the regulation of fuels. This includes not only enhancing the amount of renewable energy producing electricity to reduce upstream emissions associated with electricity generation, but also ensuring the availability of ultra-low sulfur fuels.[7] [EPA-HQ-OAR-2010-0799-9483-A1, p. A-4]

Ultra low sulfur gasoline is a key enabler for the incorporation of lean bum advanced combustion technologies that require dedicated lean NO_x after-treatment hardware. Ultra low sulfur gasoline also permits significant further fuel economy gains (8-10%) in downsized turbocharged engines by reducing the frequency and intensity of sulfur 'bum-off' cycles in exhaust after-treatment components otherwise needed to keep those devices at peak operating efficiency. DAG believes it to be feasible to achieve sulfur reduction in market fuels to 10 ppm. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-4]

Ultra low sulfur diesel fuel is also important. DAG, then as part of DaimlerChrysler, played a key role in the efforts to bring ultra low sulfur diesel fuel to the United States. These efforts were further supported when B5 biodiesel was specified as the factory fill for Jeeps equipped with the Mercedes-Benz 3.0L common rail diesel engine. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-4]

DAG remains concerned about state efforts to promote and mandate biodiesel blends of B10 or greater and encourages the EPA to employ a federal policy to promote B5 use nationwide. Doing so would create a foundation for engine, exhaust after-treatment and biodiesel technologies to mature as a system. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-4]

DAG supports EPA's efforts with regard to Tier 3, and California's efforts with regard to LEV 3, and looks forward to continuing to work with the agencies both to promote ultra low sulfur fuels and to address remaining concerns with those regulatory programs. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-4]

---

7 The agencies properly take a Tank to Wheel approach to electric battery generation, applying a factor of 0 g/m for the electric generation. Automobile manufacturers are able to apply technology, and base their compliance, only on the vehicles they sell. Automakers have no control over the sources of electricity generation, an area that EPA has ample authority to regulate independent of tailpipe emissions. Emissions, moreover, should be treated the same. Upstream emissions from the production of oil are not included; nor should those from electric vehicles be included. Finally, any information relating to upstream emissions provided to the public should be provided with regard to all vehicles. The agencies should not include only 'net' upstream emissions beyond those applicable to ICE vehicles because doing so would mislead the public into believing that only EVs involve upstream emissions.

Organization: Pennsylvania Department of Environmental Protection

We believe that EPA should change the test fuel used for certifying emission standards of passenger cars and light-duty vehicles in the laboratory. For years, EPA has been using a gasoline for emissions testing that is never used by motorists to determine if a vehicle meets emission standards. We believe this leads to an unrealistic estimate of emissions and fuel efficiency. EPA needs to follow CARB's lead and use a fuel for emissions testing that is more representative of what the nation's consumers use, such as a fuel that contains 10 percent ethanol. A representative fuel will produce more realistic emissions testing results and promote a firmer understanding of what emissions are produced in the mobile sector. [EPA-HQ-OAR-2010-0799-7821-A1, p. 4]

Organization: Volvo Car Corporation (VCC)

The same criteria that govern the need for new test procedures to measure extremely low emissions adequately and correctly also dictate the need for low-sulfur fuel. It is essential to avoid sacrificing environmental gains achieved by use of advanced technology by failing to recognize the positive effect of higher quality fuel or the impact of sulfur on catalyst efficiency over time. Lower sulfur in fuel will also result in environmental gains for the existing fleet since the catalyst deactivation will be minimized. [EPA-HQ-OAR-2010-0799-9551-A2, p.15]

Response:

The LD GHG standards are based on current certification test fuel qualities and are not dependent on any changes occurring to certification test fuel qualities. If the certification test fuel is changed through a future rulemaking, EPA would be required to address the need for a test procedure adjustment to preserve the level of stringency of the CAFÉ standards. EPA is committed to doing so in a timely manner to ensure that any change in certification fuel will not affect the stringency of future GHG emission standards.

12. Technical Assessment of the Proposed CO_2 Standards

Organizations Included in this Section

National Association of Clean Air Agencies (NACAA)
Union of Concerned Scientists (UCS)

Organization: National Association of Clean Air Agencies (NACAA)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 53.]

What we're hopeful about is that if new technologies come into vehicles are incorporated into vehicle design and production earlier, that then it will be shown that the cost of having those technologies in vehicles lessens the idea that, you know, you down the cost of -- as you move into production, you move down the cost in terms of implementing the technologies and the cost drops for production.

Organization: Union of Concerned Scientists (UCS)

The agencies based this proposal on rigorous, peer-reviewed technical analysis. We appreciate the continued commitment of the agencies to utilize independent technical analysis as well as information collected from manufacturers. In particular, UCS acknowledges the importance of the tear-down cost studies conducted by FEV, the technology effectiveness modeling conducted by Ricardo Engineering, and the mass-reduction and safety potential analysis conducted by Lotus. These studies represent the most up-to-date and highest quality work in these areas. Studies of these kinds were recommended by the National Academies as important tools in improving estimates of the cost and performance of new vehicle technologies.16 [EPA-HQ-OAR-2010-0799-9567-A2, pp. 5-6]

16 See, for example, Finding 3-3 and Finding 8-4 in the 2011 National Academies report, Assessment of Fuel Economy Technologies for Light-Duty Vehicles. [EPA-HQ-OAR-2010-0799-9567-A2, p. 5]

Response:

Regarding comments from NACAA, we fully expect that costs for GHG reducing technology will drop as these technologies are introduced and their production numbers increase. Our learning curve effect (see joint TSD 3.1.3) captures those anticipated reductions in cost.

Regarding comments from UCS, we fully agree that the many studies conducted and cited in support of our final standards—FEV teardowns, technology effectiveness modeling by Ricardo, and mass reduction studies by Lotus—are extremely important pieces of our rulemaking effort and represent the most up-to-date and highest quality work in these areas.

BASELINE AND OTHER SCENARIOS

The agencies' baseline scenario assumes that fuel economy remains at 2016 levels absent the proposed new standards. However, NHTSA also "examines the impact of an alternative 'market-driven' baseline, which allows for some increases in fuel economy due to 'voluntary overcompliance' beyond the MY 2016 levels" (NPRM p.75167). NHTSA requests comment on this alternative baseline. [EPA-HQ-OAR-2010-0799-9528-A2, p.2]

There is little historical basis for a scenario in which there is a sustained increase in fuel economy in the absence of increases in standards. Public interest in fuel economy does shift with fuel prices, but even that interest typically has followed from large, rapid changes in price and has been short-lived. The fuel prices on which the various agency analyses are largely based are EIA projections and do not contain dramatic increases in price. Under these conditions, manufacturers not constrained by fuel economy standards historically have employed technological advances to increase vehicle power and acceleration, rather than to improve fuel economy. [EPA-HQ-OAR-2010-0799-9528-A2, p.2]

Incorrect specification of the baseline scenario will lead to an incorrect valuation of the proposed standards. An alternative baseline such as the one considered by NHTSA will reduce manufacturers' costs to meet the standards, because some of the added technology required to meet the standard will already appear in the baseline. At the same time, the benefits attributable to the standards will decline. The net effect is a reduction in the cost-effectiveness of the standards, because the most cost-effective technologies are the ones that will appear in the alternative baseline scenario, leaving the more expensive technologies for the rule to bring into the market. [EPA-HQ-OAR-2010-0799-9528-A2, p.2]

The same issue arises from EIA's AEO 2012 Early Release (EIA 2012), which projects an increase in new vehicle fuel economy after 2016 without adoption of the proposed rule, and without major increases in fuel prices. Roughly one-quarter of the reduction in new vehicles' fuel consumption that would result from the proposed standards appears in the AEO 2012 Reference Case. Hence it is all the more important that NHTSA clarify that the baseline scenario used in the NPRM should be the basis for evaluating the benefits of the final rule. [EPA-HQ-OAR-2010-0799-9528-A2, p.2]

Recommendations

Clarify that the baseline scenario used to evaluate the benefits of the rule will not assume "voluntary over-compliance" by manufacturers after 2016. [EPA-HQ-OAR-2010-0799-9528-A2, p.3]
Make available on the EPA web site the OMEGA outputs for the various scenarios considered. [EPA-HQ-OAR-2010-0799-9528-A2, p.3]

Organization: Chrysler Group LLC

The Agencies provide 2008MY and 2025MY sales projections for various manufacturers in Table II-1 of the NPRM. These projections show Chrysler with annual sales of ~1.7 million light-duty vehicles, dropping to 0.8 million light-duty vehicles in 2025; a 53% decline over 17 years. [EPA-HQ-OAR-2010-0799-9495-A1, p.21]

This negative projection of Chrysler's viability is problematic. In addition, to potentially affecting the analyses upon which the Agencies have based the proposed standards, projections of this type can also affect Chrysler's relations with our suppliers and customers. When suppliers and customers see projections, supported by Federal agencies, that indicate a 53% decline in sales, they are potentially given a highly negative view of the viability of the company. These negative views may result in less favorable contracts with suppliers and lower sales to customers. [EPA-HQ-OAR-2010-0799-9495-A1, p.21]

Organization: Environmental Consultants of Michigan

Advanced Technology Has Already Been Substantially Incorporated Into the Fleet [See Table 1 on p. 7 of Docket number NHTSA-2010-0131-0166-A1]

The Agency's arbitrary selection of a four year old data set is unconscionable. Manufacturers have already implemented into their product line many of the technologies recommended by the Agency at substantially higher costs. At a minimum the Agency must postpone promulgation of the final rule until it completely recalibrates their models using up to date data on the cost and benefits of new technology along with using an up to date baseline vehicle fleet. [NHTSA-2010-0131-0166-A1, p. 7]

Organization: Environmental Defense Fund (EDF)

B. FLAT 2016 BASELINE

EDF supports EPA's proposal to assume the reference case fleet in MY 2017–2025 would have fleet wide GHG emissions performance no better than that projected to be necessary to meet the

MY 2016 standards. Because EPA is using AEO2011 fuel price forecasts, which project relatively stable fuel prices over the next 15 years, it is reasonable to assume that manufacturers will not overcomply with the 2016 standards and/or consumers will not demand fuel economy greater than the 2016 standard. It is also reasonable to assume that fleetwide overcompliance will not occur because any voluntary over-compliance by one company would generate credits that could be sold to other companies to substitute for their more expensive compliance technologies. Therefore, the ability to buy and sell credits would eliminate any over-compliance for the overall fleet. [EPA-HQ-OAR-2010-0799-9519-A1, p. 8]

Organization: International Council on Clean Transportation (ICCT)

6) Baseline Assumption Sensitivity Case

There is a difference between how EPA and NHTSA handled the modeled Reference Fleet Scenario. EPA projects that in the absence of the proposed GHG and CAFE standards, the reference case fleet in MY 2017-2025 would have fleetwide GHG emissions performance no better than that projected to be necessary to meet the MY 2016 standards. [EPA-HQ-OAR-2010-0799-9512-A1, p. 18]

While NHTSA used the same baseline assumptions for their primary analyses, they also conducted a sensitivity analysis with an alternative baseline, which assumed that fuel economy would continue to increase after 2016 without regulation. NHTSA stated:

'The assumption is that the market would drive manufacturers to put technologies into their vehicles that they believe consumers would value and be willing to pay for.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 18]

Again, while sensitivity analyses can illuminate the impacts of important uncertainties, there is little or no evidence supporting this particular case. Except during the oil crisis in the 1970s and a brief period for passenger cars in the late 2010s, the market has never driven improvements in vehicle fuel economy. Even these two examples are not relevant to the current situation. The demand for higher fuel economy in the 1970s was driven primarily by fears of oil unavailability and ongoing future increases in fuel price. The modest increase in passenger cars in the late 2010s followed 20 years of unchanging CAFE standards. Thus, NHTSA's sensitivity analysis inappropriately calculates a lower estimate of net benefits of the rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 18]

The proposed 2017-25 standards follow aggressive increases in standards from 2011 through 2016. Further, the change to a footprint-based standard means that all manufacturers must increase the efficiency of their vehicles to comply, even manufacturers of primarily smaller vehicles. Thus, the 2012-16 standards have already driven the market beyond the level of efficiency it would have demanded in the absence of standards. [EPA-HQ-OAR-2010-0799-9512-A1, p. 18]

The reason why efficiency standards are effective and needed is consumer discounting of uncertain, future fuel savings, as explained above. Efficiency standards move the market from the level of efficiency demanded by loss averse consumers to the level of efficiency desired by society. It will be many years after 2016 before additional technology development and lower cost will finally fall to the level demanded by consumers from the higher level demanded by society through efficiency standards. The historical precedent is that it took 20 years of unchanging CAFE standards combined with high real and nominal fuel prices before the market started to demand additional fuel economy for passenger cars in the late 2000s. [EPA-HQ-OAR-2010-0799-9512-A1, p. 19]

ICCT recommends that the sensitivity analysis for market-driven increases in efficiency after 2016 be removed from the Final Rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 19]

Organization: Natural Resources Defense Council (NRDC)

A. Baseline Projection

NRDC supports the baseline forecast for MY 2017 and beyond that assumes manufacturers meet but do not exceed the MY 2016 standards. Voluntary overcompliance—in which manufacturers apply efficiency technology in excess of what is needed to meet the MY 2016 standard—is possible but too uncertain to be incorporated in a baseline projection. Rapidly rising fuel prices are potentially a reason for overcompliance but during periods of only modest average annual price increases, overcompliance was not widespread. In the 1990’s and early 2000’s, real motor gasoline prices rose at an average rate of 4 percent per year yet full-line manufacturers, such as the GM, Ford and Chrysler, applied just enough technology to meet the standards. From 2017 to 2035, EIA projects motor gasoline prices that increase at a lower rate of about 1 percent per year. With the projected low rate of annual price growth, the modification of the 2016 baseline is unjustified.

Further, NRDC disagrees with NHTSA that a sensitivity analysis of voluntary overcompliance is warranted, and we recommend that it be excluded from the final rule. The voluntary overcompliance analysis is counter-productive to the goals of maximizing petroleum reductions as required by EPCA.

If, in future rulemakings, the baseline was altered to account for voluntary overcompliance—assuming it can be reasonably justified as highly likely—NHTSA would be inclined to set a lower standard than what could be achieved with appropriate cost-effective technology application. The achievement of overcompliance assumes that low-cost efficiency technologies are applied by manufacturers first (NHTSA assumes a 1-year payback). The remaining technologies to be driven by the standard would therefore be more expensive, increasing the costs associated with the standards. The standards themselves would also be associated with lower benefits because the savings from lower-cost technologies would be assigned to the market instead of the standard. The resulting reduced benefit-to-cost ratio would be a dampening force on efforts to maximize fuel efficient technology adoption and could push down the standard stringency.

If, during this scenario of a weaker standard, automakers did not overcomply, U.S. petroleum consumption would be higher and counter to the mandate of EPCA. To avoid this situation, NHTSA and EPA should continue to use a baseline that assumes automakers do not overcomply. This ensures that standards are set as strong as possible, and it provides greater certainty that needed oil consumption and GHG emission reductions will be achieved.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

Use a flat baseline in assessing post 2016 fuel efficiency: NHTSA is taking comment on the notion that the post-2016 baseline for vehicle standards should assume “market driven” improvements in fuel economy absent standards and account for those improvements in the baseline. The Knittel study, referenced above, in addition to the historic trend are evidence that absent standards automakers will not increase gas mileage. Leading up to 2008, automakers were not prepared for increasing fuel prices and shifting consumer preferences. The consequences to the auto industry and the economy were devastating. [EPA-HQ-OAR-2010-0799-9549-A2, p. 7]

NHTSA’s consideration that new vehicle labels that will provide consumers with more detailed information on mileage and savings and that this will influence consumer choices is insufficient basis for using a baseline that presumes automakers will apply technologies to meaningfully improve gas mileage beyond 2016 absent strong final 2017-2025 standards. While some automakers may voluntarily “over-comply” with the 2012-16 program due to market forces, overcompliance in one segment of a fleet (cars for example) could be used to offset lower mileage vehicles such as larger pickups and SUVs. In addition, because the compliance with the program allows for banking, trading and carry-forward and backward credits, any presumption that automakers will improve fuel economy after 2016 could be part of a compliance strategy that includes the 2012-16 model years or planned compliance with these proposed standards. Over-compliance across the entire fleet heading into the mid-term review included in the NPRM would support strengthening the overall program. The agencies should use a flat baseline beyond 2016. [EPA-HQ-OAR-2010-0799-9549-A2, p. 7]

Organization: Volkswagen Group of America

Volkswagen recognizes that the agencies are privy to confidential product plans supplied by manufacturers and that the agencies rely on this data to support future projections. However, the US has been averaging a near 50/50% split between cars and trucks for many years. Even at times of peak gasoline prices experienced during the past few years, interest in light trucks may have waned, however not to such a drastic extent as indicated by this radical shift in future product plans. Most disturbing is the recent trend back to light trucks even with fuel prices stabilizing near record highs. Volkswagen sees no evidence that would suggest a near 30% decline in truck market share from domestic OEMs. [EPA-HQ-OAR-2010-0799-9569-A1, p. 9]

Volkswagen is not privy to strategic plans by competitors, but we find it unlikely for OEMs historically focused on truck sales to so readily abandon what has proven to be a successful and profitable market segment. Dropping 30% truck share for a company like Ford would be equivalent to Ford cancelling their entire line-up of F150s, a vehicle which has remained a top, if not the top, seller in the US for many years. In addition, the proposals preferential treatment for large trucks and pick-ups further makes it unlikely that manufacturers would now prefer to market cars. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 9-10]

Response:

Response to Chrysler LLC:

The agencies' projection that Chrysler's sales would steadily decline was primarily attributable to the manufacturer- and segment-level forecasts provided in December 2009 by CSM. The agencies thought that forecast to have been credible at the time considering economic and industry conditions during the months before CSM provided the agencies with a long-range forecast, when the overall light vehicle market was severely depressed and Chrysler and GM were—with nascent federal assistance—in the process of reorganizing. We recognize that Chrysler's production has since recovered to levels suggesting much better long-term prospects than forecast by CSM in 2009. While the agencies are continuing to use the market forecast developed for the NPRM (after minor corrections unrelated to Chrysler's comments), we are also using a second market forecast we have developed for today's final rule, making use of a newer forecast (in this case, from LMC) of manufacturer- and segment-level shares, a forecast that shows significantly higher sales (more than double that of the earlier forecast) for Chrysler in 2025. This analysis is shown in Joint TSD Chapter 1.5 and the EPA modeling results are shown in RIA Chapter 10. We note further that the agencies have documented the differences in volume and characteristics of the MY 2008 based fleet and the MY 2010 based fleet, and these differences do not justify any change in the ultimate standards. See Joint TSD section 1.5. Likewise, EPA concluded that "these two market forecasts contain certain differences, although as discussed in TSD Chapter 1.5, the differences are not significant enough to change the agencies' decision as to the structure and stringency of the final standards, and indeed corroborate the reasonableness of the final standards." See Joint TSD Chapter 1.5.

Response to Environmental Consultants of Michigan

Even though the year of publication of this rule is 2012, model year 2010 was the most recent baseline dataset available due to the lag between the actual conclusion of a given model year and the submission (for CAFE compliance purposes) of production volumes for that model year. Moreover, as explained below in the joint TSD and in our respective RIAs, EPA and NHTSA measure the costs and benefits of new standards as incremental levels beyond those that would result from the application of technology given continuation of baseline standards (*i.e.*, continuation of the standards that will be in place in MY 2016). Therefore, our analysis of manufacturers' capabilities is informed by analysis of technology that could be applied in the future even absent the new standards, not just technology that had been applied in 2008 or 2010. This can be seen from the similarity in projected costs between the analyses shown in section III.D (MY 2008 based forecast) and RIA chapter 10 (MY 2010 based forecast).

Response to Environmental Defense Fund (EDF), International Council on Clean Transportation (ICCT), Sierra Club, Environment America, Safe Climate Campaign, Natural Resources Defense Council (NRDC), American Council for an Energy-Efficient Economy

(ACEEE), and Clean Air Council is in Preamble section III.D.1.a. In short, we agree with all of the commenters addressing the issue that the assumption of a flat baseline absent post-MY 2016 GHG standards for these vehicles has full historic and empirical justification.[22]

Response to Volkswagen Group of America

The actual decline agencies projected was 23%, mostly due to falling sales from Chrysler (65%). NPRM's 2008 baseline fleet was created using CSM Automotives 2009 projections market share/model mix, and AEO 2011 sales volumes and car/truck split. The forecast from CSM was greatly influenced by Chrysler's bankruptcy and accounts for the majority of the decline in trucks. For the final rulemaking, the agencies created an alternative fleet using 2010 CAFE data, a future fleet projection from LMC (JD Powers) Automotives 2011 projections of market share/model mix, and AEO 2012 sales volumes and car/truck split.

12.2. Types of Technologies Considered and Their Effectiveness

Organizations Included in this Section

Volkswagen Group of America

Organization: Alliance of Automobile Manufacturers

Examples of anticipated battery technology breakthroughs include energy storage and management as well as power electronics capabilities; new battery chemistries and materials; new types of charging and faster charging; and advances in smart grid technology. Additional anticipated breakthroughs include the emergence of new, low-global warming potential fuels; high-efficiency transmissions; new down-weighting technologies and light-weight materials. The agency should also evaluate the ability to meet increasingly stringent criteria pollutant standards using new combustion technologies for advanced internal combustion engines. [EPA-HQ-OAR-2010-0799-9487-A1, pp.18-19]

[22] See also Comments of VW p. 14: "As shown in Figure 2-4, following fuel price increases in early 2000's, there was a notable uptick in customer interest of hybrid vehicles. The fuel price spikes in 2007-2008 timeframe even brought about irrational consumer behavior in which customers traded-in large trucks to purchase small cars, sometimes at considerable loss. However as fuel prices stabilized in the mid $3 per gallon range, sales in larger vehicles and pick-up trucks returned. Often customers who had moved into smaller vehicles complained about the lack in comfort and space of the smaller cars".

Organization: BMW of North America, LLC

Many of the technologies mentioned in the draft joint TSD are already implemented in BMW Group models or will be implemented for compliance with the standards for MYs 2012-16. This high implementation rate of advanced conventional technologies will make it more challenging for BMW to comply with' proposed future standards. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 5]

This is confirmed by the projected electrification market share for each automaker by the US agencies. The market share of EV, PHEV and HEV for the BMW Group and thus the application of very cost-intensive technologies is one of the highest among all automakers. EPA confirms that'....larger volume manufacturers have levels of advanced technologies that are below the phase-in caps. Smaller 'luxury' volume manufacturers tend to require higher levels of these technologies, BMW, Daimler...... all reach the max. penetration cap for HEVs (30%) in 2021.' [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 5]

This appears to be a double penalty because in order to comply with the proposed standards, those manufacturers must invest in expensive technologies and then force their higher fleet penetration. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 5]

Organization: Center for Biological Diversity

2. The Agencies must set standards that are technology forcing

There is no doubt that EPCA is a technology-forcing statute. EPCA is meant to encourage technological innovation – meaning new technologies, not simply better versions of what exists today. As the court in Center for Auto Safety v. Thomas noted, “[t]he experience of a decade leaves little doubt that the congressional scheme in fact induced manufacturers to achieve major technological breakthroughs as they advanced towards the mandated goal.” 19 As explained by the court in Kennecott Greens Creek Min. Co. v. Mine Safety and Health Admin., “when a statute is technology forcing, the agency can impose a standard which only the most technologically advanced plants in an industry have been able to achieve – even if only in some of their operations some of the time.”20 With regard to a similar technology-forcing statute, the Clean Air Act, legislative history indicates that the primary purpose of the Act was not “to be limited by what is or appears to be technologically or economically feasible,” which may mean that “industries will be asked to do what seems impossible at the present time.”21 [EPA-HQ-OAR-2010-0799-9479-A1, p. 5]

Yet, instead of stressing that EPCA and EISA are technology forcing and intended to create technological innovation, the Agencies discuss “technological feasibility” by remarking that they are “not limited in determining the level of new standards to technology that is already being commercially applied at the time of the rulemaking.”22 This formulation of the Agencies’ duties entirely misconstrues Congressional intent. To be technology forcing, the Agencies must not limit themselves to technology already applied at the time of the rulemaking but instead must drive technological innovation. This mandate has become of utmost importance because the next ten years or so constitute a critical decade in which to avert the most dangerous consequences of climate change, and because the Agencies have chosen to set standards over a period spanning that entire decade and the following five years, an unprecedented time frame in the history of CAFE. Standards that are built solely on technologies already in use today or projected to be in use a few years from today, violate this mandate per se. [EPA-HQ-OAR-2010-0799-9479-A1, p. 5]

E. The Preferred Alternative Does Not Represent the Maximum Feasible Fuel Efficiency Standard

The rulemaking requires insufficiently stringent technological improvements as it does not reflect the historical speed of technological improvements in practically every industry over the last decades, including in the automotive industry, a trend that will undoubtedly continue in the future; as it improperly excludes the impact of technologies under development or in the research stage; and as it does nothing to force technological innovation. The failure to take these developments into account is especially egregious in a rulemaking spanning the next decade and a half. If these factors were properly accounted for, the Agencies would recommend Alternative 4 rather than the preferred alternative. [EPA-HQ-OAR-2010-0799-9479-A1, p. 19]

The Agencies state that with only a few exceptions, the technologies considered here are the same as those in the MY 2012-2016 rulemaking. This approach is completely inadequate for a rulemaking reaching nine years beyond that date. They also state that the technologies they have considered are limited to currently existing technologies and improvements to them that either are or will be available within the rulemaking timeframe. In fact, they have no such thing, as they admit that that they have only considered technologies “expected to be in production in the next 5-10 years.” Since this rulemaking will extend considerably beyond that time frame, this approach is inadequate. In addition, because the CAFE statutes are technology forcing and the rulemaking period is extraordinarily long, the Agencies must also consider technologies in the research phase. [EPA-HQ-OAR-2010-0799-9479-A1, p. 19]

Defending their refusal to consider research stage technologies, the Agencies point to uncertainties involved in the availability and feasibility of implementing them with significant penetration rates. But since the Agencies have taken it upon themselves to set standards 14 years into the future, it is their responsibility to assess those uncertainties within reasonable ranges, and include the clearly foreseeable impact of technological innovations rather than to disregard research-stage technology altogether. Moreover, it is certain that the rate of innovation will continue at least at the speed of the last decade, and that technologies now in the research stage and many not yet conceived will be in existence in 2025 and much before then. In turning a blind eye to research that is sure to bear results 14 years from now, the Agencies ignore their mandate. [EPA-HQ-OAR-2010-0799-9479-A1, p. 20]

Organization: Eaton Corporation

• Allows OEM and vehicle component suppliers to provide vehicle solutions that advance fuel economy and emissions technologies that are affordable and maintain or increase performance of the vehicle. [EPA-HQ-OAR-2010-0799-9494-A1, p. 2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 186.]

Eaton appreciates the agency's use of sound economic analysis and in-depth technology reviews during the rulemaking process. We believe that the framework outlined in the NPRM is a good step towards the final regulation that will foster innovation, foster both technology and competition while maintaining fleet diversity and incentivizing over-achievement of emissions and fuel economy targets. It is important that certain principles outlined in the notice are further developed in the upcoming period.

Organization: Honeywell Transportation Systems

The agencies have recognized three levels of technology availability: (1) technologies available in the market in the near term, (2) technologies that are not yet in production but that are under development and that may be available for deployment within the next 5 to 10 years, and (3) technologies that are in the initial stages of research. (Draft Joint Technical Support Document, p. 3-1). Included within the group of technologies that are currently under development and that may be available during the model years covered by this rulemaking are downsized and turbocharged engines operating at combustion pressures significantly higher than today’s turbocharged engines. Id. A high-performance credit would provide an incentive to encourage further deployment and use of these technologies. [EPA-HQ-OAR-2010-0799-9474-A1, p.5]

Honeywell strongly supports a technology neutral approach to regulation and to incentivizing new technology. [EPA-HQ-OAR-2010-0799-9474-A1, p.6]

Organization: International Council on Clean Transportation (ICCT)

1. Cost-effective opportunities to reduce fuel consumption and climate change emissions in the near term are far larger than most people realize. Thanks to computer aided design and computer controls, the pace of technology development is accelerating and much of the underlying data in the technology assessments is already out of date or is only representative of near term vehicles. Meeting the standards will be easier and will cost less than assumed in the proposed rule and no rollback of the stringency should be considered. [EPA-HQ-OAR-2010-0799-9512-A1, p. 2]

1) Technology Benefit and Cost Assessments

The ICCT supports the proposed standard stringency. However, it is important to understand that the simulation modeling used to assess future technology benefits is actually quite conservative and that the future technology benefits will be larger than projected and the costs lower. This is due to rapid improvements in computer-based tools, which are opening up technology gains that were never possible before. Computer simulations and computer-aided design are enabling vastly improved designs and technologies. On-board computer controls provide unprecedented integration of engine, transmission, and hybrid operation. Instead of slowing down, the pace of technology development just keeps accelerating. [EPA-HQ-OAR-2010-0799-9512-A1, p. 4]

The sophistication of assessing technology efficiency improvements has been increasing as well. The 2001 National Research Council report applied technologies stepwise to estimate fuel economy improvement possible through regulations. Some manufacturers criticized this method, claiming it could overestimate fuel economy benefits because it does not account for synergies between technologies. This is especially important as more technologies are added to the vehicle. The next step in sophistication is the use of 'lumped parameter' models that can account for first-order interactions between technologies. These models can assess the effects of technology in a broad array of vehicle types and for a class of vehicles. However, this method is generally limited to 'proven' technologies. This was fine as long as standards were set only a few years in advance, but it is not adequate for setting standards with longer leadtimes. [EPA-HQ-OAR-2010-0799-9512-A1, p. 5]

Full-system simulation modeling is needed to capture the physics of the vehicle and powertrain system and assess interactions of the various components. It can also assess new technologies or combinations of technologies when experimental data are sparse. The 2011 National Research Council report on light-duty vehicle technologies supported the need for full-system modeling:

'The committee thinks that the most accurate method of analyzing potential reductions in fuel consumption, which considers the extent to which any of the efficiency improvements or energy loss reductions identified above can be realized while maintaining energy balance criteria, utilizes full system simulation (FSS).'1 [EPA-HQ-OAR-2010-0799-9512-A1, p. 5]

To support development of 2025 standards, EPA contracted with Ricardo Inc. to conduct such simulations. Ricardo is a highly respected engineering organization that does the vast majority of its work for OEMs and suppliers. [EPA-HQ-OAR-2010-0799-9512-A1, p. 5]

ICCT was involved with this simulation modeling from the beginning, including providing the initial contract for Ricardo to start work, hiring independent experts to review Ricardo's hybrid control simulations, and participating along with CARB on an advisory committee. After intensive involvement in the simulation process for the last two years, it is clear to us that the technologies being assessed by Ricardo are on the conservative side. In fact, this is unavoidable due to the restriction to currently available data and engine maps. Engine technology is improving much faster than we can keep up with and engines better than those modeled by Ricardo are already in development. [EPA-HQ-OAR-2010-0799-9512-A1, p. 5]

• The diesel maps used by Ricardo for the US simulations are already out of date and ICCT has contracted with Ricardo to rerun the diesel simulations for Europe using maps representative of the latest diesel technology. [EPA-HQ-OAR-2010-0799-9512-A1, p. 5]

• The engine map used by Ricardo for the gasoline engine with boosted-EGR is similar to the single-stage turbocharger engine map developed by the HEDGE consortium two years ago, which is already out of date. The map used by Ricardo in the simulations for a two-stage turbocharger is shown in Figure 2 below. Figure 3 shows a boosted-EGR engine map provided by the HEDGE consortium in February 2010 for a single-stage turbocharger. The minimum brake-specific fuel consumption (BSFC) for the HEDGE engine is about 4% lower than the map used by Ricardo in the simulations. While the engine map used by Ricardo has broader BSFC contours and better efficiency at low loads, the single-stage turbocharger could not provide sufficient air under all conditions and was boost limited. The HEDGE consortium is already working on a two-stage turbocharger system that will enable larger amounts of EGR, higher compression ratio, lower minimum BSFC, and a broader range of lower fuel consumption. [See Figure 2 on p. 6 and Figure 3 on p. 7 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, pp. 5-6]

This rapid technology improvement can also be seen by looking at historical data. For example, the 2001 National Research Council report found that turbocharging and downsizing would improve fuel economy by 5 to 7 percent. The most recent estimates in the draft RIA found that turbocharging and downsizing alone will provide a 12 to 15 percent improvement with 33 percent downsizing and16 to 20 percent for higher-pressure turbos with 50 percent downsizing. This 2 to 3 times increase in the efficiency benefit of turbocharging is not due to the older estimates being wrong, but rather to rapid improvements in combustion and turbocharging technology over the last 10 years. In addition, adding cooled and boosted EGR, a technology that wasn't even considered 10 years ago, is estimated to increase the benefits of turbocharging to 20 to 24 percent, or a 4 times increase. [EPA-HQ-OAR-2010-0799-9512-A1, p. 7]

This dramatic improvement in turbocharger systems also applies to cost. The estimated manufacturing cost for a turbocharger system, including downsizing but without a reduction in the number of cylinders, for 2017 in the proposed rule is $478. This compares with an estimated manufacturing cost of $815 from NHTSA just three years ago for the 2011 CAFE standards. Other costs estimates have also fallen dramatically in the last three years:

• 6-speed automatic transmission cost for 2011 CAFE standard was a $215 cost increase, compared to a $13 cost decrease in the proposed rule.

• Dual-clutch automated transmission was a $145 cost increase for the 2011 standard, compared to a $205 cost decrease in the proposed rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 8]

It should also be noted that the estimated costs in the proposed rule to comply through 2020 are less than half of the estimated costs to comply in 2025. Passenger car costs for 2020 are $885 compared to $2,023 for 2025 and light truck costs for 2020 are $688 compared to $1,578 for 2025.3 ICCT is confident that continued technology development will reduce costs in the future and that the midterm review will find that the current estimates of compliance costs in 2025 are greatly overstated. [EPA-HQ-OAR-2010-0799-9512-A1, p. 8]

ICCT is also paying FEV to do additional teardown cost assessments in connection with our work in Europe. These include updating the P2 hybrid costs and new cost assessments for advanced diesel engines, basic stop-start systems, manual transmissions, and cooled EGR systems. P2 costs in the proposed rule are overstated, as the system size is not reduced to maintain constant performance, cost savings from deleting the torque converter are not subtracted from the system cost, and future hybrid batteries will be smaller and cheaper due to new Li-ion chemistries with much higher power to energy ratios. All of the FEV results will be shared with EPA and NHTSA as they become available. [EPA-HQ-OAR-2010-0799-9512-A1, p. 8]

The 2025 rules are 13 years away. With the rapid improvements in technology due to computer-enhanced development, it would be completely irrational to assume that there will be no further technology improvements beyond what is known today. Thus, the efficiency and cost estimates in the draft rule are quite conservative and there should be no consideration to rolling them back. [EPA-HQ-OAR-2010-0799-9512-A1, p. 8]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 31.]

Another area where costs included in the draft are too high are those for the parallel or P2 hybrid. The P2 systems evaluated by FEV for EPA assumed no reduction in IC engine size, no reduction in battery size, and did not account for the cost savings due to removing automatic transmission torque converter. The ICCT is presently engaged in an exercise to evaluate the cost of P2 systems with these issues in mind, and we expect, at least, that the updated P2 costs will be lower than the agency estimates. These updated costs should be included in the final rulemaking.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 193-195.]

The opportunities to improve efficiency in the near term are far larger than most people realize. The internal combustion engine is widely perceived as century-old technology that is at the end of its development, but the reality is exactly the opposite. Computer simulations, computer-aided design are enabling vastly improved designs and technologies. On-board computer controls provide unprecedented integration of engine, transmission and hybrids operation. Instead of slowing down, the pace of technology development just keeps accelerating.

The sophistication of assessing technology efficiency improvements has been increasing as well. To support development of the 2025 standards EPA contracted with Ricardo to conduct full-system simulation modeling of the latest technology developments.

ICCT has been intensively involved in the simulation modeling process for the last two years. It is very clear to us that the technology being assessed by Ricardo are on the conservative side. In fact, this is unavoidable due to the restriction to the currently available data and engine maps.

This rapid technology improvement can also be seen by looking at historical data. The 2001 Natural Research Council report found that turbocharging and downsizing could improve fuel economy by 5 to 7 percent. The most recent estimates in the draft RIA found this benefit is now two to three times higher. This is not due to the older estimates being wrong, but rather to rapid improvements in combustion and turbocharging technology over the last 10 years.

By comparison, the 2025 rules are 13 years away. The efficiency estimates in the draft rule are actually quite conservative and there should not be any consideration of rolling them back.

Computer simulations will especially impact lightweight material design. In the past optimization of materials was a long, slow process of gradually changing a few parts of the time to avoid unanticipated problems with safety, ride, noise and vibration.

1 Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy; National Research Council, ISBN-13: 978-0-309-15607-3, 260 pages, 81/2 x 11, 2011.

3 Preamble, Tables IV-110 and IV-111.

Organization: Jackson, F.W.

5. Comparing against current 2010 poor 27 mpgge fleet is an easy target to look better against; vs. currently on books 35.5 mpgge or better yet what other things could be done to, in addition to or in lieu of stated EPA designs, Le., how complete and objective is the EPA analyses. While I'd agree many of the EPA items in aggregate should improve the product mpgge significantly I also believe there are other items not mentioned in EPA's list, see below my lists [see pp. 4-5 of Docket number] for Mid and Max technologies that need to be fairly considered. When all fairly considered I believe a 2025 54.5 mpgge can be built without plug-ins and I believe even without HEVs and with minimum ethanol! [EPA-HQ-OAR-2010-0799-8041-A1, p. 2]

Organization: Manufacturers of Emission Controls Association (MECA)

Implicit in federal and state greenhouse gas emission analyses is the ability of these advanced powertrain options to meet the applicable criteria pollutant emission standards, such as CO, NO_X, and non-methane organic gases (NMOG). All of these advanced, light-duty powertrain options combined with the appropriately designed and optimized emission control technologies can meet all current and future federal and state criteria emission requirements. In this manner, advanced emission controls for criteria pollutants enable advanced powertrains to also be viable options for reducing greenhouse gas emissions. A range of powertrain technologies, including engine turbochargers, exhaust gas recirculation systems, advanced fuel systems, variable valve actuation technology, advanced transmissions, hybrid powertrain components, and powertrain control modules that can be applied to both light-duty gasoline and diesel powertrains to help improve overall vehicle efficiencies, reduce fuel consumption, both of which can result in lower CO_2 exhaust emissions. In many cases, the application and optimization of advanced emission control technologies on advanced powertrains can be achieved with minimal impacts on overall fuel consumption. Auto manufacturers will also take advantage of synergies between advanced emission control technologies and advanced powertrains to assist in their efforts to optimize their performance with respect to both greenhouse gas and criteria pollutant exhaust emissions. [EPA-HQ-OAR-2010-0799-9452-A3, p.2]

Future light-duty diesel powertrains will continue to use emission control technologies like diesel particulate filters, NO_X adsorber catalysts, and selective catalytic reduction catalysts to meet EPA's light-duty exhaust emission standards. Emission control manufacturers are working with their auto manufacturer partners to further optimize these emission control technologies to be more effective at reducing criteria pollutants and play a role in reducing vehicle greenhouse gas emissions. Advanced diesel emission control technologies like particulate filters with lower backpressure characteristics, SCR catalysts with improved performance at lower exhaust temperatures, and SCR catalyst coated directly on particulate filter substrates are examples of emerging diesel emission control technologies that will allow future diesel powertrains to not only be as clean as gasoline engines from a criteria pollutant perspective, but deliver improved fuel consumption characteristics and lower greenhouse gas emissions. The use of diesel particulate filters also delivers significant reductions in black carbon emissions from diesel engines, a combustion emission that also has important climate change impacts. [EPA-HQ-OAR-2010-0799-9452-A3, p.2]

For gasoline vehicles, direct injection technology enables gasoline engines to achieve greater fuel efficiency and is expected to be a dominant pathway to meeting future light-duty greenhouse gas emission standards. Again emissions controls ensure that these more fuel efficient gasoline engines meet tough EPA or California criteria emission regulations. Under stoichiometric conditions, three-way catalysts are used to achieve ultra-low emissions of NO_X, HC and CO. Advanced high performance, three-way catalysts are available and will continue to evolve and be optimized to ensure that future gasoline direct injection engines will meet the toughest criteria pollutant emissions standards with minimal impacts on overall vehicle exhaust system backpressure and fuel consumption. [EPA-HQ-OAR-2010-0799-9452-A3, p.2]

Under lean combustion conditions, similar emission control technologies used on diesel vehicles can be used to reduce emissions from lean, gasoline direct injection powertrains. These include particulate filters to reduce PM emissions, and SCR and/or lean NO_X adsorber catalysts to reduce NO_X emissions. Lean NO_X adsorber catalyst performance has a high degree of sensitivity to fuel sulfur levels. The current EPA fuel sulfur limits for gasoline (30 ppm average, 80 ppm cap) are too high to allow lean NO_X adsorber catalysts to be a viable NO_X control strategy for fuel efficient, gasoline lean-burn engines that employ direct fuel injection technology. MECA believes that EPA should lower gasoline fuel sulfur limits to a 10 ppm national average to allow

NO_X adsorber catalysts to be used on such vehicles in the future in order to provide additional options for improving the efficiency and reducing greenhouse gas emissions from gasoline vehicles. [EPA-HQ-OAR-2010-0799-9452-A3, p.3]

Organization: Volkswagen Group of America

In order to consider the technical feasibility of the proposed standards, EPA evaluated a broad range of technologies which an OEM could incorporate to help achieve compliance. Over the past several years, Volkswagen held technical meetings with agency staff and provided confidential technical details illustrating our projections for future technology:

- Cost

- Readiness

- Effectiveness

- Market Adoption

- Penetration [EPA-HQ-OAR-2010-0799-9569-A1, p. 12]

During the discussions, Volkswagen focused on several key technologies including:

- Hybrid and fully electrified vehicles

- Vehicle lightweighting

- Advanced internal combustion engines (ICE) [EPA-HQ-OAR-2010-0799-9569-A1, p. 12]

Volkswagen provided EPA and NHTSA with confidential future forecasts for technology readiness, cost, and practicability. We appreciated the opportunity to present our positions and were able to engage in technical dialogue to point out areas which were or were not consistent with the agencies understandings. Certain key technologies including electrification, lightweighting, and advanced engine technologies presented areas where there were some inconsistencies. [EPA-HQ-OAR-2010-0799-9569-A1, p. 13]

Response:

Regarding comments from the Alliance of Automobile Manufacturers, we also anticipate many breakthroughs and improvements in the area of energy management, transmissions, and lightweight materials. As discussed in TSD 3, the agencies considered technologies in many categories that manufacturers could use to improve the fuel economy and reduce CO_2 emissions of their vehicles during the MYs 2017-2025 timeframe, including technologies which may not currently be in production, but are under development and are expected to be in production in the next five to ten years. Over the next decade, it is possible that there will be advances in vehicle technology that are not discussed in this assessment. For more details, please refer to the Joint

TSD Section 3.3.3.9 regarding energy management and storage, Section 3.3.2 regarding transmission technologies, and Section 3.3.5.5 regarding mass reduction. We also agree that advanced combustion technologies need to be evaluated for compliance as they are developed.

Regarding comments from BMW, we do not disagree that BMW's costs are likely to be higher than the average. In fact, our analysis shows a 2025MY cost of $1910 for BMW, or $74 higher than the average[23]. Our analysis also shows a 9% full EV penetration rate for BMW, versus the average penetration rate of 3%. This does not mean that BMW is required to use such technologies, and we thus disagree with that portion of BMW's comment ("This appears to be a double penalty because in order to comply with the proposed standards, those manufacturers must invest in expensive technologies and then force their higher fleet penetration "). Our analysis seeks only to demonstrate a possible path toward compliance. It does not seek to demonstrate *the* path. BMW correctly points out that many of the technologies we expect will allow for compliance are already currently used in BMW vehicles. However, while those technologies are used in part for fuel efficiency, they are largely tuned to provide high power in relation to the weights of their vehicles (i.e., high power-to-weight ratios. Though the agencies do not model such options, and have included the costs of preserving all vehicle utilities found in the reference fleet(s), BMW has many compliance options that may prove less costly than those EPA modeled. For example, the company could implement more off-cycle credit technologies, use more mass reduction than EPA modeled, or reduce the acceleration performance of their vehicles and put the resultant efficiency gains to fuel economy. Further, we note that BMW has no high BMEP (24/27 bar) engines in their in-use US fleet today, no high efficiency gearbox, no shift optimizer, no 12V stop-start, and no mild hybrid. So there are still many technologies that BMW is not using that can be used in their future fleet.

Regarding comments from Center for Biological Diversity, we note that many of the comments regarding legal authority address EPCA and EISA and are not correct with regard to the Clean Air Act. See preamble section I.D.2 (explaining, among other things, that section 202 (a) is not technology-forcing, and even if it were, that EPA retains considerable discretion in weighing issues of technical feasibility, cost, and lead time). In any case, EPA believes that the rule is predicated on high penetration rates of advanced technologies, and many of these go beyond the technologies on which the MYs 2012-2016 standards are predicated. A primary technology upon which our MYs 2017-2025 standards rely is high BMEP turbocharged and downsized engines. These engines will operate at 24 and 27 bar BMEP, levels at which no current production gasoline engine operates. Although such engines are beyond the single-cylinder test-bench level of development, they are not in the marketplace and considerable work remains to bring them to the marketplace.[24] Another example is mild hybrid technology. There

[23] As pointed out in the MYs 2012-2016 rulemaking, one reason these costs are higher on average is that BMW has typically paid fines rather than complying with CAFE standards, and consequently is now required to make more improvements than those of its competitors which did comply with CAFE. See 75 FR at 25414.

[24] EPA notes that Volkswagen's comment (p. 17) documents obstacles facing development and deployment of high BMEP turbocharged engines beyond the BMEP levels used within our analysis in the TSD ("While Volkswagen acknowledges that high BMEP (27 – 31 BMEP) engines with cooled EGR are being researched, we caution that additional development is necessary to overcome obstacles to these types of engines. Volkswagen views these obstacles as significant – if not overcome the issues could preclude this type of engine as a viable greenhouse gas reduction technology.")

are vehicles being sold today that include mild hybrid technology but, importantly, not at the cost levels included in our analysis. So, while that technology is in the marketplace, it is a new and rapidly developing technology used in a very small percentage of MY 2012 sales. Reasonable engineering judgement was used to select the technologies that will be available in the timeframe of this rulemaking. Many of these technologies are still in the research phase and not planned to be in production for several years and will not be broadly applicable until MY2017-2025. The midterm review will be used to re-evaluate these technology assumptions and make appropriate changes in the analysis.

Regarding comments from Eaton Corporation, we appreciate your comments in support of the flexibility allowed in the rulemaking for vehicle manufacturers to meet the standards.

Regarding comments from Honeywell Transportation Systems, and Jackson, F.W., EPA believes that the issue of technology neutrality is a much more complex issue than some commenters suggest when they advocate for a “level playing field” and suggest that a level playing field is best achieved by no incentives. Given that internal combustion engines and petroleum-based fuels have dominated the U.S. light-duty vehicle market for 100 years, with massive sunk investments, there are major barriers for new vehicle technologies and fuels to be able to gain the opportunity to equitably compete on any type of level playing field. For example, consider a hypothetical new vehicle/fuel technology that could be superior to conventional technology from a consumer perspective if, and only if, the vehicles and fuels could be produced at similar economies of scale. But, it is very possible that such a hypothetical new technology would never get the opportunity to compete at equivalent economies of scale, because of the very large investments that are needed, up front, to support the research and development, parts and vehicle production facilities, and fuel infrastructure, none of which are needed for conventional technology as these investments have been made in the past. In this context, temporary regulatory incentives do not so much “pick winners and losers” (as an inefficient or unattractive technology is not going to achieve long-term market success based on temporary incentives) as to give new technologies more of an opportunity to compete with the established technologies.

Regarding comments from International Council on Clean Transportation (ICCT) on Computer aided modeling, the agencies assume the materials that manufacturers will use in their BIW to reduce mass include HSS, AHSS, aluminum and limited magnesium and these materials have all been modeled. The extent of modeling for composites is unknown. However, the use of composites in the BIW is still being researched with applications primarily only on some limited high end vehicles. The simulations are continuing to rapidly improve to the point where they are starting to be used to simultaneously optimize the material composition, shape, and thickness of every individual part, including secondary weight reductions. With respect to the diesel engine maps used by Ricardo, it is possible that the maps could be further optimized. The maps used were optimized by compliance with US tailpipe standards which are generally more stringent than diesel standards in Europe. That said, if our maps are not fully optimized, it suggests we have been conservative with respect to our effectiveness values. The EPA did not rely on diesel engine technology as a compliance pathway in our analysis, though that does not preclude their use in the real world (i.e. our modeled compliance pathway is not an indication of an agency preference for any technology). When the results become available, we welcome ICCT’s continued work with Ricardo using more optimized diesel engine maps. As for the rapid change in cost and effectiveness estimates since the 2001 NRC report, we do not agree that the changes from then to today suggest that our technology costs or effectiveness estimates are similarly high or low, respectively. In fact, our estimates have been generated through a much more rigorous process than the 2001 NRC values which we believe helps to explain why those values are so different than values of today. We stand by our effectiveness estimates as representing the best estimates available today. As for P2 HEV costs and future batteries being smaller and cheaper due to new chemistries, we intend to monitor any future changes in battery chemistries and their costs but have chosen not to make any anticipatory changes for the final analysis. Regarding failing to include torque converter removal in our costs, we disagree with this comment where we have included DCTs as part of the HEV package. Our DCT costs include removal of the torque converter (see U.S. EPA, "Light-duty Technology Cost Analysis – Report on Additional Case Studies," EPA-HQ-OAR-2009-0472-11604 and FEV, Inc., "Light-Duty Technology Cost Analysis, Report on Additional Transmission, Mild Hybrid, and Valvetrain Technology Case Studies", Contract No. EP-C-07-069, Work Assignment 3-3. November 2011). Where our packages include automatic transmissions—which is the case on towing vehicle types—we have chosen to remain conservative and assume that the torque converter will remain and therefore there is no cost reduction association with its removal. In these cases—towing vehicles—it is possible that the torque converter could be removed but the low end torque assist provided by the torque converter would have to be regained from somewhere (e.g., the engine, the electric motor), which would incur some costs on the order of the savings realized by torque converter removal. Therefore, we believe that the best approach is simply assuming that the torque converter will remain. (Incidentally, this is an example of how EPA's technology effectiveness and costing methodologies preserve all utilities found in the current fleet.) Lastly, as regards our purported failure to assume smaller engines on P2 HEVs, we point out that we have actually assumed downsized engines (with turbocharging) on our towing P2 HEVs. We have not assumed downsized engines on our non-towing, Atkinson engine equipped P2 HEVs and have done this to ensure maintenance of vehicle utility. We discuss both of these points in our final RIA Chapter 1.3. Reasonable engineering judgement was used to select the technologies that will be available in the timeframe of this rulemaking. Many of these technologies are still in the research phase and not planned to be in production for several years. The midterm review will used to re-evaluate these technology assumptions and make appropriate changes in the analysis.

Regarding comments from Manufacturers of Emission Controls Association (MECA), we agree that future vehicles will be able to comply with existing criteria emission standards in addition to the new GHG standards and indeed will be required to do so. The comment regarding the reduction of gasoline sulfur to enable lean-burn NOx control aftertreatment is outside the scope of this rulemaking since we are not relying on lean-burn gasoline technology to demonstrate compliance.

Regarding comments from Volkswagen Group of America, we thank you for your comments and providing this additional information. We look forward to obtaining more of this type of information to inform our future work.

Technology Market Penetration

EPA and NHTSA chose to exclude lean burn gasoline direct injection (GDI) engine technology in evaluating pathways towards meeting the proposed GHG and CAFE standards for MY 2017 – MY 2025 light-duty vehicles.17 We concur with this assessment. While EPA and NHTSA observe that the "…availability of ultra-low sulfur (ULS less than 15 ppm sulfur) gasoline is a key technical requirement for lean-burn GDI engines to meet EPA's Tier 2 NO_X emissions standards," we note that in regions of the world where 10 ppm sulfur in gasoline was mandated (i.e., Europe and Japan), the penetration of lean-burn GDI peaked at 2% and then declined as the real-world efficiency benefits of lean-burn GDI were found to be less than promised. A recent assessment of the automakers' technology introduction plans concluded that the opportunity for lean GDI in the US was limited to 0-3% market penetration over the next decade and that even a 10 ppm max sulfur limit in U.S. gasoline would not result in lean burn engine production as the automakers would pursue other, more cost-effective technologies for regulatory compliance.18 [EPA-HQ-OAR-2010-0799-9469-A1, p. 8]

Vehicle technology penetration estimates are unrealistic - Light-duty vehicle technologies requiring ultra-low sulfur gasoline are not cost-effective and are unlikely to be used to meet the proposed fuel economy and vehicle GHG standards. We note that in regions of the world where 10 ppm sulfur in gasoline was mandated (i.e., Europe and Japan) the penetration of lean-burn GDI peaked at 2% and then declined as the real-world efficiency benefits of lean-burn GDI were found to be less than promised. [EPA-HQ-OAR-2010-0799-9469-A2, p. 2]

Organization: Center for Biological Diversity

Examples of technologies improperly excluded from the rulemaking include but are not limited to higher voltage stop-start/belt integrated starter generators; integrated motor assist/crank integrated starter generators; 2-mode hybrids; and power split hybrids. As stated below, providing incentive credits instead of setting standards integrating these technologies does not comply with the statute. Among the technologies the Agencies believe are insufficiently developed are fuel cell electric vehicles, HCCI, multi-air, and camless valve actuation and other advanced engines currently under development. The decision to completely ignore the impact of these highly promising technologies, all clearly far beyond the research stage and already under development, is stunning. For example, the Agencies admit both that fuel cell electric vehicles have “the potential of achieving more than twice the efficiency of conventional internal combustion engines” and that “there will be some limited introduction of FCEVs into the market place in the time frame of this rule.” But, because the Agencies “expect this introduction to be relatively small,” they have completely excluded FCEVs from their modeling analysis. This approach is clearly wrong. [EPA-HQ-OAR-2010-0799-9479-A1, p. 20]

99 Id. [EPA-HQ-OAR-2010-0799-9479-A1, p. 20]

Organization: Delphi Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 109-111.]

First, internal combustion engines, ICE's, both gasoline and diesel, will continue to improve and, therefore, be a major propulsion source for years to come. We as an industry and you as a government agency should be supporting efforts to improve current internal combustion engine technology. And we urge the EPA and NHTSA to take a careful look at the contributions that can be made by both gasoline and diesel engines.

As I said earlier, the best potential is with improved internal combustion engine technologies. Delphi has a strong portfolio of ICE-compatible technologies including direct injection fuel systems and advanced fuel injectors for alternative fuels, such as E-85 ethanol and compressed natural gas, variable valve lift and electric cam phasing to improve engine performance over the full engine operating range and reduce pumping losses. Multi-strike emissions systems to improve advanced high dilution combustion schemes, fuel delivery modules with brushless fuel pumps to reduce parasitic losses, and evaporative emissions canisters with heated purge to improve canister purge efficiencies under low conditions common with hybrid vehicles.

Organization: Eaton Corporation

Eaton believes that many of the technologies needed to achieve the proposed standards are available. Many are already in use, while others need a path into the market. Eaton has been developing engine system technologies that enable engine down-sizing and down-speeding that help deliver significant fuel economy savings while maintaining or enhancing vehicle performance. Examples of product introductions into the market in recent years include the Variable Valve Actuation systems (Active Fuel Management) and high-efficiency supercharger boosting systems. Several other related valve train and boosting systems developments are under way for a range of engine configurations that will assist OEMs in meeting the proposed targets. [EPA-HQ-OAR-2010-0799-9494-A1, p. 2]

Organization: EcoMotors International, Inc.

EcoMotors is commercializing a revolutionary internal combustion engine (ICE) in southeast Michigan. The opoc engine is a game-changing, advanced technology offering affordable low emissions transportation. Across many applications and vehicle classes, the opoc engine produces fuel economy improvements superior to today's best electric hybrid vehicles at lower cost, and without the large and expensive battery packs required by those vehicles. The engine's unique opposed-piston opposed-cylinder architecture provides unparalleled benefits, including: [EPA-HQ-OAR-2010-0799-9594-A2, p. 2]

• The ability to deliver 50% or greater fuel efficiency in many applications, while reducing GHG emissions by half, with no loss in power, vehicle performance, drivability or utility;

• Low weight and a smaller profile - yielding unparalleled power density and exciting design opportunities with no loss of power or performance;

• The ability to run on a number of fuels, including gasoline, diesel and ethanol; and

• Functioning as a mechanical hybrid in a dual-module configuration, the opoc engine offers true modular displacement, enabling full power when needed, and shutting down one engine module when the power is not needed.1 [EPA-HQ-OAR-2010-0799-9594-A2, p. 2]

The opoc engine is manufactured using conventional components, manufacturing systems and processes. U.S. auto workers can manufacture the engine today within existing factories and without retraining. In addition, the opoc engine has a straightforward assembly, no cylinder heads or valve train, and 50% fewer parts than a conventional engine. The simplicity of its design reduces materials handling costs, and increases reliability. Moreover, with 50% fewer parts than a conventional engine, the opoc engine will cost about 20% less to manufacture.2 [EPA-HQ-OAR-2010-0799-9594-A2, p. 2]

Advanced ICE technologies, such as EcoMotors' lighter, more efficient and economical opoc engine, have the potential to contribute dramatically to our national goals of increased fuel economy and decreased GHG emissions from the transportation sector. Advanced ICE technology also continues to make good economic sense for the vast majority of consumers, and can be provided without the need for continuing subsidies or massive infrastructure investments. [See Figure 1 on p. 3 of Docket number EPA-HQ-OAR-2010-0799-9594-A2] [EPA-HQ-OAR-2010-0799-9594-A2, p. 2]

Thus, it remains extremely important for national policy and this rulemaking to encourage the commercialization and deployment of non-electric vehicles using advanced ICE technologies. Non-electric, but state-of-the-art vehicles must have the ability to compete in the market on a level playing field with electric vehicles (EVs), plug-in hybrid vehicles (PHEVs), and fuel cell vehicles (FCVs) and contribute to near-term GHG reductions and fuel economy improvements. The Proposed Rule must be modified to ensure that this level playing field exists. [EPA-HQ-OAR-2010-0799-9594-A2, p. 3]

EPA should therefore support a variety of pathways for reducing GHG emissions and achieving higher fuel economy in the U.S. fleet, including supporting the use of such innovative, advanced ICE technologies as mechanical hybrids, like the dual-module opoc engine. EcoMotors' opoc engine enables coupling of multiple engine modules to meet a wide range of power needs, while dramatically increasing the overall efficiency of the propulsion system. This modular displacement hybrid (MDH) system features an electrically-controlled clutch housed between two engine modules. When requirements dictate the need for both engine modules, the clutch automatically engages to deliver power from both modules to the drivetrain. When the power of the second module is not needed, the clutch automatically disengages, and the second engine module is completely deactivated. This coupling and de-coupling of the engine cylinders effectively provides on-demand functionality for the powertrain and improves fuel economy by 45%. EcoMotors' MDH system combines the best of a variable displacement engine system with a mild EV hybrid operation to provide unparalleled improvement in vehicle fuel economy. [EPA-HQ-OAR-2010-0799-9594-A2, p. 5]

The benefits of EcoMotors' opoc MDH system can be further extended when paired with an electric drive system to create a tribrid system (at low speeds only the electric motor runs). Mild hybridization (4-6 kW) provides optimal vehicle fuel economy - a 55% fuel efficiency gain -

without compromising vehicle performance, drivability and utility. [EPA-HQ-OAR-2010-0799-9594-A2, pp. 5-6]

The market will not accept expensive, underpowered vehicles. EcoMotors' opoc engine delivers the high mileage and levels of performance, comfort, drivability and utility consumers want - and as an ICE, it is technology consumers are familiar with and know how to use. The opoc engine has 50% fewer parts than a conventional engine so it is also more economical for consumers to maintain. Fewer engine parts means increased reliability and fewer expensive repair incidents. EcoMotors' disruptive engine technology offers significant improvements on several attribute fronts and will create market draw from the actual customer base. [See Figure 2 on p. 7 of Docket number EPA-HQ-OAR-2010-0799-9594-A2] [EPA-HQ-OAR-2010-0799-9594-A2, p. 6]

A smaller, lighter engine, with a higher power density than a conventional engine, EcoMotors' opoc engine also provides OEMs with substantial design freedom for meeting consumer preferences. With fewer parts, the engine also costs less to manufacture than conventional engines. Low cost and ease of manufacture will enable OEMs to produce and sell vehicles profitably and at a price consumers can afford. Additionally, the fact that the opoc engine can be manufactured within existing supply chains means that this engine, operating as a mechanical hybrid in a dual-module configuration, could have a substantial impact on GHG emissions, fuel economy and petroleum reduction today. [EPA-HQ-OAR-2010-0799-9594-A2, p. 7]

In a recent report, the Boston Consulting Group concluded that advanced ICE technologies will be the most cost-effective way to reduce CO_2 emissions on a broad scale because:

- ICE technologies cost between $70 and $140 for each percentage point reduction in CO_2 emissions; and
- Though propulsion systems based partially or entirely on electricity can achieve even greater reductions in CO_2 emissions, they do so at a higher cost: $140 to $280 per percentage point of reduction in CO_2 emissions. [EPA-HQ-OAR-2010-0799-9594-A2, p. 10]

EcoMotors' opoc engine, operating as a mechanical hybrid in a dual-module configuration, offers a cost-effective means for achieving significant reductions in emissions. As shown in the chart below, the opoc MDH engine offers the lowest GHG emissions footprint of any other propulsion system. With its high performance, low production costs, and resulting affordability for consumers, this mechanical hybrid is a logical choice for OEMs to meet emissions and fuel economy standards. [See Figure 3 on p. 11 of Docket number EPA-HQ-OAR-2010-0799-9594-A2] [EPA-HQ-OAR-2010-0799-9594-A2, p. 10]

1 EPA has long championed this engineering concept as a means of achieving extraordinary fuel economy and GHG reduction benefits. See EPA, 'Progress Report on Clean and Efficient Automotive Technologies under Development at EPA, Interim Technical Report,' EPA420-R-04-002 (January 2004), pp.20-23.

2 In contrast, successful commercialization of other emerging vehicle technologies-such as volume production of advanced batteries for electric vehicles-requires the establishment and growth of entirely new industries, with supporting infrastructure and workforce retraining.

Organization: Honeywell Transportation Systems

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 257.]

We believe and continue to demonstrate that the internal combustion engine has a lot of potential still remaining.

Particularly during the later years covered by this rulemaking, more advanced technologies are even more likely to enable compliance with the standards. The movement towards new powertrain technologies on the other hand is laudable but limited. The vast majority of the new vehicle fleet during the next decade, at least, will likely remain internal combustion engines. These are the vehicles which will contribute to the vast majority of greenhouse gas emissions reductions achieved under these requirements. As such, it is our position that regulatory rules should not favor new powertrains or specific technologies at the expense of technologies capable of achieving substantial gains in the near and midterm.

Organization: Honeywell Transportation Systems

Honeywell (formerly Garrett) was the first to develop turbochargers for the automotive sector fifty years ago when it supplied Caterpillar's first turbo engine. Honeywell has been the leader and principal innovator of turbo technology ever since. In the 1990s, Honeywell redefined the commercial market when it introduced Variable Nozzle Turbine technologies into turbochargers, which enabled vehicle manufacturers to fully deploy the torque and fuel economy advantages of direct injection diesel engines. Today, Honeywell supplies turbochargers for all sized automotive engines from small compact vehicle engines to some of the largest commercial vehicle engines and on diesel, gasoline and even hybrid vehicles. [EPA-HQ-OAR-2010-0799-9474-A1, p.2]

Honeywell works closely with OEMs in accordance with design specifications to manufacture and deliver turbochargers. Turbochargers facilitate the reduction of GHG emissions by enhancing the fuel economy of the engines in which they are used. Although turbo technologies do not directly control or reduce emissions, they offer OEMs the ability to downsize engines or implement other designs that lower CO_2 output, all while maintaining or improving performance. For this reason, turbochargers are traditionally considered to be an emissions-related technology and not an emissions-control technology. [EPA-HQ-OAR-2010-0799-9474-A1, p.2]

By delivering more air to the engine, turbochargers facilitate fuel combustion, which results in a cleaner engine. Turbocharged diesel engines available in the marketplace produce 50 percent less NO_X and CO_2 emissions than conventional non-turbocharged engines. Moreover, because turbochargers capture and recycle energy produced by engines, they are able to transform more fuel energy into power. A turbocharged engine can generate up to seven times more power than a naturally-aspirated (i.e., non-turbocharged) engine of equivalent displacement. As a result, OEMs using turbocharger technology can reduce their fleet engine sizes by 30 to 40 percent. This reduction in engine size in turn yields significant fuel cost advantages over naturally-aspirated engines. [EPA-HQ-OAR-2010-0799-9474-A1, p.2]

The proposed regulations account for many of the turbo advancements likely to be incorporated into the light duty fleet during the years covered by this rulemaking. Recent and upcoming advances in turbo technologies include:

1. High-Temperature Gasoline Turbocharger: Honeywell has committed substantial resources to developing materials for the turbine wheel, turbine housing and turbine end seal that allow turbochargers to function optimally and reliably under high temperature conditions. The optimum balance of performance and fuel consumption at high speeds require turbochargers to operate at turbine inlet temperatures of up to 1050 degrees Celsius.

2. Twin Scroll Turbine Technology: An emerging technology for energy boosting, this technology yields improved turbine performance by delivering high pressure exhaust pulses directly to the turbine wheel. It provides enhanced performance and fuel economy at low speeds. [EPA-HQ-OAR-2010-0799-9474-A1, p.2]

3. Electric-Actuation: Electric actuation in a turbocharger provides more accurate control for a wider range of operating conditions, while improving fuel consumption and economy, traction control, and performance levels.

4. Current Generation VNT Turbochargers: This turbo platform offered by Honeywell has spawned several high performance innovations that increase the boosting levels of previous generation VNT technology by 30%.

5. Two-Stage Turbocharging: Dual-stage turbo technology is now being applied to passenger cars, which can create substantially more torque, improve fuel consumption, and enhance vehicle acceleration.

6. Ball Bearings: Ball bearing technology dramatically reduces friction losses in the bearing system, further improves fuel consumption and transient performance, and enhances exhaust gas recirculation. Moreover, it converts more energy into aerodynamic power, which leads to better NO_X control.

7. Rotary Electric Actuator: This turbo technology provides for the electronic control of air, which yields faster response times compared to a conventional pneumatic vacuum system. [EPA-HQ-OAR-2010-0799-9474-A1, p.3]

Honeywell's concern is that providing incentives exclusively focused on electric drivetrains translates into a public policy disfavoring investment in technologies that are able to substantially advance the emissions performance of internal combustion engines. This could result in significant unrealized gains in emissions and fuel economy improvements for the model years where electric vehicles are given unique and special incentives. [EPA-HQ-OAR-2010-0799-9474-A1, p.3]

It is well recognized that the success of electric drivetrains is uncertain and will depend on the growth of infrastructure in the face of public and private budgetary constraints, technological breakthroughs to make battery costs commercially viable, and consumer confidence in EV range and safety. For example, the Boston Consulting Group projects that EVs and PHEVs could make up only 2 percent of new light-duty vehicle sales in 2020. See The Boston Consulting Group, Powering Autos to 2020: The Era of the Electric Car? at 18 (July 2011). Similarly, a recent survey by Deloitte revealed significant differences between “electric vehicle realities versus consumer expectations.” Deloitte concluded that its “study suggests that only a small niche of today’s consumers would find current technology acceptable, and that small fraction of consumers will not result in mass adoption of pure electric vehicle technology over the next decade.” See Deloitte Touche Tohmatsu Limited Global Manufacturing Industry Group, Unplugged: Electric vehicle realities versus consumer expectations at 20 (2011). [EPA-HQ-OAR-2010-0799-9474-A1, pp.3-4]

The suggested incentive, moreover, would not give credits for technology that has already been taken into consideration. The proposed standards incorporate the technology application, including the advanced turbo technologies, that the agencies believe will be cost-effective and likely measures toward compliance. This high performance credit would be an additional incentive that would encourage yet further technology deployment to achieve performance significantly beyond the footprint based target on the applicable curve. [EPA-HQ-OAR-2010-0799-9474-A1, p.5]

Honeywell encourages the agencies to adopt an incentive for high-performing ICE vehicles in order to ensure that investment in the most prevalent vehicles in the fleet continues and that these vehicles reach their full emissions improvement potential. [EPA-HQ-OAR-2010-0799-9474-A1, p.6]

---

4 Honeywell is developing start/stop turbo technology to meet the needs of the small and micro car segments. This technology can offer as much as 25 percent improved fuel economy over alternative diesel engines. While micro-turbos are more prevalent in emerging markets for new motor vehicles, with appropriate incentives micro-turbo technology can permeate through the United States fleet. Honeywell therefore endorses the agencies’ proposal to provide an off-cycle credit for start/stop and other off-cycle technologies. [EPA-HQ-OAR-2010-0799-9474-A1, p.5]

Organization: Hyundai America Technical Center

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 23.]

Some OEMs plan to focus on fuel efficiency leadership with gasoline vehicles.

Organization: Johnson Controls, Inc.

Retrofit of vehicles in the car pare with fuel saving Start-Stop technologies can reduce the country's dependence on foreign oil and reduce greenhouse gas emissions. The existing U.S. car parc exceeds 270 million vehicles and the average age of a vehicle on the road is over 10.5 years old. Retrofitting existing vehicles on the road to provide modest improvements in fuel economy could have a greater impact on reducing petroleum usage and greenhouse gas emissions than dramatic increases in fuel economy of new vehicles. Increasing new vehicle fuel economy is absolutely necessary for the longterm. However, improving the fuel economy of existing vehicles in the car parc can accelerate the reduction of petroleum usage and greenhouse gas emissions. Johnson Controls has calculated that over 400 million barrels of oil can be saved over the next 10 years if a systematic process for retrofitting existing vehicles with Start-Stop battery technology to improve fuel efficiency by 5%. This calculation assumes a retrofitting program that would convert 50% of the existing car parc by 2022. A more aggressive approach would yield bigger savings. To accomplish this, retrofit companies will need enablers such as a simplified emissions certification process. Such processes already exist for certification of some existing retrofit technologies. However, type approvals or bundling of solutions to reduce test load and certifications cost would greatly improve the ability of Start-Stop technologies to enter the market and keep costs affordable, thus supporting mass adoption. Clearer provisions are needed for ensuring that OEM warranties and. emissions components warranties are honored With the exception of any components that may be directly affected by the retrofit technology. Johnson Controls suggests that OEMs may be favorable to these provisions if, in return, they receive CAFE and/or CO_2 credits for their vehicles which are retrofitted with fuel economy technologies. [NHTSA-2010-0131-0253-A1, pp. 5-6]

Organization: Manufacturers of Emission Controls Association (MECA)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 180-183.]

Implicit in federal and state greenhouse gas emission analyses is the ability of these advanced powertrain options to meet the applicable criteria pollutant emission standards. All of these advanced light-duty powertrain options combined with the appropriately designed and optimized emission control technologies will be able to meet all current and future federal and state criteria emission requirements. In this manner, advanced emission controls for criteria pollutants enable advanced powertrains to also be viable options for reducing greenhouse gas emissions. In many cases the application and optimization of advanced emission control technologies on advanced powertrains can be achieved with minimal impacts on overall fuel consumption. Auto manufacturers will also take advantage of synergies between advanced emission control technologies and advanced powertrains to assist in their efforts to optimize their performance with respect to both greenhouse gas and criteria pollutant exhaust emissions.

For gasoline vehicles, direct injection technology enables gasoline engines to achieve fuel efficiency and is expected to be a dominant pathway to meeting future light-duty gas emission standards. Again, emission controls like secondary air injection systems and 3-way catalysts ensure that these more fuel-efficient gasoline engines meet tough EPA or California criteria emission regulations. Advanced gasoline emission controls catalysts are available and will continue to evolve and be optimized to ensure that future gasoline direct injection engines will meet the toughest criteria pollutant emission standards with minimal impacts on overall vehicle exhaust system backpressure and fuel consumption.

Under lean combustion conditions similar emission control technology used on diesel vehicles can be used to reduce emissions from lean, gas direct injection powertrains. These include the particulate filters to reduce PM emissions, SCR catalysts and/or lean NO_X adsorber catalysts known to reduce NO_X emissions. Lean NO_X adsorber catalyst performance has a high degree of sensitivity to fuel sulfur levels. The current EPA fuel sulfur limits for gasoline are too high to allow lean NO_X adsorber catalysts to be a viable NO_X control strategy for future fuel-efficient gasoline lean burn engines that employ direct fuel injection technologies. MECA believes that EPA should lower gasoline fuel sulfur limit to a 10 ppm national average and its pending Tier 3 light-duty vehicle emission standards proposal to allow NO_X adsorber catalysts to be used on such vehicles in the future in order to provide additional options for improving the efficiency and reducing greenhouse gas emissions from gasoline vehicles.

The performance of advanced emission control technologies for advanced diesel gasoline and natural gas-fueled powertrains can also be optimized to minimize nitrous oxide and methane greenhouse gas emissions from future light-duty vehicles consistent with the limits EPA set for these important greenhouse gas emissions in their initial round of light-duty vehicle greenhouse gas emission standards.

Emissions controls for gasoline and diesel engines can also be used with low carbon alternative fuels, but it's important that the specifications associated with any low carbon fuel should be compatible with the use of available exhaust emission control technology.

Organization: Nissan North America, Inc.

I. Internal Combustion Engines

Nissan is working to raise the efficiency of internal combustion engines to the ultimate level. Nissan is using three approaches in developing a range of technologies to raise engine efficiency:

More efficient combustion (higher cycle efficiency)

Lower intake and exhaust resistance (less pumping loss)

Easier rotation (lower friction) [EPA-HQ-OAR-2010-0799-9471-A1, pp.5-6]

To this end, Nissan recently announced its new generation XTRONIC CVT (Continuously Variable Transmission) for 2.0 to 3.5-liter engine vehicles. This represents an important step in Nissan's goals to improve the fuel economy and environmental performance of internal-combustion powered vehicles. The new generation XTRONIC CVT model achieves an improvement in fuel economy of up to 10%2 compared to previous CVTs for comparable vehicles. The new transmission features a world-leading ratio coverage of7.03, and friction reduced by up to 40%. Combined with Adaptive Shift Control (which adapts shifting patterns to match each driver's style and the road), the new generation XTRONIC CVT delivers responsive and powerful acceleration. These advancements, moreover, keep the engine from revving too fast at high speeds and minimize noise. The new generation XTRONIC CVT will be introduced in North America in 2012, then globally thereafter. Nissan also launched another next generation CVT last year for engines below 2.0 liters. [EPA-HQ-OAR-2010-0799-9471-A1, p.6]

In addition to drivetrain improvements, Nissan is introducing innovations such as the ECO pedal system to counteract excessive accelerator pressure and to educate drivers on their driving behaviors. Studies have shown that effective driving behavior with ECO pedal drive assist can potentially improve fuel efficiency in most driving conditions. Advanced safety technologies also contribute to reducing GHG emissions. The Predictive Forward Collision Warning System uses millimeter-wave radar to detect the deceleration of a vehicle in front of the driver and even alerts the driver in advance of a sudden drop in speed of the vehicle two cars ahead, thereby helping to avoid collisions, ensuring more consistent driving behavior and lowering overall GHG emissions resulting from even vehicle speed operation. [EPA-HQ-OAR-2010-0799-9471-A1, p.6]

Nissan has established aggressive internal goals for improving the GHG and fuel economy performance of its internal combustion fleet. Nissan's investment in electric vehicles in no way detracts from this commitment. While Nissan will promote electric vehicles and the growth of infrastructure to support it, the vast majority of Nissan's fleet will remain petroleum powered. Nissan's research and development in this area has not waned, and cannot wane given market demands, even as Nissan continues to progress vehicle technology towards zero emissions mobility. [EPA-HQ-OAR-2010-0799-9471-A1, p.6]

---

2 - According to Nissan in-house measurements using EPA's combined mode.

3 - This ratio coverage is specific to 2.0 to 2.5-liter engine vehicles.

Organization: Porsche Cars North America, Inc. (PCNA)

Diesel Technology

Many OEMs, including Porsche, plan to introduce diesel technology as a major component of their compliance strategy. The Agency's modeling assessment of potential improvements in GHG performance was built on assumptions which did not include diesels. It is not appropriate to apply a model based only on gasoline and advanced technologies across a fleet that includes significant diesel penetration. [EPA-HQ-OAR-2010-0799-9264-A1, p. 6]

Organization: Volkswagen Group of America

In the NPRM the agencies have expressed optimism in advancements in gasoline engine technology as an important pathway towards compliance with the proposed regulation. In particular, the agencies have forwarded the position that high BMEP engines coupled with cooled EGR strategies offer significant GHG reduction potential on the order of 3.5% when compared to a 24 bar downsized, turbocharged, direct injected engine. Volkswagen cautions that uncertainty remains with the viability of these high BMEP engines. This uncertainty in part is what compelled Volkswagen to suggest a more moderate stringency during the 2017-2021 phase of the regulation than the 5% average stringency proposed in the NPRM. [EPA-HQ-OAR-2010-0799-9569-A1, p. 17]

While Volkswagen acknowledges that high BMEP (27 – 31 BMEP) engines with cooled EGR are being researched, we caution that additional development is necessary to overcome obstacles to these types of engines. Volkswagen views these obstacles as significant – if not overcome the issues could preclude this type of engine as a viable greenhouse gas reduction technology. Further, Volkswagen questions the benefit potential for this type of engine technology. [EPA-HQ-OAR-2010-0799-9569-A1, p. 17]

Of particular concern is the thermal and mechanical loads imparted on the components of high BMEP concepts, requiring additional cost to improve the durability of this type of engine. In addition, a radically downsized high BMEP engine may offer benefits at peak torque but may be compromised at part load modes of operation, where low-end torque performance may be critical. It is Volkswagen's position that this type of engine may already need a two-stage charger system to address low end torque performance, adding additional cost. Considering all these factors we believe that the torque curve for future engines will be constrained over the rpm range by charging limits, exhaust temperature, peak cylinder pressures and mechanical forces that may limit the practicable increase in BMEP as shown in Figure 2-7. [See Figure 2-7 on p. 18 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 17]

Further, Volkswagen investigation indicates that while 5-6% CO_2 benefit for a high BMEP engine is possible for peak torque, the benefit at the engine speed and load range of typical two cycle testing results in a potential CO_2 benefit of approximately 2.5%. This does not indicate a high degree of additional CO_2 reduction potential for high BMEP engine concepts. [EPA-HQ-OAR-2010-0799-9569-A1, p. 18]

Response:

Regarding comments from the American Petroleum Institute (API), and MECA with respect to gasoline sulfur and spark-ignition lean-burn combustion, lean-burn combustion technology was considered in our analysis but was found to be less cost effective than other available technologies and therefore not used in our vehicle packages as shown in section 1.3 of the RIA. API's comment confirms the reasonableness of that assessment.

Regarding comments from Center for Biological Diversity, Delphi Corporation, Eaton Corporation, EcoMotors International, Inc., Growth Energy, Honeywell International, Inc., Honeywell Transportation Systems, Hyundai America Technical Center, Johnson Controls Inc., and Porsche Cars North America, Inc. (PCNA), EPA believes that the issue of technology neutrality is a much more complex issue than some commenters suggest when they advocate for a "level playing field" and suggest that a level playing field is best achieved by no incentives. Given that internal combustion engines and petroleum-based fuels have dominated the U.S.

light-duty vehicle market for 100 years, with massive sunk investments, there are major barriers for new vehicle technologies and fuels to be able to gain the opportunity to equitably compete on any type of level playing field. For example, consider a hypothetical new vehicle/fuel technology that could be superior to conventional technology from a consumer perspective if, and only if, the vehicles and fuels could be produced at similar economies of scale. But, it is very possible that such a hypothetical new technology would never get the opportunity to compete at equivalent economies of scale, because of the very large investments that are needed, up front, to support the research and development, parts and vehicle production facilities, and fuel infrastructure, none of which are needed for conventional technology as these investments have been made in the past. In this context, temporary regulatory incentives do not so much "pick winners and losers" (as an inefficient or unattractive technology is not going to achieve long-term market success based on temporary incentives) as to give new technologies more of an opportunity to compete with the established technologies.

Regarding comments from Delphi Corporation and Nissan North America, Inc., we note that our analysis of a potential compliance path for the company is consistent with its prediction that most of the improvements can come from improvements to gasoline internal combustion engines. See Tables III-28 and III-29 in the preamble to the final rule.

Regarding comments from Volkswagen Group of America, while we agree that higher BMEP engine concepts exceeding 27-bar BMEP, such as the recently announced Ricardo HyBoost project, are currently undergoing research, we limited BMEP levels to 24-bar and 27-bar for the vehicle packages used in the OMEGA modeling for the final rule since these engines are at a fairly advanced stage of research at those BMEP levels. Ricardo engineering took into consideration peak cylinder pressure limits and thermal limits such as a hard limit of 950 ºC turbine inlet temperature when working with EPA to develop the 24-27 bar BMEP engine maps used in the cycle simulation work. The high BMEP engine maps developed by Ricardo were comparable to other 24-27 bar BMEP engine maps cited from published literature (see citations 28-31 referenced in TSD 3.2.1.2.12), with comparable broad areas of high BSFC and relatively flat torque available from fairly low RPM, with >80% of peak BMEP available from 1500 – 4500 rpm. The VW comments regarding low-end torque are not consistent with the broad range of rpm, including low rpm, at which high BMEP was available for the engines cited from public literature within TSD 3.2.1.2.12. The CO_2 effectiveness used by EPA and NHTSA at 24 and 27-bar BMEP was also considerably higher than the 6% peak or 2.5% cycle efficiency cited by VW. The CO_2 cycle (not peak) effectiveness used by the Agencies ranged from approximately 16% to 24% depending on the BMEP level and combination of technologies (see TSD 3.3.1.8). The levels of effectiveness used by the agencies were also comparable to the 15 to 30% CO_2 effectiveness reported in published literature from AVL, Mahle, Ricardo and Lotus cited within the TSD. Mechanical and thermal robustness at 24-27 bar BMEP were key considerations in the cited literature from Mahle and Ricardo (citations 29 and 31 referenced in TSD 3.2.1.2.12). EPA agrees that 2-stage turbocharging may be necessary at high BMEP levels and took the cost of two-stage turbocharging into account in packages using 27-bar BMEP engines. EPA also took into account additional costs when elevating engines from 18-bar turbocharged GDI to 24-bar or 27-bar BMEP. The BMEP (or torque) curves and BSFC in the Ricardo simulation modeling and in the cited literature were representative of engines under development that are already constrained with respect to charge temperature limits, exhaust temperature limits, peak cylinder pressure and mechanical forces.

Volkswagen Group of America

Organization: Aluminum Association's Aluminum Transportation Group

Downweighting, without downsizing, has become an increasingly more important element in most comprehensive OEM vehicle efficiency improvement strategies. As automakers transition towards greater use of low weight materials, the focus is increasingly toward system cost. Aluminum is widely recognized as a cost-effective choice for reduced weight automotive components and structures. As automakers turn to greater aluminum use, secondary weight reduction is emerging as a major cost savings opportunity. Vehicle weight reduction with aluminum allows a reduction in the size, weight and cost of powertrain and chassis components (secondary weight reduction) without sacrificing performance or safety. Cost savings from secondary weight reduction can offset a majority of the cost premium associated with conversion to aluminum. This allows aluminum to compete successfully with other materials because of the advantages it brings in primary and secondary weight savings, fuel savings, structural performance and design flexibility. [NHTSA-2010-0131-0226-A1, pp. 1-2]

Since the aluminum industry provided comments on the agencies' Notice of Intent (NOI) regarding this rulemaking in October 2010, additional studies have been completed that reinforce the conclusion that downweighting with aluminum can be done both safely and economically. Simply stated, aluminum offers a safe and cost-effective way to reduce fuel consumption and reduce greenhouse gas emissions. [NHTSA-2010-0131-0226-A1, p. 2]

In this regard, we offer four new pieces of evidence: a new survey of North American automakers conducted by Ducker Worldwide, a separate and independent survey of automakers by DuPont, statements made by a high level Honda executive at the recent International Automotive Body Congress, and findings of a new report on life cycle cost analysis commissioned by the European Union, titled "Support for the Revision of Regulation (EC) No 443/2009 on CO2 Emissions from Cars." [NHTSA-2010-0131-0226-A1, p. 2]

Ducker Worldwide Survey of North American Automakers

A 2011 Ducker Worldwide Survey found that per-vehicle aluminum content will increase by 70 percent by 2025. The survey found that as lighter vehicles achieve better fuel economy with fewer emissions, aluminum is already the leading material in the engine, transmission, suspension and wheel markets, and is fast-gaining share in hoods, trunks and doors. The findings estimate that automakers will increase their use of aluminum from 327 pounds in 2009 to 550 pounds in 2025. Continued growth in overall use of aluminum reached an all-time high of 343 pounds per vehicle in 2012, up five percent from 2009. In fact, aluminum usage has increased every year for nearly 40 years (approximately seven pounds per year, per light vehicle). Market forces already in place are projected to push aluminum content to 400 pounds per vehicle in 2015/2016. The survey also confirms aluminum will play an increasingly important role in design of future safe and fuel efficient vehicles. Based on the survey and other research, the ATG believes that cars and trucks will get lighter but will not have to be made smaller or less safe. A copy of the complete Ducker Survey is attached to these comments as Attachment A [see Docket number NHTSA-2010-0131-0226-A4]. [NHTSA-2010-0131-0226-A1, p. 2]

DuPont Survey of Automakers and Suppliers

In a separate, independent survey of automakers released last year by DuPont, ‘aluminum’ was listed above all other materials by automotive engineers and executives as the “most helpful” material in meeting the new fuel economy standards (see page 7 of the DuPont survey, Attachment B [see Docket number NHTSA-2010-0131-0226-A2]). Taken together, these surveys make clear a major automotive materials shift is underway. OEM vehicle manufacturers recognize that downweighting will complement whatever other technology, design and powertrain changes are coming. Downweighting with aluminum will improve vehicle efficiency, while enabling a cost-savings from downsized powertrains, without sacrificing either safety or performance. [NHTSA-2010-0131-0226-A1, p. 2]

International Automotive Body Congress

At the recent International Automotive Body Congress held in Troy, Michigan, the senior vice president of Honda R&D Americas stated that the automaker is planning to start phasing out some steel in vehicle bodies. In a quote from a Ward’s Auto article, Frank Paluch of Honda said: “Based on our current understanding, we believe we’re approaching the practical limits of the application of high-strength steels.” Since Honda is an industry leader in the use of advanced high-strength steels in high-volume mainstream vehicles, that statement is significant. According to the same article, Mr. Paluch is among a growing number of engineers who believe it will be “increasingly difficult or impossible to meet future fuel-efficiency and carbon-dioxide emissions requirements with vehicle bodies made from steel.” [NHTSA-2010-0131-0226-A1, p. 2]

The ATG agrees with Mr. Paluch that we are fast-entering a transition stage to a more holistic vehicle design approach. That approach is premised on the greater use of lighter, stronger and more crash absorbent components utilizing low weight materials, including aluminum. These lower weight components will replace higher weight iron and steel components. And, Mr.

Paluch's statement is reflected in OEM advanced program plans and product orders from our automotive customers. [NHTSA-2010-0131-0226-A1, p. 3]

Organization: American Chemistry Council

(2) In addition to lightweighting, plastics and related materials will also contribute to fuel efficiency and emission reductions through more aerodynamic shaping and parts integration. In addition to lightweighting capabilities, thermoplastics and composites can be molded into shapes that provide superior aerodynamics. Aerodynamic drag results from the vehicle having to move air out of its way in front, and also from the turbulence created in in back as air refills the space voided by the vehicle. About 60 percent of engine power at highway cruising speed is used to overcome air resistance. As a result, improved aerodynamics translates into substantial improvements in fuel efficiency and emissions, even with vehicle size held constant. Drag coefficients (a measurement of drag forces independent of drag area or vehicle size) have improved significantly over the years, and an important element of that has been the design freedom conferred by thermoplastics and related materials. Injection-molded plastics allow for aerodynamic styling and parts integration not possible with metal or glass. Drag coefficients for present-day vehicles range between 0.30 and 0.35, but an additional 25 percent reduction in drag has been predicted in coming years.7Aerodynamic performance is generally captured in coast down testing that informs the calibration of the dynamometer. [EPA-HQ-OAR-2010-0799-9517-A2, p. 2]

(3) Lightweight plastic and plastic composite components are gaining commercial acceptance and providing lightweighting that increases fuel efficiency and reduces emissions. Plastics, plastic composites, and other materials will allow Original Equipment Manufacturers (OEMs) to move toward compliance with the Corporate Average Fuel Economy/Greenhouse Gas (CAFE/GHG) targets at a reasonable cost and independent of what power trains are chosen. Traditional vehicles will consume less gasoline or diesel; hybrids will be able to operate further on battery power, and pure electric vehicles (EVs) will enjoy a greater range, a factor critical to consumer acceptance and to their penetration of the marketplace. [EPA-HQ-OAR-2010-0799-9517-A2, pp. 2-3]

Manufacturers have already moved to the use of plastics and composites extensively in the vehicle exoskeleton and in internal components. Recent data indicate that the average vehicle already uses about 150 kg of plastics and plastics composites; that the automotive industry already uses engineered polymer composites and plastics in a wide range of applications; and that plastics are currently in use in about 50 percent of all interior automotive components, including safety subsystems and door and seat assemblies.8 [EPA-HQ-OAR-2010-0799-9517-A2, p. 3]

The Joint Technical Support Document (TSD) notes that "many manufacturers have already announced proposed future products plans reducing the weight of a vehicle body through the use of…composite body panels…"9Composites are in use by Volvo and Renault in tailgates; BMW, Peugeot and Maybach in trunk lids; and Bentley for the spare wheel/tire well.10Plastics and composites are also increasingly becoming the material of choice in applications where high performance is necessary. For example, special heat conductive plastics have been developed by

DSM for engine bay components, in which metal particles added to the plastic transfer the heat and, if needed, can also serve as electromagnetic interference (EMI) shield. Engineering plastics like DSM's polyamide grade Stanyl® keep their high level of stiffness at temperatures up to 290°C. A joint study of BMW and Mitsubishi Turbochargers demonstrated the feasibility of using plastic for the "cold" side of a turbocharger.11 [EPA-HQ-OAR-2010-0799-9517-A2, p. 3] Similarly, polycarbonate is now used extensively in lighting and selectively in rooflite glazing, and is expected to make further inroads into backlites and fixed rear windows. Polycarbonate glazing is approximately 40 percent lighter than traditional glass, and is capable of removing 25 pounds of weight reduction for a typical vehicle. Also, because it is injection molded, it can be readily combined with other materials and features, yielding parts consolidation and reducing assembly costs. These multiple advantages point to a substantial increase in the use of polycarbonate in coming years. [EPA-HQ-OAR-2010-0799-9517-A2, p. 3]

The commercialization of plastic and related components into the structure of the vehicle will also proceed during the model years covered by this rulemaking. The timeline for commercialization of structural plastics was raised at the February 25, 2011 NHTSA workshop on vehicle mass, size and safety, at which some commenters cited the relative merits and commercial promise of aluminum and high strength steel. We acknowledge that the commercial promise of structural plastics, composites and plastic/metal hybrids, is a longer-term proposition. However, it should be noted that work is well underway to understand and pursue more aggressive use of these materials. NHTSA's 2007 Report, A Safety Roadmap for Future Plastics and Composites Intensive Vehicles, extensively evaluated the potential safety benefits of Plastics and Composites Intensive Vehicles (PCIVs) to enable deployment by 2020. That document established research priorities and called for the development of test methods and timetables that allow for an orderly transition to a fleet making greater use of plastics, composites and related materials, including in the vehicle structure. [EPA-HQ-OAR-2010-0799-9517-A2, p. 3]
(4) Increasing supply and production capacity of high-tech composites and hybrid materials should be factored into agency cost estimates on an ongoing basis.

Advanced composites such as carbon fiber reinforced thermoplastics will assume a greater role in both body and structural components in the MY 2017-2025 time frame. Surveyed automotive engineers say it best: there is increasing commercial activity using existing composite technologies as well as new developments taking composites to the next level, making advanced composites the top material category poised for growth.14 Recent data suggest that the supply of plastic composite materials will continue to accelerate with an attendant decrease in costs as production processes are refined and economies of scale are realized. There is also the potential for a game-changing breakthrough that will advance commercialization, a phenomenon we have witnessed with other advanced materials.15 [EPA-HQ-OAR-2010-0799-9517-A2, p. 4]

Numerous producers have recently announced additional capacity or production for high-tech automotive plastics, composites, or constituents of high-tech composites such as carbon fiber. In March of 2011, Lanxess announced breaking ground on its first U.S.-based compounding facility for high-tech automotive plastics in Gastonia, North Carolina, with production scheduled to begin in mid-2012.16The Lanxess facility was announced to produce polyamide and polybutylene terephthalate. BMW,17 Daimler and Lamborghini18 are all involved in joint ventures with suppliers to develop and produce carbon fiber, while Oak Ridge in currently in the process of building a $35 million dollar pilot plant that will produce up to 25 tons of carbon fiber a year."19 In addition, a new joint venture between Dow and ASKA was formalized on December 20, 2011 to manufacture and globally commercialize carbon fiber.20 [EPA-HQ-OAR-2010-0799-9517-A2, p. 4]

Cost reductions are readily observable in the trade press.21 It has been reported that "carbon fiber costs have dropped ten-fold in the last decade," observing that as new production technologies become available, this "will bring the cost down further."22Benteler SGL in Germany has reported reducing cycle times from 20 to 5 minutes to enable large series production, and Styron is reported to have developed plastic resins that allow a shorter cycle time of 2 ½ minutes.23Assuming 50 weeks of production during the year and 40 hours of production during one shift in a week, this cycle time translates into 48,000 units produced a year during one shift at a plant. While such production capability will be sufficient for a large majority of the vehicle models produced (especially if two shifts are run at a given plant), multiple shifts and increased plant capacity will allow for larger production numbers. Lamborghini's Sesto Elemento concept car uses forged composites, which are predicted to be less costly than traditional carbon fiber by 'orders of magnitude.'24 Continuing cost reductions of plastic and plastic composites will quicken the pace of adoption in the commercial fleet. [EPA-HQ-OAR-2010-0799-9517-A2, p. 5]

In addition to composites, plastic/metal hybrid components are expected to become commercially significant in the structure of vehicles. A hybrid component has constituent parts from two or more materials; an example is a hollow metal pillar filled with plastic. Hybrid parts can exhibit the best aspects of both materials, for example, combining the load capacity of steel with the light weight and impact resistance of plastic. As a result, hybrid components hold promise to lower the weight of structural parts without sacrificing crashworthiness.25 [EPA-HQ-OAR-2010-0799-9517-A2, p. 5]

Organization: SABIC Innovative Plastics US LLC

Substantial investment is being put into materials research and development. Materials such as carbon fiber, magnesium and other composites have the potential to transform vehicle design, promote safety and offer considerable emissions and fuel consumption reductions. As a global innovator in the plastics industry, SABIC-IP will continue to seek out and promote such advances. SABIC-IP will also continue to offer robust technical evaluations to assist the government and the industry advance public policy through the application of cost effective product solutions. [EPA-HQ-OAR-2010-0799-9467-A1, p.15]

Organization: Society of the Plastics Industry, Inc. (SPI)

In addition to energy management systems, the current widespread use of plastics and composites in a multitude of applications helps auto designers reduce vehicle weight and increase efficiency: [EPA-HQ-OAR-2010-0799-9492-A1, p.2]

"For auto manufacturers, plastics are seen as a great way to increase vehicle efficiency. This is because… replacing steel with plastic can cut vehicles' weight. Plastic fuel tank technologies have become the tank of choice replacing steel tanks first in Europe and Asia and now North America. This is for weight reduction as well as design flexibility, corrosion resistance and safety. Plastic fuel lines have also been advancing because they are lighter in weight, lower in cost and available in various colors for tracking under the hood. Further, combinations of plastics and steel are being developed for weight reduction but also for high load-bearing capacity and high-energy absorption for front ends and doors. Similarly, automotive glazing, including both side windows and windshields, promises great potential for plastics." [[EPA-HQ-OAR-2010-0799-9492-A1, pp.2-3]

The growing potential for plastics, composites and hybrid materials pairing plastics with metal are evident at our triennial trade show, NPE. President Obama's 2009 announcement regarding fuel efficiency came one month before NPE 2009, at which innovative companies in the plastics industry unveiled new fuel-saving technologies. Automotive applications highlighted in the sustainability theme included: component weight reducing technologies (e.g., polycarbonate-based windshields and other glazing), fast-growing application of thermoplastic elastomers, new raw material formulations, new plastic/steel hybrid structures, separator films for batteries, and applications for fuel tanks such as a high-density polyethylene formulation that is more resistant to bio-diesel fuel. Nanocomposites – in which nanoscale fillers are added to standard plastics – can add strength that results in the use of less material, and therefore helps reduce vehicle weight while maintaining performance, in applications such as fuel tanks and fuel lines. SPI recognized then as we do now that plastics and associated materials contribute to fuel efficiency, innovative design, production economy, and sustainability that will help manufacturers meet their regulatory obligations while providing exciting options to their customers. [EPA-HQ-OAR-2010-0799-9492-A1, p.3]

In coming years, we expect to see even greater adoption of plastics and composites in glazing, body panels and interior parts. PC glazing is beginning to make significant inroads into the marketplace in this country and already enjoys extensive use in Europe. There, “moulded PC is used in nearly all auto glazing functions” and gaining in areas such as the front and rear quarter windows, and fixed window sections on the sides and rear doors. Bioplastics are forecasted to expand in the automotive sector, contributing to a global demand that is expected to at least triple in the next few years. Longer term, multi-material solutions (e.g., hybrid structures) and advanced composites (e.g., carbon-fiber reinforced thermoplastic) have the potential to extend lightweighting into the body-in-white stage of vehicle production, achieving mass reduction while maintaining or enhancing the structural integrity of vehicles. From electric and hybrid cars with improved electric range, to driverless pods at airports, the automotive sector will help drive a revolution in the use of plastics. SPI is proud that NPE has been a venue of choice for manufacturers to unveil their new technologies, and we look forward to the advances to come. [EPA-HQ-OAR-2010-0799-9492-A1, p.3]

Advanced Composites are Becoming a Technologically Feasible and Economically Practicable Part of Reducing Vehicle Mass [EPA-HQ-OAR-2010-0799-9492-A1, p.5]

SPI notes that the agencies’ mid-term evaluation will allow for consideration of new and innovative technologies that could contribute to vehicle mass reduction between now and model years 2022 – 2025. We appreciate that this will enable advances with PCIVs to be considered for additional credits or incentives if appropriate. [EPA-HQ-OAR-2010-0799-9492-A1, p.5]

The Increasing Use of Advanced Composites [EPA-HQ-OAR-2010-0799-9492-A1, p.5]

Advanced composites such as carbon fiber reinforced thermoplastics (CFRP) will assume a greater role in both body and structural components in the MY 2017-2025 time frame. This is clear from the increasing investment and commercial activity surrounding such materials. These include joint ventures with carbon fiber producers announced by BMW, Daimler and Lamborghini, and both a fully electric city car and a hybrid sports car exhibited last summer which make use of CFRP to offset the weight of battery systems. Other companies are working with advanced composites, and the development of a practical composite engine block is close if not achieved, shedding pounds off the traditional counterpart. Natural fiber composites will have the additional benefits of being less sharp compared to glass fiber-reinforced composites in the event of a crash, and taking up to 60% less energy to process. [EPA-HQ-OAR-2010-0799-9492-A1, p.5]

The commercial viability of CFRP and other advanced composites will depend upon increasing supply and economies of scale. Here too, progress is visible. Oak Ridge is “in the process of building a $35 million dollar pilot plant that will produce up to 25 tons of carbon fiber a year.” A new joint venture between Dow and ASKA announced in late 2011 aims to commercialize carbon fiber globally. [EPA-HQ-OAR-2010-0799-9492-A1, p.5]

Economic Benefits of Advanced Composites [EPA-HQ-OAR-2010-0799-9492-A1, p.6]

The aforementioned throttle valve housing that is 30 percent lighter than its metal counterpart is also 50 percent lower in cost. This is not the case for every component, and there are instances of higher material costs for plastics as compared to their metal and glass counterparts. However, the Technical Document notes that both EPA and NHTSA recognize that OEMs can realize reduced costs as they gain experience and scale with new technologies, through the "the manufacturing learning curve" phenomenon. And like plastics, composites offer opportunities for parts consolidation, reducing assembly costs. [EPA-HQ-OAR-2010-0799-9492-A1, p.6]

Polycarbonate Glazing is Market Ready [EPA-HQ-OAR-2010-0799-9492-A1, p.6]

PC automotive glazing for applications such as rooflites, backlites and side windows has been available for years and holds great promise. Commercial acceptance in Europe may encourage an increasing role in this country's automotive market. Polycarbonate provides high optical clarity and shatter-resistance, and can be formulated to resist deterioration and hold up to weathering conditions. Various abrasion-resistance systems allow PC glazing to be used in rooflites, backlites, and liftgates, meeting applicable standards. PC in auto glazing applications has demonstrated weight reductions of 40-50 percent as compared to traditional glass. [EPA-HQ-OAR-2010-0799-9492-A1, p.6]

Beyond weight-reduction, injection molding of PC glazing permits design flexibility that can contribute to more aerodynamic designs and increased fuel efficiency. Current drag coefficients, ranging between 0.30 and 0.35 for a typical vehicle, are likely to improve by 25% in coming years. Integration of parts can contribute to aerodynamics and simplify assembly without compromising structural integrity. [EPA-HQ-OAR-2010-0799-9492-A1, p.6]

Organization: United Automobile Workers (UAW)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 23.]

This includes an exciting advance such as 8-, 9-speed automatic transmission, both dual clutch and conventional, and engines that feature advanced valve timing and gasoline direct injection, downsized and turbocharged engines, and vehicles that are considerably lighter than the previous generations but retain the same size. Technology such as start/stop systems and electric-powered steering are also making a contribution to vehicle efficiency.

Organization: United Steel Workers (USW)

USW believes advanced high-strength steel (AHSS) vehicle technologies will assist carmakers in achieving significant reductions in both vehicle emissions and fuel consumption. [EPA-HQ-OAR-2010-0799-9580-A2, p.2]

New steels and automotive manufacturing techniques continue to be developed by the domestic steel industry and will enable significant increases in mass reduction, crashworthiness and fuel economy, while enabling reductions in total greenhouse gas emissions, during the period specified in the NPRM. [EPA-HQ-OAR-2010-0799-9580-A2, p.3]

Organization: Volkswagen Group of America

Volkswagen provided technical descriptions and estimates to the agencies regarding vehicle lightweight technology potential and cost. Volkswagen remains amongst the industry leaders in applying high technology, lightweight designs within both premium and economy vehicles. [EPA-HQ-OAR-2010-0799-9569-A1, p. 15]

To start, Volkswagen agrees with the agencies that there is a variation in the overall mass reduction potential based on the type and market segment of vehicles. Smaller cars and economy models have less potential for mass reduction than larger or more premium vehicles. Volkswagen projects full vehicle weight reductions during the time period of this regulation on average in the order of 7-10%. The NPRM predicts for large cars and some trucks upwards of 20% mass reduction potential. Volkswagen feels that this may exceed cost effective limits. With regards to electrified vehicles, Volkswagen does agree with statements in Section 3.4.5.5 of the TSD that electrical component may increase baseline vehicle mass by upwards of approximately 4-5% depending on battery pack capacity and/or other electric drive components. [EPA-HQ-OAR-2010-0799-9569-A1, p. 15]

The NPRM includes a revised cost model as described in Section 3.4.5.5 of the TSD which now properly reflects the fact that increasing levels of mass reduction results in exponentially increasing costs. Figure 2-5 illustrates the cost function for both a 3000lb and 4000lb car. Volkswagen generally agrees with the cost being represented by an exponential function. However the function remains too conservative in its overall estimate of total price increase, i.e. the curve is too 'shallow'. Volkswagen maintains that above 10%, costs accelerate at a faster rate making reductions beyond this level less economically practical. [See Figure 2-5 on p. 16 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 15]

Further, we contend that the price increase for smaller cars may actually be more severe than for larger cars or trucks. Smaller cars must meet the same safety requirements and often have fewer, more simplistic systems from which to seek weight reductions. The model included in the NPRM reflects the opposite, that larger cars may be more challenged to reduce mass. The NPRM indicates that a large truck or pick-up would have the most costly pathway for weight reduction, while a low-weight passenger car would have the least costly pathway. This in turn would indicate that a low weight passenger car could more easily further reduce weight. Volkswagen disagrees. [EPA-HQ-OAR-2010-0799-9569-A1, p. 15]

An exponential cost function is appropriate when estimating costs related to mass reduction. In many cases moving from a baseline material to a lighter alternative not only require the use of more expensive material, but can also trigger significant capital investment needed to upgrade or completely replace manufacturing infrastructure. There are periods in which a vehicle is completely redesigned and engineers will have the opportunity for a 'clean sheet' evaluation of component consolidation and material substitution. However even then, the ability to update tooling and factory systems may be limited given their longer useful life. [EPA-HQ-OAR-2010-0799-9569-A1, p. 16]

Volkswagen is also continuing to move towards a greater degree of platform sharing which will use common architecture to underpin a broad range of vehicles. An example is the recently introduced MQB (Modular Transverse) platform which will be used for Volkswagens Polo, Beetle, Golf, Scirocco, Jetta, Tiguan, Touran, Sharan, Passat and CC. In addition several other models from various Volkswagen brands will also use the platform. A concept such as MQB offers significant savings and standardization of manufacturing processes. However, designers must now account for multidimensional requirements that apply to the range of vehicles using the platform. A weight reduction technology which may be acceptable in terms of price or performance for one model may disrupt the economics or utility of another. [See Figure 2-6 on p. 16 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 16]

The materials industry continues to offer an increasing assortment of technologies from ultra-high strength steels, to alternative materials such as aluminum, magnesium, plastics, and carbon fiber. Volkswagen remains at the forefront in evaluating these materials and in some cases being first to market with exotic designs on our premium and sport vehicles. Volkswagen has had many successes in applying advanced technologies to our economy models as prices and complexity decrease, but this process is lengthy and risky. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 16-17]

Volkswagen remains concerned that the price estimates used by the agencies remain low and do not fully account for the impact that incorporating weight savings may have on retail price. Further, Volkswagen is concerned that the more stringent requirements for passenger cars will necessitate more weight reduction technologies to these vehicles and will contribute to the imbalance between prices for these cars compared to trucks. Trucks on the other hand with their lower stringency and exclusive credits may not be required to incorporate the same degree of weight reduction. [EPA-HQ-OAR-2010-0799-9569-A1, p. 17]

Response:

Regarding comments from the Aluminum Association's Aluminum Transportation Group Innovative Plastics US LLC and Society of the Plastics Industry, Inc. (SPI), SABIC Innovative Plastics US LLC and Society of the Plastics Industry, Inc. (SPI), United Steep Workers, and American Chemistry Council (ACC), we agree that engineered lightweight materials are a potential path to lower CO_2 emissions for all classes of vehicles. Please refer to the Joint TSD Section 3.3.5.5 for more detail on mass reduction.

Regarding comments from the United Automobile Workers (UAW), we appreciate your comments in support of the potential for advanced transmissions to reduce the CO_2 emissions for all classes of vehicles.

Regarding comments from Volkswagen Group of America on mass reduction costs, the agencies' basis for estimated costs of mass reduction actually appears to be conservative. As shown in joint TSD section 3, the detailed studies sponsored by the agencies suggest that 20% mass reduction is likely feasible for heavier vehicles for the rulemaking period using lightweighting materials and manufacturing technologies that have already been adopted in high volume vehicles. See joint TSD pp. 3-238 to 251. The accompanying detailed cost analysis in the joint TSD indicates that the cost of reducing mass by 20% can potentially be economical. See joint TSD section 3.3.5.5. The assumptions for mass reduction costs will be examined during the mid-term evaluation.

The total amount of mass reduction used in the agencies' analysis for this rulemaking was chosen based on the agencies' documented assumptions about how much mass reduction is technologically feasible without compromising safety. Overall, technical feasibility paths for manufacturers identified in this rulemaking include a minimal mass reduction, <5%, for the majority of passenger vehicles due to safety constraints discussed in Sec II.G of the preamble. Some trucks and CUV's have up to 15% to 20% mass reduction in the projected compliance analysis which would tend to improve highway safety. As explained in preamble section II.G, and as noted by a number of commenters (e.g. DRI, CBD), removing weight from heavier vehicles should have a positive effect on vehicle safety.

As also described in detail in preamble section II.G, the agencies have carefully documented potential compliance paths which are safety neutral, and thus do not depend on significant mass reduction from vehicles weighing less than 3,106 pounds. While EPA has shown a possible compliance pathway using one set of assumptions about the use of mass reduction, there are many alternative pathways for compliance. As discussed in EPA RIA section 3.5, this rulemaking is projected to decrease vehicle mass by approximately 4% (on average) relative to the reference case. Rather than using mass reduction technology, manufacturers could choose to use, for example, additional turbo-charging and downsizing, hybridization, or any other available technology. No manufacturer is explicitly required by this regulation to reduce the mass of their vehicles. Some manufacturers may choose not to reduce mass at all. Others may choose to reduce mass by more than the levels projected here. Using the methodology discussed in Section II.G, EPA has shown a compliance pathway that is projected to produce no net additional fatalities.

Is the Needed Fueling Infrastructure Available to Enable PHEVs, BEVs and Fuel Cell Vehicles to Penetrate the Market at the Levels Predicted? [EPA-HQ-OAR-2010-0799-9487-A1, p.22]

President Obama has set a goal to put one million plug-in electric vehicles on U.S. roads by 2015. To meet this goal, and to achieve even more ambitious targets for post-2015 electrification, the U.S. will need to invest heavily in electric charging infrastructure. The Boston Consulting Group recently estimated that $8 billion in electric vehicle charging infrastructure would be needed by 2020 to support the growing market for plug-in hybrid electric vehicles and battery electric vehicles. In addition to cost, a variety of other electric mobility infrastructure challenges remain, including development of uniform state, federal and local standards and protocols. Last year, the Alliance and AIAM issued a paper identifying these specific barriers and proposing a series of recommendations for addressing these challenges. Hydrogen infrastructure is also needed to support the commercialization of fuel cell vehicles. [EPA-HQ-OAR-2010-0799-9487-A1, p.22]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

AFPM believes that these projections of electrification are too high. This problem can be corrected by employing smaller values for phase-in caps. In the Draft Joint Technical Support Document EPA states that: “Ultimately, phase-in caps are determined by the agencies using engineering judgment.”12 This engineering judgment is arbitrary and capricious. It departs from reality and is calculated to support the proposed standards. It ignores the finding of the National Research Council, with no explanation as to why its assumptions differ. AFPM recommends lower values for this important parameter for the electrification technologies. The values used by EPA and NHTSA in this proposal are unreasonably high. [EPA-HQ-OAR-2010-0799-9485-A1, p.7]

Phase-in caps are used in EPA’s Optimization Model for reducing Emissions of Greenhouse gases from Automobiles (OMEGA) and in NHTSA’s Compliance and Effects Modeling System. Phase-in caps are a user input for individual technologies. For example, [EPA-HQ-OAR-2010-0799-9485-A1, p.7] [There are two figures associated with this statement, please refer to EPA-HQ-OAR-2010-0799-9485-A1, p.7]

These phase-in caps are optimistic and unrealistic. They contribute to the projected large increase in electrification. [EPA-HQ-OAR-2010-0799-9485-A1, p.7]

The phase-in caps assumptions may look reasonable and/or small to some, but 20% of millions of new cars and light-duty trucks represents millions of new electric cars and trucks. Given consumers’ historical rejection of these vehicles, AFPM is doubtful that this penetration will occur in this timeframe. [EPA-HQ-OAR-2010-0799-9485-A1, p.8]

This highlights the necessity of a good consumer choice model. The decision by EPA and NHTSA to use poor phase-in caps based on inadequate engineering judgment leads to flawed analyses. EPA and NHTSA should use a peer-reviewed consumer choice model and re-propose standards for new LDVs after MY 2016. [EPA-HQ-OAR-2010-0799-9485-A1, p.8]

AFPM believes that the use of a realistic consumer choice model and appropriate assumptions that model future behavior will lead NHTSA to promulgate lower CAFE standards based on a lower expectation of hybrids, plug-in hybrids and all electric vehicles. EPA and NHTSA should appreciate and understand the significance and implications of these projections, especially consumer acceptance barriers associated with vehicle cost, limited driving range and recharging. There is a large difference between the capability of automakers to produce vehicles with these technologies, the ability of automakers to sell these vehicles, and the creation and dissemination of the necessary recharging infrastructure. [EPA-HQ-OAR-2010-0799-9485-A1, p.8]

EISA requires NHTSA to increase CAFE standards for passenger and non-passenger automobiles "to achieve a combined fuel economy average for model year 2020 of at least 35 miles per gallon" and to achieve the maximum feasible average standard for the fleet for model years 2021-2030 (see section 102). As the discussion above on electrification shows, NHTSA's proposal is not feasible and therefore is in conflict with its statutory authorization. The use of a peer-reviewed consumer choice model and a new proposal would assist NHTSA's development of a proposal that is feasible and coincides with Congress' mandate in this area. [EPA-HQ-OAR-2010-0799-9485-A1, p.8]

---

12 - EPA, "Draft Joint Technical Support Document: Proposed Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards," EPA-420-D-11-901, November 2011, page 3-127.

Organization: Delphi Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 109-110.]

Second, vehicle electrification is shaping the future of automotive power and propulsion and will continue to do so for many years to come as more drivers look to hybrid electric vehicles and start/stop technology as a way to improve their efficiency and green vehicle choices. This market is expected to grow steadily for the foreseeable future and will be affected by global government regulations.

Organization: Environmental Consultants of Michigan

Hybrids Have Known Deficiencies Under Real World Conditions

EPA conducted a study in 2006 confirming that hybrids operate substantially differently on the road than they do during official testing. Based on a 2006 review of several independent studies EPA concluded:

o Hybrid vehicles showed a slightly greater impact of aggressive driving on fuel economy than conventional gasoline vehicles (33 percent lower fuel economy versus 29 percent lower fuel economy for a conventional vehicle).

o Hybrid vehicles tended to show greater sensitivity to air conditioning operation than conventional vehicles. The effect of air conditioning operation reduced hybrid fuel economy by 31 percent, compared to the 20 percent impact on conventional vehicle fuel economy.

o Overall, conventional gasoline vehicles averaged a cold temperature effect of about 11 percent lower fuel economy, while the impact on hybrid vehicles averaged about 32 percent lower fuel economy.

o The Cold Federal Test Procedure fuel economy with the heater/defroster on was significantly lower than that with the heater/defroster off, ranging from 5.8 percent lower fuel economy (~1 mile per gallon lower on a non-hybrid vehicle) to 18.4 percent lower fuel economy (~8 miles per gallon lower on a hybrid vehicle). Note the fuel economy tests used by EPA for the original fuel economy labels were conducted with the air conditioning, heater and defrosters all switched to the off position. [EPA-HQ-OAR-2010-0799-11760-A2, p.8]

Putting this in perspective, the 2012 gasoline powered Toyota Highlander loses about 1.3 miles per gallon (mpg) when the air conditioning is on and loses about 0.2 mpg in cold weather with the heater on based on EPA test data. The 2012 Highlander Hybrid on the other hand loses 15.2 mpg with the air conditioning is turned on and 10.1 mpg in cold weather with the heater on. Data on the Prius is shown below: [EPA-HQ-OAR-2010-0799-11760-A2, p.8]

The table below shows the recent US EPA data comparing how typical driving conditions may adversely impact a vehicle's fuel economy compared to the optimal driving conditions used in the standard EPA laboratory test cycle. Note that the hybrid electric vehicles (HEV) did substantially worse with the air conditioning turned on, during cold temperatures or utilizing typical urban acceleration rates and high speed driving. [EPA-HQ-OAR-2010-0799-11760-A2, p.9]

These differences in fuel economy equate to higher greenhouse gas emissions on the road. The excess emissions documented in the table below demonstrate that hybrids emit more greenhouse gases on the road under real world conditions than are counted in their compliance testing (a negative number means lower emissions; a positive number means higher emissions). [EPA-HQ-OAR-2010-0799-11760-A2, p.9]

Hybrids May Contain Defeat Devices

The fact that air conditioning operation causes or contributed to lower fuel economy and higher greenhouse gases one could argue that this is a “defeat device” which is expressly prohibited by statute. [EPA-HQ-OAR-2010-0799-11760-A2, p.10]

o According to the Environmental Protection Agency, a defeat device means any device, system or element of design which senses operation outside normal emission test conditions and reduces emission control effectiveness. A defeat device includes any auxiliary emission control device (AECD) that reduces the effectiveness of the emission control system under conditions which may reasonably be expected to be encountered in normal operation and use unless such conditions are included in the test procedure. A defeat device does not include such items that either operate only during engine starting or are necessary to protect the engine (or equipment) against damage or accident during its operation. See 40 CFR 89.107-96. An AECD is generally deemed to be a defeat device if it is determined by EPA to reduce the effectiveness of an emission control system in response to any accessory operating condition not encountered during the Federal emission test. (EPA Advisory Circular 24). In simple terms, any time a vehicle operates differently on the road than it operates during the official EPA test there is a potential that this is due to what EPA defines as a defeat device.

o A classical example is the EPA decision regarding a change in engine operating conditions when the air conditioning was turned on (A/C and the heater are turned off during official EPA testing.) In 1995 EPA forced General Motors to recall half a million Cadillac’s, GM was to pay an $11 million fine, more than $25 million to recall and retrofit the polluting vehicles, and up to $8.75 million on projects to offset emissions from these vehicles. These projects may include buying back older vehicles or purchasing new school buses that burn cleaner fuels.

o EPA determined that GM relied on a computer chip to increase the engine idle speed by about 100 revolutions per minute (RPMs) which EPA thought was excessive and beyond what was necessary to offset the additional load applied when the air conditioning or heater was turned on. [EPA-HQ-OAR-2010-0799-11760-A2, p.10]

So one must ask the question, why is hybrid electric vehicle technology not a defeat device? During the official EPA testing the HEV typically operated in battery mode for a substantial portion of the test with the engine off. During these tests, both the air conditioning and the heater are off. When either the cabin heater or the air conditioning is turned on by the customer in real world operation the engine turns on (or in the case of the models with electric air conditioners the battery discharges faster which results in the engine turning on faster) thereby increasing vehicle greenhouse gases and decreasing vehicle fuel economy. [EPA-HQ-OAR-2010-0799-11760-A2, p.11]

Conclusion

The bottom line is that EPA needs to reevaluate the costs and benefits of hybrid and all electric vehicles in its rulemaking. [EPA-HQ-OAR-2010-0799-11760-A2, p.11]

Organization: Honeywell Transportation Systems

The long term environmental benefits of electric vehicles are also unknown once the upstream emissions of generating electricity are accounted for. The emissions benefits of an electric vehicle fleet are, from a well-to-wheel perspective, highly dependent on reconstituting the nation's base energy structure to rely more exclusively on renewable energy sources and less on fossil fuels such as coal. [EPA-HQ-OAR-2010-0799-9474-A1, p.4]

This environmental uncertainty of electric vehicles needs to be viewed against the proven environmental and market benefits of enhancing internal combustion engines with innovations such as turbochargers and advanced lightweight materials.3 The lead time and financial constraints faced by OEMs require the industry to begin to choose investment now with regard to vehicles for the model years covered by the first part of this rulemaking. Encouraging investment towards electric vehicles at the expense of ICE vehicles places a heavy bet on an uncertain future while potentially diminishing the more certain gains to be had through advanced ICE technologies. The internal combustion fleet will continue to dominate for the foreseeable future, making it a logical choice for investment with the greatest promise of return. EV mandates requiring a singular investment approach suggest a solution which at best will be limited and at worst wasted given market expectations. [EPA-HQ-OAR-2010-0799-9474-A1, p.4]

---

3 Diesel vehicles with turbo technologies offer an especially beneficial approach to securing significant emissions gains. OEMs have invested heavily in developing diesel technologies for the U.S. market, and there is growing demand for diesel vehicles in the U.S. Diesels offer substantially better fuel economy over gasoline. Honeywell strongly supports any incentive that would allow the U.S. to capture and benefit from the further deployment of diesel vehicles during the model years covered by this regulation. [EPA-HQ-OAR-2010-0799-9474-A1, p.4]

Organization: International Council on Clean Transportation (ICCT)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 29.]

I also applaud federal policy in identifying the positive role of electric vehicles as critical technology to address urban and greenhouse gas pollution, fuel economy and reduced dependence on fossil fuels. Electric drive technologies are inherently clean with zero tailpipe emissions, and coupled with renewables, they are capable of zero well-to-wheel emissions and will be necessary to reach 2050 greenhouse gas targets of over 80 percent.

Organization: Nissan North America, Inc.

Nissan is also committed to hybrid technologies. Nissan has developed a modular hybrid unit for front wheel drive vehicles that can be applied to varying engine displacements. Mated to a 2.5L supercharged 4-cylinder engine, our hybrid powertrain delivers V6-like power with improved fuel economy. Mated to a small displacement 4cylinder engine (i.e. 2.0L), our hybrid powertrain will deliver the power like a 2.5L engine and offer improved fuel economy. [EPA-HQ-OAR-2010-0799-9471-A1, p.7]

The proposed standards assume a significant market penetration of both advanced ICE technology and hybrid technology. As set forth below, hybrid vehicle market penetration has only recently expanded from initial purchasers of new technology, the innovators, to the early adopters who can begin to educate and expand awareness about the new technology to a broader, national market. Thus, widespread adoption of hybrids into the pragmatic majority of consumers remains uncertain at this time. Only through a midterm review can the agencies have the requisite certainty that the standards established for GHG emissions and suggested for CAFE will in fact be technologically and economically feasible in MYs 2022-2025. [EPA-HQ-OAR-2010-0799-9471-A1, p.7]

The proposed standards also anticipate a serious influx of transformational technology to reach compliance. As the agencies made clear in the Second Supplemental Notice of Intent, '[i]n achieving the level of standards described above for the 2017-2025 program, the agencies expect automakers' use of advanced technologies to be an important element of transforming the vehicle fleet.' *See* 76 Fed. Reg. 48,758, 48,760 (Aug. 9,2011). [EPA-HQ-OAR-2010-0799-9471-A1, p.7]

Nissan has led the way: (1) in investing in battery technology for the mass market, (2) in working with the governments on every level to prepare the infrastructure, and (3) in supporting government programs to ensure the long-term viability of low and zero emission vehicles. [EPA-HQ-OAR-2010-0799-9471-A1, p.7]

Nissan began introducing the Nissan LEAF in the United States in December 2010 and has already sold more than 10,000 Nissan LEAFs in the United States and over 20,000 worldwide. The Nissan LEAF is not a niche vehicle-it is a full-service family sedan designed for range, functionality and safety. The Nissan LEAF is a Top Safety Pick by the Insurance Institute for Highway Safety and the first all-electric car to earn an overall 5 star safety rating from NHTSA. The battery contains air-cooled, stacked laminated battery cells and is located below the seats and rear foot space, keeping the center of gravity as low as possible and increasing structural rigidity compared to a conventional five-door hatchback. [EPA-HQ-OAR-2010-0799-9471-A1, p.7]

In addition to being an industry leader in EV technology and deployment, Nissan recently announced its intention to introduce a PHEV model in 2015. Nissan will introduce additional battery electric vehicles into the marketplace in the coming years. [EPA-HQ-OAR-2010-0799-9471-A1, p.8]

Nissan also recently released its Next Generation Fuel Cell Stack (2011 Model) for FCVs. Through improvements to the Membrane Electrode Assembly (MEA) and the separator flow path, which make up the structure of Fuel Cell, Nissan significantly improved the power density of Fuel Cell Stack to 2.5 times greater than its 2005 model and realized a world's best (among auto manufacturers) 2.5 kW per liter. Integrally molding the supporting frame of the MEA enabled stable, single-row lamination of the Fuel Cell, thereby significantly reducing its overall size by more than half compared to conventional models. Finally, compared with the 2005 model, both the usage of platinum and parts variation has been reduced by 25%, thereby reducing cost of the Next Generation Fuel Cell Stack to one-sixth of the 2005 model. Nissan continues to work on the development of practical applications of FCVs to realize a zero emission society. [EPA-HQ-OAR-2010-0799-9471-A1, p.8]

While Nissan has taken leadership in electric vehicles throughout the world, the widespread market adoption of the technology depends on broader industry investment and continued government support through incentive programs. With state and local governments facing budgetary constraints, economic uncertainties and potential market disruptions, the mid-term review is necessary to ensure the ability for the industry to incorporate enough advanced powertrain technology into the fleet to allow industry-wide compliance with the program in the later years. Without such a review, the standards for the later years lack the requisite certainty to assure that they will in fact be achievable. [EPA-HQ-OAR-2010-0799-9471-A1, p.8]

Organization: Securing America's Future Energy (SAFE)

Therefore, in addition to promoting the importance of improving fuel economy, which is of critical importance, especially for the short- and medium-term, SAFE is promoting the deployment of GEVs to replace petroleum powered vehicles and establish electricity as the dominant means of powering our LDV fleet in the long-term. [EPA-HQ-OAR-2010-0799-9518-A1, p. 6]

SAFE believes that electrifying the light-duty transportation system is the best way to enhance our national, economic, and environmental security in the long because:

1) Electrification allows our economy to reduce exposure to the global oil market;

2) Electrification promotes fuel diversity;

3) Electric vehicles will be powered by largely domestic fuels;

4) Electricity prices are generally more stable than oil prices;

5) Electrification has the potential to reduce carbon emissions. [EPA-HQ-OAR-2010-0799-9518-A1, p. 6]

Reduce Exposure to the Global Oil Market: As explained above, the United States dependence on the global oil market imposes substantial economic and national security costs on the nation. Using electricity to power light-duty vehicles can disconnect a portion of the fleet from the global oil market and minimize the burdens of that dependence. [EPA-HQ-OAR-2010-0799-9518-A1, p. 6]

Promotes Fuel Diversity: Petroleum is essentially the sole fuel for the nation’s cars and trucks and fuels 93 percent of our transportation system’s energy needs. This reliance exposes the entire transportation sector to the volatility endemic to the world oil market. Electricity, however, is generated by a diverse set of fuels, including coal, nuclear, natural gas, hydroelectric, wind, geothermal, solar, landfill gas, and others. An electricity-powered transportation system, therefore, is one in which an interruption of the supply of one fuel can be made up for by others, and price volatility for one fuel is dampened by stability in others—a far cry from today, when a single event on the other side of the globe can interrupt the flow of oil and dramatically increase the cost of transportation in the United States. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 6-7]

Domestic Portfolio of Fuels: While oil supplies are subject to a wide range of geopolitical risks, the fuels that we use to generate electricity are generally sourced domestically. Satisfying our transportation energy needs with these domestic fuels will not only reduce the economic risks created by highly volatile oil prices, it will significantly lower the trade deficit. [EPA-HQ-OAR-2010-0799-9518-A1, p. 7]

Reduced Price Volatility: Oil prices are highly volatile. The retail price of electricity is not. Power prices reflect a wide range of costs. Generally, the cost of fuel represents a smaller percentage of the overall cost of delivered electricity than the cost of crude oil represents as a percentage of the cost of retail gasoline. This makes retail power prices less sensitive to any volatility in fuel prices. Further, retail power prices are generally set to reflect the average cost of wholesale prices over time, promoting retail price stability. [EPA-HQ-OAR-2010-0799-9518-A1, p. 7]

Reduced Carbon Emissions: As EPA itself noted in the preamble to the proposed rule, EVs and PHEVs have the potential to transform the carbon emissions profile of the light duty sector by obtaining much or all of their power from grid electricity that could be produced from very low GHG emission feedstocks or processes, and the potential for greater transformation if at some point in the future there is comprehensive regulation of greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-9518-A1, p. 7]

Because of the role that GEVs can play in disconnecting the nation’s economy from dependence on global oil market, and the economic and national security consequences of that dependence, SAFE supports a portfolio of policies intended to facilitate their penetration of the automotive marketplace. [EPA-HQ-OAR-2010-0799-9518-A1, p. 7]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 150.]

We have been promoting plug-in vehicles for four reasons: First, the fuel that is used to power them is domestic; second is a diverse portfolio for fuels; third, the price of power is much more stable than the price of oil; and fourth, electricity has the potential to be much cleaner in the long term.

In short, electricity has the potential to address a giant set of problems for our nation that no other fuel can address. Yet, for many years, the cost of this technology is going to be more expensive.

Organization: Tesla Motors, Inc.

• EV technology is the most promising and cost-effective alternative to traditional internal combustion engines. It is available now and at price points already lower than current projections; [EPA-HQ-OAR-2010-0799-9539-A2, p. 1]

EVs are a commercially viable technology presently and are increasingly available in the current marketplace due to innovative design and the emergence of new applications for existing technologies. Lithium-ion batteries are a proven technology, currently utilized as the standard power source for consumer electronics and increasingly identified for its potential in military, aerospace and automotive applications. These batteries offer tremendous energy density, low weight, and no memory effect. Additional research into lithium-ion batteries consistently yields improvements in energy density, durability and intrinsic safety, while continuing to lower costs. [EPA-HQ-OAR-2010-0799-9539-A2, pp. 4-5]

Tesla's real world experience demonstrates an EV technology cost that is highly competitive. Again, this cost includes not only cells, but the attendant cooling, cell management and disconnect unit as well. Specifically, battery costs for production of over 2,500 Tesla Roadsters over the life of the program were in the range of $500/kWh. As the technology has improved and Tesla has gained greater efficiencies, we have been able to lower the costs for Model S and X even further to a point where battery technology is projected in the range of $350/kWh with production of at least 20,000 units/year. By the time Tesla Motors projects high volume production of Gen III platform at volumes of 100,000 to 200,000 units/year, we believe battery costs will be well south of $350kWh. These cost estimates are based not in theory, but the actual costs seen by Tesla Motors for EVs and power trains production. [EPA-HQ-OAR-2010-0799-9539-A2, p. 5]

To this end, Tesla Motors strongly believes that EVs are a compelling proposition. Not only does the Company believe that EVs are cost-effective from a manufacturing standpoint, but also from the perspective of the total cost of ownership. When consideration of the cost of gasoline, oil changes, and other routine maintenance is factored in, the cost to operate the Model S over eight years will be $30,000 less than a comparably equipped (and priced) BMW 535i. Likewise, the Tesla Gen III vehicle will cost approximately $17,000 less to operate than a Ford Fusion over that same period.[8] [EPA-HQ-OAR-2010-0799-9539-A2, p. 5]

Of course, while cost is a significant driver of EV adoption, so too is range and vehicle efficiency. Tesla continues to push forward on development in these areas as well. By way of illustrative example, if the current technology developed for Model S were installed in a Tesla Roadster, instead of 245 miles on a single charge, the Roadster would have a range in excess of 330 miles on a single charge. Improvements are not achieved solely in terms of energy density in the pack, but in several aspects of energy storage and power management. Tesla continues to push forward on EV technology and predicts even higher battery pack energy density and longer ranges as the technology continues to improve. [EPA-HQ-OAR-2010-0799-9539-A2, p. 6]

In sum, from Tesla's perspective, there is significant advancement both in the current and next generation of EVs. Both EPA and NHTSA have a long history of successfully enacting challenging standards that the industry can and does meet, from lead free gas and catalytic converters, to Tier II emission standards and the existing CAFE standards. Tesla urges both EPA and NHTSA to continue the commendable pattern of pushing industry to drive innovation in the area of fuel efficiency and GHG reduction. [EPA-HQ-OAR-2010-0799-9539-A2, p. 6]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 94.]

The benefits of EV technology are manifest: Zero emissions at point of use. Some of the prior testaments have spoken to the national security implications of reduction of foreign oil. But too little is said of the economic benefit of a transition away from the oil monopoly and transportation, notably the fact that 300 billion a year spent on foreign oil, and this represents about half of our trade deficit. It's worth imagining what that money would do if recycled in our own economy. It's also a testament -- EV technology, as it's currently being developed, is a testament to how American innovation is driving a number of positive developments in national security and economics, but also in job creation. Tesla Motors now employs just about 2,000 folks. And as we ramp up the production, we will be increasing several hundred more in this calendar year.

---

8 Assumes Fusion retails for $25,000 and gets 40mpg at $3.50/gallon over 12,000 miles per year. Tesla Gen III assumed to get 225wh/mi at $0.11/kWh and $30,000 selling price over the same mileage.

Organization: Toyota Motor North America

Fuel Cell Readiness [EPA-HQ-OAR-2010-0799-9586-A1, p.23]

For this proposed rule, the agencies considered vehicle technologies that manufacturers could use to improve the fuel economy and reduce GHGs in the 2017-2025 model year timeframe. In doing so, assumptions were made about how currently available technologies could be incorporated into vehicle product development programs to help comply with the proposed standards. The agencies classified these as 'near-term' technologies, as many are anticipated as potential compliance strategies for the 2012-2016 model year final rule. In addition, the agencies evaluated other technologies that are not projected to be in production within the next 5 to 10 years. A number of these advanced technologies are categorized as being beyond the research phase and were not considered for the purpose of evaluating the feasibility of the proposed standards because of significant uncertainty in their development and ability penetrate the fleet in large volumes. Fuel cell vehicles are one such technology, for which the NPRM states: [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

'While we expect there will be some limited introduction of FCEVs into the market place in the time frame of this rule, we expect this introduction to be relatively small, and thus FCEVs are not considered in the modeling analysis conducted for this proposal. ' [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

We are concerned that this assessment is too cursory and could be misinterpreted. There have been significant advances in fuel-cell stacks, dramatic reductions in system cost, and marked improvement in system durability and cold weather operation. In addition, manufacturers have announced vehicle introduction plans for fuel cell demonstration vehicles, beginning in 2015. Automakers have proven the viability of fuel cell vehicles. We believe the biggest remaining hurdle is refueling infrastructure. Toyota agrees with the agencies assessment that fuel cell technology is one of the key future technologies for GHG reduction. We request that the agencies' assessment of fuel cell vehicles in the final rule elaborate on the progress that has been made to date and clarify that how infrastructure remains the primary challenge toward commercialization. We also strongly encourage the agencies to support hydrogen infrastructure development, in order to ensure the timely introduction of these vehicles. [EPA-HQ-OAR-2010-0799-9586-A1, p.22]

Organization: United Automobile Workers (UAW)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 23-24.]

UAW members are also producing new technologies that may not reach large volumes for many years but represent the long-term future of the industry. That includes hybrid transmissions, electric drive components, lithium ion battery packs, and plug-in and pure electric vehicles.

Organization: Volkswagen Group of America

Volkswagen compared cost and effectiveness estimates for hybridization with those provided by EPA in both the Notice of Intent (Sept-2010) and the Joint Draft Technical Support Document (Joint TSD) which accompanied the NPRM. Volkswagen also examined HEV penetration rates projected by EPA out to 2025. [EPA-HQ-OAR-2010-0799-9569-A1, p. 13]

Accurate projections for the cost of advanced technologies, especially vehicle electrification are a challenge. Volkswagen believes that significant uncertainty will remain with regards to pricing of energy storage for many years to come. Failure to drive down costs of electric storage will directly impact the market acceptance and resulting penetration of electrified vehicles. EPA has predicted that the NPRM will force upwards of 30% HEV technology into Volkswagen's compliance fleet for 2021 with an additional 6% EV and 1% PHEV being required to achieve compliance. [EPA-HQ-OAR-2010-0799-9569-A1, p. 13]

Volkswagen is concerned that the projected 30% HEV penetration rate is unrealistic and grossly exceeds our expectations for hybrid sales rates. Volkswagen recognizes that this is only an exercise conducted by the agency to analyze potential compliance pathways. Regardless, HEV adoption by consumers remains challenging even when long-term fuel savings can be calculated to outweigh the higher upfront vehicle price. US adoption of HEV vehicles remains between 2-3% per year even in light of recent fuel price increases. [EPA-HQ-OAR-2010-0799-9569-A1, p. 13]

EPA has projected that the industry on average will increase electrified vehicles sales to approximately 7% in 2020 and 18% in 2025 1, the majority of which are hybrid vehicles. Increased adoption by consumers of hybrids and other electrics to these levels remains a critical and difficult to predict factor. Interest in HEV technologies obviously peaks during times of escalated fuel prices. However, this is often followed by receding interest as fuel prices either drop or stabilize. It is also important to note that HEV interest is often motivated by factors other than fuel savings such as access to High Occupancy Vehicles lanes, premium parking, lower property taxes, etc. Recent trends at State and local levels to eliminate some of these perks may further deteriorate interest, e.g. California expiration of HOV access for certain hybrids. [EPA-HQ-OAR-2010-0799-9569-A1, p. 13]

EPA's base assumption with the proposal is that consumers will react to long-term fuel savings, even with higher upfront costs for higher efficiency vehicles, and that the savings will motivate consumers to purchase vehicles such as hybrids. The NPRM incorporates AEO fuel price predictions as described in Section 4.2.2 of the Joint TSD. AEO predicts gasoline prices as shown in Table 2-6. AEO predicts average gasoline prices to remain essentially constant between 2012 and 2025. This means that consumers will face similar 'price at the pump' in real dollars that they see now. Regardless of short-term price swings, AEO sees no significant deviation from current pump prices. [See Table 2-6 on p. 14 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 14]

As shown in Figure 2-4, following fuel price increases in early 2000's, there was a notable uptick in customer interest of hybrid vehicles. The fuel price spikes in 2007-2008 timeframe even brought about irrational consumer behavior in which customers traded-in large trucks to purchase small cars, sometimes at considerable loss. However as fuel prices stabilized in the mid $3 per gallon range, sales in larger vehicles and pick-up trucks returned. Often customers who had moved into smaller vehicles complained about the lack in comfort and space of the smaller cars. [See Figure 2-4 on p. 14 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 14]

As shown in Figure 2-4, following fuel price increases in early 2000's, there was a notable uptick in customer interest of hybrid vehicles. The fuel price spikes in 2007-2008 timeframe even brought about irrational consumer behavior in which customers traded-in large trucks to purchase small cars, sometimes at considerable loss. However as fuel prices stabilized in the mid $3 per gallon range, sales in larger vehicles and pick-up trucks returned. Often customers who had moved into smaller vehicles complained about the lack in comfort and space of the smaller cars. [See Figure 2-4 on p. 14 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 14]

Figure 2-4 illustrates some recent market trends combined with projections within the proposal. What is most notable is recovery in the truck sector following the late 2007-2009 drop off due primarily to the US recession. During this time period the industry as a whole dropped significantly from around 16 million units to 10 million units. For 2011, the truck segment has seen accelerating recovery, once again outpacing overall car sales. Large pick-ups have seen notable gains with the F150 and Silverado/Sierra once again taking the top two sales positions. [EPA-HQ-OAR-2010-0799-9569-A1, p. 15]

Hybrid penetration rates may then be challenged to move from the 2-3% range to upwards of 7% and 18% in 2021 and 2025 respectively. Especially with gains expected to be made with conventional engine technology, Volkswagen sees no significant motivation which would drive customer interest in hybridization to these extremes. [EPA-HQ-OAR-2010-0799-9569-A1, p. 15]

1 Table 3.9-4 EPA RIA

Response:

The American Fuel and Petrochemical Manufacturers (AFPM) commented that our phase-in caps for electrification are too high resulting in projections of electrification being too high. EPA's phase-in caps are presented in Table 3-130 of the joint TSD. There we show our caps for MYs 2016, 2021 and 2025 as 15%/30%/50% for HEVs, 6%/11%/15% for EVs and 5%/10%/14% for PHEVs. In the final analysis, we have lumped mild HEVs in with HEVs so that the caps limit HEVs+mild HEVs to 15%/30%/50%. We disagree that these caps are too high. We remind the commenter that the caps are only maximum limits placed on OMEGA (for each manufacturer), they are not our projections for actual technology penetrations for the fleet. AFPM suggests that we have used the purportedly high caps to support the standards, implying that the standards can only be met with penetration rates that are higher than possible (according to AFPM). In fact, we have projected a feasible compliance pathway which relies very little on electrification to the strong hybrid (P2 HEV), EV or PHEV level. As shown in preamble Tables III-26 through III-29, our control case has essentially the same strong HEV penetration as shown in the reference case (i.e. very little addition from 2017 through 2025 beyond what's already in 2016), and the combined EV/PHEV penetration is just 2%. In the case of mild HEVs, we have a much more significant penetration rate of 26% but we believe that level of penetration can be met by industry given that a sizable number of essentially the same technology is being sold today (e.g., the GM eAssist sold on the Buick LaCrosse and Regal and the Chevrolet Malibu) and the technology is less complex than the strong HEV or EV/PHEV technologies. As regards the AFPM comments on consumer choice modeling, we address such issues in section 18.1 of this Response to Comments document.

Regarding comments from Delphi Corporation, we appreciate your comments in support of the potential for hybrid electric vehicles and start/stop technology to reduce the CO_2 emissions for all classes of vehicles.

Regarding comments from the Environmental Consultants of Michigan, EPA and NHTSA acknowledge and discuss in detail the on-road fuel economy "gap" in secton 4.2.1 of the TSD. This gap not only exists for strong HEVs. It also exists for vehicles with more conventional drivetrains. Included in this section is a discussion of the gap used by the agencies for electric drivetrains (30%) and the gap for the use of liquid fuels (20%) along with a discussion of EPA 5-cycle and derived 5-cycle MPG versus 2-cycle MPG. EPA does not need to reevaluate the costs and benefits of hybrid and all electric vehicles since the in-use gap for both conventional and hybrid vehicles has been accounted for. The agencies also do not project that a significant increase in the use of strong-HEVs will be necessary to comply with the 2017-2025 GHG standards. The commenter's remarks and specific examples were primarily with regards to strong HEV's like the Toyota Highlander HEV. Our analysis shows that strong HEVs will see only a minor increase from today's levels of approximately 4% of vehicle sales to approximately 5% of vehicle sales in 2025. Our analysis projects a much larger increase in sales of mild HEVs (approximately 30% of sales). Because the operation of mild HEV applications is limited to start/stop and mild launch assist, the differences between 2-cycle and 5-cycle MPG and CO_2 emissions would be considerably less than for strong HEVs. The comments with respect to HEVs being defeat devices are completely without merit. Like other light-duty vehicles, HEVs are subject to SFTP standards and to cold CO standards, and thus are tested under high temperature conditions with AC active (SC03 test cycle), under very aggressive driving conditions (US06 test cycle) and under cold winter conditions (Cold CO test). CO_2 emissions of more conventional vehicles also show differences during cold temperature, high temperature/AC and aggressive driving conditions, which can be seen in the differences between 2-cycle and 5-cycle CO_2 and MPG results for these vehicles.

Regarding comments from Honeywell Transportation Systems, we thank you for your comments and providing this additional information. We look forward to obtaining more of this type of information to inform our future work.

Regarding comments from the International Council on Clean Transportation (ICCT), and the United Automobile Workers (UAW), we appreciate your comments in support of the potential for electric vehicle technology to reduce the CO_2 emissions for all classes of vehicles.

Regarding comments from Nissan North America and Toyota Motor North America, Inc., we appreciate your comments in support of the potential for electric vehicle technology to reduce the CO_2 emissions for all classes of vehicles along with your efforts to introduce fuel cell vehicles. We agree the mid-term review will be used to evaluate the progress of the technologies used to meet the standards.

Regarding comments from Securing America's Future Energy (SAFE), and Tesla Motors, Inc., we appreciate your comments in support of the potential for electric vehicle technology to reduce the CO_2 emissions for all classes of vehicles while simultaneously decreasing our dependence on unstable sources of petroleum and increasing our energy security.

Volkswagen Group of America commented that our electrification penetration rates for VW in MY2021 were overly aggressive. In the proposal, we estimated VW's penetration rates at 30% HEV, 6% EV and 1% PHEV. In our final analysis, we estimate VW at 15%/0%/0% penetration of HEV/EV/PHEV in the MY2021 reference case and 1%/6%/0% penetration of HEV/EV/PHEV in the MY2021 control case along with a 29% penetration of mild HEVs. Therefore, we are actually projecting a significant decrease in HEV penetration and an increase of both mild HEVs and EVs compared to the analysis presented at proposal. We do not believe this projected compliance pathway poses the issues of consumer acceptance that VW posits in its comments. Moreover, and importantly, this represents one compliance pathway for VW, the pathway that we consider to be the most cost effective. VW may choose a different approach and is not constrained from doing so. . For example, VW has traditionally been a strong supporter of diesel technology. Nothing in the final rule precludes VW from using diesel technology to comply if VW believes that this is a more promising compliance pathway.

12.2.4.1. ANL Battery Model

Organizations Included in this Section

International Council on Clean Transportation (ICCT)
Tesla Motors, Inc.

Organization: International Council on Clean Transportation (ICCT)

8. Many, if not most, future Li-ion batteries will use air-cooling. Future versions of the ANL BatPac model should include an option to select either air or liquid cooling. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

8) Battery Cooling System Cost

The ANL report on the BatPac battery cost model 26 includes an Active Cooling System section and briefly explains why Water-50% glycol was selected:

'There are several choices of coolant that have been considered for cooling battery packs including air from the cabin, which may be heated or cooled, water-ethylene glycol solutions and dielectric liquids such as transformer coolants. Air is the least expensive, but it is less effective than the liquids because of its poor conductivity, the need for large flow passages and high pumping power. Dielectric liquids are expensive, but have the advantage of being compatible with terminals and other parts at electrical potential. Water-50% glycol solution is inexpensive and has good conductivity; we have selected it as the coolant for this study.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 21]

Unfortunately, the general design select for cost analysis does not allow for air cooling:

'We selected a general cell and battery design that can be adapted to all of the electric-drive batteries from micro-HEVs packs to EV packs (section 2). This design incorporates a hermetically sealed module closure. Unfortunately, the enclosure does not have sufficient surface area to be cooled effectively by air.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 21]

Section 5.2.3.3 Balance of Thermal Management System acknowledges that air cooled systems are less expensive and are more likely to be used in micro HEVs and HEV-HPs. In addition, air-cooling was studied by the authors of the BatPac report (docket item EPA-HQ-OAR-2010-0799-1078) and presented at the Electric Vehicle Symposium in 2009 and 2010.27,28 The initial cell design for those studies involved flat-wound cells. Flat-wound cells have more surface area and can be effectively cooled by air. Finally, it should be noted that the Nissan Leaf battery pack does not use liquid cooling, only a circulating fan inside a sealed battery pack. It is inappropriate to exclude air-cooling in the modeling of battery cost. [EPA-HQ-OAR-2010-0799-9512-A1, p. 22]

The ICCT strongly recommends that future versions of the BatPac model include an option to select either air or liquid cooling. [EPA-HQ-OAR-2010-0799-9512-A1, p. 22]

26 ANL, 2011, Modeling the Performance and Cost of Lithium-Ion Batteries for Electric-Drive Vehicles, Final Report prepared by Paul A. Nelson, Kevin G. Gallagher, Ira Bloom. and Dennis W. Dees, Argon National Laboratory, Argonne, IL' Docket EPA-HQ-OAR-2010-0799-1078

27 Nelson PA, Santini D. J' Barnes J., Factors Determining the Manufacturing Costs of Lithium-Ion Batteries for PHEVs, Electric Vehicle Symposium 24, Stavanger, Norway, May 13-16, 2009.

28 Santini D.J., Gallagher K. G., Nelson P.A., Modeling of Manufacturing Costs of Lithium-Ion Batteries for HEVs, PHEVs, and EVs, Electric Vehicle Symposium 25, Shenzhen, China, Nov. 5-9, 2010.

Organization: Tesla Motors, Inc.

The battery packs used by Tesla Motors are the result of innovative systems engineering and the Company's continual drive to forward advances in lithium-ion cell technology. Starting with the 18650 form-factor cells, Tesla takes advantage of all aspects of cell and pack design to optimize not only energy density, but structure and safety as well. For example, the 18650 cells used in Tesla vehicles and power trains allow for innovative packaging while providing an incredible level of safety not matched by any other lithium ion technology. Specifically, the unique properties of the smaller cell size enables efficient heat transfer, allow for precise charge management, improve reliability, and extend battery pack life. Tesla has also developed a unique and proprietary lithium ion chemistry engineered specifically for EVs. This chemistry has resulted in EV quality cells that have the highest energy density in the industry. [EPA-HQ-OAR-2010-0799-9539-A2, p. 5]

As noted in the NPRM, EPA and NHTSA have relied upon the battery cost model developed by Argonne National Laboratory for the Vehicle Technologies Program of the U.S. Department of Energy - Office of Energy Efficiency and Renewable Energy. Tesla understands that this model considers the vehicle application's power and energy requirements, which are two of the fundamental parameters when designing a lithium-ion battery for an HEV, PHEV, or EV. Though we appreciate the efforts of those at ANL and DOE, Tesla Motors supports a more comprehensive approach to assessing the battery cost. When calculating cost values, Tesla does not price cells alone, but factors in all the costs of the battery and attendant systems including cell management, thermal management and the disconnect unit. Tesla believes this is a more accurate method of cost calculation. [EPA-HQ-OAR-2010-0799-9539-A2, p. 5]

Response:

Regarding comments from Tesla Motors Inc, we agree that when analyzing the manufacturing costs of future HEV, PHEV and EV battery packs, all of the costs of the battery and attendant systems including cell management, thermal management and the disconnect unit should be included. That is why, in part, that EPA selected the ANL BatPaC model. EPA's cost analysis in the NPRM as described in the draft TSD included cell management, thermal management and the safety disconnect. This cost analysis was further refined for the final rule (see Chapter 3.3.3.9 of the joint TSD) and included options for selecting either:

1. Forced cabin-air cooling of the battery pack along with the necessary redesign of cell spacing to accommodate air cooling.
2. Liquid-cooling using glycol-water coolant and, in the case of PHEV applications, a dedicated lower-temperature coolant loop.

EPA selected the use of air-cooling for micro-HEV and HEV applications similar to the systems used for the Li-ion battery pack in the 2012 Hyundai Sonata HEV. EPA selected the use of liquid cooling for PHEV and EV applications similar to the cooling systems used for the GM Chevrolet Volt and the Ford Focus Electric. While the Agency acknowledges that air-cooled and passively-cooled systems may be appropriate for some EV applications, we decided that a more conservative approach was necessary to provide battery adequate pack cooling under all ambient conditions and for a broader range of vehicle applications than what is currently available.

12.3. Cost of CO_2-Reducing Technologies

Organizations Included in this Section

Aluminum Association's Aluminum Transportation Group
Center for Biological Diversity
Ceres
Delphi Corporation
Environmental Consultants of Michigan
International Council on Clean Transportation (ICCT)
National Association of Clean Air Agencies (NACAA)
Natural Resources Defense Council (NRDC)

Organization: Aluminum Association's Aluminum Transportation Group

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 226-227.]

As we think about light-weighting and advanced materials, the other question that comes up after safety is cost. Clearly strong, affordable carbon reducing materials are being used at an increasing rate to meet down-weighting objectives now and in the future. Aluminum is widely recognized as a cost-effective choice for reducing weight in automotive bodies, individual components, and vehicle structures. As auto makers turn to greater use of aluminium, secondary weight reductions are emerging as a major cost savings enabler. As we get larger and larger weight reductions, we're able to make larger and larger reductions in vehicle support systems.

Organization: Center for Biological Diversity

Moreover, the costs to manufacturers of adding technologies to increase their fuel efficiency are significantly overstated. In fact, it will be easier and far less costly to comply with any of the alternatives discussed in the NPRM than the Agencies state. The rapidity of improvements in fuel efficiency technology and the reduction in the costs of those technologies over the last decade has been startling. For example, as discussed in detail by comments submitted to this rulemaking by the International Council on Clean Transportation ("ICCT"), the National Research Counsel estimated in 2001 that turbocharging and downsizing would improve fuel economy by 5-7%, but by 2011 these technologies were estimated to improve efficiency by 12-20 percent, nearly three times the rate of improvement predicted, all due to accelerating technological advances; estimated manufacturing costs for turbocharging systems have fallen from $815 to $478 in three years; and adding 6-speed automatic transmission was estimated to cost $215 in 2011 but now is estimated to save $13.00. Similarly, the cost of light-weighting is significantly overstated. But the Agencies do not take either of these trends – rapid technological improvement and significant cost reductions – into account in their cost-benefit analysis. Indeed, instead of assuming greater cost reductions in the later years of the rulemaking, the Agencies assume larger costs in those years. These errors must be corrected. [EPA-HQ-OAR-2010-0799-9479-A1, p. 7]

Organization: Ceres

The analysis was also conservative as to assumptions regarding the costs and penetration of plug-in technologies; it focused on low cost technologies, although many predict higher penetration and decreasing costs of these technologies in 2020. Given the analysis' focus on low cost technologies, the vast majority of improvement in fuel economy was met with improvements in internal combustion engines. [EPA-HQ-OAR-2010-0799-9475-A1, p. 2]

Organization: Cuenca, M.

Transportation is critical to our quality of life and the EPA's regulation could increase the cost of a new vehicle by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. [EPA-HQ-OAR-2010-0799-10142-A1, pp. 1-2]

Organization: Delphi Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 110.]

Finally, I recommend that the National Research Council technology cost estimates and implementation cadence data be included in the agencies' analyses and be considered a primary source of information. Industry reports and other analyses can also be used to provide even more insight and sensitivity.

Organization: Environmental Consultants of Michigan

The Agency is proposing stringent greenhouse gas standards that would fundamentally change the light duty vehicle and truck market. A look at the 2012 model year vehicles shows seven current models; three all electric vehicles, three hybrid electric vehicles and one hydrogen fuel cell powered vehicle would meet the proposed standards. [EPA-HQ-OAR-2010-0799-11760-A1, p.1]

While there is scant data on the true costs of all electric vehicles there are data on the hybrids. Hybrid electric vehicle (HEV) propulsion systems were first introduced in the United States in 1999. Since that time over 2 million HEVs have been sold. Eighty-eight percent of these HEVs were produced by Toyota and Honda. The Toyota Prius is the single largest selling hybrid representing more than half the hybrids on the road today in the United States. The Honda Civic represents 11 percent of the hybrids on the road in the United States and is the second highest selling hybrid. Both these vehicles would meet the 2025 model year proposed standards. [EPA-HQ-OAR-2010-0799-11760-A1, p.1]

According to two standard valuation guides for estimating the average trade-in value, even though the Prius and the Civic carry a substantial premium initial purchase price based on manufacturer's suggested retail price by the time they are eight years old they are actually worth less than their gasoline counterparts. The same applies to the next two highest selling hybrids the Camry and the Highlander. [EPA-HQ-OAR-2010-0799-11760-A1, p.1]

This raises the question, do hybrids really save consumers money? Even though a hybrid will save on fuel costs assuming they achieve the EPA fuel economy label value, the higher financing costs, sales tax, depreciation and insurance costs more than offset the fuel savings according to the True Cost of Ownership calculations on the Edmunds.com website. [EPA-HQ-OAR-2010-0799-11760-A1, p.3]

For every mile per gallon the fuel economy label is overstated, an extra $120 is added onto the cost of ownership. Conversely, for the Prius to achieve a true cost of ownership lower than the Camry, fuel prices would have to exceed $6.55 per gallon. For the Prius to achieve a true cost of ownership lower than the Corolla, fuel prices would have to exceed $13.01 per gallon. [EPA-HQ-OAR-2010-0799-11760-A1, p.4]

The Honda Civic Hybrid also has a higher true cost to own compared to the gasoline Civic. [EPA-HQ-OAR-2010-0799-11760-A1, p.4]

For every mile per gallon the fuel economy label is overstated, an extra $154 is added onto the cost of ownership. Conversely, for the Civic Hybrid to achieve a true cost of ownership lower than the gasoline version, fuel prices would have to exceed $8 per gallon. [EPA-HQ-OAR-2010-0799-11760-A1, p.5]

Looking at the third highest selling hybrid, the Toyota Camry versus the gasoline Camry, the cost to own the hybrid is higher. [EPA-HQ-OAR-2010-0799-11760-A1, p.5]

For every mile per gallon the fuel economy label is overstated, an extra $194 is added onto the cost of ownership. Conversely, for the Camry Hybrid to achieve a true cost of ownership lower than the gasoline version, fuel prices would have to exceed $10.83 per gallon. [EPA-HQ-OAR-2010-0799-11760-A1, p.6]

Continuing the analysis to the fourth largest selling hybrid, the Toyota Highlander, the true cost of the hybrid is higher than the gasoline hybrid. The rationale for all of these cases is the same. [EPA-HQ-OAR-2010-0799-11760-A1, p.6]

For every mile per gallon the fuel economy label is overstated, an extra $385 is added onto the cost of ownership. Conversely, for the Highlander Hybrid to achieve a true cost of ownership lower than the gasoline version, fuel prices would have to exceed $9.22 per gallon. [EPA-HQ-OAR-2010-0799-11760-A1, p.7]

The higher initial purchase price of hybrids leads to higher financing costs, higher sales taxes, higher insurance costs and because of the added weight of the battery higher registration fees. These added costs more than offset the lower fuel costs. All electric vehicles will have higher financing costs, higher sales taxes, higher insurance costs and because of the added weight of the battery higher registration fees. If the higher depreciation of hybrids is due in part to the anticipated battery replacement cost, all electric vehicles will continue this trend of rapid depreciation. [EPA-HQ-OAR-2010-0799-11760-A1, p.7]

Organization: International Council on Clean Transportation (ICCT)

2. The impact of computer-aided design is especially important for lightweight materials. None of the existing studies on lightweight material costs are adequate. The results of Lotus and FEV lightweight material studies will be far more accurate for future designs and must be used to assess weight reduction costs for the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 2]

2) Lightweight Material Costs

The cost of lightweight materials in the proposed rule is roughly twice that in the TAR. It is important to understand that computer simulations will especially impact lightweight material design. In the past, interactions between the thousands of parts on the vehicles and their impacts on safety, ride, noise, and vibration were impossible to predict. [EPA-HQ-OAR-2010-0799-9512-A1, p. 8]

Optimization of materials was a long, slow process of gradually changing a few parts at a time to avoid unanticipated problems. Secondary weight reductions were similarly difficult to achieve. The recent development of sophisticated and accurate vehicle simulations is opening up a new world. The initial use of these models was to improve safety design. The simulations are so effective that 5-star crash ratings became almost universal and NHTSA had to revise their rating criteria for the 2011 model year. The simulations are continuing to rapidly improve, to the point where they are starting to be used to simultaneously optimize the material composition, shape, and thickness of every individual part, including secondary weight reductions. [EPA-HQ-OAR-2010-0799-9512-A1, p. 9]

This shift in material design capabilities also impacts the cost to reduce vehicle weight. Previous lightweight material cost studies did not assess part interactions and secondary weight reductions. While they may have accurately reflected historical costs for lightweight materials, they all overstate the cost of future vehicle weight reduction. Studies in progress by Lotus and FEV are using highly sophisticated simulation models to optimize part materials and design. [EPA-HQ-OAR-2010-0799-9512-A1, p. 9]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 195.]

The results of Lotus and FEV lightweight material studies will be far more accurate of future designs and must be used to assess weight reduction costs for the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 9]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 196-197.]

ICCT is also paying FEV to do additional teardown cost assessments in connection with our work in Europe. These include updating the future hybrid costs, new cost assessments for advanced diesel engines, basic start/stop systems, manual transmissions and cool EGR systems. These results will be shared with EPA and NHTSA as they become available.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 29-31.]

The ICCT agrees that the best way to derive direct technology to cost estimate is to conduct real-world tear-down studies. Not only is this likely to be more accurate than supplier and manufacturer estimates, but the results are public, greatly increasing the transparency of the cost information.

In our work, as well as the work conducted by the EPA and CARB, the issue of light weighting of vehicles has proven to be one of the most exciting and fertile areas for improving fuel economy without incurring exorbitant costs or jeopardizing safety. As Mr. German stated, previous lightweight material cost studies did not assess part interactions and secondary weight reductions.

Studies in progress by Lotus and FEV are using highly sophisticated simulation models to optimize part materials and design. The results of these studies will be far more accurate for future designs and must be used to assess weight reduction for the final rule. We believe that these studies will be available for inclusion in the final rule. They are likely to show costs of lightweighting to be lower than envisioned in the proposed NPRM as well as in the final 2012 to '16 rule.

These are but two examples where we feel that the costs of the proposal are likely to be too high. And we feel fully confident that the technology benefits representative of another 13 years of development will result in costs much lower than $2,000.

Organization: National Association of Clean Air Agencies (NACAA))

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 41.]

Second, EPA projects the cost of new technology will add on average about $2,000 to the price of a vehicle.

We recognize the consumers will recoup this cost. However, if vehicles equipped with the technologies needed to meet model years 2025 emissions are introduced earlier, then the projected additional cost should be lower than $2000.

Organization: Natural Resources Defense Council (NRDC)

NHSTA should remove sensitivity analyses that test cost estimates that are inapplicable and misleading for the proposed rules timeframe of 2017 and beyond, especially the near-term cost estimates from the National Academies of Science. [EPA-HQ-OAR-2010-0799-9472-A2, p. 4]

Response:

Regarding the comment from the Aluminum Association's Aluminum Transportation Group, we too are concerned with both safety and cost, and have performed detailed analyses on both of these topics which are presented in Preamble III.D, II.G and RIA chapters 3 and 4. Regarding the comments from the Center for Biological diversity, that we have significantly overstated costs, we do not agree. We have made significant effort to make the best possible direct cost estimates. Further, we have made significant effort to include only those indirect costs that would likely change in response to new regulations. Lastly, we have incorporated manufacturer learning at rates used for years by EPA and that are typical for manufacturing-heavy industries like the auto industry. As for the comments specific to mass reduction costs, we do not disagree that we have perhaps overstated those costs. In fact, we sought to have better cost estimates ready in time for the final rule. Unfortunately, that effort was not completed in time for inclusion in the final rule and, as such, we were forced to use the same costs as were presented in the proposal. As the now final report on that light weighting cost effort shows (EPA-HQ-OAR-2010-0799 "Light Duty Vehicle Mass Reduction and Cost Analysis – Midsize Crossover Utility Vehicle", FEV, 2012), the costs used in our proposal and our final rule could be high. Importantly, we conducted a sensitivity on weight reduction costs in which the low side sensitivity included costs set to 40% below the final rule values. In this case, as in the primary analysis, OMEGA projection of the use of weight reduction technology is actually quite low (4% mass reduction technology applied in the 2025MY reference case and 8% in the control case, for a net of 4%). and is driven not by cost but by safety concerns. Given this safety analysis, having lower costs for weight reduction technologies would not produce significantly lower program costs or a different resultant standard level. Lastly, we fail to understand the comment that, "instead of assuming greater cost reductions in the later years of the rulemaking, the Agencies assume larger costs in those years." In no part of our analysis have we estimated increased unit costs for any technology. Our analysis might show higher costs for a technology in later years due to higher application rates (i.e., 10% weight reduction costs less than 15% and 20%), but 10% weight reduction (for example) in 2025 will always cost less than in 2016 in our analysis.

As for comments from Ceres, that we have focused our analysis on low cost technology and, as such, compliance is done largely via low cost technology, we must disagree. We have included a very broad list of technologies ranging from low cost to high cost, from low friction lubes to full battery electric. In our analysis, rather than focusing on low cost technologies, as suggested by the comment, we have focused on the most cost effective technologies – those technologies that provide the most attractive $/% improvement in GHG emissions. This is the most likely outcome in an efficient market and a reasonable approach to regulatory cost estimation. Lastly, our analysis should not be taken as predicting the future. Instead, our analysis seeks to show a possible path to that future. Each manufacturer is able to use its own preferred technologies – diesel, hybrid, plug-in hybrid, etc. – provided compliance can be achieved. If we have, in fact, been conservative regarding our plug-in cost estimates, then perhaps more plug-ins will be sold than our analysis suggests. Presumably, that would occur only if plug-ins provide a more cost effective solution than the technologies they replace.

Regarding the comment from M. Cuenca, we note that the NADA estimate of $5,000 is based on combining the costs of the MY 2011 CAFE rule, the MYs 2012-2016 CAFE/GHG rule, and the proposed MYs 2017-2025 rule. EPA has carefully examined the costs and benefits of this rule and has appropriately included the impacts of the MYs 2012-2016 rule in the baseline with which those costs and benefits are compared. Thus, the cost of the earlier rule is reflected in our analysis. In addition, the NADA estimate assumes that indirect costs for all technologies equal the direct costs, by using a retail price equivalent multiplier of 2.0. EPA's cost estimates take into account that indirect costs for new technologies vary with the complexity of the technology and the time frame since the technology's adoption, a more reasonable approach. This issue is discussed in detail in TSD Chapter 3.1.2.2.

In any case, that summation is not correct. For example, the MYs 2012-2016 rule estimated costs of roughly $950 (2007$) in MY 2016. However, that $950 would be considerably lower by the 2025 MY due to learning on the technologies included in that 2016 MY vehicle. Also, the MY 2011 CAFE rule used an estimate of indirect costs substantially higher than that used by EPA in the MYs 2012-2016 and 2017-2025 rules. EPA finds that it is inappropriate to use the costs (or benefits) from previous rulemakings to assess the impacts of this rule. The costs (and benefits) from previous rules are used in the reference case for this rule. In fact, Table 3.9-1 of EPA's final RIA shows that the 2025MY reference case costs for this final rule (i.e., the costs of meeting the 2016MY standards in the 2025MY) are $719 (2010$) relative to the 2008 baseline and includes the additional costs of compliance with 2009-2010 CAFE, and is still far lower than the $950 (2007$) estimated to meet the 2016MY standard in the 2016MY as estimated in the MYs 2012-2016 final rule. As a result, we would roughly estimate the cost of meeting the 2025MY standard in the 2025MY as $1836+$719=$2555 relative to a 2025MY vehicle meeting the 2008MY standard.[25] Clearly, our estimate is far less than NADA's. Finally,

[25] The $719 value actually includes costs to meet NHTSA's MY2011 standards in MY2025. To clarify, in the MYs 2012-2016 final rule, we estimated the cost to meet the MY2011 standard in MY2016 at $89 (2007$) (see

as discussed in preamble section III.H.2.a, Chapter 3.1.2 of the joint TSD and below in our response to comment 12.3.2, EPA does not agree with NADA's arguments for a markup for indirect costs that doubles direct costs.

Regarding the suggestion from Delphi that the NRC technology cost estimates and implementation cadence data be included in our analysis as the primary source of information, we have not followed that suggestion. We believe that the cost teardown work conducted by FEV for EPA and the battery pack model developed by ANL represent the most up-to-date and best information available on the costs of technologies upon which our analysis relies. This issue is discussed in the final section of RIA chapter 3. The comments from NRDC are also related to the NRC report, and their comment is addressed to NHTSA.

Regarding the comment from Environmental Consultants of Michigan, the point of the comment appears to be that hybrids have higher cost of ownership than do more traditional internal combustion engine-only vehicles. These higher costs are claimed to result from higher insurance costs, higher registration fees due to higher weights, higher financing costs and sales taxes. Without addressing the merits of the metrics provided by the commenter, we wish to point out that the MYs 2012-2016 rule and 2017-2015 rules combined include a penetration rate of strong hybrid technology of 5% and of mild hybrid technology of 26% (which were not addressed by the commenter). As can be seen from this analysis, we are not relying heavily on strong hybrid technologies in projecting potential compliance paths. Further, we would expect that, at 5% penetration, most of those hybrids will be purchased by people that want the hybrid for reasons that may well extend beyond cost of ownership considerations (i.e., image, prestige, etc.). Further, the weights of the strong hybrids in our analysis are not expected to be any higher (and most are expected to be lower) than in today's vehicles. Lastly, the commenter suggests that hybrids experience more rapid depreciation than non-hybrids due, in part, to anticipated battery replacement costs. The commenter fails to consider the *possibility* that, should the assertion be true that depreciation is more rapid on hybrids, the cause may not be due to anticipated battery replacement costs but rather the rapid and ongoing improvement of new hybrid technologies making new hybrids more attractive than used hybrids. This may well be in stark contrast to the non-hybrid case where new non-hybrids are not seen as being demonstrably better than their used counterparts. Further, our review of independent reliability data suggests that hybrid vehicles are just as reliable, if not more so, than their non-hybrid counterparts (see Chapter 5.2.2.2 of the final RIA).

Regarding the comments from ICCT, we agree that the Lotus and FEV lightweight vehicle studies that were not completed in time for inclusion in the final rule analysis provide better cost estimates than those used in the final analysis. Though this study is complete now, unfortunately, we were not able to use those estimated costs, as stated above and in TSD 3.3.5.5. We agree with all of the other comments provided by ICCT concerning the Lotus and FEV lightweight material studies. We agree with ICCT that teardown studies provide better cost estimates than do paper studies. ICCT also commented that our proposed cost estimates were

EPA-420-R-10-009, Table 4-6 at page 4-18) which would probably be on the order of $50-$70 (2010$) for meeting the MY2011 standard in MY2025. Therefore, the $2555 value stated here is slightly high since it already includes the costs of meeting the MY2011 standard in MY2025.

too high and should be much lower than $2000. In fact, our final cost estimate (without using the teardown results) is $1836, or roughly $110 lower than the cost estimate we used at proposal and lower than $2000.

Regarding the comment from the NACAA, we assume that the claim that, if vehicles equipped with the technologies needed to meet the MY 2025 emissions were introduced earlier then the additional cost should be lower than $2000 is a reference to learning effects starting earlier and resulting in lower costs by 2025. While that may be true, one cannot lose sight of the need to introduce new technologies at a sustainable and reasonable pace. Our technology phase in caps describe what we believe to be the maximum rate at which technologies might be introduced. While it's possible that some manufacturers may introduce technology faster, we believe that others may be even slower. The rate of introduction of technology is an important aspect of the fleet that we will watch very closely in the future. There are some disadvantages to introducing technologies sooner, and manufacturers may not even be capable of doing so because of supplier limitations, and product redesign cycles. We have attempted to provide the auto makers sufficient time to introduce new technologies on a pace that is consistent with our understanding of technology availability and learning.

12.3.1. Direct Manufacturing Costs

Organizations Included in this Section

Natural Resources Defense Council (NRDC)
Porsche Cars North America, Inc. (PCNA)

Organization: Natural Resources Defense Council (NRDC)

EPA should continue its current practice of conducting tear-down cost analyses. [EPA-HQ-OAR-2010-0799-9472-A2, p. 4]

Organization: Porsche Cars North America, Inc. (PCNA)

Battery Costs

Porsche believes that the agencies grossly underestimate the cost of battery technology. This error inappropriately inflates the apparent cost effectiveness of the GHG program. [EPA-HQ-OAR-2010-0799-9264-A1, p. 6]

Response:

Regarding the NRDC comment, as we move forward and identify possible future needs for further teardown work, we fully intend to do so. We believe that the teardown studies conducted in support of our GHG efforts provide the highest quality and most up-to-date cost estimates for GHG reducing technologies.

Regarding the Porsche comment, we have trouble understanding why the commenter believes we have underestimated battery costs given the lack of detail provided in the comment. We welcome Porsche to submit data publicly that supports their comments. Our battery costs are based on the ANL BatPaC model, a peer reviewed model that estimates direct manufacturing costs associated with batteries used in hybrids, plug-in hybrids and full electric vehicles. For hybrids, we have taken those direct costs as being applicable in the 2017MY, which seems appropriate assuming sales of 15 million vehicles and a 3% hybrid penetration rate (the costs we used from the ANL BatPaC model assumed 450,000 units, or 3% of 15 million). We have then applied our High 1 ICM of 1.56 to those direct costs to estimate the total costs for the batteries. Further, we apply learning effects going forward from 2017 through 2025 to arrive at our 2025MY costs. For hybrids, we have assumed that the batteries are on the flat portion of the learning curve by the 2017MY and continuing through 2025 making the 2025MY costs roughly 78% of the 2017MY costs. We believe this is reasonable given the nine years of learning and cost reduction that will undoubtedly take place between 2017 and 2025.

For plug-ins and full EVs, we have taken the BatPaC direct costs as being applicable in the 2025MY, a full 14 years from now. As such, we have applied no learning curve cost reductions to plug-in and EV batteries for our 2025MY costs. We “reverse learn” (i.e., back out learning effects to increase the costs) for years prior to 2025. Further, for plug-in and full EV batteries, we have applied our High 2 ICM of 1.77 to the direct costs to estimate the total costs. Again, we believe that these cost estimates are sound. As described in TSD 3.3.3 the BatPac model is peer reviewed.

Lastly, we have conducted several sensitivities that serve to both increase and decrease our battery pack cost estimates—battery pack costs, learning effects and ICMs—and for each of these sensitivities, we see very little impact on our overall program costs and benefits. This is largely due to the low penetration rates of battery-based technologies like strong hybrids, plug-ins and full EVs.

12.3.2. Indirect Costs

Organizations Included in this Section

International Council on Clean Transportation (ICCT)
National Automobile Dealers Association (NADA)

Organization: International Council on Clean Transportation (ICCT)

7. RPE indiscriminately spreads all indirect costs over all components, while ICMs reflect only those elements of indirect costs that would be expected to change in response to a regulatory-induced technology change. The use of RPE is not appropriate and the sensitivity analyses presented in Tables IV-88, IV-89 and IV-90 should be removed from the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

7) RPE and ICM

ICCT agrees with the use of indirect cost multipliers (ICM) instead of Retail Price Equivalent (RPE) and the general approach of assigning technologies to several complexity classes for determining the ICM value. Trying to determine the indirect multiplier for each technology would be extremely difficult and time consuming, but it is also important to use more appropriate and targeted adjustments than a single, indiscriminant RPE. [EPA-HQ-OAR-2010-0799-9512-A1, p. 19]

For this rule proposal EPA improved the original ICM factors that have been used in other regulatory assessments in two ways. First, the original ICM factors for low and medium technology complexity were updated; the updated ICM factors were developed following expert panel recommendations on newer technologies (passive aero-reduction, engine downsizing and turbocharging and 40-mile range PHEV). Second, the way ICM factors are applied was modified, '...resulting in the warranty portion of the indirect costs being applied as a multiplicative factor (thereby decreasing going forward as direct manufacturing costs decrease due to learning), and the remainder of the indirect costs being applied as an additive factor (thereby remaining constant year-over-year and not being reduced due to learning)'. In addition, the original RPE values used by EPA were increased from 1.46 to 1.5 as a way to reflect long-term average RPE values. Table 3 shows the evolution of ICM and the change to RPE values on the 2017-2025 Rule (High 2, Long term). [Table 3 can be found on p. 20 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 19]

ICMs are a better methodology for indirect cost estimation than the RPE multipliers used in previous rulemakings. The development of ICMs as a tool for indirect cost assessment has been conducted in a most rigorous way and the study results have been peer reviewed in well known scientific journals.24 The most critical distinction between ICMs and RPE is that ICMs have been developed 'to reflect only those elements of indirect costs that would be expected to change in response to a regulatory-induced technology change.' [EPA-HQ-OAR-2010-0799-9512-A1, pp. 19-20]

However, in the Sensitivity Analysis section IV (NHTSA Proposed Rule for Passenger Car and Light Truck CAFE Standards for Model Years 2017-2025, page 75307 of the Federal Register), the proposal presents two sensitivity calculations that neglect the fundamental advantages of using ICMs. The first sensitivity calculation evaluated the economic impact of technology cost on CAFE fuel economy using RPE for indirect costs for all technologies instead of ICMs (Table IV-88). The second sensitivity calculation (Table IV-89) involves cost values derived from a different source, namely the National Academy of Sciences assessment on LDV fuel economy technologies; the NAS report uses two sets of RPEs, one for non-electrification technologies and another one for electrification technologies (Hybrids and EVS).25 [EPA-HQ-OAR-2010-0799-9512-A1, p. 20]

The use of a single RPE of 1.5 for all technologies, instead of a technology based ICM, inflates the costs per vehicle by 24%, from $2023 to $2509. The second method uses a RPE of 1.5 for non-electrification technologies, which are mostly low- and medium-complexity options and comprise the bulk of the technologies to be adopted in the future; as a result the cost per vehicle is inflated by 39%. [EPA-HQ-OAR-2010-0799-9512-A1, p. 20]

The ICCT believes that the use of RPE for these two sensitivity analyses is inappropriate and distorts the cost results. The problem stems from lumping indirect costs indiscriminately, as the

RPE method does. The RPE method does not consider that new technologies will not necessarily incur additional indirect costs. RPE spreads all indirect costs over all components, while ICMs reflect only those elements of indirect costs that would be expected to change in response to a regulatory-induced technology change. For example, it is appropriate to include warranty costs in the indirect costs for new technologies, while marketing costs would not change in response to adding many incremental technologies. Unless the technology is directly marketed to consumers, it is inappropriate to spread existing marketing costs to the new technology. Many individual technologies are small in scale and should reflect only a subset of RPE costs; as a result, for low complexity technologies, the ICM should be lower than the RPE. This is not always the case, as ICM estimates for particularly complex technologies, specifically hybrid technologies (for near term ICMs), and plug-in hybrid battery and full electric vehicle technologies (for near term and long term ICMs) reflect higher than average indirect costs. As a result, the ICMs for those technologies can equal or even exceed the averaged RPE for the industry.' [EPA-HQ-OAR-2010-0799-9512-A1, pp. 20-21]

The ICCT strongly supports the continued use of ICMs and the adjustments made for the proposed rule. The sensitivity analyses presented in Tables IV-88, IV-89 and IV90 should be removed from the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 21]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 29-30.]

The ICCT also agrees with EPA's assessment of indirect cost that specifically addresses the factors that increase the retail price compared to the direct costs and generally -- and the general approach of assigning technologies to several complexity classes for determining the indirect cost multipliers. The use of generic retail price equivalency markup to cover a wide range of factors that are not consistent over different technologies often results in overestimating those costs. And we would recommend the Agency to scrap the sensitivity analysis conducted using the RPE markups.

---

24 Rogozhin, A., Gallaher, M., Helfand, G., McManus,. W., Using Indirect Cost Multipliers to Estimate the Total Cost of Adding New Technology in the Automobile Industry, International Journal of Production Economics 124 (2010): 360-368.

25 NAS. (2011). Assessment of Technologies for Improving Light Duty Vehicle Fuel Economy. National Academy of Sciences, Committee on the Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy; National Research Council. National Academies Press. Washington, DC.

Organization: National Automobile Dealers Association (NADA)

The proposal fails to fully account for all of the up-front marginal costs prospective new vehicle purchasers can expect to face due to the MY 2017-2025 CAFE/GHG mandates. In doing so, it fails to appropriately recognize the potential impacts those mandates will have on light-duty vehicle affordability and sales. Specifically, the proposal uses a non-traditional approach to estimating light-duty retail cost/price called the Indirect Cost Multiplier (ICM) method. [EPA-HQ-OAR-2010-0799-9575-A1, p. 4]

The traditional approach, used for at least 30 years by NHTSA and EPA and vehicle manufacturers to calculate the cost of regulations impacting motor vehicles, involves an accounting method known as Retail Price Equivalent (RPE). The RPE method appropriately estimates the ratio of indirect costs (marketing, indirect labor, etc) to the retail price for the whole vehicle, adjusting accordingly the direct costs (engineering, manufacturing, etc.) associated with new components. [EPA-HQ-OAR-2010-0799-9575-A1, p. 4]

The ICM method, which NHTSA and EPA first attempted to use to develop their MY 2012-2016 program, involves a somewhat arbitrary selection and allocation of indirect costs to certain compliance-related components. Under this approach, by no means the standard accounting method used by vehicle manufacturers, the whole cost of the vehicle rarely if ever reflects the sum of its parts. In addition, as detailed in the attached paper comparing the use of the RPE method to the ICM method, NHTSA and EPA use their ICM method differently for this proposal than they did for the MY 2012-2016 rule. For these and other reasons detailed in Exhibit A, NHTSA and EPA should recalculate average per vehicle costs for the proposal using the RPE method of accounting. To assist with that effort, the paper in Exhibit A attempts to do so, and even assumes NHTSA and EPA's projections of the technologies manufacturers will have to adopt to achieve compliance with the proposed standards. [EPA-HQ-OAR-2010-0799-9575-A1, p. 4]

Response:

Regarding the comments from ICCT that RPE indiscriminately spreads indirect costs over all components, we agree with ICCT and that is a big part of the reason we believe that the ICM approach is more appropriate for estimating costs in response to regulatory imposed changes. As for removing the RPE sensitivity, that comment is directed at NHTSA's analysis since EPA has not conducted a sensitivity using an RPE rather than ICMs.

We also agree with ICCT that our updated approach to applying ICMs (see Chapter 3.1.2.2 of the joint TSD), as first presented in the proposal and also used in the final rule—is more appropriate than our prior approach of applying the ICM as a simple multiplier.

Regarding the NADA comments, NADA argued that the ICM approach is not valid and should be replaced with an RPE approach. Further, it argued that the RPE factor should be 2x rather than the 1.5x approach that is supported by filings to the Securities and Exchange Commission. We have conducted a thorough analysis of the NADA comments on the RPE vs. ICM approach. We disagree with NADA's arguments for both using the RPE approach and a 2x RPE factor, for the following reasons.

NADA's objections to the ICM approach include:

1. There is no evidence that the RPE method is flawed.

2. The ICMs do not include the total costs of complying with the standards, because it does not include all the costs included in the RPE.
3. The ICMs use a subjective judgment to adjust indirect costs for different technologies, while the RPE uses one value for all components and does not rely on "nearly perfect foreknowledge."
4. The ICMs do not incorporate dealer and OEM profits.

NADA's arguments for the RPE of 2x include:

5. Several scholarly papers support the use of RPEs in the 2.0 range.
6. A case study comparison of the added content of a 1971 Chevrolet Vega and 2011 Cruze shows that an RPE of 2.0 accounts for the change in retail price.

The discussion above provides background on the issue of RPEs and ICMs, and on the agencies' decision to use ICMs to estimate indirect costs for this rulemaking. Our responses here address the specific points raised by NADA.

First, the RPE approach applies the same average indirect cost markup across all technologies in the redesigned vehicle fleet, regardless of the source of the direct cost (i.e. whether a technology is simple or complex; whether the source of the additional cost is a new or a mature technology). The RPE methodology also assumes that an indirect cost is associated with the rule, even if no relation is apparent. For instance, the RPEs (until recent union contract changes) would have included the costs to the domestic auto companies of the health insurance for retired auto workers. Because the rulemaking would not affect the current retiree health care costs, (which account for about 1.5% of the RPE), they are irrelevant to the rulemaking. The ICM approach differs in that it allows indirect costs to vary with the complexity of the technology and the time frame. It is a reasonable assumption that simple technologies are expected to have fewer indirect costs per dollar than complex technologies. For instance, the use of low-rolling-resistance tires, considered by the EPA/NHTSA team to be a low-complexity technology, adds costs, but, because they require significantly less vehicle integration effort than for example, adding a hybrid powertrain would, the additional indirect costs per dollar of direct manufacturing costs may be very low. In contrast, converting a conventional vehicle to a hybrid-electric is a far more complex activity, involving increases in indirect costs such as research and development disproportionate to its direct costs. Shortly after product introduction, indirect costs for components such as warranty and research may be relatively high, but auto makers are reasonably expected to be able to reduce the costs of any specific technology over time, as they gain experience with them and, thus, redirect those expenditures to other areas of their choosing.

Second, the ICM approach excludes some costs included in the RPE when those costs are expected not to be affected by the standards. The ICM approach, as discussed above, begins with the RPE and includes all the relevant cost categories. ICMs reflect the indirect costs judged by the EPA panel (see above for further explanation) to be incurred for each technology in response to regulatory imposed changes. Any "omissions", or instances where the ICM carries no costs for a given technology, are cases where the indirect costs are considered by the EPA panel not to be impacted by regulation-imposed changes for that technology. For instance, the costs of switching from a standard tire to a low-rolling-resistance tire (the example of a low-complexity technology in Rogozhin et al. (2009)) are not expected to lead to an increase in transportation costs (i.e., costs for transporting finished vehicles from production site to retail site) because it is not expected to be any more expensive to ship a new vehicle with the new tires than with the old tires.

Third, the RPE approach relies on the assumption that applying the average RPE for the vehicle fleet as a whole will produce a reasonable average indirect cost for all technologies in the redesigned vehicle fleet resulting from these standards. The agencies believe that using the professional judgment and expertise of EPA staff with extensive experience in the auto industry provides useful insight into how a given regulation will impact indirect costs and is an improvement over ignoring differences among technologies. The agencies have therefore based their central analyses on the ICM method.

Fourth, it is incorrect that the ICMs do not include OEM profit. Although the initial ICM report reviewed by NRC did not include OEM profit, the ICM approach applied in this rulemaking does incorporate an allowance for profit, at the average corporate profit rate of 6% of sales. The inclusion of profit for the Joint NPRM is discussed in the draft Technical Support Document, and the agencies have included profit as an element of the indirect costs for the final rulemaking as well. See Joint TSD section 3.1.2.2 endnote 19 and sources there cited.

Fifth, the papers cited by NADA to support the use of an RPE of 2x are only a subset of the literature. The National Research Council (NRC) discusses the four studies that NADA's Exhibit A cites in its support of an RPE of 2.0. The NRC also notes that NHTSA used an RPE of 1.5 for its MY 2011 fuel economy rule; the NRC in 2002 used an RPE of 1.4, as did the California Air Resources Board; and EPA has used a markup factor of 1.3. The NRC report then discusses work done for the committee itself, doing a detailed analysis of a Honda Accord and a Ford F-150 truck; the former had an RPE of "1.39 to market transaction price and 1.49 to MSRP," and the latter had an RPE of "1.52 for market price and 1.54 for MSRP." Most significantly, the NRC does not recommend an RPE of 2.0. Rather, the NRC recommends, for technologies where the primary manufacturer of the technology is the automotive supply base, an RPE of 1.5, except for hybrid powertrain components from the automotive supply base, where it recommends an RPE of 1.3 due to the inclusion of several indirect costs in their base estimate. Only in the case of technologies where an automotive OEM is the primary manufacturer does the NRC recommend an RPE of 2.0. We note, without specifically commenting on the quality of the studies, that none of the papers NADA cites in support of an RPE of 2x was published in a peer-reviewed journal, and none of the studies claim to have been peer-reviewed. In contrast, the research in Rogozhin et al. (2009) was peer-reviewed twice: as documented in the Peer Review Report, and when it was submitted (and accepted) for publication in the International Journal of Production Economics. A full reading of the literature on RPEs thus shows little support for a value of 2x. Further support for an average RPE lower than 2.0 comes from an examination of industry financial statements. NHTSA examined industry 10-K submissions to the Securities and Exchange Commission from the period 1972-1997. The cost information in these submissions represents all industry operations, including both OEM and supplier-sourced technologies. During this period, the RPE averaged 1.5 while varying slightly, but never dropped below 1.4 or exceeded 1.6. At no time did the average RPE approach the 2.0 value advocated by NADA.

Sixth, the comparison of the Vega and the Cruze uses circular logic; it assumes its conclusion. The direct costs of the vehicles are calculated using an RPE of 2, and the NADA analysis then calculates a quality difference based on the change in direct costs. The magnitude of the quality difference is then discovered to correspond to an RPE of 2, although it is also an inevitable result of the initial assumption of an RPE of 2. The analysis provided can be replicated with any value of RPE. This argument thus provides no evidence on the value of the RPE.

For these reasons, we do not accept NADA's request to use an RPE of 2x, and instead continue with our use of ICMs as the basis for our central analysis. However, the agencies recognize that there is uncertainty regarding the impact on indirect costs of regulatorily imposed changes. For this reason, both agencies have conducted sensitivity analyses using different indirect cost estimates. EPA presents its sensitivities in Chapter 3.11 of its final RIA where we show costs ranging from roughly $200 less to roughly $200 more than our primary case by adjusting ICMs to the low side and the high side, respectively. Therefore, even with the considerably higher indirect cost markups, the benefits of the final rule would be significantly higher than the costs.

12.3.3. Learning

Organizations Included in this Section

Alliance of Automobile Manufacturers

Organization: Alliance of Automobile Manufacturers

Are the Costs of Advanced Technologies Declining as Predicted? [EPA-HQ-OAR-2010-0799-9487-A1, p.18]

Future technology costs are among the most difficult things to predict for MY 2020 and beyond. Factors that can change significantly over time include the availability and price of materials and parts, the number of suppliers and the rate of progress toward the production levels needed to achieve economies of scale. [EPA-HQ-OAR-2010-0799-9487-A1, p.18]

Recently, the National Research Council of the NAS issued its Assessment of Technologies for Improving Light Duty Vehicle Fuel Economy ("NAS Report"). Although the NAS report provides future cost estimates for numerous technologies, the NAS warns that data from automobile manufacturers and Tier 1 suppliers suggests a wide range of estimated incremental costs "that makes assessments of cost-effectiveness very approximate." The NAS characterizes future technology costs as more difficult to predict than the impact of these technologies on fuel consumption. In some cases, the NAS cost estimates were significantly higher than those of the agencies. [EPA-HQ-OAR-2010-0799-9487-A1, p.18]

The uncertainty surrounding the costs of integrating new technologies and then reaching economies of scale is illustrated in NHTSA's discussion of how to assign markup factors for "learning." The Preliminary Regulatory Impact Analysis describes steps that NHTSA would need to take to develop accurate historical "learning" costs estimates for seven new CAFE and safety technologies. NHTSA concludes: [EPA-HQ-OAR-2010-0799-9487-A1, p.18]

This initial analysis…indicates that adopting a cumulative production basis for learning applications could produce cost estimates that are within 4-7% of those used in the NPRM by 2025, with less variation in earlier years. However, this analysis is based on a very small sample of technologies and the data required to more precisely evaluate this issue are currently unavailable. Further, these data may not be obtainable without an extensive research effort, if at all. [EPA-HQ-OAR-2010-0799-9487-A1, p.18]

Response:

We agree that future technology costs are very difficult to predict. We also believe that the effort we have made at doing so is unprecedented for EPA transportation-related rules and that we have developed the highest quality and most up-to-date technology cost estimates available today. EPA will also continue to monitor the costs of key technologies going forward. That said, we have conducted several sensitivities that serve to both increase and decrease our cost estimates—battery pack costs, learning effects, ICMs, and weight reduction costs—and for each of these sensitivities, we see very little impact on our overall program costs and benefits.

12.3.4. Maintenance Costs

Organization: National Automobile Dealers Association (NADA)

The benefits analysis used in the proposal uses an oversimplified pay-back method that overstates potential fuel economy savings. Instead, for purposes of calculating any "pay-back," real-world finance, opportunity, and additional maintenance costs should be accounted for. In other words, the final rule should evaluate its potential impact on a vehicle's total cost of ownership. An example of such a calculator is found at http://www.nadaguides.com/Cars/Cost-to-Own. [EPA-HQ-OAR-2010-0799-0639, p.10]

Response:

We have included maintenance costs in the final analysis—in both the benefit-cost analysis and the cost of ownership and payback analysis. We present our maintenance intervals and costs per interval in Chapter 3.6 of the joint TSD. We present our full analysis of maintenance costs in Chapter 5.2.2.1 of our final RIA and our cost of ownership analysis in Chapter 5.5 of our final RIA. We also respond more fully to NADA's comments in Chapter 5.5 of the final RIA.

12.3.5. Stranded Capital

Organizations Included in this Section

Center for Biological Diversity
International Council on Clean Transportation (ICCT)

Organization: Center for Biological Diversity

Further, the Agencies must delete from their analysis the supposed cost of “stranded capital,” or capital invested in manufacturing equipment that cannot be used when new technology is introduced. Because this rulemaking stretches over at least two complete redesign cycles, there is adequate lead time to amortize such costs within industry’s normal business operations. In other words, this and other relics carried over from shorter-term rulemakings that purported to take account of concerns about inadequate lead times must be scrapped. [EPA-HQ-OAR-2010-0799-9479-A1, p. 7]

Organization: International Council on Clean Transportation (ICCT)

9. Given the long lead times in the proposed rule, stranded capital costs will be virtually eliminated and should be removed or greatly reduced in the cost analyses. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

9) Stranded Capital Costs

The agencies state that 'potential for stranded capital occurs when manufacturing equipment and facilities cannot be used in the production of a new technology'.29 This is a valid concern, but it applies primarily to rulemakings with shorter leadtimes. Perhaps the most important purpose of proposing standards through 2025 is that it gives manufacturers far more certainty about the future standards. This enables the manufacturers to plan and implement technologies and products in an orderly manner and minimizes issues with stranded capital. Also, the standards are not stringent enough to force technology introduction at a rate faster than normal production cycles. [EPA-HQ-OAR-2010-0799-9512-A1, p. 22]

The ICCT recommends that stranded capital costs be eliminated to reflect the long leadtime of the proposed standards. [EPA-HQ-OAR-2010-0799-9512-A1, p. 22]

29 section 3.2.2.3 of the TSD, Table V-24 of NHTSA RIA, and Sections 3.8.7

Response:

We believe that it is difficult to quantify accurately any capital stranding associated with new technology phase-ins, especially given the projected and unprecedented deployment of technologies in the rulemaking timeframe. The FEV analysis that looked at potential stranded capital attempted to define the possible stranded capital costs for a select set of technologies. Since the direct manufacturing costs developed by FEV assumed a 10 year production life (*i.e.*, capital costs amortized over 10 years) we applied the FEV derived stranded capital costs whenever technologies were replaced prior to being utilized for the full 10 years. The other option would have been to assume a 5 year product life (*i.e.*, capital costs amortized over 5 years), which would have increased the direct manufacturing costs. We have accounted for stranded capital costs in the instances where our fleet modeling replaced technologies before the capital costs were fully amortized. While there is uncertainty about the possible stranded capital costs (*i.e.*, understated or overstated), their impact would not call into question the overall results of our cost analysis or otherwise affect the stringency of the standards, since costs of stranded capital are a relatively minor component of the total estimated costs of the rules. Table 5.1-5 of the final RIA presents the stranded capital costs used in our analysis; this table is copied below. As shown by this table, the stranded capital costs are relatively low so, even if we have overestimated these costs, their impacts are minor.

Table 12-1 Interpolated Estimates of Stranded Capital Costs (2010$)

Company	2017	2018	2019	2020	2021	2022	2023	2024	2025
Aston Martin	$60	$54	$48	$41	$35	$31	$26	$21	$17

It is my hope that the two attachments

1. Proposed 2017 - 2025 CAFÉ, A personal study, The ICE POSSIBILITIES and OPPORTUNITIES - COSTS, FUEL ECONOMIES, and Concerns 2/7/2012

2. Supplement Proposed 2017 - 2025 CAFÉ, A personal study, The ICE POSSIBILITIES and OPPORTUNITIES - COSTS, FUEL ECONOMIES, and Concerns 2/13/2012

offer a positive and constructive technical and economic contributions toward this US effort to address future fuel consumption rates and CO_2 emissions reduction. [NHTSA-2010-0131-0240, pp.1-2]

Opportunities, and Conclusions

If these 335 (343?) vehicles were available in the US today, there is a high probability almost 23% of new US offerings would provide user experience mpg averages approaching, if not exceeding, the currently proposed NOMINAL of 54.4 mpg for 2025 CAFÉ … today … for the light-footed US drivers using these fuel frugal small displacement, generally under 2 Liters, diesel models, many already seen on the US roads using their significantly less fuel frugal gasoline powertrains, see Table 1 or Table 3 Largest Models ?60 mpg(Imp) combined for some of the model configurations studied. [NHTSA-2010-0131-0240-A2, p.4]

Of course there are questions of correlation between EPA and NEDC ratings as well as USER experience. The US VW/Audi diesels “Shared MPG Estimates” suggest viable correlations exist with NEDC. And, 'Predicting Individual Fuel Economy' by Lin, Z., and Greene, D. address other related US issues. [NHTSA-2010-0131-0240-A2, p.5]

Almost all of these fuel frugal vehicles are small displacement diesels, raising issues of emissions. Euro Step V should have resolved issues with particulates leaving the NO_X concerns since ? 180 mg NO_X/km is the current EU requirement. Most of these vehicles are currently certified between 110 and 150 mg NO_X/km. [NHTSA-2010-0131-0240-A2, p.5]

Starting 4Q 2014 (32 months) Euro Step VI requires ? 80 mg NO_X/km for all new certifications of these vehicles. That is ? 37 mg/km worst case outside the current US requirement of roughly ? 43 mg NO_X/km. [NHTSA-2010-0131-0240-A2, p.5]

Could some compromise regarding mg NO_X/km levels be allowed as long as annual sales volumes for these very fuel frugal vehicles remain below, for sake of discussion, 1 (or 0.5) million units/year? That would be an average of ?20k vehicles for each State annually. [NHTSA-2010-0131-0240-A2, p.5]

Would that level of market penetration pose an unacceptable risk to man and/or environment versus the benefits? The 2011 US clean diesel sales were ?100K, roughly 70% relatively fuel frugal from VW/Audi. [NHTSA-2010-0131-0240-A2, p.5]

Could this be allowed as a temporary legislative regulatory waiver until volumes exceed ½ million annually or 2016, whichever comes first, before enforcement of full US emissions standards, as a quick, low cost, low risk strategy to educate the US consumer and test market for determination of consumer acceptance … and preferences? [NHTSA-2010-0131-0240-A2, p.5]

This would reduce OEMs’ costs and risks (as well as objections) to introducing this relatively lower cost fuel conserving technology without Federal or State funding as a bridge to future technologies. [NHTSA-2010-0131-0240-A2, p.5]

This could offer a quick, very low cost, low risk path to saving 400~500 gallons of gasoline (about 24 barrels of crude) per vehicle year for the life of the vehicle when compared to the 2011 US fleet average of 22.2 mpg. And, achievable at a lower cost than most proposals currently under public consideration. [NHTSA-2010-0131-0240-A2, p.5]

IF, assembled in the US and reasonably priced, this should expand the current US auto market demand, increasing domestic production … creating NEW US industrial jobs simply by changing the current US powertrains to existing fuel frugal European small displacement (? 2 Liter) turbo diesel technology. [NHTSA-2010-0131-0240-A2, p.5]

Based on Table 1: Relative UK Cost and Fuel Economy BENEFIT Analysis (gasoline versus diesel), these fuel economies can, on average, be achieved with an average ? USD $2k technology cost premium per vehicle, IF … we, as a Nation, are determined … and the OEMs do offer AND deliver to the US consumer these types of fuel frugal machines with comparable EU diesel powertrain pricing differentials. [NHTSA-2010-0131-0240-A2, p.5]

Unfortunately, if Det3 US are not at parity with world fuel economy and CO_2 emissions by post 2015, they will be under constant threat from “foreign” OEMs like Kia, Hyundai, Mazda, & Volvo for importation of fuel frugal choices already offered in the EU and Asia resulting in subsequent loss of US market share & US JOBS.

It is very important to understand that FUEL FRUGAL small displacement (? 2 Liters) Euro type turbo diesels are a potentially viable near term interim bridge solution to allow time for ADVANCED transport technologies, whether plug-in, fuel cell, or other yet to be found technology, to evolve and mature (cost, reliability, durability, and economies of scale) necessary for the broader based US (and WORLD) markets, not just the elite/wealthy … in order to maintain/improve standards of living. [NHTSA-2010-0131-0240-A2, p.6]

Does the US want/NEED fuel conserving vehicles NOW? IF, yes, what should WE do to get there? This is one way. [NHTSA-2010-0131-0240-A2, p.6]

Response:

Regarding the ACEEE comment about our output sheets, these were made available in the public docket at document ID EPA-HQ-OAR-2010-0799-1105.

Regarding comments from F.W. Jackson and Frank Houston Smith, we appreciate your comments and your interest in our proposal. Regarding relaxing NOx standards to allow for diesels to more easily meet US emission standards and, therefore, play a larger role in the US auto market, we disagree with this idea. We have set stringent, fuel neutral emission standards for purposes of public health and do not believe it is appropriate or necessary to compromise public health by relaxing the standards for diesel-fueled vehicles (see 65 FR 6698). We believe that diesels can meet our stringent standards, and we welcome diesels as part of the light-duty technology mix. The lack of significant diesel penetration in our analysis simply means that we do not believe that it provides for the most cost effective path to compliance. It should not be interpreted as a condemnation of the technology or a prohibition of it as auto makers are free to use whatever technology they choose provided they can comply with applicable standards.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 168.]

Importantly, proposed targets will unlikely compromise vehicle safety. Cars have been getting safe as fuel economy has improved. And this trend will continue.

The safety of future vehicles will be dominated by vehicle design, not size and weight. Advanced materials can decouple size from mass and therefore give economy, safety and functionality that people require.

Organization: Consumers Union

Importantly, the proposed standards are unlikely to compromise vehicle safety. Cars have been getting safer as fuel economy has improved, and this trend is likely to continue. The safety of future vehicles will be dominated by vehicle design, not size or weight. Advanced materials can decouple size from mass (weight), creating important new possibilities for simultaneously improving both fuel economy and safety without compromising functionality. [EPA-HQ-OAR-2010-0799-9454-A2, pp.2-3]

Organization: Haroldson, C.

vehicles will necessarily become too small to be safe to drive. [EPA-HQ-OAR-2010-0799-11137-A1, p. 1]

Organization: Institute for Energy Research (IER)

One of the most obvious effects of higher fuel efficiency is a lighter vehicle, which (other things equal) means a vehicle that provides less safety for its occupants in the event of a crash. Anecdotally, it is typical to hear a father explain his vehicle purchase for a daughter going off to college in terms of its safety, rather than couching the decision in terms of how much money she will save in fuel expenditures. [EPA-HQ-OAR-2010-0799-9573-A1, p. 14]

Scholarly studies have attempted to quantify the extra motorist deaths attributable to the CAFE standards first put into place in the 1970s. Depending on the particular assumptions and the time frame chosen, the estimates range from 41,600 to 124,800 deaths. A 2002 National Academy of Sciences study found that the downsizing effect of CAFE led to 1,300 to 2,600 deaths in a single year and ten times that many serious injuries. Also, weight in vehicles still matters and one way to get better fuel efficiency is through weight reductions. A study from the Insurance Institute for Highway Safety recently found that “strong relationship between vehicle weight and occupant safety.” In fact, they found that “Hybrids on average are approximately 10 percent heavier than their conventional counterparts and have lower injury rates in a crash. . . the odds of sustaining an injury in a hybrid were about 25 percent lower than in a lighter non-hybrid vehicle.” [EPA-HQ-OAR-2010-0799-9573-A1, pp. 14-15]

It is important to note that even if the EPA’s analysis is correct to assume that vehicle consumers do not correctly calculate the lifetime savings from higher fuel efficiency, then by the same token we must allow for the possibility that vehicle consumers may not correctly estimate the higher probability of injury or death from driving a car that is lighter or has less space between the steering wheel and driver’s seat, etc. In order to achieve its findings of a pure boon to consumers, the EPA analysis assumes that the higher mileage standards are achieved through holding all else constant, and increasing the final price of vehicles. But in reality, in the new equilibrium the “irrational” and “myopic” consumers may buy vehicles that achieve the new efficiency mandates through a combination of less safety and only slightly higher prices. To the extent that this calculation is “irrational” and “myopic,” the regulations may reduce one type of inefficiency (i.e. excessive fuel consumption) while increasing another one (i.e. excessive crash deaths). EPA certainly has offered no argument showing that fuel consumption is a more serious social problem than traffic fatalities.37 [EPA-HQ-OAR-2010-0799-9573-A1, p. 15]

---

37 To be clear, the text refers to traffic fatalities that result from consumers incorrectly estimating the tradeoff between vehicle price and safety. The EPA analysis does incorporate costs from traffic accidents, but these appear to include only the accidents due to extra driving, not to consumer “irrationality” regarding vehicle safety.

Organization: Institute for Policy Integrity, New York University School of Law

More importantly, the relationship between size and safety is neither simple nor unidirectional. To the extent smaller cars fare worse in crashes with bigger cars, increasing size may improve an individual driver’s safety; but it may simultaneously impose a negative safety externality on other drivers, whose cars are now relatively smaller compared to the growing average fleet size. Decreasing size may have similarly opposing impacts on safety. Therefore, maintaining or increasing the average size of the entire fleet does not guarantee the safest outcome, and decreasing the fleet's average size in response to a fuel economy rule might have no overall change in safety levels (though at some point, reducing the size or changing attributes could affect the vehicle's intrinsic safety, as distinct from its relative safety). As Wenzel, a leading researcher on this subject, has explained, "a fuel economy standard that discourages vehicles with smaller footprint, or lower weight, will not necessarily reduce casualties. . . .Details of vehicle design, which can be improved through direct safety regulations, will have a greater effect on occupant safety than fuel economy standards that are structured to maintain vehicle size or weight." [This comment can also be found in section 2.1 of this comment summary.] [EPA-HQ-OAR-2010-0799-9480-A1, p. 14]

Organization: International Council on Clean Transportation (ICCT)

Even more important, all of the historical analyses of the impacts of weight on fatalities are based upon vehicles primarily using conventional steel. This means that the results implicitly assume that the materials in the vehicle will not change. However, high strength steel (HSS) and aluminum both have better crash properties than standard steel. Thus, reducing weight of small cars using better materials will reduce fatalities. Aluminum provides more uniform management of crash forces. High-strength steel helps prevent intrusion and better absorbs crash forces, which is one of the primary reasons for its rapidly increased market penetration in recent years. For example, Honda has moved aggressively towards using HSS in small cars in part because of the safety benefits: [EPA-HQ-OAR-2010-0799-9512-A1, p. 12]

'The extensive use of high-strength steel in the Advance Compatibility Engineering (ACE) body structure creates a new-generation platform that is safer and stronger, enhancing the vehicle's ability to deal with crash energy during impact.'6 [EPA-HQ-OAR-2010-0799-9512-A1, p. 12]

'A new body design with the ACE Body Structure and extensive use of high strength steel create a new generation platform that is safer and stronger.' 7 [EPA-HQ-OAR-2010-0799-9512-A1, p. 12]

In addition, fatalities are linked more strongly to intrusion into the passenger compartment than to vehicle mass. Safety experts in Japan and Europe raised this issue previously. Their research suggests the main cause of serious injuries and deaths is intrusion due to the failure of load-bearing elements to properly protect occupants in a severe crash: [EPA-HQ-OAR-2010-0799-9512-A1, p. 12]

'The results from this project have overturned the original views about compatibility, which thought that mass and the mass ratio were the dominant factors.'8 [EPA-HQ-OAR-2010-0799-9512-A1, p. 12]

'moreover, if mass appears to be the main parameter linked to aggressivity of cars, it is because this is the easiest and universal parameter that is collected in all accident databases.'9 [EPA-HQ-OAR-2010-0799-9512-A1, p. 12]

'The scientific community now agrees that mass does not playa direct role in compatibility.'10 [EPA-HQ-OAR-2010-0799-9512-A1, p. 12]

Reducing vehicle weight while maintaining size helps to reduce intrusion, as the lower weight reduces crash forces while maintaining size preserves crush space. This also supports that size-based standards that encourage the use of lightweight materials should reduce intrusion and, hence, fatalities. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 12-13]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 195-196.]

The recent development of sophisticated and accurate vehicle simulations is opening up a new world. The initial use of these models was to improve safety design. The simulations were so effective that 5 star crash ratings became almost universal and NHTSA had to revise their rating criteria. The simulations are continuing to rapidly improve to the point where they are starting to be used to simultaneously optimize the material composition, shape and thickness of every individual part, including secondary weight reductions.

Organization: Marshall, C.

Historically, there have been two topics of pushback by those who would oppose this standard. [EPA-HQ-OAR-2010-0799-5917-A2, p. 1]

Regarding highway safety, same-size cars for improving mileage can be made with lighter more energy-absorbing materials without increasing risks on the highways. [EPA-HQ-OAR-2010-0799-5917-A2, p. 2]

Organization: Rafter, M.

Car makers have made cars less safe to meet the standards that the government keeps imposing. [EPA-HQ-OAR-2010-0799-11587-A1, p. 1]

Organization: Ross, D.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 242-243.]

Are fuel-efficient vehicles unsafe? Critics anticipate that weight reduction will be a major strategy to achieve greater fuel economy in a cost-effective manner, and that this will increase the likelihood of injury or death from vehicle collisions.

They point to the 50 percent increase in fatalities resulting from accidents involving passenger cars and light-truck SUVs experienced between 1979 and 1999.

But it wasn't so much the decrease in weight of passenger cars as the dramatic increase in the light-truck SUV share of all vehicles on the road that drove that statistic.

The proposed standard limits any further worsening in vehicle weight disparities by linking fuel economy standards to vehicle footprint.

If fuel economy gains are concentrated in high-end vehicles through new materials or increasing reliance on hybrid technology, then fleet weight disparities may even diminish.

In my view, critics have failed to refute the reasonable NHTSA projections of a modest increase in safety under the 2017-25 standards.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

Smart fuel economy improvements deliver safety, as well as better mileage and lower emissions: Advanced high strength and light weight materials and other recent technological and design breakthroughs—along with well-engineered weight reduction—give us the ability to travel safely and save money in cars that cut the emission of global warming pollution by 5% and, at 54.5 mpg, ease our oil addiction. [EPA-HQ-OAR-2010-0799-9549-A2, p. 10]

The improved safety record of crossover vehicles compared to truck-based SUVs, stemming from improved technology, teaches us that manufacturers are capable of designing vehicles that are lighter, more efficient and safer as well. [EPA-HQ-OAR-2010-0799-9549-A2, p. 10]

Technology is the key to better mileage and safer cars. With strong, lightweight materials, we can have both. Better engines, transmissions and aerodynamics improve fuel economy; airbags, high-strength lightweight steel and better roofs improve safety. And reducing the throw weight of vehicles improves the safety of everyone on the road. [EPA-HQ-OAR-2010-0799-9549-A2, p. 11]

Organization: Steyn, R.

The new rule also will lead to a significant increase in the number of driving-related deaths and injuries because it can be met only by reducing the size and weight of passenger vehicles. [EPA-HQ-OAR-2010-0799-8724-A1, p. 2]

Response:

Several commenters maintained that decreased vehicle weight could lead to decreased vehicle safety. Others commented that vehicle safety is chiefly related to vehicle design, rather than to vehicle size or weight. Comments on these issues are addressed principally in section II.G of the preamble to the final rule. We add certain supplemental responses below.

The commenters who state that the standards could lead to a decrease in vehicle safety assert that the standards will be met by mass reduction, or in some cases, downsizing, and that either strategy carries with it associated safety risks. EIR points to the 1970's experience as evidence that manufacturers' use of downsizing as a compliance strategy for the flat (i.e. universal) CAFE standards can result in increased vehicle fatalities. EPA disagrees with commenter's analogy to the current rule. As the agencies explain in preamble section II.G, historic field crash data is not necessarily a predictor of safety of the current or future light duty vehicle fleets. EPA also notes that three important factors differentiate the rulemaking today from the 1970's: 1) the footprint approach to standards, 2) the presence of crash safety standards which were not in existence in the 1970's, and 3) the advancements in design tools and techniques that have occurred over the past few decades.

Footprint-based standards

After the first CAFE standards were introduced in the 1970's, manufacturers achieved compliance in part by reducing vehicle size. The use of the footprint attribute for this rulemaking largely eliminates any incentive for manufacturers to downsize vehicles as a compliance strategy, since doing so simply makes their overall fleet average target more numerically stringent, as described in section II.C of the preamble. Indeed, this was a prime motivator to adopt so-called reformed CAFE, whereby standards would no longer be flat. Furthermore, unlike a weight-based standard, a footprint based standard does not create disincentives for manufacturers to apply weight-efficient materials and designs. From the engineering and statistical safety analyses reviewed by the agencies NHTSA concluded, and EPA agrees, that the societal effect of mass reduction while maintaining footprint, if any, is small (see section II.G.3 of the preamble).

Crash safety standards

The commenters did not address the role of federal safety standards, including crash standards, to which the current and future vehicle fleet are subject. NHTSA began frontal crash testing in 1978 and adopted the five star rating in 1993, adopted the side impact crash test in 1996 and the rollover test in 2000 with an overhaul of the program in 2008. In addition, there are other tests including those by the Insurance Institute for Highway Safety tests (IIHS) and other countries, including Europe and Japan, which must be met in order to sell vehicles in those countries. This continued advancement in safety standards is reflected in the steady decline in fatality rates. As shown in the figure in Section 3.3.5.5 of the Joint TSD, the motor vehicle crash deaths per billion miles traveled in the late 1970's were 3 times that of those in 2009 (11.3 per billion in 2009). Another figure in the same chapter shows the Light duty fleet weight trends: 1975-2011. The figure shows that vehicles have increased in weight over the past 30+ years since the late 1970's and while vehicle designs today and in the future may be of similar weights, the manufacturers are accountable to safety standards today. Safety standards will stay in place, so that it is not possible for auto makers to reduce safety below those requirements in order to improve fuel economy.

Advancements in design tools and techniques

EPA agrees with commenters who observed that design plays an important role in safety (Consumers Union, D. Ross, Sierra Club). The design tools that are available today are significantly more advanced than when fuel economy standards were first established, and manufacturers now routinely utilize CAE/CAD tools to simulate crashes prior to a prototype build. This allows them to design the vehicle to reduce passenger compartment intrusion and distribute crash loads more efficiently, as well as evaluate dummy injury criteria. If all design concepts were held constant to the early 2000s then lighter cars could possibly mean higher dummy accelerations. However, vehicle designs are changing. For example, the more optimal management of crash energy in crush zones and design of multiple load paths can minimize acceleration pulses experienced in the passenger compartment of the vehicle. In addition, there has been continued advancement of restraint system technology, such as air bags that provide more complete coverage of the passenger compartment, and restraints that respond according to the specific occupant and crash conditions.

EPA notes that uncertainty still exists about whether this rule will affect how consumers evaluate fuel savings or safety. Still, EPA does not believe, as EIR suggests, that this rule will cause consumers to value safety less than they do currently. If consumer buying strategies do not change, as is very possible, then the rule will not affect how consumers evaluate these issues. It is also possible that fleet-wide efficiency increases will reduce the emphasis consumers place on fuel economy as a distinguishing attribute, and place greater emphasis on safety features, rather than less, as IER argues. Information on vehicle safety, and crashworthiness in particular, is readily available to vehicle purchasers. We note that NHTSA assigns crash ratings to each vehicle design based on the results of these tests, and this information is commonly part of the consumer's decision process in vehicle choice. Even if consumers seek a less expensive vehicle in response to the increased costs, all vehicles will continue to meet the applicable federal safety standards.

13.2. Comments on NHTSA/EPA's Engineering Analysis of Vehicle Safety Including Light Weight Materials

Organization: Alliance of Automobile Manufacturers

Automakers, in conjunction with NHTSA and others, continue to work toward a common goal of reducing the annual number of fatalities and injuries that occur in motor vehicle crashes. The

Alliance supports a CAFE and GHG rule structured to allow automakers to balance competing requirements in a manner that furthers this progress. [EPA-HQ-OAR-2010-0799-9487-A1, p.20]

Alliance members recognize that highway traffic safety is a shared responsibility and strive to do their part through the continuous improvement of the safety performance of their vehicles. NHTSA recently announced that the 2010 road fatality rate reached an historic low of 1.10 fatalities per 100 million vehicle miles traveled. Fatalities declined in most categories in 2010, including for occupants of passenger cars, SUVs, minivans and pickup trucks.7 We take pride in our contributions toward this historic achievement and continue to work toward future progress by developing additional crashworthiness enhancements and introducing crash avoidance technologies. As breakthroughs in advanced material and powertrain technologies become available and their associated costs meet customer thresholds for affordability, consumers will benefit through an increase in vehicle fuel efficiency and a decrease in greenhouse gas emissions. However, the Alliance is mindful that such improvements must be implemented in a manner that does not compromise the rate of safety improvement that has been achieved to date. [EPA-HQ-OAR-2010-0799-9487-A1, p.21]

Achieving the proposed CAFE and GHG standards will rely on the availability of commercially viable emerging technologies for manufacturers to adopt. Should these technologies fail to mature as anticipated, greater reliance on mass reduction and downsizing in order to achieve these standards could occur. The Alliance supports the proposed mid-term evaluation and urges EPA and NHTSA to continuously update the safety analysis as part of this review. [EPA-HQ-OAR-2010-0799-9487-A1, p.21]

Even though the current rulemaking extends well into the future, there is a possibility that many of the advanced technology and mass reduction projections may not be realized in the proposed timeframe. Thus, when the agencies conduct their mid-term evaluation, it is critical that the safety analysis is updated to reflect the most recent crash data and revised projections regarding mass reduction scenarios. [EPA-HQ-OAR-2010-0799-9487-A1, p.21]

The Alliance supports NHTSA's intention to examine safety from the perspective of both the historical field crash data and the engineering analysis of potential future Advanced Materials Concept vehicles. NHTSA's planned analysis rightly looks backward and forward. However, with respect to looking ahead and the evaluation of concept vehicles, the Alliance recognizes that it is not sufficient to only consider regulatory and consumer information crash tests. A comprehensive evaluation of vehicle safety must also take into account real-world impact scenarios and the special requirements of vulnerable populations (e.g., children and elderly). These must also be adequately accounted for in any agency policy decisions. [EPA-HQ-OAR-2010-0799-9487-A1, p.21]

Analysis of the Lotus and FutureSteelVehicle concepts indicates that although these concept vehicles can be designed in a virtual world to perform well in virtual Federal Motor Vehicle Safety Standards and virtual Insurance Institute for Highway Safety tests, there remain concerns that these concepts yield aggressively stiffer crash pulses that may be detrimental to rear seat occupants, vulnerable occupants and potential crash partners. Given the Computer-Aided Engineering (CAE) crash modeling uncertainties with respect to advanced materials that may possibly be available for mass production in the MY 2017-2025 time-frame, it is possible that the real-world crash behavior of these concepts may not match that predicted in those studies. [EPA-HQ-OAR-2010-0799-9487-A1, pp.21-22]

Further, significant uncertainties exist with respect to both manufacturing and CAE crash analysis of potential future advanced materials. CAE capabilities for some potential advanced materials that manufacturers are researching are far less mature than for materials currently in common use. Progress in these areas is highly competitive and therefore varies throughout the industry. As such, it will take considerable time and investment for each manufacturer to develop this knowledge and experience. Because agency projections fail to adequately take into account the timing and cost for the introduction of advanced materials, these projections are likely overly optimistic. [EPA-HQ-OAR-2010-0799-9487-A1, p.22]

Organization: Aluminum Association's Aluminum Transportation Group

The aluminum industry shares and supports the agencies' priority for continuous improvement in vehicle safety. We congratulate NHTSA for the thorough, thoughtful and professional approach taken in analyzing the relationships between vehicle design attributes and safety performance. Mass reduction has been identified as an important part of a comprehensive vehicle fuel economy improvement initiative, and must be implemented in a manner that preserves, or enhances vehicle safety. Developing an appropriate assessment of potential vehicle weight reduction opportunities requires understanding the independent influence of mass, size, design and safety features. Limitations of available historical data and currently available safety modeling make reliable assessment of individual safety technologies difficult. It is even more difficult to reliably anticipate the potential impact of future advancements in vehicle safety engineering or deployment of advanced safety enhancing technologies. [NHTSA-2010-0131-0226-A1, pp. 3-4]

Considering the uncertainties involved, we believe the agency's position on vehicle weight reduction is based on an objective and well reasoned assessment of all available information and is appropriately conservative. Recent NHTSA studies, and the NPRM indicate downweighting of large and mid-size vehicles will have a "neutral or positive" impact on overall fleet safety while improving fuel efficiency. In this vehicle segment automakers are using low weight, high-strength materials now and will increase use of these materials in the future. With respect to smaller vehicles, data clearly identifying independent impact of mass, size, design and advanced safety technologies is not available today. Due to uncertainty about the influence of mass, design and size on safety of smaller vehicles, the NPRM does not anticipate significant mass reduction in vehicles below 3,000 pounds. Analytical safety studies conducted by the ATG and others suggest vehicle size, not weight, has the largest impact on vehicle safety performance. We believe advanced small vehicle designs will be developed using aluminum body and structural components that will achieve significant weight reduction while preserving vehicle size and improving safety performance. [NHTSA-2010-0131-0226-A1, p. 4]

The ATG also serves on the steering committee for the Center for Automotive Research's (CAR) recently formed Coalition of Automotive Lightweighting Materials (CALM), which supports efforts by auto manufacturers to aggressively downweight vehicles to improve performance, fuel economy and safety. CALM's purpose is to support the cost-effective integration of mixed materials to achieve significant reductions in weight through the collaborative efforts of technology providers with the auto manufacturers. Through individual company efforts and through the new CALM partnership, the aluminum industry is committed to working with our customers and other suppliers to further accelerate and ease the adoption of advanced materials options (Attachment E [see Docket number NHTSA-2010-0131-0226-A5]). [NHTSA-2010-0131-0226-A1, p. 4]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 223-227.]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 227-228.]

So in conclusion, we see that weight reduction, weight optimized future vehicles and components will take maximum advantage of available engineering materials. These materials are continually being improved to further enhance the ability of auto designers to design efficient vehicles. Materials including aluminum, high-strength steel, magnesium and Aluminum offers a unique combination of composites will all find use in the vehicles of the future, they'll work -- live together in more efficient vehicle structures.

Aluminum offers a unique combination of attributes including low weight, high strength, excellent energy absorption capability, natural corrosion resistance at a reasonable cost. For those reasons, we believe aluminum will play an increasing role in the optimized vehicle of the future.

Organization: American Chemistry Council (ACC)

The agencies have stated their intention to achieve lightweighting of the fleet in a manner that does not compromise vehicle safety. The agencies have chosen to "provide an incentive to use lightweight materials and structures," rather than "reductions in size," by adopting a footprint approach to emission reductions. We support the agencies' adoption of the footprint approach, and our members are committed to bringing to market materials and technologies that help achieve that goal. As an industry that makes modern innovative materials, we have a proud history of our many contributions to automotive safety. Plastics are integral to airbags, seat belts, shatter resistant sunroofs, and so many more features. We strongly believe that vehicle mass reduction and overall fleet safety can be achieved hand-in-hand, and support the agencies' approach. [EPA-HQ-OAR-2010-0799-9517-A2, p. 1]

The Notice of Proposed Rule Making (NRPM) also observes that ongoing research may help refine our understanding of mass, vehicle size, and safety, particularly in connection with improved design and material use. Supporting research on safety is important to us, and the ACC Plastics Division's Auto Team has worked closely with the National Highway Traffic Safety Administration (NHTSA) on several initiatives to address automotive safety issues. For example, ACC and several member companies are participating in several NHTSA research projects on the safety of lightweight vehicles, including the Lotus Engineering and the George Washington

University studies, which seek to refine understanding of mass and crashworthiness.[3] The latter study, scheduled to conclude in July, 2012, has been highlighted by Secretary LaHood and NHTSA as one of the tools they are using to ensure safety while promoting vehicle mass reduction. [EPA-HQ-OAR-2010-0799-9517-A2, p. 1]

Through another effort with NHTSA, in November 2005, the American Plastics Council (now ACC's Plastics Division), in cooperation with NHTSA, sponsored a Technology Integration Workshop on "Enhancing Future Automotive Safety With Plastics." Findings from the workshop were published in a Technology Integration Report in May 2006, noting the major opportunities and challenges for enhancing the safety of next generation vehicles using advanced plastics and composite materials in structural and safety applications. In 2005, Congress directed NHTSA to explore the potential safety benefits of lightweight, fuel efficient Plastics and Composites Intensive Vehicles (PCIVs),[4] and develop the foundation for research in cooperation with the Department of Energy, industry, universities and other safety stakeholders. [EPA-HQ-OAR-2010-0799-9517-A2, pp. 1-2]

Significant progress has been made in this effort. NHTSA tasked the Volpe Center to assess the current state of knowledge and emerging safety technology opportunities to enhance the crash safety of PCIVs by 2020. In November 2007, NHTSA published A Safety Roadmap for Future Plastics and Composites Intensive Vehicles, and the agency is in the process of implementing the Roadmap.[5] In August 2008, NHTSA hosted a workshop entitled, The Safety Characterization of Future Plastic and Composites Intensive Vehicles.[6] NHTSA has already moved much closer towards its goal of facilitating development and deployment of next generation safe and fuel efficient PCIVs by 2020; we encourage and support NHTSA, in coordination with the private sector, to complete its work implementing the roadmap, and integrate relevant findings into this rule as appropriate. [EPA-HQ-OAR-2010-0799-9517-A2, p. 2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 265-266.]

Why is this important? The proposed rule makes clear the relationship between fuel savings and lightweight of the vehicle. The proposal acknowledges that mass reductions of vehicle can be achieved in many ways, including material substitution, design optimization and part consolidation. We agree. PCIV research amply documents the technological feasibility of designing and building vehicles with 30% or more plastic and plastic composites, and in our view, the agencies' application of mass reduction of up to 20% relative to model year 2008 levels is appropriate and achievable.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 266-267.]

But there's more. Plastics are about more than just light-weighting of vehicles, plastics and polymer composites have enabled some of the most significant vehicle safety innovations in the past several decades including seat belts, airbags, child safety seats, and the same sources of these innovations still hold significant untapped potential to further enhance vehicle safety.

We agree with the agencies that it is important that the CAFE standards be set in a way that does not encourage manufacturers to respond by selling vehicles that are in any way less safe. In particular, we agree with and support the standard applied in assessing compliance strategies, and this is articulated as no adverse effect on overall fleet safety.

In the last five years the plastics industry has worked aggressively to better understand how plastics can be used to enhance safety in automobiles and we will continue to do so. Congress recognized the importance of enhanced automobile safety by investing nearly $2 million over a four-year period and to building an ongoing partnership between the plastics industry and NHTSA, and through this partnership, NHTSA has initiated and is currently implementing a safety roadmap for future plastics and plastic composites intensive for vehicles.

This project is already yielding fruit, as ongoing research is helping to improve the performance of plastic and composite material components. We support NHTSA'S sustained work to implement the safety roadmap.

Organization: American Iron and Steel Institute (AISI)

Use of Steel in Future Vehicles [Federal Register Vol. 76, No. 231, Pg 74921 et seq.]

New steels and automotive manufacturing techniques continue to be developed by the steel industry and will enable significant increases in mass reduction, crashworthiness and fuel economy, while enabling reductions in total greenhouse gas emissions, during the period specified in the NPRM. [EPA-HQ-OAR-2010-0799-9477-A1, p. 8]

The new regulations will influence car companies to consider mass reduction as a high priority. The steel industry in collaboration with its automotive customers has a long history of providing mass reduction solutions for light-duty vehicles, most recently by developing an evolving portfolio of advanced high-strength steel (AHSS) grades over the past two decades. These steels possess tremendously improved strength over conventional steel and enable parts to be made thinner and lighter while still carrying the required loads. At the May 18, 2011, Great Designs in Steel Seminar, Ducker Worldwide9 reported that AHSS is now the fastest growing automotive material in today's new cars and trucks. From this report and from the reports of individual car companies on specific vehicles, many examples of the effectiveness of AHSS grades in achieving affordable mass reduction for carmakers are available today. Ducker10 also forecasted accelerated growth of AHSS between now and 2025 due to the proposed regulations. This fact emphasizes that, while the growth of AHSS in new vehicles has been significant and averages around 17% of the body mass today, more growth is expected in the future and, according to Ducker, can possibly triple by 2025. [EPA-HQ-OAR-2010-0799-9477-A1, pp. 8-9]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 87-88.]

Much work was necessary to increase AHSS content from essentially zero to the 17% level reported above. It was first made possible because of the global steel industry's ultra-light steel studies, called ULSAB (Ultra Light Steel Auto Body) which were completed in 2002 with the release of the final project, ULSAB-AVC (advanced vehicle concepts)11. [EPA-HQ-OAR-2010-0799-9477-A1, p. 9]

This transition from mild steel to AHSS since 2002 in vehicle structures was also facilitated by joint engineering projects with the Auto/Steel Partnership through support by the U. S. Department of Energy (DOE) and the U. S. Advanced Materials Partnership (USAMP). Important projects including Lightweight Front-end Structure12 and Future Generation Passenger Compartment13 helped to accelerate use of AHSS. Simultaneously, North American steel companies invested in the technologies to manufacture these AHSS grades. [EPA-HQ-OAR-2010-0799-9477-A1, p. 9]

To prepare for anticipated automobile design requirements for 2017- 2025, AISI together with WorldAutoSteel has again conducted a major engineering project, called FutureSteelVehicle14. This study examined the most efficient structures for electrified powertrain vehicles like battery-electric vehicles and plug-in hybrids. Twenty new grades of AHSS were developed, with many of the newest AHSS grades having strengths in the gigapascal range, over 1000 MPa. That's at least 5 times stronger than conventional steels. [EPA-HQ-OAR-2010-0799-9477-A1, p. 9]

FutureSteelVehicle (FSV) results were published in May 2011 and showed mass reduction levels of about 35% in body/structural applications. Such high mass reductions with steel are now possible because of new extremely high-strength grades, new manufacturing processes like tailor rolling or hot stamping, and new design optimization CAE (computer-aided engineering) tools. The FSV results reinforce the forecast by Ducker that AHSS growth in vehicles should continue well past 2020. FSV is an important milestone on the development path of automotive steels—it is not the endpoint. [EPA-HQ-OAR-2010-0799-9477-A1, p. 9]

Technological breakthroughs going forward are sure to enable further advances just as they have over the past two decades. [EPA-HQ-OAR-2010-0799-9477-A1, p. 10]

The results of the FSV study have been shared with North American carmakers. Importantly, it shows that significantly more mass reduction is possible using steels remains. Equally important, this study also evaluates the cost and the carbon emissions consequences of mass reduction solutions. It is significant that AHSS mass reduction solutions are often both the least expensive and the lowest carbon solutions, based on a calculation of life-cycle greenhouse gas emissions. More details on this subject of life-cycle emissions are covered in the first section above. [EPA-HQ-OAR-2010-0799-9477-A1, p. 10]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 89-90.]

Collision Injury Severity [Federal Register vol. 76, No. 231 Pg. 74949 et seq.]

AISI, WorldAutoSteel, and the Auto/Steel Partnership have conducted many studies on the effectiveness of AHSS steels in reducing mass while achieving equal or improved crashworthiness versus established steel architectures. The most notable published studies on this subject are ULSAB-AVC11 (2002), the Auto/Steel Partnership studies on front-end structure12 (2004) and on passenger compartment mass reduction13 (2006), and FutureSteelVehicle14 (2011). All of these studies make use of established vehicle FEA (finite element analysis) models, and computer aided engineering (CAE) crash simulation software. In addition, an actual vehicle crash test was conducted to validate the Auto/Steel Partnership front-end structure project and verify that the AHSS 25% reduced-mass front end behaved equivalently to the original design. [EPA-HQ-OAR-2010-0799-9477-A1, p. 10]

The scope of these steel industry-sponsored studies relied on achieving equivalent or better crash simulation performance with criteria based on limits for intrusion (into the passenger compartment) and management of the intensity of the crash pulse. Our experience in mass reduction is that vehicles can indeed be engineered to achieve equivalent performance at reduced mass against the required battery of crash tests including full frontal impact, offset frontal, rear impact, side impact, roof crush, and others. The properties of AHSS are particularly well suited for this task because of steel's high strength, high work hardening during deformation and strain-rate hardening during impact loading rates. [EPA-HQ-OAR-2010-0799-9477-A1, pp. 10-11]

Organization: Bayer Material Science

We support the agencies' decision to consider only net weight reduction of vehicles that will not compromise overall fleet safety. As a supplier of innovative materials such as polycarbonate for vehicle applications such as headlamps, interior consoles and body panels Bayer MaterialScience has a rich history of contributing to automotive safety standards. [EPA-HQ-OAR-2010-0799-9198-A2, p. 1]

Bayer MaterialScience has a rich history for contributing to automotive safety standards and is dedicated to developing innovative, high-performance materials giving automakers a choice of materials when it comes to meeting the CAFE requirements.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 270-271.]

Organization: Center for Biological Diversity

3. The Agencies must decrease weight across all vehicles to improve fuel efficiency

The Agencies correctly identify passenger safety as a factor to be considered in setting fuel efficiency standards. However, less weight does not equate to less safety. The assumption that the safest cars have been heavy and large, and that cars suffering the highest fatality-crash rates have been light and small, has led to incorrect conclusions about reducing vehicle weight. In fact, the evidence shows that weight reductions in all cars will not affect safety, though it significantly improves gas mileage. We urge the Agencies to reexamine their rulemaking and to require greater weight reductions over its effective period. [EPA-HQ-OAR-2010-0799-9479-A1, p. 5]

The Agencies themselves now agree that reducing more mass from heavier vehicles reduces safety concerns for smaller vehicles. They also note that reports they previously relied upon require updating and data correction; accordingly, the Agencies must take updated studies that will be available before the final MY 2017-2025 rulemaking into account in that final rulemaking.24 The Agencies also note the consistency among reported studies that "reducing the overall ranges of masses and mass ratios seems to reduce overall societal harm."25 Indeed, we believe the updated evidence will show that mass can safely be reduced in both light trucks and passenger vehicles as long as wheelbase and track width are maintained.26 Because light weight material can improve vehicle efficiency by 20%, its use must be encouraged. [EPA-HQ-OAR-2010-0799-9479-A1, p. 6]

The erroneous belief that heavier vehicles increase overall safety has contributed to a large increase in the weight of the American vehicle fleet over the last decades – leading to the loss of what could have been highly significant efficiency improvements.27 One study has concluded that from 1984 to 2004, the average weight of light trucks increased by 26 percent and that, if weight, horsepower, and torque had been held at their 1990 levels, fuel economy for both passenger cars and light trucks could have increased by nearly 60 percent from 1980 to 2006.28 The Agencies themselves concede that "MY 2000-2007 vehicles of all types are heavier and larger than their MY 1991-1999 counterparts. The average mass of passenger cars increased by 5 percent from 2000 to 2007 and the average mass of pickup trucks increased by 19 percent." We note that CAFE rulemakings were in effect during all of the referenced period. A correct assessment of the relationship between weight, fuel efficiency and safety must reverse this perverse trend, which is directly contrary to energy conservation. Because of its large impact on fuel efficiency, we urge the Agencies to require significant weight reduction among the vehicle fleet as part of its standards; failure to implement light-weighting across the fleet because of alleged safety concerns would be contrary to the evidence and arbitrary and capricious. These revisions must not simply lead to corrections in the text of the final rule, but also to significant increases in fuel efficiency standards in the final rulemaking. [EPA-HQ-OAR-2010-0799-9479-A1, p. 6]

27 The lower stringency targets assigned to light trucks is the other driving force of this development, as discussed below. [EPA-HQ-OAR-2010-0799-9479-A1, p. 6]

28 Christopher Knittel, Automobiles on Steroids; Product Attribute Trade-Offs and Technological Progress in the Automobile Sector, AMERICAN ECONOMIC REVIEW 2012 at 3369 (Dec 2011), available at http://www.aeaweb.org/articles.php?doi=10.1257/aer.101.7.3368. The Agencies themselves observe that MY 2000-2007. [EPA-HQ-OAR-2010-0799-9479-A1, p. 6]

Organization: Consumers Union

In fact, reducing vehicle weight will be essential in improving fuel economy. For example, a contemporary family sedan such as the Hyundai Sonata Limited weighs 3,450 pounds and still achieves a Top Safety Pick by the IIHS. The new Toyota Camry XLE V6 is even lighter at 3,375 pounds. These vehicles achieve 25 and 26 overall mpg in CR's testing. By contrast, a similarly equipped Chrysler 200 Limited V6 weighs 3,590 pounds (also a Top-Safety Pick), but with no performance or interior room advantage and partially because of the extra weight only achieves 21 mpg. The new Honda Civic at 2,810 pounds also received a Top Safety Pick and weighs 400 pounds (about 9%) less than the Chevrolet Cruze, a direct competitor, and again achieves 20% better fuel economy partially because of the lower weight. Consumer Reports is confident that lighter vehicles will not necessarily compromise vehicle safety—all vehicles will still need to conform to improving vehicle safety standards. [EPA-HQ-OAR-2010-0799-9454-A2, p.3]

Organization: Insurance Institute for Highway Safety (IIHS)

From a safety standpoint, IIHS is supportive of the proposed CAFE standards put forth by NHTSA in this proposed rule. The continued use of a size-based system will help increase fuel economy while keeping manufacturers from significantly downweighting or downsizing vehicles, and thus will mitigate the safety costs that might otherwise occur as fuel economy increases are required by the federal government. [NHTSA-2010-0131-0222-A1, p. 1]

Organization: International Council on Clean Transportation (ICCT)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 195-196.]

The shift in material design capabilities also impacts the cost to reduce vehicle weight. The studies in progress by Lotus and FEV are using highly sophisticated simulation models to optimize part material and design. The results of these studies will be far more accurate of future designs and they must be used to assess the costs of weight reduction for the final rule.

Organization: Nissan North America, Inc.

Nissan will continue to provide a full range of vehicles, and to incorporate continuous improvements throughout its vehicle fleets. This includes advances in internal combustion engines (ICEs) as well as the continued deployment of electric drivetrains. Nissan also continues to explore appropriate opportunities for mass reduction. A comprehensive mid-term evaluation is critical to determining the extent to which the market accepts the additional costs associated with more advanced internal combustion vehicles, as well as the extent to which the advanced powertrain market develops. In addition, government regulatory programs involving both fuels and safety requirements will directly affect future feasibility and must be considered in any future review. [EPA-HQ-OAR-2010-0799-9471-A1, p.5]

Organization: SABIC Innovative Plastics US LLC

SABIC-IP has been actively engaged in developing solutions to advance fuel economy and reduce greenhouse gas (GHG) emissions. In particular, automotive products made from our polymer resins are used to reduce vehicle mass while providing strong structural integrity. SABIC-IP has also developed an advanced coating solution allowing polycarbonate (PC) glazing to withstand long-term weathering and abrasion conditions. With such coating solutions, PC glazing may be used in areas specified for Item 2 glazing behind the windshield. [EPA-HQ-OAR-2010-0799-9467-A1, p.1]

The agencies are well aware of the emissions and fuel consumption benefits associated with vehicle mass reduction. SABIC-IP supports the inclusion of weight reduction as an available technology, as well as the agencies' ongoing research efforts to quantify better the implications of weight reduction for societal safety measures as lighter and smaller vehicles penetrate into the fleet. SABIC-IP has actively participated in this research, contributing a number of lightweight components, including plastic fenders, plastic front-end modules, polycarbonate glazing for roof and backlight applications, and composite liftgates for evaluation and consideration. Many of these lightweight solutions also offer component-level safety benefits, offering the capability, for example, of mitigating ejections or protecting pedestrians. [EPA-HQ-OAR-2010-0799-9467-A1, p.13]

SABIC-IP verified the traditional estimates that a 10% weight reduction produces a 6-7% increase in fuel economy. In 2008, SABIC-IP arranged for vehicles to be tested at the Mercedes-Benz Research and Development North America, Inc. facility in Ann Arbor, Michigan with two configurations – a vehicle with PC glazing and a vehicle with added weight to simulate the glass penalty due to glass having a mass density about twice that of PC. The data, which SABIC-IP initially presented in our comments to the MY 2012-2016 rulemaking, confirmed these estimates: [EPA-HQ-OAR-2010-0799-9467-A1, p.14] [For the associated table, please refer to EPA-HQ-OAR-2010-0799-9467-A1, p.14]

An additional benefit offered by engineering thermoplastics is the ability to offer enhanced aerodynamics that can be used to design more front and rear ends with a lower coefficient of drag. Drag coefficients for present day vehicles range between 0.30 and 0.35, but an additional 25% reduction in drag has been predicted in coming years. Part of this progress will derive from advances in material science. Injection-molded plastics allow for aerodynamic styling and parts integration not possible with metal or glass. Specific applications where drag coefficient reductions have been or can be achieved include spoilers, fascias, undertrays, grilles, mirrors, and lighting. [EPA-HQ-OAR-2010-0799-9467-A1, p.14]

In fact, engineering thermoplastics can be utilized in the entire front six inches and most of the rear six inches of the vehicle. In the front, these components include lighting (polycarbonate), grills (PC blends), fasciae (polypropylene), bumpers and energy absorbers (PC blends), grill opening reinforcements (polypropylene) and reflectors (polyetherimide). In the rear, the components include structural reinforcements (polypropylene), rear lighting bezels (PC blends), spoilers (PC blends), glazing (polycarbonate), liftgates (polyphenylene ether resin (PPO) and PC blends) and bumpers and energy absorbers. The aerodynamic benefits available through integrated, molded plastic components are likely to contribute substantially as new vehicles are designed with an increasing attention to employing aerodynamics to reduce greenhouse gas emissions and fuel consumption. [EPA-HQ-OAR-2010-0799-9467-A1, p.14]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 286-287.]

In addition to polycarbonate glazing technology, SABIC Innovative Plastics offers a number of other lightweight products that can advance the goals of this rulemaking. In fact, our various plastic products can comprise the entire front six inches and most of the rear six inches of a vehicle, including lights, grills, fasciae, bumpers, energy absorbers, structural reinforcements, liftgates and more. In addition to these familiar mature parts of the car, we have developed products such as the plastic steering wheel which will provide future weight benefits as they're incorporated into vehicle designs. We are also developing composite materials that can reduce vehicle mass and enhance design.

We believe that the technology of lightweight materials will advance substantially in the years covered by this regulation, as will our understanding of the benefits these materials can provide. We look forward to working with our OEM and our Tier customers to determine the most cost-effective and safest ways to incorporate advanced lightweight components and structural elements into the vehicles and components they manufacture.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

A driver in a 2,600-pound Honda Civic has greater chances of surviving an accident a driver in a 5,100-pound Ford F-150 pickup. Most fatal car crashes are single vehicle accidents where weight can be a disadvantage. In fact, the Ford's driver per fatality rate is 65 deaths per million registered vehicle years versus 55 for the 50% lighter Civic. The 3,200 pound Honda Accord is far safer than the F-150 with a driver death rate of only 19. Indeed, the mid-size Accord is safer than any standard large sedan on the road which shows that engineering, not weight, builds safety into a vehicle.35 [EPA-HQ-OAR-2010-0799-9549-A2, p. 10]

With these standards it is important recognize additional steps that will improve safety: [EPA-HQ-OAR-2010-0799-9549-A2, p. 10]

. Future vehicles will comply with new standards for electronic stability (ESC), roof crush resistance, and control of occupant ejection. These standards will substantially reduce the potential for single vehicle crashes (including rollovers) and for injuries in such crashes. [EPA-HQ-OAR-2010-0799-9549-A2, p. 11]

. New applications of high strength steels, laser welding, advanced adhesives, and nonferrous materials (aluminum and plastics) will result in major improvements in structural performance – occupant compartment integrity and crash energy management – with reduced vehicle weight. [EPA-HQ-OAR-2010-0799-9549-A2, p. 11]

Advances in electronics will lead to increased crash avoidance and better crashworthiness as electronic sensors can apply controls to prevent crashes and tune the vehicle for maximum crashworthiness by adjusting seats, head restraints, seat belts and airbags for better occupant protection when a crash is inevitable. Vehicle to vehicle communication systems can send signals to avoid intersection crashes such as when a vehicle runs a traffic light. [EPA-HQ-OAR-2010-0799-9549-A2, p. 11]

A major consequence of the new safety standards will be a dramatic reduction in rollover casualties. Until recently, NHTSA had no significant standards affecting rollover safety. Rollover fatalities increased dramatically as light trucks were increasingly used as substitutes for passenger cars in the 1980s and 1990s. Rollover fatalities will be reduced from the current level of more than 10,000 per year to fewer than 5,000 as a consequence of the new standards. [EPA-HQ-OAR-2010-0799-9549-A2, p. 11]

35 Insurance Institute for Highway Safety, June 9, 2011. [EPA-HQ-OAR-2010-0799-9549-A2, p. 10]

Organization: Society of the Plastics Industry, Inc. (SPI)

Plastics have extensive innovative automotive applications – including bumpers and energy absorbers, consoles, door components, engine covers, housings, instrument panels, lighting, grilles, side impact protection, structural reinforcement and sunroofs – that are critical to safe, lighter weight and more fuel efficient vehicles. [EPA-HQ-OAR-2010-0799-9492-A1, p.2]

From airbags to seatbelts, a wide range of plastics materials and processing methods have played a role in automotive safety. For example, composites can be produced with different levels of reinforcement for specific components to achieve improved mechanical properties that result in enhanced safety. In the event of a crash, backrests and headrests are designed to absorb and distribute energy, and highly elastic films help provide protection from glass. [EPA-HQ-OAR-2010-0799-9492-A1, p.2]

SPI strongly supports the agencies' commitment and approach to consider only vehicle mass reduction that would not have an adverse effect on overall fleet safety. The NPRM notes the historical data suggesting an inverse relationship between vehicle mass and crashworthiness, but also points out that the adoption of advanced lightweight materials has the potential to "mitigate some of the potential decrease in safety from mass reduction through improved distribution of crash pulse energy." The agencies have wisely supported continuing research into the relationship between vehicle mass and crashworthiness at research institutions like George Washington University. [EPA-HQ-OAR-2010-0799-9492-A1, p.4]

Such advances certainly require evaluation for safety. Congress' investment in enhanced automobile safety, through an ongoing partnership between the plastics industry and NHTSA, has led to the initiation and implementation by NHTSA of a Safety Roadmap for Future Plastics and Composites Intensive Vehicles. The 2007 report "summarizes the approach, activities, and results of a study to evaluate the potential safety benefits of Plastics and Composites Intensive Vehicles (PCIVs), to enable their deployment by 2020." The ACC has acknowledged that the commercial viability of PCIVs is a longer term proposition, but research is underway, including the improvement of predictive tools for reliably modeling component performance. We likewise support NHTSA's ongoing work with the Safety Roadmap and industry's research on PCIVs. [EPA-HQ-OAR-2010-0799-9492-A1, p.4]

The plastics industry is proud of its innovations that contribute to vehicle weight reduction, reduced emissions and safety improvements, such as the benefits provided by PC glazing. [EPA-HQ-OAR-2010-0799-9492-A1, p.8]

Organization: Volkswagen Group of America

To start, Volkswagen agrees with the agencies that there is a variation in the overall mass reduction potential based on the type and market segment of vehicles. Smaller cars and economy models have less potential for mass reduction than larger or more premium vehicles. Volkswagen projects full vehicle weight reductions during the time period of this regulation on average in the order of 7-10%. The NPRM predicts for large cars and some trucks upwards of 20% mass reduction potential. Volkswagen feels that this may exceed cost effective limits. With regards to electrified vehicles, Volkswagen does agree with statement sin Section 3.4.5.5. of the TSD that electrical component may increase baseline vehicle mass by upwards of approximately 4-5% depending on battery pack capacity and/or other electric drive components. [EPA-HQ-OAR-2010-0799-9569-A1, p. 15]

Organization: Volvo Car Corporation (VCC)

During the last 30 years, major breakthroughs have been made in the engineering and development of advanced safety technologies. The development, market introduction and penetration of more efficient safety technologies, both with respect to occupant protection and with respect to cost, is expected to continue, with increased intensity. During the next decade, technologies aimed at avoiding or mitigating crashes will be introduced and will achieve widespread implementation in the vehicle fleet. [EPA-HQ-OAR-2010-0799-9551-A2, p. 4]

Regardless of the anticipated development of technologies for improving both the crashworthiness and crash avoidance of vehicles towards the year 2025, the basic laws of physics still apply for incompatibilities in crashes between vehicles of different sizes and different weights. The projection of the effects of the new active safety crash technologies, even though raising a lot of future expectations, is not that crashes will be completely avoided, but that the frequency and impact of many of these crashes will be reduced. The assumptions of necessary weight and footprint reductions for meeting the fuel economy requirements will raise the question: what will be the outcome in a crash between a newer smaller vehicle that meets the requirements with an older larger heavier vehicle? [EPA-HQ-OAR-2010-0799-9551-A2, p. 4]

A smaller and lighter vehicle will be subjected to larger change of velocity than the larger heavier vehicle and, consequently, this will be reflected in the pulse that the smaller vehicle will be subjected to. This is then in turn reflected in the pulse transferred to the vehicle occupants.

Many researchers have been trying to assess the relative injury and fatality risk of occupants in two-vehicle crashes in relation to the differences in mass between the vehicles. Everything else being equal, several of the studies presented indicate a significant increase, up to a factor ten, in the fatality risk for the occupants in the lighter vehicle for a two-to-one weight ratio between the colliding vehicles in a head-on crash. [EPA-HQ-OAR-2010-0799-9551-A2, pp. 4-5]

When trying to assess the consequences of meeting the requirements on reducing the greenhouse gases and the resulting expected changes in the size and mass of the vehicle fleet, a number of uncertainties will arise that make this task very difficult and open for speculation. Will the whole vehicle population move towards lower weight and smaller size or will this only apply to certain segments? What will be the effect on size and weight of new alternative drive trains, e.g. hybrids and electrical vehicles? What will be the technical development of new safety technologies and what will be the market penetration of these systems? What will be the rate of the vehicle turn-over and how many older vehicles, pre 2017, will remain in the vehicle fleet by 2025? [EPA-HQ-OAR-2010-0799-9551-A2, p. 5]

One possible scenario presents a shift of the larger vehicle population towards a mid-segment of the population. This would then result in an overall more compatible passenger vehicle fleet and thus, reduce the negative aspects of the present fleet that has a large spread in weight and size. However, the weight ratio between larger motor vehicles, such as trucks and buses, and passenger cars will most likely increase and this incompatibility will have the opposite effect, i.e. resulting in a higher fatality risk for the car occupants. [EPA-HQ-OAR-2010-0799-9551-A2, p. 5]

Other policy actions may also have consequences on the incompatibilities of the vehicle fleet. For example, changes in crash protection requirements may result in stiffer front structures which in turn will affect the vehicle fleet compatibility. [EPA-HQ-OAR-2010-0799-9551-A2, p. 5]

VCC believes that the development of weight and size compatibilities/incompatibilities should be closely monitored and this should be linked to the development of the number of fatalities and injuries. VCC highly recommends that the midterm review evaluate safety in order to assure that the trend is not in an unfavorable direction and that no other measures are warranted. [EPA-HQ-OAR-2010-0799-9551-A2, p. 5]

Many of the negative consequences, as discussed above, can be avoided or mitigated by efficient active safety technologies. The potential of these systems is to effectively eliminate fatalities and serious injuries in traffic. The development of these systems needs, however, to be gradual and follow a step-wise approach linking technological advances with field experiences from real-life traffic. In order to acquire this knowledge, the penetration of the systems into the vehicle fleet is a key parameter. Some of the technologies have added costs due to advanced hardware and software developments. For customers who are unaware of the benefits of the systems, this added cost will not be attractive and will negatively affect the decision when buying a new car. [EPA-HQ-OAR-2010-0799-9551-A2, p. 5]

It is therefore essential that customers are informed about these benefits. Consumer information, e.g. NCAP (New Car Assessment Program) and the 'Buying a Safer Car' guide should include assessments of the systems and clear statements of the benefits. It should also be reflected on the 'Stars on Cars' statement on the Monroney label. The number of systems included in the assessments and protocols should gradually increase following the technical development. [EPA-HQ-OAR-2010-0799-9551-A2, pp. 5-6]

Response:

As explained in section II.G of the Preamble to the final rule, each agency has outlined a technically feasible compliance path available at reasonable cost and cost-effectiveness which is safety neutral. The total amount of mass reduction used in the agencies' analysis for this rulemaking was chosen based on the agencies' documented assumptions about how much mass reduction is technologically feasible without compromising safety. Overall, technical feasibility paths for manufacturers identified in this rulemaking include a minimal mass reduction, <5%, for the majority of passenger vehicles due to safety restraints identified by NHTSA. Some trucks and CUV's have up to 15% to 20% mass reduction in the projected compliance path which would lessen the impact of crash with these vehicle types. As explained in preamble section II.G, and as noted by a number of commenters (e.g. DRI, CBD), removing weight from heavier vehicles should have a positive effect on vehicle safety.

While EPA has shown a possible compliance pathway using one set of assumptions about the use of mass reduction, there are many alternative pathways for compliance. As discussed in EPA RIA section 3.5, this rulemaking is projected to decrease vehicle mass by approximately 4% (on average) relative to the reference case. Rather than using mass reduction technology, manufacturers could choose to use, for example, additional turbo-charging and downsizing, hybridization, or any other available technology. No manufacturer is explicitly required by this regulation to reduce the mass of their vehicles. Some manufacturers may choose not to reduce mass at all. Others may choose to reduce mass by more than the levels projected here. Using the NHTSA methodology discussed in Section II.G, EPA has shown a compliance pathway that is projected to produce no net additional fatalities.

EPA acknowledges the concerns by the Alliance of Automobile Manufacturers (the Alliance), Nissan North America, Inc., and Volvo Car Corporation regarding the mid-term evaluation areas of focus. The Alliance states their concern over the availability of commercially viable emerging technologies that have been assumed as part of the compliance package for this rulemaking. The Alliance supports the proposed mid-term evaluation and urges EPA and NHTSA to review the technology availabilities as well as continuously update the safety analysis as part of this review, including updating the most recent crash data and revised projections regarding mass reduction scenarios. The Alliance also expressed concerns over the Lotus and Future Steel Vehicle concepts. While these concepts do redesign body in whites in aluminum (Lotus- Toyota Venza) and AHSS (Future Steel Vehicle), EPA is releasing a new mass reduction/cost analyses which applies mass reduction ideas and materials already proven in high volume production vehicles to a Toyota Venza. The information contained in this project may address concerns by the Alliance in regards to CAE modeling with respect to advanced material simulations and material production readiness and applicability. Nissan stated that a midterm evaluation is critical to determine the extent to which the market accepts the additional costs associated with more advanced internal combustion vehicles. This issue will be part of the mid-term evaluation. Volvo highly recommends that the midterm review evaluate safety in order to assure that the trend (of weight and size compatibilities/incompatibilities) is not in an unfavorable direction and that no other measures are warranted. The midterm review will consider these issues.

Volkswagen stated that the NPRM predicts for large cars and some trucks upwards of 20% mass reduction potential. Volkswagen feels that this may exceed cost effective limits. The agencies' basis for estimated costs of mass reduction actually appears to be conservative. As shown in joint TSD section 3, the detailed studies sponsored by the agencies suggest that 20% mass reduction is likely feasible for the rulemaking period using lightweighting materials and manufacturing technologies that have already been adopted in high volume vehicles. See joint TSD pp. 3-238 to 251. The accompanying detailed cost analysis in the joint TSD indicates that the cost of reducing mass by 20% can potentially be economical. See joint TSD section 3.3.5.5. The assumptions for mass reduction costs will be examined during the mid-term evaluation.

The Alliance stated that "it is not sufficient to only consider regulatory and consumer information crash tests. A comprehensive evaluation of vehicle safety must also take into account real-world impact scenarios and the special requirements of vulnerable populations (e.g., children and elderly). These must also be adequately accounted for in any agency policy decisions." Preamble II.G.5.c. states "With respect to NHTSA's looking-ahead approach[1] in assessing the feasible amount of mass reduction and the evaluation of concept vehicles, NHTSA does its best in the fleet simulation study to consider as many real world crash scenarios as possible. In the fleet simulation study, NHTSA is including risk functions for different populations. All of the crash results are weighted for their actual occurrence rates. As stated in NHTSA's 2011-2013 research and rulemaking priority plan,[1] the agency currently has programs looking into the areas of safety for vulnerable occupants. NHTSA will monitor the performance of these vulnerable occupants in the context of the changing fleet in response to the fuel economy program."

The Alliance of Automobile Manufacturers expressed some concerns over how safety can be understood through CAE crash modeling due to modeling limitations compared to actual vehicle crash data. The mass reduction study funded by EPA (FEV/EDAG/Munro) showed the ability to achieve mass reduction through the vast majority use of production proven steel in the BIW, which is the main load bearing unit evaluated in the crash models. Discussion with FEV and EDAG revealed that there are differences between the CAE model and the actual vehicle crash results. However the differences are similar to those within vehicle to vehicle manufacturing differences. EDAG stated that the limitations from CAE modeling include material differences not modeled such as when metal is bent or cross thicknesses that may thinned in production, such as in sheet processing.

The Alliance continues to express concern over the modeling of potential future advanced materials in that "Further, significant uncertainties exist with respect to both manufacturing and CAE crash analysis of potential future advanced materials. CAE capabilities for some potential advanced materials that manufacturers are researching are far less mature than for materials currently in common use. Progress in these areas is highly competitive and therefore varies throughout the industry. As such, it will take considerable time and investment for each manufacturer to develop this knowledge and experience. Because agency projections fail to adequately take into account the timing and cost for the introduction of advanced materials, these projections are likely overly optimistic." [EPA-HQ-OAR-2010-0799-9487-A1, p.22] The materials to which the Alliance is referring in their comment in regards to CAE modeling are not stated. The agencies assume the materials that manufacturers will use in their BIW to reduce mass include HSS, AHSS, aluminum and limited magnesium and these materials have all been modeled. The extent of modeling for composites is unknown, however the use of composites in the BIW is still being researched with applications primarily only on some limited high end vehicles.

As stated at Preamble II.G. 4, "The agencies continue to believe that reasonable conclusions regarding the safety implication of mass reduction can be drawn from CAE simulations. As ICCT stated in their comments, CAE simulations are powerful tools that have improved rapidly over the years in terms of their ability to optimize vehicle designs and predict material and vehicle behavior in real life. Use of these highly sophisticated CAE tools has become standard industry practice in helping to verify and validate designs before real parts and vehicles are built. As the Alliance stated, however, CAE capabilities for conventional materials, such as steel and aluminum, are more mature than those of advanced materials, such as magnesium and composites. Steel and aluminum are the major materials used in some of the studies, such as EPA's and NHTSA's light-weighting studies that determined that a baseline vehicle's mass could be reduced by approximately 20 percent while maintaining safety comparable to the baseline vehicle." In addition, "even though CAE tools are used heavily, the agencies acknowledge the concerns the Alliance raised in its comments about CAE capabilities for some potential advanced materials for crashworthiness, and have been mindful of this issue in developing our studies."

The Center for Biological Diversity expressed the opinion that "the agencies to require significant weight reduction among the vehicle fleet as part of its standards; failure to implement light-weighting across the fleet because of alleged safety concerns would be contrary to the evidence and arbitrary and capricious. These revisions must not simply lead to corrections in the text of the final rule, but also to significant increases in fuel efficiency standards in the final rulemaking." Of course, the standards do not require use of any particular technology. Manufacturers are left to choose their own compliance paths (meeting all applicable federal safety standards in doing so). So the agencies cannot "require" manufacturers to adopt any particular compliance path. As described in detail in preamble section II.G, the agencies have carefully documented potential compliance paths which are safety neutral, and thus do not depend on significant mass reduction from vehicles weighing less than 3,106 pounds.

The International Council on Clean Transportation (ICCT) commented that "the results of these studies (Lotus and FEV) will be far more accurate of future designs and they must be used to assess the costs of weight reduction for the final rule." EPA would have considered the use of the results of these studies if they were completed at the time of the analyses for the final rulemaking. Unfortunately only the draft reports were complete and the peer review responses had not yet been addressed nor the final report completed in time for inclusion of the results into the final rulemaking. These reports will be utilized in the midterm review for this rulemaking to consider the cost curve for mass reduction.

A number of comments were received from companies and associations with information on light weight materials for use in automobiles. Commenters included the Aluminum Association, the American Chemistry Council, Bayer Material Science, SABIC Innovative Plastics, and the Society of the Plastics Industry, Inc. These commenters provide information to support the expectations that plastics and other materials being designed today can be used to make a car lighter in weight, now and in the future. Plastics can be used for the closures, such as the tailgate, and various passenger compartment items such as dash boards and venting piping. The areas containing plastic that are exposed to loads typically have an underlying structure which is load bearing – such as in doors and dash boards. Composites are being designed in high end sports vehicles and are currently too expensive for a high production vehicle. The Aluminum Association states that they believe small vehicle designs will be developed using aluminum body and structural components that will achieve significant weight reduction while preserving vehicle size and improving safety performance. EPA agrees with the commenters that significant advancements have been made in lightweight material technologies, and these developments are likely to continue in the future. As discussed in chapter 3 of the Joint TSD, the agencies believe that manufacturers will be able to meet the MY2017-2025 GHG standards through a combination of efficiency technologies, without relying on a level of mass reduction that requires a dramatic shift to exotic light-weighting materials. Section 14 of the RTC addresses comments urging the agencies to adopt a life-cycle approach whereby manufacturing emissions would be considered along with tailpipe emissions to account for reduced GHG emissions from using advanced materials

13.3. Comments on NHTSA/EPA's Statistical Analysis of Vehicle Safety

Alliance of Automobile Manufacturers
American Iron and Steel Institute (AISI)
International Council on Clean Transportation (ICCT)
DRI *(filed its study: "Updated Analysis of the Effects of Passenger Vehicle Size and Weight on Safety" as the comments to the NPRM)*
Wenzel, T.

Organization: Alliance of Automobile Manufacturers

The Alliance supports NHTSA's intention to examine safety from the perspective of both the historical field crash data and the engineering analysis of potential future Advanced Materials Concept vehicles. NHTSA's planned analysis rightly looks backward and forward. However, with respect to looking ahead and the evaluation of concept vehicles, the Alliance recognizes that it is not sufficient to only consider regulatory and consumer information crash tests. A comprehensive evaluation of vehicle safety must also take into account real-world impact scenarios and the special requirements of vulnerable populations (e.g., children and elderly). These must also be adequately accounted for in any agency policy decisions. [EPA-HQ-OAR-2010-0799-9487-A1, p.21]

Organization: American Iron and Steel Institute (AISI)

Collision Injury Severity [Federal Register vol. 76, No. 231 Pg. 74949 et seq.]

However, the effects of mass reduction on a fleet basis, considering collisions of vehicles of unequal mass and of unequal footprint, have not been studied by AISI. We have examined the most recent study by C. J. Kahane15 (NHTSA), published in November 2011. The Kahane findings put a high value on maintaining vehicle footprint. Essentially, the Kahane report suggests that it would be more effective regarding injury performance to improve fuel economy throughout the fleet by reducing mass while maintaining vehicle size, or footprint. In our experience, this is understandable since vehicle collision performance is primarily influenced by crush space, the working distance between the point of impact and the passenger space. Steel structures are particularly effective in absorbing energy during a collision over the engineered crush space (or crumple zone). Preserving crush space in the design of crashworthy vehicles is therefore consistent with our findings in cases where AHSS structures are engineered into equivalent spaces previously occupied by heavier steel structures. [EPA-HQ-OAR-2010-0799-9477-A1, p. 11]

If the Kahane findings on the importance of footprint prove to be true, new AHSS technology has already demonstrated its ability to reduce mass and maintain or improve test crashworthiness performance all within the same vehicle footprint. AISI notes the Kahane study does not dispute or overturn the inherent advantage of heavier vehicles in collisions of vehicles of the same or differing footprints. The study only suggests that if a change is made in a vehicle in order to achieve higher fuel economy, it is better to reduce mass for the same footprint rather than making the vehicle smaller. [EPA-HQ-OAR-2010-0799-9477-A1, p. 11]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 103-104.]

I think in general with regard to safety, we have done quite a bit of research over the last 10 or 15 years in the steel industry. We have proven beyond a doubt that it's very possible to use lighter structures and achieve equivalent test performance on safety.

I think that the new Kahane report is very interesting -- we're still analyzing it, by the way -- and the vehicle-to-vehicle situation is a different story. But I think that in general we don't have any objections to the initial conclusions that were drawn in that study, which really points out the importance of the footprint methodology in defining, you know, your basic vehicle structure.

So, again, steel provides with its high strength varieties the opportunity to reduce the mass in a given footprint, which I think is critically important as suggested in that Kahane study as being probably the primary factor in determining how effectively we can design vehicles to be safe in collisions within the fleet among different size vehicles.

So without changing the laws of physics, I think that this regulation should not have a serious impact on the progress that we're making now on the safety of vehicles on the road.

Organization: International Council on Clean Transportation (ICCT)

3. The use of advanced lightweight materials in smaller cars - or in any vehicle - will not increase fatalities. Analyses by DRI suggest Kahane's results are not robust, likely due to improperly controlled driver, vehicle, environment or accident factors. [EPA-HQ-OAR-2010-0799-9512-A1, p. 2]

Once these factors are appropriately controlled, the effect of weight reduction on fatalities may not be statistically significant. More importantly, high-strength steel and aluminum have better crash properties than the conventional steel used in most vehicles in the historical analysis and their use will reduce fatalities. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

3) Safety

The ICCT appreciates the much improved modeling of safety by NHTSA, in particular the separation of the impacts of size and weight and the inclusion of non-sporty 2-door cars in the analyses. This has addressed many of our comments on safety in response to the 20122016 proposed rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 9]

Despite the improvements, the latest Kahane study, referenced in the proposed rule, still finds that reducing the weight of smaller cars leads to increased fatalities. This issue is important, as the proposed rule assumed that small cars will have zero weight reduction due to the concern with potential fatality increases. The ICCT believes that this increase in fatalities is an artifact of the methodology used by Kahane and that weight reduction using lightweight materials and better vehicle design will reduce fatalities for vehicles of all sizes. [EPA-HQ-OAR-2010-0799-9512-A1, p. 9]

Dynamic Research Inc. (DRI) recently completed a Phase 2 report 4 focused on replicating Kahane's results with the updated 2000-2007 data. They were able to match Kahane's results very closely, indicating that they were able to closely duplicate Kahane's methods and data. The Phase 2 report also conducted analyses using DRI's two-stage method, which separates the fatality impacts into the number of accidents per exposure and the number of fatalities per accident. The two-stage results for lighter passenger vehicles, included in Table 1, below, indicate that the increase in fatalities for lighter vehicles is entirely due to an increase in the number of accidents per exposure. The crashworthiness and crash compatibility of the smaller cars did not contribute to the fatality increase. [Table 1 can be found on p. 10 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, pp. 9-10]

These counter-intuitive results strong suggest that Kahane's methodology has some driver, vehicle, environment or accident factors that have not been controlled for in the current analyses.

Lighter vehicles have theoretical advantages in handling and braking and should be involved in slightly few accidents, not more accidents. From a theoretical view, any increase in fatalities should be due to compatibility issues in crashes with larger vehicles, yet the results do not show any increase in the rate of fatalities once a crash occurs. [EPA-HQ-OAR-2010-0799-9512-A1, p. 10]

DRI also issued a supplemental report,5 which discussed in further detail two key assumptions used in the Kahane report and two alternative assumptions. First, Kahane assumed that the effects of vehicle weight and size can be best modeled using curb weight and footprint. DRI believes it is more appropriate to model weight and size using curb weight, wheelbase, and track width. Wheelbase and track width have different effects on vehicle crashworthiness, crash compatibility, and crash avoidance. These effects are confounded when a single 'footprint' index is used. DRI also found that using footprint and weight had more multi-collinearly than using wheelbase, track width, and weight. As indicated in Table 2, below, the use of wheelbase and track width reduced the number of fatalities associated with weight reduction and the coefficients for all of the vehicle classes are not statistically significant. [Table 2 can be found on p. 11 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 10]

Second, Kahane assumed that the crash exposure is best represented by non-culpable vehicle induced-exposure data. While there are valid reasons supporting the use of non-culpable vehicle induced-exposure data, the DRI report discussed the reasons why it may be better to represent crash exposure using stopped vehicle induced-exposure data: [EPA-HQ-OAR-2010-0799-9512-A1, pp. 10-11]

'Non-culpable vehicle induced-exposure data can include crashes where the nonculpable vehicle was moving prior to the crash. Therefore some drivers may be more likely to be involved in these crashes than other drivers, even if the driver is not culpable in the crash. This is because some drivers may be better able to avoid a crash in which they are not culpable than are other drivers, due to driver skill, driver alertness and/or ability to properly react in time to avoid a collision. Therefore this under-representation in the non-culpable induced-exposure data of good drivers, and over representation of bad drivers, is undesirable and may introduce a numerical bias in the results.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 11]

While the necessary data for evaluating the impacts of wheelbase and track width are in the updated 2000-2007 database, DRI does not yet have stopped-vehicle induced exposure data for the new dataset. Thus, DRI's supplemental report provides a rough evaluation based on the differences that DRI observed in the Phase I regression results using the older data. Assuming that the correlation in the induced exposure estimates in the new dataset will be similar to the correlation in the older data, Table 2 also shows that use of stopped vehicles for induced-exposure data creates a statistically significant reduction in fatalities for weight reduction in larger light trucks and an insignificant increase for the other vehicle classes using footprint and an insignificant decrease in fatalities for the other vehicle classes using wheelbase and track width. [Table 2 can be found on p. 11 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 11]

DRI's results strongly indicate that the fatality increase seen on smaller cars in Kahane's analysis is not robust and is likely due to improperly controlled driver, vehicle, environment or accident factors. [EPA-HQ-OAR-2010-0799-9512-A1, p. 11]

Further improvements in Kahane's methodology would likely correct the artificial increase in fatalities for reducing the weight of smaller cars and, in any case, high-strength steel and aluminum have better crash properties than the conventional steel used in most vehicles in the historical analysis. Thus, there is no basis to support the idea that using advanced lightweight materials in smaller cars - indeed in any vehicle - will increase fatalities. [EPA-HQ-OAR-2010-0799-9512-A1, p. 13]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 195-196.]

I will just make two quick observations. First, every time Kahane reanalyzes the impact of mass reduction on fatalities, the fatality increase goes down. More importantly, the coefficients in Kahane's modeling reflects the material composition in historical vehicles. This is dominated by conventional steel. This modeling implicitly assumes that lighter vehicles do not change material composition. However, future weight reduction will be accomplished primarily with use of high-strength steel and aluminum, both of which have better crash properties than the standard steel. Their use will improve vehicle crash performance and reduce fatalities, even in small cars. In fact, Honda has moved aggressively towards the use of high strength steel in small cars, in part due to the safety benefits.

Organization: Wenzel, T.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 193-197.]

I'm a Research Scientist at Lawrence Berkeley National Laboratory. I appreciate the opportunity to provide comments on the NPRM for this joint rulemaking today. My comments today are mine alone, and I do not represent the views of the U.S. Department of Energy, the Berkeley Lab, or the University of California.

For the last two years I have been under contract with DOE to assist NHTSA and EPA in their analysis of the effect of vehicle mass reduction on safety.

My work has resulted in two studies: an assessment of NHTSA's 2011 regression analysis of U.S. fatality risk per vehicle mile traveled (or VMT), and my own regression analysis of casualty risk per police-reported crash. All three of these studies are available in the public docket with this rulemaking.

My studies agree with NHTSA's conclusion, that the effect of mass reduction on U.S. fatality risk is small and is statistically significant only for lighter-than-average cars.

For lighter-than-average cars, the regression models suggest that a 100-pound reduction in mass would increase U.S. fatalities per vehicle mile traveled by less than 2%.

These results are much smaller than those NHTSA estimated in earlier studies in 1998 and 2003. Other variables that NHTSA included in their regression models have a larger effect on fatality risk than a reduction in vehicle mass.

My analysis by vehicle model indicates that on average, U.S. fatality risk does tend to increase as vehicle mass decreases, except for full-size pickups; societal risk actually decreases as full-size pickups get heavier. This is because of the high risk that full-size pickups impose on drivers of other vehicles.

Although risk increases as mass decreases for other types of vehicles, there is very little correlation between risk and mass for individual vehicle models, even after accounting for differences in other vehicle attributes, driver age and gender, and crash times and locations.

Police-reported crashes can be used to estimate four types of risk: fatality and casualty risk, either per vehicle mile traveled or per crash. Casualty risk includes fatalities plus serious or incapacitating injuries.

My analysis found comparable results in terms of casualty risk per crash to those from NHTSA's analysis of fatality risk per VMT; in most cases, mass reduction resulted in an even lower effect on risk in my analysis than in NHTSA's analysis.

I isolated the two components of fatality risk per VMT: the number of crashes per VMT (or crash frequency), and fatality risk per crash (or crashworthiness).

Crash frequency consistently increases as vehicles get lighter for all types of vehicles. However, mass reduction has only a small effect on fatality risk once a crash has occurred.

In conclusion, the three new analyses suggest the effect of mass reduction on risk is much smaller than NHTSA previously estimated and statistically significant only for lighter-than-average cars.

The agencies should keep in mind that the regression models in the three analyses are not exactly estimating the effect of mass reduction on risk; rather, they are estimating the recent historic relationship between mass and risk after accounting for most measurable differences between vehicles, drivers, and crash times.

In essence, the models are comparing the risk of a 2600-pound Dodge Neon with that of a 2500-pound Honda Civic after attempting to account for all other differences between the two vehicles. The models are not estimating the effect of literally removing 100 pounds from the Neon.

Reduced mass does not inherently decrease vehicle safety; it all depends on where and how the mass is reduced; in short, how mass production is incorporated into the overall vehicle design.

Finally, the agencies should recognize that the results of the three new studies are based on relationship of vehicle mass and footprint on risk for recent vehicle designs. These relationships may or may not continue into the future as manufacturers utilize new vehicle designs and incorporate new technologies, such as more extensive use of strong, lightweight materials and specific safety technologies.

Response:

The principal response to these comments is found in section II.G.2 and 3 of the preamble to the final rule. We supplement those responses briefly here. These comments are from *(1) Alliance of Automobile Manufacturers, (2) American Iron and Steel Institute, (3) DRI,* *(4) ICCT, (5) Wenzel, T.,* DRI and Wenzel's comments are discussed in detail in II. G. 3. h & g of the preamble.

More specifically, ICCT questioned NHTSA's estimated fatality increase for the weight reduction on small cars. ICCT believes that this increase in fatalities is an artifact of the methodology used by Kahane and that weight reduction using lightweight materials and better vehicle design will reduce fatalities for vehicles of all sizes. EPA has looked closely at the issues, and discerns a historical relationship between vehicle mass, size, and safety, including small cars, by most recent safety statistical analysis of historical crash data presented at Preamble II.G.3. As stated in the preamble (II G.3.i), "the agencies expect that the attribute-based standards will likely facilitate the design of vehicles such that manufacturers may reduce mass while maintaining footprint. Therefore, it is possible that the analysis for MYs 2000-2007 vehicles may not be fully representative of the vehicles that will be on the road in 2017 and beyond."

As also stated at the preamble, "we recognize that statistical analysis of historical crash data may not be the only way to think about the future relationship between vehicle mass and safety. However, we recognize that other assessment methods are also subject to uncertainties, which makes statistical analysis of historical data an important starting point if employed mindfully and recognized for how it can be useful and what its limitations may be."

In addition, we believe that we should assess the safety effect on weight reduction by two approaches. One is the statistical analyses approach on historical data to assess societal safety effects. Another is the engineering study approach to assess the ability of individual designs and new material to comply with the FMVSS, and perform well on NCAP and IIHS tests.

DRI filed its new study: "UPDATED ANALYSIS OF THE EFFECTS OF PASSENGER VEHICLE SIZE AND WEIGHT ON SAFETY" as comments to the NPRM. Results of DRI study have been briefly summarized at Preamble II.G.3.g. In the Supplemental report, DRI discussed in further detail two previous key assumptions that were used in the Kahane (2011), Wenzel (2011b), and DRI (2012b) reports, and describes two alternative assumptions. The previous key assumptions were that the effects of vehicle weight and size can be best modeled by curb weight and footprint; and that the crash exposure is best represented by non-culpable vehicle induced-exposure data. The alternative assumptions are that the weight and size can be best modeled by curb weight, wheelbase, and track width; and that the crash exposure is best represented by stopped-vehicle induced-exposure data (because non-culpable vehicle data may under-represent vehicles and drivers that are better at avoiding crashes, even if they would have been non-culpable in those crashes). With alternative assumptions, DRI found that estimated fatality risk due to weight reduction is much smaller than NHTSA's results. The agencies acknowledge these recommendations, and we believe that significant difference between the studies should be closely examined. EPA facilitated technical communications between DRI and NHTSA. In response to the comments, NHTSA has implemented additional sensitivity analysis. The general results of the sensitivity analysis are presented at Preamble II.G. 3. h. The agencies concluded that the difference by DRI's recommendation was within the range of the confidence interval of the estimates, and NHTSA's primary results should be used for the relationship between mass and safety.

In his comment, Wenzel points out that although his study agrees with NHTSA's conclusion, "there is very little correlation between risk and mass for individual vehicle models, even after accounting for differences in other vehicle attributes, driver age and gender, and crash time and location". In more detail, Wenzel's Phase 1 and Phase 2 reports show that when fatality or casualty rates are aggregated at the make-model level, differences between the models "overwhelm" the effect of mass. Likewise, in the basic regression analyses, the effects of many control variables are much stronger than the effect of mass. EPA acknowledges Wenzel's results and believes that Wenzel's findings are important, and it provides a relative comparison in evaluating risk factors between mass and other variables used in the regression. NHTSA indicates it does not dispute the validity of these analyses or disagree with these findings. However, as it stated at Preamble II G. 3.h, NHTSA believes these results must not be misinterpreted. Specifically, it would be wrong to conclude that the effect of mass reduction should not be estimated at all because other ambient effects are considerably stronger.

14. Treatment of Life-Cycle Emissions Related to Vehicle Manufacturing

Support for the Revision of Regulation (EC) No. 443/2009 on CO_2 Emissions from Cars

In our comments to the NOI on this rulemaking in October 2010, we noted the agencies' attempt to examine the life cycle costs of owning and operating a vehicle in conjunction with the costs and benefits of increasing CAFE standards. Since that time, a new life cycle analysis commissioned by the European Union has concluded that improvements in the use phase of vehicles are found to more than outweigh additional emissions from the manufacturing phase. More specifically: [NHTSA-2010-0131-0226-A1, p. 3]

"Changes in vehicle technologies not only affect the CO_2 emissions in the use phase, but many also lead to changes in the GHG emissions occurring in other stages of the vehicle's life cycle, specifically the manufacturing of materials and components, vehicle manufacturing and vehicle disposal and recycling. [NHTSA-2010-0131-0226-A1, p. 3]

For the CO_2-reducing technologies that are expected to be applied to conventional vehicles in response to CO_2 legislation the emission improvements in the use phase are found to more than outweigh additional emissions from the manufacturing phase. Application of light weight materials is found not to increase CO_2 emissions from vehicle production." [NHTSA-2010-0131-0226-A1, p. 3]

A copy of this quoted portion of the analysis is attached as Attachment C [see Docket number NHTSA-2010-0131-0226-A3]. [NHTSA-2010-0131-0226-A1, p. 3]

Life Cycle Assessment Study – Magnesium Front End Research Development

A 2010 life cycle CO_2 study by the Magnesium Front End Research Development (MFRED) project found that aluminum has the smallest overall carbon footprint for total life cycle emissions compared to competing materials including steel. A copy of the complete MFRED project is attached to these comments as D [see Docket number NHTSA-2010-0131-0226-A6]. [NHTSA-2010-0131-0226-A1, p. 3]

We obviously were pleased to see in the agencies' Draft Environmental Impact Statement that the agencies agree with the above conclusions, as evidenced in the statement from the conclusions section of that document: [NHTSA-2010-0131-0226-A1, p. 3]

"Aluminum and high-strength steel material substitution are both effective at reducing life-cycle energy use and GHG Emissions (i.e. the increased energy use and GHG emissions at the vehicle production stage are offset by the use-phase savings over the vehicle life)." [NHTSA-2010-0131-0226-A1, p. 3]

Organization: American Chemistry Council (ACC)

(6) The focus of the rulemaking is properly on tailpipe emissions during vehicle use phase.

ACC strongly supports the use and evaluation of well-developed, comprehensive, and complete life cycle analysis tools for materials and products consistent with International Organization for Standardization (ISO) Life Cycle Assessment standards. That said, the primary purpose of this rulemaking is directed at federal greenhouse gas and fuel economy standards, and NHTSA must develop its standards in accordance with Energy Policy and Conservation Act (EPCA) criteria. These criteria do not directly include life cycle considerations of the materials used in automobile construction. [EPA-HQ-OAR-2010-0799-9517-A2, p.6]

We believe the agencies' focus in this rulemaking – on increasing vehicle fuel economy and tailpipe emissions as a source of greenhouse gas emissions – is well supported by statutory imperatives, and also prudent. As the Environmental Protection Agency (EPA) notes, mobile sources emitted (through tailpipe emissions) 31 percent of all U.S. GHG emissions in 2007 and have been the fastest-growing source of U.S. greenhouse gas emissions since 1990.27 Certainly other phases of the product life of an automobile contribute GHG emissions, from materials manufacture, to employees commuting to the auto manufacturing job site, to container, rail and road shipment of vehicles after their manufacture, and so forth. But emissions during these other phases are nonetheless a fraction of GHG emissions during the operational or use phase of a vehicle,28 and the use phase of the vehicle is responsible for emissions of 80-90 percent of life cycle GHGs.29 LCA data consistently demonstrates that GHG savings in the use phase from using plastics to reduce weight in transportation (e.g., reducing shipping weight of goods, or weight of the vehicle used to transport people or goods) significantly outweigh GHG creation in other phases of the life cycle. A report comparing two LCA approaches and considering both a plastic fuel tank and a steel fuel tank, for example, confirms the fundamental observation relevant to automobiles – that "use phase impacts dominate total life-cycle energy use and life-cycle conventional pollutant emissions."30 [EPA-HQ-OAR-2010-0799-9517-A2, pp.6-7]

Regulatory measures addressing reduction of emissions during vehicle use phase are thus the most effective way to reduce GHGs.31 Some have argued that material-based Life Cycle Analysis (LCA) should be considered, but it does not factor into the rulemaking here. Further, this type of rulemaking is not an appropriate place to apply LCA because of the lack of consensus regarding how to calculate inputs and outputs in an LCA evaluation at this time. With respect to any future policy changes, the use of LCA can play a role, but should be evaluated carefully. LCA is very useful tool, but it cannot itself be dispositive of public policy, a fundamental point for future consideration, in part because it may inadequately address human preferences and behavior (e.g., auto selection, operation, length of ownership, and other factors); costs, job creation, and other issues important to sound policy development. [EPA-HQ-OAR-2010-0799-9517-A2, p.7]

Horvath, Department of Civil and Environmental Engineering, University of California, "Environmental assessment of passenger transportation should include infrastructure and supply chains," Environ. Res. Lett. 4 (2009), ("The dominant contributions to energy consumption and GHG emissions for onroad and air modes are from operational components. This suggests that technological advancements to improve fuel economy and switches to lower fossil carbon fuels are the most effective for improving environmental performance.")

Organization: American Iron and Steel Institute (AISI)

Requested Action

AISI argues below, based on referenced studies from around the world, that future vehicle regulations should be based on life-cycle emissions in order to ensure a net reduction in emissions from light-duty vehicles. To accomplish this, considerable collaboration is necessary among car companies, regulators and suppliers to establish the methodology for fairly accounting for life cycle emissions in vehicle regulations. [EPA-HQ-OAR-2010-0799-9477-A1, p. 1]

The steel industry recommends the formation of an advisory committee among EPA, NHTSA, automakers and suppliers to address this important challenge in time for the 2018 mid-term review with the goal of incorporating life cycle emissions into vehicle regulations for model years 2022-2025. [EPA-HQ-OAR-2010-0799-9477-A1, p. 2]

Accordingly, we suggest 40 CFR sec 86.1818-12 be amended as follows: [EPA-HQ-OAR-2010-0799-9477-A1, p. 2]

(1) Strike "and" in clause (h)(1)(vii) and insert after clause (h)(1)(vii) the following: "(viii) The Life-cycle Assessment Report required in paragraph (i) of this subsection; and"

(2) Strike "and" in clause (h)(2)(iii) and insert after clause (h)(2)(iii) the following: "(iv) The Life-cycle Assessment Report required in paragraph (i) of this subsection; and"

(3) Insert after subparagraph (h)(3) the following:

"(4) No later than November 15, 2017, the Administrator shall issue a draft assessment of the Life-cycle Assessment Report addressing all issues relevant to the inclusion of a materials life-cycle metric in standards for the 2022 through 2025 model years."

(4) Insert after paragraph (h) the following new paragraph:

"(i) Life-cycle Assessment Report. "No later than 1 year following the publication of this regulation in the Federal Register, the Administrator shall establish an advisory committee to evaluate current scientific and technical information regarding life-cycle assessment of the greenhouse gas emissions of materials used in the construction of motor vehicles. The advisory committee shall consist of representatives from the Environmental Protection Agency, the National Highway Traffic Safety Administration, automakers, suppliers to automakers and other qualified individuals with expertise in life-cycle assessment and materials used in motor vehicles. The advisory committee shall be required to issue a report by December 31, 2016. The report shall:

"(1) Address how the life-cycle greenhouse gas emissions of various materials used or planned for use in the construction of motor vehicles can be practically quantified.

"(2) Describe appropriate calculations and data sources that can be used to determine the life-cycle greenhouse gas emissions of various materials; and

"(3) Propose how a materials life-cycle metric can be incorporated within standards for motor vehicles in model years 2022-2025."

Life-cycle Greenhouse Gas Emissions

Studies at many universities including research by Roland Geyer at the University of California at Santa Barbara1 (UCSB) and by Gregory Keoleian at the University of Michigan2 have validated the use life cycle assessment (LCA) principles in determining the true impact of vehicles on total greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-9477-A1, p. 4]

Building on this base, further LCA case studies compiled by Geyer at UCSB (Sun to Wheels Study3) and Ricardo (Preparing for a Life Cycle CO_2 Measure4) show that such materials and manufacturing-related emissions are likely to grow from 15% of total emissions (today) to 50% or more by 2020 as vehicles become more fuel efficient. A tailpipe-only rule which ignores 15% of total emissions (today's situation) is much less problematic than one that ignores 50%. [EPA-HQ-OAR-2010-0799-9477-A1, p. 4]

This scenario was specifically examined by Alissa Kendall at University of California at Davis5 (UC-Davis). Dr. Kendall examined the consequences of continuing to apply tailpipe-only (that is, driving cycle only) regulations and excluding some of the critical other sources of GHG emissions such as occur during materials manufacturing. [EPA-HQ-OAR-2010-0799-9477-A1, p. 4]

A specific example given in the UC Davis study shows the potential consequences of continuing tailpipe-only regulations, i.e., that total vehicle emissions may increase. Kendall's evaluation of a modeled future Toyota Venza6 showed how emissions from the use of low density materials, as labeled in Figure 1 [See Figure 1, Comparison by Kendall of Vehicle Life cycle GHG Emissions from Lotus Study of Toyota Venza, at docket number EPA-HQ-OAR-2010-0799-9477-A1, p. 5.], can account for about 40% (17.3 mt CO_2 eq /43.8 mt CO_2 eq) of total emissions (lowest bar, 11 year life, in Figure 1). Also, it is clear that total emissions for the AHSS version for both 11 year and 16 year life spans are lowest. In this example, differences in materials emissions outweigh differences in driving emissions. [EPA-HQ-OAR-2010-0799-9477-A1, p. 4]

While the importance of life-cycle emissions in future vehicles has been clear in AISI case studies, UC Davis examples, and other academic research, it is important to note other organizations, such as Ricardo, mentioned above, Toyota7, Mercedes and domestic original equipment manufacturers (OEMs) are using LCA as an important tool to understand and manage all aspects of vehicle-related emissions. [EPA-HQ-OAR-2010-0799-9477-A1, p. 5]

One objection often raised regarding the use of life cycle principles in regulations is the perceived complexity. This is a concern to car manufacturers because of the large number of parts used to manufacture vehicles and the large number of suppliers in the supply chain. While specific details must be worked out, research by Kendall suggests that a bill-of-materials (BOM) approach, much like that used by Mercedes8 in its LCA calculations and development of Environmental Certificates for its vehicles, represents a simple approach. [EPA-HQ-OAR-2010-0799-9477-A1, p. 5] [EPA-HQ-OAR-2010-0799-9477-A1, p. 5]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 90-92.]

A schematic of the process for using the BOM for LCA calculations in a vehicle is provided in Figure 2. [See Figure 2 at docket number EPA-HQ-OAR-2010-0799-9477-A1, p. 6]

The flow diagram in Figure 2 could establish a life cycle emissions reference point based on vehicle footprint by: [EPA-HQ-OAR-2010-0799-9477-A1, p. 6]

1. Starting with 2018 vehicles of specific footprints and determining use-phase emissions in the current, tailpipe method, then expanding the approach by acquiring BOM data for the same vehicles.

2. Translating the BOM into life cycle emissions using Argonne National Lab's GREET model, or equivalent and using Oak Ridge National Lab's "Transportation Energy Data Book," or equivalent, for vehicle lifetime miles, a critical input to the GREET life cycle emissions calculation.

3. Using known CO_{2e} equations to establish a footprint-based reference for 2022 vehicles by adding the materials-related life cycle emissions to the use-phase emissions, creating a realistic total emissions limit. This is shown in Figure 3. [See Figure 3 at docket number EPA-HQ-OAR-2010-0799-9477-A1, p. 7]

In the example above, the line entitled "2022 LCA reference" represents a "shift up" of the car curves to account for life cycle emissions using existing BOM data. Please note this is one approach and is intended to show only the feasibility of life cycle based regulations. It is likely that other methods may be possible. [EPA-HQ-OAR-2010-0799-9477-A1, p. 7]

LCA methods are the most straightforward way to account for total emissions. Life cycle emission data exist today for automotive materials as do models for calculating life cycle emissions of vehicles; this is vitally important as materials will carry with them their emissions factors just as they do their strength, density, thickness, etc. The important task is to consider how these data and models can be used in future regulations and to use the time available between now and the proposed 2018 mid-term review to prepare regulations which will ensure a net reduction in emissions from light-duty vehicles. [EPA-HQ-OAR-2010-0799-9477-A1, p. 7]

In summary, AISI emphasizes the following points.

1. As vehicles become more fuel efficient, materials manufacturing emissions will become an increasingly larger contributor to total life cycle emissions to the point they cannot be ignored. Many studies indicate this will begin to occur around 2020.

2. A continued focus on tailpipe-only regulations may lead to an increase in total emissions from light-duty vehicles

3. LCA principles and materials life cycle data are well known and should allow regulators to introduce life-cycle emissions-based regulations by the time such regulations are needed, around 2022. [EPA-HQ-OAR-2010-0799-9477-A1, p. 8]

Organization: Center for Sustainable Systems, University of Michigan

Due to the various sources of GHG emissions from electrified vehicles, we feel that a life-cycle approach should be considered in order to best evaluate and set standards for all vehicle technologies. This is particularly important for EVs since the GHG emissions are upstream, while the majority of the emissions for CVs is due to combustion of fuel during vehicle operation. A life-cycle approach, to evaluating vehicle emissions, would fully account for emission sources due to upstream, vehicle operation and vehicle production life-cycle phases. Furthermore, lifecycle analysis would allow for analogous comparisons between vehicle technologies to ensure that the overall light-duty vehicle GHG emission reductions are realized. [EPA-HQ-OAR-2010-0799-9493-A1, p.2]

Regional variation in GHG intensity of electricity, as pointed out in Section III-C-2 of the proposed 2017-2025 rule, is also an important consideration which should be addressed in vehicle standards. As part of the U.S.-China Clean Energy Research Center for Clean Vehicles, we have conducted research on the total life-cycle GHG emissions from conventional and electrified vehicles using a total vehicle life-cycle (or cradle-to-grave) approach, the results of which are currently in review.3 Our analysis of a representative midsize plug-in hybrid vehicle has shown that there is over a 100 gram per mile GHG emissions variation between vehicles charged in the lowest and highest GHG intensive North American Electric Reliability Council (NERC) regions (based on an assumption of 63.5% utilization of electric mode). Our analysis showed that the Midwest Reliability Council and Southwest Power Pool North American Reliability Council (NERC) regions showed higher life-cycle GHG emissions in electric mode than for gasoline mode. Our results further showed that this difference is even greater for a representative battery electric vehicle, with a difference of over 150 life-cycle GHG grams per mile. These results highlight the importance of a life-cycle approach. [EPA-HQ-OAR-2010-0799-9493-A1, p.2]

We recognize the difficulty in instituting a life-cycle framework into the proposed GHG standards since this type of analysis has not been applied to vehicle standards in past rules. To account for the difficulty in incorporating all vehicle life-cycle stages in the standards we recommend incorporating life-cycle stages as reliable data and methodology becomes available. For instance, data on the upstream GHG emissions from electric power plants is available from sources such as EPA's eGrid database.4 Vehicle production life-cycle data for specific vehicles is less established, although frameworks such as Argonne National Laboratory's GREET Vehicle Cycle model, do exist.5 By adding in these other emission sources, which result from a significant portion of vehicle emissions shifting upstream, an inclusive approach will result in a more complete and robust standard. [EPA-HQ-OAR-2010-0799-9493-A1, p.2]

Since the contribution of GHG emissions to climate change is the same regardless of the source location, we feel that only a complete vehicle life-cycle regulatory approach will result in the necessary emissions reductions from the U.S. vehicle fleet. We would be pleased to provide more detail regarding our recent analysis of life-cycle GHG emissions for electrified vehicles. Please contact Dr. Keoleian by email at gregak@umich.edu or by phone at 734-764-3194. [EPA-HQ-OAR-2010-0799-9493-A1, pp.2-3]

Organization: Kendall, A.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 166-170.]

I hope my comments today will demonstrate that the EPA should continue advancing research by extending its scope of analysis from the tailpipes to the life cycle, including upstream impacts of materials and vehicle technology.

Previous life cycle assessments of passenger vehicles estimated use-phase emissions constitute 85 to 95 percent of life cycle greenhouse gas emissions. So standards that address fossil fuel consumption through fuel economy standards or CO_2 from the tailpipe have functioned to successfully limit or reduce life cycle emissions and will probably do so in the near future as well.

However, two trends suggest that tailpipe-only standards could miss important tradeoffs in technology and design decisions in the future. The first trend is that many technologies that reduce greenhouse gas emissions during operation increase emissions during production. This has been shown for advanced materials used in mass production and also electric power train. The second trend is that when we use reduced greenhouse gas emissions during vehicle use, the relative importance of production-related emissions increases. These trends have been highlighted previously including in the NHTSA draft Environmental Impact Statement and a recent CARB report for their advanced Clean Cars program.

EPA's greenhouse gas emission standards and NHTSA'S CAFE standard are performance-based, allowing for flexibility in how vehicle producers achieve compliance. They can select from an enormous range of technologies and innovations, each of which have unique upstream burdens associated with them. This means that among future vehicles, there may be significant differences in upstream emissions. And if upstream emissions are significant enough, there's a potential for vehicles with lower tailpipe emissions but higher life cycle emissions to be favored.

We undertook research to address these issues. The research was funded by the AISI and the World Auto Steel organization and with additional support from U.C. Davis, the U.C. Davis Institute of Transportation Studies. A summary of our research and findings is currently undergoing peer review in a scholarly journal.

Using a case study approach, we undertook a streamlined LCA for a future vehicle and tested whether tailpipe-only standards could result in the preference for vehicles with lower use-phase emissions but higher life cycle emissions. We used a vehicle designed -- developed in Lotus Engineering 2010 report, a model year 2020 [sic] Toyota Venza. Lotus redesigned the Venza for improved fuel economy while meeting predefined cost constraints and targets for equivalent consumer performance. They did this through light-weighting and power train actions such as hybridization. The high-development vehicle described in Lotus's report was the basis for our model.

To perform the LCA, we connected the bill of materials generated by computer-aided engineering software to life cycle inventory data. Life cycle inventories characterize the upstream emissions associated with material production and forming processes. Using this approach, we found the use phase responsible for 71 to 76 percent of life cycle emissions, which aligns with many previous studies of advanced power train vehicles.

We also performed a variation on the analysis where we altered Lotus's high-development vehicle by replacing the lightweight body structure with one that was 100 kilograms heavier. This was referred to as the low-development structure in the Lotus report. This heavier body structure eliminated some carbon-intensive lightweight materials, primarily magnesium and some aluminum. These materials were replaced with mild and advanced high-strength steel. The change in vehicle weight led to a decrease in fuel economy of 3 miles per gallon, which in turn increased CO_2 emissions during operation. Despite these increased emissions during vehicle use, the new design reduced total life cycle emissions by a significant amount, which approximated to 10 to 20 grams of CO_2 equivalent per mile, depending on vehicle service life.

To put this in perspective, the difference in emissions between the two designs is greater than any of the off-cycle credit provisions and similar in magnitude to many of the air-conditioning credits that the EPA has already considered in its rulemaking.

Our research process also demonstrated that by using the detailed bill of materials generated in computer-aided engineering software, we could produce a streamlined LCA quite efficiently. Since computer-aided engineering tools are widespread in the automotive industry, conducting LCAs may be less burdensome than anticipated.

To summarize, our analysis suggests that there is a potential for a tailpipe-only CO_2 standard to favor vehicles with higher life cycle emissions over those with lower life cycle emissions, shifting greenhouse gas emissions from the tailpipe to production sites. Continued research in tracking of upstream emissions for future vehicles may help manage the risk of selecting vehicle design and technologies where upstream emissions overwhelm use-phase savings. In addition, including upstream emissions in the standard could provide vehicle producers with an additional degree of flexibility to achieve CO_2 production.

Organization: Society of the Plastics Industry, Inc. (SPI)

Life Cycle Analyses of Plastics Demonstrate Favorable Environmental Performance [EPA-HQ-OAR-2010-0799-9492-A1, p.7]

SPI recognizes that the criteria contained in the Energy Policy and Conservation Act (EPCA), by which NHTSA must develop its standards, do not directly address life cycle considerations of the materials used in automotive vehicles. As a result, information on energy use during production of plastics and their chemical feedstocks, along with data on recyclability, are not directly relevant to this rulemaking. However, available information provides support for the life-cycle performance of plastics and related materials. [EPA-HQ-OAR-2010-0799-9492-A1, pp.7-8]

Compared to their alternatives, many plastic products require less energy for production, especially for use in automotive parts. Given that the use phase of a vehicle accounts for 80-90% of the life cycle GHG emissions, it would seem that regulatory measures that aim to reduce emissions during this phase where technologically feasible would be the most effective way to reduce vehicle GHG emissions. This is further supported by LCA data which demonstrates a net savings in GHG emissions when the weight reduction in the use phase is compared to the creation of GHGs elsewhere in the life cycle for the plastic components used, such as with fuel tanks. However, while it is an informative and useful tool, we share the caution and concern expressed by the ACC with the use of LCA in public policy applications given the inherent subjectivity and limitations. [EPA-HQ-OAR-2010-0799-9492-A1, p.8]

Organization: United States Steel Corporation

CAFE was initiated in 1975 in the wake of the 1973 Oil Embargo with the objective reducing dependence on foreign oil. That program adopted miles per gallon, measured in equivalent tailpipe grams of CO_2 per mile, as the metric to achieve reductions in oil consumption. It was the right approach to achieve the stated objective. [NHTSA-2010-0131-0256-A1, p. 1]

However, extending that same metric toward the new objectives of reduction of energy use and greenhouse gas emissions associated with vehicles will not achieve the intended outcome, but in contrast will result in increased total energy use and CO_2 emissions. In fact, the magnitude of these unintended consequences will increase as the fuel economy and grams of CO_2 per mile become more stringent between now and 2025. [NHTSA-2010-0131-0256-A1, p. 1]

These comments requests the EPA and NHTSA to accomplish a technical assessment of the feasibility of incorporating Life Cycle principles into regulation in support of the anticipated 2018 mid-term evaluation that will lead to an informed final agency action. Attachment 1 provides a more detailed analysis of this argument as well as the sources of references supporting documents. [NHTSA-2010-0131-0256-A1, p. 1]

To explain, a vehicle consumes energy and emits CO_2 during all phases of its life which includes manufacturing, driving, and end of life disposal. Considering all phases of a vehicle's life accurately measures its true carbon footprint. [NHTSA-2010-0131-0256-A1, p. 2]

In today's vehicles, the driving phase CO_2 emissions represent 85 percent of a vehicle's total carbon footprint arguably justifies allowing regulators to ignore the other phases of impact. However, as the fuel economy requirements double from 27.5 mpg today to 54.5 mpg in 2025, the driving phase emissions will be cut in half, thus increasing the importance of other vehicle life phases. Also, consider that many of the technologies (and materials) necessary to achieve these fuel economy improvements are energy and CO_2 intensive in the manufacturing phase and will increase the vehicle manufacturing phase CO_2 emissions, altering end-of-life impact in both relative and absolute measures. [NHTSA-2010-0131-0256-A1, p. 2]

Several recent studies demonstrate that vehicles aiming to achieve the future fuel economy and tailpipe emissions targets will have a 50-50 split between CO_2 emissions associated with the driving phase and other phases. Under the proposed regulations 50 percent or more of the total CO_2 emissions associated with these future vehicles will fall outside of the regulation. [NHTSA-2010-0131-0256-A1, p. 2]

Many of the technologies required to achieve the proposed 54.5 miles per gallon target have high manufacturing emissions. Examples of this are materials that compete with steel, such as aluminum, magnesium, and carbon fiber, which are six to twenty times more energy and carbon intensive to produce on a pound per pound basis than steel. While these materials may improve fuel economy and tailpipe CO_2 emissions in the driving phase, those improvements are not sufficient to offset the upstream CO_2 emissions associated with producing these materials. [NHTSA-2010-0131-0256-A1, p. 2]

To address these unintended consequences and achieve optimal environmental resource allocations, future regulations should evaluate the CO_2 emissions associated with all of the vehicle's life. This will ensure that technologies are not deployed that improve driving phase emissions while increasing a vehicle's overall carbon footprint. In this regard, we have been working with the EPA and NHTSA over the past several years to consider a more appropriate methodology which resulted in the section III.G.5 of the NPRM requesting additional information on this topic, for which U. S. Steel would like to thank and commend the EPA and NHTSA for their open mindedness on this issue. [NHTSA-2010-0131-0256-A1, p. 2]

There are other advantages to a vehicle CO_2 regulatory approach that incorporates life cycle principles over the current tailpipe emissions approach beyond the obvious advantage of actually achieving the intended outcome of reduced energy use and CO_2 emissions. [NHTSA-2010-0131-0256-A1, p. 2]

First, such an approach can enable vehicle makers with increased design flexibility in complying with the regulations which will result in lower cost vehicles and improved environmental performance. Vehicle makers have provided examples where the lowest life cycle CO_2 technology solution is also the low cost solution. In contrast, these examples also demonstrate that selection of the technology to improve fuel economy and tail pipe emissions alone would have resulted in increase manufacturing costs while increasing the carbon footprint of the vehicle. Regulations that drive vehicle makers toward solutions that increase cost and total carbon emissions do not make sense. Regulation that incorporates life cycle thinking will address such unintended consequences. [NHTSA-2010-0131-0256-A1, pp. 2-3]

A second advantage is that it would drive the vehicle supply chain to reduce the carbon intensity of their products because of the commercial advantage it would provide them. That is low carbon suppliers would provide a competitive advantage to their customer, the vehicle manufacturer, in complying with the regulations. Regulations, properly executed, would result in a race to the CO_2 bottom as manufactures competed to be the low carbon supplier. [NHTSA-2010-0131-0256-A1, p. 3]

A study sponsored by the steel industry and conducted by the University of California Davis proposes a methodology for CAFE regulation that incorporates life cycle thinking while maintaining the simple grams of CO_2 per mile metric on current EPA-DOT vehicle stickers today and that will dovetail into the existing CAFE regulations. This methodology addresses the unintended consequences and results in real carbon reduction associated with vehicles using information readily available to and easily executed by the vehicle makers. [NHTSA-2010-0131-0256-A1, p. 3]

This proposed life cycle methodology still needs further development in order to be incorporated into regulations, but great strides are being made and should be ready for trial in the coming years. Already, several automakers are utilizing life cycle tools during vehicle design. [NHTSA-2010-0131-0256-A1, p. 3]

The steel industry is building a consortium of stakeholders to further develop this life cycle methodology and identify the details to ensure its feasibility in regulation. Properly devised, we believe life-cycle tools incorporated into the regulation will result in a better framework that increases flexibility for auto designers and improves transparency, while enhancing the environmental integrity of the underlying regulation. The current 2017- 2025 light duty vehicle emission rules call for a mid-term evaluation that will lead to final agency action. We believe that a complete evaluation of the feasibility of incorporating life cycle thinking into vehicle emissions regulation is possible within the mid-term evaluation phase. We will continue to work closely with the EPA and NHTSA on this issue and urge the agencies to actively solicit advice and input from multidisciplinary experts prior to the mid-term review. [NHTSA-2010-0131-0256-A1, p. 3]

In 110 year history of United States Steel Corporation, we have conducted our business practices according to a framework of sustainable business conduct and corporate citizenship established by one of our founders, Judge Elbert H. Gary. These principles, known as the Gary Principles, are established in nine uncomplicated statements. The first of these states, “I believe that when a thing is right, it will ultimately and permanently succeed”. In light of that principle, life cycle thinking applied to climate change regulation is the right thing and we believe it will ultimately succeed. However, ultimately can be a long time with unintended and harmful consequences occurring before the right thing is finally deployed. There is an opportunity during the course of the 2017-2025 vehicle emissions regulations to implement the right solution and avoid unintended consequences. Vehicle emissions regulations that incorporate lifecycle principles is the right approach to achieve positive environmental and economic objectives. Accordingly, we urge regulatory policymakers to begin to investigate the application of life cycle analytics and metrics into future vehicle emissions regulations. [NHTSA-2010-0131-0256-A1, pp. 3-4]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 207-208.]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 209-210.]

So how does this conflict with the national objective of using CO_2 emissions and energy use of vehicles to address climate change? As I stated, many technologies are required to achieve the proposed 54.5 miles per gallon target of high manufacturing emissions. Examples of this: The materials that compete with steel such as aluminum, magnesium and carbon fiber, which are 6 to 20 times more energy- and carbon-intensive in the manufacturing phase on a pound-per-pound basis.

While these materials may improve fuel economy and tailpipe CO_2 emissions in the driving phase, those improvements are not sufficient to offset the upstream CO_2 emissions associated with producing these materials.

To address these unintended consequences and achieve optimal environmental resource allocation, future regulations should evaluate CO_2 emissions associated with all the vehicle's life. This will ensure that technologies are not deployed and improve the driving phase emissions while increasing a vehicle's overall carbon footprint.

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 210-213.]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 214-215.]

The intent and the examples we provided in our discussions with the EPA and NHTSA would include all the materials, but there's a bill of materials that are associated with the vehicle, and it's a standard deliverable that every vehicle comes with, and those can be interpreted with the database as the materials.

So I agree that for OEM to chase the target footprint for the whole supply chain for the thousands of suppliers that produce the vehicle won't be possible. The approach we are recommending uses the database which are available such as the national GREET model that have this data already included in there and it comes very simplified, and there are examples by the OEM of the production vehicles today that have done that.

And, also, we have shared this with, at the recommendation, to the Alliance of Automotive Manufacturers and made the same kind of discussion. Of course, adding another layer of regulation on top of these ones were not seen very positively.

So, when we got through the presentation of this idea of design increases design flexibility; they saw an opportunity in that they would have more ability to comply with the regulations; and, so, they were interested in more information, and we will continue to work with them.

Organization: United Steel Workers (USW)

Additionally, life cycle-based vehicle regulations would establish the United States as the world leader in manufacturing vehicles with the lowest possible emissions, directly resulting in job growth and retention in the domestic manufacturing sector. This is particularly important to the more than 350,000 men and women USW represents who make products – like steel - that are used in auto and light-duty vehicles. [EPA-HQ-OAR-2010-0799-9580-A2, pp. 1-2]

Life-Cycle Greenhouse Gas Emissions [EPA-HQ-OAR-2010-0799-9580-A2, p. 2]

Recent studies at the University of California at Santa Barbara[1] (UCSB) and the University of Michigan[2] have validated the use life-cycle assessment (LCA) principles in determining the true impact of vehicles on total greenhouse gas emissions. A University of California at Davis[3] (UC-Davis) study examined the consequences of continuing to apply tailpipe-only (that is, driving cycle only) regulations that exclude other critical sources of GHG emissions such as those that occur during materials manufacturing. [EPA-HQ-OAR-2010-0799-9580-A2, p. 2]

One objection often raised regarding the use of life cycle principles in regulations is the perceived complexity. This is a concern to car manufacturers because of the large number of parts used to manufacture vehicles and the large number of suppliers in the supply chain. While specific details must be worked out, the UC-Davis study[3] suggests that a bill-of-materials [BOM] approach could simplify the problem. A schematic of the process for using the BOM for LCA calculations in a vehicle is provided in Figure 3. [EPA-HQ-OAR-2010-0799-9580-A2, p. 2] [For Figure 3 please refer to EPA-HQ-OAR-2010-0799-9580-A2, p. 2]

LCA methods are the most straightforward way to account for total emissions. Life cycle emission data exist today for automotive materials [as do models for calculating life-cycle emissions of vehicles]; this is vitally important as materials will carry with them their emissions data just as they do their strength, density, thickness, etc. The important task is to consider how these data and models can be used in future regulations and to use the time available to prepare regulations which ensure a net reduction in emissions from light duty vehicles. [EPA-HQ-OAR-2010-0799-9580-A2, p. 3]

As vehicles become more fuel efficient, materials manufacturing emissions will become an increasingly larger contributor to total life cycle emissions. Several studies indicate this will begin to occur around 2020. [EPA-HQ-OAR-2010-0799-9580-A2, p. 3]

LCA principles and materials life-cycle data are well-known and should allow regulators to introduce life cycle emissions-based regulations by the time such regulations are needed, around 2020. [EPA-HQ-OAR-2010-0799-9580-A2, p. 3]

3 - Life Cycle Greenhouse Gas Emissions Standards for Passenger Vehicles – The Policy Context, Alissa Kendall, Ph. D., and Lindsay Price, University of California, Davis, December 30, 2011

Organization: World Resources Institute (WRI)

The GHG Protocol team at the World Resources Institute (WRI) would like to offer the following comment to the inquiry on page 75112, section 5 about the current state of life cycle GHG accounting. The GHG Protocol (www.ghgprotocol.org) has recently published two new GHG accounting and reporting standards: Corporate Value Chain (Scope 3) and Product Life Cycle. These standards were initiated based on stakeholder requests for a more comprehensive, life cycle based approach to measuring and mitigating GHG emissions. [EPA-HQ-OAR-2010-0799-7086, p. 1]

Both standards were developed with the participation of over 2300 stakeholders including industry, academia, NGO, and government representatives. During development, the draft standards were road tested by over 60 companies including Ford Motor Company (see the enclosed link) and WorldAutoSteel. Since publications, these standards have already been adopted and endorsed by several large consumer goods companies. In October 2011, Ford announced that they were expanding their GHG measurement program to include scope 3 emissions based on the GHG Protocol Standard (reference attached). [EPA-HQ-OAR-2010-0799-7086, p. 1]

The support we received throughout this progress shows the need for life cycle based GHG accounting. Considering the full life cycle of a product exposes not only additional GHG risk but also reduction opportunities along the supply chain that otherwise would not be discovered. Additionally, taking a life cycle approach to GHG accounting can help avoid unintended consequences associated with shifting GHG burden, especially for new and emerging technologies. Given the extensive technical research by leading experts and broad consensus developed through a three year long multi-stakeholders process, we think GHG Protocol standards provide a much needed tool to help companies, organizations, and governments perform life cycle GHG Accounting. We hope you will consider and use our standards as a tool to help you assess the life cycle GHG impacts of vehicles. [EPA-HQ-OAR-2010-0799-7086, pp. 1-2]

Organization: World Steel Association

In regard to the referenced Docket, the World Steel Association (worldsteel) commends the US EPA for its acknowledgement of the life cycle impacts of vehicle emissions. While we recognize that a life-cycle approach to emissions regulations is a significant paradigm shift, we believe it is the best methodology to truly realize a vehicle carbon footprint reduction. [EPA-HQ-OAR-2010-0799-7766-A1, p. 1]

Significant investments and efforts have been made over the years to apply Life Cycle Assessment (LCA) to products and services to reduce environmental impacts, not only through industry efforts, but through government-driven initiatives as well. While LCA is well known and accepted in scientific circles and government circles around the world, both the United Nations Environment Programme's Life Cycle Initiative and the Society of Environment Toxicology and Chemistry's regional LCA groups (LCA Advisory Group in North America and LCA Advisory Committee in Europe) have organized independently to study and advise on LCA. The World Steel Association is a Board member of this UNEP/SETAC Life Cycle Initiative. [EPA-HQ-OAR-2010-0799-7766-A1, p. 1]

However, the lack of consistency in incorporating LCA into policy and legislative measures fails to recognize these significant achievements, but most importantly fails to capitalize on the greenhouse gas (GHG) emissions reduction potential or comprehend the significant unintended consequences of increased CO2 emissions that are likely to occur unless it is addressed. The automotive industry is a clear example of this: tailpipe emissions remain the overwhelming measurement for GHG emissions in the sector. [EPA-HQ-OAR-2010-0799-7766-A1, p. 1]

Life Cycle inventory data for automotive material applications such as steel, aluminum and other competing products is robust and continues to improve and expand. Considerable academic work is being done to support the application of LCA to regulatory policies such as those aimed at improving the environmental performance of light duty vehicles. [EPA-HQ-OAR-2010-0799-7766-A1, p. 1]

As detailed in the comments submitted by WorldAutoSteel, and the American Iron and Steel Institute (AISI), more advanced internal combustion engine (ICE) technologies emerging in today's cars as well as the future direction of greener vehicles, will reduce tailpipe emissions, calling for a more integrated approach. [EPA-HQ-OAR-2010-0799-7766-A1, p. 1]

- As advanced technologies in ICE progress, tailpipe emissions will lessen, and the relative importance of vehicle manufacturing emissions will increase. The introduction of alternative powertrains, such as Battery Electric vehicles will leave more than half of the total vehicle life cycle emissions unaccounted for in the regulations. Regulations based on the tailpipe will become obsolete. Also, automaker measures taken in an effort to address tailpipe-focused regulations have a great potential to actually cause more harm through unintended consequences.
- LCA is the best methodology to encompass the full vehicle carbon footprint.
- LCA encourages the entire supply chain to optimize their environmental performance as this will become a qualifier in order to be an automotive industry supplier. [EPA-HQ-OAR-2010-0799-7766-A1, p. 2]

A life-cycle approach will drive design and manufacturing flexibility in complying with the regulations, opening the door for even more holistic, creative solutions. [EPA-HQ-OAR-2010-0799-7766-A1, p. 2]

Organization: WorldAutoSteel

WorldAutoSteel and its member companies are keenly aware of vehicle emissions regulations in the world today and would like to take this opportunity to commend the U.S. EPA for their consideration of Life Cycle Assessment (LCA) as you develop the next generation of U.S. emissions standards. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1]

We believe that a Life Cycle Assessment approach is the only way to effectively reduce vehicle carbon footprint. Regulating only tailpipe or use phase emissions could lead to industry responses that actually make things worse. Consider the use of light weight materials to reduce vehicle mass: It does decrease use-phase emissions, but since the production of light weight materials is typically GHG intensive, the emissions during vehicle production are likely to increase significantly. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1]

If the increase in embedded production emissions is greater than the decrease in use-phase emissions, this approach to vehicle light-weighting actually increases total emissions - an unintended consequence. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1]

Vehicle light-weighting is also costly, since it typically relies on expensive materials and requires retooling of manufacturing lines. There is evidence that redesigning power trains offers a better environmental return on investment than light-weighting. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1]

The problems created by ignoring emissions from vehicle production will be further aggravated by future low-carbon fuels and drive-train technologies. While a typical gasoline-powered vehicle currently emits only around 15% of its GHG during production, the use of cellulosic ethanol or a shift towards battery or hybrid electric vehicles would dramatically increase the share of vehicle production emissions. A recent Ricardo Study commissioned by the U.K.'s Low Carbon Vehicle Partnership estimates that vehicle production will grow to 57% of the total life cycle emissions due in large part to the introduction of the battery electric powertrain technology. The production portion of these embedded emissions therefore becomes more dominant and decisions made, such as material selection, become far more critical. For a battery electric vehicle powered entirely by renewable electricity, vehicle production emissions could account for as much as 85% - a complete reversal from today's ICE-powered vehicles. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1]

Without a life cycle assessment strategy in place, decisions will be made that may decrease fuel consumption, but with the unintended consequence of significantly increasing these embedded emissions. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1]

A more thorough way of measuring automotive GHG emissions is by using LCA, which takes into account all of the emissions created during the life of a product from raw material production to product end-of-life. Only when a vehicle's total life-cycle emissions are accounted for can the net environmental impact of different designs be compared. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1]

LCA methodology and practice have been developing since the early 1970s. Today, it is a mature assessment tool with global standards. Independent of legislation many car manufacturers are already using life cycle thinking and LCA, recognizing its importance and effectiveness in product and process design. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1, p. 2]

LCA is equally accepted and used by material producers. In fact, together with many of their member companies, the trade associations of the steel, aluminum, and plastic industries are among the most active members of the global LCA community. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1, p. 2]

Many environmental agencies around the world support life cycle assessment, including the European Commission which calls it "the best framework for assessing the potential environmental impacts of products currently available." Environmental regulators and policy makers have begun to draft legislation with a life cycle perspective, such as California's Low Carbon Fuel Standard3, but need to do so more frequently and consistently. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1, p. 2]

Life-cycle-based automotive GHG regulation is feasible and can be achieved by amending rather than replacing current standards. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1, p. 2]

An automotive life cycle GHG emission standard accounts for the joint emissions from fuel combustion, fuel production, and vehicle production and recycling. Fuel production emissions need to be included so that driving fuel cell or battery electric vehicles do not appear emission free, even though hydrogen and electricity production can be fairly GHG-intensive. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1, p. 2]

[See figure on page 2 of Docket number EPA-HQ-OAR-2010-0799-7174-A1, p. 1, p. 2]

The main task of accounting for vehicle production is to avoid unintended consequences such as the one discussed earlier. Science-based rules need to be established about how to measure emissions from vehicle production. A good starting point would be to multiply the materials composition of a vehicle, which is readily available in automaker bill of materials, with the GHG intensity of each material, also readily available, which would include adjustments due to materials recycling. This would cover the majority of emissions from vehicle production and recycling. Dividing the emissions from vehicle production and recycling by total driven distance, also readily available, yields a measure in grams of CO_2 equivalent per km and can be readily added to the fuel cycle measure. This is illustrated in the figure above for two compact class vehicles with differing materials compositions. This approach is simple for the vehicle makers to implement and is sufficient to avoid the unintended consequences that will occur with tailpipe only emissions. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1, p. 2]

Automotive life cycle GHG emission standards are feasible and will benefit the climate. Life Cycle Assessment is included in other industry emissions standards; however, life-cycle-based environmental regulation is in its infancy and requires an investment of resources to bring this approach to a mature state. We feel this can be accomplished in support of the interim review period anticipated in 2018. Nevertheless, the regulation of automotive GHG emissions provides a unique opportunity to align regulatory practice with the state of the art in environmental product policy and launch a new area of enlightened and successful environmental legislation. [EPA-HQ-OAR-2010-0799-7174-A1, p. 1, p. 3]

Response:

EPA recognizes that there are GHG emissions associated with vehicles beyond those emitted during vehicle operation or the “use” phase, including emissions from component and vehicle manufacturing and end-of-life disposal.[26] We thank the commenters who responded to our request for studies on this topic by providing information on their own or external research. We also appreciate the World Resources Institute’s comment highlighting two recent GHG accounting and reporting standards related to life-cycle assessments. EPA is glad to see the advances in research on this important issue and plans to continue to monitor new work in this area.

[26] For a discussion of GHG emissions associated with the production and distribution of fuel (including emissions due to electricity generation used to power EVs and PHEVs), see Sections 4 and 6 of this document.

The GHG standards we are finalizing for MY2017-MY2025 do not incorporate vehicle manufacturing or end-of-life emissions. We agree with comments by the American Chemistry Council and the Society of the Plastics Industry, Inc. that these emissions are typically small relative to GHG emissions from vehicle operation, and therefore regulating emissions from the use phase is an effective method for reducing GHG emissions from vehicles.

However, we acknowledge the point made by other commenters that the relative significance of manufacturing emissions, and other non-use phase emissions, will increase as vehicles' fuel economy improves over time. Some advanced vehicle technologies and materials designed to reduce GHG emissions at the tailpipe may also be more energy and carbon intensive to manufacture than conventional vehicles and result in vehicle production accounting for a higher fraction of total life-cycle GHG emissions (e.g., electric vehicles powered by a low-carbon grid or certain light-weighting materials).

Kendall highlighted one such example from her research at the University of California, Davis comparing life-cycle emissions from two modeled MY2020 vehicle designs. She found a more fuel-efficient vehicle (which utilizes magnesium and aluminum to reduce mass) to have higher overall life-cycle GHG emissions than a heavier, less fuel-efficient model that incorporates less of these materials. We recognize that such tradeoffs are possible and plan to monitor how materials usage for future vehicles changes over time. However, as discussed in chapter 3 of the Joint TSD, the agencies believe that manufacturers will be able to meet the MY2017-2025 GHG standards through a combination of technologies, without relying on a level of mass reduction that requires a high penetration of these light-weighting materials. Therefore, EPA believes that these standards are unlikely to significantly impact vehicle production emissions and the overall balance of GHG emissions (i.e., production versus use phase) for the light-duty fleet due to the use of these materials.

We also believe there is currently too much uncertainty about the life-cycle impacts of future advanced technologies to conduct the type of detailed, transparent, and replicable vehicle-specific assessments that would be needed in a regulatory context. The GHG standards being finalized in this rule are based on uniform test procedures that hold automobile manufacturers accountable for emissions during vehicle operation. By contrast, full life-cycle accounting would require automobile manufacturers to account for GHG emissions associated with a vehicle's complete material supply chain and would require assumptions about how materials and components would be used at the end of a vehicle's life, which are particularly uncertain for future and emerging technologies such as electric vehicle batteries.

Kendall and several organizations from the steel industry suggested a possible approach for incorporating vehicle production emissions into GHG standards by linking a vehicle's bill of materials to an established GHG emissions model. While such a framework may be possible, it would not eliminate many of the challenges associated with finding a comprehensive and consistent set of emissions data and assumptions that would be fair and robust across all technologies. Also, the bill of materials may not capture differences in material origin that could impact GHG emissions (e.g., the percentage of recycled content, and the location and processes used for production). NHTSA conducted a literature review of life-cycle studies for certain vehicle technologies as part of its Environmental Impact Statement for this rulemaking.[27] The range of different models and approaches utilized in the surveyed studies and the sensitivity of the results to study assumptions further illustrate these challenges.

Moreover, in addition to the evident difficulties in accounting for life-cycle emissions relating to upstream manufacturing in a reliable, transparent, and replicable manner, these section 202 (a) standards are in the end for control of vehicular emissions. Compliance in virtually all instances is measured at the tailpipe.[28] Standards reflecting manufacturing life-cycle GHG emissions would be more wide-ranging, changing the focus of the program at least in part from vehicular emissions to manufacturing emissions. The Clean Air Act provides direct means for control of stationary source GHG emissions, and EPA does not believe it appropriate, at least at this time, to approach these issues indirectly by means of section 202 (a) vehicle emission standards. See also the discussion in preamble section III.C.2.c.v, related to upstream accounting of emissions from sources generating electricity used to power electric and plug-in hybrid electric vehicles explaining that this rule establishes a vehicle emission program, not a fuel based program.

We note the recommendation of several organizations to further investigate incorporating life-cycle emissions, including manufacturing emissions, into later model year vehicle regulations as part of the agency's mid-term evaluation. EPA plans to consider a broad range of factors in its mid-term evaluation in order to determine whether the MY2022-2025 GHG standards are appropriate under section 202(a) of the CAA. EPA will develop and compile up-to-date information for the review through a collaborative and transparent process, including public notice and comment. See section III.B.3 of the preamble for more information on the mid-term evaluation. As noted above, EPA intends to continue to monitor new research related to vehicle life-cycle assessment and would therefore be interested in reviewing any additional work conducted to evaluate vehicle-specific production and end-of-life GHG emissions based on the bill of materials (BOM) or other approaches.

[27] See Ch. 6, "Literature Synthesis of Life-cycle Environmental Impacts of Certain Vehicle Materials and Technologies," Docket No. NHTSA-2011-0056.

[28] As explained in section III.C.2.c.v of the preamble, the rule accounts for upstream emissions attributable to energy use by EVs and PHEVs in limited circumstances. While this upstream value does not reflect a single means of generating electricity, the aggregated emissions from electricity generating facilities and their various fuels can be estimated with reasonable certainty, and so differ from evaluating the upstream GHG emissions attributable to the vast range of individual manufacturing facilities and processes.

15. Economic Assumptions Used in Analyses

15.1. On-Road Fuel Economy Gap

Organizations Included in this Section

U.S. Coalition for Advanced Diesel Cars

Organization: U.S. Coalition for Advanced Diesel Cars

Accurately account for the on-road Miles Per Gallon (MPG) gap. [NHTSA-2010-0131-0246-A1, p.2]

On-Road MPG Gap [NHTSA-2010-0131-0246-A1, p.11]

EPA is fully aware that the gap between CAFE certification and on-road fuel economy in the real world has been growing for years. The following table, which is derived from data as published in EPA's annual Light Duty Automotive Technology, Carbon Dioxide Emissions, and Fuel Economy Trends: 1975-2010 ("Trends Report") demonstrates the growing gap. [NHTSA-2010-0131-0246-A1, p.11]

As shown above, the gap between CAFE and 5-cycle label mpg, which was just 2.2 miles per gallon in 1975, has increased to 5.8 mpg through 2010, or a gap of more than 20.5 percent. While the fleet average gap was an even 20% in 2005, it jumped to 20.5% in 2010, following a decade's long upward trend. In terms of GHG emissions, the gap is now close to 26 percent between emissions that are measured under certification tests and emissions that occur in real-world driving. EPA is aware of this growing gap and also is aware that certain technologies are driving the fleet average gap to increase much faster than others. [NHTSA-2010-0131-0246-A1, p.12] [For the figure referenced 'above', please refer to NHTSA-2010-0131-0246-A1, p.11]

"This greater impact occurs primarily because a number of the fuel efficient aspects of hybrid vehicles produce their maximum benefit under conditions akin to the FTP and HFET tests, and are somewhat less beneficial during aggressive driving, colder ambient temperatures and when the air conditioner is turned on." [NHTSA-2010-0131-0246-A1, p.12]

The following exhibit shows the growing gap between the 2-cycle CAFE tests and 5-cycle label fuel economy, based on EPA's 2012 Fuel Economy.gov database of all light duty vehicles available in the U.S. market.[12] [NHTSA-2010-0131-0246-A1, p.12] [For the associated 'exhibit' please refer to NHTSA-2010-0131-0246-A1, p.12]

Just as EPA found in its 2006 analysis, the fuel economy gap for hybrid electric vehicles is far greater than the fleet average. In fact, the on-road gap for several HEVs is well above 30%. Under rapidly increasing fuel economy standards, the on-the road gap will continue to grow unless test procedures are brought up to date. [NHTSA-2010-0131-0246-A1, pp.12-13]

When calculating the benefits of the proposed rule, EPA fails to recognize the diminishing correlation between lab and on-the-road fuel economy. Instead, EPA risks to freeze the gap at 20 percent for purposes of measuring benefits consumers will realize under the rules, where the CAFE mpg is multiplied by 0.80 to estimate on-road fuel economy. As shown in the table above, although the Trends Report shows a gap of 20% for 2005, by 2010 the gap had risen to 20.5%. Instead of relying on fleet average label values from the Trends report, EPA and NHTSA, beginning on page 4-4 of the Joint TSD, explain that they are relying on the Federal Highway Administration's (FHWA) estimation of the fuel economy cars and light-duty trucks achieve as Americans drive in the real world. In describing the reasons that they are using a constant 20% on-the-road gap, rather than a growing gap as evidenced in the Trends Report, the agencies state: [NHTSA-2010-0131-0246-A1, p.13]

'We are not aware of the precise methodology used to develop the distinct on-road fuel economy estimates for cars and trucks developed by FHWA." [NHTSA-2010-0131-0246-A1, p.13]

The Coalition recommends that the agencies look at U.S. DOT Publication No. FHWA-PL-121-031, published August, 2011. This document provides a detailed description of the methodology FHWA uses to estimate on-the-road fuel economy for light duty vehicles as it attempts to mathematically allocate how much fuel is consumed by each class of vehicle in the nation (cars, motorcycles, busses and heavy trucks, etc.) On page 8 of this report, FHWA states that the EPA Trends Report 5-cycle label values are the source for estimating on-the-road fuel economy for vehicles in the fleet. In summary, FHWA uses EPA 5-cycle label fuel economy as an input to its complex model to allocate fuel use by vehicle type while EPA does not use the same procedure. [NHTSA-2010-0131-0246-A1, p.13]

Since EPA is actively promoting hybridization through its rulemaking, we question why it has elected to freeze the on-road gap at 20% when calculating benefits, since its own data shows this gap has and will continue to expand through the duration of the rule. If the EPA is not planning to update test procedures for purposes of administering fleet average rules and reporting fuel economy to consumers on EPA labels, then we urge the agency to show the range of benefits it is able to calculate as the gap between laboratory and real, on the road fuel economy continues to grow through 2025. [NHTSA-2010-0131-0246-A1, p.13]

12 - Data from EPA/DOE www.fueleconomy.gov 2012 Fuel Economy Datafile. Analysis by the Martec Group.

<u>Response:</u>

This comment is discussed in TSD 4.2.1. As noted there, the U.S. Coalition for Advanced Diesel Cars suggested that the on-road gap used in the proposal was overly conservative, and that advanced technology vehicles may have on-road gaps larger than 20%. The agencies recognize this potential issue – future changes in driver behavior or vehicle technology may change the on-road gap. The Coalition states that the EPA 2012 Trends Report shows that the gap for gasoline vehicles grew from 20% in 2005 to 20.5% in 2010, and that therefore the 20% value used by the agencies is understated. We note that in recognition of the potentially greater gap for electrification technologies, the agencies are using a 30% adjustment for wall electricity; but more broadly, to the extent that the Coalition is suggesting that the agencies extrapolate the growth trend in the gap into the future, the agencies do not agree that the estimate of the future on-road gap would be appropriately estimated by extrapolating the historical relationship between the test procedure and real world fuel consumption and emissions. That historical rate of change occurred as a result of the specific technological changes in vehicles over that timeframe. In the future, different technologies will be employed, that are likely to affect the gap differently. As an example, while some technologies such as electrification may increase the on-road gap, other off-cycle technologies such as tire pressure management systems, air conditioning improvements and aerodynamic improvements may decrease it. Thus, the agencies are continuing to use the same on-road gap methodology as in the proposal for this final rulemaking, but will monitor the EPA fuel economy database as these vehicles enter the fleet.

With regard to the comments regarding FHWA-PL-121-031, we appreciate the reference, although, we believe the commenters mean FHWA-PL-11-031. We have removed the relevant sentences from the text.

Plant Oil Powered Diesel Fuel Systems, Inc.

Organization: Consumer Federation of America (CFA)

- The rebound effect in the national cost-benefit analysis should be smaller. [EPA-HQ-OAR-2010-0799-9419-A1, p. 14]

Rebound effect: When U.S. consumers drive vehicles that get more miles to the gallon, they save money on their gasoline bills. They have more money in their pockets to spend. Whether or not they choose to use some of that extra spending money to drive more, they are still better off.19 From a national cost-benefit point of view, the rebound effect should be subtracted from the fuel savings, but from the point of view of the individual consumer, the analysis must assume that all of the savings increase consumer welfare and that consumers choose to use those savings in a manner that maximizes their individual welfare. For this reason, the rebound effect should be subtracted in the national cost benefits analysis but not the consumer pocketbook analysis.[EPA-HQ-OAR-2010-0799-9419-A1, p. 52]

---

19 We have argued that the rebound effect should be taken into account only in the national cost-benefit analysis and then modelled as an income effect, not a price effect. That is, the consumer would devote extra dollars of disposable income to gasoline expenditures reflecting the marginal value of gasoline. This would put the current rebound effect in the range of 5%, which is what more recent studies have found.

Organization: Defour Group LLC

V. Social Benefits and Costs of the 49.6 mpg Standard

In Table VIII-27b, page 715 of the PRIA, the agencies estimate a net social loss of $2.2 billion in MY 2025, which in a 17 million unit sales year comes to a loss of just over $100 per vehicle. This estimate is the sum of $2.5 billion in "Reduced Health Benefits from Criteria Emissions," $9.7 billion in "Climate Damages from CO_2 Emissions," and $4.4 billion in "Reduced Petroleum Market Externalities," less a $9.6 billion "Change in [loss of] Fuel Tax Revenues" and $9.3 billion in "Increased Costs of Congestion, etc." [EPA-HQ-OAR-2010-0799-9319-A1 p. 10]

These estimates reflect a rebound effect – the impact of reduced fuel costs on increased vehicle driving and thus increased fuel consumption -- of just 10% and totally ignore the impact of the so-called clunker effect, which is the effect of higher vehicle prices and consumer welfare losses on the retention of older and higher emitting used vehicles.12 If, consistent with the mainstream literature, we assume a 20% rebound effect (see Part VII) and, following Goulder et al, a clunker effect of 31.5%,13 the estimates of emissions reductions and fuel tax revenue losses in the table should be reduced by 45% and the estimates of congestion and other externality costs (including highway accident externality costs) should be increased by a factor of 2.14 The net result is a social welfare loss of $900 per vehicle (as always, rounded to the nearest $100 per vehicle).15 [EPA-HQ-OAR-2010-0799-9319-A1 p. 10]

This initial estimate is substantially understated. The higher rebound effect combined with the clunker effect means that criteria pollution emissions will actually increase as a result of the standard, as criteria pollution is the product of vehicles miles traveled, which increases with the rebound effect, and emissions per vehicle on the road, which rises because of the clunker effect as more higher emitting used vehicles remain on the road. Gruenspecht found, for example, that because of the clunker effect, California's Zero Emission Standard for MY 2003 would actually increase criteria pollution emissions by 3 to 15 times the amount of the estimated emissions reductions for new vehicles.16 [EPA-HQ-OAR-2010-0799-9319-A1 p. 10]

VIII. The Rebound Effect: Crucial Determinant of Private and Social Welfare Effects

As we have shown, estimates of the rebound effect – the offsetting increase in fuel consumption caused by increased driving in response to higher fuel economy and thus lower fuel costs –are critical to the estimates of both private and social benefits of the standards. A higher rebound effect means lower private fuel savings and lower estimates of climate and energy security benefits. It also means proportionately higher estimates of congestion and accident externality costs that must be subtracted from the nowreduced climate and energy security estimates. [EPA-HQ-OAR-2010-0799-9319-A1 p. 16]

We find that the agencies' use of a 10% rebound effect understates the actual level by at least a factor of two. The agencies justify their 10% estimate on the basis of two studies: a forthcoming study of rebound effects that is as yet unavailable to the public, but which the author, Dr. Greene, graciously provided to these reviewers, and an earlier study by Small and Van Dender, which Greene (appropriately) rejects as an inadequate reflection of reality and as a violation of economic first principles. Dr. Greene found a negative (albeit statistically insignificant), relationship between fuel economy (mpg) and vehicle miles traveled (vmt) as opposed to the predicted, intuitively appealing positive value. However, when several errors in his study are corrected, it supports other recent studies that imply fuel price elasticities and thus rebound effects of 30% and higher. [EPA-HQ-OAR-2010-0799-9319-A1 p. 16]

Of particular concern in Greene's study is the aggregation problem – a problem that can cause dramatic over estimates of implicit consumer discount rates and underestimates of the responsiveness of automotive fuel economy levels to fuel prices.26 Work by Resources for the Future economist Elsheba Spiller, for example, shows that Greene's use of one overall car and light truck light-duty fleet could bias his results downward by as much as 51%. That is because it fails to allow enough margins over which auto buyers can adjust their purchasing decisions in response to changing fuel prices and levels of fuel economy. If there is only one level of aggregation – the entire fleet of cars and light trucks, it may not be possible to tell whether a rising level of fuel prices or fuel costs is causing a shift within the aggregate fleet to more fuel-efficient vehicles. The modeler's regression study could show little or no response on the aggregate when there has been a substantial movement to higher mpg vehicles at lower levels of aggregation.27 [EPA-HQ-OAR-2010-0799-9319-A1 p. 16]

In Greene's study light truck vehicle miles traveled (vmt) exceeded that of passenger cars by as much as 1,500 miles per year, which has nothing to do with the influence of fuel cost on vmt. So as the light truck market share and thus vmt increased over the period, Greene's proxy for fuel cost, gallons per mile (the reciprocal of fuel economy or miles per gallon), also rose, causing a spurious positive correlation between his measure of fuel cost and vmt. It is not surprising, then, that his point estimate for the influence of fuel costs on vehicle miles traveled (vmt) is positive – that as fuel economy falls and thus his measure of "fuel costs" rises, his model finds that consumers will drive their vehicles more, not less (and conversely). [EPA-HQ-OAR-2010-0799-9319-A1 p. 17]

It would also seem that gallons per mile is not a good measure of fuel cost, which requires the dollar sign in the numerator. Without the price of gasoline in the numerator, the measured level of fuel costs -- gallons per mile -- can increase even when fuel cost per mile is falling and can fall when fuel cost per mile is actually rising. Certainly, real-world consumers would be foolish to look at mpg or its reciprocal in a vacuum. [EPA-HQ-OAR-2010-0799-9319-A1 p. 17]

We agree with Dr. Greene that his result – that as fuel costs rise auto owners do not respond by reducing their driving (and possibly even increase their driving) -- is counter intuitive. Indeed, it violates the most well-established finding in all of economics, what economists call the “First Law of Demand” – that, all else equal, when the price of a good or service rises, less is demanded, not more or none at all.28 [EPA-HQ-OAR-2010-0799-9319-A1 p. 17]

His rationale for finding that owners do not reduce their driving when fuel costs rise is that binding fuel economy standards cause vehicle prices to rise and that increased amortization of the higher purchase prices partially offsets the reduction in fuel costs. To be sure, binding mandates do raise the average price of the new car fleet. But much of the increase is an increase in fixed costs that, unlike reductions in fuel costs, does not affect the marginal and thus variable cost of driving. Much of the increase is dissipated immediately after the vehicle is taken home from the showroom and a further amount later by vehicle obsolescence that is related solely to age and not to the wear and tear that comes with vehicle miles traveled. [EPA-HQ-OAR-2010-0799-9319-A1 p. 17]

The only empirical evidence Greene offers in support of a negative or zero rebound effect is Greene’s downward-biased estimate and that of Small and Van Dender – the other study on which the agencies rely for their estimate of a 10% effect. But Greene, correctly, in our view, rejects the Small and Van Dender rebound study, the update of which now finds a 15% rebound effect,, because, as he says, it “does not represent an adequate representation of the effect of fuel economy standards,” and because, as he also points out, it finds a lack of statistical significance for the fuel price variable, which “creates doubts about the validity of the methodology.” Indeed, economists at NERA Consulting found that Small and Van Dender failed to account for cost of living differences across the metropolitan areas covered by his study, so that seemingly high fuel prices in some areas were actually lower than fuel prices in other areas. Correcting for this error and for certain econometric shortcomings, they found a statistically significant rebound effect of a positive 0.24.29 [EPA-HQ-OAR-2010-0799-9319-A1 p. 18]

As Greene observes, “Most studies [of rebound effects] base their estimates on the elasticity of vehicle travel with respect to fuel cost per mile, thereby constraining the elasticity of fuel price to be equal and opposite in sign to the elasticity of fuel economy.” As he also notes, they make this assumption because “the two affect fuel cost per mile in equal and opposite ways.”30 Greene’s own study rejects that hypothesis, finding a (longrun) fuel price elasticity of 0.30 and finding a statistically insignificant fuel cost elasticity. [EPA-HQ-OAR-2010-0799-9319-A1 p. 18]

Greene cites two other studies of this issue. He reports that one (Schimek31) “estimated the elasticities of vehicle travel with respect to fuel price and with respect to fuel economy individually,” finding, in Greene’s words, that fuel price elasticity and fuel economy elasticity – the rebound effect – were “almost precisely equal and opposite in sign as theory would predict.”

Greene co-authored the other study, which, in his words, did not reject the hypothesis of "equal and opposite effects" for the fuel price and mpg elasticities. Greene ignores yet two other studies, one of which was performed by Yale Professor Pinelopi Goldberg, current editor-in-chief of the American Economic Review, and both of which found fuel price and fuel cost elasticities of equal and opposite magnitude.32 Clearly, the weight of the literature is on the side of equal and opposite effects. [EPA-HQ-OAR-2010-0799-9319-A1 p. 18]

In our view, the agencies should, therefore, take account of recent research by Spiller and by Greene himself, that finds fuel price elasticities far higher (in absolute values) than the minus 0.20 reported in much of the econometric literature. Greene finds an elasticity of minus 0.30. As previously noted, Spiller finds base elasticities of minus 0.30, rising to as "high" as minus 0.43 when aggregation errors are taken into account33 – suggesting similar real-world values for the rebound effect. At a minimum, an estimate of at least 25% seems warranted at this time. [EPA-HQ-OAR-2010-0799-9319-A1 p. 19]

Finally, Greene finds that there has been a secular decline in the rebound effect in response to rising incomes, mirroring the results of Small and Van Dender's regressions. However, as we have shown, those regression studies contain serious errors that bias the estimates of rebound effects and their mirror image, fuel price elasticities (in absolute values), dramatically downward. What's more, the decline that he tracks occurred during a period of record low fuel prices and recent research, including Spiller's for the years 2001 through 2009 and his own, finds a sharp uptick even as fuel prices have rebounded to record highs. This suggests that as fuel prices have risen, fuel costs have become a higher percentage of the household budget, which renders households more, not less responsive to fuel prices and thus fuel costs. It further suggests that as time goes on rebound effects may rise along with rising fuel prices and as consumer expectations catch up with those increases over the years. EPA-HQ-OAR-2010-0799-9319-A1 p. 19]

14 - If the rebound effect of 20% reduces fuel savings and attendant ghg and energy security benefits to 80% of those in the table and if the clunker effect cuts that 80% by another 31.5%, the net effect is a 55% reduction of those values. Raising the rebound effect from 10% to 20% implies a doubling of the estimate for the externality costs of raising the standards, which bear a straight-line relationship to the rebound effect.

15 - Total Social Benefits in Table VIII-27b, page 715 of the PRIA come to $16.7 billion in MY 2025. Total Social costs come to the sum of Lost Fuel Tax Revenues of $9.6 billion and

Increased Congestion (and accident) Costs of $9.3 billion, or $18.9 billion, for a net social welfare loss of $2.2 billion, which divided by 17 million unit sales comes to a loss of $129 per vehicle. The 45% offset for the combined leakage associated with the rebound and clunker effects reduces total benefits to $9.15 billion and reduces fuel tax revenue losses to $5.26 billion. The doubling of the rebound effect raises Increased Congestion (and accident) Costs to $18.6 billion. Total net costs or welfare losses are increased to $14.7 billion, or $864 per vehicle.

12. Historical VMT rebound estimates should not be used, as they do not consider the impacts of personal income, vehicle efficiency, and fuel prices. Only dynamic models of the future VMT rebound effect are appropriate and should be used in the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

12) VMT Rebound Effect

The agencies used a fixed estimate of 10% for the rebound effect. This estimate was not based upon the latest research, but instead was a compromise between the latest research and outdated historical data:

'In summary, the 10 percent value was not derived from a single estimate or particular study, but instead represents a compromise between historical estimates and projected future estimates.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 24]

'As we discussed in the 2012-2016 rulemaking and in Chapter 4 of the Joint TSD, this value was not derived from a single point estimate from a particular study, but instead represents a reasonable compromise between the historical estimates and the projected future estimates.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 24]

The agencies quoted the latest research from Small and VanDender and David Greene demonstrating that the rebound effect is linked to personal income and vehicle efficiency, as well as fuel prices, and has been declining over time. EPA also referenced recent work by Kenneth Gillingham, who provides suggestive evidence that consumers may be less responsive to changes in fuel efficiency than to changes in fuel prices. Yet, when it came time to select the number used for the rebound effect, outdated studies with strictly historical effects were given equal weight to the recent studies projecting the future VMT effect. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 24-25]

The proposed rule asks for the submission of new data regarding estimates of the rebound effect and comments on the methodology for applying the rebound effect. Additional data is not needed. The Greene and Small and VanDender work is the proper basis for calculating the rebound effect. They made a major contribution to the field by incorporating economic impacts and the cost of driving into calculations of price elasticity of demand. This is much more appropriate than assuming a fixed 10% rebound effect that does not take into account future changes in vehicle efficiency, fuel prices, and future income. Only future projections of the rebound effect that include the impacts of personal income, vehicle efficiency, and fuel price should be used to calculate the future rebound effect. [EPA-HQ-OAR-2010-0799-9512-A1, p. 25]

Organization: Plant Oil Powered Diesel Fuel Systems, Inc.

1. The Proposed GHG Standards are inconsistent with law because do not regulate greenhouse gasses. Instead, their main thrust is to regulate fuel economy. Fuel economy is not an accurate surrogate for greenhouse gas emissions because of the rebound effect, whereby an improvement in diesel engines' fuel efficiency has, in the aggregate, the paradoxical result of increasing

consumption of the energy resource necessary to run the engines, and consequently, increasing GHG emissions. While the Proposed Regulations acknowledge the factual existence of the rebound effect, their analysis of it is incomplete and unduly limited. The expert opinion of Dr. Harry D. Saunders ("Dr. Saunders") demonstrates that the Proposed Regulations, as drafted, "grossly overestimate the savings in total overall energy consumed, and CO_2 emissions reduced," resulting from the Proposed Rules. Declaration of Dr. Saunders ("Saunders decl."), paragraph 18 (Exhibit 1). [EPA-HQ-OAR-2010-0799-10337-A2, pp. 1-2]

a. re-do their assessment of the rebound effect on GHG emissions resulting from the Proposed GHG Standards, in light of Dr. Saunders's information and opinion (Exhibit 1 [Docket number EPA-HQ-OAR-2010-0799-9882-A2]); [EPA-HQ-OAR-2010-0799-10337-A2, p. 2]

While relying on other, preexisting EPA Regulations, the main mechanism that the Proposed GHG Standards utilize for reducing fuel consumption and GHG emissions is fuel economy. The Agencies couple improvements in fuel economy with a corresponding equivalent decrease in GHG emissions, CO_2 being by far the biggest constituent of GHG emissions from mobile sources. [EPA-HQ-OAR-2010-0799-10337-A2, p. 3]

The Agencies acknowledge that a rebound effect exists, but they limit consideration of the rebound effect to narrow grounds: the result that improved fuel economy will lead to an increase in vehicle miles traveled ("VMT"). [EPA-HQ-OAR-2010-0799-10337-A2, p. 3]

POP DieselTM herewith submits evidence responding to the Agencies' appeal for more information on the rebound effect. This evidence is in the form of the declaration by Dr. Saunders, a leading American scholar and researcher on the rebound effect. Saunders decl. (Exhibit 1). In summary, Dr. Saunders states that the rebound effect, properly understood, has both direct and indirect manifestations in the economy. The Proposed Regulations' treatment of the rebound effect ignores all indirect effects. Saunders decl., paragraphs 14-15 (Exhibit 1). [EPA-HQ-OAR-2010-0799-10337-A2, pp. 3-4]

The Agencies' consideration of direct rebound is limited to only one aspect of direct rebound: an increase in vehicle miles traveled ("VMT") caused by lowered engine operating costs due to improved fuel efficiency. Saunders decl. (Exhibit 1). The Proposed Regulations estimate a 10 percent rebound effect due to increased VMT occasioned by more fuel efficient light duty engines. However, a study of the passenger vehicle market in Germany put this figure of rebound caused by increased VMT at 58 percent. Saunders decl., at paragraph 12 (Exhibit 1). [EPA-HQ-OAR-2010-0799-10337-A2, p. 4]

A recent article from the Wall Street Journal illustrates an aspect of the direct rebound effect that the Agencies do not consider, but automakers acknowledge: the head of marketing for Chevrolet states that improved fuel economy spurs demand for bigger sport utility vehicles and pick-up trucks. "Americans Embrace SUV's Again," Dec. 2, 2011, at page 1 (Exhibit 2). This phenomenon lowers, if not defeats, the overall fuel economy savings that would result if consumers stayed with more fuel efficient, smaller motor vehicles. The Proposed Regulations play into this shift towards bigger, higher fuel consuming vehicles, which erases expected gains from improved fuel economy. [EPA-HQ-OAR-2010-0799-10337-A2, p. 4]

A recent study by C.R. Knittel of the Massachusetts Institute of Technology gauges the direct rebound effect in the light duty market, including shifts to bigger engines and vehicles, and not just VMT, at 75 percent. Saunders decl., at paragraph 6 (Exhibit 1). Others raise the prospect that engine efficiency rules like those incorporated into the Proposed Regulations may lead to “energy backfire,” a condition of greater than 100 percent rebound, “wherein an energy efficiency gain leads to an absolute increase in overall energy use.” Saunders decl., paragraph 8 (Exhibit 1) (referring to study from Austria). [EPA-HQ-OAR-2010-0799-10337-A2, pp. 4-5]

Furthermore, the Agencies underplay the uncertainty of their estimates of the rebound effect. Saunders decl., paragraph 16 (Exhibit 1). This underestimated uncertainty undermines the credibility of their predictions for total overall fuel savings resulting from the Proposed Regulations’ mandate for better fuel economy. Saunders decl., paragraph 17 (Exhibit 1). All of the foregoing flaws in the Agencies’ analysis of the rebound effect increase the chance that due to the true magnitude of the rebound effect, the Proposed Regulations may not, in fact, reduce GHG emissions, but may backfire and make them worse. [EPA-HQ-OAR-2010-0799-10337-A2, p. 5]

The Latest Evidence of the Rebound Effect Shows That the Proposed Regulations Will Actually Backfire and Produce More New Greenhouse Gas Emissions Than They Save.

In support of POP Diesel™'s position criticizing reliance on Fuel Economy Standards to achieve Greenhouse Gas Reductions, POP Diesel™ submits herewith in their entirety two copyrighted academic studies:
1. Christopher Knittel, "Automobiles on Steroids: Product Attribute Trade-Offs and Technological Progress in the Automobile Sector," American Economic Review 2012, 101 (December 2011): 3368-3399 (Exhibit 1). This study points out that sales-weighted CAFE standard has changed little since 1983 because automakers have increased the size of vehicles in their fleets to take advantage of mandated improvements in fuel economy.
2. Kate S. Whitefoot and Steven J. Skerlos, "Design Incentives to Increase Vehicle Size Created from the U.S. Footprint-Based Fuel Economy Standards," Energy Policy 41 (2012), 402-411 (Exhibit 2). This article quantifies the effectiveness or lack of effectiveness of the footprint-based approach taken in the Proposed Regulations to countering the rebound effect. The Agencies have not conducted such a quantitative analysis. This article concludes that, for instance, in 2017, a rebound effect of at least 71 percent will ensue and that the rebound effect will more likely than not be above 100 percent, producing a backfire condition by which the Proposed Regulations' dependence on Fuel Efficiency Standards will actually increase the overall amount of energy consumed and greenhouse gases emitted. [These comments were submitted late on July 31, 2012, EPA-HQ-OAR-2010-0799-11820]

Response:

Commenters suggested that EPA should use values both lower and higher than our proposed value of the VMT rebound effect. We did not find that the commenters presented any persuasive new data or analysis that justify revising the 10 percent value at this time, so we continued to assume a 10 percent value in the final rule (i.e., we assume a 10 percent decrease in fuel cost per mile from our standards would result in a 1 percent increase in VMT). We relied on a wide range of peer-reviewed literature to inform our estimate of the VMT rebound effect, including recent studies and projected estimates as well as a larger body of historic literature using both aggregate and household level data. As we discussed in the preamble (section III.H.4.c) and Chapter 4.2.5.3 of the Joint TSD, the 10 percent value was not derived from a single point estimate or from a particular study, but instead represents a reasonable compromise between historical estimates and projected future estimates.

The Consumer Federation of America (CFA) suggested that we use 5 percent in our national analysis since it would better reflect the income effect (consumers having more money in their pockets to spend on driving) and not the price effect (consumers wanting to drive more because it costs less) associated with lower driving costs. Much of the literature we reviewed to inform our analysis of the rebound effect controls for income (since all sources of income, not just income associated with fuel savings, can influence VMT) and, therefore, only captures the price effect.

CFA also suggested that any additional driving due to the rebound effect increases consumer welfare and therefore the rebound effect should not be subtracted in the consumer pocketbook analysis. However, in both our proposed and final rules, we did not incorporate the rebound effect in our consumer payback analysis (i.e., we calculate the consumer payback associated with reference case VMT, which does not include rebound VMT). See RIA Chapter 5.5. As CFA recommends, we only considered the additional fuel consumption and fuel costs associated with rebound driving in our overall, national-level analysis of costs and benefits. Additionally, we quantify the value that consumers derive from additional rebound driving in our analysis of national-level costs and benefits.

The Defour Group suggested using an estimate of 20 percent or higher for the VMT rebound effect. The Defour Group cited potential methodological shortcomings in two studies that informed our analysis of the rebound effect (Greene and Small and Van Dender[29]); suggested that EPA should instead consider findings from studies evaluating the price elasticity of demand for gasoline; and further suggested that the magnitude of the rebound effect might increase rather than decrease in the future. The Defour Group also commented that Greene's study was not available for public review and that EPA relied solely on studies from Greene and Small and Van Dender in selecting the 10 percent value.

We found a number of errors and misrepresentations in the Defour Group's interpretation of Greene and Small and Van Dender's studies.[30] For example, the commenter suggests that

[29] While not specified in their comments, we assume the Defour Group is referring to the online version of Greene, David, 2012. "Rebound 2007: Analysis of U.S. light-duty vehicle travel statistics," *Energy Policy*, vol. 41, pp. 14-28 (which was publically available on the journal's website as of February 9, 2010) and Small, K. and K. Van Dender, 2007a. "Fuel Efficiency and Motor Vehicle Travel: The Declining Rebound Effect." *The Energy Journal*, vol. 28, no. 1, pp. 25-51. We referenced both studies in the NPRM and placed copies in the docket (EPA-HQ-OAR-2010-0799-0759 for Greene's paper and EPA-HQ-OAR-2010-0799-0755 for Small and Van Dender's paper).

[30] The examples included here are illustrative and are by no means exhaustive. There are a plentitude of errors and misrepresentations of equal magnitude throughout the Defour Group's comment. Additional examples include a statement, without citation, that Small and Van Dender updated their study and now find a 15% rebound effect; however Small and Van Dender have reported no such estimate. The Defour Group also states that Greene

Greene's study rejects the findings from Small and Van Dender's study, however, Greene's study actually provides broad confirmation of their work using a different dataset and method.[31] As another example, the Defour Group critiques Greene's purported use of gallon/mile as a surrogate for fuel costs whereas Greene actually used $/mile in his analysis. As yet another example, the Defour Group suggests that, in contrast to findings in Greene's study and to a certain extent in Small and Van Dender's study, the weight of literature supports the hypothesis that elasticities of VMT with respect to fuel prices and fuel efficiency are of equal and opposite magnitude, however, neither of the studies the Defour Group cited seems to support this claim.[32]

The Defour Group references findings in research from Spiller[33] as evidence that the rebound effect should be higher than 10 percent and compares these findings to Greene's analysis of the rebound effect. The findings in Spiller's research, however, are related to the price elasticity of demand for gasoline. This type of elasticity, while a useful point of comparison, is not appropriate for measuring the VMT rebound effect because it reflects consumer selection of vehicle fuel efficiency (both via vehicle choice as well as vehicle

---

finds that auto "owners do not reduce their driving when fuel costs rise", which is not true. Greene does not conclude that auto owners do not respond to changes in fuel costs. Greene is simply unable to find a statistically significant relationship between VMT and fuel efficiency (i.e., he is unable to find empirical evidence), but he goes on to evaluate the rebound effect by looking at VMT responsiveness to changes in fuel cost per mile rather than fuel efficiency and he produces statistically significant results (indicative that auto owners are responsive to fuel costs, but not necessarily fuel efficiency).

[31] For example, Greene states in the conclusion of his study, "The results obtained here with national time series data are quite consistent with Small and Van Dender's estimates using state level time series, cross sectional data." (pg. 27). Greene's inability to find a statistically significant elasticity of VMT with respect to fuel economy "is not new, having been previously reported by Small and Van Dender." (pg. 26). Greene goes on to explain on pg. 26, "What is new is the finding that the hypothesis that the elasticities of vehicle travel with respect to fuel price and fuel efficiency (gallons per mile) are equal, as predicted by theory, is now rejected by the national time series data." This hypothesis is mainstream, having been adopted by many modelers examining the rebound effect, not just Small and Van Dender (we discuss this topic in section 4.5 of the Joint TSD as a potential reason why rebound estimates in the literature may overestimate the magnitude if, for example, people are more responsive to fuel prices than to fuel efficiency).

[32] The first study they cited did not find evidence that a change in the price per mile of driving impacts VMT (Goldberg, Pinelopi, 1998, "The Effects of the Corporate Average Fuel Efficiency Standards in the US", *Journal of Industrial Economics*, vol. XLVI) (Docket EPA-HQ-OAR-2010-0799). There is no mention of rebound in the second study they cited as it focuses on willingness to pay for fuel efficiency, not VMT responsiveness to fuel efficiency or fuel prices (Bento et al., 2010, "Is There an Energy Paradox in Fuel Economy? A Note on the Role of Consumer Heterogeneity and Sorting Bias", Resources for the Future Discussion Paper available at http://www.rff.org/RFF/Documents/RFF-DP-10-56.pdf) (Docket EPA-HQ-OAR-2010-0799).

[33] Spiller, E. "Household Vehicle Bundle Choices and Gasoline Demand," Resources for the Future and Duke University, paper from January 2011availavble at http://fds.duke.edu/db/aas/Economics/phd/elisheba.spiller/files/Elisheba%20Spiller%20Job%20Market%20Paper.pdf and PowerPoint from July 2011 available at http://emf.stanford.edu/files/docs/322/SPILLER.pdf. (Docket EPA-HQ-OAR-2010-0799)

operation and maintenance) in addition to VMT.[34] Along these lines, the Defour Group cites two other studies (Busse et al.[35] and Sallee et al.[36]) that find fuel prices have a much stronger impact on consumer purchase of fuel efficient vehicles than previous studies have found, but again these findings are not directly relevant to estimating the VMT rebound effect since the rebound effect is a measure of the additional VMT as a result of increased fuel efficiency, which is a separate consumer behavior (modeled differently) than consumer choice of fuel efficiency. In addition, the Busse et al. and Sallee et al. studies draw their conclusions based on analysis of the used vehicle market, which may not behave in the same way as the new vehicle market.

The Defour Group also suggests that the magnitude of the rebound effect could increase if fuel prices rise in the future, since this will cause fuel costs to represent a greater share of household budgets, which in turn makes households more responsive to fuel costs. While this is not implausible, the same logic holds that the rebound effect would continue to decline if other driving costs (such as the time cost of driving associated with income and congestion levels, and costs of other vehicle ownership and operational categories such as insurance, maintenance, and tolls) increase enough to counteract the effect of higher fuel prices. Income is anticipated to increase in the future and, as we discuss in the Chapter 4.2.5.2 of the Joint TSD, Small and Van Dender (2007) and Hymel, Small, and Van Dender (2010) find that the rebound effect is more strongly dependant on income than on fuel costs.

With respect to the Defour Group's comment on the availability of Greene's study, EPA included in the NPRM docket the version that was accepted into the journal, *Energy Policy*, and published in early 2012.[37] This version was also available online at the journal's website as of February 2010. Finally, the Defour Group's assertion that EPA justified our selection of a 10

[34] We sought comment in the MYs 2012-2016 rulemaking on using the elasticity of demand for gasoline to estimate the VMT rebound effect. We received one comment during that rulemaking, from ICCT, that this elasticity should not be used to guide the choice of a value for the VMT rebound effect.

[35] Busse, M., Knittel, C., and Zettelmeyer, F.. "Pain at the Pump: The Effect of Gasoline Prices on New and Used Automobile Markets", September 2011. (Docket EPA-HQ-OAR-2010-0799)

[36]The authors of this study clearly note that it is preliminary and incomplete and request that it be cited only with permission. It is not clear if the Defour Group had permission to cite it in their comments. Sallee, J., West, S., and Fan, W., "The Effect of Gasoline Prices on the Demand for Fuel Economy in Used Vehicles: Empirical Evidence and Policy Implications," May 24, 2011, funded by the Energy Initiative at the University of Chicago and by the Keck Foundation of Macalister College. (Docket EPA-HQ-OAR-2010-0799).

[37] We included the following citation in the NPRM preamble (76 FR at 75126) and in Chapter 4.2.5.2 of the Draft Joint TSD:
Greene, David, "Rebound 2007: Analysis of National Light-Duty Vehicle Travel Statistics," February 9, 2010. This paper has been accepted for an upcoming special issue of Energy Policy, although the publication date has not yet been determined. (Docket EPA-HQ-OAR-2010-0799)

percent rebound value solely on the basis of two studies is not accurate, as we discuss above, in preamble section III.H.4.c, and at section 4.2.5.3 of the Joint TSD.

The Defour Group also suggests that there will be a potential delay in fleet turnover (i.e., the retirement of used vehicles and their replacement by new models) as a result of our rule, which the Defour Group refers to as "the clunker effect" in its comments. We discuss this topic (which is unrelated to the VMT rebound effect) in section III.H.11.a of the preamble. In brief, the effect of this rule on the use and scrappage of older vehicles is influenced by a number of factors, including the rule's impacts on vehicle prices, the fuel efficiency of new vehicle models, the fuel efficiency of used vehicles, and the total sales of new vehicles. If the value of fuel savings resulting from improved fuel efficiency to the typical potential buyer of a new vehicle outweighs the average increase in new models' prices, sales of new vehicles could rise, the used vehicle market may increase in volume as new vehicle buyers sell their older vehicles, and scrappage rates of used vehicles may increase slightly. This will cause both an influx of more efficient vehicles into the used vehicle market and an increase in the turnover of the vehicle fleet, thus accentuating the anticipated effect of the rule on fleet-wide fuel consumption and CO_2 emissions. The opposite scenario, as the commenter suggests, is also possible. Because we do not have good estimates of the relationships between the new and used vehicle markets, we have not attempted to estimate explicitly the effects of the rule on the used vehicle market, scrappage of older vehicles, and the turnover of the vehicle fleet. EPA's analysis of the effects of the rule on new vehicle sales, however, reasonably indicates that it is possible for the rule to increase vehicle sales through its role in promoting social learning, reducing risk and uncertainty for manufacturers, and promoting innovation (as discussed in section III.H.11.a of the preamble). Our response to this commenter on vehicle sales impacts is available in section 18.7 of this RTC document.

The International Council for Clean Transportation (ICCT) suggested we should rely solely on projected estimates of the VMT rebound effect that account for future incomes and fuel prices, which tend to be lower than 10 percent for the years covered by this rule. We recognize the merit of projected estimates of the VMT rebound effect that take into account future incomes, fuel efficiency, and fuel prices over the period impacted by our rulemaking, particularly since the recent studies ICCT cites (from Greene and from Small and Van Dender) have found evidence that the VMT rebound effect is declining over time (see Joint TSD section 4.2.5.2). However, as discussed above, we determined it was appropriate to consider projected estimates from recent studies as well as the larger body of literature on this topic, reflecting a range of different analytical methods and results, in selecting the most appropriate value to use in this rulemaking.

Plant Oil Powered Diesel Fuel Systems, Inc. (POP Diesel) cited a recent study in Germany (Frondel et al., 2011) based on household survey data as evidence that EPA had underestimated the VMT rebound effect. We focused on U.S.-based studies of the VMT rebound effect to inform our regulatory analysis because driver behavior in the U.S. may differ from driver behavior in other countries (e.g., there is likely to be less elastic demand for VMT in the U.S. than Germany because of longer driving distances and fewer transportation alternatives).[38] The declaration from Dr. Saunders that POP Diesel referenced in its comments also suggested that EPA relied too heavily on older analyses that use older data and that recent studies using recent data tend to show a rebound effect that is larger than 10 percent. As discussed above, we relied on a wide range of studies to inform our analysis, which were based on data that spanned multiple decades. Recent studies have actually found evidence that the rebound effect has declined in recent years and could be less than 10 percent in the years covered by our rule (as we discuss in preamble section III.H.4.c and Joint TSD Chapter 4.2.5.2). POP Diesel also suggested that EPA and NHTSA's uncertainty analysis was too narrow (referencing the declaration from Dr. Saunders which cites the agencies' range as 5-15 percent). EPA and NHTSA, however, conducted sensitivity and uncertainly analyses over a broader range of estimates of the direct VMT rebound. EPA's sensitivity analysis covered a range of 0-20 percent (see EPA RIA section 4.5.1) and NHTSA's uncertainty analysis, which we reference in the introduction to preamble III.H, covered a range of 5-30 percent. Even assuming the higher end of these ranges for rebound, EPA would not have changed the standards. Among other things, the benefits of the rule would still vastly exceed the costs.

POP Diesel also suggested that EPA should account for the energy and GHG emissions impact associated with the so-called "indirect rebound effects" (distinct from the VMT rebound effect) of consumers using the increased disposable income they gain from fuel savings to purchase goods and services that were produced with energy or that consume energy. We are not aware of any data on the magnitude of potential indirect rebound effects, if any, from our rule. Research on indirect rebound effects is nascent and POP Diesel did not provide analysis in its comments indicating an appropriate method or value to use to estimate these putative effects from our rule.[39] We therefore believe it is unreasonable to consider potential indirect rebound effects, if any, from our rule based on the commenter's speculative assertions. Furthermore, as noted in the previous footnote, there are additional benefits to consumers associated with increased consumption of goods and services, which would be important to consider if we were

[38] Frondel, Manuel and Vance, Colin, 2011. "Re-Identifying the Rebound – What About Asymmetry?", Ruhr Economic Papers #276. (Docket EPA-HQ-OAR-2010-0799)

[39] The declaration from Dr. Saunders that POP Diesel referenced in their comments cited only one study on indirect rebound effects (Druckman et al., 2011 , "Missing carbon reductions? Exploring rebound and backfire effects in UK households", *Energy Policy*, vol. 39, pp. 3572-3581.) (Docket EPA-HQ-OAR-2010-0799). While this UK-based study could offer insights into how to estimate indirect rebound effects, the method is not appropriate for use in our rule for many reasons. First, the U.S. economy and consumer behavior is likely to differ from other countries (e.g., Americans have different product and service preferences and our products and services have different levels of embedded energy). Similar data and models may not exist to replicate the UK study in a U.S.-context. Second, the study is designed to examine behavioral strategies (e.g., lowering thermostats, reducing food waste, and biking instead of using a car) rather than improving technology. Among other things, the study does not consider capital expenditures associated with energy savings that could dampen any increase in disposable income (e.g., our rule increases the cost of new vehicles, which decreases disposable income). Third, the study does not consider the potential for economic restructuring in response to decreased energy consumption (i.e., it does not consider "general equilibrium" effects), which could lead to either lower or higher energy consumption as a result of our rule. Fourth, the authors recognize that there is a major limitation of the study: they have only a very small number of expenditure categories in their model and there is considerable disparity in GHG intensities of commodities within each category (p. 3578). Finally, the authors do not attempt to quantify the additional benefits to consumers associated with increased consumption of goods and services, which would be important to consider if we were assessing the overall costs and benefits associated with potential indirect rebound effects from our rule.

assessing the overall costs and benefits associated with potential indirect rebound effects from our rule.

POP Diesel also commented that there is a potential for consumers to shift to larger, more powerful vehicles that are less fuel-efficient in response to our standards. POP Diesel described this as a direct rebound effect; however, since this behavior does not influence VMT, we consider it to be another type of indirect effect unrelated to the direct VMT rebound effect. As discussed above, we are not aware of any data on the magnitude of potential indirect rebound effects from this rule, let alone whether they would be significant. POP Diesel's specific assertion that people will spend some of the money they expect to gain from fuel savings on larger, more powerful vehicles is highly uncertain. It assumes that not only would consumers not be put off by what are likely to be higher vehicle prices, but would purchase disproportionate numbers of the more expensive large footprint vehicles because of the perceived fuel savings. First, as we discuss in preamble III.H.1.a and in response to comments in section 18.1, predicting consumer preferences (and therefore the future fleet mix) is challenging. It is difficult to isolate the influence of fuel efficiency standards from other factors (e.g., fuel prices, consumer taste, demographics) on consumer vehicle choice. It is not yet clear whether vehicle choice models can provide reasonable predictions of future fleet mixes with and without our rule. While it is possible people will buy bigger, more powerful cars in response to our rule, it is also possible they will do the opposite. Comments from the Institute for Policy Integrity suggest our rule could actually make fuel-efficient vehicles more popular and that we have therefore underestimated the benefits of our rule (see its discussion of "positionality" and the "bandwagon effect" in EPA-HQ-OAR-2010-0799-9480-A1, pp. 19-21). Second, the commenter does not seem to account for the fact that our rule sets attribute-based standards (whereby every size vehicle has an emissions target), which reduces incentives to change the size distribution of vehicles in the fleet (see preamble section II.C and joint TSD chapter 2.1 and 2.2).[40] In late-filed comments on July 31, 2012, POP Diesel submitted a study from Whitefoot and Skerlos[41] claiming it as evidence that our rule will lead to vehicle upsizing that results in a large rebound

[40] Ironically, the Knittel study cited in the declaration from Dr. Saunders that POP Diesel submitted with their comments, and cited again by POP Diesel in their late-filed comment of July 31, 2012, maintains that manufacturers will have to downsize their fleets to meet even the MY 2016 standards (Knittel, Christopher R., 2011, "Automobiles on Steroids: Product Attribute Trade-Offs and Technological Progress in the Automobile Sector." *American Economic Review*, 101(7): 3368–99) (Docket EPA-HQ-OAR-2010-0799). See Knittel at 3388. Although EPA disagrees (as explained at RIA 1-40 and section 18.1 of this RTC, this rule includes costs of maintaining all vehicle attributes of the existing fleet, including size, weight, torque, and horsepower), this study appears to contradict POP Diesel's ultimate point. Furthermore, the Knittel study does not discuss rebound effects, so EPA does not see that the study can properly be cited as support for a quantified rebound effect between 1980-2006 as suggested in the Saunders declaration.

[41] Whitefoot, Kate and Skerlos, Steven, 2012. "Design Incentives to Increase Vehicle Size Created from the U.S. Footprint-Based Fuel Economy Standards," *Energy Policy* 41, pp. 402-411 (EPA Docket EPA-HQ-OAR-2010-0799).

effect that negates much, if not all, of the estimated fuel and GHG savings. This study does not deal with rebound effects (nor does it purport to), and EPA disagrees that the standards will result in a significant upsizing of the fleet in any case.[42] We respond to comments on car and light truck footprint curve shapes and level of the standards, including comments from Whitefoot and Skerlos and other commenters who cite this study, in section 2.2.2 of the RTC (see also a summary of our response in the previous footnote).

Our analysis of this rule has shown that it is possible to maintain vehicle characteristics (including safety, size, and horsepower) and improve fuel economy (see EPA RIA at 1-40). It should also be possible, though of course with increased cost, to have more fuel economy as well as more size, safety, and/or horsepower. Nothing in our rule precludes these changes in vehicles. We have assumed, however, that the fleet mix will not need to change in response to this rule since we have factored in the cost of preserving the vehicle utility present in the existing fleet. If, as POP Diesel suggests, changes occur in response to market forces, it is reasonable to assume that those changes will reduce the costs or increase the benefits associated with consumer ownership of the vehicles. We will review the environmental implications of any changes in the vehicle fleet during the mid-term evaluation (see preamble section I.B.5 for information on the mid-term evaluation).

[42] In its late-filed comments, POP Diesel states that the Whitefoot and Skerlos study posits a rebound effect of at least 71 percent will ensue and that the rebound effect will more likely than not be above 100 percent, producing a backfire condition. In fact, the Whitefoot and Skerlos study does not discuss any type of rebound effect, much less the quantified values attributed to the study by the commenter. Rather, the primary focus of the study is on issues of curve shape and standard stringency. The authors analyze the 2012-2016 CAFE standards (not the standards proposed in this rule), and do so assuming different inputs than the agencies actually used in the MYs 2012-2016 rule regarding the baseline fleet, the cost and efficacy of potential future technologies, and the relationship between vehicle footprint and fuel economy. Were the agencies to use the Whitefoot and Skerlos methodology with the actual inputs to the MYs 2012-2016 rules, it is likely that different results would be obtained from those in the Whitefoot and Skerlos study. We have responded to these issues in detail in section 2.4 of the Joint TSD, RTC 2.2.2, and preamble section II.C. We also explain that the gradual extension of the cutpoint in the right hand portion of the truck curve does not create an incentive to upsize. See preamble section II.C.5.b and Joint TSD section 2.5.2. Thus, this study does not deal with rebound effects at all (nor does it purport to), and EPA disagrees that the standards will result in a significant upsizing of the fleet in any case. We therefore believe that POP Diesel has significantly mischaracterized the Whitefoot and Skerlos study, and that it does not support the commenter's assertions regarding rebound effects. We also note that the other study submitted by POP Diesel, by Knittel, postulates a reverse effect: that manufacturers will necessarily have to downsize the fleet to meet the standards. Although we disagree (see footnote discussing the Knittel study, which precedes the previous footnote citing the Whitefoot and Skerlos study), the study is illustrative of the range of views in the literature on the potential effects of the standards.

16. Analysis of GHG Emissions Reductions and Their Associated Effects

16.1. Impact on GHG emissions

Weighted Average CO_2 Content for Diesel Fuel [EPA-HQ-OAR-2010-0799-9487-A1, p.91]

Footnote 164 on page 74933 of the NPRM states that the Agencies used 10,200 grams/gallon as an estimated weighted average CO_2 content for diesel fuel. This is not consistent with the 2012-16MY rule, where the Agencies had used the estimated weighted average CO_2 content for diesel fuel of 10,180 grams/gallon. (See footnote 20 of the 2012-2016 Light-Duty Vehicle Greenhouse Gas and CAFE rulemaking; 75 Fed. Reg. 25324, 25330 (May 7, 2010)) To stay consistent, 10,180 should be used in the 2017-25MY rule. [EPA-HQ-OAR-2010-0799-9487-A1, pp.91-92]

Organization: National Wildlife Federation (NWF)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 29.]

Taken together with light- and heavy-duty standards being implemented now, the proposed standards will cut carbon pollution by over 650 million metric tons by year by 2030, about 10 percent of the total carbon pollution today. This is a historic step forward to combat our climate challenge.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 123-124.]

Finally these standards will keep 280 million metric tons of carbon pollution out of the atmosphere. That's the equivalent of shuttering 72 coal-fired power plants for one year.

Organization: Union of Concerned Scientists (UCS)

Environmental Benefits

The proposed standards will also deliver significant reductions in the greenhouse gas emissions that cause climate change. Based on UCS analysis, the 2017-2025 standards would reduce global warming pollution by as much as 290 million metric tons (MMT) in 2030 alone. This is equivalent to shutting down 62 (600 megawatt) coal-fired power plants for an entire year. When combined with the final standards for MYs 2012-2016, the National Program will reduce U.S. greenhouse gas emissions by more than 630 MMT in 2030. [EPA-HQ-OAR-2010-0799-9567-A2, p. 3]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 216.]

Based on UCS analysis, the 2017 through 2025 standards alone would reduce global warming pollution by as much as 290 million metric tons in 2030. This is equivalent to shutting down 62 600-mega watt coal-fired power plants for an entire year. Cumulatively, this program will reduce emissions by more than 1.7 billion metric tons through 2030.

Organization: U.S. Coalition for Advanced Diesel Cars

The success of the new rules ultimately will be judged by reductions in real-world petroleum barrels and real-world GHG tons from 2017 through 2025. [NHTSA-2010-0131-0246-A1, p.2]

Organization: Weiner, L.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 106.]

In relation to carbon pollution, the reduction of carbon pollution by implementing these standards, as you well understand, is another significant benefit. Cutting carbon pollution by 2 billion metric tons is equivalent to the annual emissions from 474 coal-fired power plants. And as I'm sure you are aware, coal-fired power plants are very high makers of carbon pollution. This is a considerable reduction of a dangerous greenhouse gas. The reality, as we know, is that global efforts in reducing climate change have been slow.

Response:

EPA appreciates the many commenters (NWF; Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council; UCS; Weiner, L.) who recognized the significant GHG reductions that we expect from this rule. We agree with the U.S. Coalition for Advanced Diesel Cars that the success of our rule is tied to the real-world fuel and GHG savings it will achieve, which we have estimated using best available methods.

With respect to the Alliance of Automobile Manufacturer's comment, the CO_2 content for diesel fuel in EPA's analysis is consistent with the MYs 2012-2016 rulemaking value (10,180 grams/gallon) (see section 4.3.6 of the RIA). The 10,200 gram/gallon value presented in footnote 164 on page 74933 of the NPRM was an approximate value.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 75.]

Strong standards will also serve to mitigate climate change risks and the very significant economic as well as environmental and human disruption that a changing climate will likely cause -- and, in fact, is already causing.

Organization: Cuenca, M.

Lastly, the EPA claims these regulations are necessary because of carbon dioxide emissions. However the EPA admits this rule will, at best, reduce global temperature by 0.0184 °C by 2100. Less than two hundredths of a single degree Celsius is not enough to have an impact on the climate therefore, the EPA should not claim any climate benefits from this silly mandate. [EPA-HQ-OAR-2010-0799-10142-A1, p. 2]

Organization: Environmental Defense Fund (EDF)

Our petroleum addiction has significant environmental consequences. The combustion of oil in our nation's fleet of light-duty vehicles emits about 20 percent of total U.S. greenhouse gases emissions. Carbon dioxide and other potent heat-trapping gases contribute to climate change, which can threaten us at home and abroad. [EPA-HQ-OAR-2010-0799-9519-A1, p. 2]

The U.S. Global Change Research Program has found that climate changes "are already affecting water, energy, transportation, agriculture, ecosystems, and health." Its 2009 Assessment predicts that water resources will be further stressed, crop and livestock production will be increasingly challenged, coastal areas will be increasingly threatened, and human health will be impacted due to heat stress, waterborne diseases, poor air quality, extreme weather events, and diseases transmitted by insects and rodents. [EPA-HQ-OAR-2010-0799-9519-A1, p. 2]

The number of people at risk due to droughts will increase because many low-rainfall areas are projected to receive less rain and because rising temperatures and evaporation will cause soils to dry. Seasonal snow packs in the Western United States will shrink, endangering water supplies relied upon by Western communities. The number and extent of wildfires, insect outbreaks, and tree mortality in the interior West, the Southwest, and Alaska will likely expand. And damaging impacts outside of the United States may harm our trade, humanitarian, and national security interests. [EPA-HQ-OAR-2010-0799-9519-A1, p. 2]

Natural disasters in 2011 wielded the costliest toll in history — a massive $380 billion worth of losses from earthquakes, floods, tornadoes, hurricanes, wildfires, tsunamis and more. And that figure does not include the expenses associated with sickness or injuries triggered by the disasters.10 [EPA-HQ-OAR-2010-0799-9519-A1, p. 2]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 287-288.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 173.]

With respect to climate security, the combustion of oil in our nation's fleet of passenger vehicles accounts for about 20 percent of U.S. greenhouse gas emissions. Together with the first-phase standards, the proposed standard under consideration will cut heat-trapping carbon dioxide pollution by over 6 million metric tons.

These emission reductions are an important part of a national and global effort to ward off the worst consequences of climate change. The U.S. Global Change Research Program has found that climate change is already affecting water, energy, transportation, agriculture ecosystems and health.

Organization: Faria, R.

Lastly, EPA claims these regulations are necessary because of carbon dioxide emissions. But EPA admits that this rule will, at most, reduce global temperature by 0.0184 °C by 2100. Two hundredths of a degree Celsius is not enough to have an impact on the climate and therefore, EPA cannot claim any climate benefits from this mandate. [EPA-HQ-OAR-2010-0799-9834-A1, p. 2]

Organization: Haroldson, C.

Climate change concerns are becoming increasingly debunked and should no longer be a concern. [EPA-HQ-OAR-2010-0799-11137-A1, p. 1]

Organization: Institute for Energy Research (IER)

This comment explains that EPA, and by extension NHTSA, fail to justify increasing the greenhouse gas emissions standards for light-duty vehicles. EPA's rule does not affect the pace of climate change in any meaningful way. Therefore, this rule is fatally flawed or the endangerment finding is fatally flawed. After all, EPA is regulating greenhouse gases in order to reduce climate change. [EPA-HQ-OAR-2010-0799-9573-A1, p. 1]

EPA fails to provide any justification to regulate greenhouse gas emissions from light-duty vehicles. In fact, EPA's proposed rule clearly demonstrates that greenhouse gas emissions from light-duty vehicles do not "endanger public health or welfare" as required by section 202 of the Clean Air Act. For these reasons, EPA should not regulate greenhouse gases using the Clean Air Act. [EPA-HQ-OAR-2010-0799-9573-A1, p. 23]

Organization: International Council on Clean Transportation (ICCT)

18. Black carbon is an important climate-forcing agent. EPA should regulate black carbon indirectly via stringent limits on particulate matter and expedite the congressionally mandated black carbon study report followed by all appropriate steps to regulate this pollutant as a climate-forcing agent. [EPA-HQ-OAR-2010-0799-9512-A1, p. 4]

18) Black Carbon

Black carbon is the light-absorbing fraction of particulate matter that causes warming. In January 2012 an article published in the journal Science found emission standards for new light- and heavy-duty vehicles, as well as scrappage of high emitting vehicles, to be one of a handful of measures to control black carbon that are necessary to guarantee stabilization of global average temperatures no greater than 2°C above temperatures in the pre-industrial period.[81] [EPA-HQ-OAR-2010-0799-9512-A1, p. 51]

EPA acknowledges the climate benefits of reductions in particulate matter emissions that would be generated by this rule, though they would be smal1.82 However, EPA does not evaluate the concomitant reductions in black carbon, nor does it propose to regulate black carbon. Previously the agency cited its concern that no definitive scientific assessment on the climate impacts of black carbon had been made.83 EPA has been directed by Congress to conduct a review of black carbon climate science to be completed in 2010, but this is now overdue and remains unpublished. [EPA-HQ-OAR-2010-0799-9512-A1, p. 51]

Other actions on black carbon are worth noting. In December 2010, the executive body of the Convention on Long Range Transport of Air Pollution directed its Working Group on Strategies and Review to consider the inclusion of black carbon in the revision of the Gothenburg Protocol.[84]In May 2011 the Arctic Council put forward an assessment of emissions and mitigation options for control of black carbon climate impacts on the Arctic. In June 2011, the

International Maritime Organization adopted a workplan to investigate the definition, measurement, and control options for black carbon. In November 2011, the Arctic Monitoring and Assessment Program published a report on the impact of black carbon on Arctic Climate. And in January 2012, CARB issued a staff report that captures the current state of scientific knowledge and remaining areas of investigation for black carbon.[85] These actions reflect a growing international scientific and policy interest in identifying mechanisms to regulate the climate impacts of black carbon. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 51-52]

There is reason to believe that black carbon emissions from current on-road vehicles have been underestimated. Testing conducted by EPA and CARB staff of PFI engines caused an upward revision of emission factors for PM in the California emissions inventory from less than 1 mg per mile to 4 mg per mile.[86]This suggests that black carbon emissions have also been underestimated, although speciation of these emissions was not conducted. High cold start emissions contributed the bulk of this increase, but oil burning and engine degradation also contribute. According to our calculations, a light-duty vehicle emitting on average 0.004 g PM/mile would represent approximately 2.4 g CO_2-eq/mile black carbon emissions assuming 75% of PM is black carbon and the GWP-100 value, is 800.[EPA-HQ-OAR-2010-0799-9512-A1, p. 52]

Both the US EPA and CARB have regulatory provisions for non-CO_2 climate forcing agents, such as methane, nitrous oxide, and hydrofluorocarbons. The IPCC in its Fourth Assessment Report quantified estimated that the radiative forcing of black carbon ranks third among the climate pollutants. Meanwhile, research conducted more recently by Ramanathan and Carmichael concluded that IPCC estimates of radiative forcing are overly conservative, putting black carbon second after carbon dioxide in terms of global contribution to radiative forcing.[87] From this perspective, black carbon deserves greater priority than other climate forcing agents currently regulated by EPA. [EPA-HQ-OAR-2010-0799-9512-A1, p. 52]

We recognize that EPA must initiate a process to bring black carbon into the basket of regulated climate forcing agents, so regulation under this rulemaking may be premature. In light of this, we strongly urge the agency to consider (a) regulating black carbon indirectly via stringent limits on particulate matter in future rulemakings; and (b) expeditiously finalizing the congressionally mandated black carbon study report to inform future direct regulation of this pollutant. [EPA-HQ-OAR-2010-0799-9512-A1, p. 52]

Organization: Manufacturers of Emission Controls Association (MECA)

There is a significant linkage between ground level ozone concentrations and climate change impacts. One example was detailed by a group of researchers from the United Kingdom in a 2007 *Nature* publication. In this work, ground-level ozone was shown to damage plant photosynthesis resulting in lower carbon dioxide uptake from plants that have been exposed to higher levels of ozone. Other studies have shown that increasing average annual temperatures are likely to result in even higher levels of ozone in the environment. Emission reductions aimed at lowering ambient ozone levels, such as lower emissions of volatile organic compounds (VOCs) and NO_x, will have a positive impact on climate change, as well as human health. Policies that aim to reduce ambient ozone levels may also become more necessary and important to either mitigate the climate change impacts of ground level ozone or to mitigate higher ozone levels that result from climate change. [EPA-HQ-OAR-2010-0799-9452-A3, p.4]

Black carbon is a major component of particulate matter emissions from mobile sources and is believed to have a significant net atmospheric warming effect by enhancing the absorption of sunlight. Black carbon is a mix of elemental and organic carbon emitted by fossil fuel combustion, bio-mass burning, and bio-fuel cooking as soot. Black carbon is a dominant absorber of visible solar radiation in the atmosphere. Anthropogenic sources of black carbon are transported over long distances and are most concentrated in the tropics where solar irradiance is highest. Because of the combination of high absorption, a regional distribution roughly aligned with solar irradiance, and the capacity to form widespread atmospheric brown clouds in a mixture with other aerosols, emissions of black carbon are thought to be the second strongest contribution to current climate change, after CO_2 emissions. [EPA-HQ-OAR-2010-0799-9452-A3, p.5]

According to scientists at the Scripps Institute of Oceanography and University of Iowa, soot and other forms of black carbon could have as much as 60% of the current global warming effect of carbon dioxide. Black carbon plays a major role in the dimming of the surface and a correspondingly large solar heating of the atmosphere. For example, the retreat of the Himalayan-Hindu Kush glaciers is one of the major environmental problems facing the Asian region. The glacier retreat has accelerated since the 1970s and several scientists have speculated that solar heating by soot in atmospheric brown clouds and deposition of dark soot over bright snow surfaces may be an important contributing factor for the acceleration of glacier retreat. A recent study published in a 2009 issue of *Nature Geoscience* (vol. 2, 2009) by researchers from the NASA Goddard Institute and Columbia University found that black carbon is responsible for 50% of the total Arctic warming observed from 1890 to 2007 (most of the observed Arctic warming over this timeframe occurred from 1976 to 2007). [EPA-HQ-OAR-2010-0799-9452-A3, p.5]

It is estimated that 70% of the black carbon emissions from mobile sources are from diesel-fueled vehicles, with the assumption that 40% of gasoline PM is black carbon and 60% of diesel PM is black carbon. Up to 25% of the carbon footprint of a heavy-duty diesel truck is associated with black carbon exhaust emissions. Since black carbon particles only remain airborne for weeks at most compared to carbon dioxide, which can remain in the atmosphere for more than a century, removing black carbon would have an immediate benefit to both global warming and public health. The black carbon concentration and its global heating will decrease almost immediately after reduction of its emission. For these reasons and the growing body of scientific evidence that links black carbon emissions with climate change, MECA believes that EPA should include black carbon emissions as part of its overall greenhouse gas emission control strategy. [EPA-HQ-OAR-2010-0799-9452-A3, p.5]

Black carbon from diesel vehicles can be significantly reduced through emission control technology that is already commercially available. High efficiency diesel particulate filters (DPFs) on new and existing diesel engines provide nearly 99.9% reductions of carbon emissions. During the regeneration of DPFs, captured carbon is oxidized to CO_2 but this filter regeneration still results in a net climate change benefit since global warming potential of black carbon has been estimated to be as high as 4,500 times higher than that of CO_2 on a per gram of emission basis. To meet EPA's 2007-2010 heavy-duty engine PM standards, essentially all new, on-road heavy-duty diesel engines are now equipped with high efficiency DPFs. It is estimated that the installation of DPFs will reduce PM emissions from U.S. heavy-duty diesel vehicles by 110,000 tons per year. Current California and EPA light-duty emission standards for diesel particulate matter also require the use of a high efficiency DPF on new light-duty diesel vehicles. [EPA-HQ-OAR-2010-0799-9452-A3, pp.5-6]

Because older diesel engines emit significant amounts of PM, there are also significant opportunities to reduce black carbon emissions through diesel retrofit programs that make use of retrofit DPF technology. The number of vehicles retrofitted, the number of programs, and the interest in new programs for DPFs have grown significantly over the past few years with more than 250,000 DPFs installed as retrofits to date in a variety of world markets. Retrofit filters can provide large benefits in human health through reductions in diesel PM and climate change benefits through reductions in black carbon emissions on both existing, on-road and off-road diesel engines. California has already tackled black carbon emissions from existing mobile sources through its ambitious Diesel Risk Reduction Plan and their associated regulatory initiatives that target the reduction of diesel particulate emissions from existing diesel engines over the next fifteen years. In many of these California regulatory programs existing diesel engines will need to be retrofit with high efficiency DPFs or replaced/repowered with engines that are equipped with high efficiency filters by OEMs. Similar regulatory programs could be implemented within other states or by EPA to reap the public health and climate change co-benefits associated with reductions in black carbon emissions. Incentive funding programs like California's Carl Moyer program or the federal Diesel Emission Reduction Act (DERA) also can be used as a strategy for mobile source retrofit programs at the state or federal level that target black carbon reductions. Incentive funds for filter retrofits might also be generated by a state or national greenhouse gas cap-and-trade programs. [EPA-HQ-OAR-2010-0799-9452-A3, p.6]

In the case of gasoline vehicles, additional climate change benefits could be obtained by lowering federal gasoline fuel sulfur levels to enable the use of lean NO_x adsorber catalysts on gasoline lean-burn engines. [EPA-HQ-OAR-2010-0799-9452-A3, p.6]

Organization: National Wildlife Federation (NWF)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 28-29.]

Carbon pollution is warming our climate locally and worldwide. These changes threaten people and global security right now, and they are a most profoundly threatening force against the future of wildlife. Rising temperatures, flood, fires, droughts and ecosystem alterations are creating direct habitat loss, increased invasive species and other threats for wildlife species, and many of those species may not adapt.

Organization: Parker, M.

Lastly, EPA claims these regulations are necessary because of carbon dioxide emissions. But EPA admits that this rule will, at most, reduce global temperature by 0.0184 °C by 2100. THAT'S JUST TWO **HUNDREDTHS** OF A DEGREE CELSIUS !!! [EPA-HQ-OAR-2010-0799-9027-A1, p. 2]

Therefore, EPA CANNOT CLAIM any appreciable climate benefits from this mandate. Just 2/100ths of a degree Celsius IS ••NOT•• ENOUGH TO HAVE AN IMPACT ON THE CLIMATE OF THE EARTH AND... [EPA-HQ-OAR-2010-0799-9027-A1, p. 2]

Organization: Pearce, F.

The EPA claims these regulations are necessary because of carbon dioxide emissions. Global Warming has been exposed to be nothing but a scam created through falsified data. Even then the EPA admits that the additional regulations would reduce global temperature minimally at best. [EPA-HQ-OAR-2010-0799-10343-A1, p. 1]

Organization: Smith, G.

'Reduce carbon dioxide pollution by over 6 billion metric tons over the life of the program equivalent to the emissions from the United States in 2010.' Who cares? CO_2 is not a problem. It has zip to do with global warming and our air is more pure than it has been for 200 years. [EPA-HQ-OAR-2010-0799-8438-A1, p. 1]

Organization: Steffanoff, N.

Lastly, EPA claims these regulations are necessary because of carbon dioxide emissions. But EPA admits that this rule will, at most, reduce global temperature by 0.0184 °C by 2100. Two hundredths of a degree Celsius is not enough to have an impact on the climate and therefore, EPA cannot claim any climate benefits from this mandate. [EPA-HQ-OAR-2010-0799-9335-A1, p. 2]

Organization: Steyn, R.

* EPA claims its proposed increase is necessary to reduce carbon dioxide emissions, supposedly to reduce global warming. Again, EPA has NO statutory authority to regulate greenhouse gases such as carbon dioxide, which is not a pollutant and indeed is vital to the biosphere's life cycle. Moreover, EPA admits that this rule will, at most, reduce global temperature by 0.0184 °C by 2100. Two hundredths of a degree Celsius is not enough to have an impact on the climate. Therefore, EPA cannot claim any climate benefits from this mandate. [EPA-HQ-OAR-2010-0799-8724-A1, p. 2]

* The very scientific basis upon which EPA bases its illegal rule-making to reduce greenhouse gases is under increasing challenge. According to a recent editorial in the Wall Street Journal signed by a two dozen respected, senior scientists and engineers, "...a large and growing number of distinguished scientists and engineers do not agree that drastic actions on global warming are needed." [EPA-HQ-OAR-2010-0799-8724-A1, p. 2]

Organization: Sullivan, T.

Lastly, EPA claims these regulations are necessary because of carbon dioxide emissions. But EPA admits that this rule will, at most, reduce global temperature by 0.0184 °C by 2100. Two hundredths of a degree Celsius is not enough to have an impact on the climate and therefore, EPA cannot claim any climate benefits from this mandate. Besides, the theory of global warming is a failure, since none of their predictions are coming true. Not one. CO_2 is harmless, and is in fact beneficial to plant life, and thus to all animal life including mankind. [EPA-HQ-OAR-2010-0799-10341-A1, p. 2]

Organization: Union of Concerned Scientists (UCS)

Finally, strong standards will help reduce the heat-trapping emissions that cause global warming. Current and projected climate change impacts pose significant risks to public health, the economy, and the environment. Delaying action now and waiting for the future before initiating accelerated action to reduce global warming emissions would be more costly than initiating action now. [EPA-HQ-OAR-2010-0799-9713-A1, p. 2]

Organization: Van Coppenolle, J. and L.

Climate change, as you at the EPA should well know, is not just theory and not a diabolical scheme on the part of climate scientists to punish corporations. It is a threatening reality that should have been vigorously addressed a decade or more ago. [EPA-HQ-OAR-2010-0799-1284-A1, p. 1]

You at the EPA have the opportunity to address a major component of climate change with the proposed new standards. Please take this opportunity to do as much as reasonably possible to mitigate that phenomenon. [EPA-HQ-OAR-2010-0799-1284-A1, p. 1]

Response:

Commenters in this section fall into three categories, one supportive of the rule's impact on reducing future climate change, one discussing the role of black carbon and other non-GHG forcing agents in climate change, and one dismissive of the rule either because the magnitude of the estimated impacts are small or because of doubts regarding the science underlying those impacts. Each category will be addressed in turn.

The EPA agrees with the commenters who support the benefits of the rule. We agree with Ceres, EDF, NWF, UCS, the Van Coppenolles, and Weiner that these standards will serve to mitigate climate change risks by reducing emissions of the greenhouse gases which are reasonably anticipated to endanger human health and welfare. We also agree with the American Medical Association that certain groups such as children, the elderly, and the poor are most vulnerable to climate-related health effects.

Issues regarding black carbon were raised by ICCT and MECA. These organizations urge the regulation of black carbon (potentially through limits on PM) and request the expediting of the black carbon report to congress. Since the proposed rule, EPA has recently released a Report to Congress addressing black carbon.[43] EPA continues to recognize that black carbon is an important climate forcing agent and takes very seriously the emerging science on black carbon's contribution to global climate change in general and the high rates of observed climate change in

[43] EPA, March 2012. *Report to Congress on Black Carbon* (EPA-450/R-12-001) available at http://epa.gov/blackcarbon

the Arctic in particular. See generally 77 FR at 38991-993 (June 29, 2012) (proposal for revised PM NAAQS discussing effects of black carbon on climate). However, issues of control of black carbon are beyond the scope of this rulemaking, which implements section 202 (a) of the CAA and focuses on control of the vehicular GHG emissions of CO_2, CH_4, N_2O and HFCs. MECA also mentioned the effects of NOx on climate. As discussed above, changes in NOx emissions are included as an input into the MAGICC model. However, the effects due to NOx changes alone have not been isolated, and because NOx emissions lead to decreased levels of methane in addition to increased levels of ozone, the net effect on climate of changes in NOx emissions is unclear.

A number of commenters criticized the rules. The most common criticism was that because the climate impacts were small, that two hundredths of a degree Celsius is not enough to have an impact on the climate (Axford, Cafagna, Cuenca, Faria, Lennon, Links, Parker, Paul, Pearce, Smith, Steffanoff, Steyn, Sullivan), and that therefore EPA cannot claim any benefits from the standards. EPA responds that, as stated in section III.F.2 of the Preamble, no one rule is expected to prevent climate change by itself. As stated in the Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act; Final Rule (74 FR at 66543), "The commenters' approach, if used globally, would effectively lead to a tragedy of the commons, whereby no country or source category would be accountable for contributing to the global problem of climate change, and nobody would take action as the problem persists and worsens."[44] While this rule does not single-handedly eliminate climate change, it is an important contribution to reducing the rate of change, and this reduction in rate is global and long-lived. EPA appropriately placed the benefits of reductions in context in the rule, by calculating the likely reductions in temperature and comparing them to total projected changes in temperature over the same time period. In addition, EPA used the social cost of carbon methodology in order to estimate a monetization of the benefits of these reductions (see section III.H.6), and the net present value resulting from the CO_2 reductions due to this rule (between years 2017 and 2050) was calculated to be between tens to hundreds of billions of dollars. The D.C. Circuit pointedly rejected the argument that EPA should refrain from issuing GHG standards under section 202 (a) due to claimed lack of mitigating effect on the endangerment, and further held that "the emission standards would result in meaningful mitigation of greenhouse gas emissions" in the form of "960 million metric tons of CO2e over the lifetime of the model year 2012-2016 vehicles". Coalition for Responsible Regulation v. EPA, No. 09-1322 (June 26, 2012)) slip op. p 43; projected emissions reductions of this MYs 2017-2025 rule are projected to be approximately double those of the MYs 2012-2016 rule.

Some commenters (Haroldson, Pearce, Steyn) additionally claimed that climate change science is "becoming increasingly debunked" and "a scam created through falsified data". However, these commenters provide no support for their assertions except for one quote from an

[44] The Supreme Court likewise spoke to this issue, stating that "[a]gencies, like legislatures, do not generally resolve massive problems" like climate change "in one fell regulatory swoop." Massachusetts v. EPA, 549 U.S. at 524. They "whittle away at them over time." Id. The Supreme Court additionally emphasized that "reducing domestic automobile [greenhouse gas] emissions is hardly a tentative step" toward addressing climate change, inasmuch as "the United States transportation sector emits an enormous quantity of carbon dioxide into the atmosphere." Id. Thus, "[j]udged by any standard, U.S. motor-vehicle emissions make a meaningful contribution to greenhouse gas concentrations." Id. at 525.

editorial in the Wall Street Journal. These claims are contrary to the conclusions of the major scientific assessments by the National Academies, the US Global Change Research Program, and the Intergovernmental Panel on Climate Change. Responses to similar but more detailed comments may also be found in the Response to Comments and the Response to Petitions for the original Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act (74 FR 66496, December 15, 2009). Finally, see Coalition for Responsible Regulation v. EPA, No. 09-1322 (June 26, 2012) (D.C. Circuit) slip op. p. 30, upholding all of EPA's findings and stating "EPA had before it substantial record evidence that anthropogenic emissions of greenhouse gases 'very likely' caused warming of the climate over the last several decades. EPA further had evidence of current and future effects of this warming on public health and welfare. Relying again upon substantial scientific evidence, EPA determined that anthropogenically induced climate change threatens both public health and public welfare. It found that extreme weather events, changes in air quality, increases in food- and water-borne pathogens, and increases in temperatures are likely to have adverse health effects. The record also supports EPA's conclusion that climate change endangers human welfare by creating risk to food production and agriculture, forestry, energy, infrastructure, ecosystems, and wildlife. Substantial evidence further supported EPA's conclusion that the warming resulting from the greenhouse gas emissions could be expected to create risks to water resources and in general to coastal areas as a result of expected increase in sea level."

16.3. Changes in Global Climate Indicators Associated with the GHG Emissions Reductions

Organizations Included in this Section

Institute for Energy Research (IER)

Organization: Institute for Energy Research (IER)

A. ACCORDING TO EPA, THIS PROPOSED RULE WILL ONLY REDUCE GLOBAL TEMPERATURE 0.0076–0.0184 °C BY 2100—TOO LITTLE TO AFFECT CLIMATE IN A MEANINGFUL WAY OR BE DETECTABLE AGAINST BACKGROUND NATURAL VARIABILITY

This proposed rule to regulate greenhouse gas emissions from light-duty vehicles (as well as EPA's endangerment finding for greenhouse gases under section 202 of the Clean Air Act), and Massachusetts v. EPA are all predicated on the assumption that regulating greenhouse gas emissions from light-duty vehicles will reduce the impacts of climate change in a meaningful way. According to this proposed rule, however, the climatic benefits from reducing greenhouse gas emissions from light-duty vehicles are very, very small. Because the climatic benefits are so small, this rule will not affect climate change in a meaningful way. [EPA-HQ-OAR-2010-0799-9573-A1, p. 2]

1. Climate Concerns in Massachusetts v. EPA—regulating vehicle emissions should result in a “meaningful contribution” to “global warming”

In Massachusetts v. EPA the Supreme Court argued that greenhouse gas emissions were causing a number of harms including, “the global retreat of mountain glaciers, reduction in snow-cover extent, the earlier spring melting of ice on rivers and lakes, [and] the accelerated rate of rise of sea levels during the 20th century relative to the past few thousand years . . . .” [EPA-HQ-OAR-2010-0799-9573-A1, p. 3]

The Court continued to explain global warming harms:

If sea levels continue to rise as predicted, one Massachusetts official believes that a significant fraction of coastal property will be ‘either permanently lost through inundation or temporarily lost through periodic storm surge and flooding events.’ Remediation costs alone, petitioners allege, could run well into the hundreds of millions of dollars. [internal citations omitted] [EPA-HQ-OAR-2010-0799-9573-A1, p. 3]

The failure to regulate greenhouse gas emissions, according to the Court, “contributes” to Massachusetts’ injuries and therefore, EPA could take steps to remedy the injuries caused by climate change. The Court further argued that “reducing domestic automobile emissions is hardly a tentative step” and EPA could regulate greenhouse gas emissions from motor vehicles because, “[j]udged by any standard, U.S. motor-vehicle emissions make a meaningful contribution to greenhouse gas concentrations and hence . . . to global warming.” [emphasis added] [EPA-HQ-OAR-2010-0799-9573-A1, p. 3]

2. Climate Concerns in EPA’s Proposed Endangerment Finding

On December 15, 2009, EPA found that greenhouse gases in the atmosphere “endanger public health and public welfare.” In the endangerment finding, EPA argued that increased levels of greenhouse gases were leading to increased temperatures, decreased Arctic sea ice extent, increased precipitation, an increase in sea level rise, increased forest fires, reduced snowpack, increased droughts, and “endangers the water resources important for public welfare” among other concerns. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 3-4]

3. Climate Concerns in EPA’s Proposed Rule to Regulate GHGs from Light-Duty Vehicles 2017–2025

As EPA explains in the current proposed rule, “light-duty vehicles, heavy-duty trucks, buses, and motorcycles—accounted for 23 percent of all U.S. GHG in 2007.” Because greenhouse gas emissions from light-duty vehicles represent a large portion of U.S. greenhouse gas emissions, EPA argues light-duty vehicles contribute to the effects of climate change: [EPA-HQ-OAR-2010-0799-9573-A1, p. 4]

the health effects of climate change linked to observed and projected elevated concentrations of GHGs include the increased likelihood of more frequent and intense heat waves, increases in ozone concentrations over broad areas of the country, an increase of the severity of extreme weather events such as hurricanes and floods, and increasing severity of coastal storms due to rising sea levels. These effects can all increase mortality and morbidity, especially in vulnerable populations such as children, the elderly, and the poor.

The proposed rule also states there is a “critical need to address global climate change.” [EPA-HQ-OAR-2010-0799-9573-A1, p. 4]

4. Despite these concerns, the proposed rule does not affect climate in a meaningful way, but instead results in, at most, 0.02°C less warming by the year 2100

According to statements from the Supreme Court and EPA on the need to address climate change, this rule would not affect global warming or climate change in any meaningful way. This is because, according to EPA’s modeling, the proposed rule would result in an incredibly small reduction in the increase in global temperature. According to EPA: [EPA-HQ-OAR-2010-0799-9573-A1, p. 4]

The results of the analysis demonstrate that relative to the reference case, projected atmospheric CO_2 concentrations are estimated by 2100 to be reduced by 3.29 to 3.68 part per million by volume (ppmv), global mean temperature is estimated to be reduced by 0.0076 to 0.0184 °C, and sea-level rise is projected to be reduced by approximately 0.074– 0.166 cm, based on a range of climate sensitivities. The analysis also demonstrates that ocean pH will increase by 0.0018 pH units by 2100 relative to the reference case. [EPA-HQ-OAR-2010-0799-9573-A1, p. 5]

A reduction of global temperature by 0.0076–0.018°C 90 years in the future is too small an amount to affect heat waves, air quality, precipitation, intense storms, harm agriculture, wildlife, or ecosystems in any way. A decrease in sea level rise of 0.0074–0.166 cm, 90 years in the future will not reduce the loss of costal property that the Supreme Court was concerned about in Massachusetts v. EPA. [EPA-HQ-OAR-2010-0799-9573-A1, p. 5]

Because EPA’s regulation of greenhouse gases from light-duty vehicles does not impact global warming in a meaningful way, EPA’s regulation is not rational. Either global warming and climate change is a problem that can and should be addressed in a meaningful way through the regulation of greenhouse gas emissions from vehicles or EPA should not be regulating greenhouse gases from vehicles. Instead, EPA claims global warming is a problem but takes no meaningful steps to do anything about it. This is not rational. [EPA-HQ-OAR-2010-0799-9573-A1, p. 5]

EPA’s regulations themselves are very significant. The regulations would double fuel economy standards from 2010 to 2025. But even this will not result in a meaningful reduction in the increase in temperature. Therefore, it does not appear that U.S. greenhouse gas emissions from light-duty vehicles endanger public health and welfare. [EPA-HQ-OAR-2010-0799-9573-A1, p. 5]

In the proposed rule, EPA obfuscates the fact that the rule does not make any meaningful contribution to global warming by stating that the climate impacts are merely “small.” EPA states: [EPA-HQ-OAR-2010-0799-9573-A1, p. 5]

Although the projected reductions and improvements are small in comparison to the total projected climate change, they are quantifiable, directionally consistent, and will contribute to reducing the risks associated with climate change. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 5-6]

EPA's explanation is not sufficient. Just because EPA can quantify something using a computer model or a hand-held calculator, does not mean that it is either detectable or meaningful. [EPA-HQ-OAR-2010-0799-9573-A1, p. 6]

For instance, Hansen et al. 2006 reported that that the precision of their estimate of the annual global temperature anomaly is only known (with 95% confidence) within a range of +/-0.05°C. Thus the error in our measurement of the global temperature is more than twice as great as the highest level of temperature savings calculated by the EPA (which is 0.0184°C). [EPA-HQ-OAR-2010-0799-9573-A1, p. 6]

The error is compounded when calculating a trend over the long-term (like out to the year 2100—or a timescale of about a century). For instance, using a least-squares statistical fit to the temperature annual global temperature anomalies in Hansen's dataset from 1900–2011 shows that the temperatures have risen at a rate of 0.681 +/- 0.074°C per century. So for a century-long trend, the error is more than 4 times as large as the EPA's highest amount of temperature savings. [EPA-HQ-OAR-2010-0799-9573-A1, p. 6]

While EPA's temperature savings is quantifiable, it is not detectable. Since it is not detectable, it means that we cannot assess any sort of scientific meaningfulness from such a change. [EPA-HQ-OAR-2010-0799-9573-A1, p. 6]

This lack of scientific meaningfulness in EPA's regulation is a problem. EPA is supposed to protect the public health and welfare. EPA's regulations should be meaningful, not merely "quantifiable," and "directionally consistent." EPA's statement about quantifiability and directionality would be equally true if greenhouse gas emissions standards were increased by 1 gram per mile (i.e. 249 grams per mile instead of 250). But instead of tightening the standard to 249 grams per mile, EPA sets the standard at 163 grams per mile in 2025. EPA gives no rational basis for choosing 163 grams per mile instead of 249 grams per mile. [EPA-HQ-OAR-2010-0799-9573-A1, p. 6]

For all practical purposes, in the context of human welfare, setting the GHG emission standard at 249 grams per mile would result in the same climate impact as setting the standard at 163 grams per mile. The theoretical temperature impact of a 1 gram per mile standard would be even less than 0.0076–0.018°C, but because 0.0076–0.018°C is so small, the difference would be indistinguishable in the real world. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 6-7]

It should be noted that the EPA Administrator is required to explain the reasonableness of her regulatory response. For example, Motor Vehicle Mfrs.' Ass'n v. State Farm Mut. Auto. Ins. Co., requires the agency to "examine the relevant data and articulate … a 'rational connection between the facts found and the choice made.'" The EPA has not done that in this case—there is no rational connection between EPA finding that greenhouse gases endanger public health and welfare and a rule which does not result in a meaningful impact on the imperiled public health and welfare. [EPA-HQ-OAR-2010-0799-9573-A1, p. 7]

5. The climate impact of the proposed rule, though small, may nevertheless be overstated

It is quite possible that EPA's estimate of the reduction in temperature and sea level rise is an overestimate. EPA used a climate sensitivity of 1.5 to 6°C. More recent science argues that the climate sensitivity is likely to be below or in the low range of this estimate. For example, one recent paper found it likely that that climate sensitivity is between 1.7°C and 2.6°C. Another recent paper found a "Transient Climate Response of 1.3–1.8°C". [EPA-HQ-OAR-2010-0799-9573-A1, p. 7]

Previously, EPA has avoided considering climate sensitivities lower than the AR4 range arguing that the IPCC was correct. In 2010, EPA stated: [EPA-HQ-OAR-2010-0799-9573-A1, p. 7]

"the IPCC indicates the levels of understanding and confidence in quantitative estimates of equilibrium climate sensitivity have increased substantially and there is increased confidence of key processes that are important to climate sensitivity due to improved comparisons of models to one another and to observations. Thus EPA concludes that the use of the climate sensitivity range for the climate analysis for this rule is appropriate and supported by the scientific literature from the major assessment reports." [EPA-HQ-OAR-2010-0799-9573-A1, pp. 7-8]

In this proposed rule, it is good to see EPA consider a climate sensitivity lower than the IPCC's standard climate sensitivity of 2 to 4.5°C. EPA's past response is now inadequate because of more recent science. Furthermore, the more recent science argues for climate sensitivity nearer the low end of the range and discounts the top end of the range EPA used. [EPA-HQ-OAR-2010-0799-9573-A1, p. 8]

The climate sensitivity is important because it forms the basis for EPA's justification for regulating greenhouse gases from light-duty vehicles. If the lower bound for climate sensitivity is correct, the impact of this proposed rule would only be about 0.008°C by 2100—an incredibly small amount to say the least. [EPA-HQ-OAR-2010-0799-9573-A1, p. 8]

6. Because these regulations would not affect climate in a meaningful way, this calls into question EPA's Endangerment Finding

This proposed rule is a follow-up to EPA's proposal that greenhouse gases from motor vehicles "endanger public health or welfare" under section 202 of the Clean Air Act. The 2017-2025 light-duty vehicle standard demonstrates that the Endangerment Finding is on shaky ground. If greenhouse gas emissions from motor vehicles "endanger public health or welfare," it stands to reason that this proposed rule should lead to meaningful climatic benefits. However, because this proposed rule would only lead to a reduction in global temperature by 0.0076–0.0184°C by 2100 that is both climatically meaningless and undetectable against background natural variability, this rule does not create a meaningful impact. [EPA-HQ-OAR-2010-0799-9573-A1, p. 8]

7. Conclusion to Section A

Because this rule fails to affect climate in a meaningful way, and because reducing climate harms is the point of EPA's regulatory authority under Massachusetts v. EPA and the proposed endangerment finding, EPA should not regulate greenhouse gases from light-duty vehicles. [EPA-HQ-OAR-2010-0799-9573-A1, p. 8]

Response:

The Institute for Energy Research (IER) makes two major claims in order to argue against the standard. First, that the estimated reductions in climate change in the rule do "not affect climate in a meaningful way." This argument has been addressed in Section 16.2. As noted there, the commenter's argument has been decisively and pointedly rejected by the D.C. Circuit. It also bears mention that regardless of the degree to which this rule will, in and of itself, ameliorate global climate change, EPA has clear discretion under section 202 (a) to issue these standards following its positive endangerment finding. Section 202 (a) does not specify any minimum level of effectiveness for standards. Rather, section 202 (a) directs EPA to set the standards at a level that is reasonable in light of applicable compliance cost and technology considerations. Like any other technology based standard, the rule's stringency is not dependent on any particular environmental outcome but rather on a weighing of the statutorily specified criteria relating to feasibility, cost and available lead time. The second claim by IER is that the climate impact of the rule has been overstated. IER references two new studies in order to argue that the climate sensitivity of the Earth system to a doubling of carbon dioxide concentrations is at or below the low end of the range used by the EPA (which was 1.5 to 6.0 degrees C). While this new research is of interest, these studies are not definitive. The EPA has reasonably relied on comprehensive assessments like those of the National Academies, US Global Change Research Program, and IPCC because assessments cover the full range of the literature and place the individual studies in context.

The first study cited by IER is Schmittner et al., 2011, which estimates a likely range of climate sensitivity of 1.7 to 2.6 degrees C. This climate sensitivity is on the low end of the IPCC estimates. This study is a useful contribution, but depends on a single computer model as well as on estimates of conditions during the last glacial maximum (such as temperature and forcing) that are difficult to calculate. For example, the authors acknowledge that their estimates of global mean temperatures in the last glacial maximum are 30 to 40 percent smaller than previous estimates, and only 2.2 degrees C cooler than present, and a recent review of paleoclimate studies shows that the Schmittner et al. estimate of global glacial temperatures remains an outlier (Braconnot et al., 2012[45]). Meanwhile, other recent studies estimating climate sensitivity have come to the conclusion that the IPCC range is possibly an underestimate rather than an overestimate (Pagani et al., 2009[46]). Therefore, it would be premature at this time to conclude based on Schmittner et al. that the climate sensitivity range used by the EPA is either an over or an underestimate.

[45] Braconnot P. et al., Evaluation of climate models using palaeoclimatic data, Nature Climate Change (2012), doi:10.1038/nclimate1456. (Docket EPA EPA-HQ-OAR-2010-0799)
[46] Pagani, M., Z. Liu, J. LaRiviere, and A. Ravelo, 2010: High Earth-system climate sensitivity determined from Pliocene carbon dioxide concentrations. *Nature Geoscience*, 3, 27-30. (Docket EPA EPA-HQ-OAR-2010-0799)

The second paper cited by IER estimated the "Transient Climate Response" (TCR), and IER incorrectly compares this TCR estimate to the range of equilibrium climate sensitivity estimates used by the EPA. Transient sensitivity is a measure of the temperature change precisely at the time of doubling of CO_2 concentrations, before the climate system has come to equilibrium, in contrast to the climate sensitivity which is related to the temperature response after the system has come to equilibrium. The IPCC fourth assessment report, in Table 8.2 (Randall et al., 2007[47]), shows how the TCR compares to the climate sensitivity in a number of climate models. The climate sensitivity in this table ranges from 1.3 to 2.3 times the TCR. Applying these ratios to the TCR estimates provided by the commenter results in a range of CS from 1.7 to 4.2, which is similar to the likely range of 2 to 4.5 provided by the IPCC.

Therefore, the EPA finds that the range of climate sensitivity used in this rule is appropriate, and that the analysis of climate impacts was appropriate and reasonable.

Clean Fuels Development Coalition (CDFC)
Growth Energy

Comments on GDI and PM

Organization: Clean Fuels Development Coalition (CDFC)

OEMs NEED CLEANER FUELS IN ORDER TO FULLY AND COST EFFECTIVELY COMPLY WITH THE RULE.

To meet the aggressive targets established by this rule, OEMs will employ advanced engine technologies that would benefit from and require fuel quality improvements in order to meet the fuel efficiency and lower carbon goals without worsening other forms of pollution and contributing to air quality backsliding. The OEMs will bundle multiple advanced engine technologies to meet the stricter targets. Notably, the Agencies project that for spark ignition (SI) engines, gasoline direct injection (GDI) will be an especially important compliance tool, and they expect the OEMs to rapidly adopt it, projecting 85% penetration by 2016, and 100% by 2020 and beyond. However, as will be discussed more below, absent fuel composition changes, experts warn that for all of its mileage efficiency and carbon reduction benefits, GDI technology is expected to result in substantial increases in urban ambient particulate matter, especially the highly pathogenic $PM_{2.5}$ that includes UFPs.5 Unfortunately, if regulators ultimately decide to deal with that problem by requiring the OEMs to install filters and traps on SIDI engines (as is now done with diesel engines), adverse consequences are likely to ensue. Engine efficiencies and costs to consumers will be compromised. The Agencies will limit the ability of the OEMs to utilize engineering expertise to develop the optimal solution to reach the goals of this regulation. Experts warn that gasoline UFPs are so much smaller than diesel PM, use of filters will be ineffective, cost prohibitive, and counterproductive, leading to increased carbon emissions and reduced engine efficiency.6 In short, failure to synchronize fuel composition changes with advanced engine technologies could negate many of the positive outcomes this rule is designed to achieve. [EPA-HQ-OAR-2010-0799-9574-A3, p. 3]

As previously discussed, experts warn that advanced engine designs needed for automakers to comply with tighter fuel efficiency rules could lead to a significant increase in the UFP fraction of $PM_{2.5}$ emissions unless fuel composition is upgraded to replace the toxic octane components of Aromatic Group Compounds with Clean Octane components.24 [Attachment E can be found in Docket number EPA-HQ-OAR-2010-0799-9574-A8] [EPA-HQ-OAR-2010-0799-9574-A3, p. 7]

PAHQs are combustion byproducts and derivatives of Aromatic Group Compounds (see Attachment C for the discussion in the 2010 Honda SAE paper), and could be inadvertently and substantially increased by this rulemaking in the absence of fuel composition changes. [EPA-HQ-OAR-2010-0799-9574-A3, p. 7]

As the 2007 Tufts University study warned, this oversight represents a major deficiency in transportation fuels regulatory policy, especially since vehicle GHG reduction technologies expected to come into widespread use as a result of this rule are likely to increase these pollutants dramatically.29 [EPA-HQ-OAR-2010-0799-9574-A3, p. 8]

VEHICLE FILTERS INEFFECTIVE FOR GASOLINE‘S SMALLER PARTICLES.

A number of recent studies have concluded that requiring the OEMs to fit gasoline-powered vehicles with filters or traps, as they have done with diesel engines, would be cost prohibitive, ineffective, and counterproductive. For example, according to the Delphi Powertrain International 2011 SAE study, ". . . the number size distributions show for homogeneous gasoline engines compared to Diesel engines typically a higher number of particles at smaller sizes…the typically smaller particles generated by gasoline engines require a finer filter characteristic…which consistently leads to a negative impact on performance, fuel consumption, and CO_2 emissions." For that reason, we firmly believe that the most cost effective, and technologically efficient, solution to these undesirable tradeoffs is to upgrade fuel standards to significantly reduce Aromatic Group Compounds, which are the primary source of the $PM_{2.5}$ and particle-bound toxics. [EPA-HQ-OAR-2010-0799-9574-A3, p. 7]

Organization: Governors' Biofuels Coalition

Recent reports indicate that the failure to establish tighter fuel standards to complement advanced engine designs could result in dramatic increases in a major health threat in urban areas: fine and ultrafine particulate matter. [EPA-HQ-OAR-2010-0799-9570-A1, p. 2]

Organization: Growth Energy

This Attachment explains why, in the Joint NPRM, the Agencies should have thoroughly examined the impacts of new technologies used to meet the GHG standards on PM emissions. There are many studies that indicate that gasoline direct injection, a technology which will be used to meet the GHG standards, will increase both particulate matter mass and particulate number emissions. The Agencies need to consider an alternative approach, which would include fuel parameter changes that could enable additional engine technologies to be used to improve efficiency and reduce emissions. The Agencies' proposal requires new technology to be used on vehicles using old technology fuels. It has long been recognized that vehicles and fuels operate as a system. To undertake significant changes and increases in the stringency of tailpipe GHG standards without a parallel and integrated examination of potential changes in the fuel used by these vehicles is inappropriate. [EPA-HQ-OAR-2010-0799-9505-A1, p. 22]

I. Relevant Emissions Impacts

The Joint NPRM includes extensive discussion of the technologies, costs, and benefits of the proposal, seeking comments on many aspects of the proposal. In addition, EPA “seeks comment on whether there are any other health and environmental impacts associated with advancements in vehicle GHG reduction technologies that should be considered.” These are the salient points:

- EPA and NHTSA project widespread use of gasoline direct injection (GDI) in meeting the proposed CAFÉ and GHG standards.
- There is substantial evidence that GDI increases PM mass and PM number emissions compared to the conventional port fuel injection (PFI) technology now in widespread use.
- There is also substantial evidence that increased ethanol use will decrease PM mass and PM number emissions from the affected vehicles.
- The EPA and NHTSA proposal does not account for the increased PM emissions from GDI technology.
- The benefits from the proposal are sensitive to the PM effects assumed by the Agencies.
- Therefore, the final rule should evaluate and consider both the increased PM due to GDI use and the potential for more widespread ethanol use to decrease PM mass and number emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 23]

A. EPA and NHTSA project widespread use of gasoline direct injection (GDI) in meeting the proposed CAFÉ and GHG standards.

The proposed rule discusses technologies that can increase fuel economy, indicating that many of the technologies are already available, and that manufacturers will be able to meet the standards through significant efficiency improvements in these technologies as well as a significant penetration of these technologies across the fleet. [EPA-HQ-OAR-2010-0799-9505-A1, p. 23]

The proposed rule indicates:

There are a number of competing gasoline engine technologies, with one in particular that the agencies project will be common beyond 2016. This is the gasoline direct injection and downsized engines equipped with turbochargers and cooled exhaust gas recirculation, which has performance characteristics similar to that of larger, less efficient engines. [EPA-HQ-OAR-2010-0799-9505-A1, p. 24]

The Joint NPRM also provides estimates of the penetration of various technologies in 2021 and 2025. GDI penetrations are forecast to be greater than 90% in both cars and trucks by 2025 as shown in Tables III-42 and III-43. Therefore, widespread use of GDI is one of the technologies that the Agencies are relying on in the proposal. [EPA-HQ-OAR-2010-0799-9505-A1, p. 24]

34 In the recent California GHG rulemaking, the Air Resources Board avoided this issue by assuming that PM mass emissions from PFI and GDI would be similar based primarily on speculative assumptions about future GDI technology and deterioration rates.

The Joint NPRM considers several impacts of the proposal on non-GHGs, both positive and negative. For example, the analysis evaluates the impact that reductions in domestic fuel refining and distribution due to lower fuel consumption will have on U.S. emissions of various pollutants. In addition, the analysis evaluates the increase in emissions from additional vehicle use associated with the rebound effect from higher fuel economy. As the various positive and negative impacts on non-GHGs and considered, the proposal indicates: [EPA-HQ-OAR-2010-0799-9505-A1, p. 30]

Thus the net effect of stricter CAFE standards on emissions of each pollutant depends on the relative magnitudes of its reduced emissions in fuel refining and distribution, and increases in its emissions from vehicle use. [EPA-HQ-OAR-2010-0799-9505-A1, p. 30]

One aspect of these “complex interactions” that certainly merits attention is the potential effect of technological innovation on criteria and toxic pollutants, in the absence of improved in-use fuel standards. As HEI’s February 2011 study noted, the use of GDI technology increases some current gasolines’ particulate emissions. Without NHTSA having directly addressing that study in the DEIS, the Agencies simply note in the NPRM that “the net effect of stricter standards on emissions of each criteria pollutant depends on the relative magnitudes of reduced emissions from fuel refining and distribution, and increases in emissions resulting from added vehicle use.” 76 Fed. Reg. at 74,933. That cursory observation does not meet the requirements of NEPA for a “thorough investigation” and a “candid acknowledgment” of risks. Nat’l Audubon Soc. v. Dept. Navy, 422 F.3d 174, 185 (4th Cir. 2005; see also Natural Resources Defense Council, Inc. v. Morton, 458 F.2d 827, 838 (D.C. Cir. 1972); Kleppe v. Sierra Club, 427 U.S. 390, 410 fn. 21 (1976); 'Ilio'ulaokalani Coalition v. Rumsfeld, 464 F.3d 1083, 1094 (9th Cir. 2006; accord, Ctr. for Biological Diversity v. Nat’l Highway Traffic Safety Admin., 538 F.3d 1172, 1223 (9th Cir. 2008). [EPA-HQ-OAR-2010-0799-9505-A1, p. 31]

B. There is substantial evidence that GDI increases PM mass and PM number emissions compared to the conventional PFI technology now in widespread use.

A recent Myung and Park review of nano-particle emissions from internal combustion engines indicates that GDI engines produce considerably more particles than conventional port fuel injection ones and that “much of the research indicates that GDI engines produce significantly more particulates than conventional PFI engines, especially during the cold start phase and during stratified operation.” Myong and Park provide numerous references to support their findings, including textbooks, literature surveys, research studies using single-cylinder and multi-cylinder engines in which various parameters can be changed, measurements from production engines, and studies of various potential after-treatment systems. [EPA-HQ-OAR-2010-0799-9505-A1, p. 24]

The California Air Resources Board (CARB) in 2010 acknowledged that GDI increased PM mass and number emissions substantially. The CARB report indicated “GDI technology tends to have higher PM mass and particle number emissions than conventional PFI technology.” The

CARB report noted that the published literature points to GDI PM mass emissions in the range of 2 to 20 mg/mi, and indicated that, if not abated, the GDI combustion system has the potential to emit two to eight times more PM mass than PFI vehicles. [EPA-HQ-OAR-2010-0799-9505-A1, p. 24]

Szybist et al., 2011 also report that "while gasoline DI technology is beneficial for fuel economy, it produces an increase in particulate matter emissions in comparison to PFI engines" and provide several references to support that fact. Maricq also notes the DI PM issue: [EPA-HQ-OAR-2010-0799-9505-A1, pp. 24-25]

GDI engines offer a number of opportunities for improved fuel efficiency, such as reduced pumping losses, charge air cooling, and downsizing when turbocharged. But, direct injection of fuel into the engine cylinder is susceptible to incomplete fuel evaporation and to fuel impingement on piston and cylinder walls, both of which lead to combustion of liquid fuel and, consequently, to increased PM emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 25]

A recent report by the Health Effects Institute's Special Committee on Emerging Technologies states that the need to improve fuel economy and the need to reduce GHG emissions are driving the introduction of gasoline direct injection (GDI) technology because it improves fuel economy and performance. They state GDI is more expensive than the port fuel injection (PFI) system that it is replacing. They also point out that because of less complete mixing of the fuel vapor and air in GDI systems, particulate emissions of the engine increase, including the number of ultrafine particles (UFPs defined as particles that are less than 100 nanometers (nm) in diameter). Thus additional technological fixes may be required to meet the Tier 2 $PM_{2.5}$ emission standards for GDI vehicles which would incur additional costs. More recently, similar concerns were echoed by Ayala, Brauer, Mauderly and Samet. [EPA-HQ-OAR-2010-0799-9505-A1, p. 25]

With respect to current production vehicles, Piock et al., 2011 present results for particle number and particle mass for a number of production European vehicles that meet the Euro 4 (2005) standards in their Figure 1. The seven GDI vehicles have an order of magnitude higher PM mass and PM number emissions than do the three PFI vehicles. [EPA-HQ-OAR-2010-0799-9505-A1, p. 25]

Because a limit on PM number emissions is under discussion for implementation in 2014 in Europe, effort toward understanding and reducing PM mass and PM number emissions from GDI engines is underway. There are two basic approaches on the emitted by the engine, and (2) aftertreatment particulate filters. It is not clear how successful either of these approaches can be. With manufacturers under strong incentives to optimize engines for fuel economy and cost, optimization for minimum PM mass and number emissions may conflict with optimization for fuel economy or may add additional cost for hardware and development. With regard to particulate filters, Piock et al. indicate: [EPA-HQ-OAR-2010-0799-9505-A1, pp. 25-26]

In principle, particulate filters already in standard use on modern Diesel engine powered passenger cars can be applied to gasoline engines as well. The typically smaller particles generated by gasoline engines require a finer filter characteristics (e.g. cell density, mean pore size and porosity) which consequently leads to a higher exhaust system backpressure with a negative impact on performance, fuel consumption and CO_2 emissions. The addition of a particulate filter system would cause a significant increase of the overall aftertreatment system complexity and cost. [EPA-HQ-OAR-2010-0799-9505-A1, p. 26]

The proposed rule is silent on the potential increase in PM mass and number emissions due to the widespread use of GDI. As noted above, this is a major oversight. EPA and NHTSA have an obligation to insure that any new fuel or technology developed for transportation must not adversely impact health or the environment. [EPA-HQ-OAR-2010-0799-9505-A1, p. 26]

Despite the evidence that widespread use of GDI may increase PM emissions, the proposal does not address the issue. The proposal does note that:

EPA has the discretion under the CAA to consider many related factors, such as the availability of technologies, the appropriate lead time for introduction of technology, and based on this the feasibility and practicability of their standards; the impacts of their standards on emissions reductions (of both GHGs and non- GHGs); [EPA-HQ-OAR-2010-0799-9505-A1, p. 30]

Therefore, even if EPA determines that it cannot implement Growth Energy's proposal at the current time, given the limits on the current rulemaking, the Final Rule should evaluate and consider both the increased PM due to GDI use and the potential for more widespread ethanol use to decrease PM emissions. In considering the increased PM due to widespread use of GDI technology, the final rule should consider the increase in PM mass as well as particle number.34 The emission of, effects from, and potential mitigation of ultrafine particles from vehicles are all active research areas. In addition, various approaches for setting particle number standards for vehicles are being considered in Europe and California. Within the time frame of the regulations in the proposed rule, the importance of ultrafine particles and their control will be understood. [EPA-HQ-OAR-2010-0799-9505-A1, p. 40]

The final rule should also consider potential ways of mitigating the PM increases from GDI use. The mitigation methods examined should include both fuel-related methods and aftertreatment. Higher ethanol use should be thoroughly evaluated. [EPA-HQ-OAR-2010-0799-9505-A1, p. 40]

However, there is no discussion in the in the proposal indicating that EPA considered whether the technologies assumed in the proposal would increase non-GHG emissions. This is an important oversight. Instead, EPA merely assumed that they would not. For example, the proposal indicates: [EPA-HQ-OAR-2010-0799-9505-A1, p. 30]

The agencies' analysis assumes that the per-mile emission rates for cars and light trucks produced during the model years affected by the proposed rule will remain constant at the levels resulting from EPA's Tier 2 light duty vehicle emissions standards. [EPA-HQ-OAR-2010-0799-9505-A1, p. 30]

Organization: Boyden Gray & Associates PLLC

As air toxics, PAHs must be removed under the MSAT provisions, because there are ample substitutes. It is especially important to do this before efficiency technologies such as direct injection are adopted. Such technologies will increase PAH emissions, compounding the problem and necessitating expensive future tailpipe adjustment for pollution that is the fault of the fuel, not the car, and that could be addressed at no cost today. [EPA-HQ-OAR-2010-0799-9506-A1, pp. 8-9]

Organization: Marz, Loren C.

GDI technology (especially lean-burn GDI) may have difficulty meeting future PM emission limits as currently proposed by the California Air Resources Board (CARB) based on several studies (e.g., 'Preliminary Discussion Paper – Proposed Amendments To California's Low-Emission Vehicle Regulations – Particulate Matter Mass, Ultrafine Solid Particle Number, And Black Carbon Emissions.' CARB, http://www.arb.ca.gov/msprog/levprog/leviii/meetings/051810/pm_disc_paper-v6.pdf; Walter Piock et al, "Strategies Towards Meeting Future Particulate Matter Emission Requirements in Homogeneous Gasoline Direct Injection Engines." SAE International, 2011-01-1212, http://delphi.com/pdf/techpapers/2011-01-1212.pdf; Kody Klindt, IAV Automotive Engineering Inc., 'Reducing the particulate emission numbers in DI Gasoline Engines.' http://www1.eere.energy.gov/vehiclesandfuels/pdfs/deer_2010/monday/presentations/deer10_klindt.pdf). This has the potential of effectively requiring particulate filters (GPF) on GDI vehicles, which in turn has the potential of significantly increasing the price of GDI technology and/or reducing the assumed efficiency of GDI technology. [NHTSA-2010-0131-0213-A1, pp.4-5]

<u>Response to GDI-PM Comments:</u>

As discussed in Preamble section III. G.1 and RIA Chapter 6.2, EPA is finalizing greenhouse gas emissions standards that will result in a net reduction of $PM_{2.5}$. In 2030, the EPA estimates that the MY 2017-2025 light-duty standards will reduce total $PM_{2.5}$ inventories by 1,254 short tons. The EPA analyzed the impact the MY 2017-2025 light-duty vehicle GHG rule will have on $PM_{2.5}$ and other non-GHG pollutants in both 2020 and 2030. For $PM_{2.5}$ the EPA estimates reductions in "upstream" $PM_{2.5}$ emissions, including reductions from fuel refining, distribution and transport as a result of the standards, We also estimated "downstream" increase in $PM_{2.5}$ due to people driving more. The rule effectively makes the cost per mile of driving lower for consumers by improving fuel economy, increasing the likelihood that they will drive more. This is known as the "rebound effect." Thus this small downstream $PM_{2.5}$ increase is a result of a predicted change in driving behavior consistent with the economics literature, as well as the past four Corporate Average Fuel Economy (CAFE) rulemakings. In addition, we also estimate a small increase in $PM_{2.5}$ from power plants as electric powertrain vehicles increase in prevalence as a result of this rule.

With regard to advanced engine technologies, such as "gasoline direct injection fuel systems" or GDI, there are various forms of this technology in production today. While some initial designs are not yet optimized for PM emissions performance, the EPA believes that industry will have adopted the cleanest forms of GDI by the timeframe of this rule.

We received several comments on $PM_{2.5}$ emissions from advanced technology vehicles. Growth Energy commented that "There is substantial evidence that GDI increases PM mass and PM number emissions compared to the conventional port fuel injection (PFI) technology now in widespread use… Therefore, the final rule should evaluate and consider both the increased PM due to GDI use and the potential for more widespread ethanol use to decrease PM mass and number emissions." The Clean Fuels Development Coalition and Loren Marz submitted similar comments. EPA agrees with the commenter that testing on initial GDI technology, primarily wall-guided systems, has shown an increase in PM emissions over the FTP as compared to conventional PFI gasoline engines. However as noted above, the technology is still evolving, making it difficult to predict future PM emission performance of GDI vehicles. Testing on initial spray-guided GDI systems has shown less of a PM increase over the FTP, and even reduced PM emissions over the US06 compared to PFI vehicles.[48] Due to the improved fuel economy and reduced emissions offered by spray-guided GDI technology, it is anticipated that spray-guided GDI will replace wall-guided systems in the 2017 to 2025 timeframe.[49] As a result, in the technical assessment conducted by the agencies as part of this rulemaking, the agencies assessed the emissions and fuel consumption improvements associated with spray-guided GDI systems and assumed that their overall in-use PM emission performance was comparable to that of PFI vehicles.

Regarding comments from Clean Fuels Development Council (CFDC) on use of Aromatics as ethanol use in gasoline has continued to rise in response to market forces and RFS, the additional octane provided by ethanol has been used by refiners to reduce the concentration of aromatics (another source of octane) in the gasoline they supply. As shown below in figure below, there has been a 15 percent decrease in aromatics with the rise in ethanol use over the past decade. Some recent research[50] suggests that this aromatics reduction has lead to reductions in both PM emissions and improvement in PM air quality. Instead of allowing aromatics levels to fall naturally as ethanol levels increase, an aromatics standard could ensure that gasoline aromatic levels fell in proportion to the projected increase in ethanol use. With the increased use of ethanol, not only have the aromatic levels in gasoline been declining, but we project that they will continue to decline. The average level of aromatics in gasoline today is around 22 percent, although it ranges from 3 to 47 percent on a batch basis, and 10 to 40 percent on a refinery average basis due to the wide variation in refinery configuration, crude oil source, and available product markets.[51] Some stakeholders have stated that EPA should mandate even larger reductions in the aromatics content of gasoline in order to provide an incentive for increased ethanol use in gasoline beyond RFS levels. They believe that the country would benefit from reduced air pollution (air toxics, PM emissions and secondarily-formed PM) resulting from the reduction in the aromatic content of gasoline. Such regulatory action is clearly outside the scope of this light-duty GHG standards rulemaking. However, given the potential PM emission benefits, it is something that may warrant further study in the future.

Increases in Pollutants due to the Final Standards

Organization: American Lung Association of the Mid-Atlantic

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 81-82.]

Although reducing traditional air pollution emissions is not the primary focus of the proposed rules, in some scenarios result in increases for particular vehicle pollutants, notably carbon monoxide and aldehydes.

ALA nevertheless recognizes that the general trend across the alternatives considered is to lower emissions of ambient air pollutants when compared with the no action alternative.

Not only does the preferred alternative, the proposed standards, result in significantly lower carbon dioxide emissions.

But these standards also result in lower levels of sulfur dioxide, fine particle pollution, volatile organic compounds, nitrogen oxides, benzene and diesel particulate matter once fleet turnover would be substantially complete by 2040 with the reduction in VOCs and NO_x yielding corresponding increases in ground level ozone.

Organization: Boyden Gray & Associates PLLC

Again, at the very least, EPA must address this issue: if it is going to rely on the CAA for authority to reduce mobile CO_2, it cannot ignore the same statute's requirements to reduce mobile source air toxics, especially if that reduction also reduces CO_2. At the very least, EPA cannot under the CAA cause an increase of one form of regulated pollution that causes serious health problems by reducing another that does not. [EPA-HQ-OAR-2010-0799-9506-A1, p. 10]

There are other factors at work in addition to the rebound effect. The California Air Resources Board's (CARB) pending proposal for lowering PM standards charts the increase in PM that is expected to result from new technologies such as GDI. CARB's proposed tightened PM limits are thus designed to counteract this "backsliding"—an increase in addition to that caused by the rebound effect. But fuel reformation with alcohol blending or CNG could produce reductions and block this "backsliding" at far less cost than tailpipe regulations. At the very least, this issue must be addressed in this proceeding, which will otherwise cause pollution increases that are likely to be held illegal under the CAA and which might never be precluded by any Tier III rule. [EPA-HQ-OAR-2010-0799-9506-A1, p. 10]

Response:

As we state in Section 11 of this Response to Comments document, reducing the aromatic content of gasoline is clearly outside the scope of this LD GHG standards rulemaking. However given the potential PM emission benefits, the Agency is continuing to study the effects of aromatics on vehicle emissions and air quality. The innuendo that this rule will significantly increase emissions of air toxics as a trade-off for controlling GHGs is misplaced. EPA performed national-scale air quality modeling to estimate future year annual $PM_{2.5}$ concentrations, 24-hour $PM_{2.5}$ concentrations, 8-hour ozone concentrations, air toxics concentrations, visibility levels and nitrogen and sulfur deposition levels based on the final vehicle standards and, as detailed in Section 6.2.2 of the RIA, our modeling indicates that there will be only small changes in ambient concentrations of criteria and air toxics pollutants as a result of this rule. The overall small impacts of the final vehicle standards are a function of emissions changes related to VMT increases from rebound, upstream reductions in petroleum consumption from crude oil production and transport, and gasoline production, distribution and transport, and changes in location and amount of electricity generation.

Comments on Regional Modeling

Organization: Clean Fuels Development Coalition (CDFC)

5. Update the CMAQ model to ensure full capture of the benefits derived from the significant reductions in urban $PM_{2.5}$ secondary organic aerosol (SOA) that will occur due to the reductions in gasoline "Aromatic Group Compounds" made possible by E30+ blends' substitution (especially significant for OMB cost – benefit analysis purposes, see discussion on p. 6 and Attachment D). [This attachment can be found in Docket number EPA-HQ-OAR-2010-0799-9574-A7] [EPA-HQ-OAR-2010-0799-9574-A3, p. 1]

As will be discussed in more detail below, the Agencies have stated their intention to incorporate more detailed findings in the final rule from new science and model improvements. For example, the EPA says it will use its updated CMAQv.5.0 model to ―…analyze the impact of the standards on PM2.5, ozone, and selected air toxics.‖ This is potentially significant because EPA has known for years that its CMAQ model was substantially under-reporting the formation of mobile source PM2.5 secondary organic aerosols (SOAs). In urban areas, PM2.5 SOAs primarily originate from mobile sources, most importantly from toluene within the Aromatic Group Compounds. It must be assumed that incorporation of these new findings will also require NHTSA to make adjustments to its draft EIS, which gives insufficient attention to mobile source PM2.5, particularly the future health and welfare costs which will be imposed by increases in gasoline-derived particulate matter emissions, and will most severely impact the nation's highly vulnerable urban population. New science suggests that the particulate bound toxics can be found at elevated levels up to 2,500 meters from congested roadways, thus exposing a vast majority of Americans to these deadly pollutants.

- We also note that the EPA's October 19, 2011, announcement of the completion of its CMAQ 5.0 model means that it will be better able to measure localized pollution impacts, such as those that occur near congested roadways.18 As a 2007 Tufts University study19 and others have warned, EPA's regional modeling approach has seriously masked the true health costs of gasoline Aromatic Group Compounds and their primary role in urban PM emissions.

P. 75109, EXPOSURE AND HEALTH EFFECTS ASSOCIATED WITH TRAFFIC-RELATED AIR POLLUTION. We strongly urge the Agencies to update their database and assumptions with regard to how far mobile source air pollutants can travel at elevated levels. The Agencies, both EPA in the rulemaking, and NHTSA in its EIS, assume populations are exposed only 300 – 500 meters from congested roadways. (Even at this limited range, the Agencies note that 48 million people would be subjected to these elevated pollutant levels.) However, more recent studies (such as 2009 CARB, UCLA, and University of Southern California research) show that mobile source-generated PAHs can be found at elevated levels as far away as 2,500 meters, or more than 1.5 miles. The report states that these findings have "significant exposure implications, since most people are in their homes during the hours before sunrise, and outdoor pollutants penetrate into indoor environments."28 This means that the vast majority of Americans are exposed to pathogenic PAHs and other particle-bound toxics that this rulemaking does not consider. As the 2007 Tufts University study warned, this oversight represents a major deficiency in transportation fuels regulatory policy, especially since vehicle GHG reduction technologies expected to come into widespread use as a result of this rule are likely to increase these pollutants dramatically.29 [EPA-HQ-OAR-2010-0799-9574-A3, p. 8]

Response:

EPA performed national-scale air quality modeling using CMAQ v4.7.1 for the final rule. The air quality modeling for these final standards was initiated prior to February 2012, when CMAQ 5.0 was publically released. CMAQ 4.7.1 was used since it was the most current version of the model available at the time the air quality modeling started. CMAQ v4.7.1 includes updates related to secondary organic aerosol (SOA) chemistry. SOA chemistry research, described in Section 6.2.1.2.2 of the RIA, has led to implementation of new pathways for SOA in CMAQ 4.7, based on recommendations of Edney et al. and the recent work of Carlton et al.[52, 53] In previous versions of CMAQ, all SOA was semivolatile and resulted from the oxidation of compounds emitted entirely in the gas-phase. In CMAQ v4.7, parameters in existing pathways were revised and new formation mechanisms were added. Some of the new pathways, such as low-NO_X oxidation of aromatics and particle-phase oligomerization, result in nonvolatile SOA.

Section 6.1.1.10 of the RIA presents information on exposure and health effects associated with traffic-related air pollution near roads. This information is focused within 500 meters of a road because that range includes the distance that review articles show as the range where most studies indicate that pollutants reach background levels. There is research, such as the 2009 study cited by the commenter, indicating that depending on meteorological conditions, near road pollutants can be transported further than 500 meters.

The CMAQ model, described in Section 6.2.1 of the RIA, does not make any assumptions about exposure at various distances from roads. Instead it models the transport and dispersion of pollutants based on numerous science modules that simulate the emission, production, decay, deposition and transport of organic and inorganic gas-phase and particle-phase pollutants in the atmosphere. In addition, as noted above, there are various forms of advanced engine technologies such as GDI, and EPA believes that over the timeframe addressed by this rule, manufacturers will have adopted the cleanest forms of GDI which are expected to have emission performance comparable to PFI vehicles.

Comments on Health Effects of Acetaldehyde

Organization: Clean Fuels Development Coalition (CDFC)

P. 75107, ACETALDEHYDE. We note that EPA states it is currently “conducting a reassessment of cancer risk from inhalation exposure to acetaldehyde,” which is the only hazardous air pollutant associated with increased use of E30+ blends. Attachment F provides preliminary details on acetaldehyde‘s extremely low ranking in terms of Inhalation Risk Factor (IRF), as reported by DOE, CARB, and other experts (1, 3 butadiene = 100; formaldehyde = 4.6; benzene = 3.0; acetaldehyde = 0.8). We will be submitting a more detailed analysis on this subject for the Tier 3 rulemaking, but, in the meantime, we respectfully request that the Agencies take this information into account as they finalize this rule. [Attachment F can be found in Docket number EPA-HQ-OAR-2010-0799-9574-A10] [EPA-HQ-OAR-2010-0799-9574-A3, p. 8]

The Agencies cite the fact that the rulemaking's benefits far outweigh their costs as an indication of its reasonableness. But the opposite is true. In light of the statutory mandate to achieve energy conservation, it is unreasonable to design a rulemaking that so obviously undervalues benefits. Here, technologies that can improve fuel efficiency significantly have been ruled out because of alleged cost concerns by manufacturers. Yet, the rulemaking's benefits exceed its costs by many hundreds of billions of dollars.39 The fuel savings alone pay for the costs of additional technologies many times over, leaving billions of dollars in consumer pockets. The Agencies have thus left substantial, achievable fuel economy improvements and public benefits unrealized due to industry objections. Plainly, a rulemaking that elevates the protection of industry profits over energy conservation is contrary to EPCA and EISA. This calculus underlying the preferred alternative is anything but reasonable. [EPA-HQ-OAR-2010-0799-9479-A1, p. 8]

Response:

EPA agrees with the commenter's assessment that the projected benefits of the final standards far exceed the projected costs. Given the entire impact analysis set forth in the preamble and the RIA, EPA concludes that the final standards are reasonable and feasible. However, the commenter's claim that even more stringent standards would be reasonable (because benefits so far exceed projected costs) does not take into account that the benefits of the rule are dependent on vehicles actually being built and purchased when one takes into consideration issues of cost, consumer acceptance, and available lead time. Note that EPA also responds to comments regarding the stringency of the standards in Section 2.

EPA has analyzed these issues in detail, including a projection of technology penetration rates needed to meet more stringent car and truck standards. As set out in detail in Section III.D.6 of the preamble to the final rule, truck and car standards which are 20 grams/mile more stringent would result in significantly increased penetration rates for advanced technologies. This is true in both MY 2021 and even more so in MY 2025. See Tables III-35 and III-37 for trucks, Tables III-42 and III-44 for cars. In addition, as discussed in that section of the preamble, a 20 g mile more stringent truck standard in MY 2021 would raise issues of available lead time and consumer acceptance for introducing challenging technologies into large pickup trucks. -This rapid influx of technologies (and costs) is also illustrated in figures III-3 and III-4. The tables and figures show that more stringent standards add costs and technologies in a non-linear fashion, as costs greatly increase as the rate of electrification increases. This commenter advocated alternative 4 (cars -20g/mi) as its preferred alternative, which is equivalent to an average of 6.5% annual rate of increase in stringency for cars.

This level of stringency increase leads not only to increased costs, but raises issues of consumer acceptance due not only to the cost increases but in response to a marked increase in technology in vehicles. These technology increases include a doubling of electric vehicles and hybrid electric vehicles. For the MY 2025 standards, our analysis indicates that some manufacturers would be required to use the maximum amount of advanced technology we consider feasible (i.e. the phase-in cap amount) to achieve the 20 grams per mile more stringent standard and in some cases add even further advanced technology (see Table III-54 for the alternative 4 example). A number of commenters have noted that current penetration rates of HEVs are low (see discussion in Response to Comments section 18.1). Preamble III.H.1.b discusses issues related to consumer acceptance of EVs. As discussed there, we consider the projected level of EVs and PHEVs in this rule to be small enough that the market is likely to absorb the vehicles, but we acknowledge that we do not have sufficient information to estimate consumer response to these unconventional technologies. Increasing stringency of the standards would of course raise even more questions about market acceptance. In addition, more aggressive standards would raise significant issues not only of cost and consumer acceptance, but available lead time as well.

Additionally, EPA feels that there are substantial uncertainties about the ability of consumers and automakers to absorb the total cost of a program where the total lifetime benefits equal the costs of the program. Although the commenter does not explicitly espouse such stringent standards, the commenter states that “fuel savings alone pay for the costs of additional technologies many times over, leaving billions of dollars in consumer pockets.” Simultaneously the commenter must acknowledge the market limitations associated with such radically high costs as in the alternative where total costs equals total benefits (which would be significantly more stringent than the standards in this rule). Some, if not all, of the increasing costs associated with this rule will be passed along to consumers (see discussions of cost pass-through in Preamble Section III.H.11.a and Response to Comments Section 18.7.1); thus, it is incorrect to imply that “industry profits” are the primary beneficiary of the standards in this rule relative to more stringent standards. Various public commenters (see discussion in Response to Comments Section 18.1) already raise concerns about public acceptance of the increased costs and new technologies resulting from this rule; other commenters express more optimism. As discussed in Response to Comments Section 18.1, consumer acceptance of the vehicles subject to these standards is necessary for the standards to have the impacts predicted in this rule. We believe that the standards in this rule achieve a reasonable balance in promoting technological innovation while maintaining consumer acceptance. Tighter standards would involve significant uncertainties about these factors.

We note that analyses substantially similar to these were presented in the proposed rule, and the commenter does not raise any questions as to the accuracy of these analyses. EPA has made a reasonable policy choice to encourage more rapid penetration of advanced technology, especially into the heavy truck sector, by means of incentives and credit mechanisms, rather than by adopting aggressive standards under which the projected benefits may not accrue in whole or in part for the reasons just given.

Organization: Institute for Energy Research (IER)

Depending on the discount rate used, and the value attributed to the social benefits from reduced greenhouse gas emissions, EPA estimates that through the year 2050, the proposed rule will have net benefits (i.e. benefits exceeding costs) ranging from $460 billion to $1.7 trillion (in 2009 dollars). [EPA-HQ-OAR-2010-0799-9573-A1, p. 9]

However, EPA's cost-benefit analysis rests upon several dubious assumptions, at times straining to account for various possible benefits from the new rule while ignoring quite plausible drawbacks. Even a cursory inspection of EPA's own breakdown of the numbers should give EPA pause before implementing the rule. Because of the sensitivity of the results to the controversial assumptions, it is not merely that EPA may be overstating the net benefits of the rule. Rather, the new rule may impose large net costs. [EPA-HQ-OAR-2010-0799-9573-A1, p. 9]

Furthermore, EPA's cost-benefit analysis for this rule is fatally flawed. [EPA-HQ-OAR-2010-0799-9573-A1, p. 23]

Response:

EPA disagrees with the commenter's assertion that the cost-benefit analysis is fatally flawed. EPA uses standard economic parameters (including discount rates) to measure the monetary value of the rule's impacts. These parameters, methods and assumptions are based on the best available data at the time and are documented extensively in the Preamble, RIA, and Joint TSD that accompanies this rule.

EPA acknowledges that a wide range of estimates is available for many of the primary inputs that are used in the GHG emissions models. EPA recognizes that each of these values has some degree of uncertainty, which we discuss in the Joint TSD. EPA tested the sensitivity of their estimates of costs and benefits to a range of assumptions about each of these inputs, and found that the magnitude of these variations would not have changed the final standards. EPA conducted sensitivity analyses on discount rates (throughout the rulemaking package, but see specifically preamble III.H.10 and RIA Chapter 7.3), the social cost of carbon (preamble III.H.6 and RIA Chapter 7.2), the rebound effect (RIA Chapter 4.5.1), and battery costs, mass reduction costs, the indirect cost markup factor and on the cost learning curves used in this analysis (RIA Chapter 3.11).

In total, EPA's analysis found that the benefits of the final rulemaking, including fuel savings and many other benefit categories such as the Social Cost of Carbon, far outweigh the costs of the standards. See, for example, preamble Table I-17; preamble section III.H.10.

Organization: Investor Network on Climate Risk (INCR) - Ceres

Finally, strong standards will serve to mitigate the economic risks associated with our continuing dependence on oil as well as climate change. In light of the inevitable rise in oil prices given increased demand from China, India and Brazil, we need strong standards in order to reduce transportation costs for businesses and consumers. In addition, climate change presents significant long-term risks to the global economy, and to investors across all asset classes. Strong standards will serve to mitigate that risk by providing significant GHG reductions; the proposed standards would save approximately two billion metric tons of GHG emissions. [EPA-HQ-OAR-2010-0799-9516-A1, p. 2]

Response:

We agree that world oil demand could be relatively strong over the time frame of this rule and that lower demand for petroleum as a result of this rule could help to lower fuel costs in the U.S. transportation sector. We also agree that climate presents significant long-term risks to the global economy and that our climate impacts analysis and valuation show notable benefits associated with GHG reductions. We refer the commenter to the climate impacts and SCC sections in Preamble Section III.H.6, Section III.F.2, RIA Chapter 7, and the Joint TSD Chapter 4 for more details about the benefits.

Organization: Mass Comment Campaign (20) (Union of Concerned Scientists-1)

The proposed standards can bring significant economic, environmental, and energy security benefits. [EPA-HQ-OAR-2010-0799-1558-A1_MASS, p.1]

Organization: National Association of Clean Air Agencies (NACAA)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 37-38.]

The estimated benefits of this proposal include a reduction in oil consumption of four billion barrels, a reduction in greenhouse gas emissions of two billion million metric tons, fuel savings on the order of $347 to $444 billion and a monetized net benefit to society in the range of $311 to $421 billion.

Organization: New Jersey Senate, Third Legislative District

The projected annual benefits of such standards by 2030 are enormous:

• $45 billion in savings at the gas pump

• 23 billion gallons of gasoline saved

• 280 million metric tons of global warming pollution avoided [EPA-HQ-OAR-2010-0799-9970-A1, p. 1]

Organization: New York City Council, 35th District

On behalf of my constituents urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rulemaking process.

The projected annual benefits of such standards are enormous. By 2030 the standards would:

• Save Americans $45 billion at the gas pump

• Cut annual oil use by an amount equivalent to our imports from Saudi Arabia and Iraq in 2010

• Reduce annual global warming pollution by the amount equivalent to shutting down 70 coal-fired power plants for one year [EPA-HQ-OAR-2010-0799-9901-A2, p. 1]

Organization: New York State Assembly Committee on Government Operations

On behalf of my constituents urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rulemaking process.

The projected annual benefits of such standards are enormous. By 2030 the standards would:

- Save Americans $45 billion at the gas pump
- Cut annual oil use by an amount equivalent to our imports from Saudi Arabia and Iraq in 2010
- Reduce annual global warming pollution by the amount equivalent to shutting down 70 coal-fired power plants for one year [EPA-HQ-OAR-2010-0799-9453-A2, p. 1]

Organization: New York State Senate, 26th District

On behalf of my constituents I urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rulemaking process.

The projected annual benefits of such standards are enormous. By 2030 the standards would:

• Save Americans $45 billion at the gas pump

• Cut annual oil use by an amount equivalent to our imports from Saudi Arabia and Iraq in 2010

• Reduce annual global warming pollution by the amount equivalent to shutting down 70 coal-fired power plants for one year [EPA-HQ-OAR-2010-0799-9884-A1, p. 1]

Organization: State of New York The Assembly

On behalf of my constituents urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rulemaking process.

The projected annual benefits of such standards are enormous. By 2030 the standards would:

• Save Americans $45 billion at the gas pump

• Cut annual oil use by an amount equivalent to our imports from Saudi Arabia and Iraq in 2010

• Reduce annual global warming pollution by the amount equivalent to shutting down 70 coal-fired power plants for one year [EPA-HQ-OAR-2010-0799-10155-A1, p. 1]

Organization: The Catskill Center for Conservation and Development

The projected annual benefits of such standards by 2030 are enormous:

• $45 billion in savings at the gas pump

• 23 billion gallons of gasoline saved

• 280 million metric tons of global warming pollution avoided [EPA-HQ-OAR-2010-0799-9913-A1, p. 1]

Organization: Weiner, L.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 105.]

The scale of benefits far outweighs any opposition: Reducing reliance on foreign oil, saving American families thousands of dollars in gas, cutting pollution, creating jobs and revitalizing the American auto industry as an engine of economic growth and innovation, as you heard.

Organization: Center for Biological Diversity

39 The Agencies state the net benefits of the rulemaking as between $311 billion and $421 billion, at 7 and 3% discount rates, respectively, over the lifetimes of the vehicles sold during MY 2017-2025. NPRM, 76 Fed. Reg. 74859 [EPA-HQ-OAR-2010-0799-9479-A1, p. 8]

Response:

EPA thanks the commenters for pointing out the clear benefits associated with the final standards and agrees that the benefits of the standards far outweigh the costs.

Organization: Shick, R.

If enacted, these new regulations will increase average vehicle costs by $5000 (source: NADA study) and drastically limit consumers' choices as popular and useful vehicles as pickup trucks and SUVs are either removed from the market or simply become unaffordable. [EPA-HQ-OAR-2010-0799-6215-A1, p. 1]

The regulations will also reduce vehicle sales and production which will reduce employment, cause people to drive their vehicles longer, and risk safety by forcing vehicles to be smaller and lighter weight. [EPA-HQ-OAR-2010-0799-6215-A1, p. 1]

I have seen first hand the incredible expense of the technologies required to meet these requirements and they are certainly not justified by the limited potential benefits in fuel savings. Even if fuel usage were drastically reduced, state and federal governments would increase the gasoline taxes to make up for the reduced gasoline tax revenue, thus negating the savings to consumers. [EPA-HQ-OAR-2010-0799-6215-A1, p. 1]

Response:

EPA disagrees with the commenter's assertion that the expense of the technologies is not justified by the potential benefits of fuel savings. Our analysis found that the benefits of the final rulemaking, including fuel savings and many other benefit categories such as the Social Cost of Carbon, far outweighed the costs of the standards. See, for example, preamble Table I-17. How state and federal governments address the impacts of this rule on gasoline taxes is beyond the scope of this rule. The benefit-cost analysis does not include sales tax, because sales tax revenues are a transfer of income, not income created or reduced by this rule.

Regarding the other points the commenter makes, we address these concerns elsewhere in our Response to Comments document: costs are addressed in Section 12.3, safety in Section 13, fuel savings in Section 18.3, vehicle sales in Section 18.7, and employment in Section 18.8.

Organization: Smith, Frank Houston

The range of impacts extend well beyond ... automotive fuel economy, lack of US parity with world CO_2/fuel economy standards NOW & post 2014, 2025 CAFE, US industrial base, US jobs creation/loss, oil imports/energy independence, balance of trade, US economic expansion without requiring TAXPAYER MONEY, preventing the demise of Det3 (& general) US auto industry post 2016, ultimately ... Our US ECONOMY … and … NATION SECURITY. [NHTSA-2010-0131-0240, p.2]

Concerns or Opportunity?

President Obama's 2012 STATE of the UNION address praised the auto industry recovery and the idea/opportunity of exporting US automotive product. [NHTSA-2010-0131-0240-A2, p.6]

Unfortunately, the EU and South Korea will require, by statute, ≤ 140 gCO_2/km in 2015 to avoid severe financial penalties (> USD $25/gram minimum over limit, in some jurisdictions increasing to almost $90/gram by 2020) for each noncompliant vehicle sold. This requires minimum fuel economy of 40 and 44 mpg(US) combine for gasoline and diesel vehicles respectively to avoid these penalties. It is reasonable to believe China and India will be following soon after. Table 4 offers an assessment of the current UK/EU market status to allow appreciation of future expectations. [NHTSA-2010-0131-0240-A2, p.6]

For reference 22.2 (the 2011 US fleet average) and 30 mpg combined are roughly 250 and 182 g CO_2/km respectively. [NHTSA-2010-0131-0240-A2, p.6]

Are there any current or proposed US manufactured vehicles that would NOT be subject to penalties when exported to those 4 regions constituting about 70% [and growing] of world automotive markets in 2011? [NHTSA-2010-0131-0240-A2, p.6]

Will these external CO_2 limits make it more difficult to export US manufactured automotive product based on foreseeable offering and emerging US powertrain technologies? See Table 4 above for UK/EU market status. [NHTSA-2010-0131-0240-A2, p.6]

This may be a serious problem ... except for the niche high end segments where price/cost is of no concern. The down side of this is that the rich can only buy a relatively limited number of vehicles per year. [NHTSA-2010-0131-0240-A2, p.6]

Response:

EPA thanks Mr. Smith for his thoughtful comment. The final standards will move automakers towards more fuel efficient vehicles and move the US toward lower GHG emissions. However, it is up to the automakers to decide how to respond to environmental standards in other countries. We believe that it is possible that the standards will facilitate meeting increasingly stringent international standards, which may reduce coordination costs, and thus overall costs for the standards. We discuss this issue in Preamble III.H.11.a.

Since the first CAFE standard was established in 1975, automotive technologies have advanced to provide consumers with a range of choices for automobiles that meet mobility needs, are safe, and fulfill a desire for fuel economy. AAA hopes that the CAFE reforms sought under this rulemaking will continue the progress we have made as a country in improving automobiles from all perspectives. [EPA-HQ-OAR-2010-0799-9484-A1, p. 1]

AAA's interest in CAFE has always been to represent the motorist, while leaving the establishment of specific target numbers to manufacturers, researchers and policymakers. In this capacity, AAA's position and policy has remained that the federal government should establish fuel economy standards that are ambitious enough to result in marked improvements in overall efficiency but realistic enough to maintain passenger safety and consumer choice. [EPA-HQ-OAR-2010-0799-9484-A1, p. 1]

Organization: Alexandria Hyundai

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 64-68.]

Safety, reliability, styling and fuel economy are all key considerations for our customers when selecting a vehicle brand or model.

I believe our customers will continue to value and place great emphasis on fuel economy. And that is one of the reasons I generally support the proposed standards.

I have seen firsthand how customers are open to new platforms and technologies when selecting a new vehicle.

Achieving the 54.5 MPG target will most certainly require a great deal of automotive ingenuity and substantial investment on the part of all key stakeholders.

However, I am certain consumers will continue to demand improvements in fuel economy and purchase vehicles from manufacturer vehicle offerings achieving that target.

I state this example to underscore that while we must remain sensitive to cost increases, consumers will see value in and pay for advancements in technologies that improve their lives and the lives of those around them.

Organization: Alliance of Automobile Manufacturers

Even assuming that the energy cost savings will far exceed the increased up-front vehicle costs, consumer response is difficult to predict. The NPRM describes what the agencies call an "energy paradox" whereby consumers appear not to purchase products featuring levels of energy efficiency that, according to some metrics, might appear to be in their economic self-interest: [EPA-HQ-OAR-2010-0799-9487-A1, p.19]

Of 27 studies, significant numbers of them find that consumers undervalue, overvalue, or value approximately correctly the fuel savings that they will receive from improved fuel economy. The variation in the value of fuel economy in these studies is so high that it appears to be inappropriate to identify one central estimate of value from the literature. Thus, estimating consumer response to higher vehicle fuel economy is still unsettled science. Regarding consumer response to [fuel economy] labeling information on cost savings: Whether the new label will help consumers to overcome the ''energy paradox'' is not known at this point. [EPA-HQ-OAR-2010-0799-9487-A1, p.19]

Are Consumers Purchasing the Technologies Needed to Achieve the Goals of the Rulemaking? [EPA-HQ-OAR-2010-0799-9487-A1, p.23]

Of course, the ultimate question will be whether mainstream consumers will be able and willing to purchase the technologies needed to achieve this country's fuel economy energy security and environmental goals – particularly as the federal and state governments phase out many of the financial incentives that are available today.[10] The proposed regulatory language does not include this single most critical factor. Will mainstream consumers be willing and able to purchase vehicles with more fuel efficient technologies? As the NPRM states, "there is considerable uncertainty in the economics literature about the extent to which consumers value fuel savings from increased fuel economy." [EPA-HQ-OAR-2010-0799-9487-A1, p.23]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 97.]

In fact, consumer acceptance is the most critical – and unpredictable – component of advanced technology vehicle deployment. Manufacturers strive to understand how their advanced technology vehicles will be used and fueled and what combination of pricing, incentives and vehicle attributes are needed to convince mainstream consumers to invest in new technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.23]

Recognizing the critical role of customers in determining the viability of future vehicle technologies, the NAS wrote: [EPA-HQ-OAR-2010-0799-9487-A1, p.23]

Manufacturers will choose fuel economy technologies based on what they think will be most effective and best received by consumers. Customers also will have a central role in what technologies are actually chosen and will make those choices based partly on initial and operating costs. Subsidies and other incentives also can significantly impact the market acceptance rate of technologies that reduce fuel consumption. Finally, adoption of these technologies must play out in a sometimes unpredictable marketplace and policy setting, with changing standards for emissions and fuel economy, government incentives, consumer preferences, and other events impacting their adoption. Thus, the committee acknowledges that technologies downplayed here may play a bigger role than anticipated, or that technologies covered in this report may never emerge in the marketplace. [EPA-HQ-OAR-2010-0799-9487-A1, p.23]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 96-98.]

The unprecedented effort of the coming 13 years to further our country's energy and environmental goals will succeed only, only if consumers buy the fuel-efficient technologies that we will be offering.

Looking into the future, consumer purchasing patterns will be the biggest unknown. Besides fuel economy, we know that consumers demand affordability, safety, convenience and utility. One challenge we have is that fuel economy considerations often rank below those other factors. Fuel prices are especially difficult to predict and have a huge impact on how consumers weigh fuel economy at the dealership.

First, let consumers determine the winning fuels and technologies. Ultimately consumers should decide what best meets their needs. Vehicles that run on gasoline, diesel, biofuels, electricity, hydrogen and natural gas will all play a role in improving fuel efficiency and reduce greenhouse gas emissions.

---

10 - In 2011, when automakers offered 231 models that achieved 30 miles per gallon or more on the highway, these vehicles represented about 37% of U.S. sales. More than ten years after hybrids were introduced to the U.S. market, in a year when there were 38 different models of hybrids on sale in the United States, these vehicles represented only 2.1% of new vehicle sales. In 2011, the top-selling pickup truck outsold all hybrids combined by a factor of two to one. (Data in this footnote is computed based on data from www.fueleconomy.gov and from WardsAuto

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

II. NHTSA should adopt feasible CAFE standards. [EPA-HQ-OAR-2010-0799-9485-A1, p.3]

NHTSA’s authority to issue these CAFE standards is set forth at 49 U.S.C.§ 32902(b)(2)(B). That statute requires NHTSA’s CAFE standards to be “feasible” and practicable and states: [EPA-HQ-OAR-2010-0799-9485-A1, p.3]

When deciding maximum feasible average fuel economy under this section, the Secretary of Transportation shall consider technological feasibility, economic practicability, the effect of other motor vehicle standards of the government on fuel economy, and the need of the United States to conserve energy. [EPA-HQ-OAR-2010-0799-9485-A1, p.3]

In analyzing the latest round of CAFE standards, NHTSA recognized that some technologies currently have limited commercial use and require a realistic schedule for widespread commercialization to be feasible. We note that consumer acceptability is an important element of economic practicability. [EPA-HQ-OAR-2010-0799-9485-A1, p.3]

AFPM is very concerned that this proposal is based on an analysis that does not incorporate a vehicle choice model that appropriately considers the impacts of consumer choice upon industries and individuals that will be affected by the rulemaking. This is a serious deficiency that must be addressed to properly understand the implications of this proposal. EPA acknowledges this need with the following excerpt from the proposal: [EPA-HQ-OAR-2010-0799-9485-A1, p.4]

The agency hopes to evaluate those potential impacts through use of a ‘‘market shift’’ or ‘‘consumer vehicle choice’’ model, discussed in Section IV of the NPRM preamble. With an integrated market share model, the CAFE model would then estimate how the sales volumes of individual vehicle models would change in response to changes in fuel economy levels and prices throughout the light vehicle market, possibly taking into account interactions with the used vehicle market. Having done so, the model would replace the sales estimates in the original market forecast with those reflecting these model-estimated shifts, repeating the entire modeling cycle until converging on a stable solution. We seek comment on the potential for this approach to help the agency estimate sales effects for the final rule. [EPA-HQ-OAR-2010-0799-9485-A1, p.4]

Using a new consumer choice model to evaluate the impacts of the final rule is appropriate, but requires the agency to re-propose the rule and offer its revised conclusions on sales estimates and market forecasts for public comment. It is inappropriate and a violation of the Administrative Procedure Act to promulgate a final rule without first seeking comment on the changes caused by the application of the revised model. A new consumer vehicle choice model should have been peer-reviewed and then employed in this proposal to permit public review and comment on the impacts of this proposal. It is improper to propose a rule, accept comments, change the methodology for analyzing the rule’s impact and finalize the rule without providing an additional opportunity for comment on the impacts of the final rule. How can affected parties provide informed comments to the agency when the proposed rule excludes the agency’s understanding of the potential impacts of the proposed rule? Under these circumstances, the Administrative Procedure Act requires the agency to apply the vehicle choice model, describe its impact, and issue a supplemental notice of proposed rulemaking to facilitate informed comment on the potential impact of the rule. [EPA-HQ-OAR-2010-0799-9485-A1, p.4]

The agency’s failure to apply an appropriate vehicle choice model has resulted in proposed standards that are not feasible. Electrification is a good example. The following chart reflects the unwarranted optimism of attaining sufficient sales volumes for electric vehicles: [EPA-HQ-OAR-2010-0799-9485-A1, p.4] [For the associated chart please refer to EPA-HQ-OAR-2010-0799-9485-A1, p.5]

Conclusion [EPA-HQ-OAR-2010-0799-9485-A1, p.9]

AFPM believes that this rule needs to be re-proposed with the inclusion of a consumer choice model that reflects a feasible and practicable market penetration of alternative fuel vehicles. [EPA-HQ-OAR-2010-0799-9485-A1, p.9]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 201.]

We echo the support and the comments made regarding savings for consumers. We think those are going to be very real.

Organization: BlueGreen Alliance

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 58-60.]

Based on the agencies' initial technical assessment, the net consumer savings of fuel expenditures will be very substantial and will provide much needed relief at the pump. By developing and producing advanced fuel- saving technology in the United States, automakers and suppliers can create quality jobs and provide the clean, fuel-efficient cars and light-duty trucks consumers want.

We also request continuing federal programs to support these auto industry efforts in retooling to meet the demand for cleaner, more efficient cars.

Consumers looking to purchase vehicles in the next few years are expressing interest in higher fuel economy. Building the next generation of advanced vehicles in the United States will create tens of thousands of new engineering and manufacturing jobs and strengthen America's rebounding sector.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 38.]

This standard will give Americans more advanced vehicle choices, which in turn will help consumers save money at the pump. By making it less expensive to drive, by covering the same ground but using less fuel, consumers will have more money left over to spend or invest in other economically beneficial ways.

Organization: BMW of North America, LLC

To reiterate, achievable greenhouse gas emission reductions and commensurate fuel economy increases depend on both designing more fuel-efficient vehicles AND increasing market demand for such vehicles. We can build the vehicles, but consumers must buy them. The implementation of new greenhouse gas-reducing technologies, alternative powertrains, and fuels strongly depends on customer acceptance. The proposed standards were developed based on today's best estimates of future technology, market developments, and assumed customer acceptance. A comprehensive emission reduction policy needs to consider all aspects, including the customer. [EPA-HQ-OAR-2010-0799-9579-A1, p. 3]

Organization: Competitive Enterprise Institute (CEI)

The agencies project net benefits ranging from $262 billion (assuming a 7% discount rate) to $358 billion (assuming a 3% discount rate).2 These projections are based on assumptions regarding vehicle cost, fuel prices, and consumer acceptance that may or may not be borne out by events. Skepticism is justified. If the proposed standards are as beneficial to consumers and automakers as the agencies contend, why wouldn‘t consumers demand and profit-seeking manufacturers produce vehicles built to the same or similar standards without regulatory compulsion? Fuel economy regulation assumes that auto buyers do not want to avoid pain at the pump and automakers do not want to get rich. [EPA-HQ-OAR-2010-0799-9552-A1, p. 1]

Organization: Consumer Federation of America (CFA)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 39-41.]

These potential consumer benefits come at a moment when American consumers are in desperate need of relief from rising and volatile gasoline prices. Gasoline prices set a record in 2011 in both nominal and real terms, averaging $3.53 per gallon. This week's price is a record for the month of January, and that clobbers the economy and the consumer pocketbook.

So if there is one thing you take away from this hearing today, remember this is a consumer benefit program. This is a wonderful consumer program. In fact, we estimate that 80 percent, 500 billion of the $600 billion of total benefits are the consumer savings. So this is a consumer program.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 87-89.]

I gladly appreciate the opportunity to appear today because we believe that the benefits of this proposed rule are obvious.

They lower the cost of driving and will save consumers thousands of dollars per vehicle. It will save the national economy hundreds of billions of dollars.

They lower our imports, lower our vulnerability to supply disruptions. Above all, these are a consumer-friendly set of rules. This is the consumer policy that will benefit American consumers.

Consumers will buy the new fuel-efficient vehicles enabling auto makers to reach the targets that have been set. Not because they're so beneficial in terms of economics. That's important.

But also because the rules have been written in a consumer-friendly fashion that is sensitive to the needs of the industry. And that is the backbone of the political consensus that you have heard this morning.

First, the public is concerned about gasoline and that leads to support for higher fuel economy and it changes consumer behavior.

Seventy-five percent or more of respondents to our public opinion polls. And we've conducted a dozen over the last six or seven years.

Second of all, consumers have shown a willingness to shift their buying patterns in light of recent gas price spikes.

Americans are meeting their needs for driving with vastly more fuel-efficient vehicles. They are ready to do this. They have already started, and they are way ahead of the auto industry.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 59-61.]

The car dealers say that fuel economy performance is typically not high on the consumer's list of priorities. If this were, in fact, true, why do we see so many car companies advertising fuel economy as a selling point. The car manufacturers who spend millions of dollars studying consumer behavior obviously disagree with their dealers. Fuel economy is the very top priority for consumers looking to purchase a new car. In fact, Consumers Union, the publishers of Consumer Reports, determined that fuel economy was the number two reason why consumers would change their brands of vehicle.

The NADA has said that just because vehicles can be built doesn't mean that they will be bought. Actual sales data, however, is very clear. Consumers want and will pay for more fuel-efficient vehicles. And the manufacturers supporting this new standard have agreed to make them. Consider Ford, for example. The combined sales of their two new fuel-efficient cars, the Fiesta and the Focus, in May 2011 are up 74 percent in one year.

Like everyone in the economy, car dealers are reeling from the financial setbacks. The reduction in the cost of driving from these new standards, however, will cause more autos to be sold and over 100,000 jobs to be created. More jobs and vehicles that are less expensive to drive means more consumers, not less, will be buying cars.

Consumers are desperate for more fuel-efficient vehicles. Consumer pocketbooks are hurting and more fuel-efficient vehicles will drive more and more consumers into the showroom. Right now, there are not enough fuel-efficient vehicles on the market to meet consumer demand.

V. NATIONAL COST BENEFIT: HIGHER FUEL ECONOMY STANDARDS DELIVER LARGE AND DIVERSE BENEFITS

Exhibit S-5 shows CFA's estimates of national benefits and costs. [See Exhibit S-5 on p. 7 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

The total discounted national benefits are close to $600 billion, a value that is well over three times the cost. [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

Higher fuel economy standards are primarily a consumer benefit program, with consumer savings of close to $500 billion, over 80 percent of the total national benefits. [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

Environmental and public health benefits will be almost $60 billion (just over 10 percent of the total). [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

Exhibit S-6 presents the full range of cases and scenarios considered by the agencies. It plots the costs (on the x-axis) and the benefits (on the y-axis) for the eight different target levels considered with each target level evaluated at discount rates of 3% and 7%. It also shows the results of the sensitivity analyses that were conducted at the 3% discount rate. In all, there are 28 cases/scenarios shown. The Exhibit also includes a break even line. If a case/scenario falls above the line, the benefits exceed the costs. [See Exhibit S-6 on p. 9 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, p. 8]

In every sensitivity analysis conducted by the agencies, no matter how extreme the assumptions, the benefits exceed the costs. [EPA-HQ-OAR-2010-0799-9419-A1, p. 8]

The exhibit makes it clear that the benefits are likely to exceed the costs by a wide margin. Even under the most extreme assumption – i.e. that consumer pocketbook savings are only one-quarter of the base case calculation, the benefits are almost twice as large as the costs at the 3% discount rate. [EPA-HQ-OAR-2010-0799-9419-A1, p. 8]

VIII. NHTSA AND EPA HAVE SERIOUSLY UNDERESTIMATED THE BENEFITS OF THE STANDARDS

There are both quantitative and qualitative flaws in the agency analysis that must be corrected. The analyses presented in the attached Technical Appendices reflect our independent calculation of the costs and benefits which includes corrections of the flaws in the underlying agency analyses. At the outset, we want to stress that neither the standards nor the cost benefit analyses are perfect, but the perfect must not be the enemy of the excellent. Increasing the fuel economy of the vehicle fleet to the levels proposed by the standards represents such major progress towards important national policy goals and the approach taken by the standards is so well crafted that we believe it is of the utmost importance to adopt the standards and move vigorously to implement them. Our primary concern is that the agencies have underestimated the value of the standards in several important ways. Even with the flaws, the benefits of the standards are shown to far outweigh the costs, but it is important for the final rule to correct the flaws we identify. [The Technical Appendices can be found on pp. 16-55 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, pp. 11-12]

- NHTSA will be issuing final rules periodically over the next decade and a half, and the agencies will jointly conduct a mid-course review in a decade; the errors should not be allowed to become engrained in the analytic structure. [EPA-HQ-OAR-2010-0799-9419-A1, p. 12]

While the current standards are well within the frontier of what is technologically feasible and economically practicable (which are two key standards that in the authorizing legislation for NHTSA), over time, the standards may move closer to the frontier. [EPA-HQ-OAR-2010-0799-9419-A1, p. 12]

- As the fuel economy standards rise, they will be closer to the economic margin, which will make it more important for the agencies to get it right, so that future rules do not demur from setting standards that are in the public interest because benefits have been underestimated. [EPA-HQ-OAR-2010-0799-9419-A1, p. 12]

The agencies need to articulate the analytic justification for the standards more clearly and forcefully. The Preliminary Regulatory Impact Analysis contains a lengthy discussion of what has been called the "efficiency gap" or the "efficiency paradox" for several decades. In many ways, this discussion is far superior to earlier discussions in the sense that it recognizes there are both supply-side and demand-side factors that may cause the market for new autos to under invest in fuel economy technologies. The "efficiency gap" is identified by the economic/engineering analysis, where, under reasonable and realistic assumptions about cost and value, there are many technologies available that would produce substantial net benefits to consumers if they were included in the new vehicles. The failure of the auto market to include these technologies raises the question of why, in a capitalist economy, where markets are presumed to be efficient, so much economic value is left unrealized. The answer, as we have pointed out in the all of the recent rulemakings dealing with the fuel economy of light duty vehicles is that there are market imperfections that suppress investment in fuel efficient technologies. [EPA-HQ-OAR-2010-0799-9419-A1, p. 12]

Our earlier analyses are summarized in Exhibit S-9. The imperfections [See Exhibit S-9 on p. 13 of Docket number EPA-HQ-OAR-2010-0799-9419-A1]

- affect both the demand side and the supply-side of the light duty vehicle market,
- go well beyond the problems of externalities and information problems, and
- include significant market structural conditions, transaction costs and behavioral factors. [EPA-HQ-OAR-2010-0799-9419-A1, p. 12]

The fact that the market has begun to move in the right direction is encouraging. The fact that it has taken almost a doubling of the cost of gasoline in real terms to get it to move is testimony to the strength of the barriers to optimal investment in fuel economy in the market. In spite of the fact that the agency discussion of market imperfections is incomplete, the agencies conclude, correctly, that the base case analysis should be the pillar on which the choice of a standard rests. We agree with that conclusion. The agencies treat the base case with a 3% discount rate as the starting point for the sensitivity analysis. [EPA-HQ-OAR-2010-0799-9419-A1, p. 12]

We do not agree with the decision to conduct a "fudge" factor analysis that arbitrarily slashed the size of the efficiency gap and the magnitude of consumer welfare gains. The analysis offers no empirical justification for doing so. Moreover, the general discussion of consumer welfare combined with the traditional sensitivity analysis has already addressed the underlying uncertainties. Uncertainties about the price of gasoline, the cost and effectiveness of technologies, the value of externalities are already incorporated in the sensitivity analysis. The "fudge" factor analysis is unnecessary and double counts uncertainty. [EPA-HQ-OAR-2010-0799-9419-A1, p. 12]

Organization: Consumer Reports

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 165-166.]

It is our view that implementing these proposed fuel economy standards, will increase vehicle choice and provide consumers with more efficient and alternative fuel vehicles.

In a recent Consumer Reports survey, consumers demonstrated a strong support for fuel economy standards and alternative fuel vehicles and a willingness to pay more for these technologies.

Consumers want it all. They want function, performance, a variety of choices, and better fuel economy. And they have indicated that they'd rather pay slightly more for these vehicles if it means they would save money at the gas pump.

According to the survey, 93 percent believe that the fuel efficiency standards for all vehicles should be improved. Nearly 80 percent support the 55 miles per gallon target for the fleet by 2025.

As the availability of these vehicles, many consumers would buy or consider an alternative fuel vehicle such as a hybrid, electric vehicle or natural gas.

Organization: Consumers Union

Finally, the standards are likely to improve the choices available to consumers. Because CAFE standards are now footprint-based, improvements are required across all vehicle sizes, so each class of car will likely see efficiency gains. Because the standards are scaled by size, there is no incentive for automakers to downsize vehicles. Consumers will have more efficient options across vehicle classes and are likely to see more partially and fully electrified options from many or all automakers. [EPA-HQ-OAR-2010-0799-9454-A2, p.3]

II. Consumers support a strong CAFE standard

Improving fuel economy also provides intangible benefits and acts as insurance against unstable oil prices. Uncertainty in fuel prices and price spikes take an emotional toll that is not easily captured in modeling or consumer choice analysis. Spikes in gasoline prices cause immediate and keenly noticed financial pain for many consumers. Consumers support improving fuel economy in large part because it provides peace of mind by improving energy security for individual consumers and the nation. The CAFE program is an effective, proactive option when it comes to dealing with rising gas prices. [EPA-HQ-OAR-2010-0799-9454-A2, p.3]

In a recent Consumer Reports survey, consumers demonstrated strong support for fuel efficiency standards, a desire for alternative fuel vehicle options and a willingness to pay for more efficient technology.7 Consumers want it all—function, performance, a variety of choices and better fuel economy, and they would rather pay more for a vehicle in order to save on gasoline. According to the nationally representative survey conducted in October 2011: 93% believe that fuel efficiency standards for all vehicles should be improved; 80% support at least 55 mpg as a target fleet average for 2025; as availability improves, 72% ofconsumers who plan to buy a vehicle would consider an alternative power train, such as hybrid, electric, flex-fuel or natural gas; and

83% are willing to pay extra for more fuel efficient vehicle if the payback from lower fuel costs is less than five years.8 [EPA-HQ-OAR-2010-0799-9454-A2, pp.3-4]

Although surveys have limitations in capturing consumer preferences, relying solely on market data for consumer preferences is imperfect as well. Consumers are not satisfied with the status quo, but they generally must buy a vehicle from the available fleet. By expressing support for improved standards, they are essentially stating a preference for better options in the future. A strong CAFE program gives credence to this consumer preference that is not being communicated effectively in the marketplace. [EPA-HQ-OAR-2010-0799-9454-A2, p.4]

It is true that when gas prices are relatively low, consumers tend to put less emphasis on fuel economy when buying a car. But as we saw in 2008, when gas prices soar, consumers quickly try and sell their gas guzzler and buy a more fuel efficient vehicle. Unfortunately, vehicle manufacturers cannot design, build and supply different vehicles on a monthly basis. A typical model cycle is about five years, and to take the best advantage of all the weight saving and new fuel efficient technologies, these decisions need to be made at the beginning of a model concept and cannot be easily retrofitted. The CAFE standard targets for 2017-2025 give manufacturers a predictable roadmap and the impetus to incorporate these technologies and sell desirable vehicles that achieve better fuel economy and save consumers money in the future. [EPA-HQ-OAR-2010-0799-9454-A2, p.4]

Organization: Dawid, I.

Its' clear that Detroit and the overseas manufacturers can meet the 54.5 mpg regulation. What's NOT clear is whether the market wants them! [EPA-HQ-OAR-2010-0799-6325-A1, p. 1]

We know 2 things: new EV, EREV, and hybrids sell at a premium cost. Consumers determine whether to purchase them, or a comparable, ICE model at a significantly lower price, based on:

1. Price of gas

2. How high the premium is. [EPA-HQ-OAR-2010-0799-6325-A1, p. 1]

I urge the EPA to consider how the market affects the marketability of the vehicles they regulate. [EPA-HQ-OAR-2010-0799-6325-A1, p. 1]

Organization: Defour Group LLC

I. Willingness to Pay for Fuel Economy: Revealed Preference

The agencies erroneously assume that auto buyers will be willing to pay for 100% of their projected fuel economy gains. The real-world impact of the proposed standards, however, flow from actual consumer purchase decisions. There is a great deal of research supporting our conclusion that consumers are not willing to pay 100% for fuel economy gains. Thus, our first correction to the agencies' analysis is based on real-world or revealed preference willingness to pay at $3.54 per gallon regular unleaded fuel, the price the agencies use to project their benefit and cost estimates for MY 2025 vehicles. [EPA-HQ-OAR-2010-0799-9319-A1 p.2]

We utilize a 25% U.S. consumer willingness to pay for fuel efficiency technology improvements. We derive this estimate from the MIT study, *On the Road in 2035*, which was published in 2008 and found that U.S. consumers are not willing to spend any of the increases in the value of fuel efficiency technologies – the value of increases in gallons per ton mile -- on fuel economy (miles per gallon), but rather would prefer to spend all of the value of any potential gains on other vehicle attributes of greater value to them such as improved performance, carrying capacity, towing capacity, comfort, and safety. [EPA-HQ-OAR-2010-0799-9319-A1 p.2]

They also found that European consumers are willing to spend roughly 50% of any gains in fuel efficiency on fuel economy and prefer to spend the rest of any such gains on the afore-mentioned other vehicle attributes.[1] Their study was for the years 1995- 2006 -- years in which U.S. regular unleaded gasoline sold for an average $2.07 per gallon ($2009) and European premium unleaded fuel prices that power most of their gasolinepowered vehicles sold for an average of $5.15 per gallon (median of $5.30 per gallon). The actual relevant fuel cost in Europe, of course, is much higher when their substantial engine displacement taxes are factored in. [EPA-HQ-OAR-2010-0799-9319-A1 p.2]

We conservatively assume a $5.50 per gallon average price in Europe as the level of fuel prices at which auto buyers will be willing to take – i.e. pay for -- 50% of fuel efficiency gains as fuel economy improvements, and $2.10 per gallon as the price at which they are willing to pay for no increases in vehicle mpg. This gives us a midpoint estimate of about $3.80 per gallon as the point at which auto buyers are willing to spend 25% of any increase in fuel efficiency on fuel economy. NHTSA uses a gasoline price of $3.54 per gallon as their projection for MY 2025, so our estimate of willingness to pay is somewhat overstated. [EPA-HQ-OAR-2010-0799-9319-A1 p.2]

II. Private Benefits vs. Private Costs of the Proposed Standard Lower Bound Estimate

In their Preliminary Regulatory Impact Analysis (PRIA) the National Highway Traffic Safety Administration (NHTSA) and U.S. Environmental Protection Agency (EPA) find that U.S auto buyers will be willing to pay $6,000 per vehicle for standards achieving a combined 49.6 mpg in MY 2025 (56.0 mpg for cars and 40.3 mpg for light trucks) at $3.54 per gallon gasoline ($2009) – or $4,200 more than their estimated $1,800 per vehicle increase in retail price.[2] We first multiply the agencies' estimate of $6,000 per vehicle present discounted fuel savings by the 25% willingness to pay, which comes to a revised estimate of $1,500 per vehicle. The literature also shows that their estimate of the retail price increase necessitated by the proposed standards, or $1,800 per vehicle, is too low by at least 60%.[3] Making just these two adjustments off their baseline of MY 2016 34.1 mpg results in a $4,500 per vehicle *reduction* in willingness to pay to

$1500 per vehicle, and a $1,100 per vehicle *increase* in retail price to $2,900 per vehicle (all estimates rounded to the nearest $100 per vehicle). The fuel savings for a 49.6 mpg MY 2025 are worth $1500 per vehicle, but it costs $2900 to get them. [EPA-HQ-OAR-2010-0799-9319-A1 p.3]

Net willingness to pay, the bottom-line number and what the agencies call "net lifetime owner fuel savings," or the difference between the present value of the expected fuel savings less the increased retail price of the vehicle, is a *negative* $1,400. [EPA-HQ-OAR-2010-0799-9319-A1 p.3]

For our lower bound estimate, we further adjust willingness to pay for more realistic assumptions for the rebound effect and for consumer interest rates. The agencies assume a rebound effect of 10% and a discount rate of 3% for the above estimates. Using a mainstream historical literature estimate of 20% for the rebound effect and assuming the historical, long-term consumer auto loan rate of 9%, we further reduce willingness to pay from 25% to 15% of the agencies estimates $6,000 per vehicle. This yields a bottomline willingness to pay of $900 per vehicle and a net consumer or private welfare loss of $1,900 per vehicle. [EPA-HQ-OAR-2010-0799-9319-A1 p.3]

Mid-Range Estimate

Defour estimated willingness to pay in a study of the proposed standards that has been accepted for publication by the Society of Automotive Engineers and that was derived from the agencies' earlier estimates of consumer benefits and costs in their Joint Technical Assessment Report (JTAR).[4] Our estimates are for a scenario comparable to that of the Preferred Alternative, and which approximates the 51 mpg scenario in the Joint Technical Assessment Report. Adjusting their estimates of benefits for the 25% willingness to pay and for technology costs contained in the National Research Council's 2010 report,[5] we found consumer welfare losses of $2,900 per vehicle – our minimum estimate for the JTAR's 4% growth scenarios. (There were four scenarios with losses ranging from $2,900 to $3,200 per vehicle.) Of course, a lower and more realistic baseline beyond which fuel economy standards become binding constraints would imply a still higher retail price increase and still higher losses in consumer welfare or net willingness to pay. That is why we call this a "mid-range" estimate. [EPA-HQ-OAR-2010-0799-9319-A1 p.4]

Reality Check

To subject these estimates to other authoritative sources, we compare our results to a study by the Energy Information Administration (EIA). In its 2011 Energy Outlook,[6] the EIA concluded that a CAFE standard of 46.1 mpg (3.5 mpg lower than the proposed 2025 standard) would result in an 8% loss in new vehicle sales in 2025. Congress established the Energy Information Administration as a source of independent estimates of the impacts of alternative governmental policies, including the corporate average fuel economy standards. Applying the agencies' unitary new vehicle price elasticity estimate implies an equal and opposite percentage increase in prices, which on the average $28,000 vehicle transaction price comes to $2,200 per vehicle. The EIA's estimate is for a 46.1 mpg standard, which is 12 mpg above the baseline 34.1 mpg for MY 2016. Assuming a straight-line welfare loss yields an estimate of $2,900 per vehicle. Of course, the straight-line assumption understates the actual cost increase because of the laws of diminishing marginal returns and increasing marginal costs. [EPA-HQ-OAR-2010-0799-9319-A1 p.4]

Figure 1 compares estimates of consumer willingness to pay (PV Benefits), retail price increase, and net willingness to pay (NPV Benefits) for the proposed MY 2025 fuel economy mandate under our three alternative methodologies. (We are only able to infer net lifetime owner savings values from the EIA study.) The agencies' estimates of benefits, as shown by the vertical blue line for PRIA are 6 times higher than our midrange estimate, while our mid-range estimate for the requisite retail price increase is roughly twice the agencies'. The bottom line estimate, NPV Benefits, the increase in willingness to pay less the increase in retail price on MY 2025 vehicles, ranges from the *loss* of $1,900 to $2,900 per vehicle to the positive *gain* of $4,200 per vehicle in the PRIA. [Please refer to EPA-HQ-OAR-2010-0799-9319-A1 p.5 for Figure 1.] [EPA-HQ-OAR-2010-0799-9319-A1 p.5]

Both our estimates and those inferred from the EIA study are considerably understated when compared to those implied by the research of economists at Resources for the Future (RFF), the Environmental Protection Agency, and at the Congressional Budget Office – research that the agencies did not but should consider in this rulemaking. [EPA-HQ-OAR-2010-0799-9319-A1 p.5]

An RFF November 2010 study co-authored by David Evans of the EPA,[7] finds that "using standards to cut fuel use by 5 percent under a standard value for CO_2 damages is warranted only if consumers fail to internalize 44 percent of the savings from fuel economy. In fact recent rulings that rapidly ramp up the corporate average fuel economy CAFE standards are not supported on welfare grounds, even under our bounding case for market failures. . . . In our bounding case for these failures, a standard that cut fuel use by 8.9 percent would be optimal, though potential welfare gains are only about a third of those for the fuel tax." [EPA-HQ-OAR-2010-0799-9319-A1 p.6]

Dr. Evans and co-authors assume a baseline free expression combined fleet fuel economy level of 23 mpg and the 5% and 8.9% reductions in fuel consumption represent 10 to 36% of the 25% cut mandated by the 2012- 2016 MY standards relative to that baseline. They find that the marginal welfare costs of increasing the standards rapidly escalate to $6 per gallon and higher well before required fuel savings approaches the 25% that would be achieved under the MY 2016 standards. Going another 12.9 mpg to MY 2025 standards would dramatically increase these estimates. [EPA-HQ-OAR-2010-0799-9319-A1 p.6]

Earlier studies by economists at RFF and the Congressional Budget Office came to similar conclusions, finding that raising mandated fuel economy levels like those proposed would impose very substantial welfare losses on consumers and on the broader economy.[8] These conclusions are summarized in the survey of mainstream research by economists at Resources for the Future, which was published in the *Journal of Economic Literature*, the leading survey journal for economic scholars, It is important to note that the authors address much smaller increases in the standards than here and from a much lower base mpg. The authors concluded:

Whether higher fuel-economy standards would increase or reduce efficiency or have little effect remains unsettled. Kleit (2004) and Austin and Dinan (2005) find that costs from binding increases in standards of 3−4 miles per gallon would cost around $3−4 billion or more, assuming market adoption of all privately cost-effective technologies. Higher fuel-economy standards significantly increase efficiency only if carbon and oil dependence externalities greatly exceed the mainstream estimates in Table 2, or if consumers perceive only about a third of the actual fuel-economy benefits (Fischer, Harrington, and Parry 2006).[9] [EPA-HQ-OAR-2010-0799-9319-A1 p.6]

IX Summary and Conclusions

The agencies find net positive owner lifetime fuel savings or "willingness to pay" of $4,200 per vehicle in part because they ignore consumer tradeoffs between fuel economy and other vehicle attributes and assume auto buyers are willing to pay for 100% of the agencies' projected fuel efficiency technology gains to 2025. But mainstream research shows that at fuel prices of the projected $3.54 per gallon consumers will be willing to pay for no more than 25% of any potential fuel economy improvements. When this adjustment is made, when further adjustments for a more realistic rebound effect and discount rate are made, and when the agencies' estimate of retail technology costs is increased by a factor of 60% to reflect real-world retail price mark ups, we find the agencies' Preferred Alternative for MY 2025 standards imposes net private welfare losses of at least $2,900 per vehicle. [EPA-HQ-OAR-2010-0799-9319-A1 p.20]

Applying agency estimates of vehicle price elasticities and employment multiplier effects shows that the $2,900 per vehicle net consumer welfare cost will cause a loss of more than 1.8 million industry sales and more than 200,000 industry, supplier, and dealer jobs. The proposal is extremely regressive -- imposing disproportionately higher hardships on those who are the poorest and least able to afford personal transportation. Fuel prices well above $5.00 per gallon are necessary if consumers are to embrace these standards and eliminate the adverse impacts on sales and employment. [EPA-HQ-OAR-2010-0799-9319-A1 p.20]

Use of a more realistic estimate for the rebound effect and incorporation of a similarly realistic estimate of the clunker effect increases the agencies' already negative estimate of social benefits from a minus $100 per vehicle to minus $900 per vehicle. [EPA-HQ-OAR-2010-0799-9319-A1 p.20]

These results are consistent with the findings of numerous studies by economists at the Energy Information Administration, Resources for the Future, the Congressional Budget Office, and even the Environmental Protection Agency. Those studies show that improving consumer and social welfare requires a reduction, not an increase in the standards from MY 2016 levels. [EPA-HQ-OAR-2010-0799-9319-A1 p.20]

In the public interest, it is incumbent on the agencies to consider all of these studies their rulemaking. [EPA-HQ-OAR-2010-0799-9319-A1 p.20]

Based on real-world, revealed auto buyer preferences, we find that the proposed MY 2025 49.6 mpg fuel economy standard for the combined passenger car and light truck fleet will result in net consumer welfare losses of at least $2,900 per vehicle relative to the base MY 2016. This compares to the Preliminary Regulatory Impact Analysis' (PRIA's) estimate of net positive private benefits of $4,200 per vehicle. (All estimates are rounded to the nearest $100 per vehicle.) We find that implementation of the MY 2025 fuel economy standards will result in a loss of more than 1.8 million industry sales and a loss of more than 200,000 jobs in auto manufacturing, supply and retail distribution. [EPA-HQ-OAR-2010-0799-9319-A1, p. 1]

We also find that the standard will impose additional net social externality costs of more than $900 per vehicle versus an agency net cost estimate of $100 per vehicle. We estimate the sum of net private and social welfare *costs* to be more than $3,800 per vehicle. This compares to the agencies' estimate of $4,100 in net private and social *benefits* per vehicle. We find that the fuel economy standards are extremely regressive, imposing markedly disproportionate costs on the group of lowest-income households relative to those imposed on the highest-income households. [EPA-HQ-OAR-2010-0799-9319-A1, p. 1]

Our findings of substantial private net welfare losses result from a much:

- Lower, real-word assessment of auto buyer willingness to pay, and
- Higher, real-world assessment of markups from direct manufacturing cost to retail consumer price than the agencies assume in their engineering/mathematical model.

Our findings of substantially higher net societal costs follow from higher and more realistic estimates of the rebound effect –the offsetting impact of higher fuel economy on vehicle miles traveled and thus fuel consumption -- and from taking account of the "clunker effect," or the impact of higher new vehicle prices on encouraging the retention of older and higher emitting vehicles. [EPA-HQ-OAR-2010-0799-9319-A1, p. 1]

We find that fuel prices well above $5.00 per gallon would be required to render the standards "consumer friendly." We conclude that consumer or societal welfare is optimized at a level below the MY 2016 fuel economy standards. All of our findings are supported by mainstream research at leading governmental and academic institutions, including the Energy Information Administration, the Congressional Budget Office, Resources for the Future, and the Environmental Protection Agency. We urge the agencies to consider all of this research in finalizing their proposed rule. [EPA-HQ-OAR-2010-0799-9319-A1, p. 1]

III. Fuel Prices and Willingness to Pay

The next question is what fuel price would be necessary for auto buyers to freely purchase a combined fleet with 49.6 mpg fuel economy? [EPA-HQ-OAR-2010-0799-9319-A1, p. 7]

The short answer is "well in excess of $5.00 per gallon." As shown in Figure 2 below, the Energy Information Administration projects unconstrained or free expression levels of fuel economy for MY 2025 at 35.3 mpg for $3.54 gasoline (40.0 mpg for cars and 29.6 mpg for light trucks). It also finds that at $5.12 per gallon -- its highest fuel price scenario for 2025 -- the combined new vehicle fleet would attain 36.8 mpg with cars at 41.1 mpg and light trucks at 30.4 mpg, well below the agencies' proposed mandate.[10] [EPA-HQ-OAR-2010-0799-9319-A1, p. 7]

Another estimate is provided by the European experience with much higher fuel prices when there were no fuel economy regulations. Estimates of willingness to pay at higher fuel prices can be derived from European levels of fuel economy that existed in the late 1990s and early 2000s, before their standards became binding and which thus represent free expression levels that their consumers would be willing to pay for. Customer demand for passenger cars never exceeded 40 mpg – well below the agencies' projection of a 56.0 mpg achievable level in 2025 -- and this was so even with $7 and $8 per gallon gasoline, with heavy engine displacement taxes, and with substantial subsidies for diesel fuel. [EPA-HQ-OAR-2010-0799-9319-A1, p. 7]

A third estimate can be inferred from a 2010 study by the National Research Council, which found that if consumers were willing to pay for 50% of potential fuel economy improvements the government could achieve a level of just 40 mpg for combined cars and light trucks and in MY 2035. This was at the $5.50 or higher fuel price equivalents for the study period of 1995 to 2006.[11] Of course, the 50% willingness to pay is more than double the 25% willingness to pay we derived from the MIT study cited above, and the learning curve effect means that 2025 technologies will cost more than the NRC's estimate for MY 2035. [EPA-HQ-OAR-2010-0799-9319-A1, p. 7] [For figure 2 please refer to EPA-HQ-OAR-2010-0799-9319-A1, p. 8.]

2 - Derived from Table VIII-27b, page 715 of the NHTSA PRIA. See also "Dealers Fight Mileage Rules," The Wall Street Journal, January 28, 2012. The mandated level is 49.6 mpg. The agencies estimate that consumers will also be willing to pay for achieved levels of 56.0 mpg for MY 2025 cars and 40.3 mpg for MY 2025 light trucks. We derive a slightly lower estimate of the retail price increase, or $1,800 per vehicle versus the $2,000 per vehicle reported in the article. We derive a slightly lower estimate of $4,200 willingness to pay than the reported $4400 per vehicle.

VII. The "Energy Paradox" and Willingness to Pay

The agencies suggest that consumer myopia – auto buyer systematic undervaluation of future fuel economy benefits -- and not any errors in their analysis, explains what they call the "Energy Paradox," or why today's auto buyers would be "hesitant" to buy vehicles that achieve 49.6 mpg on average and provide, by their reckoning, more than $4,000 worth of fuel savings net of retail price increases. [EPA-HQ-OAR-2010-0799-9319-A1, p. 14]

The Congressional Budget Office (CBO), in a study commissioned by the U.S. Senate in 2002, addressed this contention, noting that many proponents of increased fuel economy standards argue that the market for fuel economy is inefficient because consumers either "lack information about vehicles' fuel efficiency or that producers lack an incentive to respond to consumers' preferences for fuel efficiency." The CBO concluded:

"Most economists do not believe that either assumption is valid. Vehicles' current level of fuel efficiency most likely reflects consumers' trade-offs between fuel economy and other characteristics that drivers want, such as vehicle size, horsepower, and safety. The same technologies that can be used to boost fuel economy can be used to hold fuel economy constant while increasing the vehicles' weight, size, or power. Thus, the fact that producers have done the latter rather than the former in recent years suggest that they have responded to buyers' preferences by targeting available technologies toward other features that consumers desire. Raising CAFE standards would impose costs on both consumers and automobile producers by forcing improvements in fuel economy that car buyers may not want."[22] [EPA-HQ-OAR-2010-0799-9319-A1, p. 14]

Or, to quote the most recent, and we believe, most definitive study of this issue by economists at MIT and Northwestern University:

We find little evidence that consumers "undervalue" future gasoline costs when purchasing cars. The implied discount rates we calculate correspond reasonably closely to interest rates that customers pay when they finance their car purchases.[23] [EPA-HQ-OAR-2010-0799-9319-A1, p. 14]

Whether or not auto buyers know what they are doing, their choices do, in the final analysis, determine the demand for new cars and light trucks in the marketplace. When, for whatever reason, their willingness to pay for increased fuel economy falls short of the increased retail vehicle price necessary to attain that level, industry sales losses necessarily ensue, as the EIA analysis found.[24] This is so even if better informed and more intelligent auto buyers would be willing to pay for 100% of the "cost-effective" fuel efficiency gains assumed in the agencies' mathematical model. [EPA-HQ-OAR-2010-0799-9319-A1, p. 15]

Moreover, if the mainstream studies that we cited are correct, the standards cannot be justified on benefit-cost grounds even if the supposed consumer undervaluations are corrected using the literature's most optimistic, "upper bound" assumptions and even using the most optimistic, "upper bound" assumptions regarding externality costs of climate change and energy security.[25] There is no basis for increasing the standard – neither on the consumers' behalf nor on the public's behalf. The proposed increase will make everyone worse off. As these studies demonstrate, improving either consumer or societal welfare requires a *reduction*, not an increase in the standards from MY 2016 levels. [EPA-HQ-OAR-2010-0799-9319-A1, p. 15]

Organization: Detroit NAACP

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 140-141.]

So, for us, you know, this is about countenance. For the NAACP these proposed standards will help families, families with passenger cars, light trucks, SUVs. It will help them save money, put more money back in your pocket. To extend the standards enacted last year that cover vehicles sold in 2012-2016 will raise the average fuel economy by 2016, but the first ever fuel-efficiency standards for medium- and heavy-duty trucks from 2014 to 2018 will also be enacted this year. So, the common sense standards that are represented here will be our largest reduction in oil consumption in the history of the United States of America.

As I said earlier, the average American household spends approximately $2,000 per year on gasoline. I don't know if I have $2,000 a year to spend on gasoline anymore, but the daily gasoline costs in the United States is astronomical. And adopting these standards of fuel efficiency and emissions performance, to take it to 54.5 miles per gallon by 2025 will save me, my mom, my family and consumers across the country about $6,000 a year, maybe more, which is very significant, and when it can go to so many other places to do so many other positive things other than going to a foreign oil distributor.

Organization: E100 Ethanol Group

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 202-203.]

Depending on electric cars to meet the program's objectives is a quote 'big bet; a huge bet,' end of quote. That is a direct quote from Bill Ford, Jr., Chairman of the Ford Motor Company at a talk that he gave at the Commonwealth Club here in San Francisco last October 27 about his agenda.

Current lithium ion battery vehicles are not selling. Only 17,345 of the almost 13 million light-duty vehicles sold in 2011 were Chevy Volts and Nissan Leafs, a little more than one-tenth of 1%. The Volt base price is $40,000 and the Leaf's is $36,050 after their large price increase in December.

Comparably-sized and equipped gasoline versions of these vehicles, the Chevy Cruz and Nissan Versa, are at least $20,000 less than the price of the electrics.

So the question becomes, will millions of consumers spend $20,000 up front to save the $8200 over the life of the proposed standards? The answer, we believe, is clearly not.

Organization: Eaton Corporation

Allows OEM to bring safe, affordable vehicles to market that customers want to purchase. [EPA-HQ-OAR-2010-0799-9494-A1, p. 2]

Organization: Ecology Center

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 189.]

but that they will also lead to big savings by consumers at the pump as well as to the economy generally. The estimated consumer savings of approximately $3,000 to $4,400 in net lifetime savings is almost certainly a conservative estimate when considering likely increases in the fuel prices and improvements in technology. The estimated social level benefits of $311 to $421 billion are, therefore, likely conservative as well. We certainly think that consumers and businesses alike who rely on transportation will all significantly benefit from having the 300-plus billion dollars more in their pocketbooks to spend on other things.

Organization: EcoMotors International, Inc.

The agencies have gone to great lengths in the Proposed Rule to stress how they have designed the standards to preserve consumer choice. EcoMotors suggests that EPA go a step further by acknowledging consumers' preference for familiar vehicle technologies and building in additional compliance flexibilities to enable OEMs to choose alternative advanced technology paths for achieving the same CO_2 reductions and fuel economy improvements. OEMs should not be forced to produce vehicles that consumers may not want. Furthermore, if consumers are dissatisfied with the range or price of LDVs being offered, they could choose to keep their existing vehicles longer, reducing new vehicle sales and resulting in increased GHG emissions - a scenario that could be avoided if EPA were less aggressive in promoting a small, select group of hybrids. [EPA-HQ-OAR-2010-0799-9594-A2, p. 6]

If a vehicle technology doesn't create a value proposition all the way through to the customer base, it will not succeed. Market forces will ultimately drive consumers' vehicle decisions - not intangible regulatory credits and incentives that only benefit automotive manufacturers. If there is not enough consumer demand for EVs, PHEVs and FCVs today, how will consumers react to even more expensive, high-mileage vehicles in the future? The agencies risk undermining their ultimate energy and environmental objectives if they fail to acknowledge this fact, and choose to remain firmly wedded to promoting only a small group of unfamiliar and expensive technologies - EVs, PHEVs and FCVs. [EPA-HQ-OAR-2010-0799-9594-A2, p. 6]

Organization: Edmunds.com

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 102-104.]

Our second point is that, by their nature, the proposed CAFE standards force automakers to focus their efforts on improving fuel economy. This dictates the nature of competition. Automakers focus on fuel economy rather than letting consumer preferences determine on what basis they compete. This focus on fuel economy for all automakers limits competition in other dimensions, such as safety, comfort, performance, design and electronics. In fact, the focus on fuel economy could limit the innovation of these other features, especially for automakers that have fewer resources or that need to work relatively harder to meet their fuel economy target. Moreover, the proposed rules have the potential to limit innovation of fuel economy itself by offering favored status to certain technologies via special credits, which could then deter automakers from developing other technologies.

First, the current proposal needs to address the potential consequences of mandated increased focus on fuel economy for competition and innovation in the automotive industry. The proposed rules need to more fully explore how such consequences could force consumers to make sacrifices to get the desired emissions results.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 100-103.]

Many parties involved in the CAFE process have asserted why the proposed rules should make sense for consumers, why consumers should embrace these rules, how consumers should benefit from these rules, despite higher vehicle prices, and so on. The problem is that while they purport to represent consumers, these parties typically do not represent consumers. In our view, it's better to go straight to the source, rather than to presume to know what is best for a particular group.

First of all, the improved fuel economy results for the proposed CAFE standards for 2017 to 2025 are based on production forecasts and do not account for how consumer demand for and willingness to pay for fuel economy will keep pace with the more fuel-efficient fleet built. To date, consumers have demonstrated relatively little preference for high-mileage vehicles, and then usually just for brief periods during high gas prices. If reality differs significantly from key assumptions used in these forecasts, for example, if gas prices drop and consumer demand for fuel efficiency then decreases, a disconnect could arise between what consumers want and what automakers supply under the proposed standard. This has the potential to result in more limited choice, higher prices, and decreased auto sales.

Our third point is that the multiple measures of MPG that have emerged from the rulemaking process add excessive complexity to the consumer decision-making process, making it harder, not easier, for consumers to assess fuel economy, compare vehicles, and decide which vehicle works best for them.

Organization: Environmental Defense Fund (EDF)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 287.]

With respect to economic security, again, combined with the Phase I standards, the proposed rule will provide families with more than $8,000 in fuel savings over the lifetime of the new vehicle by 2025, for a total of $1.7 seven trillion and national fuel savings over the life of the program.

Organization: Ford Motor Company

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 43-44.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 32.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 85-86.]

The key is to ensure that the proposed targets do not outpace consumer demand or the affordability of the technologies needed for compliance. As a full-line manufacturer, we are challenged to meet a broad range of customer wants, such as function, performance, comfort and convenience, safety and fuel economy. And all these attributes need to come together in a line of vehicles that consumers can afford. After all, attainment of our national goals for CO_2 reduction and energy security cannot be met by niche products and technologies. It does little good to produce vehicles with improved fuel efficiency unless those vehicles are actually purchased by a wide range of American consumers. Further, the technologies must be self-sustaining in the marketplace and not dependent on long-term government subsidies.

We must also acknowledge that market success is dependent upon many factors outside of our control, such as the price of fuel, the state of the economy or the availability of affordable technologies and materials. The further we look into the future, the more difficult it is to predict these factors with accuracy.

Organization: General Motors Company

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 37-38.]

Let me also note that the proposed standards will not be easy; they will be difficult and they will be expensive. The success of our current new offerings in the marketplace like the Chevy Malibu, Equinox, Cruze and the Volt convince us we are on a good path toward meeting these early requirements the proposal will create, but we will need further breakthroughs in technology and good customer acceptance of the additional vehicle changes, technologies and costs that will be associated with providing the vehicles needed in the future years to allow us continued success in meeting the aggressive requirements down the road.

Organization: Gilles, B.

It will hurt the consumer by making vehicles much more expensive. [EPA-HQ-OAR-2010-0799-8065-A1, p. 1]

Organization: Institute for Energy Research (IER)

EPA's cost-benefit analysis for this rule is also fatally flawed. EPA's cost-benefit analysis shows positive net benefits only because EPA omits the cost to consumers of limiting consumer choice. Instead, EPA credits forced fuel savings as a benefit. Because the rule increases the upfront cost of buying a car, the rule forces 7 million drivers out of the car market. This means that 7 million people will not be able to enjoy the fuel savings calculated by EPA because they will not be able to afford a car in the first place. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 1-2]

As EPA's own discussion indicates, its modeling assumes that the current market for fuel economy is incredibly inefficient, with consumers and businesses making massive, systematic errors in their behavior over the course of decades. If, in reality, households and businesses are not as shortsighted as the EPA analysis assumes—perhaps because the EPA modeling leaves out one or more important factors that matter to vehicle buyers in the real world—then the EPA's cost-benefit analysis collapses. [EPA-HQ-OAR-2010-0799-9573-A1, p. 9]

1. EPA Assumes That in Absence of Fuel Economy Regulations, Vehicle Buyers Would Ignore Hundreds of Billions of Dollars in Potential Gains [EPA-HQ-OAR-2010-0799-9573-A1, p. 9]

In standard economic models, it is assumed that households rationally act in their interest, and spend their incomes in ways that maximize utility. It is not that economists literally believe each consumer is a robot capable of performing complex calculus problems with each item in the grocery store, but instead economists believe that rationality is a safe benchmark assumption. This is because the forces of competition, learning from the examples of others, and the ubiquity of product ratings and other information will tend to limit systematic errors on the part of consumers, especially for expensive, recurring purchases and in markets that have many customers. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 9-10]

To be sure, standard economic theory allows a role for government intervention in the case of "negative externalities," which can include greenhouse gas emissions. In this case, although motorists (for example) would presumably make vehicle purchases that tended to equate marginal private benefits with marginal private costs, nonetheless their behavior would be suboptimal since each vehicle buyer would ignore the social costs of his or her behavior. In this setting, the typical economic textbook might recommend a carbon tax or a cap-and-trade framework to force consumers to "internalize the externality" and to once again have their private incentives aligned with social welfare. [EPA-HQ-OAR-2010-0799-9573-A1, p. 10]

To be clear, the above analysis is typical in standard economic theory, but this is not how EPA approaches the cost-benefit assessment of the proposed rule. Instead, EPA assumes that the new rule will benefit vehicle buyers even considering only their narrow self-interest, and then on top of these net private benefits, EPA adds the social benefits of reduced greenhouse gas emissions. In other words, EPA attempts to justify the new rule not simply on the grounds that individual consumers are ignorant of how their behavior will affect global temperatures in the year 2100, but EPA also assumes that consumers are ignorant of how their behavior will affect their gasoline purchases next year. [EPA-HQ-OAR-2010-0799-9573-A1, p. 10]

EPA recognizes the problem:

For this proposed rule, EPA projects significant private gains to consumers in three major areas: (1) Reductions in spending on fuel, (2) for gasoline-fueled vehicles, for time saved due to less refueling, and (3) additional driving that results from the rebound effect. In combination, these private benefits, mostly from fuel savings, appear to outweigh the costs of the standards, even without accounting for externalities. [EPA-HQ-OAR-2010-0799-9573-A1, p. 10]

Admittedly, these findings pose an economic conundrum….If our analysis projects net private benefits that consumers have not realized…then, [assuming efficient markets], there must be additional costs of these private net benefits that are not accounted for [in the EPA analysis]….The estimate of large private net benefits from this rule, then, suggests either that the assumptions [of efficient markets and rational consumers] do not hold, or that EPA's analysis has missed some factor(s) tied to improved fuel economy that reduce(s) consumer welfare. [Bold added.] [EPA-HQ-OAR-2010-0799-9573-A1, p. 11]

To see just how important EPA's assumption of consumer error is to its overall cost-benefit results, consider the following table: [See table on p. 11 of Docket number EPA-HQ-OAR-2010-0799-9573-A1]

The above table shows the breakdown of the aggregate net benefits figures quoted earlier. For example, if we assume a discount rate of 7% and take the lowest estimate of the SCC that EPA uses, then the cost of the proposed rule (through 2050) has an estimated present value of $243 billion, in the form of higher vehicle costs passed on to the purchaser. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 11-12]

However, this gross cost is offset by (a) fuel savings of $579 billion and (b) other benefits (including avoided climate-change damages) of $124 billion. On net, therefore, the high discount rate and low SCC yield benefits of ($579 billion + $124 billion) - $243 billion = $460 billion. Similar calculations show that if we assume a low discount rate of 3%, and a high SCC, then the net benefits rise to $1.72 trillion. [EPA-HQ-OAR-2010-0799-9573-A1, p. 12]

IER has added the row entitled "Implicit Assumed Consumer Error." These values are the difference between the fuel savings and the assumed technology cost (i.e. higher vehicle price, holding all else constant except for fuel efficiency) for each time period. For example, in the year 2040 EPA assumes consumers will suffer $39.8 billion in the form of higher vehicle prices. However, consumers will benefit from saving $144 billion in fuel expenditures. This means that looking solely at private costs and benefits, in the year 2040 the rule will ostensibly provide net benefits to consumers of $104.2 billion. [EPA-HQ-OAR-2010-0799-9573-A1, p. 12]

This is quite a large error to attribute to consumers, and to repeat, this is an annual figure (for the year 2040), and it is reckoned in inflation-adjusted 2009 dollars. The reader should recall EPA's own admission: Either consumers are going to systemically ignore hundreds of billions of dollars in free money, or the EPA's modeling omits important real-world considerations. In the next subsection this comment will explore what these considerations might be. [EPA-HQ-OAR-2010-0799-9573-A1, p. 12]

Before doing so, it should be reiterated just how significant this assumption of consumer irrationality is to EPA's overall cost-benefit assessment. For the high discount rate, low SCC scenario, the implicit consumer error through 2050 is $336 billion, compared to total net benefits of $460 billion. Thus 73 percent of the total net benefits allegedly accruing from the proposed rules (in this particular scenario) are due to the assumed consumer error. In the scenario assuming a low discount rate and high SCC, the implicit consumer error accounts for 56 percent of the total estimated net benefits. [EPA-HQ-OAR-2010-0799-9573-A1, p. 12]

In other words, if it turns out that EPA is indeed omitting important factor(s) from its modeling—such that consumers wouldn't systematically miss out on hundreds of billions of dollars over the course of decades if the government doesn't force them to reap this free money—then EPA's claimed net benefits from the proposed rules would fall by roughly one-half to three-fourths, depending on the other parameter values. [EPA-HQ-OAR-2010-0799-9573-A1, p. 12]

As explained in the previous subsection, EPA's analysis rests on the assumption that consumers are irrationally unwilling to pay a higher price for "the same" vehicle that is equal in all respects to another, cheaper vehicle, except for superior fuel economy. This behavior is assumed true even when the present value of lifetime savings on fuel expenditures would more than compensate for the higher initial purchase price, leading to the term "energy paradox" in the literature. The EPA discussion relates some of the theories in the literature to explain this "conundrum," such as consumers incorrectly calculating the fuel savings from differences in mpg ratings, consumers using rules of thumb when making purchases rather than optimizing calculations, etc. [EPA-HQ-OAR-2010-0799-9573-A1, p. 13]

The problem with these ad hoc explanations is that they ignore the tremendous profit opportunities such massive consumer irrationality would leave open to enterprising firms. For example, even if one were to believe that individual motorists could make gross computational errors of this magnitude, surely entire taxicab fleets wouldn't be plagued by these simple mistakes. (And yet, in 2011 New York City Mayor Bloomberg sought the power to regulate fuel economy standards for NYC cabs.) Another obvious industry—and one that is more open to competition than taxi fleets—to benefit from this alleged inefficiency is the rental car market. It might take some ingenuity to implement, but if the EPA's analysis is correct, then a rental car company could presumably profit by buying only vehicles with very high fuel-efficiency, and coming up with various methods for capturing the savings this would allow for its customers. (For example, it would be fairly easy to estimate the dollar savings in fuel for a given trip that would last only a few days—as opposed to estimating the lifetime fuel savings when buying a new car.) The fact that rental car agencies currently don't consist entirely of the highest fuel-efficient models is yet more evidence that EPA's modeling leaves out important factors. [EPA-HQ-OAR-2010-0799-9573-A1, p. 13]

Consider the following table produced from data from U.S. Department of Energy and EPA. In every case, the 2010 version of each car is larger, has a larger engine, has more passenger volume, and more luggage volume. The fuel economy is similar with the 2010 version generally getting slightly worse city fuel economy and slightly better highway fuel economy. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 13-14]

Consumers demand a certain fuel economy, but consumers also want to maximize other attributes such as performance and size (then again, maybe the fuel economy of these cars is actually higher than consumers' actual preferences because of CAFE standards). If consumers really demanded very fuel efficient cars, Honda would still make a car today that gets better gas mileage than the 1985 Honda Civic Coupe HF. The Civic Coupe HF got nearly 50 mpg on the highway a quarter century ago. Today, the Honda's most fuel efficient car is a hybrid sedan Civic that gets 44 mpg in the city and 44 mpg on the highway. The better explanation for this outcome is that consumers have preferences for a variety of attributes that the EPA analysis omits, not that consumer irrationality increased over the last 25 years. [EPA-HQ-OAR-2010-0799-9573-A1, p. 14]

Besides the possibility of other factors entering into the consideration, another explanation for the ostensible "irrationality" of consumers is that they treat the uncertainty of the future differently from how the EPA's modeling approach requires. When evaluating the present monetary value of improvements in fuel efficiency, two of the most important considerations are future interest rates and the price of gasoline. These are highly volatile, and consumers quite rationally may not place much weight on expected savings from fuel economy occurring several years in the future. [EPA-HQ-OAR-2010-0799-9573-A1, p. 16]

In other words, consumers may rationally have much higher discount rates than EPA assumes they should have. Consider this research presented by economist Ronald J. Sutherland in the context of a previous NHTSA rulemaking: [EPA-HQ-OAR-2010-0799-9573-A1, p. 16]

Corporations frequently require high hurdle rates in excess of 12 percent to undertake capital investments. Dixit and Pindyck present a compelling analysis of observed high discount rates for irreversible investments. The technical literature indicates that irreversible investments may require hurdle rates two to four times the average discount rate in order to trigger an investment. However, fuel economy standards have the unattractive investment properties of being irreversible, whereas common stocks are highly liquid. Metcalf and Rosenthal and Hassett and Metcalf explain how this irreversibility property warrants discount rates of at least two or three times higher than may be expected. Allowing for the irreversibility property of such investments, a required rate of return of at least 20% appears reasonable for high-income households. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 16-17]

Energy saving investments are typically irreversible investments and therefore require an even higher premium. The proposed fuel economy standards for light trucks are irreversible investments. The investment in fuel economy is a sunk cost at time of purchase. The investment cannot be reversed, should the consumer decide that the investment is unwarranted. Hassett and Metcalf apply the irreversible investment model to investments in energy conservation and conclude that an appropriate hurdle rate would be about four times greater than the standard discount rate. Metcalf and Rosenthal reach a similar conclusion in applying the model to commercial lighting and to energy efficient refrigerators. If the government imposed discount rate of 7 percent is considered standard, an appropriate discount rate for the fuel economy benefits would be at least 14 percent, but probably closer to 21 percent or event 28 percent. [EPA-HQ-OAR-2010-0799-9573-A1, p. 17]

The application of higher hurdle rates indicates that the benefits from fuel economy standards should be revised downward. The NHSTA study calculates consumer benefits as the present value of future energy saving using a 7 percent discount rate. However, the evidence on discount rates, as well as revealed consumer preferences, indicates that an appropriate discount rate is at least 2 or 3 times higher that [sic] the government imposed rate. [EPA-HQ-OAR-2010-0799-9573-A1, p. 17]

Consumers may not act as EPA assumes they should act, but that is no proof that consumers act against their rational economic self-interest. Consumers may be maximizing other dimensions that EPA is not considering. [EPA-HQ-OAR-2010-0799-9573-A1, p. 17]Responding to this argument in the past, EPA has argued that we are suggesting that “there must be a loss associated with improving fuel economy, because many consumers do not purchase highly fuel-efficient vehicles already on the market.” Furthermore, EPA states: [EPA-HQ-OAR-2010-0799-9573-A1, p. 17]

OMB Circular A-4 notes that “Economists ordinarily consider market prices as the most accurate measure of the marginal value of goods and services to society.” The fuel savings that consumers will receive are directly measurable using market prices for fuel, while the values that consumers reveal through their purchase decisions are indirect measures and may therefore be less reliable. [EPA-HQ-OAR-2010-0799-9573-A1, p. 18]

EPA, along with most commenters on the rule, finds that there are cost-effective fuel savings that the market has not at this time provided to consumers and includes those benefits in our analysis. [EPA-HQ-OAR-2010-0799-9573-A1, p. 18]

In other words, EPA is ignoring (or at least heavily discounting) people’s actual purchase decisions and only considering what EPA can measure—fuel consumption. This same logic is contained in this proposed rule. Just because people may value safety, power, four wheel drive, comfort, convenience, size, more than fuel economy does not mean EPA can discount those choices. It is not necessarily irrational to value other characteristics more than fuel savings as EPA assumes. [EPA-HQ-OAR-2010-0799-9573-A1, p. 18]

The EPA’s logic can be turned on its head, to show the problem with its approach. Currently, it is unprofitable for manufacturers to produce vehicles with the specific combination of attributes that would satisfy the proposed mileage standard. That means the amount consumers would be willing to pay for these compliant vehicles is less than the market value of the resources that would be required to produce them; that’s what it means to say their production is currently unprofitable. Thus EPA’s own criterion shows that its rule would force vehicle manufacturers to devote scarce resources into channels that are less valuable than other potential outlets. [EPA-HQ-OAR-2010-0799-9573-A1, p. 18]

3. Models which purport to show consumers do not act in their rational economic self-interest are crude at best [EPA-HQ-OAR-2010-0799-9573-A1, p. 18]

To reiterate, the EPA cost-benefit analysis relies on a particular theory of consumer behavior—namely that it is prone to extreme error in the context of vehicle fuel economy. In the literature modeling consumer behavior, the estimated valuations of fuel economy vary by an order of magnitude, suggesting that the econometricians do not understand this issue very well. In practice, there are no “controlled experiments” where consumers are offered the choice between two otherwise identical vehicles, where one is more expensive yet has better fuel economy. On the contrary, in the real world there are tradeoffs between vehicles that simultaneously differ on vehicle size, acceleration, price, safety, and finally fuel economy. More recent modeling has done a better job capturing these nuances, but economists have still not reached a consensus on exactly what motivates consumers when making vehicle purchases. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 18-19]

To give a concrete example of the problem, the EPA's discussion of the "energy paradox" acknowledges that consumers in practice do not always have a full spectrum of vehicle attributes varying in each dimension, and then says in a footnote: "For instance, in [model year] 2010, the range of fuel economy (combined city and highway) available among all listed 6- cylinder minivans was 18 to 20 miles per gallon. With a manual transmission, 4-cylinder minivan, it is possible to get 24 mpg." [EPA-HQ-OAR-2010-0799-9573-A1, p. 19]

The EPA discussion is here trying to explain why the energy paradox persists; in EPA's view, the market for some inexplicable reason isn't offering minivans getting 24 mpg, and so consumers have no choice but to buy the less fuel efficient models, even though the savings in price is swamped by the long-run fuel expenditures that these cheaper minivans will require. [EPA-HQ-OAR-2010-0799-9573-A1, p. 19]

But the EPA discussion fails to ask: Why did the market for minivans concentrate on automatic transmission, 6-cyclinder models that only got 18 to 20 mpg? After all, car companies in the past offered manual transmissions in their station wagons and vans. So why are car companies not offering manual transmissions in their minivans now? Could it be that many of the households in the market for a new minivan weren't interested in an option that would require using the clutch while taking the kids to soccer games and other activities throughout the week in stop-and-go driving? In the EPA's crude modeling, if these households had instead been forced to buy a more expensive, 4-cylinder minivan with a stick shift, EPA's rule would be doing them a favor in the long run. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 19-20]

4. A one-size-fits-all regulatory policy is not the answer for people with heterogeneous tastes and preferences

As another specific example of the true subtleties involved—which are ignored by simplistic models—we must remember that a typical suburban family might purchase a "gas guzzling" SUV in order to make large grocery runs, pick up furniture, pull a boat, etc., while it also purchases a fuel efficient car for other travel. Depending on future movements in gasoline prices, the family can then adjust its driving accordingly, using the SUV more when gasoline is cheap, while relying more heavily on the hybrid when gasoline prices are relatively high. The typical model looking for "the" consumer valuation of fuel economy currently does not capture the flexibility and needs of actual motorists. By imposing a one-size-fits-all decision that raises fuel economy (while hurting other attributes) across the board, the government would be taking away options from families and making them worse off. [EPA-HQ-OAR-2010-0799-9573-A1, p. 20]

Another problem with the entire approach is to assume that consumers have identical tastes regarding fuel economy. In reality, some consumers may be very concerned, while others may not be. Thus even if the proposed rule made the "representative consumer" better off, in practice it would still harm those consumers who (for whatever reason) do not place a high subjective value on fuel economy. [EPA-HQ-OAR-2010-0799-9573-A1, p. 20]

As a final example showing the problem in the EPA's assumption of a typical vehicle buyer, consider that the proposed rule increases the upfront cost of buying a car, and thereby forces an estimated 7 million drivers out of the car market. This means that 7 million people will not be able to enjoy the fuel savings calculated by EPA because they will not be able to afford a car in the first place. Thus the alleged fuel economy benefits to vehicle buyers who are still able to afford their purchase must be weighed against the psychic losses to those who now must postpone or abandon their purchases altogether. Aggregating subjective preferences together to achieve a single number of "net benefits" is a very controversial area of economic theory, though EPA hardly discusses the issue. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 20-21]

EPA's cost-benefit analysis shows positive net benefits only because EPA omits the cost to consumers of limiting consumer choice. [EPA-HQ-OAR-2010-0799-9573-A1, p. 23]

Organization: Institute for Policy Integrity, New York University School of Law

The agencies constant performance cost projections are likely to be an overestimate of the risk of lost consumer welfare. Since attributes like size and performance are at least partly relative, changing the fleet-wide average size or performance may not significantly impact overall consumer welfare. Manufacturers may not have to spend as much as the agencies' assume in order to prevent any aggregate consumer welfare loss. Similarly, any risk of lost consumer welfare unaccounted for in the agencies' constant performance cost projections is mitigated by the positionality of attributes. [EPA-HQ-OAR-2010-0799-9480-A1, p. 2]

The agencies should consider how positionality and the bandwagon effect will shape the consumer market for new technologies. As fuel-efficient vehicles become more visible and more common, the perceived attractiveness of fuel efficiency may increase. Information diffusion and habit formation will also affect the future of the market for electric vehicles and other new technologies. [EPA-HQ-OAR-2010-0799-9480-A1, p. 2]

Constant Performance Cost Projections Likely Overestimate the Risk of Lost Consumer Welfare, and the Agencies Should Treat Them as an Upper Bound

The agencies build an assumption of constant performance into their compliance cost estimates. They believe that manufacturers will spend whatever extra it costs to maintain current vehicle attributes as they increase fuel economy, in order to preserve consumer welfare. The cost projections therefore depend on the agencies' best guesses about how changed attributes would impact consumer preferences and welfare. As the agencies note, "[b]ecause welfare losses are monetary estimates of how much consumers would have to be compensated to be made as well as in the absence of the change, the price increase measures the loss to the buyer." [EPA-HQ-OAR-2010-0799-9480-A1, p. 15]

As a result, if the agencies are wrong about how changing attributes would impact consumer preferences, then they are overestimating how much manufacturers will need to spend to maintain consumer welfare. The agencies acknowledge that their cost estimate is likely to be an overestimate: [EPA-HQ-OAR-2010-0799-9480-A1, p. 15] because the consumer has choices other than buying the same vehicle with a higher price; she could choose a different vehicle, or decide not to buy a new vehicle. The consumer would choose one of those options only if the alternative involves less loss than paying the higher price. Thus, the increase in price that the consumer faces would be the upper bound of loss of consumer welfare, unless there are other changes to the vehicle due to the fuel economy improvements that make the vehicle less desirable to consumers."98 [EPA-HQ-OAR-2010-0799-9480-A1, pp. 15-16]

Positional goods theory reinforces the conclusion that the agencies' cost estimate is an upper bound and is likely an overestimate. 99 The value of a "positional good" depends on how it compares with similar goods possessed by others.100 The owner of a positional good derives more welfare from that good than expected when considering only its functional qualities. The prominent explanation for this phenomenon is that highly visible consumption becomes a signal for status,101 and people value status because they anticipate it will translate into more favorable treatment in economic and social interactions.102 For example, jewelry, silk ties, and expensive champagne all have very little functional value, but their consumption is conspicuous and conveys status to others. [EPA-HQ-OAR-2010-0799-9480-A1, p. 16]

Other goods, like cars, have both functional and positional value. Consumers may partially value vehicle size and horsepower for their functional utility like hauling capacity and speed, but a growing body of research indicates that many consumers do not necessarily want the biggest and fastest car, so long as their car is bigger and faster than their friends' and neighbors'. According to a recent U.S. survey on the visibility of 31 expenditure categories (from food to mobile phones), new or used motor vehicle purchases were the second most visible expenditure; related expenditures on gasoline/diesel, vehicle maintenance, and insurance were all substantially less visible. 103 Surveys also consistently confirm that cars are highly positional goods, that people prefer a relative increase in a car's value to an absolute increase,104 and that the more visible features of cars are more positional.105 Financial savings, in contrast, are typically considered non-positional.106 [EPA-HQ-OAR-2010-0799-9480-A1, p. 16]

The more observable prestige features of vehicles include newness, brand, size, design, and power. While all these traits have functional value (such as capacity, safety, and performance),107 they also all have relative value: consumers value power not just for speed but for the status signal and for the ability to out-accelerate others at a traffic light; consumers do not necessarily want a big car, but they do want a bigger car.108 As Bob Lutz, Vice Chairman of General Motors, has stated, "aspirational aspects overwhelm the functional differences" when customers choose cars.109 Importantly, many vehicle prestige features—especially larger size and increased performance—reduce fuel economy.110And given the low visibility of gasoline expenditures and of financial savings, fuel efficiency itself is currently a relatively non-positional good (though there is some chance that the agencies' new vehicle labeling requirements could start to make fuel economy more visible and positional). [EPA-HQ-OAR-2010-0799-9480-A1, p. 17]

A vehicle's size and weight are also positional for safety reasons, in addition to status motivations. To the extent smaller cars fare worse in crashes with bigger cars, consumers may value bigger cars not because of any intrinsic safety value, but because of the average fleet size.

According to Wenzel's research on the relationship between vehicle weight/size and safety, while an increase in footprint decreases the risk of casualty to the driver, an increase in footprint—especially for pick-up trucks and sports cars—raises the risk of both fatality and casualty to other drivers. 111 [EPA-HQ-OAR-2010-0799-9480-A1, p. 17]

The trouble with positional goods is they impose externalities. This is obvious in the safety context: if Joan upgrades from her compact car to a large pick-up truck, she may feel somewhat safer, but her purchase marginally increases the risk to all other drivers. It also applies in the status context. Again, if Joan buys a big, fast, flashy car to move up the status hierarchy, John's big, fast, flashy car is no longer as rare. John feels relatively worse off and so will have to invest in an even bigger, faster, flashier car just to restore his previous status position. As a result, both consumers spend resources without actually improving their relative status. [EPA-HQ-OAR-2010-0799-9480-A1, p. 17]

Because vehicle purchase decisions are made non-cooperatively but in fact alter the spending behavior and relative safety of others, consumers get stuck on a "positional treadmill" that does not increase welfare.112 Yet if any individual opts out of this "expenditure arms race," it would only move that consumer backwards on the status or safety hierarchy, which for most consumers is unacceptable.113 And given limited resources and limited market options, the over-consumption of positional goods results in under-consumption of non-positional goods (such as fuel efficiency). If consumers could maintain their relative economic position, they might be more willing to pay for non-positional goods.114 [EPA-HQ-OAR-2010-0799-9480-A1, pp. 17-18]

Fuel economy regulation, therefore, is a cooperative solution that allows consumers to achieve what they could not in the non-cooperative open market: namely, an increase in fuel economy without losing position in the status hierarchy.115 Regulations similarly help consumers select fuel economy without falling behind in the safety/size rankings, since with time the average fleet size will shift.116 [EPA-HQ-OAR-2010-0799-9480-A1, p. 18]

In other words, positional goods theory explains that consumer valuations of vehicle attributes like size and performance are relative, which means consumer preferences can adjust as average fleet-wide attributes shift. As a result, changing the fleet-wide average size or performance may not significantly impact overall consumer welfare. In the context of the agencies' cost estimates, this means that manufacturers may not have to spend as much as the agencies' assume in order to prevent any aggregate consumer welfare loss. Consequently, the agencies' constant performance cost projects likely overestimate the actual cost of the regulation. [EPA-HQ-OAR-2010-0799-9480-A1, p. 18]

To improve the accuracy of their cost estimates, the agencies should reanalyze their assumption that "changes in vehicle attributes can significantly affect the overall utility that vehicles offer to potential buyers," in light of positional goods theory. A better understanding of the positionality of cars will help the agencies refine their projections for how much manufacturers will need to spend to maintain actual consumer welfare. Even if a more accurate cost estimate is unlikely to change the stringency or structure of the proposed rule,118 refining the cost estimate remains important. Not only is an accurate cost-benefit analysis based on the best available evidence required by professional and legal norms,119 but a better cost estimate will enhance confidence in justifications for the rule, will improve the public debate over fuel economy, and will set a valuable precedent for future rulemakings.120 [EPA-HQ-OAR-2010-0799-9480-A1, pp. 18-19]

Any Risk of Lost Consumer Welfare Unaccounted for in the Agencies' Constant Performance Cost Projections Is Mitigated by the Positionality of Attributes

Despite the constant performance price projection model, the agencies worry that "if estimates do not include adequate allowances to prevent attribute sacrifices, technological costs will underestimate true economic costs." The agencies acknowledge that, even with footprint-based standards and a constant performance approach, the proposed rule could cause manufacturers to forego future planned attribute improvements or even, "[i]n extreme cases," to change current attributes.122 NHTSA conducted a sensitivity analysis to test this possibility, and found that even if lost consumer welfare equaled 50% of total private benefits, the rule would still be cost-benefit justified.123 [EPA-HQ-OAR-2010-0799-9480-A1, p. 19]

Nevertheless, for use in the final rulemaking, NHTSA is developing a fuller model of buyers' decisions to estimate explicitly any welfare changes that could result from the combination of price increases, fuel economy increases, and altered vehicle attributes.124 NHTSA should be sure to build the lessons from positional goods theory into its model, and the agencies should use the positionality of vehicle attributes and explain why their cost estimates are not likely to underestimate consumer welfare losses; in fact, to the contrary, position goods theory would predict that the cost projections are more likely to be overestimates. [EPA-HQ-OAR-2010-0799-9480-A1, p. 19]

Positionality and the Bandwagon Effect Will Shape the Consumer Market for New Technology

The agencies ask for comment on factors that may affect the consumer market for electric vehicles and other advanced technologies. In conducting this analysis, the agencies should consider the malleability of consumer preferences and valuations for new technologies. [EPA-HQ-OAR-2010-0799-9480-A1, p. 19]

If fuel efficiency becomes a sufficiently visibility trait (perhaps as a result of the vehicle labeling rule, marketing campaigns, and related efforts), it is possible that consumers could start competing for the highest fuel efficiency. But even if that does not happen, consumers' valuation of fuel efficiency will undoubtedly change over time and as a result of the proposed regulation.126 [EPA-HQ-OAR-2010-0799-9480-A1, p. 19]

The bandwagon effect occurs when the perceived attractiveness of a good increases as more people consume it. Growing empirical evidence suggests an environmental bandwagon: people are more likely to make environmental choices when they think everyone else is doing the same.127 [EPA-HQ-OAR-2010-0799-9480-A1, p. 19]

The separate though conceptually related effects of information diffusion and habit formation might also affect the market for more fuel-efficient vehicles. Car choices are strongly influenced by the purchases of peers, 128 perhaps because consumers often deal with the need to justify their choices by deferring to the preferences of others.129 Consumers might currently have a negative opinion of vehicles running on unknown technology or of unknown model types;130 but once more fuel-efficient vehicles increase market share and become more familiar to consumers as a result of the proposed regulations, new consumer habits will form, and willingness to pay for fuel efficiency might increase. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 19-20]

The agencies should treat their constant performance cost projections as an overestimate of the risk of lost consumer welfare. Positional goods theory explains that vehicle attributes like size, power, and safety have relative value. Since attributes like size and performance are at least partly relative, changing the fleet-wide average size or performance may not significantly impact overall consumer welfare. Manufacturers may not have to spend as much as the agencies' assume in order to prevent any aggregate consumer welfare loss. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 20-21]

The agencies should consider how positionality and the bandwagon effect will shape the consumer market for new technologies. As fuel-efficient vehicles become more visible and more common, the perceived attractiveness of fuel efficiency may increase. Information diffusion and habit formation will also affect the future of the market for electric vehicles and other new technologies. [EPA-HQ-OAR-2010-0799-9480-A1, p. 21]

99 See attached symposium paper on positional goods for additional details.

100 Robert H. Frank, The Demand for Unobservable and Other Nonpositional Goods, 75 AM. ECON. REV. 101, 101 (1985).

101 Id. at 107 ("When an individual's ability level cannot be observed directly, such observable components of his consumption bundle constitute a signal to others about his total income level, and on average, therefore, about his level of ability. . . . [I]mperfect information about ability might create incentives for people to rearrange consumption patterns to favor observable goods."). Consumption patterns might vary depending on the relevant population in the status competition. People might compete among friends, neighbors, and coworkers; within their socio-economic class; with higher classes; or on a society-wide basis. See Fredrik Carlsson et al., Do You Enjoy Having More than Others? Survey Evidence of Positional Goods, 74 ECONOMICA 586, 590 (2007). If a particular population has more reliable, independent information on abilities or income, consumption patterns for observable goods might shift. Frank, supra note 100, at 108.

102 Y. Weiss & C. Fershtman, Social Status and Economic Performance: A Survey, 42 EURO. ECON. REV 801, 802 (1998). Status can be instrumental, in that higher status can carry better consumption opportunities, access to better employment, and even better marriage prospects. Ed Hopkins & Tatiana Kornienko, Running to Keep in the Same Place: Consumer Choice as a

Game of Status, 94 AM. ECON. REV. 1085, 1087 (2004). Factors like psychology, biological hardwiring, and envy also should not be ignored.

103 Ori Heffetz, A Test of Conspicuous Consumption: Visibility and Income Elasticities, 93 REV. OF ECON. & STAT. 1101, 1106 (2011) (vehicle purchase had a visibility index of 0.73, second only to tobacco products (0.76); gasoline/diesel had a visibility index of 0.39, car repairs were at 0.42, and car insurance fell near the bottom at 0.23).

104 Specifically, a majority of people surveyed would prefer a world in which their car is superior to other people's but less valuable overall, versus a world in which their car has more absolute value but is inferior to the societal average. See, e.g., Carlsson et al., supra note 101, at 588, 593 (reporting results of a Swedish survey); Francisco Alpizar et al., How Much Do We Care About Absolute Versus Relative Income and Consumption?, 56 J. OF ECON. BEHAVIOR & ORG. 405, 412 (2005) (reporting results of Costa Rican survey). Though some such surveys were conducted in other countries, if anything positionality for cars could be stronger in the United States, given the American affinity for cars and the income distribution. See Reid R. Heffner et al., Effects of Vehicle Image in Gasoline-Hybrid Electric Vehicles 2 (U.C. Davis Inst. of Transportation Studies UCD-ITS-RR-05-08, 2005) ("In the words of automobile psychologist G. Clotaire Rapaille, Americans are in 'a permanent search of an identity' and 'cars are very key . . . [they are] maybe the best way for Americans to express themselves.'"); Hopkins & Kornienko, supra note 102 (noting that positional effects increase as society's income increases, because the portion of income spent on conspicuous consumption increases). On the other hand, cars are often more a necessity and less a luxury in the United States than in other countries. See Mark Grinblatt et al., Interpersonal Effects in Consumption: Evidence from the Automobile Purchases of Neighbors (Yale ICF Working Paper No. 04-10, 2004).

105 Carlsson et al., supra note 101, at 588, 593 (finding support for hypothesis that 'visible goods and their characteristics, such as the value of cars, are more positional than less visible goods and their characteristics, such as car safety.').

106 See, e.g. Omer Moav & Zvika Neeman, Savings Rates and Poverty: The Role of Conspicuous Consumption and Human Capital (2009), available at http://www.hecer.fi/Seminars/Papers/moav_paper.pdf.

107 Carlsson et al., supra note 101, at 595, could not provide a clear answer to the question of whether cars are completely positional. On average cars are highly positional, but that reflects a good deal of heterogeneity: cars may be completely positional for some people, but are possibly completely non-positional for others. Id. at 596.

108 Erik Verhoef & Bert van Wee, Car Ownership and Status: Implications for Fuel Efficiency Policies from the Viewpoint of Theories of Happiness and Welfare Economics 4 (Tinbergen Institute Discussion Paper TI 2000-076/3, 2000) ('However, most cars in most Western countries have engines with much more power than needed, given the characteristics of infrastructure, speed limits, and travel distances.').

109 George Will, Americans and Their Cars, TOWNHALL DAILY, Apr. 18, 2002, available at http://townhall.com/columnists/GeorgeWill/2002/04/18/americans_and_their_cars.

110 See Knittel, supra note 84.

111 Wenzel, supra note 85, at 19, 36. Effect of footprint on fatality risk to driver: P-value 0.215, R2 value 0.01. Effect of footprint on fatality risk to other drivers: P-value <0.001, R2 value 0.38 (though the data for trucks drives this relationship much more than for cars). Effect of footprint on casualty risk to driver: P-value <0.001, R2 value 0.26. Effect of footprint on casualty risk to other drivers: P-value <0.001, R2 value 0.26 (though again the data for trucks drives this relationship much more than for cars).

113 Frank, supra note 100, at 105-06.

114 Robert H. Frank & Cass R. Sunstein, Cost-Benefit Analysis and Relative Position, 68 UNIV. OF CHICAGO LAW REV. 323, 326 (2001) ("If people could maintain their relative economic position, they would be willing to pay more, and possibly a great deal more, to purchase many of the goods that regulation attempts to deliver. . . .[W]hen an individual buys additional safety in isolation, he experiences not only an absolute decline in the amounts of other goods and services he can buy, but also a decline in his relative living standards. In contrast, when a regulation requires all workers to purchase additional safety, each worker gives up the same amount of other goods, so no worker experiences a decline in relative living standards. If relative living standards matter, then an individual will value an across-the-board increase in safety more highly than an increase in safety that he alone purchases.").

115 Correcting for negative externalities and collective action problems is a classic case for regulation. "Analytically, positional externalities are no different from ordinary environmental pollutants." Id. at 364. Such regulation is not about taking public action just because one consumer's increased consumption makes another consumer unhappy or envious; rather, regulation is justified to address a market failure. Id. at 365. Even if not everyone wants to solve this particular collective action problem, "we do not require unanimity as a precondition for unquestionably legitimate collective action in other spheres." Id. at 366. See also Verhoef & van Wee, supra note 91, at 13-14. ("On the free market, consumers would inefficiently strongly stimulate each other to purchase more luxurious variants. Corrective taxes [or a CAFE standard with tradable permits] may protect consumers against such treadmills.").

116 Regulations also correct a supply-side problem, since theory predicts manufacturers will devote their research and development budget to status goods until government adjusts the incentives. Ben Cooper et al., Status Effects and Negative Utility Growth, 111 ECON. J. 642 (2001).

118 See supra note 63, and accompanying text.

119 See supra note 62, and accompanying text.

120 See supra notes 65-67, and accompanying text.

Organization: International Council on Clean Transportation (ICCT)

The agencies may be confused by studies that rely on standard economic theory, which says that assuming full information and no uncertainty, consumers will make optimal tradeoffs between the purchase price and subsequent operating costs. However, the standard economic theory does not apply in this case because mainstream consumers undervalue fuel savings due to uncertainty and loss-aversion. [EPA-HQ-OAR-2010-0799-9512-A1, p. 15]

There is substantial circumstantial evidence that most consumers in the U.S. place a low value on fuel economy. For example, Turrentine and Kurani18 conducted an in depth survey of the car-buying histories of 57 California households. None of these 57 households made any kind of quantitative assessment of the value of fuel savings and only 9 stated they compared the fuel economy of vehicles in making their choice. The selected consumers were largely unaware of their annual fuel cost, in contrast to general knowledge of the daily price fluctuations of a gallon of gasoline. Turrentine and Kurani concluded that: 'When consumers buy a vehicle, they have neither the tools nor the motivation nor the basic building blocks of knowledge to make a calculated decision about fuel costs.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 15]

The question that has been debated for decades is simply - why? This is an extremely important question, as most of the calculation of consumer welfare is based on the answer. If consumers are already receiving their optimum level of fuel economy, then efficiency standards will decrease their welfare. However, if there are valid reasons why consumers are not making optimal tradeoffs at the time of vehicle purchase, or if the entire question is not being framed properly, then efficiency standards would increase consumer welfare. [EPA-HQ-OAR-2010-0799-9512-A1, p. 16]

ICCT believes uncertainties about the cost and value of fuel economy improvements, combined with general loss-averse behavior by consumers, offers a rational and accurate explanation of the failure of the market to optimize fuel cost savings. Green 201019 found that using reasonable estimates of the uncertainty offing-use fuel economy, future fuel prices, annual vehicle use, vehicle lifetime, and incremental vehicle price yielded an average customer payback period of roughly 3 years. While economists refer to this as a market failure, given the large uncertainties in the actual amount of future fuel cost savings and the other ways that consumers can spend their money, the typically loss-averse customer is being quite rational in only wanting to pay for 2-5 years of projected fuel savings. [EPA-HQ-OAR-2010-0799-9512-A1, p. 16]

If consumers only value 2-5 years of fuel savings, does this mean their consumer welfare will decrease if standards force them to save money on fuel from technologies that achieve a fuel-savings based payback in more than 2-5 years? Greene's paper also addressed this issue and found there are two important issues that invalidate this conclusion: [EPA-HQ-OAR-2010-0799-9512-A1, p. 16]

(1) Standards change the status quo by removing the option to buy a vehicle without the additional efficiency technology - it is not presented to the customer at all. Loss aversion is context dependent, which leads to the paradox that consumers who would decline a risky bet may reach a higher level of utility if forced to accept the bet. Efficiency standards mandate that only vehicles with additional efficiency technology can be sold. There is no reason why consumers should evaluate the choice limited by standards in the same way they perceive the choice without standards. ICCT believes the only valid reference point for loss aversion is the updated status quo that exists when the consumer actually makes the purchase decision. [EPA-HQ-OAR-2010-0799-9512-A1, p. 16]

(2) Standards require everyone to purchase higher levels of efficiency technology, not just individual customers, leading to indirect consumer welfare benefits. The concept of consumer welfare under standard economic theory is based upon individual choices. However, efficiency standards affect everyone, not just individual customers. The individual's welfare is now the sum of the direct impact on the individual and the indirect benefit to the individual of forcing other customers to buy more efficient vehicles. There are substantial benefits to an individual if everyone else buys more efficient vehicles. It reduces demand for oil, which leads to lower fuel prices and reduced energy security risks. It also reduces carbon emissions and slows down global warming. Most people are aware of these benefits if standards are imposed on everyone and place significant value on them. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 16-17]

18 Turrentine, Thomas S., and Kenneth S. Kurani, 'Car Buyers and Fuel Economy?' Energy Policy 35 (2007): 1213-1223.

19 Greene, David 2010. 'Uncertainty, loss aversion, and markets for energy efficiency', Energy Economics.

6. Mainstream customers severely discount the value of future, highly uncertain fuel savings. The primary purpose of efficiency standards is to make up for this discounting and push technology into the fleet beyond what would have otherwise been demanded by the market. Considering the stringency of the 2011-2016 standards, the sensitivity analysis for market-driven increases in efficiency after 2016 should be removed from the Final Rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

11. The estimates of net benefits should fully value fuel savings over the lifetime of the vehicle. The alternative NHTSA estimates reducing the net benefits are speculative and should be removed from the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

11) Discounting of Consumer Benefits

The NPRM evaluates the costs and benefits of the proposed rule, and concludes that the net benefits to society of the National Program will be in the range of $311 billion to $421 billion (7 and 3 percent discount rates, respectively) over the lifetimes of those vehicles sold in MY 2017-2025. Most of these benefits are attributed to reductions in fuel consumption. [EPA-HQ-OAR-2010-0799-9512-A1, p. 23]

The reference case analysis of benefits includes the value of fuel savings over the entire lifetime of the vehicle. EPA summarizes its rationale for this approach as follows: [EPA-HQ-OAR-2010-0799-9512-A1, p. 23]

EPA continues to value fuel savings from the proposed standards using the projected market value over the vehicles' entire lifetimes, and to report that value among private benefits of the proposed rule. Improved fuel economy will significantly reduce consumer expenditures on fuel, thus benefiting consumers. Real money is being saved and accrued by the initial buyer and subsequent owners. In addition, using a measure based on consumer consideration at the time of vehicle purchase would involve a very wide range of uncertainty, due to the lack of consensus on the value of additional fuel economy in vehicle choice models. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 23-24]

NHTSA's reference case analysis similarly assumes that there is no loss in value to consumers resulting from vehicles that have an increase in price and higher fuel economy. However, NHTSA also performed sensitivity analyses that assumed that there is a 25 percent or 50 percent loss in value to consumers--equivalent to the assumption that consumers will only value the calculated benefits they will achieve at 75, or 50 percent, respectively of the main analysis estimates. This is intended to account for possible unspecified or poorly understood negative impacts of the rule on consumer preferences. [EPA-HQ-OAR-2010-0799-9512-A1, p. 24]

The sensitivity analyses conclude that these alternative assumptions have a large impact on the magnitude of net benefits, reducing the estimated net benefit by 63.0% and 31.5% respectively. Even in the worst case, however, total benefits still exceed costs. [EPA-HQ-OAR-2010-0799-9512-A1, p. 24]

ICCT agrees that estimates of net benefits should fully value fuel savings over the lifetime of the vehicle. As noted by EPA these are real-world impacts that have tangible value. The alternative NHTSA estimates presented in the NPRM are speculative and should not be given any consideration. [EPA-HQ-OAR-2010-0799-9512-A1, p. 24]

Organization: Michigan State Senate, District 18

But increased fuel economy will also save working families already feeling the pinch at the pump. Americans spend approximately $2,000 a year on gasoline, and at this rate the costs quickly add up. In fact, all together Americans spend more than $1.3 billion filling up each day. The proposed 54.5 fuel economy standard will save consumers who buy cars after 2025 up to $6,600 in fuel costs over the life of their vehicle. [EPA-HQ-OAR-2010-0799-5594-A1, p. 1]

And anyone who has filled up their car in the last few years is all too familiar with the price volatility of gas. In 2008, the price of oil stood at $147 a barrel. By 2009, it had dipped to $35 a barrel, but in 2011 it once again climbed to $120 per barrel. Greater fuel economy will insulate consumers and businesses from this constant rollercoaster and save us all money at the pump. [EPA-HQ-OAR-2010-0799-5594-A1, p. 1]

Organization: National Association of Clean Air Agencies (NACAA)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 34.]

Buffering against gasoline price volatility for consumers and a hedge against rising fuel prices due to increased use of domestic and alternative fuel sources;

Organization: National Automobile Dealers Association (NADA)

Since the enactment of EPCA in 1975, NADA has supported the goal of continuous fuel economy improvements. At the same time, NADA recognizes the constraints inherent in a 'push' approach to achieving such improvements. The success of mandates on vehicle manufacturers to research, develop, design, and manufacture vehicles to meet fuel economy performance targets is limited necessarily by the fact that their regulatory obligations end when those vehicles are delivered to the 17,000+ independent businesses licensed to sell or lease them to the motoring public. Real life fuel economy improvements cannot be achieved, and related policy benefits cannot be realized, unless and until consumers actually buy (or lease) and use those new vehicles. [EPA-HQ-OAR-2010-0799-9575-A1, p. 2]

'Push' mandates do not necessarily mean that 'if they build them, they will come.' It is this simple fact that serves as the basis for NADA’s concern. First, prospective new light-duty vehicle purchasers must need or desire to purchase or lease a new vehicle for there to be demand. And, the demand for new light-duty vehicles is and always will be constrained by choices, including the used vehicle marketplace, vehicle service and repair options, and alternatives to light-duty vehicle transportation. [EPA-HQ-OAR-2010-0799-9575-A1, p. 2]

Lastly, prospective new light-duty vehicle purchasers must be willing to make a purchase, assuming they have the need and/or desire and the ability to do so. Factors influencing customer willingness to purchase a new light-duty motor vehicle include, but are not limited to, consumer confidence, perceived operating costs, and expected residual values. [EPA-HQ-OAR-2010-0799-9575-A1, p. 6]

B. Assuming a Need or Desire, and the Ability to Purchase a New Vehicle Covered by the MY 2017-25 Standards, Will Consumers Be Willing to Do So?

Notwithstanding the very significant impact the MY 2017-2025 proposed rule could have on the ability of consumers to purchase or lease new vehicles subject to the rule, many other prospective purchasers with a need or desire to do so will have the ability to buy. For those customers, the issue is whether and to what extent they will be willing to 'pay-up' for fuel economy improvements. Answering this question is not a simple task in that it involves several key hard-to-predict variables and is dependent on the circumstances of individual consumers. [EPA-HQ-OAR-2010-0799-9575-A1, p. 7]

A couple of facts are clear, however. First, as described above, vehicle lenders and lessors do not account for any potential reductions in vehicle operating costs, such as may result from lower household fuel costs, since they cannot predict actuarially if those avoided costs will be saved, let alone be applied to the loan or lease. Second, when assessing the willingness of prospective new vehicle purchases, it is neither appropriate nor fair to rely on surveys of what consumers say they might do if and when offered a new vehicle with improved fuel economy performance. This is especially true when the questioner neglects to note that the respondent must pay a premium up front for that improved fuel economy performance, or fails to accurately quantify that up-front cost premium, or the higher operating costs associated with that premium (additional interest, insurance, taxes, etc.). Indeed, many pollsters in this area fail to accurately inform the respondent of the degree to which the up-front cost premium and higher operating costs will off-set any potential reductions in household fuel expenses, or may fail to remind those polled of any trade-offs that may be involved with vehicles designed to achieve improved fuel economy performance, let alone that they always have used vehicle, vehicle service and repair, and alternative transportation choices. Of course, consumer surveys can play a valuable role in assessing actual behavior, such as when used to evaluate why consumers do what they do or did what they did. But surveys with queries aimed at determining consumer willingness to pay for fuel economy performance 5 to 13 years into the future, which fail to provide respondents with information appropriate to make reasoned responses are of no value and should be considered as such by NHTSA and EPA. [EPA-HQ-OAR-2010-0799-9575-A1, pp. 7-8]

If and to the extent prospective purchasers are unwilling to pay some or all of a regulatory premium for mandated fuel economy improvements, it will negatively impact new vehicle sales and reduce forecasted regulatory benefits. The proposal characterizes increased fuel economy performance (i.e., fuel cost reductions, discounted to the present) as the future benefit that offsets the higher up-front and operating costs needed to buy such performance. In and of itself, this cost/benefit analysis is problematic given that correct estimates of future fuel savings are not simple financial calculations in which one can estimate a discount rate as a corporation might for its cost of money when calculating the net present value of a potential project. It is incumbent upon EPA and NHTSA to accurately consider the expectations of able and willing prospective purchasers, because those expectations will ultimately determine their behavior in the marketplace. As illustrated in and supported by the paper attached as Exhibit D, prospective purchasers form expectations of the net present value of future fuel savings that are related, but not closely related, to a standardized financial calculation. During dramatic upward swings in the price of gasoline followed by heavy media coverage, consumers place a large value on fuel economy, as revealed by shifts in demand to more fuel efficient portion of the market. During slow and steady increases in the price of gasoline with little or no media attention, consumer demand shifts reveal a much diminished value for fuel economy.[15] [EPA-HQ-OAR-2010-0799-9575-A1, p. 8]

In addition, when assessing the valuation of fuel economy improvements by prospective purchasers, the financial benefits of reduced future fuel savings cannot be separated from the utility lost by necessary reductions to other vehicle qualities and performance. For example, if a consumer values an increase in fuel economy of 1 mpg at $500, but gaining this 1 mpg forces a reduction in power or safety valued at $600, then for this consumer the value of the fuel economy gain is negative. [EPA-HQ-OAR-2010-0799-9575-A1, p. 9]

Consumer behavior indicates how these tradeoffs are valued. Indeed, these tradeoffs are available today in dealership showrooms which offer new light-duty vehicles with a wide variety of fuel economy performance, along with variations in other safety and performance features. A classic example of actual prospective purchaser willingness to pay involves a look at sales of models with both a hybrid electric and a conventional powertrain (e.g., Honda Civic, Ford Escape or Focus, Toyota Camry). The average fuel economy spread is approximately 20 mpg at a cost premium of approximately $5,000. In virtually every instance, hybrid sales have been very small and in total, have made up well below 3% of annual light-duty new vehicle sales. The proposed regulations will mandate this tradeoff for all new vehicle buyers. Admittedly, some of this lack of consumer willingness to pay may derive from concerns about new technologies, as suggested by sales experience with the Mercury Milan hybrid which had an up-front price close to a similar, but conventionally-powered model. [EPA-HQ-OAR-2010-0799-9575-A1, p. 9]

Exhibit D includes a review of the pertinent 'willingness to pay' literature, finding that statistical models that do not properly account for the tradeoff between fuel economy and other vehicle attributes will generate a false positive relationship between price and fuel costs, highlighting the significance of these tradeoffs in the mind the average consumer. Based on these revealed preferences, consumers are unlikely to value the proposal’s mandated fuel economy improvements more than the sum of the higher up-front costs for such improvements and other reductions to vehicle quality. In fact, when more reasonable estimates of per vehicle regulatory costs are used, the perceived net benefit will be negative for the average consumer. As a result, many prospective purchasers of new light-duty motor vehicles will be unwilling to 'pay-up' for costly fuel economy improvements, instead opting for less expensive and less fuel efficient options in the used vehicle market or the vehicle service and repair market, or for alternate transportation, thus reducing the proposal’s projected regulatory benefits. [EPA-HQ-OAR-2010-0799-9575-A1, p. 9]

[This comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 57.]

Now, finally, America's auto dealers support continuous improvement to fuel economy. Instead of fighting the customer, we urge the administration to act in a measure [sic] that will leverage consumer demand, maximize fleet turnover and ensuring maximum feasible fuel economy increases.

[Supplemental comemnt to testimony]

I. Fuel Economy Program Success Depends on Consumer Affordability and Acceptance

Several individuals and organizations presented testimony at the hearings suggesting that higher fuel economy production mandates necessarily will result in consumers achieving net fuel economy “savings,” “pay backs,” or “benefits”. Such assertions ignore the fact that no such “savings,” pay-backs,” or “benefits” are achieved unless, if, and until new vehicles covered by the proposed mandates are actually bought and used. The follow key factors do not allow one simply to assume that production mandates will equate to profitable retail sales:

1. The fundamentals of new vehicle financing.

2. The relative importance of fuel economy performance as a purchase criterion.

3. Consumer alternatives to high-priced new light-duty vehicles.

4. The degree to which high fuel prices undermine new vehicle affordability.

5. That any operational “savings” will vary depending on an individual’s or households’ transportation profile. [NHTSA-2010-0131-0267-A1, p.2]

III. Fuel Economy is But One of Many Factors Consumers Consider When Purchasing New Vehicles

When evaluating consumer behavior, the proposal understandably is fuel economy performance focused. In reality, consumers interested in purchasing new vehicles consider a variety of factors. Fuel economy performance may be high on their list, or it may not be there at all. Naturally, when fuel economy performance enhancements involve no additional up-front costs or trade-offs, they are readily accepted by the marketplace. Similarly, as demonstrated by the 2009 Cash-for-Clunkers program, consumers readily accept enhanced fuel economy performance when someone else pays for it. Unfortunately, the proposed fuel economy mandates involve significantly higher up-front costs and/or vehicle performance trade-offs which no one but consumers themselves must pay for. [NHTSA-2010-0131-0267-A1, p.3]

NADA's written comments discussed how the overall new sales mix can vary significantly with dramatic fuel price swings and with the general perception of where fuel prices are headed. However, even when fuel prices are rising, fuel economy is rarely a high consumer priority.4 Since at least 2002, there has been an overall increase in new light-duty fleet fuel economy paralleling a overall increase in real fuel prices (2008 being the exception), with fuel economy standards serving as a back-stop. At the same time, consumers consistently have demonstrated a limited willingness to "pay-up" for higher fuel economy performance. Contrary to the suggestion of many including CFA6, Consumer Reports7, and others, it matters much less what consumers say they will or might do, and much more what they actually do. [NHTSA-2010-0131-0267-A1, p.3]

Actual consumer behavior with respect to "buying" fuel economy is perhaps no more evident than with conventional hybrids. Offering significantly higher fuel economy performance versus their conventional counterparts, hybrids typically are offered at significantly higher prices. To date, hybrid sales have peaked at just above 2% of the new light-duty sales market, despite strong interest from early adopters and car pool lane devotees. For many consumers, they simply do not offer a sufficient total cost of ownership value proposition. [NHTSA-2010-0131-0267-A1, pp.3-4]

IV. Consumers Unable to Afford or Unwilling to Pay Higher Prices Have Other Options

NHTSA and EPA recognize the existence of a "jalopy effect" that occurs when consumers face higher priced vehicles they are unable or unwilling to pay for. This behavioral effect is a cumulative measurement of the degree to which regulatory mandates that increase new vehicle costs or decrease (compromise) new vehicle performance can cause consumers to turn to the used vehicle marketplace, to hold on to their current vehicles longer (the service/repair marketplace), or to seek transportation alternatives. The first two of these consumer choices, if exercised, will inhibit fleet turnover and thereby eliminate regulatory benefits. Depending on the transportation option selected, the third choice actually may result in measurable "benefits," but not without significant negative economic costs. [NHTSA-2010-0131-0267-A1, p.4]

V. Higher Fuel Prices Can Create a Greater Interest in Fuel Economy Performance, But Also Act To Reduce Vehicle Affordability

Consumer interest in fuel economy performance increases as fuel prices rise and when they are expected to trend higher. At the same time, NHTSA and EPA cannot ignore that many individuals and households are less able to afford a new (or new used) vehicle when higher transportation expenses eat into their ability to muster a down payment. [NHTSA-2010-0131-0267-A1, p.4]

---

15 Analysis of wholesale used vehicle transaction data show that demand reactions to significant changes in gasoline prices between 2005 and 2011 vary significantly depending on media reaction, the speed at which the price of gasoline changes, and other economic circumstances. For example between February and July 2008, the price of gasoline (regular, national average)

increased by $1.14/gal. At that time, approximately 70% of the price change for a given vehicle relative to the market average can be explained by its MPG rating, equivalent to a 1.7% relative price per MPG variation for a $1.00/gal. change in the price of gasoline. But when gasoline increased by $0.97/gal. in 2007, consumer reaction was less distinct, with just 8% of the price change for a given vehicle relative to the market average explained by its MPG rating, equivalent to a 0.3% relative price per MPG variation for a $1.00/gal. change in the price of gasoline. Media coverage played a role in the difference in these reactions, as coverage in 2008 was significantly stronger than in 2007. For the 2008 events, a Google News search found approximately 21,700 gasoline price articles (an average of the total referencing 'Gas Prices' and the total referencing 'Gasoline Prices'), while a search for 2007 shows less than half that amount or 8,745.

4 Since 2005, AutoPacific has conducted a bi-monthly Internet survey designed to measure the impact of fuel prices on consumer vehicle purchase decisions and driving behavior. This Fuel Price Impact Study puts years of trend data to work to understand how consumers react to fluctuating fuel prices and how the impact has changed over time. In April 2011, AutoPacific's analysis revealed that, unlike in 2008, a run up in fuel prices from 2010 to 2011 did not drive the market to smaller vehicles and that, while fuel economy improvements are of value in the context of increasing fuel prices, the vehicle type and functionality is of greater importance. Moreover, the run up in fuel prices did not cause a rush to hybrids, with only 21 percent of surveyed consumers stating even a willingness to consider purchasing one. AutoPacific, Americans Want Fuel Efficiency, Not Smaller Cars: No Wholesale Move to Small Cars, Even With High Gas Prices (April 2011). To the extent that the MY 2012-2025 contemplates mix shifting and downsizing as important compliance strategies, the AutoPacific analysis is concerning. See, Knittel, Automobiles on Steroids: Product Attribute Trade-Offs and Technological Progress in the Automobile Sector (July 2009). [NHTSA-2010-0131-0267-A1, p.3]

Organization: National Caucus of Environmental Legislators

Strong standards maximize consumer savings at the pump. Under the 54.5mpg-by-2025 standard that you recently proposed Americans would save nearly $45 billion at the gas pump annually by 2030, even after accounting for the cost of new technology. [EPA-HQ-OAR-2010-0799-9443-A1, p. 1]

Organization: National Wildlife Federation (NWF)

These standards don't just deliver for America's outdoor heritage, but for consumers and the economy

Consumers save big. The 2017-2025 proposed standards will save Americans half a trillion dollars. That's tens of billions of dollars a year American families and businesses can spend at home building jobs instead of overseas for oil. Families and businesses will save more than $4,000 in the life-cycle cost of a car or truck, after accounting for the costs of more fuel-efficient technology. [EPA-HQ-OAR-2010-0799-9887-A2, p. 3]

What’s more, many consumers will see saving the moment they drive off the lot. EPA and NHTSA estimate that the gas savings from the more efficient vehicle will offset the additional upfront cost of new technology in under 4 years. But this kind of payback assumes that drivers pay for their vehicles in cash. In fact, most consumers finance their vehicles, and in that case, many will see savings from day one, since the savings monthly on gas outpace the small added finance charge from a modestly higher purchase price. 4 [EPA-HQ-OAR-2010-0799-9887-A2, p. 3]

Put differently, for household budgets, doubling fuel economy is like cutting the price of gasoline in half. For those concerned about cutting dependence on foreign oil and reducing pain at the pump, the best place to drill for oil is under the hoods of our cars. [EPA-HQ-OAR-2010-0799-9887-A2, p. 4]

These standards bring innovation and fuel savings to owners of all kinds of vehicles. For many of our members, the outdoor traditions that mean most to them include getting together with family and friends, loading gear into the truck and heading out hunting or fishing. Across the country, communities and businesses that depend on outdoor recreation depend on these trips. For those who rely on larger vehicles, high gas prices hit particularly hard, and achieving robust fuel efficiency improvements is critical and welcome. [EPA-HQ-OAR-2010-0799-9887-A2, p. 4]

Fortunately, today’s fuel economy standards don’t just focus on cars, but ensure improvement across all vehicle sizes and types to achieve an overall increase in fuel economy and reduction in pollution. And innovation is delivering far better fuel efficiency together with improved power and performance. This means not just financial savings but improved choices for consumers. [EPA-HQ-OAR-2010-0799-9887-A2, p. 4]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 30-31.]

Today’s new vehicles provide a case in point. In a report NWF released in August 2011, we compared the fuel economy, power and performance options available to buyers of the 2011 Ford F-150 pickup truck against a 2005 model they might trade in. The F150 is America’s bestselling vehicle, and the 2011 model incorporated the EcoBoost engine and other innovations that will be widely used to meet the new light duty standards. As shown in Figure 2 below, the 2011 F150’s were more efficient while delivering greater horsepower and better torque, enabling customers to achieve more than 25% increase in fuel economy while still gaining greater performance. [Figure 2 can be found on p. 5 of Docket number EPA-HQ-OAR-2010-0799-9887-A2] [EPA-HQ-OAR-2010-0799-9887-A2, p. 4]

Consumers have responded positively to the more fuel efficient models. The EcoBoost turbocharged V6 model costs approximately $750 more than the comparable V8, but has sold strongly accounting for more than 40% of total sales – and exceeding the company’s sales forecasts. 5 [EPA-HQ-OAR-2010-0799-9887-A2, p. 4]

Consumer support for the most advanced vehicles is also growing. In a recent Consumer Reports survey 56% of adult car buyers said they would “consider an electric or hybrid for their next car”. 8 Sales of plug-in hybrid electric vehicles and battery electric vehicles in 2011, while still relatively modest, were easily comparable to the sales of the first hybrids in 2000 and 2001. 9 [EPA-HQ-OAR-2010-0799-9887-A2, p. 6]

There are many reasons for optimism regarding consumer acceptance of the most advanced vehicles. Compared to most alternative fuels, infrastructure needs for electric vehicles – especially PHEV’s – are relatively modest. As early as this year, automakers will be offering a wide range of alternatives to consumers on the hybrid/ PHEV/ BEV continuum – again providing greatly enhanced powertrain options to consumers, along with other vehicle benefits. Utilities and communities across the country are preparing to facilitate EV adoption, while technology companies are preparing to capture the benefits of connecting vehicles to home and business energy systems. [EPA-HQ-OAR-2010-0799-9887-A2, p. 6]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 199-200.]

Consumers would have an additional $200 billion in their pockets to spend on the economy, thanks to the fuel sipping vehicles.

Consumers win under this proposal because they have more choices of cleaner, fuel-efficient offerings in the showroom. As the agencies' analysis shows, consumers will have net savings of up to $4,400 over the life of their vehicle under the standard. Importantly, for most consumers that finance their vehicles, the net savings will be brought home immediately.

Under the standards the combination of fuel expenditures and new car payments will be lower in the first month. By 2030 the aggregate national savings will provide the equivalent of an annual tax rebate of $330 for every American household.

Consumers want cleaner, more fuel-efficient vehicles, and they are buying them. According to data from the University of Michigan, the average fuel economy of new vehicles since data was first collected in October 2007 has been increasing year over year.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 70.]

Consumers will benefit from decreased vulnerability to fuel price volatility, and from the long-term fuel cost savings it will more than offset the initial added vehicle costs necessary to meet the standards.

Organization: Pennsylvania State Senate et al.

Under the 54.5mpg-by-2025 standard that you outlined in July, Americans would save over $80 billion at the gas pump annually by 2030. [EPA-HQ-OAR-2010-0799-9914-A1, p. 1]

Organization: Rafter, M.

They also make cars that no one wants to buy. [EPA-HQ-OAR-2010-0799-11587-A1, p. 1]

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

Enhancing Consumer Choice and Savings: Americans do not want to guzzle gas or waste billions at the pump, and they want a range of vehicle choices that reflect that. Polls consistently show that Americans support higher standards and are willing to pay more upfront for fuel-saving technology in order to use less gas and spend much less money at the pump. [EPA-HQ-OAR-2010-0799-9549-A2, p. 2]

A recent poll by Consumers Union finds that consumers are increasingly supporting stronger fuel efficiency standards, and the driving force is the cost of gasoline.4 Many consumers are considering more efficient vehicles, including advanced technology vehicles. Over half (56 percent) of respondents said they were considering an electric vehicle for their next vehicle, and 89 percent of consumers who are considering these vehicles cited lower fuel costs as the reason for their choice. [EPA-HQ-OAR-2010-0799-9549-A2, p. 2]

The results of the Consumers Union poll are consistent with polling done by the Go60 campaign in September of 2010. The September 2010 Mellman Poll released by the Go60 campaign found that an overwhelming majority support significantly increasing vehicle standards, even when told it would add $3,000 to the price of a new vehicle. When respondents were informed that the added cost of technology would be offset within four years by savings at the pump, 83% of respondents expressed support for higher standards (67% strongly).5 [EPA-HQ-OAR-2010-0799-9549-A2, p. 2]

It is crucial that the agencies not use inflated and arbitrary discount rates when considering consumer benefits, such as the 25% and 50% discount rates considered in sensitivity analysis for NHTSA's PRIA. Given the consequences of our oil addiction on our economy, environment, national security and on consumer's individual pocketbooks, the full value of the savings and benefits must be accounted for. [EPA-HQ-OAR-2010-0799-9549-A2, p. 3]

While the polling and recent study of Gen Y consumers supports consumer interest in fuel efficiency and willingness to pay for the technologies that will reduce oil consumption and emissions, the auto industry has, historically allowed new vehicle fuel consumption to stagnate absent rising standards. This conclusion is supported by the recent study, Automobiles on Steriods which concludes that between 1980 and 2006 (a period that includes increases due to the original CAFE program) average gas mileage increased 15% and application of technologies that could have significanlty reduced fuel consumption went to support increased vehicle weight and acceleration.10 [EPA-HQ-OAR-2010-0799-9549-A2, p. 3]

The EPA and NHTSA both note that the proposed standards preserve consumer choice by basing the standards on vehicle footprint. The fact is that these standards enhance consumer choice. Consumers today already enjoy a full range of more efficient and less polluting vehicles. A new analysis shows that new vehicles purchased last year "averaged a half-mile more per gallon than those purchased in 2010, an improvement that saved $722 million at the gas pump, where consumers bought 214 million fewer gallons of gas than a year earlier." [EPA-HQ-OAR-2010-0799-9549-A2, p. 3]

This year, Automotive News included in its top 10 new things of 2011, Ford's Ecoboost engine for its F150 trucks – the top selling vehicle in the country. Automotive News writes: "A year ago, who would have guessed that Ford's F-150 pickup buyers would prefer an EcoBoost v-6 to a traditional V-8." This shows that the technologies exist and automakers are putting them to work to improve efficiency and reduce emissions, even in the largest pickup trucks, and that consumers will buy cars and trucks that go further on a gallon of gas. [EPA-HQ-OAR-2010-0799-9549-A2, p. 3]

A recent study by University of Michigan Transportation researchers found that all classes of vehicles offered for sale in the U.S from 2008 to 2011 show improvements in fuel economy.12 [EPA-HQ-OAR-2010-0799-9549-A2, p. 3]

On average, compact cars' fuel economy increased 3.8 mpg to 25.6 mpg, and small pick ups increased 0.4 mpg to 18.6 mpg. While this may not sound like much, the study indicates that automakers are making more fuel efficient vehicles available across the board. Even with these small gains consumers are now able to buy greater fuel efficiency without having to express it as a preference. Absent standards, however, automakers cannot be relied upon to produce fuel efficient vehicles. [EPA-HQ-OAR-2010-0799-9549-A2, p. 4]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 123-124.]

Consumers will save more than $3,500 at the pump even after paying for the fuel-saving technology. Savings will be even greater if gas prices rise above current levels. According to DOT and the EPA these standards will save our economy and consumers more than 311 to 421 billion dollars. These hundreds of billions of dollars will translate into new jobs.

Americans want choices in the vehicle market but they do not want to guzzle gas nor do they want to waste billions at the pump. Americans consistently support higher standards and are willing to pay more to save oil. We can now be confident that technology once used to make vehicles more powerful will be used to improve fuel efficiency from improving the internal combustion engine, better transmissions, high strength lightweight materials, and to hybrid and plug-in vehicles.

The EPA and NHTSA both note the proposed standards preserve consumer choice. The fact is that these standards enhance consumer choice. Consumers today already enjoy a full range of more efficient and less polluting vehicles. The new analysis shows that new vehicles purchased last year averaged a half mile more per gallon than those in 2010, an improvement that saved $722 million at the gas pump where consumers bought 214 fewer billion gallons of gas than the year earlier.

Most people cannot or should not spend this much money on a new vehicle. A lot of bigger vehicles are needed for business and bigger families. The average household will not get any benefit from these vehicles. [EPA-HQ-OAR-2010-0799-6314-A1, p. 1]

Organization: U.S. Coalition for Advanced Diesel Cars

Our comments below assert that technology neutral policies and consumer acceptance are the only proven methods for the automotive industry to move forward with certainty and with the flexibility to seek and strive for new innovations that will dramatically improve fuel economy and reduce emissions. [NHTSA-2010-0131-0246-A1, p.1] [This statement also cross-referenced with section 4]

Market acceptance is also critical to defining the best technology or portfolio of technologies necessary to reach the targets set by government. Failure to adopt technology neutral policies and reality-based vehicle ratings will undermine consumer choice and drive a systematic shortfall in achieving the benefits promised by the new rulemaking. [NHTSA-2010-0131-0246-A1, p.2]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 240-241.]

Predictions in the NPRM regarding consumer preference and driving habits within the NPRM ignore current data and are inaccurate. The agencies need only look to their predictions for 500,000 electric vehicles to be sold for model years 2012-2016. [NHTSA-2010-0131-0246-A1, pp.2-3]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 244-246.]

Current take rates for passenger HEV's clearly demonstrate consumer hesitance to invest in a vehicle that, while it's fuel efficient on the test cycle, does not fulfill their driving needs. When we refer to take rates, we're referring to the percentage of consumers who purchase an advanced technology powertrain over a standard gasoline powertrain when the option exists on the same vehicle.

From June 2010 to June 2011, the average take rate for HEV's was 5%. That means consumers chose a standard gasoline engine over the HEV version of the same vehicle 95% of the time. Comparing that to the take rate of the clean diesel technology over the same period, consumers chose the diesel option over the standard gasoline version 39% of the time. While both technologies offer comparable fuel savings over a standard gasoline vehicle, diesel technologies lower purchase price, and greater functionality proved more attractive to consumers than the HEV. The Coalition recognizes there are some popular vehicles such as the Toyota Prius that only offer the HEV option, therefore, do not factor into that average take rate referenced above. However, when provided the option, the vast majority of consumers are still choosing the standard gasoline vehicles over HEV.

EPA and NHTSA do not show any market data to suggest consumers will treat full-sized HEV pickup vehicle that, while it's fuel efficient on the test cycle, does not fulfill their driving needs. When we refer to take rates, we're referring to the percentage of consumers who purchase an advanced technology powertrain over a standard gasoline powertrain when the option exists on the same vehicle.

From June 2010 to June 2011, the average take rate for HEV's was 5%. That means consumers chose a standard gasoline engine over the HEV version of the same vehicle 95% of the time. Comparing that to the take rate of the clean diesel technology over the same period, consumers chose the diesel option over the standard gasoline version 39% of the time. While both technologies offer comparable fuel savings over a standard gasoline vehicle, diesel technologies lower purchase price, and greater functionality proved more attractive to consumers than the HEV. The Coalition recognizes there are some popular vehicles such as the Toyota Prius that only offer the HEV option, therefore, do not factor into that average take rate referenced above. However, when provided the option, the vast majority of consumers are still choosing the standard gasoline vehicles over HEV.

EPA and NHTSA do not show any market data to suggest consumers will treat full-sized HEV pickup trucks any differently. In fact, consumers have already displayed significant reluctance to make an investment in a full-sized hybrid truck. In model year 2010, consumers showed the GMC Sierra and Chevy Silverado hybrid .23% of the time preferring the gasoline option in more than 99% of the cases. This amounts to 1165 hybrid models out of nearly 500,000 Sierra and Silverados sold in 2010, yet the incentive assumes consumers will flock to this option.

Organization: Union of Concerned Scientists (UCS)

Consumer and Economic Benefits

According to UCS analysis, full implementation of the proposed 2017-2025 standards would save consumers, cumulatively, $535 billion in avoided fuel expenses through 2030 – over $90 billion in 2030 alone. Even after paying for the additional cost of better technology, consumers would see over $260 billion in net savings through 2030—over $50 billion in 2030 alone. [EPA-HQ-OAR-2010-0799-9567-A2, p. 2]

And while the cost of clean car technology will lead to a modest increase in new vehicle price, the average consumer will save money the moment they drive off the lot. Since most Americans finance the purchase of a new vehicle (or lease it), the higher vehicle price is borne as a slightly higher monthly loan payment, which is more than offset by avoided monthly fuel expenses. Based on an average 5-year, 5% APR loan and the agencies' estimate that the most stringent standards will increase the average vehicle price by approximately $2,000, a consumer's monthly loan payment would increase by $36. However, the standards would save that consumer $81 per month at the gas pump, assuming a price of $3.50 per gallon, resulting in a net monthly consumer savings of $45.2 Further, the consumer will capture the entire value of fuel-savings after the end of the loan period, resulting in even greater savings. [EPA-HQ-OAR-2010-0799-9567-A2, p. 2]

Beyond the monetary benefits to consumers, these standards will provide greater choice in the new and used vehicle markets. Currently, many consumers do not have meaningful options for better fuel efficiency and lower emissions depending on vehicle class. For instance, consumers interested in purchasing full-size minivans in today's marketplace have virtually no clean vehicle options. If fully implemented, the 2017-2025 standards would ensure that automakers apply clean, fuel-efficient technology across the entire fleet of new vehicles for nearly the next decade and a half. [EPA-HQ-OAR-2010-0799-9567-A2, p. 2]

(f) Discount Rates & Consumer Welfare

UCS supports the agencies' decision to continue the use of discount rates of 3 and 7% in the proposed rule. As we have stated previously in both the MY2012-2016 rulemaking and our NOI comments, these discount rates properly reflect realistic interest rates and opportunity costs consumers face in the marketplace. [EPA-HQ-OAR-2010-0799-9567-A2, p. 12]

However, we are concerned that the proposed rule continues to include some debate about the role of private benefits and potential loss in consumer welfare in assessing the total benefits and costs of the program. In the proposed rule, EPA states that, "assuming full information, perfect foresight, perfect competition, and financially rational consumers and producers, standard economic theory suggests that normal market operations would have provided the private net gains to consumers, and the only benefits of the rule would be due to external benefits." [EPA-HQ-OAR-2010-0799-9567-A2, p. 12]

The problem is that none of these assumptions accurately reflect the automotive market or consumer behavior. In the real world, we know that consumers cannot have full information and perfect foresight. For example, EPA window stickers and the EPA Fuel Economy Guide note that "Your Fuel Economy Will Vary." Further, despite having extensive modeling experience and expertise, even the EIA has not accurately predicted gasoline prices – it is a stretch to think that an individual consumer would have more certainty. Consumers also cannot predict future traffic patterns, changes in job location and many other factors that will influence how much they could save on gasoline from various vehicle choices. Consumers also have not had perfect substitutes available in the market. The assertion that "financially savvy consumers could have sought vehicles with improved fuel efficiency, and auto makers seeking those customers could have offered them," indicates unfamiliarity with actual vehicle offerings and a misunderstanding of the risk averseness of highly capitalized industries. [EPA-HQ-OAR-2010-0799-9567-A2, p. 12]

Consider the following example: In model year 2010, the fuel economy range of full-size minivans spanned a mere two mpg, from 18 to 20 miles per gallon. To achieve higher fuel economy, a consumer had one choice, a 23 mpg model that was smaller and less powerful than the others on the market. While a consumer choosing the 20 mpg model instead of the 23 mpg model does indicate that they place more value on the available size and performance than on the benefit of a 3 mpg increase, it does not imply that they would experience a welfare loss should they be given a 23 mpg vehicle with the same size and performance as the 20 mpg model. [EPA-HQ-OAR-2010-0799-9567-A2, pp. 12-13]

Given this market reality, UCS is deeply concerned that NHTSA evaluated scenarios in the proposed rule that would reduce consumer benefits by nearly 25 and 50%.37 This is an unprecedented shift in evaluating the CAFE program and should not be included in the final rule. Unless the agencies can demonstrate that consumers do not value one dollar in fuel savings as being worth one dollar, this is pure conjecture based on economic theory that seeks to apply an ideal market model that does not comport with actual consumer experience in the marketplace. [EPA-HQ-OAR-2010-0799-9567-A2, p. 13]

The agencies should continue including the full private benefits to consumers, using discount rates that reflect market conditions, when calculating the total benefits of the program and should not shift to a system that would include highly uncertain and idealized consumer choice models in the benefits assessments. It was those same consumer choice models that led many companies to dismiss hybrid-electric vehicles like the Prius, airbags, and many other innovations that have seen significant market success. [EPA-HQ-OAR-2010-0799-9567-A2, p. 13]

Strong, cost-effective standards will provide consumers with a wider choice of cleaner and more fuel efficient vehicles that save drivers money. In the absence of standards, market barriers prevent drivers from realizing these savings, leaving drivers without the options they need to respond to volatile and rising gasoline prices. Standards are the right policy approach given the realities of this marketplace. [EPA-HQ-OAR-2010-0799-9713-A1, p. 2]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 217-223.]

Even after paying for the additional cost of better technology, consumers would still see over $260 billion of that savings through 2030.

While the cost of clean car technology will lead to an increase in vehicle price, the average consumer will save money the moment they drive off a lot.

Since most Americans finance the purchase of a new vehicle, the higher vehicle price is borne as a slightly higher monthly loan payment, which is more than off-set by avoided monthly fuel expenses.

The standards also strengthen our economy. By spending less on oil, consumers will have more money to spend on goods and services that will create U.S. jobs.

Hence, the CAFE and GHG standards being discussed in this meeting appear to be necessary from the consumer choice side; that the U.S. auto industry has been party to the setting of this specific standards under discussion in the case; that the standards are feasible and not unduly burdensome. Both sides of the auto market stand to benefit.

---

2 Analysis assumes on-road values of 22 mpg and 37 mpg, corresponding to unadjusted 2-cycle fuel economies of 28 mpg and 50 mpg, respectively.

Organization: United Automobile Workers (UAW)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 24-25.]

One obvious reason is that consumers are demanding more fuel-efficient vehicles, and meeting that demand is an increasingly important part of the business. In an age of rising and volatile fuel prices, American families want to save money on fuel.

Organization: Volkswagen Group of America

Customer shopping habits for cars is highly personal with individuals balancing competing needs and wants against cost. For many people a car will amount to one of their most expensive purchases ever in their lifetime. If an individual is not comfortable with the capabilities or limitations of an advanced technology car, or if they fail to appreciate the long-term benefit, the car will simply remain unsold. Advanced technology left on a dealer’s lot provides no benefit to the environment or return on investment to the company who leveraged capital to develop the car.[EPA-HQ-OAR-2010-0799-9569-A1, p. 13]

Volkswagen applies technologies which we expect will offer consumers with a market acceptable balance of performance and cost. Early adopters excited by the prospects of owning the latest technology will be open to explore new advancements in their purchase decision. However, for many mainstream consumers, the consideration of newer, more expensive, or alternative technology may invoke another set of considerations. Some people may choose more incremental gains of an evolved, but familiar technology, as opposed to jumping into something completely new. [EPA-HQ-OAR-2010-0799-9569-A1, p. 13]

Volkswagen expressed some contrarian views with regards to projected estimates for future technology adoption by consumers. This was even more evident in terms of comprehending consumer demand for the longer 2022-2025 future timeframe. Volkswagen feels it is especially difficult to confidently predict consumer behavior that far into the future.[EPA-HQ-OAR-2010-0799-9569-A1, p. 13]

Organization: Volvo Car Corporation (VCC)

Regardless of the environmental imperatives, it remains difficult to assess what will motivate tomorrow's consumers to actually purchase these highly advanced vehicles in requisite numbers, both to achieve the desired environmental impact and to provide economies of scale. [EPA-HQ-OAR-2010-0799-9551-A2, p.2]

Response:

Comments in this section relate to the effect of the rule on the range of choices available to consumers, consumer acceptance of vehicles built in response to these standards, the use of consumer vehicle choice models to estimate what vehicles consumers will buy, and the role of fuel economy in consumer vehicle purchases (willingness to pay for fuel economy).

Effect of the Rule on Choices to Consumers

EPA agrees with all of these commenters that consumer acceptance of the new technologies used to meet the standards is an important component of the program’s success.

These comments show a diversity of views on consumer response to the vehicles with compliance technologies under these standards.

Some comments indicate that consumers are eager for more fuel-efficient vehicles, with their resulting fuel savings, and the increased choices of technologies and fuel economies that will result from this rule. These commenters find that consumers are willing to pay higher vehicle prices to get greater fuel savings. Some note that consumers want improvements in fuel economy in all vehicle categories, and the footprint-based standards encourage improvements across all vehicle types.

Other comments indicate that consumers are not willing to pay the higher up-front costs required for some of the technologies, especially electric vehicles. Some raise concerns over consumer willingness to change to unfamiliar technologies, and cite low adoption levels of hybrid vehicles as evidence of this reluctance. Others note that improving fuel economy comes at the expense of other vehicle features, such as performance or size, because of technological tradeoffs. Some comments suggest that consumer interest in fuel economy varies with the price of gasoline.

EPA has sought to achieve the goals of reducing GHG emissions and improving efficiency while maintaining safety and consumer choice. The use of the footprint-based standard is intended to maintain the size distribution of vehicles in the fleet; downsizing is not expected to be a compliance strategy. The engineering assessment is based on the costs of adding GHG-reducing technologies while maintaining all other vehicle characteristics at their current levels, with minor exceptions (such as electric vehicles where purchasers nonetheless would knowingly accept limited vehicle range). See EPA RIA Chapter 1.3 explaining how the agencies' methodology for evaluating cost and effectiveness of the various technology packages preserves all existing vehicle utilities as part of the methodology. Thus, we reiterate that the agencies' estimates of the estimated compliance costs of their respective rules include the costs of preserving all the utilities found in the present-day fleet. This analysis thus demonstrates that it is possible to improve efficiency without eliminating other vehicle attributes. That improvement comes at a cost, but the value of the fuel savings is expected to exceed those costs with a payback period of 3.2-3.4 years (see RIA Chapter 5.5) (for purchases in cash; there would be immediate savings for purchases made under now-standard credit arrangements). As discussed in Preamble III.H.1.a, by maintaining all other vehicle characteristics and utilities in its cost estimates, EPA's cost estimates have accounted for tradeoffs with other vehicle characteristics in the reference fleet. Those commenters (e.g., Edmunds.com, IER, and NADA) that indicated that the rules would cause a reduction in vehicle utility – in essence that other desirable features would be sacrificed as fuel economy improved – overlook that the agencies' analyses reflect the costs of preserving all of those flexibilities. The agencies have consequently reasonably concluded that nothing in these standards causes manufacturers to reduce vehicle utility, or results in a situation where consumers no longer have access to some type of vehicle attribute in the present fleet considered to be desirable. See preamble section II.C. We thus disagree with IER that the benefit-cost analysis is fatally flawed because it "omits the cost to consumers of limiting consumer choice." We discuss the (incorrect) assertion from NADA and others that the rule "forces 7 million drivers out of the car market" in Preamble Section III.H.11.b and Section 18.7.1 of this Response to Comments.

At the same time, notwithstanding that both agencies have demonstrated compliance paths that are feasible at reasonable cost without any diminution of present vehicle attributes and utility, the agencies are sensitive to the possibility that the standards may create incentives for manufacturers to reduce utility. For example, as explained in sections II.C.4.aand III.D.6, the agencies were sensitive about truck standards (curve shapes) and stringencies that would create incentives to reduce towing and hauling utility as a compliance path for larger trucks, and also sought to craft standards for which anticipated compliance paths are safety neutral.

The new standards may provide consumers with greater choices in vehicle technologies and fuels, as automakers identify compliance approaches to these rules and may provide multiple versions of models – for instance, the choice between a Ford F-150 with an 8-cylinder engine and a Ford F-150 with a 6-cylinder Ecoboost engine, or hybrid and conventional models of the same vehicle. Consumers then have the opportunity to respond in their purchase patterns. Greater choices should generally improve consumer welfare.

EPA agrees that consumer interest in additional fuel economy in vehicles depends in part on the price of fuel. Because the price of fuel fluctuates rapidly, the resulting varying level of interest in fuel economy on the part of vehicle buyers can lead to problems for auto producers, who need much more lead time to change production and technology levels on vehicles. For instance, when gasoline prices rose suddenly in 2008, many vehicles with poor fuel economy went unsold, and many vehicles with high fuel economy were in high demand. Improving fuel economy reduces vulnerability to fuel price fluctuations; using a footprint-based standard encourages improvements in fuel economy across the fleet, rather than in just some market segments.

The low adoption of hybrids (to date) is not expected to be a good model of consumer response to the technologies used to comply with these standards because we expect most of the technologies used for compliance to involve smaller cost increases and less apparent changes (except to fuel economy) than hybridizing a vehicle. On average, the GHG-reducing technologies expected to be used will involve lower cost increases than strong hybrids. For instance, though the Toyota Camry hybrid has an MSRP roughly $3,000 higher than the cost of a conventional Camry, the average cost of achieving the MY 2025 standards under this rule is about $1,800; in earlier years, those costs are lower. Other commenters (including Ford itself) point out that Ford's EcoBoost engine in the Ford F-150 pickup is proving very popular: though costing $750 more than the comparable V8, it is accounting for more than 40% of sales of those trucks. For most vehicles, then, consumer response to the EcoBoost engine may be a more appropriate model than consumer response to hybrids. Among other things, EPA's projected compliance paths utilize the turbocharged downsized engine technology far more than strong hybrid technology; see Preamble Tables III-47 and III-51.

<u>Consumer Acceptance of Vehicles from Fleets Achieving the Standards</u>

EPA agrees that consumer acceptance of the new vehicles is very important for the success of the program. Commenters show mixed responses: some state that consumers actively want more fuel-efficient vehicles and will respond very positively to the program, while others express concern that consumers may be hesitant about the new technologies and the costs associated with them. We agree with the Alliance of Automobile Manufacturers that it is difficult to predict how consumers will respond to vehicles designed to comply with the standards. We note that sales of vehicles subject to the MY 2012 GHG/CAFE standards have been strong, though we acknowledge that some of the strong sales is due to improvement in economic conditions relative to the low point of the recession. The midterm evaluation provides an opportunity to evaluate the effects of GHG/fuel economy standards on the auto market.

Consumer Vehicle Choice Models

American Fuel and Petrochemical Manufacturers (AFPM) maintains that principles of administrative law compel EPA first to develop a quantitative sales analysis including a vehicle choice model, and to provide notice and opportunity for comment before adopting rules based upon the results of such a model.[54] The premise of its comment is that a quantitative sales analysis based on the results of a consumer choice model is critical to the rule, and that such critical information must be subject to notice and opportunity for comment before a rule can be adopted. AFPM quotes language from the preamble to the proposed rule, which it attributes (incorrectly) to EPA,[55] in support of its premise. Id.

AFPM's premise regarding the centrality of a quantified sales analysis based on consumer vehicle choice models is mistaken. Consistent with CAA section 202 (a), the MYs 2017-2025 greenhouse gas standards for light duty vehicles are premised on the standards being technically feasible at reasonable cost during the lead time provided by the rule. It is correct that, for the GHG rule's objectives to be fulfilled, consumers will have to purchase the vehicles with the added technology, and EPA has carefully considered that issue. Among the factors that lead EPA to reasonably believe that the final standards will result in vehicles that consumers will purchase are: a) the short payback period and net financial benefits to consumers due to fuel savings; b) the auto industry's support for the standards (presumably the industry would not support standards for vehicles which could not be sold); c) due to the footprint-based standards, fuel economy and CO2 emission improvements will likely include the entire range of vehicle footprints (see Preamble section II.C), meaning that there will be more efficient vehicles of every type available for purchase; d) the agencies' costing methodology includes the cost of preserving all vehicle utilities found in the present fleet (see, e.g. EPA RIA Chapter 1.3), meaning that nothing in the GHG rule prevents consumers from purchasing the type of vehicle that best satisfies their needs. None of these bases for EPA's belief that the rule establishes reasonable and feasible standards depends on a quantified sales analysis (much less use of a consumer vehicle choice model).

EPA in fact discussed U.S. vehicle sales impacts at proposal, indicating why the rule could have a positive impact on vehicle sales. 76 FR at 75150-53. This analysis likewise supports the reasonableness of the standards. A quantified sales analysis reflecting consumer choice modeling is thus not critical to EPA's analysis.

[54] These comments were addressed to NHTSA because, at the time, the D.C. Circuit had not yet ruled on industry challenges to EPA's MYs 2012-2016 light duty vehicle standards. Since the time of the comment, the D.C. Circuit rejected all challenges to that rule, as well as all challenges to EPA's endangerment finding and tailoring and timing rules. Coalition for Responsible Regulation v. EPA, no. 09-1322 (D.C. Cir. June 26, 2012). Consequently, EPA is considering these comments to be addressed to EPA as well as to NHTSA.

[55] In fact, the quoted excerpt was a statement made exclusively by NHTSA.

As discussed in Preamble Section III.H.1.a and RIA Chapter 8.1.2, EPA has done extensive research on consumer vehicle choice models. A number of such models exist, but the predictions from those models have rarely been evaluated against each other, or against actual vehicle sales. As also discussed in those sections, EPA has been developing a consumer vehicle choice model, with the goals of better understanding these models as well as the potential impacts of our rules. Those sections explain that EPA does not consider the model to be ready for use in regulatory analysis, in part because we have not had sufficient opportunity to evaluate its performance for predicting impacts on vehicle markets. We also discuss the even greater difficulties in predicting the effects of the rules on sales of advanced technology vehicles, such as electric vehicles, in Preamble Section III.H.1.b and RIA Chapter 8.1.2.7. EPA thus disagrees with American Fuels and Petroleum Manufacturers that using a vehicle choice model is necessary, because it is not yet clear whether vehicle choice models can provide reasonable predictions of the effects of this rule on vehicle sales, especially for advanced technology vehicles.

In place of using vehicle choice models, EPA has provided a robust discussion of the expected impacts of this rule on aggregate vehicle sales and on the factors that are important in determining those impacts in Preamble Section III.H.11.a and RIA Chapter 8.1. As discussed above, we believe that we can reach reasonable conclusions about the feasibility of the rule without use of a vehicle choice model. Moreover, the discussion of these issues in the final rule (see EPA RIA section 8.1.1) is very similar to the information and analysis on vehicle sales EPA presented at proposal. See preamble section III.H.11. Thus, no legitimate issues of adequacy of notice and opportunity for comment arise. In any case, this analysis corroborates the information and analysis on vehicle sales EPA presented at proposal. It has long been held that agencies' use of such corroborative information does not necessitate giving further notice and opportunity for public comment. Community Nutrition Inst. v. Block, 749 F. 2d 50, 57-58 (D.C. Cir. 1984); Chemical Mfr's Ass'n v. EPA, 870 F. 2d 177, 202 (5th Cir. 1989); Time Warner Entertainment v. FCC, 240 F. 3d 1126, 1140 (D.C. Cir. 2001); Chamber of Commerce of United States v. SEC, 443 F. 3d 890, 900-901 (D.C. Cir. 2006). Therefore, no such notice is required here.

The Energy Paradox and the Role of Fuel Economy in Consumer Vehicle Purchases

We agree with several of these commenters that, if our rule analyses are correct, standard economic theory suggests that many of these fuel-saving technologies should be adopted in the absence of the rule, and that it is puzzling that both consumer benefits and producer profits of the magnitudes we estimate are left unadopted. In practice, though, many of these technologies have existed but not been widely adopted. Preamble III.H.1.a. and RIA Section 8.1.2.6 discuss this phenomenon, commonly called the energy paradox or efficiency gap, including the range of hypotheses for its existence and the lack of definitive empirical evidence to explain the apparent gap. The hypotheses mentioned by some reviewers, including uncertainty of future benefits, loss aversion, irreversibility of investments, tradeoffs with other vehicle attributes, and the "positional" nature of vehicles, are discussed in those sections.

On the role of uncertainty of future benefits and irreversibility of investments, we note that high discount rates, attributed to investments in fuel economy being uncertain and irreversible, are a symptom of the issue rather than an explanation. The implicit discount rates found for many energy-saving technologies are far beyond any reasonable market rates. Left unexplained is why the discount rates are so high. We agree with ICCT that this rule may change the reference point consumers use in considering additional technology, and that the rule provides external benefits for energy security (discussed in Section 18.5 of this Response to Comments) and climate change (see Section 16 of this Response to Comments). We nevertheless use a different rationale (see below) for why these standards will increase consumer welfare, by distinguishing between how consumers think of fuel savings when buying a vehicle compared to their post-purchase experience.

The theory that consumers prefer other attributes to fuel economy, or are heterogeneous in their taste for other attributes, does not solve the conundrum, because it is possible to have both the existing vehicle attributes and additional fuel-saving technology. As noted above, EPA's cost estimates include costs of preserving all vehicle utilities found in the present fleet, as well as the costs of adding greenhouse gas emission control technologies. See e.g. RIA at p. 1-40.) Thus, it is incorrect for the IER to say that markets operated efficiently if consumers chose 6-cylinder minivans over more efficient 4-cylinder minivans because they preferred greater power to fuel savings; the conundrum is why 6-cylinder minivans in MY 2010 got 18-20 mpg, when it was possible for them to get higher fuel economy with no loss of power and relatively short payback periods.[56] For the same reason, it is irrelevant to compare, as NADA does, an increase in fuel economy worth $500 to a consumer with a reduction in power or safety valued at $600; a more relevant comparison for the $500 value of fuel economy is the cost of the fuel economy increase for a specified level of safety or power.

We disagree that our rule omits costs associated with limiting choice. As noted above, the standards and analysis in this rule are based on maintaining the diversity of the vehicle fleet – including all the utility of the vehicles comprising that fleet -- and improving fuel efficiency across the fleet. The commenters on this issue did not fully address the implications of the agencies' cost methodology including the costs of preserving vehicle utilities found in the existing fleet. If auto makers choose to change the range of vehicles offered, they would do so only in response to market forces. The diversity of the fleet may increase, if auto makers add alternative-fuel or advanced technology alternatives for existing vehicles to their fleets without removing the conventional versions of these vehicles from their fleets.

We do not know how positionality and the bandwagon effect will affect the markets for more fuel efficiency. If, as the Institute for Policy Integrity (IPI) suggests, greater fuel efficiency starts to confer status for consumers, then acceptance of these more efficient vehicles should be high. If less compensation is needed than the technology costs for consumers to accept these vehicles, as IPI observes, then EPA has overstated the costs to consumers. We note this possibility but are not able to estimate this effect. We also note that the footprint-based standard is aimed to minimize the incentives for automakers to change their fleet size distribution purely in response to the rule. As a result, we do not expect changes in the utility associated with the positionality of autos unless what makes a vehicle confer status changes, a trend about which we do not make predictions.

[56] Indeed, in MY 2012 it is already possible to get a 6-speed minivan rated at 22 mpg. www.fueleconomy.gov.

We note that the commenters critical of EPA's use of the market value for fuel savings in the benefit-cost analysis, including the Walton and Drake study[57] included in the NADA and Defour Group comments, do not provide comments disputing the reductions in fuel use predicted by the proposed MY2017-2025 GHG and CAFE rule, but rather argue that these fuel savings are not worth their market value to consumers. Here we find it important to distinguish between the role of fuel economy in consumers' vehicle purchase decisions and the value of fuel savings that they will receive once the new vehicles are purchased. It is possible that these amounts differ; indeed, the "energy paradox" is defined as this gap between what consumers would "rationally" consider and what they actually consider, as discussed in Preamble Section III.H.1.a. Because reducing fuel consumption saves consumers money, a "rational economic actor" would take into account the expected lifetime fuel savings that s/he would experience when deciding what vehicle to buy.[58] In reality, the role of fuel savings in consumer new vehicle purchases appears to be poorly estimated statistically. A review of the literature finds tremendous variation in the role of fuel economy in consumer purchase decisions.[59] The Defour Group is incorrect, then, when it claims that we "erroneously assume that auto buyers will be willing to pay for 100% of their projected fuel economy gains." It is also incorrect to say that we "find that U.S auto buyers will be willing to pay $6,000 per vehicle for standards achieving a combined 49.6 mpg in MY 2025." As discussed in Preamble Section III.H.11 and RIA Chapter 8.1, EPA has in the past used a five-year payback period in its vehicle sales analysis. This corresponds to 30 to 50% of the expected future fuel savings resulting from these standards.

We note an internal inconsistency in the Walton and Drake study in their arguing both that consumers are behaving fully rationally, and that consumers are not willing to pay the full lifetime value of fuel savings in their vehicle purchase decisions. Economic studies that estimate whether vehicle buyers consider fuel economy "rationally" do so by comparing the estimated willingness to pay for additional fuel economy from their studies with estimates of the *lifetime* fuel savings of vehicles.[60] These calculations of lifetime fuel savings commonly draw on the

[57] Walton, Thomas, and Dean Drake (2012). "Willingness to Pay for MY 2025 Fuel Economy Mandates: Government Estimates vs. Economic Reality." Docket EPA-HQ-OAR-2010-0799-9575 and EPA-HQ-OAR-2010-0799-9319.

[58] Even if the buyer does not expect to own the vehicle for its full lifetime, more fuel-efficient vehicles should be worth more than less fuel-efficient vehicles. Working papers by Allcott and Wozny, Busse et al., and Sallee et al. find that a large portion (arguably all) of the expected future fuel savings of used vehicles is reflected in their purchase prices. Allcott, H., and N. Wozny (2010). "Gasoline Prices, Fuel Economy, and the Energy Paradox." Center for Energy and Environmental Policy Research Working Paper 10-003, Massachusetts Institute of Technology (Docket EPA-HQ-OAR-2010-0799). Busse, M., C. Knittel, and F. Zettelmeyer (2010). Knittel, and F. Zettlemeyer. May 2011. "Pain at the Pump: The Effects of Gasoline Prices on New and Used Automobile Markets." Working paper, pp. 21-22 (Docket EPA-HQ-OAR-2010-0799); Sallee, J., S. West, and W. Fan. May 2011. "The Effect of Gasoline Prices on

agencies' estimates of expected future driving and fuel economy and use methods similar to those of the agencies. Thus, a claim that consumers are rational in their approach suggests that EPA should assume that consumers take into consideration the lifetime fuel savings of more efficient vehicles not only in its net benefits calculation, but also in any vehicle sales analysis. As discussed above and in Preamble Section III.H.1 and RIA Chapter 8.1.2.5, EPA instead finds that the value of fuel savings that consumers consider in their buying decisions is likely to differ from full lifetime fuel savings. The Walton and Drake study thus does not provide clear guidance into how to consider consumer fuel savings in either the vehicle buying decision or the benefit-cost analysis, because it asserts two claims that cannot both be true.

If there are two values for fuel economy – the expected future fuel savings over the vehicle's lifetime, and the amount of fuel savings that consumers consider when buying a vehicle – which value should be used in the benefit-cost analysis? Here, commenters differ, with ICCT, Sierra Club et al., and UCS arguing for use of the expected value of future fuel savings, using standard economic parameters including the discount rate, while CEI, the Defour Group, IER, and NADA argue that this approach omits hidden costs or overstates benefits. IPI argues that EPA's cost estimates are likely to overstate costs, but it does not speak specifically to the value of fuel savings in the benefit-cost analysis.

EPA's principle for the benefit-cost analysis is to measure the actual expected impacts of the policy and use standard economic parameters (including discount rates) to measure their monetary value, because those are intended to measure the impacts projected to occur. Using only the amount of fuel savings that consumers think about when buying vehicles is inappropriate because it may not reflect actual fuel expenditure changes due to the rule. Consumers are under no obligation to think "rationally" about fuel savings when buying vehicles; indeed, they are not obligated to consider fuel economy at all. Similar principles apply with discount rates: 3 and 7 percent discount rates represent the opportunity cost of capital to consumers and producers in practice. As mentioned above, very high estimated discount rates for fuel savings in consumer vehicle purchases are a symptom rather than an explanation of the energy paradox. If the rule reduces the fuel consumption of the vehicles that consumers purchase, though, EPA estimates the impacts expected of the rule based on the market opportunity costs.

We note that the Walton and Drake study bases its argument that consumers are willing to pay for 25 percent of fuel savings on a study of technology costs (Laboratory for Energy and the Environment, *On the Road in 2035: Reducing Transportation's Petroleum Consumption and GHG Emissions*, Massachusetts Institute of Technology, July 2008, pp. 61, 156-157). EPA considers using technology costs an indirect approach at best to estimating consumer response, and considers it more appropriate to use the substantial literature (see Greene, footnote 59) specifically looking at consumer decisions on fuel economy. We thus find the 25 percent figure to be derived from a source less relevant to the analysis than those that EPA uses. Walton and Drake, in discussing Greene, state that "The most significant and widespread error – the very same error that is inherent to the agencies' model of consumer choice – is that most of the studies

the Demand for Fuel Economy in Used Vehicles: Empirical Evidence and Policy Implications", Working paper, pp. 12-17 (Docket EPA-HQ-OAR-2010-0799).

and surveys fail to account for tradeoffs between fuel economy and other vehicle attributes of value to consumers – what the studies call 'fixed effects.'"[61] This statement is incorrect. In the studies that Greene reviews, virtually all of them account for other vehicle attributes. As noted above, the agencies' costing methodology also prices in preservation of existing vehicle utilities. We appreciate the effort in Walton and Drake to identify reasons that the existing studies of the willingness to pay for fuel economy find varying results, although they do not provide a recommendation resulting from this critique. We agree that a number of statistical issues arise in estimating this parameter. This problem may not yet be solved. As a result, EPA has approached the use of consumer vehicle choice models cautiously.

We agree that fuel economy changes are likely to influence consumers' vehicle purchase decisions. We discuss the effects of this rule on vehicle sales in Preamble Section III.H.11 and RIA Chapter 8.1.

On the cost side, we base our estimates on the best available engineering data, as discussed in RIA Chapter 5. IER does not identify hidden costs of the rule; rather, it asserts that they must exist. In Preamble III.H.1.a., EPA explains that holding all vehicle attributes other than fuel economy and cost constant allows for direct measure of the welfare costs of the rule. If a vehicle buyer were given an amount equal to the price increase resulting from this rule, she could not be worse off than in the absence of the rule, because she would be able to buy her originally chosen vehicle (though with improved fuel economy). If the vehicle price increases by the same amount as technology cost, as would be expected in a perfectly competitive market,[62] giving her the technology cost fully compensates her for any losses that the rule might impose; it is thus a measure of the full cost of the rule. The technology cost may actually overstate the cost to her, because she may choose to buy a different vehicle and save some of the compensation money for other purposes. IPI argues as well that the technology costs may overstate the rule costs, if the chosen vehicle ends up conferring greater status that makes it more attractive and thus needing less compensation. EPA agrees that this is a possible reason that lower compensation might be required than the technology costs, but we do not have a basis to say that more efficient vehicles will confer greater status in the future.

The Defour Group (Walton and Drake) cites the National Research Council (NRC) for its claim that our cost estimates for this rule are too low. We note that the NRC cost estimates are "for technologies that are commercially available and can be implemented within 5 years."[63] We thus consider the NRC report an inappropriate source for adjusting the cost estimates of this rule, because the cost estimates are based on a much shorter lead time than is available under this rule. Because we consider both the willingness to pay (see above) and cost adjustments used in the

[61] The reference to fixed effects is puzzling: fixed effects are not tradeoffs, but rather dummy variables used in regressions to account for discrete characteristics, such as vehicle type.

[62] The auto market is not generally assumed to be perfectly competitive. In general, though, cost pass-through is commonly less in imperfectly competitive markets. See discussion in Preamble Section III.H.11.a, and Gron, Ann, and Deborah Swenson, 2000. "Cost Pass-Through in the U.S. Automobile Market," Review of Economics and Statistics 82: 316-324 (Docket EPA-HQ-OAR-2010-0799-0675), who found significantly less than full-cost pass-through in the auto industry.

[63] National Research Council, 2011. Assessment of Fuel Economy Technologies for Light-Duty Vehicles. Washington, D.C.: National Academies Press, p. S-1 (Docket EPA-HQ-OAR-2010-0799).

Walton and Drake study to be based on an inappropriate sources, we consider their net benefits estimate of the rule of -$1,400 to -$2,900 to be fatally flawed. Their adjustment to the discount rate is discussed above. Loan rates are discussed in TSD Chapter 4.2.13. Rebound rate is discussed in Section 15.3.3 of this Response to Comments and TSD Chapter 4.2.5. Section 18.7 discusses the Defour and EIA estimates of the effects of this rule on vehicle sales. Preamble Section III.H.11.a and Section 18.7 of this Response to Comments address the comments on vehicle sales. Preamble Section III.H.12 and Section 18.8 of this Response to Comments address the comments on employment. Preamble Section III.H.11.b and Section 18.7.1 of this Response to Comments address the comment on whether these standards are regressive.

Whether these technologies would be adopted in the absence of the rule is discussed in Preamble Section III.D.1 and in Section 12.1 of this Response to Comments. Walton and Drake cite two studies that predict achievement of average fuel economy levels in future years below the fuel economy levels of the rulemaking in the absence of regulation. EPA uses as its baseline a 2008 based model fleet[64] projected out to MY 2025 and meeting the MY 2016 GHG standards in the absence of new standards; there are strong reasons for doing so, as explained in preamble section III.D.1.a. We agree that private market interactions may not provide the level of fuel economy that would occur with the rulemaking. This lack of provision of fuel economy, with its concomitant impacts on greenhouse gas emissions, is a motivation for the rule.

Comments from the National Automobile Dealers Association state that consumers consider at most five years of fuel savings in their vehicle purchase decisions. As discussed in Preamble Section III.H.5, the payback period for the new technologies EPA projects to be needed in MY 2025 is 3.2-3.4 years (see RIA Chapter 5.5).

The assertion from the IER that the rule will drive an estimated 7 million drivers out of the car market is erroneous in that it does not have any relationship to new vehicle purchasers or to new vehicle sales. The analysis that produced this value is not based on households in the market for new vehicles and thus includes many households who will not face direct effects of this rule. This issue is discussed in Preamble Section III.H.11.b. and in Section 18.7.1 of this Response to Comments.

We agree that consumers can and do respond more quickly than automakers to changes in fuel prices. Consumers can easily decide to buy different vehicles, but automakers need lead times to redesign vehicles in response to market signals. Because the rule allows for great diversity in the kinds of vehicles available to consumers – indeed, as discussed in Preamble III.H.1.a, it may increase choices to consumers – consumers will continue to be able to choose among a variety of vehicles, with improved fuel economy expected to be available in virtually all vehicle classes.

Walton and Drake cite criticism of the survey results presented by Consumer Reports (CR). The fundamental question is whether survey results are informative sources for public policy. EPA's analysis of the net benefits of the rule does not rely on survey results of the popularity of fuel economy standards. We note, though, that one criticism raised is that the CR

[64] In an alternative analysis, EPA uses a 2010 based model fleet. See RIA chapter 10.

polling does not ask questions in terms of tradeoffs. In fact, one CR question asked whether the respondent agreed or disagreed with the statement, "I am willing to pay extra for a more fuel efficient vehicle if I can recover the additional cost through lower fuel costs within 5 years," which identifies the opportunity costs. A total of 83 percent agreed, with 48 percent strongly agreeing.[65]

Walton and Drake note that, when presented with the choice of using additional technology to add fuel economy to an existing vehicle or making that existing vehicle larger with constant fuel economy, people have chosen the larger vehicle. Their examples suggest that consumers are likely to pursue additional fuel economy in various market segments: the larger vehicles, after all, are more efficient than without the added technology. Because the rule seeks to encourage additional fuel economy in all vehicle segments, the commenter's argument here appears to support the structure of the rule. The agencies seek to maintain the range of vehicle choices currently available to consumers, but with additional fuel savings across the entire range of vehicle footprints (i.e., to all market segments. For any level of fuel economy, additional power or other vehicle characteristics can be achieved by adding more technology. The rule does not restrict these possibilities.

The Walton and Drake study discusses several papers in seeking to bolster its argument that fuel economy standards impose significant welfare losses. These studies all use older estimates of technology and fuel costs than those used in this rule. Several of them focus on the use of a gasoline tax compared to fuel economy standards. EPA does not tax gasoline. In economic theory, a gasoline tax may have a number of advantages relative to standards, as these papers discuss. Because EPA does not tax gasoline, though, the relative merits of GHG standards versus a tax are not relevant to the MYs 2017-2025 standards. We note, though, that the studies cited[66] note reasons that increased fuel economy standards may be desirable policies in the absence of gasoline taxes. Fischer et al. note that regulation may promote the development of fuel-saving technologies with significant social returns (p. 25). The Congressional Budget Office study states, "If [consumers do not receive adequate information about the fuel savings offered by different vehicles and do not correctly value those savings], then the advantages of an increase in CAFE standards could be greater than assumed here" (p. 4). Parry et al. state that "using standards to cut fuel use by 5 percent under a standard value for CO_2 damages is warranted only if consumers fail to internalize 44 percent of the savings from higher fuel economy" (p. 3). Five years of fuel savings for MY 2025 vehicles, the amount NADA states as an upper limit on how much consumers consider in their vehicle purchases, is approximately 30-50% percent (depending on the discount rate) of the lifetime fuel savings; in other words, under that assumption, consumers fail to consider 50–70% of fuel savings. Using a 5-year or less payback period for vehicle sales purchases, as NADA suggests, may thus mean consumers are

[65] Consumer Reports National Research Center. November 2011. "Consumer Reports Fuel Economy Poll." CU Project #2012.51, p. 22 (Docket EPA-HQ-OAR-2010-0799).

likely to "fail to internalize [more than] 44 percent of the savings from fuel economy" – the circumstance under which Parry et al. state that such standards are warranted.

Miscellaneous and Addressed Elsewhere

Fuel Savings to Consumers and Energy Shocks

EPA agrees with commenters that the rule will provide substantial fuel savings for consumers and will reduce vulnerability to shocks in international oil prices. The energy security impacts of the rule are discussed in Preamble Section III.H.8 and in Section 18.5 of this Response to Comments.

Impacts of the Rule on Employment

The impacts of this rule on employment in the U.S. are discussed in Preamble Section III.H.12 and RIA Chapter 8.2. We agree that developing and implementing the new technologies will require additional employment. As discussed in Preamble III.H.11 and III.H.12, employment would increase even more if there are increases in vehicle sales (though we do not quantify vehicle sales impacts). We are not able to predict how employment will change due to changing labor intensity of the new technologies; our analysis of employment in the auto sector is thus partial. The total effects of this rule on employment in the U.S. overall are even more difficult to predict. The effect of a rule on total employment in the U.S. depends heavily on the overall macroeconomic conditions of the country. When the economy is at or near full employment, the primary effect of this rule will be to reallocate workers among sectors, rather than to create or reduce employment; when the economy has substantial unemployment, the rule may have an impact on total employment, through its effects on the auto market, on auto suppliers and other related sectors, on fuel suppliers, and on consumer expenditure patterns.

Continuing Federal Programs for Retooling in the Auto Industry

Providing continuing federal programs to support retooling in the auto industry is beyond the scope of EPA authority.

Multiple measures of MPG

We do not understand Edmunds.com's comment on the "multiple measures of MPG that have emerged from the rule-making process." This rule does not change the information provided to consumers about mpg.

Vehicle Electrification Impacts [EPA-HQ-OAR-2010-0799-9485-A1, p.6]

Recharging during peak hours could increase peak electricity demand. For example, this could happen if many consumers in an area recharge their plug-in vehicle simultaneously in the early evening of a weekday after returning home from work. It could be necessary to restrict recharging to late-night off-peak hours and this could adversely impact the market penetration of EVs. These potential impacts must be analyzed by the agency and presented for comment. Moreover, if electrification requires additional fossil fuel-generated electricity (whether peak or off-peak), then these technologies will not deliver substantial carbon reductions. The proposed rule does not properly analyze these potential impacts, making it impossible to provide meaningful comment upon the agency's estimates of GHG reductions. [EPA-HQ-OAR-2010-0799-9485-A1, p.6]

The agency states that "The analysis in this [EPA/NHTSA] proposal assumes that the consumer market is sufficient to absorb the expected number of EVs without subsidies." 76 Federal Register 75118 This assumption is unrealistic. [EPA-HQ-OAR-2010-0799-9485-A1, p.6]

The National Research Council (NRC) analyzed PHEVs and concluded the following: [EPA-HQ-OAR-2010-0799-9485-A1, p.6]

PHEVs will recoup some of their incremental cost, because a mile driven on electricity will be cheaper than a mile on gasoline, but it is likely to be several decades before lifetime fuel savings start to balance the higher first cost of the vehicles. Subsidies of tens to hundreds of billions of dollars will be needed for the transition to cost-effectiveness. Higher oil prices or rapid reductions in battery costs could reduce the time and subsidies required to attain cost-effectiveness.[11] [EPA-HQ-OAR-2010-0799-9485-A1, p.6]

This NRC committee's realistic assessment is ignored in this rulemaking. The agency must consider these real world implications in assessing the costs and benefits of this rulemaking. [EPA-HQ-OAR-2010-0799-9485-A1, p.7]

11 - “Transitions to Alternative transportation Technologies—Plug-In Hybrid Electric Vehicles, “ 2010, p. 33

Organization: Defour Group LLC

The government and automotive industry are engaged in an ambitious program to raise the fuel economy of today’s new vehicle fleet to 49.6 mpg by 2025. This program is primarily embodied in two rulemakings: one for model years 2012 – 2016 and the rulemaking covered in this NPRM from model years 2017 – 2025. Taken together, these rulemakings represent what may well be the most expensive government-mandated program in automotive history. As such, it is essential that the cost of this program be estimated using the best information available. Unfortunately, in both this rulemaking and the previous one, the agencies involved have deviated from using mainstream economic assumptions to estimate costs in favor of new and unorthodox methodologies. [EPA-HQ-OAR-2010-0799-9319-A1, p. i]

Attached to this letter and incorporated in our official comments by reference is a study by Dr. Thomas Walton detailing our concerns with the economic assumptions made in this rulemaking. Dr. Walton is uniquely qualified to perform this study. Academically, he holds a BA in Economics from the University of Missouri, Columbia and a Ph.D. in Economics from the University of California at Los Angeles. He has extensive experience within government, having served as Special Advisor for Regulatory Affairs, United States Federal Trade Commission and is a former Vice Chair of the Business Research Advisory Council to the United States Bureau of Labor Statistics. He has 24 years of experience within the automotive industry as Director of Economic Policy Analysis for General Motors. [EPA-HQ-OAR-2010-0799-9319-A1, p. i]

It is more important now than ever that government agencies use the best accounting procedures to estimate costs. Historically, government cost estimates were one of many independent cost estimates: today, the government is either directly or indirectly involved in every major effort to estimate the cost of this rulemaking. Government cost estimates are now used both within and outside of government to guide regulatory and investment decisions. [EPA-HQ-OAR-2010-0799-9319-A1, p. ii]

If the government estimates of costs are too low, then the automotive industry may well find itself in the position of producing vehicles that consumers are unwilling to purchase. This could have profound impacts on the U.S. economy. Preliminary analysis by the Defour Group of the cost of this program indicate that consumer demand for fuel economy, which is primarily driven by fuel prices, may wane well before the 2017 model year. If our conclusions are correct, the automotive industry could find that the market for more fuel efficient vehicles will disappear before these standards are due to be implemented. Without additional policies in place to enhance consumer willingness to pay, sales and employment will be adversely impacted. [EPA-HQ-OAR-2010-0799-9319-A1, p. ii]

In conclusion, we urge the agencies to re-estimate the costs of this program using the most mainstream and conservative accounting methodology available. [EPA-HQ-OAR-2010-0799-9319-A1, p. ii]

Organization: Growth Energy

Attachment 1 [pp. 7-15 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] to this letter explains why Growth Energy believes that the analyses supporting the Joint NPRM's electric vehicle cost estimates are not reliable. Under the applicable Executive Orders governing cost-benefit analyses, we believe that the Agencies need to reconsider and revise the current cost-benefit analyses. In addition, given the significant under-estimation of electric vehicle costs in the Joint NPRM's current analysis, Growth Energy questions whether EPA and NHTSA can properly determine that proposed standards are economically practicable and take proper account of the state of technology, as required by the governing statutes. If EPA and NHTSA believe that those methods of estimating the market impacts of regulatory programs that rely upon or require electric vehicles are inadequate or unnecessary, the Agencies should explain why. [EPA-HQ-OAR-2010-0799-9505-A1, p. 2]

Organization: Haroldson, C.

The proposed standards will either make all new vehicles too expensive to purchase or the vehicles will necessarily become too small to be safe to drive. Instead, let's increase our domestic drilling for oil and reduce our dependence on foreign oil. [EPA-HQ-OAR-2010-0799-11137-A1, p. 1]

Organization: International Council on Clean Transportation (ICCT)

5. While the 2011 NAS Report was well done, it specifically stated that only current and near term technologies and costs were analyzed. Thus, the sensitivity analysis using the 2011 NAS Report benefits and costs is inappropriate and should be removed from the Final Rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

5) Sensitivity Case using the 2011 NAS Report Benefits and Costs

NHTSA included a sensitivity case using costs and effectiveness from the 2011 NAS Report. This sensitivity run increases vehicle cost by 40 to 50 percent, adding about $800 to the per vehicle cost. [EPA-HQ-OAR-2010-0799-9512-A1, p. 17]

It is inappropriate to use the 2011 NAS Report technologies and technology benefits and costs for 2017 to 2025 efficiency regulations. While the 2011 NAS Report is an excellent report, it makes several explicit statements constraining the applicability of its technology and cost data to the very near term, e.g.: [EPA-HQ-OAR-2010-0799-9512-A1, p. 17]

'Tables S-1 and S-2 show the committee's estimates of fuel consumption benefits and costs for technologies that are commercially available and can be implemented within 5 years. The cost estimates represent estimates for the current (2009/2010) time period to about 5 years in the future.' [NA5 report page S-1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 17]

'Again, except where indicated otherwise, the cost estimates provided are based on current conditions and do not attempt to estimate economic conditions and hence predict prices 5, 10, or 15 years into the future.' [NA5 report page S-6] [EPA-HQ-OAR-2010-0799-9512-A1, p. 17]

'The cost estimates represent estimates for the current (2009/2010) time period to about 5 years in the future,' [NAS report page 9-8] [EPA-HQ-OAR-2010-0799-9512-A1, p. 17]

While sensitivity analyses can illuminate the impacts of important uncertainties, in this case the 2011 NAS Report expressly states that it is not applicable to the period considered by the proposed rule. In addition, as noted in our comments in section 1, above, the technology benefit and costs in the proposed rule are conservative and overstate the costs of the rule, not understate them. [EPA-HQ-OAR-2010-0799-9512-A1, p. 18]

Organization: Jackson, F.W.

'Faulty' analyses used to create more favorable values: 1. Points to limited areas to make a point without also pointing out complete impact, Le., at National level, 2. Poor competition selected to compare against instead of showing all possibilities and comparing against the best, 3. Using a reference case while 'flexibility' in the law allows far more expensive and less beneficial cases to be selected by profit motivated manufacturers. [EPA-HQ-OAR-2010-0799-8041-A1, p. 1]

So starting with EPA's vehicle lifetime average mileage of 161,851 (cars) & 190,030 (trucks & MPVs) miles and 201635.5 mpgge vs. 2025 54.5 mpgge EPA proposal mix, I calc (assuming gasoline pre taxes at $3.00 per gallon fuel only at pump discounted 20% because it is spread out over many years to reflect the cost as at 2025 to with interest pay for the fuel) fuel savings at $4,333 less $ 1946 added vehicle cost reduces savings to $ 2,387 over the vehicles lifetime. Include taxes based on purchase price and claimed savings are further reduced. And this is against the 2016 35.5 mpgge, i.e., not the best competition; improve the competition, e.g. My Max technologies ICEs vs. EPA Proposal fleet I calc Max ICEs at $4,785 ($ 7,178 with assumed pass throughs) less over the vehicle lifetime. And vs. 36 Bgal corn ethanol 2025 proposal fleet $ 8,004 and $ 12,006 (with pass throughs) less. [EPA-HQ-OAR-2010-0799-8041-A1, p. 2]

6. to account for Business/Govt pass throughs, i.e., inflation/taxes (very significant, albeit not included in most of my data), e.g., assuming for every consumer vehicle lifetime cost business+Govt also have some added cost then the delta cost (all factors included) would be an increase to consumers/taxpayers. For my analyses I assumed a 50 % pass throughs increase/decrease. [EPA-HQ-OAR-2010-0799-8041-A1, p. 2]

Taking all the above into effect and using ref 2 (tables 3.8-23 thru 25) proposal fleet here is what I calc for the 2025 proposal fleet VS. 2025 54.5 mpgge fleet:

EPA proposed fleet vs. 2025 new fleet (54.5 ave mpgge), both using gasoline liquid fuel; system lifetime cost up $174 ($ 261 with my assumed Govt/Business pass throughs), lifetime gCO_2/mile up 14 g/mile. The EPA Proposal fleet has 2.8 % BEVs and 0 % PHEVs. [EPA-HQ-OAR-2010-0799-8041-A1, p. 3]

Conclusion: when all factors fully and properly counted my calc indicates 2025 new fleet lifetime cost due to all Govt actions up, i.e., not down as shown in articles & references! [EPA-HQ-OAR-2010-0799-8041-A1, p. 3]

So while EPA picks and chooses assumptions & methods & credits & multipliers to arrive at 'make believe' savings my analyses yield: the cost to consumers & taxpayers is exceedingly high. And this is when EPA's proposed mix is used and as another 'mix' with increased % of more expensive Plug-ins, e.g., see EPRI mix, that allow more 'guzzlers' I would expect the numbers to get even worse! Also while EPA factors in a strong 2025 EV learning (which I have not factored in), it is also true EPA proposed 2025 fleet has very few Plug-ins so I would not expect a significant cost 'swing' from electrical equipment 'learning' with only minor plug-in penetration. [EPA-HQ-OAR-2010-0799-8041-A1, p. 3]

Summary table of my evaluated 'mix's; 2025 57.4 % cars, 42.6 % Trucks & MPVs: [See table on pp. 3-4 of Docket number EPA-HQ-OAR-2010-0799-8041-A1] [EPA-HQ-OAR-2010-0799-8041-A1, p. 3]

Note: above numbers for EPA & EPRI vehicles include allowed increase in 'guzzlers' that I believe should be added to numbers for allowing them. Other above table numbers do not include 'guzzler' impact as while Govt plan is to allow them, I would not plan to allow them. [EPA-HQ-OAR-2010-0799-8041-A1, p. 4]

Bundling obscures individual vehicle impacts: pretty clear, at National level, plug-ins exceedingly more expensive than ICEs and HEVs; they are also less efficient in fossil BTUs and produce far more National CO_2! Expect EPA knows this, hence very limited penetration in EPA defined 2025 proposal fleet (zero penetration in my Mid and Max). E.g, if in the EPA proposal case with the 36 billion gallons of corn ethanol the HEVs were PHEVs instead, I calc, with assumed pass throughs, the consumer & taxpayer added cost per vehicle at $ 11,745. [EPA-HQ-OAR-2010-0799-8041-A1, p. 4]

Question: with such poor performance and minor PHEV & BEV penetration EPA proposal & reference cases why is Govt promoting and subsidizing plug-ins?? Could it be the only way to get Industry to go along with 54.5 mpgge target is if they have a path to continue highly profitable 'guzzlers'; e.g., if 54.5 average gge is target and for every 101 mpgge vehicle BEV they are able to build 1.5 23.5 mpgge 'guzzlers'. Bummer, Govt borrows money to subsidize BEVs so industry can build 'guzzlers'; taxes & inflation & deficit all up as is system CO_2 and fossil fuel btus! Looks more to me like a 'guzzler protection ace than reducing overall cost, oil and CO_2 greenhouse gas. More specifically, a 101 mpg BEV may not reduce gasoline demand because it could allow 1.5 23.6 mpgg vehicles instead of 1.5 54.5 mpgg, or 1.5 23.6 mpgg vehicles requires 6.36 gg for 150 miles traveled vs. 2.75 gg for 1.554.5 mpgg, a net increase of 3.61 gg which when I credit to the BEV (for allowing the 'guzzlers') I calc reality a 101 mpgge BEV could be 29.4 mpgge when all it's possible National results duly credited! And if Govt allows a 2 multiplier the mpgge 29.4 would drop to 17.2 mpgge Bundling a few BEVs &

'guzzlers' with other vehicles can obscure impact and changing the mix of other vehicles from ICEs to HEVs and/or improved technologies can obscure totally, even show improvement! [EPA-HQ-OAR-2010-0799-8041-A1, p. 4]

Additional relevant comments: [EPA-HQ-OAR-2010-0799-8041-A1, p. 6]

Nation needs much more efficient for Nation energy and money and CO_2 products. I also recognize car companies are a business and have to watch their bottom lines; and I understand their desire to minimize investment, minimize risk and maximize return and early. So to me the answer is for Govt to get involved big time (a Manhattan Project) so development is supported, risk is protected and prices held down by Govt support. After all how do we get the tanks and planes the Nation's military needs, the Govt funds the development and risk and buys the products. Why not use same approach with some mods, e.g., for all Govt vehicle, light and heavy duty, procurements spec vehicles at what the Nation needs and a subsidy for non Govt vehicles based on actual gasoline/Diesel powered real mpg, i.e., higher mpg, higher subsidy, e.g., for Light Duty vehicles costing less than 20 $K then sliding scale to 30$k and over $ 30 $K they should be expected to 'pay their own way' to get the vehicles the Nation needs? As a discussion starting point for Light Duty vehicles I'd suggest Govt offer a $ 250 subsidy for each non Govt Light Duty system mpgge a vehicle gets above that years new vehicle target mpg (I'd even consider adjusting the subsidy up or down based on driver's historical miles per year); and with 2013 target set at 33 mpgge, 2015 at 38, 2018 at 50, 2020 and after at 75mpgge and by 2020 project future dates for more than 75 mpgge (system). The subsidies to be paid for as much as practical as used, i.e., at purchase not a delayed tax rebate, with 'real' today's money; and to benefit from Govt program businesses cannot also engage in counterproductive actions like promoting 'guzzlers' because they are more profitable per vehicle produced and businesses have to show, commit to and get approval by Govt a plan (research, development and production) with measurable by Govt 'benchmarks' and progress reviews. And Govt doesn't have to give money away, i.e., any Govt monies can be repayable loans or stock of equivalent value. And if Congress fails to provide necessary Law for private sector make sure info is clearly articulated, and current Law permitting, consider Govt to sell Govt Spec vehicles to Public and/or Govt buy excess vehicles for resale to Public or Govt require mfgrs to offer Govt equivalent vehicles to Public or update Govt fleet sooner so more resale vehicles are offered to Public. And the Press needs to do and report full & accurate information based on thorough investigative reporting by qualified & objective individuals. [EPA-HQ-OAR-2010-0799-8041-A1, pp. 6-7]

This leaves where does the money come from, how about 'scooping' up other monies of lesser or no equivalent value to Nation's wellbeing: No corn ethanol subsidies and no ethanol mandates, no plug-in subsidies, bump up the gas tax, 'guzzler' tax for individual vehicles not meeting target (e.g., $ 250, or more, for each total to Nation "fossil fuel' gpmgge over target), reduce vehicle emissions testing to minimum based on actual statistical need for most cost-effective necessary plan, no NASA Mars mission (this money and the technical talent can do far more for solving Nation's problems than an interesting venture that doesn't improve citizens lifestyles here on earth), 'capture' some of consumers savings (with hard facts to show savings; e.g., savings per vehicle mile with my Mid or Max technology plan vs. Govt & lndustry E36 'smoke and mirrors' 54.5 mpgg plan and longer lasting vehicles to lower purchase cents/mile); Govt & lndustry plan cost per mile up big time when 'honest' analyses used. Put Nation's resources to use where it benefits the Nation & all citizens the most. [EPA-HQ-OAR-2010-0799-8041-A1, p. 7]

2. EPA Draft Regulatory Impact Analysis 'Proposed Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards' EPA-420-D-11-004 November 2011

Organization: Knapp, B.

With our economy remaining is a severe slump, this is no time to increase the cost of a vehicle. [EPA-HQ-OAR-2010-0799-8255-A1, p. 1]

Organization: Lipetzky, P.

This will only lead to higher fuel and vehicle cost and in the end will amount to the same. [EPA-HQ-OAR-2010-0799-8184-A1, p. 1]

Organization: Marshall, C.

Historically, there have been two topics of pushback by those who would oppose this standard. [EPA-HQ-OAR-2010-0799-5917-A2, p. 1]

Regarding increased costs, my hunch is that the greater than $2K in the added cost of new cars is a worst-case analysis. As a contractor for both EPA and OSHA in rulemaking matters, there were reasons that cost estimates for compliance tended to be higher than what happened in reality under a regulation. We couldn’t easily take into account control cost savings that were expected because of innovation. I suggest putting further thought into finding methods of affordability for people to pay for the incremental capital costs of vehicles. Perhaps an affordability improvement mechanism could be implemented after the regulatory review is performed in 2021 (or 2019) and might depend on revised costs at that time taking into account improvements in powertrain technologies and advances in carbon and composite materials for replacing steel. [EPA-HQ-OAR-2010-0799-5917-A2, p. 1]

Organization: National Association of Clean Air Agencies (NACAA)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 41.]

Measures that could lead to greater penetration to vehicles earlier in the programs could bring down vehicle cost.

Organization: National Automobile Dealers Association (NADA)

NADA is also urging NHTSA and EPA to conduct and include in its final rule a worse case cost scenario reflecting a $12,349 average per vehicle cost to comply with the proposed mandate for MY 2025. This suggestion is being made to reflect the fact NHTSA and EPA are engaged in a rulemaking earlier than necessary aimed at applying mandates further out than necessary where many dynamic and hard to forecast variables are involved. These factors include conventional fuel costs, alternate fuel availability and costs, compliance technologies and their costs, interest rates, the general economy, etc. [EPA-HQ-OAR-2010-0799-9575-A1, p. 5]

If NHTSA and EPA were practiced at setting far-in-the-future standards based on hard to forecast variables, NADA would not be concerned. However, both agencies have historically set new CAFE and emissions mandates consistent with specific statutory time frames and in conformance with the statutory requirements for lead time and duration discussed in detail below. That is, with one major exception. [EPA-HQ-OAR-2010-0799-9575-A1, p. 5]

In the mid to late 1990s, EPA began the process of setting new tailpipe standards for on-road commercial trucks and engines, culminating in rules issued in 1997, 2000, and 2001 for MYs 2004-2010. Largely due to EPA's failure to accurately forecast compliance technologies and costs far into the future, these rules underestimated compliance costs by some 2-5 times what actually were incurred. In addition to detailing this forecasting failure, the attached look-back paper reviews some of the devastating impacts these truck mandates generally had on the new truck marketplace, and in particular on new truck customers, on truck and engine manufacturers and suppliers, and on dealers. [EPA-HQ-OAR-2010-0799-9575-A1, p. 5]

In summary, given this recent and devastating example of what can happened when mandates are set too far into the future, the final rule should include a worse case MY 2025 cost scenario of $12,349 per vehicle, which approximates roughly 4.2 times the $2,936 NHTSA cost estimate discussed above. [EPA-HQ-OAR-2010-0799-9575-A1, p. 5]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 69-71.]

And, third, the proposal dramatically underestimates cost impacts on new vehicles.

To work, fuel economy rules must require improvements that are affordable. Why? Because you can mandate what the manufacturers must build but you can't dictate what consumers will buy. If our customers do not purchase these products, we all lose.

Not that we're not suggesting the proposal is technologically infeasible. For example, my manufacturer Ford Motor Company has or can develop the engineering and manufacturing expertise necessary to comply, but at what costs. Our concern is for our customers and the prices that they will face.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 55-56.]

The total cost of the administration's three fuel economy rules is approximately 210 billion. To put this figure into perspective, that's more than twice the amount of total government aid to the auto industry in 2009 and '10. The $157 billion proposal is by far the costliest auto regulation ever, and comes on the heels of the 2010 record-setting $51 billion fuel economy rule. I always have to remember that a billion is a thousand million.

And of course, these new regulatory costs will be borne by customers. And they exclude the billions of dollars in other new regulations you and California regulators have planned. No one in the government seems to be looking at the bigger picture of what all this regulatory activity is doing to the affordability for the average American.

Organization: Natural Resources Defense Council (NRDC)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 199.]

Under the rule, the U.S. would invest about $300 billion in new vehicle technologies bringing cleaner, more fuel-efficient cars and trucks to the marketplace.

Organization: Pennsylvania Department of Environmental Protection

The Agencies Should Evaluate Fuel Costs, Availability, and Impacts of Higher Octane Gasoline.

Costs and Life-Cycle Costs. The extra cost for higher octane gasoline should be used to estimate the costs for this rulemaking. It appears that EPA used the cost of regular gasoline in their RIA (p. 3-15) for this rulemaking. Also, the increased performance that EPA is expecting to achieve from turbocharging and other technologies seems to be based on the vehicle using higher octane fuel. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

All potential costs and environmental impacts must be considered such as supply chain burdens, transportation availability, market transition costs, capital investments for higher octane gasoline and/or for production of additional ethanol or alkylates and the possibility of shortages in some areas of the country. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Nevertheless, we are concerned that much of the nation's gasoline supply will require higher octane levels to meet these GHG standards and that EPA has not considered the implications. EPA either needs to address (in the face of manufacturers' current recommendations) why more mid-grade gasoline will not be needed to run turbocharged, high-compression engines or the implications of greater use of higher octane gasoline should be fully evaluated. [EPA-HQ-OAR-2010-0799-7821-A1, p. 5]

Organization: Ross, D.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 242.]

Anticipated net savings could be much greater if the real price of gasoline rises between now and 2025 as seems all too plausible given rising demand for fossil fuels in low income countries, political and economic unrest in oil-rich regions, and the eventual recognition by the public and political elites of the dire consequences of human-influenced climate change.

Organization: Smith, Frank Houston

State of current ICE technology and Comparative Costs

This clearly demonstrates that the worst case average 'diesel vehicle price premium' is less than $1,800 for European small displacement diesels ... offering a minimum gain in fuel economy of 50% [18 mpg(US)]. [NHTSA-2010-0131-0240-A2, p.2]

For example the new Chevrolet New MY 2012 Aveo 1.3VCDi eco (95PS) (US Sonic?), and Kia 5 door '1 Air' 1.1 CRDi 74bhp ISG Rio are NEDC rated above 78 mpg(Imperial) [≈65 mpg(US)] combined. After excluding value add (VAT) and other EU taxes, both should have list export prices below $15,000 USD including the less than a $1,500 premium for 62% and 40% fuel economy improvements over their respective significantly less fuel frugal gasoline counterparts rated 48 and 56 mpg(Imp) combined, again NEDC. [NHTSA-2010-0131-0240-A2, p.2]

The 1.6 TDCi 95 Edge Econetic Fiesta Titanium offers similar fuel economies for about $18.9k and only roughly $1.3K more than its' 48.7 mpg(Imperial) [≈41 mpg(US)] combined 1.6 Liter gasoline counterpart. The 1.6 L diesel Edge Econetic should export for roughly $16.9K with a possibility of 1.5 gallons/100 miles. [NHTSA-2010-0131-0240-A2, p.3]

In fact there is an 8.5K pound GVW diesel Sprinter 2500 planned for the US in 2013 expected to provide an average 30 mpg(US) in mixed driving… better than the base Sonic. Size/weight may not be the major issues. [NHTSA-2010-0131-0240-A2, p.3]

This leads to the question of which models might already have been (or might be) seen on US highways and what is the best fuel economy they currently offer outside the US results in the following analysis. [NHTSA-2010-0131-0240-A2, p.3] [[See Tables 2 &3 in Docket Number NHTSA-2010-0131-0240-A2, pp.3-4]]

Organization: Tarazevich, Yegor

Introduce gas tax that will gradually grow to $2 per gallon by 2025 to reduce air pollution and oil dependence. Otherwise with high MPG cars will just drive more. With high MPG cars people will still pay less for car ownership than they do today. [NHTSA-2010-0131-0199, p.1]

Organization: Van Voorhies, M.

It is lunacy to think that driving up the cost of cars and trucks is worth the time, effort and cost!! [EPA-HQ-OAR-2010-0799-1629-A1, p. 1]

Organization: Volkswagen Group of America

The 2012-2016 rulemaking will, according to the agencies, cost automakers more than $52 billion – a higher cost than any rulemaking has ever imposed on any regulated industry. Volkswagen continues to make significant investments to both improve our conventional technologies and introduce advanced concepts into the US market. We have crafted a product portfolio that will be attractive to consumers while also achieving compliance with stringent 2012-2016 CO_2 and fuel economy targets. [EPA-HQ-OAR-2010-0799-9569-A1, p. 3]

Cost of compliance for manufacturers weighted more towards light truck sales is projected to be on the order of $1,300-1,600 for 2012-2021. A Wall Street Journal article that appeared online on July 18, 2011 ('White House Offers Auto Makers Concessions to Win Mileage Support') describes how proposals to improve the fuel economy of pickups and sport utility vehicles at a slower pace than passenger cars would 'benefit Detroit manufacturers.' [EPA-HQ-OAR-2010-0799-9569-A1, p. 10]

Response:

Regarding the comments from AFPM that the potential need to restrict recharging times could adversely impact market penetration of electrified vehicles, we do not believe that the market penetrations shown by our analysis (~2% increase in EVs and PHEVs in the 2025MY, see Table III-29 of the preamble) will have sufficient impact on the electrical grid to require any such restrictions to recharging times. As for the AFPM comment that we have not properly analyzed the impacts on carbon emissions that could result from increased electricity demands, this is not correct. We have accounted for increased electricity demands in our analysis as well as the increased carbon and other emissions associated with that increased demand. See preamble section III.F.1 and Table III-64 (showing quantified estimates of upstream electricity and associated GHG emissions attributable to EVs, as there explained, electricity emission factors used in those estimates were derived from EPA's Integrated Planning Model). AFPM also commented that we have made an unrealistic assumption by assuming that the consumer market is sufficient to absorb the expected number of EVs without subsidies. Again, we disagree. We believe that the low penetration rates of EVs and PHEVs shown in our analysis can be made up by early adopters and the kinds of consumers that want such vehicles despite their payback characteristics. Further, we have not suggested that EVs or PHEVs are as cost effective as more traditional technologies; this is why their predicted penetration rate for MY 2025 is quite modest and why they are not projected to be needed at all to meet the MY 2021 standards. What we have shown is that the final standards provide significant public benefit and a path exists toward attaining both the standards and those benefits.

The Defour Group argues that the agencies have deviated from using mainstream economic assumptions to estimate costs in favor of new and unorthodox methodologies. It is not clear what methodologies the commenter considers to be unorthodox. If the meaning is that our use of teardown studies to estimate technology costs was unorthodox, then we disagree strongly. We believe, and nearly all commenters have agreed, that teardown studies represent the best method of estimating technology costs. See Chapter 3.1.1.1 of the joint TSD where we describe the teardown studies conducted for our GHG rules, the peer reviews that have been done and changes made in response to them. Further, we believe that our technology cost estimates represent the best and most up-to-date estimates available today. The commenter also questions our accounting procedures used to estimate costs. The commenter claims that, if the government's cost estimates are too low, auto makers may find themselves building vehicles that consumers are unwilling to purchase. We believe that recent trends suggest otherwise, such as the unexpectedly high sales of the Ford EcoBoost engine despite its higher cost relative to lower fuel economy engine choices for the same vehicle model. Further, at least thirteen automakers have expressed strong support for the proposed standards. We do not believe that they would have done so if they believed the standards compelled production of unsalable vehicles. See also the detailed responses to the Walter and Drake study and critique in section 18.1 above.

Regarding comments from Growth Energy, we have based on EV/PHEV cost estimates on the ANL BatPaC model (battery pack costs) and on FEV teardown studies (electric motors, etc.). We believe that the costs we are using are the best available cost estimates for EV/PHEV technology available. We have also used our High 1 and High 2 markups to estimate indirect costs, and have applied learning effects that are in line with the literature. We disagree with Growth Energy when they claim that we have not estimated costs reliably. Importantly, the information upon which Growth Energy appears to have based this claim is the NAS 2011 report. In that report, NAS states the following about their report, "The cost estimates represent estimates for the current (2009/2010) time period to about 5 years in the future." (See "Assessment of Fuel Economy Technologies for Light-Duty Vehicles," National Academy of Sciences 2011, Summary at page 1.) Therefore, the NAS costs are not applicable for the MYs 2017-2025 rulemaking timeframe. We have discussion of this in RIA Chapter 3.11.7 Further, our final analysis does not project a significant penetration of EV/PHEV technology so the impacts on our program costs are not significant. Lastly, we conducted a sensitivity surrounding our battery-pack costs and our indirect cost markups (which would also impact battery-pack costs) and neither sensitivity suggests significant impacts on the program.

Regarding the comment from Mr. Haroldson, we disagree that vehicles will become too expensive to purchase, especially in light of the significant savings that owners will realize on lower fuel expenditures. Our analysis shows that the cumulative fuel savings will exceed cumulative costs in just over 3 years, well within the typical vehicle ownership period, and that consumers purchasing new vehicles with credit will see immediate reductions in monthly payment amount. See preamble tables III-84 and III-85 and accompanying text. As for safety, we also disagree that vehicles will become too small to be safe to drive. In fact, our analysis was done assuming that vehicles would not change size at all (footprint will not change and, thus, passenger volume will not change). As explained in preamble section II.C and II.G, the footprint attribute removes inherent incentives to downsize as a compliance strategy (downsizing just makes the fleet average more stringent), and the agencies have developed safety neutral compliance paths limiting use of mass reduction as a compliance pathway for lower weight vehicles. Indeed, there were pointed comments (e.g. from CBD and ACEEE) that the proposed standards created incentives to upsize the fleet. Although we disagree with those comments, they stand in stark contrast to the assertions made here. Lastly, while reducing our dependence on foreign oil is a significant benefit of our standards, the primary intent is to reduce GHG emissions. That cannot be done by simply replacing consumption of foreign oil with consumption of domestic oil without a corresponding reduction in oil consumption and related vehicular GHG emissions.

Regarding comments from ICCT, we have not included a sensitivity using the 2011 NAS costs. We agree with the commenter that the costs contained in the 2011 NAS report were meant for the more immediate timeframe and are not necessarily appropriate for use in the 2017-2025 timeframe.

Regarding the comments from Mr. Jackson, the primary point of the comments appears to be that EPA has conducted a faulty analysis in support of the proposal. Mr. Jackson also appears to be concerned that we have assumed certain technology penetration rates to ensure that our rule has the appearance of being beneficial while, if different penetration rates were to occur, our rule would have different costs and benefits. This is incorrect. EPA's OMEGA modeling, the source of the technology penetration rate projections, is entirely transparent and refutes this unfounded comment in all respects. See, e.g. RIA sections 3.1to3.11. Thus, we have not prejudged the technology penetration outcome nor have we forced certain technologies into the mix with the intent of forcing them on the American car buyer. Instead, we have demonstrated what we believe to be the most cost effective approach for each individual auto maker to reach compliance with the final standards given the makeup of that particular manufacturer's fleet. EPA's technology penetrations projections are not binding in any way on the manufacturers, and manufacturers are free to choose any technology pathway for the fleets so long as they are meeting their CO2 target compliance levels. The possible technology outcomes are the result of the standard in conjunction with the footprint basis of the standard and, of course, the technologies available to reach the standards. The outcomes are not predetermined by EPA. Therefore, it is true that a different fleet mix might result in different program costs and benefits, but the fleet mix that will exists in the 2025MY will be driven by the auto makers and the vehicle buying public within the constraints of the standards, not by EPA. Mr. Jackson is also concerned about the multiplier credit available to EVs as a means of encouraging the development of EV technology, which is addressed in Section 4 of this document as well as in preamble section III.C.2.

Regarding comments from Mr. Knapp and Mr. Lipetzky, we disagree that the final rule will result in higher fuel costs—why would fuel costs rise when so much less gasoline will be used—and we disagree with the implication that our rule will be harmful to our slumping economy. In fact, our analysis suggests that the final rule will not only provide significant public benefit, but it may also increase sales and jobs (see preamble sections III.H.11 and 12 and Chapter 8 of the final RIA).

Regarding the comment from Mr. Marshall, we agree that regulatory cost estimates probably overstate reality in general. However, this is a very difficult thing to prove or even analyze. That said, we have attempted to estimate the impacts of learning by doing in making our cost estimates (see preamble section II.D.2.d and Chapter 3.1.3 of the joint TSD). While not overly aggressive in that attempt, we believe that our learning effects strike the proper balance between being conservative and respectful of auto maker and supplier ingenuity.

Regarding the comment from the NACAA, we assume that the claim that, if vehicles equipped with the technologies needed to meet the MY 2025 emissions were introduced earlier then the additional cost per vehicle should be lower than $2000, is a reference to learning effects starting earlier and resulting in lower costs by 2025. While that may be true, one cannot lose sight of the need to introduce new technologies at a sustainable and reasonable pace. We have attempted to provide auto makers sufficient time to introduce new technologies on a pace that will not result in scrapping of new model introductions or requiring model introduction outside of the existing model redesign schedules (thus serving to reduce costs[67]) and on a pace that will not result in costly mistakes and technology failures. in addition, a more rapid phase-in of the standards than we have provided for may well reduce some technology costs by 2025 (due to a longer learning period) but may also increase warranty costs and stranded capital costs, etc..

Regarding the comments from NADA, we have conducted a separate analysis of NADA's (incorrect) claims about the impacts of our heavy-duty highway 2007-2010 rulemaking on the industry. That analysis, given its length and detail, is presented in its entirety at the end of this response section 18.2 as a supplemental response to NADA Exhibit B.. In short, we disagree with NADA's claims and NADA's assertions that we should apply a 4.2x factor to our cost estimates to shed light on the "worse case" (*sic*) scenario. NADA also claims that the rule will result in cars that consumers do not want to buy and, if so, we all lose. We agree that we all lose in that scenario, but disagree that the scenario will play out. In fact, we believe that, for the most part, 2025MY vehicles will look and feel much the same as today's vehicles. There is no reason to believe that the highly boosted and downsized engines upon which the final rule overwhelmingly relies will be unattractive to consumers. In fact, Ford is selling considerably more of its turbocharged and downsized engine equipped F150 pickups than they expected and fewer of the F150s equipped with more traditional V8 naturally aspirated engines. And this is true in a market segment – large pickup trucks – that has traditionally been the one of the least concerned with fuel economy and the most reluctant to accept smaller engines.

NADA also expressed concerns about the high costs of the Administration's three fuel economy/greenhouse gas emission rules. These rules certainly have costs, which the agencies have estimated carefully, but the rules also provide unparalleled savings to consumers and benefits to society that far outweigh the expected costs. We discuss NADA's inappropriate accounting of costs for the rules in section 18.2.1, below. Moreover, these rules have been actively supported by the auto manufacturing industry. EPA strongly doubts that the industry would offer this strong support if manufacturers' believed that the increased costs of installing new technology was either unaffordable or led to unmarketable vehicles.

Regarding comments from the Pennsylvania Department of Environmental Protection, we do not agree that higher octane fuel will be necessary for high compression turbocharged and downsized engines to prevent the onset of combustion knock. EPA assumed no change in the octane of certification or in-use gasoline within its analysis and the effectiveness values used for the high BMEP engines reflect that fact. The current Ford EcoBoost turbocharged GDI engines do not require the use of premium fuel, although those engines are not operating at BMEP levels as high as those expected under our rule. Importantly, a combination of both intake charge dilution (e.g., cooled EGR) and in-cylinder evaporative fuel cooling (e.g., direct injection) are expected to allow higher BMEP GDI engines to operate on regular grade gasoline. All packages

[67] See 75 FR at 25451 describing increased costs associated with introduction of major vehicle changes outside the normal redesign cycle ("[t]he amortized cost of the capital necessary to produce a new vehicle design will increase by 23%, from one-fifth of the capital cost to one-fourth …This would be on top of the cost of the emission control equipment itself. …The capital costs associated with vehicle redesign go beyond CO2 emission control and potentially involve every aspect of the vehicle and can represent thousands of dollars").

at 27 bar BMEP analyzed by EPA included cooled EGR to allow higher BMEP operation and prevent the onset of combustion knock on current certification or in-use fuels. See Joint TSD p. 3-88 ("Use of GDI systems with turbocharged engines and air-to-air charge air cooling also reduces the fuel octane requirements for knock limited combustion and allows the use of higher compression ratios.")

Regarding the comment from D. Ross, we agree that fuel savings will be greater should future fuel prices be higher than projected in the AEO 2012 early release. However, we believe that the AEO projections are the best available projections and that they represent the best projected fuel prices for use in our analysis.

Regarding the comment from Frank Houston Smith, the primary point of the comment appears to be that small engine displacement diesel vehicles like those popular in Europe and other countries provide a possible bridge technology to a future fleet with much lower CO2 emission characteristics. EPA has no preference for the technologies chosen by auto makers, our only requirement is that the standards be met. While it is true that some technologies are receiving credits in the final rule, those credits are meant to incentivize newer and/or emerging technologies. Also, Mr. Smith suggests that it might be necessary to relax the NOx standard such that small engine displacement diesels could more easily meet criteria emissions standards in the US (NOx standards are generally lower for diesels in other parts of the world). This is an idea that EPA opposes for reasons discussed at length in our Tier 2 Highway rulemaking where we took a fuel neutral approach to setting criteria emission standards (see 65 FR 6698 at page 6728, February 10, 2000).

Yegor Tarazevich suggested that EPA introduce a gas tax that would grow to $2 per gallon by 2025 as a means of reducing air pollution and oil dependence. Such an approach is outside EPA's regulatory authority and outside of the scope of this rulemaking.

Michelle Van Voorhies believes that it is lunacy to think that driving up the cost of cars and trucks is worth the time, effort and cost. There are no other details to suggest why Ms. Van Voorhies believes this. We disagree with this comment, since our Benefit Cost Analysis provides considerable detail to support our belief that the new standards will results in significant public benefits and significant savings of fuel resulting in significant reductions of GHG emissions despite the expected increase in new vehicle costs.

In their comment, the Volkswagen Group of America suggests that the costs of compliance for makers of pickups and SUVs is lower than the costs for auto makers whose fleets consist of only cars. Further, the commenter appears to suggest that the standards are structured to benefit the domestic auto makers over other auto makers. Neither comment is true. In fact, each auto maker has a unique standard based on the makeup of its fleet. Likewise, each auto maker has a unique starting point, or baseline or reference point, from which it is starting based, again, on the makeup of its fleet. Another critical factor is the power-to-weight ratio of the vehicles in each manufacturer's fleet, so a vehicle with a footprint of 50 square feet and a high power-to-weight ratio may experience higher costs of compliance than another 50 square foot footprint vehicle with a low power-to-weight ratio. Such is the nature of the footprint based standard. (Many of the manufacturers of these vehicles also chose to pay fines, rather than comply with earlier year CAFE standards. As a result, they have further catching up to do, and hence higher costs.) The point is that the costs for full line manufacturers (i.e., makers of cars and pickups and SUVs) may be lower than for makers of cars only as a result of power-to-weight ratio characteristics more than fleet makeup. A good example of this would be Hyundai and Kia, who have fleet makeups similar to Volkswagen (mostly cars, some SUVs and cross-over utility vehicles/vans, no pickups), but costs of compliance in line with the full line auto makers.

Supplemental response to NADA Exhibit B, "A Look Back at EPA's Cost and Other Impact Projections for MY 2004-2010 Heavy-Duty Truck Emissions Standards", attached to the comments of the National Automobile Dealers Association (on the EPA/NHTSA proposal, "2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards," EPA-HQ-OAR-2010-0799-9575).

In general, and as discussed in detail below, EPA believes NADA's statements included in Exhibit B to its public comments related to the costs of past heavy-duty criteria emission standards are irrelevant to the Light-Duty Vehicle GHG standards and are incorrect in any case.

Heavy-Duty Vehicle Focus in NADA's Exhibit B

Exhibit B in NADA's comments focuses on Class 4 through 8 heavy-duty trucks. In the exhibit, NADA does not describe the relationship between these heavy-duty vehicles and the light-duty market, which consists primarily of passenger vehicles, or how concerns in one market are relevant to the other market. Further, NADA ignores the Class 2b-3 segment of vehicles which share a stronger resemblance to light-duty vehicles in terms of vehicle types, fuels used to power the vehicles, purchasers, uses, and manufacturers.

There are significant differences between the light-duty and the Class 4-8 heavy-duty vehicle markets. Light-duty vehicles include passenger cars, crossover vehicles, sport utility vehicles (SUVs), minivans, and light pickup trucks. On the other hand, the vehicles that NADA discusses in its comments include vehicles such as tractor-trailers, delivery trucks, cement haulers, utility trucks, street sweepers, and urban buses. There is also a significant difference in the engines used in light-duty vehicles when compared to heavy-duty vehicles. Light-duty vehicles are dominated by the use of gasoline engines, while heavy-duty market contains a mix of gasoline and diesel engines but heavy-duty vehicles are predominately diesel powered. The purchasers also differ. Consumers typically purchase light-duty vehicles for their own personal transportation. In contrast, heavy-duty vehicles are most often purchased by commercial fleets and municipalities for the purpose of moving freight or conducting vocational activities, such as street sweepers.

In Exhibit B, NADA ignores the segment of light heavy-duty vehicles which is dominated by the Class 2b-3 pickup trucks. These Class 2b-3 pickup trucks closely resemble their light-duty pickup truck counterparts and are more relevant to any light-duty vehicle discussion. All three of the major U.S. manufacturers offer a light-duty truck, which are often referred to as "half ton" trucks and are sold as the Ford F150, Ram 1500, and GM Silverado/Sierra 1500. The same manufacturers also offer "three-quarter ton" and "one ton" versions of these pickup trucks sold as the Ford F250/350, Ram 2500/3500, and GM

Silverado/Sierra 2500/3500 trucks. The Class 2b-3 trucks are considered heavy-duty vehicles because their gross vehicle weight rating is over 8,500 pounds. The light and heavy pickup trucks share a number of vehicle characteristics, including some common components and, to some extent, the typical vehicle use. See 76 FR at 57160-61 (Sept. 15, 2011).

Table 1 includes a summary of the vehicle characteristics of the light-duty vehicles covered under the MYs 2017-2025 Light-Duty Vehicle GHG rule, the heavy-duty vehicles discussed in NADA's Exhibit B, and the heavy-duty pickup trucks and vans which were not discussed by NADA in Exhibit B.

Table 2: Light-Duty and Heavy-Duty Vehicle Characteristics

	Light-Duty Vehicles Covered by LD Vehicle GHG Rule	Heavy-Duty Vehicles Discussed in NADA Exhibit B	Heavy-Duty Vehicles <u>Not</u> Included in NADA's Exhibit B Discussion
Vehicle Architectures	Passenger cars, SUVs, crossover vehicles, minivans, light pickup trucks (like Ford F150)	Tractor-trailers, delivery vehicles, construction vehicles, utility trucks, buses, and many others	Heavy-duty pickup trucks and vans (like the Ford F250)
Fuel Use	Significant majority are gasoline powered vehicles	Majority are diesel powered vehicles	Split between gasoline and diesel powered vehicles
Typical Purchaser	Individual consumer	Commercial fleets, municipalities, utility companies, and single truck owners	Mix of individual consumers and small businesses (such as landscape companies)
Vehicle Purposes	Personal transportation. Hauling and towing primarily limited to light trucks and vans.	Delivery of freight or other goods, transportation of people, transportation to worksite, worksite power	Mix of personal transportation and hauling/towing.
Major Vehicle Manufacturers	Chrysler, Ford, General Motors, BMW, Mercedes, Toyota, Honda, Kia, Nissan, and many others	Daimler Trucks, PACCAR, Navistar, Volvo, Hino, Ford, and others	Chrysler, Ford, General Motors, Isuzu, Daimler, Nissan, and others

<u>NADA's Market Disruption Claim</u>

NADA claims that "Implementation of EPA's MY 2004-2010 emission mandates directly resulted in higher truck prices, increased operating costs, reduced reliability, and lower fuel economy performance, which caused dramatic disruptions to the new truck marketplace." (Exhibit B, page 3) NADA's exhibit goes on to state that "Many informed prospective new truck purchasers rushed to 'pre-buy' trucks with pre-compliant technologies to avoid the effects of EPA's mandates." (Exhibit B, page 3) NADA uses the heavy-duty exhibit as support for its (strident) assertion that setting standards "further out than necessary" may have "devastating impacts" on the marketplace (NADA comments, Docket EPA-HQ-OAR-2010-0799-9575, page 5). EPA believes that NADA's heavy-duty market disruption claims are not relevant to the Light-Duty Vehicle GHG proposal because of the differences in vehicle types, usage, and markets as discussed above. NADA did not make any claim of pre-buy relative to the heavy-duty pickup trucks and vans (the most analogous heavy-duty vehicle segment, as just explained), and EPA did not find any evidence to support pre-buys in that vehicle segment. Further, EPA discusses three additional reasons why any heavy-duty market disruption claim is irrelevant to the MYs 2012-2017 light-duty vehicle rulemaking.

First, there is a significant difference in the regulatory structure between the heavy-duty standards for criteria pollutants and the light-duty vehicle GHG standards. NADA's pre-buy argument is not applicable to the light-duty vehicle GHG program because of this difference in structure. Under the Clean Air Act Section 202(a)(3)(C), the heavy-duty criteria emission standards are required to apply for a period of no less than three model years, which is commonly referred to as the stability requirement.[68] As NADA points out in Exhibit B, EPA promulgated new heavy-duty criteria pollutant emission standards in 2004 and 2007, with the 2007 standards phased in through 2010. However, unlike heavy-duty vehicle and engine emission standards, the Clean Air Act does not require a minimum stability period for light-duty vehicle emission standards. NHTSA and EPA have structured the light-duty vehicle fuel economy and GHG final standards such that they require *annual* improvements for MYs 2017 to 2025. This builds on the MYs 2012-2016 light-duty vehicle GHG and fuel economy standards. The annual increase in CAFE standards for light-duty trucks actually began for MY 2005 and the annual increase for passenger cars for MY 2011.[69] In addition, the light-duty vehicle GHG standards are a fleet average standard where each manufacturer may select a different standard and compliance path unique to its fleet. For example, some vehicles may see changes in one model year, while others will remain constant. As such, the light-duty vehicle market is not expected to experience a significant change in the vehicles available for sale in any given year. NADA's claim that pre-buys disrupt markets is therefore not relevant to the light-duty vehicle GHG standards because the light-duty program requires modest, annual incremental increases in the stringency and costs of emission standards which are unlikely to have a substantial effect on purchasing behavior.

Second, it is not appropriate to apply NADA's claim of "pre-buy" in the heavy-duty market, in response to the costs of heavy-duty criteria pollutant emission rules, to the light-duty vehicle GHG standards because of the significant financial benefit to consumers accruing from the GHG rules. As documented in the proposal and final rule, the standards will result in a significant improvement in fuel economy and therefore reduce operating costs. Though the standards increase the upfront costs of the vehicles, owners will experience lower operating costs due to the improved fuel economy and reduced GHG emissions. In fact, in the MYs 2012-2016 light-duty vehicle GHG rule, EPA projected an increase in vehicle sales in the 2012 through 2016 timeframe if consumers take into consideration at least five years' worth of fuel savings

[68] United States Code, Title 42, Chapter 85. May be accessed at http://epa.gov/oar/caa/title2.html
[69] U.S. National Highway Traffic Safety Administration. May be accessed at http://www.nhtsa.gov/fuel-economy.

when considering whether to buy a new vehicle.[70] Similarly, as highlighted in the proposal, a light-duty vehicle consumer who purchases a vehicle in the 2017 through 2025 timeframe would not have any financial incentive to avoid the purchase because the average consumer would see a payback in the upfront costs in less than four years and on average gain a net savings of $3,000 to $4,400 over the lifetime of the vehicle based on the proposed standards (discount rates of both seven and three percent, respectively).[71] Consumers purchasing vehicles on credit would see immediate savings because monthly fuel savings more than offset the increase in monthly loan payment amount. Preamble section I.C.

Third, finalizing light-duty vehicle standards for the MYs 2017-2025 timeframe now provides regulatory certainty to auto manufacturers and suppliers along with the opportunity for long-term planning and time for continued development and deployment of GHG emission reducing technologies across the light-duty vehicle fleet. By setting standards with a significant amount of lead time, EPA is addressing one of the concerns raised by a General Accounting Office (GAO) study related to the 2007 heavy-duty standards.[72] GAO suggested that EPA should address concerns raised by purchasers about whether new engines will be ready in time for validation testing by the vehicle manufacturers and truck fleets to help prevent any potential pre-buy of older engines before 2007. Longer lead times, such as those provided in the 2017-2025 light-duty vehicle GHG program, could help consumers be more confident in the performance and durability of these new technologies because it provides the time for auto manufacturers and suppliers to develop and implement technologies in a robust manner and with sufficient time to ensure durability and reliability targets are met.

Finally, NADA's assertions that the 2004 and 2007/2010 heavy-duty emission standards caused the heavy-duty truck sales fluctuations over the past decade are mistaken. EPA believes that there are many factors that impact truck sales in any given year. For example, the American Trucking Associations develops the U.S. Freight Transportation Forecast based on factors such as the change in the U.S. gross domestic product, consumer confidence, housing, capital equipment purchases, government spending, imports and exports, bond yields, and truck capacity utilization.[73] Figure 1 below shows the annual sales of heavy-duty trucks (those with a gross vehicle weight rating of over 14,000 pounds) and the annual rate of change of the U.S. Gross Domestic Product (GDP) since 2000. Although the figure is not intended to imply causality, because other factors are expected to influence vehicle sales, it does provide an indication that factors such as the annual growth rate of the U.S. GDP may have an impact on truck sales.[74]

Projected Cost of Compliance

NADA's Exhibit B also discusses EPA's projected fixed and operating costs of medium and heavy heavy-duty engines related to the 2004 and 2007/2010 criteria pollutant emission standards. NADA claims that by setting standards seven to ten years before implementation, EPA "dramatically underestimated" the costs associated with the program (Exhibit B, page 3). NADA makes no attempt to comment on the specific details of EPA's detailed cost analysis for the proposed MYs 2017-2025 light duty vehicle standards (with the exception of indirect costs which we address in responding to NADA's Exhibit A) and NADA's discussion is focused on costs that are not related to the light-duty vehicle GHG standards. We nonetheless explain why NADA is incorrect as to that other rule.

As stated in the 2007/2010 heavy-duty emissions rule, EPA developed the compliance costs of the NOx standard assuming that NOx adsorbers would be the most likely technology

[75] U.S. Truck Sales represent Class 4-8 truck sales from Ward's Auto Group's "U.S. Truck Sales by GVW by Month" 2000 through 2011. U.S. Gross Domestic Product percent change based on current dollars from the Bureau of Economic Analysis. Last accessed on May 8, 2012 at http://www.bea.gov/national/index.htm#gdp

applied by industry in order to meet the NOx standards.[76] As noted in the 2007/2010 HD rule, we recognized that manufacturers had several years before implementation of the standards and we expected research would lead to enhanced emission control technologies with focused research efforts on drawbacks, such as fuel economy impacts, in an effort to minimize any potential negative effects.[77] As a result of the industry's research and development efforts, most heavy-duty engine manufacturers selected a technology path that included selective catalytic reduction (SCR) for 2010 NOx compliance rather than NOx adsorbers. There are several reasons why manufacturers selected this technology for the market. For one thing, manufacturers introduced SCR into the European heavy-duty market in the 2006 timeframe to meet the Euro V emission standards.[78] The earlier introduction of the technology in Europe provided engine manufacturers time to gain experience with the technology in the marketplace before it was implemented in the United States. The use of SCR in the U.S. also provides global engine manufacturers with ability to use the research and development experience that they gained in Europe in addition to the potential economies of scale to reduce costs. SCR also provides the manufacturers with the flexibility to balance engine-out NOx emissions and fuel consumption to meet market demands. We believe, and manufacturers have provided confidential business information to support, that manufacturers have the ability to raise the engine-out NOx emissions of 2010 engines equipped with SCR to levels above the 2004 NOx levels in an effort to improve fuel consumption while remaining in compliance with NOx emission standards.

We would expect the cost analysis conducted by NADA to show that the compliance costs and manufacturer surcharges with respect to the 2007/2010 rule are different for two reasons. First, EPA developed costs in the 2007/2010 rule for a different emission reducing technology than the technology that was actually used in the market. Second, NADA used manufacturer surcharges in the comparison. Manufacturer surcharges are not equivalent to compliance costs. As would be expected, surcharges are often greater than the compliance cost because they are set by the manufacturers based upon what they believe the market will bear. This premise is supported by confidential business information submitted to EPA for the Heavy-Duty Engine Nonconformance Penalty proposal.[79]

EPA attempted to conduct a retrospective analysis of our projected costs of the heavy-duty gasoline engine emission standards. However, we were unable to develop a robust method to identify the gasoline engine price (or cost) increases that were solely related to emissions which were passed along to consumers in the heavy-duty pickup market.

However, EPA has conducted a simple analysis of the projected costs of the 2004 and 2007/2010 light heavy-duty diesel engine standards relative to the price increases that one major manufacturer actually placed on their heavy-duty diesel pickup trucks. As noted above, these pickup trucks are more similar to the half-ton pickup trucks included in the light-duty vehicle segment than are the heavier trucks referred to by NADA. EPA is utilizing manufacturer

[79] 77 FR at 4736, January 31, 2012.

surcharges in this analysis as a proxy for cost, similar to the approach taken in the NADA analysis, though we have no reason to believe that these particular surcharges were equal to costs associated with emissions abatement equipment.[80] In the analysis below, EPA compares the cost increase that we projected in the 2004 rule, adjusted to 2004 dollars, to the price difference of the diesel engine option on a Ram 2500 pickup truck between 2003 and 2004. As shown in Table 2, the cost increase projected by EPA for the 2004 standard was $541 and Chrysler increased the price of the diesel engine option on the Ram 2500 by $330. By this comparison, EPA's projected cost increase of the 2004 emission standards was $211 greater than the manufacturer's actual price increase.

Table 3: EPA Cost Estimate and Manufacturer Price Increase for 2004 Light Heavy-Duty Diesel Engine Standard (all values in 2004$)

Manufacturer Price Increase[A,B]	$330
EPA Cost Estimate[C]	$541
Manufacturer Price – EPA Cost	**-$211**

Notes:
[A] Manufacturer Surcharge for Diesel Engines from Pickup Trucks.com Standard Equipment and Options. 2003 Surcharge was $5,225. Last accessed on May 7, 2012 at http://www.pickuptrucks.com/dodge/ram-2500/2003/standard-equipment/
[B] Manufacturer Surcharge for Diesel Engines from Pickup Trucks.com Standard Equipment and Options. 2004 Surcharge was $5,555 (2004$). Last accessed on May 7, 2012 at http://www.pickuptrucks.com/dodge/ram-2500/2004/standard-equipment/
[C] 2004 Light Heavy-Duty Emission Standard Cost was $485 (1999$). See 65 FR October 6, 2000 at 59936.

Next, EPA compared the cost increase projected in the 2007 heavy-duty rule, adjusted to 2007 dollars, to the price difference of the diesel engine option on a Ram 2500 pickup truck between 2006 and 2007. As shown below in Table 3, EPA's projected cost increase for the 2007 standard was $2,429 and Chrysler increased the price of the diesel engine option on the Ram 2500 by $545. EPA's projected cost increase of the 2007 emission standard was $1,884 more than the price increase of the diesel engine option for this category of engines.

[80] The Agency believes that the heavy-duty engine industry may not be a perfectly competitive market due to the limited number of manufacturers. In a concentrated market like this, pricing strategies such as surcharges may include additional costs for non-regulatory imposed features, non-emission-related regulatory imposed features or additional profit margin.

Table 4: EPA Cost Estimate and Manufacturer Price Increase for 2007 Light Heavy-Duty Diesel Engine Standard (all values in 2007$)

Manufacturer Price Increase[A,B]	$545
EPA Cost Estimate[C]	$2,429
Manufacturer Price – EPA Cost	**-$1,884**

[B] Manufacturer Surcharge for Diesel Engines from Pickup Trucks.com Standard Equipment and Options was $6,100 in 2007. Last accessed on May 7, 2012 at http://www.pickuptrucks.com/dodge/ram-2500/2007/standard-equipment/
[C] 2007 Emission Standard Cost was $1,986 (1999$). Regulatory Impact Analysis: Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements (EPA 420-R-00-026), page V-38. Last accessed on May 7, 2011 at http://www.epa.gov/otaq/highway-diesel/regs/ria-v.pdf

Finally, we compare the cost increase projected in 2010 for the 2007/2010 heavy-duty rule, adjusted to 2010 dollars, to the price difference of the diesel engine option on a Ram 2500 pickup truck between 2009 and 2010. As shown below in Table 4, the projected cost increase for the 2010 standard was $2,046 and Chrysler increased the price of the diesel engine option on the Ram 2500 by $2,060 in 2010. In this instance, the projected the cost increase of the 2010 emission standards was $14 less than the manufacturer's price increase for this category of engines.

Table 5: EPA Cost Estimate and Manufacturer Price Increase for 2010 Light Heavy-Duty Diesel Engine Standard (all values in 2010$)

Manufacturer Price Increase[A,B]	$2,060
EPA Cost Estimate[C]	$2,046
Manufacturer Price – EPA Cost	**$14**

[C] 2010 Emission Standard Cost was $1,601 (1999$). Regulatory Impact Analysis: Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements (EPA 420-R-00-026), page V-38. Last accessed on May 7, 2011 at http://www.epa.gov/otaq/highway-diesel/regs/ria-v.pdf

In summary, the most relevant heavy-duty engine cost discussion for the light-duty vehicle GHG standards did not show that EPA underpredicted costs by "two to five times the actual costs" as incorrectly claimed by NADA (Exhibit B, page 11).

Conclusion

In conclusion, NADA commented on the 2017-2025 Light-Duty Vehicle GHG proposal by submitting a review of the costs of EPA's 2004-2010 heavy-duty standards and a discussion on other impacts on heavy-duty vehicles. Two of the premises of the NADA exhibit were that rulemakings which provide seven to ten years of lead time lead to misrepresented costs and result in market disruptions. This memo discusses why EPA believes that any heavy-duty market disruption claim is irrelevant for the Light-Duty Vehicle GHG program because the regulatory structures of the programs are different and because the GHG program reduces operator costs, unlike a criteria pollutant emission program. NADA fails to discuss any of the market differences between passenger cars and commercial heavy-duty vehicles. In addition, NADA ignores the most relevant segment of the heavy-duty market, the large pickup trucks, for comparison to light-duty vehicles. EPA has examined the actual price increase for the heavy-duty pickup trucks and found they were generally less than the EPA cost estimates, not greater as NADA mistakenly asserts. In addition, we found no evidence of market disruptions for these vehicles during the implementation of the 2004 or 2007/2010 emission standards.

18.2.1. Per Vehicle Average Costs

The market place will determine the need for premium (higher octane) fuel

The EPA and NHTSA note that their assessment of the cost of technologies adopted to comply with the proposed CAFE and GHG standards was not predicated on the need for premium gasoline, and they request comment on this assumption. API concurs with the approach used by EPA and NHTSA in this regard. The market place will address and determine the octane needs of motor vehicles – as it has done, successfully, for decades. There is no need for government agencies to adopt a regulatory approach that pre-determines, prescribes, or specifies vehicle octane requirements. [EPA-HQ-OAR-2010-0799-9469-A1, p. 11]

Octane needs are already addressed by the market and do not require government intervention
The market place will address octane needs of vehicles as it has done successfully for decades.

There is no need for government agencies to pre-determine, prescribe, or specify vehicle octane levels. [EPA-HQ-OAR-2010-0799-9469-A2, p. 2]

Questionable Vehicle Cost and Consumer Benefit Estimates

EPA and NHTSA state that the proposed standards “would have significant savings for consumers.” This is based on an average increased cost of $2,000 for a MY 2025 new vehicle and a present value of fuel savings over the vehicle lifetime ranging from $5,200 to $6,600, depending on whether a 7% or 3% discount rate is used. The uncertainty over increased vehicle cost and the discount rate consumers would implicitly use to value fuel savings raises significant questions about the EPA/NHTSA claim that a consumer would see a “net lifetime savings of $3,000 to $4,400.” [EPA-HQ-OAR-2010-0799-9469-A1, pp. 9-10]

As one example, it should be noted that the Energy Information Administration’s Annual Energy Outlook 2011 included a sensitivity case with a 6% per year increase in CAFE -- reaching approximately 55 mpg in 2025. That sensitivity case estimated that such a CAFE requirement would increase the average cost of a new 2025 vehicles by about $4,600 relative to vehicles meeting the existing 2016 mpg requirement. The EIA cost increment is more than twice that of the EPA/NHTSA estimate, and likely reflects the use of a different set of assumptions that drive significantly higher penetrations of electric vehicle and diesel technologies into the light-duty vehicle fleet.22 Additionally, EIA uses a 15% consumer-relevant discount rate when evaluating the economic cost effectiveness of new vehicle efficiency technologies. A 15% discount rate would reduce the present value of fuel savings by about 40% to 50% compared to the EPA/NHTSA calculations. Combining EIA’s higher vehicle cost with a consumer relevant discount rate would turn the EPA/NHTSA consumer net benefit conclusion into at best a consumer break-even and more likely a consumer net cost. Furthermore, the EPA/NHTSA conclusion that a consumer paying cash for a new MY 2025 vehicle would see the added vehicle cost offset within 4 years by fuel savings would no longer be accurate. [EPA-HQ-OAR-2010-0799-9469-A1, p. 10]

Given these uncertainties, it is not at all clear that the EPA/NHTSA proposal would, as claimed, “preserve consumer choice – that is, the proposed standards should not affect consumers’ opportunity to purchase the size of vehicles with the performance, utility and safety features that meets their needs.” [EPA-HQ-OAR-2010-0799-9469-A1, p. 10]

---

22 When viewed in relation to projections made in similar studies conducted by the National Research Council (http://www.nap.edu/catalog.php?record_id=12924) and by the Massachusetts Institute of Technology (http://web.mit.edu/sloan-auto-lab/research/beforeh2/otr2035/On%20the%20Road%20in%202035_MIT_July%202008.pdf) , one observes a substantial range in the estimates of future incremental automotive technology costs, effectiveness and market penetrations, even in the near - to medium-term timeframe. In this context, the longer term projections made by EPA and NHTSA for the subject NPRM are particularly uncertain, reflecting, as they do, specific assumptions regarding future fuel prices,

product lifecycles, impacts of other anticipated regulatory initiatives, etc., etc. [EPA-HQ-OAR-2010-0799-9469-A1, p. 10]

Organization: BMW of North America, LLC

The projected cost increase of US $734 in MY 2021 and US $1946 in MY 2025 relative to 2016 in the joint draft TSD is only valid for the average new US vehicle. The actual cost increase for the average BMW Group vehicle is much higher than projected in the joint draft TSD just because of the higher E-mobility share needed for future compliance (as mentioned above) and the need for much more expensive conventional improvement technologies (high-cost lightweight materials, etc.). [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 5]

Regarding the calculations of the projected cost increase per automaker in the joint draft TSD, the projected cost increase for the BMW Group fleet at the level of a large volume manufacturer or slightly lower is not at all accurate if considering the above mentioned high E-mobility share needed for the BMW Group. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 6]

Organization: Consumer Federation of America (CFA)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 61.]

The past 16 years, automobiles have increased an average of $500 a year. So this is a small price to pay for extra fuel economy and extra savings.

Organization: Cuenca, M.

Transportation is critical to our quality of life and the EPA's regulation could increase the cost of a new vehicle by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. [EPA-HQ-OAR-2010-0799-10142-A1, pp. 1-2] (Also in Section 18.8)

Organization: Jackson, F.W.

3. EPA 11/16/11 Article '..... 2016 through 2025 model year. .. increase by $ 1,946 per vehicle' Not so 'per vehicle', Le., while each individual by class vehicle average might increase by this amount to incorporate the defined (e.g., turbochargers) technologies, there is also a class 'mix' impact that does not appear to be factored in by EPA to obtain their $ 1946; e.g., if I take a 2016 Camry and spend $ 1,946 to increase its mpg, fine; but if I build one less Camry and build one more Prius (both with same defined technologies upgrade) I also increase the cost another 4-6 $sK to convert to a Hybrid; and by not considering fleet 'mix' change impact the Hybrid cost does not show! And building a plug-in (e.g., Volt with 'fast' charging stations) instead of an ICE and the 4-6 $sK additional for a HEV grows to about 20 $s K per switch to a PHEV (e.g., Volt). Even 15% (EPA proposal percentage ref 23.8-21-23) HEVs in 2025 at 4 K$s added would alone be 600 $s - subtracting the $ 600 from the reported $ 1946 cost increase leaves $1346 for all

other upgrades and ref. 2 shows up to $ 1426 for high level turbo boost, $ 338 for V-6 Direct injection plus a number of other upgrades in the $100-200 range. We need to hear from EPA on whether the 'mix' factor is included in their reported $ 1946 value but from my brief look at their document it didn't appear to me it was in; the fact that EPA has one value ($ 1946) would support mix impact not factored in, i.e., different mixes would have different numbers! I also note in Ref. 2 EPA proposal fleet 2025 technology penetration 'low balls' cost by assuming low (ref. 2 table 3.8-19) penetration of PHEVs (0%) & BEVs (2.8%) while to comply manufacturers could opt for more Volts & LEAFs class vehicles so they could sell more 'guzzlers' these would raise the 'mix' cost and with the more weight of the 'guzzlers', mpgge would be less than EPA claim. [EPA-HQ-OAR-2010-0799-8041-A1, pp. 1-2]

Organization: National Association of Clean Air Agencies (NACAA)

Second, EPA projects the cost of new technology will add, on average, about $2,000 to the price of a MY 2025 vehicle. NACAA recognizes that consumers will recoup this cost through fuel savings. However, we believe that the average vehicle cost could be brought down if cleaner vehicles were introduced earlier. If vehicles equipped with the technologies needed to meet MY 2025 emissions and fuel economy requirements are introduced earlier, then by 2025 the projected additional cost should be lower than $2,000. In addition, early introduction of cleaner vehicles will provide added assurance that the projected fleet performance is achieved by 2025. Measures that lead to greater penetration of cleaner vehicles earlier in the program could bring down vehicle costs in later years of the program. Further, zero-emission vehicles and alternative-fuel vehicles would help to further reduce criteria pollutant emissions as well as GHGs. [EPA-HQ-OAR-2010-0799-8084-A1, pp. 3-4]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 36.]

Organization: National Automobile Dealers Association (NADA)

The proposal is drafted in a manner that makes it difficult to tease out the per vehicle costs associated with compliance. There are several reasons for this:

1. As with all estimates made in the proposal and in supporting documents, NHTSA and EPA struggle to forecast costs based on assumptions involving vehicles that will hit the market 5 to 13 years out into the future. Given the potential for extreme variability for any number of factors, MY 2017-2025 predictions of average per vehicle cost/price are inherently suspect.[EPA-HQ-OAR-2010-0799-9575-A1, p. 3]

2. Each agency uses different models to calculate different and, in some cases, a variety of average per vehicle costs that do not mesh well together. This is just one example of why the so-called 'single national program' is a misnomer. The final rule should harmonize and clearly delineate a single set of average per vehicle costs, for both light-duty cars and trucks, using only one marginal 'cost-to-consumer' number. NHTSA and EPA should strive to ensure that these cost figures accurately depict for prospective purchasers what the final rule will cost, on average. [EPA-HQ-OAR-2010-0799-9575-A1, p. 3]

3. The proposal and related fact sheets and press releases obfuscate cost projections. Instead of appropriately delineating costs, separately delineating benefits, and comparing the two, NHTSA and EPA go out of their way to emphasize gross and net benefits with little or no reference to costs. While by no means excusable, perhaps the unprecedented per vehicle and total costs have influenced EPA and NHTSA to do so. Regardless, the final rule should clearly show the average per vehicle costs prospective consumers should expect to have to pay up front. [EPA-HQ-OAR-2010-0799-9575-A1, pp. 3-4]

For purposes of understanding how the proposal will impact prospective new vehicle purchasers, these comments use the average per vehicle estimates NHTSA has set out in the proposal, adjusted to 2010 dollars. Moreover, NADA takes the position that the MY 2011, 2012-2016, and 2017-2025 standards constitute a single post-EISA program. Thus, for purpose of its analyses, NADA characterizes the government's total average per vehicle cost estimate to be $2936 (in 2010 dollars), reflecting $91 dollars for MY 2011 adjusted to $95, $903 for MY 2016 adjusted to $945, and $1876 for 2025 adjusted to $1896. [EPA-HQ-OAR-2010-0799-9575-A1, p. 4]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 72-74.]

By EPA's own estimates, current prices would go up over today $3,200. I heard different numbers thrown around, but a third of that are the mandates that are just now going into effect through 2016 and then another $2000, or a little over 2,000 on the mandates from 2017 to 2025, which will total in today's dollars $3,200 over today's prices. This would raise payments between $60 and $70 a month in a typical automobile loan.

A study that the NADA will release next month will raise significant concerns regarding how the proposal calculates retail price impacts. By using a more realistic analytical approach, our initial analysis shows the proposal underestimates the cost at retail and suggests a compliance-related price increase in my showroom could be at least 60 percent higher than that which would be up to $5,000 increase.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 53-55.]

Totaling the administration's final and proposed fuel economy mandates results in an average vehicle cost increase of at least $3,200, a substantial amount that every new car buyer will have to pay up front. As Don Chalmers explained last week, NADA believes that the actual total increase will be even higher. Thus, customers who come into my showroom in 2025 will face vehicles that, as a result of these rulings, are dramatically more expensive than they are today.

Moreover, the U.S. Energy Information Administration finds that this proposal will regulate out of existence the most affordable cars on the market today. Adjusting for inflation, the Energy Economic Information Administration claims that in 2025, there will no longer be new vehicles on the market costing $15,000 or less. These are the vehicles I sell to smart frugal buyers, college students and working families. How can a rule that eliminates the most affordable new cars on the market be pro-consumer? You're right; it's not.

Organization: Ross, D.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 241-242.]

Critics see the new standards as a formula for sticker shock. With price increases of $2,000 to $3,100, making automobiles unaffordable for low income consumers.

Well, history demonstrates that initial estimates of the cost of complying with new environmental standards have proven grossly exaggerated as human ingenuity, when facing the proper incentives, finds novel cost-effective solutions.

But suppose those purchase price estimates are accurate, at current, gasoline prices, the savings and lower fuel costs over the lifetime of the vehicle would be approximately $6,000.

Organization: Steyn, R.

* Clearly, the proposed two-fold increase in CAFE standards is a “drastic” action that will likely increase the cost of a new car by $5,000—$6,000. [EPA-HQ-OAR-2010-0799-8724-A1, p. 2]

Response:

The API questions EPA’s estimates of consumer savings resulting from lower fuel expenditures. They correctly point out that the savings as calculated in our analysis depend on the discount rate used. EPA has shown savings using both a 3% and a 7% discount rate. These discount rates are generally accepted rates at which social costs should be discounted. Clearly, using a higher discount rate as suggested by API would result in lower present value fuel savings. The goal behind our payback analysis was to shed light on the real situation rather than attempting to determine how consumers might value future savings versus current and/or future costs. While inflation in recent years has been extremely low, inflation in the 3-7% range is not atypical. Inflation in the 15% range, in the United States, is not typical. Therefore, we do not agree that discounting future fuel savings at 15% as the commenter recommends would be more appropriate than what we have done. In the end, the point of our payback analysis is not to shed light on when consumers would perceive the future savings to outweigh their costs, but rather to shed light on when those savings actually would outweigh their costs. Lastly, we disagree that our standards may have any negative impact on the ability of consumers to purchase the size of vehicles with the performance, utility and safety features that meets their needs. The agencies’ cost estimates include the costs of preserving all of the utilities of the present vehicle fleet. See. e.g. EPA RIA pp. 1-39 to 40. We believe that the compliance path we have shown maintains utility of the existing fleet (with two limited exceptions as discussed in Chapter 1.3 of our RIA) and maintains the safety characteristics of today’s fleet as discussed in section II.G of the preamble and in Chapters 3.4 and 4.4 of our RIA. Regarding octane requirements, we address octane-related issues in section 11.2 of this Response to Comments document.

Regarding comments from BMW, we do not disagree that BMW’s costs are likely to be higher than the average. In fact, our analysis shows a 2025MY cost of $1910 for BMW, or $74 higher than the average. Our analysis also shows a 9% full EV penetration rate for BMW, versus the average penetration rate of 3%. While BMW might argue that those results suggest a BMW-fleet utility considerably lower than their current utility (since full EVs, in our analysis, have a 75 to 150 mile range versus the typical gasoline vehicle range of roughly 400 miles), we suggest that buyers of full electric BMWs are likely to purchase the full EV despite the shorter range for reasons other than utility (i.e., status, prestige, environmental stewardship, etc.). Therefore, we do not believe that those BMW buyers will perceive any loss in expected utility.

Regarding the Consumer Federation of America, we have not studied the average cost increase of new vehicles over the past 15 years, so we will not comment on the claim that cars have increased $500 per year for 15 years. However, we do not ascribe unthinkingly to the comment that the cost of the final standards is a "small price to pay for extra fuel economy and extra savings." In fact, an average $1800 cost increase is not a small price to pay. Many commenters have expressed considerable concerns with the costs and we do not want to suggest that it is insignificant. Instead, we want to focus on the net impact which shows that there will be considerable social benefits that result from the final standards, these benefits vastly outweigh the rule's costs, and the fuel savings of the rule pay back the increased vehicle costs in a comparatively short time. We will all pay more for future vehicles, but we will certainly enjoy the savings that we realize as a result.

Regarding the comment from Mr. Jackson, please refer to our earlier response to Mr. Jackson in section 18.2.

Regarding comments from NACAA, please refer to our earlier response to NACAA in section 18.2.

Regarding the comments from NADA, we agree that there is uncertainty in our cost analysis given the long timeframe between now and 2025. For that reason, we have conducted several sensitivities surrounding costs and have found that the standards are very cost beneficial in each of our sensitivity cases as well as in our primary analysis. We present this sensitivity analysis in Chapter 3.11 of the RIA. NADA also suggests that EPA and NHTSA should use one marginal cost-to-consumer number and that, by not doing so, calling the rules a single national program is a misnomer. We disagree with this assertion. In fact, each agency has a different set of requirements to meet due to the different statutes that provide authority to each agency. NHTSA has a model that helps them estimate costs and benefits within the constraints of its statute. EPA has a model that helps it do the same. In fact, the estimated costs by each agency, using its respective models and analytic techniques, are corroborative. EPA believes that these corroborative analyses makes the overall conclusions more robust (and not in some way weaker, as the commenter would have it). We note further that the costs estimated by each agency will inherently be different for several reasons but, most notably, because NHTSA's standard does not reflect the full array of AC-related improvements that EPA's does, and EPCA/EISA allows manufacturers to pay fines rather than comply with the standards. Compliance is mandatory under the Clean Air Act. However, even though manufacturers will not be able to pay fines to comply with EPA standards (so that the ability to pay fines under the CAFE program becomes of no practical consequence), NHTSA still analyzes its program as though those fines will be paid.

As for NADA's claims that we have obfuscated cost projections, focusing only on benefits, we simply do not understand. Far from hiding or disguising costs, there are many prominent tables throughout the preamble and each agency's RIAs that clearly present the costs of the programs. Nor are those costs aggregated in a way making it harder to evaluate individualized impacts. EPA has estimated technology penetration and associated costs for each manufacturer, for example. See e.g. preamble tables III-25, 28, and 29.

Regarding the $2936 cost claimed by NADA for the three recent fuel consumption and GHG reducing rules, again we disagree. In addition, even if (against our view) we accept that it is appropriate to aggregate the different rules' costs here, NADA has made a number of factual errors in doing so. We have estimated the 2025MY reference case costs (i.e, the cost to meet the 2016 standards in the 2025MY) at $719 (see RIA Table 3.6-1). We have also estimated 2025MY control case costs (i.e., the cost to meet the 2025 standards in the 2025MY) at $1836 (see RIA Table 3.6-3). The total cost of the two rules would then be $2555, or $381 lower than that suggested by NADA. In fact, the $719 value actually includes costs to meet NHTSA's MY2011 standards in MY2025. To clarify, in the MYs 2012-2016 final rule, we estimated the cost to meet the MY2011 standard in MY2016 at $89 (2007$) (see EPA-420-R-10-009, Table 4-6 at page 4-18) which would probably be on the order of $50-$70 (2010$) for meeting the MY2011 standard in MY2025. Therefore, the $2555 value stated here is slightly high since it already includes the costs of meeting the MY2011 standard in MY2025. In adding their costs, NADA has inappropriately added the costs presented in each of the rulemakings they mention. However, the cost they used for the MYs 2012-2016 rule, or $903 adjusted to $945, is the cost of complying with the 2016 standards in the 2016MY, not the 2025MY. To properly add the costs, one needs to use the cost of the 2016 standards in the 2025MY as we have done here. Curiously, NADA does not suggest adding together the cumulative benefits of these standards, which again vastly outweigh the standards' cumulative costs.

Regarding NADA's comments on calculating retail price impacts, please refer to our earlier response to NADA in section 12.3.2. Regarding NADA's claims about lower priced vehicles and the ability of frugal buyers, students and working families to afford new cars, we have a response to that argument in section 18.7.1, below.

Regarding comments from David Ross, EPA would like to thank Mr. Ross for his comments and interest in our rule. As explained in section III.H.11 of the preamble, EPA agrees that vehicles in the low-priced (economy-class) segment will bear technology costs needed to meet the new standards, but it is not known how manufacturers will decide to pass on these costs across their vehicle fleets, including in the low-priced vehicle segment. If manufacturers decide to pass on the full cost of compliance in this segment, then it is possible that consumers who might barely afford new vehicles may be priced out of the new-vehicle market or may not have access to loans. However, the rule's impacts on availability of loans are unclear, because some lenders do factor fuel economy into their loans, and it is possible that this trend may expand. In addition, as the Union of Concerned Scientists comments, auto makers have some flexibility in how both technologies and price changes are applied to these vehicles; auto makers have ways to keep some vehicles in the low-priced vehicle segment if they so choose. Though the rule is expected to increase the prices of these vehicles, the degrees of price increase and the impacts of the price increases, especially when combined with the fuel savings that will accompany these changes, are much less clear. See also responses in section 18.7.1 below.

Regarding comments from Ruth Steyn and Mark Cuenca, we disagree that the rule will result in new car costs increasing $5000-$6000 as made clear in the response to the NADA comments above, and in our response in section 12.3, above.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 40.]

Household gasoline expenditures set a record in 2011 reaching an average of over $2,850 per year which means that gasoline expenditures were 40 percent higher than expenditures on home energy, electricity, natural gas and heating oil. Ten years ago gasoline expenditures were 13 percent lower than home energy and that is why consumers are so troubled by gasoline prices.

But rising gasoline prices have also changed the structure of the cost of driving. Ten years ago the cost of owning a vehicle as reported in the consumer expenditure survey was the largest single component of the cost of driving by far, about three times as high as the cost of gasoline. In 2011 the cost of gasoline will equal or exceed the cost of ownership in the consumer expenditure survey. This is an entirely new automobile market.

IV. CONSUMER POCKETBOOK IMPACT: THE PROPOSED FUEL ECONOMY STANDARDS WILL PROVIDE SIGNIFICANT CONSUMER COST SAVINGS

The impact of the standards on consumers can be measured in a variety of ways – pocketbook cash flow, vehicle net benefit, and simple payback periods. By every consumer impact measure, the standards deliver substantial benefits to consumers. [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

As Exhibit S-4 shows, for the typical consumer who purchases a new auto that complies with the 2025 standard with a five year auto loan, the higher fuel economy lowers the cost of driving from the first month because the reduction in gasoline expenditures is greater than the increase in the monthly payment to cover the cost of fuel saving technology. [See Exhibit S-4 on p. 6 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

At the end of the auto loan, the consumer will have saved an average of about $800.

By the tenth year, the vehicle will have generated an average of over $3,000 in savings, which means resale values are likely to be much higher, by $1,000 to $2,000.

Simple payback periods for new cars are less than three years; for new trucks, it will be less than two. [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 39.]

Higher fuel economy standards lower the cost of driving from the first month. They are cash flow positive because the reduction in gasoline expenditures is greater than the increase in the monthly payment to cover the cost of fuel saving technology. At the end of the auto loan the consumer will have saved an average of $800. By the tenth year the vehicle will have generated an average of over $3,000 in savings. Therefore, the resale value of the vehicle is likely to be much higher.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 89.]

Almost two-thirds of respondents support a 60-mile per gallon standard as long as the payback period is within three to five years. And that is the case with these standards.

There are several flaws in quantitative analysis that cause the agencies to seriously underestimate the value of higher fuel economy standards. We have pointed out these flaws in past analyses. [EPA-HQ-OAR-2010-0799-9419-A1, pp. 12-13]

- The rebound effect should not be included in the consumer pocketbook analysis.

Organization: Consumer Reports

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 167.]

Most are willing to pay extra for the extra fuel economy if the payback is -- will mean a lower overall cost of that vehicle over five years.

Organization: Consumers Union

Once fully implemented, the standards will save most car buyers money in the very first month of ownership. According to CNW Marketing Research, approximately two-thirds of new car buyers finance their new vehicle purchases with an average five-year loan.[4] Because average monthly fuel savings is greater than the additional monthly payment from a higher purchase price, consumers start saving right away. For car buyers who pay cash for a new vehicle, the payback period is less than four years, even with EIA's modest fuel price projections. Although consumers will be paying slightly more money for more efficient vehicles, they will more than recover this investment through savings at the pump. [EPA-HQ-OAR-2010-0799-9454-A2, p.2]

---

4 - According to CNW Marketing Research, 67.38% of new-car purchases were financed in 2010. The average length of time for a new car loan in November 2011 was 57.22 months. See Appendix B CNW Marketing Research on Financing Data and Appendix C CNW Marketing Research on Payment Type for data tables.

Organization: Delphi Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 110.]

Third, this rulemaking will enable the consumer to experience the inherent value of technologies that have a reasonable payback period.

Organization: Environmental Defense Fund (EDF)

C. PAYBACK PERIOD

EDF supports the use of a 5-year or greater payback period as an input to estimate the value of fuel economy improvements to potential vehicle buyers. A payback period of anything less than 5 years would not accurately reflect the current and forecasted buying trends of consumers. In 2010, consumers owned vehicles for an average of 63.9 months, or just over 5 years.19 The average length of ownership of new vehicles has been on a steady rise since the economic and auto industry downturn in 2008 and is expected to continue to rise. 20 Therefore, the period of time that potential vehicle buyers can be assumed to value fuel economy improvements in making their purchasing decisions may also be increasing. For this reason, we strongly urge the Agency to use a payback period that accurately reflects the forecasted purchasing behavior of consumers. [EPA-HQ-OAR-2010-0799-9519-A1, p. 8]

Organization: National Automobile Dealers Association (NADA)

IV. THERE IS A NEED FOR ADDITIONAL CONSUMER INFORMATION ON LOWER OPERATING COSTS AND FUEL ECONOMY 'PAY-BACK'

Prospective purchasers able and willing to consider buying new vehicles covered by the proposal could benefit from additional information designed to enable them to better understand the value of investing in fuel economy performance. Current EPA/NHTSA fuel economy labels provide prospective purchasers with the tools necessary to make good comparisons between new vehicles, and between new and used vehicles. NADA is engaged with EPA on how best to use this tool to educate interested prospective purchasers on comparative fuel economy performance. In addition, dealers work with the Department of Energy to make available to consumers the annual DOE/EPA Fuel Economy Guide. In additon, a wealth of useful information is found on fueleconomy.gov and on other non-governmental websites devoted to the topic. [EPA-HQ-OAR-2010-0799-9575-A1, pp. 9-10]

Section 105 of EISA specifically directed DOT, in consultation with DOE and EPA, to implement a vehicle fuel efficiency and alternative fuel consumer education program. Pursuant to that mandate, NADA urges NHTSA to exercise its authority to collect annually from vehicle manufacturers, and to make available to the public, the actual cost of compliance with the so-called 'National Program' for each make, model, and powertrain. This key piece of information, not currently available, will enable prospective new vehicle shoppers to conduct a pay-back analysis for each new vehicle they are considering by measuring actual compliance costs against potential fuel savings. The availability of actual compliance cost data also will assist NHTSA and EPA with determining how best to make further modifications to the 'National Program' so as to improve its effectiveness. In short, enabling the transparency of actual compliance cost data will help to maximize the efficiency of consumer fuel economy decision making and to maximize net regulatory benefits. [EPA-HQ-OAR-2010-0799-9575-A1, p. 10]

The final rule should assume that, at most, buyers value any fuel savings associated with the purchase of a new motor vehicle over a five-year period. As discussed above, except in rare instances of high and increasing fuel prices, consumers who view fuel economy as an important purchase criteria will be hard pressed to make the case for buying a more fuel efficient new vehicle if the up-front capital costs associated with doing so cannot be recouped in short order. [EPA-HQ-OAR-2010-0799-9575-A1, p. 10]

The benefits analysis used in the proposal uses an oversimplified pay-back method that overstates potential fuel economy savings. Instead, for purposes of calculating any 'pay-back,' real-world finance, opportunity, and additional maintenance costs should be accounted for. In other words, the final rule should evaluate its potential impact on a vehicle’s total cost of ownership. An example of such a calculator is found at http://www.nadaguides.com/Cars/Cost-to-Own. NADA would welcome the opportunity to discuss further with EPA and NHTSA how prospective purchasers of new light-duty customers would be better served by a total cost of ownership approach to understanding a given vehicle’s future costs of operation. [EPA-HQ-OAR-2010-0799-9575-A1, p. 10]

Dealers will continue their efforts to educate consumers on how best to make fuel efficient purchases, and on how actual mileage may vary from that set out on Monroney labels. Through efforts such as NADA’s Green Campaign (http://www.nada.org/green), dealers also will continue to educate customers on how to maximize in-use fuel economy performance. [EPA-HQ-OAR-2010-0799-9575-A1, p. 10]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 94-95.]

Proponents of the model year 2017 through 2025 proposal assert that higher upfront costs will pay back for purchases of the -- in the form of fuel cost savings.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

A consistent Consumer Federation Poll released in September of 2010 also showed consumers are willing to pay more for greater fuel efficiency. A majority (62 percent) were willing to pay more for efficiency if they recovered the added cost with a five-year payback period.6 [EPA-HQ-OAR-2010-0799-9549-A2, p. 2]

A more recent study by Deloitte reveals that Generation Y consumers show a strong preference for electric vehicles and hybrids and will pay more for these advanced technology vehicles. A strong majority (56 percent) prefer an electric vehicle over any other type of vehicle, while almost half (49 percent) said they would pay $300 for each mile per gallon of fuel economy improvement that a hybrid gets over a traditional model.7

The above mentioned polls and the Deloitte study support the agencies' use of a 5 year pay back for the cost of technologies using a 3 and 7% discount rates. Significantly, the agencies find that consumers who use a standard 5-year loan to purchase a new vehicle will begin saving they when the drive off the lot, with monthly savings at the pump exceeding the increased loan payments associated with fuel saving technologies by $12 per month (or more).

6 http://consumerfed.org/pdfs/Consumer_Savings_Survey_Fact_Sheet092710.pdf

Organization: Volkswagen Group of America

An implication of the lack of cost parity is the impact on consumer payback. The agencies state that an average consumer will face just less than 4 years to achieve pay-back on the higher upfront investment. Clearly the payback time for a consumer purchasing a passenger car will be longer than a consumer purchasing a light truck, especially a larger pick-up. While Volkswagen has not directly calculated what the expected implication could be on a consumer evaluating two vehicles with different payback periods, it would seem anecdotally that in most cases the consumers would tend towards the shorter period. [EPA-HQ-OAR-2010-0799-9569-A1, p. 10]

Organization: U.S. Chamber of Commerce

EPA states that the new rules will save consumers money under three scenarios: (1) the vehicle is driven by one owner for its entire life span; (2) the customer pays cash and keeps the vehicle for at least four years; or (3) the customer finances the car with a five-year loan and keeps the car for at least those five years. EPA appears to imply that anyone in a typical two-, three- or four-year lease will pay more for their vehicle as a result of the new fuel economy standards. EPA also appears to imply that anyone purchasing a vehicle with a loan that lasts less than five years will pay more for their vehicle as a result of the new fuel economy standards. [EPA-HQ-OAR-2010-0799-9521-A1, p. 2]

A large swath of the car buying public—i.e. anyone owning or leasing a new car for less than four years—will therefore be exposed to higher vehicle costs as a result of the proposed rule. Given that the driving force for this rule is fuel economy, if consumers are unwilling or unable to pay the added cost for this benefit, EPA and NHTSA must be prepared to make changes to the program. [EPA-HQ-OAR-2010-0799-9521-A1, p. 2]

Response:

Regarding comments from CFA, we agree that consumers will save money due to the final standards through decreased fuel expenditures despite the higher new vehicle costs. Furthermore, we do not include rebound miles driven in our consumer payback analysis, although we do include rebound miles driven in our benefit-cost analysis. We present our consumer cost of ownership (payback) analysis in section III.H.5 of the preamble and in Chapter 5.5 of EPA's final RIA.

Regarding the comments from Consumer Reports and Consumers Union, our analysis shows that the payback period will indeed be within 5 years for the average new vehicle purchase (3.3 years using 3% discounting and a cash purchase). For credit purchases, the savings being in the first month as the fuel savings outweigh the increased loan payments assuming a 5 year loan at average national loan rates. We present our consumer cost of ownership (payback) analysis in section III.H.5 of the preamble and in Chapter 5.5 of EPA's final RIA.

We addressed the concerns expressed by the Defour Group in our section 18.1 responses to the Defour Group.

We agree with the Delphi Corporation that the rule will enable the consumer to experience in inherent value of technologies that have a reasonable payback period.

EPA would like to thank the Environmental Defense Fund for their comment and interest in our rule.

Regarding comments from NADA, that NHTSA should collect annually and make available to the public the actual cost of compliance with the National Program for each make, model, and powertrain, EPA doubts this could be done. It is one thing to require industry, any industry, to make available its costs of doing business—this is required by the Security and Exchange Commission for all public companies—but quite another to require that information at the product level. What NADA suggests is akin to requiring Apple to make available to the public the cost of producing a single iPad or iPhone. While no doubt interesting to the consumer, such information is among the most closely guarded information within most public companies. Further, it would require each auto maker to make available to the public their pricing strategy for each of their vehicles. Regarding the time period over which consumers value fuel savings, we note that our OMEGA model runs calculate fuel savings, and discount those fuel savings, over a five year period, consistent with NADA's recommendation. Our payback analysis shows a 3.3 year payback, on average, for 2025MY cash purchases. Regarding what NADA considers our oversimplified payback analysis, we note that our final payback analysis includes increased maintenance costs as the commenter suggested (as well as sales taxes, financing costs for credit purchases and increased insurance costs on the more valuable vehicles, again consistent with the commenter's suggested approach).

Regarding comments from the Sierra Club, et al, we agree that a five year payback period, as mentioned above in our response to NADA, is the appropriate period to use within OMEGA when determining the packages of technologies that are most appropriate for achieving compliance.

Regarding the comment from Volkswagen that the payback period for cars will be longer than for trucks, VW appears concerned that comparison shoppers will gravitate toward the shorter payback periods (trucks) and away from the longer periods (cars). Being largely a car maker for the US market, this would be a concern for VW. However, the comment implies that potential car buyers are comparison shopping against trucks and vice versa. It seems just as probable, if not more so, that potential car buyers are shopping for a car while potential truck buyers are shopping for a truck. As such, their comparisons would be within class and not across class, at least for the most part. Nonetheless, while VW admits that they have not done the calculations to know whether paybacks are longer or shorter for cars versus trucks, we have. As noted, our payback period for a 2025MY cash purchase of the average vehicle is 3.3 years. For a 2025MY car, the payback would be 3.5 years, and for a truck would be 3.2 years. We doubt that such a comparison would drive a potential car buyer to a truck since, despite a shorter payback period, the overall fuel costs would presumably be higher for the truck than the car. But, we leave it to VW to understand their potential customers.

Regarding comments from the U.S. Chamber of Commerce, there appears to be a misunderstanding with respect to our payback, or consumer cost of ownership, analysis. In fact, we fully acknowledge that MYs 2017-2025 vehicles are expected to have increased costs as a result of this rule, and that those costs will be borne in part or in total by the purchasers of the vehicles. The terms of the purchase do not matter in that respect – cars and light trucks are expected to cost more regardless of purchase option. Our analysis was meant to highlight that, despite the higher costs, consumers would actually save money through reduced fuel expenditures. The point at which the savings outweigh the costs is when we consider the savings to have "paid back" the increased costs. Since the cost side of the calculation varies depending on the purchase option – cash vs credit via 5 year loan vs credit via 4 year loan vs lease vs etc. – we chose to focus on what seemed to be the most prevalent purchase options. Those options being cash purchase and credit purchase via 5 year loan. Focusing on those two purchase options should not be interpreted as meaning that purchasers choosing other purchase options will not experience the same fuel savings and/or nearly the same net savings.

Organization: Alliance of Automobile Manufacturers

The importance of gasoline pricing (including tax policy) cannot be underestimated, particularly for the post-MY 2020 timeframe, when policy makers are counting on a rapid transition to non-petroleum transportation fuels. The report from Resources for the Future noted that “it is an open question whether carbon prices at the levels currently under discussion will be sufficient, by themselves, to bring ‘new’ fuel efficiency technology into the marketplace.” Yet the Energy Information Administration projects that fuel prices will be relatively stable over the next 15 years, with gasoline prices rising by less than 4 cents per year. [EPA-HQ-OAR-2010-0799-9487-A1, p.19]

What Impact are the New Requirements Having on Government Revenues and How Are Governments Responding? [EPA-HQ-OAR-2010-0799-9487-A1, p.20]

As gas tax revenues decrease due to rising adoption of electric vehicles (EVs) and improved fuel economy, both the federal government and the states will need to determine how to address budget shortfalls resulting from falling gas tax revenues. In February 2009, the National Surface Transportation Infrastructure Financing Commission released a study recommending a shift from the present reliance on federal fuel taxes to fund federal surface transportation programs to a federal funding system based on more direct forms of ‘user pay’ charges, in the form of a charge for each mile driven (commonly referred to as a vehicle miles traveled or VMT fee system). [EPA-HQ-OAR-2010-0799-9487-A1, p.20]

Recently, certain states have been considering a vehicle miles traveled (VMT) tax or an annual registration fee on EVs as an alternative method to raise revenue for the state’s transportation system. Legislation has been introduced in several states attempting to recover these lost tax revenues. State legislators in Arizona, Washington, Oregon, Texas, Indiana and Mississippi have attempted to address declining revenues with bills that would place fees (i.e., a road usage charge) on EVs, and in some cases, hybrid motor vehicles. States are expected to intensify such efforts to maintain their transportation infrastructure in light of these declining gas tax revenues. If states begin to enact such legislation, the agencies will need to evaluate how this could impact consumers' willingness to invest in advanced technology vehicles. [EPA-HQ-OAR-2010-0799-9487-A1, p.20]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

RECOMMENDATIONS

Include an estimate of the impact of the rule on vehicle sales. Use the approach taken for the 2012-2016 rule unless a better approach is available.

Include economic benefits of the decline in fuel price as a result of the rule. [EPA-HQ-OAR-2010-0799-9528-A2, p.2]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 109-110.]

We concur with the agencies' assessment that in order to thrive in the global automotive market, domestic manufacturers will need to invest consistently in technologies to improve fuel efficiency. We believe that the standards now proposed can help achieve that outcome. And in our testimony, we make three points:

First, that there is a huge potential for cost-effective investments in energy efficiency improvements across all sectors of the economy.

So what is that potential for cost-effective efficiency improvements? In a report we released two weeks ago titled, The Long-Term Energy Efficiency Potential; What the Evidence Suggests, we show that by investing in greater levels of energy productivity, we can slash the nation's energy use by 40 to 60 percent by the year 2050 as we create nearly 2 million more jobs and save the equivalent of $2600 per household annually across all sectors of the economy.

Second, fuel economy standards are a critical first step in capturing the full economic potential.

And third, promoting these standards will be good for jobs, even as the fuel economy improvements will save household consumers and businesses money that almost immediately will be respent in the broader economy.

How do fuel standards then become a critical step in that economic performance? Anytime we can promote cost-effective alternatives to the current pattern of technologies and services, the productivity of the economy is improved. And the evidence here suggests that improved fuel economy provides a significantly improved alternative to the purchase of gasoline. Drawing on data from EPA/NHTSA, we estimate that in constant 2009 dollars that efficiency might cost on the order of 50 cents to $1.20 per gallon of gasoline equivalent compared to the 4, 5 or 6 dollars per gallon of gasoline we may have to pay in the year 2025.

Organization: American Road & Transportation Builders Association (ARTBA)

ARTBA appreciates both EPA and NHTSA's goals of decreasing emissions generated by the burning of fossil fuels in automobile usage. There is already a well-documented history of reductions in fossil fuel emissions occurring through advances in automotive technology. According to the EPA, fuel economy is up 61 percent since 1975. [EPA-HQ-OAR-2010-0799-9403-A1, p. 1]

In 2009, the average personal vehicle got 21.1 miles per gallon, while its 1975 counterpart only managed 13.1 miles per gallon.1 As America's fleet of vehicles become more and more fuel efficient, they will become less and less carbon emitting. For example, tighter fuel economy standards proposed in May 2009 by the Obama Administration will reduce vehicle greenhouse gas emissions by an estimated 900 million metric tons between 2012 and 2016. This is the equivalent of removing 177 million tons of today's automobiles from the nation's roadways.2 Additionally, CO_2 emissions are down 38 percent since 1975: A 2009 model car or light-duty truck (SUV, minivan, pickup) generates 422 grams of CO_2 per mile compared a 1975 model car, which emitted 679 grams per mile.3 [EPA-HQ-OAR-2010-0799-9403-A1, p. 2]

Further, data from the U.S. Environmental Protection Agency (EPA) and the Federal Highway Administration (FHWA) shows substantial progress towards emissions reductions in a growing economy. According to both agencies, despite substantial gains in population, employment, gross domestic product (GDP), number of drivers, number of vehicles, and vehicle miles traveled (VMT) since 1970, the nation's air quality has improved. Specifically, over the same time period, the transportation sector has reduced volatile organic compounds (VOCs) by 73 percent, nitrous oxides (NO_x) by 41 percent, particulate matter (PM) by 50 percent, and carbon monoxide (CO) by 62 percent. NO_x and VOCs are precursors to ozone and associated with GHGs and climate change. As levels of VOCs and NO_x continue to decrease, so will ozone and GHGs. [EPA-HQ-OAR-2010-0799-9403-A1, p. 2]

ARTBA supports efforts to reduce emissions and improve fuel economy. It is inappropriate, however, to promulgate such proposals without acknowledging and attempting to mitigate the adverse effect they would have on other areas of federal responsibility. ARTBA is particularly concerned with the potential effect of EPA and NHTSA's proposed rule on revenues generated for the Highway Trust Fund (HTF). The HTF was created in 1956 as an investment construct by which users of the national highway infrastructure are charged a direct user fee to maintain and improve the system on which they rely. Currently, 18.4 cents are directed to the federal HTF from each gallon of gasoline purchased and federal highway investment accounts for 45 percent of the national capital investment in highway and bridge construction. [EPA-HQ-OAR-2010-0799-9403-A1, p. 2]

As fuel efficiency has increased and innovations in automotive technologies have progressed, revenues into the HTF have been negatively impacted. These positive developments in reducing the motor fuel usage, however, do not have to be inconsistent with the goal of meeting the nation's transportation infrastructure needs. Unfortunately, policymakers in the legislative and executive branches have not increased the per gallon rate of the federal motor fuels user fee since 1993 and as a result the revenues flowing into the HTF and their corresponding purchasing power has fallen further behind the documented needs of the nation's surface transportation system. This problem affects the amount of funding that all 50 states receive from the federal government to build and maintain their transportation infrastructure. [EPA-HQ-OAR-2010-0799-9403-A1, p. 2]

To illustrate the magnitude of the effect of the proposed CAFE Standards on HTF revenues, ARTBA has attached a memo which was distributed to Congress on July 28, 2011. According to ARTBA's research, the proposed CAFE standards will result in a loss of $75,651.7 million dollars through the year 2025. At a time when the nation is struggling to find funding for long term solutions to pay for pressing transportation infrastructure needs, this kind of cut in HTF revenues could put the nation's entire transportation program in jeopardy. [The memo can be found on p. 4 of Docket number EPA-HQ-OAR-2010-0799-9403-A1] [EPA-HQ-OAR-2010-0799-9403-A1, pp. 2-3]

ARTBA encourages the development and use of more energy efficient vehicles and supports the EPA and NHTSA proposal to raise the CAFE standards. This proposal, however, should be expanded to ensure it does not dilute existing or future federal HTF revenues. This adjustment could include an increase in the federal motor fuels tax or some other method of generating federal revenues that will accurately capture the benefit received by users of the system and protect against the effects of inflation, increases in construction costs, and advances in fuel efficiency. [EPA-HQ-OAR-2010-0799-9403-A1, p. 3]

Organization: BlueGreen Alliance

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 38-39.]

Some of the fuel savings created by the standard will go to cover the modest incremental cost of higher performing vehicles. This diversion of spending from fuel to vehicle improvements also has the effect of boosting job creation. This is because vehicle manufacturing is more labor intensive per dollar spent.

Organization: Consumer Federation of America (CFA)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 88-89.]

Seventy-five percent are concerned about gasoline prices and dependence on Mideast oil. They think it is important to reduce oil consumption. They support higher fuel economy standards as a good way to do so.

There are several flaws in quantitative analysis that cause the agencies to seriously underestimate the value of higher fuel economy standards. We have pointed out these flaws in past analyses. [EPA-HQ-OAR-2010-0799-9419-A1, pp. 12-13]

- The base case price of gasoline is too low. The Energy Information Administration has recently raised its estimate of gasoline prices by an average 30 cents per gallon. [EPA-HQ-OAR-2010-0799-9419-A1, p. 13]

Significant macroeconomic benefits of greater fuel economy have been ignored.

- A “price effect” must be included that recognizes that the reduction in U. S. gasoline consumption lowers the world price of crude substantially. This is a true (consumption) externality and the agencies have estimated its value at $0.30 per gallon, but failed to include it in the analysis.

Organization: Consumers Union

As noted in the analysis of the proposed rule, the benefits of the rule far outweigh the costs of compliance. The vast majority of the benefits are direct consumer benefits in the form of fuel savings, while the costs are primarily investments in deploying (and to some extent. developing) more efficient and alternative fuel technologies. In making its cost-benefit calculations, NHTSA relies on the Energy Information Administration’s (EIA) future forecasts of gasoline prices. Consumers Union notes that since 2004, actual oil prices were significantly higher than EIA’s five and ten year forecasts had predicted.[3] While it is not feasible for EIA to predict oil price shocks—such as the one we experienced in 2008—with any certainty, the risks and costs of price spikes are nonetheless very real and likely to occur again in the near future. Consumers Union expects that the consumer savings will be even greater than the sizable benefits predicted by the rule. [EPA-HQ-OAR-2010-0799-9454-A2, p.2]

---

3 - See Appendix A EIA Understimation of Oil Prices

Organization: E100 Ethanol Group

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 202.]

If fully implemented, this plan would save 12 billion barrels of crude oil over the 14-year period between 2012 and 2025. This represents only 26 percent of our crude oil imports for that time period. Thus, it is not possible to achieve crude oil independence by increasing CAFE alone.

Organization: Environmental Consultants of Michigan

As a further the drawback of CAFÉ policy, the proposed higher fuel economy standards would cost $76 billion in lost fuel tax revenue. [NHTSA-2010-0131-0166-A1, p. 3]

Organization: Environmental Defense Fund (EDF)

D. GASOLINE PRICE

Projected future fuel price is the key input in estimating the fuel savings to consumers and society, which accounts for the majority of the proposed program's benefits. Therefore, the agencies' choice of fuel price is very important as it impacts the perceived feasibility of the proposed program. For this proposed rule, the agencies use the most recent fuel price projections from the U.S. Energy Information Administration's (EIA) Annual Energy Outlook (AEO) 2011 reference case forecast. While we agree that the AEO is a very credible source for fuel price forecast, it is important to remember that forecasts are based on models, which are not crystal balls (i.e. there is always some amount of uncertainty). For example, the EIA's AEO2005 forecast for fuel prices for 2005 to 2010 underestimated actual prices over those six years on average by 31%.21 This illustrates the importance of the use of a sensitivity analysis with significantly higher gasoline prices. [EPA-HQ-OAR-2010-0799-9519-A1, pp. 8-9]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 173.]

With respect to economic security, combined again with the Phase 1 standards, the proposed rule will provide families with more than $8,000 in fuel savings over the lifetime of the new vehicle for a total of 1.7 trillion in national fuel savings over the life of the program.

Organization: Jackson, F.W.

"…no amount of domestic production could offset…."Increasing domestic production is a lengthy process, where I've seen it documented it says, and I accept, from start to 1st barrel is at least a decade. So, to have more domestic production available Bush would have to have initiated it over a decade ago. So, not Obama's fault until several more years have passed; if Republican's want to blame someone it's Bush and Congress of a decade ago. [EPA-HQ-OAR-2010-0799-11785-A1, p. 1]

"….little he could do in the short run to ease the pain at the pump" Let's change criteria to from what he can do to what could be done that he could speak out for and lead: Pain at the pump is more than posted price, e.g., drop ethanol mandate to lower per gallon price and require less gallons because a less ethanol content a gallon would have more btus. And there are others, some we have used before like reduced highway limits, politically very unpopular but would help (I do not recommend this but it is something that we could do). But the most important action would be to implement a program that moves us as fast as practical to implement cost-effective maximum efficient technologies – see more specifics starting on bottom of page 7 “Additional relevant comments” and continuing on page 8; and this he could/should do today, i.e., embark on lowest future cost and maximum efficiency , no smoke and mirrors fleet!! [EPA-HQ-OAR-2010-0799-11785-A1, p. 2]

“….US producing more oil than any time during the last eight years…” This comes from pre-Obama actions, i.e., not traceable to Obama actions.

“Neither he nor anyone else can do much about oil prices,…” He now, I accept, but statement to broad to be completely correct. Oil producers, e.g., Saudis, could increase production and lower price, i.e., they qualify as anyone else; and while Obama has very little he can do today with immediate price impact, he does have some, e.g., “lead” cut back on ethanol. And that is for today, there is much he can do to lower future price and price volatility, see below table on page 5. “……new fuel economy standards….average nearly 55 mpg by….” Some “smoke and mirrors” here. Question of how one calculates, i.e., if I take a NHTSA 97 mpgge Leaf with a 12 mpg guzzler I average (unweighted) 54.5 mpg but reality is if I take the gallons of gas equivalent vehicles weighted average I get 21.4 mpggev. Big difference and the one that matters is how many gallons, or ggeqv, in total to move the fleet, i.e., Govt always flashes the 54.5 (and reporters report), it sounds good but not reality as far as oil (the issue at hand) demand is concerned! Obama has tried but he is following his advisers (or handlers) and while making some future progress potentially not the max that Nation needs and could/should have. Potentially is a key word: true CAFÉ unweighted Target raised to 54.5 mpg: problem is with way calculated and big loophole for manufacturers (see above build one LEAF and you can build a “Guzzler”), and unweighted mpg calc, i.e., reality is: weighted calc more fuel required than advertised! [EPA-HQ-OAR-2010-0799-11785-A1, p. 2]

So, Obama has potentially moved the “goal posts” but with big “loopholes” which I expect will be used, otherwise why were they put in! Obama not an Engineer so he may really believe the 54.5, but what about NHTSA&EPA they have technical talent, why do they not tell him, or do they?? Anyway, here is what I calc for EPA 2025 Proposal with 36 BGals ethanol per year mandate fleet (see EPA references) vs. 2016 35.5 mpg: [EPA-HQ-OAR-2010-0799-11785-A1, p. 2]

2016 35.5 mpg E15 fuel: 23.17 total (to Nation) cents per mile 3.15 ggeq/100 miles, or 31.75 mpggeq EPA Proposal 2025 fleet 36 BGal ethanol per year: 23.56 total cents per mile and 2.24 gge/100 miles, or 44.6 mggeq, i.e., not 54.5; and at higher cost. [EPA-HQ-OAR-2010-0799-11785-A1, pp. 2-3]

EPRI with it’s 50% plugins: 29.71 total cents per mile and 2.36 ggeq/100 miles, or 42.4 mpggeq at much higher cost!

Max technologies with minimum ethanol no hybrids or plugins: 17.83 total cents per mile and 1.18 gg/100 miles, or 84.75 mpggev [EPA-HQ-OAR-2010-0799-11785-A1, p. 3]

Pretty clear plug-in and ethanol both very expensive and require more energy on-board vehicle (and in total) than Max (and or Min) technologies, e.g., EPRI with high plug-in % over the 174,000 mile life of a vehicle (vs. Max) of $ 20,671 added total cost per vehicle (and with an assumed Taxes & inflation 50 % pass throughs $ 31,007) – quite a load. Even EPA's Proposal case $ 9,970 added cost vs. Max (and with 50 % for Taxes & inflation pass throughs $14,955! And as I believe manufacturers will continue to find larger more powerful vehicles more profitable I believe EPA's proposal case cost understated and actual mpgge overstated. [EPA-HQ-OAR-2010-0799-11785-A1, p. 3]

Bottom line: while Obama has moved the goal posts on gge from 35.5 mpg, it is at added cost (and potentially much more added cost with methods of calc and/or plugins) with "smoke and mirrors" numbers offered while better alternatives (Mid, Max) available that reduce fuel demand far more while actually saving consumers & taxpayers a bundle! Obama needs to realize the problem is high cost and increasing cost more to Nation, as he is currently promoting, undefendable and is a lost cause if/when the truth gets out; better now than September & October. The President is on exceedingly treacherous thin ice and needs to move now while he has time to demonstrate a new much better for Nation direction; and 36 BGals ethanol was instituted in 2007 before he came to office; the longer Obama continues to promote 36 BGals, the more difficult disowning it will be. And removing the faulty 54.5 analyses & claims now with President orchestrating the information release rather than his adversaries next fall will be far less treacherous during November!!! And he needs to officially chastise NHTSA and EPA for faulty analyses and claims and openly send message he is not happy with Govt performance and wants full and "honest" information in the future from all Govt entities. [EPA-HQ-OAR-2010-0799-11785-A1, p. 3]

Otherwise he depends on the other candidate to look so bad that he still looks the better choice in November. "Drill baby drill" not a better alternative at least a decade for impact and probably inadequate price impact as world demand for oil increases and turmoil in producing areas continue and depletes our reserves at a faster rate, why speed up the date we run out?? And even though Obama's approach is better than "drill baby drill" the voters could be so blinded by unhappiness with Obama's performance in this area as to blindly opt for a change without rationally recognizing they will have two choices in November and unhappiness with continuing the one they have and are not happy with may get them to take a chance that I am confident they would later regret. [EPA-HQ-OAR-2010-0799-11785-A1, p. 3]

EPA&NHTSA

1/27/12 Rev. D 2/18/12 [EPA-HQ-OAR-2010-0799-11785-A1, p. 3]

Subject: Updated (mainly at paragraphs at end Re: messages sent to oil exporters) comments on Docket ID Nos. EPA-HQ-OAR-2010-0799 and NHTSA-2010-0131 "2017 and Later Model

Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy" [EPA-HQ-OAR-2010-0799-11785-A1, p. 4]

Per my above table let's examine Govt proposal with 60 BGals corn ethanol vs. 2016 35.5 mpg standard using gasoline; and then compare against other options: Max technologies gasoline fueled. [See table on pp. 3-4 of Docket number EPA-HQ-OAR-2010-0799-8041-A1] [EPA-HQ-OAR-2010-0799-11785-A1, p. 11]

2016 35.5 CAFÉ gasoline fueled 20.98 cents/mile system 2.97 gg/100 miles. Vs. EPA proposal's E36 (36 BGals corn ethanol of 23.56 cents/mile and 1.41 gal gas/100 miles; or, at 174,000 lifetime miles deltas of 2.69 more cents/mile to reduce gasoline 1.56 gg/100 miles. Doing the math (includes backing out the 20 % fuel discount to get $s we are used to seeing, i.e., about $100/brl): lifetime gasoline reduced but at a cost of $ 1.72 more per gal reduced; adding in the $3.00 for gasoline yields $ 4.72 per gallon to drive vehicle. $ 4.72 equates to $ 198 per brl gasoline or about $ 168 per brl crude offset. Wrong message to oil exporters, our alternative to your $ 100/brl crude is to pay $ 168! [EPA-HQ-OAR-2010-0799-11785-A1, p. 11]

Now examine Max technologies ICEs at 17.83 cents per mile and 1.18 gg/100 miles; or save 3.15 cents per mile while saving 1.79 gg/100 miles. Much better message to oil exporters: our alternative to your oil is to offset our demand for your oil several mbd while saving a couple of hundred $Billion per year. And with significantly reduced demand, the crude cost should be lower which would apply to all oil demand and would further increase our savings: e.g., if crude price dropped from $100/brl to $ 50/brl and our demand dropped 6mbd (from 20mbd to 14) and world followed and world demand dropped 20 mbd, I calc US crude savings at just under (0.47) half a $ Trillion per year staying in Nation's economy; and with 0.065 $ Trillion less cost for crude to US consumers &Taxpayers, I make it 0.535 $sT/year consumer/taxpayer savings . In addition to savings at home more efficient military vehicles would require less fuel to support missions meaning less frequent fuel convoys saving both money and lives! [EPA-HQ-OAR-2010-0799-11785-A1, p. 11]

Factor in a large number of plugins (EPRI case) and I calc $ 347 per brl crude (vs. $ 168 for EPA proposal, save $s for Max Tech). Need to stop showing oil exporters their oil as a bargain and show them oil should be cost plus a "reasonable" profit!!!! [EPA-HQ-OAR-2010-0799-11785-A1, p. 11]

Once we are moving on Mid & Max the numbers might convince some exporters that a stable for 5 or 10 year price for a guaranteed volume during the transition might be to both our & their benefit ; worth a try, especially close exporters. And we could make this more attractive by working with them to reduce their domestic demand by increased efficiency allowing more to be available for export instead of being used inefficiently (wasting a valuable saleable resource) at home! [EPA-HQ-OAR-2010-0799-11785-A1, pp. 11-12]

I'd also consider increasing our online production capacity but capping it (and even some existing) and buying low cost foreign oil when available; saves our oil until last and in the interim it is available to help stabilize US "pump" price if world crude market goes wild. Keep US price lowest by when National energy resources put out for bid include a condition as follows: crude and Nat Gas will be sold for use within US and in addition to current bid $s (up front cost and royalties) at not to exceed prices must be included as part of bid and lower price needs to be properly accounted for Re: consumer cost; and Govt to have the right to reject all bids if they believe it would be better (lowest consumer's prices) for Nation and all citizens for Corps of Engineers to do the production. [EPA-HQ-OAR-2010-0799-11785-A1, p. 12]

And as increased efficiency will reduce cost and jobs in fuel sector we need to apply these saved resources to other areas to keep the economy & jobs at high level. So a question becomes where to apply freed up resources in the most productive way for Nation to maximize goods & services and foreign sales to pay down debt. [EPA-HQ-OAR-2010-0799-11785-A1, p. 12]

And there is more: many other areas (all need to be evaluated) should be likewise completely & objectively evaluated; I'd start with the tax code. It shouldn't matter how you get your money (earn it at work, earn it from investments or an inheritance) get so much less a base amount based on number in family (max number children 2 – over 2 pay for your own hobby) then a fixed %! Free enterprise Ideology, with Free enterprise focused on their bottom lines vs. taxes a specious argument. Republican's declared Free enterprise the winners a decade ago promising a great economy – well here we are a decade later. What really matters is what we get for our resources and each action needs to stand on it's own merits; is free enterprise the way, sometimes but not always; is Govt tax and spend better, sometimes but not always; or is it better for Nation & citizens for individuals to use the resources as they see fit, also true sometimes but not always! My answer: on a case by case basis it is not how we pay but what do we get for what we pay regardless of how we pay – this needs to be the objective discussion: for each way, case by case, what do we pay and what do we & Nation get, and how, case by case, do we maximize short & long term, with strong emphasis on long term, benefit with availability and price "stability" to Nation & citizens, i.e., get the resources to the sector that will make the best investment – one that creates more value than the resources expended so economic activity is sustainable and growing! [EPA-HQ-OAR-2010-0799-11785-A1, p. 12]

And all changes need to be fair and equitable Re. benefits & burdens to all, i.e., not politicians protecting their special interests – every time politicians provide an advantage to a special interest Consumers & Taxpayers have to pay for it; there is no free lunch for Consumers & Taxpayers!!! Also true when Govt causes cost to go up for same output, e.g., cents per mile total, fixed income citizens have to reduce support in other economic sectors thereby reducing economic support & jobs there; e.g., while plugins add jobs in manufacturing plugins the less money to support other economic sectors results in job losses in these other sectors. And in addition to money and jobs, goods and services produced (miles traveled, houses built, food produced, etc.) is what we get to support our lifestyle – we need to watch goods & services criteria carefully as this sets our standard of living, which is what really counts and we need to focus on! [EPA-HQ-OAR-2010-0799-11785-A1, pp. 12-13]

4. Additionally, Govt is mandating more expensive liquid fuel when all Govt actions counted, Le., 36 billion barrels per year of ethanol most all of which I expect will be corn based, and do not forget to include all impacts, including taxes & inflation. I calc cost to the Nation for 36 BBris ethanol to be another $ 3220 added fuel cost per vehicle for EPA's proposal mix unaccounted for. [EPA-HQ-OAR-2010-0799-8041-A1, p. 2]

Organization: Mass Comment Campaign (20) (Union of Concerned Scientists-1)

A strong clean car program is good for all Americans. The proposed standards would save the average consumer $6,000 over the lifetime of a new 2025 vehicle, even after accounting for the additional costs of clean car technology. This estimate assumes gas prices will remain below the 2011 average until at least 2025; if gas prices instead continue to rise, savings from increased fuel efficiency will rise as well. [EPA-HQ-OAR-2010-0799-1558-A1_MASS, p.1]

Organization: Mass Comment Campaign (39) (Unknown Organization)

Aside from health benefits, I am especially impressed by how these standards can reduce the nation's oil consumption by 12 billion barrels in the next 13 years. This will ultimately lead to a decrease in our reliance on foreign oil, which is a great step forward for the United States security. [EPA-HQ-OAR-2010-0799-1245-A1_MASS, p.1]

Organization: National Association of Clean Air Agencies (NACAA)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 41.]

In addition, earlier introduction of cleaner vehicles will provide added assurance that the projected fuel performance is achieved by 2025.

Organization: National Automobile Dealers Association (NADA)

[Supplemental comments to the testimony]

VI. Any "Savings" Related To Particular Purchases Will Vary Depending On an Individual's or Household's Transportation Profile

In addition to falling prey to a "if they build it, they will come" mentality, several folks testifying at the hearings, along with EPA and NHTSA, mistakenly used macro data to back into assertions of "consumer savings." It is both inappropriate and overly simplistic to suggest that a new vehicle fleet phased-in over a certain number of years which may result in gross reductions in fuel use compared to a base scenario, necessarily will result in "the average consumer saving X dollars, " assuming an average vehicle miles travelled (VMTs)and a certain fuel price. [NHTSA-2010-0131-0267-A1, p.5]

Such an analysis raises at least two significant problems. First, to make assumptions so many years in advance based on historically volatile variables is an inherently weak proposition. Second, if and to what extent a given household may achieve a "pay-back" depends on its individual baseline, not on an assumed national average. NHTSA and EPA should conduct a more nuanced analysis of potential "fuel savings," including a careful review of the economic status of prospective purchasers, of whether new vehicle purchases will serve as replacements or as new additions, of the spectrum of VMTs for a set of foreseeable fuel price scenarios, etc, rather make crude, backed-into estimates of “consumer savings” using macro assumptions. [NHTSA-2010-0131-0267-A1, p.5]

Organization: Natural Resources Defense Council (NRDC)

EPA and NHSTA should update fuel price inputs to reflect current forecasts which are higher than those used by the agencies and demonstrate that the agencies took a conservative approach in setting stringency. [EPA-HQ-OAR-2010-0799-9472-A2, p. 3]

NHTSA’s baseline sensitivities based on voluntary overcompliance should be excluded from the final rule. [EPA-HQ-OAR-2010-0799-9472-A2, p. 4]

III. Design of the Standards

A. Stringency

1. Stringency Should be Higher Based on Most Recent Fuel Price Forecasts

The 54.5 mpg standards are strong but stronger standards are feasible and cost-effective, especially under higher fuel prices predicted by the Energy Information Administration (EIA). To develop an economically feasible and cost-effective standard, the agencies used a projection of fuel prices from the EIA Annual Energy Outlook (AEO) 2011. Since the proposal, the EIA has published AEO 2012 Early Release Reference Case, which projects prices to be $0.24 - $0.34 per gallon higher than the AEO 2011 Reference Case during 2017 to 2035. The higher gasoline prices would increase the fuel-saving technologies that could be applied cost effectively and justify a higher standard. [EPA-HQ-OAR-2010-0799-9472-A2, p. 9]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

Transportation Program Funding

The overall reduction in fuel consumption resulting from this rule will affect fuel tax revenues and by extension, transportation funding that relies on per-gallon fuel taxes. While such revenue losses are a legitimate concern, this issue should not be a determinant of the final GHG standards adopted under this rule. For many reasons, federal and state agencies responsible for transportation infrastructure are faced with having to consider non-traditional mechanisms to ensure sustained funding into the future. Funding for transportation infrastructure should be addressed in a broader context outside of this regulatory proceeding. [EPA-HQ-OAR-2010-0799-9476-A1, p. 3]

As expected, a 6 percent annual rate of improvement in fuel economy would have a modestly greater impact on fuel tax revenues compared to the 5 percent rate proposed in the regulation. In either case, a reduction in tax revenue equates to a tax savings of the same amount for consumers. Over a span of 9 years (2017 – 2025) under the proposed 5 percent scenario, total tax revenue in the NESCAUM region from gasoline sales is estimated to be between $28 and $39 billion, depending on the discount rate applied to the net present dollar value. Under the 6 percent scenario in the same timeframe, this amount would be reduced by between $130 and $190 million, or around 0.5 percent of total revenues. By year 2025, the percentage reduction in revenues would be around 1.3 percent and from that point would gradually increase due to continued attrition of older vehicles in the fleet and top out in approximately 20 years at around a 3.5 percent reduction in revenues. [EPA-HQ-OAR-2010-0799-9476-A1, p. 3]

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

Consider more realistic gas price projections: When considering gas prices, the agencies use AEO's 2011 Reference Case. AEO's forecast assumes that gas prices will average $3.54 per gallon in 2025 (in 2009 dollars). According to EIA's own "This Week in Petroleum," gas prices the week of February 6, 2012 averaged $3.48 per gallon nationwide.33 It is shocking to think that gas prices will barely rise from 2012-2025. Although the agencies do consider higher gas prices in sensitivity analyses, when considering setting standards and the benefits derived from those standards, the agencies should place greater emphasis on the high gas price scenarios. We have attached comments submitted to the docket previously by Sierra Club regarding gas price assumptions. [See Docket number EPA-HQ-OAR-2010-0799-9549-A3 for previous comments.] [EPA-HQ-OAR-2010-0799-9549-A2, 10]

Organization: Smith, G.

'Save families an estimated $8,200 in fuel savings over the lifetime of a new vehicle by 2025, for a total of $1.7 trillion in national fuel savings over the life of the program.' They fail to point out the 1) extra cost of fuel efficiency in vehicles 2) discomfort of the considerably smaller vehicles we will have to drive 3) loss of sales by domestic auto companies because they are perceived as not being able to build good small cars. [EPA-HQ-OAR-2010-0799-8438-A1, p. 1]

Organization: Union of Concerned Scientists (UCS)

(g) Gasoline Prices

As noted above, the Energy Information Administration's Annual Energy Outlook (AEO) has become a common source used in many energy-related projections. However, that fact does not justify applying the AEO "reference case" projection, when there are very clear indications that the price projection is poor at best. According to AEO2011 – the projection used in this proposed rule – gasoline prices will range from $3.25-$3.55 per gasoline (in 2009 dollars) between 2017 and 2025. It is hard to accept this as reasonable, given that the actual 2011 average price was $3.53, a mere two cents per gallon shy of EIA's 2025 gasoline price projection. Further, AEO2011 projects regular gasoline prices will rise to a peak of $3.71 per gallon in 2035, a pump price not infrequently seen across the nation today. Clearly, the use of AEO2011 reference case gasoline price projection is inappropriate and should not be used in the agencies' final rule, as it unfairly diminishes the monetary value of fuel saved under the program. [EPA-HQ-OAR-2010-0799-9567-A2, p. 13]

Within the past few weeks, EIA issued the AEO2012 Early Release, which includes a notable increase in gasoline prices over AEO2011. For the 2017-2035 window, AEO2012 Early Release reflects per-gallon prices $0.24 to $0.34 higher than AEO2011 values (converted to 2010 dollars). EPA and NHTSA should, at a minimum, adopt the higher AEO2012 price projections, and investigate the historical accuracy of AEO's High Price scenarios. If it is deemed that AEO's High Price scenarios have, over the past 15 years, been better predictors of actual pump prices, the agencies should utilize High Price Scenario prices for assessing monetary benefits of fuel savings at the pump. [EPA-HQ-OAR-2010-0799-9567-A2, p. 13]

Finally, as UCS has noted in prior comment submissions, AEO's projection does not account for inevitable price spikes that will occur during the lifetime of the vehicles assessed under this rule. Such spikes are closely tied to our nation's inflation and GDP, and thus can have serious economic consequences. With this in mind, the agencies should attempt to quantify the benefits of reduced susceptibility to such spikes, and incorporate them into the program's benefits writ large. [EPA-HQ-OAR-2010-0799-9567-A2, p. 13]

Response:

The Alliance of Automobile Manufacturers suggests that, if states begin to enact legislation to maintain their transportation infrastructure to offset declining gas tax revenues, EPA will then need to evaluate how this could impact consumers' willingness to invest in advanced technology vehicles. However, our analysis shows that compliance can be achieved with less than three percent EVs and PHEVs and just five percent strong HEVs, and those percentages are relative to today's fleet, not the 2025 reference case fleet. See preamble section III.D.6 generally and Table III-52. So our analysis is not heavily reliant on the advanced technology vehicles of which API speaks. Of course, EPA expects to continue conducting analyses of our new standards—most notably for the mid-term review—and will analyze the necessary and pertinent issues as they arise.

Regarding the recommendations from ACEEE, we address the impact of the rule on vehicle sales in Chapter 8.1 of our final RIA and in section 18.7, below. We address the fuel price issue in section 18.5, below. Regarding ACEEE's comments on the "Baseline and other scenarios," we note that these comments appear directed to NHTSA as EPA has not done any analysis assuming that fuel economy will improve after the 2016MY absent any new regulatory requirements.

Regarding comments from ARTBA suggesting that the proposal should include a method of generating federal revenues to offset lost revenue on fuel taxes, we note that EPA and NHTSA do not have the authority to enact revenue generating programs. Such programs must be enacted by Congress. We show the estimated lost revenue in Chapter 5.4 of the final RIA. Our estimates suggest lost tax revenue of roughly $17 billion for the calendar years 2017 through 2025 due to the MYs 2017-2025 standards, and $51 billion over the lifetimes of MYs 2017-2025 vehicles (which includes calendar years 2017 to beyond 2050 for the longest running 2025MY vehicles), both of which are considerably less than the $76 billion through 2025 suggested by ARTBA.

Regarding the comments from BlueGreen Alliance, we discuss vehicle sales in preamble section III.H.11, in Chapter 8.1 of our final RIA and in section 18.7, below.

Regarding comments from CFA, we have used the most recent projected fuel prices available to us at the time modeling inputs had to be locked down. Those fuel prices are taken from the AEO 2012 Early Release. The AEO Early Release projections reflect detailed analysis and are used government-wide. EPA regards this estimate as a reasonable projection (although, like any such projection, actual prices over this period may deviate from those estimated). See also further response on this issue below. Regarding the "price effect," we respond to these comments in section 18.5, below.

Regarding comments from Consumers Union regarding fuel price projections, we agree that predicting future oil and fuel prices is very difficult. EPA leaves that task to the experts at EIA. We believe that the projections provided by EIA represent that best future fuel prices for use in our analysis.

Regarding the comment from the E100 Ethanol Group, we agree that we cannot achieve crude oil independence by increasing CAFE, or GHG standards, alone. However, we can reduce our dependence on foreign oil, consistent with that goal.

Environmental Consultants of Michigan point out that the standards would cost $76 billion in lost fuel tax revenue. EPA agrees that fuel tax revenue will fall if current tax rates remain in place (fewer gallons consumed results in less tax revenue). However, as stated above, our estimates suggest lost tax revenue of roughly $17 billion for the calendar years 2017 through 2025 due to the MYs 2017-2025 standards, and $51 billion over the lifetimes of MYs 2017-2025 vehicles (which includes calendar years 2017 to beyond 2050 for the longest running 2025MY vehicles), both of which are considerably less than the $76 billion suggested by the commenter.

The Environmental Defense Fund commented similarly to the Consumers Union, above. Please refer to our response to Consumers Union. As for sensitivities around fuel prices, we have not done this because doing so would be far more complex than it appears on the surface. To conduct a fuel price sensitivity correctly, we would need to generate unique fleet projections since our fleet projections depend on a macro-economic outlook that would change were we to use different projections of future fuel prices. We have two projected fleets already in our final rule (2008 and 2010 based reference fleets) and could not have added more given the time constraints we had. An alternative approach would have been to use our existing fleet projections and simply use higher/lower fuel prices. However, this would simply show how much our estimated benefits would change with different fuel prices given our existing fleet projections. This would simply show the program to be more or less cost beneficial and, given the magnitude of our fuel savings, higher or lower fuel prices would not change the conclusion that the rule is very cost beneficial.

EPA would like to thank Francis Jackson, the commenters that were part of the mass comment campaigns and NACAA for their comments and interest in our rule.

NADA commented that our payback analysis was not appropriate for every household. EPA does not disagree. However, we cannot calculate the payback period for every household given, as noted by NADA, that the payback period depends on each unique household's transportation profile, their current vehicle's fuel consumption, the new vehicle's fuel consumption, etc. We have attempted to make clear that our payback analysis assumes the average driver that purchases the average vehicle and drives the average number of miles purchasing fuel at the prices projected by AEO in the 2012 Early Release. We have stated that drivers driving more miles will experience a shorter payback while those driving fewer miles will experience a slower payback. We have not meant to imply that everyone that purchases a new 2025MY car will experience the payback we have estimated. For the final rule, we have also included a payback estimate for purchasers of used vehicles to shed light on how their payback might differ from purchasers of new vehicles. We also analyze the issue of low priced vehicles in preamble section III.H.11.b and in section 18.7.1, below.

NRDC suggests that we update our fuel price inputs. We have done so since the proposal and are now using the AEO 2012 Early Release projections. As for standard stringency, we address such comments in section 2 of this Response to Comments document as well as in section III.D of the preamble to the final rule.

NESCAUM commented that funding for transportation infrastructure in light of falling gasoline tax revenues should be addressed in a broader context outside of this regulatory proceeding. We agree and are not addressing this issue in this rule.

Sierra Club, et al, commented that we should use higher fuel price projections in our analysis. We disagree that we should place greater emphasis on the high gas price scenarios rather than the reference case projections generated by EIA. In the AEO 2012 Early Release, EIA states that the Reference case focuses on the factors that shape U.S. energy markets in the long term, under the assumption that current laws and regulations remain generally unchanged throughout the projection period. They further state that the AEO2012 Reference case provides the basis for examination and discussion of energy market trends and serves as a starting point for analysis of potential changes in U.S. energy policies, rules, or regulations or potential technology breakthroughs. As such, we believe that the reference case prices represent the best prices for use in our primary analysis.

Gerald Smith commented in opposition to the rule. Mr. Smith incorrectly claims that supporters of the rule fail to acknowledge the cost of fuel efficiency in vehicles. We have made quite clear in our proposal and our final rule that we expect the cost of new vehicles to increase. For the final rule, we have estimated that cost at $1836 for a 2025MY vehicle meeting the 2025MY standards when compared to one meeting the 2016MY standards. Mr. Smith also suggests that future vehicles will be considerably smaller and less comfortable than today's vehicles. Again, we disagree. Our analysis assumes no change in vehicle size will result from the new standards, and we have still shown a very cost effective path to compliance. Mr. Smith also claims that domestic auto makers will lose sales due to the perception that they cannot build good small cars. Again, we disagree. The new Ford Fiesta and Focus and the Chevy Cruze and Sonic prove that the domestic auto makers can and do produce small cars that consumers want.

The Union of Concerned Scientists commented that we should update our fuel prices to use the AEO 2012 Early Release. We have done so. UCS also commented that we should consider using the AEO high price projections rather than or in addition to the reference case projections. Please refer to our responses to the Environmental Defense Fund and Sierra Club, et al, above. Lastly, UCS suggests that we attempt to quantify the benefits of reduced susceptibility to fuel price spikes that can result from inflation and GDP and can have serious economic consequences. We have not done so for the final rule.

18.4.1.1 Comments about Social Cost of Non-CO_2 GHG Emissions

Organization: Center for Biological Diversity

B. The Agencies' Cost-Benefit Analysis is Faulty

Our January 31, 2012 comments to the DEIS contain an extensive discussion of the ways in which the Agencies' cost-benefit analysis must be corrected. We incorporate that discussion here, but add the following observations. [EPA-HQ-OAR-2010-0799-9479-A1, p. 6]

The Agencies acknowledge that they fail to quantify the benefits and costs of a number of the environmental impacts of the rulemaking. These benefits or costs, however, do not have a value of zero, and a number of them can be estimated and those estimates quantified. For example, monetized GHG benefits "exclude the value of reductions in non-CO_2 GHG emissions (HFC, CH4 and N2O) expected under this proposal." The Agencies do not dispute that the value of these benefits is not zero and can be ascertained – indeed, they set themselves a deadline to do so. The decision to delay the analysis is arbitrary and capricious. Similarly, the Agencies exclude the costs of maintaining a U.S. military presence to secure imported oil supplies from unstable regions "because their attribution to particular missions or activities is difficult." "Difficulty" does not justify conducting a cost-benefit analysis that improperly puts a thumb on one side of the scale.33 [EPA-HQ-OAR-2010-0799-9479-A1, p. 7]

Organization: Environmental Defense Fund (EDF)

IV. AGENCIES SHOULD INCLUDE MORE COMPREHENSIVE ESTIMATION OF BENEFITS

F. EPA SHOULD INCLUDE A QUANTIFICATION OF THE SOCIAL BENEFITS OF NON-CO_2 GREENHOUSE GAS REDUCTIONS

EPA's Regulatory Impact Analysis does not currently include estimates for the monetized impacts of this rule for reductions of non-CO_2 greenhouse gases. 28 The Interagency Working Group on SCC did not estimate the social costs of non-CO_2 GHGs when it developed the current SCC values. The agency has requested comment on whether the "global warming potential (GWP) approach" should be used as an interim approach to valuing the costs of non-CO_2 GHGs (as it did in their proposed New Source Performance Standards (NSPS) for oil and gas exploration). This approach uses the GWP of non-CO_2 gases to estimate CO_2 equivalents and then multiplies these CO_2 equivalent emission reductions by the social cost of CO_2. Further, the agency has requested comment more broadly regarding methodologies for monetizing the benefits of reductions of non-CO_2 GHGs. [EPA-HQ-OAR-2010-0799-9519-A1, pp. 11-12]

EPA should include a range of estimates for the monetized benefits of reduced emissions of non-CO_2 GHGs that will result from this rule (methane, nitrous oxides, hydrofluorocarbons). While there remain uncertainties associated with the currently available methodologies for estimating these benefits, it is clear that there are real benefits; they are most certainly not zero. Therefore, the omission of any estimate at all is unsatisfactory, and EDF strongly recommends the agency include and consider a range of potential estimates. [EPA-HQ-OAR-2010-0799-9519-A1, p. 12]

There are currently two useful quantification methods available for the benefits of reducing non-CO_2 GHGs. First, Marten and Newbold estimate the social costs of methane and nitrous oxide in a recent National Center for Environmental Economics working paper,29 and second, the GWP method, while imperfect, is better than not estimating the benefits at all, and can be used as a proxy. The agency should use these tools to report a range of monetized benefits for the rule. Since the agency has a quantitative foundation in the form of two methodologies for estimating the social costs of these non-CO_2 GHGs, it should provide monetized benefits using both of these methodologies (accompanied by an explanation of any limitations and/or uncertainties in each methodology, as necessary). [EPA-HQ-OAR-2010-0799-9519-A1, p. 12]

In Marten and Newbold, the authors directly calculate the social cost of methane and nitrous oxide using the methodology used by the Interagency Working Group on the SCC, with some updates. This direct method would be the most straightforward, defensible, and consistent with earlier valuation efforts of greenhouse gases. As Marten and Newbold's method is a valid and analytically supportable method, EPA should include figures calculated using their approach. [EPA-HQ-OAR-2010-0799-9519-A1, p. 12]

The GWP method consists of converting the non-CO_2 GHG emission reductions to CO_2-equivalent using global warming potentials (GWPs), then multiplying the resulting CO_{2e} figure by the SCC. As noted by Marten and Newbold, this approximation of the climate benefits of methane and nitrous oxide reductions has the potential for significant error: in 2010 emission reductions for methane valued using the 100 year GWP could be underestimated by as much as 36% while nitrous oxide could be overvalued by as much as 60%, depending on the discount rate. However, they specifically point out that for some policies, such as the light duty vehicle rule30 where non-CO_2 gases represent only a fraction of the anticipated GHG reductions, the error induced by using the GWP method may be small. And most importantly, the authors also note, " . . . if estimates of the social cost are not available, the value of non-CO_2 GHG reductions estimated using GWPs and the $SCCO_2$ will typically have lower absolute errors than default estimates of zero." In other words, using GWP and the SCC to calculate the value of non-CO_2 emissions reductions is more accurate than not calculating the value, particularly in the case of policies such as this one where the reductions of non-CO_2 gases are a small portion of the overall GHG reductions. If EPA is unable to include directly-calculated social costs in support of the final rule due to methodological problems and uncertainties, it should (after identifying and explaining those problems) include an estimate of climate benefits calculated using this GWP method. [EPA-HQ-OAR-2010-0799-9519-A1, pp. 12-13]

Regarding the specific GWP values, EPA should be commended for using the most recent Intergovernmental Panel on Climate Change (IPCC) GWP value for methane (25) from the Fourth Assessment Report in this rule proposal. However, even the most recent IPCC GWP from the Fourth Assessment Report may somewhat undervalue methane's strength as a climate forcer. [EPA-HQ-OAR-2010-0799-9519-A1, p. 13]

EPA should, at least, include a sensitivity analysis using the more recent estimate from Shindell et al. (2009) of 33.31 EPA should provide a range of benefits yielded from the various methods and assumptions (c.f. table 1 in Marten and Newbold), as well as a clear, tabular, demonstration of how it has calculated the monetized benefits. [EPA-HQ-OAR-2010-0799-9519-A1, p. 13]

Organization: Institute for Policy Integrity, New York University School of Law

The Agencies Should Work Toward Developing Non-Carbon Dioxide Benefits Estimates

The Working Group had also planned to develop better methods for estimating the benefits of reducing non-carbon dioxide greenhouse gases within the same two-year timeframe mentioned above.70 The SCC does not smoothly translate into damage figures for other greenhouse gases like methane and hydrofluorocarbons, because of different radiative forcing, atmospheric lifetimes, and environmental impacts.71 As a result, the proposed rule excludes the monetized value of non-carbon dioxide greenhouse gas reductions, even though such reductions make important contributions to the program's climate benefits. [EPA-HQ-OAR-2010-0799-9480-A1, p. 11]

Organization: Natural Resources Defense Council (NRDC)

Our recommendations regarding the GWP method and SCC are summarized as follows [*Note: NRDC recommendations regarding SCC are listed below in section 18.4.1.2*]:

1) GWP Method. Because models directly estimating climate mitigation benefits for other gases are still in their early stages of development, GWPs should be used to calculate climate benefits from reducing non-CO_2 greenhouse gases (Recommendation #1). In so doing, 100 year GWPs should be used, following domestic and international conventions. Further, the most recent GWP estimates from the IPCC's Fourth Assessment Report should be used (rather than GWP estimates from the Second Assessment Report, as was recently used in the proposed oil and gas new source performance standards for methane). For methane calculations and carbon monoxide, EPA should do a sensitivity analysis using the most recently published GWP estimates (Shindel et al.4) (Recommendation #2); in addition, CO_2 fertilization benefits need to be adjusted to reflect non-CO_2 gases actual contribution of CO_2 to the atmosphere, which is less than direct CO_2 emissions (Recommendation #3). [EPA-HQ-OAR-2010-0799-9472-A1, p. 5]

Response:

EPA reviewed the comments regarding monetization of non-CO_2 GHG impacts (CH_4, N_2O, HFCs) and recognizes that the rulemaking will achieve non-zero, economic benefits through reductions in these gases. EPA estimated the non-CO_2 GHG benefits in a sensitivity analysis for the final rule using the GWP approach because directly modeled interagency estimates are not available. The GWP approach entails converting the reductions of each non-CO_2 gas to CO_2-equivalents using the GWP and then valuing the CO_2-equivalents with the SCC. EPA presented these estimates for illustrative purposes and did not include them in our total benefits estimate for this rulemaking because of the following GWP approach limitations.

While the GWP approach would provide an approximation of the monetized value of the non-CO_2 GHG reductions anticipated from this rule, it produces estimates that are less accurate than those obtained from direct model computations for a variety of reasons, including the differences in atmospheric lifetime of non-CO_2 gases relative to CO_2. This is a potentially confounding issue given that the social cost of GHGs is based on a discounted stream of damages—i.e., they are not constant over time—and that are non-linear in temperature. For example, CH_4 has an expected adjusted atmospheric lifetime of about 12 years and associated GWP of 25 (IPCC Fourth Assessment Report (AR4) 100-year GWP estimate). Gases with a relatively shorter lifetime, such as methane, have impacts that occur primarily in the near term and thus are not discounted as heavily as those caused by longer-lived gases such as CO_2, while the GWP treats additional forcing the same independent of when it occurs in time. Furthermore, the baseline temperature change is lower in the near term and therefore the additional warming from relatively short-lived gases will have a lower marginal impact relative to longer-lived gases that have an impact further out in the future when baseline warming is higher.

In addition, impacts other than temperature change also vary across gases in ways that are not captured by GWP. As noted in NRDC's comments, CO_2 emissions, unlike CH_4, N_2O, or HFCs, will result in CO_2 passive fertilization to plants. EPA recognizes this limitation but cannot, as NRDC recommended, simply adjust the GWP to account for the difference. The only way to adequately resolve this limitation is to directly model each non-CO_2 gas cycle. As discussed further below, EPA believes there are several key modeling issues that must be addressed before non-CO_2 gases can be modeled, and thus the interagency group has not yet directly modeled non-CO_2 GHGs.

A limited number of studies in the published literature explore the implications of using a GWP versus a direct estimation approach to quantify the benefits of changes in non-CO_2 GHG emissions from a given policy. One recent working paper (Marten and Newbold, 2011), found that the GWP-weighted benefit estimates for CH_4 and N_2O are likely to be lower than those that would be derived using a directly modeled social cost of these gases for a variety of reasons.[81] The GWP reflects only the integrated radiative forcing of a gas over 100 years. In contrast, the directly modeled social cost differs from the GWP because the differences in timing of the warming between gases are explicitly modeled, the non-linear effects of temperature change on economic damages are included, and rather than treating all impacts over a hundred years equally, the modeled social cost applies a discount rate but calculates impacts through the year 2300.

EPA has determined that key modeling issues must be addressed before directly modeling CH_4, N_2O, HFCs in a manner consistent with the 2009-2010 interagency modeling exercise. For example, a challenging issue in estimating the social cost of non-CO_2 GHGs is that the integrated assessment models vary in how they represent the atmospheric chemistry for these gases. DICE (Dynamic Integrated Climate and Economy) in particular poses a challenge because it does not directly model the atmospheric gas cycle for any GHG other than CO_2. Instead, it jointly represents all non-CO_2 GHGs through a single net radiative forcing vector. The other integrated assessment models, PAGE (Policy Analysis of the Greenhouse Effect) and FUND (Climate Framework for Uncertainty, Negotiation, and Distribution), directly represent the atmospheric chemistry for several non-CO_2 GHGs (noting that for PAGE not all gas cycles, such as methane, were used in the analysis).

There are options to incorporate a defensible cycle for methane in the DICE model, such as supplementing DICE with changes in radiative forcing estimates from MAGICC, a climate model that incorporates important interactions between various gases in the atmosphere.[82] This modification, however, would differ from the methodology established by the 2009-2010 Interagency Work Group.

In addition, EPA has reviewed the comments recommending use of alternative GWPs, in particular Shindell et al's recent estimate of 33 for a 100-year GWP of methane. However, EPA is continuing to use the 100-year GWP approach recommended by the IPCC, consistent with the UNFCCC reporting requirements and the values used in the regulations and analyses for this rule. EPA believes it would be inappropriate to use alternative GWP estimates in the analyses,

[81] Marten, A. and S. Newbold. 2011. "Estimating the Social Cost of Non-CO2 GHG Emissions: Methane and Nitrous Oxide." NCEE Working Paper Series #11-01. http://yosemite.epa.gov/ee/epa/eed.nsf/WPNumber/2011-01?opendocument. Accessed May 24, 2012.

[82] For example, see Marten and Newbold (2011) "Estimating the Social Cost of Non-CO2 GHG Emissions: Methane and Nitrous Oxide." NCEE Working Paper Series #11-01. http://yosemite.epa.gov/ee/epa/eed.nsf/WPNumber/2011-01?opendocument. Accessed May 24, 2012.

even in sensitivity analyses, that have received relatively less scrutiny than those cited in the IPCC reports.

The results of the sensitivity analysis are presented for illustrative purposes in preamble section III.H.6 and in Chapter 7 of EPA's RIA. In sum, the total net present value of annual 2017 through 2050 GHG benefits for this rulemaking would increase by about \$3 billion to \$50 billion, depending on discount rate, or roughly 10 percent if these non-CO_2 estimates were included. Given the magnitude of this increase in the context of the total costs and benefits considered in this rule and other critical decision factors related to technical issues, inclusion of these estimates in the primary analysis would not affect any of the decisions regarding the appropriateness of the standards EPA is adopting here.

Regarding presentation of the non-CO_2 GHG benefits, EPA agrees that a clear, tabular summary would be useful to the reader and has therefore included them in Table III-89 in the RIA for illustrative purposes.

EPA has responded to comments regarding improvements to the social cost of CO_2 in the next section, 18.4.1.2.

Finally, EPA has responded to several of the comments above in other sections. For a response to comments about the treatment of "costs of maintaining a U.S. military presence to secure imported oil supplies from unstable regions," please see section 18.5 in this document. Regarding comments that the agencies should incorporate potential benefit revisions in the mid-term evaluation process and account for the net upstream emissions from electric vehicles, please see section 2.4 (mid-term evaluation) and section 4 (electric vehicles) for EPA's response.

18.4.1.2 Comments about Social Cost of CO_2 (Support for and recommendations to improve estimates)

Organization: Environmental Defense Fund (EDF)

IV. AGENCIES SHOULD INCLUDE MORE COMPREHENSIVE ESTIMATION OF BENEFITS

A. AGENCIES SHOULD ACCOUNT FOR ALL QUANTITATIVE AND QUALITATIVE BENEFITS

EDF recommends, where feasible, the agencies must estimate the monetized health, environmental and economic benefits. We also recommend that where monetization is not feasible, the Agency must present a qualitative list of benefits and explain why it is not feasible to monetize such benefits. This recommendation is in accordance with a January 2011 Presidential Executive Order18: "It must take into account benefits and costs, both quantitative and qualitative." "(c) In applying these principles, each agency is directed to use the best available techniques to quantify anticipated present and future benefits and costs as accurately as possible. Where appropriate and permitted by law, each agency may consider (and discuss qualitatively) values that are difficult or impossible to quantify, including equity, human dignity, fairness, and distributive impacts.” [EPA-HQ-OAR-2010-0799-9519-A1, pp. 7-8]

E. SOCIAL COST OF CARBON

It is critical that NHTSA and EPA collaborate with other agencies and carry out their responsibilities to accurately account for the Social Cost of Carbon (SCC). Cf. Ctr. for Biological Diversity v. Nat'l Highway Traffic Safety Admin., 538 F.3d 1172, 1185 (9th Cir. 2008) (finding a NHTSA fuel economy rule arbitrary and capricious where “[t]he value of carbon emissions reduction [was] nowhere accounted for in the agency's analysis, whether quantitatively or qualitatively”). [EPA-HQ-OAR-2010-0799-9519-A1, p. 9]

The social cost of carbon is a monetary measure of the incremental damage resulting from greenhouse gas (GHG) emissions. The SCC assigns a net present value to the marginal impact of one additional ton of carbon dioxide-equivalent emissions released at a specific point in time. EDF commented extensively on the consideration of the SCC in the first light-duty greenhouse gas rulemaking, the heavy-duty greenhouse gas rulemaking, and the Notice of Intent for Draft EIS. Those comments are hereby incorporated. [EPA-HQ-OAR-2010-0799-9519-A1, p. 9]

It is imperative that the Agencies rigorously and transparently account for the SCC in carrying out responsibilities under NEPA, EISA, and EPCA. In the proposal, it is noted that the Agencies adopted an approach that relies on estimates of the social cost of carbon (SCC) developed by the Interagency Working Group on Social Cost of Carbon. While we support the collaboration and work of the Group, the SCC used should always be based on models reflecting the latest science, as the Agency has itself committed to do. All three modeling teams, whose work led to the report by the Interagency Working Group, have since updated their models to reflect the latest research and methodological developments. At the very least, the SCC used should be updated using the current versions of the models. [EPA-HQ-OAR-2010-0799-9519-A1, p. 9]

We make additional suggestions below as to how current modeling approaches can and should be improved in order to meet the Agency’s commitment to update the social cost of carbon as the underlying models and methodologies are improved22: [EPA-HQ-OAR-2010-0799-9519-A1, p. 9]

- Declining discount rate over time: In assigning a dollar value to reductions in CO_2 emissions, the Agencies use the social cost of carbon and the discount rates included in the Interagency Working Group on Social Cost of Carbon. This includes the use of 5 percent, 3 percent and 2.5 percent discount rates. Recent advances in economic theory indicate that it is not appropriate to use such high and constant discount rates in the context of the social cost of carbon analysis, with a constant 5 percent discount rate being particularly inappropriate. A certainty-equivalent approach, for example, would yield much lower constant discount rates than those currently used. At the very least, we encourage the Agency to use a range of discount rates of 3 percent and below in its SCC analysis. We strongly recommend, however, that the Agency move as soon as possible to the use of a declining social discount rate. Appropriately accounting for uncertainty around the discount rate over long time horizons generates a discount rate that declines over time. As demonstrated at an academic workshop convened by Resources for the Future on Intergenerational Discounting, September 22-23, 2011, there is broad support for the use of declining discount rates within the relevant community of experts.23 These declining rates reflect the scientific, economic, and ethical complexities and uncertainties inherent in intergenerational discounting. [EPA-HQ-OAR-2010-0799-9519-A1, pp. 9-10]

- Evaluating catastrophic risks: The SCC numbers currently used seriously undervalue low-probability/high-consequence climate impacts. Functional form assumptions in the models used in the Interagency Report misrepresent these risks and lead to inaccurately-low SCC numbers. In particular, they cut off the tails of distribution functions too quickly, ignoring potentially catastrophic climate risks.24 The SCC numbers used should reflect the uncertainty range around different functional forms and standard assumptions around risk aversion in order to more accurately value potentially catastrophic climate impacts.25 [EPA-HQ-OAR-2010-0799-9519-A1, p. 10]
- Evaluating Non-Monetized Benefits: GHG reduction policies can significantly undervalue benefits simply because some of these benefits are not easily quantifiable. The White House Office of Management and Budget recognizes that some costs and benefits will be difficult to monetize, but directs agencies to consider other means of quantification.26 We request that the social cost calculations be updated to include the latest results on newly monetized benefits. All additional climate impacts omitted from the models should at the very least be identified explicitly. A table should be provided that lists, for each economic model, what impacts were not included in the model's estimate of monetized damages. Accompanying text should serve to explain and complement the table entries but not be a substitute for them. Below, we have provided an example table listing impacts typically omitted from SCC models. [EPA-HQ-OAR-2010-0799-9519-A1, p. 10]

[See list on p. 12 of Docket number EPA-HQ-OAR-2010-0799-9519-A1]

Organization: Institute for Policy Integrity, New York University School of Law

The rule would raise the corporate average fuel economy standards for new automobiles and restrict the levels of greenhouse gases that vehicles may emit. While the proposed rule will generate large net social benefits, prior to the rule's final publication, the agencies should consider adopting several refinements to their calculation of benefits and their approach to vehicle attributes. [EPA-HQ-OAR-2010-0799-9480-A1, p. 1]

• The agencies should increase estimates of climate benefits to more accurately value the chance of catastrophic damages. Substantial economic literature, including much published in the last two years, supports the conclusion that current models do not place enough emphasis on catastrophic scenarios and, consequently, that some adjustment to the calculation of benefits is necessary. Disagreement over the exact size of that adjustment does not suggest the risk of catastrophe should be valued at zero. [EPA-HQ-OAR-2010-0799-9480-A1, p. 1]

• The agencies should increase estimates of climate benefits to account for risk aversion. Climate change is a categorically different kind of social problem: no single government can self-insure against the risk of irreversible, planet-wide damages. The government, therefore, should be risk averse toward climate change. Though the degree of risk society faces is a subject of contention, most economists believe there is some non-negligible amount of risk that must be accounted for. A risk premium should be incorporated, either as an adder to the value of climate benefits, or as a downward adjustment to discount rates. [EPA-HQ-OAR-2010-0799-9480-A1, p. 1]

• The agencies should continually revise estimates of climate benefits to reflect the most recent scientific and economic knowledge. Even if a better estimate of benefits will not change the stringency or structure of the proposed rule, accuracy remains important. Professional and legal norms for economic analysis require it; accurate benefits estimates will increase confidence in the justifications for the rule and inform the public debate; and the agencies' impact analysis will set a precedent for future rulemakings. The agencies should take the lead on adjusting estimates to account for risk and catastrophic damages, as well as the latest climate science. [EPA-HQ-OAR-2010-0799-9480-A1, p. 2]

• The agencies should make several other improvements in the valuation of climate benefits, including development of non-carbon dioxide estimates, incorporation of potential benefit revisions in the mid-term evaluation process, and accounting for the net upstream emissions from electric vehicles. [EPA-HQ-OAR-2010-0799-9480-A1, p. 2]

Part I. Climate Benefits

The proposed rule will significantly reduce greenhouse gas emissions and takes an important step in addressing climate change. However, the proposed rule underestimates the benefits of these emissions reductions. In so doing, it understates the need for increased reductions and sets standards that are more lenient than socially optimal. Developing the most accurate estimates of climate benefits and the appropriate stringency for emissions standards will set a valuable precedent for all future rulemakings that affect greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-9480-A1, p. 2]

The agencies should make several improvements to their calculation of the rule's climate benefits. Most importantly, the agencies should update the social cost of carbon (SCC) estimate to: (1) reflect risk aversion, (2) appropriately weigh the possibility of catastrophic climate change, and (3) incorporate the most recent scientific advances on the relationship between greenhouse gas emissions and climatic stability. [EPA-HQ-OAR-2010-0799-9480-A1, p. 2]

Disagreement over the size of risk aversion and catastrophic risk does not mean they should be valued at zero. Without more fully accounting for risk aversion and catastrophic climate outcomes, the SCC estimates used in the rule will be too low. [EPA-HQ-OAR-2010-0799-9480-A1, p. 2]

The SCC revision process should be understood as an on-going activity that continually updates estimates to reflect the most recent science. The state of science on this issue continues to expand at a rapid pace, and it is important that the agencies incorporate recent insights as quickly as possible. The agencies should also seek to develop estimates for the benefits of non-carbon dioxide reductions, and the SCC revision process should be extended and incorporated into the mid-term evaluation of the regulation. Finally, the agencies should rethink the way they calculate emissions from alternative fuel vehicles. [EPA-HQ-OAR-2010-0799-9480-A1, p. 3]

Background on the Social Cost of Carbon

The social cost of carbon (SCC) is an "estimate of the monetized damages associated with an incremental increase in carbon emissions in a given year. It is intended to include (but is not limited to) changes in net agricultural productivity, human health, property damages from increased flood risk, and the value of ecosystem services due to climate change."2 Theoretically, the SCC includes all the economic losses associated with global climate change. An interagency working group (Working Group), which included both EPA and DOT, released initial estimates of the SCC in February 2010.3 [EPA-HQ-OAR-2010-0799-9480-A1, p. 3]

That report harmonized the federal government's approach to valuing climate benefits and developed an initial set of four alternative estimates. The four estimates were built around the results from three integrated assessment models (IAMs), which "translate emissions into changes in atmospheric greenhouse concentrations, atmospheric concentrations into changes in temperature, and changes in temperature into economic damages." 4 The proposed rule discusses all four SCC estimates, but relies mostly on the "central" value, which is based on a 3% discount rate.5 However, both the Working Group and the proposed rule note that the IAMs and the current SCC estimates contain significant limitations: incomplete treatment of catastrophe, uncertainty in the extrapolation of damages to high temperatures, and underdeveloped assumptions about risk aversion.6 The agencies seek comment on the assumptions used to determine the SCC.7 [EPA-HQ-OAR-2010-0799-9480-A1, p. 3]

The Agencies Should Increase the SCC Estimates to More Accurately Value Catastrophic Change

The possible levels of climate damages are often modeled as a distribution describing the probabilities of various economic outcomes. The Working Group estimated the SCC by analyzing probability distributions generated by three IAMs, using those distributions to calculate the expected climate damages society would experience at various concentrations of greenhouse gases. IAMs, however, generally undervalue the possible damages associated with catastrophic climate change by reducing the complexity of the problem8—though scientific research predicts a non-negligible chance of a planet-wide, truly disastrous climate catastrophe, IAMs do not give much weight to such low-probability scenarios that exist on the far end of the probability distribution curves.9 [EPA-HQ-OAR-2010-0799-9480-A1, p. 3]

In short, the true probability distribution of climate damages has a longer and fatter right-hand tail than is represented in IAMs. 10 Weitzman argues that considering such "fat tails" increases the expected damages significantly, which could exert enormous influence on society's willingness to pay for emissions abatement.11 That is, because extreme climate outcomes would impose such enormous economic losses, even relatively unlikely scenarios can shift the expected damages from climate change dramatically to the right. Should the possibility of these outcomes be great enough, the effect of such catastrophic damages could dominate the analysis. Tol notes similar difficulties with IAMs,12 and the National Academy of Sciences found that IAMs insufficiently measure the totality of these effects.13 (The fact that both Weitzman and Tol find similar problems with IAMs14 [EPA-HQ-OAR-2010-0799-9480-A1, p. 4]

In early 2010, the Working Group suggested that scholarly disagreement warranted further investigation before it would be appropriate to adjust the SCC to account for catastrophic damages. is notable given their history of disagreement over optimal mitigation policies.) Because the Working Group's analysis relied heavily on IAMs that do not fully account for the possibility of catastrophic damages, the agencies should adjust SCC estimates upward to properly value expected climate damages.15 The Working Group referred to the work of Nordhaus,16 Pindyck,17 and Newbold and Daigneault18 to support its decision to delay addressing catastrophic damages. While Nordhaus's work is seminal in many ways, it is often recognized as undervaluing catastrophic outcomes. He relies heavily on one IAM (namely, DICE) that suffers from the problems explained above: it fails to fully account for the influence of catastrophic climate outcomes.19 Newbold and Daigneault's results indicate that basing substantial SCC adjustments on catastrophic damages would depend heavily on the values assigned to model parameters. This merely shows that calculation of expected values is difficult and that extreme results such as Weitzman's20 do not always hold. Their basic conclusion that current IAMs inadequately account for catastrophic damages21 still cuts in favor of some upward adjustment to the SCC, not waiting for further research. Pindyck finds only moderate expected utility differences when considering a wide distribution of climate outcomes.22 However, he uses a simplified IAM with different damage and growth functions that do not assume fat tails. Yet it is fat tails and the growing possibility of extreme outcomes that drives much of the catastrophic damage analysis. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 4-5]

The Working Group claimed that "further research in this area is needed before its practical significance can be fully understood and a reasonable approach developed to account for such risks in regulatory analysis."23 In fact, no amount of research can lead to a "full understanding" of this problem. Nevertheless, a practical approach to treating catastrophe can be developed and implemented. Indeed, because a greater possibility of catastrophic damages exists than is included in the IAMs used by the Working Group (the Working Group essentially admits that this is the case24), the practical approach is to adjust the SCC upward. The fact that there is disagreement about the size of this catastrophic damage adjustment does not suggest that it should be zero.25 [EPA-HQ-OAR-2010-0799-9480-A1, p. 5]

Moreover, a substantial amount of research has been published since the Working Group's report, adding to a growing body of literature that highlights the limitations of IAMs with regard to catastrophic damages. In the next revision of the SCC estimates, the agencies and the Working Group must address the relevance of work by Pycroft, Vergano, Hope, Paci, and Ciscar, 26 Millner,27 Ackerman, Stanton, and Bueno,28 Dietz,29 and Gerst, Howarth, and Borsuk.30 Combined with the work of climate scholars like Weitzman and Tol,31 the economic literature supports the proposition that IAMs do not place enough emphasis on catastrophic damages and, consequently, some adjustment should be made to account for this limitation. [EPA-HQ-OAR-2010-0799-9480-A1, p. 5]

The studies that attempt to calculate the amount of adjustment necessary generally find it to be large. Yohe and Tol opine that increasing the SCC by 50% "is not out of the question" given the non-zero risk of catastrophic climate change. 32 In stylized conditions of structural uncertainty, Weitzman shows that the SCC might be infinite.33 This seems implausible, and several studies react by restricting the damage function to avoid this result.34 Pycroft, Vergano, Hope, Paci, and Ciscar find that allowing for the possibility of different tail sizes in both the climate sensitivity parameter and the damage function lead to increases in the SCC of 33% to 115%.35 A number of other studies suggest methods for addressing the problem of catastrophic changes. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 5-6]

Rather than waiting an indefinite amount of time for further insights, the agencies and the Working Group should evaluate the existing literature, make a decision about the best way to apply it, and begin incorporating greater consideration of catastrophic damages into the analysis to produce the most accurate SCC estimates available. If the agencies do not make an adjustment to the SCC estimates for catastrophic damages, the rule will underestimate greenhouse gas reduction benefits and will risk setting a precedent for future emissions standards to be less stringent than socially optimal. [EPA-HQ-OAR-2010-0799-9480-A1, p. 6]

The Agencies Should Increase the SCC Estimates to Account for Risk Aversion36

Climate change outcomes are uncertain: the exact damages each additional unit of greenhouse gas emissions will cause are unknown. Consequently, each unit of emissions contributes additional risk that climate damages will be worse than expected. [EPA-HQ-OAR-2010-0799-9480-A1, p. 6]

This risk can be valued by thinking of climate abatement as an investment. Most people are naturally risk averse; when investments involve risk, people are willing to pay for greater certainty than when only considering the expected returns of the investment.37 For example, an investment option with less risk will typically sell at a higher price than a risky investment, even if the two alternatives have an equal expected payout. In portfolio theory, that price differential represents the risk premium that risk-averse actors demand for holding a risky asset. Investors also mitigate risk by buying investments that co-vary so that, ideally, when one investment performs poorly, the other performs well, increasing the certainty that the total investment portfolio will have positive returns. Thus, when investing in a range of assets, the covariance of the assets helps determine the price investors will pay for those assets. [EPA-HQ-OAR-2010-0799-9480-A1, p. 6]

The Working Group decided in early 2010 to continue “investigating” the issue of risk aversion in lieu of including a risk premium in the SCC. The Working Group did note that Anthoff, Tol, and Yohe found that risk aversion is at least as important as the rate of time preference 38 —a topic that the Working Group discusses in great detail. However, without citing studies with different results, it still concluded that further investigation was necessary before including a risk premium in the SCC. [EPA-HQ-OAR-2010-0799-9480-A1, p. 6]

It failed to mention the work of Heal and Kristrom,39 Heal,40 Hennlock,41 Tol,42 Yohe and Tol,43 or additional work by Weitzman,44 among many others that suggest the use of significant risk premiums. In short, the decision to delay inclusion of a risk premium in the SCC is inconsistent with the literature. Although scholars use different methods for calculating risk premiums and arrive at different results, disagreement over the size of these values does not suggest that they should be zero.45 The degree of risk society faces is a subject of contention, but most economists believe that there is some non-negligible risk premium that must be accounted for in the SCC.46 [EPA-HQ-OAR-2010-0799-9480-A1, p. 7]

More important than the precise value is the realization that positive risk aversion warrants incorporating a positive risk premium into the SCC.47 There are two different pathways for risk aversion to be important for calculating the value of greenhouse gas abatement. In the first, mitigation steps taken today can be understood as an investment that is part of a larger portfolio of investments made by society. Under this framework, risk aversion can lead to a higher or lower social cost of carbon, depending on whether the value of greenhouse gas emissions in the future are correlated with the overall growth rate of the economy. To the extent that many of the effects of climate change will involve non-market impacts—the decimation of coral reefs, for example, or widespread extinction of terrestrial species—they may be substantially unrelated to the returns in the economy as a whole. If a substantial share of the damages from climate change is expected to be uncorrelated to returns in the economy as a whole, the discount rate should move toward the risk-free rate. [EPA-HQ-OAR-2010-0799-9480-A1, p. 7]

For policymakers today, there is also a great deal of uncertainty about the relationship between the greenhouse gas emissions and climate outcomes. Resolution of that uncertainty is structurally similar to the realization of a risk that is uncorrelated with market returns, and can be thought of as serving the same function within an investment portfolio. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 7-8]

In addition, the relationship between reductions in greenhouse gas emissions and economic growth reflects causation as well as correlation. Severe climate change could bear negatively and directly on overall economic productivity. For example, sea level rise could threaten large parts of the coastal United States, especially low-lying areas like Florida. In effect, such a causal relationship will be a source of negative correlation between the benefits of mitigation and broader market returns. In climate scenarios with greater temperature change, total damages from climate change will be higher, but total economic activity will be lower (ceteris paribus)—marginal damages and therefore marginal benefits of mitigation will be high (due to convexity of damages) while the returns to the broader economy will tend to be low (the productivity effect). [EPA-HQ-OAR-2010-0799-9480-A1, p. 8]

The second pathway for risk aversion to impact the SCC concerns how investment in climate change mitigation reduces the variance of expected outcomes for the economy as a whole. The distribution of possible climate outcomes is a function of emissions, such that each ton of emissions can amplify the variance of aggregate economic damages and thereby further increase systematic risk. This means that, in addition to increasing the likelihood of catastrophic outcomes, each additional unit of emissions also increases the uncertainty about which outcome will occur. Thus, a full risk premium in the climate change context values the ability of emissions abatement to reduce the variance of outcomes. [EPA-HQ-OAR-2010-0799-9480-A1, p. 8]

Despite these justifications, the Working Group noted that government is usually risk neutral and questioned whether the climate change context merits different treatment. In fact, the nature of the climate problem requires government to be risk averse. For most social problems, the government is large enough that it can self-insure against disaster and act without aversion to risk. But because climate change is qualitatively different than other social problems involving risk, the agencies should treat it differently. The Working Group noted the suggestion in the Office of Management and Budget's Circular A-4 that government agencies should "generally" assume the perspective of a risk neutral actor. But it also observed that society should not always be risk neutral, that Circular A-4 "allows for a different assumption on risk preference in regulatory analysis if it is adequately justified,"48 and that agencies should deviate from the risk neutral perspective when necessary.49 The global nature of climate change catastrophes requires such a deviation. Circular A-4 endorses the use of expected values without a risk premium—here, the average damages of all possible climate outcomes—only when society is risk neutral. However, society will not be neutral when risks cannot be offset by other investments. Compensating for the loss of habitability on Earth is impossible; the ability of the planet to sustain human life is irreplaceable. The magnitude of the damages associated with the risk of catastrophic climate change overwhelms the ability of society to match these damages with gains from other investments.50This suggests that risk aversion is necessary for society to account for the uniquely problematic nature of climate change. [EPA-HQ-OAR-2010-0799-9480-A1, p. 8]

The Working Group attempted to account for risk aversion by including a 95th percentile SCC estimate at a 3% discount rate. 51 The decision to include consideration of risk aversion in one of four estimated SCC values misses the point. Risk and uncertainty are systematic in the climate change context. Consequently, all SCC estimates should include risk premiums to account for these factors. Furthermore, it is not clear whether the selection of the 95th percentile SCC estimate was chosen based on a reasoned connection to the risks under consideration, or out of simple convenience. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 8-9]

Studies that either calculate a risk premium or that include a risk premium when estimating the SCC generally find such premiums to be substantial. Heal finds a premium between 0.1% and 8.13% of national income.52 Tol calculates a risk premium with "conservative assumptions" around $6-$7/ton of carbon dioxide.53 Antoff, Tol, and Yohe report SCCs from about $16/ton of carbon dioxide to over $5,000/ton when incorporating uncertainty into the calculation.54 Finding that uncertainty and equity interact to increase the SCC, they report a final SCC estimate of more than $50/ton of carbon dioxide.55 [EPA-HQ-OAR-2010-0799-9480-A1, p. 9]

These studies constitute several ballpark examples of premium size. Other studies suggest both higher 56 and lower57values for risk premiums. Different assumptions about the degree of risk aversion and parameters in IAMs can radically change modeling outcomes. The point is that the values under consideration are often very large relative to current SCC estimates. The presence of many high estimates for risk premiums suggests that they should be given substantial weight in determining the SCC. [EPA-HQ-OAR-2010-0799-9480-A1, p. 9]

The wealth of studies on this subject provides the agencies with sufficient know-how to incorporate a risk premium into the SCC estimates. The agencies and the Working Group should analyze the range of approaches toward risk and implement the best method for incorporating a defensible risk premium into the SCC. In particular, the agencies should consider including either a "risk adder" or a downward adjustment of the discount rate. 58Without a risk premium, the SCC estimates will be too low and the rule will undervalue benefits from greenhouse gas reductions, setting a precedent for future emissions standards to be inefficiently lenient. [EPA-HQ-OAR-2010-0799-9480-A1, p. 9]

Risk Aversion and Catastrophic Damages Likely Interact, Necessitating Even Larger SCC Values

The combination of risk aversion and uncertainty about catastrophic damages implies an even greater upward adjustment to SCC estimates may be necessary. Millner, Deitz, and Heal argue that differences among complex climate change models expose large gaps in our knowledge regarding climate damages.59 Substantial uncertainty remains for a variety of IAM parameters.60 In the presence of risk aversion, this deep uncertainty coupled with the possibility of catastrophic climate damages implies that the risk adjustment may need to be very large to account for society's desire to avoid catastrophic climate damages. Each unit of emissions reduction not only decreases the average expected future damages, but also thins the fat tails in damage probability distributions, thereby reducing the likelihood of catastrophic outcomes.61 If the government is risk averse, the SCC should include a large risk premium to account for all of these effects. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 9-10]

The Agencies Should Continually Revise the SCC to Reflect the Most Recent Scientific Knowledge

Since the Working Group report, there have been substantial advances in climate science that should be taken into account in the models that underlie the SCC. Several arguments favor revising the SCC to account for the most recent scientific advances as soon as possible in advance of the final rulemaking. First, professional and legal norms for accurate cost-benefit analysis require doing so. Executive Orders instruct federal agencies to accurately weigh the costs and benefits of regulation and base decisions on "the best reasonably obtainable scientific, technical, [and] economic . . . information."62

Although the stringency of the proposed emissions standards was negotiated prior to the rulemaking,63 and the rule will remain cost-benefit justified even with the underestimated SCC values, developing an accurate cost-benefit analysis for the final rule is still important. Given that the tremendous private benefits of the rule are somewhat controversial (though they are clearly real and should be counted),65 accuracy in the estimation of social benefits will help increase confidence in the judgment that total benefits will outweigh costs. Moreover, in addition to aiding the choice between regulatory alternatives, cost-benefit analysis is a way of presenting information to the public and decisionmakers.66 The analysis shapes the public debate not just about this rule, but about future related rulemakings on climate or efficiency. [EPA-HQ-OAR-2010-0799-9480-A1, p. 10]

Second, regulatory impact analysis often builds off of methodologies established in previous rulemakings. EPA and DOT's regulatory impact analyses in particular have a history of setting a precedent for other federal—and even state—agencies to consider the SCC in their own rulemakings. 67 Even if improving the accuracy of the SCC will not affect the stringency or structure of the present rulemaking, it could influence future emissions and efficiency standards developed in other rulemaking contexts or by other agencies. EPA and NHTSA therefore have a responsibility to include the most accurate SCC values, reflecting the most up-to-date scientific and economic literature, in their final rulemaking. [EPA-HQ-OAR-2010-0799-9480-A1, p. 10]

Third, by incorporating the latest scientific developments, the agencies ensure that their analyses do not fall out of date, and can help encourage climate research. Revising the SCC to account for the most recent scientific developments will signal to researchers that the government cares deeply about better understanding these issues, stimulating additional research into these topics. The agencies can even use the revision as an opportunity to identify key outstanding questions, in order to direct future research. [EPA-HQ-OAR-2010-0799-9480-A1, p. 10]

In its February 2010 report, the Working Group committed to “updating these [initial] estimates as the science and economic understanding of climate change . . . improves” and “revisiting the SCC values within two years or at such time as substantially updated models become available.”68 The agencies can make good on this commitment by ensuring that the SCC used in the final rulemaking is based on the most recent climate science.69 [EPA-HQ-OAR-2010-0799-9480-A1, pp. 10-11]

Conclusion

The agencies should increase their estimates of climate benefits to more accurately value the chance of catastrophic damages. Substantial economic literature, including much published in the last two years, supports the conclusion that current models do not place enough emphasis on catastrophic scenarios and, consequently, that some adjustment to the calculation of benefits is necessary. Disagreement over the exact size of that adjustment does not suggest the risk of catastrophe should be valued at zero. [EPA-HQ-OAR-2010-0799-9480-A1, p. 20]

The agencies should increase their estimates of climate benefits to account for risk aversion. Climate change is a categorically different kind of social problem: no single government can self-insure against the risk of irreversible, planet-wide damages. The government, therefore, should be risk averse toward climate change. Though the degree of risk society faces is a subject of contention, most economists believe there is some non-negligible amount of risk that must be accounted for. A risk premium should be incorporated, either as an adder to the value of climate benefits, or as a downward adjustment to discount rates. [EPA-HQ-OAR-2010-0799-9480-A1, p. 20]

The agencies should continually revise their estimates of climate benefits to reflect the most recent scientific and economic knowledge. Even if a better estimate of benefits will not change the stringency or structure of the proposed rule, accuracy remains important. Professional and legal norms for economic analysis require it; accurate benefits estimates will increase confidence in the justifications for the rule and inform the public debate; and the agencies’ impact analysis will set a precedent for future rulemakings. The agencies should take the lead on adjusting estimates to account for risk and catastrophic damages, as well as the latest climate science. [EPA-HQ-OAR-2010-0799-9480-A1, p. 20]

The agencies should make several other improvements in the valuation of climate benefits, including development of non-carbon dioxide estimates, incorporation of potential benefit revisions in the mid-term evaluation process, and accounting for the net upstream emissions from electric vehicles. [EPA-HQ-OAR-2010-0799-9480-A1, p. 20]

36 Some of the literature on risk premiums distinguishes risk and uncertainty based on Knight's definitions: risk involves known probabilities, while uncertainty involves the inability to determine the probabilities of different outcomes. FRANK H. KNIGHT, RISK, UNCERTAINTY, AND PROFIT (1921). However, the distinction between uncertainty and risk is not always clear. We do know that climate damages are not certain. We also know that people are willing to pay to increase the certainty of damages. For the sake of simplicity, these comments recommend a "risk" premium to account for the affects of aversion to both risk and uncertainty.

58 Reducing the discount rate is one way to account for risk aversion. See Kousky et al., supra note 19, at 4. However, the effect of emissions abatement investments on the overall level of risk in the economy does not affect the discount rate as described by modern portfolio theory. There are also independent reasons for lowering the discount rates used by the Working Group, see Letter from Institute for Policy Integrity & Environmental Defense Fund, to Lisa P. Jackson, Administrator, EPA, 15 (Nov. 27, 2009) available at http://www.policyintegrity.org. Any downward adjustment to the discount rate to account for risk should not diminish those independent reasons to also lower the discount rate.

71 Id.

Organization: National Association of Clean Air Agencies (NACAA)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 33.]

The estimated benefits of this proposal include a reduction in oil consumption of 4 billion barrels and a reduction in greenhouse gas emissions of 2 billion metric tons, fuel savings on the order of 347 to $444 billion, at a monetized net benefit to society in the range of 311 to $421 billion.

Organization: Natural Resources Defense Council (NRDC)

EPA and NHTSA should use a social cost of carbon estimated using an improved methodology. NRDC's recommendations authored by Dr. Laurie Johnson, Chief Economist of NRDC's Climate and Clean Air Program, have been submitted as a separately docketed item from these broader comments. [See pp. 1-24 of Docket number EPA-HQ-OAR-2010-0799-9472-A1 for more detail on social cost of carbon.] [EPA-HQ-OAR-2010-0799-9472-A2, p. 4]

In the Regulatory Impact Analysis accompanying the proposed light-duty vehicle greenhouse gas and CAFE rulemaking, EPA and DOT included benefits estimates for CO_2 emission reductions —a monetized value of the marginal benefit of reducing a ton of CO_2—using the social cost of carbon (SCC) as estimated by the Obama Administration's Interagency Working Group on the Social Cost of Carbon (February 2010). Because the use of the Working Group's SCC in this proposed ruling has implications beyond this regulation, we are submitting these comments separately from our more specific comments on the proposed motor vehicle standards. Most of our comments are recommendations for improving the methodology for estimating the SCC for future regulations. NRDC recognizes that implementing many of these recommendations will not be possible within the time frame of this ruling. Nevertheless, they should inform what the agencies decide to do in both the short- and longer-term. [EPA-HQ-OAR-2010-0799-9472-A1, p. 2]

Our recommendations regarding the GWP method and SCC are summarized as follows [*Note: NRDC recommendations regarding the GWP method are listed above in Section 18.4.1.1*]:

2) Improved SCC.

a. Use the updated versions of the social cost of carbon models that were used for the 2010 estimates to re-estimate the SCC for this rulemaking (Recommendation #4). [EPA-HQ-OAR-2010-0799-9472-A1, p. 5]

b. Use a lower discount rate. We recommend 0.7%, the average return on 6 month U.S. Treasury Notes (Recommendation #5), for several reasons (see discussions in Section I.2. and d) and e) in Section II. At a minimum, whatever discount rates the agencies adopt, it needs to include an estimate of the SCC using the government's own recommended lower bound sensitivity value for intergenerational discounting, of 1% (OMB, Circular A-4).5 The choice by the Working Group not to use the lower bound was not justified, and should not be continued. If the agencies elect not implement this recommendation, we request it provide a justification (Recommendation #6). [EPA-HQ-OAR-2010-0799-9472-A1, p. 5]

c. Short of our preferred 0.7% rate, the agencies should at least use a more representative set of discount rates that take into account long run uncertainty in interest rates. The range should include Weitzman6 and UK Greenbook7 declining discount rate schedules, not just the Newell-Pizer estimate already used by the Working Group (Recommendation #7). If the agencies elect not implement this recommendation, we request it provide a justification. [EPA-HQ-OAR-2010-0799-9472-A1, pp. 5-6]

3) Transparency of SCC. EPA should provide a more transparent presentation of the social cost of carbon used in the calculations, such that it better conveys the limitations of the models to handle catastrophic risks and many damage categories, by

a. Providing a detailed list of damages included and excluded from the models in tabular format (Recommendation #8). If the agencies elect not implement this recommendation, we request it provide a justification.

b. Providing the 99th percentile social cost of carbon estimates (Recommendation #9). If the agencies elect not implement this recommendation, we request it provide a justification. [EPA-HQ-OAR-2010-0799-9472-A1, p. 6]

4) Recommendations for the Interagency Working Group. The agencies should recommend to the Interagency Working Group, along with Recommendations above, that the Group:

a. Incorporate risk aversion according to different available methodologies as summarized in Kosky and Kopp (2011)8 (Recommendation #10). [EPA-HQ-OAR-2010-0799-9472-A1, p. 6]

b. In addition to incorporating risk aversion, better integrate the very high and catastrophic damages to which individuals are risk averse into all three models. Specifically, the Working Group should 1) use Weitzman's analysis (2009)9 to 'extend the grid' in the Monte Carlo simulations; 2) for catastrophic outcomes, consider using as an estimate of damages Weitzman's implied ?value of statistical life on Earth as we know it,? the VSL (value-of-a-statistical life), multiplied by world population; 3) reduce the amount of low cost adaptation assumed in the models; and 4) modify damage functions to reflect cross-sectoral damages (Recommendations #11, 12, 13, 14). [EPA-HQ-OAR-2010-0799-9472-A1, p. 6]

c. Conduct sensitivity analyses equity weighting the SCC according to different available methods (Recommendations #15, 16). [EPA-HQ-OAR-2010-0799-9472-A1, p. 6]

d. Review the literature for estimates of the ratio between non-use and use values, and develop a methodology to apply a multiplication factor (or factors) to relevant use values included in the models (Recommendation #17). [EPA-HQ-OAR-2010-0799-9472-A1, p. 6]

e. Dedicate full time staff to collecting and reviewing new climate science and economic modeling on an ongoing basis, and regularly incorporate these developments into the SCC models. As they become available, post findings on a public website with links to sources (Recommendations #18, 19). [EPA-HQ-OAR-2010-0799-9472-A1, p. 6]

f. Update the models to reflect recent research on agricultural changes, which suggest the CO_2 fertilization is overestimated in the FUND model, and that much, if not all, fertilization benefits may be cancelled out by negative impacts on agriculture (e.g. extreme heat, pests, and weeds) (Recommendation #20). [EPA-HQ-OAR-2010-0799-9472-A1, p. 7]

g. Examine whether the upper ends of the 612 to 889 ppm of CO_2 in the four business-as-usual scenarios used by the Working Group reflect current worse-case estimates (Recommendation #21). [EPA-HQ-OAR-2010-0799-9472-A1, p. 7]

Section I below provides a more detailed summary discussion of these comments and recommendations, while Sections II and III provide extended discussions of discounting and equity weighting, and catastrophic risk representation in Monte Carlo analysis, respectively. [See Docket number EPA-HQ-OAR-2010-0799-9472-A1 pp. 8-24 for Sections I, II, and III.] [EPA-HQ-OAR-2010-0799-9472-A1, p. 7]

Response:

EPA appreciates the commenters' recommendations to modify the methodology underlying the SCC estimates and has considered each one in the context of this rulemaking. The interagency group committed to update the SCC estimates as the science and economic understanding of climate change and its impacts on society improves over time. To help motivate and inform this process, DOE and EPA hosted a series of workshops. The first workshop focused on conceptual and methodological issues related to integrated assessment modeling and valuing climate change impacts, along with methods of incorporating these estimates into policy analysis.[83] The second workshop reviewed research on estimating impacts and valuing damages on a sectoral basis.[84]

In sum, EPA has determined that the SCC methodological recommendations require additional research, review, and public comment before it can apply them to a rulemaking context. EPA has therefore presented the SCC estimates developed through the 2009-2010 interagency process in this rulemaking. EPA will continue to consider these comments and will share the recommendations with the interagency group for consideration in future reviews of the current SCC estimates.

Regarding comments that the agencies should rethink the way they calculate emissions from alternative fuel vehicles, please see section 6.5 of this document for EPA's response.

The remainder of this section provides more detailed responses to the recommendations.

Recommendations regarding treatment of uncertainty, catastrophic impacts, and risk.

The interagency group specified three parameters—climate sensitivity, socioeconomic and emissions trajectories, and discount rate—as inputs into three integrated assessment models, leaving other key parameters unchanged from those specified by the authors but ran the models probabilistically for purposes of formal uncertainty analysis in the interagency modeling exercise. A probability distribution was specified for climate sensitivity and used as an input in the three models. A probability distribution was not specified for the other two parameters because of uncertainty about how to model them probabilistically for purposes of formal uncertainty analysis. For example, while models can project potential emissions pathways, assigning probability weights to different states of the world in an analytically rigorous way proved challenging given the dearth of information on the likelihood of a full range of future socio-economic pathways. Likewise, there is broad disagreement in the published literature on what discount rate is appropriate to use in an intergenerational setting. Therefore, the modeling exercise used multiple scenarios that span a range of socio-economic parameters and multiple values for the discount rate.

EPA recognizes the need to review how the models incorporate catastrophic damages and to account for uncertainties and risks in its analysis. EPA also agrees that it is important to account for these issues and notes that the rulemaking documents, in particular the SCC TSD, provide a thorough discussion about these considerations, the ongoing challenge to incorporate them into the SCC estimates, and the implications for the benefits analysis (for example, see Section V of the SCC TSD).

EPA has continued to explore the literature and assess it in the context of its SCC analysis. For example, the DOE/EPA workshop series on integrated assessment modeling reviewed the emerging literature about treatment of economic catastrophes and risk aversion. Overall, the discussions revealed progress in understanding the implications of potential

[83] For workshop proceedings, see http://go.usa.gov/426
[84] For workshop proceedings, see http://go.usa.gov/42F

catastrophes while underscoring the need for additional research regarding optimal ways to incorporate such information into regulatory rulemakings. Likewise, EPA carefully reviewed the commenters' synthesis of the emerging literature regarding treatment of risk aversion, catastrophic impacts, and the calculation of a risk premium, but continues to believe that additional deliberation is required to better characterize these issues and identify the optimal way to modify the interagency group's methodology and incorporate it in rulemakings. Furthermore, other federal agencies use the SCC estimates to analyze benefits of rulemakings and it is important to ensure consistency in the SCC estimates used across the government analyses. This is not consistency for the sake of consistency, but rather using well-documented, scientifically supported estimates, while at the same time continuing the iterative process of analyzing, reviewing, and updating the SCC to reflect best available science. Therefore, EPA will continue to research these important issues and to include the submitted comments in any review process to update the SCC estimates.

Recommendations regarding model vintage.

EPA has also begun to explore the updated versions of DICE, FUND, and PAGE. Additional analysis of the model updates is required before EPA can incorporate them in rulemakings. Furthermore, other federal agencies use the SCC estimates to analyze benefits of rulemakings and it is important to ensure consistency in the SCC estimates used across the government analyses.

Recommendations regarding CO_2 fertilization.

EPA considered the comments regarding CO_2 fertilization benefits in FUND and has determined that additional research would be required to implement these recommendations. EPA has recognized the need for a thorough review of damage functions in all three models that the interagency group used to estimate SCC. In addition to supporting the 2010-2011 DOE/EPA workshop series that explored treatment of impacts in the models, EPA initiated a review of the literature in agriculture and other sectors to help researchers more easily improve representation of damages. Consistent with the commenter's recommendation, EPA is particularly interested in examining recent publications about the role of assumptions regarding carbon fertilization. EPA appreciates the references provided by the commenter and will continue to analyze the components of agricultural impacts.

In the meantime, EPA determined that modifying the FUND structure would be counterproductive, given that the latest version incorporates changes in the estimation of agricultural impacts. These changes are undergoing peer review and EPA looks forward to exploring these changes.

Furthermore, introducing changes beyond those implemented by the model authors would conflict with the methodology established by the interagency working group. A key objective of the interagency process was to enable a consistent exploration of the three models while respecting the different approaches to quantifying damages taken by the key modelers in the field. After conducting an extensive literature review, the interagency group selected three sets of input parameters (climate sensitivity, socio-economic and emissions trajectories, and discount rates) to use consistently in each model. All other model features were left unchanged, relying on the model developers' best estimates and judgments.

Recommendations regarding omitted impacts.

EPA disagrees with the comments that the agency has not responded to repeated requests for more information about how the models treat climate change impacts, i.e., which impacts are therefore included or excluded from the monetized estimates. Specifically, EPA has published written responses to this same comment in other rulemakings—see Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, EPA Response to Comments Document for Joint Rulemaking and Greenhouse Gas Emission Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles, EPA Response to Comments Document for Joint Rulemaking. In short, it is not possible at this time to provide a precise list of each model's treatment (i.e., included, excluded) of climate impacts. Instead, the SCC TSD presents a robust discussion of this key analytical issue, e.g., how each model estimates climate impacts, the known parameters and assumptions underlying those models, and the implications of incomplete treatment of impacts (catastrophic and non-catastrophic) for the SCC estimates. Moreover, the discussion in the SCC TSD underscores the difficulty in accurately distilling the models' treatment of impacts in table-form. Most notably, the use of aggregate damage functions—which consolidate information about impacts from multiple studies—in two of the models poses a challenge in listing included impacts. For example, within the broad agricultural impacts category, some of the sub-grouped impacts are not explicitly modeled but are highly correlated to other subcategories that are explicitly modeled. Therefore, it may be misleading to identify these kinds of impacts as either "included" or "omitted" from the model. Along those lines, impacts may be included in models but not directly; the Dynamic Integrated Climate and Economy (DICE) model represents adaptation implicitly through the choice of studies used to calibrate the aggregate damage function, and the Climate Framework for Uncertainty, Negotiation, and Distribution (FUND) model includes adaptation both implicitly and explicitly (see the SCC TSD for details).

Recommendations regarding discount rate.

Regarding the recommendations for discount rate selection, EPA finds it to be defensible and transparent given its consistency with the standard contemporary theoretical foundations of benefit-cost analysis. The basis for the current discounting approach is discussed in detail in the SCC TSD. In sum, the interagency group applied three constant certainty-equivalent discount rates (2.5, 3, and 5 percent) to the SCC estimates to account for various perspectives about risk and uncertainty. The upper value of 5 percent accounts for the view that there may be a high correlation between climate damages and market returns while the rest of the SCC analysis centers on a discount rate consistent with concerns about risk aversion. The SCC TSD also summarizes the consideration of the literature about handling uncertainty in discounting (e.g., Newell and Pizer (2003), Weitzman (2001), and the UK's "Green Book" for regulatory analysis) and concludes that the proper way to model discount rate uncertainty remains an active area of research.

In addition, EPA finds this approach to be consistent with OMB Circular A-4. Circular A-4 discusses the analytical challenges for discounting in an intergeneration context and concludes that agencies "might consider a further sensitivity analysis using a lower but positive discount rate in addition to calculating net benefits using discount rates of 3 and 7 percent." Specifically, Circular A-4 states that "estimates of the appropriate discount rate" in an intergenerational context ranged from 1 to 3 percent." Two of the three discount rates used in the interagency exercise fall within this range.

However, EPA recognizes the limitations of the discounting approach used in the interagency modeling exercise. Accordingly, EPA funded a workshop on discounting in September 2011 that invited world-recognized experts to discuss how the benefits and costs of regulations should be discounted for projects with long horizons. In particular, it explored what principles should be used to determine the rates at which to discount the costs and benefits of regulatory programs when costs and benefits extend over very long horizons. The charge questions that were the subject of the workshops discussion focused on three main areas: (1) whether and in what context it is appropriate to apply a Ramsey discounting framework in an intergenerational setting; (2) whether and how to directly estimate discount rates over long time horizons; and (3) how to apply discounting in a regulation where some costs and benefits accrue intra-generationally while others accrue inter-generationally. See http://rff.org/Events/Pages/Intergenerational-Discounting-Workshop.aspx for a summary of the main discussion points. EPA is in the process of evaluating next steps with regard to possible methodological improvements in intergenerational discounting.

Recommendations regarding SCC presentation.

Regarding the recommendation to provide the 99th percentile estimates of the social cost of carbon, EPA notes that these estimates are presented in the Appendix, Table A2, in the SCC Technical Support Document, "Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866 SCC TSD," (SCC TSD), which is referenced in both the preamble and RIA. The SCC provides extensive information about the SCC estimates and the underlying parameters, which serve as the basis for the estimates of methane co-benefits. For example, the SCC TSD shows how SCC values for 2010 vary across model, scenario, and discount rate; it also presents the distribution of SCC estimates, including benefit estimates at the 95th and 99th percentiles for each model. EPA has determined that it is more appropriate to place such detailed technical information in the rulemaking's technical supporting documents, i.e., the SCC TSD, rather than the co-benefits section of the RIA, which gives an overview of the calculation as well as a detailed table with the methane co-benefit estimates. The RIA also provides references to the SCC TSD for those seeking further information about the distribution.

Recommendations regarding global estimates of SCC.

EPA agrees with the comment regarding use of a global SCC value and notes that the agencies have in fact used global estimates to assess the benefits of this rulemaking. See preamble Section III.H.6 and Chapter 7 of the RIA for the SCC estimates.

18.4.1.3 Comments about Social Cost of CO_2 (Opposition to estimates)

Organization: Institute for Energy Research (IER)

Furthermore, EPA's cost-benefit analysis utilizes the "social cost of carbon." The estimates developed through EPA's social cost of carbon analysis are arbitrary and capricious as the social cost of carbon is an unsupportable metric for use in federal rulemaking. Even on its own terms, the social cost of carbon estimate is inapplicable for EPA's analysis, because of what is called "leakage" in the climate change literature. Specifically, EPA ignores the possibility that its rule will increase greenhouse gas emissions outside of the United States, through mechanisms such as a lower world price of oil due to restricted American demand. [EPA-HQ-OAR-2010-0799-9573-A1, p. 2]

In addition to basing its case on an assumption that households and businesses irrationally fail to reap advantageous fuel economy savings, EPA's estimates also incorrectly deploy the concept of "Social Cost of Carbon" (SCC) from the climate change literature. Although the SCC is a useful theoretical concept in discussions of worldwide carbon taxes or other frameworks, there are several problems with EPA's invocation of the concept in the context of US-based fuel economy mandates. [EPA-HQ-OAR-2010-0799-9573-A1, p. 9]

5. The "Social Cost of Carbon" is used improperly in the EPA's assessment

Besides the problems with overriding consumers' voluntary choices, part of EPA's analysis is methodologically flawed because EPA uses the "social cost of carbon" in its cost-benefit analysis. As a concept, the social cost of carbon has the appearance of specificity without necessarily reflecting reality in a meaningful way. [EPA-HQ-OAR-2010-0799-9573-A1, p. 21]

EPA and NHTSA explain the social cost of carbon thusly:

EPA has assigned a dollar value to reductions in CO_2 emissions using global estimates of the social cost of carbon (SCC). The SCC is an estimate of the monetized damages associated with an incremental increase in carbon emissions in a given year. It is intended to include (but is not limited to) changes in net agricultural productivity, human health, property damages from increased flood risk, and the value of ecosystem services due to climate change. [EPA-HQ-OAR-2010-0799-9573-A1, p. 21]

EPA argues that by reducing greenhouse gas emissions, this rule would produce benefits, as measured by the social cost of carbon, of a discounted present value of $32.8 billion (using a 5% discount rate) to $522 billion (using a 3% discount rate) and 95th percentile social cost of carbon assumption. But these amounts are almost certainly overestimates. As EPA admits, this rule will only reduce global temperature by 0.0076–0.0184 °C by 2100. Even in the scenario with the most warming, a 0.02°C reduction in temperature is not enough to have any impact on the damages EPA claims will occur with higher temperatures—i.e. "changes in net agricultural productivity, human health, property damages from increased flood risk, and the value of ecosystem services due to climate change." Without having an impact on these damages, there are no real benefits. [EPA-HQ-OAR-2010-0799-9573-A1, p. 21]

In the economics of climate change literature, the social cost of carbon (SCC) is calculated by reducing the absolute amount of greenhouse gas emissions by one (carbon-dioxide-equivalent) ton and estimating the corresponding reduction in the present-discounted value of total long-run climate damages. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 21-22]

EPA's cost-benefit methodology assumes that a proposal that reduces greenhouse gas emissions by a certain quantity R will therefore yield social benefits (from reduced climate damages) of R x SCC. However, this overstates the benefits, because of a phenomenon called "leakage." The calculation of benefits using SCC assumes that if the United States foregoes greenhouse gas emissions as a result of this rule, then those emissions will not happen. This fails to include the impact of these rules outside the United States. Specifically, it is not the case that global emissions from all other sources will be unaffected by the proposed rules. For example, the new rules (and accompanying higher prices for new vehicles) will lead motorists to drive their older, less fuel efficient cars for longer than they otherwise would have, and in the extreme more people will emigrate to jurisdictions that have looser standards and buy more vehicles from exempt manufacturers than would otherwise have occurred. Another major consideration is that reduced U.S. demand for oil will depress world oil prices and lead to greater fuel use by motorists around the world. In the aggregate and over several decades, the actual reduction in global emissions will be lower—and possibly significantly lower—than a naïve estimate would indicate. [EPA-HQ-OAR-2010-0799-9573-A1, p. 22]

EPA's cost-benefit analysis utilizes the "social cost of carbon," which estimates in this proposed rule demonstrate to be an arbitrary and unsupportable metric for use in federal rulemaking. [EPA-HQ-OAR-2010-0799-9573-A1, p. 23]

Response:

EPA disagrees with the commenter's characterization of the SCC as an "unsupportable metric for use in federal rulemaking." While there are inherent uncertainties associated with modeling climate and economic systems over long time spans, the SCC estimates used in the rulemaking analysis were developed from three integrated assessment models that synthesize available scientific and economic research and have been used in the IPCC assessment. Integrated assessment models are particularly well suited to the estimation of SCC because they combine climate processes, economic growth, and feedbacks between the climate and global economy into a single modeling framework. See the SCC TSD for a complete discussion about the three models used to develop the SCC estimates. See also Coalition for Responsible Regulation v. EPA, No. 09-1322 (D.C. Cir. June 26, 2012) slip op. p. 27 ("State and Industry Petitioners assert that EPA 'delegated' its judgment to the IPCC, USGCRP, and NRC by relying on these assessments of clime-change science. This argument is little more than a semantic trick….EPA simply did here what it and other decision-makers often must do to make a science-based judgment: it sought out and reviewed existing scientific evidence to determine whether a particular finding was warranted. It makes no difference that much of the scientific evidence in large part consisted of 'syntheses' of individual studies and research. Even individual studies and research papers often synthesize past work in an area and then build upon it. This is how science works. EPA is not required to re-prove the existence of the atom every time it approaches a scientific question.")

In addition, EPA disagrees that SCC overstates the benefits of mitigation. The SCC estimates do not include all significant climate changes damages and are therefore likely underestimates. In addition, the SCC estimate is for CO_2 only, as noted in the previous comment response. As a result, EPA has supplemented the quantified benefit estimates with a qualitative discussion about benefits.

Furthermore, EPA disagrees with the commenter's conclusions about the potential for emission leakage—in this case, the potential for the rule to "increase greenhouse gas emissions outside of the United States, through mechanisms such as a lower world price of oil due to restricted American demand"—and that SCC is therefore irrelevant. First, EPA disagrees that the rule would necessarily result in emission leakage. The analysis conducted for this rule estimates that the world price of oil will fall modestly in response to lower U.S. demand for refined fuel (see preamble section III.H.8.c for discussion). One potential result of this decline in the world price of oil would be an increase in the consumption of petroleum products, particularly outside the U.S. In addition, other fuels could be displaced from the increased use of oil worldwide. For example, if a decline in the world oil price causes an increase in oil use in China, India, or another country's industrial sector, this increase in oil consumption may displace natural gas usage. Alternatively, the increased oil use could result in a decrease in coal used to produce electricity. An increase in the consumption of petroleum products particularly outside the U.S., could lead to a modest increase in emissions of greenhouse gases, as well as criteria air pollutants, and airborne toxics from their refining and use. However, lower usage of, for example, displaced coal would result in a decrease in greenhouse gas emissions. Therefore, any assessment of the impacts on GHG emissions from a potential increase in world oil demand would need to take into account market impacts in all segments of the global energy sector. Given the complexity of analyzing these multiple market impacts globally, the agencies' analyses have not attempted to estimate these effects.

Second, even if emissions leakage were relevant to this rulemaking, it would affect the estimate of total emissions, not the estimate of the value of damages per ton. In other words, emission leakage is not relevant to the value of a one ton reduction in CO_2 emissions (i.e., SCC). As discussed in the preamble we have assumed that this rule would result in small (marginal) impacts on cumulative global emissions. Even in the unlikely event that emissions leakage occurred under this rulemaking, it would be unlikely to alter the cumulative global emissions trajectory underlying the SCC estimates.

18.4.2. Estimated Non-GHG Health and Environmental Impacts

Organization: American Lung Association

The benefits anticipated from the proposed standards are significant. The preferred alternative directly reduces emissions of carbon dioxide, but should also result in reduced emissions of sulfur dioxide, $PM_{2.5}$, volatile organic compounds (VOCs), nitrogen oxides, benzene, and diesel particulates. [EPA-HQ-OAR-2010-0799-9902-A2, p. 1]

Many of the emissions reduced because of the proposed rule directly impact the health, particularly the lung health, of millions of Americans. The American Lung Association's 2011 State of the Air report found that half the nation - over 154 million Americans - continues to live in areas with dangerous levels of ozone or particulate matter. Current studies warn of significant and complex impacts on particulate matter and tropospheric ozone from climate change. Areas already suffering from poor air quality will find it much harder to clean up ozone and particulate matter, as well as other emissions because of the added burden from the changes to climate. The proposed rule helps to mitigate the short and long-term health impacts of these pollutants as well as the targeted issue of climate change. [EPA-HQ-OAR-2010-0799-9902-A2, p. 1]

Response:

EPA agrees that the benefits of the standards are significant and clearly outweigh the costs. In the RIA that accompanies the final rulemaking (Chapters 6 and 7), we discuss the breadth of benefits associated with both reductions in GHG emissions and non-GHG emissions associated with the standards, including (and especially) reductions in risk to human health and welfare.

Organization: Boyden Gray & Associates PLLC

Supporting action to address these toxic compounds in gasoline in this rulemaking through use of alternative fuels is EPA's own acknowledgement that increased fuel efficiency results in what is known as the "rebound effect"—that is, an actual increase in driving that results from its lowered cost due to greater efficiency. The increased driving in turn means increased tailpipe emissions.30 EPA indicates that overall there is a decrease on these criteria pollutants because of offsetting decreases in upstream emissions. But there are at least two gaps in EPA's reasoning. [EPA-HQ-OAR-2010-0799-9506-A1, p. 9]

First, it is not at all clear that the upstream reductions can offset increases in tailpipe emissions on a population-weighted basis, since tailpipe emissions occur on roadways, where the exposure is greatest, as EPA acknowledges in this rulemaking.31 The goal of EPA regulations under the CAA should be a reduction of human exposure to toxics, not simply the reduction of emissions in general. In fact, motor vehicle tailpipe emissions are the largest single source of air pollution affecting urban populations, and this exposure will not be significantly affected by upstream reductions.32 At the very least, EPA needs to address this point. [EPA-HQ-OAR-2010-0799-9506-A1, p. 9]

Second, and perhaps more important, it is not clear how EPA is calculating the benefits in Chapter 6 of the DRIA. EPA provides charts and citations (i.e., Fann et al., 2007) that calculate the public health benefits per ton of reduction of “direct” PM at $300,000 per ton. At the same time, EPA states that the heavy molecular weight components of gasoline create what EPA classifies as “direct” PM emissions.33 These direct PM emissions are among those that will increase at the tailpipe under the proposal due to the rebound effect, but it is unlikely that this increase will be offset by upstream decreases, because these direct emissions are not associated with upstream operations. And it is not clear that secondary aerosols are associated with upstream operations, either. [EPA-HQ-OAR-2010-0799-9506-A1, p. 9]

In all of issues noted herein, EPA’s proposal raises not merely questions of law but also fundamental questions of regulatory costs and benefits. By undermining NHTSA’s incentives for CNG and alternative fuels, EPA will increase pollution. By requiring auto companies to reduce carbon output, EPA will exacerbate non-GHG pollution, both through the “rebound effect” and through the promotion of advanced engine technologies (such as direct injection) that increase pollution when not paired with cleaner, higher-octane fuel. As EPA itself noted in the DRIA (at p. 6-32), an accurate and thorough consideration of all costs and benefits is critically important to ensure that the agencies’ new standards will promote public health, not harm it. Accordingly, EPA and NHTSA must revisit their cost-benefit analyses, to account for each of those adverse effects of EPA's standards. [EPA-HQ-OAR-2010-0799-9506-A1, p. 11]

Organization: Growth Energy

The oversight with regard to potential PM increases due to widespread DGI use is important because PM effects are a substantial consideration in the cost-benefit analysis. In summarizing the benefits analysis, the proposal emphasizes PM benefits noting:

The benefits include all benefits considered by EPA such as GHG reductions, PM benefits, energy security and other externalities such as reduced refueling time and accidents, congestion and noise. [EPA-HQ-OAR-2010-0799-9505-A1, p. 39]

Organization: Union of Concerned Scientists (UCS)

In our original comments to the NOI, UCS urged the agencies to set standards based on the full set of societal benefits, not just fuel savings. Specifically, we stated “monetization of the full set of societal benefits should be assessed, including (but not limited to) improved energy security through reduced oil consumption, lower carbon emissions, and enhanced economic security in the face of likely gasoline price spikes.”19 [EPA-HQ-OAR-2010-0799-9567-A2, p. 5]

Response:

We refer the commenters to Preamble Section III.G.1 and RIA Chapter 4 for a complete discussion of the emissions impacts associated with this rulemaking and the methods used to estimate them. As the commenters note, we estimate that there will be slight emissions increases associated with rebound driving as well as emission reductions associated with upstream sources such as power plants, refineries, and related emission reductions due to reductions in upstream distribution and transport of fuels (associated with the rule's fuel savings impacts).

The emission impacts associated with the standards serve as inputs to the non-GHG photochemical air quality modeling analysis and the associated health impacts analysis. As shown in RIA Chapter 6, our air quality modeling results indicate that there are very small non-GHG impacts over the majority of the country. For PM, the results indicate that in 2030, a population weighted average reduction of approximately 0.01 ug/m3 can be expected (see RIA Chapter 6.3.1). For ozone, we estimate that in 2030, on a population-weighted basis, there is virtually no change in ambient concentrations in ozone. For the commenter's reference, we further discuss the impact of the rebound effect and advance engine technologies on emissions in Section 17 of this response to comments document.

In terms of health impacts, however, it is clear that upstream reductions in emissions related to ambient concentrations of both direct and indirect PM outweigh the slight emission increases associated with rebound driving. In terms of PM-related health impacts, we estimate that in 2030, emission reductions associated with the rule will result in between 110 to 280 fewer premature mortalities across the U.S. Compared to the estimate of 1 to 3 additional ozone-related premature mortalities associated with rebound-related emission increases, it is clear that upstream emission reductions outweigh the slight downstream emission increases and in fact improve health on a national basis. We note that EPA conducted full-scale photochemical air quality modeling to capture the impacts both upstream and downstream emissions have on ambient ozone formation direct and indirectly formed ambient $PM_{2.5}$ formation. We also note that all fine particles, regardless of their chemical composition, are equally potent in causing health impacts. EPA has also concluded that the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type (See EPA's Integrated Science Assessment for Particulate Matter - http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=216546#Download). Please refer to RIA Chapter 6 for a full discussion of the non-GHG health benefits associated with the rule.

Finally, in response to the comment made by the Union of Concerned Scientists, we note that on a nationally aggregated basis, our analysis shows that the standards do not increase pollution but in fact significantly reduces GHG emissions and improves ambient concentrations of PM. Our analysis in the final rulemaking (of all benefits categories such as GHG reductions, non-GHG benefits, fuel savings, energy security and other externalities such as reduced refueling time and accidents, congestion and noise) is an accurate and thorough consideration of all costs and benefits, and demonstrates that the new standards will promote public health, not harm it.

Organization: Environmental Defense Fund (EDF)

I. EPA'S MONETIZED HEALTH BENEFITS OF AIR QUALITY IMPROVEMENTS ARE UNDERESTIMATED

As explained in the proposal and EPA's Draft Regulatory Impact Analysis (DRIA), EPA calculates the premature-mortality-related effect coefficients that underlie the benefits per- ton estimates of reductions in criteria pollutants from only the American Cancer Society cohort (Pope et al. 2002). The Agency does not present the benefits-per-ton estimates using the Harvard Six Cities cohort (Laden et al. 2006), even though EPA states, "If the benefit-per-ton estimates were based on the Six-Cities study (Laden et al., 2006), the values would be approximately 245% (nearly two-and-a-half times) larger." (Proposal Preamble, page 75131; DRIA, Page 6-33) In fact, EPA admits that, "…using the benefit per-ton value derived from the ACS study (Pope et al., 2002) alone provides an incomplete characterization of $PM_{2.5}$ benefits." [EPA-HQ-OAR-2010-0799-9519-A1, p. 15]

In NHTSA's DEIS, the Agency provides the benefits-per-ton estimates from both studies side-by-side. In fact, NHTSA states the reason it does so is because of a recommendation by EPA. "EPA calculated the premature-mortality-related effect coefficients that underlie the benefits-per-ton estimates from epidemiology studies that examined two large population cohorts – the American Cancer Society cohort (Pope et al. 2002) and the Harvard Six Cities cohort (Laden et al. 2006)…According to EPA, both studies should be used to generate benefits estimates." (DEIS, Page 4-24) [EPA-HQ-OAR-2010-0799-9519-A1, pp. 15-16]

EDF requests that EPA present the results based on both the Pope et. al. and the Laden studies to ensure that a more transparent and comprehensive estimate of the monetized health benefits of air quality improvements are developed. [EPA-HQ-OAR-2010-0799-9519-A1, p. 16]

Organization: Growth Energy

The proposed rule also acknowledges that the agencies' analysis includes no estimates of the direct health or other benefits associated with reductions in emissions of criteria pollutants other than PM. Therefore, two of the major drivers in the list of cost-benefit categories above, "other air pollutants" and "increased driving due to the rebound effect" are determined by PM emissions. The reason that PM dominates the EPA non- GHG analysis is that the damage cost in Table II-8 is much greater for PM than for other criteria pollutants. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 39-40]

Response:

For the FRM, we are conducting full-scale air quality modeling to assess the rule's impact on ambient concentrations of ozone and PM in 2030 and the associated quantified/monetized health impacts. The analysis includes a co-equal presentation of PM-related premature mortality based on Pope and Laden (Tables III-85, III-87, and III-89 of Preamble III, and corresponding tables in Chapter 6 of the RIA) along with a full accounting of the morbidity impacts associated with PM and ozone. Time and resource constraints preclude the agency from running air quality modeling for the Model Year analysis. We therefore continue to use a dollar-per-ton method (consistent with the 2012-2016 LD GHG approach) to monetize the PM-related benefits associated with the standards over the lifetime of each 2017-2025 Model Year vehicle. Because the difference between the Pope- and Laden-based estimates are so slight, relative to the other cost and benefits monetized in the analysis (they represent between ~1-3% of total benefits, depending on the study and discount rate), we chose to simplify the presentation of PM-related benefits in the cost-benefit summary tables by presenting only the Pope-based value, while qualitatively describing that the Laden-based estimate would increase PM-related benefits by ~2.5 times. Even though the Pope-based value is the more conservative end of the range of PM-related benefits, the inclusion of Laden would not provide the reader with a meaningful difference when assessing the comparison of total costs and benefits of the rulemaking.

We have, however, revised our text in Preamble Section III.H.7 (Table III-90) and in FRM TSD 4 - Joint Economic Assumptions (Table 4-13) to present, for reference purposes, the range of Pope- and Laden-based dollar-per-ton values. We have also edited the text to more clearly state that the presentation of the low end of the range of PM-related benefits is in no way meant to convey a preference for one study over the other (see Preamble III.H.7.b and RIA Chapter 6.3.2).

We continue to acknowledge that there are several health impact categories that EPA was unable to quantify in the Model Year analysis due to limitations associated with using dollar-per-ton estimates. Because NOx and VOC emissions are also precursors to ozone, changes in NOX and VOC would also impact ozone formation and the health effects associated with ozone exposure. Dollar-per-ton estimates for ozone, however, do not exist due to issues associated with the complexity of the atmospheric air chemistry and nonlinearities associated with ozone formation. However, given the magnitude of the ozone impacts modeled in the Calendar Year analysis, it is reasonable to assume that the ozone-related impacts would be minimal and would not make a difference when assessing the comparison of total costs and benefits of the rulemaking.

Organization: Mass Comment Campaign (20,500) (Union of Concerned Scientists-3)

The proposal largely ignores the pollution released from power plants when electric cars are recharged. The Environmental Protection Agency should require automakers to fully account for their vehicles' pollution--whether from petroleum or power plants. [EPA-HQ-OAR-2010-0799-10166-A2_MASS, p.1]

Organization: Mass Comment Campaign (375) (Union of Concerned Scientists-2)

The proposal largely ignores the pollution released from power plants when electric cars are recharged. The Environmental Protection Agency should require automakers to fully account for their vehicles' pollution--whether from petroleum or power plants. [EPA-HQ-OAR-2010-0799-1246-A1_MASS, p.1]

Organization: Mass Comment Campaign (9,570) (Unknown Organization)

The proposal largely ignores the pollution released from power plants when electric cars are recharged. The Environmental Protection Agency should require automakers to fully account for their vehicles' pollution--whether from petroleum or power plants. [EPA-HQ-OAR-2010-0799-9578-A1_MASS, p.1]

Response:

EPA estimates the full range of pollution impacts from the standards, including emissions at the tailpipe and emissions from "upstream" sources such as power plants, refineries, and fuel transportation and distribution. Please refer to Preamble Section III.G.1 and RIA Chapter 4 for a complete description of the emissions impacts of the rulemaking and the estimation methodology. Included in our analysis are power plant emissions related to increased penetration of electric vehicles in the future light duty vehicle fleet. These emissions were included in the air quality modeling conducted for this analysis, the output of which were used in the health impacts analysis. Refer to Chapter 6 of the RIA for a description of both the air quality modeling and health impact analyses. Taken together, the non-GHG emission changes yield a net reduction in human health risk and contribute to the overall benefits of the standards.

Organization: Pennsylvania Department of Environmental Protection

Air Quality Effects. In addition to examining the air quality effects of the factors above [see section 18.2 of this comment summary], the increase in volatile organic compounds (VOC) emissions needs to be estimated due to the possible increase in Reid vapor pressure in gasoline from the increased use of higher octane gasoline. Higher emissions of VOC can lead to increased ground-level ozone concentrations. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Response:

Regarding comments from the Pennsylvania Department of Environmental Protection, we do not agree that higher octane fuel will be necessary. As explained in section 3.3.1.8 of the joint TSD, higher octane fuel is not necessary for high compression turbocharged and downsized engines to prevent the onset of combustion knock. EPA therefore assumed no change in the octane of certification or in-use gasoline within its analysis and the effectiveness values used for the high BMEP engines reflect that fact.

In partial confirmation, the current Ford EcoBoost turbocharged GDI engines do not require the use of premium fuel, although those engines are not operating at BMEP levels as high as those expected under our rule. Importantly, a combination of both intake charge dilution (e.g., cooled EGR) and in-cylinder evaporative fuel cooling (e.g., direct injection) are expected to allow higher BMEP GDI engines to operate on regular grade gasoline. All packages at 27 bar BMEP analyzed by EPA included cooled EGR to allow higher BMEP operation and prevent the onset of combustion knock on current certification or in-use fuels.

EPA estimates the full range of pollution impacts from the standards, including emissions at the tailpipe and emissions from "upstream" sources such as power plants, refineries, and fuel transportation and distribution. Please refer to Preamble Section III.G.1 and RIA Chapter 4 for a complete description of the emissions impacts of the rulemaking and the estimation methodology. This includes both upstream and tailpipe VOC emissions associated with the final standards. We use these non-GHG inventories to estimate the changes in ambient concentrations of PM, ozone, and selected air toxics. Please refer to Chapter 6 of the RIA for a description of both the air quality modeling and health impact analyses. Taken together, the non-GHG emission changes yield a net reduction in human health risk and contribute to the overall benefits of the standards.

Organization: American Council for an Energy-Efficient Economy (ACEEE)

At the same time, this kind of savings will put a downward pressure on the price of all petroleum products. If that holds, then fuel economy standards might generate, we estimate, an additional $25 billion in price-related fuel savings. That means even if you're not driving a new car, but if you're heating your home with fuel oil, or if you're using petroleum as a chemical feed stock, or if you're flying from San Francisco to Washington, D.C., you're benefiting from a lower price of oil or gasoline, and that benefits everyone.

The agencies also decline to count the monopsony benefit of the rule, under which reduced U.S. demand leads to lower oil prices globally. This is a departure from previous rules, and is justified by the argument that the monopsony benefit is of a “redistributive nature” when viewed from a global perspective (NPRM p.74932). However, even if all petroleum were produced domestically, reduction in the price of petroleum would bring a net economic benefit in terms of job creation, for example, as explained previously, due to the low labor intensity of the energy sector. Thus it is a mistake to exclude these effects from the analysis of the economic benefits of the rule. The agencies also do not take into account the price reduction following from the fact that reduced demand will generally mean that the most expensive sources of petroleum are not used, which also reduces the price of all petroleum. [EPA-HQ-OAR-2010-0799-9528-A2, pp. 1-2]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 111-112.]

Organization: America's Natural Gas Alliance (ANGA) and American Gas Association (AGA)

C. The Agencies’ Analysis of the Benefits of this Rule Should Include More Complete Energy Security Costs

Energy Security Costs [EPA-HQ-OAR-2010-0799-9548-A1, p. 5]

In response to the agencies’ request for comment on whether to include costs of the relevant U.S. overseas military presence in the energy security benefits analysis (76 FR 75136), AGA and ANGA strongly support doing so. To include only “the macroeconomic disruption and adjustment costs portion of the energy security benefits to estimate the monetary value of the total energy security benefits of this program” (*id.* at 74932) ignores enormous costs that are directly attributable to U.S. dependence on overseas oil supplies. A single example should suffice: the express purpose of the Navy’s Fifth Fleet – reestablished in 1995 and based in Bahrain – is to secure the Persian Gulf sea-lanes, and the annual cost of maintaining this force is in the billions of dollars. [EPA-HQ-OAR-2010-0799-9548-A1, pp. 5-6]

Organization: American Petroleum Institute (API)

Comments on Petroleum Consumption and Import Externalities

The issue of petroleum consumption and import externalities is discussed on page 74898 of the Preamble, consisting of a one-paragraph summary of the issue. The Preamble notes the following externalities are not reflected in the market price for crude: (1) higher price for petroleum products from the effect of U.S. demand on world oil prices; (2) the risk of disruptions caused by sudden reductions in the supply of imported crude; and (3) the expenses of maintaining a military presence to secure imported oil supplies and for maintaining the strategic petroleum reserve. This summary paragraph goes on to say that higher volumes of imported crude and refined products increases the magnitude of these external economic costs (increasing the true economic costs of transportation fuels above the resource costs of producing them), and that reducing volumes of imports or reducing fuel consumption can reduce these external costs. [EPA-HQ-OAR-2010-0799-9469-A1, p. 11]

In the Preliminary Regulatory Impact Analysis (PRIA) developed for this rulemaking, NHTSA stated the following with respect to issue of military expenses associated with protection of supply (page 643): [EPA-HQ-OAR-2010-0799-9469-A1, p. 11]

NHTSA currently believes that while costs for U.S. military security may vary over time in response to long-term changes in the actual level of oil imports into the U.S., these costs are unlikely to decline in response to any reduction in U.S. oil imports resulting from raising future CAFE standards for light-duty vehicles. U.S. military activities in regions that represent vital sources of oil imports also serve a broader range of security and foreign policy objectives than simply protecting oil supplies, and as a consequence are unlikely to vary significantly in response to changes in the level of oil imports prompted by higher standards. [EPA-HQ-OAR-2010-0799-9469-A1, pp. 11-12]

Neither the Congress nor the Executive Branch has ever attempted to calibrate U.S. military expenditures, force levels, or deployments to any oil market variable, or to some calculation of the projected economic consequences of hostilities in the Persian Gulf. Instead, changes in U.S. force levels, deployments, and thus military spending in that region have been largely governed by political events, emerging threats, and other military and political considerations, rather than by shifts in U.S. oil consumption or imports. NHTSA thus concludes that the levels of U.S. military activity and expenditures are likely to remain unaffected by even relatively large changes in light duty vehicle fuel consumption. As a consequence, the agency's analysis of alternative CAFE standards for MYs 2017-2025 does not include savings in budgetary outlays to support U.S. military activities among the benefits of higher fuel economy and the resulting fuel savings. [EPA-HQ-OAR-2010-0799-9469-A1, p. 12]

The above PRIA statements are important points with respect to military expenditures and the protection of crude supply. They are very consistent with the points made by EPA during the RFS2 rulemaking that were included in the "Renewable Fuel Standard Program (RFS2) Summary and Analysis of Comments" document (page 7-248).25 Further, a 2010 report prepared by the National Research Council also considered the issue of military protection of crude supply and found the following: [EPA-HQ-OAR-2010-0799-9469-A1, p. 12]

Dependence on imported oil has well-recognized implications for foreign policy, and although we find that some of the effects can be viewed as external costs, it is currently impossible to quantify them. For example, the role of the military in safeguarding foreign supplies of oil is often identified as a relevant factor. However, the energy-related reasons for a military presence in certain areas of the world cannot readily be disentangled from the non energy-related reasons. Moreover, much of the military cost is likely to be fixed in nature. For example, even a 20 per cent reduction in oil consumption, we believe, would probably have little impact on the strategic positioning of U.S. military forces throughout the world. [EPA-HQ-OAR-2010-0799-9469-A1, p. 12]

Although NHTSA conducted a sensitivity analysis of the impact of some reduction in military spending as a result of this rule, it was not included in the baseline assessment for the very good reasons spelled out above. The Preamble should note the highly speculative nature of this kind of assessment and provide the reader with the appropriate caveats that were included by NHTSA in the PRIA. [EPA-HQ-OAR-2010-0799-9469-A1, p. 12]

Organization: American Public Gas Association (APGA)

APGA has long recognized that the United States' dependence on foreign oil is one of the foremost threats to our nation both economically and militarily. The U.S. economy is dangerously dependent upon crude oil for stability and economic growth and in no area is this dependence more evident than in the transportation sector. Even slight increases in the price of gasoline can send shock waves throughout the economy, reduce consumers' purchasing power and spending, cause financial markets to tumble, and inhibit economic growth. [EPA-HQ-OAR-2010-0799-9448-A1, p-.1]

Moreover, it is on the foundation of our economic strength that our military might depends. The sad fact remains that the main sources of crude oil are outside the U.S. According to the Energy Information Administration, the U.S. imports approximately 51 per cent of the oil it consumes (2009 data), meaning that America's economic prosperity (and therefore its military strength) is tied to purchasing crude oil from foreign countries, many of which have interests that are antithetical to our own. In short, the U.S. sends billions of dollars to potentially hostile nations, upon which it is dependent for its prosperity and ultimately its security. [EPA-HQ-OAR-2010-0799-9448-A1, p. 1

Organization: Applied Materials

And we think that it's very important from a security standpoint, as several speakers have stated, as well.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 201.]

Organization: BlueGreen Alliance

Every day our country sends an estimated $1 billion to foreign countries for oil. Strong standards will keep more of the dollars here in the United States and move America to a more efficient advanced vehicle fleet creating hundreds of thousands of jobs, economic opportunities both inside and outside the auto industry.

In 2008 we saw the consequences when automakers had difficulty responding to consumer shifts in response to volatile fuel prices. So these strong feasibility standards will provide long-term certainty to the industry and ensure that innovation continues and recent investments in advanced technology pay off. They will also set the stage for weaning America off oil dependence for good and for the long-term reductions in greenhouse gas pollution we need to create a sustainable clean energy economy.

In addition to the direct savings for those purchasing new cars and light trucks, the proposed standard will also put downward pressure on gasoline prices by reducing demand. Simple demand-supply logic suggests that the standard will put downward pressure on the transportation fuel prices by putting downward pressure on the demand for transportation fuels. All drivers will benefit through lower gas prices than would be expected otherwise.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 38-39.]

Organization: Center for Biological Diversity

Similarly, the Agencies exclude the costs of maintaining a U.S. military presence to secure imported oil supplies from unstable regions "because their attribution to particular missions or activities is difficult." "Difficulty" does not justify conducting a cost-benefit analysis that improperly puts a thumb on one side of the scale. [EPA-HQ-OAR-2010-0799-9479-A1, p. 7]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 59.]

Organization: Consumer Federation of America (CFA)

Given the burden on household budgets and the continuing problem of oil vulnerability, it is not surprising to find that in our surveys, over a dozen in the past six or seven years, we find that three-quarters or more of respondents are concerned about gasoline prices and dependence on Mideast oil. They get the fact oil imports are a political problem.

They think it is important to reduce oil consumption and they support higher fuel economy standards as a way to do so. Almost two-thirds of the respondents' records supported 60-miles-per-gallon standards with a payback of three to five years, and this proposed standard meets and exceeds that. They also think a higher standard will be good for automakers.

There are several flaws in quantitative analysis that cause the agencies to seriously underestimate the value of higher fuel economy standards. We have pointed out these flaws in past analyses. [EPA-HQ-OAR-2010-0799-9419-A1, pp. 12-13]

- Oil has a strategic and security value that must be reflected in the analysis. [EPA-HQ-OAR-2010-0799-9419-A1, p. 14]

Indirect national security and economic benefits will be just over $40 billion (about 7 percent of the total) and include progress on major national public policy goals, such as reducing oil consumption and imports by almost 4 billion barrels and cutting the balance of payments deficit by $370 billion, which will produce a major boost to domestic economic growth by driving down the price of oil by $0.25 per gallon, lowering vulnerability to oil price shocks, and reducing the need for national security expenditures. [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 40-41.]

Organization: Defour Group LLC

Most studies show that increases in fuel economy standards will not enhance energy security and that the impacts on catastrophic global warming are negligible. To quote Michael Boskin, head of the first President Bush's Council of Economic Advisers, concluded in testimony before the National Academy of Sciences in 1991:

In my view, the presumption that U.S. energy security is directly tied to our level of gasoline consumption does not withstand close scrutiny. Given the increasing integration of world economies and the total integration of the world oil market, our energy security cannot be defined independently of our trading partners. Moreover, when one considers our own situation or, more properly, that of the world economy as a whole, even the most optimistic assessment of the oil consumption effects of higher CAFE standards cannot conceivably push us past the threshold where we would no longer have a vital security interest in the major oil-exporting regions of the world.[17] [EPA-HQ-OAR-2010-0799-9319-A1, p.11]

Or in the words of Resources for the Future economists, Douglass Bohi and Michael Toman, in their seminal 1996 study:

There is so much uncertainty about the costs used to calculate [energy security] premiums that it is impossible to make a credible judgment about the correct magnitude of the premium that should be attached to oil imports, oil consumption, or strategic oil storage. This very uncertainty should engender great caution about any efforts to apply energy security premiums in energy policy analysis. In particular, the energy security argument is a weak basis for supporting oil import controls, conservation of oil consumption, or larger strategic oil stocks. Because of the uncertainties, only win-win policies that offer prospects for benefits under a variety of circumstances can be recommended unambiguously. Such policies include support for energy research and development to improve energy efficiency and to diversity energy supplies.[18] [EPA-HQ-OAR-2010-0799-9319-A1, p.11]

Organization: Detroit NAACP

These standards mean reducing our dependence on foreign oil and it also, as was said earlier, will strengthen national security. In 2010 the United States imported more than 4.3 billion barrels of oil sending billions and billions of dollars to other nations where our economy suffered immensely and struggled.

These proposed standards will reduce oil consumption, greenhouse gas emissions, and air pollution. They will reduce dependence on oil by 4 billion barrels which is very, very significant, and it will slash 2 billion metric tons on greenhouse gas emissions.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 140.]

Organization: Ecology Center

We are especially supportive of the fact that the proposed rules will not only lead to significant reductions in petroleum use and greenhouse gas emissions.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 189.]

Organization: Environmental Defense Fund (EDF)

With respect to the energy security, when combined with Phase 1 clean car standards, the proposed rule's fuel economy and emissions standards will cut our oil consumption by over 2 million barrels a day, more than we import from the Persian Gulf.

Our nation’s dependence on oil is a threat to national security. The U.S. consumes nearly 25 percent of the world’s oil production, but controls less than 2 percent of the supply. And over half of the oil we use each day is imported from foreign countries, many of which do not like us. In 2008, we sent over $1 billion a day overseas to pay for oil, the majority of it going to nations deemed “dangerous or unstable.” The rate at which we consume oil helps our enemies by paying to finance and sustain their unfriendly regimes. And the longer the U.S. remains dependent on petroleum, the more the U.S. will have to engage in tough fights just to protect our energy supplies. [EPA-HQ-OAR-2010-0799-9519-A1, p. 2]

Additionally, the high price of oil threatens our fragile economy. Gasoline and diesel fuel prices remain high, leaving consumers with less money to spend elsewhere. More than 70 percent of the oil we consume is for transportation, and more than 60 percent of that is used to fuel passenger cars and light trucks. If we want to reduce our dependence on oil, we must address fuel consumption from our fleet of highway cars and trucks. [EPA-HQ-OAR-2010-0799-9519-A1, p. 2]

One piece of the economic picture that is often not considered is the economic impact of unexpected spikes in oil prices, price volatility. One of EDF’s economists, Jamie Fine, has worked with collaborators to show that policies that lower energy demand also provide a hedge against rising energy prices. Their study – which will soon be published in the Journal, Energy Policy – looked at the energy use that will be avoided and the resulting savings by California’s entire plan to reduce GHGs to 1990 levels by 2020, of which the current GHG standards are a critical part. They found that cost savings from avoided gasoline and diesel use in the event of an energy price shock in 2020 could be in the range of $2.4 to $5.2 billion for the state of California alone.11 [EPA-HQ-OAR-2010-0799-9519-A1, p. 2-3]

Agencies should include additional Energy Security Benefit

Oil dependence has serious consequences. The US consumes nearly 19 million barrels of oil a day, which is nearly a quarter of the oil consumed in the entire world, and more than all EU nations combined. Over half of the oil we use each day is imported from foreign countries and more than 70 percent of the oil we consume is used for transportation. Our addiction to oil threatens our national security and puts our service men and women at risk. [EPA-HQ-OAR-2010-0799-9519-A1, p. 13]

Our petroleum addiction also has significant environmental consequences. Extracting oil fouls land and water, kills wildlife, and destroys habitat. Refining oil creates air pollution and water pollution. Combustion of oil—burning oil and oil-based fuels in engines—releases CO_2, which causes global warming (about 42 percent of the world's energy-related CO_2 emissions come from oil). Emissions from oil refining and combustion also contribute to ozone, which worsens asthma, causes premature death and contributes to other health problems.32 [EPA-HQ-OAR-2010-0799-9519-A1, p. 13]

In addition, oil dependence makes the U.S. economy vulnerable to short-and long-term increases in energy costs. In terms of imported oil, an increase in the price of imported oil could lead to ‘imported inflation’ and vulnerability of the local manufacturers and consumers alike. [EPA-HQ-OAR-2010-0799-9519-A1, p. 13]

We commend the Administration for recognizing the importance of U.S. energy security and the positive impact more efficient use of transportation rules would have. However, we believe the Agencies have consistently undervalued the benefits of past fuel economy and GHG rules, and this proposed rule, on U.S. energy security. Therefore, we recommend that the final rule include the following additional inputs. [EPA-HQ-OAR-2010-0799-9519-A1, pp. 13-14]

In determining the full benefits of fuel consumption reduction and energy security, the Agencies did not attempt to quantify the reduction in U.S. military spending associated with the reduction in U.S. oil imports. The Agencies state in the proposal that “attributing military spending to particular missions or activities is difficult.” (Proposal preamble, page 75136) While we agree that such a quantitative analysis would result in uncertainties, that is not a reason to assign the benefits a zero value. It is important the Agencies develop a methodology to value the benefits of reduced oil imports on U.S. military spending for this rule, and future rules that reduce our dependence on foreign oil. We request that the Agencies at least report a range of estimates for these benefits. [EPA-HQ-OAR-2010-0799-9519-A1, p. 14]

We also recommend that the Agencies consider cost estimation proposals such as that included in Sen. Richard Lugar’s (R-Ind.) Practical Energy and Climate Plan, S. 3464. See Attachment A. This proposed legislation included both an extensive list of potential impacts of energy security to be considered and an alternative approximation valuation methodology for the “external cost of petroleum use” (i.e. this does not include the actual fuel savings). For inputs that the Agencies cannot quantify, the final rule should include a list and explain that the benefits of the rule are likely undervalued due to such factors. [EPA-HQ-OAR-2010-0799-9519-A1, p. 14]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 287.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 173.]

Organization: International Council on Clean Transportation (ICCT)

There are other advantages to society from reducing the amount of fuel we consume. The benefits for energy security are the same as investing in new oil wells - reduced oil imports, improved balance of trade, and downward pressure on worldwide oil prices. [EPA-HQ-OAR-2010-0799-9512-A1, p. 13]

Organization: Kobus, D.

America's dependence on oil puts our environment, economy, and national security at risk. You recently took an important step toward addressing this problem when you proposed new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of a 54.5 mpg fleet-wide standard by 2025. [EPA-HQ-OAR-2010-0799-1370-A1, p. 2]

Organization: Marks, R.

I question the use of CAFE to reduce oil consumption. For the last 40 years, CAFE has had the opposite affect. People bought bigger cars and trucks and drove them more miles per year and consumed more gallons of gas per vehicle. 40 years ago, we were 25% dependent on foreign oil and today we are about 66% dependent. CAFE has not done what you claim, ever! The only reason gas consumption has dropped recently is that the price of gas has risen to between $3 and $4 per gallon. It has nothing to do with vehicle miles per gallon! Are you serious about our dependence on oil or not? If you are serious, then this Nation needs a National Energy Policy which will 1. Reduce our dependency on foreign oil, by using less, 2. Improve World climate concerns through reduction in fossil fuel consumption, 3. Develop alternative fuel solutions in both transportation and energy sectors, and 4. Keep America growing, moving forward and secure. CAFE does not do this. [EPA-HQ-OAR-2010-0799-1680-A1, p. 1]

CAFE is stupid and there are much better market driven ways to create National security. Read your history! CAFE does not work. [EPA-HQ-OAR-2010-0799-1680-A1, p. 1]

Organization: Representative from Michigan House of Representatives, 49th District

Greater fuel economy will also help reduce our dangerous addiction to foreign oil and keep the members of our armed services out of danger. The United States imported more than 4.3 billion barrels of oil in 2010. This dependency places increasing demands on American security forces to keep the peace in many of the most dangerous areas of the world. [EPA-HQ-OAR-2010-0799-7983-A1, p. 2]

Organization: State Senator from Michigan State Senate, District 18

Greater fuel economy benefits all of us in four ways: firstly, it benefits our environment by reducing greenhouse gas emissions; secondly, it secures our energy independence; thirdly, its saves us money at the pump; and finally, it creates high-quality U.S. jobs that strengthen the economy. [EPA-HQ-OAR-2010-0799-5594-A1, p. 1]

Increased fuel economy will first benefit the environment by reducing greenhouse gas emissions and air pollution that stem from oil consumption. The proposed fuel economy standards will reduce our dependence on oil by 4 billion barrels and slash 2 billion metric tons in greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-5594-A1, p. 1]

In turn, we will also be gaining energy independence. In 2010, the United States imported more than 4.3 billion barrels of oil, sending billions of dollars to other nations while our own economy struggled to recover from recession. This dependence on foreign oil has threatened our national security and our economic progress for far too long. [EPA-HQ-OAR-2010-0799-5594-A1, p. 1]

Organization: National Wildlife Federation (NWF)

Our reliance on oil is a fundamental threat to wildlife, as well as to people and the economy

Our members and millions of Americans like them want to see America’s outdoor heritage sustained for their children. All too often, our heavy dependence on oil stands in the way. [EPA-HQ-OAR-2010-0799-9887-A2, p. 2]

Carbon pollution is warming our climate locally and worldwide. These changes threaten people and global security right now, and they are the most profoundly threatening force against the future of wildlife. Rising temperatures, floods, fires, droughts and ecosystem alterations are creating direct habitat loss, increased invasive species and other threats for wildlife species – many may never adapt. [EPA-HQ-OAR-2010-0799-9887-A2, p. 2]

The 20 million barrels of oil America uses every day (mostly for transportation) account for 40% of the US carbon pollution that causes climate change.1 [EPA-HQ-OAR-2010-0799-9887-A2, p. 2]

Meanwhile, when drilling projects go wrong, whole ecosystems are threatened by disasters like the Deepwater Horizon spill in 2010. And smaller leaks and spills, like the recent Enbridge oil spill in Michigan, do grave harm right in our backyards: to residents, to wildlife like herons, muskrats, ducks, geese, and to decades of community efforts to restore rivers like the Kalamazoo. [EPA-HQ-OAR-2010-0799-9887-A2, p. 2]

These standards make real and significant steps to reduce these threats [EPA-HQ-OAR-2010-0799-9887-A2, p. 2]

The proposed 2017 through '25 standards will double the fuel economy for our cars, SUVs and pickups from today's levels to an average of 54.5 miles per gallon by 2025. These vehicles will save Americans 4 billion barrels of oil and 2 billion metric tons of carbon pollution.

Together these standards will cut our demand for oil by 3.4 million barrels per day; more than all the oil we get today from the Persian Gulf, Venezuela and Russia combined.

As we are ensuring that every car and truck uses less fuel, steady expansion of electric and advanced vehicle technology can lead us even further into mass markets, high performance vehicle fleet that uses little oil and produce nearly zero pollution.

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 28-30.]

Organization: Pew Charitable Trusts

We have also sought to inform the public and policymakers across the nation about the dangers of U.S. oil dependence to our nation’s economy, national security and to the lives of the U.S. servicemen and women who defend oil transit routes and chokepoints around the world. The RAND Corporation estimates that the U.S. military spends between $67 and $83 billion annually defending oil chokepoints around the world. [EPA-HQ-OAR-2010-0799-9496-A2, p. 1]

As you know, the public strongly supports reducing U.S. oil dependence through higher fuel economy. Our bipartisan poll commissioned in July 2011 found that 91 percent of Americans identify U.S. dependence on foreign oil as a threat to our national security, and significant bipartisan majorities in every region of the country believe that adopting stronger fuel economy standards is the best way to lessen that dependence. [EPA-HQ-OAR-2010-0799-9496-A2, p. 2]

[This comment was also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2009-2010-1788, pp.190-20.]

Organization: Renewable Energy Long Island

America's deepening dependence on oil puts our economy, environment, and national security at risk. I am writing to applaud you for taking an important step to confront the dangers of this dependence by proposing new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of the 54.5-mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-7933-A1, p. 1]

The projected annual benefits of such standards by 2030 are enormous:

- $45 billion in savings at the gas pump
- 23 billion gallons of gasoline saved
- 280 million metric tons of global warming pollution avoided [EPA-HQ-OAR-2010-0799-7933-A1, p. 1]

Organization: Securing America's Future Energy

More than 70 percent of the oil consumed in the United States is used to fuel our transportation sector. The more than 240 million cars and light-duty trucks on the road in the United States in 2010 accounted for approximately 40 percent of total oil demand and those vehicles were fueled almost entirely by oil or other liquid fuels. Throughout the entire transportation sector, 93 percent of delivered energy is derived from oil. Simply put, our economy is heavily dependent on oil, and there are no substitutes available at scale today. [EPA-HQ-OAR-2010-0799-9518-A1, p. 2]

We have made tremendous strides in reducing the petroleum intensity as traditionally measured. In terms of barrels of oil consumed per dollar of gross domestic product (GDP), we have reduced petroleum intensity by about 50 percent since the early 1970s, as shown in Figure 2. Yet, despite this progress we remain highly dependent on oil to fuel our economy. It remains our primary transportation fuel and demand remains highly inelastic, especially in the short-term. It also is important to appreciate that the price of oil is set in a dynamic global market and our reduced use of several million barrels a day over a period of 15 years as the result of improved fuel economy is just as likely to result in lower production of oil as resulting in a lower price. Stated differently, over time, reducing domestic demand for oil will not necessarily lead to lower prices but might instead lead to production levels that are adjusted downward by producers based on expectations that increased fuel economy will reduce aggregate demand; in fact, oil prices can easily rise even in periods of shrinking domestic demand. [Figure 2 can be found on p. 5 of Docket number EPA-HQ-OAR-2010-0799-9518-A1] [EPA-HQ-OAR-2010-0799-9518-A1, p. 4]

A different measure of petroleum intensity than the traditional measure of barrels per $1,000 of GDP, our degree of dependence on oil is approaching levels we reached in the late 1970s. While our economy is becoming more fuel efficient and oil demand is stable in recent years, we are spending a growing portion of our national income on oil, even with relatively stable demand, due to rising oil prices. Although fuel economy requirements last year were at their highest level ever, our overall expenditure on oil and oil related products of $900 billion was far above historic levels, as shown in Figure 3. This represents about 6 percent of GDP, nearly twice the levels in the 1990s (see Figure 2), though we consumed approximately the same volume of oil. [Figure 3 can be found on p. 6 of Docket number EPA-HQ-OAR-2010-0799-9518-A1] [EPA-HQ-OAR-2010-0799-9518-A1, pp. 4-5]

Stated most simply, a portion of the benefit of increased fuel economy is being lost to high oil prices. And in a world with rising demand for oil, in which demand is being met by oil that is increasingly complex and expensive to produce, we must recognize that while improving fuel economy is an important measure, it cannot fully address the challenge posed to our energy and national security by persistently high and volatile oil prices. [EPA-HQ-OAR-2010-0799-9518-A1, p. 5]

This oil dependence constrains our foreign policy and forces the United States military to accept the responsibility of securing the world's oil supply. A RAND Corporation study showed the ongoing expense of oil dependence to the U.S. military is between $67.5 billion and $83 billion annually, while the cost of the constraints imposed on our foreign policy by our oil dependence may be impossible to calculate. Oil dependence also imposes significant costs on the nation's economy. Sending about $1 billion abroad each day to pay for expensive oil drains our economic resources and strengthens oil-exporting countries that are often hostile to U.S. interests. In 2011 alone, American businesses and consumers spent nearly $900 billion on gasoline, diesel and other refined petroleum products. This is part of an upward trend that has hit the average household particularly hard as oil prices have risen in recent years. As shown in Figure 1, annual household expenditures on gasoline have risen from about $1,800 in 2000 (representing 4.4 percent of median household income) to $4,050 in 2011 (representing 8.2 percent of median household income). Separate from the out-of-pocket costs for oil incurred by consumers, Department of Energy researchers at Oak Ridge National Laboratory have estimated the economic cost of U.S. oil dependence to be more than $5 trillion since the early 1970s. [Figure 1 can be found on p. 3 of Docket number EPA-HQ-OAR-2010-0799-9518-A1] [EPA-HQ-OAR-2010-0799-9518-A1, pp. 2-3]

In recognition of the threat to our nation posed by reliance on a single fuel whose market is dominated by governments that often share neither our interests nor our values, the United States has made genuine progress toward advancing energy security since we first became aware of the problem in the early 1970s. Most importantly, fuel economy has improved by more than 110 percent, from 13.6 MPG in 1974 to 29.6 MPG in 2011 (although much of that progress was made between 1975 and 1986), helping reduce the petroleum intensity of the economy by nearly 50 percent over the same period. This means that we are both spending less on oil, and that we are less affected by oil price volatility than we would have been in the absence of improved fuel economy. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 3-4]

These improvements in fuel economy certainly have enhanced our economic and national security. Although we have faced serious challenges as a nation over the past forty years as a result of our dependence on oil, there is no question that they would have been far more serious without the progress we have made thus far. [EPA-HQ-OAR-2010-0799-9518-A1, p. 4]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 149-150.]

There's no question that using less oil is better than using more oil, especially for the environment. And these standards are an important tool to help us achieve that goal. But from an energy-security perspective, this rule is really requiring simply to maintain our current level of security. It's often overlooked that our dependence on oil arises not from how much oil we use but from how much we spend on oil, the volatility of that total expenditure, and the effect of volatility on the economy.

The price of oil is set in a dynamic global market, and our reduced use of several million barrels per day over a period of 15 years is just as likely to result in lower production as it is to result in higher prices. As we all know, growing demand from the developing world is increasing upward pressure on oil prices.

And, in fact, just yesterday, the EIA posted on its website the early release of the 2012 Annual Energy Outlook, which is calling for oil prices to reach up to $146 per barrel in 2010 dollars by the end of the forecast period. In fact, if you look at the chart which I handed out and we'll stick in the record, what you can see here is, even if the energy intensity of the economy is improved over the past several decades, the actual percentage of our economy that we are spending, the percentage of GDP that we're spending on oil is actually increasing, which goes directly to the question of oil dependence.

The only way to address this price volatility, which is a threat of our nation, we believe, is to stop using oil.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

As we noted in our report to hear on the issues of the American Securities Project, much of our oil comes from countries at high risk of instability several of which work actively against U.S. interests. Recent developments with Iran are yet another reminder of this fact.

By 2030 we will be using 1.5 million barrels less oil every day due to these standards.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 122-123.]

Organization: Smith, G.

'Reduce oil consumption by an estimated 2.2 million barrels a day by 2025 more than our daily 2010 oil imports from the entire Persian Gulf.' Here they fail to point out that by opening up and encouraging exploitation of our domestic oil and gas, we will not need to be reliant on any imports. [EPA-HQ-OAR-2010-0799-8438-A1, p. 1]

Organization: Tesla Motors, Inc.

Enacting a final rule that forces alternative technology is necessary to reduce dependence on the monopoly of oil in transportation fuel for national security, the economy and the environment; [EPA-HQ-OAR-2010-0799-9539-A2, p. 1]

Reducing our dependence on petroleum in the transportation sector is a national imperative. By shifting the transportation sector to electricity, the United States can significantly reduce GHGs. Displacing traditional internal combustion engines with EVs can assist significantly in meeting this goal. EVs such as the Tesla Roadster, the Model S, and Model X generate zero greenhouse gases. Thanks to the over 2,500 all electric Roadsters in 31 countries on the roads today, Tesla customers have accumulated nearly 20 million pure EV miles displacing the need to utilize nearly 50,000 barrels of oil. Even when taking into consideration the source of the electricity stored on the vehicles, the GHG profile of EVs is lower than their internal combustion engine counterparts. A study by the Natural Resources Defense Council (NRDC) and the Electric Power Research Institute (EPRI) demonstrated that on a well-to- wheels comparison, use of plug-in hybrid electric vehicles (PHEVs) would result in reductions of anywhere from 3.4 to 10.3 billion metric tons of GHGs from 2010 to 2050 depending on the penetration level of PHEVs. With EVs that utilize no gasoline whatsoever, this reduction should be even higher. With the impacts of climate change caused by excessive GHGs evident today, switching away from traditional ICE equipped vehicles is an environmental imperative. [EPA-HQ-OAR-2010-0799-9539-A2, p. 3]

In addition to the environmental benefits, there are other compelling justifications for moving away from oil dependent modes of transportation. The United States currently accounts for 25% of world oil consumption. According to the Department of Energy, the U.S. transportation system remains dependent on petroleum for 97% of its energy needs. This dependence has left our nation vulnerable to various externalities that have placed undue burdens on the domestic economy. In fact, a 2005 study by Oakridge National Laboratory confirmed that the U.S. economy has lost trillions of dollars in the past 30 years due to our oil dependence. A recent blog post in the Washington Post put this figure in real terms: [EPA-HQ-OAR-2010-0799-9539-A2, p. 3]

In 2011, the United States paid about $125 billion more for oil imports than it did in 2010 (thanks, in part, to the disruptions caused by civil war in Libya). That “oil tax” was essentially enough to wipe out the entire stimulative effects of Barack Obama’s middle-class tax cut. A similar oil spike this year would cancel out a hefty chunk of the benefits of extending the $200 billion payroll tax cut bill that Congress is fighting over. [EPA-HQ-OAR-2010-0799-9539-A2, pp. 3-4]

The recent volatility and steady rise in oil prices highlights the economic vulnerability of America to foreign sources of oil. For example, OPEC forecasted revenues of over $1 trillion dollars for 2011, which represents a *32.5%* increase since 2010. For comparison, this is approximately 1.6% of global GDP in 2010. With a trade deficit of nearly $500 billion for 2010, eliminating our dependence on foreign oil could cut that deficit nearly in half. These economic benefits are in addition to the number of jobs created by moving to clean technology vehicles like Tesla EVs. As noted earlier, Tesla projects total employment of over 3,000 employees by end of 2012. [EPA-HQ-OAR-2010-0799-9539-A2, p. 4]

Moreover, being dependent on foreign sources of oil from volatile regions of the world requires the U.S. to spend more and more of its military budget on assisting in stabilizing these regions, even as the war in Iraq has ended. Iran’s recent threats to close the Strait of Hormuz (through which about 20 percent of the world’s oil flows) required redeployment of a U.S. Navy carrier group in order to ensure the security of that oil flow. Maintaining a strong and continuous military presence in the Middle East necessitates large expenditures by the federal government to support these operations. Such spending can and does contribute to the national deficit. More importantly, this puts America’s young men and women serving in the military in harm’s way to feed our national thirst for ever more oil resource. Reducing our dependence on foreign oil is, therefore, more than an environmental issue; it is a matter of economic and national security. [EPA-HQ-OAR-2010-0799-9539-A2, p. 4]

The U.S.’s dependence on oil – both of foreign and domestic origin, has been due in part to a verifiable lack of competitive market alternatives. Due to developments by innovative companies like Tesla Motors, alternative technologies are emerging as true competitors to the oil dominated marketplace. EPA and NHTSA are in a unique position to help push this innovation through a robust GHG/CAFE final rule. In fact, as is demonstrated below the case for EV technology is so compelling, EPA's and NHTSA's proposed standards are not only a step in the right direction; they can be further strengthened to encourage cost-effective, feasible EV technology. [EPA-HQ-OAR-2010-0799-9539-A2, p. 4]

Organization: Union of Concerned Scientists (UCS)

Energy Security & Oil Savings

The proposed standards will also dramatically reduce U.S. oil consumption by as much as 1.5 million barrels per day (mbd) – roughly 23 billion gallons of gasoline annually – in 2030 alone. This is equivalent to 2010 U.S. imports from Saudi Arabia and Iraq combined. And the cumulative oil savings of the National Program (MYs 2012-2025) could result in a total reduction in U.S. oil consumption of nearly 3.5 mbd in 2030, nearly double the amount the U.S. currently imports from the entire Persian Gulf. No other federal policy has delivered greater oil savings, energy security benefits, or greenhouse gas emissions reductions to the country. [EPA-HQ-OAR-2010-0799-9567-A2, p. 4]

It appears that the agencies did not fully account for key societal benefits in the proposed rule. Specifically, the agencies did not account for the economic benefits from reduced oil imports for either the 'monopsony' effect or U.S. military expenditures. In both cases, real-world experience would dictate there are clear benefits to the United States. First, the U.S. spends significant resources defending oil shipping channels around the world and responding to threats of terrorism, which are often funded with profits from oil sales.20 We appreciate the agencies concern that it is a challenge to quantify these costs, however, such potentially significant costs cannot be discounted. For instance, a recent peer-reviewed study found that the U.S. military spent $7.3 trillion maintaining aircraft carriers in the Persian Gulf from 1976-2007.21 Since this presence is largely purposed to protect key oil shipping lanes, it provides an indication of the significant cost to the U.S. economy as a result of our reliance on oil. [EPA-HQ-OAR-2010-0799-9567-A2, pp. 5-6]

Further, the agencies state that they did not include the benefits of the monopsony effects because of "the redistributive nature of this 'monopsony effect' when viewed from a global perspective." The agencies elaborate: "Although there is clearly a benefit to the U.S. when considered from a domestic perspective, the decrease in price due to decreased demand in the U.S. also represents a loss to other countries." This argument runs counter to the original intent of the CAFE program and its stated requirement to consider the need of the United States to conserve energy (49 U.S.C. 32902). Congress has consistently set CAFE standards for the exact purpose of delivering "energy security through improved vehicle fuel economy."24 Energy security includes, though is not limited to, reducing U.S. exposure to volatile global oil markets, regardless of whether this results in an economic loss to oil-producing nations. To exclude this benefit when it is so fundamentally tied to the goals of the CAFE program is an abdication of NHTSA's statutory responsibility. [EPA-HQ-OAR-2010-0799-9567-A2, p. 6]

Our continued dependence on oil puts our economy at risk from the effects of oil price volatility and energy insecurity. Oil price spikes were associated with most of the U.S. recessions in the past 40 years. The United States currently sends $1 billion each day to foreign countries to pay for oil and other petroleum products—that is equivalent to more than half of the average daily U.S. trade deficit over the last decade. [EPA-HQ-OAR-2010-0799-9713-A1, p. 2]

Finally, as UCS has noted in prior comment submissions, AEO's projection does not account for inevitable price spikes that will occur during the lifetime of the vehicles assessed under this rule. Such spikes are closely tied to our nation's inflation and GDP, and thus can have serious economic consequences. With this in mind, the agencies should attempt to quantify the benefits of reduced susceptibility to such spikes, and incorporate them into the program's benefits writ large. [EPA-HQ-OAR-2010-0799-9567-A2, p. 13]

Organization: Thirty Senators from the United States Senate

The proposed standards have broad industry support, but they will also reduce petroleum use and pollution on an aggressive schedule, as Congress required in the 2007 statute. As the latest Energy Information Administration's Annual Energy Outlook has concluded, increases in fuel economy have contributed to our declining dependence on oil imports. [NHTSA-2010-0131-0264-A1, p.1]

Further progress will be made with the implementation of the proposed standards, which taken together with the recently adopted standards for model years 2012 to 2016, will remove the need for as much as 3.8 million barrels of petroleum per day by 2030. Consumers will save thousands of dollars at the pump over the lifetime of their vehicles, and both our economy and our security will be less dependent on imported oil. [NHTSA-2010-0131-0264-A1, p.2]

Organization: Lieutenant General Rick Zilmer (Retired)

On 01/19/2012 at Philadelphia, PA, Lieutenant General Rick Zilmer (Retired) testified in support of this rule. Highlights from his testimony are below:

- He discussed the findings of a recently completed study entitled, "Ensuring America's Freedom of Movement, a National Security Imperative to Reduce U.S. Oil Dependence", developed by the Military Advisory Board at the Center for Naval Analyses (CNA). He testified that "[t]his…study looked a little bit outside of our lane by bringing it into looking at what the potential would be for incorporating the use of alternative fuels to reduce our dependency on U.S. oil and U.S. oil imports into this nation." He went on to testify that there are about 11 members on the Military Advisory Board and between them, they have 400 years of collective experience.

- In the study, it concluded that "…if the Strait of Hormuz closed for 30 days, it would bring our trucking industry to its knees, it would reduce our gross domestic product by somewhere in the order of four billion dollars just over a 30-day period."

- The study concluded that "[w]e could reduce our consumption within ten years by 30 percent, and we could take some of these emergent technologies of alternatives fuels that are not yet ready for marketplace forces. They need more support. They need policy, national leadership, that is going to create the environment through which these emergent technologies can develop."

- Finally, he testified that "[the energy security/fuel issue is] not going to get solved by hoping and praying that we can drill more. That's not the answer. It's looking to efficiency. And in closing, thank you again, and we do strongly from CNA support and urge the National Highway Traffic Safety Administration and EPA to finalize these rules that will set the bar at 54 and a half miles per gallon by 2025 for this simple reason, better gas mileage is simply a matter of national security."

Response:

The American Council for an Energy-Efficient Economy (ACEEE), America's Natural Gas Alliance (ANGA) and American Gas Association (AGA), American Public Gas Association (APGA), Applied Materials, BlueGreen Alliance, Consumer Federation of America, Detroit NAACP, Ecology Center, Environmental Defense Fund, International Council on Clean Transportation, National Wildlife Federation, a Representative from the Michigan House of Representatives (489th District), a Senator from the Michigan State Senate (District 18), Pew Charitable Trusts, Renewable Energy Long Island, Securing America's Future Energy, Sierra Club, Environment America, Safe Climate Campaign, Clean Air Council, Tesla Motors Inc., Union of Concerned Scientists, and thirty Senators from the United States Senate and a couple of private citizens (Kobus, Smith) all commented that the U.S. transportation sector is highly dependent upon foreign oil, and that this rule will have the beneficial effect of reducing that dependency. R. Mark questioned the effectiveness of previous CAFE standards and suggested that the current rule would have little impact on U.S. oil import reductions. We agree with the vast majority of commenters that this rule will reduce U.S. oil consumption and imports of oil and improve the energy security position of the U.S. Using detailed estimates of future technology penetration and vehicle fleet projections, EPA estimates that this rule will reduce oil consumption in the U.S. by 3.87 billion barrels over the lifetimes of the 2017 to 2025 model year vehicles covered by this rule, which, in turn, will reduce U.S. oil imports. (See Section I.D.2 of the Preamble.)

EPA received numerous comments about the treatment and valuation of energy security benefits from this rule. The American Council for an Energy-Efficient Economy (ACEEE), the Union of Concerned Scientists and the BlueGreen Alliance recommended that the monopsony benefit of the rule be included in EPA's overall estimates of the energy security benefits, since it is a benefit to the U.S. Alternatively, instead of focusing simply upon the economic benefits of lower petroleum prices on consumers, ACEEE specifically commented that the lower price of oil would result in job creation in the U.S. According to ACEEE, the employment benefits of the lower oil prices from the rule should be counted as a benefit to the U.S. as well as the monoposony benefit. EPA continues to view energy security from a global perspective, and therefore excludes the monopsony benefit to the U.S. since this benefit is offset by losses to foreign oil producers. (See Section III.H.8.c of the Preamble for more discussion of this topic.) Also, EPA has not been able to develop a robust estimate of the impacts of lower oil prices on overall economic activity or employment in the U.S. as a result of this rule. Therefore, we cannot draw conclusions as to the employment impacts of a decline in the world price of oil on the U.S. economy. (See Section III. H.12.c. of the Preamble for more discussion of this topic.)

In contrast, the other portion of the energy security premium, the U.S. macroeconomic disruption and adjustment cost that arises from U.S. petroleum imports, does not have offsetting impacts outside of the U.S., and is thus included in the energy security benefits estimated for this program. Therefore, EPA has included only the macroeconomic disruption portion of the energy security benefits to estimate the monetary value of the total energy security benefits of this program. EPA has calculated energy security in very specific terms, as the reduction in both financial and strategic risks caused by potential sudden disruptions in the supply of imported petroleum to the U.S. Reducing the amount of oil imported reduces those risks, and thus increases the nation's energy security. (See Section III.H.8.b of the Preamble for more discussion of this topic.)

The Defour Group commented that there is no relationship between the energy security benefits of the U.S. and reduced oil consumption by the U.S., since the world economies are all tied together, thus calling into question estimates of the energy security benefits of these rules. As mentioned above, EPA does not count economic transfers between countries as a part of the energy security benefits of this rule, but we do count the macroeconomic disruption component of the energy security premium, which directly influences the performance of the U.S. economy. The macroeconomic disruption component of the energy security premium is specific to the U.S.

Moreover, the Defour Group believes there is too much uncertainty in generating energy security premiums, and asserted that the energy security premiums are not a credible approach to providing estimates of energy security benefits of the rule. The EPA sponsored an extensive peer review of the methodology on which the energy security benefits for the rule is based. (See Section III.H.8.b of the Preamble for more discussion of this topic.) The methodology of estimating the energy security benefits of particular actions, policies, and rules has been well documented and is well accepted by the energy security community. Thus, EPA continues to use the current methodology for estimating the energy security benefits of our rules.

Many commenters in both written comments and at the public hearings expressed their belief that these standards will have significant benefits for U.S. military-related energy and national security. A number of commenters, including consumer advocacy and environmental organizations, organizations representing labor, and state and local governments, as well as energy security advocates and numerous private individuals, felt that the EPA should quantify, to the extent possible, a military component of the energy security benefits associated with this rulemaking. These commenters felt that, although they understand that the EPA would have difficulties in determining a point estimate of the energy security benefits from reduced military costs as a result of the rule, that even ranges would be useful. The American Petroleum Institute suggested that quantification of this category of benefits—U.S. energy security and national security benefits—was too difficult, and it should be left unquantified.

As Lieutenant General (Ret.) Richard Zilmer, commander of U.S. coalition forces in Anbar province in Iraq in 2006-2007, testified at the Philadelphia public hearing in support of the proposed standards: "better gas mileage is simply a matter of national security." Lt. Gen. (Ret.) Zilmer contributed to a report of the Center for Naval Analyses (CNA) that discussed the implications of oil import reductions and energy security. The report focused on changes in the American transportation sector, in terms of fuel efficiency, alternative fuels, and transportation habits that would be needed in order for the U.S. economy to have enough resilience to sustain a drastic disruption in oil supply. Among its findings and recommendations, the report states that "[t]he federal government fuel economy standards have proven to be effective at increasing efficiency and reducing the use of oil...These standards should be supported and strengthened as a means of making our nation more secure." The report states that "[t]he benefits of efficiency are so obvious and sizeable that it is amazing to consider how or why our country has failed to insist on (or at least incentivize) it up to now.¨

One of the goals of a U.S. military presence in the Persian Gulf is to avoid the impacts oil price shocks from a supply cut-off on the U.S. economy. Although CNA did not conduct an economy-wide analysis of an oil supply shock, it did consider the impact of such a shock on one industrial sector that is heavily dependent on petroleum: the U.S. trucking transportation industry. CNA then considered a 100 per cent disruption in the flow of oil, lasting 30 days in the Strait of Hormuz. They estimated that such a disruption would have caused losses of $3.3 billion or 2.9 percent of the U.S. trucking industry's output in 2009. According to CNA, this disruption would have caused 37,500 truckers to lose their jobs. This analysis concludes with "[i]f the U.S. – and this industry in particular – could reduce its use of petroleum by 30 percent, the effect of such supply disruptions would be nearly zero." Although CNA's report focused on the trucking sector, EPA believes that these findings are The Department of the Navy has also stated that the Navy and Marine Corps rely far too much on petroleum, which "degrades the strategic position of our country and the tactical performance of our forces. The global supply of oil is finite, it is becoming increasingly difficult to find and exploit, and over time cost continues to rise." In remarks given to the White House Energy Security Summit on April 26, 2011, Deputy Security of Defense William J. Lynn, III noted the direct impact of energy security on military readiness and flexibility. According to relevant to this rule since both the heavy-duty and light-duty vehicles in the U.S. are highly dependent upon petroleum.

Moreover, the military itself is heavily dependent on oil. To maintain such military effectiveness and flexibility, the Department of Defense identified in the Quadrennial Defense Review that it is “increasing its use of renewable energy supplies and reducing energy demand to improve operational effectiveness, reduce greenhouse gas emissions in support of U.S. climate change initiatives, and protect the Department from energy price fluctuations.” Deputy Security Lynn, “Today, energy technology remains a critical element of our military superiority. Addressing energy needs must be a fundamental part of our military planning.”

EPA’s analysis of energy security benefits from reducing U.S. oil imports did not include an estimate of potential reductions in costs for maintaining a U.S. military presence to help secure stable oil supply from potentially vulnerable regions of the world because attributing military spending to particular missions or activities is difficult.

SAFE commented on a study by RAND that showed the ongoing expense of oil dependence to the U.S. military. RAND considered military force reductions and cost savings that could be achieved if oil security were no longer a consideration. Taking two approaches, and guided by post Cold-War force draw downs and by a top-down look at the current U.S. allocation of defense resources, RAND concluded that $75–$91 billion, or 12–15 per cent of the U.S. defense budget in 2009 could be reduced if U.S. dependence on imported oil were eliminated entirely. However, the study also concludes that the reduction in military costs from a partial reduction in the U.S. dependence on imported oil would be minimal.

America’s Natural Gas Alliance, the American Gas Association, and Tesla Motors, Inc. pointed specifically to the expense of maintaining naval forces in the Persian Gulf as an important factor in this rulemaking. EPA reviewed a study by Stern that presents an estimate of military cost for Persian Gulf force projection, addressing the challenge of cost allocation with an activity-based cost method. Stern used information on actual naval force deployments rather than budgets, focusing on the costs of aircraft carrier deployment. For the 1976–2007 time frame, Stern estimated an average military cost of $212 billion per year and $500 billion for 2007 alone, that could be potentially reduced will lower oil imports.

Although these recent studies provide significant, useful insights into the military components of U.S. energy security, they do not provide enough substantive analysis to develop a robust methodology for quantifying the military components of energy security for this rulemaking. Even for studies that provide insight into the attribution of specific missions to the objective of securing international oil production and distribution, they provide little guidance on the degree to which incremental reductions in the U.S. dependence on imported oil would reduce or eliminate those missions or programs. Thus, while EPA plans to continue to review newer studies and literature to better estimate the military components of U.S. energy security benefits, for this rulemaking EPA continues to exclude military cost components in our quantified energy security benefits. (See Section III.H.8.e of the Preamble for more discussion on this topic.) To summarize, EPA has been unable to calculate the monetary benefit that the United States will receive from the improvements in national security expected to result from our standards.

18.6. Other Impacts

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 28-29.]

The 20 million barrels of oil America uses every day accounts for 40 percent of the U.S. carbon pollution load that causes climate changes. Meanwhile, when drilling projects go wrong, whole ecosystems are threatened by disasters like the Deepwater Horizon spill in 2010, and smaller leaks and spills like the recent Enbridge oil spill here in Michigan. Recent pipeline spills do grave harm right in our backyards: to residents, to wildlife like herons, muskrats, and ducks and geese and destroy decades of community efforts that were intended on restoring rivers like the Kalamazoo. Today we have real opportunity to combat these threats.

Response:

EPA has estimated that there will be significant fuel savings associated with the final standards. In addition to the monetized fuel savings benefits EPA has estimated in its cost-benefit analysis, it is likely that there are many additional impacts associated with the standards that have gone unquantified due to data, methodological, or resource limitations (for example, see RIA Chapter 6). To the extent that there are omitted beneficial impacts associated with reducing fuel consumption like those listed by the commenter, our benefits analysis can be considered conservative. However, such an analysis was beyond the scope of this rulemaking.

18.6.1. Added Costs from Congestion, Accidents, and Noise

Organizations Included in this Section

American Road & Transportation Builders Association (ARTBA)
Mercedes-Benz USA, LLC

Organization: American Road & Transportation Builders Association (ARTBA)

Further, to improve traffic flow and reduce emissions and fuel waste, we must increase surface transportation system capacity. VMT has grown by over 150 percent since the 1970s. In stark contrast, the number of new lane miles in the United States has increased by only six percent. Providing additional lane miles requires a significant investment in our nation’s future and we must update the HTF to adequately reflect changing circumstances. [EPA-HQ-OAR-2010-0799-9403-A1, p. 3]

Congestion levels have grown continuously between 1982 and 2007. Since 1982, the number of hours spent in congested traffic in the nation’s largest metropolitan areas increased from 21 hours to 51 hours. In addition to losing valuable time in traffic, travelers are also wasting an estimated 4.2 billion gallons of fuel due to congestion. 4 Simply put, the nation's road system is falling far behind growth in usage. The direct consequence is rampant traffic congestion and, with it, unnecessarily increased emissions and pollution. [EPA-HQ-OAR-2010-0799-9403-A1, p. 3]

Insufficient capacity already produces specific bottlenecks cause 50 percent of total congestion on the nation's freeways. In 2004, a study of the nation's most severely congested highways highlighted the reality that significant reductions in emissions require a reduction in vehicle time traveled, not vehicle miles traveled. The study concluded that modest improvements to traffic flow at 233 bottlenecks would reduce carbon dioxide emissions by as much as 77 percent and conserve more than 40 billion gallons of fuel over a 20-year period.5 These fuel savings translate directly into lower CO_2 emissions. [EPA-HQ-OAR-2010-0799-9403-A1, p. 3]

4 Texas Transportation Institute, 2009 "Urban Mobility Report,"2009.

5 Unclogging America's Arteries, Effective Relief for Highway, Cambridge Systematics, Inc., February 2004

Organization: Mercedes-Benz USA, LLC

The Relationship Between Congestion, Fuel Use and GHG Emissions Is Well Established

Congestion has a direct and well-documented impact on fuel economy and emissions. As shown through a 2010 Urban Mobility Report developed by the Texas Transportation Institute, traffic congestion has resulted in billions of gallons of wasted fuel each year: [See chart on p. A-9 of Docket number [EPA-HQ-OAR-2010-0799-9483-A1] [EPA-HQ-OAR-2010-0799-9483-A1, p. A-8]

Response:

While consideration of the need to increase surface transportation system capacity to improve traffic flow and reduce emissions and fuel waste is beyond the scope of this rulemaking, EPA does account for the fact that increased vehicle use associated with the rebound effect contributes to increased traffic congestion. As described in Joint TSD 4.2.7 and Preamble III.H.9, EPA monetizes the higher costs imposed by added delays to drivers and other vehicle occupants in the form of increased travel time and operating expenses.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 66-67.]

The agencies have acknowledged the technologies needed to meet regulations will increase the cost of vehicles. Thus for all stakeholders involved, including consumers, auto dealers and manufacturers, we must have a clear understanding of how much vehicle costs will increase, and whether consumers will perceive sufficient value in those increases to pay for them.

Organization: Alliance of Automobile Manufacturers

Automakers today are driving this country's economic recovery. Yet, in light of the uncertainty over consumer valuation of fuel savings and other factors, the agencies have not included an estimate of sales or employment impacts in the NPRM or supporting documents. [EPA-HQ-OAR-2010-0799-9487-A1, p.20] [This comment can also be found in section18.8 of this comment summary.]

The agencies need to understand and take these impacts into account to assure that the standards being put in place for MY 2022-25 do not reverse the economic gains and environmental benefits that have come from the industry's recent recovery. [EPA-HQ-OAR-

2010-0799-9487-A1, p.20] [This comment can also be found in section18.8 of this comment summary.]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

For the MY2012-2016 rule, the agencies projected an increase in vehicle sales, using an approach that is equally applicable to the current proposal. The approach considers five years of discounted fuel savings, minus the incremental cost of a more efficient vehicle, as the net added value to the buyer at the time of purchase. As noted in the current NPRM, the change in sales is among the factors determining the impacts of the rule on auto sector employment (NPRM p.75155). Despite this, the agencies do not quantify the sales impacts of the MY2017-2025 rule. We believe that the approach previously taken is reasonable and yields a better estimate than a default value of zero (for change in sales). [EPA-HQ-OAR-2010-0799-9528-A2 p.2]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 112.]

One important question, clearly: What will the higher cost per vehicle do to car sales? This effect can be challenging to predict. But recent evidence from new polls and industry trends suggest a growing demand for fuel economy by consumers. And there, moreover, appears to be a strong link between consumer confidence and the purchase of new cars. So by enacting the proposed standards, EPA and NHTSA could positively influence consumer confidence, pushing it up, and by ensuring that we are moving in a positive direction with our energy use, they are likely to stimulate consumer spending in highly positive ways which, in turn, would result in greater gains from the proposed fuel economy standards. And equally critical, that would drive the positive job and other financial benefits to the U.S. economy.

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

These standards are based on an unreasonably aggressive expectation of increased electrification. The agency predicts that annual sales of hybrids, plug-in hybrids and all electric vehicles could represent 15% of new sales by 2025 (see footnote 13 at 76 Federal Register 74860; 17 – 35% in Figure 5 at 76 Federal Register 75081 for manufacturers with annual sales above 500,000 vehicles; about 30% in Figure 6 at 76 FR 75082 for manufacturers with annual sales 30,000 – 500,000 vehicles). [EPA-HQ-OAR-2010-0799-9485-A1, p.5]

In reality, electric vehicle sales have been a huge disappointment for automakers. The Chevy Volt, the American-made plug-in hybrid that General Motors had high hopes for going into 2011, fell short of GM's planned sales target of 10,000 units for the year. [EPA-HQ-OAR-2010-0799-9485-A1, p.5]

This exuberant and unwarranted optimism also extends to hybrid electric vehicles as shown below: [EPA-HQ-OAR-2010-0799-9485-A1, p.5] [For the figure 'shown below' please refer to EPA-HQ-OAR-2010-0799-9485-A1, p.6]

Organization: Ceres

The analysis concluded that, under the proposed standards, the auto industry as a whole is likely to see sales improve by 4.7%, and profits by 4.2%. The Detroit 3 are in the best position; they are likely to see sales increase by 5%, and profits by 5.2%. The rest of the industry, while benefiting from the standards, does not fare quite as well as the Detroit 3; it is likely to see sales increase by 4.4% and profits by 3.4%. [EPA-HQ-OAR-2010-0799-9475-A1, p. 1]

Organization: Consumer Federation of America (CFA)

VII. AUTOMAKER INCENTIVES: THE AUTO INDUSTRY HAS STRONG INCENTIVES TO COMPLY WITH THE STANDARDS

Globalization of the auto industry means it is no longer possible to be a successful automaker without being able to compete globally. [EPA-HQ-OAR-2010-0799-9419-A1, p. 8]

As shown in Exhibit S-7, the proposed standard brings U.S. standards up to international levels. [Exhibit S-7 can be found on p. 10 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, p. 8]

The proposed standard reduces the supply-side risk of introducing new fuel savings technologies and triggers competition around fuel economy. [EPA-HQ-OAR-2010-0799-9419-A1, p. 8]

Automakers know they can sell quality. As shown in Exhibit S-8, according to statistics compiled by the Bureau of Labor Statistics, which is responsible for the Producer Price Index, [Exhibit S-8 can be found on p. 11 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, p. 10]

- Over the past fifteen years, automakers have added three times as much value (and cost) with optional improvements in quality than mandatory (safety and environmental) improvements.
- The overall increase in MSRP tends to track closely to the increase in real disposable income.
- The cost increases that the long-term standards will require over the next 15 years are well below the cost of quality improvement over the past 15 years.
- Unlike most other quality additions, fuel economy improvements deliver pocketbook savings to consumers.
- In today’s market, fuel economy is a major determinant of vehicle quality that the market can easily absorb. [EPA-HQ-OAR-2010-0799-9419-A1, p. 10]

And that leads me to the fourth and most important reason. There is no sticker shock here, none whatsoever. There is no big jump year to year. It's a slow increase in prices. There are uniform price increases across all manufacturers because they all have to comply.

The cost of driving goes down. The value of vehicles goes up. There is no reason to believe that consumers will not buy these vehicles. And in fact, they've shown by their attitudes and the behaviors they are ready to do so.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 59.]

Car dealers have expressed concern about jobs and dealerships, implying that the standards might further hurt them.

Organization: Defour Group LLC

IV. Impact of the Standard on Industry Sales and Employment

Assuming the agencies' baseline sales of 17 million units in 2025, assuming a baseline combined auto and light truck retail transactions price of $28,000 per light duty vehicle ($2009), and assuming, with the agencies, a -1.0 industry demand price elasticity, our lower bound estimate of $1900 per vehicle net welfare loss yields a loss of 1.1 million industry combined car and light truck sales in 2025 relative to the MY 2016 baseline. Further assuming, also with the agencies, that every 1,000 unit sales provides 11.3 auto and supplier jobs yields a loss of just over 100,000 auto industry and supplier jobs. We estimate another 35,000 jobs lost at auto dealers, based on BLS data, which brings the total to a loss of 135,000 jobs in MY 2025 (rounded to the nearest 5,000 jobs). [EPA-HQ-OAR-2010-0799-9319-A1, p. 9]

Our mid-range estimate for industry sales losses is 1.8 million units relative to the baseline, which translates into a loss of 155,000 jobs in manufacturing and supply, plus another 50,000 jobs in distribution for a total job loss of 205,000 jobs in auto manufacturing, supply, and distribution. [EPA-HQ-OAR-2010-0799-9319-A1, p. 9] [Cross-referenced with section 16.8]

By comparison, the EIA estimates a loss of 8% of industry sales in 2025 for a 46.1 mpg standard relative to the baseline. Scaling this estimate up to the mandated 49.6 mpg yields a loss of 10.3% of industry sales or 1.8 million units off the 17 million unit baseline sales —the same as our mid-range estimate. This further translates into the identical loss of 205,000 in the manufacture, supply, and distribution of cars and light trucks. [EPA-HQ-OAR-2010-0799-9319-A1, p. 9]

All of these estimates are extremely conservative because they assume the 34.1 mpg mandate for MY 2016 as their baseline. This is inconsistent with the mainstream research cited in Part II and that found baselines of 23 mpg much closer to the level beyond which consumers would be unwilling to pay for increases in fuel economy. The laws of declining marginal benefits (utility) and increasing marginal costs imply that the actual level of net consumer welfare losses and the attendant sales and employment losses are exponentially higher. [EPA-HQ-OAR-2010-0799-9319-A1, p. 9]

Organization: Edmunds.com

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 103-104.]

Decreased competition or innovation of any features, including fuel economy, poses the risk that vehicles will be less differentiated, and thus offer decreased utility to certain consumers, especially those who strongly value the affected features. This could decrease new car sales, if consumers are less motivated to replace their cars as frequently and/or if consumers turn to used cars. Given the sizable contribution of auto sales to the U.S. economy, any slowdown in auto sales has the potential to generate significant adverse effects in other parts of the economy as well.

Secondly, the current proposal needs to demonstrate a fuller understanding of consumer demand for vehicles and how adding higher prices, decreased innovation and choice, and excessively complex information could affect consumer decision-making on new vehicle purchases and potentially result in lower auto sales.

Organization: Environmental Defense Fund (EDF)

H. FINAL RULE SHOULD INCLUDE QUANTITATIVE ESTIMATES OF VEHICLES SALES AND AUTO MANUFACTURING EMPLOYMENT BENEFITS

EPA and NHTSA conducted quantitative vehicle sales and auto manufacturing employment analyses in previous rulemakings and had prepared an estimate of these same indices for the rulemaking action at issue here using the same methodologies. However, the results of these analyses were not included in the published proposal. The changes occurred during the OMB review process. The docket for this rulemaking includes interagency drafts of the proposal submitted to OMB with the quantitative analyses included. The docket also includes the request by OMB to remove the quantitative analyses from the proposal33 and responses from EPA and NHTSA stating the importance of the quantitative analyses and requesting they be left in the final proposal.34 See Attachment B. We incorporate this document as an integral part of EDF's comments for inclusion in the administrative record for this rulemaking action. [EPA-HQ-OAR-2010-0799-9519-A1, p. 14]

We respectfully request that the quantitative vehicle sales and auto manufacturing employment benefits be included in the final rule to fully reflect the comprehensive societal benefits of the proposed program. [EPA-HQ-OAR-2010-0799-9519-A1, p. 14]

[The above comments can also be found in section 18.8 of this comment summary.]

i. VEHICLE SALES

EPA and NHTSA conducted a vehicle sales analysis in previous rulemakings by comparing the up-front costs of the vehicles with the present value of five years' worth of fuel savings. The Agencies used the same methodology to quantify vehicle sales impacts for the current proposed standards, finding that in 2025, combined new car and light truck sales could increase by an estimated 644,000 vehicles.35 However, these results were not included in the final proposed rulemaking, which states, "This rule takes effect for MY 2017–2025. In the intervening years, it is possible that the assumptions underlying this analysis, as well as market conditions, might change." (Proposal preamble, page 75,151) The proposal therefore concludes, "In light of the relevant uncertainties, the agency therefore decided not to include a quantitative sales estimate…" (Proposal preamble, page 75,320) While we agree that uncertainties indeed exist in such an analysis, we strongly believe that a quantitative analysis should at the very least have been presented in the proposal for the public to review and comment on. We strongly encourage the Agencies to include quantitative vehicle sales estimates in the final rule to reflect full transparency and the true estimated benefits of the proposed standards [EPA-HQ-OAR-2010-0799-9519-A1, pp. 14-15]

Organization: National Automobile Dealers Association (NADA)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 69-71.]

But dealers are concerned about the accelerated schedule in this proposal. The mandates for model year 2011 to 2016 just now being implemented aggressively move up the 2020 goal of 35 miles per gallon by four years. If this proposal aims to set mandates for model years 2017 through 2025, five of the thirteen years out in the future will more than double the fuel economy of the vehicles I now sell.

The showroom realities I see suggest that we should take the time to evaluate how consumers react to the higher-mileage/higher-cost vehicles manufacturers will build in the next few years. In other words, if we want, if we wait two years, manufacturers would still have the time necessary to comply and we would all have better data on which to make decisions. Sales of new vehicles were 12.7 million last year, a far cry from the 17-plus million in the high water market in the mid 2000s, but much better than the 10.4 million sold in 2009.

Dealers embrace the pivotal role we are playing to help lead our nation back to the road of prosperity, but we are wary of anything that might depress sales and turn back the gains being made. Simply put, before rushing head-long into a new set of mandates aimed at doubling today's fleet fuel economy, we need to know better what the ramifications will be.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 94.]

Next month NADA intends to release a detailed analysis of the proposal's impact on sales, especially with respect to certain sensitive market segments.

[Supplemental comments to the testimony]

IV. Consumers Unable to Afford or Unwilling to Pay Higher Prices Have Other Options

New light-duty vehicle sales plummeted in 2008 and 2009, largely due to the recession. The measurable increases in average new light-duty vehicle fleet fuel economy performance which have occurred since then must be balanced against a dramatic reduction fleet turnover. Currently, the in-use fleet is the oldest it has ever been (almost 11 years, on average). Annual new light-duty sales have increased steadily since 2009, but have a long way to go before reaching the once "normal" 16 million vehicles per year level. As noted in NADA's comments, effective fuel economy mandates must enhance new light-duty sales and fleet turnover, not retard them, especially given that increases in average new vehicle fuel economy otherwise is expected to occur "naturally" as fuel prices trend higher. [NHTSA-2010-0131-0267-A1, p.4]

Organization: National Wildlife Federation (NWF)

Overall, in 2011, a new study out this week confirms month by month increases in new vehicle fuel efficiency, while, despite continued economic uncertainty, vehicle sales were up about 10% - far outpacing overall economic growth. 6 7 [EPA-HQ-OAR-2010-0799-9887-A2, p. 4]

Organization: Natural Resources Defense Council (NRDC)

EPA and NHTSA should include a sales impact assessment using a methodology consistent with previous rules. [EPA-HQ-OAR-2010-0799-9472-A2, p. 4]

NHTSA should not use a vehicle choice model in its CAFE assessment without opportunity for public review and comment. [EPA-HQ-OAR-2010-0799-9472-A2, p. 4]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 71.]

As part of the basis for the proposed rates of improvement, EPA projects that battery electric vehicles and plug-in hybrid electric vehicles will account for as little as one percent of sales in 2021 and three percent of sales in 2025.

Yet nearly every major auto manufacturer will have EVs and PHEVs in production within the three years -- within three years.

EPA and the Department of Transportation previously estimated that a fleet-wide six-percent annual rate of improvement could be achieved with as little as four percent combined sale share of EVs and PHEVs in 2025, provided that sales of conventional hybrids continue to increase.

Four counts of significant reductions in the weight and cost of electric vehicle technologies further support our conclusion that the most increase in sales of these advanced technology vehicles require to achieve a fleet-wide six-percent annual rate of improvement is viable.

Organization: Ross, D.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 243.]

Now some automobile dealers groups claim harm through lost sales and lost jobs. In reality, all else equal, the projected drop in the net cost of vehicle ownership will result in an increase in sales.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

The new proposed standards will continue push improved technologies into the market and boost auto sales. In their initial submission to OMB, the agencies conducted a basic sales analysis and concluded that the effect on vehicle sales would be positive. Assuming a 3% discount rate, the agencies found that car sales would increase by 319,700 in 2025 and truck sales would increase by 324,600.13 This analysis was similar to that done in the 2012-16 rule. The final rule should include ta sale analysis consistent with that done for the prior rule. [EPA-HQ-OAR-2010-0799-9549-A2, p. 4]

13 EO12866 Review-Interagency Review material Part 1- 2017-2025 Vehicle GHG and Fuel Economy Standard and NPRM 2060 AQ54, Document ID: EPA-HQ-OAR-2010-0799-1224, pgs. 891-892 of PDF [EPA-HQ-OAR-2010-0799-9549-A2, p. 4]

Organization: Union of Concerned Scientists (UCS)

Sales of new light-duty vehicles are also projected to increase under these standards. The Ceres analysis found an increase of light-duty vehicles sales compared to business as usual, resulting in an additional $37.4 billion in sales 2030.8 While not included in the proposed rule, interagency review documents show that EPA has projected a 2.8% increase in car sales and a 5.7% increase in light truck sales compared to business as usual.9 [EPA-HQ-OAR-2010-0799-9567-A2, p. 3]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 217-218.]

A recent report from CERES found that standards similar to those proposed by the agencies would create nearly 500,000 new jobs nationwide in 2030.

Moreover, better fuel efficiency and greenhouse gas performance will improve the competitiveness of the American auto industry.

In 2008, in the face of rising gas prices and declining economy, American auto makers were ill prepared to meet consumers' needs. These standards will ensure that manufacturers continue to innovate over the coming decade, providing consumers clean and efficient vehicle choices that will help them fight for years to come.

8 Ceres. More Jobs Per Gallon. Management Information Services, Inc. July, 2011. p. 14 [EPA-HQ-OAR-2010-0799-9567-A2, p. 3]

9 Interagency review document, EPA-HQ-OAR-20100799-1224, Joint Rulemaking to Establish 2017 and Later Model Year Light Duty Vehicle GHG Emissions and CAFE Standards, p. 891-892. [EPA-HQ-OAR-2010-0799-9567-A2, p. 3]

Organization: United Automobile Workers (UAW)

Unfortunately, this has become as much a political concern as an analytical one, which the UAW believes is to the detriment of a broader view of the demand for light-duty vehicles in the United States. New vehicle sales are largely driven by employment and income levels and the need for replacement vehicles as older vehicles are taken out of service. For example, the drastic reduction in vehicle sales that occurred in model year 2009 was caused by the economic crisis, and nearly all observers agree that auto sales will increase only to the extent that the economy continues to recover. [EPA-HQ-OAR-2010-0799-9563-A2, pp.6-7]

The history of light-duty vehicle sales over the period that CAFE has been in effect shows that economic factors, not changes in CAFE requirements, are the main determinant of vehicle sales. The chart below provides a quick visual reference that shows no evident relationship between CAFE and sales when viewed in the context of the overall level of sales. [EPA-HQ-OAR-2010-0799-9563-A2, p.7] [To see the chart below please refer to EPA-HQ-OAR-2010-0799-9563-A2, p.7]

While the UAW believes that efforts to understand how sales are affected by increased vehicle prices for more efficient vehicles are worthwhile and should be continued, the history of new vehicle sales makes it clear that the best way to increase vehicle sales to former levels is to focus on efforts to improve the economy and increase employment. [EPA-HQ-OAR-2010-0799-9563-A2, p.7]

Organization: U.S. Coalition for Advanced Diesel Cars

Overstated Residual Value: In its 2012-2016 Final Rule, EPA discussed the importance of a vehicle's residual value retention over time as a component of the consumer's total cost of ownership. This language appears again in the current NPRM as EPA states, "it is reasonable to estimate that the added technology to improve CO_2 level and fuel economy will retain the same percentage of value when the vehicle is five years old." In the case of hybrid pickup trucks, the marketplace has proven EPA's estimation to be entirely unreasonable. Leading consumer websites, such as Edmunds and Kelley Blue Book, project hybrid pickup trucks depreciate faster than trucks with standard engine, resulting in the loss of thousands of dollars to consumers at trade-in time. Indeed, the extra depreciation caused by the hybrid content can erase much, if not all, of the fuel savings which can potentially accrue to the consumer. [NHTSA-2010-0131-0246-A1, p.5]

Organization: Volvo Car Corporation (VCC)

The proposed regulations are, and will be, very challenging. One of the challenges is to identify the correct pacing of the introduction to the market of the Advanced Technology Vehicles (ATV) that are anticipated in the proposal. EPA and NHTSA are trying to clarify the environmental needs that are to push a more intensified introduction of ATV's. The intensified introduction of ATV's will create many significant challenges and require risk taking for VCC. [EPA-HQ-OAR-2010-0799-9551-A2, p.2]

Response:

These comments show a diversity of opinion on whether this rule will affect vehicle sales either positively or negatively. Some put the emphasis on up-front costs and predict reductions in vehicle sales; others put the emphasis on the net savings to consumers, based on fuel savings outweighing technology costs over the vehicle's lifetime, and say that vehicle sales will increase. The UAW states that vehicle sales are mostly determined by the overall state of the economy. ACEEE says that enacting the proposed standards could lead to a positive effect on consumer confidence, and thus contribute to stimulating the economy. AFPM expresses concern over "an unreasonably aggressive expectation of increased electrification" of the vehicle fleet, while NESCAUM says that sales of EVs sufficient to meet even more stringent standards than those set here are viable.

As ACEEE, EDF, Sierra Club et al., and UCS note, in the MYs 2012-16 GHG and CAFE rule, EPA conducted a vehicle sales analysis based on a comparison of the tradeoff between the desirability of additional fuel savings and the up-front costs of new vehicles (including sales tax, insurance, and vehicle financing costs). Several of these organizations recommended that we conduct an analysis using the same methodology for this rule. As discussed in Preamble III.H.11 and RIA Chapter 8.1, we do not quantify vehicle sales impacts, because of uncertainties involved in the responses of consumers and automakers in the time horizon of this rule. As the United Auto Workers points out, for instance, the state of the economy is a major, if not the primary, determinant of total vehicle sales. The impact of the rule on sales may therefore depend, among other factors, on changes in the state of the economy. Other commenters discussed the importance of consumer confidence, fuel prices, and even of publicity over fuel prices, in consumers' interest in additional fuel economy. EPA agrees that these factors are important; indeed, fuel prices play an important role in estimating the fuel savings used in analyzing vehicle sales, as discussed in RIA Chapters 5.4 and 8.1.1. For other factors, including consumer confidence and publicity over fuel prices, we acknowledge their potential for impacts on vehicle sales. Even if we did quantify vehicle sales, though, we are not sufficiently confident in quantitative estimates of the impacts of those factors to develop numerical estimates.

Another method to estimate effects on vehicle sales is to model the market for vehicles. Consumer vehicle choice models estimate what vehicles consumers buy based on vehicle and consumer characteristics. As discussed in Section III.H.1.a, Chapter 8.1.2.8 of the RIA, and Section 18.1 of this Response to Comments, EPA has been exploring use of a consumer vehicle choice model, but we consider it premature to use the model in this rulemaking.

The studies by Ceres and by the Defour Group (including the 2011 EIA study cited by the latter) show how the results of vehicle sales analyses depend on the underlying assumptions. The Ceres and Defour analyses, like the method that EPA has used in the past, are based on an adjusted consumer price that reflects the increase in vehicle cost less a proportion of the expected future fuel savings; the EIA study does not consider consumer fuel savings. The per-vehicle technology cost estimates in Ceres' study (for MY 2020) appear to be somewhat lower than EPA's estimates; EIA's cost estimates are higher; and the Defour Group's cost estimates are substantially higher.[85] In the Ceres and Defour cases the estimates take into account estimates of the amount of fuel savings that vehicle buyers consider when deciding what vehicles to buy; EIA does not consider fuel savings. Ceres estimates that vehicle buyers consider 7 years of fuel savings, with sensitivity analysis of 3 to 15 years; we estimate that the Defour Group's estimate, of 25 percent of expected lifetime fuel savings, corresponds roughly to an assumption that buyers consider less than 3 years of fuel savings. Because the Defour Group and EIA analyses uses higher costs and lower benefits than the Ceres analysis, it is unsurprising that the three studies come up with very different vehicle sales estimates. EPA does not endorse the results of any of these studies.

As discussed in Section III.D.6 of the Preamble, in this final rule we project very low rates of EV penetration as part of a compliance strategy for the rule – around 2 percent in MY 2025 – and a combined penetration of strong HEVs, EVs, and PHEVs of around 7 percent (see Preamble Table III-52). We consider these penetration rates to be low enough that the new vehicle market will absorb these vehicles. We note that automakers are not obliged to use electrification as part of their strategies for compliance.

We agree that enacting these standards should contribute to the development and use of advanced technologies that will have applicability for meeting standards in other countries. As a result, vehicles built in the U.S. are more likely to achieve international standards. The ability to design vehicles that meet standards in foreign as well as domestic markets can be expected to reduce costs of design for automakers.

We agree that the macroeconomy both affects and is affected by the auto industry's condition, and by the level of production and sales of autos. The vehicle sales projections that we use for the rule analysis, as discussed in TSD Chapter 1, are based on models that incorporate projections of the economy into the future.

We disagree with Edmunds that there will be decreased competition or innovation of any features. As discussed in Preamble III.H.1, RIA Chapter 8.1, and Section 18.1 of this Response to Comments, it is possible for automakers to achieve both improved fuel economy and maintained levels of other vehicle attributes, including fleet diversity; it should thus be possible for automakers to improve both fuel economy and other vehicle attributes, if consumers are

[85] The Defour Group's cost estimates are based on the technology costs of MYs 2011-25 rulemakings, not the costs just of this rule. EPA considers it appropriate to examine the costs and benefits of this rule, with the impacts of other rules included in its baseline for analysis. In addition, the Defour Group assumes that indirect costs for all technologies equal the direct costs, by using a retail price equivalent multiplier of 2.0; EPA's cost estimates take into account that indirect costs for new technologies vary with the complexity of the technology and the time frame since its adoption. This issue is discussed in detail in TSD Chapter 3.1.2.2.

willing to pay for those other attributes. The agencies' cost methodology in fact includes cost of preserving all vehicle utilities found in the present fleet. See EPA RIA at pp. 1-39 to 40. The rule provides a thorough review of the literature on consumer demand for vehicles and how fuel economy affects it, in Preamble III.H.1 and RIA Chapter 8.1.2.

We do not understand what Edmunds means in expressing concern over "excessively complex information." Vehicle technology has been increasing in complexity probably since the invention of the automobile. For most vehicles, technologies that will satisfy the rule, such as improved transmissions, require little, if any, additional explanation, because their use is unlikely to play much of a direct role in vehicle purchase decisions.

The U.S. Coalition for Advanced Diesel Cars calls into question application of the same residual value to hybrid vehicles as to other vehicles in the cost of ownership analysis. The cost of ownership analysis (see Preamble III.H.5 and RIA Chapter 5.5) does not make use of residual value. The vehicle sales analysis that EPA has used in the past does take into account residual value, as described in RIA Chapter 8.1.1. That vehicle sales analysis was done at an aggregate level, though; it does not have the precision to separate effects for individual models or classes. For that purpose, we consider the use of an average residual value to be appropriate.

18.7.1. Access to Auto Loans and Effects on Low-Income Consumers

Organizations Included in this Section

Organization: Consumer Federation of America (CFA)

- Automakers adjust MSRP and discounts and auto financing in response to much larger changes in affordability. [EPA-HQ-OAR-2010-0799-9419-A1, p. 10]

Concerns about a negative impact of the standards on consumers and the auto market are unfounded, even in the case of low income consumers because they rest on faulty assumptions that are contradicted by the above analysis. [EPA-HQ-OAR-2010-0799-9419-A1, p. 10]

- When the costs of driving go down, vehicle ownership becomes more affordable, so output and employment in the industry will expand. [EPA-HQ-OAR-2010-0799-9419-A1, p. 10]
- Households with income below $20,000 made up approximately 22 percent of all households in 2010, but they accounted for only 2 percent of the money spent on new vehicles. [EPA-HQ-OAR-2010-0799-9419-A1, p. 11]

- Gasoline expenditures are a much bigger problem for these households. In 2010, households with incomes below $20,000 spent 7.3 times as much on gasoline as they spent on new car payments. [EPA-HQ-OAR-2010-0799-9419-A1, p. 11]
- Low-income households are much more involved in the used car market, in which we see an increase in supply of vehicles and lower prices as the standards accelerate the fleet turnover. [EPA-HQ-OAR-2010-0799-9419-A1, p. 11]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 61.]

So we are not worried about the increase in price associated with the technology because that increase in price will be paid back to the consumer who takes a typical five-month [sic] loan out during that very first month [sic].

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 39.]

By far, the single largest benefit is the reduction of consumer expenditure on gasoline and the decrease in the cost of driving. For the typical consumer who purchases a new auto that complies with the 2025 standard with a 5-year auto loan, the average life of auto loans these days, consumer pocketbook savings will be immediate and substantial.

Organization: Consumers Union

III. Low-Income Households Benefit from the Standards

Car prices have been remarkably stable over the last two decades, even as new features have proliferated and enormous safety gains have been achieved. Improving fuel economy is likely to have a modest price impact at most, while the savings on fuel will be tremendous. These net savings will benefit nearly all consumers, particularly low-income consumers. We are not aware of an in-depth, independent study that analyzes the impact of the proposed standards on low-income households. However, our best estimate is that they will see even greater net benefits. Low-income households pay a disproportionately large portion of their income on fuel, so will benefit greatly from greater fuel economy. At the same time, they are primarily insulated from the costs of the new standards because they account for a very small portion of new car buyers. [EPA-HQ-OAR-2010-0799-9454-A2, p.4]

Low-income consumers are the most vulnerable to price spikes in gasoline. Energy expenses in general and gasoline in particular constitute a disproportionately greater burden for low-income households.9 Decreasing national demand for oil by creating a gas-sipping fleet will help relieve this burden for low-income households. The Consumer Federation of America calculated that in 2010, households with incomes below $20,000 spent 7.3 times as much on gasoline as the spent on new car payments.10 In comparison, households with incomes above $70,000 spent 1.2 times as much on gasoline as they did on new car payments.11 Reducing demand for gasoline and making vehicles more efficient is a very effective tool to combat vulnerability to gas price spikes, which is a real threat to low-income households. Some financial institutions already recognize that lower operating costs lower credit and default risk and offer consumers lower interest rates for vehicles with superior fuel economy.12 [EPA-HQ-OAR-2010-0799-9454-A2, pp.4-5]

Low-income households are more likely to buy used rather than new vehicles, and as a consequence, they have lower depreciation costs than those absorbed by new car buyers. New vehicles lose an average of 65% of their value after five years of purchase.13 If the average cost increase for a new car is approximately $2,000, then the average cost increase of a five-year old car that meets the new standards would be about $700 (35%). The amount of savings depends largely on the starting point for the original vehicle's fuel economy, but earning back the difference (assuming 10% interest loan: $770 difference, assuming cash purchase: $700) could be recouped quickly by fuel savings. For example, moving from 20 to 24 mpg, from 28 to 36 mpg, or from 32 to 44 mpg would provide this level of savings within 2 years.14 Each of these examples is well within the expected average improvement that will result from the new standards, and average savings from the new standards are likely to be even greater. In addition, the standards are likely to diminish the premium often charged for more efficient used vehicles, making "efficiency" as an attribute relatively cheaper. [EPA-HQ-OAR-2010-0799-9454-A2, pp.5-6]

Consumer Reports survey data show that low-income households want more efficient vehicles and support the fuel economy standards. While 59% of respondents in moderate and high-income households expect their next vehicle purchase to have better fuel economy, 71% of low-income households expect to choose a model with better fuel economy.15 While an impressive 78% of moderate and high-income households support fuel economy standards that increase to at least 55 mpg by 2025, an even greater number (85%) of low-income households support these standards.16 Although more expensive cars create a greater initial hardship for low-income households than for higher-income households, 79% of low-income respondents are still willing to pay extra for a more fuel efficient vehicle if they can recover the additional cost through lower fuel costs within five years (compared to 86% of moderate and high-income respondents).17 [EPA-HQ-OAR-2010-0799-9454-A2, p.6]

VI. Impact of the Standards on the Poor

The agencies' assessment of the impacts of their fuel economy proposal fails to consider the proposed standard's severely adverse impacts on the poor and otherwise disadvantaged. A recent study by Professor Mark Jacobsen (University of California at San Diego) found that fuel economy standards are "sharply regressive" and that the costs of fuel economy mandates "fall disproportionately on low-income households." He found, for example, that "low-income households" buying ten-year-old vehicles are "suffering welfare losses (as a fraction of income) more than three times as large as those of the high-income group."[20] [EPA-HQ-OAR-2010-0799-9319-A1, p. 13]

This finding is important because used cars play an essential role in the escape from inner-city poverty. Studies show that car ownership rates are lower among minority groups, and this appears to be a significant factor in explaining the lower employment rates of these groups. A study conducted by researchers at the University of California at Berkeley estimated that raising minority car ownership rates to the white car ownership rate would eliminate 45 percent of the black-white employment rate differential and 17 percent of the comparable Latino-white differential.[21] By raising the cost of vehicle ownership, fuel economy standards work in precisely the opposite direction. [EPA-HQ-OAR-2010-0799-9319-A1, p. 13]

The standards will also save consumers at the pump and help insulate them, especially those on fixed incomes like retirees and seniors, from the volatility of gas prices. As we have a debate here in Michigan about how to adequately invest in our roads and bridges, I will be working to make sure any solution considers how it impacts middle-class families that are already struggling. Increased fuel economy will help them by putting more discretionary income in their pockets so that they can spend more money on other goods and services. Over the lifecycle of a model year 2025 vehicle, consumers will in fact save up to $6,600 in fuel costs, which they can then use to help support local businesses and jobs. [EPA-HQ-OAR-2010-0799-7983-A1, p. 1]

Organization: National Automobile Dealers Association (NADA)

Second, prospective new light-duty vehicle purchasers must have the ability to make a purchase or lease. Ability involves critical factors like financial wherewithal (for most consumers, this means creditworthiness), a driver's license, and for certain alternative and new technology vehicles, the availability of convenient refueling. Third, prospective new light-duty vehicle purchasers must be willing to purchase, assuming they have the need and/or desire and the ability to do so. [EPA-HQ-OAR-2010-0799-9575-A1, p. 2]

The proposal gives remarkably short shrift to these marketplace realities. A cynical view would argue that, under a 'push' mandate, regulators need not care if the vehicles they are mandating actually get sold or leased. These comments do not take that position, but instead suggest that a careful consideration of actual customer behaviors and marketplace realities will enable NHTSA and EPA to leverage customer demand to maximize fleet turnover, thus maximizing program effectiveness. Doing so is critical given that, by a wide margin, the proposal is the costliest of any ever considered for the U.S. automobile industry. [EPA-HQ-OAR-2010-0799-9575-A1, p. 3]

III. THE PROPOSED MY 2017-2025 STANDARDS WILL DRAMATICALLY IMPACT THE ABILITY AND THE WILLINGNESS OF CUSTOMERS TO PURCHASE NEW LIGHT-DUTY MOTOR VEHICLES.

As noted above, the demand for new light-duty motor vehicles, not unlike for most consumer goods, derives solely from and to the degree prospective purchasers need or desire them. Moreover, the demand for new light-duty vehicles is and always will be constrained by choices, including the used vehicle marketplace, vehicle service and repair options, and a variety of transportation alternatives that conceivably may satisfy those same needs and desires. [EPA-HQ-OAR-2010-0799-9575-A1, p. 6]

Assuming the requisite need or desire, prospective purchasers of new light-duty vehicles must have the ability to buy. For most households, a light-duty car or truck is the most expensive consumer purchase they make. Unlike for most other consumer goods, in excess of 90% of purchasers finance the new light-duty vehicles they acquire by means of a credit sale or lease, with less than ten percent involved in all-cash transactions. Thus, the single most important ability factor is creditworthiness. When prospective purchasers lack sufficient creditworthiness to enable a lender or lessor to finance the new light-duty vehicle they need or desire, they must consider other options. In addition to the alternate transportation choices noted above, prospective purchasers may be able to consider a less expensive new vehicle option that meets their needs or desires but, as discussed below, at some point no such new vehicle option will be available. [EPA-HQ-OAR-2010-0799-9575-A1, p. 6]

A. The Ability of Prospective Purchasers of New Light-Duty Purchasers to Pay for the Costs of the Proposed Standards

However much prospective purchasers may need or desire new vehicles covered by the proposal, they must be able to afford them. Of course, other ability factors often come into play, such as meeting legal requirements for a license and obtaining liability insurance, or having reasonably available refueling options for alternative fuel and plug-in vehicles. Importantly, it matters not whether the new vehicles in question offer improved fuel economy performance characteristics compared to the transportation options currently being used by prospective purchasers. When underwriting loans or leases, lenders and lessors simply do not account for whether new vehicles offer more torque or horsepower, improved fuel economy, reduced GHGs, ubiquitous cup holders, or prettier paint. All that matters is whether prospective purchasers are creditworthy, that is, whether they will comply with their payment obligations as spelled out in the loan or lease. Regarding the new vehicles themselves, these decisions principally involve objective criteria and one key factor: the total amount of the up-front cost being financed. [EPA-HQ-OAR-2010-0799-9575-A1, p. 6]

Nowhere does the proposal properly account for ability to pay. Consequently, the proposal significantly understates potential impacts on prospective new vehicle purchasers and overstates regulatory benefits. The paper Attached as Exhibit C lays out, for three cost-increase scenarios, how the proposal will impact on the ability of consumers to pay for vehicles covered by the rule, assuming the need or desire, and willingness, of those prospective purchasers to do so.13 Note that these cost increase scenarios only reflect what it will cost prospective purchasers up front due to the mandates imposed by the MY 2011-2025 standards. They do not take into account other potentially significant regulatory costs above the assumed baseline, including compliance with expected Tier III emissions standards and an array of new safety standards. [EPA-HQ-OAR-2010-0799-9575-A1, pp. 6-7]

The attached paper analyzes Bureau of Labor Statistics Consumer Expenditure Survey data to show how each average per vehicle cost increase scenario will impact the least expensive new vehicle in the market. For example, a regulatory cost of $2,937 (in 2010 dollars) could increase the cost of the least expensive new vehicle to approximately $15,700 versus the current $12,750. In doing so approximately 6.8 million licensed drivers will no longer qualify for a loan on that least expensive new vehicle and thus will have to turn to the other transportation options discussed above. In fact, projected per vehicle average cost increases will knock licensed drivers out of the market for all new light-duty vehicle segments, as illustrated by the fact that, at the same average per vehicle price increase of $2,937, another 6.8 million licensed drivers will no longer qualify for the purchase of the minimum cost new vehicle that accommodates more than 5 people (or more than 2 child safety seats), currently selling for approximately $20,000. EPA and NHTSA must take these significant economic impacts into account, especially given that they have will have the greatest effect on lower income families at the margins of the market. [EPA-HQ-OAR-2010-0799-9575-A1, p. 7]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 54-55.]

Some tout that the cost of the proposal is essentially free because of fuel savings. But before any fuel savings can be realized, customers must have the ability to buy. For over 90 percent of Americans, the purchase of a new vehicle is contingent on getting approved for a loan or a lease. If they don't qualify, they can't buy. They can't buy, they can't save money on fuel.

So as someone who works every day to secure financing for my customers, I'm unaware of anybody who will fund auto loans based on the promises of fuel savings. Loan qualification is based mainly on the income of the customer and on the vehicle price. What's clear is this proposal will make it harder for many customers to obtain financing, eliminating their ability to realize any fuel savings.

Specifically, NADA is preparing an analysis that conservatively estimates that about 7 million licensed drivers will be priced out of the new car market entirely when this proposal is fully implemented. But this consequence is not limited to those motorists who can only afford the most inexpensive vehicle. Let's talk about the family buyer. For example, our study also estimates that over 7 million licensed drivers would no longer qualify for financing to buy the lowest cost family vehicle, such as the Dodge Journey, which accommodates more than five people or more than two child passenger safety seats. This will be devastating for large families or families with small children that would like to carpool. And the burden of this rule is not even spread evenly. California, the most populous state, will see 662,000 of its citizens no longer able to qualify for a new car loan. In Tennessee, 5 percent of licensed drivers will be shut out of the new car market.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 53-55.]

Moreover, the U.S. Energy Information Administration finds that this proposal will regulate out of existence the most affordable cars on the market today. Adjusting for inflation, the Energy Economic Information Administration claims that in 2025, there will no longer be new vehicles on the market costing $15,000 or less. These are the vehicles I sell to smart frugal buyers, college students and working families. How can a rule that eliminates the most affordable new cars on the market be pro-consumer? You're right; it's not.

[This comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 57.]

We all want fuel economy, but it's not free. By adding $3,200 to the cost of a car, over seven million Americans will be priced out of the market, fleet turnover will be reduced and global warning benefits will be delayed. [Supplemental comment to testimony]

II. Financing Constraints Limit New Light-Duty Vehicle Affordability

NADA's February 13th comments discussed at length the incontrovertible fact that affordability limits the new vehicle marketplace. For any given vehicle price increase, some portion of the market for that vehicle will disappear to the extent that they will be unable to qualify for a loan or lease. This issue is critical given that over 90% of all new vehicle transactions involve loans or leases, but is by no means limited to price increases associated with fuel economy or emissions mandates. At the same time, the fact that a vehicle's higher price is associated with an improved performance characteristic (fuel economy or otherwise) is of no consequence to lenders and lessors as they almost exclusively focus on the likelihood of prospective borrowers or lessees to repay their prospective loans or leases in a full and timely manner. Testimony presented by the Consumers Union (CU), the Consumer Federation of America (CFA), the National Resources Defense Council (NRDC), Consumer Reports, and others ignored this critical affordability factor, in all likelihood because of their lack of a real-world understanding of how and why consumers actually buy new vehicles at retail. [NHTSA-2010-0131-0267-A1, pp.2-3]

Organization: Ross, D.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 242.]

And most low income consumers finance vehicle purchases so that their net out-of-pocket expense would actually be lower from day one.

Organization: Union of Concerned Scientists (UCS)

(h) Impact on Entry-Level Vehicles

One of the criticisms leveled at the proposed rule in the media over the past few months is that new standards will elevate costs of low-priced vehicles, pricing shoppers for those models out of the market. This is faulty logic for a few reasons. First, increased costs to a given model will not necessarily directly translate to increased price in those models. It is common knowledge that entry-level models are a sought-after market by automakers, as they represent an opportunity to build a long-term customer base through brand allegiance. Automakers seeking to reach that market are likely to keep prices of those models down and use other higher-profit margin vehicles to help defray costs of technology placed on entry-level models. [EPA-HQ-OAR-2010-0799-9567-A2, pp. 13-14]

Even given that fact, however, it is important to note that the cost of technology in this market segment is not untenably high. Take for example, the Hyundai Elantra. The 2010 model, outfitted with stability and traction control but lacking the fuel-saving technologies that subsequently appeared on the 2011 model, achieved a fuel economy of 26/34/29 (city/hwy/comb) at an MSRP of $17,845.38 The comparable 2011 Hyundai Elantra, by contrast – a model outfitted with a host of fuel-saving, emissions reducing technologies such as an efficient 1.8-liter engine and a 6-speed automatic transmission – achieved a fuel economy of 29/40/33 (city/hwy/comb) at an MSRP of $17,195. Thus, the 2011 model (a) offers a 12% reduction in fuel use from the prior model, (b) already meets its GHG target through 2020, and (c) does so at a price reduction of $650. While this is but one example, clearly there is flexibility in the way automakers distribute costs among their model offerings. [EPA-HQ-OAR-2010-0799-9567-A2, p. 14]

Finally, arguments over the initial price of the vehicle ignore the substantial savings purchasers of those vehicles will see due to the improvements under this proposal. These savings will increase consumers' ability to afford vehicles because they can shift money from gasoline expenditures to vehicle expenditures. As noted earlier in our comments, EPA has indicated that such savings will drive an increase in vehicle sales, quite the opposite of pricing consumers out of the market. [EPA-HQ-OAR-2010-0799-9567-A2, p. 14]

UCS urges the agencies to dismiss the argument that the MY2017-2025 standards unfairly penalize shoppers of entry-level vehicles, and to dismiss any proposed modifications to stringency based on that argument. [EPA-HQ-OAR-2010-0799-9713-A1, p. 2]

Response:

These comments raise several related, but somewhat separable issues: the impacts of this rule on vehicle sales; the impacts of this rule on the ability of consumers to buy new vehicles; the impacts of this rule on low-income households; and the impacts of this rule on low-priced vehicles. Section 18.7 of this Response to Comments, along with Preamble III.H.11.a, discuss the impacts of this rule on vehicle sales. Here we focus on the latter three issues. We first note that, in response to these comments, EPA has added a new section, III.H.11.b, to the Preamble, and Chapter 8.1.3 to the RIA, that discuss these issues.

Vehicle Affordability

Comments on the impacts of the rule on the ability of consumers to buy new vehicles discuss the role of costs, fuel savings, and the vehicle loan market. A number of organizations find, as does EPA (see Preamble III.H.5 and RIA Chapter 5.5), that, for those who buy vehicles on credit, the fuel savings exceed the up-front costs from the time of purchase; for those who buy vehicles using cash, the payback period is 3.2-3.4 years (see RIA Chapter 5.5). For those who buy used vehicles, the payback period is expected to be even shorter: the costs of the vehicles (and thus the increased technology costs due to this rule) will go down, but the fuel-saving technologies will maintain their effectiveness. These arguments suggest that the rule will increase the affordability of new vehicles.

In contrast, NADA emphasizes the increase in up-front vehicle costs as a factor in consumers' abilities to purchase. In particular, they state that new vehicle buyers may not be able to get loans for vehicles that have become more expensive as a result of new standards, because they cannot get access to sufficient credit for the additional cost. As a result, they will be unable to participate in the new vehicle market even if the new vehicles offer significant fuel savings. NADA says that auto lenders do not take into account the fuel economy of the vehicles when they are deciding on providing loans; the lenders consider only consumers' debt-to-income ratios. NADA provided an analysis that concludes that up to 6.8 million licensed drivers may no longer have access to new vehicles as a result of the standards. According to NADA's analysis, this estimate is the number of licensed drivers who live in the 3.1 – 4.2 million households that could borrow $11,750, the loan amount for the least expensive new vehicle in 2011 after a $1000 down payment, but could not borrow $14,750.[86] This difference of $3,000 is meant to represent what NADA views as the cost increase of new fuel economy standards, which EPA believes is incorrect and responds to further below.

In assessing these comments, EPA finds that the NADA study does not provide a usable estimate of those consumers in the market for new vehicles who might have trouble getting loans, nor does it provide a usable estimate of the impacts of the rule on the new vehicle market. Because the NADA study does not separate consumers in the market for new vehicles from consumers who are not in the market for new vehicles, the 6.8 million licensed driver figure significantly overestimates any impact of this rule on the new vehicle market. Preamble Section III.H.11.b. includes a detailed response on the key issues raised in the NADA study. The key points from that response include:

- The NADA study is based on the entire population of the U.S., not those who are in the market for vehicles. Its results do not provide useful insights into the effects of the rule on sales of low-priced vehicles, on vehicle sales overall, or on low-income households, because the analysis is not based on households in the market for vehicles. For example, NADA cites 7 million licensed drivers who will not be eligible to get financing for a Dodge Journey. With a total vehicle market estimated to be 17.2 million vehicles in 2025, it is highly unlikely that 7 million people were intending to buy the Dodge Journey but will not do so because of the rule. Sales of the Dodge Journey are unlikely to be as high as 7 million, and even the most negative estimates of vehicle sales impacts from this rule (a loss of 1.8 million vehicles, estimated by the Defour Group; see Section 18.7 of this Response to Comments) do not approach 7 million. We thus find that the NADA study does not provide policy-relevant estimates of rule impacts.
- The NADA estimate of 6.8 million licensed drivers is not the appropriate measure within its own study. In the NADA study, the unit of analysis for affordability is households. Even if there are 6.8 million licensed drivers in those households, they are not independently buying new vehicles; the households can barely afford one, much less multiple, new vehicles. An accurate statement of the findings of the study is that there are 3.1 to 4.2 million households in the U.S. who could theoretically qualify to borrow $11,750 but not $14,750, based purely on having a debt-to-income ratio less than 40 percent.[87]
- NADA's assumption of a $3,000 cost increase per vehicle is based on inappropriately summing the costs of MY 2011, MYs 2012-16, and MYs 2017-25 rules, double-counting MY 2011 costs, and overstating MY 2016 costs. It is also not true that all vehicles will experience the same price increase. See, for instance, RIA Tables 5.1-1, 5.1-6, and 5.1-7 for the variation in costs predicted for different auto companies. It is likely, as discussed in Preamble Section III.H.11.b, that auto makers have discretion to use different profit margins in different vehicle segments; if the auto manufacturers want to preserve access to low-priced vehicles, they are likely to have the ability to do so.

[86] Wagner, D., P. Nusinovich, and E. Plaza-Jennings, National Automobile Dealers Association (February 13, 2012). "The Effect of Proposed MY 2017-2025 Corporate Average Fuel Economy (CAFE) Standards on the New Vehicle Market Population." Docket EPA-HQ-OAR-0799.

[87] As noted, these amounts are based on the cost of the least expensive vehicle in 2011, with $1000 down payment, with the assumption that it will become $3000 more expensive as the result of three rulemakings, for MYs 2011, 2012-16, and 2017-25 (see Wagner et al., footnote 86).

- It is incorrect that no lenders consider the fuel savings of more efficient vehicles in deciding on vehicle loans. As Consumers Union points out and as EPA has found,[88] a number of financial institutions currently provide discounted loans for more efficient vehicles. Indeed, it is possible (though unknown at this time) that the auto loan market may evolve to include further consideration of fuel savings, as those savings play a significant factor in offsetting the increase in up-front costs of vehicles. Thus, the premise underlying NADA's argument is overstated or misplaced.

EPA recognizes that higher vehicle costs will be a disadvantage for vehicle buyers, and that fuel savings will benefit owners of the more fuel-efficient vehicles. Our analysis shows, as does that of a number of commenters, that the fuel savings will considerably outweigh the technology costs and, considering that factor alone, the rule should increase the affordability of new vehicles. See Preamble III.H.5. We recognize that negative impacts on the market for vehicle loans due to these changes are possible, but it is also possible that the loan market may expand its attention to consider fuel savings and thus reduce any negative impacts.

Impact on Low-Income Households

EPA agrees with CFA, CU, and others that low-income households are more likely to buy used vehicles than new vehicles, and appear to be more vulnerable to swings in fuel prices than other households. Because the payback period for used vehicles is shorter than that for new vehicles (see Preamble III.H.5 and RIA Chapter 5.5), it is possible that low-income households may benefit from the rule. As discussed in Preamble III.H.11.a, sales impacts in the market for new vehicles may affect the availability of used vehicles.

The NADA analysis does not distinguish impacts on low-income households from impacts in other sectors and thus does not provide insights into impacts on low-income households.

The Defour Group suggests that the standards are regressive, with adverse impacts falling disproportionately on low-income households, and possibly limiting their ability to obtain employment because of limited mobility. As discussed in Preamble III.H.11.b, the commenter's regressivity assessment is based on an inappropriate application of the cited Jacobsen study.[89] Jacobsen examined the non-footprint-based fuel economy program; the disproportionate impact on low-income households is based on the increased prices of used vehicles and the shift toward smaller vehicles. As discussed above in Section III.H.11.a, EPA finds that the impact on the used vehicle market depends on the impact of the rule on new vehicle sales, which we do not quantify. Because the footprint-based standard sharply reduces incentives to downsize vehicles, we do not accept the conclusion that the rule will result in buyers of used vehicles getting smaller

[88] An internet search on the term "green auto loan" produced more than 50 lending institutions that provide reduced rates for more efficient vehicles. See Helfand, Gloria (2012). "Memorandum: Lending institutions that provide discounts for more fuel-efficient vehicles." Assessment and Standards Division, Office of Transportation and Air Quality, U.S. Environmental Protection Agency, Docket EPA-HQ-OAR-0799.

[89] Jacobsen, Mark. "Evaluating U.S. Fuel Economy Standards In a Model with Producer and Household Heterogeneity." Working paper, University of California, San Diego, September 2010 (Docket EPA-HQ-OAR-2010-0799).

ones, with a consequent welfare loss. For these reasons, the regressivity finding from Jacobsen's paper is not applicable to the effects of this rule.

Impact on Low-Priced Vehicles

The NADA analysis assumes that an average cost increase of $3000 per vehicle applies to vehicles in the low-priced vehicle segment. See above in this section, under "Vehicle Affordability," for our discussion of the cost estimate itself. This segment of the market is of particular interest because it may be the entry class for first-time new vehicle buyers, who may develop brand loyalty and later aim to purchase other new vehicles. NADA argues further that this rule will eliminate from the market vehicles costing $15,000 or less, citing the Energy Information Administration.

As discussed in Preamble III.H.11.b, EPA agrees that some vehicles in the low-priced (economy-class) segment will bear technology costs needed to meet the new standards, but it is not known how manufacturers will decide to pass on these costs across their vehicle fleets, including in the low-priced vehicle segment. As the Union of Concerned Scientists comments, auto makers have some flexibility in which segments will bear more costs, and how those costs will be passed along to consumers in vehicle prices. Because of this flexibility, it is difficult to predict how costs will be translated into vehicle prices. UCS provides the example of the Hyundai Elantra, where the MY 2011 model has higher fuel economy and a lower price than the MY 2010 version, and meets its GHG target through 2020. Though this vehicle may not be considered to be in the lowest-price segment, it demonstrates that added technology does not necessarily translate directly into a higher price.

Moreover, because the standards are established as individual manufacturer fleet average standards, manufacturers can choose the vehicles on which to add controls. It may be, for example, that manufacturers will add fewer controls to smaller, less expensive vehicles, because these vehicles may already be meeting their regulatory targets, because it is more cost effective to add controls to larger less efficient vehicles, to preserve profit margins on lower-margin smaller vehicles, or for a combination of these reasons.

In addition, the average per-vehicle cost increase EPA estimated for the entire industry (both cars and trucks) varies by company. As shown in Table III-25 of the Preamble, while the average MY2025 cost increase for passenger cars across the industry is estimated to be $1,836, EPA estimated that Ferrari's cost would be $7,864/car, Porsche costs would increase by $4,044/vehicle, and Tata-Jaguar-LandRover would increase by $3,390/vehicle. At the same time, several other companies had cost increases for passenger cars lower than the industry average: Toyota at $1,407, Kia at $1,658, and Honda at $1,642/car. Companies such as Ferrari, Porsche, Tata-Jaguar-LandRover, Daimler, and Geely-Volvo, all with estimated costs for passenger cars higher than the industry average, do not sell cars in the lowest price segments of the car market. However, companies such as Toyota, Kia, and Honda do sell to that market, and EPA estimated these companies' cost increases for passenger cars to be lower than the industry average.

The Energy Information Administration's 2011 estimates[90] cited by NADA are based on more stringent standards than those in this rule; are based on cost estimates using a more restricted set of technologies than those examined in this rule (and what appear to be higher costs); and appear to have lower technology phase-in rates than estimated for this rule. Indeed, the timing of the Annual Energy Outlook release is such that even the 2012 AEO analysis of the rulemaking notes that, "due to the timing of the modeling process, [it] does not incorporate all information from the pending rulemaking process, to assess potential energy impacts of the regulatory proposal."[91] We thus do not consider it appropriate to base estimates of vehicle price changes on the 2011 AEO analysis, which uses even less of the data from this rulemaking.

Though the rule is expected to increase the prices of low-price vehicles, the degrees of price increase and the impacts of the price increases, especially when combined with the fuel savings that will accompany these changes, are much less clear. We thus disagree that it is inevitable that vehicles with prices less than $15,000 will disappear from the market.

Automakers today are driving this country's economic recovery. Yet, in light of the uncertainty over consumer valuation of fuel savings and other factors, the agencies have not included an estimate of sales or employment impacts in the NPRM or supporting documents. [EPA-HQ-OAR-2010-0799-9487-A1, p.20] [This comment can also be found in section18.7 of this comment summary]

The agencies need to understand and take these impacts into account to assure that the standards being put in place for MY 2022-25 do not reverse the economic gains and environmental benefits that have come from the industry's recent recovery. [EPA-HQ-OAR-2010-0799-9487-A1, p.20] [This comment can also be found in section18.7 of this comment summary]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Economic Impacts

Benefits of the proposed rule include major macroeconomic benefits in the form of increased jobs and GDP. The primary mechanism for these increases is the shifting of spending from the energy sector to the broader economy, which employs more people per dollar spent, on average. This shift comes about through consumer spending of the money saved on fuel expenditures.1 The attached ACEEE testimony, delivered at the January 24th hearing on the NPRM in San Francisco, provides a summary of this and related issues, as well as a preliminary quantification of the magnitude of these effects. ACEEE is now refining these estimates in conjunction with work with the BlueGreen Alliance and plans to submit this information to the record in the near future. [EPA-HQ-OAR-2010-0799-9528-A2, p.2] [Refer to EPA-HQ-OAR-2010-0799-9528-A1 regarding the ACEEE testimony referenced above.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 109-111.]

And third, promoting these standards will be good for jobs, even as the fuel economy improvements will save household consumers and businesses money that almost immediately will be respent in the broader economy.

But more importantly, by redirecting the investment in fuel efficiency savings into other sectors of the economy, we support the increased number of jobs. How might that be? Tapping into the evidence, the economic accounts for the U.S. turns out that, directly and indirectly, the total jobs supported by a million dollars of the purchase of gasoline sales supports only 11 jobs per million dollars. But the sale and manufacturing of automobiles, 17 jobs, and in the economy as a whole, 17 to 18 jobs. So anytime we cost-effectively redirect resources away from gasoline purchases into those sectors, we support a net gain of six to seven jobs. Using that logic but in a more sophisticated modeling exercise, we estimate these standards will provide, on average over the period 2017 to 2025, about 300- to 400,000 jobs for the larger economy.

We're going to update those in about a month, but, in effect, the evidence shows that efficiency and improved fuel economy provides more jobs per gallon equivalent.

---

Organization: Anonymous public citizen 4

The added cost being forced on consumers will squeeze middle class Americans. They will no longer be able to contribute to the support of those not working. [EPA-HQ-OAR-2010-0799-10317, p.1]

Realize that most Americans do not have the income to support this proposal. Don't do anything else to us that does not apply to ALL government workers including congress and the president. [EPA-HQ-OAR-2010-0799-10317, p.1]

Organization: Axford, H.

Transportation is critical to our quality of life and EPA’s regulation could increase the cost of a new car up by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. [EPA-HQ-OAR-2010-0799-9149-A1, p. 2]

Organization: Bassett, S.

This is just another program to drive up auto prices, thereby eliminating jobs. [EPA-HQ-OAR-2010-0799-8123-A1, p. 1]

Organization: BlueGreen Alliance

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 58-60.]

Consumers looking to purchase vehicles in the next few years are expressing interest in higher fuel economy. Building the next generation of advanced vehicles in the United States will create tens of thousands of new engineering and manufacturing jobs and strengthen America's rebounding sector.

Evidence already exists that bringing cleaner vehicles into the market creates American jobs. We have, by example, the Advanced Technology Vehicle Manufacturing loan program that will preserve or create nearly 40,000 jobs in the U.S. auto sector, retooling America's factories to produce advanced technology vehicles and their key components.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 38.]

Crucially, the proposed standard will help to create many thousands of jobs through net consumer savings on fuel, as well as spending on higher performing vehicles. An initial assessment of the job impact by the University of California Professor David Roland-Holst finds that the proposed standard will create more than 200,000 jobs by the year 2025 in California alone.

Organization: Business for Innovative Climate & Energy Policy (BICEP)

Strong standards will lead to U.S. job growth by creating jobs in the auto industry, and more broadly by diverting consumer spending away from fuel. The July 2011 report "More Jobs Per Gallon: How Strong Fuel Economy/GHG Standards Will Fuel American Jobs;" an economic analysis authored for Ceres by Management Information Services, Inc., found that a 54.5 mpg fuel economy standard3 would create approximately 484,000 economy-wide new U.S. jobs, with 43,000 in the auto industry and net job gains in 49 states in 2030. [EPA-HQ-OAR-2010-0799-9450-A1, p. 1]

Further, under the proposed standard, the report found that in 2030 national gross economic output, or sales, is projected to be $21.3 billion higher; personal income is projected to increase by approximately $14.2 billion, and revenue for cash strapped federal, state and local governments is projected to be approximately $12.7 billion higher in 2030. It is important to note that the higher the standard, the greater the economic benefits;4 thus it is critical that the standards be as strong as possible. [EPA-HQ-OAR-2010-0799-9450-A1, pp. 1-2]

Given its links to so many other sectors of the economy, the health of the auto industry has a significant impact on the economy as a whole. Thus, we find the, recent analysis conducted by Walter McManus of the School of Business Administration at Oakland University, Alan Baum of Baum and Associates, and Dan Meszler of Meszler Engineering Services, in collaboration with Ceres, to be of particular interest. The analysis looked at the impact of the proposed standards (approximately 40 mpg) on the auto industry in 2020. The analysis found that the proposed standards will benefit the auto industry, a major creator of U.S. jobs, and a key player in U.S. manufacturing. In addition, the analysis found that Detroit 3 will see greater benefits than the rest of the industry. Finally, the analysis found that the proposed 2020 standard is cost-effective at a fuel price of $1.50 per gallon. Since this is well below expected fuel prices in 2020, it is clear that the standards will ensure significant savings in fuel costs for consumers, and increase consumer spending in other sectors of the economy. [EPA-HQ-OAR-2010-0799-9450-A1, p. 2]

---

3 Approximately equivalent to the 4% scenario presented in EPA and NHTSA's Joint Notice of Intent, "2017 and Later Model Year Light Duty Vehicle GHG Emissions and CAFE Standards;" EPA 40 CFR Parts 85, 86, and 600; http://edocket.access.gpo.gov/2010/2010-25444.htm

4 For example, the report found that under a 6% improvement scenario, net job gains were projected to be 684,000.

Organization: Cafagna, R.

Transportation is critical to our quality of life and EPA's regulation could increase the cost of a new car up by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. Set the example, ride a burro or bicycle instead of S.U.V. Range Rovers and will follow. Do what I tell you don`t do what I do it does not work. EPA needs to go to China India Korea to see How Much Pollution they produce instead of destroying jobs in the U.S. Solar and wind DO NOT PUSH MY CAR TO WORK. [EPA-HQ-OAR-2010-0799-11689-A1, pp. 1-2]

Organization: Center for Biological Diversity

We also note that the Agencies' initial submission of the rulemaking for review by OMB included additional economic benefits in the form of consumer welfare, increased sales and employment, and increased gross domestic product. These benefits have been deleted from the NPRM without explanation. Absent a rational explanation for this deletion, it must be reversed. [EPA-HQ-OAR-2010-0799-9479-A1, p. 7]

Organization: Ceres

We would like to call your attention to recent analysis conducted by Walter McManus of the School of Business Administration at Oakland University, Alan Baum of Baum and Associates, and Dan Meszler of Meszler Engineering Services, in collaboration with Ceres, on the impact of the proposed standards (approximately 40 mpg) on the auto industry in 2020. The analysis found that the proposed standards will benefit the auto industry, a major creator of U.S. jobs, and a key player in U.S. manufacturing. In addition, the Detroit 3 will see greater benefits than the rest of the industry. [See Docket number EPA-HQ-OAR-2010-0799-9475-A2 for a comprehensive presentation.] [EPA-HQ-OAR-2010-0799-9475-A1, p. 1]

Note that the underlying assumptions for this analysis were conservative; for example it assumed a gas price of $3.50, equal to the average price in 2011, although increased demand from countries such as China, India and Brazil is projected to result in higher prices by 2020. Note also that the analysis found that the proposed 2020 standard would be cost-effective at a fuel price of $1.50 per gallon, well below expected fuel prices in 2020. In fact, a 53 mpg standard would be cost effective at current average gas prices of $3.50 per gallon. [EPA-HQ-OAR-2010-0799-9475-A1, pp. 1-2]

Further, under the proposed standard, the report found that in 2030, national gross economic output, or sales, is projected to be $21.3 billion higher; personal income is projected to increase by approximately $14.2 billion, and revenue for cash strapped federal, state and local governments is projected to be approximately $12.7 billion higher. It is important to note that the higher the standard, the greater the economic benefits; thus it is critical that the standards be as strong as possible. [EPA-HQ-OAR-2010-0799-9475-A1, p. 2]

In addition to increased profits to the auto industry, the proposed standards will also bring job growth by creating jobs in the auto industry, and, more broadly, by diverting consumer spending away from fuel. The July 2011 report “More Jobs Per Gallon: How Strong Fuel Economy/GHG Standards Will Fuel American Jobs;” an economic analysis authored for Ceres by Management Information Services, Inc., found that a 54.5 mpg fuel economy standard would create approximately 484,000 economy-wide new U.S. jobs, with 43,000 in the auto industry and net job gains in 49 states in 2030. [EPA-HQ-OAR-2010-0799-9475-A1, p. 2]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 74-76.]

Ceres' July 2011 report, 'More Jobs Per Gallon: How Strong Fuel Economy/Greenhouse Gas Standards Will Fuel American Jobs,' found that a 54.5 mpg standard will create about 484,000 economy-wide new U.S. jobs, including 43,000 in the auto industry alone and net job gains in 49 of the 50 U.S. states. National gross economic output would rise by tens of billions of dollars. And it's very important to note that the higher the standard, the greater the economic gain. This is from the report that we put out last summer.

A second report we collaborated on last year with Citi Investment Research, a bank in New York, found that stricter fuel economy standards will bring economic benefits to auto manufacturers, especially the Detroit 3 and their suppliers. The report shows that strong standards will improve the competitive positioning of U.S. automakers and provide the regulatory certainty needed to promote innovation and investment in the industries of the future.

Strong standards will reduce America's and California's dependence on foreign oil, save vast amounts of money for consumers at the gas tank and as well as money for businesses and bolster America's world-class vehicle technology companies, many of them based right here in California.

Organization: Consumer Federation of America (CFA)

Significant macroeconomic benefits of greater fuel economy have been ignored.

- A GDP multiplier must be included that recognizes increases in national output and employment that result from reducing imports and puts more purchasing power in consumer pockets. The estimation of this type of GDP multiplier is a routine practice in policy analysis, and the agencies have calculated its value to be hundreds of billions of dollars but failed to include them in the analysis. [EPA-HQ-OAR-2010-0799-9419-A1, p. 14]

Exhibit S-10 summarizes the key issues that should be addressed, giving a sense of how important they are expressed as a percentage of the total national benefit in the bases case NHTSA-EPA analysis. [See Exhibit S-10 on p. 14 of Docket number EPA-HQ-OAR-2010-0799-9419-A1]

- We believe that the base case analysis underestimates the benefits by at least 20 percent. In dollar terms, that is over $100 billion.
- Since the total cost of adding the fuel economy technologies necessary to meet the standard is only $132 billion and the calculated benefits are in the range of $500 billion, this underestimation of benefits is substantial.
- Inclusion of the GDP multiplier alone could raise the estimated benefits substantially. [EPA-HQ-OAR-2010-0799-9419-A1, p. 14]

The estimates of benefits presented above include the first five factors, but not the last two. Therefore, although our estimates of consumer and national benefits are higher than the agencies, the actual benefits are likely to be even higher. [EPA-HQ-OAR-2010-0799-9419-A1, p. 14]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 90-91.]

Organization: Cuenca, M.

Transportation is critical to our quality of life and the EPA's regulation could increase the cost of a new vehicle by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. [EPA-HQ-OAR-2010-0799-10142-A1, pp. 1-2]

Organization: Defour Group LLC

Our mid-range estimate for industry sales losses is 1.8 million units relative to the baseline, which translates into a loss of 155,000 jobs in manufacturing and supply, plus another 50,000 jobs in distribution for a total job loss of 205,000 jobs in auto manufacturing, supply, and distribution. [EPA-HQ-OAR-2010-0799-9319-A1, p. 9] [This comment can also be found at section 18.7. of this comment summary.]

Organization: Detroit NAACP

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 141.]

Promoting fuel efficiency will create high quality jobs right here in the United States. As said earlier, one of the biggest things they outsourced in the past 20 years has been jobs, and the City of Detroit has felt it more than anybody else, I would say.

Organization: Ecology Center

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 189-190.]

Equally impressive are estimates of job creation and benefits to the manufacturing sector.

According to research commissioned by Ceres more than 500,000 new jobs would be created as a result of the new standards, many of them here in Michigan. Another study on the automotive supply chain for fuel-efficient vehicle technologies found there were already more than 150,000 people employed in the advanced engine, transmission and other electric vehicle supply sectors with over 38,000 of those jobs here in Michigan. Jobs in these automotive supply chains could be expected to nearly double with the implementation of the new proposed standards.

It's important to note that while significant job losses have been sustained in the automotive industry in recent years, investments and new fuel-efficient technologies now provide a strong basis for new manufacturing job growth, providing even greater competitiveness for the U.S. going forward. The proposed standards along with other policies to facilitate research, development, and commercialization of new technologies will help to ensure those job gains continue to be realized here in the region as well as in the U.S. more broadly.

Organization: Environmental Defense Fund (EDF)

H. FINAL RULE SHOULD INCLUDE QUANTITATIVE ESTIMATES OF VEHICLES SALES AND AUTO MANUFACTURING EMPLOYMENT BENEFITS

EPA and NHTSA conducted quantitative vehicle sales and auto manufacturing employment analyses in previous rulemakings and had prepared an estimate of these same indices for the rulemaking action at issue here using the same methodologies. However, the results of these analyses were not included in the published proposal. The changes occurred during the OMB review process. The docket for this rulemaking includes interagency drafts of the proposal submitted to OMB with the quantitative analyses included. The docket also includes the request by OMB to remove the quantitative analyses from the proposal33 and responses from EPA and NHTSA stating the importance of the quantitative analyses and requesting they be left in the final proposal.34 See Attachment B. We incorporate this document as an integral part of EDF's comments for inclusion in the administrative record for this rulemaking action. [EPA-HQ-OAR-2010-0799-9519-A1, p. 14]

We respectfully request that the quantitative vehicle sales and auto manufacturing employment benefits be included in the final rule to fully reflect the comprehensive societal benefits of the proposed program. [EPA-HQ-OAR-2010-0799-9519-A1, p. 14]

[The above comments can also be found in section 18.7 of this comment summary.]

ii. EMPLOYMENT

Additionally, the proposal fails to include the Agencies' results of the quantitative employment analysis, which found that at a 3 percent discount rate, the proposed standards could add more than 65,000 jobs by 2025.36 While the proposal acknowledges, "…this program is expected to affect employment in the regulated sector (auto manufacturing) and other sectors directly affected by the proposal…", the proposal also states, "EPA does not attempt to quantify the net effects of the regulation on overall national employment." (Page 75,156) Again, we recognize the inherent uncertainties in estimating these impacts, but believe the public should have the opportunity to comment on the analysis and request the Agencies include the results of the analysis in the final rule. [EPA-HQ-OAR-2010-0799-9519-A1, p. 15]

Organization: Faria, R.

Transportation is critical to our quality of life and EPA's regulation could increase the cost of a new car up by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. [EPA-HQ-OAR-2010-0799-9834-A1, p. 2]

Organization: Feinstein, C.

America's dependence on oil should create jobs here at home. Let's make some jobs first before imposing unreasonable burdens on citizens. [EPA-HQ-OAR-2010-0799-6745-A1, p. 1]

Organization: Ford Motor Company

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 45.]

For example, if a lack of adequate infrastructure hinders the introduction of new fuel-saving technologies or if fuel prices turn out to be substantially lower than anticipated, it might be necessary to change the standards in order to avoid damage to American jobs and the U.S. economy.

Organization: International Council on Clean Transportation (ICCT)

4. The benefits of the proposed rule on consumer welfare and jobs are very large and should be included in the final rule. In particular, the economy-wide benefits from reduced fuel

consumption on GDP, employment, and energy security are large and indisputable. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

4) Sales, Employment and GDP

As proposed, the 2017-2025 standards will have major economic benefits. Analyses conducted for the initial submission for interagency review, but not included in the NPRM, concluded that:

• New vehicle sales will increase by more than 300,000 vehicles by 2025

• Net employment will increase by between 1,800 and 4,500 jobs in 2017 and between 22,300 and 56,100 jobs in 2025

• US GDP will increase by 0.26% in 2020 and by 0.88% in 2030 [EPA-HQ-OAR-2010-0799-9512-A1, p. 13]

As discussed above, the cost to comply with the proposed requirements is likely to be substantially less than estimated by EPA and NHTSA. The fuel savings will pay for the cost of the technology many times over, effectively putting billions of dollars into consumers' pockets to buy other products. This will raise the standard of living, increase GDP and create economy-wide jobs. [EPA-HQ-OAR-2010-0799-9512-A1, p. 13]

Given these huge and obvious benefits, it is essential that the rule assess the beneficial impacts of the rule on sales, jobs, and GDP. The initial submission for interagency review contains these analyses, but they were not included in the final rule proposal. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 13-14]

These sales impact results are also required as input to other economic impact analyses, such as employment and GDP. As a result of the lack of new vehicle sales impact data, the employment impacts due to changes in the demand of new vehicles was not estimated in the proposed rule. The initial submission for interagency review also conducted a careful analysis of associated increases in employment.13 The method for calculating employment effects included the demand effect, or the labor required to build more vehicles; the cost effect, which represents the labor required for new technologies manufacturing; and the factor shift effect, which looks at labor intensity changes due to changes in technology. The effect on employment was originally estimated to add between 1800 and 4500 jobs in 2017 and to add between 22300 and 56100 jobs in 2025.14 ICCT supports these analyses and believes they are appropriate and should be included in the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 14]

Most importantly, the effect of the rule on GDP was also not included in the proposed rule. The initial submission for interagency review used computable general equilibrium (CGE) modeling to evaluate the effects of this rule on consumer expenditure and predicted that the US GDP would increase over time as a result of the increase in consumer expenditure (by 0.26% in 2020 and by 0.88% in 2030),15 This is an appropriate methodology and clearly shows that, due to fuel savings, consumer expenditure and consumer demand would increase, with substantial economy-wide benefits on GDP and employment. [EPA-HQ-OAR-2010-0799-9512-A1, p. 14]

ICCT has reviewed the methodology EPA used for estimating the impact on vehicle sales in the initial submission for interagency review. We find that it is consistent with the approach in the 2012-16 light-duty GHG and CAFE rule, and in several previous CAFE rulemakings by NHTSA. The method balances the changes in demand due to vehicle price increase and the economic benefits of fuel economy using a 5-year payback period, and found an increase in new vehicle sales of more than 300,000 vehicles by 2025 due to the fuel savings benefit,12 [EPA-HQ-OAR-2010-0799-9512-A1, p. 14]

The agencies state that the reason they do not include sales impact estimates is that there is no good analytical basis to make this calculation: [EPA-HQ-OAR-2010-0799-9512-A1, p. 14]

USEPA: 'The empirical literature does not provide clear evidence on whether consumers fully consider the value of fuel savings at the time of purchase. It also generally does not speak to the efficiency of manufacturing and dealer pricing decisions. Thus, for the proposal we do not provide quantified estimates of potential sales impacts. Rather, we solicit comment on the issues raised here and on methods for estimating the effect of this rule on vehicle sales.' [EPA-HQ-OAR-2010-0799-9512-A1, pp. 14-15]

NHTSA: *'As* discussed below, for this analysis we have conducted a fresh search of the literature for additional estimates of consumer valuation of fuel savings, in order to determine whether the 5 year assumption was accurate or whether it should be revised. That search has led us to the conclusion for this proposed rule that consumer valuation of future fuel savings is highly uncertain. A negative impact on sales is certainly possible, because the proposed rule will lead to an increase in the initial price of vehicles. A positive impact is also possible, because the proposed rule will lead to a significant decrease in the lifetime cost of vehicles, and with consumer learning over time, this effect may produce an increase in sales. In light of the relevant uncertainties, the agency therefore decided not to include a quantitative sales estimate and requests comments on all of the discussion here, including the question whether a quantitative estimate (or range) is possible. [EPA-HQ-OAR-2010-0799-9512-A1, p. 15]

ICCT is not in agreement with the agencies assertion that the analytical basis for sales, employment, and GDP analyses is inadequate. While there are large uncertainties in how customers behave, such analyses are widely used in other contexts (e.g. the CARB analysis of the LEV III GHG rule uses CGE modeling and includes employment and GDP impacts) and are appropriate here as well. Further, the uncertainty in consumer behavior does not change the fact that the fuel savings will pay for the cost of the technology many times over. [EPA-HQ-OAR-2010-0799-9512-A1, p. 15]

The ICCT strongly supports adding consumer welfare analyses back into the final rule, as they provide relevant and important information regarding employment and GDP. In particular, the economy-wide benefits from reduced fuel consumption are large and indisputable. [EPA-HQ-OAR-2010-0799-9512-A1, p. 17]

While the ICCT believes it is clear that the standards will have a positive impact on vehicle sales and direct vehicle-related employment, we do acknowledge that there is substantial uncertainty in how consumers will react to the higher vehicle prices, new technology, and lower fuel payments. It is possible that the direct sales and employment benefits might be small. However, it is inexcusable to ignore the economy-wide benefits from the large reduction in vehicle fuel consumption. No matter how customers react, the fuel savings will pay for the cost of the technology many times over. This will give customers billions of dollars to buy other products, raising their standard of living, increasing GDP, and creating economy-wide jobs.20 [EPA-HQ-OAR-2010-0799-9512-A1, p. 17]

There will be further economy-wide and energy security benefits from reducing oil imports and helping our balance of trade. These economy-wide benefits are certain and their exclusion from the proposed rule is inappropriate. [EPA-HQ-OAR-2010-0799-9512-A1, p. 17]

Organization: Investor Network on Climate Risk (INCR) - Ceres

Strong standards will lead to job growth by creating jobs in the auto industry, and more broadly by diverting consumer spending away from fuel. The July 2011 report “More Jobs Per Gallon: How Strong Fuel Economy/GHG Standards Will Fuel American Jobs;”3 an economic analysis authored for Ceres by Management Information Services, Inc., found that a 54.5 mpg fuel economy standard would create approximately 484,000 economy-wide new U.S. jobs, with 43,000 in the auto industry and net job gains in 49 states. [EPA-HQ-OAR-2010-0799-9516-A1, p. 1]

Further, under the proposed standard, the report found that national gross economic output, or sales, is projected to be $21.3 billion higher; personal income is projected to increase by approximately $14.2 billion, and revenue for cash strapped federal, state and local governments is projected to be approximately $12.7 billion higher. It is important to note that the higher the standard, the greater the economic benefits;4 thus it is critical that the standards be as strong as possible. [EPA-HQ-OAR-2010-0799-9516-A1, pp. 1-2]

Independent analysis also indicates that stronger standards will benefit the auto industry, a major creator of U.S. jobs, and a key player in U.S. manufacturing. Earlier this year, Ceres partnered with Citi Investment Research to produce “Fuel Economy Focus: Perspectives on 2020 (Auto)

Industry Implications," which found that strict fuel economy standards would bring economic benefits to auto manufacturers, particularly the Detroit 3, and their suppliers. Strong standards will improve the competitive positioning of U.S. automakers, and provide the regulatory certainty needed to promote innovation and investment in the industries of the future, such as clean tech and high tech sectors. [EPA-HQ-OAR-2010-0799-9516-A1, p. 2]

---

3 Approximately equivalent to the 4% scenario presented in EPA and NHTSA's Joint Notice of Intent, "2017 and Later Model Year Light Duty Vehicle GHG Emissions and CAFE Standards;" EPA 40 CFR Parts 85, 86, and 600; http://edocket.access.gpo.gov/2010/2010-25444.htm

4 For example, the report found that under a 6% improvement scenario, net job gains were projected to be 684,000.

Organization: Johnson, C.

Passing ARBITRARY rules hurts the economy and hurts my employment. [EPA-HQ-OAR-2010-0799-6528-A1, p. 1]

Organization: Lennon, S.

Transportation is critical to our quality of life and EPA's regulation could increase the cost of a new car up by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. [EPA-HQ-OAR-2010-0799-9019-A1, p. 1]

Transportation is critical to our quality of life and EPA's regulation could increase the cost of a new car up by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. [EPA-HQ-OAR-2010-0799-10348-A1, p. 2]

Organization: Mass Comment Campaign (39) (Unknown Organization)

These rules will lead to substantial savings for American families. They will keep more money in American communities, and the economic multiplier will be a boon for the economy. [EPA-HQ-OAR-2010-0799-1245-A1_MASS, p.1]

Finally, I strongly support the new technologies and innovations that will come from the standards set fourth in this proposal, and the resulting high quality jobs that will be necessary to create them. The new standards give automakers clear, long-term direction, and will help American car companies compete in an increasingly efficient global market. [EPA-HQ-OAR-2010-0799-1245-A1_MASS, p.1]

I look forward to the improvements in public health, economy, environment, and national security that will result from these proposed CAFE standards. [EPA-HQ-OAR-2010-0799-1245-A1_MASS, p.1]

Organization: Representative from Michigan House of Representatives, 49th District

The standards will help create and retain the good paying automotive jobs essential to the prosperity of states like Michigan and communities like Genesee County. A recent report by the United Auto Workers (UAW), National Wildlife Federation (NWF), and Natural Resources Defense Council (NRDC) found that Michigan employs the most at over 38,000 workers at 97 facilities in the manufacture of fuel-efficient parts of the automotive supply chain. That's not news to Flint: local auto suppliers employ hundreds of workers and substantially contribute to our region's economy. [EPA-HQ-OAR-2010-0799-7983-A1, p. 1]

Organization: Senator from Michigan State Senate, District 18

Finally, increased fuel economy standards will continue to create jobs: good paying jobs that employ Michigan workers. A recent report by the Natural Resources Defense Council (NRDC), National Wildlife Federation (NWF), and United Auto Workers (UAW) found that the auto industry currently employs over 151,168 autoworkers at 504 facilities building cars with clean, efficient technology-and 38,067 of those jobs are in 97 facilities right here in Michigan. It might not surprise you to learn that Michigan has more autoworkers employed in building clean, efficient cars, than any other state in the nation. [EPA-HQ-OAR-2010-0799-5594-A1, p. 1]

If you want proof, you do not have to go far to see how we are benefitting from the production of this new technology. As we speak, the battery pack for the Chevy Volt is being produced in Brownstown, and the vehicle is being built in Detroit. In my own district, Ford's hybrid electric vehicle battery pack assembly is coming to the Rawsonville plant, a facility that was once slated to close, and the vehicles will be fully constructed at the Michigan Assembly Plant in Wayne. That is work that is being brought back from Mexico. [EPA-HQ-OAR-2010-0799-5594-A1, pp. 1-2]

Organization: National Association of Clean Air Agencies (NACAA)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 34.]

Economic growth and the creation of high-quality jobs across the country due to the need for innovative automotive technologies upon which the standards rely;

Organization: National Wildlife Federation (NWF)

Fuel economy standards are working now to build jobs.

This past summer NWF, with the UAW and NRDC, released Supplying Ingenuity a report that found 150,000 workers in 43 states employed today in more than 300 companies that make technology that specifically contribute to increasing fuel economy. These jobs were spread widely across traditional vehicles and components, materials, electronics, hybrids and batteries and electric technology. 10 [Figure 3 can be found on p. 6 of Docket number EPA-HQ-OAR-2010-0799-9887-A2] [EPA-HQ-OAR-2010-0799-9887-A2, pp. 6-7]

This study follows a 2010 study, Driving Growth that found that incremental net content added to vehicles to achieve higher fuel economy means more manufacturing jobs. The study predicted that achieving 40mpg by 2020 would add up to 150,000 manufacturing jobs in the US. 11 [EPA-HQ-OAR-2010-0799-9887-A2, p. 7]

Also in 2011, More Jobs Per Gallon a report by Management Information Systems for Ceres found that new 2017-2025 standards would add nearly 500,000 jobs once the economy wide impacts of consumer and business net savings on fuel were taken into account. The study found that stronger 2017-2025 fuel economy standards would also increase gross economic output, personal income and tax revenues. 12 [EPA-HQ-OAR-2010-0799-9887-A2, p. 7]

Testing these studies against reality, Bureau of Labor Statistics data shows the auto sector added 100,000 direct jobs building and selling the next generation of clean cars and trucks in 2011 alone.

[This comment was also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 32.]

These direct jobs anchor hundreds of thousands of additional jobs throughout American communities. 13 [EPA-HQ-OAR-2010-0799-9887-A2, p. 7]

These manufacturing and technical jobs are critical today in an industry and in communities which have seen deep job losses over the past decade, and to bolstering the overall strength of the economy today and in decades to come. The standards help ensure the US auto manufacturing captures its full share of today's competitive global auto market, and that Americans are able to increasingly spend their money building jobs in their communities at instead of leaving household and national budgets at the mercy of rising, volatile, global oil prices. [EPA-HQ-OAR-2010-0799-9887-A2, p. 7]

These results show why it matters for America to lead in the clean energy economy. The standards the agencies have proposed are essential to sustaining that progress. [EPA-HQ-OAR-2010-0799-9887-A2, p. 7]

Organization: Natural Resources Defense Council (NRDC)

EPA and NHTSA should dramatically improve the employment and economic impact analysis by accounting for sales impacts using the methodology consistent with previous rules, creating an alternative non-full employment scenario, and fully accounting for economy-wide impacts. [EPA-HQ-OAR-2010-0799-9472-A2, p. 4]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 199.]

Making better vehicles means more U.S. jobs. A recent report from the investor group Ceres estimates that the auto industry investments and consumer savings triggered by the proposed standards would generate 484,000 jobs across the country. This is not surprising.

NRC recently partnered with the UAW and the National Wildlife Federation to quantify the jobs being spurred by the current 2012 to 2016 standards. In our joint report, 'Supplying Ingenuity,' we found that over 150,000 workers are currently employed in 300 automotive supply companies across 43 states to make parts that enable cars and trucks to cut pollution and go further on a gallon of gas.

Organization: Parker, M.

Transportation is critical to our quality of life and EPA's regulation could increase the cost of a new car up by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs. [EPA-HQ-OAR-2010-0799-9017-A1, p. 2]

Organization: Paul, M.

Transportation is critical to our quality of life and the EPA's CAFE mandates could... INCREASE THE COST OF A NEW CAR BY $6,000 according to the Center for Automotive Research AND... $5,000 according to the National Automobile Dealers Association. [EPA-HQ-OAR-2010-0799-9027-A1, p. 2]

EITHER OF THESE PRICE INCREASES WOULD LEAD TO A REDUCTION OF TENS OF THOUSANDS OR SORELY NEEDED JOBS due to people not being able to afford these more expensive cars. Thus... the car companies will not have to produce as many cars, and as a consequence, will employ fewer workers to produce fewer cars. [EPA-HQ-OAR-2010-0799-9027-A1, p. 2]

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air

Council

Increasing sales and creating jobs: Increased vehicle sales and advanced vehicle technologies will create jobs in the automotive manufacturing sector. In their initial submission to OMB, the agencies estimated that between 22,300-56,100 jobs would be created in the vehicle manufacturing sector as a result of these standards.14 Outside groups have reached similar conclusions that these standards will create jobs. A study by the investor network, Ceres, found that the proposed standards would create 43,000 jobs in the automotive industry and 484,000 jobs economy-wide. The agencies' jobs and sales analyses, as proposed in the initial submission to OMB, should stand in the final rule. [EPA-HQ-OAR-2010-0799-9549-A2, p. 4]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 123.]

The report from Ceres estimates that nearly half a million jobs may be added to the economy between jobs and the auto industry.

Organization: Stirling, D.

How many jobs will this cost? I am not in favor of the the government adding additional new standards when I cannot be employed as an engineer with thirty five years of experience designing computer equipment. [EPA-HQ-OAR-2010-0799-10065-A1, p. 1]

Organization: Sullivan, T.

Transportation is critical to our quality of life. EPA's regulation could increase the cost of a new car up by $6,000 according to the Center for Automotive Research and $5,000 according to the National Automobile Dealers Association. This price increase would lead to a reduction of tens of thousands of jobs (at least). [EPA-HQ-OAR-2010-0799-10341-A1, p. 2]

Organization: Union of Concerned Scientists (UCS)

The standards also deliver important economy-wide benefits. By spending less on oil, consumers have more income to spend on other goods and services. This has a direct effect on both national gross domestic product and U.S. employment. A recent report from Ceres found that standards similar to those proposed by the agencies would create nearly 500,000 new jobs nationwide in 2030. The report also found that gross economic activity would increase more than $21 billion in 2030.3 [EPA-HQ-OAR-2010-0799-9567-A2, p. 2]

Strong standards that save drivers money can also support robust employment. Increasing standards will promote new vehicle technologies and increase investment in the auto industry, generating new jobs throughout that sector. The savings consumers realize at the pump will also shift consumer purchases away from the petroleum and wholesale industries to other parts of the economy that generate more jobs for every dollar spent. [EPA-HQ-OAR-2010-0799-9713-A1, p. 2]

The agencies' own analysis of the proposed standards showed similar positive economic benefits to the U.S. economy. Specifically, EPA found that the proposed standards would increase U.S. Gross Domestic Product (GDP) by over $100 billion in 2025 (a 0.48% increase) and over $400 (a 1.31% increase) in 2040. [EPA-HQ-OAR-2010-0799-9567-A2, p. 2]

These standards will not only deliver positive benefits to the American economy, they will also benefit the domestic auto industry and its workers. Investing in fuel-saving and pollution reduction technology will increase value throughout the supply chain, creating new jobs. A recent report found that there are already over 151,000 people employed in the United States building fuel efficient vehicles and components.5 Under the proposed standards, analysis by Ceres projected that the automotive industry would gain an additional 43,000 jobs in 2030.6 EPA also projects an increase in employment of 23,400-56,100 new jobs in the automotive sector as a result of these standards.7 [EPA-HQ-OAR-2010-0799-9567-A2, p. 3]

In addition to job creation and increased sales, better fuel efficiency and greenhouse gas performance will improve the competitiveness of the American auto industry. Unlike in 2008, when American automakers faced severe financial hardship as a result of rising oil prices, these standards will ensure that manufacturers continue to innovate over the coming decade resulting in a product line that is both fuel efficient and at the forefront of automotive technology. Across the world, consumers and government standards are demanding greater fuel efficiency and lower emissions. These standards will help ensure that American automakers remain globally competitive. A recent report by Citigroup and Ceres found that a fuel economy standard of 42 mile-per-gallon by 2020 (more stringent than the proposed standards) would increase the profitability and competitiveness of American automakers.10 [EPA-HQ-OAR-2010-0799-9567-A2, p. 3]

As shown above, the literature and the agencies' own analyses demonstrate that the proposed standards will deliver important benefits to consumers, the U.S. economy, automakers, and American autoworkers. While the agency's economic analysis is discussed in the interagency review documents, it is surprising that this data on increased vehicle sales, GDP, and employment were not included in the proposed rule. UCS strongly encourages the agencies to include these figures in the final rule in order to educate the public on the positive economic benefits of strong fuel efficiency and greenhouse gas standards. [EPA-HQ-OAR-2010-0799-9567-A2, p. 3]

As has been stated in prior comments, UCS objects to the agencies' underestimation of long-term fuel price projections. In this proposed rule, the agencies again rely on the Energy Information Administration's (EIA) Annual Energy Outlook for long-term fuel price projections. We elaborate more on gasoline price projections in Section II(g) below, and thus will only remark here that EIA's core projections have consistently underestimated future fuel prices. Moreover, EIA projects only very modest, steady changes in fuel prices, without any significant volatility. Oil and gasoline price spikes have occurred about twice each decade for the last 30 years and almost every one was followed by a U.S. recession.25 Given these facts, the agencies should include such price spikes in their projections. At a minimum, UCS encourages the agencies to continually evaluate projections for future fuel prices and include sensitivity analysis demonstrating potential cost-effectiveness at higher stringency levels under more realistic fuel price scenarios. [EPA-HQ-OAR-2010-0799-9567-A2, p. 6]

By undervaluing the energy security costs and fuel-savings, the agencies are not fully evaluating the potential cost-effectiveness of more stringent standards. If the agencies properly valued the full set of societal costs and benefits, a more stringent standard of 143 g/mi and approximately 60 miles-per-gallon in MY 2025 would deliver greater net societal benefits. [EPA-HQ-OAR-2010-0799-9567-A2, p. 6]

25 http://www1.eere.energy.gov/vehiclesandfuels/facts/2009_fotw579.html [EPA-HQ-OAR-2010-0799-9567-A2, p. 6]

Organization: United Automobile Workers (UAW)

The UAW believes strongly that the proposed rules will strengthen the overall economy and the domestic auto industry. The economy will benefit because consumers will spend less on fuel for vehicles and more on other goods and services. [EPA-HQ-OAR-2010-0799-9563-A2, p.1]

This proposal will lead to significant net job creation. [EPA-HQ-OAR-2010-0799-9563-A2, p.1]

Increasing the efficiency of light-duty vehicles leads directly to the creation of jobs in the auto industry because the technology needed to increase efficiency represents incremental net content on each vehicle, and that additional content must be engineered and produced by additional employees. [EPA-HQ-OAR-2010-0799-9563-A2, p.1]

Employment Effects [EPA-HQ-OAR-2010-0799-9563-A2, p.4]

The UAW represents about 150,000 members in the light-duty vehicle assembly and parts sectors, so understanding the effects of significant rulemaking in the automobile industry is important to the UAW and its members. The UAW has taken an active role in efforts to identify and quantify how the drive to improve the efficiency of automobiles affects employment in the domestic auto industry. [EPA-HQ-OAR-2010-0799-9563-A2, p.4]

The UAW believes very strongly that because improving the efficiency of light-duty vehicles requires additional content on each vehicle, and that additional content requires more engineers and production workers, developing and producing cleaner cars increases employment in the auto industry. [EPA-HQ-OAR-2010-0799-9563-A2, p.5]

In 2010, the UAW, along with the Natural Resources Defense Council (NRDC) and the Center for American Progress, published a report titled “Driving Growth” that used the net cost of equipment added to increase vehicle efficiency to estimate how many jobs could be created by the addition of enough fuel-saving technology for the new vehicle fleet to reach 40 miles per gallon by 2020. [EPA-HQ-OAR-2010-0799-9563-A2, p.5]

The study found that the additional content needed to reach 40 miles per gallon would create 190,000 jobs of all types somewhere in the world. The number of jobs this would create in the United States is dependent on how much of the additional content is produced domestically. The results estimate that if 75% of the additional content were produced in the United States, as many as 150,000 jobs would be created. The study is attached to these comments. [EPA-HQ-OAR-2010-0799-9563-A2, p.5]

In 2011, the UAW, NRDC and the National Wildlife Foundation published a report titled “Supplying Ingenuity,” which was meant to identify the wide variety of jobs and locations associated with clean car technology. The report identified 504 facilities across 43 states employing over 500,000 people where some or all of the work is researching, developing or producing clean-car technologies. One significant finding is that fully 67% of these jobs are related to advanced conventional technologies such as better engines and transmissions and components like electric power steering and high-strength steel. The "Supplying Ingenuity" report is also attached to these comments. [EPA-HQ-OAR-2010-0799-9563-A2, p.5]

Because of the UAW's interest in seeing improved fuel economy and reduced tailpipe pollution bolster the domestic auto industry, we were particularly pleased that in President Obama's 2010 memo directing the agencies to develop rules extending beyond 2016, he also directed that the proposed program "…should strengthen the industry and enhance job creation in the United States." [EPA-HQ-OAR-2010-0799-9563-A2, p.5]

Accordingly, EPA made an effort to estimate the employment effects of the proposed regulation in order to demonstrate the proposal was constructed so that its effect would meet the conditions set forth in President Obama's memo. The UAW commends the EPA for its extensive consideration and extended discussion of the issues associated with estimating the employment effects of the proposed rule. [EPA-HQ-OAR-2010-0799-9563-A2, p.5]

Although the EPA was unable to complete and publish estimates of several important ways that the rule could affect employment, the UAW applauds EPA's findings that the additional content on each vehicle needed to reduce tailpipe emissions does indeed result in increased employment in the auto industry and the intermediate and basic industries that supply the auto industry. By estimating broad employment effects in the auto industry using data on the number of employees per million dollars of expenditure, EPA has outlined a useful approach for understanding how cleaner cars can create jobs. The UAW is also encouraged by the EPA's recognition that the import share of additional production must be taken into consideration when estimating these domestic employment effects. [EPA-HQ-OAR-2010-0799-9563-A2, pp.5-6]

The UAW also believes that in the Draft Regulatory Impact Analysis (DRIA) that accompanies the proposed rules, the EPA has provided excellent and useful examples of how to assess the change in labor demand for several of the fuel-saving technology packages that are projected to be widely applied during the 2017 – 2025 period. This methodology centers on tear-down studies of fuel-saving technology packages by EPA's engineering consultant that accounts for the net incremental content in that specific package. [EPA-HQ-OAR-2010-0799-9563-A2, p.6]

The results, as summarized in table 8.2-3 of the DRIA, show that in each of the six technologies evaluated, additional labor is required to produce the technology. In the case of switching from a six-speed to an eight-speed transmission, an additional .33 hours of labor are required for each unit. This result suggests that one full-time job will be created for each increment of about 4,500 eight speed transmissions when upgrading from a six-speed. [EPA-HQ-OAR-2010-0799-9563-A2, p.6]

In the example of a downsized, turbocharged gas direct injection V-6 that replaces a V-8 engine, similar to the EcoBoost engine offered by Ford in its full-size pick-up trucks, the additional labor requirement is estimated at 1.82 hours per unit. This implies that a full-time position is created for each increment of about 825 such engines. [EPA-HQ-OAR-2010-0799-9563-A2, p.6]

More complicated technology packages with greatly increased content require even more labor. A full hybrid with a power-split design is estimated to require an additional 8.54 hours of labor, which implies an additional full-time employee for each 175 units produced. [EPA-HQ-OAR-2010-0799-9563-A2, p.6]

However, because EPA was unable to evaluate the additional labor requirement for all the technologies that were considered in the technical analysis, EPA was not able to give a complete estimate of the potential employment effects using this excellent methodology. The UAW urges EPA to continue this work in its ongoing evaluation of the cost and effectiveness of fuel-saving technologies. [EPA-HQ-OAR-2010-0799-9563-A2, p.6]

EPA was also unable to quantify the employment effects of any potential change in sales resulting from the increase in the price of vehicles accounted for by the additional content. This is a tortured subject, studied repeatedly with conflicting results across studies at even the basic level of whether the effect is positive or negative. The UAW recognizes EPA’s effort to discuss and sort through the issues involved with estimating change in sales due to the regulation of tailpipe emissions. [EPA-HQ-OAR-2010-0799-9563-A2, p.6]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 22-25.]

Adopting the proposed rules will give an additional boost to the revitalization of the auto industry that began with President Obama's courageous action in the depths of the industry's crisis to save American manufacturing jobs by giving GM and Chrysler the breathing room they needed to restructure.

After a painful process in which workers and retirees made significant sacrifices, the industry is coming back strong. Our units with collective bargaining agreements with Ford, General Motors and Chrysler include substantial investments by all three companies, in some cases bringing back work from overseas.

The 20,000 UAW-represented hourly jobs that will be protected and added over the next four years will have a substantial and positive ripple effect throughout the supply chain as well as the local communities.

One important reason we are so confident that the industry's future -- in the industry's future is that we are excited about the new green technologies that are being developed in the United States and produced in UAW-represented facilities. The drive to bringing innovative fuel-saving technologies to market is transforming the auto industry in the United States in creating good jobs in the research labs to the factory floor. General Motors, Ford and Chrysler have made unprecedented commitments to invest billions of dollars in their U.S. operations over the next few years and in every case the investment of supporting new vehicles and powertrains that will be more efficient than the previous generation.

There's a common element in all of these technologies. They are all now or will soon be produced by UAW members and factories located in the United States, and that's just the beginning.

Although most auto makers will continue to meet fuel efficiency and tailpipe emissions through improvements in conventional vehicles, we are excited that these new transforming technologies are being produced by UAW members. These are the automotive jobs of the future. We are very pleased that they are starting to ramp up here in the United States.

Thanks to the fresh start President Obama gave to the domestic auto industry, new labor agreements that are the result of innovative, problem-solving approach in bargaining and the strong transparent working relationships we have with UAW employers, the U.S. auto industry is growing and adding employees. These proposed rules are the cornerstone of that growth. It provides certainty as manufacturers map out their product investment plans.

I want to underscore why we believe the drive to increase fuel efficiency and reduce tailpipe pollution is creating jobs in the U.S. auto industry.

A second, more fundamental reason is because the technology needed to improve efficiency and reduce pollution represents additional content on each vehicle. That additional content must be engineered and produced by additional employees.

Last year the UAW and the Natural Resources Defense Council and Larry's organization, The National Wildlife Federation, produced a report called Supplying Ingenuity. That report identifies more than 500 separate facilities in the United States, employing over 150,000 people, where some or all the employees are working to invent, engineer, or produce advanced vehicles and fuel- savings components. These are real jobs supporting real American families.

Response:

Several commenters specifically requested inclusion of employment impacts in the analysis for this rule. EPA discusses employment impacts in Preamble Section III.H.12 and RIA Chapter 8.2. We include a detailed discussion of the expected impacts of this rule on employment, and on methods for measuring employment impacts. We also present a partial quantification of the impacts of this rule on employment in the auto sector, in our estimates of the effects on employment due to developing and using the technologies expected to be used for compliance with the standards (the "cost effect"). Our discussion explains that we do not provide fuller quantification for several reasons. First, we do not quantify the impacts of the rule on auto sector employment due to changes in vehicle sales (the "demand effect") or due to the labor intensity of vehicle production (the "factor shift effect"), other pathways for employment impacts, due to insufficient data to support that analysis. Second, the impacts of the rule on national employment depend heavily on the state of the macroeconomy at the time of implementation, which begins in MY 2017. If the economy is at or close to full employment, the primary effect of the rule on employment will be to shift employment among sectors, rather than to create or reduce job availability. On the other hand, if there is substantial involuntary unemployment at the time of implementation, the rule may affect aggregate employment levels. Difficulties in estimating unemployment rates in the future imply that the impacts of the rule on employment in the wider economy will be highly uncertain. We offer the detailed discussion of these issues as the explanation for our decision to quantify some but not all employment impacts of the rule. We appreciate the support from the UAW of our identification of these multiple effects, our identification of domestic versus foreign impacts, and our discussion of these complexities. We did not receive comments identifying problems with our analysis.

A major conclusion from this review is that increasing standards does not inevitably cause losses in employment, either in the auto sector or in the economy as a whole. Because employment impacts in the auto industry result from expenditures on new technologies as well as effects on vehicle sales, it is possible that employment may increase; the analysis in Preamble section III.H.12 and RIA Chapter 8.2 in fact show increases. Employment impacts in the rest of the economy may be positive in some sectors (such as suppliers of materials for auto parts) and negative in others (such as gasoline production), as further discussed in those sections.

Comments from the Defour Group estimating employment losses of about 200,000 from the rule analyze impacts in the auto and distribution sector due only to the demand effect; they do not consider impacts due to the cost or the factor-shift effects. As discussed in Section 18.7 of this Response to Comments, the negative vehicle sales estimates from the Defour Group are based on cost estimates substantially higher, and a smaller role for fuel savings, than those found in this rule. TSD Chapter 3.1.2.2 discusses the Defour Group/NADA cost estimates – in particular, the higher indirect cost estimates; Section 18.2.1 of this Response to Comments discusses those cost estimates as well as those from the Center for Automotive Research mentioned by several individuals. The omission in its study of cost-effect employment impacts leaves out a potentially significant source of employment gains. Impacts due to the factor-shift effect may increase or decrease employment. Because the Defour Group uses costs significantly higher than those we have estimated, and because they do not consider some of the channels through which employment in the auto sector is likely to be affected by the standards, we do not rely on these results.

Other commenters point to expected increases in vehicle sales as a source of increased employment; these analyses are based on lower per-vehicle cost estimates and possibly greater consideration of fuel savings in the vehicle purchase decision. As discussed in Section 18.7 of this Response to Comments, the difference between the results in these studies and those from the Defour Group appear to be due to lower cost estimates and a greater role for fuel economy in vehicle purchase decisions in the former group. Several commenters specifically cite a study by Ceres showing an increase of 43,000 jobs in the auto industry in 2030. This employment appears to be driven by the need for additional workers to reconfigure vehicles and add technology (the cost effect), though it also estimates increases in vehicle sales. Ceres also shows job gains in the broader economy. As discussed in Preamble Section III.H.12 and RIA Chapter 8.2, we do not extend our analysis to the broader economy, because of uncertainty over the state of the macroeconomy in the time frame for this rule.

Additional comments point to gains in employment associated with developing the technologies that companies will use to comply with the standards. Several commenters cite a report from NRDC, NWF, and UAW, "Supplying Ingenuity," which estimates that 150,000 people are currently employed in companies that make "clean, fuel-efficient" technologies. As discussed in Preamble Section III.H.12 and RIA Chapter 8.2, we agree that the employment effects of this rule in the auto sector depend, not only on vehicle sales, but also on the need to develop and use the technologies for compliance with the standards, and any changes in labor intensity of production associated with the new technologies. EPA, in MY 2025, estimates increases due solely to increased expenditures on technologies on the order of 6,000-31,000 jobs in the auto industry.

A few commenters argue that, although employment may go down in fuel-related sectors, switching consumer spending from fuel to other sectors should increase employment, because fuel sectors have lower labor intensity than the economy as a whole. EPA acknowledges this possibility but has not estimated this effect in this rule.

Commenters differ on the effects of this rule on the competitiveness of the auto industry and its ability to innovate. Those who state that the rule will increase competitiveness and innovation cite increasingly stringent fuel economy standards in other countries; this rule will provide further incentives to coordinate vehicle and technology development for all these markets and speed cost reductions. In addition, they state that the standards will provide the regulatory certainty needed for increased investment in research and development and ensure continued innovation. The increased investment and innovation, they say, will increase employment in the auto industry. Those who state that innovation will decrease cite the need for auto manufacturers to invest specifically in fuel-saving technology, which will reduce their ability to invest in technological advances for other vehicle qualities and attributes (see comments from Edmunds.com). EPA disagrees that investing more in fuel economy requires reduced investments in improving other aspects of the vehicles; it is possible for auto makers to do both, except under the circumstances that they are unable to convince potential investors of the merits of those other improvements. As noted earlier in section 18.1, the agencies' costing methodology includes the costs of preserving all attributes in the present vehicle fleet. In addition, because all major auto makers selling vehicles in the U.S. are subject to the same rule requirements, we do not expect changes in the competitive structure of the industry, nor in where vehicles are produced, in response to these standards. EPA agrees that the standards are stringent enough to encourage continuing innovation on technologies that reduce GHG emissions and improve fuel economy, and that these innovations are likely to be useful for meeting standards in other countries besides the U.S. Companies that make the greatest advances in these innovations may increase their competitive position in both the U.S. and world markets.

A number of comments state that this rule will increase economic growth in the U.S. Several commenters recommend that EPA include an analysis of the economy-wide impacts of the rule, including impacts on U.S. gross domestic product (GDP) and consumption patterns. They say that fuel savings from the rule would allow consumers to increase their spending on other goods and services in more productive sectors of the economy, which would likely increase GDP and consumption in the U.S. CFA specifically recommended that EPA use a GDP multiplier approach that recognizes that national output would increase from the rule as a result of reducing U.S. oil imports and reducing consumer expenditures on fuel. Several commenters cite a report for Ceres by Management Information Services, Inc. that found that a 4 per cent annual improvement in fuel economy would increase U.S. gross economic output by $21.3 billion, personal income by $14.2 billion, and revenue for federal, state, and local governments by $12.7 billion in 2030.[92] On the other hand, other comments express concern that the economy could be harmed as a result of this rule, because increased vehicle costs will reduce vehicle sales and employment. Analyzing the economy-wide impacts from this rule is challenging due to the inherent uncertainty in projecting a myriad of economic parameters into the future (e.g., levels of employment of labor and capital, the structure of the economy, prices of goods and services) and determining an appropriate economic framework to model (e.g., supply equaling demand in all markets and specific forms of market interactions). EPA has not been able to identify a widely agreed upon methodology and thus we continue to not quantify the impacts of the rule on overall economic patterns in the U.S.

V. The 2017 Car Rule Would Also Be Arbitrary and Capricious Because It Is Based on an Invalid Endangerment Finding [EPA-HQ-OAR-2010-0799-9509-A1, p. 10]

Lastly, finalizing the 2017 Car Rule would also be arbitrary and capricious because the rule is predicated on an invalid endangerment finding. As the 2017 Car Rule itself explains, EPA's authority to propose the rule flows from the Endangerment Finding for GHGs. 76 Fed. Reg. 74,964. Thus, if the Endangerment Finding is invalid, EPA has no authority to finalize the 2017 Car Rule. For this reason, the Associations briefly explain some of the reasons why the Endangerment Finding is arbitrary and capricious. A more complete explanation is contained in the Associations' comments, which are also submitted here. Exhs. A-B. EPA's Endangerment Finding is arbitrary and capricious for several reasons: [EPA-HQ-OAR-2010-0799-9509-A1, pp. 10-11]

- The Endangerment Finding failed to weigh offsetting or beneficial effects of climate change against its threatened harms. Exh. A. at 7.
- The Endangerment Finding improperly failed to consider the possibility of adaptation to climate change. Id. at 8–9.
- The Endangerment Finding improperly relied on effects of climate change occurring outside of the United States, in violation of the CAA. Id. at 9–10.

- The Technical Support Document for the Endangerment Finding does not contain the critical review of all the science that EPA's Information Quality Act Guidelines require. Id. at 10-28.
- EPA's finding that GHGs endanger public health is not scientifically supported or justifiable under the CAA. Id. at 28–33.
- EPA's finding that GHGs endanger public welfare is not supported. Id. at 33–38.
- EPA's assertion that current atmospheric levels of GHGs endanger public health and welfare is not supported. Id. at 38–39.
- The Endangerment Finding is inappropriate because GHG emissions from motor vehicles are insubstantial. Id. at 40–42.
- The Endangerment Finding improperly includes two pollutants not emitted by mobile sources—perfluorocarbons and sulfur hexafluoride. Id. at 42–43.
- EPA failed to adequately explain its decision to exclude the most abundant GHG—water vapor—from its Endangerment Finding. Id. at 43–44.
- EPA should have proposed its rules for motor vehicles at the same time as its Endangerment Finding. Id. at 44.
- EPA failed to analyze the possible affect of its Endangerment Finding on stationary source permitting requirements. Id. at 45–49.
- EPA failed to explain why it did not use alternative approaches to addressing climate change, such as CAA Section 115. Id. at 49–50. [EPA-HQ-OAR-2010-0799-9509-A1, p. 11]

Organization: Competitive Enterprise Institute (CEI)

Experts will likely debate for years the net benefits of the rule as data become available regarding vehicle costs and sales and auto industry profits and employment. This comment letter examines a cost most experts have not addressed: the damage the Obama Administration's fuel economy agenda does to our constitutional system of separated powers and democratic accountability. [EPA-HQ-OAR-2010-0799-9552-A1, p. 1]

I. End Run Around Congress

In the press release announcing their proposed MY 2017-2025 GHG/fuel economy standards, EPA Administrator Lisa Jackson and Transportation Secretary Ray LaHood boast that they are bypassing Congress: "Today's announcement is the latest in a series of executive actions the Obama Administration is taking to strengthen the economy and move the country forward because we can't wait for Congressional Republicans to act" [emphasis added].3 [EPA-HQ-OAR-2010-0799-9552-A1, pp. 1-2]

A legislative proposal boosting average fuel economy to 54.5 mpg would not pass in the 112th Congress. Note also that NHTSA need not propose fuel economy standards for MY 2017 until 2014. "We can't wait" really means: We won't let the people's representatives decide, either now or after the 2012 elections. [EPA-HQ-OAR-2010-0799-9552-A1, p. 2]

Circumventing Congress has, alas, become the Administration's preferred M.O. Under the statutory scheme Congress created, one agency –NHTSA – regulates fuel efficiency through one set of standards – Corporate Average Fuel Economy (CAFE) – under one statute – the Energy Policy Conservation Act (EPCA). Yet today, three agencies – EPA, NHTSA, and the California Air Resources Board (CARB) – regulate fuel efficiency via three sets of standards under three statutes – the Clean Air Act (CAA), EPCA, and California Assembly Bill 1493. The CAA provides no authority to prescribe fuel economy standards, and EPCA specifically prohibits states from adopting laws or regulations "related to" fuel economy standards. [EPA-HQ-OAR-2010-0799-9552-A1, p. 2]

II. GHG, Fuel Economy Standards: Highly Related

EPA and CARB claim they are regulating GHG emissions, not fuel economy. But greenhouse gas emission standards implicitly regulate fuel economy. As EPA and NHTSA's May 2010 Tailpipe Rule explains, no commercially available technologies exist to capture or filter out carbon dioxide (CO_2) emissions from motor vehicles. Consequently, the only feasible way to decrease CO_2 emissions per mile is to reduce fuel consumption per mile — that is, increase fuel economy. Carbon dioxide constitutes 94.9% of vehicular greenhouse gas emissions, and "there is a single pool of technologies… that reduce fuel consumption and thereby CO_2 emissions as well."4 [EPA-HQ-OAR-2010-0799-9552-A1, p. 2]

That EPA and CARB are regulating fuel economy is also apparent from EPA, NHTSA, and CARB's Interim Joint Technical Assessment Report, the framework document for the agencies' proposed rule.5 The document considers four fuel economy standards, ranging from 47 mpg to 62 mpg; each is the simple reciprocal of an associated CO_2 emission reduction scenario. The 54.5 mpg standard is a negotiated compromise between the 4% (51 mpg) and 5% (56 mpg) CO_2 reduction scenarios. [EPA-HQ-OAR-2010-0799-9552-A1, p. 2]

CARB's 2004 Staff Report presenting the agency's plan to implement AB 1493 is another smoking gun.6 Nearly all of CARB's recommended technologies for reducing GHG emissions (Table 5.2-3) were previously recommended in a 2002 National Research Council study on fuel economy (Tables 3-1, 3-2).7 CARB proposes a few additional options, but each is a fuel-saving technology, not an emissions-control technology. [EPA-HQ-OAR-2010-0799-9552-A1, p. 2]

Even the text of AB 1493 implies that CARB is to regulate fuel economy. CARB's GHG standards are to be "cost-effective," defined as "Economical to an owner or operator of a vehicle, taking into account the full life-cycle costs of the vehicle."8 CARB reasonably interprets this to mean that the reduction in "operating expenses" over the average life of the vehicle must exceed the expected increase in vehicle cost.9 Virtually all such "operating expenses" are expenditures for fuel. The CARB program cannot be "cost-effective" unless CARB regulates fuel economy. [EPA-HQ-OAR-2010-0799-9552-A1, pp. 2-3]

V. Constitutional Common Sense

EPA contends that its current and future GHG rules derive from the CAA as interpreted by Supreme Court in Massachusetts v. EPA (April 2007). The D.C. Circuit Court of Appeals is now reviewing arguments regarding that claim in Coalition for Responsible Regulation v. EPA. [EPA-HQ-OAR-2010-0799-9552-A1, p. 4]

However that case is decided, EPA is clearly wielding powers Congress never intentionally delegated. [EPA-HQ-OAR-2010-0799-9552-A1, p. 4]

Congress declined to give EPA explicit authority to regulate GHGs only last year, when Senate leaders pulled the plug on companion legislation to the American Clean Energy and Security Act (ACESA) – the House-passed cap-and-trade bill sponsored by Reps. Henry Waxman (D-Calif.) and Ed Markey (D-Mass.). [EPA-HQ-OAR-2010-0799-9552-A1, p. 5]

One of ACESA's selling points was precisely that it would preempt regulation of GHGs under several CAA programs. If instead of proposing cap-and-trade, Waxman and Markey had introduced legislation authorizing EPA to do exactly what it is doing now – regulating GHGs via the CAA as it sees fit – their bill would have been dead on arrival. [EPA-HQ-OAR-2010-0799-9552-A1, p. 5]

The notion that Congress gave EPA such expansive authority when it enacted the CAA in 1970, years before global warming emerged as a public policy concern, defies both history and logic. [EPA-HQ-OAR-2010-0799-9552-A1, p. 5]

[See footnote list for this comment on pp. 5-6 of Docket number EPA-HQ-OAR-2010-0799-9552-A1]

Organization: Environmental Consultants of Michigan

EPA erred in its implementation of the Supreme Court decision on GHG emissions [NHTSA-2010-0131-0166-A1, p. 4]

On April 2, 2007, the U.S. Supreme Court issued its opinion in Massachusetts v. EPA, a case involving EPA's 2003 denial of a petition for rulemaking to regulate GHG emissions from motor vehicles under section 202(a) of the Clean Air Act (CAA). The Court held that GHGs fit within the definition of air pollutant in the Clean Air Act and further held that the Administrator must determine whether or not emissions from new motor vehicles cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare, or whether the science is too uncertain to make a reasoned decision. The Court further ruled that, in making these decisions, the EPA Administrator is required to follow the language of section 202(a) of the CAA. The Court rejected the argument that EPA cannot regulate CO_2 from motor vehicles because to do so would de facto tighten fuel economy standards, authority over which has been assigned by Congress to DOT. The Court stated that ''[b]ut that DOT sets mileage standards in no way licenses EPA to shirk its environmental responsibilities. EPA has been charged with protecting the public's 'health' and 'welfare', a statutory obligation wholly independent of DOT's mandate to promote energy efficiency.'' The Court concluded that ''[t]he two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.'' The case was remanded back to the Agency for reconsideration in light of the Court's decision. [NHTSA-2010-0131-0166-A1, pp. 4-5]

EPA could have honored the decision of the Supreme Court by regulating the carbon content of the fuel as is done in Europe; instead, they immediately began a duplicative tailpipe carbon dioxide standard. EPA initially argued that their greenhouse gas standard was necessary because there were vehicle emissions that were not covered by the CAFÉ equivalent standard. All of these other GHG pollutants are currently regulated by the existing EPA tailpipe or evaporative emission standards. In May 2009, the National Fuel Efficiency Policy was announced that for the first time provided what amounted to double jeopardy for vehicle manufacturers with duplicative greenhouse gas standards and CAFÉ standards. This unprecedented level of control provides two sets of compliance regulations and two sets of penalties (fines) for what amounts to a single action. [NHTSA-2010-0131-0166-A1, p. 5]

EPA should have done a thorough analysis of the policy alternatives prior to arbitrarily jumping to vehicle tailpipe standards. A fair and balanced policy review would have led to a different policy to achieve the target, one that changes the fuel such as the required use of a renewable Fischer-Thropsch fuel. The DoE GREET model demonstrates that usage of this fuel can be an effective strategy for achieving GHG reductions unlike the slow and limited progress that accompanies tailpipe standards. This policy would have the secondary effect of reducing petroleum consumption. [NHTSA-2010-0131-0166-A1, p. 5]

Organization: Environmental Defense Fund (EDF)

III. EPA HAS EXPANSIVE AUTHORITY UNDER THE CAA TO REGULATE GHG EMISSIONS FROM LIGHT DUTY VEHICLES AND NHTSA'S AUTHORITY IS MORE CONSTRAINED IN SEVERAL IMPORTANT WAYS

A. EPA and NHTSA have Different Statutory Mandates

The primary purpose of EPA's regulation under the Clean Air Act is "to protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population." 42 U.S.C. § 7401(b)(1) (emphasis added). This protective purpose is reflected in the text of Section 202 of the Act. Section 202(a) requires the EPA Administrator to promulgate standards for the emission of air pollutants from new motor vehicles "which in his [her] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a) (emphasis added). Both the "may reasonably be anticipated" and "endanger" language reflect Congress' intent for EPA to act in a manner that prevents, rather than merely responds to, harm. See Ethyl Corp. v. EPA, 541 F.2d 1, 12 (D.C. Cir. 1976) ("[E]ndangers means something less than actual harm. When one is endangered, harm is threatened; no actual injury need ever occur."). Because of the important public health purpose and preventative nature of the Clean Air Act's mandate, EPA's authority to regulate under it is far-reaching. [EPA-HQ-OAR-2010-0799-9519-A1, pp. 4-5]

The National Highway Traffic Safety Administration (NHTSA)'s purpose in implementing the Energy Policy Conservation Act (EPCA) is "to provide for improved energy efficiency of motor vehicles." 42 U.S.C. § 6201(5). This mandate, while vital to curbing our Nation's energy use, is narrowly focused on one aspect of motor vehicles— fuel efficiency—without regard to the vehicles' effects on public health and welfare. The purposes of these two Acts are "wholly independent," as the Supreme Court made clear in Massachusetts v. EPA, 549 U.S. 497, 531-32 (2007): [EPA-HQ-OAR-2010-0799-9519-A1, p. 5]

EPA finally argues that it cannot regulate carbon dioxide emissions from motor vehicles because doing so would require it to tighten mileage standards, a job (according to EPA) that Congress has assigned to DOT. See 68 Fed. Reg. 52929. But that DOT sets mileage standards in no way licenses EPA to shirk its environmental responsibilities. EPA has been charged with protecting the public's "health" and "welfare," 42 U. S. C. 7521(a)(1), a statutory obligation wholly independent of DOT's mandate to promote energy efficiency. See Energy Policy and Conservation Act, §2(5), 89 Stat. 874, 42 U. S. C. §6201(5). The two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency. [EPA-HQ-OAR-2010-0799-9519-A1, p. 5]

B. EPA's Expansive Authority under Section 202

For light-duty vehicles, as well as heavy-duty vehicles, EPA's authority, and imperative, to protect human health and the environment through rigorous emission standards is more far-reaching and effective than the U.S. Department of Transportation's authority to set standards for fuel economy because of EPA's ability to address all greenhouse gases, to efficiently and effectively address the interactions between all vehicle components, and due to the breadth of the delegated rulemaking authority and associated protections under the Clean Air Act. [EPA-HQ-OAR-2010-0799-9519-A1, p. 5]

EPA has broad authority under Section 202(a)(1) of the Clean Air Act to "prescribe . . . standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a)(1) (emphasis added); see also id. §7521 (a) (EPA authorized to set standards for air pollutants from vehicles and engines "whether such vehicles and engines are designed as complete systems or incorporate devices to prevent or control such pollution"). This language clearly delegates to EPA the responsibility to adopt standards for air pollutants. EPA relies on this authority in the proposed rule to regulate, in addition to CO_2, N2O, CH4, and hydrofluorocarbon (HFC) emissions. All of these substances are listed among the "primary GHGs of concern" as contributors to global warming. 76 Fed. Reg. at 74,963. [EPA-HQ-OAR-2010-0799-9519-A1, pp. 5-6]

C. Constraints on NHTSA's Authority

In contrast to EPA's expansive authority under Section 202 of the Clean Air Act, EPCA as amended by EISA includes limitations on NHTSA's authority to regulate fuel economy. NHTSA's authority is focused on fuel economy and not air pollution, and as a result, NHTSA is constrained in regulating direct discharges of N20, CH4, and HFC emissions from automobiles. 76 Fed. Reg. at 74,902. [EPA-HQ-OAR-2010-0799-9519-A1, p. 6]

Within its focus on fuel economy, EPCA contains additional, limitations on NHTSA's discretion to establish CAFE standards including the nexus to fuel efficiency. And, of particular importance, any proposed expansion of NHTSA's fuel economy analysis must be consistent with EPA's statutorily-mandated procedures to test fuel economy. [EPA-HQ-OAR-2010-0799-9519-A1, p. 6]

EPCA directs the Secretary of Transportation to prescribe CAFE standards, which "shall be the maximum feasible average fuel economy level that the Secretary decides the manufacturers can achieve in that model year." 49 U.S.C. § 32902; see also § 32902(f) (directing the Secretary to consider statutorily-enumerated factors in making this determination). While NHTSA has discretion in standard setting, under EPCA, EPA alone has the authority to measure fuel economy and to calculate CAFE values, 49 U.S.C. § 32904(a). In doing so, EPA "shall use the same procedures for passenger automobiles the Administrator used for model year 1975 . . . or procedures that give comparable results." Id. at 32904(c). The D.C. Circuit has concluded that, to produce "comparable results," "[t]he critical fact is that a procedure . . . was available for MY1975 testing, and those manufacturers, however few in number, that found it advantageous to do so, employed that procedure." Center for Auto Safety v. EPA, 806 F.2d 1071, 1077 (D.C. Cir. 1986). [EPA-HQ-OAR-2010-0799-9519-A1, p. 6]

In a previous rulemaking, the agencies concluded that this statutory structure did not allow for incorporation of air-conditioning efficiency improvement and off-cycle technology credits into NHTSA's fuel economy analysis. 75 Fed. Reg. at 25,544 ("The CAFE standards and compliance testing cannot capture all of the real world CO_2 emissions, because EPCA currently requires EPA to use the 1975 passenger car test procedures under which vehicle air conditioners are not turned on during fuel economy testing."); 25,663 (requesting comment on including air conditioning credits in light-truck testing requirements but emphasizing "that modernizing the passenger car test procedures as well would not be possible under EPCA as currently written."). [EPA-HQ-OAR-2010-0799-9519-A1, p. 6]

In this proposal, however, the agencies forward different legal rationales, id. at 74,998, which they characterize as "major changes" from past practice, id., that would allow them to incorporate air-conditioning efficiency and off-cycle technology improvements into NHTSA standard setting. Both the agencies themselves, supra, and regulated industry have raised questions regarding this conclusion. See EPA Doc. No. OAR-2009- 0472-7123.1 at 17 (Comments of Association of International Automakers on LDV Phase I) (noting that the Association "does not support fundamentally changing the fuel economy/greenhouse gas test procedures at this time"); see also EPA Doc. No. EPA-HQOAR- 2003-0214-0208 at 10 (Comments of the Alliance of Automobile Manufacturers) (noting that any change in test procedures would require EPA "to develop a complex set of test procedure adjustment factors to ensure that the new procedures 'give comparable results' to the existing ones"). [EPA-HQ-OAR-2010-0799-9519-A1, pp. 6-7]

D. EPA and NHTSA Must Carefully Coordinate the Joint Rulemaking

Alone, NHTSA's CAFE standards cannot capture the significant opportunities for meaningful greenhouse gas reductions available to EPA pursuant to its broad authority under the Clean Air Act to address air pollution for the protection of human health and welfare. As such, EDF strongly supports the agencies' focus on a joint rulemaking proposal that is "carefully coordinated and harmonized," and, like the agencies, EDF recognizes that such coordination must be "in accordance with all substantive and procedural requirements imposed by law" to achieve durable and legally-defensible results. 76 Fed. Reg. 74,860; see also 76 Fed. Reg. at 74,902 (describing differences in the agencies' statutory authorities, including EPA's ability to address various GHGs and EPA's ability to account for certain compliance adaptability). Indeed, the regulated community has long questioned the scope of NHTSA's authority. In contrast, there is a well established body of law affirming the broad authority of EPA under the Clean Air Act to adopt emission standards protecting human health and welfare from air pollutants. [EPA-HQ-OAR-2010-0799-9519-A1, p. 7]

EDF applauds the agencies' efforts to collaborate on regulations to reduce greenhouse gas emission and improve fuel economy and recognizes the imperative of doing so consistent with the agencies' separate statutory mandates. EDF also recognizes the imperative of EPA action under the full breadth and protections of the Clean Air Act to safeguard human health and the environment from harmful air pollutants and to ensure those protections are lasting through EPA's durable, tested delegated rulemaking authority. [EPA-HQ-OAR-2010-0799-9519-A1, p. 7]

Organization: Growth Energy

If EPA believes that the examination of the proposal to increase octane outlined in Attachment 3 is unnecessary or inappropriate because it lacks authority under section 211 of the Clean Air Act to take the recommended action, then the Agency should fully explain why it believes it lacks that authority, among other reasons so that Congress can consider appropriate changes in the statute. [EPA-HQ-OAR-2010-0799-9505-A1. p. 6]

Organization: Natural Resources Defense Council (NRDC)

With this proposal, EPA is leveraging four decades of authority and expertise in successfully regulating conventional pollutants from mobile sources to establish controls on GHG emissions. While past improvements to Corporate Average Fuel Economy (CAFE) have made some progress in reducing GHG emissions, the Clean Air Act authority is a far superior statute for the purpose of controlling greenhouse gas (GHG) emissions since it provides the agency the ability to adopt forward looking standards that are consistent with long-term environmental targets, address all GHG emissions—not just carbon dioxide, and accurately reflect the true carbon impacts of substituting different fuels for gasoline through life-cycle analysis. [EPA-HQ-OAR-2010-0799-9472-A2, p. 2]

II. Clean Air Act is Appropriate Statute for Regulating Greenhouse Gases from Motor Vehicles

The Supreme Court in Massachusetts v. EPA ruled that the Clean Air Act (CAA) requires the adoption of standards to control greenhouse gas (GHG) pollution from motor vehicles if EPA determines that these emissions contribute to endangerment of public health or welfare. With the model year 2012-2016 National Program Final Rule, the U.S. EPA and NHTSA established an important partnership that ensures that the pollution and health protections of the CAA are appropriately aligned with the fuel-conservation directive of the Energy Policy and Conservation Act (EPCA). The latest proposal maintains that current partnership and alignment. [EPA-HQ-OAR-2010-0799-9472-A2, p. 7]

EPA has used its authority and technical expertise to successfully regulate conventional pollutants from mobile source emissions for nearly four decades. Since the 1970s, EPA has significantly reduced transportation emissions by establishing performance-based standards for all categories of mobile sources. The impact has led to tremendous success -- EPA's mobile source emission programs have reduced conventional pollutants from today's new personal vehicles by 98-99 percent compared to those sold in the 1960s. EPA's fuel programs have effectively removed lead from gasoline and most recently, led to the development of ultra low sulfur diesel in the U.S. and advanced clean diesel technologies. [EPA-HQ-OAR-2010-0799-9472-A2, p. 7]

Several major factors have led to EPA's success in controlling conventional pollutants from mobile sources. These same factors provide the Agency with distinct advantages in terms of regulating greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-9472-A2, p. 7]

First, unlike EPCA which limits NHTSA to setting standards just five years into the future, the CAA allows EPA to set technology-forcing standards that consider longer-term environmental targets. With this latest proposal, EPA is proposing standards for a nine-year period into the future, consistent with previous pollution emission standards. Addressing the multi-generational environmental challenges of climate change is virtually impossible with only a five-year perspective that necessarily relies upon only incremental additions of new technologies. This longer-term, innovation-based approach creates the regulatory certainty necessary for automakers to strategically plan for and invest in emerging and advanced technologies that are needed to meet climate stabilization goals. [EPA-HQ-OAR-2010-0799-9472-A2, pp. 7-8]

Second, it is critical to address all GHG emissions, not just CO_2. Unlike EPCA, the CAA allows EPA to set standards that directly address non-CO_2 GHG pollutants, in particular HFC-134a, N2O, and CH4. According to EPA, these latter GHG pollutants currently compose 7.2 percent of the effective vehicle GHG emissions.31 Inclusions of these pollutants enable EPA to adopt GHG standards that achieve the maximum feasible reductions in GHGs in the most flexible and cost-effective manner possible. [EPA-HQ-OAR-2010-0799-9472-A2, p. 8]

Third, the CAA allows EPA to adopt standards that accurately reflect the true impacts of substituting different fuels for gasoline. Environmentally effective GHG standards must consider both the carbon content and lifecycle emissions. Since fuel economy standards only consider the miles driven per gallon of fuel used, it fails to account for the fact that a fuel such as diesel has a higher carbon content per gallon than gasoline. Fuel economy standards under EPCA also do not properly account for the differences in upstream emissions of different types of fuels. Ignoring upstream emissions for fuels such as electricity, hydrogen, biofuels and diesel tend to inflate their GHG benefits in comparison to gasoline. For example, a diesel-fueled vehicle that achieves a fuel economy benefit of 20 percent or more versus a conventional gasoline-fueled vehicle using diesel produced from coal (i.e. coal-to-liquid) could result in almost two times greater GHG life-cycle on a per mile basis due to the inherently higher carbon content of diesel and the extremely high carbon emissions associated with producing a diesel-like fuel from coal. [EPA-HQ-OAR-2010-0799-9472-A2, p. 8]

It is important to note that using the Clean Air Act to control carbon pollution was first initiated by the Bush administration. In fact, in May 2007, a month after the Supreme Court's landmark decision in Massachusetts v. EPA, President Bush went to the Rose Garden and ordered EPA Administrator Johnson to carry it out by setting carbon pollution standards for new vehicles. [EPA-HQ-OAR-2010-0799-9472-A2, p. 8]

In January 2008, Administrator Johnson appealed directly – albeit unsuccessfully – to President Bush to allow EPA to carry out the law. His letter to the president stated that the science supported "a positive endangerment determination" on carbon pollution and "does not permit a negative finding."32 The Johnson letter reveals three important facts: [EPA-HQ-OAR-2010-0799-9472-A2, p. 8]

(1) That the Bush administration's EPA thought "a positive endangerment finding" was compelled by both the science and the law. Johnson wrote that the Supreme Court's decision "combined with the latest science of climate change requires the Agency to propose a positive endangerment finding." He continued: "the state of the latest climate change science does not permit a negative finding, nor does it permit a credible finding that we need to wait for more research." [EPA-HQ-OAR-2010-0799-9472-A2, pp. 8-9]

(2) That Johnson's action plan – to issue an endangerment finding, set vehicle standards, and more – had "Cabinet-level" buy-in. Johnson wrote that the scientific and legal need to issue a positive endangerment finding "was agreed to at the Cabinet-level meeting in November." He continued: "A robust interagency policy process involving principal meetings over the past eight months has enabled me to formulate a plan that is prudent and cautious yet forward thinking." [EPA-HQ-OAR-2010-0799-9472-A2, p. 9]

(3) That Johnson's action plan contained exactly the same steps that his successor, Lisa Jackson, has carried out. Johnson told President Bush he had formulated a "prudent and cautious yet forward thinking" action plan that "will fulfill your Administration's obligations under the Supreme Court decision." Phase 1 of the plan called for these actions: [EPA-HQ-OAR-2010-0799-9472-A2, p. 9]

In response to the Supreme Court mandate in Massachusetts v EPA, issue a proposed positive endangerment finding for public notice and comment as agreed to in the policy process. [EPA-HQ-OAR-2010-0799-9472-A2, p. 9]

In response to the direction in [the Energy Independence and Security Act], issue a proposed vehicles rule jointly with the Department of Transportation to implement the new EISA and address issues raised in the Supreme Court case. [EPA-HQ-OAR-2010-0799-9472-A2, p. 9]

To address requirements under the Clean Air Act, issue a proposed rule to update the New Source Review program to raise greenhouse gas thresholds to avoid covering small sources and to better define cost-effective, available technology. [EPA-HQ-OAR-2010-0799-9472-A2, p. 9]

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

The National Program accounts for both EPA's and NHTSA's authority and requires no additional action: NHTSA notes that it is "confronted with the issue of how to treat" EPA standards in setting its own standards under EPCA and EISA. The Supreme Court has ruled that EPA has the authority to regulate greenhouse gases such as CO_2, holding that the Clean Air act "is unambiguous" in its "sweeping definition of 'air pollutant';" that the statute "embraces all airborne compounds of whatever stripe," including the greenhouse gasses "[c]arbon dioxide, methane, nitrous oxide, and hydrofluorocarbons."34 Both the prior rule for MY 2012-16 vehicles and this NPRM, which continues the process of joint standard setting with California and EPA carries out the Mass. v. EPA decision. The NPRM and the prior rule demonstrate successful cooperation and NHTSA's capacity to both account for, and in fact, improve upon its standard setting process. A Call to EPA and NHTSA to Consider the Consumer Fuel Usage Reduction Options in the Mid-term Evaluation of the Greenhouse-Gas Emission and Corporate Average Fuel Economy Standards for Light-Duty Vehicles. [EPA-HQ-OAR-2010-0799-7986-A1, p. 1] [This comment can also be found in section 2.4 of this comment summary.]

The emission standard is completely based on vehicle technology applied to a specific drive cycle. Even the potential off-cycle credits are based on technology advancements or vehicle hardware improvements. In the past, meeting the emission standards for regulated pollutants has been the sole responsibility of the vehicle manufacturers. This is appropriate since (1) only the manufacturers can implement the emission control technologies on the vehicles, (2) the impact of fuels and vehicle usage on pollutant emissions are relatively limited, and (3) the cost of such implementation has not been excessive even though we may be approaching the state of diminishing return. In the case of GHG emissions from light-duty vehicles, however, vehicle technology is only one of three contributors. The others are vehicle fuels and consumer usage. Vehicle technology alone cannot shoulder the full burden of CO_2 emission reductions in mobile sources when carbon-containing fuels are used. CO_2 emissions are directly proportional to the amount of carbon-containing fuels (in the well-to-wheels sense) used in propelling the vehicles. [EPA-HQ-OAR-2010-0799-7986-A1, pp. 1-2]

The laws of physics dictate the limits of technology capability in CO_2 emission reduction. Economics and material resource availability further constrain the potential affordability of some new technologies, low-carbon fuels and their accompanying infrastructure, even when financial incentives are provided to cushion the costs of initial investments. It is obvious that in the effort toward increasingly stringent reductions of GHG emissions, the role of consumer fuel usage can no longer be ignored. As both the EPA and NHTSA will be undertaking the midterm evaluation of the GHG emission and the corporate average fuel economy standard for model year 2022-2025 vehicles in due course, we recommend that meaningful incentives for consumer fuel usage reduction be taken into consideration. [EPA-HQ-OAR-2010-0799-7986-A1, p. 2] [The last sentence of this comment can also be found in section 2.4 of Docket number EPA-HQ-OAR-2010-0799-7986-A1]

Bringing the consumer's energy usage into the picture for CO_2 emission reduction is obviously nontrivial. Cap-and-trade and carbon tax are two known economically efficient approaches in reducing CO_2 emissions. Cap and trade is a massive undertaking and can be achieved by an upstream and/or a downstream approach. In the upstream approach, carbon trading is achieved at the level of fuel producers with the incurred cost adjustments being eventually borne by fuel users. In the downstream approach, consumers directly adjust their fuel usage through available fuel or carbon tradable credits available to them. Anticipating the advent of cap and trade in the US at the time, Ellerman, Jacoby and Zimmerman (2006) proposed a mechanism to bring the CAFE standard into the realm of cap and trade. Their rationale and proposed mechanism are most definitely worthy of further consideration. Carbon tax is considerably simpler to design and administer but will likely face substantial political resistance in the US, perhaps even when the designed carbon-tax system is revenue neutral. [EPA-HQ-OAR-2010-0799-7986-A1, pp. 2-3]

In the absence of the two most efficient fossil-carbon-fuel usage reduction programs, other options need to be explored. Opportunities abound in the design of new mobility options. Key among them includes incentives for transit usage (both public and private in the broadest sense) that can be translated into verifiable CO_2 emission and equivalent fuel-economy credits; manufacturer's or consumer credits for encouragement of telecommuting, car pooling, use of public and private transit options, credits for coupling of private and public transportation modes for trip completion; credits for use of car-share systems as well as taxi and private shuttle use that lead to actual fuel use reduction; use of mileage-based vehicle-insurance policies, and other new incentives for total annual trip mileage reduction that can be translated into CO_2 reduction credit. While it is difficult to assess the most feasible and equitable fuel-usage reduction programs at this time, this fact should not deter the EPA and NHTSA to explore and to encourage the public to explore these options. It is only a matter of time that non- hardware-related, carbon-fuel usage reduction options must become an integral part of a workable and meaningful CO_2 and GHG emission reduction program. It is high time that we seriously consider novel ways to power our vehicles and facilitate innovation in broader approaches to mobility to create new options and incentivize behavior that reduces CO_2 and GHG emission. [EPA-HQ-OAR-2010-0799-7986-A1, pp. 3-4]

Organization: U.S. Chamber of Commerce

Moreover, as was the case with the 2012-2016 fuel economy rule, the Chamber has serious concerns with the redundant regulatory framework proposed for 2017-25, and recommends consolidation into a single program administered by NHTSA. [EPA-HQ-OAR-2010-0799-9521-A1, p. 1]

II. There Must Be One Fuel Economy Rule, Administered By NHTSA

The Chamber believes there should be only one rule governing fuel economy, administered by NHTSA under its existing authority. The Energy Policy and Conservation Act (EPCA)3 gives NHTSA authority to set mandatory CAFE standards for motor vehicles. To the extent that EPA’s rule is the same as NHTSA’s, there is no need for the rule. If EPA’s rule provides added benefits, then those benefits should be identified with specificity and any EPA regulations should be narrowly tailored to achieve those additional objectives.4 [EPA-HQ-OAR-2010-0799-9521-A1, p. 3]

EPA attempts to justify two rules on the basis that its standards, unlike NHTSA’s, include air conditioning improvements and slightly different compliance flexibilities. However, just a few sentences later, EPA admits the obvious: [EPA-HQ-OAR-2010-0799-9521-A1, p. 3]

These differences, however, do not change the fact that in many critical ways the two agencies are charged with addressing the same basic issue of reducing GHG emissions and improving fuel economy. The agencies are looking at the same set of control technologies (with the exception of the air conditioning leakage-related technologies). The standards set by each agency will drive the kind and degree of penetration of this set of technologies across the vehicle fleet. As a result, each agency is trying to answer the same basic question—what kind and degree of technology penetration is necessary to achieve the agencies’ objectives in the rulemaking time frame, given the agencies’ respective statutory authorities?5 [EPA-HQ-OAR-2010-0799-9521-A1, pp. 3-4]

In other words, there is little to no need for dual sets of regulations by EPA and NHTSA. [EPA-HQ-OAR-2010-0799-9521-A1, p. 4]

As the Chamber pointed out in its comments on the 2012-2016 program, EPA can regulate air conditioning improvements without even using Title II of the Clean Air Act. Title VI of the Act, “Stratospheric Ozone Protection,” gives EPA wide flexibility to regulate motor vehicle air conditioners and their emissions.6 Section 608 and its corresponding regulations govern the use and disposal of ozone-depleting substances—of which air conditioning refrigerant qualifies—and prohibits the knowing release of these substances into the atmosphere.7 Section 609, entitled "Servicing of motor vehicle air conditioners," and the regulations at 40 C.F.R. Part 82 subpart B, set forth specific regulations for the handling of motor vehicle air conditioning refrigerant during servicing and upon disposal.8 Section 612 and its corresponding regulations set forth criteria for evaluation of substitutes for existing ozone-depleting substances.9 [EPA-HQ-OAR-2010-0799-9521-A1, p. 4]

It seems as though the only reason EPA feels the need to regulate fuel economy is to pacify California, which remains the driving force behind the continuation of this bizarre tripartite fuel economy arrangement. But the California problem is one of EPA's own making, one that could have easily been avoided by denying its request for a waiver to regulate greenhouse gases from motor vehicles. [EPA-HQ-OAR-2010-0799-9521-A1, p. 4]

The Clean Air Act requires EPA to justify its emissions standards by articulating a rational connection between the alleged risk and the selected standards.10 To avoid irrational regulation, EPA must explain how its emissions standards will meaningfully ameliorate the endangerment risk it has identified.11 EPA once again appears to provide shaky evidence regarding whether its own rule will meaningfully avert any predicted danger not already averted by NHTSA's standards. Likewise, EPA appears to overstate the potential benefits that accrue from EPA's rule that would not otherwise occur from NHTSA's. [EPA-HQ-OAR-2010-0799-9521-A1, pp. 4-5]

EPA has consistently maintained that Massachusetts v. EPA12 recognized that EPA has a statutory obligation "wholly independent" from NHTSA. But the Supreme Court was only recognizing that EPA had an obligation to examine the issue of GHG regulation and could not side-step that obligation merely because NHTSA has authority to regulate fuel economy. Nothing in Massachusetts suggests that EPA should ignore NHTSA's specific fuel-economy regulations or that EPA may refuse to consider whether those regulations are sufficient to realize its own GHG reduction goals. Indeed, Massachusetts made clear that "there is no reason" NHTSA and EPA could not "administer their obligations" in a way that "avoid[s] inconsistency."13 There is accordingly no reason EPA should not take into account GHG reductions achieved by NHTSA's rules, especially because Congress has given NHTSA (unlike EPA) a mandatory, specific instruction to promulgate fuel-economy standards. [EPA-HQ-OAR-2010-0799-9521-A1, p. 5]

For all of the foregoing reasons, the Chamber strongly recommends issuing a single fuel economy rule for the 2017-2025 period, administered by NHTSA. [EPA-HQ-OAR-2010-0799-9521-A1, p. 5]

---

4 To the extent EPA continues to interpret this rule as triggering absurd regulation on other sources that requires rewriting of the statute (i.e. the Tailoring Rule), then this rule relies on an improper and untenable construction of the statutory requirements. Moreover, EPA must consider all of the costs and consequences of its rule in a meaningful fashion.

6 Congress even recognized the ability to limit greenhouse gas emissions through Title VI: Section 602(e), entitled "Ozone-depletion and global warming potential," requires the Administrator to assess the global warming potential of each ozone-depleting substance covered by Title VI.

Response:

The comments that EPA lacks authority to issue standards controlling GHG emissions from new motor vehicles, that EPA's regulations rest on an incorrect finding that greenhouse gases endanger public health and welfare, and that EPA should defer any regulation to NHTSA under the CAFE program, have all been rejected by the D.C. Circuit in Coalition for Responsible Regulation v. EPA, No. 09-1322 (June 26, 2012). In particular, the court held that the endangerment finding was reasonable and fully grounded and supported by the vast body of scientific literature and information on climate change, and that EPA had a mandatory duty under section 202 (a) to issue the MYs 2012-2016 standards. Slip op. pp. 22-34, 40-43. Section 202 (a) (1) further provides that EPA may revise section 202 (a) "from time to time", which authority EPA is exercising in this proceeding. The Coalition for Responsible Regulation court likewise rejected arguments that EPA had any discretion to defer regulation of vehicular GHGs due to NHTSA's authority under EPCA/EISA: "Just as EPA lacks authority to refuse to regulate on the grounds of NHTSA's regulatory authority, EPA cannot defer regulation on that basis." Slip op. p. 41. The commenters' argument that the EPA and NHTSA programs are duplicative is also factually wrong. As with the MYs 2012-2016 rules, the section 202 (a) GHG standards "provide benefits above and beyond those resulting from NHTSA's fuel-economy standards." Slip op. p. 42. These benefits "above and beyond" are not just from control of direct air conditioning emissions, as the commenters mistakenly would have it. The GHG rules result in more reductions of CO_2 emissions (see preamble Tables III-61 and IV-42), and more reductions in petroleum consumption than the CAFE rules (see preamble Tables III-80 and IV-41). These incrementally greater reductions of both GHGs and savings of petroleum are substantial: Thus, even assuming that the MYs 2022-2025 augural CAFE standards were actually in place, the GHG rules are estimated to achieve 17%, 23%, and 27% greater reductions in GHG emissions in calendar years 2030, 2040, and 2050, and to achieve 9%, 18%, and 20% greater reductions in petroleum than the CAFE standards in those same calendar years. The differences are far greater in fact, since there are no CAFE standards after MY 2021.

The comment that these rules are an end-run on Congressional authority are likewise misplaced. Section 202 (a) has been definitively construed as applying to carbon pollution, and EPA's duty to determine if carbon pollution endangers public health and welfare, and to issue standards to control emissions of the pollutants which endanger is mandatory. EPA is thus implementing the authority delegated by Congress, not flouting Congressional authority.

Comments that the GHG rules should reflect fuel content, or otherwise should be based on lifecycle analysis rather than tailpipe emissions are addressed in sections 6 and 14 of this document. We note here that section 202(a) standards address control of vehicular emissions. Converting that program into a fuel-based program would constitute a dramatic distortion of the purpose and structure of the *vehicle* emissions standard program. There is no good reason to consider such a result, and that is especially the case here where there is a separate fuel based program, the RFS program, that achieves a reduction in lifecycle GHG emissions associated with the diesel fuel used by motor vehicles, through a mandate to use certain renewable diesel fuels.

Regarding comments from the University of Michigan, some of the concepts suggested by the commenter go beyond the scope of this rule. Nevertheless, EPA appreciates the suggestions of the commenter, and notes that we have been involved in programs that encourage the voluntary change in travel behavior, such as encouraging commuters to use public transportation.

Contrary to the text of the statute, and the Supreme Court's direction in Massachusetts, EPA failed to consider the cost of compliance with the stationary source regulations that the 2017 Car Rule could trigger. [EPA-HQ-OAR-2010-0799-9509-A1, p. 9]

EPA failed to perform a host of other mandatory analyses, including but not limited to: [EPA-HQ-OAR-2010-0799-9509-A1, p. 9]

- Under the Regulatory Flexibility Act (RFA), 5 U.S.C. §§ 603(a) & 605(b), EPA must prepare an analysis that describes the effects of a proposed rule on small businesses, or certify that there are no such effects. Despite EPA's assertion that vehicle emissions standards trigger permitting requirements for stationary sources, it certified that the 2017 Car Rule would "not have a significant economic impact on a substantial number of small entities." 2017 Car Rule, 76 Fed. Reg. at 75,161. EPA's reliance on Mid-Tex. Elec. Coop v. FERC, 773 F.2d 327 (D.C. Cir. 1985), and Cement Kiln Recycling Coalition v. EPA, 255 F.3d 855 (D.C. Cir. 2001), is misplaced because the 2017 Car Rule's impact on small businesses is not merely an indirect effect of the 2017 Car Rule's impact on regulated entities. Instead, as a result of the triggering effect of the 2017 Car Rule for stationary source permitting requirements, many small businesses will be regulated directly by EPA as a result of this rule. EPA is required to analyze these impacts in accordance with the RFA before issuing a rule. Instead, EPA asserts that any impact on small businesses should be attributed to express statutory requirements in the CAA or previously promulgated EPA regulations. 76 Fed. Reg. at 75,162 n.597. EPA ignores the fact that once the Car Rule and Truck Rule are vacated, the 2017 Car Rule will be sole "trigger" for EPA's GHG permitting requirements for stationary sources. [EPA-HQ-OAR-2010-0799-9509-A1, p. 9]
- Under the Unfunded Mandates Reform Act (UMRA) 2 U.S.C. § 1535, EPA must consider regulatory alternatives and adopt the least costly, most cost-effective, or least burdensome alternative that achieves the objectives of the rule. Here, EPA's sole proclaimed goal is regulating emissions from vehicles, yet it has ignored apparent alternatives that would fully realize that goal while avoiding the heavy burdens on stationary sources. See Section I supra. [EPA-HQ-OAR-2010-0799-9509-A1, p. 10]

- Similarly, under the Paperwork Reduction Act (PRA), 44 U.S.C. §§ 3501-3521, EPA must seek approval from the Office of Management and Budget before creating rules that will involve information collection requirements. EPA never submitted a request for approval of the massive information collection requirements that the 2017 Car Rule could impose on stationary sources newly subject to permitting requirements. 76 Fed. Reg. at 75,160. [EPA-HQ-OAR-2010-0799-9509-A1, p. 10]
- EPA has also failed to perform the economic impact assessment required by CAA § 317, 42 U.S.C. § 7617, which, by law, must contain an analysis of a proposed rule's compliance costs, inflationary or recessionary effects, competitive effects, effect on consumers, and impact on energy use. [EPA-HQ-OAR-2010-0799-9509-A1, p. 10]
- Finally, the proposed rule fails to satisfy Executive Order 13211's requirement that EPA conduct an analysis of its actions' impact on energy supply, distribution, and use, 76 Fed. Reg. at 75,163, as well as Executive Order 12898's requirement that EPA identify and address disproportionate effects of its actions on minority and low-income populations in the United States, id. Triggering stationary source permitting requirements for GHGs will undoubtedly raise energy prices, thereby harming low-income populations that are most vulnerable to high energy prices. EPA failed to consider these impacts in proposing its rule. [EPA-HQ-OAR-2010-0799-9509-A1, p. 10]

Thus, in the proposed rule, EPA has "entirely failed to consider an important aspect of the problem," making the proposed GHG Truck Rule arbitrary and capricious. Motor Vehicle Mfrs., 463 U.S. at 43. [EPA-HQ-OAR-2010-0799-9509-A1, p. 10]

Response:

These incorrect assertions were rejected in their entirety by the D.C. Circuit in Coalition for Responsible Regulation v. EPA, No. 09-1322 (D.C. Cir. June 26, 2012) slip op. pp. 44-45. The commenter is equally mistaken in this rulemaking. Thus, EPA has prepared an RIA which assesses, among other things, costs of the vehicle program, impacts and assessment of standards both more and less stringent than those adopted, vehicle sales impacts, employment impacts in the light duty vehicle sector, consumer lifetime savings on new vehicle purchases, energy use impacts, and small business impacts. Substantially the same analysis was available as part of the record for the proposed rule. This analysis fully satisfies the requirement in CAA section 317. The commenter is equally incorrect regarding requirements of the Paperwork Reduction Act. See 76 FR 75160 ("[t]he information collection requirements in this proposed rule have been submitted for approval to the Office of Management and Budget … under the Paperwork Reduction Act… The Information Collection Request …document prepared by EPA has been assigned EPA ICR number 0783.61"). The remaining assertions are predicated on the incorrect assumption that EPA must account for stationary source burdens flowing from this rule, an argument rejected in its entirety by the D.C. Circuit in Coalition for Responsible Regulation v. EPA. In any case, this rule has no such effect on stationary sources, since greenhouse gases are already "regulated pollutants" under the Act by virtue of the MYs 2012-2016 rule, as well as other regulatory actions which control emissions of GHGs.

Organization: Center for Biological Diversity

A. The Agencies Misapprehend the Nature and Relative Weight of the Factors They Must Consider Under EPCA and EISA

In enacting EPCA in 1975, shortly after the energy crisis of 1973, Congress observed that "[t]e fundamental reality is that this nation has entered a new era in which energy resources previously abundant, will remain in short supply retarding our economic growth and necessitating an alteration in our life's habitats and expectations."7 Among the goals of EPCA are to "'decrease dependence on foreign imports, enhance national security [and to] achieve the efficient utilization of scarce resources . . .'"8 The fundamental purpose of EPCA, however, is energy conservation.9 [EPA-HQ-OAR-2010-0799-9479-A1, p. 3]

In furtherance of the overarching goal of energy conservation, NHTSA must set fuel economy standards at "the maximum feasible average fuel economy level that the Secretary decides the manufacturers can achieve in that model year." 10 The statute provides that "[w]hen deciding maximum feasible average fuel economy under this section, the Secretary . . . shall consider technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need for the United States to conserve cannot balance them in a manner that is contrary to fuel conservation: NHTSA "cannot set fuel economy standards that are contrary to Congress' purpose in enacting the EPCA – energy conservation."12 Further, NHTSA cannot give so much weight to any factor, including consumer choice or demand, that the goal of fuel conservation is undercut: "NHTSA may consider consumer demand, but 'it would clearly be impermissible for NHTSA to rely on consumer demand to such an extent that it ignored the overarching goal of fuel conservation.'"13 The Agencies also cannot act arbitrarily or capriciously; cannot advance conclusions unsupported by the evidence; if they conduct cost-benefit analyses, they may not assign values of zero to benefits that can be ascertained within a range; and they cannot bias their cost-benefit analysis. [EPA-HQ-OAR-2010-0799-9479-A1, pp. 3-4]

I. The Agencies must Complete an Endangered Species Act Section 7 Consultation to Ensure that their Action will not Jeopardize or Adversely Modify the Critical Habitat of any Species Listed as "Threatened" or "Endangered"

To our knowledge the Agencies have not initiated consultation with the U.S. Fish and Wildlife Service and National Oceanic and Atmospheric Administration Fisheries Service under Section 7 of the federal Endangered Species Act to ensure that this action will not jeopardize or adversely modify the critical habitat of any species listed as "threatened" or "endangered." [EPA-HQ-OAR-2010-0799-9479-A1, p. 25]

Congress enacted the Endangered Species Act ("ESA") to conserve endangered and threatened species and the ecosystems upon which they depend.111 The Supreme Court's review of the ESA's "language, history, and structure" convinced the Court "beyond a doubt" that "Congress intended endangered species to be afforded the highest of priorities."112 As the Court found, "the plain intent of Congress in enacting this statute was to halt and reverse the trend toward species extinction, whatever the cost."113 Species are added to the lists of endangered and threatened species by the U.S. Fish and Wildlife Service (with jurisdiction over most terrestrial and freshwater species) and the National Marine Fisheries Service (with jurisdiction over most marine species) (collectively, the "Services"). A species is "endangered" if it "is in danger of extinction throughout all or a significant portion of its range." 114 A species is "threatened" if it "is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range."115 Once a species is listed under the ESA, Section 7 requires all federal agencies to "insure" that their actions neither "jeopardize the continued existence" of any listed species nor "result in the destruction or adverse modification" of its "critical habitat."116 In addition, the "take" of listed species is generally prohibited.117 "Take" means "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct."118 The Services may, however, permit "incidental" take on a case-by-case basis if it finds, among other things, that such take will be minimized and mitigated and that such take will not "appreciably reduce the likelihood of survival and recovery of the species."119 [EPA-HQ-OAR-2010-0799-9479-A1, pp. 25-26]

Section 7 consultation is required for "any action [that] may affect listed species or critical habitat."120 Agency "action" is defined in the ESA's implementing regulations to include "all activities or programs of any kind authorized, funded, or carried out, in whole or in part, by Federal agencies in the United States or upon the high seas. Examples include, but are not limited to: (a) actions intended to conserve listed species or their habitat; (b) the promulgation of regulations; (c) the granting of licenses, contracts, leases, easements, rights-of-way, permits, or grants-in-aid; or (d) actions directly or indirectly causing modifications to the land, water, or air."121 This regulatory definition of "action" clearly encompasses the Agencies' rulemaking, since the emissions from the regulated vehicles unquestionably will cause "modification to the land, water, or air." The U.S. Fish and Wildlife Service's and National Marine Fisheries Service's Consultation Handbook, Procedures for Conducting Consultation and Conference Activities under Section 7 of the Endangered Species Act (March 1998,) explains the above terms and definitions. There can also be no question that the enormous volume of direct, indirect, and cumulative emissions from the regulated vehicles "may affect" listed species, and therefore the Agencies must consult. [EPA-HQ-OAR-2010-0799-9479-A1, p. 26]

The rulemaking will impact species listed as threatened and endangered in several ways, yet the Agencies have failed to initiate the required Section 7 consultations with the Services on its impact. If the Agencies fail to initiate and complete the required Section 7 consultations on the rulemaking, they may be held liable for take of listed species caused by the impacts of their action, including increased greenhouse gas emissions and other emissions such as NO_x. On May 15, 2008, the U.S. Fish and Wildlife Service listed the polar bear as a threatened species throughout is range due to global warming. 122 The Agencies must consult on the impact of the rulemaking on the polar bear. [EPA-HQ-OAR-2010-0799-9479-A1, p. 26]

On May 9, 2006, the National Marine Fisheries Service listed the staghorn and elkhorn corals as threatened due in part to increasing ocean temperature and ocean acidification due to anthropogenic greenhouse emissions. 123 The Agencies must consult on the impact of the rulemaking on these coral species. The Agencies must also consult on the impact of the rulemaking on the polar bear's and the corals' critical habitat, once such habitat is designated. [EPA-HQ-OAR-2010-0799-9479-A1, p. 26]

Global warming was cited by the U.S. Fish and Wildlife Service in its critical habitat rulemakings for the Quino Checkerspot and Bay Checkerspot butterflies.124 The Agencies must consult on the impact of the rulemaking on these species and their critical habitat as well. [EPA-HQ-OAR-2010-0799-9479-A1, p. 26]

The Agencies must not limit their consultation, however, to species like the polar bear, corals, and checkerspot butterflies for which anthropogenic greenhouse emissions were cited as a reason for listing or as an impact in the listing or critical habitat rules. Numerous species are affected by climate change as reflected in the recovery plans for those species and other documents. [EPA-HQ-OAR-2010-0799-9479-A1, p. 27]

There at least 124 listed species for which a recovery plan has been adopted that specifically identifies climate change or a projected impact of climate change as a direct or indirect threat to the species, as a critical impact to be mitigated, as a critical issue to be monitored, and/or as a component of the recovery criteria.125 These findings constitute clear evidence that the Agencies' rulemaking "may affect" these species, and that they must consult on the impact of this action on all listed species which may be affected. [EPA-HQ-OAR-2010-0799-9479-A1, p. 27]

The rulemaking will impact listed species in ways beyond global warming and ocean acidification. For example, vehicles are a primary source of excess nitrogen in the environment. Excess nitrogen contributes to major environmental problems including reduced water quality, eutrophication of estuaries, nitrate-induced toxic effects on freshwater biota, changes in plant community composition, disruptions in nutrient cycling, and increased emissions from soil of nitrogenous greenhouse gases.126 Nitrogen deposition therefore impacts species listed under the Endangered Species Act in a number of ways. [EPA-HQ-OAR-2010-0799-9479-A1, p. 27]

The direct, indirect, and cumulative impacts of setting fuel economy standards for all passenger vehicles and light trucks nationally are extraordinarily significant, and therefore a large number of species may be implicated. Where, as here, the Agencies' rulemaking is national in scope, they should conduct a nationally focused consultation. The agencies must not attempt to use the large scale of the rulemaking as an excuse for ignoring its environmental review duties; instead, the scope of the action only makes it more important to thoroughly review its impacts under all applicable laws. Nor can the mere fact that a large geographical area or large number of species will be affected be used as an excuse for inaction.127 If anything, a nationally focused consultation will provide the opportunity to most efficiently analyze the impact of the rulemaking on species and groups of species. [EPA-HQ-OAR-2010-0799-9479-A1, p. 27]

Response:

Section 7(a)(2) of the Endangered Species Act (ESA) requires federal agencies, in consultation with the National Oceanic and Atmospheric Administration Fisheries Service (NOAA Fisheries) and/or the U.S. Fish and Wildlife Service (FWS, and, with NOAA Fisheries, the Services), to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of federally-listed threatened or endangered species, or result in the destruction or adverse modification of designated critical habitat of such species. 16 U.S.C. § 1536(a)(2). Under the Services' relevant implementing regulations, consultation is required for actions that "may affect" listed species or designated critical habitat. 50 CFR § 402.14. Consultation is not required where the action has "no effect" on such listed species or critical habitat. Under this standard, it is the federal agency taking the action that evaluates the action and determines whether consultation is required. See 51 FR 19926, 19949 (June 3, 1986). The effects of a federal action are defined by regulation to include both the direct and indirect effects of the action on listed species or designated critical habitat. 50 CFR § 402.02. Indirect effects are those that are caused by the action and are later in time, but still are reasonably certain to occur. *Id.*; *Cf.*, 51 FR at 19932-19933 (discussing "reasonably certain to occur" in the context of cumulative effects analysis and noting that only matters that are likely to occur – and not speculative matters – are included within the standard).

Pursuant to Section 7(a)(2) of the ESA, EPA has carefully considered the effects of its MYs 2017-2025 light duty motor vehicle rule and has reviewed applicable ESA regulations, case law, and guidance to determine what, if any, impact there may be to listed species or designated critical habitat. EPA has considered issues relating to emissions of carbon dioxide (CO_2) and other greenhouse gases (GHGs) as well as issues relating to emissions of non-GHG air pollutants. EPA has also coordinated with NHTSA to assess ESA requirements in connection with EPA's rulemaking and NHTSA's related CAFE Standards. EPA notes that NHTSA's response to the ESA comment submitted on the NPRM is found in Chapter 9 (pages 9-99 through 9-102) of its Final EIS. EPA agrees with the reasoning in NHTSA's response as applied to EPA's rulemaking. Based on EPA's assessment, EPA has determined that the agency's rulemaking action, which will generally result in emissions reductions from what would otherwise occur in the absence of this rule, does not require consultation with the Services under Section 7(a)(2) of the ESA.

EPA notes that similar issues regarding applicability of ESA Section 7(a)(2) consultation requirements were raised by the same commenter in connection with EPA's MY 2012-2016 light duty motor vehicle rulemaking. In that context, EPA addressed in detail issues regarding ESA Section 7(a)(2) in its Response To Comment document at pages 4-94 through 4-103 (the MY

2012-2016 ESA Response). EPA believes that the same basic rationale as set forth in that response also applies to the current comment and rulemaking, and EPA adopts and incorporates that prior response here.

In particular, EPA notes that its rulemaking will result in GHG emissions reductions that would be expected to have beneficial effects with respect to global climate change and associated impacts. The commenter appears to generally misunderstand the effect of the rule and to attribute the entire volume of emissions from the regulated sector to EPA's action. To the contrary, the rule will generally reduce the impacts of climate change and will, therefore, be expected to have a beneficial effect with respect to global climate change. EPA believes, however, that any potential for a specific impact to particular listed species and their habitats associated with the emission changes achieved by this rulemaking is too uncertain and remote to trigger the threshold for ESA Section 7(a)(2) consultation.

As detailed in the MY 2012-2016 ESA Response, EPA's conclusion that ESA Section 7(a)(2) consultation is not required relies on the significant legal and technical analysis undertaken by FWS, the Department of the Interior (DOI), and EPA regarding GHG emissions and the ESA. As explained in that response, FWS and DOI have – in the context of various documents relating to the listing of the polar bear as a threatened species – determined that it is not possible, for ESA purposes, to trace a causal link between a single stationary source's GHG emissions and any reasonably certain effect on a specific species in a specific habitat.[93] Although EPA's rule involves GHG reductions from mobile sources rather than emissions from a single stationary source, EPA believes that the analysis regarding causation is relevant here. EPA agrees that there must be a causal connection between a federal action and a potential effect on listed species or critical habitat for Section 7(a)(2) consultation requirements to apply, and that the potential effect must be reasonably certain to occur.

In addition, as EPA did in the MY 2012-2016 ESA Response, EPA has also considered the specific GHG emissions reductions achieved by the current rule in light of any potential impacts on listed species or designated critical habitat. In the MY 2012-2016 ESA Response, EPA explained that it had previously attempted to analyze the impacts on temperature and tropical ocean pH of GHG emissions from a single large stationary source. In that prior analysis, EPA concluded that any such potential effects were too remote to trigger ESA Section 7(a)(2) consultation requirements. In the MY 2012-2016 ESA Response, EPA extended that analysis to the magnitude of GHG emission changes resulting from implementation of that rule and for similar reasons concluded that ESA consultation was not required. EPA has also considered the magnitude of GHG emission changes achieved by the current rule and finds that for the same reasons described in the MY 2012-2016 ESA Response, any potential effects attributable to such

[93] One of the principal relevant documents from the polar bear listing is FWS' Final Special Rule for the Polar Bear (73 FR 76249 (Dec. 16, 2008)). EPA is aware that the Federal District Court for the District of Columbia has found that the Final Special Rule did not comply with requirements of the National Environmental Policy Act (NEPA). See *In re Polar Bear Endangered Species Act Listing and § 4(d) Rule Litigation*, 818 F. Supp.2d 214 (D.D.C. 2011). Importantly, however, the District Court did uphold FWS' approach regarding ESA Section 7(a)(2), which supports the relevant analytical framework addressed in EPA's MY 2012-2016 ESA Response and adopted as part of the current response set forth here.

changes are too remote to trigger ESA consultation. In particular, the EPA technical analysis for MY 2017-2025 concludes that, relative to the reference case, by 2100 projected atmospheric CO_2 concentrations are estimated to be reduced by 3.21 to 3.58 part per million by volume (ppmv), global mean temperature is estimated to be reduced by 0.0074 to 0.0176°C, and sea-level rise is projected to be reduced by approximately 0.071-0.159 cm, based on a range of climate sensitivities. The analysis also demonstrates that ocean pH will increase by 0.0017 pH units by 2100 relative to the reference case (ie, reduced acidification). As noted above, EPA believes that these results fit within the analytical framework of EPA's prior ESA/GHG assessments as described in the MY 2012-2016 ESA Response.

In the MY 2012-2016 ESA Response, EPA also considered non-GHG air pollutant emissions and concluded – for similar reasons as explained in relation to GHG emission changes – that the changes in emissions of such pollutants attributable to that rule did not trigger ESA Section 7(a)(2) consultation. EPA has also considered changes in non-GHG pollutant emissions associated with the current rulemaking. The following chart provides EPA's estimated changes for each of the non-GHG pollutants.

Annual Non-GHG Pollutant Emission Impacts of Program (short tons)

	CY 2020		CY 2030	
Pollutant	Impacts (Short Tons)	% of Total US Inventory	Impacts (Short Tons)	% of Total US Inventory
VOC	-11,712	-0.1%	-123,070	-1.0%
CO	14,164	0.0%	224,875	0.4%
NO_X	-904	0.0%	-6,509	-0.1%
PM2.5	-136	0.0%	-1,254	0.0%
SO_X	-1,270	0.0%	-13,377	-0.2%
1,3-Butadiene	1	0.0%	25	0.2%
Acetaldehyde	3	0.0%	57	0.1%
Acrolein	0	0.0%	2	0.0%
Benzene	-16	0.0%	-101	0.0%
Formaldehyde	-7	0.0%	-43	0.0%

Source: RIA Table 4.3-19

Consistent with the MY 2012-2016 ESA Response, EPA notes that the modeling tools available for EPA's regulatory analysis of the non-GHG pollutants are not designed to trace fluctuations in ambient concentration levels to potential impacts on particular species. EPA believes that such models do not, therefore, attribute any biological response or impact on listed species to the ambient concentration changes with the degree of reasonable certainty required under the ESA. In addition, EPA is unaware of information identifying any effects on listed species from the small fluctuations in amounts of non-GHG pollutants indicated in the chart. For the same reasons identified in the MY 2012-2016 ESA Response, EPA thus concludes that ESA consultation is not required with respect to the non-GHG emission changes attributable to the current light duty motor vehicle rule.

For additional discussion of EPA's analysis regarding the light duty motor vehicle rule and ESA Section 7(a)(2) requirements, see the MY 2012-2016 ESA Response.

Organization: Competitive Enterprise Institute (CEI)

III. EPA/NHTSA: Denying Plain Facts They Must Know to be True

At a recent hearing before a House oversight panel, three Obama Administration witnesses — NHTSA Administrator David Strickland, EPA Assistant Air Administrator Gina McCarthy, and EPA Transportation and Air Quality Director Margo Oge – denied under oath that motor vehicle GHG emission standards are "related to" fuel economy standards.10 In so doing, they denied plain facts they must know to be true. They lied to Congress. [EPA-HQ-OAR-2010-0799-9552-A1, p. 3]

House Government Oversight and Reform Chairman Darrell Issa put it more diplomatically: "Your statements under oath misrepresented the relationship between regulating greenhouse gases and regulating fuel economy." By "obstinately insisting" that regulating greenhouse gases and fuel economy are "separate and unrelated endeavors," he said, the Administration officials "impede the Committee's important oversight work." [EPA-HQ-OAR-2010-0799-9552-A1, p. 3]

Why did they "misrepresent" and "impede"? Had they answered truthfully, they would have to admit that California's greenhouse gas motor vehicle emissions law, AB 1493, which EPA approved in June 2009,11 violates EPCA's express preemption of state laws or regulations "related to" fuel economy.12 The officials would also have to admit that EPA is effectively regulating fuel economy, a function outside the scope of its statutory authority. [EPA-HQ-OAR-2010-0799-9552-A1, p. 3]

IV. Power Grab

The falsehood that GHG emission standards are not related to fuel economy standards does more than mask EPA and CARB's poaching of NHTSA's statutory authority. It also protects EPA's efforts to legislate climate policy under the guise of implementing the CAA. [EPA-HQ-OAR-2010-0799-9552-A1, p. 3]

To begin with, the falsehood facilitated a regulatory extortion strategy enabling the Obama Administration to convert the auto industry from opponent to ally in any congressional debate on EPA's greenhouse gas regulations. [EPA-HQ-OAR-2010-0799-9552-A1, p. 3]

In February 2009, EPA Administrator Jackson decided to reconsider13 Bush EPA Administrator Stephen Johnson's denial of California's request for a waiver to implement AB 1493.14 Because GHG emissions standards implicitly regulate fuel economy, because the waiver would allow other states to follow suit, and because auto makers would have to reshuffle the mix of vehicles sold in each "California" state to achieve the same average fuel economy, Jackson confronted the financially-distressed auto industry with the prospect of a market-balkanizing fuel-economy "patchwork."15 [EPA-HQ-OAR-2010-0799-9552-A1, p. 3]

Then, in May 2009, in backdoor negotiations conducted under a vow of silence ("We put nothing in writing, ever," CARB Chairman Mary Nichols told the New York Times),16 the White House offered to protect auto makers from the patchwork threat if – but only if – they agreed to support EPA and CARB's newfound careers as GHG/fuel economy regulators. [EPA-HQ-OAR-2010-0799-9552-A1, p. 3]

Specifically, under what President Obama dubbed the "Historic Agreement,"17 California and other states agreed18 to deem compliance with EPA's GHG standards as compliance with their own in return for auto makers' pledge19 not to challenge either the Tailpipe Rule or the California waiver. The Administration may also have tied its offer of bailout money to automakers' acceptance of the 'triplification' of fuel economy regulation.20 Outsiders may never know the details, because participants, in apparent defiance of the Presidential Records Act,21 kept no minutes or notes of the meetings. [EPA-HQ-OAR-2010-0799-9552-A1, p. 4]

The political payoff for EPA and CARB was not long in coming. In 2010, Alaska Sen. Lisa Murkowski introduced a resolution22 to overturn EPA's greenhouse gas Endangerment Rule,23 the prerequisite for the Tailpipe Rule and all other EPA greenhouse gas regulations. The auto industry lobbied against the resolution,24 warning that it would undo the Historic Agreement and, thus, expose auto makers to a "multitude" of conflicting state and federal standards.25 [EPA-HQ-OAR-2010-0799-9552-A1, p. 4]

Of course, the threat of a patchwork exists only because Jackson, disregarding the EPCA preemption, granted the waiver in the first place. [EPA-HQ-OAR-2010-0799-9552-A1, p. 4]

EPA then parlayed its new role as de-facto fuel economy regulator into a mandate to regulate GHG emissions throughout the economy. The Tailpipe Rule – at least as EPA reads the CAA26 – compels the agency to regulate GHGs from "major emitting facilities." EPA is now applying CAA preconstruction and operating permit requirements to large CO_2 emitters such as coal-fired power plants, petroleum refineries, cement production facilities, steel mills, and pulp and paper factories.27 [EPA-HQ-OAR-2010-0799-9552-A1, p. 4]

Given these precedents, it was inevitable that EPA would settle environmental lawsuits by consenting to develop GHG "performance standards" for power plants28 and refineries,29 with GHG performance standards for other industrial categories sure to follow. In time, litigants will likely induce EPA to establish quasi-fuel economy standards for marine vessels, aircraft, and non-road engines,30 even though no agency sets such standards under any existing statute. [EPA-HQ-OAR-2010-0799-9552-A1, p. 4]

Because the Endangerment Rule identifies the "elevated concentration" of GHGs as the source of endangerment,31 EPA has logically committed itself to develop national ambient air quality standards (NAAQS) for GHGs set below current atmospheric concentrations.32 In an August

2010 brief to the Supreme Court in American Electric Power v. State of Connecticut, the Department of Justice favorably cited the NAAQS program as a potential regulatory tool displacing federal common law tort action against GHG emitters.33 [EPA-HQ-OAR-2010-0799-9552-A1, p. 4]

[See footnote list for this comment on pp. 5-6 of Docket number EPA-HQ-OAR-2010-0799-9552-A1]

Response:

Most of this comment again reflects reasoning repudiated by the D.C. Circuit in Coalition for Responsible Regulation v. EPA. In addition, the stationary source consequences that the commenter decries occur essentially by operation of statute, not because of EPA action. Coalition for Responsible Regulation v. EPA, no. 09-1322 (D.C. Cir. June 26, 2012) slip op. pp. 40-41, 54-59.

Organization: Pacific Legal Foundation (PLF)

We address two issues regarding the Proposed Regulations. First, the Proposed Regulations must be submitted to EPA's Science Advisory Board ("SAB") for review during the public comment period, pursuant to 42 U.S.C. § 4365. In addition, the preamble to the final regulations should set forth in detail the time and circumstances of EPA's submittal of the Proposed Regulations to SAB, as well as any comments provided by SAB, whether EPA made changes to the Proposed Regulations in response to such comments, and why or why not. [Refer to pp. 2-4 of Docket number EPA-HQ-OAR-2010-0799-8108-A1 for detailed information] [EPA-HQ-OAR-2010-0799-8108-A1, p. 2]

Second, EPA must comply with the special rulemaking provisions of 42 U.S.C. § 7607(d) in connection with the promulgation of the Proposed Regulations. Among other things, that subsection of the Clean Air Act sets forth detailed requirements for EPA's "promulgation ... of regulations under section 202" of the Clean Air Act. Because EPA is promulgating the regulations under section 202 (a) (1) of the Clean Air Act, the regulations are subject to the special rulemaking requirements of 42 U.S.C. § 7607(d). EPA must document in detail in the preamble to the final LDVR II regulations the precise manner in which it has complied (or not complied) with such requirements. The remainder of this letter sets forth in detail the reasons EPA must perform the two actions summarized above. [Refer to pp. 4-7 of Docket number EPA-HQ-OAR-2010-0799-8108-A1 for detailed information] [EPA-HQ-OAR-2010-0799-8108-A1, p. 2]

Response:

The commenter is factually mistaken. In fact, EPA submitted the proposed rule to the SAB at its meeting of March 23, 2012. The SAB declined to consider the proposed rule. Surprisingly, given the commenter's professed interest in the matter, it failed to submit either written or oral comments to the SAB, even though notice of the meeting was published in the

Federal register and other entities submitted comments on matters discussed at the meeting. See 77 FR 12579, 12580 (March 1, 2012). EPA-HQ-OAR-2010-0799-11793.

In addition, the commenter fails to demonstrate that 42 USC. 4365 ©(1) is applicable. That provision applies only when EPA submits documents to other agencies "for formal review and comment." The light duty vehicle GHG rule implements section 202 (a) of the Clean Air Act. That provision contains no requirement that implementing regulations be submitted to other federal agencies for formal review and comment, nor did EPA do so. EPA submitted the draft of the proposed rule to the Office of Management and Budget for informal review, pursuant to Executive Order 12866, but this is not the type of formal review to which section 4365 (c)(1) speaks. See Coalition for Responsible Regulation v. EPA, No. 09-1322 (D.C. Cir. June 26, 2012) slip op. pp. 35-36 (noting this distinction).

Finally, EPA agrees that the procedures set out in section 307 (d) apply to this rulemaking, and EPA has followed all of those procedures in promulgating the proposed and final rules setting GHG emission standards for MYs 2017-2025 light duty motor vehicles. The commenter does not allege otherwise. Rather, the commenter maintains (comment pp. 6-7) that EPA must document in the preamble compliance with each of the procedural requirements of section 307 (d). This argument lacks any statutory foundation. The commenter mistakenly cites section 307 (d)(3)(C) as support. This provision states that a proposed rule shall "set forth … any pertinent finding, recommendations, and comments of the Scientific Review Committee established under section 109 (d)". Section 109 (d) applies exclusively to establishment of National Ambient Air Quality Standards, so section 307 (d)(3)(C) is inapplicable here. EPA in fact established a docket for the proposed and final rule (see 76 FR 74855-56), announced and held public hearings (76 FR at 74857), set forth in the preamble, draft TSD and DRIA the basis and purposes of the proposed rule, etc. The commenter is consequently mistaken as a matter of both fact and law.

Organization: RVIA

Cost considerations per Executive Order # 13563 [EPA-HQ-OAR-2010-0799-9550-A2, p.3]

In accordance with Section 1(b) of Executive Order 13563 (Improving *Regulations and Regulatory Review*), when issuing new regulations, agencies shall tailor their regulations to impose the least burden on society, consistent with obtaining regulatory objectives, taking into account, among other things, and to the extent practicable, the costs of cumulative regulations." In proposing the 2017-2025 GHG and CAFÉ standards for light duty vehicles, RVIA believes that EPA and NHTSA have failed to fully comply with this directive. While the agencies have informed the public of what the cost impact of the proposed standards are projected to be, they have not informed the public of the cumulative costs of their regulations. When informing the public of the cost of the impact, we believe that, as a matter of good public policy, the public should be informed that the vehicle is going to realize additional price increases due to other EPA and NHTSA regulations that will be implemented during these same model years. NHTSA rules that will likely be implemented in the future and thus add additional cost to new vehicles include the following: [EPA-HQ-OAR-2010-0799-9550-A2, p.3]

1. FMVSS 111 backup camera [EPA-HQ-OAR-2010-0799-9550-A2, p.3]

2. FMVSS 124 accelerator control update [EPA-HQ-OAR-2010-0799-9550-A2, p.3]

3. FMVSS 214 side impact upgrade [EPA-HQ-OAR-2010-0799-9550-A2, p.3]

4. FMVSS 216 roof crush upgrade [EPA-HQ-OAR-2010-0799-9550-A2, p.3]

5. FMVSS 226 ejection mitigation [EPA-HQ-OAR-2010-0799-9550-A2, p.3]

6. 49 CFR Part 563 Event Data Recorder mandate [EPA-HQ-OAR-2010-0799-9550-A2, p.3]

7. Pedestrian Safety Enhancement Act audible alert [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

8. Pedestrian safety Global Technical Regulation [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

9. Brake override mandate [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

For the above rules that have already been finalized but not yet fully implemented, NHTSA has projected that the costs per rule could be as much as: [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

$299/vehicle for the ejection mitigation rule [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

$243/vehicle for the side impact rule [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

$203/vehicle for the backup camera rule [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

$114/vehicle for the roof crush rule [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

These four rules alone cumulatively could increase the price of a new vehicle by $859 (eight hundred and fifty-nine dollars). [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

EPA (along with CARB) will also introduce new requirements like the Tier 3 emissions standards. If the cost of implementing Tier 3 standards compares to the cost of implementing Tier 2 emissions standards, one can expect the average price of a passenger car to increase by $100 and the average price of a light truck to increase by $200. [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

Just the five rules mentioned here could potentially increase the cost of a new light vehicle by another $1,000 (one-thousand dollars). Consumers have a right to know the cumulative cost impact of the EPA/NHTSA regulations. RVIA therefore recommends that the agencies take these cumulative costs into consideration when setting future standards and that you inform the public of the cumulative cost impacts of EPA/NHTSA regulations on new vehicle prices. [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

With regard to all light vehicles, EPA and NHTSA should take the cumulative costs of its regulations into consideration when setting future standards and inform the public of the impact on new car prices. In this rulemaking, EPA and NHTSA did not fully consider the cumulative costs of its regulations on new car prices. We have listed several EPA and NHTSA rules that were not discussed in the NPRM that will drive up new car prices by possibly another $1,000. [EPA-HQ-OAR-2010-0799-9550-A2, p.5]

Response:

EPA believes it has **f**ollowed both Executive Orders 12866 and 13563 both in the proposal and in this final rulemaking. Specifically, Executive Order 13563 was published January 21, 2011 (76 FR 3821) to, "supplement and reaffirm the principles, structures and definitions of government contemporary regulatory review that were established in Executive Order 12866 of September 30 1993."

In responding to these executive orders, EPA has provided detailed costs analysis of this action in both the Preamble and Final Regulatory Impact Analysis (FRIA). EPA submitted this action to the Office of Management and Budget (OMB) as required under these Executive Orders for review and any changes made in response to OMB recommendations have been documented in the docket for this action as required by CAA section 307(d)(4)(B)(ii). **.**

Specifically, section III. H of the preamble provides an in-depth discussion of the estimated costs, economic and other impacts of this final rule. This is supplemented by further detailed discussion in the FRIA, Chapter 3. Regarding the treatment of cumulative costs from previous light-duty vehicle rule**s**, EPA for this final rule, has estimated the 2025MY reference case costs (i.e, the cost to meet the 2016 standards in the 2025MY) at $719 (see RIA Table 3.6-1). We have also estimated 2025MY control case costs (i.e., the cost to meet the 2025 standards in the 2025MY) at $1836. The total cost of these rules would then be $2555. To properly add the costs, one needs to use the cost of the 2016 standards in the 2025MY as we have done. With regard to Tier 2 costs which became effective in 2004MY EPA has not specially highlighted those costs but they are part of the baseline for the 2025 reference case costs. Given that EPA has not even proposed Tier 3 rules, it would be premature (at best) and merely speculative (at worst) to estimate those costs here. Neither executive order addresses, or contemplates including costs of pre-proposal nascent regulatory potential actions.

Proportion of Recovered Braking Energy for Hybrid Electric Vehicles [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

The following comments address EPA's proposed changes to 40 C.F.R. §600.116-12(c) for determining the proportion of recovered braking energy for hybrid electric vehicles. [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

In 40 C.F.R. §600.116-12(c)(1)(i)(A) and (B), it is unclear whether road load power and applied deceleration power are to be calculated from scheduled speed or measured speed. We recommend that Vmph, V and Vt+1 be defined as "measured velocity in miles/hour, rounded to the nearest 0.01 miles/hour…" [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

In 40 C.F.R. §600.116-12(c)(1)(C), EPA proposes to determine braking power by the following equation: [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

Pbrake = Paccel – Proadload [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

We recommend that the equation be changed to the following: [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

Pbrake = Paccel + Proadload and if Pbrake >0, set Pbrake = 0 [EPA-HQ-OAR-2010-0799-9487-A1, p.88]

The Proadload should decrease the magnitude of the Pbrake term. As it is currently written, the magnitude of Pbrake is not decreased by Proadload during deceleration. If Pbrake isn't decreased by Proadload, the Emax equation would assume that the roadload force could be recovered by regenerative braking, and this would cause the Emax calculation to give a higher value than is possible (thus lowering the eventual Energy Recovered %). [EPA-HQ-OAR-2010-0799-9487-A1, p.89]

As can be seen in the following chart, the proposed equation would indicate that roadload during steady cruising would be able to be recaptured as regeneration (red line). The green line is Emax when you replace the '-' sign with a '+' sign in the Pbrake equation and revise the Pbrake = 0 criteria. [EPA-HQ-OAR-2010-0799-9487-A1, p.89] [For the chart please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.89]

Therefore, it would be more appropriate if the equation were written as Pbrake = Paccel + Proadload with the additional criteria that Pbrake = 0 whenever the calculation results in a positive value. [EPA-HQ-OAR-2010-0799-9487-A1, p.89]

In addition, the following clerical errors were discovered during our review of the NPRM: [EPA-HQ-OAR-2010-0799-9487-A1, p.89]

§600.116-12(c)(1)(i)(A): Road load equation has an extra “x” between 0.47704 and 4.448 [EPA-HQ-OAR-2010-0799-9487-A1, p.89]

§600.116-12(c)(3)(iii): “battery” is misspelled as “batter” [EPA-HQ-OAR-2010-0799-9487-A1, p.89]

§600.116-12(c)(4)(3)(iii): Definition of Erec under the Energy Recovered % equation references paragraph (c)(2)(iii), should reference paragraph (c)(3)(iii) instead [EPA-HQ-OAR-2010-0799-9487-A1, p.89]

§600.116-12(c)(4)(3)(iii): Conflicting nomenclature. Energy Recovered % equation uses Emax, which appears to be called Ebrake in the paragraph referenced by the Emax definition, §600.116-12(c)(2). [EPA-HQ-OAR-2010-0799-9487-A1, p.89]

Further, prior to the final rule, we plan to engage the agency technical experts to ensure that the test procedure specifications and regulatory language for determining the proportion of recovered braking energy is clear, accurate and consistent with previous hybrid procedural guidance (e.g., SAE J1711, Part 86, Part 600), where applicable. [EPA-HQ-OAR-2010-0799-9487-A1, pp.89-90]

Fuel Economy Calculations [EPA-HQ-OAR-2010-0799-9487-A1, p.91]

The Alliance suggests following corrections to the fuel economy calculations in § 600.113–12 (fuel economy, CO_2 emissions, and carbon-related exhaust emission calculations for FTP, HFET, US06, SC03 and cold temperature FTP tests): [EPA-HQ-OAR-2010-0799-9487-A1, p.91]

(l)(1) Ethanol FE equation: [EPA-HQ-OAR-2010-0799-9487-A1, p.91]
mpg = (CWF × SG × 3781.8)/((CWFexHC × HC) + (0.429 × CO) + (0.273 × CO_2) + (0.375 × CH3OH) + (0.400 × HCHO) + (0.521 × C2H5OH) + (0.545 × C2H4O)) [EPA-HQ-OAR-2010-0799-9487-A1, p.91]

Comment: This entire section needs review of equations, but specifically the ethanol equation and its importance to E15/E10 testing. The referenced FE equation is incorrect. The equation does not utilize net heating value (NHV) as an adjustment for different ethanol blends, so it is unclear how this equation accounts for different ethanol blends or equivalence back to the conventional gasoline FE equation. This equation will produce lower FE due to the fact that ethanol blended fuels have less energy content (NHV) per gallon than conventional gasoline. [EPA-HQ-OAR-2010-0799-9487-A1, p.91]

The Alliance requests a test procedure adjustment (TPA) that references the carbon weight fraction (CWF), net heating value, and specific gravity of the 1975 E0 reference fuel that was used to establish the initial CAFE baseline. A TPA (including coverage of the density and R-Factor) is necessary to maintain consistency with the 1975 test procedures. [EPA-HQ-OAR-2010-0799-9487-A1, p.91]

86.1866-12(b)(2)(ii) [EPA-HQ-OAR-2010-0799-9487-A1, p.92]

The reference to the annual refrigerant leakage rate in the definition section should be titled “LeakScore” instead of “Leakage” to align with the terminology in the Leakage Credit equation. [EPA-HQ-OAR-2010-0799-9487-A1, p.92]

Organization: American Honda Motor Co., Inc.

- U.S. “Production” vs. “Sales”: §86.1866-12(d)(1) shows a table that identifies certain off-cycle technologies, their credits for passenger cars and light trucks, and the “minimum percent of U.S. production” that must have a feature applied before receiving the off-cycle credit. We believe the intent of this section is better understood to be “minimum percent of U.S. Sales,” since many U.S. – produced vehicles are intended for export and are not relevant. Similarly, it is unclear how imported vehicles would be treated. [EPA-HQ-OAR-2010-0799-9489-A1, p. 6]

Organization: Toyota Motor North America

U.S. Production Criteria

There are provisions in the proposed regulations that reference U.S. production as a component of applicability or eligibility for those provisions. For example, in describing the minimum sales volume threshold for the list of pre-determined off-cycle technologies, §86.1866-12 (d)(l)(i) states 'The manufacturer may generate a CO_2 gram/mile credit ... provided that each technology is applied to the minimum percentage of the manufacturer's U.S. production of passenger automobiles ... for which credit is claimed'. Similarly, the provisions for advanced technology vehicles in §86.1866-12 (a)(l) state 'Electric vehicles, plug-in hybrid electric vehicles, and fuel cell vehicles...that are certified, produced, and delivered for sale in the United States ... may use a value of zero (0) grams/mile ofCO_2''. [EPA-HQ-OAR-2010-0799-9586-A1, p.23]

A reasonable interpretation of the provisions above could imply they are applicable only to vehicles produced in the U.S. Toyota understands the agencies do not intend for the applicability or eligibility of the proposed regulations to depend on a vehicle's origin. [EPA-HQ-OAR-2010-0799-9586-A1, p.24]

Toyota requests that the agencies clarify that the eligibility and applicability of the provisions being proposed are not contingent on a manufacturer producing vehicles in the United States. We suggest that where the agencies currently reference 'U.S. production' in a provision, that language be revised to instead use the term "production for U.S. sale' which is consistent with the intent of the provisions in both the CAA and EISA/EPCA. [EPA-HQ-OAR-2010-0799-9586-A1, p.24]

Organization: Association of Global Automakers, Inc. (Global Automakers)

Global Automakers is concerned that the proposed regulatory language is not sufficient to truly make the MY 2022-2025 standards “conditional;” rather, they have all of the hallmarks of final standards that are simply subject to possible revision at a later time. As such, we believe that the proposed regulatory language violates the prohibition against adopting standards for more than five model years found in 49 U.S.C. § 32902(b)(3)(b). Global Automakers suggests that a better—and more legally defensible—approach would be to draft 49 C.F.R. § 531.5(c) to cover only vehicles through MY 2021, and to have MY 2022 through 2025 covered in a separate subsection that explicitly states that the standards for those model years are not final, but rather have been conditionally set at these levels subject to future de novo final rulemaking. [EPA-HQ-OAR-2010-0799-9466-A1, p. 10]

Organization: Borg Warner, Inc.

Additionally, for the “Engine Heat Recovery” off-cycle credit, although a clear definition is not provided in the Technical Support Document, it uses a term “thermoelectric device”. This term is normally applied to devices using the Peltier–Seebeck effect. We request that the EPA and NHTSA clarify the definition of “Engine Heat Recovery” to be technology neutral and include any device that captures waste heat energy and converts it into electricity for use on the vehicle. [EPA-HQ-OAR-2010-0799-9320-A1, p. 2]

Organization: Ferrari

40 CFR § 86.1838-01(b) is amended by adding a new subparagraph (4) as follows: [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(4)(a) Notwithstanding the provisions of subparagraph (b)(3), upon application to the Administrator, a manufacturer may be classified as a small volume manufacturer for purposes of this section, if the Administrator determines that it is operationally independent of the manufacturer that owns 10 percent or more of the applicant and, for the three years preceding the year in which the initial application is submitted, the average United States sales for the applicant does not exceed 5,000 vehicles per year. The Administrator may make a determination of operational independence if the criteria in (i)-(vii) are met for the at least 24 months preceding the application. [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(i) No financial or other support of economic value is provided by related manufacturers for purposes of design, parts procurement, R&D and production facilities and operation, and any other transactions between related manufacturers are conducted under normal commercial arrangements like those conducted with other parties, at competitive pricing rates to the manufacturer; [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(ii) related manufacturers maintain separate and independent research and development, testing, and production facilities; [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(iii) the applicant does not use any vehicle powertrains or platforms developed or produced by related manufacturers; [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(iv) patents are not held jointly with related manufacturers; [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(v) related manufacturers maintain separate business administration, legal, purchasing, sales, and marketing departments, as well as autonomous decision making on commercial matters; [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(vi) the overlap of the Board of Directors between related manufacturers is limited to 25% with no sharing of top operational management, including president, chief executive officer, chief financial officer, and chief operating officer, and provided that no individual overlapping director or combination of overlapping directors exercises exclusive management control over either or both companies; and [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(vii) parts or components supply between related companies must be established through open market process, and to the extent that the manufacturer sells parts/components to non-related manufacturers, it does so through the open market a competitive pricing. [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(b)(i) The Administrator shall require the applicant to submit information to update any of these factors as material changes to any factor occur. If there are no material changes to any of the factors, the applicant shall certify to the Administrator on an annual basis. With respect to any such changes, the Administrator may consider extraordinary conditions (e.g., changes to economic conditions, unanticipated market changes, etc.) and may continue to find the applicant to be operationally independent. [EPA-HQ-OAR-2010-0799-9535-A2, p.7]

(c) If a manufacturer loses its eligibility as an operationally independent small volume manufacturer at any time, the manufacturer must begin compliance with the primary greenhouse gas emissions program in the third model year after the manufacturer loses its eligibility. [EPA-HQ-OAR-2010-0799-9535-A2, p.8]

(d) If a manufacturer loses its eligibility as an operationally independent small volume manufacturer at any point in time, the manufacturer must meet the criteria in (a)(i)-(vii) for three consecutive years before applying to the Administrator to be again considered operationally independent. [EPA-HQ-OAR-2010-0799-9535-A2, p.8]

(e) The manufacturer applying for operational independence shall engage an independent certified public accountant, or firm of such accountants (hereinafter referred to as “CPA”), to perform an agreed-upon procedures attestation engagement of the underlying documentation that forms the basis of the application as required in (a)(i)-(vii). [EPA-HQ-OAR-2010-0799-9535-A2, p.8]

(i) The CPA shall perform the attestation engagements in accordance with the Statements on Standards for Attestation Engagements. [EPA-HQ-OAR-2010-0799-9535-A2, p.8]

(ii) The CPA may complete the requirements of this paragraph with the assistance of internal auditors who are employees or agents of the application, so long as such assistance is in accordance with the Statements on Standards for Attestation Engagements. [EPA-HQ-OAR-2010-0799-9535-A2, p.8]

(iii) Notwithstanding the requirements of subparagraph (ii) of this section, an applicant may satisfy the requirements of this paragraph if the requirements of this paragraph are completed by an auditor who is an employee of the applicant, provided that such employee: a. Is an internal auditor certified by the Institute of Internal Auditors, Inc. (hereinafter referred to as “CIA”); and b. Completes the internal audits in accordance with the Codification of Standards for the Professional Practice of Internal Auditing. [EPA-HQ-OAR-2010-0799-9535-A2, p.8]

(iv) Use of a CPA or CIA who is debarred, suspended, or proposed for debarment pursuant to the Government wide Debarment and Suspension Regulations, 2 CFR part 1532, or the Debarment, Suspension, and Ineligibility Provisions of the Federal Acquisition Regulations, 48 CFR part 9, subpart 9.4, shall be deemed in noncompliance with the requirements of this section. [EPA-HQ-OAR-2010-0799-9535-A2, p.8]

(v) The following documents are incorporated by reference: the Statements on Standards for Attestation Engagements, Codification of Statements on Auditing Standards, written by the American Institute of Certified Public Accountants, Inc., 1991, and published by the Commerce Clearing House, Inc., Identification Number 059021, and the Codification of Standards for the Professional Practice of Internal Auditing, written and published by the Institute of Internal Auditors, Inc., 1989, Identification Number ISBN 0- 89413-207-5. These incorporations by reference were approved by the Director of the Federal Register in accordance with 5 U.S.C. 552(a) and 1 CFR part 51. Copies of the Statements on Standards for Attestation Engagements may be obtained from the American Institute of Certified Public Accountants, Inc., 1211 Avenue of the Americas, New York, New York 10036, and copies of the Codification of Standards for the Professional Practice of Internal Auditing may be obtained from the Institute of Internal Auditors, Inc., 249 Maitland Avenue, Altamonte Springs, Florida 32701- 4201. Copies may be inspected at the U.S. Environmental Protection Agency, Office of the Air Docket, 401 M St., SW., Washington, DC., or at the National Archives and Records Administration (NARA). For information on the availability of this material at NARA, call 202-741-6030, or go to: http://www.archives.gov/federal_register/code_of_federal_regulations/ibr_lo cations.html. [EPA-HQ-OAR-2010-0799-9535-A2, pp.8-9]

Organization: Fisker Automotive, Inc.

Given the feasibility of optionally complying to the greenhouse gas standards beginning with the 2012 model year, Fisker Automotive respectfully proposes the following modifications to the regulatory language: [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

§ 86.1801–12 Applicability.

(j) Exemption from greenhouse gas emission standards for small businesses.

(2) ~~Effective for the 2014 and later model years, a~~ A manufacturer that would otherwise be exempt under the provisions of paragraph (j)(1) of this section may optionally comply with the greenhouse gas emission standards specified in § 86.1818. A manufacturer making this choice is required to comply with all the applicable standards and provisions in § 86.1818 and in associated provisions in this part and in part 600 of this chapter. <u>A manufacturer may optionally comply with the greenhouse gas emission standards as soon as the rule goes into effect, beginning with the 2012 model year.</u> ~~Manufacturers may optionally earn early credits in the 2012 and/or 2013 model years by demonstrating CO_2 emission levels below the fleet average CO_2 standard that would have been applicable in those model years if the manufacturer had not been exempt. Manufacturers electing to earn these early credits must comply with the model year reporting requirements in § 600.512–12 for each model year.~~ [EPA-HQ-OAR-2010-0799-9266-A1, p. 3]

Organization: Ford Motor Company

Also related to the 5-cycle demonstration methodology, we believe there is a typographical error in the calculation described in 40 CFR § 86.1866-12(d)(2)(iii). The text indicates that the 5-cycle weighted city/highway value from paragraph (d)(2)(i) [without the off-cycle technology operating] should be subtracted from the value from paragraph (d)(2)(ii) [with the off-cycle technology operating] to determine the off-cycle benefit. Presumably, the carbon-related exhaust emissions from (d)(2)(ii) will be lower than those from (d)(2)(i), resulting in a negative value for the credit calculation. To remedy this, Ford believes the text of 40 CFR § 86.1866-12(d)(2)(iii) should be revised to state the following: [EPA-HQ-OAR-2010-0799-9463-A1, p. 17]

“Subtract the combined city/highway value determined in paragraph (d)(2)(ii) of this section from the value determined in paragraph (d)(2)(i) of this section”….. [EPA-HQ-OAR-2010-0799-9463-A1, p. 18]

Regulatory text clarification: With regard to the production volume multiplier and the 0 gram per mile emissions value, the proposed regulatory text reads as follows:

86.1866-12(a)(1) and (2) Electric vehicles, plug-in hybrid electric vehicles, and fuel cell vehicles, as those terms are defined in S.86.1803-01, that are certified and produced and delivered for sale in the United States… [EPA-HQ-OAR-2010-0799-9463-A1, p. 20]

We request clarification that the intent is that the provisions apply to those vehicles “delivered for sale” in the United States, and that production in the United States is not a new conditional provision, per the following recommended revision:

86.1866-12(a)(1) and (2) Electric vehicles, plug-in hybrid electric vehicles, and fuel cell vehicles, as those terms are defined in S.86.1803-01, that are certified and ~~produced and~~ delivered for sale in the United States… [EPA-HQ-OAR-2010-0799-9463-A1, p. 20]

Organization: Motor & Equipment Manufacturers Association (MEMA)

The definition in the proposed regulatory text at § 86.1866–12 (d)(1)(i) for active seat ventilation is "a device which draws air from the seating surface … and exhausts it … away from the seat." MEMA believes this definition is narrow in scope because there are other mechanisms for active seat ventilation available. For example, systems that push the air (versus drawing the air) to the seating surface and remove the heated, humid air between the seat surface and the passenger contact points just like the drawing type of active seat ventilation. Therefore, MEMA requests the agencies modify the definition to also include a push type system. [EPA-HQ-OAR-2010-0799-9478-A1, p.8]

In the NPRM's regulatory text for this section, § 86.1866–12 "CO_2 fleet average credit and incentive programs" Subpart (e) "Credits for certain full-size pickup trucks"9 there are several places where the mild and strong hybrid propulsions are referenced as "gasoline-electric." There are several other technical possibilities for full-size pick-up truck hybrids – such as, diesel-electric, gasoline-hydraulic, diesel-hydraulic. Therefore, MEMA strongly recommends that the agencies change the regulatory text to simply the term "hybrid" and to remove specific descriptive terms "gasoline-electric." Otherwise, the credits in this area would only be narrowly restricted to "gasoline-electric" hybrids, which MEMA believes is counter to the intent of the standards. [EPA-HQ-OAR-2010-0799-9478-A1, p.11]

---

11 - In the NPRM, it is proposed to issue a credit of 10g/mile (MY2017-2021) for mild hybrid full size pickup trucks, on the condition that the vehicle manufacturer produces a minimum of 30 percent of total full-size pickups as mild hybrids in 2017 subsequently increasing them to 80 percent of total full size pickups by 2021. A credit of 20g/mile will be issued if the manufacturer produces 10 percent of total full size pickups as strong hybrids.

Organization: Roush Industries, Inc.

Upon review of the subject document the absence of regulations to calculate constituent fuel economy, CREE and CAFÉ for the LPG alternate fuel was noted. [EPA-HQ-OAR-2010-0799-7823-A2, p. 1]

The LPG regulation proposal is recommended for inclusion in CFR 40 commencing Part 600.113-12 amongst the regulatory description for the other fuels. Also reference of LPG in Part 600.510-12 (Calculation of average fuel economy and average carbon-related exhaust emissions) is desirable. [EPA-HQ-OAR-2010-0799-7823-A2, p. 1]

Response:

Proportion of Recovered Braking Energy

The comments from the Alliance pointed out confusion over the appropriate sign for the terms in the equation used in this calculation. The regulations have been amended to clarify the appropriate sign for each term that will result in the equation being correct.

EPA appreciates the comments pointing out various clerical errors and conflicting nomenclature, and appropriate corrections have been made.

Fuel Economy Calculations

The ethanol equation was finalized in the MY 2012-2016 program, and EPA believes it to be correct. However, the regulations always permit manufacturers to approach EPA with alternative calculations that yield similar or improved results.

Production vs. Sales and U.S. Production Criteria

EPA agrees with the comment that suggests clarification. Certainly EPA does not intend any provision to be limited to vehicles produced in the U.S.

MY 2022-2025 Standards

The comments from the Association of Global Automakers are principally directed at NHTSA and that agency's statutory limitation regarding the establishing of CAFE standards. EPA does not face such a restriction, and EPA regulations are drafted accordingly.

Engine Heat Recovery

EPA has modified the definition in the final rule to read as follows. We believe this is consistent with the comments from Borg Warner.

(viii) *Waste heat recovery* means a system that captures heat that would otherwise be lost through the engine, exhaust system, or the radiator or other sources and converting that heat to electrical energy that is used to meet the electrical requirements of the vehicle or used to augment the warming of other load reduction technologies (e.g., cabin warming, active engine or transmission warm-up technologies).

Operational Independence Regulatory Provisions

The provisions regarding small volume manufacturers and operational independence provisions are discussed in detail in section III.B.5 of the preamble to the final rule. Ferrari was the strongest advocate of the operational independence provisions, and, as shown above, they proposed specific regulatory language. EPA agrees with the substance of the operational independence provisions as outlined in Ferrari's comments, and we note that their proposed regulatory language is essentially identical to the language in the preamble to the proposed rule. As described in the preamble to the final rule, EPA is finalizing the operational independence criteria that were described in the request for comments in the proposal (see 76 FR 74922).

Although our final regulations regarding operational independence criteria are consistent with our proposal and with Ferrari's proposed regulations, there is one key difference between our final rule and Ferrari's proposal. Ferrari proposed a regulatory structure that would broadly amend the existing definition of small volume manufacturer and would appear to expand the use of the operational independence provisions to a broad set of EPA emission control programs. EPA did not propose such a broad use of the operational independence criteria, and although the elements of the criteria are virtually the same as those proposed by Ferrari, we are finalizing the provisions such that their applicability is limited to determining eligibility for the specific GHG programs contemplated in the proposal (i.e., the remaining years of the conditional exemption for small manufacturers available through the 2016 model year, and the alternative standards for small manufacturers in the 2017 and later model years). The final operational independence regulations are structured such that other EPA programs could incorporate them, but doing so would require an evaluation of the impact and appropriateness of doing so and would have to be conducted via a separate notice and comment process.

Optional Small Business Compliance

At least one small business manufacturer, Fisker Automotive, in discussions with EPA prior to proposal, suggested that small businesses should have the option of voluntarily opting-in to the GHG standards. This manufacturer sells electric vehicles, and sees a potential market for selling credits to other manufacturers. As discussed in the proposal, EPA believes that there could be several benefits to this approach, as it would allow small businesses an opportunity to generate revenue to offset their technology investments and to encourage commercialization of the innovative technology. There would likewise be a benefit to any manufacturer seeking those credits to meet their compliance obligations. EPA proposed and is finalizing allowing small businesses to waive their small entity exemption and opt-in to the primary GHG standards based on this same rationale. This will allow small business manufacturers to earn CO_2 credits under the program, which may be an especially attractive option for the new electric vehicle manufacturers entering the market. The small business would have to meet the primary standard for its fleet (that is, the small business would be allowed to opt-in to the primary program standard, but not the small volume manufacturer standards, since SVMs are not eligible to generate credits for trading as explained above). As proposed, manufacturers waiving their small entity exemption must meet all aspects of the GHG standards and program requirements across their entire product line.

EPA proposed to make the opt-in available starting in MY 2014, as the MY 2012, and potentially the MY 2013, certification process will have already occurred by the time this rulemaking is finalized. See 76 FR at 74994. EPA proposed this timing to avoid retroactively certifying vehicles that have already been produced. EPA proposed, however, that manufacturers certifying to the GHG standards for MY 2014 would be eligible to generate credits for vehicles sold in MY 2012 and MY 2013 based on the number of vehicles sold and the manufacturer's footprint-based standard under the primary program that would have otherwise applied to the manufacturer if it were a large manufacturer. This approach would be similar to that used by EPA for early credits generated in MYs 2009-2011, where manufacturers did not certify vehicles to CO_2 standards in those years but were able to generate credits. See 75 FR at 25441.

EPA received comments from Fisker requesting that EPA reconsider the timing of the opt-in provisions. Fisker commented that under EPA's proposal, manufacturers would not be able to generate credits until the end of MY 2014, even for vehicles that are produced in MYs 2012-2013. Fisker commented that this would significantly diminish the revenue generating benefit of these credits, particularly during the critical early years of their company when potential credit revenues would be of most benefit to the company. EPA is persuaded by this reasoning, and the final rule therefore provides that believes that the opt-in provisions begin with MY 2013. See §86.1801-12(j)(2)(i). The timing of the final rule will allow the GHG requirements to be integrated into the MY 2013 certification process for these small businesses. Once the small business manufacturer opting into the GHG program completes certification for MY 2013, the company will be eligible to generate GHG credits for their MY 2012 production. Manufacturers will not have to wait until the end of MY 2013 to generate MY 2012 credits. EPA believes this provision is responsive to the concerns of the commenter while still ensuring that the manufacturer is certified under the GHG program prior to generating credits.

Regulatory Text Clarifications from Ford

EPA appreciates the detailed look that Ford and some other manufacturers took at the regulations, and informing us of errors and useful clarifications. These have been incorporated to the extent that is appropriate.

Active Seat Ventilation Definition

EPA agrees with the commenter and has modified the definition to read as follows:

(ix) *Active seat ventilation* means a device which draws air, pushes or forces air, or otherwise transfers heat from the seating surface which is in contact with the seat occupant and exhausts it to a location away from the seat. At a minimum, the driver and front passenger seat must utilize this technology for a vehicle to be eligible for credit.

Definition of Mild and Strong Hybrid Electric Vehicles

EPA agrees with the commenter and the regulations have been amended to no longer use the phrase "gasoline-electric." The final regulations should be neutral regarding the fuel that is paired with a hybrid battery system.

Calculation of Values for LPG

In response to the comments, EPA has added equations for calculating the MPG for LPG vehicles.

22. Comments Regarding EPA Tier 3 Rulemaking

Organizations Included in this Section

American Lung Association of the Mid-Atlantic
Environmental Defense Fund (EDF)
Union of Concerned Scientists (UCS)

Organization: American Lung Association of the Mid-Atlantic

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 83-84.]

Therefore, just last week the American Lung Association nationally in concert with six other leading public health and medical organizations wrote to EPA Administrator Lisa Jackson to request that she should move forward with Tier 3 vehicle emission and fuel standards, and that she finalize those standards as soon as possible.

According to the National Association of Clean Air Agencies, by 2030 such standards will reduce overall mobile source emission of NO_x by 29 percent, CO by 38 percent and VOCs by 26 percent.

Organization: Environmental Defense Fund (EDF)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 175.]

We respectfully urge EPA to build from the foundation forged by California's leadership and immediately propose Tier 3 emissions and gasoline fuel standards for passenger vehicles and to finalize these protections by the summer of 2012. Such rigorous programs would have immediate and far-reaching health and environmental benefits.

Organization: Union of Concerned Scientists (UCS)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 140-141.]

In addition, we urge the EPA to move forward expeditiously with the next round of criteria pollutant standards -- the Tier 3 emissions and gasoline standards for passenger vehicles -- and to finalize these protections by the summer of 2012. A rigorous Tier 3 program would have immediate and far-reaching health and environmental benefits: Reducing harmful airborne contaminants, ensuring longer and healthier lives, and helping states and communities across our country to restore healthy air. These vital health protections will be achieved at an extremely modest cost. Timely finalization of Tier 3 standards would allow manufacturers to efficiently align technology upgrades with the proposed 2017 through 2025 fuel efficiency and greenhouse gas emissions standards.

Response:

These comments deal with a different rulemaking matter and so are outside the scope of this rulemaking.

22.1. Tier 3 Standards

Organizations Included in this Section

American Lung Association
California Air Resources Board (CARB)
Environmental Defense Fund (EDF)
Mercedes-Benz USA, LLC
Renewable Fuels Association (RFA)
South Coast AQMD

Organization: American Lung Association

Also, promulgation of a Tier 3 vehicle and fuels standard would complement the proposed rule while reducing overall mobile source emissions of nitrogen oxides by 29 percent, carbon monoxide by 38 percent and volatile organic compounds by 26 percent by 2030. [EPA-HQ-OAR-2010-0799-9902-A2, p. 2]

Organization: California Air Resources Board (CARB)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 14.]

We know that EPA is nearing completion of its Tier 3 proposal to address these same pollutants from passenger vehicles. We know this because we shared with you our assessment of the feasible standards and the implementation schedule, and we've worked together to reach a common understanding of the many testing and compliance details.

We urge you to propose and finalize this Tier 3 regulation as soon as possible. It will benefit the vehicle manufacturers in that they'll be able to build one car that meets California and EPA standards. And it will benefit California and our partner states by assuring that federally certified new cars that subsequently operate in our states will be as clean as those sold here and purchased by our citizens.

Organization: Environmental Defense Fund (EDF)

II. EDF URGES EPA TO FINALIZE TIER 3 STANDARDS IN 2012

We strongly urge EPA to immediately propose Tier 3 emissions and gasoline standards for passenger vehicles and to finalize these protections by the summer of 2012. A rigorous Tier 3 program would have immediate and far-reaching health and environmental benefits: reducing a cascade of harmful airborne contaminants, ensuring longer and healthier lives, and helping states and communities across our country restore healthy air. [EPA-HQ-OAR-2010-0799-9519-A1, p. 3]

In a May 2010 Rose Garden ceremony, President Obama announced his intention to finalize a Tier 3 program by 2012 that would reduce sulfur levels in gasoline and introduce cleaner cars and light trucks on the same schedule as his already-finalized greenhouse gas program. Proposing this program now will help ensure that the President's commitment is kept. And timely finalization of Tier 3 standards would allow manufacturers to efficiently align technology upgrades with the proposed fuel efficiency and greenhouse gas emissions standards. [EPA-HQ-OAR-2010-0799-9519-A1, pp. 3-4]

Millions of Americans breathe cleaner, healthier air as a result of the U.S. Environmental Protection Agency's leadership in carrying out our nation's clean air laws. But serious challenges remain. More than 1 in 3 Americans still live in areas where air pollutant levels exceed at least one of the health-based National Ambient Air Quality Standards. And passenger vehicles remain the second largest emitters of oxides of nitrogen and volatile organic compounds in the U.S. – the primary pollutants that form ozone. These vehicles also emit more than half of all carbon monoxide pollution and contribute significantly to lethal particulate matter emissions.15 [EPA-HQ-OAR-2010-0799-9519-A1, p. 3]

A protective Tier 3 program has the potential to cut gasoline vehicle emissions of nitrogen oxides by nearly sixty percent, carbon monoxide by about 38 percent, and volatile organic compounds by close to a third when these protections are carried out. The substantial emissions reductions from all vehicles will translate into more than 400 avoided premature deaths and 52,000 avoided lost workdays each year.16 [EPA-HQ-OAR-2010-0799-9519-A1, p. 4]

Reducing sulfur in gasoline will also result in an immediate reduction in emissions from the existing fleet – on the order of approximately 260,000 tons of nitrogen oxides in 2017 when the program begins – equivalent to taking 33 million cars off our nation's roads. And the additional cost to consumers of the cleaner gasoline would be less than a penny a gallon.17 [EPA-HQ-OAR-2010-0799-9519-A1, p. 4]

A timely federal Tier 3 program is also imperative for states to meet the health-based National Ambient Air Quality Standards, including the ozone standard adopted in 2008, which assumed final Tier 3 emissions and gasoline standards in its baseline. Emissions reductions not achieved through a rigorous Tier 3 program would have to come from controls on local sources, which could be far less significant in magnitude and less cost-effective. [EPA-HQ-OAR-2010-0799-9519-A1, p. 4]

Organization: Mercedes-Benz USA, LLC

DAG supports the agencies' efforts to implement the Tier III and LEV III programs and will continue to work towards a nationwide requirement for ultra low sulfur gasoline to maximize the potential for direct injection gasoline engines. [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

Organization: Renewable Fuels Association (RFA)

EPA/NHTSA must ensure the final standards are harmonized with the upcoming "Tier 3" vehicle and fuel standards. [EPA-HQ-OAR-2010-0799-9490-A1, p.2]

IN ADDITION TO MAKING CERTAIN THE PROPOSED CAFE/GHG STANDARDS ARE COMPLEMENTARY TO THE REQUIREMENTS OF RFS2, EPA MUST ALSO ENSURE THE FINAL STANDARDS ARE HARMONIZED WITH THE UPCOMING "TIER 3" VEHICLE AND FUEL STANDARDS. [EPA-HQ-OAR-2010-0799-9490-A1, p.6]

In the current CAFE/GHG proposal, EPA states that it will propose Tier 3 vehicle and fuel standards "in the near future." The Tier 3 rulemaking, which EPA acknowledges will generally apply to the "same set of new vehicles…as would the proposed light-duty GHG emissions standards," is expected to set new limits for tailpipe and evaporative emissions from light-duty vehicles, including volatile organic compounds, nitrogen oxides, particulate matter, and air toxics. EPA acknowledges the need for close coordination of the Tier 3 rules with the CAFE/GHG standards, such that automakers and fuel providers can most effectively plan for the future regulatory landscape. [EPA-HQ-OAR-2010-0799-9490-A1, p.7]

Vehicle engines, the fuels that power them, and emissions control systems must be considered as equally important components of integrated systems. Thus, EPA/NHTSA should take a systems approach to the coordination of pending and existing regulations that affect both future fuel composition and future vehicle and engine technology. It is absolutely critical that EPA/NHTSA ensure the requirements of one rule don't impede the regulated community's ability to comply with the requirements of separate, but related, rules. [EPA-HQ-OAR-2010-0799-9490-A1, p.7]

Organization: South Coast AQMD

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 70-71.]

While the focus of the proposed rule is on greenhouse gas emissions, we urge U.S. EPA to move forward with proposals to set criteria pollutant tailpipe emissions standards as soon as possible.

Response:

These comments all deal with issues outside the scope of this rulemaking.

22.2. Changes to Fuel Specifications

Organizations Included in this Section

Alliance of Automobile Manufacturers
American Petroleum Institute (API)
Growth Energy
Volvo Car Corporation (VCC)

Organization: Alliance of Automobile Manufacturers

Fuel quality improvement can help further the program goals. As EPA has requested, the Alliance plans to make its substantive comments about market fuel quality specifications within the context of the pending EPA "Tier 3" proposed rule (and perhaps independently as well, separate from the Tier 3 rulemaking) and will not elaborate on them here. We want to note, however, that fuel quality can have a significant impact on fuel efficiency and GHG emission reductions. [EPA-HQ-OAR-2010-0799-9487-A1, pp.5-6]

In the meantime, it is expected that market fuel sulfur content and possibly other fuel properties will be addressed as part of the pending EPA "Tier 3" rulemaking. As noted above, market fuel developments need to be part of the planned Mid Term Evaluation incorporated in this rule. [EPA-HQ-OAR-2010-0799-9487-A1, p.85]

As EPA has requested, the Alliance plans to make its substantive comments about market fuel quality specifications within the context of the pending EPA "Tier 3" proposed rule (and perhaps independently as well, separate from the Tier 3 rulemaking) and will not elaborate on them here. [EPA-HQ-OAR-2010-0799-9487-A1, p.85]

Alliance members want to underscore for the rulemaking record and any future regulatory review that in reserving substantive comments on fuel quality to the pending Tier 3 rulemaking as requested, we recognize that considerable benefits could inure to fuel efficiency and economy, and GHG emission reductions (and thus to the relevant statutory authority for this rulemaking), from fuel quality changes addressed elsewhere. We are relying on the agency that consideration of such benefits and reliance on such authority will not be foreclosed by reserving our fuel quality comments for the Tier 3 rulemaking or other rulemaking initiatives. [EPA-HQ-OAR-2010-0799-9487-A1, p.85]

Organization: American Petroleum Institute (API)

EPA's Plans for Further Standards for Light-Duty Vehicle Criteria Pollutants and Gasoline Fuel Quality

EPA references plans to propose a "Tier 3" program of emissions and fuel quality standards intended to further reduce non-GHG pollutants (including volatile organic compounds, nitrogen oxides, particulate matter, and air toxics) from new light-duty vehicles. API and its members firmly support the principle that no Tier 3 regulation of fuel quality should be proposed without first providing a thorough science-based justification that demonstrates the health benefits along with a rigorous economic and supply impact analysis that assesses fundamental cost and energy security consequences related to the viability of a domestic refining industry. As noted above, vehicle technologies that might require fuel changes are not likely to be employed for meeting the CAFE standards proposed for MY 2017 – 2025 light-duty vehicles. [EPA-HQ-OAR-2010-0799-9469-A1, p. 8]

Until EPA releases data and analysis on the benefits of the Tier 3 standards under consideration, a comprehensive fuel/vehicle system-focused assessment cannot be conducted or evaluated by stakeholders and/or the public. In this regard, EPA should complete an Anti-Backsliding study of the RFS program and make it available for public scrutiny and comment prior to proposing any rule to change fuel quality. Congress mandated the study, which is now more than two years overdue. In addition, EPA has indicated to industry that it has been performing emissions measurements on in-use vehicles operated on gasoline fuels containing significantly lower levels of sulfur. These data and EPA's associated analyses also need to be made publicly available prior to the issuance of a proposed rule. Absent these actions and a demonstration that fuel changes will achieve cost effective emissions reductions that would improve air quality or have other health benefits, EPA should not propose a Tier 3 Rule. By moving forward with a Tier 3 proposal, EPA is making conclusions based on an incompletely vetted set of data and analysis and is allowing scant time for scrutiny from interested stakeholders. [EPA-HQ-OAR-2010-0799-9469-A1, p. 9]

• Tier 3 fuel requirements are unnecessary and unjustified - The EPA should not link a Tier 3 program of non-GHG emissions and fuel quality standards for new light-duty vehicles to the referenced proposed rulemaking. The EPA has not yet completed long overdue studies mandated by Congress, nor has it conducted and released a thorough science-based justification that demonstrates the need for Tier 3. Finally, the Agency has yet to provide stakeholders with adequate opportunity to evaluate and submit input on all of the data and analysis that it has collected and performed to support such an initiative. [EPA-HQ-OAR-2010-0799-9469-A2, p. 2]

Organization: Growth Energy

II. Potential Fuel Parameter Changes

A. Background

In the Joint NPRM EPA did not evaluate potential fuel quality changes in the GHG proposal. The proposed rule contains the following discussion with respect to the Tier 3 standards and possible fuel changes: In the May 21, 2010 Presidential Memorandum, in addition to addressing GHGs and fuel economy, the President also requested that EPA examine its broader motor vehicle air pollution control program. The President requested that ''[t]he Administrator of the EPA review for adequacy the current nongreenhouse gas emissions regulations for new motor vehicles, new motor vehicle engines, and motor vehicle fuels, including tailpipe emissions standards for nitrogen oxides and air toxics, and sulfur standards for gasoline. If the Administrator of the EPA finds that new emissions regulations are required, then I request that the Administrator of the EPA promulgate such regulations as part of a comprehensive approach toward regulating motor vehicles.'' [EPA-HQ-OAR-2010-0799-9505-A1, p. 31]

EPA is currently in the process of conducting an assessment of the potential need for additional controls on light-duty vehicle non-GHG emissions and gasoline fuel quality. EPA has been actively engaging in technical conversations with the automobile industry, the oil industry, nongovernmental organizations, the states, and other stakeholders on the potential need for new regulatory action, including the areas that are specifically mentioned in the Presidential

Memorandum. EPA will coordinate all future actions in this area with the State of California. [EPA-HQ-OAR-2010-0799-9505-A1, p. 32]

Based on this assessment, in the near future, EPA expects to propose a separate but related program that would, in general, affect the same set of new vehicles on the same timeline as would the proposed light-duty GHG emissions standards. It would be designed to address air quality problems with ozone and PM, which continue to be serious problems in many parts of the country, and light-duty vehicles continue to play a significant role. [EPA-HQ-OAR-2010-0799-9505-A1, p. 32]

EPA expects that this related program, called ''Tier 3'' vehicle and fuel standards, would among other things propose tailpipe and evaporative standards to reduce non-GHG pollutants from light-duty vehicles, including volatile organic compounds, nitrogen oxides, particulate matter, and air toxics. EPA's intent, based on extensive interaction to date with the automobile manufacturers and other stakeholders, is to propose a Tier 3 program that would allow manufacturers to proceed with coordinated future product development plans with a full understanding of the major regulatory requirements they will be facing over the long term. This coordinated regulatory approach would allow manufacturers to design their future vehicles so that any technological challenges associated with meeting both the GHG and Tier 3 standards could be efficiently addressed. [EPA-HQ-OAR-2010-0799-9505-A1, p. 32]

It should be noted that under EPA's current regulations, GHG emissions and CAFE compliance testing for gasoline vehicles is conducted using a defined fuel that does not include any amount of ethanol. If the certification test fuel is changed to some ethanol-based fuel through a future rulemaking, EPA would be required under EPCA to address the need for a test procedure adjustment to preserve the level of stringency of the CAFE standards.26 EPA is committed to doing so in a timely manner to ensure that any change in certification fuel will not affect the stringency of future GHG emission standards. [EPA-HQ-OAR-2010-0799-9505-A1, p. 32]

The discussion indicates EPA will evaluate changes to certification fuel in Tier 3, and if there are changes made to this certification fuel, that EPA would be required under EPCA to preserve the stringency of the GHG standards. Thus, EPA acknowledges that certification fuel has an effect on GHG emissions, and therefore also acknowledges that vehicles and fuels operate as a system, not only for the criteria pollutants like PM and NO_x, but also GHGs. And yet, EPA did not evaluate changes in fuel for the GHG rule. Growth Energy believes that because vehicles and fuels are obviously inseparable when it comes to both criteria pollutants and GHG emissions, that the Agencies should have evaluated both changes to vehicles and fuels for the GHG rule. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 32-33]

EPA has not yet published its Tier 3 proposal, and it is possible that EPA will propose new certification fuel requirements that directly affects the ability of automakers to meet the GHG requirements. Therefore, new certification fuels should have been examined in the GHG requirements, and it is in this context that Growth Energy proposes a new certification and in-use fuel for 2017 and later cars and light duty trucks. We believe that EPA and the Agencies should examine this proposed certification and in-use fuel as an alternative in developing the final GHG/CAFÉ rules for 2017-2025 vehicles. [EPA-HQ-OAR-2010-0799-9505-A1, p. 33]

Growth Energy's proposal for 2017 certification fuel is shown in Table 3. This certification fuel is essentially the same as the Alliance of Automobile Manufacturer's proposal to CARB, but with the addition of 20 volume percent more ethanol, so that octane is higher, the distillation parameters are changed, and other parameters are lower by dilution. [Table 3 can be found on p. 33 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, p. 33]

Fuel marketers would be required to produce fuel that would be similar to this proposed fuel for 2017+ vehicles.27 In conventional areas of the U.S., it would meet EPA's sulfur, MSAT and RVP regulations, but still have 94 octane and 30% ethanol. In reformulated gasoline areas, it would meet the requirements of the RFG regulations, the low sulfur regulations, and the MSAT and RVP regulations, but otherwise have 94 octane and 30% ethanol. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 33-34]

Most of the U.S. already has E10, so both RFG and conventional fuel already contains E10 for the current fleet. Adding 20% more ethanol to these fuels would increase octane, reduce sulfur, reduce RVP, reduce total and multi-substituted aromatics, olefins, benzene, and change the T50 and T90 points. [EPA-HQ-OAR-2010-0799-9505-A1, p. 34]

Other concepts of this proposal are as follows:

- Automakers would certify 2017+ vehicles only on E30, they would not be required to certify on E10. The legacy fleet would continue to operate on E10
- Ramp-up of ethanol for E30 would build with the introduction of each successive model year of 2017+ vehicles. Ethanol would have to be used preferentially for E30, then for E10 in the legacy fleet.
- There may be a net positive impact on upstream GHG emissions from producing the base gasoline (normalized to gasoline volume); this would have to be evaluated [EPA-HQ-OAR-2010-0799-9505-A1, p. 34]

The primary advantages of implementing this type of fuel are:

- Low carbon intensity ethanol volumes ramp up slowly from calendar year 2017 as the new vehicles using this fuel are introduced into the fleet, and continue ramping up well beyond the 2020-2022 timeframe, providing ongoing upstream (i.e., lifecycle) GHG reductions well into the future (through 2040) beyond the RFS.
- Currently the cellulosic projections in the RFS are not being met in part because the United States ethanol market is saturated by E10. Creating an E30 certification fuel would send a fresh market signal to the cellulosic industry that market space is being created through this new fuel standard. To meet the 36 billion gallon biofuel projection by 2022, market access for advanced (50% lifecycle emissions reduction) and cellulosic ethanol (60% lifecycle emissions reduction) must be offered a path. This proposal would provide that opportunity as well as the other benefits a higher octane standard would offer.
- Automakers should be able to use the higher octane ethanol fuel to boost engine efficiency beyond the engine efficiency obtained from the current Agency proposal

(tailpipe GHG emissions would be the same as the Agency proposal), maintaining the same fuel economy and vehicle range

- Importantly, exhaust Particulate Matter (PM) emissions and carbon monoxide (CO) emissions from 2017-2025 model year vehicles would be much lower than the current proposal because of increased fuel oxygen content. [EPA-HQ-OAR-2010-0799-9505-A1, p. 34]

Other criteria pollutant emissions (exhaust and evaporative NMOG and NO_x) from onroad 2017+ motor vehicles should be the same with E30 as with current certification fuel, whether they are Tier 2 or Tier 3 vehicles, since the same tailpipe and evaporative standards must be met. Distribution of the E30 fuel should ultimately be no more difficult than E85 distribution, which has to take place anyway because of the RFS. The slow phase-in of E30 gives time for additional low carbon intensity (i.e., cellulose and other) ethanol supplies to develop. [EPA-HQ-OAR-2010-0799-9505-A1, p. 35]

It is also important to note that Tier 2 and Tier 3 vehicles will have to meet very low emission standards for evaporative NMOG, exhaust NMOG, CO, and NO_x, no matter what fuel they are certified on. So ultimately, there should be no difference in these emissions between an E10 fuel and an E30 fuel. A number of manufacturers offer FFVs that meet Tier 2 and emission standards on E85 and E0 now. Increasing ethanol from E10 to E30 reduces fuel volatility, so depending on a final volatility specification, meeting evaporative requirements could be somewhat less difficult with an E30 blend. Fuel system permeation also contributes to evaporative emissions. Permeation emissions have not been studied on E30 blends, but a Coordinating Research Council study on permeation from ethanol blends between E6 and E20 found that increasing ethanol content from E10 to E20 increased diurnal permeation emissions by about 16% on five vehicles, however, one FFV that was tested experienced lower permeation emissions on E20 than E10. This factor should also be considered in a revised cost-benefit analysis. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 40-41]

---

26 EPCA requires that CAFE tests be determined from the EPA test procedures in place as of 1975, or procedures that give comparable results. 49 USC 32904(c).

27 Subject to approval/oversight by EPA and others, E30 could be marketed to FFVs prior to calendar year 2017. Current FFV customers probably often have E30 in their fuel tanks if they switch back-and-forth between E85 and E0.

Organization: Volvo Car Corporation (VCC)

Certification Gasoline and Harmonization

VCC supports a single certification fuel for EPA and CARB. It is expensive and inefficient to develop toward and store several different fuels to meet two nearly identical regulations. [EPA-HQ-OAR-2010-0799-9551-A2, p. 13]

When EPA/NHTSA/CARB require different fuels, it effectively doubles the amount of testing manufacturers are required to perform, while yielding limited, if any, additional environmental benefit. Even though it appears that 10% ethanol is likely to be the most common fuel on the U.S. market for the foreseeable future, EPA has, through the upcoming TIER3 regulation, indicated that it will require E15. [EPA-HQ-OAR-2010-0799-9551-A2, p. 13]

The consequence of this would be that CARB and EPA will have different certification gasoline requirements. To eliminate unnecessary duplicative testing, VCC has requested that CARB accept certification using the EPA proposed fuel from MY2017. VCC requests though that EPA/NHTSA/CARB reach a harmonized approach toward a national fuel for certification after reaching a common approach towards harmonized definition of CO_2 and fuel economy. [EPA-HQ-OAR-2010-0799-9551-A2, p. 14]

Response:

These comments regarding possible changes to fuel specifications under a future EPA Tier 3 rulemaking are outside the scope this GHG rulemaking.

23. Request for Extension of the Comment Period

Organizations Included in this Section

Association of Global Automakers, Inc. (Global Automakers)
National Automobile Dealers Association (NADA)
Volkswagen

Organization: Association of Global Automakers, Inc. (Global Automakers)

The Association of Global Automakers, Inc. hereby requests a 30-day extension from January 30, 2012 to March 1, 2012 to submit its comments on the Notice of Proposed Rulemaking (NPRM) for 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards [76 FR 74854, December 1, 2011]. [EPA-HQ-OAR-2010-0799-1307-A1, p.1]

The need for this extension is underscored by the following: [EPA-HQ-OAR-2010-0799-1307-A1, p.1]

1. The complexity, cost, and importance of this rulemaking warrant allowing all stakeholders sufficient time to review and understand the extensive Federal Register and supporting documents and to provide meaningful feedback to the agencies. Although the basic outline of the proposal was announced in advance through a supplemental notice of intent, the details of the proposal were not publicly available until the issuance of the proposal. These details are of critical importance to participants in the rulemaking in developing a full understanding of the potential impacts of this far-reaching rulemaking. [EPA-HQ-OAR-2010-0799-1307-A1, p.1]

2. The release of this rulemaking corresponds to the release of other complex and significant rulemaking documents by the California Air Resources Board (ARB), which are not limited to GHG standards but also include proposals for the next round of low emission vehicle criteria pollutant standards for 2015+ vehicles, zero emission vehicles, clean fuels outlets, and environmental performance labeling. [EPA-HQ-OAR-2010-0799-1307-A1, p.1]

3. The current end date of the comment period falls on the heels of the public hearings, which will require additional time and resource commitments: [EPA-HQ-OAR-2010-0799-1307-A1, p.1]

a. The public hearings for the EPA-NHTSA proposal are scheduled on January 17, 19, and 24, 2012. [EPA-HQ-OAR-2010-0799-1307-A1, p.1]

b. The ARB Board hearing on the aforementioned California regulations is scheduled for January 26-27, 2012. [EPA-HQ-OAR-2010-0799-1307-A1, p.1]

These overlapping and important rulemaking activities, in combination with the approaching holiday season, make a modest extension of the comment period even more compelling. All of our member companies and the auto industry generally are closed during the week between Christmas and New Years Day, making communications among the Association and our members extremely difficult. [EPA-HQ-OAR-2010-0799-1307-A1, pp.1-2]

Furthermore, as noted in the NPRM and the Notice of Public Hearings for the proposal [76 FR 76932, December 9, 2011], NHTSA and EPA are required to “keep the official record of each hearing open for 30 days to allow speakers to submit supplementary information” [76 FR 76933], as required by § 7607 (d)(5)(iv) of the Clean Air Act. Therefore, the public hearing record must remain open until February 23, 2012 or so. Thus, approving our request would have no material impact on the rulemaking schedule. [EPA-HQ-OAR-2010-0799-1307-A1, p.2]

Organization: National Automobile Dealers Association (NADA)

By this letter, NADA requests an extension of the January 30, 2012, comment period deadline for the above-referenced proposed rulemaking for an additional 30 days or until February 29, 2012. 76 Fed. Reg. 76932, et seq. (December 9, 2011). In support of this request, please recognize and consider the following: [EPA-HQ-OAR-2010-0799-1308-A1, p.1]

1. The joint proposal is 567 Federal Register pages long. It is accompanied by a 482 page Draft Joint Technical Support Document, an 833 page Preliminary Regulatory Impact Analysis, and a 482 page Draft Environmental Impact Statement. These three documents cite hundreds of other documents. In addition, the EPA docket currently contains 726 non-comment documents and the NHTSA docket currently contains 148 non-comment documents. Despite an intention to devote substantial resources to the task, NADA cannot complete a review of these documents by January 30, 2012. [EPA-HQ-OAR-2010-0799-1308-A1, p.1]

2. On December 9, 2011, NHTSA and EPA issued a notice with details regarding three public hearings on the proposal. 76 Fed. Reg. 76932-3 (December 9, 2011). NADA immediately arranged for three dealers to testify at these hearings, sending an e-mail to EPA with the specifics requested in the December 9 notice. Consequently, in addition to developing comments responding to the joint proposal, NADA will be working diligently to assist these dealers with the development of their testimony. Given the short time frame involved, this will be a daunting task. [EPA-HQ-OAR-2010-0799-1308-A1, p.2]

3. As recognized by EPA and NHTSA, the Clean Air Act requires that the records for the hearings discussed above be kept open for at least 30 days following each hearing. 42 USC §7607(d)(5). At the very least, this means that EPA must accept written submissions pertaining to the January 24, 2012, hearing until at least February 23, 2012. 42 USC §7607(d)(5). Consequently, extension of the comment period to February 29, 2012, will have no negative consequences for the regulatory development process. [EPA-HQ-OAR-2010-0799-1308-A1, p.2]

4. On December 7, 2011, the California Air Resources Board (CARB) announced a voluminous package of advanced Clean Car Rules. These rules in part relate to the NHTSA/EPA proposal and, if promulgated and granted a preemption waiver, will apply (at least in part) in as many as

15 states. Consequently, NADA's limited resources also are burdened with reviewing and responding to this CARB proposal, a hearing for which is scheduled for January 26-27, 2012. [EPA-HQ-OAR-2010-0799-1308-A1, p.2]

5. The NHTSA/EPA proposal seeks to establish CAFE and GHG mandates which, at the earliest, would begin to take effect in MY 2017. The proposal is not tied to a specific statutory deadline. Indeed, the 35 mpg standard recently promulgated for MY 2016 will kick in some four years earlier than Congress contemplated. 49 USC §32902(b)(2)(A). In any event, new CAFE standards must be issued at least 18 months prior to the model year in question. 49 USC §32902(a). In addition, new GHG standards may not issue sooner than the model year commencing 4 years after they are promulgated. 42 USC §7521(a)((3)(C). Thus, affording interested parties an additional 30 days to submit comments will neither conflict with a statutory deadline nor interfere with existing statutory mandates designed to provide vehicle manufacturers with adequate lead time. [EPA-HQ-OAR-2010-0799-1308-A1, p.2]

6. Of primary importance is the issue of fair and adequate due process. Persons potentially impacted by the December 1, 2011, proposal are entitled to a reasonable opportunity to provide comment and testimony to the record. In this regard, NADA appreciates the fact that NHTSA and EPA allowed interested parties the opportunity to provide input in response to several Notices of Intent leading up to the proposal. NADA also applauds the three hearing opportunities mentioned above. It is in light of these fair and adequate opportunities for public participation that NADA urges NHTSA and EPA to recognize that 60 days is an insufficient amount of time for interested parties to develop and submit written comments on what may well be the most voluminous, most far reaching, and most expensive regulatory proposal ever issued by the Federal government. [EPA-HQ-OAR-2010-0799-1308-A1, p.2]

7. For comparison purposes, NADA pulled from its stack of regulatory notices two recently issued items of interest to its members. The first, an EPA notice of some 89 pages involving proposed management standards for the underground storage tanks sometimes found at dealerships, allows for a 90 day comment period. 76 Fed. Reg. 71708, et seq. (November 18, 2011). The docket for this proposal currently contains a mere 211 documents. The second, a NHTSA notice involving Theft Protection and Rollaway Prevention is 17 pages long yet it also affords 90 days for public comment. 76 Fed. Reg. 77183, et seq. (December 12, 2011). The docket for that proposal currently contains roughly 2 documents. Note that NADA is in no way suggesting that these proposals are any less important than the joint CAFE/GHG proposal, only that they would appear to be no more (and arguably far less) complex and burdensome for interested parties to digest and respond to. [EPA-HQ-OAR-2010-0799-1308-A1, p.3]

For all of the above-listed reasons, NADA urges NHTSA and EPA to extend the comment period in this matter to February 29, 2012. [EPA-HQ-OAR-2010-0799-1308-A1, p.3]

In mid-December, NADA petitioned NHTSA and EPA for a 30 day extension of the 60 day comment period. A month later, a 14 calendar day extension was granted. Hearings on the proposal were held on January 17, January 19, and January 24, 2012, with NADA dealer-directors presenting testimony at each. The hearing records remain open for 30 days. [EPA-HQ-OAR-2010-0799-9575-A1, p. 2]

Organization: Volkswagen

With this letter Volkswagen Group of America (Volkswagen) requests a 30 day extension to the comment period for the Notice of Proposed Rulemaking (NPRM) for 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards (76 FR 748S4, December 1, 2011). Volkswagen requests that the comment period be extended from January 30, 2012 to February 29, 2012. [EPA-HQ-OAR-2010-0799-1309-A1, p.1]

The reasons to extend the comment period are compelling. [EPA-HQ-OAR-2010-0799-1309-A1, p.1]

• The regulation is extremely long, complex and costly. Sufficient time is required for all stakeholders to thoroughly review the regulation and all the supporting documents that detail the agency analysis that has led to the proposal published on December 1, 2011. While the overall program was outlined earlier this year with the publication of the Supplemental Notice of Intent (SNOI), there are many aspects of the joint regulation that are available for the very first time with the publication of the NPRM. [EPA-HQ-OAR-2010-0799-1309-A1, p.1]

• During the month of January EPA and NHTSA have scheduled 3 hearings to present this complex regulation to the public and allow all stakeholders a chance to comment on the details of the regulation. The short time frame between the hearings and the close of the comment period and the fact that discussions that result from the hearings may also need to be addressed in stakeholder comments lends additional need for an extension. [EPA-HQ-OAR-2010-0799-1309-A1, p.2]

• This joint regulation from EPA and NHTSA also coincides with a lengthy and complex regulation issued by the state of California. The proposed regulation from California, in addition to detailing their version of the Greenhouse Gas regulation that will be part of the National Program, also proposes complex and costly regulations for criteria pollutants, evaporative emissions, the California 2EV Program, changes to certification fuel and the Clean Fuels Outlet Program. [EPA-HQ-OAR-2010-0799-1309-A1, p.2]

• Ninety day comment periods are typical and are appropriate given the size and scope of this regulation and the sheer volume of supporting documents. [EPA-HQ-OAR-2010-0799-1309-A1, p.2]

• A 30 day extension should have no impact on the timing for the publication of the final regulation. [EPA-HQ-OAR-2010-0799-1309-A1, p.2]

<u>Response:</u>

EPA in fact extended the public comment period in response to the above requests.

24. Comments Regarding PSD/Title V Implications and Pending GHG Lawsuits

Organizations Included in this Section

American Fuel and Petrochemical Manufacturers (AFPM)
American Petroleum Institute (API), National Association of Manufacturers (NAM), and American Fuel & Petrochemical Manufacturers (AFPM)
National Association of Manufacturers (NAM)
Utility Air Regulatory Group (UARG)

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

I. EPA's GHG CAFE Standards are Under Judicial Review. [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

The legal effect of EPA's original light-duty vehicle GHG regulation is under judicial review and the implications of that challenge likely will impact this rulemaking. Extensive, unreasonably stringent GHG emissions standards for light-duty vehicles (LDVs) are not required by statute or by the 2007 U.S. Supreme Court decision in Massachusetts v. EPA. Although section 102 of the Energy Independence and Security Act of 2007 (Public Law 110-140, hereinafter EISA) requires the Secretary of Transportation to establish automobile fuel economy standards for model years through 2020, there is no statute requiring EPA to set GHG emission standards for LDVs. While section 202(a) of the Clean Air Act (CAA) requires the Administrator of EPA to set standards "which in [her] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare," the CAA does not require excessive or stretch standards. [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

On April 2, 2007, the U.S. Supreme Court held that EPA has the statutory authority to regulate GHG emissions from new motor vehicles. Although the Supreme Court recognized that EPA has "significant latitude as to the manner, timing, [and] content" of its regulations, this Supreme Court decision in 2007 did not mandate GHG emissions rulemakings. [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

EPA is involved in at least four related lawsuits: [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

• GHG endangerment, [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

• GHG/CAFE standards for LDVs (MYs 2012-2016), [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

• GHG Prevention of Significant Deterioration (PSD) "tailoring," and [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

• GHG PSD, review of 12/18/08 "Johnson memo" - also called "grounds arising after." [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

Oral argument is scheduled for February 28 and 29, 2012 by the U.S. Court of Appeals for the D.C. Circuit for all four of these lawsuits. A decision is expected in 2012 and will have ramifications for a final rule for LDVs beginning with MY 2017. Judicial decisions on all four lawsuits are likely before EPA and NHTSA promulgate a joint final rule for LDVs after MY 2016. Therefore, this proposal for MYs after 2016 is premature and presumptive. [EPA-HQ-OAR-2010-0799-9485-A1, p.2]

EPA's LDV rule for MYs 2012-2016 has been challenged as arbitrary, capricious, and otherwise not in accordance with law because EPA: (1) failed to address the broad consequences for stationary sources that automatically result from that rule; (2) refused to analyze the extraordinary burdens on other source categories imposed by that rule; (3) failed to give meaningful consideration to the option of deferring regulation; and (4) failed to justify its rule by articulating any rational connection between the alleged endangerment and EPA's selected standards. EPA should delay promulgation of this rule to fully consider the implications of this judicial review. The agency's LDV proposal is similarly arbitrary and capricious in its failure to address these problems for LDVs with MYs after 2016. [EPA-HQ-OAR-2010-0799-9485-A1, pp.2-3]

As a result of its improper interpretation of the Clean Air Act, EPA has also asserted that the LDV rule for MYs 2012-2016 triggers an obligation to regulate GHG emissions from stationary sources under the Prevention of Significant Deterioration (PSD) and Title V permitting programs. AFPM strongly opposes any approach to implementing mobile source standards that could impact such a wide swath of unrelated stationary sources. AFPM has filed joint comments with American Petroleum Institute and the National Association of Manufacturers that address the proposed rule's potential impact on stationary sources and explain why EPA's improper interpretation renders the rulemaking arbitrary and capricious. We hereby incorporate by reference those joint comments in this submission. In short, EPA should not assert that this rule acts as an independent trigger for the PSD program, requiring regulation of GHG emissions from stationary sources, particularly in the face of an imminent court decision vacating elements of EPA's existing GHG regulatory regime. [EPA-HQ-OAR-2010-0799-9485-A1, p.3]

Organization: American Petroleum Institute (API), National Association of Manufacturers (NAM), and American Fuel & Petrochemical Manufacturers (AFPM)

Regardless of the substance and stringency of the actual greenhouse gas (GHG) standards that EPA proposes to impose on light-duty vehicles, the Associations strongly oppose any approach to implementing mobile source standards in a manner that impacts a wide swath of unrelated stationary sources.1 As of January 2, 2011, as a result of a prior rulemaking for model year 2012-2016 light-duty vehicles, EPA has begun imposing significant and unprecedented GHG permitting requirements on stationary sources around the nation. It has accomplished this through "four related actions that, taken together, trigger [permitting requirements] for GHG sources on and after January 2, 2011." Action to Ensure Auth. to Issue Permits under the Prevention of Significant Deterioration Program to Sources of Greenhouse Gas Emissions: Finding of Substantial Inadequacy and SIP Call (Proposed SIP Call), 75 Fed. Reg. 53,892, 53,895 (Sept. 2, 2010) (emphasis added). These four actions are: [EPA-HQ-OAR-2010-0799-9509-A1, p. 2]

- the “Endangerment Finding,” Endangerment and Cause or Contribute Findings for GHGs under Section 202(a) of the Clean Air Act, 74 Fed. Reg. 66,496 (Dec. 15, 2009);
- the “Car Rule,” Light-Duty Vehicle GHG Emission Standards and Corporate Average Fuel Economy Standards, 75 Fed. Reg. 25,324 (May 7, 2010);
- the “PSD Interpretive Memorandum,” Reconsideration of Interpretation of Regulations that Determine Pollutants Covered by Clean Air Act Permitting Programs, 75 Fed. Reg.
- 17,004 (April 2, 2010); and
- the “Tailoring Rule,” Prevention of Significant Deterioration and Title V Greenhouse Gas Tailoring Rule, 75 Fed. Reg. 31,514, 31,557 (June 3, 2010). [EPA-HQ-OAR-2010-0799-9509-A1, p. 2]

EPA explained that, in its view, the Car Rule regulations, “when they [took] effect on January 2, 2011, . . . subject GHGs emitted from stationary sources to” permitting requirements. Proposed SIP Call, 75 Fed. Reg. at 53,892. [EPA-HQ-OAR-2010-0799-9509-A1, p. 3]

As explained in the Associations’ comments on each of these four actions, EPA’s decision to impose GHG permitting requirements on stationary sources as a result of the implementation of mobile source standards is “arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law” as well as being adopted “without observance of procedure required by law.” 42 U.S.C. § 9607(d)(9)(A),(D). Consequently, the Associations, as part of a coalition of trade associations, have petitioned the United States Court of Appeals for the District of Columbia Circuit to review each of the four related actions, that, in EPA’s view, trigger GHG permitting requirements. See National Association of Manufacturers et al. v. EPA, D.C. Cir Nos. 10-1044, 10-1127, 10-1166, 10-1218. The Associations have also challenged other EPA regulations that EPA has suggested could have a role in triggering GHG permitting requirements. See National Association of Manufacturers et al v. EPA, D.C. Cir. Nos. 10-1177, 10-1178, 10-1179, 10-1180. Oral argument is scheduled in these cases for February 28 and 29, 2012. [EPA-HQ-OAR-2010-0799-9509-A1, p. 3]

EPA has taken additional action by promulgating the “Truck Rule,” Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles, 76 Fed. Reg. 57,106 (Sept. 15, 2011). The Truck Rule is analogous to the Car Rule in that it sets standards for the quantity of GHGs that a vehicle may emit for a given amount of distance covered or work performed. Id. at 57,115. In the likely event that the Car Rule is vacated by the D.C. Circuit, EPA may continue to assert that the Truck Rule serves as a trigger for GHG permitting requirements for stationary sources. See EPA, “Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Vehicles: EPA Response to Comments Document for Joint Rulemaking,” EPA-420-11-004, at p. 2-8 (Aug. 2011). Thus, several of the Associations, as part of a coalition of trade associations, have also petitioned the United States Court of Appeals for the District of Columbia Circuit to review the Truck Rule. See American Petroleum Institute et al v. EPA, D.C. Cir No. 10-1440. That case has not yet been briefed or set for argument. [EPA-HQ-OAR-2010-0799-9509-A1, p. 3]

Like the initial Car Rule, the 2017 Car Rule sets standards for the quantity of GHGs that a vehicle may emit for a given distance travelled. 2017 Car Rule, 76 Fed. Reg. 74,976. In the context of the initial car rule, EPA inappropriately and illegally took the position that the Car

Rule triggers GHG permitting requirements for stationary sources. Consequently, as it did in the Car Rule and Truck Rule dockets, the Associations submit these comments explaining why it is arbitrary and capricious or otherwise unlawful for EPA to adopt the 2017 Car Rule while maintaining its illegal interpretation that Clean Air Act (CAA) permitting requirements for stationary sources are triggered by vehicle emissions standards such as those proposed here or adopted in the Car Rule and Truck Rule. [EPA-HQ-OAR-2010-0799-9509-A1, p. 3]

EPA has not yet asserted that this rulemaking would independently have the same triggering effect on stationary source GHG regulations as the Car Rule and Truck Rule despite the fact that it also seeks to regulate GHG emissions from the transportation sector. 2017 Car Rule, 76 Fed. Reg. 74,963. In general, EPA's position is that "any impacts on stationary sources arise because of express statutory requirements in the CAA, not as a result of vehicle regulation. Moreover, GHGs have become subject to regulation under the CAA by virtue of other regulatory actions taken by EPA before this proposal." Id. at 75,162. In the final 2017 Car Rule, EPA should clarify whether, in the likely event that the Car Rule and Truck Rule are vacated, it would cite to the 2017 Car Rule as an independent trigger for GHG stationary source permitting requirements. [EPA-HQ-OAR-2010-0799-9509-A1, pp. 3-4]

As explained below, finalizing the 2017 Car Rule would be arbitrary and capricious and unlawful because EPA has not corrected its interpretation of the CAA to provide that vehicle emission standards do not trigger GHG stationary source permitting requirements. Thus, EPA should not finalize the 2017 Car Rule with an incorrect interpretation of the CAA. In the alternative, the NHTSA standards would realize equivalent GHG reductions without CAA ramifications on stationary sources. Further, EPA has not considered the costs or ramifications that the 2017 Car Rule will impose on stationary sources by triggering GHG permitting requirements in violation of numerous laws and Executive Orders, as well as the Administrative Procedure Act. Lastly, finalizing the 2017 Car Rule would also be arbitrary and capricious and unlawful because the rule is predicated on an invalid endangerment finding. [EPA-HQ-OAR-2010-0799-9509-A1, p. 4]

The Associations further elaborate on these issues below. They also incorporate by reference here each of the comments that they submitted on the actions that comprise EPA's regulatory scheme to impose PSD permitting requirements as a result of mobile source standards2 as well as their Petition to Reconsider, Rescind and/or Revise EPA's Prevention of Significant Deterioration Regulations. Because EPA is relying on a similar flawed approach and interpretation in the context of the 2017 Car Rule, the Associations' positions in those comments are germane here and are incorporated herein in their entirety. These comments, hereby submitted as comments to the 2017 Car Rule docket, are attached as Exhibits A through J, and should be considered as part of and incorporated into the Associations' submission of comments to the 2017 Car Rule. Below, the Associations summarize key positions but do not waive the more complete set of arguments made in the comments in the five rulemakings and attached herein. [Exhibits A through J can be found on pp. 12-397 of Docket number EPA-HQ-OAR-2010-0799-9509-A1] [EPA-HQ-OAR-2010-0799-9509-A1, p. 4]

I. EPA Must Correct Its Mistaken View That Mobile Source Emission Standards Trigger GHG Permitting Requirements

EPA has stated that, in its view, the Car Rule's vehicle emission standards took effect on January 2, 2011, and as a result triggered GHG permitting requirements for stationary sources as of that date under two programs: the Title V operating permit program; and the Prevention of Significant Deterioration (PSD) pre-construction permit program. PSD Interpretive Rule, 75 Fed. Reg. at 17,019–20. EPA has not expressly announced whether it would take the same position regarding the vehicle emission standards proposed in the 2017 Car Rule. Instead, it has simply asserted that "GHGs have become subject to regulation under the CAA by virtue of other regulatory actions taken by EPA before this proposal." 76 Fed. Reg. 75,162 n.597. But to the extent EPA believes that regulations of GHGs from model year 2017-2025 light-duty vehicles, like those from model year 2012-2016 light-duty vehicles, trigger stationary source permitting ramifications, such position is inconsistent with the CAA, as explained below. [EPA-HQ-OAR-2010-0799-9509-A1, p. 4]

A. The Title V Operating Permit Program and the PSD Preconstruction Permit Program

Added by Congress in the 1990 amendments, CAA Title V requires a source that emits, or has the potential to emit, more than 100 tpy of any air pollutant to obtain an operating permit that lists applicable regulatory requirements. See, e.g., 42 U.S.C. §§ 7661a(b), 7661c. [EPA-HQ-OAR-2010-0799-9509-A1, p. 5]

The PSD program is significantly more complex. It was designed to help states maintain the National Ambient Air Quality Standards (NAAQS) prescribed by EPA for specific air pollutants known as "criteria pollutants." Under CAA § 107, EPA establishes geographic air quality districts and designates them as (a) in attainment, (b) in non-attainment, or (c) unclassifiable for each criteria pollutant. 42 U.S.C. § 7407(d). The CAA treats areas designated attainment and unclassifiable for a particular pollutant—hereinafter "attainment areas"— identically for PSD purposes. States apply NAAQS to individual stationary sources through a State Implementation Plan (SIP) "for each 'air quality control region' within the state," which ensures that the region meets the applicable NAAQS. Alabama Power Co. v. Costle, 636 F.2d 323, 346 (D.C. Cir. 1979); 42 U.S.C. § 7410. [EPA-HQ-OAR-2010-0799-9509-A1, p. 5]

Congress enacted the PSD program to prevent "a decline of air quality to the minimum level permitted by NAAQS." Wisconsin Elec. Power Co. v. Reilly, 893 F.2d 901, 904 (7th Cir. 1990). Consequently, it requires a facility in an attainment area for a specific criteria pollutant to obtain a pre-construction permit when it has the potential to emit more than the CAA threshold for that pollutant, either 100 or 250 tons per year (tpy), depending on the source. 42 U.S.C. §§ 7471, 7475(a), 7479. No construction may begin on a new or modified source until a final PSD permit is obtained. Sources subject to PSD must adopt Best Available Control Technology (BACT) for emissions of pollutants "subject to regulation" under the CAA. 42 U.S.C. § 7475(a). [EPA-HQ-OAR-2010-0799-9509-A1, p. 5]

EPA's view that mobile source emission standards trigger GHG permitting requirements hinges on this final point—that sources subject to PSD permitting must adopt BACT for pollutants "subject to regulation" under the CAA. EPA argues that GHGs became "subject to regulation" under the CAA when the Car Rule took effect because that rule imposed GHG emission standards. PSD Interpretive Rule, 75 Fed. Reg. at 17,019–20. Consequently, EPA asserted that, starting January 2, 2011, stationary sources that require a PSD permit must adopt the BACT for GHGs. Id. As explained in Section I.C. below, that argument is mistaken—mobile source emission standards do not make GHGs subject to regulation for purposes of the PSD program. [EPA-HQ-OAR-2010-0799-9509-A1, p. 5]

EPA goes even further, however, arguing that GHG emissions, standing alone, may trigger the need for a PSD permit. Tailoring Rule, 75 Fed. Reg. 31,560-62. As explained in Section I.B. below, this violates the plain text of the CAA. Briefly, as noted above, PSD permits are only required in "attainment areas." 42 U.S.C. § 7471. And areas are only designated "attainment" in reference to a NAAQS. 42 U.S.C. § 7407(d). Thus, it is logically impossible for there to be "attainment areas" for GHG, and so GHG emissions cannot necessitate a PSD permit. That is, even if EPA is correct that a source that already must obtain a PSD permit due to emissions of other pollutants for which the area is in attainment must therefore adopt BACT for GHGs, that does not mean that GHGs can trigger the prerequisite need for a PSD permit. [EPA-HQ-OAR-2010-0799-9509-A1, p. 5]

B. A Source Triggers PSD Permitting Only if it Emits a NAAQS Pollutant in an Area Designated Attainment for That Pollutant

CAA Section 107(d) establishes the process of designating an area as "attainment," "nonattainment," or "unclassifiable" for each pollutant for which "a new or revised [NAAQS]" has been issued. 42 U.S.C. § 7407(d). Section 107(d) thus explicitly links the designation determinations exclusively to NAAQS criteria pollutants. In turn, Section 107's designation determinations are the critical prerequisite to determining if the PSD program is triggered. [EPA-HQ-OAR-2010-0799-9509-A1, p. 6]

CAA Section 161, the first substantive provision of Part C (the PSD provisions), incorporates those prerequisites by limiting the PSD program to areas designated under Section 107 as attainment or unclassifiable:

In accordance with the policy of section 7401(b)(1) of this title, each applicable implementation plan shall contain emission limitations and such other measures as may be necessary, as determined under regulations promulgated under this part, to prevent significant deterioration of air quality in each region (or portion thereof) designated pursuant to section 7407 of this title as attainment or unclassifiable. [EPA-HQ-OAR-2010-0799-9509-A1, p. 6]

42 U.S.C. § 7471 (emphasis added). These geographic limitations make sense because the purpose of the PSD program is to assure that NAAQS continue to be achieved. See 42 U.S.C. § 7410(a)(2)(C) (describing PSD permit program as "necessary to assure that [NAAQS] are achieved"). In fact, almost all of the 1977 CAA amendments focused on attainment of NAAQS, and essentially codified EPA's original PSD program, which had been focused solely on NAAQS pollutants. See S 95-127 (95th Cong., 1st Sess.), at 27; Tailoring Rule, 75 Fed. Reg. at 31,549. Finally, CAA § 165(a) limits the facilities for which a PSD permit is required to facilities constructed "in any area to which this part applies." 42 U.S.C. § 7475(a) (emphasis added). [EPA-HQ-OAR-2010-0799-9509-A1, p. 6]

Because there is no NAAQS for GHGs, no region is designated attainment or unclassifiable for GHGs. No stationary source, then, is located in a region designated attainment or unclassifiable for GHGs. Consequently, no source triggers PSD permitting simply because it emits GHGs above the statutory thresholds. The D.C. Circuit, indeed, has mandated this interpretation in Alabama Power Co. v. Costle, 636 F.2d 323 (D.C. Cir. 1980), where it held that location is the key determinant for PSD applicability. EPA had argued that PSD permitting requirements should apply not only to sources in attainment areas for a given pollutant, but to sources located any place where a new emitting facility would "adversely affect the air quality of an area to which" PSD requirements apply. Id. at 364. The Court held that EPA's reading violated the CAA's plain language: "The plain meaning of the inclusion in [Section 165, 42 U.S.C. § 7475] of the words 'any area to which this part applies' is that Congress intended location to be the key determinant of the applicability of the PSD review requirements." Id. at 365. [EPA-HQ-OAR-2010-0799-9509-A1, p. 6]

Rather than comply with the D.C. Circuit's ruling, EPA's interpretation defies it. EPA's position requires permits for a source emitting above the statutory thresholds for one pollutant as long as the source is located in an area that is in attainment for any pollutant. See 45 Fed. Reg. 52,675, 52,677 (Aug. 7, 1980) ("PSD requirements apply to any area that is "designated ... as 'attainment' or 'unclassifiable' for any pollutant for which a national ambient air quality standard exists."); 40 C.F.R. § 52.21(i)(2) (PSD "shall not apply to a major stationary source or major modification with respect to a particular pollutant if … the source or modification is located in an area designated as nonattainment under section 107"). That is no limitation at all. Every area of the country is, and always has been, in attainment for at least one criteria pollutant. Id. at 31,561. Thus, in response to Alabama Power's holding that EPA has improperly broadened the geographic confines of the PSD program, EPA actually broadened the geographic scope even further, so that, under EPA's current interpretation, it now applies to every area of the country. EPA's view defies both Alabama Power and the language of the CAA that it was interpreting. [EPA-HQ-OAR-2010-0799-9509-A1, pp. 6-7]

C. GHGs Are Not Subject to Regulation Under the PSD Program

Furthermore, Title II GHG vehicle emission standards cannot make GHGs "subject to regulation" within the meaning of the CAA's PSD program. Congress did not intend for PSD requirements to apply to unconventional, non-NAAQS pollutants, particularly GHGs. EPA readily concedes Congress did not have GHGs in mind when it formulated the PSD provisions of the Act. Tailoring Rule, 75 Fed. Reg. at 31,549, 31,555, 31,561, 31,559 n.41 (Congress "might not have appreciated the possibility that burning fossil fuels could lead to global warming"). The text of the PSD provisions and their application to GHGs bear that out. [EPA-HQ-OAR-2010-0799-9509-A1, p. 7]

The 28 source categories listed in Section 169(1) as major emitting facilities potentially subject to the PSD program are the very ones EPA thought (in 1977, when the PSD program was added) posed the greatest threat to air degradation because they emitted conventional air pollutants—that is, pollutants with local air quality impacts. Naturally, Congress included only those source categories in Section 169(1) because Congress, too, was concerned about only conventional pollutants. GHGs, by contrast, are emitted by many more categories of sources. The emissions cutoffs in Section 169(1) reflect the same concern. Whereas conventional pollutant emissions of 100 and 250 tpy are significant, GHG emissions of 100 and 250 tpy are commonplace. The thresholds make sense only if Congress envisioned only conventional pollutants as "subject to regulation." [EPA-HQ-OAR-2010-0799-9509-A1, p. 7]

The PSD program itself is geared toward conventional pollutants. The program is principally concerned with "air quality," 42 U.S.C. § 7471, that is, the air people breathe. GHG emissions have no nexus to local air quality. Instead, they are distributed globally. For that reason, PSD provisions focusing on local or regional impacts of a pollutant cannot encompass GHGs. For instance, the provisions of Sections 165(a) and (e) require air quality monitoring and air quality impact analysis. Such local monitoring and local analysis is illogical for emissions of GHGs. [EPA-HQ-OAR-2010-0799-9509-A1, p. 7]

D. EPA's Interpretation of the CAA Is Unreasonable [EPA-HQ-OAR-2010-0799-9509-A1, p. 7]

EPA's contrary interpretation, that GHGs are made subject to regulation by vehicle emissions standards, is unreasonable. EPA has admitted that its approach leads to burdens that "should be considered 'absurd results.'" Tailoring Rule, 75 Fed. Reg. at 31,517. According to EPA, its interpretation creates a scenario where "PSD permit issuance would be unable to keep up with the flood of incoming applications, resulting in delays, at the outset, that would be at least a decade or longer." 75 Fed. Reg. at 31,557. "During this time, tens of thousands of sources a year would be prevented from constructing or modifying." Id. As a result, EPA's interpretation "slow[s] construction nationwide for years, with all of the adverse effects that this would have on economic development." Id. EPA has said this outcome would be "administratively infeasible," 75 Fed. Reg. at 31,516, and would "adversely affect national economic development," id. at 31,557. As EPA has acknowledged, this outcome is absurd. Contrary to EPA's assertions, an agency interpretation of a statute that is absurd cannot also be reasonable. Courts "must reject administrative constructions of [a] statute … that frustrate the policy that Congress sought to implement." Continental Air Lines v. Dep't of Transp., 843 F.2d 1444, 1453 (D.C. Cir. 1988); see also Int'l Alliance of Theatrical & Stage Employees v. NLRB, 334 F.3d 27, 35 (D.C. Cir. 2003). EPA must, instead, adopt the reasonable interpretations proposed by the Associations. [EPA-HQ-OAR-2010-0799-9509-A1, pp. 7-8]

II. EPA Should Delay Finalizing The 2017 Car Rule Until It Has Corrected Its Mistaken Interpretation of the CAA, Allowing NHTSA to Move Forward

EPA has broad discretion to delay finalizing the 2017 Car Rule under the "rule of reason" that courts employ in assessing delay in agency decision making. Telecommunications Research & Action Center v. FCC, 750 F.2d 70, 80 (D.C. Cir. 1984); see also Massachusetts v. EPA, 549 U.S. 497, 533 (2007) (EPA has "significant latitude as to the manner, timing, content, and coordination of its regulations with those of other agencies"). Given this discretion, it would be arbitrary and capricious for EPA to finalize the CAA component of the 2017 Car Rule at this time; instead, it should allow NHTSA to finalize the rule independently. When the D.C. Circuit vacates EPA's Car Rule and Truck Rule for the reasons stated in the Associations' Comments, see Exhs. A–J, the 2017 Car Rule could cause the same harm that the Car Rule (and Truck Rule) threatened: triggering massive and unwarranted permitting burdens. Tailoring Rule, 75 Fed. Reg. at 31,517. [EPA-HQ-OAR-2010-0799-9509-A1, p. 8]

These harms entirely outweigh any possible benefit from finalizing the rule, because the rule was jointly proposed by EPA and NHTSA. This means the NHTSA portion of the 2017 Car Rule could be finalized under NHTSA authority, avoiding triggering permitting requirements under the CAA. Consequently, delaying the EPA rule (but not the NHTSA rule) would not cause any serious disruption to implementing GHG emission standards for model years 2017-2025 light-duty vehicles, but would avoid massive harm to stationary sources. Furthermore, the delay need not be long—if EPA implemented the interpretation offered in Section I, above, it could then finalize the 2017 Car Rule without harming stationary sources. [EPA-HQ-OAR-2010-0799-9509-A1, p. 8]

III. EPA Failed to Assess the Consequences of Its Rule and Alternatives to Its Actions Rendering the Rulemakings Arbitrary and Capricious [EPA-HQ-OAR-2010-0799-9509-A1, p. 8]

Given EPA's interpretation that vehicle emissions standards trigger stationary source GHG permitting requirements, PSD Interpretive Rule, 75 Fed. Reg. at 17,019–20, EPA is required to consider the ramifications on stationary sources subject to those permitting requirements before promulgating the 2017 Car Rule. EPA has entirely failed to perform this duty—the proposed 2017 Car Rule contains no discussion of its impacts on stationary sources. Instead, it states in cursory fashion that impacts on stationary sources are attributable to EPA's upon are subject to pending legal challenges and are at risk for being vacated.3 [EPA-HQ-OAR-2010-0799-9509-A1, pp. 8-9]

EPA's refusal to consider the effects of its Rule makes the rule "arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law" as well as being adopted "without observance of procedure required by law." 42 U.S.C. § 9607(d)(9)(A),(D). An agency acts arbitrarily and capriciously if it does not "examine the relevant data," Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43 (1983), or fails to make its decision "based on a consideration of the relevant factors," Bowman Transp., Inc. v. Arkansas-Best Freight Sys., Inc., 419 U.S. 281, 285 (1974). [EPA-HQ-OAR-2010-0799-9509-A1, p. 9]

Congress and the Executive Branch have directed EPA, before taking final action, to assess all the impacts of its actions and to consider the benefits of alternative approaches. Under the very section discussed, Section 202(a), regulations may only "take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period." 42 U.S.C. § 7621(a); see also Massachusetts v. EPA, 549 U.S at 529 (GHG regulation cannot be "extreme" because EPA must "delay any action to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance"). [EPA-HQ-OAR-2010-0799-9509-A1, p. 9]

IV. EPA Should Clarify Whether the 2017 Car Rule Triggers Stationary Source Impacts in the Absence of Another Trigger

The Associations believe EPA's position to be that, absent any other trigger such as the Car Rule or Truck Rule, the 2017 Car Rule will trigger applicability of the Title V and PSD programs to GHG emissions from stationary sources. Thus, for example, should the Car Rule and Truck Rule be vacated by the Court, the 2017 Car Rule would become the regulation that triggers the stationary source regulation of GHGs. If that is not EPA's position, EPA should so clarify and explain its position. [EPA-HQ-OAR-2010-0799-9509-A1, p. 10]

1 These comments do not address the substance and stringency of the actual GHG standards that EPA proposes to impose on light-duty vehicles. Each Association is filing individual comments that discuss various policy and technological impacts of the GHG standards in the 2017 Car Rule.

2 Because the Truck Rule will undoubtedly serve the same role in EPA's justifications after the Car Rule is vacated, the Associations also incorporate by reference their comments on the Truck Rule.

3 At a minimum, EPA should delay finalizing the 2017 Car Rule until after the D.C. Circuit has issued decisions in the challenges to the Car Rule and Truck Rule. Until these decisions become final, EPA cannot accurately assess the impact that the 2017 Car Rule will have on stationary sources.

Organization: National Association of Manufacturers (NAM)

In addition, the NAM, along with American Petroleum Institute and American Fuel & Petrochemical Manufacturers (Associations) have submitted joint comments on this proposed rule opposing any approach to implementing of mobile source standards that will impact a wide swath of stationary sources. We hereby incorporate by reference those joint comments in this submission. This proposed rule is the EPA's third rulemaking to regulate greenhouse gas (GHG) emissions from mobile sources, following the Light Duty Vehicle GHG Emission Standards and Corporate Fuel Economy Standards, 75 Fed. Reg. 25,324 (May 7, 2010) and Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy- Duty Engines and Vehicles, 76 Fed. Reg. 57,105 (Sept. 15, 2011). The EPA has taken the position that these mobile source standards – along with related regulations and guidance – require it to regulate GHG emissions from stationary sources under the Prevention of Significant Deterioration (PSD) and Title V Programs. Both of those rules are currently subject to judicial review and the Associations are concerned that once they are vacated the EPA will assert that this rule serves as an independent trigger for the regulation of GHG emissions from stationary sources.

In the joint comments, we explain why the EPA's view that mobile source emission standards trigger GHG permitting requirements for stationary sources is mistaken and urge it to correct its interpretation. Further, because NHTSA can issue the same mobile source standards without creating the risk of adverse impacts on stationary sources, we urge the EPA to defer any further action on the proposed rule until it corrects its interpretation, allowing NHTSA to proceed alone at this time. The joint comments also explain why the EPA's failure to consider the consequences of the proposed rule on stationary sources and alternatives to its proposed actions render the rulemaking arbitrary and capricious. Finally, we explain that the rulemaking is arbitrary and capricious because it is based on an invalid endangerment finding for GHGs that is likely to be vacated upon judicial review. [Joint comments can be found in Docket number EPA-HQ-OAR-2010-0799-9509-A1] [EPA-HQ-OAR-2010-0799-9538-A2, pp. 1-2]

Organization: Utility Air Regulatory Group (UARG)

UARG submits these comments solely for the purpose of addressing possible alleged stationary source effects under the Clean Air Act's ("CAA" or "Act") prevention of significant deterioration ("PSD") and Title V permitting programs that might result from promulgation of a final rule in the present rulemaking. [EPA-HQ-OAR-2010-0799-9510-A1, p. 1]

On May 7, 2010, EPA published a final rule establishing greenhouse gas ("GHG") emissions standards for model year 2012-2016 light-duty vehicles. 75 Fed. Reg. 25324 (hereinafter the "2012 Light-Duty Rule"). EPA has adopted an interpretation of the CAA under which promulgation of the 2012 Light-Duty Rule made GHGs subject to the CAA's PSD and Title V permitting programs for stationary sources beginning on January 2, 2011. See Reconsideration of Interpretation of Regulations That Determine Pollutants Covered by Clean Air Act Permitting Programs, 75 Fed. Reg. 17004 (Apr. 2, 2010) (hereinafter the "Reconsideration Rule"). EPA's regulation of GHG emissions from stationary sources under the PSD and Title V programs is the subject of considerable controversy, and every major EPA rule related to the Agency effort to require regulation of GHG emissions under those programs is, in one respect or another, the subject of pending petitions for review filed in the U.S. Court of Appeals for the District of Columbia Circuit by numerous parties, including UARG. See, e.g., Coalition for Responsible Regulation, et al. v. EPA, No. 09-1322 (and consolidated cases) (D.C. Cir.) (petitions for review of EPA's GHG "endangerment" and "cause or contribute" findings for motor vehicles under CAA section 202(a)); Coalition for Responsible Regulation, et al. v. EPA, No. 10-1073 (and consolidated cases) (D.C. Cir.) (petitions for review of the Reconsideration Rule); Coalition for Responsible Regulation, et al. v. EPA, No. 10-1092 (and consolidated cases) (D.C. Cir.) (petitions for review of the 2012 Light-Duty Rule); Southeastern Legal Foundation, et al. v. EPA, No. 10-1131 (and consolidated cases) (D.C. Cir.) (petitions for review of EPA's Tailoring Rule for GHGs under the PSD and Title V programs). [EPA-HQ-OAR-2010-0799-9510-A1, p. 1]

Depending on the outcome of these pending cases, it is possible that the current PSD and Title V permitting rules as they are deemed by EPA to apply to stationary sources' GHG emissions may be vacated in whole or in part or otherwise changed significantly as a result of judicial review. If that occurs, it is possible that the proposed 2017 Light-Duty Rule, if made final by EPA at the conclusion of the present rulemaking, could be interpreted by the Agency to be the rule that makes GHGs subject to the PSD and Title V permitting requirements.1 To protect its interests in the event that occurs, UARG submits the following comments to the docket for the present rulemaking: [EPA-HQ-OAR-2010-0799-9510-A1, p. 2]

- The proposed 2017 Light-Duty Rule relies on EPA's final endangerment and "cause or contribute" findings for GHGs under section 202(a) of the Act, which EPA published at

74 Fed. Reg. 66496 (Dec. 15, 2009); see, e.g., 76 Fed. Reg. at 74861, 74964. UARG filed three sets of comments on EPA's proposed endangerment and cause or contribute findings under section 202(a): (1) Comments of the Utility Air Regulatory Group on the Proposed Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act, EPA Docket ID No. EPA-HQ-OAR-2009-0171-3394.1 (Attachment 1 to these comments [Attachment 1 can be found on pp. 5-265 of Docket number EPA-HQ-OAR-2010-0799-9510-A1]); (2) Supplemental Comments of the Utility Air Regulatory Group on the Proposed Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act, EPA Docket ID No. EPA-HQ-OAR-2009-0171-4932.1 (Attachment 2 to these comments [Attachment 2 can be found on pp. 266-279 of Docket number EPA-HQ-OAR-2010-0799-9510-A1]); and (3) the Utility Air Regulatory Group's Additional Supplemental Comments on the Proposed Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act, EPA Docket ID No. EPA-HQ-OAR-2009-0171-11491.1 (Attachment 3 to these comments [Attachment 3 can be found on pp. 280-291 of Docket number EPA-HQ-OAR-2010-0799-9510-A1]). UARG incorporates all of these comments herein by reference. [EPA-HQ-OAR-2010-0799-9510-A1, p. 2]

- As discussed in UARG's previous comments incorporated herein, the proper purpose of any EPA endangerment finding under the CAA is to avert or prevent the danger the Agency concludes is presented by the emissions that are the subject of the finding, or at least to significantly mitigate that danger. This principle is reflected in the CAA's legislative history and the decision in Ethyl Corp. v. EPA, 541 F.2d 1 (D.C. Cir. 1976) (en banc). As the legislative history and Ethyl make clear, the fundamental purpose of the CAA provisions that incorporate the endangerment criterion, such as section 202(a)(1), is to authorize regulation of emissions when and to the extent such regulation will be effective in fruitfully attacking the cause of the endangerment, and not to impose "regulation for regulation's sake." The proposed 2017 Light-Duty Rule does not meet this standard. EPA analyzed the reductions in GHG emissions that would result from the proposed 2017 Light-Duty Rule by the year 2100 and projected the effects those reductions would have on atmospheric carbon dioxide concentrations, global mean surface temperature, sea-level rise, and ocean-water acidity. 76 Fed. Reg. at 75097-99 & Table III-62. EPA acknowledges that "[t]he projected reductions are small." Id. at 75099. EPA makes the following projections for the year 2100 as a result of the proposed 2017 Light-Duty Rule: (1) atmospheric carbon dioxide concentrations will be reduced by 3.29 to 3.68 parts per million by volume; (2) global mean surface temperature will be reduced by 0.0076°C to 0.0184°C; (3) sea-level rise will be reduced by 0.074 to 0.166 centimeter; and (4) ocean pH will increase by 0.0018 pH unit. Id. at 75097-99 & Table III- 62. These amounts constitute a minuscule fraction of changes projected by the Intergovernmental Panel on Climate Change, on whose reports EPA relies. See, e.g., id. at 75096, 75098 & nn.385, 386. Even assuming that EPA's proposed 2017 Light-Duty Rule would achieve the maximum EPA-projected reductions, these reductions are vanishingly small, to the point of being all but unquantifiable and, in any event, imperceptible on any human scale. Thus, the proposed 2017 Light-Duty Rule does not meet the Ethyl standard for regulation under section 202. See Attachment 3; Comments of the Utility Air Regulatory Group on the Proposed Rulemaking To Establish Light-Duty Vehicle Greenhouse Gas Emission

Standards and Corporate Average Fuel Economy Standards, EPA Docket ID No. EPA-HQ-OAR-2009-0472-7262, at 7-10 (Attachment 4 to these comments; incorporated herein by reference [Attachment 4 can be found on pp. 292-329 of Docket number EPA-HQ-OAR-2010-0799-9510-A1]). [EPA-HQ-OAR-2010-0799-9510-A1, pp. 2-3]

- Furthermore, EPA appears to analyze the projected GHG emission reductions from the proposed 2017 Light-Duty Rule by including the projected GHG emission reductions that would occur from the vehicle fuel efficiency standards proposed by the National Highway Traffic Safety Administration ("NHTSA") concurrently with EPA's proposed rule. It appears that the majority of the emission reductions projected by EPA likely would occur anyway as a result of promulgation of the NHTSA fuel efficiency standards. Accordingly, the already minuscule projected effects from EPA's proposed rule, noted above, become even smaller if one excludes (as one should) the projected effects from the NHTSA standards. See Attachment 3; Attachment 4 at 10-15. [EPA-HQ-OAR-2010-0799-9510-A1, p. 3]
- If the proposed 2017 Light-Duty Rule, if made final, is interpreted by EPA to be the rule that makes GHGs subject to PSD and Title V requirements, then -- accepting arguendo such an EPA interpretation -- the date on which, according to EPA, that rule "takes effect" for purposes of commencing the applicability (in EPA's view) of PSD and Title V requirements to GHGs should be no earlier than the date on which the applicable model year begins pursuant to NHTSA rules or practice, i.e., October 1 of the preceding calendar year (e.g., October 1, 2016, for model year 2017). See Utility Air Regulatory Group Petition for Reconsideration and Request for Administrative Stay, EPA Docket ID No. EPA-HQ-OAR- 2009-0597, at 11-13 (June 1, 2010) (Attachment 5 to these comments; incorporated herein by reference [Attachment 5 can be found on pp. 330-350 of Docket number EPA-HQ-OAR-2010-0799-9510-A1]).2 [EPA-HQ-OAR-2010-0799-9510-A1, p. 3]
- EPA published its final Tailoring Rule on June 3, 2010. Prevention of Significant Deterioration and Title V Greenhouse Gas Tailoring Rule, 75 Fed. Reg. 31514. EPA promulgated the Tailoring Rule because the Agency concluded that application of the PSD and Title V requirements to stationary sources of GHG emissions would, due to the Act's PSD and Title V applicability thresholds, produce absurd results contrary to congressional intent. For the reasons described in UARG's comments on the proposed Tailoring Rule, however, EPA instead could have avoided, and should have avoided, such results by adopting the approaches described in those UARG comments, and, in particular, by determining that carbon dioxide is excluded from the scope of the PSD requirements under the CAA and EPA's regulations. See Comments of the Utility Air Regulatory Group on the Proposed Prevention of Significant Deterioration and Title V Greenhouse Gas Tailoring Rule, EPA Docket ID No. EPA-HQ-OAR-2009-0517-5317.1, at 19-27 (Attachment 6 to these comments; incorporated herein by reference [Attachment 6 can be found on pp. 351-424 of Docket number EPA-HQ-OAR-2010-0799-9510-A1]). [EPA-HQ-OAR-2010-0799-9510-A1, pp. 3-4]

---

1 Nothing herein should be construed as suggesting that UARG would agree with any such interpretation.

2 EPA has not responded to this petition.

Response:

The District of Columbia Circuit recently held that the unambiguous language of the Clean Air Act makes stationary source permitting requirements applicable automatically to a pollutant when that pollutant is regulated under the Act (including Title II of the Act). Coalition for Responsible Regulation v. EPA, No. 09-1322 (D.C. Cir. June 26, 2012), slip op. pp. 50-77. This decision expressly and implicitly rejects the arguments advanced by comments against regulation of GHG under the Prevention of Significant Deterioration (PSD) and Title V permitting programs. The court held that the PSD requirements apply to all air pollutants anywhere in the atmosphere and are not limited to only pollutants that affect public health at ground level or in local areas near the source of the air pollutants. The court rejected the argument that PSD requirements are only applicable to pollutants for which EPA has promulgated a National Ambient Air Quality Standard. The court also recognized that EPA was not required to promulgate regulations under section 166 of the Act before the permitting programs may apply to greenhouse gases.

The price of gas is once again squeezing the budgets of American families, who already are forced to cut back in other areas just to pay for basic transportation needs.This needs to happen, in order to break our dependence on fossil fuel, both foreign and domestic. [EPA-HQ-OAR-2010-0799-1550-A1, p. 1]

I believe there is a lot to be said for switching FROM non-tariff regulation of pollution including greenhouse gases TO excise taxes high enough to account for all external costs. This would create LOTS of CONSUMER pressure to improve efficiency of all consumer energy-using products. If Detroit insists on producing gas hogs, they can go the way of the Edsel. It should increase demand for sustainable energy in all areas of the economy. Already, in Connecticut where consumers are allowed to choose their electric generation firm, while stuck with the distributing utility where they live, sustainable source electricity ranges from the same price as fossil fuel electricity to only about one half cent per kWh more. I believe there is a lot to be said for bribing fossil fuel firms to invest in sustainable energy by accepting such investment as payment of the excise tax on the greenhouse gas part of pollution. While sustainable energy also helps cut toxic pollution from fossil fuel, it will take so long (approximately twenty years) to replace all our fossil fuel-fired electric generators with sustainable energy electric generators that fossil fuel firms should be allowed write off each year against toxic pollution excise tax only as much toxic pollution as would be emitted by the fossil fuel being replaced by the sustainable energy generator that year. [EPA-HQ-OAR-2010-0799-1550-A1, pp. 1-2]

Build More Oil Refinerys, Drill for oil and gas in America and put more people back to work!! Approve the Pipeline you have tabled, and call all the drilling bands off, and call our rigs and workwes back from South America where many have gone. Chose to be an American President, instead of a apoligetic pice of junk politics. You can not do for others what they refuse to do for themselves, stop being a fundamentel Liberal Marxtist and seek Freedom and Liberty for all our financial and religious freedoms that were established by our founders. [EPA-HQ-OAR-2010-0799-9149-A1, pp. 1-2]

Organization: Climate Institute

I also, however, would note that actions are needed to reduce emissions from all types of transportation, not just automobiles, so please keep working to do more. Making the voluntary black carbon reduction program mandatory would be a great step as well--perhaps by requiring all construction vehicles working on federally funded transportation projects to be equipped with black carbon capture equipment. This might be done by allowing the installation of black carbon filters to be a legitimate charge to the construction project, and this would have the effect of getting at the very high emissions from older, long-lasting equipment. The US per capita black carbon emissions are higher than the global average--we need to act and act now. [EPA-HQ-OAR-2010-0799-7944-A1, p. 1]

And there is more that can be done on methane--also by making voluntary programs mandatory (and many of the steps are cost effective for other reasons). So, please keep aggressively working to limit warming influences. [EPA-HQ-OAR-2010-0799-7944-A1, p. 1]

Organization: EutecticSolutions Inc.

As you are working towards reducing GHGs and improving fuel economy, don't forget the issue of HD trucks with excessive air brake leaks. Many need to idle for extended periods of time when the air supply has leaked below 60psi over night. FYI when an air brake system leaks its air below 60psi, the parking brake system comes ON and the vehicle cannot move until the pressure is built back up over 60 psi (sometimes more). A vehicle that has lost all of its air may need to idle for as much as 15 minutes before it can be moved to do useful work. [NHTSA-2010-0131-0270, p. 1]

This is not a rare occurrence and many HD trucks are operating with large leaks that technicians cannot find or repair. These vehicles use more fuel than necessary and add to the GHG issue. [NHTSA-2010-0131-0270, p. 1]

Organization: Green, K.

The price of gas is once again squeezing the budgets of American families, who already are forced to cut back in other areas just to pay for basic transportation needs. While this may be true - this situation did not have to arise! [EPA-HQ-OAR-2010-0799-1524-A1, p. 1]

The introduction of mandatory bio-fuel quotas has been a tragic and immoral mistake that has enriched a few and brought hunger to many! It is not an answer that can prevail for very long! [EPA-HQ-OAR-2010-0799-1524-A1, p. 1]

America has, within its borders, immense potential for energy independence. It has the opportunity to purchase even more fossil fuel from a friendly neighbor, Canada. Look realistically at the future and devise a more intelligent Energy Plan! [EPA-HQ-OAR-2010-0799-1524-A1, p. 1]

Organization: Haroldson, C.

Instead, let's increase our domestic drilling for oil and reduce our dependence on foreign oil. Of course this is a much safer alternative than shipping oil from the middle east and it will also create jobs at home. [EPA-HQ-OAR-2010-0799-11137-A1, p. 1]

Organization: Hohenstein, H.

I support greater drilling in America to reduce U.S. dependence on imported oil.

The price of gas is once again squeezing the budgets of American families, therefore the market will cause Americans to drive more efficient cars.

Close DOE permanently, use more CNG, drill in the productive deposits in America and allow American entrepreneurs to develop the necessary technology to buy American. [EPA-HQ-OAR-2010-0799-1515-A1, p. 1]

Organization: Integrated Consultants, Inc.

Integrated Consultants, Inc. (ICI) is a Military prototype hardware R&D firm. During our efforts on extended Battery range/life research for electric powered devices we developed a New Operator Driving Feature that Increases Vehicle Efficiency. Although initially for electric cars a modified regeneration arrangement could potentially increase the mileage range/efficiency of all vehicles. [NHTSA-2010-0131-0217, p. 1]

The issue for vehicle manufacturers becomes the adoption of a new indicator standard for vehicles, and vehicle safety. Manufacturers are reluctant to apply non adopted options that could affect vehicle safety, and efficiencies that can be easily leveraged are being abandoned. As electric vehicles and electric assist motor vehicles proliferate, the adoption of a standard will be required from a motor vehicle operator safety standpoint. [NHTSA-2010-0131-0217, p. 1]

ICI has been researching this topic for over 2 years, and we believe the regenerator slowing indicator is a more significant indicator than the high center “third brake light”. Could someone kindly visit http://www.integratedconsultants.com/ and view the data listed on our home page. [NHTSA-2010-0131-0217, p. 1]

Organization: Kobus, D.

We must stop the PetroChemical/Agribusiness lock on the direction of our nation and future. Healthcare, the environment, and energy can all be targeted through correcting the nation's food sources. We must stop targeting extreme energy sources (oil sands, hydrofracturing, deep ocean drilling), GMOs, and nanoparticles. We are launching full-on into realms of science that are untested and unsafe in standard scientific terms. It is not right, and it is our right as Americans to say so. [EPA-HQ-OAR-2010-0799-1370-A1, p. 2]

Organization: Lipetzky, P.

Just think what we can do for the economy RIGHT NOW if we lower gas by $1/gallon. Let's focus on the economy NOW. [EPA-HQ-OAR-2010-0799-8184-A1, p. 1]

Organization: Marks, R.

We need an immediate $1.00 per gallon tax on gas, followed each year for the next 8 years with an additional $0.50. This sets a long term term vision to start to change our wasteful habits. This tax money needs to be strictly allocated with public oversight, to develop alternative energy sources - 35%, build mass transit - 20%, into infrastructure of roads and rails - 10%, help those caught in the cost shift - 25% going to 0% and rebuild our cities - 10% going to 35%. If you want to extend to dirty coal used in electricity generation, now is the time to tax it. [EPA-HQ-OAR-2010-0799-1680-A1, p. 1]

Organization: Marlinghaus, E.

The price of gas is once again squeezing the budgets of American families, who already are forced to cut back in other areas just to pay for basic transportation needs. But, what the American people don't seem to realize, is that the price of gas is this country is really way below what it should be. If all the real costs of our addiction to oil were factored in, the true cost of a gallon of gasoline would be at least 2-3 times the current price. I can't help but believe that if even a portion of these costs were allowed to be added in that our government, bolstered by the insistence of the American public, would finally get their priorities straight and demand that our automotive industry make fuel economy their highest priority. [EPA-HQ-OAR-2010-0799-1581-A1, p. 1]

Organization: Marshall, C.

It may also be a good idea to encourage that highway funds be switched from a tax on gasoline to a tax on vehicle miles traveled. As less gasoline is used to meet this standard, fewer revenues will come into the highway funding programs. [EPA-HQ-OAR-2010-0799-5917-A2, p. 1]

Organization: Miller, P.

The price of gas is once again squeezing the budgets of American families, who already are forced to cut back in other areas just to pay for basic transportation needs. We need to move ahead much more strongly! [EPA-HQ-OAR-2010-0799-1755-A1, p. 1]

Organization: National Association of Convenience Stores (NACS)

Cost of Satisfying the RFS

Currently, the market is struggling to accommodate the 'blend-wall,' that point beyond which traditional blends of E10 and E85 cannot satisfy the mandated volumes of the RFS. EPA has sought to relieve this pressure for a short period of time by authorizing the sale of E15 for vehicles manufactured in and after model year 2001. However, automobile manufacturers are concerned that even these vehicles are not suitable for this fuel and there is ongoing litigation concerning the authorization to use E15. [EPA-HQ-OAR-2010-0799-9543-A1, p. 3]

For retailers, the challenge is two-fold: equipment compatibility and consumer demand.

Current federal law requires retail equipment to be listed by a nationally recognized testing laboratory as compatible with the fuel they wish to sell. The vast majority of equipment, however, is listed as compatible with fuels containing no more than 10% ethanol. Underwriters Laboratories (most equipment is listed by Underwriters Laboratories) does not recertify equipment after it has been manufactured. Consequently, retailers wishing to sell fuels containing more than 10% ethanol are required to replace their underground storage tank systems and dispensers with equipment that is certified as compatible with the new fuels. This is an extremely costly proposition. Underground storage tank systems can cost $100,000 to $200,000 and dispensers can cost up to and above $20,000 per unit. Retailers interested in pursuing a fuel like E15 may find the investment difficult to justify, especially considering the automobile manufacturers' opposition to the fuel and the uncertainty regarding consumer demand. [EPA-HQ-OAR-2010-0799-9543-A1, p. 3]

Similar equipment compatibility conditions apply for E85. However, there is the additional concern regarding consumer demand. At the end of 2010, the number of flexible fuel vehicles (FFVs), which are designed to operate on fuels containing between 0% and 85% ethanol, represented only 3.6% of the market. By 2025, EIA projects FFVs will represent only 16% of the vehicles on the market. Further, FFV customers, who have the ability to purchase regular gasoline or E85, for a variety of reasons often do not purchase E85 when available. Consequently, this is a very limited potential market and this can dissuade retailers from making the considerable investment to upgrade a facility to sell E85. [EPA-HQ-OAR-2010-0799-9543-A1, p. 3]

These are the current challenges associated with overcoming the blend-wall that exists in 2012. With the proposed CAFE revisions, the problem becomes exponentially more serious over the next 10 years. By 2022, to satisfy the RFS every gallon of gasoline must contain nearly 40% renewable fuels. This means that every fuel retailer will be required to replace all of their fueling equipment. This will cost the industry billions of dollars. [EPA-HQ-OAR-2010-0799-9543-A1, p. 3]

The average convenience store selling fuel operates four dispensers and two underground storage tanks. Assuming the average price for a dispenser is $20,000 and the average price for a new underground storage tank system is $100,000, the typical store will be required to invest $180,000 to accommodate the fuels required by the RFS. Multiply the per-store total by the 120,950 convenience stores that sell fuels and the industry-wide cost is staggering: $21.7 billion. After this enormous investment, it may still be impossible to satisfy the RFS considering that only one in six consumers will drive vehicles capable of running on the mandated fuels: EIA projects only 16% of consumers will drive FFVs by 2035. [EPA-HQ-OAR-2010-0799-9543-A1, p. 3]

Of the 120,950 convenience stores that sell fuel, 58% are one-store companies and fewer than 1% are owned by an integrated oil company. Therefore the burden for satisfying the RFS under the new CAFE standards will fall squarely on the small businesses that dominate the fuels retailing market and many will likely go out of business. [EPA-HQ-OAR-2010-0799-9543-A1, p. 4]

Conclusion

NACS members strongly support efforts to enhance the nation's energy security and do not oppose improving the fuel efficiency of the nation's vehicle fleet. However, they are very concerned that the policies being enacted and proposed are not effectively coordinated. The effect of the proposed rule on overall fuel consumption in the United States will greatly exacerbate the difficulties associated with implementation of the Renewable Fuels Standard. NACS members are concerned that this incompatibility has not been recognized or considered by the Agency. [EPA-HQ-OAR-2010-0799-9543-A1, p. 4]

Further, NACS is concerned that if policies like these cannot be designed in a manner that compliments rather that compromises the other, countless small businesses will be forced to examine whether they want to spend the money for upgrades or exit the business. Either way, the consumer ultimately loses. [EPA-HQ-OAR-2010-0799-9543-A1, p. 4]

NACS urges EPA to consider the implications of this proposed rule on other regulatory requirements already affecting not just the automobile industry but the fuels industry as well. NACS does not believe that improved efficiency, enhanced sustainability, national energy security and economic growth are mutually exclusive objectives. But if they are not pursued in a strategic, coordinated effort they can lead to unintended consequences that can derail progress towards all of the objectives. [EPA-HQ-OAR-2010-0799-9543-A1, p. 4]

Organization: South Coast AQMD

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 70-71.]

Lastly, we urge U.S. EPA to begin analysis to set criteria and greenhouse gas emissions standards for vehicles produced after 2025. It is critically important, given that many areas in the

U.S. must meet the new eight-hour ozone standard and the potential for ever tighter ambient air quality standards.

Organization: Statman, P.

The price of gas is once again squeezing the budgets of American families, who already are forced to cut back in other areas just to pay for basic transportation needs. [EPA-HQ-OAR-2010-0799-1472-A1, p. 1]

Response:

These comments, although clearly sincere, concern issues beyond the scope of this rulemaking and therefore no response is necessary.
