EPA-420-R-12-017
August 2012

Introduction

The following is the Environmental Protection Agency's (EPA) Response to Comments document for the EPA and National Highway Traffic Safety Administration (NHTSA) Joint Rulemaking: 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards. The following document contains verbatim excerpts of the commenter's text followed by EPA's responses. Citizen comments that raised unique substantive issues are included. In addition, nearly 300,000 citizens provided comments in support of the program and about 400 people provided testimony at three public hearings held for the rulemaking; these comments are not listed or summarized individually, but rather examples are provided. All of the comments and public hearing transcripts are available in docket EPA-HQ-OAR-2010-0799 and/or NHTSA-2010-0131. The comments and responses are organized by topic (see Table of Contents) to help the reader find comments and responses of interest. An index of commenters and the associated docket numbers is also provided.

This is an EPA document and does not contain NHTSA's responses to comments. NHTSA's responses to comments are contained in the preamble Section IV and the NHTSA Final Regulatory Impact Analysis (RIA) for the rule.

Organization: Alexandria Hyundai

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 63.]

Along with my Hyundai colleague, I appreciate the effort on the part of all agencies in developing feasible and harmonized national greenhouse gas and CAFE standards.

Organization: Alliance of Automobile Manufacturers

Two years ago the Alliance testified and commented in support of the model year (MY) 2012-16 greenhouse gas (GHG) and corporate average fuel economy (CAFE) rule and encouraged EPA, NHTSA and the California Air Resources Board (CARB) to continue the single National Program beyond MY 2016. We continue to support having a single National Program and appreciate the agencies' efforts to pursue this goal. [EPA-HQ-OAR-2010-0799-9487-A1, p.3]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 95.]

Organization: Aluminum Association's Aluminum Transportation Group

We congratulate EPA and NHTSA on the outstanding body of work reflected in the NPRM. [NHTSA-2010-0131-0226-A1, p. 1]

In sum, we want to thank the agencies for their continued emphasis on reducing fuel consumption and GHG emissions and commitment to size-based standards. [NHTSA-2010-0131-0226-A1, p. 4]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 219-220.]

We recognize that developing a comprehensive national fuel economy regulation is a formidable task with profound consequences, and we want to sincerely congratulate the agencies on the outstanding job. We sincerely see it as an outstanding body of work and the conclusions are realistic, attainable and will achieve our national objectives in energy so we think it's an outstanding job and a credit to all of the agencies and individuals who are involved. It's been a pleasure to work with the organizations.

Organization: American Chemistry Council (ACC)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 264-265.]

We do want to state on the record that we support the CAFE standards moving forward. We think that they are aggressive but achievable.

The American Chemistry Council's plastics division would like commend both EPA and NHTSA on its approach and on this proposal. We believe the proposal takes a huge step forward in increasing fuel efficiency requirements in automobiles.

Organization: American Council for an Energy-Efficient Economy (ACEEE)

The American Council for an Energy-Efficient Economy (ACEEE) supports the light-duty fuel economy and greenhouse gas rule proposed by NHTSA and the EPA for model years 2017-2025. The proposal represents a very substantial reduction in fuel consumption and greenhouse gas emissions relative to business as usual, as well as enormous saving at the pump for consumers. The economic impacts of the rule will be substantial and net positive. [EPA-HQ-OAR-2010-0799-9528-A2, p.1]

Conclusions

Notwithstanding the multiple recommendations we have made that we believe would strengthen the final rule, we reiterate here our strong support for the proposed standards. We believe that the joint work done by NHTSA and the EPA, along with the California ARB, has resulted in a proposal that is highly significant and sound, from both policy and technical perspectives. We thank the agencies for the opportunity to provide comments and hope that our comments can help to bring about an even better final rule. [EPA-HQ-OAR-2010-0799-9528-A2, p.9]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 108-113.]

On behalf of ACEEE, I'm here to actively support the role of productive investments in more energy-efficient technologies as they might positively improve the robustness of the U.S. economy. In particular, we applaud the U.S. Environmental Protection Agency, the National Highway Traffic Safety Administration, the administration more generally, and the State of California for taking steps that will improve the fuel economy of our nation's light-duty vehicles.

So in sum, the rule, we think, will drive further gains in gasoline vehicles and begin to pull advanced technologies into the market. Cost-effective investments in more fuel-efficient vehicles resulting from this rule should accelerate and optimize benefits, whether jobs, cleaner air and a more robust economy, especially when we take recent consumer interest in fuel economy into account.

Organization: American Honda Motor Co., Inc.

American Honda Motor Co., Inc. (“Honda”) appreciates the efforts made by EPA and NHTSA to create the single national program to address motor vehicle greenhouse gas emissions and fuel economy standards for model years 2017 – 2025. [EPA-HQ-OAR-2010-0799-9489-A1, p. 1]

Honda supports the overarching goal of the NPRM, which is to establish a “coordinated and harmonized approach” to implementing the Clean Air Act’s mandate that EPA regulate motor vehicle emissions, and the mandate in the Energy Policy and Conservation Act (EPCA) that NHTSA regulate motor vehicle fuel economy. [EPA-HQ-OAR-2010-0799-9489-A1, p. 1]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 115-116.]

This NPRM builds upon the important foundation established by the seminal greenhouse gas and CAFE standards adopted for the '12 to '16 model years. These newly proposed standards represent an ambitious, challenging, and dramatic set of goals for most of the automobile industry.

These proposed regulations set forth in the NPRM when harmonized with the proposed regulations now under consideration in California have the potential to simplify and rationalize OEM obligations throughout the United States. Without these harmonized regulations, there is a significant risk that OEMs would face fragmented, conflicting and burdensome regulation of fuel economy and greenhouse gases. There's a strong likelihood that the California regulations, which likely would be adopted by additional states, would diverge from the Federal Regulations resulting in a patchwork of standards that differed in stringency, testing requirements, and flexibilities throughout the country.

Organization: American Lung Association

The American Lung Association is pleased that the U.S. Environmental Protection Agency seeks to reduce these emissions from light-duty vehicles. The joint proposed Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards will reduce carbon dioxide emissions to 163 grams per mile while mandating an average economy of 54.5 miles per gallon in 2025. [EPA-HQ-OAR-2010-0799-9902-A2, p. 1]

While the proposed rule will have significant benefits, there are still areas of critical need. Implementation of the proposed rule will benefit from improved testing and calculation of actual vehicle emissions, reliable air quality impacts assessments of electric vehicles, and averted costs associated with higher projected fuel costs. [EPA-HQ-OAR-2010-0799-9902-A2, p. 2]

The American Lung Association again thanks the U.S. Environmental Protection Agency for consideration of our comments and for the Agency's effort to curb the impacts of air pollution. The American Lung Association urges the Agency to promulgate the proposed rule. The true cost of pollution from mobile sources is paid in compromised human health. As such, the proposed rule will help to reduce those costs. [EPA-HQ-OAR-2010-0799-9902-A2, p. 2]

Organization: American Lung Association of the Mid-Atlantic

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 80-82.]

American Lung Association of the Mid-Atlantic is pleased that the Environmental Protection Agency and the National Highway Traffic Safety Administration have jointly proposed more stringent national standards to reduce greenhouse gas emissions and to increase corporate average fuel economy.

When implemented the new standards will be remarkable achievements.

We support the proposed rule, and we encourage EPA and NHTSA to promulgate a final rule that achieves at least the degree of reduction in air pollutants as a proposal would accomplish.

Organization: American Medical Association of California

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 44-48.]

The American Lung Association in California applauds the collaborative effort put forth by the Obama administration, the State of California, automakers and environmental stakeholders to develop this proposal that we believe will have a lasting impact on improving public health. The American Lung Association in California encourages the administration to pursue strong, clean air programs to improve the health and air of not only Californians, but all Americans.

Increasing fuel economy standards to 54.5 miles per gallon in 2025 and tightening emissions standards to halve greenhouse gas emissions by 2025 compared to today has the potential to transform our nation's vehicles into a cleaner, more efficient fleet that will reduce our addiction to oil, save consumers at the pump, provide expanded choices in cleaner vehicle technologies, and at the same time, cut harmful emissions that endanger the public's health.

The new greenhouse gas and fuel economy standards are an important milestone in the fight against climate change, air pollution and the serious public health impacts of our petroleum dependency and consumption.

Therefore, we urge you to implement strong rules that will withstand any attempts to undermine these goals.

Organization: American Suzuki Motor Corporation

Suzuki Motor Corporation ('Suzuki') supports the concept of a harmonized national approach to reducing greenhouse gas (GHG) emissions and improving fuel economy. [EPA-HQ-OAR-2010-0799-9523-A1, p.1]

Organization: Applied Materials

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 198-201.]

But we are very supportive of the proposal that's being reviewed today; the NHTSA and EPA proposal, and we applaud the Obama Administration for proposing these historic fuel economy and greenhouse gas emission standards.

We believe that sound public policy can be a critical accelerator for industrial development, and we think that's embodied in this current proposal.

No. 1, we do believe that sound science-based standards can drive innovation.

We think that the standards as proposed are achievable.

Lastly, again, in terms of industrial development, we're very supportive of the mile per gallon standard and we believe it's important that there be a domestic industry in this sector as well. And we think that while this is going to be a global effort, it's going to lead to our domestic industry being stimulated as well.

Organization: Association of Global Automakers, Inc. (Global Automakers)

This notice of proposed rulemaking brings us another step closer to the goal of having a long term harmonized national program. Global Automakers and its members have always endorsed a comprehensive and harmonized national approach to reducing GHG emissions and improving fuel economy. [EPA-HQ-OAR-2010-0799-9466-A1, letter p. 1]

We have been working diligently with the agencies, including the California Air Resources Board, to create a harmonized program that meets our national environmental and energy objectives while providing manufacturers the needed flexibility and lead-time to design and build a full range of advanced technology vehicles that consumers want to buy. [EPA-HQ-OAR-2010-0799-9466-A1, letter p. 1]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 65.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 49-50.]

Global Automakers and its members have always endorsed a comprehensive and harmonized national approach to reducing GHG emissions and improving fuel economy. The alternative of having to comply with a patchwork of state requirements would add significant costs resulting in higher vehicle prices, with no corresponding environmental or energy security benefits. We have been working with the Environmental Protection Agency (EPA), Department of Transportation's (DOT) National Highway Traffic Safety Administration (NHTSA), and California Air Resources Board (ARB) to create a program that meets national environmental and energy objectives while providing manufacturers the flexibility and lead-time necessary to design and build advanced technology vehicles that will provide consumers a full range of vehicle choices. This notice of proposed rulemaking (NPRM) brings us another step closer to the goal of having a long term, single national program. [EPA-HQ-OAR-2010-0799-9466-A1, p. 1]

Organization: Aston Martin Lagonda Limited, Lotus Cars Limited and McLaren Automotive

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 117-118.]

We all fully support the EPA and NHTSA proposal.

Organization: Biery-Hamilton, Dr. G.

I strongly support the proposed new fuel efficiency and greenhouse gas standards for cars and trucks to require cars and trucks to an average 54.5 miles per gallon by model year 2025. [EPA-HQ-OAR-2010-0799-9033-A1,p.1]

Together with the 'Phase One' model year 2012-2016 rule finalized in 2010, these tough new standards would more than double America's average fuel economy and are expected to:

-- Save families an estimated $8,200 in fuel savings over the lifetime of a new vehicle by 2025, for a total of $1.7 trillion in national fuel savings over the life of the program.

-- Reduce oil consumption by an estimated 2.2 million barrels a day by 2025 more than our daily 2010 oil imports from the entire Persian Gulf.

-- Reduce carbon dioxide pollution by over 6 billion metric tons over the life of the program equivalent to the emissions from the United States in 2010. [EPA-HQ-OAR-2010-0799-9033-A1, p.1]

Generating less pollution, putting more money in consumers' wallets, easing our addiction to oil, modernizing America's fleet of cars and trucks what's not to like? [EPA-HQ-OAR-2010-0799-9033-A1, p.1]

I am thrilled that this dramatic and bold proposal has earned the support of automakers, autoworkers, national security groups, environmental groups, and many other key stakeholders. And I am proud to add my support to this important rule. [EPA-HQ-OAR-2010-0799-9033-A1, p.1]

I have a small child. Do you have children or grandchildren? If you love them and want them to have a good future, you will support ANY measure to reduce the use of fossil fuels, and the resulting CO_2 emissions. Furthermore, you will support policies to change our industrial farming to reduce methane emissions, also, which change the atmosphere around the planet. [EPA-HQ-OAR-2010-0799-9033-A1, p.1]

Organization: BlueGreen Alliance

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 58-60.]

The BlueGreen Alliance strongly supports the light-duty vehicle standards for model year 2017 to 2025 that will raise fuel efficiency to 54.5 miles per gallon, nearly double what today's fuel efficiency standard is and limit the greenhouses gas emissions as it's been noted to 163 grams per mile.

We also request continuing federal programs to support these auto industry efforts in retooling to meet the demand for cleaner, more efficient cars.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 60-61.]

This is a unique opportunity to fulfill your commitments to create American jobs, protect consumers whether they drive a car or truck from high gas prices and to cut America's dependence on foreign oil. Our 15 BlueGreen Alliance partners and their 15 million members are committed to promoting the fact that green auto jobs are a win-win for all Americans, and we're committed to raise awareness among consumers of the significance of these fuel-saving technologies.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 37-40.]

We strongly support the proposed vehicle standards, which are a great example of how we can achieve simultaneous progress on our economic and environmental challenges. The proposed standard offers the opportunity to create quality manufacturing jobs, to reduce our reliance on imported energy, to reduce our vulnerability to crude oil price volatility, to lean the air and reduce the accumulation of heat-trapping gases in the atmosphere, and to improve our energy security and national security.

While job creation is a paramount concern, we should not discount the other benefits that the proposal will consider. If we are ever to make meaningful progress on our imported energy dependency and avoid accelerated climate destabilization, we will need well-conceived policies such as these.

Organization: BMW of North America, LLC

BMW is committed to working constructively with both EPA and NHTSA to continue a Single National Program for MYs 2017 through 2025 that also realizes the aggressive greenhouse gas reductions sought by the State of California in this timeframe. [EPA-HQ-OAR-2010-0799-9579-A1, p. 1]

The continuation of Single National Program is critical to BMW's ability to plan, design, and build the most efficient vehicles for all of America. [EPA-HQ-OAR-2010-0799-9579-A1, p. 1]

BMW is committed to delivering sustainable products and supports such standards because we think it is the right step in order to successfully address the global environmental challenge facing all nations. [EPA-HQ-OAR-2010-0799-9579-A1, p. 2]

In keeping with our corporate commitment to reduce vehicle greenhouse gas (GHG) emissions, BMW commends both EPA and NHTSA for their efforts to continue to refine the program established for MYs 2012 through 2016 that permits automakers to build a single light duty national fleet, satisfying the requirements of each Agency program as well as those of the State of California. We also greatly appreciate the efforts of the State of California to ensure this outcome. A Single National Program is critical for us so we can plan, design, and build the most efficient vehicles for all of America. [EPA-HQ-OAR-2010-0799-9579-A1, p. 2]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 78.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 78-79.]

We commend both the EPA and the NHTSA for the efforts to continue to refine the program that was previously established for model years 2012 to 2016.

And that program permits auto makers to build a single light-duty national fleet supplying the requirements of each agency program as well as those of the State of California.

Achievable greenhouse gas emission reductions and commensurate fuel economy increases depends on both designing more fuel-efficient vehicles and increasing market demand for such vehicles. We can build the vehicles, but consumers must buy them.

A comprehensive emission reduction policy needs to consider all aspects, most importantly consumer demand.

In conclusion, the BMW Group is committed to working constructively with EPA and NHTSA to continue a single national program for model years 2017 to 2025.

We very much appreciate the efforts of the State of California to ensure the continuation of a single national program going forward.

Organization: Borg Warner, Inc.

BorgWarner would first like to commend the EPA and NHTSA for their combined efforts to continue to harmonize these footprint-based standards and give the automotive industry some much needed long term clarity. [EPA-HQ-OAR-2010-0799-9320-A1, p. 1]

As a global technology leader focused on improving fuel economy and reducing emissions, BorgWarner has experienced what can be achieved in other parts of the world and we are eager to help the U.S. market reach the new standards. [EPA-HQ-OAR-2010-0799-9320-A1, p. 1]

In closing, BorgWarner is supportive of the EPA's and NHTSA's efforts and sees the proposal as a major step forward in our desire for energy independence and reduced CO_2 emissions. We urge the EPA and NHTSA to revisit the proposed rulemaking to ensure it is purely performance based, technology neutral and uses accurate measurement and calculation methods. The marketplace will see the real world results, making the auto industry more stable, globally competitive and a larger contributor to achieving our nation's goals. [EPA-HQ-OAR-2010-0799-9320-A1, p. 2]

Organization: Business for Innovative Climate & Energy Policy (BICEP)

As major U.S. businesses representing nearly 500,000 American jobs and over $100 billion in annual revenue, we are writing to voice our strong support for the proposed Greenhouse Gas (GHG) Emissions and Corporate Average Fuel Economy (CAFE) Standards. These standards represent a critical opportunity to strengthen our economy by creating jobs, benefiting the U.S. auto industry, saving consumers and businesses money on fuel, and reducing greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-9450-A1, p. 1]

As successful American businesses, we know the importance of recognizing and seizing opportunities. This rulemaking is a rare opportunity to strengthen our economy, save consumers and businesses money, create jobs, and mitigate climate risk. We urge the adoption of the strongest possible fuel economy and GHG standards. [EPA-HQ-OAR-2010-0799-9450-A1, p. 2]

Organization: California Air Resources Board (CARB)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket number EPA-HQ-OAR-2010-0799-11787, pp. 11-12.]

As you know, the results of our efforts reveal the enormous benefits of the proposed greenhouse gas standards. Greenhouse gas emissions of 2025 models will be a third lower than those of 2016. Fuel savings will be so substantial that the total cost of owning and operating a low greenhouse gas vehicle will be less than it is today, despite the higher initial cost of the vehicle. And the fuel savings means money that would have gone overseas to produce petroleum will stay in our country where it will be spent and create new jobs for Americans. This is truly a win-win proposal that will benefit America.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 12-13]

As part of our effort to ensure a national program, CARB has committed to accept compliance with the EPA greenhouse gas standards as compliance with our state standards. Once this occurs, hopefully by this summer, CARB will hold another hearing to consider a regulatory provision to formalize our commitment allowing compliance with EPA standards to fully satisfy the states' regulation. This is the same process and sequence of events we followed to allow EPA's compliance with 2012 to 2016 greenhouse gas standards to satisfy CARB standards for those years. Our intent is clear from our proposal and it will be memorialized in a formal resolution that would go before our board later this week.

Organization: Capozzelli, J.

The proposed fuel-efficiency and greenhouse gas standards for passenger vehicles and light trucks are a good step in reducing dangerous global warming, increasing national security and improving our economy. Compared to business as usual, they will prevent millions of tons of global warming emissions, save consumers billions of dollars at the gas pump and reduce America's dependence on dirty fossil fuels. [NHTSA-2010-0131-0221-A1, p.1]

We can no longer afford to pass up this tremendous opportunity. Setting fuel efficiency standards, because curbing global warming pollution from our transportation sector is one of the easiest and most effective ways to slow the quickening pace of climate change. [NHTSA-2010-0131-0221-A1, p.1]

Please adopt the strongest possible standards and close the SUV loophole. We must reduce carbon pollution from our cars, not increase it.

Organization: Center for Biological Diversity

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 214-216.]

We really appreciate the effort of the EPA in the sense that it should be ruled, and it's a laudable effort.

Organization: CEO Pipe Organs/Golden Ponds Farm

I support the proposed rule to increase fuel economy for new passenger vehicles to an average of 54.5 miles per gallon by 2025, which will allow cars and light trucks to drive farther on a gallon of gas and reduce USA dependence on imported oil. The price of gas is once again squeezing the budgets of USA families, who already are forced to cut back in other areas just to pay for basic transportation needs. [EPA-HQ-OAR-2010-0799-9229-A1, p.1]

This spring, you set a goal of reducing oil imports by one-third this decade, and in November you proposed fuel efficiency standards that will effectively double current requirements. I commend your efforts. I believe it is important to increase USA investment in fuel efficient technologies, save consumers money at the pump, help this country break its dependence on foreign oil, and protect the global environment. [EPA-HQ-OAR-2010-0799-9229-A1, p.1]

Do not let these standards be watered down. Protect and finalize the new fuel efficiency rules. [EPA-HQ-OAR-2010-0799-9229-A1, p.1]

Organization: Ceres

As a national coalition of investors, environmental organizations and other public interest groups working with companies to address sustainability challenges such as global climate change, we are writing to voice our strong support for the proposed Greenhouse Gas (GHG) Emissions and Corporate Average Fuel Economy (CAFE) Standards. [EPA-HQ-OAR-2010-0799-9475-A1, p. 1]

In sum, independent, credible analysis shows that the proposed standards will both benefit the auto industry, especially the Detroit 3, and create jobs. In addition, the proposed standards will spur innovation, reduce both our dependence on oil and climate risk, and save businesses and consumers money. Accordingly, we urge the adoption of the strongest standards possible. [EPA-HQ-OAR-2010-0799-9475-A1, p. 2]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 74-76.]

Organization: Chrysler Group LLC

Chrysler strongly supports a single, harmonized national greenhouse gas and fuel economy performance standard ("National Program") that allows manufacturers to build "a single fleet of U.S. vehicles that [will] satisfy all requirements under both programs as well as under California's [greenhouse gas] program, helping to reduce costs and regulatory complexity while providing significant energy and environmental benefits." In its letter of support for the proposed 2017-2025 model year ("MY") National Program, Chrysler committed to the proposed standards as substantially described in the agencies' August 2011 Supplemental Notice of Intent. [EPA-HQ-OAR-2010-0799-9495-A1, p. 1]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 52-53.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 25.]

This rulemaking builds upon the landmark Federal greenhouse gas and CAFE program for model year ("MY") 2012-2016 light-duty vehicles, referred to as the "National Program". Chrysler has long supported both the original National Program and this extension to it. [EPA-HQ-OAR-2010-0799-9495-A1, p. 5]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 51.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 57-60.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 24-25.]

Chrysler recognizes the benefit for the country of continuing the national program to address fuel economy and greenhouse gases. EPA and NHTSA began this program in 2009 with standards for model years 2012 through '16, and now the agencies are continuing for model years 2017 through '25.

Chrysler supports the goals of the program.

The foundation principles are: (1) strong performance requirements, (2) a midterm review to assess customer acceptance, and (3) a broad use of incentives to encourage technology innovations and early integration into production vehicles.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 52-53.]

However, Chrysler fully supports the goals of this program. Sergio Marchionne, our CEO is also the CEO of Fiat, which is the industry's fuel economy leader in Europe. He understands and endorses these commitments and is determined to pursue the product actions necessary for Chrysler to meet these 2017 and beyond goals.

Chrysler will support the final rules if they reflect the commitments and the foundational principles of the framework agreement. These foundational principles are one, strong performance requirements; two, a mid-term review to assess customer acceptance; and, three, the broad use of incentives to encourage technology innovations and early integration into production vehicles.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 55.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 62.]

In conclusion, I reiterate Chrysler's support for a single harmonized national standard for fuel economy and greenhouse gas emissions.

Organization: Climate Institute

I am writing in support of the strong fuel-efficiency and carbon pollution standards for new cars and trucks. Having been the scientist whose brief Justice Stevens cited in his majority opinion in Massachusetts et al. v. EPA to justify granting standing, I would reiterate that the damages occurring now and projected in the future as a result of greenhouse gas emissions are significant and the risk of much more severe conditions ahead is very great. [EPA-HQ-OAR-2010-0799-7944-A1, p. 1]

As my brief also made clear, the transport sector is a key contributor to CO_2 emissions and they must be reduced. Greatly increasing the mileage standards is a critical step and I urge you to move forward. [EPA-HQ-OAR-2010-0799-7944-A1, p.1]

Organization: Consumer Federation of America (CFA)

A LANDMARK POLICY SUPPORTED BY AN UNPRECEDENTED CONSENSUS

Seven Presidents have declared the goal of reducing U.S. dependence on oil, but little progress has been made. Statements at the public hearings held by the National Highway Traffic Safety Administration (NHTSA) and the Environmental Protection Agency (EPA) on the recently proposed auto standards for 2017-2025 indicate a remarkable shift in the policy landscape with the emergence of an unprecedented consensus in support of fuel economy standards that would double the efficiency of cars and trucks in less than two decades and dramatically reduce oil consumption and imports. [EPA-HQ-OAR-2010-0799-9419-A1, p. 1]

Public witnesses say and consumer advocates present survey and behavioral evidence that consumers want and will pay for more fuel efficient vehicles.

Automakers and auto workers say they can and will manufacture those vehicles.

National security experts and environmentalists say the nation will benefit from the standards.

The only stakeholder that does not seem “to get” it is the National Automotive Dealers Association. [EPA-HQ-OAR-2010-0799-9419-A1, p. 1]

Over the course of a decade, the growing public concern about gasoline and its burden on household budgets drove a policy consensus in support of higher standards. This consensus includes not only almost all of the stakeholders in the industry, but it also crosses the federal and state levels, all branches of government, and both political parties. [EPA-HQ-OAR-2010-0799-9419-A1, p. 1]

These comments and the attached Technical Appendices explain why the standards have earned such widespread support and why the concerns of the dealers, genuine though they may be, are unfounded. We present over a dozen reasons that the standards will benefits consumers, the economy, national security, and the environment. [EPA-HQ-OAR-2010-0799-9419-A1, p. 1]

The future of the auto industry lies in developing and delivering more fuel efficient vehicles. The future of the American economy lies in using energy much more efficiently. The proposed standards will help to ensure that the U.S. auto industry and the U.S. economy successfully negotiate the transition. These comments show that because these fuel economy standards are the most important energy policy in a quarter of century, they deserve the remarkable national consensus support they have received. [EPA-HQ-OAR-2010-0799-9419-A1, p. 1]

CONSUMER GROUP COMMENTERS AND APPROACH

The Consumer Federation of America (CFA) and 23 of its member groups appreciate the opportunity to submit comments on the proposed standards for cars and light duty trucks. As summarized in Exhibit S-1, we have been actively involved in this important area of energy policymaking at both the federal and state levels. Over the past seven years, CFA has issued dozens of reports on the technology, auto market behavior and consumer economics of auto fuel economy, as well as conducted numerous surveys on consumer attitudes about gasoline consumption and fuel economy standards. [See Exhibit S-1 on p. 2 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, p. 1]

CFA has analyzed the economics of fuel economy and monitors the development of fuel economy standards in an effort to ensure that policymakers set a standard that is good for consumers and the nation. These comments build on that background and incorporate several of the early analyses as technical appendices. The comments launch from and focus on the key factors that impact the consumer, but also reflect the factors that affect the industry and the conditions that Congress has required the agencies to take into account in the rulemaking. The following list summarizes the analyses we have conducted to reach the conclusion that the proposed standards will benefit consumers. The Roman numerals identify the section in the technical appendix in which data is presented addressing each issue. [EPA-HQ-OAR-2010-0799-9419-A1, p. 1]

I. CONSUMER REALITY: CONSUMERS NEED MORE FUEL EFFICIENT VEHICLES

Over the past decade, gasoline prices have gyrated wildly around a strong upward trend. Exhibit S-2 shows the average annual expenditure on vehicle ownership (new and used vehicles) compared to the expenditure on gasoline, as reported in Bureau of Labor Statistics' annual Consumer Expenditure Survey. [See Exhibit S-2 on p. 3 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, p. 3]

Gasoline prices set a record high in 2011 averaging $3.53 per gallon. The average price for January 2012 was the highest on record for the month of January. [EPA-HQ-OAR-2010-0799-9419-A1, p. 3]

Household gasoline expenditures set a record last year, reaching an average of over $2,850 per year. [EPA-HQ-OAR-2010-0799-9419-A1, p. 3]

Rising gasoline prices have changed the structure of the cost of driving. Ten years ago, the average cost of owning a vehicle was the largest single component of the cost of driving. Today, the average cost of owning a vehicle has come down approximately 20% and the cost of gasoline has tripled. [EPA-HQ-OAR-2010-0799-9419-A1, p. 3]

In 2011, the cost of gasoline will equal or exceed the cost of owning the vehicle for the first time. [EPA-HQ-OAR-2010-0799-9419-A1, p. 3]

In 2011, gasoline expenditures were 40 percent higher than expenditures on home energy (electricity, natural gas and heating oil); ten years ago, they were 13% lower. [EPA-HQ-OAR-2010-0799-9419-A1, p. 3]

II. CONSUMERS ATTITUDES: CONSUMERS WANT MORE FUEL EFFICIENT VEHICLES AND SUPPORT FUEL ECONOMY STANDARDS.

Given the burden on household budgets and the continuing problem of oil vulnerability, it is not surprising to find that 75 percent or more of respondents to our public opinion polls: [EPA-HQ-OAR-2010-0799-9419-A1, p. 4]

- are concerned about gasoline prices and dependence on Mid-East oil;
- think it is important to reduce oil consumption; and,
- support higher fuel economy standards as a good way to do so.
- In fact, almost two-thirds of the respondents support a 60 mile per gallon standard with a payback period of 3-5 years and think it will be good for automakers. [EPA-HQ-OAR-2010-0799-9419-A1, p. 4]

Exhibit S-3 shows widespread support for fuel economy standards that are even higher than those proposed by NHTSA-EPA in a national random sample poll of over 2000 respondents. Substantial majorities support standards across different types of states and the political spectrum, even with payback periods of ten years. [See Exhibit S-3 on p. 4 of Docket number EPA-HQ-OAR-2010-0799-9419-A1] [EPA-HQ-OAR-2010-0799-9419-A1, p. 4]

III. CONSUMER BEHAVIOR: CONSUMERS HAVE SHOWN THEY ARE WILLING TO PAY FOR MORE FUEL EFFICIENT VEHICLES

Consumers don’t just say they want more fuel efficient vehicles--they have shown they are willing to buy them. Looking at the total light duty markets (cars and light trucks) between 2004, the year when the worst price increases began, and 2011, the market shares of:] [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

- cars increased from 48% to 59% of all vehicles,
- 4-cylinder engines increased from 28% to 48%,
- the use of variable transmissions and the number of gears has increase dramatically, and
- sales of small and mid-sized SUVs increased by more than one-third to almost 21% of all vehicles sold, while large SUVs dropped by 70% to less than 2% of vehicles sold.

Looking at cars only, [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

- hybrids increased from less than 1% of cars sold to more than 6%, but
- small cars remained constant at 47% of all cars sold. [EPA-HQ-OAR-2010-0799-9419-A1, p. 5]

THE EMERGENCE OF A NATIONAL POLICY CONSENSUS

The reality of soaring consumer expenditures on gasoline and the response by consumers in the marketplace provides the context for the dramatic shift in public policy and the growth of a political consensus over the first decade of the 21st century. Although the gasoline price spike of 2000-2001 proved to be a blip, compared to later developments, it got the attention of the public and policy makers. [EPA-HQ-OAR-2010-0799-9419-A1, p. 14]

At least since the National Academy of Sciences concluded in 2002 that technologies exist to dramatically increase fuel economy at manageable costs, the public policy debate has been about how far and how fast the fuel economy of the vehicle fleet can be raised. In the early 2000s, California exercised its authority under the Clean Air Act to propose new standards to cut emissions from automobiles, which have the effect of also increasing fuel economy. When 13 states and the District of Columbia adopted the Clean Cars Program, they created a market that ranks in the top five in the world and gave a big push to raising standards.1 The automakers could not ignore such a market. [EPA-HQ-OAR-2010-0799-9419-A1, p. 15]

The much more dramatic price spikes of the middle of the decade moved concerns about gasoline consumption to center stage, so much so that President Bush made a dramatic statement about it in his 2006 State of the Union Address by declaring “here we have a serious problem: America is addicted to oil, which is often imported from unstable parts of the world. The best way to break this addiction is through technology.”2 Democrat and Republican legislators, federal and state policy makers as well as all three branches came together to support a significant increase in fuel economy standards. [EPA-HQ-OAR-2010-0799-9419-A1, p. 15]

In response, Congress, with Republican majorities in both houses, enacted the Energy Independence and Security Act of 2007 (EISA). The law, which both the Bush administration and the Obama administration moved quickly to implement, reformed and improved the approach to standards and restarted the process of setting standards, after almost three decades in which the fuel economy standards program had been essentially dormant. [EPA-HQ-OAR-2010-0799-9419-A1, p. 15]

Congressional action significantly improved the approach to standard setting in several ways. For example, by requiring NHTSA to set an attribute-based standard, the incentive to downsize the fleet is reduced. Authorizing several forms of flexibility promotes efficiency in meeting the standard. Incentives encourage development of new technologies. The momentum for higher standards was reinforced by the courts and legal action. A Supreme Court decision upholding the authority of the U. S. Environmental Protection Agency (EPA) to regulate greenhouse gasses as a pollutant strengthened federal authority. The federal government supported the Clean Cars program and the courts upheld state authority. [EPA-HQ-OAR-2010-0799-9419-A1, p. 15]

The Obama Administration has used Executive Branch authority to improve the overall process. The White House issued an executive order that required EPA and NHTSA to coordinate with each other and the California Air Resources Board--coordination that immediately led to increases in the standard that will save consumers over $35 billion in the 2012-2015 period alone. The ongoing effort to set a long-term standard responds to the oft repeated observation that the auto industry needs time to adapt. [EPA-HQ-OAR-2010-0799-9419-A1, p. 15]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 42.]

The simple fact of the matter is that with every scenario considered by the two agencies the benefits vastly exceed the costs, and everyone gets that. That's why you heard labor, you have heard the environmentalist, you've heard automakers and you've heard consumers support this program.

Simply put, these standards may well be the most important energy policy of the last quarter of a century. They are a win-win-win for consumers, for the economy, for national security and the environment.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 58.]

The proposed standards will deliver major economic security, air quality benefits to consumers and the nation while putting the U.S. auto industry back on the path to global success.

We are not alone in the support of this standard. Consumers, automakers and autoworkers recognize the important need for achievability of more fuel-efficient vehicles.

It is remarkable that 13 of the 16 major car manufacturers support these standards. Clearly, they know they can manufacture the vehicles that meet the standard, and they understand it's what their consumers want and will pay for.

The only major opponents of this consumer-backed policy are the car dealers. Their opposition shows what I believe to be an incomprehensible reaction to the desires of their customers, the capability of manufacturers that they sell the cars for, and the critically important need to reduce our dependency on foreign oil. So we appreciate the opportunity to respond to our good friends in the auto dealers community.

---

1 The Clean Cars states (Arizona, Connecticut, Washington D.C., Florida, Maine, Maryland, Massachusetts, New Jersey, New Mexico, New York, Oregon, Rhode Island, Vermont, and Washington). account for 40% of U.S. registered vehicles (Bureau of the Census, STATISTICAL ABSTRACT OF THE UNITED STATES http://www.census.gov/compendia/statab/2006/transportation/motor_vehicle_registrations/) making the market larger than all markets except the rest of the U.S., the European Union and Japan,

2 'Here we have a serious problem: America is addicted to oil, which is often imported from unstable parts of the world. The best way to break this addiction is through technology,' he said,

adding that technological advances will help achieve a 'great goal: to replace more than 75 percent of our oil imports from the Middle East by 2025.” http://articles.cnn.com/2006-01-31/politics/sotu.energy_1_oil-prices-oil-imports-big-oil?_s=PM:POLITICS

Organization: Consumer Reports

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 168-169.]

In summary, we support the proposed fuel economy standards because in addition to achieving national security and environmental goals, they will save consumers thousands of dollars, and improve the selection of fuel efficient and alternative fuel vehicles and maintain the range of wide vehicle options.

Organization: Consumers Union

Introduction

Consumers Union supports the proposed Corporate Average Fuel Economy (CAFE) standards and recommends that the National Highway Traffic Safety Administration (NHTSA) and the Environmental Protection Agency (EPA) move forward to update the program for 2017-2025 to build upon the progress made in the last CAFE rulemaking for model years 2012-2016. While we believe a higher CAFE target, particularly for light trucks, would drive even greater fuel savings and technological advancement, the proposed target is reasonable and provides excellent value for consumers. [EPA-HQ-OAR-2010-0799-9454-A2, p.1]

Comments

I. Consumers benefit from the proposed standards

Improving fuel economy standards serves important national security, economic, and environmental goals and provides outstanding consumer benefits. Requiring better fuel efficiency from every auto manufacturers’ fleet will drive innovation, provide more certainty for investment in cleaner and more efficient technologies, and help erode the price premium often charged for superior fuel economy. Right now, many automakers charge more for more fuel efficient versions of certain vehicles,[2] and hybrid power trains often run thousands of dollars more expensive than their traditional counterparts. Improving fuel economy standards will spur greater investment and deployment of more efficient gasoline engines and create incentive for improvements in battery technology that will lower costs and improve performance of electric and hybrid-electric power trains. [EPA-HQ-OAR-2010-0799-9454-A2, pp.1-2]

In conclusion, Consumers Union commends NHTSA and EPA for developing robust, forward-looking CAFE standards that should yield substantial consumer benefits and encourages the agencies to head off and monitor any compliance strategies that undermine the projected benefits. A more efficient fleet will save consumers thousands of dollars in fuel costs, improve selection of fuel efficient and alternative fuel vehicles, and maintain a range of options across vehicle class. Thank you for considering our views. [EPA-HQ-OAR-2010-0799-9454-A2, pp.7-8]

---

2 - Examples include the Ford Fiesta SFE, Ford Focus SFE and Honda Civic HF.

Organization: Delphi Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 108-112.]

We support the continuation of a national program that incorporates energy efficiency and emission reduction benefits, while remaining technology neutral without favoring selective approaches.

Again, we feel a national program that incorporates energy efficiency and emission reduction benefits should remain technology neutral. I think you can see that Delphi has taken this approach in order to provide its customers the broadest range of technologies to meet their individual requirements.

Organization: Detroit NAACP

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 139.]

We applaud the EPA, NHTSA as well as DOT as well as California and the Obama Administration for taking another large step along a long road to sustainable transportation systems.

Organization: E100 Ethanol Group

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 202.]

The E100 Ethanol Group fully supports the objectives of this program as evidenced by the White House graphic released last July.

Organization: Eaton Corporation

Our comments are meant to strike a balance between GHG reduction goals and the economic realities of the U.S. automotive and transportation industries, taking into account the diverse goals of all stakeholders ranging from original equipment manufacturers (OEM), automotive technology suppliers, dealers and environmental advocates. We believe that the framework outlined in the NPRM is a good step toward a final regulation that will drive innovation and foster both technology and competition, while maintaining fleet diversity and incentivizing over-achievement of emissions and fuel economy targets. [EPA-HQ-OAR-2010-0799-9494-A1, p. 2]

We hope that our comments contribute to the current framework outlined in the NPRM and lead to a final regulation that will drive innovation and foster both technology and competition, while maintaining vehicle performance, safety and affordability. [EPA-HQ-OAR-2010-0799-9494-A1, p. 3]

Organization: Ecology Center

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 191.]

Beyond the direct benefits of the standard, the Ecology Center would like to commend the EPA and NHTSA on its successful negotiation that is reflected in the standards we are discussing here today. It is no small feat to be able to bring together such a broad representation of interests including the automotive, environmental and consumer groups as well as the State of California to negotiate a rule that all parties can support. We believe it is important to recognize the successful process that the agencies have managed and led, including the cooperation between the two agencies itself.

Organization: EcoMotors International, Inc.

EcoMotors supports continuation of a coordinated National Program to reduce GHG emissions and improve fuel economy, and generally supports the manner in which the agencies have proposed to harmonize their regulations. [EPA-HQ-OAR-2010-0799-9594-A2, p. 1]

Organization: Edmunds.com

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 100.]

I'd like to first note that the Edmunds.com agrees with the motivation behind the proposed CAFE standards; that is, we agree it is necessary for the government to intervene in the market in order to significantly reduce vehicle emissions and increase reliance on foreign oil.

Organization: Electric Drive Transportation Association

EDTA supports many aspects of this proposal, including the zero-emissions compliance value and the inclusion of a multiplier for electric drive vehicles. These incentives will enable manufacturers to accelerate the development and deployment of electric drive technologies, which will give consumers a wide array of vehicle choices, while also helping to reduce emissions and reduce our dependence on petroleum fuels. [EPA-HQ-OAR-2010-0799-9449-A1, p. 1]

We urge EPA and NHTSA to finalize a rule that retains strong incentives for electric drive vehicles, while also addressing the specific concerns raised in these comments. [EPA-HQ-OAR-2010-0799-9449-A1, p. 7]

Organization: Environmental Defense Fund (EDF)

We applaud the collaboration between EPA, NHTSA, auto companies, the workers that forge cleaner cars and the state of California in building this proposal, together, through tough negotiations and an abiding commitment to a common good for our nation. The success of this collaboration is reflected in the broad support for this rule from small businesses, consumers, veterans, national security experts, and many more across our land. [EPA-HQ-OAR-2010-0799-9519-A1, p.2]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 171.]

In 2010, NHTSA and EPA together finalized the first-ever joint greenhouse gas and fuel economy standards for light-duty vehicles – a laudable achievement. The Agencies estimate that the standards for MY2012-2016 cars and light trucks will save consumers more than $3000 over the lifetime of a 2016 vehicle. The rule is also expected to reduce GHG emissions from the light-duty fleet by approximately 21 percent by 2030 and save 1.8 billion barrels of oil over the lifetime of the fleet.12 [EPA-HQ-OAR-2010-0799-9519-A1, p.3]

Following this first phase of fuel economy and GHG standards, in a May 2010 Presidential Memorandum, President Obama requested that EPA and NHTSA continue a coordinated National Program to improve fuel efficiency and reduce greenhouse gas emissions of light-duty vehicles for MY2017–2025. The President stated that the second phase should “seek to achieve substantial annual progress in reducing transportation sector greenhouse gas emissions and fossil fuel consumption” and “strengthen the industry and enhance job creation in the United States.”13 In this proposal the agencies estimate the second phase of the National Program will save approximately 4 billion barrels of oil and 2 billion metric tons of GHG emissions over the lifetimes of those vehicles sold in MY 2017-2025. The agencies also estimate that the fuel savings will far outweigh higher vehicle costs, and that the net benefits to society of the proposed standards will be as much as $421 billion over the lifetime of MY 2017-2025 vehicles.14 [EPA-HQ-OAR-2010-0799-9519-A1, p.3]

If finalized, these standards, together with MY 2012-2016 standards, will create a formidable National Program that will greatly reduce our reliance on foreign oil and our contribution to climate altering greenhouse gas emissions, while saving Americans over a trillion dollars. [EPA-HQ-OAR-2010-0799-9519-A1, p.3]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 287.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 172-173.]

The proposed rule under consideration today will help to provide energy security, economic security and climate security for our nation. Increasing the efficiency of our passenger fleet is one of the single most effective solutions we can employ to reduce our dependence on oil, and will likely be President Obama's greatest climate and energy security legacy.

Organization: Ferrari

Ferrari appreciates the efforts made by EPA and NHTSA to work closely together and with CARB in order to develop a proposal for a single coordinated national program (herewith National Program) to regulate greenhouse gases and fuel economy for the period MYs 2017-2025, as it was done for the final rule for MYs 2012-16. This is a prerequisite that allows auto manufacturers to build a single national light-duty fleet that would comply with both the GHG and the CAFE standards, and also with CARB GHG regulation. [EPA-HQ-OAR-2010-0799-9535-A2, p.10]

We deem it is essential to have federal regulations on these important topics, to avoid a patchwork of different State rules. Accordingly, it is necessary that, once the National Program is adopted as final rule, the California will accept the compliance with it and no other State rules on this subject will be enacted in the future years. [EPA-HQ-OAR-2010-0799-9535-A2, p.10]

It is important to define regulations which do not penalize certain types of vehicles, and manufacturers to allow consumers to choose from the same mix of vehicles that are currently in the marketplace. [EPA-HQ-OAR-2010-0799-9535-A2, p.10]

CO_2 emissions and fuel economy are strictly related to each other. Therefore, we appreciate the effort of EPA and NHTSA to harmonize the corresponding regulations to the greatest extent feasible, taking into account the respective statutory obligations. Hopefully such harmonization should be extended to the provisions reserved to small-volume manufacturers and small business entities. [EPA-HQ-OAR-2010-0799-9535-A2, p.14]

Organization: Fisker Automotive, Inc.

Fisker Automotive applauds EPA and NHTSA for their leadership in establishing a National Program that jointly reduces greenhouse gas emissions and improves fuel economy in the light-duty fleet. This is an important step the builds upon the groundbreaking May 7, 2010 rule to establish fleet greenhouse gas emissions and fuel economy standards for model years 2012-2016. [EPA-HQ-OAR-2010-0799-9266-A1, p. 1]

Fisker believes that protecting the environment and the nation’s energy security are important goals that play an increasingly prominent role in car buying decisions. We also believe that car buyers would like to reduce their impact without compromising the performance, luxury, or freedom that they expect from today’s cars. [EPA-HQ-OAR-2010-0799-9266-A1, p. 1]

We remain overall strongly supportive of both agencies’ efforts to reduce emissions and fuel consumption, and urge them to allow our company to fully participate in these efforts as soon as reasonably possible. [EPA-HQ-OAR-2010-0799-9266-A1, p. 5]

Organization: Ford Motor Company

Just over two years ago we provided comments on the regulation that harmonized greenhouse gas emissions and CAFE standards for passenger cars and light duty trucks for model years 2012 through 2016. At that time we encouraged the Agencies to continue to work together to ensure continuation of the harmonized requirements beyond 2016. This proposal seeks to achieve that goal. We applaud the combined efforts of EPA and NHTSA in the development of a joint proposal to extend One National Program. Only a harmonized, nationwide set of GHG and fuel economy standards will enable manufacturers to plan and invest for the future with confidence. [EPA-HQ-OAR-2010-0799-9463-A1, p. 1]

While the new requirements go far beyond the first regulation, both in the timeframe covered as well as the challenges they pose for our industry, we support the national goals for greenhouse gas reduction and energy independence that have driven these aggressive targets. [EPA-HQ-OAR-2010-0799-9463-A1, p. 1]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 42-43.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 30-31.]

We applaud the combined efforts of the EPA and NHTSA, as well as the California Air Resources Board. This proposal provides our industry both the single program moving forward, as well as the regulatory framework that enables manufacturers to plan and invest for the future with confidence.

As a result, we are continually investing in our product strategy to improve the fuel economy and reduce the greenhouse gas emissions of our fleet.

Starting this year, one-third of our vehicle line up will offer a model that achieve at least 40 miles per gallon.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 43.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 30-31.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 10-11.]

The standards proposed are aggressive, but so are the demands from our customers for greater fuel efficiency.

Organization: General Motors Company

General Motors Company recognizes the benefits to the country and to vehicle manufacturers of continuing the National Program to address fuel economy and greenhouse gases that the Environmental Protection Agency (EPA) and the National Highway Traffic Safety Administration (NHTSA) began in 2009 with the standards for model years 2012 through 2016, and that those agencies are proposing to continue for 2017 and later model years. As indicated in our comments at the January 17, 2012 public hearing in Detroit, General Motors Company supports the proposal and hopes it serves as the basis for a continued National Program. [EPA-HQ-OAR-2010-0799-9465-A1, p. 2]

The agencies' have crafted a proposal that is consistent with the intent of the framework announced by the administration on July 29, 2011. We commend the technical staffs of both agencies for working together on this highly complex issue, and appreciate their efforts to produce a harmonized approach for federal regulation of new vehicle fuel economy and greenhouse gas emissions. We further commend the agencies for the leadership that the federal government has shown in trying to minimize the disruptive impacts of having multiple and different programs at the federal and state levels. [EPA-HQ-OAR-2010-0799-9465-A1, p. 2]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 34-35.]

GM supports the flexibilities in the proposal. They reflect due consideration of the technical data and are appropriately designed to encourage early investment in technologies that will produce both fuel consumption and environmental benefits -- the same technologies that will be necessary to meet the challenging future standards. [EPA-HQ-OAR-2010-0799-9465-A1, p 3]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 38.]

In conclusion, we urge both EPA and NHTSA to continue the strong leadership role they have displayed at the federal level with an integrated approach that addresses infrastructure of vehicles themselves, fuels, and customer behavior as well as all other sectors of the economy. This proposal is a positive first step and a good foundation on which we can all build.

Organization: Growth Energy

Growth Energy and its members salute the efforts by NHTSA and EPA (collectively, "the Agencies") to solicit data, analysis and views on the Joint NPRM, and to respond to the public's comments. [EPA-HQ-OAR-2010-0799-9505-A1, p. 1]

Organization: Guardian Automotive Products, Inc.

Guardian also applauds the harmonization of fuel economy and CO_2 emissions credits. [EPA-HQ-OAR-2010-0799-9299-A1, p. 1]

Organization: Honeywell International, Inc.

Honeywell commends EPA and NHTSA for their hard work and foresight in developing a Proposed Rule that responds to 'our country's critical need to address global climate change and to reduce oil consumption' for the foreseeable future. [EPA-HQ-OAR-2010-0799-9497-A1, p.3]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 206.]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 259.]

Honeywell supports the National Program of increasing fuel economy and reducing greenhouse gas emissions. A harmonized regulatory structure allows OEMs to define product pathways forward toward compliance. This, in turn, allows suppliers to focus research and development in order to provide the most substantial short and long-term benefits.

Organization: Honeywell Transportation Systems

Honeywell appreciates the opportunity to contribute to this rulemaking and remains committed to offering solutions to reduce GHG emissions in the United States in a manner that allows the nation’s automotive industry to thrive. [EPA-HQ-OAR-2010-0799-9474-A1, p.6]

Organization: House of Representatives, Congress of the United States

We write to commend you for bringing certainty to fuel economy and tailpipe emission standards for model years 2017-25 cars and light trucks to 54.5 miles per gallon (mpg). [EPA–HQ–OAR–2010–0799-1221-A1, p. 1]

The framework agreement brought together automotive manufacturers, labor, the environmental community, and government agencies. Industry groups such as the National Association of Manufacturers praised the agreement as a 'positive step.' As a result, automakers will enjoy regulatory certainty, which will help them design and build the advanced technology vehicles of the future and compete in an increasingly global marketplace. The agreement protects American jobs and consumers, and as such was a remarkable achievement. [EPA–HQ–OAR–2010–0799-1221-A1, p. 1]

These regulations, taken together with the first phase of the standards for model years 2012-16 vehicles, will remove the need for as much as 3.8 million barrels of petroleum per day by 2030. Consumers will save thousands of dollars at the pump for gasoline they will no longer need to buy over the lifetime of their vehicles. [EPA–HQ–OAR–2010–0799-1221-A1, p. 1]

In conclusion, we believe that these standards to reduce petroleum use in cars and light trucks represent an opportunity to increase our national and economic security in an unprecedented way by dramatically decreasing our dependence on foreign sources of petroleum. They also bring a certainty to the regulatory framework for the industry and workers who design and build these vehicles. [EPA–HQ–OAR–2010–0799-1221-A1, p. 1]

Organization: Howard, P.

I am writing in support of the strong fuel-efficiency and carbon pollution standards for new cars and trucks. [EPA-HQ-OAR-2010-0799-10063-A1, p. 1]

The benefits of strong standards are overwhelming. By giving automakers a clear direction for improving their new vehicles, EPA and DOT together are ensuring that new vehicles in 2025 will be almost twice as efficient as new vehicles today. I know the automakers can do better and these standards will ensure that automakers innovate and put the best technologies to work to cut dangerous carbon pollution and help America move beyond oil. [EPA-HQ-OAR-2010-0799-10063-A1, p. 1]

I applaud the EPA and DOT for working together to propose these standards that will strengthen fuel efficiency and carbon pollution standards for new passenger cars and trucks to 54.5 mpg by 2025. It matters to me that we take this critical step to curb the dangers of climate disruption, cut our addiction to oil, and keep billions of dollars in our economy instead of spending them on oil. [EPA-HQ-OAR-2010-0799-10063-A1, p. 1]

Organization: Hyundai America Technical Center

The improvement of fuel economy and the control of GHGs are very important to Hyundai. Hyundai has long been an industry fuel efficiency leader and, in 2010, we publicly pledged to reach fleet-wide performance of 50 plus mpg by 2025. In our discussions with the agencies on this rulemaking, we have consistently supported a standard in excess of 50 mpg and we continue to support the agencies on this rulemaking. [EPA-HQ-OAR-2010-0799-9547-A1, p.1]

We appreciate the significant effort on the part of all the agencies in the difficult task of developing feasible and harmonized national greenhouse gas and CAFE standards. We believe that it is the right thing to do for the environment and for the nation's energy security. [EPA-HQ-OAR-2010-0799-9547-A1, p.1]

In summary, Hyundai applauds the agencies' efforts in putting together a national program to reduce GHG emissions and improve fuel economy. [EPA-HQ-OAR-2010-0799-9547-A1, p.8]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 172.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 22.]

We continue to support the agencies in this rulemaking. We believe that it's the right thing to do for the environment and for the nation's energy security.

Organization: ICM Inc.

There are a multitude of reasons for pursuing higher fuel economy fuel standards in light-duty trucks and passenger vehicles ranging from energy security to improved air quality to economic development. We believe the CAFE Rule presents an opportunity to touch all of these objectives, which, of course, begin with the simple notion of reducing our use of imported petroleum. [EPA-HQ-OAR-2010-0799-9541-A2, p.1]

Organization: Insurance Institute for Highway Safety (IIHS)

As we have done in the past, IIHS supports NHTSA's efforts to increase fuel economy while maintaining vehicle safety through the use of a size-based system. [NHTSA-2010-0131-0222-A1, p.1]

Organization: International Council on Clean Transportation (ICCT)

This proposed rule builds upon the impressive improvements in the 2012---16 final rules and takes another large step towards catching up with vehicle efficiency in Europe, Japan, and other nations (Figure 1). We applaud EPA and NHTSA, along with California, the Administration, and the vehicle manufacturers, for taking another step along the road to a sustainable transportation system and enhancing U.S. credibility worldwide. [See Figure 1 on p. 1 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 1]

There are tremendous opportunities to dramatically reduce climate change emissions from passenger vehicles in the near term. Internal combustion engines are over a century old and are widely perceived as nearing the end of their development, but the reality is exactly the opposite. The same is true for materials that make up the vehicle body and parts. Rapid improvements in computer---based tools are opening up technology gains that were never possible before. Computer simulations and computer---aided---design are enabling vastly improved designs and on---board computers allow unprecedented integration of engine, transmission, and hybrid operation. Instead of slowing down, the pace of technology development just keeps accelerating. This is especially true of lightweight material design. [EPA-HQ-OAR-2010-0799-9512-A1, p. 2]

Aggressive standards and long---term signals are needed to fully realize this technology potential. ICCT strongly supports a strong federal rule and recognizes and applauds the constructive role that California has played in building the technical and public support for this critical rulemaking. [EPA-HQ-OAR-2010-0799-9512-A1, p. 2]

The proposed 2017---25 rules provide the long---term goals needed for manufacturers to develop consistent, long---term technology and product plans, and serves as a valuable precedent for other countries worldwide evaluating future efficiency and greenhouse gas standards. The overall stringency of the proposed rules is potentially adequate, provided that it is not eroded significantly by additional credits or changes in the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 2]

As shown in Figure 1, countries worldwide are also adopting efficiency standards and promoting technology improvements. Similar standards are needed in the US to ensure that our domestic manufacturers remain fully competitive in the world market and maintain domestic employment.

[Figure 1 can be found on p. 1 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 13]

Efficiency standards are a win for consumers, a win for energy security, a win for manufacturers, and a win for the economy. It is all paid for by oil exporting countries, as efficiency standards will both reduce their oil exports and depress the amount they get paid per barrel. [EPA-HQ-OAR-2010-0799-9512-A1, p. 13]

Efficiency standards or incentives tied directly to vehicle efficiency are necessary to capture these huge benefits for energy security and the economy. There are no other options. Certainly, care must be taken to set the standards appropriately, as has been done in the proposed rule, but rolling back or stopping the standards is equivalent to shutting down oil wells in the US. In fact, it is worse due to the missed opportunity to improve the economy. [EPA-HQ-OAR-2010-0799-9512-A1, p. 13]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 192.]

We applaud EPA, NHTSA, along with California, the Administration and the vehicle manufacturers for taking another large step along the road to a sustainable transportation system.

In closing the ultimate goal is to create a sustainable transportation system. ICCT looks forward to working with everyone involved including, first of all, including the federal and state agencies and vehicle manufacturers to help shape the best policies and programs to meet our clean air, energy security and climate change objectives.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 28-29.]

I want to congratulate you and the staff of EPA, as well as the California Resources Board, NHTSA, for building on the earlier rule and aggressively setting the stage so that the U.S. can not only catch up but surpass countries in the world in the desire to improve fuel economy, reduce greenhouse gases and reduce dependence on fossil fuels.

Organization: Investor Network on Climate Risk (INCR) - Ceres

As long-term investors, and as members of the Investor Network on Climate Risk (INCR), which represents over $10 trillion in assets, we are writing to voice our strong support for the proposed Greenhouse Gas (GHG) Emissions and Corporate Average Fuel Economy (CAFE) Standards. Independent analysis shows that strong standards will lead to job creation across the country, as well as increased profitability for the auto industry, a major driver of the economy. Further, these standards represent an unprecedented opportunity to shield us from volatile oil price spikes as well as to reduce climate risk.[EPA-HQ-OAR-2010-0799-9516-A1, p. 1]

In sum, strong standards will strengthen our economy, spur innovation, reduce both our dependence on oil and climate risk, save businesses and consumers money, and create jobs.

Accordingly, we urge the adoption of the strongest standards possible. [EPA-HQ-OAR-2010-0799-9516-A1, p. 2]

Organization: Jaguar Land Rover North America, LLC (JLRNA)

We would like to take the opportunity to thank both the Environmental Protection Agency and National Highway Traffic Safety Administration for their efforts in pulling together this proposal for a single national standard for 2017 – 2025 model years. Going forward this will continue to provide stability to enable future business and product strategy planning to take place. [EPA-HQ-OAR-2010-0799-8102-A1, cover letter]

Organization: Johnson Controls, Inc.

Johnson Controls is encouraged that NHTSA and EPA are continuing to work together on this second phase of the national program for MYs 2017-2025. Johnson Controls strongly supports the continuation of a uniform national program. It allows vehicle manufacturers to focus investments on cost-effective technologies for their fleets in order to meet the requirements of the proposed rule, while delivering products that consumers will want and represents a viable economic solution. This activity allows the energy storage manufacturer to continually innovate, advancing development, and deliver commercially viable products. [NHTSA-2010-0131-0253-A1, p. 2]

Furthermore, Johnson Controls supports the efforts of the agencies to harmonize and align their respective standards, where appropriate. Synchronizing standards improves regulatory clarity and provides certainty. [NHTSA-2010-0131-0253-A1, p. 4]

• Harmonization for this next phase of the National Program is critical to its long-term success. Johnson Controls supports the proposals to harmonize the GHG emissions and CAFE standards.

Organization: Kendall, A.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 166.]

I'd also like to state my support for the rulemaking or proposed rulemaking and offer praise for all the in-depth research that's already happened.

Organization: Kia Motors

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 100-101.]

I want to start by saying that Kia emphatically supports the proposal and believes that it is important for the agencies to set tough but feasible standards while providing flexibilities which allow each automaker to maximize their strengths in achieving the standards.

Organization: Kobus, D.

As an Environmental Scientist, I know the importance of this kind of policy in turning our future toward one of renewables in the time we need to do it. [EPA-HQ-OAR-2010-0799-1370-A1, p. 2]

The projected annual benefits of such standards by 2030 are enormous:

* 23 billion gallons of gasoline saved

* 280 million metric tons of global warming pollution avoided

* $45 billion in savings at the gas pump [EPA-HQ-OAR-2010-0799-1370-A1, p. 2]

I support the proposed standards, and I urge you to ensure that these projected benefits become a reality by keeping these standards free of loopholes that could undermine their environmental and economic benefits. [EPA-HQ-OAR-2010-0799-1370-A1, pp. 2-3]

Organization: League of Women Voters of Michigan

The League of Women Voters of Michigan supports the proposed rules for fuel efficiency and emissions standards and believes they will have significant public health and economic benefits. [NHTSA-2010-0131-0198, p.1]

We support the new standards because they will substantially reduce pollution caused by vehicle emissions. We know that air pollution damages people's health and causes premature death, particularly in children, the elderly, and people with chronic health problems. Air pollution is a major trigger of asthma attacks. [NHTSA-2010-0131-0198, p.1]

We support these regulations for the benefit of our children's health and future. [NHTSA-2010-0131-0198, p.1]

In addition to lives saved and quality of life benefits, air quality improvements have tangible economic benefits, due to better health and productivity and reduced medical expenses. The new vehicle standards will also spur innovation and investment in new technologies, which will create jobs in advanced automotive technology [NHTSA-2010-0131-0198, p.1]

Organization: Magna E-Car Systems

I'm pleased to comment in support of the 54.5 mpg proposed fuel economy standards put forward by the Environmental Protection Agency (EPA) and National Highway Traffic Safety Administration (NHTSA). [EPA-HQ-OAR-2010-0799-9263-A1, p. 1]

The 54.5 mpg fuel economy standards are necessary spur investment and innovation in the hybrid and electric vehicle technologies, like Magna E-Car Systems and other automotive suppliers essential to meeting our growing 21st century transportation energy needs. [EPA-HQ-OAR-2010-0799-9263-A1, p. 2]

Organization: Manufacturers of Emission Controls Association (MECA)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 179-183.]

We believe an important opportunity exists to significantly reduce greenhouse gas emissions and improve fuel economy from passenger cars, light-duty vehicle trucks and medium duty passenger vehicles.

To conclude, MECA commends EPA, NHTSA and California for taking important steps to further reduce greenhouse gas emissions and improve fuel economy for light-duty vehicles. Our industry is prepared to do its part and deliver cost-effective advanced emission control technologies to the market for these more fuel efficient vehicles.

Organization: Marshall, C.

When I first read of the goal of 54.5 mpg for the year 2025, my reaction was that I liked the rule, but it seemed ambitious. Then I read that the rule was a negotiated rulemaking, and that the auto community participated. My spirits soared. I think negotiated rulemakings that include members of the affected community make better regulations in the long-run than imposed regulations. [EPA-HQ-OAR-2010-0799-5917-A2, p. 1]

I think this particular regulation is a win-win-win program because of all the benefits for (1) reducing carbon emissions, ozone precursors, and other auto emission pollutants, (2) reducing oil consumption, imports, and extraction, and (3) making the U.S. more competitive in this technological realm. [EPA-HQ-OAR-2010-0799-5917-A2, p. 1]

Organization: Marz, Loren C.

I generally support the proposed rule to increase fuel economy of cars and light trucks from 2017 to 2025. EPA and NHTSA are to be commended for proposing such significant increases in the Corporate Average Fuel Economy (CAFE). Our economy and climate would benefit from such reductions in fuel consumption and greenhouse gas (GHG) emissions. [NHTSA-2010-0131-0213-A1, p.1]

Organization: Mass Comment Campaign (1,121) (World Wildlife Fund)

I am writing in support of the proposed fuel efficiency standards for new cars and light trucks. [EPA-HQ-OAR-2010-0799-5181_MASS, p.1]

The proposed standards will strengthen fuel efficiency and reduce the carbon pollution contributing to climate change. By increasing standards for new passenger cars and light trucks to 54.5 mpg by 2025, we will show the world that the U.S. is serious about curbing climate change and reducing our dependence on oil. [EPA-HQ-OAR-2010-0799-5181_MASS, p.1]

I urge both the Environmental Protection Agency and the Department of Transportation to finalize these strong standards. [EPA-HQ-OAR-2010-0799-5181_MASS, p.1]

Organization: Mass Comment Campaign (1,338) (Sierra Club-2)

America's dependence on oil puts our environment, economy and national security at risk. You recently took an important step toward addressing this problem when you outlined new vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of a 54.5 mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-11762-A1, p.1]

The projected annual benefits of such a standard by 2030 are enormous:

-$80 billion in savings at the gas pump

-23 billion gallons of gasoline saved

-280 million metric tons of global warming pollution avoided [EPA-HQ-OAR-2010-0799-11762-A1, p.1]

Moving forward, I urge you to ensure that these projected benefits become a reality by keeping this standard as strong as possible through the rulemaking process, and avoiding loopholes that could undermine the standard's environmental and economic benefits. [EPA-HQ-OAR-2010-0799-11762-A1, p.1]

Organization: Mass Comment Campaign (13,300) (National Wildlife Federation Action Fund-3)

I am submitting the following comments in support of strong fuel efficiency standards, along with the names of the 13,300 supporters of the National Wildlife Federation Action Fund who have sent similar comments to the docket via emails to a-and-r-Docket@epa.gov: [EPA-HQ-OAR-2010-0799-9965_MASS, p.1]

I support making our nation's cars and trucks more efficient to cut the carbon pollution from car exhaust that is driving global warming, which threatens the future of American wildlife. [EPA-HQ-OAR-2010-0799-9965_MASS, p.1]

Taken together, the new and proposed fuel economy standards will cut our demand for oil by 3.4 million barrels per day. That equates to nearly a third of today's transportation fuel use and it cuts carbon pollution by more than 600 million metric tons per year in 2030--that's about 10% of total US carbon pollution today. [EPA-HQ-OAR-2010-0799-9965_MASS, p.1]

These deep oil savings also mean less pressure for risky new drilling projects in the Arctic or to clear cut forest for Canadian tar sands. [EPA-HQ-OAR-2010-0799-9965_MASS, p.1]

Please move forward with strong fuel efficiency standards that cut oil use and reduce carbon pollution. [EPA-HQ-OAR-2010-0799-9965_MASS, p.1]

Organization: Mass Comment Campaign (137 (Citizens for Pennsylvania's Future (PennFuture))

I applaud you and President Obama for proposing strong new fuel economy and tailpipe pollution standards that will result in cleaner cars and cleaner air. The reduction in greenhouse gas and criteria pollution that these standards would achieve are critically important in stabilizing the climate and protecting human health. [EPA-HQ-OAR-2010-0799-3114-A1_MASS, p.1]

-By 2030, the standards would cut annual global warming pollution the equivalent of shutting down 80 coal-fired power plants for a year. This would be of tremendous benefit in slowing climate change.

-The proposed standards would create almost 500,000 jobs across the country, including 21,000 in Pennsylvania.

-The standards would save as much oil in 2030 alone as we currently import from Saudi Arabia and Iraq. [EPA-HQ-OAR-2010-0799-3114-A1_MASS, p.1]

Please make sure the proposed standards are not weakened in any way before being enacted. I am copying my Congressional representatives on this email so that they know how important a strong clean cars rule is to me, and that I want them to support a strong rule as well. Thank you for your efforts reflected in this proposal that will improve public health, enhance national security, protect the environment, and strengthen our economy. [EPA-HQ-OAR-2010-0799-3114-A1_MASS, p.1]

Organization: Mass Comment Campaign (15) (League of Conservation Voters)

I support the proposed new rules that would increase national fuel economy standards to 54.5 miles per gallon by the year 2025 and I commend the Obama administration for continuing to pursue strong, clean vehicle standards that will reduce our dangerous dependence on oil and cut global warming pollution, while creating much-needed jobs and saving drivers money at the pump. Additionally, these landmark standards remind us of the valuable role that the federal government can play in strengthening the economy and protecting the planet. [EPA-HQ-OAR-2010-0799-1555-A1_MASS, p.1]

We can do this! [EPA-HQ-OAR-2010-0799-1555-A1_MASS, p.1]

Organization: Mass Comment Campaign (15) (Sierra Club-3)

Electric vehicles can help America move beyond oil. I support your effort to improve fuel efficiency and carbon pollution standards for new cars and light trucks to 54.5 mpg and 163 grams per mile carbon pollution in 2025. These standards ensure that Americans will have better fuel efficiency and advanced technology choices in their new vehicles for years to come. [EPA-HQ-OAR-2010-0799-11763-A1, p.1]

Americans can expect real benefits from your standards. In 2030 alone, strong standards will deliver:

• $44 billion in net savings at the gas pump

• 23 billion gallons of gasoline saved

• 280 million metric tons of carbon pollution avoided. [EPA-HQ-OAR-2010-0799-11763-A1, p.1]

A well designed program will help bring electric vehicles to the market while ensuring that the pollution reduction, oil savings and consumer benefits of the standards are achieved. I urge you to ensure these standards deliver real benefits for America and avoid loopholes that could undermine the program. [EPA-HQ-OAR-2010-0799-11763-A1, p.1]

Organization: Mass Comment Campaign (195) (Environment New Mexico-1)

America's dependence on oil puts our environment, economy, and national security at risk. Your recent proposal of new fuel efficiency standards was a historic step toward addressing this problem. [EPA-HQ-OAR-2010-0799-9577-A1_MASS, p.1]

The environmental benefits of such a standard by 2030 are enormous. By 2030, we could:

-save more oil than we imported from Saudi Arabia last year, and

-slash global warming pollution by an amount equivalent to shutting down 70 coal-fired power plants. [EPA-HQ-OAR-2010-0799-9577-A1_MASS, p.1]

Moving forward, I urge you to ensure that these projected benefits become a reality by keeping this standard as strong as possible through the rulemaking process, and avoiding loopholes that could undermine the standard's environmental benefits. [EPA-HQ-OAR-2010-0799-9577-A1_MASS, p.1]

Organization: Mass Comment Campaign (2,120) (Pew Environmental Group)

I support the proposed rule to increase fuel economy for new passenger vehicles to an average of 54.5 miles per gallon by 2025, which will allow cars and light trucks to drive farther on a gallon of gas and reduce U.S. dependence on imported oil. The price of gas is once again squeezing the budgets of American families, who already are forced to cut back in other areas just to pay for basic transportation needs. [EPA-HQ-OAR-2010-0799-1247-A1_MASS, p.1]

This spring, you set a goal of reducing oil imports by one-third this decade, and in November you proposed fuel efficiency standards that will effectively double current requirements. I commend your efforts. I believe it is important to increase U.S. investment in fuel efficient technologies, save consumers money at the pump, help this country break its dependence on foreign oil, and protect the environment. Don't let these standards be watered down--protect and finalize the new fuel efficiency rules. [EPA-HQ-OAR-2010-0799-1247-A1_MASS, p.1]

Organization: Mass Comment Campaign (2,156) (Environment Michigan)

America's dependence on oil puts our environment, economy and national security at risk. You recently took an important step toward addressing this problem when you proposed new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of a 54.5 mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-9683-A1_MASS, p.1]

The projected annual benefits of such standards by 2030 are enormous:

• $45 billion in savings at the gas pump

• 23 billion gallons of gasoline saved

• 280 million metric tons of global warming pollution avoided [EPA-HQ-OAR-2010-0799-9683-A1_MASS, p.1]

I support the proposed standards, and I urge you to ensure that these projected benefits become a reality by keeping these standards free of loopholes that could undermine their environmental and economic benefits. [EPA-HQ-OAR-2010-0799-9683-A1_MASS, p.1]

Organization: Mass Comment Campaign (2,851) (Unknown Organization)

I'm writing today in support of stronger fuel-economy and carbon pollution standards for new cars and trucks. [EPA-HQ-OAR-2010-0799-9591-A1_MASS, p.1]

The EPA and the Department of Transportation have an opportunity to ensure that new vehicles in 2025 will be nearly twice as fuel efficient as vehicles today. Adopting stronger standards will drive innovation and incentivize automakers to put their best technologies to work. [EPA-HQ-OAR-2010-0799-9591-A1_MASS, p.1]

The proposed 54.5 mpg standard will be a major step forward to reduce our dependence on fossil fuels. Additionally, it will save Americans billions of dollars annually which can be reinvested in our economy. [EPA-HQ-OAR-2010-0799-9591-A1_MASS, p.1]

Please adopt the strongest fuel-economy and carbon pollution standards possible. [EPA-HQ-OAR-2010-0799-9591-A1_MASS, p.1]

Organization: Mass Comment Campaign (20) (Union of Concerned Scientists-1)

As a scientist, I believe it is vitally important to take this major step to reduce global warming emissions. As proposed, the standard would reduce U.S. emissions by as much as 290 million metric tons in 2030, the equivalent of taking over 40 million of today's typical cars and trucks off the road for a year. [EPA-HQ-OAR-2010-0799-1558-A1_MASS, p.1]

Strong fuel efficiency and vehicle emissions standards have the potential to cut America's oil dependence by 1.5 million barrels per day in 2030, more oil than we currently import from Saudi Arabia and Iraq combined. [EPA-HQ-OAR-2010-0799-1558-A1_MASS, p.1]

A strong clean car program is good for all Americans. [EPA-HQ-OAR-2010-0799-1558-A1_MASS, p.1]

Organization: Mass Comment Campaign (20,500) (Union of Concerned Scientists-3)

UCS applauds the agencies for proposing standards that represent historic progress for American consumers, the U.S. auto industry, clean air, and U.S. energy security. However, key provisions in the proposal could erode these benefits if automakers exploit them, and should be addressed by the agencies before the standards are finalized. [EPA-HQ-OAR-2010-0799-10166-A1_MASS, p.1]

America's dangerous dependence on oil puts our environment, economy, and national security at risk. That's why I strongly support the proposed fuel efficiency and global warming emissions standards for new cars and light trucks sold in model years 2017-2025. [EPA-HQ-OAR-2010-0799-10166-A2_MASS, p.1]

The proposed standards are achievable and reasonable and will save me money at the pump, curb millions of tons of harmful global warming emissions, and save as much oil in 2030 alone as we currently import from Saudi Arabia and Iraq. They will also drive innovation in the U.S. auto industry, creating new jobs across the country. [EPA-HQ-OAR-2010-0799-10166-A2_MASS, p.1]

Though I strongly support these standards, I am concerned about possible loopholes that automakers could exploit. [EPA-HQ-OAR-2010-0799-10166-A2_MASS, p.1]

We cannot afford to delay in confronting the threats of climate change and our dangerous oil dependence. I urge you to move forward with the strongest possible standards free of harmful loopholes. [EPA-HQ-OAR-2010-0799-10166-A2_MASS, p.2]

Organization: Mass Comment Campaign (213) (Environment Virginia)

America's dependence on oil puts our environment, economy, and national security at risk. You recently took an important step toward addressing this problem when you proposed new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of a 54.5 mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-9576-A1_MASS, p.1]

The projected annual benefits of such standards by 2030 are enormous:

-- 23 billion gallons of gasoline saved

-- 280 million metric tons of global warming pollution avoided

-- $45 billion in savings at the gas pump [EPA-HQ-OAR-2010-0799-9576-A1_MASS, p.1]

I support the proposed standards, and I urge you to ensure that these projected benefits become a reality by keeping these standards free of loopholes that could undermine their environmental and economic benefits. [EPA-HQ-OAR-2010-0799-9576-A1_MASS, p.1]

Organization: Mass Comment Campaign (22,122) (Unknown Organization)

I support the proposed rule to increase fuel economy for new passenger vehicles to an average of 54.5 miles per gallon by 2025, which will allow cars and light trucks to drive farther on a gallon of gas and reduce U.S. dependence on imported oil. [EPA-HQ-OAR-2010-0799-9736_MASS, p.1]

The price of gas is once again squeezing the budgets of American families, who already are forced to cut back in other areas just to pay or basic transportation needs. [EPA-HQ-OAR-2010-0799-9736_MASS,p.1]

This spring, you set a goal of reducing oil imports by one-third this decade, and in November you proposed fuel efficiency standards that will effectively double current requirements. I commend your efforts. I believe it is important to increase U.S. investment in fuel efficient technologies, save consumers money at the pump, help this country break its dependence on foreign oil, and protect the environment. Don't let these standards be watered down -- protect and finalize the new fuel efficiency rules. [EPA-HQ-OAR-2010-0799-9736_MASS, p.1]

Organization: Mass Comment Campaign (262) (Environment New Mexico-2)

America's dependence on oil puts our environment, economy and national security at risk. You recently took an important step toward addressing this problem when you proposed new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of a 54.5 mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-9700-A1_MASS, p.1]

The projected annual benefits of such standards by 2030 are enormous:

• $45 billion in savings at the gas pump

• 23 billion gallons of gasoline saved

• 280 million metric tons of global warming pollution avoided [EPA-HQ-OAR-2010-0799-9700-A1_MASS, p.1]

I support the proposed standards, and I urge you to ensure that these projected benefits become a reality by keeping these standards free of loopholes that could undermine their environmental and economic benefits. [EPA-HQ-OAR-2010-0799-9700-A1_MASS, p.1]

Organization: Mass Comment Campaign (27,108) (Unknown Organization)

I am writing in support of the strong fuel-efficiency and carbon pollution standards for new cars and trucks. [EPA-HQ-OAR-2010-0799-9596-A1_MASS, p.1]

The benefits of strong standards are overwhelming. By giving automakers a clear direction for improving their new vehicles, EPA and DOT together are ensuring that new vehicles in 2025 will be almost twice as efficient as new vehicles today. I know the automakers can do better and these standards will ensure that automakers innovate and put the best technologies to work to cut dangerous carbon pollution and help America move beyond oil. [EPA-HQ-OAR-2010-0799-9596-A1_MASS, p.1]

I applaud the EPA and DOT for working together to propose these standards that will strengthen fuel efficiency and carbon pollution standards for new passenger cars and trucks to 54.5 mpg by 2025. It matters to me that we take this critical step to curb the dangers of climate disruption, cut our addiction to oil, and keep billions of dollars in our economy instead of spending them on oil. [EPA-HQ-OAR-2010-0799-9596-A1_MASS,p.1]

Organization: Mass Comment campaign (3,855) (National Wildlife Federation Action Fund-2)

I support making our nation's cars and trucks more efficient to cut the carbon pollution from car exhaust that is driving global warming, which threatens the future of American wildlife. [EPA-HQ-OAR-2010-0799-1557-A1_MASS, p.1]

Taken together, the new and proposed fuel economy standards will cut our demand for oil by 3.4 million barrels per day. That equates to nearly a third of today's transportation fuel use and it cuts carbon pollution by more than 600 million metric tons per year in 2030--that's about 10% of total US carbon pollution today. [EPA-HQ-OAR-2010-0799-1557-A1_MAS, p.1]

These deep oil savings also mean less pressure for risky new drilling projects in the Arctic or to clear cut forest for Canadian tar sands. [EPA-HQ-OAR-2010-0799-1557-A1_MASS, p.1]

Please move forward with strong fuel efficiency standards that cut oil use and reduce carbon pollution. [EPA-HQ-OAR-2010-0799-1557-A1_MASS, p.1]

Organization: Mass Comment Campaign (375) (Union of Concerned Scientists-2)

America's dangerous dependence on oil puts our environment, economy, and national security at risk. That's why I strongly support the proposed fuel efficiency and global warming emissions standards for new cars and light trucks sold in model years 2017-2025. [EPA-HQ-OAR-2010-0799-1246-A1_MASS, p.1]

The proposed standards are achievable and reasonable and will save me money at the pump, curb millions of tons of harmful global warming emissions, and save as much oil in 2030 alone as we currently import from Saudi Arabia and Iraq. They will also drive innovation in the U.S. auto industry, creating new jobs across the country. [EPA-HQ-OAR-2010-0799-1246-A1_MASS, p.1]

Though I strongly support these standards, I am concerned about possible loopholes that automakers could exploit. [EPA-HQ-OAR-2010-0799-1246-A1_MASS, p.1]

We cannot afford to delay in confronting the threats of climate change and our dangerous oil dependence. I urge you to move forward with the strongest possible standards free of harmful loopholes. [EPA-HQ-OAR-2010-0799-1246-A1_MASS, p.1]

We cannot afford to delay in confronting the threats of climate change and our dangerous oil dependence. I urge you to move forward with the strongest possible standards free of harmful loopholes. [EPA-HQ-OAR-2010-0799-1246-A1_MASS, p.1]

Organization: Mass Comment Campaign (39) (Unknown Organization)

I strongly support the proposed CAFE standards for cars and light trucks from 2017 to 2025. The goals summarized in these standards (Docket ID No. EPA-HQ-OAR-2010-0799 and/or NHTSA-2010-0131) show a promising future for the nation's health, environment, national security, and economy. [EPA-HQ-OAR-2010-0799-1245-A1_MASS, p.1]

The estimates released by the White House show the potential for an enormous reduction in green house gas emissions. The decrease in air pollution will be substantial. I am happy to support this strong environmental regulation - one that will directly improve citizen health. [EPA-HQ-OAR-2010-0799-1245-A1_MASS, p.1]

Organization: Mass Comment Campaign (39,464) (Environmental Defense Fund (EDF))

I strongly support the proposed new fuel efficiency and greenhouse gas standards for cars and trucks to require cars and trucks to an average 54.5 miles per gallon by model year 2025. [EPA-HQ-OAR-2010-0799-9590-A1_MASS, p.1]

Together with the 'Phase One' model year 2012-2016 rule finalized in 2010, these tough new standards would more than double America's average fuel economy and are expected to:

-- Save families an estimated $8,200 in fuel savings over the lifetime of a new vehicle by 2025, for a total of $1.7 trillion in national fuel savings over the life of the program.

-- Reduce oil consumption by an estimated 2.2 million barrels a day by 2025 more than our daily 2010 oil imports from the entire Persian Gulf.

-- Reduce carbon dioxide pollution by over 6 billion metric tons over the life of the program equivalent to the emissions from the United States in 2010. [EPA-HQ-OAR-2010-0799-9590-A1_MASS, p.1]

Generating less pollution, putting more money in consumers' wallets, easing our addiction to oil, modernizing America's fleet of cars and trucks what's not to like? [EPA-HQ-OAR-2010-0799-9590-A1_MASS, p.1]

I am thrilled that this dramatic and bold proposal has earned the support of automakers, autoworkers, national security groups, environmental groups, and many other key stakeholders. And I am proud to add my support to this important rule. [EPA-HQ-OAR-2010-0799-9590-A1_MASS, p.1]

Organization: Mass Comment Campaign (399) (Rhode Island Sierra Club)

Dear President Obama,

You recently highlighted the urgency of moving beyond oil and pledged to reduce America's dependence on foreign oil by one third. [EPA-HQ-OAR-2010-0799-11761-A1, p.1]

You can deliver on your pledge to American people by setting new standards requiring cars and light trucks to achieve the standard of at least 60 miles per gallon and emit no more than 143 grams of global warming pollution per mile by 2025. [EPA-HQ-OAR-2010-0799-11761-A1, p.1]

Using American ingenuity, we can build cars and trucks that will reduce our dependence on oil by 2.5 million barrels each day by 2030 - that's almost 50 percent more oil than we currently import from the entire Persian Gulf. We need your leadership to set strong pollution and fuel efficiency standards for new cars and trucks that will help break our county's dependence on oil. [EPA-HQ-OAR-2010-0799-11761-A1, p.1]

Organization: Mass Comment Campaign (4,505) (Unknown Organization)

The proposed fuel-efficiency and greenhouse gas standards for passenger vehicles and light trucks are a laudable step in reducing dangerous global warming, increasing national security and improving our economy. Compared to business as usual, they will prevent millions of tons of global warming emissions, save consumers billions of dollars at the gas pump and reduce America's dependence on dirty fossil fuels. But these rules can and should be significantly strengthened. [EPA-HQ-OAR-2010-0799-9595-A1_MASS, p.1]

Increasing the fuel efficiency of our vehicles is the low-hanging fruit in the battle against dangerous climate change, and we can no longer afford to pass up this tremendous opportunity. Please adopt the strongest possible standards and close the SUV loophole. [EPA-HQ-OAR-2010-0799-9595-A1_MASS, p.1]

Organization: Mass Comment Campaign (45) (Environment Minnesota)

America's dependence on oil puts our environment, economy, and national security at risk. Your recent proposal of new fuel efficiency standards was a historic step toward addressing this problem. [EPA-HQ-OAR-2010-0799-9588-A1_MASS, p.1]

THANK YOU. Let's please keep working on cutting our dependence on oil. [EPA-HQ-OAR-2010-0799-9588-A1_MASS, p.1]

The environmental benefits of such a standard by 2030 are enormous:

- save more oil than we imported from Saudi Arabia last year, and

- slash global warming pollution by an amount equivalent to shutting down 70 coal-fired power plants. [EPA-HQ-OAR-2010-0799-9588-A1_MASS, p.1]

Moving forward, I urge you to ensure that these projected benefits become a reality by keeping this standard as strong as possible through the rule-making process, and avoiding loopholes that could undermine the standard's environmental benefits. [EPA-HQ-OAR-2010-0799-9588-A1_MASS, p.1]

Organization: Mass Comment Campaign (61) (The Social Justice Group))

We support these improved fuel efficiency standards not only for our own personal benefit, but also for the sake of our national security, our economy, and the world's environment. [EPA-HQ-OAR-2010-0799-7406-A1_MASS, p.2]

THE ISSUE: Support clean air and fight global warming by endorsing the Obama administration's proposal to raise automobile fuel efficiency standards.

The Obama administration has proposed a historic 54.5 miles per gallon fuel efficiency standard. Under this new proposal, it is estimated that American drivers would collectively save $80 billion a year at the pump, a savings that over time would outweigh the cost of the lower emission technology. We would make a significant dent in carbon emissions and drastically reduce our need for oil consumption in transportation. The new standard would mean that cars and trucks would achieve roughly double the fuel economy of the average vehicle on the road today. [EPA-HQ-OAR-2010-0799-7406-A1_MASS, p.6]

Some cars can already meet these standards, but most do not. This is a huge opportunity for American automakers. To remain competitive in the global marketplace. our automakers must make more fuel-efficient vehicles. These new standards will encourage investments in technology and produce new jobs in our domestic auto industry. [EPA-HQ-OAR-2010-0799-7406-A1_MASS, p.6]

The EPA estimates the 54.5 mpg standards will:

** save consumers a net of $4,400. based on the expected fuel savings and the cost of the lower emissions technology

** reduce U.S. dependence on oil by 1 .7 million barrels per day. more than we imported from Saudi Arabia and Iraq in 2010:

** reduce harmful air pollution that causes climate change by 297 million metric tons per year by 2030, which is equivalent to the annual emissions of 76 coal-fired power plants. [EPA-HQ-OAR-2010-0799-7406-A1_MASS, p.6]

This petition will be forwarded to the administration during the public comment period for these proposed standards. [EPA-HQ-OAR-2010-0799-7406-A1_MASS, p.6]

Organization: Mass Comment Campaign (680) (PennEvironment)

America's dependence on oil puts our environment, economy, and national security at risk. You recently took an important step toward addressing this problem when you proposed new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of a 54.5mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-1556-A1_MASS, p.1]

The projected annual benefits of such standards by 2030 are enormous:

* 23 billion gallons of gasoline saved

* 280 million metric tons of global warming pollution avoided

* $45 billion in savings at the gas pump [EPA-HQ-OAR-2010-0799-1556-A1_MASS, p.1]

I support the proposed standards, and I urge you to ensure that these projected benefits become a reality by keeping these standards free of loopholes that could undermine their environmental and economic benefits. [EPA-HQ-OAR-2010-0799-1556-A1_MASS, p.1]

Organization: Mass Comment Campaign (80) (Unknown Organization)

I support the Environmental Protection Agency's (EPA) joint proposal with the National Highway Traffic Safety Administration (NHTSA) to improve fuel economy and reduce greenhouse gas (GHG) emissions for passenger cars and light-trucks for model years 2017 through 2025. The proposed fleet-wide average of 49.6 mpg will create a new generation of clean vehicles and respond to our country's critical need to reduce oil consumption. [EPA-HQ-OAR-2010-0799-9682-A1_MASS, p.1]

This proposal will save four billion barrels of oil and two million metric tons of greenhouse gas emissions over the lifetime of those vehicles. The proposal also incentivizes the expanded production of hybrid and electric vehicles, which will further reduce our dependence on foreign oil and cut greenhouse gases. [EPA-HQ-OAR-2010-0799-9682-A1_MASS, p.1]

I also strongly urge the agencies to carefully evaluate whether basing these fuel standards on the size of a vehicle will incentivize manufacturers to build larger vehicles. Ensuring manufacturers do not benefit from building larger vehicles that emit more emissions is fundamental to the success of the National Program. [EPA-HQ-OAR-2010-0799-9682-A1_MASS, p.1]

Organization: Mass Comment Campaign (9,570) (Unknown Organization)

The proposed standards are achievable and reasonable and will save me money at the pump, curb millions of tons of harmful global warming emissions, and save as much oil in 2030 alone as we currently import from Saudi Arabia and Iraq. They will also drive innovation in the U.S. auto industry, creating new jobs across the country. [EPA-HQ-OAR-2010-0799-9578-A1_MASS, p.1]

Though I strongly support these standards, I am concerned about possible loopholes that automakers could exploit. [EPA-HQ-OAR-2010-0799-9578-A1_MASS, p.1]

We cannot afford to delay in confronting the threats of climate change and our dangerous oil dependence. I urge you to move forward with the strongest possible standards free of harmful loopholes. [EPA-HQ-OAR-2010-0799-9578-A1_MASS, p.1]

Organization: Mass Comment Campaign (927) (Sierra Club-1)

I am writing in support of the proposed fuel-efficiency and carbon pollution standards for new cars and trucks. [EPA-HQ-OAR-2010-0799-1554-A1_MASS, p.1]

I applaud the EPA and DOT for working together to propose these standards that will strengthen fuel efficiency and carbon pollution standards for new passenger cars and trucks to 54.5 mpg by 2025. This is a critical step we can take to curb climate disruption, cut our addiction to oil, and keep billions of dollars in our economy instead of spending them on oil. [EPA-HQ-OAR-2010-0799-1554-A1_MASS, p.1]

In these tough economic times I celebrate these efforts because they will promote innovation and job growth not just in the automotive industry but across the nation, all while helping the U.S. cut dangerous carbon pollution and our addiction to oil. [EPA-HQ-OAR-2010-0799-1554-A1_MASS, p.1]

Once again, I strongly support these vitally important standards that will protect our environment, economy, and national security. I urge both the EPA and DOT to finalize these strong standards. [EPA-HQ-OAR-2010-0799-1554-A1_MASS, p.1]

Organization: Mass Comment Campaign (99) (Environment Texas)

America's dependence on oil puts our environment, economy and national security at risk. You recently took an important step toward addressing this problem when you proposed new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of a 54.5 mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-9701-A1_MASS, p.1]

The projected annual benefits of such standards by 2030 are enormous:

• $45 billion in savings at the gas pump

• 23 billion gallons of gasoline saved

• 280 million metric tons of global warming pollution avoided [EPA-HQ-OAR-2010-0799-9701-A1_MASS, p.1]

I support the proposed standards, and I urge you to ensure that these projected benefits become a reality by keeping these standards free of loopholes that could undermine their environmental and economic benefits.[EPA-HQ-OAR-2010-0799-9701-A1_MASS, p.1]

Organization: Mass Comment Campaign (Multiple Submitters) (Unknown Organization)

The rising price of gas is once again squeezing the budgets of American families, who are being forced to cut back in other areas to pay for basic transportation needs. Please take action to ensure that cars and light trucks can drive farther on a gallon of gas and reduce our dependence on imported oil. [NHTSA-2010-0131-0219-A1_MASS, p.1]

This spring, you set a goal of reducing oil imports by one-third this decade. Fuels efficiency standards of up to 60 miles per gallon by 2025 would increase investments in fuel efficient technologies, save consumers money at the pump, and help the United States break its cycle of addiction to foreign oil by saving more than 1.3 billion barrels. I urge you to support new fuel efficiency standards of up to 60 miles per gallon. [NHTSA-2010-0131-0219-A1_MASS,p.1]

The rising price of gas is once again squeezing the budgets of American families, who are being forced to cut back in other areas to pay for basic transportation needs. Organization: Mazda North American Operations

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 63.]

As one of the 13 auto makers that signed the letter of commitment, Mazda welcomes the opportunity to be a partner in helping to advance a continued, harmonized national program on fuel economy and greenhouse gas emissions for the 2017 to 2025 model years. While offering manufacturers the certainty of knowing the fuel economy targets for many years into the future, the proposed standards do represent an extreme technical challenge for the auto industry, and especially for smaller automakers, such as Mazda, who have more limited resources to develop and market advanced technology vehicles. Nonetheless, we are committed to making our best efforts to meet the proposed targets.

Organization: Mehrotra, Rahul

Thank you for even considering proposing a rule to raise average fuel economy standards. [NHTSA-2010-0131-0206, p.1]

Organization: Mercedes-Benz USA, LLC

DAG fully supports the agencies' effort to create a unified program that allows one product pathway towards compliance. [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

Organization: Michigan House of Representatives, 49th District

I'm State Representative Jim Ananich of Flint and I have the distinct honor of serving Michigan's 49th House District. I'm pleased to comment today on and in support of the proposed 54.5 mpg fuel economy standards proposed by the Environmental Protection Agency (EPA) and National Highway Traffic Safety Administration (NHTSA). [EPA-HQ-OAR-2010-0799-7983-A1, p. 1]

Since I took office last year, my top priority has been to improve our economy and help get the people of Genesee County and Michigan back to work. The proposed 54.5 mpg fuel economy standards will be a significant step forward in accomplishing these goals. These standards will help create jobs, save consumers money, and keep the members of our armed services out of harm's way. [EPA-HQ-OAR-2010-0799-7983-A1, p. 1]

The Obama Administration and automakers deserve recognition for their collaborative efforts to reach an agreement on fuel economy at a time when leaders in Washington cannot seem to agree on anything. This shows that we can rise above the divisive rhetoric of our politics and reach agreement on commonsense solutions to our most pressing issues. [EPA-HQ-OAR-2010-0799-7983-A1, p. 2]

Organization: Michigan State House of Representatives

I'm State Rep. Jim Townsend & am pleased to offer my comments on the fuel economy standards proposed by the Environmental Protection Agency & National Highway Traffic Safety Administration.

I serve the 26th Michigan House District, which covers the cities of Madison Heights & Royal Oak. My district includes many people who work in the auto industry & many more earn a living as a result of those who do. I also have worked in the auto industry & would like to recognize the automakers leadership in reaching an agreement with the Obama Administration that's as good for jobs & the economy as it is for consumers. [EPA-HQ-OAR-2010-0799-9175, p. 1]

The 54.5 mpg fuel economy standard will create good paying jobs for American autoworkers. A recent study conducted by the United Auto Workers, Natural Resources Defense Council & National Wildlife Federation found that the proposed standards would create over 150,000 jobs at over 500 facilities that produce parts for advanced internal combustion engines, hybrid & alternative fuel vehicles, plug-in electric vehicles, & shared components. Here in Michigan the standards will create a little more than 38,000 jobs at nearly 100 facilities. [EPA-HQ-OAR-2010-0799-9175, p. 1]

Also, for consumers, who spend about $2,000 a year on fuel, these fuel economy standards can quickly add up to big savings. Americans spend over $1.3 billion each day on gas. Greater fuel efficiency will save consumers up to $6,600 in fuel costs over the lifecycle of a 2025 model. [EPA-HQ-OAR-2010-0799-9175, p. 1]

Finally, the big growth markets for the auto industry are dominated by countries whose consumers expect leadership in fuel economy. These standards will help prepare the industry for the export market & give American-made cars a leg up in other countries. [EPA-HQ-OAR-2010-0799-9175, pp. 1-2]

These standards will spur innovation & encourage the development the hybrids, electric, & more fuel efficient vehicles crucial to the continued success of automakers. I thank the EPA & NHTSA for opportunity to comment. [EPA-HQ-OAR-2010-0799-9175, p. 2]

Organization: Michigan State Senate, District 18

I'm pleased to comment today on the fuel economy rules proposed by the Environmental Protection Agency (EPA) and Department of Transportation (DOT), and to lend my strong support for standards that would increase the fuel efficiency of light duty vehicles to a fleet wide average of 54.5 mpg. [EPA-HQ-OAR-2010-0799-5594-A1, p. 1]

In short, as the auto industry enters this new chapter, all the signs point to a market for more fuel efficient cars, and all the roads to get there run through Greater Metro Detroit. [EPA-HQ-OAR-2010-0799-5594-A1, p. 2]

Organization: Miller, P.

Though I heartily support the proposed rule to increase fuel economy for new passenger vehicles to an average of 54.5 miles per gallon by 2025, we can do better!!! [EPA-HQ-OAR-2010-0799-1755-A1, p. 1]

This spring, you set a goal of reducing oil imports by one-third this decade, (make that two-thirds and you would be closer to what we need) and in November you proposed fuel efficiency standards that will effectively double current requirements. I commend your efforts. I believe it is important to increase U.S. investment in fuel efficient technologies, save consumers money at the pump, help this country break its dependence on foreign oil, and protect the environment. Don't let these standards be watered down--protect and finalize the new fuel efficiency rules. [EPA-HQ-OAR-2010-0799-1755-A1, p. 1]

Organization: Minnesota Department of Commerce

I support the stated goals of the proposed rule to improve fuel economy of light-duty vehicles for model years 2017–2025 as a means to further reduce greenhouse gas emissions and reduce oil consumption. [EPA-HQ-OAR-2010-0799-7363-A1, p. 1]

Organization: Mitsubishi Motors R&D of America, Inc. (MRDA)

On May 21, 2010, President Obama issued a Memorandum requesting EPA and NHTSA to jointly develop a coordinated National Program to improve fuel efficiency and reduce GHG emissions of passenger cars and light-duty trucks for MYs 2017 through 2025. To that end, EPA and NHTSA, with continuous consultation from the California Air Resources Board (CARB), published several notices leading up to the NPRM. Mitsubishi Motors applauds the efforts of the Administration and agencies to follow through on their commitment to continue the National Program to regulate GHG emissions and fuel economy of light-duty vehicles for MY 2017 and later MYs. For this reason, in July 2011, Mitsubishi Motors demonstrated its support of the National Program by signing a letter of commitment to the process and structure of the overall program as described in the NPRM. [EPA-HQ-OAR-2010-0799-9507-A1, p.2]

Mitsubishi Motors is appreciative of the inclusive rulemaking process. We stand committed to the continued development of a National Program based on the technical, economic and consumer realities of the United States light-duty automotive market. [EPA-HQ-OAR-2010-0799-9507-A1, p.2]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 95-99.]

Mitsubishi Motors applauds the efforts of the Obama administration and agency staff to follow through on their commitments to continue one national program on the federal level for these model years.

Similarly, Mitsubishi Motors is appreciative of the inclusive process that led to the publication of this NPRM. Mitsubishi Motors stands committed to continuing the development of the national program based on technical, economic and consumer realities in the United States' light-duty automotive market. To ensure these realities are fully considered in setting fuel economy and greenhouse gas standards for these later model years included in this rulemaking, a midterm evaluation is critical to this process.

Organization: Moravian College

Please do your part, in bringing our nation of drivers into welcoming a new generation of automobiles that are more fuel efficient and burn their fuels more cleanly. We need this for energy independence as well as health benefits of a cleaner environment. [EPA-HQ-OAR-2010-0799-5536-A1, p. 1]

Organization: Motor & Equipment Manufacturers Association (MEMA)

In order to meet regulatory requirements and consumer demand for cleaner, more fuel-efficient advanced vehicles, motor vehicle parts manufacturers have increasingly taken on a significant role in the research, development, engineering, and manufacturing of the advanced technologies necessary to meet these ever-increasing goals. Working together, suppliers and vehicle manufacturers develop an assortment of technologies and products that improve vehicle performance, safety, fuel efficiency, and emissions. These components and systems are rigorously tested on a range of platforms, each with varying degrees of performance. [EPA-HQ-OAR-2010-0799-9478-A1, p.1]

MEMA is encouraged that NHTSA and EPA are continuing to work together on this second phase of the National Program for Model Years (MY) 2017-2025. MEMA strongly supports the continuation of a uniform, footprint-based National Program because it permits vehicle manufacturers to focus their resources on investing in the best technologies available for their fleet in order to achieve the levels prescribed by the program. This, in turn, feeds the ability of the supplier base to continually innovate, to advance development, and to turn research technologies into commercially viable products. [EPA-HQ-OAR-2010-0799-9478-A1, pp.1-2]

Furthermore, MEMA supports the efforts of the agencies to harmonize and align their respective standards, where appropriate. Synchronizing improves regulatory clarity and provides certainty. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

Harmonization for this next phase of the National Program is important to its long-term success. MEMA supports the proposals to harmonize the GHG emissions and CAFE standards, as appropriate. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

MEMA welcomes and supports the proposals to harmonize the GHG emissions and CAFE standards, as appropriate. Synchronizing improves regulatory clarity and provides certainty. We support the agencies’ decision to parallel the efficiency credits and fuel consumption improvement values for compliance calculations for their respective GHG emissions and CAFE standards programs. Specifically, aligning the air conditioning and off-cycle elements such that the efficiency improvement credits have an equivalent fuel consumption improvement in the compliance calculations is an appropriate, and needed, improvement to the National Program. Credits are an important tool and can be positively applied and provide the industry necessary options to achieve future standards. [EPA-HQ-OAR-2010-0799-9478-A1, p.4]

Excluding the internal harmonization between the respective EPA and NHTSA programs in this NPRM, MEMA asks the agencies to take into account other regulatory endeavors that may impact the ultimate efficacy of National Program standards. For example, subtle differences in California’s program (compared to the National Program), and the state’s other vehicle-related requirements, are just different enough such that suppliers have to conduct multiple compliance test regimens. On the global front, a multitude of similar, but different regulations and requirements for other parts of the world, further burden companies with compounding testing and compliance costs. [EPA-HQ-OAR-2010-0799-9478-A1, p.4]

A truly harmonized regulatory framework will help with economies of scale and avert multiple layers of compliance programs. Essentially, since motor vehicle parts manufacturers bear a significant proportion of research, development and testing costs, any opportunities for government entities to synergize, harmonize and align related regulatory frameworks and compliance needs are important and should be considered by all stakeholders and, where appropriate, take corrective action. Continued cooperation and harmonization of the EPA, DOT/NHTSA, the State of California and others is extremely important for the long-term success of the Program. [EPA-HQ-OAR-2010-0799-9478-A1, pp.4-5]

Motor vehicle parts manufacturers develop a wide variety of technologies and products that continually improve vehicle performance, safety, fuel efficiency, and emissions. The entire motor vehicle industry needs consistent, long-term policies so that all stakeholders can more effectively meet the regulatory requirements and consumer demands for cleaner, efficient advanced technology vehicles and thrive in the current economic environment. MEMA and the supplier industry are committed to policies that enable the introduction of new technologies needed to support sustainable mobility. MEMA strongly supports the continuation of a uniform National Program because it permits vehicle manufacturers to focus their resources on investing in the best technologies available for their fleet in order to achieve the levels prescribed by the program. Furthermore, these standards must be technology-neutral, performance-based, not impose “preferred technology” pathways and allow for a fully competitive marketplace. [EPA-HQ-OAR-2010-0799-9478-A1, p.13]

Organization: National Association of Clean Air Agencies (NACAA)

NACAA is very pleased to support this proposal. We note also that there is a broad group of stakeholders that supports EPA’s and NHTSA’s actions to continue, and build upon, the national programs adopted in 2010 to reduce greenhouse gas (GHG) emissions from, and improve the fuel economy of, model year (MY) 2011 through 2016 light-duty vehicles (LDVs). On July 29, 2010, 13 major automakers sent letters to EPA and the U.S. Department of Transportation expressing their support for a next phase of the national vehicle program to further reduce GHG emissions and increase fuel economy. These automakers together manufacture over 90 percent of all vehicles sold in the U.S. In their respective letters, the automakers commit to “working with EPA and NHTSA, the states, and other stakeholders to help our country address the need to reduce dependence on oil, to save consumers money, and to ensure regulatory predictability and certainty by developing this kind of strong, coordinated National Program.” The California Air Resources Board, the United Auto Workers and numerous environmental and consumer organizations have also offered their support for this program. [EPA-HQ-OAR-2010-0799-8084-A1, p. 1]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 37.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 33.]

This proposal to further the LDV GHG emissions and CAFE standards programs is also consistent with and complementary to the federal GHG and fuel economy standards for MY 2014 through 2018 medium and heavy-duty vehicles adopted in 2011. [EPA-HQ-OAR-2010-0799-8084-A1, p. 2]

In 2007, 31 percent of all U.S. GHGs were emitted by mobile sources, which, since 1990, have been the fastest-growing source of U.S. GHG emissions. LDVs emit carbon dioxide (CO_2), methane, nitrous oxide and hydrofluorocarbons (HFCs) and are responsible for almost 60 percent of all mobile source GHG emissions. CO_2 emissions in 2007 represented approximately 94 percent of all LDV GHG emissions (including HFCs). [EPA-HQ-OAR-2010-0799-8084-A1, p. 2]

Relative to the national objective of improving energy and national security by reducing dependence on foreign oil, net petroleum imports in 2009 accounted for about 51 percent of U.S. petroleum consumption. In that same year, transportation was responsible for approximately 71 percent of petroleum consumption, with LDVs accounting for about 60 percent of transportation oil use, which equates to about 40 percent of all U.S. oil consumption. [EPA-HQ-OAR-2010-0799-8084-A1, p. 2]

The estimated benefits of this proposal (over the lifetime of the MY 2017 through 2025 vehicles) are a reduction in oil consumption of 4 billion barrels and a reduction in GHG emissions of 2 billion metric tons. The anticipated fuel savings amounts to $347 billion to $444 billion (based on a gasoline price of $3.38 per gallon in 2015 and $3.64 per gallon in 2020). [EPA-HQ-OAR-2010-0799-8084-A1, p. 2]

The total estimated costs of this program (over the lifetime of the MY 2017 through 2025 vehicles) will be around $140 billion and the total monetized benefits will be on the order of $449 billion to $561 billion, for a net benefit to society in the range of $311 billion to $421 billion. [EPA-HQ-OAR-2010-0799-8084-A1, p. 2]

Based on EPA's analysis, the fuel cost savings will "far outweigh" higher vehicle costs. For consumers, the new standards would add, on average, about $2,000 to the cost of a new vehicle in MY 2025. However, a consumer who pays cash when purchasing a MY 2025 vehicle can expect to make up this cost in about three and a half years and, thereafter, continue to accrue savings in fuels costs. A consumer who purchases a MY 2025 vehicle using credit will save more each year in fuel costs than the amount of the increased payments on the car loan. [EPA-HQ-OAR-2010-0799-8084-A1, p. 2]

The co-benefits to be derived from such a program extend far beyond climate change, fuel savings and energy security, and include the following:

- reduced $PM_{2.5}$ and NO_x emissions due to reduced gasoline distribution emissions associated with tanker trucks; [EPA-HQ-OAR-2010-0799-8084-A1, p. 2]

- mitigation of some of the disproportionate adverse health impacts (including those associated with toxic air pollutants and criteria pollutants) on environmental justice communities affected by emissions from high traffic and located near gasoline refining and distribution facilities; [EPA-HQ-OAR-2010-0799-8084-A1, p. 3]
- reduced adverse health impacts near roadways due to the increase in cleaner vehicles;
- reduced risk of accidental spills of volatile crude oil due to proportional reduction in oil imports via marine tankers;
- buffering against gasoline price volatility for consumers and a hedge against rising fuel prices due to the increased use of domestic and alternative fuel sources;
- economic growth and the creation of high-quality jobs across the country due to the need for the innovative automotive technologies upon which the standards rely; and
- reduced hydrocarbon emissions due to lower fuel throughput at retail distribution outlets. [EPA-HQ-OAR-2010-0799-8084-A1, p. 3]

Fourth, NACAA is aware that state and local governments are struggling to maintain current road infrastructure and to fund enhancements. NACAA believes that the issue of how to provide longterm transportation infrastructure funding is a critical national need that should be addressed. However, the debate over long-term transportation funding should not affect the level or delay adoption of the proposed fuel economy standards. [EPA-HQ-OAR-2010-0799-8084-A1, p. 4]

Finally, NACAA urges that EPA and NHTSA ensure that this final rule is promulgated by July 2012, as planned. Further, NACAA encourages EPA, upon promulgation of this rule, to begin assessing the efficacy of another phase of standards to apply to post-2025 MY vehicles. [EPA-HQ-OAR-2010-0799-8084-A1, p. 4]

Organization: National Automobile Dealers Association (NADA)

NADA continues to believe that a single national light-duty vehicle fuel-economy/GHG program is essential to the extent that it avoids any unworkable patchwork of state laws. The EISA mandate for a fleet-wide combined fuel economy average of at least 35 miles per gallon by 2020 (with a commensurate reduction in GHGs of at least 30 percent), followed by standards set to achieve maximum achievable performance is Congress' clear direction. [EPA-HQ-OAR-2010-0799-9575-A1, p. 12]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 69.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 92.]

NADA supports a single national program for light vehicle fuel economy.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 56-57.]

NADA strongly believes that the issues and goals involved in this rulemaking are national in scope, and that California regulators should not be dictating national policy or setting fuel economy standards.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 69.]

NADA supports the single national program governing light-duty vehicle fuel economy as that is what Congress sought in 2007 when it enacted the Energy Independence and Security Act.

Organization: National Caucus of Environmental Legislators

America's deepening dependence on oil puts our economy, environment, and national security at risk. The introduction of new global warming pollution and vehicle efficiency standards ensuring new cars and light trucks meet the equivalent of 54.5 miles per gallon fleet-wide by 2025 is an important step in the right direction. These standards will reduce pollution and save Americans money through greater fuel efficiency. [EPA-HQ-OAR-2010-0799-9443-A1, p. 1]

Reducing the nation’s reliance on foreign oil is an important objective that these standards can help to achieve. It is critical that the consumer and environmental benefits of these standards are maximized by rejecting efforts to weaken the standards. We support keeping the standards as strong as possible through the rulemaking process. [EPA-HQ-OAR-2010-0799-9443-A1, p. 1]

Americans understand that cleaner, more fuel-efficient vehicles can help break our addiction to oil, and they overwhelmingly support strong fuel efficiency and pollution standards. In a recent poll, Consumer Reports found that 80 percent of survey respondents favored raising the national standard to around 55-mpg. [EPA-HQ-OAR-2010-0799-9443-A1, p. 1]

The standards proposed for 2017-2025 will greatly decrease the average new vehicle's global warming pollution, cutting annual nationwide emissions by 280 million metric tons in 2030— equivalent to the annual emissions from roughly 70 coal-fired power plants. The standards outlined will also reduce U.S. gasoline consumption by 23 billion gallons in 2030— equivalent to the 2010 U.S. imports from Saudi Arabia and Iraq. Allowing for loopholes to weaken these standards would needlessly send money to foreign countries and extend our dependence on oil. [EPA-HQ-OAR-2010-0799-9443-A1, pp. 1-2]

These standards will determine the efficiency of cars and trucks our children will drive decades from now. As state legislators, on behalf of our constituents we applaud efforts to break America's addiction to oil, keep billions of dollars in our economy and reduce the threat of climate change. We urge your administration to ensure that the standards developed for 2017-2025 vehicles are as strong as possible, in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-9443-A1, p. 2]

Organization: National Propane Gas Association (NPGA)

NPGA supports the Environmental Protection Agency's (EPA) and the National Highway Traffic Safety Administration's (NHTSA) goals to further reduce Greenhouse Gas (GHG) emissions and improve fuel economy for light-duty vehicles for model years 2017-2025. Further, we support the President's request to address global climate change and reduce our nation's oil consumption. And, we firmly believe the use of Liquefied Petroleum Gas (LPG), an EPA approved clean alternative fuel, will help reduce our nation's dependency on oil and reduce CO_2 emissions, a stated goal of the subject proposed rulemaking. [EPA-HQ-OAR-2010-0799-9482-A1, p. 1]

Organization: National Wildlife Federation (NWF)

The standards are also an example of how industry, labor, and conservationists can and must continue to work together to use the Clean Air Act as a tool for innovation and to solve critical environmental, energy and economic challenges that we face. [EPA-HQ-OAR-2010-0799-9887-A2, pp. 1-2]

The proposed 2017-2025 standards will approximately double fuel economy of our cars, SUV's and pickups from today's levels to an average of 54.5 miles per gallon by 2025. Vehicles built under the standard will save America 4 billion barrels of oil and 2 billion metric tons of carbon pollution. [EPA-HQ-OAR-2010-0799-9887-A2, pp. 2-3]

Taken together with the 2012-2016 light duty standards and the 2014-2018 medium and heavy duty standards being implemented now, the proposed standards will cut carbon pollution over 650 million metric tons a year in 2030 – about 10% of total US carbon pollution today. This is an historic step forward to combat our climate challenge. [EPA-HQ-OAR-2010-0799-9887-A2, p. 3]

Taken together these standards are also the largest step the nation has ever taken to cut oil use and enhance our energy security. As shown in Figure 1, above, these standards together will cut our demand for oil by 3.6 million barrels per day; more than all the oil we import today from the Persian Gulf, Venezuela and Russia combined. [Figure 1 can be found on p. 2 of Docket number EPA-HQ-OAR-2010-0799-9887-A2] [EPA-HQ-OAR-2010-0799-9887-A2, p. 3]

And as we are ensuring that every car and truck uses less fuel, steady expansion of electric and advanced vehicle technology can take us even further– to a mass market, high performance vehicle fleet that uses little oil and produces near zero pollution. [EPA-HQ-OAR-2010-0799-9887-A2, p. 3]

Deep cuts in the oil we need means less pressure for risky new drilling projects in the Arctic or for clear cutting forest for Canadian tar sands. It means less need for new pipelines, fewer leaks and threats to people, wildlife and our public and private lands. [EPA-HQ-OAR-2010-0799-9887-A2, p. 3]

These standards show we can take real steps to roll back climate change and protect wildlife for generations to come. [EPA-HQ-OAR-2010-0799-9887-A2, p. 3]

The proposed standard is also critical to regain and sustain our leadership in the most advanced vehicle technologies - including hybrid and electric cars and trucks. The strong long term targets embodied in the 2017-2025 rule are essential to justify ongoing investments in hybrid and electric technology necessary to combat high fuel prices and environmental challenges, and to ensure the competitiveness of the American auto industry in a changing world. Weto [*sic*] meet to build robust network of domestic innovators, suppliers and manufacturers ready to meet national and global demand, to ensure an industry able to lead the clean global auto industry of the future, and to ensure consumers are protected against the real and present risk of rising and volatile oil prices. [EPA-HQ-OAR-2010-0799-9887-A2, pp. 5-6]

Standards are also strongly supported by the public.

A recent survey by Consumers Reports found 80% of car owners in support of fuel economy standards that would achieve 55 mpg by 2025, and the agencies' recent field hearings were swamped with overwhelmingly positive testimony. 14 The public knows fuel economy standards work. They work for wildlife, they work American families, they work for the auto industry and autoworkers and they work for the economy. [EPA-HQ-OAR-2010-0799-9887-A2, p. 7]

We thank the agencies for their clarity of vision and perseverance in developing this essential standard. [EPA-HQ-OAR-2010-0799-9887-A2, p. 7]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 27-28.]

America needs a strong, clean industrial sector that employs billions with good jobs while producing the most efficient products possible. Our members depend on all kinds of vehicles from small hybrids to cars to pick-ups to off-road vehicles. We still believe in the potential of the American auto industry.

Over the past two years, the hard working people here in Detroit and in Ohio and Missouri and North Carolina and all across the country have been proving dramatically that they have what it takes for America to lead in a prosperous clean energy future. Their efforts, combined with these new standards, and effective public and private investment show how an industry can be retooled to be vibrant in the present and even more relevant and powerful in the future. Strong standards through the 2025 year are critical to staying on this path.

The standards are also an example of how an industry and labor and the conservation community can and must work together to use the Clean Air Act as a tool for innovation and to solve critical and environmental energy and economic changes we face today.

These standards deliver.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 31-32.]

The proposed standard is also critical to regain and sustain our leadership in the most advanced vehicle technologies including hybrid electric cars and trucks. These technologies will be critical to combating high fuel prices and environmental challenges into the future and the competitiveness of the American auto industry in a changing world.

Investments in cutting edge electric vehicles and other innovations increase fuel efficiency across the board, and long-term targets create certainty in a world tyrannized by volatile oil prices and availability.

Together we must work to build a robust network of innovators, suppliers and caring consumers to lead in the global economy for the auto industry's future.

---

14 http://news.consumerreports.org/cars/2011/11/survey-car-owners-want-better-fuel-economy-supportincreased- standards.html. This recent survey finds comparable results to many previous polls.

Organization: Natural Resources Defense Council (NRDC)

The U.S. EPA and NHTSA proposed passenger vehicle carbon pollution fuel economy standards for model years 2017-2025 is the third historic agreement to bring us cleaner cars and trucks. The latest announcement follows on the joint NHSTA and EPA rules for model years 2012 to 2016 passenger vehicles and for model years 2014 to 2018 medium- and heavy-duty trucks.1,2 These agreements exemplify how leadership, partnership, and compromise can help solve the enormous environmental, economic and energy challenges facing our country. [EPA-HQ-OAR-2010-0799-9472-A2, p. 2]

The model year 2017-2025 National Program standards will act as a powerful economic stimulus by keeping a total of $350 billion in the U.S. economy by 2030 instead of sending it overseas to Saudi Arabia, Iran, Venezuela and other oil-exporting nations.5 This higher level of investment in the U.S. economy, especially auto manufacturing, will result in roughly half a million more jobs by 2030.6 [EPA-HQ-OAR-2010-0799-9472-A2, p. 3]

American consumers are already benefiting from the more fuel-efficient vehicle options available due to the current National Program requirements and will benefit more as the standards get stronger. By 2030, the new agreement will provide the equivalent of a $330 tax rebate to every American household.12 Compared to today’s average vehicle, a 54.5 mpg-equivalent standard will save the average driver $6,600 over the vehicle’s lifetime, with most drivers seeing benefits immediately in the form of reduced total monthly payments for the car and fuel. [EPA-HQ-OAR-2010-0799-9472-A2, p. 5]

The most recent clean car agreement enjoys an unprecedented breadth and depth of support including from almost all of the auto industry14, and from Republicans and Democrats15, consumer advocacy groups16, 17, national security groups18, 19, economists20, business leaders21, small business owners22, the UAW23, and environmental organizations24. [EPA-HQ-OAR-2010-0799-9472-A2, p. 6]

Numerous polls show that a large majority of Americans support substantially strengthening of clean car standards. A Consumer Federation of America found 60 percent of American consumers support a 60 mpg standard with a payback of three and five years.25 A poll for national environmental groups found 83 percent of voters support a 60 mpg standard with a payback of four years.26 Polls by the investor group Ceres found 56 percent of Michigan voters and 59 percent of Ohio voters support 60 mpg with a payback time of four years.27 According to a recent poll by the Consumer Reports National Research Center, 80 percent agreed that fuel economy standards should require auto manufacturers to increase the overall fleet average to at least 55 miles per gallon by 2025.28 Finally, a poll by the Public Policy Institute of California found that an overwhelming 84 percent of Californians support requiring automakers to significantly improve fuel efficiency, including 76 percent of Republicans.29 [EPA-HQ-OAR-2010-0799-9472-A2, pp. 6-7]

Small business owners – many of whom buy cars and trucks for their businesses – also strongly support higher fuel economy standards. A recent poll by the Small Business Majority found that 87 percent of small business owners overwhelmingly support adopting strong fuel efficiency standards now and 80 percent support requiring the auto industry to increase mileage to 60 mpg by 2025.30 According to the Small Business Majority poll: “Small business owners say that in order to survive and remain competitive, they need automobiles that get better gas mileage and cost less to operate.” [EPA-HQ-OAR-2010-0799-9472-A2, p. 7]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 198-201.]

The proposed standards are a giant step forward. The standards are good for the environment, consumers, and the economy. The standards ensure that as a nation we are investing in our future instead of being beholden to a status quo of heavy dependence on oil which is fueling dangerous emissions of carbon pollution and draining our economic wealth.

These standards will help protect our economy by helping reduce extreme weather events such as hurricanes, heat waves and floods.

The national program and this latest set of standards are examples of good government. Despite the gridlock in Congress, the EPA, NHTSA and the California Air Resources Board have demonstrated an effective partnership to develop policies that meet the objectives of the Clean Air Act and the Energy Policy and Conservation Act.

Each agency has played an important and critical role in shaping this proposal. This proposal is also a product of discussions with the automotive industry, labor, environmental, and consumer stakeholders, and the result is a strong set of standards.

Organization: New Jersey Senate, Third Legislative District

America's deepening dependence on oil puts our economy, environment, and national security at risk. I am writing to applaud you for taking an important step to confront the dangers of this dependence by proposing new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of the 54.5-mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-9970-A1, p. 1]

I applaud you for seizing this historic opportunity to do more than any previous administration to break America's dependence on oil, keep billions of dollars in our economy and reduce the threat of climate change, I urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rulemaking process in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-9970-A1, p. 1]

Organization: New York City Council, 35th District

Your administration has taken important steps to confront the dangers of our dependence on oil—most recently, proposing new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of the 54.5-mpg fleetwide standard by 2025. I am writing to applaud you for developing these standards. [EPA-HQ-OAR-2010-0799-9901-A2, p. 1]

These standards will determine the efficiency of cars and trucks our children will drive decades from now. I applaud you for seizing this historic opportunity to do more than any previous administration to break America's addiction to oil, keep billions of dollars in our economy and reduce the threat of climate change. I urge you to ensure that the standards your administration develops for 2017-2025 vehicles are as strong as possible, in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-9901-A2, p. 1]

Organization: New York State Assembly Committee on Government Operations

Your administration has taken important steps to confront the dangers of our dependence on oil—most recently, proposing new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of the 54.5-mpg fleetwide standard by 2025. I am writing to applaud you for developing these standards. [EPA-HQ-OAR-2010-0799-9453-A2, p. 1]

These standards will determine the efficiency of cars and trucks our children will drive decades from now. I commend you for seizing this historic opportunity to do more than any previous administration to break America's addiction to oil, keep billions of dollars in our economy and reduce the threat of global climate change. I urge you to ensure that the standards your administration develops for 2017-2025 vehicles are as strong as possible, in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-9453-A2, p. 1]

Organization: New York State Senate, 26th District

Your administration has taken important steps to confront the dangers of our dependence on oil-most recently, proposing new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of the 54.5-mpg fleetwide standard by 2025. I am writing to applaud you for developing these standards. [EPA-HQ-OAR-2010-0799-9884-A1, p. 1]

These standards will determine the efficiency of cars and trucks our country's children will drive decades from now. I applaud you for seizing this historic opportunity to do more than any previous administration to break America's addiction to oil, keep billions of dollars in our economy and reduce the threat of climate change. I urge you to ensure that the standards your administration develops for 2017-2025 vehicles are as strong as possible. in order to maximize their benefits for our economy, our environment, and our national security. [EPA-HQ-OAR-2010-0799-9884-A1, pp. 1-2]

Organization: Nissan North America, Inc.

Nissan remains committed to the program and to the terms and conditions set forth in Nissan's letter dated July 29, 2011, and in the agencies' Second Supplemental Notice of Intent published in the Federal Register on the same date. The following comments further demonstrate the overall benefits and technological underpinning of the proposal, as well as identifying additional improvements and corresponding benefits. [EPA-HQ-OAR-2010-0799-9471-A1, p.1]

Nissan's environmental commitment extends beyond the regulatory program. As a leader in electric powertrains, Nissan brought to market the all-electric Nissan LEAF and will continue to drive development and deployment of electric powertrains. Nissan also remains dedicated to continued improvements in internal-combustion powered vehicles, safe weight reduction and advances in traditional hybrid technology. Nissan expects its fleet during the model years covered by this rulemaking to include a diverse array of technologies and powertrains. [EPA-HQ-OAR-2010-0799-9471-A1, p.1]

Industry-wide success in meeting the proposed standards will certainly depend on the extent to which the market for new vehicle technologies develops during the covered model years. Widespread adoption of battery electric vehicles and other advanced powertrains requires not only industry to broadly embrace investment in these technologies, but also for consumers to adopt these new technologies. Given the planning and lead-times necessary for such a market shift, the proposed incentives for battery electric powertrains (multiplier credit and zero emissions compliance value) and other proposed incentives are essential. Only through the government's support of industrial innovation in the transportation sector can the U.S. achieve its long-term greenhouse gas (GHG) public policy objectives. Not including the proposed Incentives In the final rulemaking will discourage manufacturer investment in these technologies, and signal a significant change in Administration policy and delay the realization of the substantial long-term greenhouse gas reductions associated with these transformational, 'game changing' vehicle technologies. [EPA-HQ-OAR-2010-0799-9471-A1, pp.1-2]

Nissan believes that the proposed program strikes an appropriate balance between aggressive standards and the encouragement of advanced technologies necessary to meet those standards. As proposed, the regulatory program recognizes that although the automobile manufacturers must invest significantly in technological advances, the economic and market conditions-both within the U.S. and globally-must also support such an investment. Thus the structure of the proposal-with standards firmly established for MYs 2017-2021 and with a robust mid-term evaluation of technological and market feasibility for MYs 2022-2025-is essential. [EPA-HQ-OAR-2010-0799-9471-A1, p.2]

Nissan commends the agencies for the comprehensive joint rulemaking, and strongly supports global efforts to curb greenhouse gas emissions. Success in reducing the impact of mobile source greenhouse gas emissions requires a coordinated and thoughtful effort that goes beyond the automobile industry, however. Nissan, for its part, is committed to improving existing internal combustion engines and investing in a future of electric vehicles and other advanced powertrains to reduce the transportation sector's GHG emissions. [EPA-HQ-OAR-2010-0799-9471-A1, p.24]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 126-131.]

Nissan supports the national program and remains committed to the regulatory program as set forth in the notices of intent and the proposed rule.

The proposal also represents a significant leap forward in advancing more environmentally friendly vehicles and zero emissions transportation.

The national program represents a significant step forward in reducing greenhouse gas emissions and fuel consumption through a unified federal and state regulatory structure. We appreciate the efforts of federal agencies and California in providing a regulatory program that allows for one product pathway to compliance and that includes incentives to promote longer term public policy.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 69-74.]

The proposed rule is a positive step that builds on the progress made under the current CAFE rules, and will achieve important economic and environmental benefits.

These proposed new standards will significantly reduce fuel consumption and greenhouse gas emissions and expand the use of alternative fuels.

We urge EPA to continue to evaluate the greenhouse gas effects of these provisions, and take the necessary steps to ensure preservation of the overall goals of the program.

In summary, the joint EPA/NHTSA effort to address greenhouse gas emissions and fuel consumption through this rulemaking is a positive step that builds on the progress of the current CAFE rules.

Organization: Oblong Land Conservancy

Your agency, with the President's support, is taking the right steps to improve fuel economy in America's fleet of vehicles.

In order to reduce our dependence on foreign oil, and all the costs and dangers that this economic relationship entails, we must wean ourselves from this wasteful source.

There are immense savings at the gas pumps that will benefit almost all Americans, and contribute to economic prosperity.

It will substantially reduce air pollution and reduce the threats of global warming.

Please do your share to maximize the clear benefits to America's economy, our national security and our environment.

The Oblong Land Conservancy commends your efforts, and supports these goals. [EPA-HQ-OAR-2010-0799-9915-A1, p. 1]

Organization: Pennsylvania Department of Environmental Protection

The Commonwealth of Pennsylvania appreciates the opportunity to submit comments on the "2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas (GHG) Emissions and Corporate Average Fuel Economy Standards" proposed by the Environmental Protection Agency (EPA) and the National Highway Traffic Safety Administration (NHTSA) on December 1, 2011. The proposal is designed to "represent a continued harmonized and consistent National Program" (76 FR 74854). We are pleased that EPA and NHTSA (the agencies) continue to work with automobile manufacturers to harness the large number of available energy efficient engine technologies that offer the potential to increase the nation's energy efficiency. This continued initiative to ensure greater vehicle fuel efficiency will reduce the nation's dependence on foreign sources of energy, help promote an American energy infrastructure that will support the country's transportation needs and save motorists money at the pump. [EPA-HQ-OAR-2010-0799-7821-A1, p. 1]

The benefits of the agencies' final coordinated rule in terms of fuel savings will be substantial. According to the proposed rule, from model years 2017 through 2025, the fuel cost savings will outweigh the higher vehicle costs based on today's price of gasoline. A consumer who pays cash when purchasing a model year 2025 vehicle can expect to recover the $2,000 extra cost for a vehicle through fuel savings in about 3.5 years. Also, according to the proposed rulemaking, passenger cars will see an average annualized rate of carbon dioxide (CO_2) emission reductions of five percent. For light trucks, the average annualized rate of CO_2 emission reductions would be 3.5 percent per year for model years 2017 through 2021 and increase to five percent per year for model years 2022 through 2025. Finally, the proposed rule indicates that the new fuel economy standards will also result in small reductions in criteria pollutant emissions. The Commonwealth urges the agencies to ensure that all of the proposed emission reduction milestones are achieved expeditiously. [EPA-HQ-OAR-2010-0799-7821-A1, p. 2]

It is also imperative that EPA and NHTSA harmonize the National Program with the program established by the California Air Resources Board (CARB) for motor vehicles. For example, harmonization will allow automobile manufacturers to produce similar vehicles for states that require CARB-certified vehicles and those that require Federally-certified vehicles. We support harmonization because of its significant benefits for both the environment and consumers. [EPA-HQ-OAR-2010-0799-7821-A1, p. 2]

We support the agencies' proposed rulemaking (CAFE and GHG emission standards) for motor vehicles including passenger cars and light-duty trucks, which would create more fuel-efficient light-duty vehicles in this country as governments in countries around the world are considering similar efforts. Keeping the nation's vehicle fleet fuel efficient is important for reducing our dependence on unreliable sources of fossil fuels, promoting a homegrown energy supply and infrastructure, and maintaining our nation's competitiveness and standard of living. We also support EPA's efforts to harmonize Federal light-duty vehicle standards with light-duty vehicle standards developed by CARB. [EPA-HQ-OAR-2010-0799-7821-A1, p. 5]

Finally, EPA should properly account for GHG emissions, which includes extending the harmonization effort with CARB by adopting the same position on test fuels as the California program. [EPA-HQ-OAR-2010-0799-7821-A1, p. 5]

Organization: Pennsylvania State Senate et al.

America's deepening dependence on oil puts our economy, environment, and national security at risk. Your administration has taken important steps to confront this challenge-most recently, announcing an outline for a new phase of fuel efficiency and auto pollution standards through 2025. I am writing to applaud you for developing these standards, and urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rulemaking process. [EPA-HQ-OAR-2010-0799-9914-A1, p. 1]

Americans understand that cleaner, more fuel-efficient vehicles can help break our addiction to oil, and they overwhelmingly support strong fuel efficiency and pollution standards. In a nationwide poll, the Mellman Group found that 83 percent of likely voters favored a 60 miles-per-gallon standard -- even if it would add $3,000 to the up-front price of a new vehicle. Strong standards maximize consumer savings at the pump. [EPA-HQ-OAR-2010-0799-9914-A1, p. 1]

The standards your administration has outlined for 2017-2025 will greatly decrease the average new vehicle's global warming pollution, cutting annual nationwide emissions by 280 million metric tons in 2030-equivalent to the annual emissions from 72 coal-fired power plants. The standards you outlined will also reduce U.S. gasoline consumption by 23 billion gallons in 2030-roughly equivalent to the 2010 U.S. imports from Saudi Arabia and Iraq. Allowing for loopholes to weaken these standards would needlessly send money to foreign countries and extend our dependence on oil. [EPA-HQ-OAR-2010-0799-9914-A1, p. 1]

These standards will determine the efficiency of cars and trucks our children will drive decades from now. We applaud you for seizing a historic opportunity to do more than any previous president to break America's addiction to oil, keep billions of dollars in our economy and reduce the threat of climate change. I urge you to ensure that the standards your administration develops for 2017-2025 vehicles are as strong as possible, in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-9914-A1, p. 1]

Organization: Pew Charitable Trusts

Attached please find comments from The Pew Charitable Trusts and more than 36,000 Americans in support of the proposed fuel efficiency rules for model years 2017-2025 light duty cars and trucks under consideration by the Environmental Protection Agency and Department of Transportation. [EPA-HQ-OAR-2010-0799-9496, p. 1]

The proposed rule would double passenger vehicle fuel efficiency from the level enacted in 2007, a significant increase that will save consumers money at the pump, blunt the economic and national security threats presented by oil dependence and price volatility, and help American manufacturers develop new technologies that spur investment in research, development, and production of advanced vehicles. [EPA-HQ-OAR-2010-0799-9496-A2, p. 1]

Pew has long supported higher federal fuel economy standards. In 2007, we worked to help achieve overwhelming bipartisan support in Congress on the first fuel economy increase in 30 years. [EPA-HQ-OAR-2010-0799-9496-A2, p. 1]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2009-2010-0799-11788, p.17]

In addition to the petition submitted to President Obama on November 1, 2011 and signed by more than 31,000 Americans, Pew has, and will continue to, highlight the importance of fuel efficiency with auto supply manufacturers, working families, and veterans at events around the nation. We have also attached a follow-up petition that includes more than 36,000 signatures of Americans that urge EPA and DOT to adopt a strong final rule. [EPA-HQ-OAR-2010-0799-9496-A2, p. 2]

Dear Mr. President:

I support the proposed rule to increase fuel economy for new passenger vehicles to an average of 54.5 miles per gallon by 2025, which will allow cars and light trucks to drive farther on a gallon of gas and reduce U.S. dependence on imported oil. The price of gas is once again squeezing the budgets of American families, who already are forced to cut back in other areas just to pay for basic transportation needs. [EPA-HQ-OAR-2010-0799-9496-A3, p. 1]

This spring, you set a goal of reducing oil imports by one-third this decade, and in November you proposed fuel efficiency standards that will effectively double current requirements. I commend your efforts. I believe it is important to increase U.S. investment in fuel efficient technologies, save consumers money at the pump, help this country break its dependence on foreign oil, and protect the environment. Don’t let these standards be watered down—protect and finalize the new fuel efficiency rules. [EPA-HQ-OAR-2010-0799-9496-A3, p. 1]

[Note: This comment was signed by 36,000 Americans.]

We have also sought to inform the public and policymakers across the nation about the dangers of U.S. oil dependence to our nation's economy, national security, and to the lives of the U.S. servicemen and women who defend oil transit routes and chokepoints around the world. [These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp.17-18.]

Organization: Porsche Cars North America, Inc. (PCNA)

Porsche supports the goal of setting ambitious targets for long-range reduction in fuel consumption. Most importantly, it is critical to establish a single National standard for GHG so that manufacturers are able to integrate technologies consistently. [EPA-HQ-OAR-2010-0799-9264-A1, p. 2]

Organization: Renewable Energy Long Island

I applaud you for seizing this historic opportunity to do more than any previous administration to break America's dependence on oil, keep billions of dollars in our economy and reduce the threat of climate change. I urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rulemaking process, in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-7933-A1, p. 1]

Organization: Renewable Fuels Association (RFA)

As detailed in the attached comments, RFA is supportive of the stated goals of the CAFE/GHG program. However, we are concerned by several elements of the proposal, as summarized below: [EPA-HQ-OAR-2010-0799-9490-A1, p.1]

While RFA is supportive of the stated goals of the program, which are "to address global climate change and to reduce oil consumption," we are concerned by several elements of the proposal that appear to discourage the future production of flexible fuel vehicles (FFVs) capable of operating on gasoline blends containing greater than 15%vol. fuel ethanol (E15). [EPA-HQ-OAR-2010-0799-9490-A1, p.3]

Additionally, we believe the agencies must ensure the final CAFE/GHG regulation is harmonized with, and does not undermine the requirements of, other related regulations, such as the Renewable Fuel Standard (RFS) and pending "Tier 3" rules. Vehicle engines, emissions controls, and motor fuels operate as highly integrated systems. Therefore, as they finalize the CAFE/GHG rule, the agencies must carefully consider what fuel properties and characteristics will be necessary for automakers to achieve the proposed standards. [EPA-HQ-OAR-2010-0799-9490-A1, p.3]

In closing, RFA remains steadfastly supportive of consistent, science-based policies that reduce petroleum consumption, decrease transportation costs, and reduce GHG emissions. These objectives work in concert to enhance national energy security, strengthen our economy, and protect our environment. While we applaud EPA/NHTSA for endeavoring toward these goals in the current CAFE/GHG proposal, we are concerned that progress may be undermined by several elements of the proposal that discourage the future production of FFVs. [EPA-HQ-OAR-2010-0799-9490-A1, p.8]

Organization: Ross, D.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 240-244.]

In our very imperfect world, the ongoing political grid-lock, the proposed CAFE and greenhouse gas standards are the single most effective policy option on the table for addressing our over-dependence on fossil fuels.

As an economist and a local government official, I'm clear that the benefits of these standards far outweigh the cost for our environment and our economy.

I thank everyone involved in developing the proposed standards. I thank you for your patience in hearing me out, and urge finalization of strong standards for model years 2017, 2025 this summer.

Organization: Salinas, A.

With transportation accounting for 20% of all U.S. greenhouse gas emissions, the new fuel-efficiency and global warming pollution reduction proposals by the Department of Transportation and the EPA are encouraging. However, the proposed rules need strengthening. [EPA-HQ-OAR-2010-0799-7119-A1, p. 1]

Organization: Securing America's Future Energy (SAFE)

SAFE has long advocated increasing the fuel economy of the light-duty vehicle (LDV) fleet. Doing so is, in the short- to medium-term, one of the most effective ways to decrease the petroleum intensity of our economy, thereby enhancing our energy, economic, and national security. For that reason, SAFE strongly supports the general framework and overall fuel economy and emission reduction goals that were the subject of an agreement between the automakers and the regulators last summer, whose components were incorporated into the proposed rule. SAFE also believes that the rule has the potential to help support the adoption of grid-enabled vehicles (GEVs) (electric vehicles (EVs) and plug-in hybrid electric vehicles (PHEVs)), which rely entirely on grid-delivered electricity or use substantially less liquid fuels than traditional vehicles with internal combustion engines, substantially enhancing our economic and national security by relying on a diverse portfolio of domestic fuels, with stable prices, instead of the highly volatile global oil market. [EPA-HQ-OAR-2010-0799-9518-A1, p. 2]

SAFE expresses its appreciation for the agencies ongoing efforts to improve fuel economy in order to improve our national and economic security, and hopes that its comments contribute to the agencies ongoing efforts to do so as in a responsible and aggressive manner. SAFE is committed to providing the regulating agencies any possible assistance that will help them as they proceed through this rulemaking process. [EPA-HQ-OAR-2010-0799-9518-A1, p. 19]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 148.]

We strongly support the agreement reached last summer between the administration and automakers and its embodiment in the proposed regulation because of the amount of the oil savings that it will achieve.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

The Sierra Club, Environment America, Safe Climate Campaign and the Clean Air Council applaud EPA and NHTSA for proposing to strengthen vehicle fuel efficiency and greenhouse gas standards for MY 2017-2025 cars and light trucks – what is now called the National Program. Together with standards for 2012-2016 vehicles, this Administration has put new cars on a path to being twice as efficient in 2025 as new vehicles today. More stringent fuel economy and greenhouse gas standards are the biggest single step we can take to curb dangerous climate change and tackle our addiction to oil. [EPA-HQ-OAR-2010-0799-9549-A2, p. 1]

Conclusion: When finalized, strong 2017-2025 standards will provide automakers with a longterm direction for safely improving fuel efficiency and reducing greenhouse gas emissions from new vehicles. There is no doubt that with these standards, combined with the historic standards that these agencies completed for 2012-2016, are the biggest single step we can take to help move American beyond oil and curb dangerous carbon pollution. This long-term path that a full 14 years of standards offers is critical and will unleash innovation. [EPA-HQ-OAR-2010-0799-9549-A2, p. 11]

As proposed, these standards are demanding significant change in the vehicles automakers make and sell with the promise that these vehicles will emit less greenhouse gas emissions. These changes will benefit consumers, our economy, national security and environment. A strong final rule is needed, with limits on the overall impacts of the flexibilities the proposal offers. To fully realize the promised oil savings and emission reductions from these standards the agencies must ensure the program continues though 2025. [EPA-HQ-OAR-2010-0799-9549-A2, p. 11]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 121-126.]

Sierra Club applauds EPA and NHTSA for proposing to strengthen vehicle efficiency and greenhouse gas standards for model year 2017 to 2025 cars and light trucks. Together with the standards for 2012 to 2016 vehicles this Administration has put new cars on the path of being twice as efficient as new cars today. By 2025, the new vehicles are expected to average 54.5 miles per gallon and emit 162 grams per mile of greenhouse gas pollution delivering to consumers vehicles down the road according to the agencies will average 37 miles per gallon.

These standards are the biggest single step we can take to reduce greenhouse gas emissions and tackle our oil addiction. Cars and light trucks drive our addiction to oil to consume over 8 million barrels of oil a day and CO_2 nearly 20 percent of U.S. climate-destructing pollution. Our oil addiction drains our economy as much as $1 billion every day costing jobs and threatening our national security.

There is no doubt with these standards that these are the biggest single steps we can take to move Americans beyond oil and curb carbon pollution. However, more needs to be done. Even with more efficient vehicle standards, we must increase our transportation choices to reduce how much people drive and reduce the carbon content of the fuels we use. When it comes to vehicles, however, President Obama and EPA and NHTSA have guaranteed progress for the next 13 years. We urge EPA and DOT to finalize strong standards in July.

Organization: Society of the Plastics Industry, Inc. (SPI)

SPI appreciates the proposal’s response to the critical need to address global climate change. Our policy statement on climate change encourages continued research to develop strategies to conserve energy and reduce emissions, and expresses our belief in the importance of developing innovative technologies to minimize the impact on climate change. [EPA-HQ-OAR-2010-0799-9492-A1, pp.1-2]

We thank the EPA and NHTSA for collaborating with vehicle manufacturers in the development of the NPRM, [EPA-HQ-OAR-2010-0799-9492-A1, p.2]

Organization: South Coast AQMD

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 68-71.]

The South Coast AQMD staff supports overall the proposed greenhouse gas emissions standards and timeline. The proposed emissions standards and companion fuel economy standards will result in a significant reduction in greenhouse gas emissions, as well as provide crucially important co-benefits in reducing criteria emissions in support of attainment of federal and state air quality standards for ozone and particulates.

In summary, we strongly urge U.S. EPA and NHTSA to finalize the proposed rule as early as possible.

Organization: State of New York The Assembly

Your administration has taken important steps to confront the dangers of our dependence on oil most recently, proposing new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of the 54.5-mpg fleetwide standard by 2025. I am writing to applaud you for developing these standards. [EPA-HQ-OAR-2010-0799-10155-A1, p. 1]

These standards will determine the efficiency of cars and trucks our children will drive decades from now. I applaud you for seizing this historic opportunity to do more than any previous administration to break America's addiction to oil, keep billions of dollars in our economy and reduce the threat of climate change. I urge you to ensure that the standards your administration develops for 2017-2025 vehicles are as strong as possible, in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-10155-A1, p. 1]

Organization: Tarazevich, Yegor

While I do strongly support reducing air pollution and oil dependency by increasing the fuel economy [NHTSA-2010-0131-0199, p.1]

According to a new study from University of Michigan researchers Kate Whitefoot and Steven Skerlos, with new CAFE standard it would be more profitable for automakers to keep building larger and larger vehicles:

http://www.washingtonpost.com/blogs/ezra-klein/post/cafe-loophole-could-lead-to-bigger-cars/2011/12/14/gIQA3bGLuO_blog.html [NHTSA-2010-0131-0199, p.1]

Organization: Tesla Motors, Inc.

As a California based manufacturer devoted solely to the development and manufacture of electric vehicles and electric vehicle batteries and drivetrain systems, Tesla views EPA's and NHTSA's proposal as a step in the right direction. As detailed in these comments, however, Tesla believes there is still room for improvement, as well as a better understanding of the increasing capabilities and decreasing costs of electric vehicle technology. [EPA-HQ-OAR-2010-0799-9539-A2, p. 1]

As an initial matter, Tesla Motors supports the general direction of EPA’s and NHTSA’s proposal. [EPA-HQ-OAR-2010-0799-9539-A2, p. 3]

Tesla Motors again appreciates the opportunity to provide these comments. With reduction of our dependence on petroleum as the exclusive source of transportation fuel a national imperative, EPA and NHTSA are in a unique position to establish a final rule that encourages the promotes the development of alternatives like electric vehicle technology. As Tesla continues to demonstrate the feasibility of ever improving EV technology at lower price points, we would encourage EPA and NHTSA to continue a leadership position by enacting a final rule that pushes technology forward. [EPA-HQ-OAR-2010-0799-9539-A2, pp. 7-8]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 90-93.]

We are largely supportive of the effort to increase vehicle efficiency and to reduce greenhouse gas emissions, and I thank you for your work in this sector.

Thus, while we applaud EPA and NHTSA's proposal, we believe that it represents a good start, but it doesn't properly -- that it doesn't fully take into account the full potential of EV technology. And so we believe that standards could, indeed, be much higher.

Organization: The Catskill Center for Conservation and Development

America's deepening dependence on oil puts our economy, environment, and national security at risk. I am writing to applaud you for taking an important step to confront the dangers of this dependence by proposing new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of the 54.5-mpg fleetwide standard by 2025. [EPA-HQ-OAR-2010-0799-9913-A1, p. 1]

I applaud you for seizing this historic opportunity to do more than any previous administration to break America's dependence on oil, keep billions of dollars in our economy and reduce the threat of climate change. I urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rulemaking process, in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-9913-A1, p. 1]

Organization: Toyota Motor North America

Toyota views the joint EPA and NHTSA rulemaking process as a necessary step toward our ultimate objective - a true, single national standard governing fuel economy and greenhouse gas emissions in the future. [EPA-HQ-OAR-2010-0799-9586-A1, p.1]

Toyota appreciates the measures the agencies have taken to further harmonize certain aspects of the two regulations. Yet, the different underlying legal frameworks of each agency prevent harmonization in a few key areas, resulting in differing levels of stringency. [EPA-HQ-OAR-2010-0799-9586-A1, p.2]

Recognizing that Toyota's ultimate goal of a single national standard governing fuel economy and GHG's may not be practical under current law, we appreciate the efforts by the agencies to harmonize as much as possible the various provisions of NHTSA's CAFE standards and EPA's GHG standards. In particular, subject to specific comments provided later in this document, Toyota generally supports NHTSA's adoption of the following provisions in order to further harmonize with EPA's GHG regulations: (1) full-size hybrid pick-up truck credits; (2) A/C efficiency credits; and (3) off-cycle technology credits. [EPA-HQ-OAR-2010-0799-9586-A1, p.5]

Organization: U.S. Coalition for Advanced Diesel Cars

The Coalition expresses its support for federal policies that are aimed at increasing America’s twin goals of energy independence and reducing vehicle emissions. [NHTSA-2010-0131-0246-A1, p.1]

As stated throughout these comments, the Coalition is strongly in favor of the EPA and NHTSA’s twin objectives to increase America’s energy independence through better fuel economy and attempts to reduce GHG emissions from new vehicles. [NHTSA-2010-0131-0246-A1, p.8]

Organization: Union of Concerned Scientists (UCS)

On behalf of the Union of Concerned Scientists and our more than 350,000 supporters, please accept the attached technical comments regarding the proposed rule for 2017 and later model year light-duty vehicle greenhouse gas emissions and corporate average fuel economy standards. [EPA-HQ-OAR-2010-0799-9567-A2, letter p. 1]

UCS strongly supports the proposed standards, and applauds the work of the U.S. Environmental Protection Agency (EPA), the National Highway Traffic Safety Administration (NHTSA), and the California Air Resources Board (CARB) for their respective roles in the development of the proposed standards. [EPA-HQ-OAR-2010-0799-9567-A2, letter p. 1]

Your proposal represents historic progress, simultaneously helping tackle the threat of climate change, assisting the recovery of our domestic automotive industry, improving our nation's energy security, and strengthening the economy by saving consumers money at the pump. [EPA-HQ-OAR-2010-0799-9567-A2, letter p. 1]

Importantly, however, key provisions included in the proposal could erode these benefits, and should be addressed by the agencies before the standards are finalized. We provide further detail on these issues in our submitted comments. We urge the agencies to address these concerns and finalize strong vehicle standards for model years 2017-2025 by July 2012, consistent with the timeline issued in the most recent Notice of Intent. [EPA-HQ-OAR-2010-0799-9567-A2, letter p. 1]

Whether it is the threat of international terrorism, the devastating impacts of global climate change, or lost income and jobs due to oil price shocks, the damage caused by America's heavy reliance on oil is clear. Since transportation accounts for the majority of America's oil consumption, making our cars and light trucks cleaner and more fuel efficient is one of the most effective steps we can take to cut our reliance on oil, reduce the heat-trapping pollution that causes global warming, and put money back into the pockets of American consumers. [EPA-HQ-OAR-2010-0799-9567-A2, p. 1]

The proposed light-duty vehicle standards for model years (MYs) 2017-2025 represent a historic step forward. Combined with the existing standards for MYs 2012-2016, the proposed standards would nearly double the fuel efficiency and halve the greenhouse gas emissions of light duty vehicles sold in MY2025 compared to new vehicles sold today. This represents the most significant action ever taken by the federal government to cut America's oil dependence and curb global warming pollution. [EPA-HQ-OAR-2010-0799-9567-A2, p. 1]

Automakers have the technology to make all new light-duty vehicles cleaner and more fuel-efficient. The proposed standards would ensure that this technology is used to finally give consumers a real choice of fuel efficient vehicles – in the car, pickups minivan, and SUV segments alike – when they purchase a new vehicle. In addition, investing in new fuel-saving and pollution control technology will add value to vehicles and enhance the competitiveness of the U.S. auto industry. This will help continue the economic recovery of the American auto industry, protect existing jobs, and create new good-paying jobs into the future. [EPA-HQ-OAR-2010-0799-9567-A2, p. 1]

UCS applauds the important work of the U.S. Environmental Protection Agency (EPA), the National Highway Traffic Safety Administration (NHTSA), and the California Air Resources Board (CARB) for their respective roles in the development of the proposed standards. Throughout the regulatory process, the agencies have been transparent, relied heavily on independent technical analysis, and sought ongoing input from the public and other stakeholders. UCS urges the agencies to finalize strong vehicle standards, with attention paid to provisions in the proposal (noted in Section II below) that, if exploited by automakers, would reduce the program's anticipated benefits. [EPA-HQ-OAR-2010-0799-9567-A2, p. 1]

The agencies have proposed new light-duty vehicle standards for MYs 2017-2025, which would result in an anticipated fleetwide average greenhouse gas emissions level of 163 grams-per-mile and a fleetwide average CAFE level of 49.6 miles-per-gallon in MY2025. If finalized and fully implemented, these standards would deliver significant benefits to consumers, the domestic auto industry, the environment, and U.S. energy security. [EPA-HQ-OAR-2010-0799-9567-A2, p. 2]

The National Program Harmonizes Fuel Economy and Greenhouse Gas Standards while Maintaining California Authority

The proposed standards for MYs 2017-2025 build on the successful framework established originally in the rulemaking for fuel efficiency and greenhouse gas standards of MY2012-2016 vehicles. This National Program allows automakers to sell a single national fleet of new light-duty vehicles that comply with federal and state requirements under the Clean Air Act and the Corporate Average Fuel Economy (CAFE) program. Under this structure, EPA continues to set and administer national greenhouse gas standards under the Clean Air Act, while NHTSA sets and administers CAFE standards. Throughout this process, both EPA and NHTSA have coordinated with CARB, which will establish its own greenhouse gas standards, as allowed under the Clean Air Act. However, CARB has indicated that it will once again accept compliance with the National Program as compliance with its own program, based on conditions articulated in the letters of commitment signed in July 2011 and reiterated in the resolution language adopted by the Air Resources Board at their January 27th 2012 hearing.11, 12 [EPA-HQ-OAR-2010-0799-9567-A2, p. 4]

Since President Obama first directed the agencies to develop the second phase of the National Program in May 2010, both EPA and NHTSA have worked constructively to develop the proposed standards, based on rigorous technical analysis and public input. The agencies released a Notice of Intent (NOI) and supporting Technical Assessment Report (TAR) in September 2010. This was followed by a supplemental NOI in November 2010. Finally, the agencies released a second supplemental NOI in July 2011, and in November 2011 a robust Technical Support Document that accompanied the MY2017-2025 proposed rule. Throughout the process, both the public and key stakeholders were invited to submit comments to the agencies. In addition to the formal regulatory announcements, the agencies met routinely with key stakeholders, both individually and through stakeholder panels, throughout the regulatory process. UCS commends the agencies for conducting a thorough, transparent, and inclusive regulatory process to this point. [EPA-HQ-OAR-2010-0799-9567-A2, p. 4]

UCS applauds the agencies for proposing standards that represent historic progress for American consumers, the U.S. auto industry, clean air, and U.S. energy security. However, key provisions included in the proposal could erode these benefits, and should be addressed by the agencies before the standards are finalized. We provide further detail on these issues in the remaining portion of our comments. We urge the agencies to address these concerns and finalize strong standards for model years 2017-2025 by July 2012, consistent with the timeline issued in the most recent Notice of Intent. [EPA-HQ-OAR-2010-0799-9567-A2, p. 5]

As important and promising as the proposal is, there are several areas that should be improved to more accurately reflect current data and research on key issues, while other areas should be changed to avoid opportunities for automakers to exploit several provisions in the proposal. UCS encourages the agency to address these items before finalizing standards for model year 2017-2025 vehicles. [EPA-HQ-OAR-2010-0799-9567-A2, p. 5]

Again, UCS commends and thanks the agencies for their diligent work in developing the proposed MY2017-2025 standards. We look forward to the agencies addressing the issues noted above, and finalizing strong standards through 2025 by July 2012. [EPA-HQ-OAR-2010-0799-9567-A2, p. 14]

America's dangerous dependence on oil puts our environment, economy, and national security at risk. That's why I strongly support the proposed fuel efficiency and global warming emissions standards for new cars and light trucks sold in model years 2017-2025. [EPA-HQ-OAR-2010-0799-9713-A2, p. 2]

The proposed standards are achievable and reasonable and will save me money at the pump, cur millions of tons of harmful global warming emissions, and save as much oil in 2030 alone as we currently import from Saudi Arabia and Iraq. They will also drive innovation in the U.S. auto industry, creating new jobs across the country. [EPA-HQ-OAR-2010-0799-9713-A2, p. 2]

We cannot afford to delay in confronting the threats of climate change and our dangerous oil dependence. I urge you to move forward with the strongest possible standards free of harmful loopholes. [EPA-HQ-OAR-2010-0799-9713-A2, p. 2]

We support these efforts to reduce global warming emissions, improve the fuel efficiency of our vehicles, reduce our dependence on oil, and protect public health by ensuring drivers have more choices for clean cars and light trucks through the use of strong, cost-effective standards. [EPA-HQ-OAR-2010-0799-9713-A2, p. 3]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 214-220.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 137-140.]

39 Vehicles that Meet or Exceed Proposed Targets With Current Powertrain Designs. Draft Joint Regulatory Impact Analysis, Table 3.12-1.

Organization: United Automobile Workers (UAW)

The UAW applauds NHTSA and EPA for their efforts in developing these proposed standards and urges the agencies to issue final regulations based on them. [EPA-HQ-OAR-2010-0799-9563-A2, p.1]

These proposed standards are NHTSA's proposal to implement the continuance of fuel economy standards in accordance with the Energy Independence and Security Act of 2007 (EISA) and EPA's proposal to continue the regulation of greenhouse gas emissions from light-duty vehicles under the Clean Air Act (CAA). [EPA-HQ-OAR-2010-0799-9563-A2, p.1]

The UAW commends both agencies and the Obama administration for putting forth proposals that extend and strengthen the unified national system of fuel economy and greenhouse gas emission regulation established for model years 2012-2016. These proposals provide needed regulatory certainty to the automobile industry by removing the threat of a confusing and costly patchwork of state and federal regulation of light-duty greenhouse gas emissions beginning in model year 2017. [EPA-HQ-OAR-2010-0799-9563-A2, p.1]

The proposed rules will benefit the nation by reducing greenhouse gas pollution and lessening the nation's dependence on foreign oil, while at the same time giving consumers relief from rising and volatile fuel prices and lowering the overall cost of owning and operating a light-duty vehicle. [EPA-HQ-OAR-2010-0799-9563-A2, p.1]

The UAW is pleased that the proposals recognize the complexities of the automobile market and the wide variety of products that consumers demand. These proposals call for improvements in fuel efficiency and reductions in tailpipe pollution that are fair, sensible and achievable across the many classes of cars and trucks sold in the United States. The proposed federal programs create a level playing field for manufacturers across the market. [EPA-HQ-OAR-2010-0799-9563-A2, pp.1-2]

In conclusion, the UAW is pleased to offer its strong support for the proposals put forward by NHTSA and EPA. We commend the Obama administration for its success in implementing the 2012-2016 rules and developing these proposed rules for 2017–2025 with an open process of stakeholder engagement. It is wise and efficient to gather as much information as possible from a wide variety of stakeholders before crafting proposed regulations, especially so when much of that information is deeply technical and closely held by the automakers. [EPA-HQ-OAR-2010-0799-9563-A2, p.7]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 21-26.]

It's an honor to be here this morning on behalf of our membership to voice UAW's full and strong support for the proposed rules, regulating greenhouse gas emissions and fuel economy.

The proposed rules are sensible, achievable and needed. They are good for the auto industry and its workers, good for the broader economy, good for the environment and good for our national security.

Also I want to say that UAW believes that the auto manufacturers, all the companies that participated in the technical discussions about these proposals and signed a letter of commitment to support its frameworks deserves tremendous credit for their commitment to dramatically increase the efficiency and reduce the emissions of vehicles sold in the United States.

This is a testament to good government. It shows how government can bring disparate stakeholders together to solve problems that are important to the American public. These proposed rules will reduce the pollution that contributes to climate change, significantly reduce America's dependence on foreign oil and save American families money at the pump. They will also create jobs in the auto industry and throughout the economy.

That's an incredible set of positive effects from these proposed rules, and it sums up why the United Auto Workers are in strong support of these proposals.

President Obama and his Administration, including the two agencies here today, did a tremendous job in developing the proposed rules. We thank the President for all the great work he has done to strengthen the American auto industry and automotive communities.

Organization: United States Senate

We are writing to express our support for your efforts to establish a coordinated national program for fuel economy and emissions standards for model year 2017 to 2025 cars, light trucks, and SUVs. The proposed regulations will increase nationwide fleetwide fuel economy to 54.5 miles per gallon by 2025. The standards will implement Federal law in a manner that provides industry with certainty, saves consumers billions of dollars at the pump, reduces our dependence on oil, and improves the health of American communities. [NHTSA-2010-0131-0264-A1, p.1]

These proposed regulations implement the policies set forth in the 2007 Ten in Ten Fuel Economy Act (Title I of Public Law 11 0-140) in a manner supported by many automotive manufacturers, as well as the labor and environmental community. Industry groups such as the National Association of Manufacturers praised the agreement on the proposed standards as a 'positive step.' The regulatory certainty created by this proposal, which unifies state and Federal regulations into a single regime, will help automakers to design and build advanced technology vehicles and compete in an increasingly global marketplace. [NHTSA-2010-0131-0264-A1, p.1]

We appreciate your efforts to achieve your statutory mandates of reducing oil use and pollution in a manner that will allow the automobile industry to grow and thrive. We encourage you to continue working with stakeholders to attain the critical national objectives of reduced pollution, improved energy security, and lower consumer gasoline costs while reducing compliance costs. [NHTSA-2010-0131-0264-A1, p.2]

Organization: United States Steel Corporation

U. S. Steel supports the objectives of the EPA and NHTSA to improve fuel economy and reduce the greenhouse gas emissions associated with light vehicles. U. S. Steel also supports the Energy Independence and Security Act (EISA) of 2007 and the President's May 21, 2010 request that EPA and NHTSA work together to develop a national program that would "…produce a new generation of clean vehicles" and responds to the country's goal of reducing carbon emissions and reducing oil consumption. [NHTSA-2010-0131-0256-A1, p. 1]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 207.]

Organization: United Steel Workers (USW)

The United Steelworkers strongly supports the Administration's goals to increase fuel efficiency standards for America's cars and trucks. Efficiency measures – whether they pertain to vehicles or industry – can have the dual benefit of achieving greenhouse gas emission reductions and making American businesses more globally competitive. We believe the vehicle emissions reduction and fuel economy improvement as proposed by this joint NHTSA/EPA document will serve both of these goals. [EPA-HQ-OAR-2010-0799-9580-A2, p.1]

Organization: Volkswagen Group of America

Following the establishment of the 2012-2016 National Program, Volkswagen continued to engage with agency staff to evaluate and discuss future potential for further improvements in light duty GHG emissions and fuel economy. [EPA-HQ-OAR-2010-0799-9569-A1, letter p. 1]

Volkswagen Group of America, Inc. (Volkswagen) supports the vision expressed by this rulemaking which is to continue into the 2017-2025 timeframe a harmonized National GHG and CAFE program. Volkswagen would like to acknowledge the effort made by EPA, NHTSA, and the State of California in building upon the previous 2012-2016 rulemaking. Volkswagen participated in the negotiations during the development of the previous National program and we have continued to meet with agency technical staff on a regular basis to provide updates regarding our input on future technology trends and efficiency improvements. We are appreciative of the opportunity to supply the agencies with these comments and we look forward to continued constructive dialogue. [EPA-HQ-OAR-2010-0799-9569-A1, p. 3]

Volkswagen elected not to endorse the Supplemental Notice of Intent (SNOI) released prior to this NPRM. We were encouraged that the proposal retains the framework for a single, national fuel economy program. However, we were concerned that the framework resulted in an unbalanced distribution of burden and that targeted flexibilities further amplified the inequities of the program. Volkswagen could not responsibly endorse a proposal that conflicted with our key principles stated above. [EPA-HQ-OAR-2010-0799-9569-A1, p. 6]

Volkswagen wishes to once again acknowledge the hard work and dedication by agency staff in crafting this proposal. Volkswagen appreciates the enormous complexity involved in evaluating future technology developments which attempt to balance the needs of diverse stakeholders. We are pleased to have the opportunity to provide these comments and look forward to continued technical dialogue with agency staff. [EPA-HQ-OAR-2010-0799-9569-A1, p. 29]

Organization: Volvo Car Corporation (VCC)

VCC supported the adoption of a single national program to address both greenhouse gases and fuel economy for model years 2012-2016 and commends the federal government for taking a leadership role in the evolution of these regulations. [EPA-HQ-OAR-2010-0799-9551-A2, p. 1]

VCC supports the effort of the Environmental Protection Agency (EPA), the National Highway Traffic Safety Administration (NHTSA) and the California Air Resources Board (CARB) to work towards the continuation of the single national program. This will allow the long-term development of a national program that enables a robust and realistic development process towards environmental vehicles which address greenhouse gases and fuel economy for the period 2017-2025. [EPA-HQ-OAR-2010-0799-9551-A2, p. 1]

The joint efforts of EPA and NHTSA to achieve harmonized requirements are essential to reach the overall objectives. [EPA-HQ-OAR-2010-0799-9551-A2, p. 4]

Application of Credits for Both GHG - EPA and CARB and CAFE-NHTSA

The proposed EPA and NHTSA requirements are coordinated, but not fully harmonized. They are also coordinated with CARB but are not completely harmonized. VCC suggests providing equivalent fuel consumption and CO_2 credit values toward both the GHG (EPA and CARB) and CAFE programs (NHTSA). [EPA-HQ-OAR-2010-0799-9551-A2, p.9]

The current economic situation limits the opportunities for financial incentives to deploy new environmental innovations. These constraints affect both industry and government opportunities and mean we must manage our available resources very carefully. [EPA-HQ-OAR-2010-0799-9551-A2, p. 15]

It is therefore a balancing act and extremely important that the mechanisms built into the EPA and NHTSA regulations are flexible. [EPA-HQ-OAR-2010-0799-9551-A2, p. 15]

Organization: Weiner, L.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 105.]

I'm here today to support proposed standards and grateful to EPA and NHTSA for putting this forth.

Organization: WESPAC Foundation

America's deepening dependence on oil puts our economy, environment, and national security at risk. I am writing to applaud you for taking an important step to confront the dangers of this dependence by proposing new global warming pollution and vehicle efficiency standards that would ensure new cars and light trucks meet the equivalent of the 54.5-mpg fleet-wide standard by 2025. [EPA-HQ-OAR-2010-0799-9459-A1, p.1]

The projected annual benefits of such standards by 2030 are enormous: [EPA-HQ-OAR-2010-0799-9459-A1, p.1]

$45 billion in savings at the gas pump [EPA-HQ-OAR-2010-0799-9459-A1, p.1]

23 billion gallons of gasoline saved [EPA-HQ-OAR-2010-0799-9459-A1, p.1]

280 million metric tons of global warming pollution avoided [EPA-HQ-OAR-2010-0799-9459-A1, p.1]

I applaud you for seizing this historic opportunity to do more than any previous administration to break America's dependence on oil, keep billions of dollars in our economy and reduce the threat of climate change. I urge you to maximize the consumer and environmental benefits of these standards by keeping the standards as strong as possible through the rule-making process, in order to maximize their benefits for our economy, our environment and our national security. [EPA-HQ-OAR-2010-0799-9459-A1, p.1]

Organization: Whitefoot, K. and Skerlos, S.

This proposed rule takes important steps toward reducing oil consumption and greenhouse gas emissions. However, further measures are needed to ensure that the projected fuel economy improvements actually occur, and that incentives to upsize the vehicle fleet are reduced. [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

Response:

EPA acknowledges the general support for the proposed rule expressed by a very wide range of commenters. The commenters supported the proposal for many reasons, including the following: Appreciation of the effort to align the program with NHTSA's and CARB's programs; the aggressive but achievable standards that send a long-term signal to auto manufactures for their future planning; the expectation of significantly reduced CO_2 emissions and large fuel savings; expectation that the program will benefit businesses (including the auto industry), create jobs, benefit consumers, and spur innovation. EPA is maintaining all key provisions of the proposed rule that prompted these comments.

I oppose the proposed rule to increase fuel economy for new passenger vehicles to an average of 54.5 miles per gallon by 2025, which will allow cars and light trucks to drive farther on a gallon of gas and reduce U.S. dependence on imported oil. [EPA-HQ-OAR-2010-0799-1550-A1, p. 1]

This spring, you set a goal of reducing oil imports by one-third this decade, and in November you proposed fuel efficiency standards that will effectively double current requirements. I question your efforts. I believe it is important to increase U.S. investment in sustainable energy technologies including fuel efficient technologies, charge consumers even more money with taxes at the pump, help this country break its dependence on foreign oil, and protect the environment. Don't let these standards be watered down--protect and finalize new fuel efficiency rules in all areas, not only in transportation. [EPA-HQ-OAR-2010-0799-1550-A1, p. 1]

Organization: Addam, Mary

In the face of peak oil and climate change, why are we waiting til 2017 for better fuel standards? It should have been done 40 years ago. [NHTSA-2010-0131-0208, p.1]

Organization: Anonymous public citizen 4

I read the letter written by several governors to support this proposal. California is not a wise choice to model ourselves after, a bankrupt state. I do not support this proposal. Add this on top of everything else we are burdened with and our economy will soon reach the point of no recovery. If the future of the automobile industry is restricted to building electric and hybrid vehicles, then I will probably be walking. [EPA-HQ-OAR-2010-0799-10317, p.1]

Organization: Anonymous public citizen 5

The general public does not want this bill, and it would be irresponsible to pass it. It should not be passed. [EPA-HQ-OAR-2010-0799-2010, p.1]

Organization: Axford, H.

Mr. President [sic] You leave My Choice of Vehicles Up to My Needs, And What I CAN AFFORD. You are destroying our economy by many of your actions. [EPA-HQ-OAR-2010-0799-9149-A1, p. 1]

Environmental Protection Agency should not increase the CAFE mandate. American families should decide which cars and light-trucks fit their needs and not have our choices dramatically limited by EPA. [EPA-HQ-OAR-2010-0799-9149-A1, p. 2]

These regulations are based on one simple assumption—that federal bureaucrats know better than American families what is best for us. This assumption is wrong. EPA does not know which cars are best for me and my family and should therefore not limit my choices through regulation. [EPA-HQ-OAR-2010-0799-9149-A1, p. 2]

When EPA claims that it has “designed proposed standards to preserve consumer choice” this is only true if you are rich. The rest of us will pay dearly. [EPA-HQ-OAR-2010-0799-9149-A1, p. 2]

EPA should allow people to make our car choices for themselves based on our needs instead of imposing more mandates from Washington, D.C. [EPA-HQ-OAR-2010-0799-9149-A1, p. 2]

Organization: Bassett, S.

I strongly do not support the proposed new fuel efficiency and greenhouse gas standards for cars and trucks to require cars and trucks to an average 54.5 miles per gallon by model year 2025. [EPA-HQ-OAR-2010-0799-8123-A1, p. 1]

Organization: Defour Group

Regarding climate change and CAFE, President Carter's former White House economic advisor on energy policy, William Nordhaus of Yale concludes:

The measure of whether someone is serious about tackling the global warming problem can be readily gauged by listening to what they say about the carbon price. Suppose you hear a public figure who speaks eloquently of the perils of global warming and proposes that the nation should move urgently to slow climate change. Suppose that person proposes regulating the fuel efficiency of cars, or requiring high-efficiency light bulbs, or subsidizing ethanol, or providing research for solar power – but nowhere mentions the need to raise the price of carbon. You should conclude that the proposal is not serious and does not recognize the central economic message about how to slow climate change. To a first approximation, raising the price of carbon is a necessary and sufficient step for tackling global warming. The rest is largely fluff.19 [EPA-HQ-OAR-2010-0799-9319-A1, p. 12]

Organization: Ennis, M.

I strongly oppose these standards.

We cannot afford any of these absurd idea's. [EPA-HQ-OAR-2010-0799-5612-A1, p. 1]

Organization: Environmental Consultants of Michigan

Agency Was Arbitrary and Capricious In the Selection of Policy

The Agency's stated goal is to achieve important reductions in greenhouse gas emissions and fuel consumption from the light-duty vehicle part of the transportation sector claiming that the affected vehicles contribute substantially to greenhouse gas emissions (GHG) and petroleum fuel usage. Since 2002, the Agency has set a goal of carbon neutrality. With this goal in mind, the Agency has the obligation to conduct a fair and balanced evaluation of policy options to achieve this goal. [NHTSA-2010-0131-0166-A1, p. 1]

CAFÉ Has Been a Policy Failure [NHTSA-2010-0131-0166-A1, p. 1]

We now have over thirty years of history to determine the viability of continuing the use of CAFÉ (or its EPA equivalent tailpipe greenhouse gas standards) as a policy tool. In evaluating the official government CAFÉ data1 we find that three of the nine highest volume manufacturers2, Honda, Nissan and Mercedes Benz have DECREASED their combined car and truck fleet average CAFÉ since 1980. Although the Korean based companies were not in the market in 1980, they have reduced their CAFÉ since entering the market in 1986. This can hardly be considered a successful policy when fully half the major participants have actually backslid on CAFÉ over thirty years. [NHTSA-2010-0131-0166-A1, pp. 1-2]

It is impossible to conclude that CAFÉ has been a successful national policy.

- Japanese based companies have increased their CAFÉ performance by only 2 mpg in the past 30 years (Figure 12) [Figure 12 can be found on p. 19 of Docket number NHTSA-2010-0131-0166-A1]

  o Sales increased by a factor of 2.4

- European based companies have DECREASED their CAFÉ performance by almost a mile per gallon (0.9 mpg) in the past 30 years (Figure 13) [Figure 13 can be found on p. 20 of Docket number NHTSA-2010-0131-0166-A1]

  o Sales have been essentially flat

- Korean based companies have DECREASED their CAFÉ performance by one mile per gallon since they entered the US market in 1986 (Figure 14) [Figure 14 can be found on p. 21 of Docket number NHTSA-2010-0131-0166-A1]

  o Sales increased by a factor of 4

- The 3 remaining domestic companies have increased their CAFÉ performance by about 5 mpg (4.8 mpg) in the past 30 years (Figure 15) [Figure 15 can be found on p. 22 of Docket number NHTSA-2010-0131-0166-A1]

  o Sales decreased by almost half

- The limited success in increasing fuel economy over the past thirty years was the result of fuel price swings (Figure 16) and shifting sales from domestic manufacturers to Asian based companies. [Figure 16 can be found on p. 23 of Docket number NHTSA-2010-0131-0166-A1] [NHTSA-2010-0131-0166-A1, p. 2]

In looking at the domestic industry, history shows that there were 5 domestic based companies in 1980;

- American Motors went bankrupt (only the Jeep brand survived);
- International Harvester (now Navistar) left the segment;
- Chrysler required two federal bailouts and one bankruptcy filing;
- General Motors required one federal bailout and one bankruptcy filing [NHTSA-2010-0131-0166-A1, p. 2]

Given this history and a complete lack of regional progress it is impossible to conclude that CAFÉ has been a successful national policy. [NHTSA-2010-0131-0166-A1, p. 2]

Conclusion

These proposed standards are unfair to environmentalists, to manufacturers and to consumers. Instead of wasting another thirty plus years on CAFÉ and its duplicative tailpipe counterpart, the Federal government has no choice but to scrap this proposal and eliminate the existing tailpipe greenhouse gas standards. EPA should immediately begin work on a National low carbon fuel standard. [NHTSA-2010-0131-0166-A1, p. 8]

1 October 2011 Summary of Fuel Economy Performance – October 28, 2011; U. S. Department of Transportation; NHTSA, NVS-220

2 These companies represent over 93% of US sales

Organization: Faria, R.

Environmental Protection Agency must not increase the CAFE mandate. American families will decide which cars and light-trucks fit their needs and not have our choices dramatically limited by EPA. [EPA-HQ-OAR-2010-0799-9834-A1, p. 1]

These regulations are based on one simple assumption—that federal bureaucrats know better than American families what is best for Americans. This assumption is wrong. EPA does not know which cars are best for me and my family and will therefore not limit my choices through regulation. The EPA must be disbanded...!!! [EPA-HQ-OAR-2010-0799-9834-A1, p. 1]

When EPA claims that it has “designed proposed standards to preserve consumer choice”, it simply means that they wish to expand their size and control over the American people. Disband the EPA now...!!! [EPA-HQ-OAR-2010-0799-9834-A1, p. 2]

I will not allow the EPA to make my car choices. The EPA only wishes to impose more mandates from Washington, D.C. thereby increasing their size and control over Americans. [EPA-HQ-OAR-2010-0799-9834-A1, p. 2]

Organization: Feinstein, C.

Organization: Gilles, B.

I strongly oppose the proposed new fuel efficiency and greenhouse gas standards for cars and trucks to require cars and trucks to an average 54.5 miles per gallon by model year 2025. [EPA-HQ-OAR-2010-0799-8065-A1, p. 1]

Organization: Gordon, Michael

I oppose these regulations. There is no evidence whatsoever that greenhouse gas emissions harm the environment and thus this regulation is not necessary. [EPA-HQ-OAR-2010-0799-9625, p.1]

Organization: Green, K.

I question the proposed rule to increase fuel economy for new passenger vehicles to an average of 54.5 miles per gallon by 2025, which will allow cars and light trucks to drive farther on a gallon of gas and reduce U.S. dependence on imported oil. [EPA-HQ-OAR-2010-0799-1524-A1, p. 1]

This spring, you set a goal of reducing oil imports by one-third this decade, and in November you proposed fuel efficiency standards that will effectively double current requirements (for fuel efficiency?). I question your efforts. While I agree that it is important to increase U.S. investment in fuel efficient technologies, save consumers money at the pump, help this country break its dependence on foreign oil, and protect the environment. [EPA-HQ-OAR-2010-0799-1524-A1, p. 1]

Setting standards that are impossible to meet does nothing to help American consumers; nor does it ensure future energy independence for the country. [EPA-HQ-OAR-2010-0799-1524-A1, p. 1]

Organization: Haroldson, C.

I am writing in OPPOSITION of the strong fuel-efficiency and carbon pollution standards for new cars and trucks. [EPA-HQ-OAR-2010-0799-11137-A1, p. 1]

Organization: Hohenstein, H.

I do NOT support the proposed rule to increase fuel economy for new passenger vehicles.

I do not believe - I think it is important to increase private U.S. investment in fuel efficient technologies, save consumers money at the pump, help this country drill more crude in America and become less dependence on foreign oil. Consequently our environment will improve. Do NOT let these standards be mandated on the American people. They have lost enough freedom.

Organization: Horst, R.

I'm strongly opposed the any governmental agency regulating fuel mileage standards under the guise of clean air! [EPA-HQ-OAR-2010-0799-6353-A1, p. 1]

Organization: Houston Tea Party Society

My name is Neal Meyer and I am a member of the Houston Tea Party Society, a Tea Party group with some 3,500 members. My comment is in regards to the U.S. EPA rule mandate that motor vehicles must achieve greater fuel economy standards. [EPA-HQ-OAR-2010-0799-9583, p. 1]

My belief, and I believe I am speaking for many, is that the U.S. government should not be setting fuel economy standards for motor vehicles. The price of crude oil has gone up from $20 per barrel back in 2000, to $100 per barrel in 2012, with the price of gasoline having gone up from $1.00 per gallon to $3.50 - $4.00 per gallon during the year 2000 - 2012 time frame. There is evidence that this increase in fuel prices has caused Americans to decide to drive fewer vehicle miles and to start buying motor vehicles that get better fuel economy on their own, without the requirement of a mandate from the federal government. It is this sort of meddling, where the federal government substitutes its judgment for those of Americans, that has angered many Americans. [EPA-HQ-OAR-2010-0799-9583, p. 1]

So, in conclusion, on behalf of the Houston Tea Party Society, I would say to the U.S. EPA to no not enact, adopt, or enforce this rule. [EPA-HQ-OAR-2010-0799-9583, p. 1]

Organization: Institute for Energy Research (IER)

Lastly, EPA is legally required to consider less restrictive alternatives to achieve their goals of greenhouse gas emission reductions from motor vehicles. EPA does not conduct this analysis in this proposed rule.[EPA-HQ-OAR-2010-0799-9573-A1, p. 2]

For these reasons, EPA should not regulate greenhouse gases from vehicles using the Clean Air Act. [EPA-HQ-OAR-2010-0799-9573-A1, p. 2]

Another problem is that the EPA's analysis doesn't ask whether the proposed rules would reduce greenhouse gas emissions in the most efficient manner. In the economics of climate change literature, it theoretically improves social welfare if governments around the world jointly implement a uniform carbon tax equal to the estimated Social Cost of Carbon. The higher price on carbon emissions leads to reductions by precisely those emitters that are most able to afford it. As a result, this "market-based" (though the term is somewhat of a misnomer since it results from government tax policy) approach to fighting climate change would achieve the correct reduction in total emissions in the least-cost manner. [EPA-HQ-OAR-2010-0799-9573-A1, p. 22]

In this theoretically optimal scenario, it is very improbable that the worldwide response to the new carbon tax regime would consist of U.S. manufacturers sharply increasing the fuel efficiency of light duty cars and trucks. There are other, cheaper ways of reducing carbon emissions by a desired quantity. By eschewing "market-based" approaches and directly ordering the particular form of emission reductions—namely by increasing the fuel efficiency of new vehicles in certain classes by specific amounts by specific deadlines—the proposed rules are economically inefficient, relative to other possible policies. [EPA-HQ-OAR-2010-0799-9573-A1, pp. 22-23]

Organization: Mehrotra, Rahul

I believe these efforts are too little, too late.

We have already scorched our planet beyond the tipping point.

It may help if this standard was made effective right away, with punitive damages for delays. [NHTSA-2010-0131-0206, p.1]

Your leadership and initiative in this matter needs to be dictated by the mess we have caused, and not the conveniences of those who have created the mess.

After all, we are only asking to get back to where we were. [NHTSA-2010-0131-0206, p.1]

Organization: National Automobile Dealers Association (NADA)

Yet, the proposal continues to ignore this direction, opting instead for a bureaucratic cobbling together of NHTSA’s CAFE standards with EPA’s largely redundant GHG standards. [EPA-HQ-OAR-2010-0799-9575-A1, p. 12]

The time-honored EPA test procedures used to calculate NHTSA’s CAFE standards rely on equations involving a carbon balance technique where fuel economy is calculated from the measurement of exhaust emissions, and an assumption that the quantity of carbon in a vehicle's exhaust gas is equal to the quantity of carbon consumed by the engine as fuel. The physics and chemistry involved spell a direct relationship; controlling fuel economy controls GHGs and controlling GHGs controls fuel economy. NADA continues to believe that any further rulemakings in this area should involve NHTSA CAFE standards, supplemented by a few appropriately tailored EPA rules governing motor vehicle air conditioning, fuels, and vehicle use. Moreover, EPA should focus its resources on 'doing no harm,' such as by ensuring that its emissions standards, including potential Tier III standards, avoid conflicting with mandates aimed at achieving fuel economy improvements. Indeed, this is yet another lesson learned from the commercial truck experience where the emissions mandates at issue served to severely undermine fuel economy performance. [EPA-HQ-OAR-2010-0799-9575-A1, p. 12]

Lastly, NADA continues to strongly object to the needless deference being given to the California Air Resources Board and to its unnecessary and arguably preempted fuel economy rules. NHTSA and EPA should take the policy position that the issuance of a final national rule should eliminate, once and for all, any basis for the state regulation of fuel economy. NADA strongly suggests that EPCA's explicit preemption of the adoption or enforcement of state laws 'related to' fuel economy was necessary to ensure national uniformity and to avoid a patchwork of state-by-state mandates that would conflict a 'National Program,' and undermine the safety, job loss, equity, and consumer affordability and choice considerations required by EPCA. [EPA-HQ-OAR-2010-0799-9575-A1, pp. 12-13]

Organization: Parker, M.

Environmental Protection Agency should not increase the CAFE mandate. American families should decide which cars and light-trucks fit their needs and not have our choices dramatically limited by EPA. [EPA-HQ-OAR-2010-0799-9017-A1, p. 2]

These regulations are based on one simple assumption—that federal bureaucrats know better than American families what is best for us. This assumption is wrong. EPA does not know which cars are best for me and my family and should therefore not limit my choices through regulation. [EPA-HQ-OAR-2010-0799-9017-A1, p. 2]

When EPA claims that it has “designed proposed standards to preserve consumer choice” this is only true if you are rich. The rest of us will pay dearly. [EPA-HQ-OAR-2010-0799-9017-A1, p. 2]

EPA should allow people to make our car choices for themselves based on our needs instead of imposing more mandates from Washington, D.C. [EPA-HQ-OAR-2010-0799-9017-A1, p. 2]

Get the overreaching theiving goverment out of the American peoples lives. The last thing this country needs is more regulation. You don't enforce the laws we do have so stop making ridiculous new ones. This Republic government that has been over taken by democacy (a failing government) is failing. The depts that have been set up such as the dept of energy has failed and you can't fix it. You are destroying the very freedoms and even the illusion of freedom we still have. Government is not the solution, the Constitution is; Freedom and Liberty. The only thing that you are succeeding at is destroying this country, but that has been your malicious intent all along. [EPA-HQ-OAR-2010-0799-9017-A1, p. 2]

Organization: Paul, M.

Environmental Protection Agency (EPA) should ••NOT•• increase the Corporate Average Fuel Economy (CAFE) mandates. AMERICAN FAMILIES should be able to decide which cars and light-trucks fit their needs and ••NOT•• HAVE OUR CHOICES DRAMATICALLY LIMITED... BY THE EPA. [EPA-HQ-OAR-2010-0799-9027-A1, p. 2]

Increased CAFE mandates are based on one simple ASSUMPTION—that federal bureaucrats 'know better' than American families what is best for us. THIS ASSUMPTION IS WRONG.. EPA does ••NOT•• know which cars are best for me and my family AND should therefore ••NOT•• limit my choices through regulation. [EPA-HQ-OAR-2010-0799-9027-A1, p. 2]

When EPA claims that it has “designed proposed standards to PRESERVE CONSUMER CHOICE”... WHAT 'HOGWASH'!!!. IN FACT, THIS REGULATION WOULD IN FACT, ELIMINATE CHOOSING A CAR THAT DIDN'T MEET THE CAFE MANDATE AND... RAISE THE COSTS ON ALL VEHICLES...,THUS ••ELIMINATING•• CONSUMER CHOICE, [EPA-HQ-OAR-2010-0799-9027-A1, p. 2]

IT IS THEREFORE ••ANOTHER USELESS REGULATION•• ATTEMPTING TO FURTHER CONTROL... THE AMERICAN PUBLIC, THE ECONOMY, AND... IT WILL ONLY HAVE NEGATIVE IMPACTS ON OUR COUNTRY. [EPA-HQ-OAR-2010-0799-9027-A1, pp. 2-3]

Organization: Pearce, F.

Environmental Protection Agency should not increase the CAFE mandate. American families should decide which cars and light-trucks fit their needs. It is unreasonable and against the best interests of our nation to have choices limited by the EPA.

It appears that you assume federal bureaucrats know better than American families what is best for us. This assumption is wrong. EPA does not know which cars are best for me and my family and must not limit my choices through such regulation. [EPA-HQ-OAR-2010-0799-10343-A1, p.1]

EPA should allow people to make car choices for ourselves based on our needs instead of imposing more mandates from Washington, D.C. [EPA-HQ-OAR-2010-0799-10343-A1, p. 1]

I vehemently oppose the Environmental Protection Agency’s proposal to increase the CAFE standards for the following reasons: [EPA-HQ-OAR-2010-0799-8724-A1, p. 2]

* American families should decide which cars and light-trucks fit their needs and not have our choices dramatically limited by the EPA or any other government bureaucracy. That is called FREEDOM, which the Obama administration and its bureaucratic minions are intentionally and rapidly stripping from the American people. [EPA-HQ-OAR-2010-0799-8724-A1, p. 2]

Organization: Sullivan, T.

Environmental Protection Agency should not increase the CAFE mandate. American families should decide which cars and light trucks fit their needs. We should not have our choices dramatically limited by EPA or any government agency. [EPA-HQ-OAR-2010-0799-10341-A1, p. 1]

These regulations are based on one simple assumption - that federal bureaucrats know better than American families what is best for us. This assumption is wrong. EPA does not know which cars are best for me and my family and should therefore not limit my choices through regulation. [EPA-HQ-OAR-2010-0799-10341-A1, pp. 1-2]

When EPA claims that it has “designed proposed standards to preserve consumer choice” this is only true if you are rich. The rest of us will pay dearly. The EPA is not being truthful. [EPA-HQ-OAR-2010-0799-10341-A1, p. 2]

EPA should allow people to make our car choices for themselves based on our needs instead of imposing more mandates from Washington, D.C. Stop ruining our economy trying to satisfy the false theory of global warming. [EPA-HQ-OAR-2010-0799-10341-A1, p. 2]

Organization: Van Voorhies, M.

I DO NOT SUPPORT THIS PROPOSAL. [EPA-HQ-OAR-2010-0799-1629-A1, p. 1]

Organization: Varley, R.

I have great concern that this is asking far far too little. It seems ridiculous to me that it should take 28 years (from 1997 to 2025) to do less than double that mileage. It needs to be done much faster than this. I hope that by then we will not be using petroleum gas at all. [EPA-HQ-OAR-2010-0799-1948-A1, p. 1]

Response:

EPA acknowledges several general comments opposing the proposed program. A few of these commenters expressed that the program should be more stringent and be implemented sooner. Issues of stringency and timing are addressed in RTC Section 2.2 below.

Most commenters opposing the program express a general belief that the proposed rule is unnecessary, in some cases stating that market forces would be sufficient to achieve the environmental, fuel savings, and energy security goals of the program. These comments are strongly controverted by historic evidence. As discussed in preamble section III.D.1.a, fuel economy improvements have historically remained unchanged in periods of flat CAFE standards -- absent price spikes in automotive fuels. These historic trends, coupled with the AEO2011 projection of largely stable gasoline prices through MY 2025, strongly support EPA's conclusion that market forces alone will not result in the improvements projected for the rule. All the written public comments on this issue strongly supported EPA's analysis. See preamble section III.D.1.a. In addition, since the MYs 2012-2016 standards are footprint-based, every major manufacturer is expected to be constrained by the new standards in 2016, and manufacturers of small vehicles will not routinely over-comply as they had with the past universal CAFE standards. There are additional factors that reinforce the historical evidence. While it is possible that one or two companies may over-comply, any voluntary over-compliance by one company would generate credits that could be sold to other companies to substitute for their more expensive compliance technologies. This ability to buy and sell credits could eliminate any over-compliance for the overall fleet, absent the GHG rule. Throughout the preamble, technical documents, and this Response to Comments document, EPA presents its broad analytical rationale for the program and will finalize all the major aspects of the proposed rulemaking.

A number of commenters expressed the belief that the proposed program would limit the vehicle choices available to consumers. This is not the case. As discussed in more detail in the preamble and in other comment responses, the footprint attribute-based standard tends to force improvement across the entire spectrum of vehicle footprints and reduces incentive to downsize vehicles as a compliance strategy. In addition, the agencies have included costs of preserving all vehicle utility found in the present fleet (see e.g. EPA RIA at p. 1-40), and demonstrated feasible, cost-effective compliance paths to meet the standards without eliminating any utility found in the present fleet. Consequently, any changes in types of vehicle offered for sale would be a result of market forces and manufacturer responses thereto, but would not be a direct consequence of this rule. EPA addresses impacts on consumers, including vehicle choice issues, in Section 18.1 below.

One commenter stated that because past CAFE standards had not resulted in significant improvements in fuel economy, EPA and NHTSA should not pursue new GHG and CAFE standards. On the contrary, EPA has shown in the earlier GHG rulemaking and in this one that new, stringent CAFE and GHG standards can be expected to result in large reductions in emissions and in fuel consumption in the coming years, precisely because they are more stringent than earlier standards, as described in Section 16.1 below. Also in Section 16.1, EPA addresses the need for GHG reductions.

With respect to comments from the Defour Group and Institute for Energy Research, we note that the merits of carbon pricing schemes are outside the scope of this rule. EPA has taken a common-sense approach to developing standards for greenhouse gas emissions from mobile sources under the Clean Air Act. These actions have focused on reducing greenhouse gas emissions by increasing the efficiency of cars and trucks. EPA's analyses show that these regulations will save consumers money at the pump, improve energy security by reducing oil consumption, and cut millions of tons of harmful greenhouse gas emissions.

Continued Use of Footprint Attribute [EPA-HQ-OAR-2010-0799-9487-A1, p.85]

The Alliance agrees that footprint is integral to a vehicle's design and is dictated by the vehicle platform, which is typically used for a multi-year model life cycle. As such, it continues to be a reasonable choice for setting standards. Further, since footprint was the basis for all regulatory discussions, it remains the appropriate attribute. [EPA-HQ-OAR-2010-0799-9487-A1, p.85]

Analysis of manufacturer data and understanding of the vehicle energy efficiency dependence on footprint suggests that linear attribute curves based on gym (gallons per mile) versus footprint is an appropriate way to adjust for size differences across the industry. Vehicle efficiency is driven by road load, mass, and powertrain/driveline efficiency. Regressions of vehicle road load energy over EPA driving cycles, frontal area and mass show strong linear relationships with footprint. [EPA-HQ-OAR-2010-0799-9487-A1, p.85]

Weighting and Regression Analysis [EPA-HQ-OAR-2010-0799-9487-A1, p.86]

The Alliance also supports the weighting and regression analysis used to develop the 2017-2021 model year CAFE and GHG curves. We further support the derived relationships between the vehicles' CO_2/fuel consumption and their related footprints as an appropriate attribute. However, as mentioned elsewhere in our comments, these weightings and analysis should be reviewed during the midterm evaluation for the MY 2022-2025 model years. [EPA-HQ-OAR-2010-0799-9487-A1, p.86]

Organization: BMW of North America, LLC

BMW fully supports the continued use an attribute-based program. [EPA-HQ-OAR-2010-0799-9579-A1, p. 1]

With respect to a Single National Program, BMW fully supports the continued use an attribute-based program for passenger cars and light trucks as proposed by EPA and NHTSA. Compared to a uniform standard for passenger cars and light trucks, an attribute-based standard drives fuel efficiency and GHG reduction in all segments while taking into account the manufacturer's product portfolio. However, because BMW offers a worldwide product portfolio and most of the CO_2 and fuel economy regulations worldwide are based on vehicle weight instead of footprint, BMW continues to recommend that these regulations be harmonized as much as possible. [EPA-HQ-OAR-2010-0799-9579-A1, p. 3]

Organization: Consumer Federation of America (CFA)

The attribute-based approach ensures that the standards do not require radical changes in the types or size of vehicles consumers drive; so, the full range of choices will be available to consumers. [EPA-HQ-OAR-2010-0799-9419-A1, p. 8]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 90.]

Third, the approach to setting standards is consumer friendly and facilitates auto maker compliance.

The new attribute-based approach as you've heard provides no incentive to change the size of the vehicles. Consumers will get the cars they want; they'll all be more fuel efficient.

Organization: Consumer Reports

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 168.]

Because the CAFE standards are now footprint-based, improvements across all vehicle sizes, so each class will see an efficiency.

Organization: Ecology Center

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 188.]

One is that the proposed standards continue the attribute-based structure and requirements for steady improvement that were established in the current standards. When first proposed by the agencies in 2009 following the historic 2007 Energy Independence and Security Act, this new approach represented a breakthrough in regulation for this sector. Not only were the requirements more fairly applied among vehicle manufacturers but the rules also more effectively stimulated innovation by requiring improvements across all vehicle sizes and classes. The rules also included provisions that help ensure the continued production of domestic fuel-efficient vehicles, and we support those as well.

Organization: Ferrari

1) Vehicle attributes to be considered [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

We agree that the CO_2 and CAFE standards are based on one or more vehicle attributes. The footprint is the attribute selected first by NHTSA since 2011 MY CAFE regulation and then in the joint National Program MYs 2012-16 for both CO_2 and CAFE standards. [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

The footprint alone does not take into account many of a vehicles' other characteristics that greatly affect the fuel economy/ CO_2 emissions, like the engine displacement and power, transmission, curb weight, aerodynamics, etc. This fact is recognized by both EPA and NHTSA, as written in Section II.C.2. (pages 74912 and 74913): [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

There are several policy and technical reasons why NHTSA and EPA believe that footprint is the most appropriate attribute on which to base the standards, even though some other vehicle attributes (notably curb weight) are better correlated to fuel economy and emissions. [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

Further…we recognize that weight is better correlated with fuel economy and CO_2 emissions than is footprint. [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

We sent our comments on this important issue in the previous rulemaking for MYs 2012- 16. We would prefer at least a second attribute to be considered, in addition to the footprint. For example: the power to curb weight ratio. Nonetheless, we admit that it seems logical to continue with the footprint, as proposed, to be consistent with the final regulation enacted for MYs 2012-16. [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

We agree to keep the type and shape of curves that define CO_2 and fuel economy standards. [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

Organization: Ford Motor Company

Ford supports the continuation of footprint-based standards with separate car and truck fleets based on NHTSA vehicle definitions for both the GHG and CAFE programs. [EPA-HQ-OAR-2010-0799-9463-A1, p. 8]

Ford and the auto industry have long supported separate car and truck attribute-based standards because cars and trucks have different functional characteristics, even if they have the same footprint and nearly the same base curb weights. For example, the Ford Edge and the Ford Taurus have the same footprint, but vastly different capabilities with respect to cargo space and towing capacity. Some of the key features incorporated on the Edge that enables the larger tow capability include an engine oil cooler, larger radiator and updated cooling fans. This is just one of the many examples that show the functional difference between cars and trucks and further support the need to maintain separate car and truck attribute-based standards. [EPA-HQ-OAR-2010-0799-9463-A1, p. 8]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 34.]

Turning now to more specific comments of the proposed rulemaking, we support the relative manner in which car and truck targets have been set to reflect their respective capabilities to improve fuel economy.

Organization: General Motors Company

GM supports the proposed footprint-based CO_2 and CAFE standards for 2017-2021. [EPA-HQ-OAR-2010-0799-9465-A1, p. 2]

Organization: Institute for Policy Integrity, New York University School of Law

The agencies should rethink their footprint-based standards, which may be unnecessary to respect consumer preferences, may negatively impact safety, and are likely to be overall inefficient. Increasing the safety of one car can impose a negative safety externality on others, and consumer preferences can adjust as average fleet-wide attributes shift. As a result, trying to eliminate the incentive to build smaller cars may block a cost-effective compliance strategy and may not guarantee a safer fleet. [EPA-HQ-OAR-2010-0799-9480-A1, p. 2]

Part II. Vehicle Attributes

The agencies assume that the current market accurately reflects the range of consumer preferences for vehicle attributes like performance, carrying capacity, safety, and comfort, failing only with respect to fuel economy technology. The agencies want to ensure that the proposed rule will preserve both consumer choice and the same mix of vehicle options. If instead the rule were to impact vehicle attributes like size and power, the agencies worry that consumers might experience a loss in welfare, erasing some of the large net benefits the rule should generate for consumers and society. [EPA-HQ-OAR-2010-0799-9480-A1, p. 12]

To this end, the agencies take two steps. First, they tie the prescribed standards to vehicle footprint, so that larger vehicles will generally be subject to less stringent controls compared to smaller vehicles. Second, the agencies apply an assumption of constant performance to their cost estimates, believing that manufacturers will spend whatever extra it costs to maintain current vehicle attributes as they increase fuel economy. [EPA-HQ-OAR-2010-0799-9480-A1, p. 12]

The agencies should rethink both their attribute-based standards and their estimation of costs. First, the footprint-based standards may be unnecessary to respect consumer preferences, may negatively impact safety, and may be overall inefficient. Several arguments call into question the footprint-based approach, but a particularly important one is that large vehicles can impose a negative safety externality on other drivers. [EPA-HQ-OAR-2010-0799-9480-A1, p. 12]

Second, the agencies' constant performance cost estimates represent an upper bound to possible consumer welfare losses and are most likely overestimates, because vehicle attributes are partly positional and consumer preferences can shift with changing attributes. Similarly, the unlikely chance that the agencies' cost projections underestimate consumer welfare losses is further mitigated by the actual nature of consumer preferences. Finally, those same insights from positional goods theory and the bandwagon effect should be considered in the agencies' forecast for the future consumer market for new technologies like electric vehicles. [EPA-HQ-OAR-2010-0799-9480-A1, p. 12]

Footprint-Based Standards May Be Unnecessary to Respect Consumer Preferences, May Negatively Impact Safety, and May Be Overall Inefficient

The agencies choose to set regulatory stringency according to vehicle footprint, in part because the statute requires NHTSA to base standards on attributes related to fuel economy. The agencies offer five justifications for choosing a footprint-based approach: [EPA-HQ-OAR-2010-0799-9480-A1, p. 13]

• First, they claim the optimal attribute-based standard will achieve greater overall fuel savings than the optimal flat standard, since an attribute-based approach encourages all manufacturers to add new technologies every year, even those manufacturers with fleets that are already relatively efficient.

• Second, out of concerns for safety, the agencies want to remove the incentive to build smaller cars in order to comply with the standard.

• Third, the agencies believe the attribute-based approach will be more equitable than a flat standard, which could impose disproportionate burdens on some manufacturers.

• Fourth, the agencies want to preserve the current vehicle mix in the marketplace in order to respect consumer choice.

• Fifth, the agencies believe a footprint-based approach involves a lower risk of manufacturers "gaming" the system, at least compared to a weight-based approach. [EPA-HQ-OAR-2010-0799-9480-A1, p. 13]

All five justifications are problematic. [EPA-HQ-OAR-2010-0799-9480-A1, p. 13]

The first justification assumes that attribute-based approaches will increase overall fuel savings since, under a flat standard, manufacturers with fleets that are already relatively fuel efficient would have little incentive to continue upgrading. However, this claim very much depends on whether the proposed attribute-based standard is actually optimal: an inefficient footprint-based standard is unlikely to achieve greater overall fuel savings than the optimal flat standard. [EPA-HQ-OAR-2010-0799-9480-A1, p. 13]

Moreover, given that reducing vehicle size, weight, and performance are relatively cheap and readily available compliance options,84 even the optimal footprint-based standard may suffer from inefficiencies by disincentivizing an otherwise cost-effective strategy. Wenzel's research suggests that "a fuel economy standard that discourages vehicles with smaller footprint . . . will not be as effective in reducing fuel consumption and associated greenhouse gas emissions as a single stringent standard applied across all vehicle sizes. . . . A single stringent fuel economy standard would discourage the continued use of light trucks (with low fuel economy) as essentially substitutes for cars, and encourage greater use of lighter and smaller vehicles."85 [EPA-HQ-OAR-2010-0799-9480-A1, p. 13]

NHTSA should consider the advantages and disadvantages of all fuel economy-related attributes, and choose the attribute-based approach that will allow it to maximize net benefits of the rule; EPA should do the same with all possible approaches, including non-attribute, flat standards. One fuel economy-related attribute the agencies do not seem to have considered that may warrant analysis is vehicle fuel type. [EPA-HQ-OAR-2010-0799-9480-A1, p. 13]

Manufacturers could also decrease weight without decreasing footprint as a compliance strategy. The overall effects of such a choice on safety are not immediately clear, though at least some evidence suggests that redesigning truck-based SUVs into car-based crossover SUVs resulted in both lighter vehicles and decreased safety risks to drivers and others.91 [EPA-HQ-OAR-2010-0799-9480-A1, p. 14]

More importantly, the relationship between size and safety is neither simple nor unidirectional. To the extent smaller cars fare worse in crashes with bigger cars, increasing size may improve an individual driver's safety; but it may simultaneously impose a negative safety externality on other drivers, whose cars are now relatively smaller compared to the growing average fleet size. Decreasing size may have similarly opposing impacts on safety. Therefore, maintaining or increasing the average size of the entire fleet does not guarantee the safest outcome, and decreasing the fleet's average size in response to a fuel economy rule might have no overall change in safety levels (though at some point, reducing the size or changing attributes could affect the vehicle's intrinsic safety, as distinct from its relative safety). As Wenzel, a leading researcher on this subject, has explained, "a fuel economy standard that discourages vehicles with smaller footprint, or lower weight, will not necessarily reduce casualties. . . .Details of vehicle design, which can be improved through direct safety regulations, will have a greater effect on occupant safety than fuel economy standards that are structured to maintain vehicle size or weight."92 [This comment can also be found in section 13.1 of this comment summary.] [EPA-HQ-OAR-2010-0799-9480-A1, p. 14]

The third justification put forward is that a flat standard would inequitably affect some manufacturers more. However, to the extent that the fuel economy program can incorporate a trading scheme for compliance credits, the market would help smooth out any disproportionate impacts on certain manufacturers. Additionally, trading will ensure that manufacturers with relatively efficient fleets still have an incentive to continue improving fuel economy (in order to generate credits), which will further mitigate the agencies' first concern, mentioned above. [EPA-HQ-OAR-2010-0799-9480-A1, p. 14]

The fourth justification states that the agencies need to preserve the current vehicle mix in order to respect consumer choice. The agencies do not, however, adequately explain why maintaining the current vehicle mix is necessary to protect consumer welfare. The negative safety externality generated by larger vehicles indicates that the vehicle fleet may, on average, be too big; furthermore, some vehicle downsizing may represent a cost-effective method for compliance and have little impact on consumer welfare (as explained below). 94 Preserving the current vehicle mix is therefore not necessary to protect consumer welfare, and there is no reason to preserve the current mix as an end unto itself. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 14-15]

The fifth justification sees a footprint-based standard as a way to discourage "gaming" behavior, especially compared to a weight-based standard. A weight-based standard may be easier to game than a footprint-based standard, but that does not mean that manufacturers will not still game the proposed regulation in ways that reduce overall efficiency. In fact, it seems the footprint-based standard creates an incentive to expand vehicle size in order to relax the applicable standard. Given that automobile manufacturers already respond to very fine-tuned tax incentives for fuel economy,95 it certainly seems possible that the proposed rule will encourage some gaming of the average footprint. [EPA-HQ-OAR-2010-0799-9480-A1, p. 15]

NHTSA should remember that footprint and weight are not the only possible fuel economy-related attributes on which to base policy. For example, it might be much harder for manufacturers to game either a much flatter attribute-based standard or a standard differentiated by vehicle fuel type. EPA should assess whether a different approach, including a non-attribute, flat standard, might be the best at discouraging gaming. [EPA-HQ-OAR-2010-0799-9480-A1, p. 15]

In conclusion, a footprint-based standard may be unnecessary to respect consumer preferences, and may interfere with downsizing that could be, on the whole, consumer-welfare enhancing; it may have negative impacts on safety, given the negative safety externality that relative size can generate; and it may simply be inefficient compared to a more optimal, flatter standard. The agencies should seriously rethink whether the footprint-based approach is the best option. [EPA-HQ-OAR-2010-0799-9480-A1, p. 15]

If the agencies do go forward with a footprint-based approach, they should study its effects carefully and revisit the matter when more evidence is available. The first footprint-based fuel economy standards took effect with model year 2012.96The agencies therefore now have an opportunity to begin analyzing how the attribute-based standards influence manufacturers' production decisions. The agencies should consider whether the results of such a study challenge the footprint-based approach, at least during the planned mid-term evaluation, if not sooner. [EPA-HQ-OAR-2010-0799-9480-A1, p. 15]

The agencies should rethink their footprint-based standards, which may be unnecessary to respect consumer preferences, may negatively impact safety, and may be overall inefficient. Increasing the safety of one car can impose a negative safety externality on others, and consumer preferences can adjust as average fleet-wide attributes shift. As a result, trying to eliminate the incentive to build smaller cars may block a cost-effective compliance strategy and may not guarantee a safer fleet. [EPA-HQ-OAR-2010-0799-9480-A1, p. 20]

95 James Sallee & Joel Slemrod, *Car Notches: Strategic Automaker Responses to Fuel Economy Policy* (NBER Working PaperNo. 16604, 2010). Also see attached symposium paper on the energy paradox, at 11-12.

96 Proposed Rule, *supra* note 5, at 74,912.

Organization: Insurance Institute for Highway Safety (IIHS)

NHTSA has again proposed using vehicle footprint as the measure for varying CAFE requirements, and IIHS agrees that this will reduce the incentive for automakers to downweight or downsize vehicles to improve fuel economy. [NHTSA-2010-0131-0222-A1, p. 1]

Organization: International Council on Clean Transportation (ICCT)

17) Footprint Curves

We commend EPA and NHTSA for continuing to use a footprint-based adjustment to the CAFE standards instead of weight-based adjustments. Footprint-based adjustments fully encourage manufacturers to introduce lightweight materials, which can improve vehicle efficiency by 20% or more in the long run. Lightweight materials also extend the electric drive range of fuel cell and plug-in vehicles by a similar amount. This is one area of policymaking where the U.S. is ahead of the rest of the world. Japan, Europe, and China have all adopted standards with weight-based adjustments that effectively discourage the use of lightweight materials. [EPA-HQ-OAR-2010-0799-9512-A1, p. 48]

Organization: Mercedes-Benz USA, LLC

DAG also supports the overall structure of the attribute-based program and the provisions for transferring and trading credits. [This comment can also be found in section 10.1.2 of this comment summary.] [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

Organization: National Automobile Dealers Association (NADA)

All things being equal, NADA supports a final rule that provides vehicle manufacturers with the greatest degree of compliance flexibility. In most instances, compliance flexibilities are nothing more than accommodations designed to recognize, harness, and leverage consumer demand. Perhaps the best example of a well-designed compliance flexibility is the attribute based framework, which recognizes that the motoring public demands a range of light-duty vehicle types to meet their needs and desires. By preserving access to an essential mix of cars and trucks, the proposal leverages consumer demand to facilitate continuous improvements across all vehicle types, regardless of product mix. Moreover, when fuel economy standards are set properly, under the direction enacted by Congress, the incentive to downsize or down-weight is reduced, helping to preserve passenger safety. [EPA-HQ-OAR-2010-0799-9575-A1, p. 11]

Organization: Society of the Plastics Industry, Inc. (SPI)

SPI also supports the agencies' choice to incentivize the use of advanced lightweight materials and structures versus reductions in vehicle size by adopting a "footprint" approach to emission reductions. Composite throttle valve housing can be 30 percent lighter than its metal equivalent, and high precision engineering is producing replacements for metal parts. Body panels and bumpers made of plastic composites that perform comparably to those made of metal can be as much as 50 percent lighter, contributing to both greater fuel efficiency and safety by lowering the vehicle's center of gravity. And while approximately eight percent of the total vehicle weight of the average U.S. light vehicle is plastics and composites, a minimum of 30 percent (by weight; in one or more subsystems beyond interior trim) is achievable. [EPA-HQ-OAR-2010-0799-9492-A1, p.4]

Organization: United Automobile Workers (UAW)

First, the UAW is pleased that the EPA and NHTSA are proposing to continue the joint system that preserves in both regulations the attribute-based framework mandated by EISA. This structure eliminates the discriminatory impact of the old CAFE system on full-line producers and allows for greater fuel savings and greenhouse gas emissions reductions by requiring improvements from all manufacturers regardless of their product mix. [EPA-HQ-OAR-2010-0799-9563-A2, p.2]

Response:

Most of the comments received on this issue support the continued use of footprint from the MYs 2012-2016 rule as the most appropriate vehicle characteristic for a single-attribute standard (AAM, Consumer Reports, IIHS, ICCT, NADA, UAW, and others). Commenters requesting that EPA use a different approach generally suggested one of two alternatives: either use a weight-based standard to harmonize with the standards of other nations, or use a multi-attribute standard which accounts for vehicle characteristics that impact performance, such as engine power. IPI suggested that the agencies consider a flat standard. Detailed responses to these comments are provided in preamble II.C.

Regarding international harmonization, EPA agrees with BMW that the use of vehicle weight as the primary attribute would result in standards that, in that respect, are similar to those in Europe, China, and Japan. However, as in the MYs 2012-2016 rule, EPA continues to believe that the benefits of harmonization with the European standards do not outweigh the detriments. Setting a weight-based GHG standard removes much of the incentive for manufacturers to use weight saving materials as a technique to reduce fuel consumption and CO2 emissions. Manufactures are currently using various mass reduction techniques across the light-duty fleet, and are likely to continue to do so throughout the MYs 2017-2025 rulemaking timeframe. When combined with other technologies, EPA believes that manufacturers can achieve compliance with the standards by applying mass reduction at levels that do not affect overall societal safety, as discussed in chapter 3.3.5 of the Joint TSD and section II.G of the preamble. Significantly, the agencies believe that a footprint based standard is also more difficult to game and has inherent advantages in terms of providing appropriate compliance options for vehicles at all sizes and cargo carrying capabilities, as discussed in preamble II.C.2.

Regarding the use of a multi-attribute standard, EPA believes that it would be inappropriate to base the GHG standard on engine power as an explicit attribute, as requested by Ferrari and Porsche. Vehicles with higher engine power tend to have higher CO2 emissions due to their typically larger displacements, and the fact that the engines operate at lower average loads over the two-cycle test procedure. To base the GHG standard on engine power would encourage manufactures to forego technologies and design strategies that decrease fuel economy and CO2 emissions, and could encourage vehicles with inherently higher power and consequently innately higher CO2 emissions as a means of compliance.

EPA acknowledges that there is a demand for high performance vehicles and provided a number of compliance mechanisms for manufacturers of these vehicles in this regulation. No individual vehicle need meet its target, allowing larger manufacturers to account for high performance vehicles by averaging with vehicles with more typical levels of acceleration performance. Smaller manufacturer provisions such as the intermediate volume and SVM flexibilities provide allowances for smaller manufacturers which typically have limited product lines and fewer opportunities to average. Due to their performance and luxury features, these vehicles also tend to have higher prices and higher profits. Thus it is possible that these vehicles will be better able to absorb the cost of higher cost vehicle efficiency technologies than vehicles with lower profit margins. Limited line manufacturers may also choose to purchase credits as a compliance mechanism. See section III.B.6 and III.C for a greater discussion of these program provisions.

As a further response, the analysis supporting this rule considers the adoption of technologies which maintain all vehicle attributes and includes the costs to do so as a cost of the rule. See EPA RIA at 1-40. It is important to note that these standards have been appropriately designed to maintain consumer choice. See International Harvester v. EPA, 478 F. 2d 615, 640 (D.C. Cir. 1973) (EPA required to consider issues of basic demand for passenger vehicles in making technical feasibility and lead time determinations in section 202 rules). The footprint based standards have been designed to discourage changes in vehicle size as a compliance strategy, and the agencies' technology penetration analysis for these standards included costs to preserve the utility of vehicles in the current fleet.

IPI presented a number of comments on the form of the standard, and suggested that the agencies consider flat standards, or alternatively, a standard whose form maximizes net benefits. These issues are discussed in preamble II.C.2. In short, with regard to a flat standard, NHTSA is required by statute to issue an attribute based standard, and for purposes of harmonization (in addition to those reasons are articulated in TSD 2.1 and 2.2), EPA has also issued an attribute based standard. While IPI's suggestion that the agencies select the attribute-based approach that maximizes net benefits may have merit, net benefits are but one of many considerations which led to the setting of the standard. Estimations of net benefits in future analyses are subject to significant uncertainties, which is among the reasons EPA uses technical analysis and reasonable judgement to inform its regulatory policies.

IPI also commented that "given that reducing vehicle size, weight, and performance are relatively cheap and readily available compliance options, even the optimal footprint-based standard may suffer from inefficiencies by disincentivizing an otherwise cost-effective strategy." While downsizing and downpowering vehicles may be relatively inexpensive techniques (from a manufacturer's perspective) to reduce GHG emissions, changes to these attributes may have unintended consequences for consumer welfare. In addition, as many commenters (e.g. NADA) have legitimately pointed out, the rule's benefits only accrue if consumers purchase the new vehicles with GHG emission reducing technologies. Removing otherwise desired vehicle attributes could lead to less consumer acceptance. See Preamble section III.H.1.a noting that one reason for the so-called energy paradox (why consumers have in the past valued fuel economy less than its actual value) is that consumers might associate higher fuel economy with inexpensive, less well designed vehicles. As such, EPA has promulgated a standard and shown a compliance path that doesn't require changes to these attributes.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 66.]

The 54.5 MPG target for 2025 represents a significant advance from where we are as an industry today.

Organization: Alliance of Automobile Manufacturers

The agencies should assure equivalent program stringency. The proposed EPA and NHTSA requirements are coordinated, but not fully harmonized. The Alliance believes that adjustments to the NHTSA program are needed to ensure that it properly harmonizes with the EPA requirements under the differing statutory authorities provided to the agencies. [EPA-HQ-OAR-2010-0799-9487-A1, p.4]

Adjusting for Year-Over-Year Stringency [EPA-HQ-OAR-2010-0799-9487-A1, p.86]

The NPRM describes the methodology for adjusting standard curves for year-over-year stringency increases, noting that for the MY 2017-2025 rules, the curves are adjusted on a relative basis (applying the same percentage reductions in a given year across the entire footprint range). This method is in contrast to the methodology used in the MY 2012-2016 rules, where curves were adjusted on an absolute basis (applying the same absolute gram per mile and fuel consumption reductions in a given year across the entire footprint range). The agencies request comment on their conclusions and invite further recommendations for other means to adjust the standard curves for year over year stringency increases. [EPA-HQ-OAR-2010-0799-9487-A1, p.86]

Given that many of our member companies support the standards as proposed, the Alliance declines to make comments on specific changes. However, we believe that the agencies should examine their approach to adjusting the curves for year-over-year stringency as part of the mid-term evaluation to determine if actual improvements made in the 2012-2016 model year period suggest a declining correlation between the footprint attribute and vehicle emissions/fuel consumption (supporting adjustments on a relative basis) or whether the correlation remains roughly the same as observed in the 2008 model year fleet (supporting adjustments on an absolute basis). [EPA-HQ-OAR-2010-0799-9487-A1, p.86]

Organization: American Chemistry Council (ACC)

We do not comment on the CAFE levels proposed except to reaffirm that the levels proposed by the agencies are technologically feasible and economically practicable as a matter of statue. [EPA-HQ-OAR-2010-0799-9517-A1, p. 2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 264.]

We support the specific fuel efficiency goals and time limits proposed in the standard.

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Overall Stringency of Standards

The agencies propose target curves for the standards obtained by adjusting the curves discussed in the previous section. We support the agencies' decision to shift the target curves vertically by application of fixed percentages rather than by simply translating them up or down, as was done previously (Joint TSD 2-51). The new approach is clearly more consistent with the objective of preserving the relationships among stringencies of the targets across footprints. [EPA-HQ-OAR-2010-0799-9528-A2, p.7]

We do, however, have concerns about the agencies' choice of curves among all the curves generated in this way. Section III.D.6 of the NPRM discusses the alternatives considered by EPA, a total of four in addition to the proposal and a reference case. Each of the four considers a standard for either cars or trucks that is 20 gpm more or less stringent that the proposed standards. All four alternatives, in addition to the proposed standards, are found to be achievable, except by a single, small-volume manufacturer (Ferrari). Based on this result, it is unclear why one of the more stringent alternatives, e.g. Alternative 2, or another more stringent standard, would not be superior to the proposed standard. EPA shows that Alternative 2 would cost about $500 more per vehicle, but does not make the case that Alternative 2 is not cost-effective. The crux of EPA's lengthy argument that it has chosen the best standard seems to be that more stringent alternatives such as Alternative 2 call for a substantially greater penetration of advanced technologies, particularly hybrids but also including EVs and PHEVs. These alternatives adhere to technology penetration rates that fall within the caps set by EPA to ensure feasibility, however. Within those parameters, it seems reasonable that an alternative demanding higher penetration rates for advances technologies is preferable, especially given that promoting the development of advanced technologies is among the objectives of the rule. [EPA-HQ-OAR-2010-0799-9528-A2, pp.7-8]

The argument for the superiority of the proposed standards is all the weaker in view of the fact that EPA did not take into account the various flexibilities that have been proposed, such as credits for plug-in vehicles and hybrid credits for large pickups. We also note that the projected percentage of hybrids purchased in 2025 (15 percent, NPRM p.75061) is at the low end of the penetration suggested in the NOI (3-14 percent in the 4 percent per year scenario, 25-65 percent in the 5 percent per year scenario), once again raising the question of whether the proposed standards are the maximum achievable. [EPA-HQ-OAR-2010-0799-9528-A2, p.8]

Recommendations Reconsider whether alternative standards such as Alternative 2 that deliver greater benefits than the proposed standards are achievable and cost-effective. Show compliance costs by manufacturer for all years in the NPRM. [EPA-HQ-OAR-2010-0799-9528-A2, p.8]

Organization: Anonymous public citizen 2

The most obvious and most simple is not to use more corn gasoline, but to double the efficiency of vehicles. Lead consumers to purchase smaller cars and trucks. To see what the auto makers have done just take a look at pickup trucks. They have discontinued smaller trucks and cars. Each year they are just a little bigger. [EPA-HQ-OAR-2010-0799-1359, p.1]

Instead of giving subsidies to grow alternative fuels, lets give incentives to have consumers smaller vehicles. [EPA-HQ-OAR-2010-0799-1359, p.1]

We also need to develop more efficient vehicles. But reducing the vehicle mass would result in less fuel being used. [EPA-HQ-OAR-2010-0799-1359, p.1]

Organization: Anonymous public citizen 3

Increase the goal from 54.5 mpg to 100 mpg. It's time to lead. [EPA-HQ-OAR-2010-0799-2001, p.1]

Organization: Anonymous public citizen 5

The Proposed Legislation is not founded on any sound scientific conclusions. The affects of basing legislation on technology that does not exist is irresponsible and irrational. Instead of punishing the consumer by forcing pseudoscience based laws onto the manufacturers, why don't you create incentives for innovation? [EPA-HQ-OAR-2010-0799-2010, p.1]

Organization: Association of Global Automakers, Inc. (Global Automakers)

The standards proposed by the agencies are extremely stringent and are based on a large number of assumptions about technology and the auto market over the next decade. By extending the standards for many years into the future, the agencies provide manufacturers with substantial lead-time, which is of great value in compliance planning. On the other hand, the long time frame means that standards in the later years will be based on relatively long-range projections and assumptions. [EPA-HQ-OAR-2010-0799-9466-A1, p. 1]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 65-66.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 50.]

Organization: Bassett, S.

Also a true 54.5 MPG is unrealistic. Have you people never heard of the laws of physics? It will take x amount of energy (regardless of fuel type) to move a weight (auto) a distance of x. [EPA-HQ-OAR-2010-0799-8123-A1, p. 1]

Organization: BMW of North America, LLC.

The framework for model years 2017-2025 sets very ambitious GHG and fuel economy standards which can only be achieved through the adoption of all proposed compliance flexibilities. [EPA-HQ-OAR-2010-0799-9579-A1, p. 1]

Compliance will also require significant automaker efforts to reduce vehicle emissions coupled with public policy measures for steering market demand towards more fuel efficient vehicles. This is particularly true for E-mobility where customer acceptance and future growth in demand will depend largely on vehicle affordability, measures to address range concerns, and infrastructure availability for public recharging. Significant market penetration of electric vehicles, especially in the latter years, is needed to ensure automakers' compliance with these proposed standards covering MYs 2017 through 2025. [EPA-HQ-OAR-2010-0799-9579-A1, p. 2]

As a premium manufacturer, BMW designs and builds vehicles with outstanding product characteristics in order to satisfy higher customer expectations compared to other manufacturers, yet with similar vehicle footprints. Consequently, our product and specific US premium vehicle market characteristics require increased levels of technology in order to meet future standards compared to other manufacturers. Many of the technologies mentioned in the draft joint Technical Support Document have already been implemented in BMW Group models. Therefore, the significant penetration of these advanced conventional technologies in our existing fleet will make it even more challenging for BMW to achieve compliance with these very stringent standards. [EPA-HQ-OAR-2010-0799-9579-A1, pp. 3-4]

Organization: California Air Resources Board (CARB)

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 10-12]

As you know, at the President's request, CARB participated in the development of the greenhouse gas standards that you are considering today. We shared our knowledge developing the nation's first greenhouse gas standards which were adopted back in 2004 and became effective in California and 10 other states with the 2009 models. We contributed to new studies that form some of the technical underpinnings of the EPA proposal and co-authored with the federal agencies the Technical Assessment Report that was issued in late 2010. We continue to work with the federal agencies to ensure that the proposed EPA greenhouse gas standards could be used as an alternative to California's standards and result in a unified set of regulations that would allow vehicle manufacturers to produce a single vehicle model that would meet state and federal greenhouse gases and federal fuel economy standards. We believe your proposal is consistent with these objectives.

Our proposed greenhouse gas standards are nearly identical to what you are proposing. Our analysis of the costs and benefits draws from the many hours of discussion we had with your staff on the best information and the latest analytical techniques to use in our respective regulatory documents.

For this to become a reality, EPA needs to finalize its standards largely as currently proposed.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 13-15.]

In addition to the greenhouse gas standards, CARB's Advanced Clean Car proposal includes new exhaust and evaporative emission standards for hydrocarbons, oxides and nitrogen and particulate matter starting with 2015 models. These standards will reduce the said emissions by roughly 75 percent by the 2025 models with similar reductions in particulate conditions.

These reductions will help our urban areas meet the more stringent health-based ambient air quality standards that are forthcoming. And the costs of achieving these standards is low and the technology is readily available. We have tailored the implementation schedule of these standards to be compatible with the gradual tightening of greenhouse gas standards, so that the greenhouse gas, smog-forming and soot-emission reductions can be addressed in an efficient manner by the development engineers of the car companies.

Our Advanced Clean Car package also includes a proposal to strengthen the ZEV mandate. Ten other states and the District of Columbia have adopted this program which collectively account for a little more than a quarter of all sales of passenger vehicles in the nation. By 2025 we are proposing that 15 percent of all passenger vehicles sold in California and its partner states be ZEVs, which include battery, hybrid and fuel cell vehicles.

We point this out because the extremely low or nonexistent greenhouse gas emissions of these zero-emission vehicles will count towards compliance with the national standards. As you know, the analysis of the proposed federal standards indicates a significant number of ZEVs will not be needed to achieve compliance with the federal rules. Thus, placement of ZEVs in California and its partner states to meet the California ZEV mandate provides the emission reduction credits that reduce the reductions that must be achieved from the remainder of a vehicle manufacturer's fleet. This, of course, is only a side benefit of strengthening the ZEV mandate whose main objective is to push technology onto a sustainable pathway that will take us to an 80 percent reduction in greenhouse gas emissions by 2050.

Organization: Capozzelli, J.

However. the proposed rules are not strong enough. They contain a dangerous loophole that lets SUVs improve gas-mileage standards later than passenger vehicles. This will spur production of even more SUVs, and the auto industry is attempting to weaken these already-inadequate standards. Increasing the fuel efficiency of our vehicles is essential in the battle against dangerous climate change. [NHTSA-2010-0131-0221-A1, p.1]

These standards leave the United States behind Europe. Japan and China in fuel efficiency. In the long run, higher standards will benefit both American consumers and manufacturers by pushing innovation instead of stagnation. [NHTSA-2010-0131-0221-A1, p.1]

These rules can and should be significantly strengthened. [NHTSA-2010-0131-0221-A1, p.1]

All but one of the alternative standards discussed in the rule's would allow greenhouse gas emissions from cars and light trucks to increase through 2025; but dangerous climate change cannot be avoided unless greenhouse gases actually, decrease. The rules should adopt the alternative that actually decreases carbon pollution ever year through 2025. [NHTSA-2010-0131-0221-A1, p.1]

Organization: Center for Biological Diversity

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 214-216.]

We also do believe, though, the rules are not good enough. They are certainly not good enough when you look at the scale of the problems we face; and they are also not good enough when you look at what is technologically feasible and what is going on around the world.

And so while we really appreciate the fact that the rule is willing to increase fuel efficiency, we don't believe they do so fast enough, and they leave the U.S. far behind fuel efficiency standards in the European Union, Japan and China.

So we fear that putting these standards, which are a step forward and we appreciate the effort in place for the next 13 years until 2025, would still leave the U.S. behind what's happening in the EU, China and Japan instead of putting it as a forefront.

Clearly, the transportation sector is the low hanging fruit here and I realize a lot can be done here, a lot is being done, and we appreciate that effort, but we hope that you will look at strengthening these rules because of the gravity of the crises we are facing when you issue the final rule.

The Center supports the Agencies' efforts to limit greenhouse gas pollution from new passenger vehicles and light trucks, and we appreciate efforts the Agencies have made to respond to our comments to earlier CAFE and vehicle greenhouse gas rulemakings. But as we point out below, the current NPRM contains a number of significant flaws. We request that the Agencies remedy them to bring the forthcoming final MY 2017-2025 vehicle and greenhouse gas rulemaking into compliance with the Energy Policy and Conservation Act ("EPCA"), as amended by the Energy Independence and Security Act of 2007 ("EISA"), and the Clean Air Act ("CAA"). [EPA-HQ-OAR-2010-0799-9479-A1, p. 2]

The importance of achieving maximum feasible fuel efficiency, along with maximum feasible greenhouse gas reductions, in the 14 years between now and the end of 2025 cannot be overstated. As the Agencies themselves observe, "DOE has stated that vehicle efficiency has the greatest short-to mid-term impact on oil consumption." 1 Further, "20% of total U.S. CO_2 emissions come from passenger cars and light trucks," a total that amounts to 4% of global emissions. But the CAFE rules issued by the Agencies over the years, and therefore their effect on reducing greenhouse gas emissions, has failed to make inroads on the problem: "Passenger cars and light trucks . . . account for more than half of U.S. transportation CO_2 emissions, and CO_2 emissions from these vehicles have increased by 17 percent since 1990." The alternative the Agencies prefer would continue to increase greenhouse gas emissions through 2025. The Agencies should, for the first time in their history, reverse this trend and promulgate a rulemaking that reduces rather than increases greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-9479-A1, p. 2]

The targets adopted by the Agencies as the "preferred alternative" do not achieve emissions reductions, and do not constitute the maximum feasible fuel efficiency level under EPCA/EISA, nor protect the public health and welfare with an adequate margin of safety under the CAA. The "preferred" alternative would arrive at what is described in the NPRM as the "equivalent" of 54.5 mpg in 2025. This number, when expressed without adequate explanation, is misleading. In fact, when not inflated by air conditioning credits that lower greenhouse gas emissions but do nothing to increase fuel efficiency, the number is 49.6 mpg – though even that number signifies only the "estimated average required fleet-wide fuel economy"; once carmakers' use of various "flexibilities" and credits are accounted for, the estimated average "achieved" mileage drops to just 46.7 mpg. The actual real-world fleet-wide fuel efficiency number is even lower, translating to no more than approximately just 40 mpg (and 223 grams per mile). Because fuel efficiency itself, regardless of how it is counted, never exceeds 49.6 mpg, it is simply incorrect to claim a fuel efficiency "equivalent to" 54.5 mpg, and we urge the Agencies to clarify the effects of the rulemaking without referring to the highly ambiguous concept of equivalency. Equivalency relates to calculations of greenhouse gas emissions but in no way to mileage standards, a distinction certain to escape the average reader. But whether stated as 46.7 mpg or 49.6 mpg, the target is insufficient. [EPA-HQ-OAR-2010-0799-9479-A1, pp. 2-3]

The failure to implement maximum feasible mileage standards through the next 14 years – a period exceeding the years between 2010 and 2020 that have been named the "critical decade" because of their unparalleled importance in the effort to avoid the most drastic effects of climate change – would not only be in violation of Congressional mandates, but would also constitute a regulatory failure of potentially irremediable proportions. Only Alternative 4 actually reduces greenhouse gas emissions. Adopting any other alternative will also continue to leave the U.S. far behind its competitors in the global automotive market. The preferred alternative is far from what is both technically and economically feasible to reduce the nation's dependence on foreign oil. [EPA-HQ-OAR-2010-0799-9479-A1, p. 3]

Below we point out the various deficiencies inherent in the rulemaking. Among the most egregious is the laundry list of near-exemptions, credits, and other give-aways that would be provided to the largest and least efficient vehicles covered by the rulemaking: the SUVs, pickup trucks and other "light trucks" that have constituted the most profitable vehicle class, and that have proliferated on America's highways while stymieing real progress on fuel efficiency for decades. Yet, this rulemaking would reintroduce the SUV loophole with a vengeance. We encourage the Agencies to address these deficiencies, abandon the preferred alternative and instead drive industry to use the next 14 years to overhaul, rather than merely tinker with, vehicle technology and achieve the results the statutes demand. [EPA-HQ-OAR-2010-0799-9479-A1, p. 3]

1. The Agencies must set fuel efficiency standards that achieve maximum fuel efficiency and energy conservation

The Agencies' discussion of the factors that must be considered in setting CAFE standards – and, more importantly, the manner in which the Agencies weigh them – must be corrected in a number of ways. While noting in passing that they cannot undermine energy conservation, the Agencies nonetheless list energy conservation merely as one among many factors to consider, failing to discern that it is the overriding purpose of the statutes. That energy conservation has been ignored or, at a minimum, arbitrarily relegated to secondary or tertiary importance, is evident from the following statement: [EPA-HQ-OAR-2010-0799-9479-A1, p. 4]

While the GHG emissions targets do become more stringent each year, the emissions targets have been selected to allow compliance by vehicles of all sizes and with current levels of vehicle attributes such as utility, size, safety, and performance. Accordingly, these proposed standards are projected to allow consumers to choose from the same mix of vehicles that are currently in the marketplace. [EPA-HQ-OAR-2010-0799-9479-A1, p. 4]

In other words, the Agencies have selected standards that value purported consumer choice and the continued production of every vehicle in its current form over the need to conserve energy: as soon as increased fuel efficiency begins to affect any attribute of any existing vehicle, stringency increases cease. That is clearly impermissible and contrary to Congressional purpose.17 Given this outcome, it is not surprising that, as has been widely reported, the NPRM is the result of an "agreement" between the Agencies and the regulated industries – something that, at a minimum, taints the objectivity of the rulemaking process but instead is touted as an accomplishment.18

Protecting “the same mix of vehicles currently on the market” or the “current levels of vehicle attributes” is decidedly not the Agencies’ task. [EPA-HQ-OAR-2010-0799-9479-A1, p. 4]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 215-216.]

Secondly, all but one of the alternative standards discussed in the rules would allow overall greenhouse gas emissions from cars and light trucks to increase in 2025. And given the climate crisis, we don't believe we can afford this, and so we would look at pushing for fuel efficiency standards in the range of 60 miles per gallon rather than 54, which is the current proposal, and real world looks more like something like 49.

G. The Agencies Should Adopt Alternative 4

As we pointed out in our comments to the DEIS, only Alternative 4 would actually reduce greenhouse gas emissions from the nation’s vehicle fleet; for all of the reasons stated, adopting this standard is a necessity if exceptional damage from climate change is to be avoided. [EPA-HQ-OAR-2010-0799-9479-A1, p. 23]

Cars achieving and even exceeding the fuel economy level of 69 mpg, reached by Alternative 4 by 2025, are already on the road today, such as the Toyota Prius and the Nissan Leaf.106 Accordingly, it is clear that 69 mpg by 2025 is technically feasible 14 years from now. Indeed, it is beyond question that a fleet-wide average of 62 mpg (representing approximately a 6% annual increase) can be achieved based mostly on existing, off-the-shelf technologies, such as downsized turbocharged engines, electric power-train design, regenerative breaking, six-and seven-speed transmissions, high strength, high-strength lightweight materials, and enhanced aerodynamic designs.107 As stated above, to arrive at a technology-forcing alternative, NHTSA must push beyond existing technologies and include those still in the research and development stage in its modeling assumptions, which can model uncertainties concerning adoption and fleet penetration the Agencies perceive. Doing so demonstrates that Alternative 4 will be technologically feasible in the time provided. [EPA-HQ-OAR-2010-0799-9479-A1, p. 23]

The Agencies in the past have justified decisions not to adopt higher stringency standards because of concerns about economic feasibility. But the economic benefits of the rulemaking here would exceed its costs by more than $300 billion, at a minimum. And, even leaving aside the huge benefits external to the immediate purchase transaction, it is clear that fuel savings alone will more than make up for realistically estimated vehicle cost increases. We note here that the Agencies present no analysis of maximized societal benefits, where the benefits most optimally compare to the anticipated costs. In other words, there is no rigorous analysis of economic feasibility that justifies rejecting Alternative 4 as the appropriate standard for this rulemaking. Energy conservation along with the prevention of extreme climate change damages, however, demands it. Because Alternative 4 is both technological and economic feasible and best promotes energy conservation, it must be adopted. [EPA-HQ-OAR-2010-0799-9479-A1, p. 23]

The Agencies' preferred alternative of 49.6 mpg clearly does not constitute the maximum feasible fuel economy level because other countries will surpass that number (and in case of the EU, far surpass it) five years earlier, by 2020: by then, the EU will have achieved 64.8 mpg, Japan 55.1 mpg, and China 50.1 mpg.108 The following graph demonstrates this point: [See figure on p. 24 of Docket number EPA-HQ-OAR-2010-0799-9479-A1] [EPA-HQ-OAR-2010-0799-9479-A1, p. 24]

Given the accelerating rapidity of technical improvements, reaching 69 mpg by 2025, five years after Europe reaches 64.8 mpg, is clearly feasible and is the alternative the Agencies should embrace. [EPA-HQ-OAR-2010-0799-9479-A1, p. 24]

---

106 The Prius, for example, achieves 71 mpg in CAFE testing. Organization: Chrysler Group LLC

The challenge of meeting the proposed 2025 MY standards must not be underestimated. We believe it's important to observe that reaching the projected overall average of 163 grams per mile of carbon dioxide will require manufacturers to make unprecedented reductions in light-duty vehicle greenhouse gas emissions and fuel consumption following the large improvements which will be necessary in the 2012-2016 model years. Market acceptance of the technologies required (and costs incurred) to meet these standards will be a critical factor in the success of the 2017-2025 MY National Program; customer choice and uptake will ultimately determine the success of this program. [EPA-HQ-OAR-2010-0799-9495-A1, p. 1]

The proposed 2017-2025 standards are very aggressive. Manufacturers are only beginning their compliance with the 2012-2016 National Program, which will drive a 24% improvement over the 2008 MY baseline to achieve the 2016 MY standard. The proposed standards for 2017-2025 model years continue this unprecedented rate of improvement, driving an additional 35% improvement over roughly two product cycles. These improvements will be made possible, in part, through flexibilities such the recognition of air conditioning and off-cycle improvements and incentive programs such as the "game-changing" pickup truck incentives and advanced technology vehicle multipliers for electric, plug-in hybrid electric and CNG vehicles. [EPA-HQ-OAR-2010-0799-9495-A1, p. 5]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 51-52.]

The challenge of meeting the proposed standards must not be underestimated. We believe it's important to observe that reaching the projected overall average of 163 grams per mile of carbon dioxide in model year 2025 will have to be achieved within 13 years or approximately two product cycles.

[This comment was also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 24.]

The proposed 2017-2025 National Program reaches thirteen years into the future. Setting standards this far into the future provides long-term fuel economy and greenhouse gas goals to automotive manufacturers and suppliers enabling strategic planning for the needed improvements. However, this lead-time comes at the cost of less certain estimates for technology development, cost, and customer acceptance and demand. [EPA-HQ-OAR-2010-0799-9495-A1, p. 5]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 58.]

We believe it is important to observe that reaching the projected overall average of 163 grams per mile carbon dioxide in model year 2025 will have to be achieved within 13 years or roughly two product cycles.

Organization: Consumer Federation of America (CFA)

The proposed rule recognizes the need to keep the standards in touch with reality in several important ways.

The standards are set at a moderately aggressive level that is clearly beneficial and achievable.

The cost estimates are consistent with the results of independent analyses of technology costs made over the past decade.

The proposed standards are consistent with the rate of improvement that the auto industry achieved in the first decade of the fuel economy standard setting program.

The new approach to setting standards is consumer-friendly and facilitates automaker compliance. The standards do not require dramatic shifts in power train technologies or reductions in weight and offer flexibility and incentives for new technologies, and include a mid-term review.

The setting of a coordinated national standard that lays out a steady rate of increase over a long time period gives consumers and the industry certainty and time to adapt to change. [EPA-HQ-OAR-2010-0799-9419-A1, p. 8]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 90-91.]

The standards accelerate the adoption of existing technologies at costs that are widely recognized. They provide incentives in flexibility for new technologies.

The setting of a long steady path over a long time period coordinated across all the agencies in this country gives consumers and the industry the time they need to adjust.

Fifth, the auto industry has a strong incentive to comply. The standard takes the risk out of investing in fuel efficiency. All the auto makers have to do -- you don't have to worry about some guy manufacturing cheap fuel inefficient cars. They all have to comply.

Organization: Consumer Reports

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 168.]

The proposed targets are aggressive, but they're also conservative enough to allow the manufacturers to increase the deployment of new technologies to meet these requirements.

Organization: Consumers Union

Because the proposed rule provides ample lead time—approximately two and a half design cycles by 2025—automakers will be able to incorporate more efficient technologies and materials into the vehicles at a measured pace, thus reducing compliance costs and putting everyone on the same playing field in the race to find the best, most efficient way to meet new fuel economy targets. The proposed targets are aggressive enough to encourage groundbreaking new technological advances, but conservative enough to be attained even with strong incremental improvements and increased deployment of existing technology. [EPA-HQ-OAR-2010-0799-9454-A2, p.2]

Organization: Ecology Center

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 188-189.]

Second, we do like the longer time frame contained in the proposed rules. By looking out further into the future the rules can ensure consistency of approach and allow manufacturers to better plan for the vehicles that they will need to develop.

Organization: Environmental Consultants of Michigan

Tailpipe greenhouse gas standards (the flip side of CAFÉ) cannot achieve the target reductions

Using the latest government greenhouse gas lifecycle model for the transportation sector, GREET 2011, one can conclude that achieving carbon neutrality through tailpipe emission standards is not within the realm of possibility. [NHTSA-2010-0131-0166-A1, p. 3]

According to the 2011 Department of Energy greenhouse gas model, replacing the entire on road fleet of light duty cars and trucks with gasoline powered vehicles that achieve over 125 miles per gallon is necessary to reduce segment GHGs by 80%. This is not a CAFÉ standard of 125 mpg but every car and truck on the road would have to achieve this level of on-road efficiency. These levels are more than double the proposal. [NHTSA-2010-0131-0166-A1, p. 3]

Battery electric vehicles are even less useful in reaching the goal of carbon neutrality. Replacing every car and truck on the road with electric vehicles would reduce GHG emissions by only 26% at a cost of $2.5 trillion plus the cost of additional fuel production. Advocates of the electric option opine that use of carbon free electricity will be prevalent in the future. The federal government recently invested a half trillion dollars in the solar power company Solyndra only to have the company go bankrupt. The dream of solar power is a long way off. Others point to wind power as the solution for electricity. Already environmentalists are lining up protesting wind farms because of the noise pollution and the fact that the turbine blades kill large numbers of migratory birds7. Nuclear power is not supported by environmentalists and hydropower can also present problems for endangered species. [NHTSA-2010-0131-0166-A1, pp. 3-4]

Replacing every car and truck on the road with a hydrogen fuel cell powered vehicle would reduce GHG emissions by only 41% at a cost of $2.5 trillion not counting the fuel infrastructure cost. Hydrogen is one of the most difficult fuels to transport because of the corrosive effect of hydrogen on most metals. [NHTSA-2010-0131-0166-A1, p. 4]

Agency Was Arbitrary and Capricious In Its Selection of Standards

The Agency suggests the proposed standards of 50 miles per gallon could be achieved at a cost of about $2000 per vehicle. Even a cursory look at the data from EPAs 2012 model year fuel economy mileage guide demonstrates this review was arbitrary and capricious. [NHTSA-2010-0131-0166-A1, p. 5]

Only seven of the 900 plus models listed in the 2012 model year fuel economy guide would meet the 2025 model year proposed standards; one hydrogen fuel cell vehicle, three battery electric vehicles and three hybrid electric vehicles. As demonstrated above, hydrogen and electric vehicles cannot achieve the necessary greenhouse gas emissions and cost substantially more than $2000 per vehicle. [NHTSA-2010-0131-0166-A1, p. 6]

The median MSRP price increase for a hybrid electric vehicle in the 2011 model year was over $7000. Using the EPAs own fuel economy benefit and annual fuel costs published in the fuel economy guide it would take over 273,000 miles of driving to pay off the initial price premium for the average hybrid10 not counting the battery11 replacement every 10 years. The breakeven mileage for the highest selling hybrid electric vehicle, the Toyota Prius, is over 226,000 miles not counting the battery replacements. The second highest selling hybrid electric vehicle, the Honda Civic, never reaches its breakeven mileage. Over half the hybrid electric vehicles in the market last year would never12 reach their breakeven point according to EPA annual fuel costs not factoring in the cost of replacement batteries. More than half (60%) of 2012 model year hybrid electric vehicles (Table 3) were more than 10 miles per gallon below their 2025 model year target and all the hybrid electric vehicles have 6 or more forward gears. The average shortfall for all hybrid electric vehicles was over 9 miles per gallon. [Table 3 can be found on p. 24 of Docket number NHTSA-2010-0131-0166-A1] [NHTSA-2010-0131-0166-A1, p. 6]

Hybrid electric vehicles have been in the market for fourteen years and still represent less than 2.5% of sales despite generous subsidies. There were 26 hybrid electric vehicles in the market in 2011 yet over half the sales were a single model. Hybrids are having a difficult time gaining acceptance in the marketplace likely due to the economic reality that they do not save consumers money. [NHTSA-2010-0131-0166-A1, p. 6]

The median price increase for a diesel engine in the 2012 model year is over $5000. Using the EPA fuel economy benefit and annual fuel costs it would take over 214,000 miles of driving to pay off the initial price premium. Eighty-five percent of 2012 model year diesel equipped vehicles (Table 4) were more than 10 miles per gallon below their 2025 model year target despite having six or more forward gears. The average shortfall was over 12 miles per gallon. Thus advanced technology diesel and hybrid technology as currently deployed in the market are insufficient to meet the projected standards and cost substantially more than the Agency estimates. [Table 4 can be found on p. 25 of Docket number NHTSA-2010-0131-0166-A1] [NHTSA-2010-0131-0166-A1, p. 6]

Ninety percent of the 50 most fuel efficient non-hybrid 2012 model year trucks (Table 7) were more than 10 miles per gallon short of their 2025 model year target. The average shortfall was over 23 miles per gallon. [Table 7 can be found on p. 27 of Docket number NHTSA-2010-0131-0166-A1] [NHTSA-2010-0131-0166-A1, p. 7]

Ninety-four percent of the 50 most fuel efficient non-hybrid 2012 model year passenger cars (Table 8) were more than 10 miles per gallon short of their 2025 model year target. The average shortfall was over 15 miles per gallon. [Table 8 can be found on p. 28 of Docket number NHTSA-2010-0131-0166-A1] [NHTSA-2010-0131-0166-A1, p. 7]

Collectively, the 2012 model year data clearly demonstrates that the proposed targets cannot be achieved at the costs assumed by the Agency or with conventional technology. [NHTSA-2010-0131-0166-A1, p. 7]

Applying the technology already present in the 2012 model year mileage guide to the Agencies projected penetration rates result in a sizable shortfall to the proposed standards. Even using the best available hybrid technology in the market today, a manufacturer would have to have a penetration rate of over 70% hybrid electric vehicle and 3% electric vehicles to achieve the proposed standards. This is substantially higher than the rates projected by the Agency. [See Table 2 on p. 8 of Docket number NHTSA-2010-0131-0166-A1] [NHTSA-2010-0131-0166-A1, pp. 7-8]

---

7 Wind power is the fastest developing source of energy in the United States and can be an important part of the solution to climate change. However, wind farms can kill birds through collisions with turbines and associated structures, and also harm them through the loss of habitat that birds need for survival. A 2008 Department of Energy report calls for the U.S. to generate 20% of its electricity from wind by 2030. By then, wind turbines are expected to be killing at least one million birds each year, and probably significantly more, depending on the final scale of wind build-out. Wind farms are also expected to impact almost 20,000 square miles of terrestrial habitat, and over 4,000 square miles of marine habitat by 2030, some critical to threatened species. (American Bird Conservancy)

10 Comparisons are to gasoline counterpart similar to consumers’ purchase decisions; the proposal counts fuel savings from the fleet average and does not use a comparable vehicle as the basis for fuel saving.

11 The Agency values the battery at about $4000; requiring over 150,000 miles of additional driving to pay back; Honda also lists the battery at about $4000

12 Defined as having a breakeven mileage in excess of 300,000 miles

Organization: Ferrari

We believe that it is right to propose now a CAFE regulation that covers the entire 9-year period MYs 2017-25, but it is necessary to make a mid-term review, to verify the consistency of the proposed standards, due to the many uncertainties that are implicit in the technical and economic assumptions that form the basis for the proposed standards. In case of any changes or mores\ stringent requirements, enough lead-time should be allowed. It is important for vehicle manufacturers to have clear and stable regulations, and enough lead-time before they are first adopted or modified. [EPA-HQ-OAR-2010-0799-9535-A2, p.14]

Organization: Ford Motor Company

The standards that have been proposed by EPA and NHTSA through the 2025 model year represent the most significant federal action ever taken by the US federal government to improve fuel economy and reduce greenhouse gas emissions – nearly doubling the standards that were in place for the 2010 model year. To meet these requirements throughout the 2017-2025 period, substantial capital investments will be necessary to meet consumer demand for more fuel-efficient vehicles, to incorporate new technologies that consumers want, and to compete against other automakers in the marketplace. Some examples of the major planned investments include converting three truck and SUV plants to build small cars, re-tooling our powertrain facilities to manufacture fuel-efficient EcoBoost engines, offering more advanced six-speed transmissions, leveraging our global platforms, increasing our hybrid offerings and production, and moving forward with an aggressive electrification strategy. [EPA-HQ-OAR-2010-0799-9463-A1, p. 8]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 33.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 86.]

The proposed rules extend through the 2025 model year, which is an unprecedented time frame in the context of fuel economy regulations. This presents a significant challenge for manufacturers. While the establishment of longer-term standards provides manufacturers with targets for future product planning and investment, the longer time frame leads to greater risk that the assumptions underlying the standards do not come to fruition. For example, if the lack of adequate infrastructure hinders the introduction of new fuel-saving technologies, or if fuel prices turn out to be substantially lower than anticipated, it might be necessary to change the standards in order to avoid damage to American auto jobs and the U.S. economy.

Organization: Growth Energy

The fuel economy and GHG standards proposed by the Agencies sent ambitious targets for the automobile industry. The standards and other requirements that the Joint NPRM propose, along with other safety and emissions programs, will determine how the U.S. automobile industry allocates its human and financial resources for the next decade. The new-vehicle market will determine whether the automobile industry's efforts to comply with the Agencies' GHG and fuel economy standards are successful. Greenhouse gas standards of the type being proposed by EPA are, for all practical purposes, fuel economy standards, and like fuel economy standards such standards affect nearly every attribute of vehicle design and performance, as well as vehicle retail and operating costs. One of the most ambitious aspects of the Joint NPRM is that it would set standards for the industry over a much longer time frame than any previous fuel economy standards established by NHTSA, including the model-year ("MY") 2012-2016 GHG standards recently promulgated by EPA. [EPA-HQ-OAR-2010-0799-9505-A1, p. 1]

Programs that try to force the market to purchase electric vehicles that the public does not want to buy require public subsidies, increases in the prices of conventional vehicles to subsidize the manufacturers' cost, or both. While California may have some discretion under the Clean Air Act to experiment with its own new-vehicle market, and while the Joint NPRM's approach may have the support of some stakeholders in addition to California, NHTSA and EPA have independent duties to determine whether the standards it adopts are economically practicable and take proper account of the state of technology, including the costs of technology. See 49 U.S.C. § 32902(f); 42 U.S.C. § 7521 (a)(2). If the reliance on electric vehicles is misplaced, because there is no statutory mandate for such vehicles in federal law nor any requirement that the Agencies rely on such vehicles in writing GHG or fuel economy standards, the proposed standards in the Joint NPRM need to be scaled back to conform to levels that are economically practicable and also technologically feasible after accounting for costs. [EPA-HQ-OAR-2010-0799-9505-A1, p. 2]

Organization: Haroldson, C.

The proposed standards are too strict [EPA-HQ-OAR-2010-0799-11137-A1, p. 1]

Organization: Honeywell International, Inc.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 257.]

The program should instead remain technology neutral and recognize all significant performance improvements.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 209-210.]

Manufacturers must have confidence in a regulatory approach to take the risks necessary to innovate and world's most pressing environment and energy security challenges. We believe that better regulatory approaches are performance-driven, technology neutral, and provide some flexibility, and they must reflect the best available data and signs incorporating the most up-to-date research and technical information.

Organization: Honeywell Transportation Systems

Honeywell strongly endorses a performance-based, technology-neutral approach to regulating emissions and fuel consumption. Honeywell believes that government policy should promote all technology in the same way. Even at the end of the MY 2025 timeframe, internal combustion engine vehicles will continue to dominate the new light duty fleet. Proven, cost-effective technologies that use the nation's current infrastructure and numerous breakthroughs in many internal combustion engine technologies will become available in the years ahead, substantially improving the environmental performance of the vehicle fleet. Yet those benefits could be lost or diminished if the government directs investment towards electric vehicles without simultaneously encouraging continued investment in advanced ICE technologies. [EPA-HQ-OAR-2010-0799-9474-A1, pp.1-2]

Although we recognize that the overall stringency of the regulations encourages investment and improvement throughout the fleet, it is also true that an OEM may gain significant compliance advantage from EVs and PHEVs -- a compliance advantage that would be further enhanced if the credit multipliers are finalized. Much of the technology utilized to obtain that advantage is limited to the battery technology so that the technological advancement does not necessarily transfer to other vehicles. [EPA-HQ-OAR-2010-0799-9474-A1, p.5]

Organization: Howard, P.

One thing I would like to see is that these standards only apply to newly manufactured vehicles and that there will be absolutely no provisions or punishments requiring people to get rid of their perfectly good and operating older vehicles. [EPA-HQ-OAR-2010-0799-10063-A1, p. 1]

Organization: Hrin, S.

It would be good for our national security if cars were required to get more miles to the gallon. I'm not talking about a few miles per gallon more, but much more. [EPA-HQ-OAR-2010-0799-1568, p.1]

I believe car makers should be required to get 100/gallon by 2025. Anything less would be a travesty. [EPA-HQ-OAR-2010-0799-1568, p.1]

Organization: Hyundai America Technical Center

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 22.]

In our discussions with the agencies on this rulemaking, we have consistently supported the standard in excess of 50 miles per gallon.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 24.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 23.]

Finally, Hyundai appreciates a substantial lead time for these regulations which will provide stability for long-term product planning.

Organization: International Council on Clean Transportation (ICCT)

The ICCT has two overall objectives for our comments. First, given the accelerating pace of technology development and cost reduction, the proposed standards are not pushing the limits of technology and it will not be difficult or expensive for manufacturers to meet them. Second, many cost effective technologies may not be adopted should the stringency be weakened due to unwarranted credits. Our comments are focused on ensuring that the final rule is as robust as possible, including data and information on technology and consumers and suggestions for improvements to the credits. [EPA-HQ-OAR-2010-0799-9512-A1, p. 2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 196.]

ICCT strongly supports the overall program stringency. However, we are concerned some cost-effective reductions may not be achieved due to certain elements found in the performance rule.

Organization: Jackson, F.W.

10. Equating a 54.5 mpgge average EPA proposal 'mix' to 54.5 mpgg vehicle performance, they are not interchangeable because the 'mix' vehicles need to consider each vehicles 'weight' while a 54.5 mpgge average implies no 'weighting'; e.g. to show the point, a 54.5 mpgge vehicle performance calcs to 1.835 gge to go 100 miles; whereas one 60 mpgge Volt and one 49 mpg HEV also average 54.5 mpgge but the 49 mpg uses 2.04 gg per 100 miles and the 60 mpgge uses 1.67 gge per 100 miles for 2 vehicles using 3.71 gge for 200 miles or an average of 53.9 gge, i.e., not 54.5. Clearly not equivalent. and the farther the vehicles are from the average the more impact, e.g., use one Leaf at 97 mpgge and one 12 mpg 'guzzler' and average is still 54.5 but 'guzzler' alone for 100 miles is by itself 8.33 gge! Then add the 1.03 gge for the Leaf for a 200 mile total of 9.36 gge, or per 100 miles 4.68 gge (21.4 mpgge), or 155% more gge than a 54.5 vehicle. While EPA ref 2 shows 6 vehicle mix scenarios, plug in penetrations minor in all 6, however the option for manufacturers to sell plug-ins to obtain credits and/or multipliers to allow more profitable 'guzzlers' is available and where profitable I expect the profit motive will prevail; yet in EPA's Ref. 2 scenarios I did not find a 2025 model year scenario with high plug-in penetration! [EPA-HQ-OAR-2010-0799-8041-A1, pp. 5-6]

---

2. EPA Draft Regulatory Impact Analysis 'Proposed Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards' EPA-420-D-11-004 November 2011

Organization: Manufacturers of Emission Controls Association (MECA)

The Manufacturers of Emission Controls Association (MECA) is pleased to provide comments in support of the U.S. EPA's proposed rulemaking to establish 2017 and later model year light-duty vehicle greenhouse gas emission standards and corporate average fuel economy standards.

We believe an important opportunity exists to significantly reduce greenhouse gas emissions and improve fuel economy from passenger cars, light-duty trucks, and medium-duty passenger vehicles. [EPA-HQ-OAR-2010-0799-9452-A3, p.1]

Controlling greenhouse gas emissions from the transportation sector is essential to the overall efforts to alleviate long-term impacts on the climate. As detailed in EPA's proposal, there are a large set of technology combinations that are available to reduce greenhouse gas emissions from passenger vehicles and light-duty trucks, including fuel efficient, state-of-the-art and future advanced gasoline and diesel powertrains. [EPA-HQ-OAR-2010-0799-9452-A3, pp.1-2]

In summary, there are significant opportunities to reduce greenhouse gas emissions from the transportation sector through the design of fuel efficient powertrains that include advanced exhaust emission controls for meeting even the most stringent criteria pollutant standards. MECA believes that advanced emission control systems have a critically important role in future policies that aim to reduce mobile source greenhouse gas emissions. These emission control technologies allow all high efficiency powertrains to compete in the marketplace by enabling these powertrains to meet current and future criteria pollutant standards. In nearly all cases, these fuel-efficient powertrain designs, combined with appropriate emission controls, can be optimized to either minimize fuel consumption impacts associated with the emission control technology, or, in some cases, improve overall fuel consumption of the vehicle. This optimization extends beyond carbon dioxide emissions to include other significant greenhouse gases such as methane, nitrous oxide, and black carbon. [EPA-HQ-OAR-2010-0799-9452-A3, p.6]

MECA commends EPA for taking important steps to reduce greenhouse gas emissions and improve fuel economy from light-duty vehicles. Our industry is prepared to do its part and deliver cost effective, advanced emission control technologies to the market. [EPA-HQ-OAR-2010-0799-9452-A3, p.6]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 180.]

MECA, like many commented already today, supports performance-based standards that are technology neutral.

Organization: Marlinghaus, E.

The stakes are too high. We must dramatically reduce our consumption of fossil fuels - imported or domestic - if we are to prevent catastrophic climate change. Although I support the proposed rule to increase fuel economy for new passenger vehicles to an average of 54.5 miles per gallon by 2025, personally I feel that the date for reaching this standard should be moved forward to at least 2020. [EPA-HQ-OAR-2010-0799-1581-A1, p. 1]

This spring, you set a goal of reducing oil imports by one-third this decade, and in November you proposed fuel efficiency standards that will effectively double current requirements. I commend your efforts, but urge you to set your goals even higher. I believe it is important to increase U.S. investment in fuel efficient technologies, save consumers money at the pump, help this country break its dependence on oil & all fossil/carbon based fuels, and most importantly, protect the environment. Do NOT let these standards be watered down--protect and finalize the new fuel efficiency rules. [EPA-HQ-OAR-2010-0799-1581-A1, p. 1]

Organization: Marshall, C.

Promulgating the standard might best be done by also implementing companion federal programs involving other agencies, e.g., a financing program allowing U.S. auto manufacturers to retool plants and re-train workers. [EPA-HQ-OAR-2010-0799-5917-A2, p. 1]

Organization: Mass Comment Campaign (10) (National Wildlife Federation Action Fund-1)

President Obama pledged to reduce our oil imports by one-third by 2025. Setting strong vehicle efficiency and emissions standards is the most effective, common-sense step we can take to reduce our dependence on oil. [EPA-HQ-OAR-2010-0799-1244-A1_MASS, p.1]

These standards would also deeply cut US global warming pollution, and help speed the adoption of technology domestically and globally to cut emissions even further. The deep cuts in oil use that result from setting the strongest standards are also critical to reducing the need to drill for oil in increasingly risky, environmentally destructive and higher emitting locations. [EPA-HQ-OAR-2010-0799-1244-A1_MASS, p.1]

From more advanced engines to stronger lightweight materials, automakers have the technology to reach standards of at least 60 miles per gallon by 2025 and achieve the President's goal. Strong standards would also spur American innovation to help our auto industry compete and thrive in a global marketplace, while helping households and businesses save money. [EPA-HQ-OAR-2010-0799-1244-A1_MASS, p.1]

The difference between the strongest and weakest standards you are considering would cost Americans $370 billion at the pump (with most of the money ending up outside of the U.S.), and add twice as much global warming pollution to the atmosphere. [EPA-HQ-OAR-2010-0799-1244-A1_MASS, p.1]

We need your leadership to set strong fuel economy standards that will break our dependence on oil, curb global warming pollution and provide consumers with more choices of fuel efficient our cars and trucks. [EPA-HQ-OAR-2010-0799-1244-A1_MASS, p.1]

Organization: Mass Comment Campaign (4,505) (Unknown Organization)

All but one of the alternative standards discussed in the rules would allow greenhouse gas emissions from cars and light trucks to increase through 2025; but dangerous climate change cannot be avoided unless greenhouse gases actually decrease. The rules should adopt the alternative that actually decreases carbon pollution every year through 2025. [EPA-HQ-OAR-2010-0799-9595-A1_MASS, p.1]

The rules do not push car makers to look for technological innovation; they allow manufacturers to simply rely on small improvements to technology that already exists. As a result even 13 years from now, in 2025, the U.S. fleet would still do no better than what some cars can already achieve today. By 2025 the United States should do better than the European Union, China and Japan, not continue to lag behind them. [EPA-HQ-OAR-2010-0799-9595-A1_MASS, p.1]

Organization: Mass Comment Campaign (61) (The Social Justice Group)

We, the undersigned, applaud the proposed 54.5 miles per gallon carbon and fuel efficiency standards for cars and light trucks. We urge you to maintain these strong standards and make them final in July of this year. [EPA-HQ-OAR-2010-0799-7406-A1_MASS, p.2]

Organization: Massachusetts Institute of Technology (MIT)

In our Report, we have shown that the proposed regulations are highly demanding on both technological and market deployment fronts. Strong coordinated policies in addition to stringent CAFE requirements will thus be required to incentivize aggressive development of greatly improved propulsion system and vehicle technologies as well as the rapid market penetration of that technology, along with increasing deployment of alternative vehicles and fuels, into actual use. [NHTSA-2010-0131-0229-A1,p.1]

We are submitting our Report titled “U.S. CAFE Standards: Potential for Meeting Light-duty Vehicle Fuel Economy Targets, 2016-2025” which we have prepared as our response to the joint NHTSA and EPA proposal for extending the U.S. National Program to further improve light-duty vehicle fuel economy and reduce greenhouse gas emissions, for model years 2017 through 2025. It is based on our research of the past year or so, using a forwardlooking stochastic fleet assessment model for analyzing the impact of uncertainly on projected future light-duty vehicle fuel use and greenhouse gas emissions (Bastani, P. Heywood, J.B., Hope, C., SAE paper 2012-01-0647, SAE 2012 World Congress, Detroit, MI), with appropriate assumptions for future average car and light-truck operating characteristics and sales volumes. [NHTSA-2010-0131-0229-A1, p.1] [[See Docket Number NHTSA-2010-0131-0229-A1, pp3-35 for the report.]]

We quantitatively analyze three different scenarios. First, we define an “operational space” within which we evaluate specific scenarios, using evolving upper and lower bounds on the assumed vehicle characteristics, sales volumes of each major technology, and anticipated travel demand. Within this context we show that:

1. With our “plausible yet ambitious” scenario, (see Bastani, P., Heywood, J.B., & Hope, C., Transportation Research Part A, vol. 46, pp. 517-548, 2012) the likelihood of exceeding the 2016 fleet average targets is moderate for passenger cars, but very low for the combined car plus light-truck new vehicle fleets. The prospects of meeting the 2025 targets with this scenario are extremely low. [NHTSA-2010-0131-0229-A1, p.1]

2. With a more optimistic scenario where, for example, vehicle performance remains unchanged (a significant departure from the history of the last two or so decades), the prospects for meeting the 2016 fleet targets with passenger cars rises to some 50% but for the combined cars and light

trucks sales are still only a few percent. The potential for the combined car and light truck sales meeting the 2025 targets on time is very low indeed. [NHTSA-2010-0131-0229-A1,p.1]

3. With the proposed EPA/DOT preferred alternative scenario, as spelled out in the proposed rule making, the prospects for meeting these targets are better: some 20% for the combined car and light truck fleet meeting the 2016 CAFE fleet-average targets, but still only about 15% for the 2025 targets. [NHTSA-2010-0131-0229-A1, p.1]

We hope that this probabilistic analysis with the logic behind its assumptions carefully explained (and referenced), with it's detailed results and findings, will prove useful to you in your deliberations of these proposed CAFE requirements. [NHTSA-2010-0131-0229-A1, p.2]

Organization: Mercedes-Benz USA, LLC

Despite this overall support, the continuing stringency increases in the proposal are extremely aggressive, especially for a company that traditionally sells in the luxury car market and with modest volumes over which to spread its compliance obligations. As more fully explained in the Attachment to this letter, DAG suggests the following additional flexibilities and provisions. These measures would assist companies in overcoming market barriers, bringing new and advanced vehicles to market and combining advancements in crash avoidance technology with the fuel consumption reduction and emissions benefits they produce: [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

The final regulation will impose a set of aggressive and challenging standards. As a technology leader, DAG will continue to employ in its fleet all available technological advancements and will gain real world CO_2 and fuel economy benefits through off-cycle technologies. DAG appreciates the opportunity to comment upon the proposal and looks forward to continuing to work with the agencies during finalization and implementation of the regulations. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-19]

• DAG supports establishing an alternative compliance pathway for companies to choose more stringent standards in the later model years to allow more lead time to diversify their U.S. product line-ups and to bring additional advance technology vehicles, such as fuel cell vehicles, to the U.S. market. [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

DAG supports a concept introduced in the proposal to provide an alternative compliance pathway to allow manufacturers additional lead time to reconstitute the light duty vehicle fleet. This suggestion was raised in the context of explaining that the agency would not extend the Temporary Leadtime Allowance Alternative Standard ('TLAAS'). The agency requested comments on whether the intermediate-volume, limited-line manufacturers should receive additional flexibility in the latter years of the proposal, and whether the phase-in should be spread over more years for lower volume manufacturers. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-1]

DAG understands the agency's decision not to extend the TLAAS beyond its original terms. However, DAG agrees that manufacturers be accorded an option to adopt an alternative compliance pathway. The alternative would reduce the grams per mile reduction requirements during earlier model years and then make up most, or all of those carbon reductions in later model years.[3] [EPA-HQ-OAR-2010-0799-9483-A1, p. A-1]

The alternative pathway would be available to all manufacturers. We anticipate, however, that most manufacturers, who are able to spread compliance costs across a broader fleet, would continue to choose the basic option since doing so would allow those manufacturers more consistency across model years. The alternative pathway would likely be utilized primarily by the small number of manufacturers with more concentrated product line-ups in order to diversify their U.S. market fleets and to bring more long-ranging advanced technology vehicles, such as fuel cell or dedicated CNG vehicles, to market. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-1-A-2]

DAG looks forward to discussing this option with the agencies and to developing an alternative compliance pathway that is likely to provide the necessary assistance while maintaining similar or equal overall levels of CO_2 reduction. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-2]

---

3 One possibility within the first four model years, MYs 2017-2020, would be to adjust the grams per mile reductions during the first two model years with corresponding increases in the latter two model years. Another possibility would be to spread the alternative pathway across the eight model years covered by the overall rulemaking.

Organization: Miller, P.

This rule should be moved to 2020 with an addition of a separate part which provides far more federal R&D for cars that don't use fossil fuels at all -- including hydrogen and advanced electric cars, funds for plug ins, etc. This would help global warming by reducing carbon emissions while it developed entire new industries that keep our energy dollars in the US = lasting industries. [EPA-HQ-OAR-2010-0799-1755-A1, p. 1]

Organization: National Association of Clean Air Agencies (NACAA)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 42.]

And go to finally, NACAA urges that EPA and NHTSA ensure that this final rule is promulgated by July 2012 as planned, and encourages EPA upon promulgation of this rule to begin assessing the efficacy of another phase of standards to apply to post 2025 model year vehicles.

Organization: National Automobile Dealers Association (NADA)

These comments do not devote much attention to technological feasibility, largely taking on faith the proposal's assumptions in that regard. Likewise, little attention is paid to the proposal's assumptions regarding program benefits, except to stress that if and to the extent vehicles covered by the program rule are not sold and used as predicted, those benefits will be reduced. [EPA-HQ-OAR-2010-0799-9575-A1, p. 3]

The proposal seeks to establish CAFE and GHG mandates which would take effect with MY 2017. No statutory mandate requires that standards be set so far in advance, for so long a period of time. In fact, the 35.5 mpg standard recently promulgated for MY 2016 will kick in some four years earlier than Congress contemplated in EISA. [EPA-HQ-OAR-2010-0799-9575-A1, p. 11]

Absent a specific statutory direction, NHTSA and EPA should be guided by three principal factors. First, a timetable should be designed to provide adequate lead-time for manufacturers to achieve technologically feasible standards. Statutory language on lead-time is found in both the Energy Policy and Conservation Act and the Clean Air Act. CAFE standards must be issued at least 18 months prior to the model year in question and for no more than 5 model years. In addition, new GHG standards may not take effect sooner than the model year commencing 4 years after they are promulgated. Technological feasibility directly relates to what manufacturers can do and when they can do it. The longer out into the future standards are set, the less likely NHTSA and EPA will have credible information to accurately predict technological feasibility. This is one of the key lessons taught by the heavy-duty truck emissions look-back discussed above and found in Exhibit B. Setting standards too far in advance dramatically increases the risk that those standards will prove to be technologically infeasible. [EPA-HQ-OAR-2010-0799-9575-A1, p. 11]

Proposed standards also must be economically practicable. Although NADA has considerable confidence that vehicle manufacturers will be able to research, design, manufacture, and incorporate technologies and designs aimed to meet the proposed standards, serious questions exist regarding whether they will be able to do so in a cost effective or economically practicable manner. As discussed at length above, regulatory benefits will not attain unless and until vehicles subject to the proposal are bought. And, to the extent they prove unaffordable, they will not be bought. There are simply too many variables involved with the reasonable modeling of economic practicability to warrant the setting of standards unnecessarily too far in advance. Fuel costs, materials costs, general economic conditions, and interest rates are but a few of these very hard to forecast, yet critical variables. In short, NHTSA and EPA have no justification for setting standards for longer than the statutory five year period. [EPA-HQ-OAR-2010-0799-9575-A1, pp. 11-12]

Prospective light-duty vehicle purchasers, and the dealers who sell to them, will be directly impacted by the vehicle production mandates under consideration. If no rule were to issue, in-use passenger car and light truck fuel economy and GHG performance would continue to improve, as older, less fuel-efficient vehicles are replaced by newer ones offering comparable performance with improved fuel economy. NHTSA and EPA must preserve this trend by avoiding mandates which, through product compromises or high costs, would impede fleet turnover. [EPA-HQ-OAR-2010-0799-9575-A1, p. 13]

The automobile industry has traveled a steep technology path over the last century, resulting in astounding improvements to light-duty cars and trucks. Today's vehicles are lighter and more powerful, yet safer and more fuel efficient than ever in history. Fuel economy/GHG standards should encourage manufacturers to continue along this technology path, but only if it allows them to deliver to new vehicle showrooms products that are acceptable by and affordable to consumers. Future light-duty vehicles must be affordable up-front, and must also offer a total value package that includes fuel economy, but with no safety or performance trade-offs. Unless and until new vehicles sell, regulatory benefits will be unrealized. [EPA-HQ-OAR-2010-0799-9575-A1, p. 13]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 69.]

Secondly, NADA wants the highest fuel economy that we can get as long as the mandates are feasible and affordable as customers do have choices.

Organization: National Wildlife Federation (NWF)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 32.]

A recent survey by Consumers Reports found that 93 percent of the public is in support of stricter fuel economy standards. The public understands how the fuel standards work. They work for wildlife, they work for American families and they work for the auto industry and autoworkers and for the overall economy.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

Annual Rates of Emissions Reductions

EPA's proposed rule would incorporate a carbon dioxide equivalent standard that requires annual average reduction rates of 5 percent for passenger cars and 3.5 percent for light trucks in model years (MY) 2017 to 2021 and 5 percent for all light-duty vehicles for MY 2022 to 2025. For reasons set forth herein and in our November 1, 2010 letter (attached), NESCAUM believes a 6 percent rate for passenger cars is technically feasible and economically practicable. We strongly encourage EPA to consider incorporating a more stringent rate of improvement in this rule.[EPA-HQ-OAR-2010-0799-9476-A1, p. 1]

EPA's technology analysis projects that battery electric vehicles (BEVs) and plug-in hybrid electric vehicles (PHEVs) will account for as little as 1 percent of sales in 2021 and 3 percent of sales in 2025. EPA and the NHSTA previously estimated that a 6 percent annual rate of improvement for the combined passenger car and truck fleet could be achieved with as little as 4 percent combined sales share of BEVs and PHEVs in 2025, provided that sales of conventional hybrids continue to increase. Given the proposed rule initially establishes a less stringent standard for light trucks (3.5 percent reduction rate from MY 2017 to 2021), achieving a 6 percent reduction rate for passenger cars alone would likely require even lower penetration rates than EPA's previous estimates. The majority of major auto manufacturers will be selling BEVs or PHEVs as part of their offering of passenger cars, beginning with MY 2013. Forecasts of significant reductions in the weight and cost of electric vehicle technologies further support our conclusion that the modest increase in sales of these advanced technology vehicles required to achieve a fleet-wide 6 percent annual rate of improvement for passenger cars is viable.4 [EPA-HQ-OAR-2010-0799-9476-A1, pp. 1-2]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 70-74.]

The proposed rule before us today incorporates carbon dioxide emissions reduction at average annual rates in model years 2017 through 2021 of five percent for passenger cars and three point five percent for light trucks.

For model years '22 through 2025 the rate is set at five percent for all light-duty vehicles.

NESCAUM states continue to affirm our previous position that a six-percent rate is technically feasible and economically practical and encourage EPA to strongly consider incorporating this more stringent rate of improvement into the rule.

NESCAUM states encourage EPA to consider the six-percent annual rate of improvement.

Organization: RVIA

EPA and NHTSA should closely examine whether they have appropriately considered future light vehicle towing trends in setting standards for light duty passenger cars, cross-over vehicles, minivans and other vehicles that will be used more in the future to tow RV trailers and similar towable products. [EPA-HQ-OAR-2010-0799-9550-A2, p.5]

Organization: Smith, Frank Houston

Please note that the current 40 UK gasoline vehicle configurations rated >60 mpg(Imperial) combined are generally similar in size to the Fiat 500 or for two. This suggests something more than "advanced" gasoline ICE technologies are necessary to accomplish fuel economies above 45~50 mpg(US) combined for machines currently considered mid and compact sized light passenger vehicles in the US. [NHTSA-2010-0131-0240-A1, p.2]

Here are the 20 US vehicles that have broken the 50 mpg highway barrier since 1984: http://www.fueleconomy.gov/feg/Power...g=50&maxmpg=70 [NHTSA-2010-0131-0240-A1, p.2]

51~53 mpg - Chevy Sprinter ER 1986~1987

51 mpg - Chevy Sprint Metro 1988

52 mpg - Chevy Sprint Metro 1989~1994

51 mpg - Civic CRX HF 1986~1987

50 mpg - Civic HB VX 1994~1995

58~61 mpg - Honda Insight 2001~2006

A total of 20 vehicles in the last 28 years, with nothing post 2006. [NHTSA-2010-0131-0240-A1, p.2]

And, here are the only 11 vehicles recognized by http://www.fueleconomy.gov/feg/powerSearch.jsp to have achieved ≥ 50 mpg(US) combined since 1984:

50 mpg(US) combined - Toyota Prius C 2012 & Prius 2010 through 2012

52~53 mpg(US) combined - Honda Insight 2000 through 2006 [NHTSA-2010-0131-0240-A1, p.3]

Organization: Society of the Plastics Industry, Inc. (SPI)

SPI supports the aim to preserve consumer choice in vehicles, and likewise seeks for manufacturers to have a fully captured and incentivized range of technological options to reduce emissions and increase fuel efficiency. [EPA-HQ-OAR-2010-0799-9492-A1, p.2]

Organization: Susan R.

Please increase the minimum MPG. If auto makers will routinely offer vehicles that offer a 50+ MPG, the gas savings alone would pay for an upgrade in vehicle. PLEASE - for our environment and just plain common sense, increase the minimums! [EPA-HQ-OAR-2010-0799-10792-A1, p. 1]

Organization: Tarazevich, Yegor

There should be one target for everyone (by 2025 it will be CAFE 54.5 MPG which is equal EPA 40 MPG). Every new car that does not meet the target should pay a penalty of $500 per every MPG under the standard. If one wants to buy a huge 20 MPG gas guzzler he will pay a $10,000 penalty for air pollution and oil dependency. This is the only way to eliminate all loopholes. [NHTSA-2010-0131-0199,p.1]

Organization: Toyota Motor North America

The 163 grams per mile (54.5 miles per gallon equivalent) proposed standard for 2025 model year is truly groundbreaking and will provide significant environmental and energy savings benefits. While Toyota feels confident that our leadership in advanced technology vehicles provides a strong foundation, meeting the proposed standards poses a formidable challenge for our engineers and product planners. [EPA-HQ-OAR-2010-0799-9586-A1, p.2]

The overall level of the proposed standards in 2025 model year is consistent with the agreement signed by Toyota last July and the joint Supplemental Notice of Intent (NOI) published last August. These standards will pose a substantial challenge our engineers and product planners, but Toyota is prepared to make every effort to comply. [EPA-HQ-OAR-2010-0799-9586-A1, p.5]

Further, subject to specific comments provided later in this document, Toyota generally supports the added flexibilities proposed by EPA in the form of the following provisions: (1) sales multipliers for advanced technology vehicles; (2) unlimited transfer of credits between fleets; (3) A/C system leakage credits; and (4) one-time carry forward of 20102016 model year GHG credits through the 2021 model year. Unfortunately, NHTSA does not believe it can propose or adopt these same flexibility provisions for the CAFE regulations. To account for these differences, NHTSA has proposed to set the CAFE target curves at different (lower) 'MPGe' levels than EPA's GHG target curves for a given model year. However, Toyota's understanding is that NHTSA's target curves have only been adjusted to account for the lack of sales multiplier and A/C system leakage credits in the proposed NHTSA regulations, while no adjustments have been made to account the lack of unlimited credit trading and one-time carry forward in the proposed NHTSA regulations. The result of this difference in flexibility is a difference in .stringency between the programs. Granted, the one-time carry forward is a temporary flexibility that has no impact beyond 2021 model year, so the long-term effect of this difference is less material. However, the difference in credit trading and transferring is a significant and long-term (fixed) difference that substantively affects stringency. [EPA-HQ-OAR-2010-0799-9586-A1, pp.5-6]

We request that the agencies further evaluate this potential stringency gap and take measures to address this gap, either through increased flexibility in the NHTSA program or by adjusting the NHTSA curves to account for the difference in stringency. [EPA-HQ-OAR-2010-0799-9586-A1, p.6]

Organization: Union of Concerned Scientists (UCS)

(a) Overall Stringency & Technical Feasibility

In the proposed rule, EPA presents standards yielding a projected fleetwide greenhouse gas average of 163 g/mi in model year 2025. NHTSA is proposing a harmonized CAFE standard yielding a projected fleet average of 40.9 mpg in MY2021 and 49.6 mpg in MY2025 – due to its statutory limitations requiring rulemakings no longer than five model years. While the proposed standards represent significant progress, the technology exists to establish even more stringent standards consistent with the agencies' statutory obligations. [EPA-HQ-OAR-2010-0799-9567-A2, p. 5]

The agencies' original TAR laid out four scenarios ranging from a 3-6% annual reduction in greenhouse gas emissions. As stated in our original comments to the NOI, the data continue to support a 6% annual reduction (143 g/mi in MY2025) as technically feasible and increasing the net societal benefits as demonstrated by our joint technical analysis with the Natural Resources Defense Council that has already been submitted to the docket. [EPA-HQ-OAR-2010-0799-9567-A2, p. 5]

Current market conditions reflect that more stringent standards are achievable. According to UCS analysis, 39 models sold today – including conventional, hybrid, and advanced technology – are already sold in a version that meets their MY2017 proposed targets. Of these models, nearly two dozen meet the target for MY2020.26 An analysis in the Draft Joint Regulatory Impact Analysis confirms these findings, and identifies another 33 nameplates sold today that nearly meet their MY2017 targets, missing them by five percent or less.27 These data, as well as the agencies' data on technology potential, indicate that higher stringencies should be set – particularly in the light-truck fleet, where the proposed annual rate of improvement is exceedingly weak for large footprint models. We provide further detail regarding our concerns on the light truck standards in Section II(b) below. [EPA-HQ-OAR-2010-0799-9567-A2, pp. 6-7]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 215.]

UCS urges the agencies to finalize strong vehicle standards with the attention paid to susceptible provisions in the proposal that if exploited by auto makers would reduce the programs anticipated benefits.

27 Draft Joint Regulatory Analysis, Table 3.12-1

Organization: United Automobile Workers (UAW)

The UAW believes strongly that the proposed regulations are sensible, achievable and needed. They are good for the auto industry and its workers, good for the broader economy, good for the environment and good for our national security. Adopting the proposed rules will give an additional boost to the ongoing revitalization of the auto industry, and for those reasons we recommend adoption of these proposals in the final rules. Thank you for considering the views of the UAW on these important issues. [EPA-HQ-OAR-2010-0799-9563-A2, p.8]

Organization: Van Coppenolle, J. and L.

The need for stringent vehicle performance standards is critical. Vehicles are a major cause of poor air quality and adverse climate conditions, and the larger the vehicle, the greater the effect. [EPA-HQ-OAR-2010-0799-1284-A1, p. 1]

1) The higher standards do not apply to all vehicles across the board, allowing automakers a potential loophole if they decide to reclassify cars as SUVs, pick up trucks, etc., which have lower proposed standards. [EPA-HQ-OAR-2010-0799-1284-A1, p. 1]

2) The new standards take effect only in 2017, though automakers are fully capable of implementing them far sooner than that. The effective date should be moved forward, to 2015 at the very latest. Please do not allow automakers to deceive you into believing they cannot meet an earlier deadline. [EPA-HQ-OAR-2010-0799-1284-A1, p. 1]

Please revise the standards so that the highest ones apply to all vehicles and they take effect within the next three years. [EPA-HQ-OAR-2010-0799-1284-A1, p. 1]

Organization: Volkswagen Group of America

Volkswagen provided a framework of what we believe to be an achievable and balanced regulatory program aimed at advancing environmental and energy objectives while maintaining market feasibility and customer acceptance. In general Volkswagen put forward a concept for a regulation with equitable CO_2 reductions amongst all segments and sizes of vehicles. We combined this with broad incentives targeted at advancing interest by consumers into more efficient, lower emitting vehicles. We further proposed incentives to promote use of bio-based fuels which would help drive low emitting technology into vehicles while also advancing the goals of the US Renewable Fuels Standards. [EPA-HQ-OAR-2010-0799-9569-A1, letter p. 2]

Volkswagen remains predominantly a passenger cars manufacturer. We believe that cars offering a balanced mix of premium features, advanced safety, and invigorating dynamics can deliver a first order reduction in CO_2 emissions versus other common choices made for daily consumer use. [EPA-HQ-OAR-2010-0799-9569-A1, letter p. 2]

The SNOI and subsequent NPRM outline an aggressive advancement of CO_2 emission targets. However Volkswagen disagrees with details of the framework, primarily the imbalanced distribution of burden and the inclusion of targeted, segment and technology specific incentives. As such, we were not in a position to endorse the proposal as did many of our industry counterparts. Instead, Volkswagen will offer within these comments a suite of proposals aimed at improving the overall balance of the proposal. [EPA-HQ-OAR-2010-0799-9569-A1, letter p. 2]

Volkswagen markets a broad range of fuel efficient passenger cars and light trucks in the US. We understand the importance of increasing fuel economy with standards that are:

- Aimed at reaching aggressive environmental targets

- Achievable with an assortment of conventional and advanced technology

- Flexible and feature a broad package of flexibility

- Most importantly, affordable for consumers [EPA-HQ-OAR-2010-0799-9569-A1, p. 3]

We are committed to continually offering fuel efficient vehicles, such as the new mid-size, clean diesel Passat TDI, available to the U.S. market.

- Built in our new LEED Platinum Certified factory in Chattanooga, TN

- Passat TDI achieves 43 mpg highway and can travel almost 800 miles on a single tank of fuel

- Volkswagen anticipates that over 30% of our customers will select the fuel-saving TDI Passat [EPA-HQ-OAR-2010-0799-9569-A1, p. 3]

In addition, Volkswagen continues to develop vehicles featuring a broad array of fuel saving technologies. It is our overall goal to offer a competitive suite of market viable technologies for our customers to choose from. We recognize that a full range of affordable technologies and vehicles will be needed to fit the diverse needs of our customers. [EPA-HQ-OAR-2010-0799-9569-A1, p. 3]

Volkswagen actively engaged with the agencies at a technical level to provide estimates of future emissions reduction and fuel economy technology. During this time, Volkswagen outlined a series of key principles to help define a balanced regulatory program for 2017+. However, following our review of the 2010 Supplemental Notice of Intent (SNOI) and subsequently the Notice of Proposed Rulemaking (NPRM), Volkswagen was concerned that the proposed regulation contained elements which would eventually produce an unbalanced, inequitable rule. [EPA-HQ-OAR-2010-0799-9569-A1, p. 3]

Organization: Volvo Car Corporation (VCC)

VCC believes that the current classification framework, the footprint attribute, and the footprint cut-points are reasonable and should be retained. Moreover, any changes to these fundamental elements of the program could have a major impact on the stringency of the standards themselves, and would require extensive reevaluation. [EPA-HQ-OAR-2010-0799-9551-A2, p. 12]

Response:

The majority of comments received on the topic of the stringency of the standards were supportive, with many commenters noting that the standards are challenging but achievable, and will result in significant reductions in GHG emissions and significant fuel savings. Comments on the topic were also received requesting modifications to the stringency of the proposed standards, either increasing or decreasing the year-to-year reduction in target emissions, and either increasing or decreasing the lead time provided for manufacturers to adopt new technologies. A detailed description of the selection of the curve shapes, stringency, and alternatives considered are provided in sections II.C, III.B.2, and III.D.6 of the preamble, and section 2.5.3 of the joint TSD. These sections contain detailed responses to most of the comments received on the topic of stringency and curve shape, while a summary of these responses, along with additional information, is provided below.

Response to comments that standards should be more or less stringent

EPA considered standards that were less stringent and more stringent than those adopted. The analysis of technology penetration rates and costs of these alternative standards is described in section III.D.6 of the preamble. EPA believes the final standards are preferable to the more stringent alternatives based on considerations of cost – both to manufacturers and consumers – and the potential for exceeding feasible penetration rates with sufficient lead-time for advanced technologies, especially given the unknown degree of consumer acceptance of both the increased costs and of the technologies themselves. EPA's analysis of more stringent alternatives as set out in section III.D.6 of the preamble, which encompass the alternatives suggested by commenters, supports these conclusions. At the same time, EPA believes the final standards are preferable to the less stringent alternatives EPA examined, given that the final standards provide significant reductions in GHG emissions and save consumers significant fuel – and thereby, money – that far exceed the costs. These benefits would be foregone with less stringent standards.

ACEEE stated that the alternative standards demanding higher penetration rates of advanced technologies are preferable because "[t]hese alternatives adhere to technology penetration rates that fall within the caps set by EPA to ensure feasibility." EPA agrees with the observation, but disagrees that this (by itself) is a justification for increasing the stringency of the standards. This is because EPA believes that ACEEE has misinterpreted the purpose of the technology caps, which are discussed in detail in chapter 3.4.2 of the joint TSD and section III.D.6 of the preamble. As a modeling tool, EPA imposes upper limits on the penetration rates allowed under our modeling. These maximum penetration rates are intended to account for the physical limits of technical capability in light of conditions such as supplier capacity, up-front investment capital requirements, manufacturability, and other factors. While they may reflect technical judgments about technology feasibility and availability, consumer acceptance, lead time, and other factors, these caps are not meant to imply that rates below that cap are *a priori* practical or reasonable. That so many manufacturers are pushing up against those limits for the alternative standard advocated by the commenter raises legitimate issues of not only lead time and cost, but consumer acceptance as well.

ACEEE further commented that EPA did not take into account the various proposed flexibilities, such as credits for plug-in vehicles and hybrid credits for large pickups. EPA has certainly considered carefully the role of incentives and flexibilities for advanced technologies versus adopting standards predicated on wide-scale use of those technologies. We explained in sections III.C.3 and III.D.6 of the preamble that there is a legitimate policy decision to be made regarding whether to potentially jeopardize much of the rule's benefits due to lack of consumer acceptance of trucks with advanced technologies (for example due to cost, or discomfort with power train electrification on hauling vehicles). EPA has reasonably chosen instead to adopt aggressive standards which nonetheless do not force such technologies' use as sharply but rather promote penetration of these technologies by means of incentives and flexibilities. We note the comments of the U.S. Coalition for Advanced Diesel Engines, among others, which documented the low rates of penetration of hybridization in large footprint trucks in the current fleet as evidence of a lack of consumer demand for these technologies. We note further that we have incorporated the credits for use of hybrid technologies on pickup trucks into the OMEGA modeling (see preamble section III.D.5). Our analysis shows that on a fleet-wide basis, the impact of these pickup truck flexibilities in 2025 is small, as shown in Table III.2 of the preamble. Therefore, EPA believes it is reasonable to rely on incentives, rather than rely exclusively on potentially overly-aggressive standards, to obtain market penetration of these potentially game-changing technologies.

Some commenters (CBD, J. Capozzelli, Mass Campaign) expressed concern that the standards will not result in an overall reduction in greenhouse gas emissions over the rulemaking timeframe. However, CBD's observation that "[t]he alternative the Agencies prefer would continue to increase greenhouse gas emissions through 2025" is incorrect. EPA believes that the commenters incorrectly read Table 5.4.1-2-B of the DEIS, which shows that even when future projected VMT growth is accounted for, net greenhouse gas emissions from light-duty vehicles are reduced under the preferred alternative through 2040. As shown in Table III-60 in the preamble, without these standards, overall emissions from light-duty vehicles in the U.S. would increase from 1,100 MMTCO2 eq. per year in 2010 to 1,600 in 2050. In the analysis conducted for this rule, total light-duty vehicle emissions in 2050 are calculated to be reduced by 569 MMTOCO2 eq. per year, as shown in Table III-61. This will result in total light-duty vehicle emissions of 1,031 MMTCO2 eq. per year in 2050 – a reduction from the 2010 level.

CBD, a mass comment campaign, and several individuals commented that these standards are not as stringent as certain other standards internationally, specifically those in the European Union, Japan, and China. EPA notes that the standards in this rule are not directly comparable to foreign fuel economy or emissions standards because 1) the standards are based on a footprint attribute whereas foreign standards are based on other attributes, 2) the measurement test cycles are different than foreign standards, and 3) the composition of each country's vehicle fleet reflects the unique consumer preferences and vehicle usage patterns of that country. Regarding the last point, as a result of differences in consumer preference and vehicle usage, the fleet make-up in other nations is quite different than that of the United States. These regions cited by the commenters have a large fraction of small vehicles (with lower average weight, and footprint size) when compared to vehicles in the U.S. Also the U.S. has a much greater fraction of light-duty trucks. When looked at from a technology-basis, with the exception of the existing large penetration of diesels and manual transmissions in the European fleet – there is no unique technology in the European and Japanese markets which leads to lower fleet-wide CO2 emissions. The commenters have not provided any detailed analysis of what technologies are available in these regions which EPA is not considering – and indeed, there are no such “magic” technologies. The vast majority of the differences between the current and future CO2 performance of the Japanese and European light-duty vehicle fleets are due to differences in the size and current composition of the vehicle fleets in those two regions – not because EPA has ignored technologies which are available for application to the U.S. market during the rulemaking time frame.

CBD commented that more stringent standards are possible, stating “it is clear that 69 mpg by 2025 is technically feasible 14 years from now. Indeed, it is beyond question that a fleet-wide average of 62 mpg (representing approximately a 6% annual increase) can be achieved based mostly on existing, off-the-shelf technologies …”. CBD went on to advocate that the agencies adopt the most stringent alternative from the DEIS, which would require a 7 percent annual increase for the car and truck fleets. UCS proposed more stringent standards of 6 percent for cars and trucks, while NESCAUM proposed higher stringency for the car standard only, stating that they believe “a 6 percent rate for passenger cars is technically feasible and economically practicable”. In support of its position, CBD cited as evidence two of the most efficient vehicles currently available (the Toyota Prius and the Nissan Leaf). EPA agrees that technologies are currently available that will enable significant reductions in fuel use and emissions under this rule. However, EPA does not agree, as the commenter suggests, that feasible improvements in smaller footprint cars are representative of gains that can be achieved in a cost-effective manner by all vehicles, noting that this rule promulgates standards for manufacturers’ fleets which consist of a wide range of vehicles and footprints.

In the analysis conducted for this rule, among the alternatives considered were Alternatives 2 and 4, both of which have higher stringencies than the standards being finalized by this rule. While EPA believes that the technology penetration required for these more stringent alternatives are, in the narrow sense, technically achievable, they were not selected. EPA explains in detail in sections III.D.6 and 7 of the preamble to the final rule that our analyses have shown that increasing the stringency beyond the promulgated levels would add significant cost with diminishing additional benefit, and for light trucks, potentially leading to overly aggressive penetration rates of certain advanced technologies, raising issues of lead time, costs, and consumer acceptance, as well as creating incentives to comply by reducing vehicle utility. As explained in section III.D.6.d of the preamble, the more stringent alternatives we considered would affect penetration rates of MHEVs, HEVs, EVs, and PHEVs, especially in MY2025. Alternative 4, which would require a similar increase in car stringency to the NESCAUM’s proposed 6 percent, would lead to penetration rates of 7 percent for PHEVs and EVs, and much higher penetration (up to 45 percent) for some individual manufacturers, as shown in Table III-54 of the preamble. The UCS and CBD proposals for 6 and 7 percent increases, respectively, for both cars and trucks would be more stringent than both Alternatives 2 and 4 considered by the EPA, with correspondingly higher penetration of PHEVs and EVs. These increases in technology penetration rates raise serious concerns about the ability and likelihood manufacturers can smoothly implement the increased technology penetration in a fleet that has so far seen limited usage of these technologies. While this is more pronounced for 2025, lead time issues would also exist for MY 2021 and earlier years. As such, EPA has not made changes to increase or decrease the overall stringency across the car and truck fleets from the levels of the proposal, as advocated by these commenters.

CBD also expressed concern that agencies have "selected standards that value purported consumer choice and the continued production of every vehicle in its current form over the need to conserve energy: as soon as increased fuel efficiency begins to affect any attribute of any existing vehicle, stringency increases cease." EPA disagrees with this comment. It is important to note that the standards do not apply to individual vehicles, so that manufacturers can produce, and consumers can purchase, vehicles with attributes that differ from those of existing vehicles. Furthermore, in evaluating the costs of the rule, the agencies have included costs to preserve vehicle utility (see EPA RIA 1-40) but have not "ceased … increases in stringency" in the face of those costs. Indeed, were the commenter correct, the standards for cars and trucks would not increase in stringency at all, much less in each model year. Furthermore, EPA acknowledges that multiple pathways exist for manufacturers to come into compliance. One way is through the reduction of some vehicle attribute. That attribute may be content, acceleration performance, hauling, towing, all wheel drive, NVH, ride height, etc. However, EPA has not captured these options in the analysis as we are showing compliance choosing pathways through the addition of technology that maintain these consumer desirable attribute(s). A more detailed response to CBD's comment is provided in the introductory portion of section III.D of the preamble.

Several commenters referred to an "SUV loophole" in expressing their concern that these standards will encourage the production of more trucks, thereby diminishing the benefits of the rule (CBD, J. Capozzelli, J. and L. Van Coppenolle). EPA disagrees with these comments. As discussed in section III.D.6 of the preamble and section 2.2.2 of this document, EPA believes the car and truck curves appropriately reflect the differences in cost between the car and truck fleets for adding efficiency technologies. Moreover, intentional "gaming", whereby a manufacturer modifies a design so that a car can be reclassified as a truck, comes at significant cost to the manufacture, with added production and component costs, and to the consumer in the form of reduced fuel savings and a higher purchase price. Therefore, EPA does not agree that manufacturers will shift production to trucks as a result of this rule.

EPA recognizes that a challenge faced by manufacturers of luxury vehicles will likely be higher compliance costs than other manufacturers. BMW commented that the "significant penetration of these advanced conventional technologies in our existing fleet will make it even more challenging for BMW to achieve compliance." However, compliance challenges should not be interpreted to mean that the standard is unreasonable or infeasible. Furthermore, EPA recognizes that each manufacturer's unique combination of vehicle types, sizes, and previously adopted technologies may result in variation among manufacturers in the technologies available for achieving compliance and their associated costs. EPA notes that some of this variation is the result of product decisions made by the manufacturers to offer consumers additional vehicle features and enhanced attributes, such as higher engine power. Some of the variation also reflects that these manufacturers for years paid fines (or civil penalties) in lieu of compliance with CAFE standards and now have further improvements to make to attain the same level of control as other manufacturers. See 75 FR at 25414. In the analysis conducted for this rule, and described in section III.D.6 and 8 of the preamble and chapter 3.4.1 of the RIA, we considered that manufacturers have already adopted, to varying degrees, some of the advanced technologies that will enable emissions reductions, and demonstrate that a feasible compliance path exists for all manufacturers.

ECM commented that "achieving carbon neutrality through tailpipe emission standards is not within the realm of possibility". EPA notes that the objective of this rule is not to achieve "carbon neutrality", but rather to reduce GHG emissions through technology-based standards, while considering issues of technical feasibility, cost, and available lead time, as discussed in section I.A.1.b of the preamble. See Coalition for Responsible Regulation v. EPA, No. 09-1322 (D.C. Cir. June 26, 2012) slip op. p. 43 (in setting section 202 (a) standards, EPA is not required to adopt standards that mitigate a specific quantum of the endangerment caused or contributed to by vehicular GHG emissions). Nevertheless, in the context of the standards in this rule, ECM's observations about some of the obstacles to the development of low-carbon technologies for electricity generation are still relevant. However, the availability of these electricity generation technologies will not have a major impact on a manufacturer's ability to comply with the standard. EPA's Integrated Planning Model (IPM) predicts that only a small fraction of the incremental electricity generation will come from renewable sources in 2030, as described in section III.C.2.c.vi. Furthermore, EPA's analysis shows that manufacturers will be able to achieve compliance with relatively modest penetrations of PHEV and EV technologies. At the same time, EPA recognizes that the accelerated development of low-carbon electricity sources will result in emissions reductions beyond what are projected by the analysis for this rule.

EPA does not agree with the comments that the proposed targets cannot be achieved primarily through improvements in gasoline ICE technologies (Frank Houston Smith) or that MY 2012 fuel economy and purchase price data show that "the proposed targets cannot be achieved at the costs assumed by the Agency or with conventional technology" (ECM). As described in section III.D.8 of the preamble, a significant number of MY 2012 vehicles achieve or surpass targets for MYs 2017-2022. The compliance pathways for each manufacturer set forth in section III.D.6 of the preamble likewise are predicated largely on improvements to internal combustion engines, indicating that 'conventional technology' compliance pathways are not only feasible, but expected. Additionally, further advancements in technology are likely that will enable more manufactures to adopt technologies that currently exist, but are not yet implemented in full production, for compliance in the latter years of the rulemaking. For this reason, EPA does not agree with ECM's conclusion that, as evidenced by the low number of MY2012 vehicles that comply with MY2025 standards, the standards are not achievable using conventional technologies. In the latter years of the rule making, vehicle designs will certainly be different from those of today, and manufacturers are expected to adopt additional technologies as a result of this rule – indeed that is the primary mechanism of a technology-based standard.

We also disagree with ECM's statement that compliance will require a "penetration rate of over 70% hybrid electric vehicle and 3% electric vehicles". According to our technology penetration analysis, HEVs, PHEVs, and EVs will comprise only 7 percent of the fleet in MY2025, while diesel engines will comprise less than 1 percent, as shown in Table III-52 of the preamble and Table 3-25 of EPA's RIA. Finally, we do not believe that most of major vehicle manufacturers would support the standards if basic feasibility was at issue. See, e.g. Comments of the Alliance quoted above ("Given that many of our member companies support the standards as proposed….").

ECM also argued that the agencies underestimated the costs of the rule, and provided their own calculations for payback periods for selected hybrid and diesel vehicles. As noted above, our technology penetration analysis concludes that compliance for these standards can be achieved primarily through the adoption of technologies applied to internal combustion engines, such as turbo downsizing. In cases where more advanced technologies are applied, we do not believe the MSRP values used by the commenter in these calculations accurately represent the actual costs that will be paid by consumers, now or in the future. For example, while the commenter assumes a cost of $7000 for hybrid technology, EPA reasonably has estimated a cost of $2,861 for a midsize car in MY2025 (in 2010 dollars, see Table III-23). This basis for this estimate is set out in detail in joint TSD section 3. 3.3.6. Furthermore, as discussed in section III.H.5 of the preamble, although payback analysis in this rule considers the average number of vehicle miles traveled per year, in reality, drivers who travel more than average will incur fuel-related savings more quickly, and therefore, the payback will come sooner. For these reasons, EPA does not agree with the commenter's assertion that a long payback period for efficiency technologies for some drivers will present an obstacle to their adoption.

Several private citizens commented that the standards are too stringent, while the environmental and regional planning organizations mentioned above and private citizens requested that the NPRM stringency be increased. As stated earlier, EPA believes that the final standards will result in significant reductions in GHG emissions and fuel savings at a reasonable cost, and are preferable to the more stringent alternative standards EPA considered (which bound the ranges of more stringent standards requested by commenters), taking into account costs, manufacturer lead time, product development cycles, and consumer acceptance. See Preamble sections III.D.6 and 7 for more details.

<u>Response to comments that lead time is too long or too short</u>

EPA's analysis of the technologies that will enable manufacturers to achieve the emissions reductions required by this rule includes technologies that are either currently commercially available, or (for a few technologies) projected to be commercially available during the rulemaking timeframe. EPA agrees with comments expressing support for the lead time and period covered by this rule (ACC, CFA, Ecology Center, Ferrari, Hyundai), and those commenters who noted that the rule provides a reasonable amount of time for manufacturers to plan for and implement technologies for reducing emissions (CFA, Consumers Union, Ecology Center).

A number of commenters noted that the long lead time and number model years covered by this rule will provide a level of certainty that will allow manufacturers to plan and adjust future product. While EPA agrees with these commenters, we also recognize the difficulty of forecasting consumer preferences into the future (Mitsubishi, Suzuki, Chrysler, NADA[1]), and the greater uncertainty in the assumptions used for future production planning and investment (Ford, Global Automakers) that arise from the longer lead time covered by the rules. The mid-term evaluation is planned as the chief mechanism to address uncertainties like those noted by the commenters, and at that time, EPA will evaluate the assumptions upon which the rules are based.

Mercedes-Benz proposed an alternative compliance pathway, which would reduce the emissions target levels in early years of the rule, and make up most or all of the reductions in later years. EPA agrees that flexibility is an integral part of the standard setting in order to help manufacturers phase-in technologies given their typical redesign schedules. In this rule, these flexibilities are provided, in part, through the Averaging, Banking, and Trading Provisions (ABT) described in detail in section III.B.4 of the preamble. These ABT provisions achieve the aim of the commenter, which is to provide additional lead time as necessary without reducing the GHG emissions reductions and fuel savings benefits of the rule. For example, ABT provides three year credit carry-back provisions which allow a manufacturer to run a deficit and cover that deficit with future credits (i.e., carry back credits to a previous year). This is conceptually very similar to the alternative pathway approach suggested by the commenter. Therefore EPA, believes that additional flexibilities are not justified.

Porsche, Jaguar Land Rover, and Suzuki raised concerns about feasibility and adequate lead time for intermediate volume, limited line manufacturers. As discussed in section III.B.6, EPA is providing intermediate volume manufacturers with additional lead time to meet the principal standards in response to these comments.

Response to other comments on stringency

RVIA suggested that the agencies "closely examine whether they have appropriately considered future light vehicle towing trends in setting standards…". EPA agrees with the commenter that towing is an important attribute for many consumers, and notes the technology penetration and cost analyses for this rule were all conducted with the underlying requirement that vehicle utility be maintained. EPA believes that there is no contradiction between the adoption of certain efficiency technologies to reduce GHG emissions, and the preservation of other vehicle attributes, such as towing capability. For example, turbo-downsizing can be adopted without reducing performance, as evidenced by the MY2012 Ford F150, for which the optional 3.5L EcoBoost® V6 has a higher maximum towing capacity than the 5.0L V8.

EPA appreciates the work done by the faculty and students of MIT, and their probabilistic analysis of the impact of uncertainty on projecting fuel use and GHG emissions. We recognize the importance of considering uncertainty, and for that reason conduct sensitivity analyses, which is described in chapters 3.11, 4.5, and 8.1 of the EPA RIA.

[1] NADA cited the 2007/2010 heavy-duty emissions rule as an example of how setting standards with a long-lead time can cause difficulty in estimating costs. A detailed response to this comment is provided in chapter 18.2 of this document.

EPA agrees with the suggestion of the Alliance of Automobile Manufacturers to "examine [the] approach to adjusting the curves for year-over-year stringency." As discussed in sections II.C.4 and III.D.7 of the preamble, we plan to review the estimation and selection of the target curves during the mid-term evaluation. We also plan on reviewing the fleet data as it becomes available: this includes footprint distribution, technology content, safety, changes in attributes (such as acceleration performance), credit balances etc. to determine what strategies manufacturers are employing to come into compliance with the standards.

Organization: American Council for an Energy-Efficient Economy (ACEEE)

We do have concerns regarding the structure of the proposed rule, especially its lenient treatment of large light trucks in the early years and the resulting increase in the slope of the light truck target curves. Below we provide comments and recommendations on these issues, among others. While we take issue with a few aspects of the analysis, on the whole the process and the analysis were thorough, transparent, and well documented. [EPA-HQ-OAR-2010-0799-9528-A2, p.1]

The concluding argument regarding the superiority of the proposed standard (NPRM p.75084) is not compelling, and Table III-53 begs the question of how the compliance cost differential between cars and trucks in 2017-2020 can be justified. This concern would presumably be amplified by further disaggregation, showing that in fact incremental costs for large trucks are negligible in those years. The proposal appears to favor (in the near term) manufacturers with disproportionate production of large trucks during those years. EPA should show compliance costs by manufacturer, not just for 2021 and 2025, but for all years. The small improvements required of large trucks in 2017-2020, followed by a larger improvement in 2021 is of particular concern given the agencies' plan to conduct a midterm evaluation. This situation raises the possibility that the more significant improvements proposed for large trucks in the period 2021-2025 will never be realized, because manufacturers may allow technology development for these vehicles to stagnate in the early years of the rule and use this to influence the outcome of the midterm evaluation. [EPA-HQ-OAR-2010-0799-9528-A2, p.8]Shape of the Light Truck Target Curves

An issue of particular concern in the proposal is the lenient treatment of large light trucks. In 2017-2020, emissions reductions required of the heaviest light trucks are small. This reflects the agencies' recognition of "manufacturers' technical concerns regarding their abilities to comply with a similarly shallow curve after MY2016 given the anticipated mix of light trucks in MYs 2017–2025." We have not, however, been able to find a clear technical explanation of the justification for these concerns, or of the approach taken, in the proposed rule or in related documents. [EPA-HQ-OAR-2010-0799-9528-A2, p.3]

The agencies refer to the possibility of compromising load-carrying and towing capability of full-size pickups (NPRM p.74915), but neither evidence nor quantification of such a problem is provided. Similarly, section 2.4.2.2 of the TSD discusses the decision to increase the slope of the light truck curve at length, yet the justification remains unclear. The agencies' methodologies for generating the curves and for simulating manufacturers' compliance strategies are quite capable of taking into account any such constraints to the extent that they actually exist. The agencies do explain that the aggregation of models in some cases results in treating non-towing vehicles as towing vehicles, and vice versa; but this appears to apply mostly to smaller vehicles, and certainly not to the large pickups that have prompted the agencies to increase the slopes of the target curves. [EPA-HQ-OAR-2010-0799-9528-A2, p.3]

The agencies also state: "Flatter standards (i.e., curves) increase the risk that both the weight and size of vehicles will be reduced, compromising highway safety" (NPRM p.74915). What the agencies have proposed, however, is to increase the slope of the truck curve, relative to what it would have been using the curve-fitting approach used for MY2012-2016. We do not believe, and presumably the agencies do not believe, that the curves in the rule now in place are dangerously flat. [EPA-HQ-OAR-2010-0799-9528-A2, p.3]

Technical basis for curve / rate of improvement

The approach to selecting the target curves in the current proposal deviates from the approach used for the 2012-2016 rule in several respects that substantially alter the relative stringencies of small truck and large truck standards. The most significant change is that the agencies have adjusted the technology-corrected data points for “density”, i.e., weight-to-footprint ratio. This results in a steeper slope for the light truck curve, because pickup trucks, and in particular the large pickups that dominate the high end of the footprint spectrum, have low densities due to their flat beds (TSD p.2-17). Adjusting the data to reflect this means that large pickup data points are pushed up vertically on a footprint vs. emissions/consumption curve to reflect the higher weight (and hence higher fuel consumption) that would be expected based on the footprints of those trucks. [EPA-HQ-OAR-2010-0799-9528-A2, p.3]

The rationale offered for this adjustment is as follows: “The agencies agree with manufacturers of full-size pick-up trucks that in order to maintain towing and hauling utility, the engines on pick-up trucks must be more powerful, than their low ‘density’ nature would statistically suggest based on the agencies’ current MY2008-based market forecast and the agencies’ current estimates of the effectiveness of different fuel-saving technologies” (TSD 2043). This suggests that the reference fleet, after all available gasoline technologies have been added, is incorrect and shows unrealistically low pickup truck fuel consumption, due to the overstatement of the benefits of certain technologies. If that is the case, the agencies should revisit the adjustments made to generate the reference fleet and remove technologies from pickups that are not suited to those trucks. This would be a far more satisfactory approach than the speculative and non-quantitative approach of adjusting for vehicle density. [EPA-HQ-OAR-2010-0799-9528-A2, pp.3-4]

Indeed, it is important to note that the fuel consumption trend that the density adjustment is meant to correct appears in the unadjusted fleet as well as the technology-adjusted fleet of light trucks (TSD Figures 2-1 and 2-2). That is, the flattening of fuel consumption at higher footprints is not a byproduct of unrealistic technology adjustments, but rather a reflection of actual fuel economy trends in today’s market. That being the case, adjusting fuel consumption of “low-density” trucks upwards before fitting the curve simply does not make sense. It is also puzzling that the agencies’ analysis shows that trucks’ HP-to-weight ratio increases only slightly with footprint (TSD p.2-17), yet “pick-up trucks must be more powerful, than their low ‘density’ nature would statistically suggest.” If pick-up trucks have high horsepower and low weight, their HP-to-weight ratios should be especially high. An explanation of this apparent contradiction would be helpful. [EPA-HQ-OAR-2010-0799-9528-A2, p.4]

The agencies explored a similar adjustment to the curve to reflect increasing HP-to-weight ratios, but did not adopt it. This adjustment is effectively the approach used to develop weight-based CO_2 targets in the EU and results in flatter curves (Mock 2011). In the EU, the adjustment was made to ensure that the standards do not provide an incentive to increase vehicle weight. In the U.S., the agencies’ decision not to apply this correction in the proposed rule yields steeper curves than the alternative choice, as does the decision to apply the correction for density. Both help to ensure that the proposed curves will provide an incentive to upsize vehicles. [EPA-HQ-OAR-2010-0799-9528-A2, p.4]

After adjusting the data based on density, the agencies fit lines to the adjusted data. This process differs from that used for MY2012-2016 rule, in that the data is sales-weighted and the fit uses an ordinary least squares (OLS) method instead of minimum absolute deviation (MAD). In that case, the agencies were “concerned that the steeper curves resulting from weighted least-squares analysis would increase the risk that energy savings and environmental benefits would be lower than projected, because the steeper curves would provide a greater incentive to increase sales of larger vehicles with lower fuel economy levels” (MY2012-2016 TSD p.2-13). That concern remains valid for the current rulemaking. While we agree with the agencies’ position that either method of fitting is technically sound, we note that in this NPRM, the agencies have consistently made choices that have the effect of increasing the slopes of the light truck curves, namely to adjust for density and not to adjust for HP-to-weight ratio, as well as to alter the curve-fitting method, as just mentioned. [EPA-HQ-OAR-2010-0799-9528-A2, p.4]

Large truck cutpoint

The problems created by increasing the slope of the truck curve are aggravated by the decision to move the right-hand cutpoint (i.e., the point at which the curve becomes flat) out to 74 square feet, up from 66 square feet in the MY2012-2016 rule. Not only will targets be less stringent for large trucks than they should be, but also the target emissions will continue to rise with truck footprint well beyond the point at which they flattened out in the MY2012-2016 rule. [EPA-HQ-OAR-2010-0799-9528-A2, p.4]

In the MY2012-16 rule, the agencies rejected the requests of auto manufacturers to raise the right-hand truck cutpoint from 66 square feet: [EPA-HQ-OAR-2010-0799-9528-A2, p.4]

The agencies also disagree with comments by the Alliance and several individual manufacturers that the cut-off point for light trucks should be shifted to 72 square feet (from the proposed 66 square feet) to ease compliance burdens facing manufacturers serving the large pickup market. Such a shift would increase the risk that energy and environmental benefits of the standards would be compromised by induced increases in the sales of large pickups, in situations where the increased compliance burden is feasible and appropriate. Also, the agencies‘ market forecast suggests that most of the light trucks models with footprints larger than 66 square feet have curb weights near or above 5,000 pounds. This suggests, in turn, that in terms of highway safety, there is little or no need to discourage downsizing of light trucks with footprints larger than 66 square feet. Based on these energy, environmental, technological feasibility, economic practicability, and safety considerations, the agencies conclude that the light truck curve should be cut off at 66 square feet, as proposed, rather than at 72 square feet. (2012-2016 Final Rule p.25363) [EPA-HQ-OAR-2010-0799-9528-A2, pp.4-5]

Yet this time, the discussion of policy considerations in developing the target curves includes the following: “If cutpoints are adopted, given the same industry-wide average required fuel economy, moving large-vehicle cutpoints to the right (i.e., down in terms of fuel economy, up in terms of CO_2 emissions) better accommodates the unique design requirements of larger vehicles—especially large pickups—and extends the size range over which downsizing is discouraged." (NPRM p.74915). While the agencies note that they had previously "underestimate[d] the impact of the different pickup truck model configurations above 66 square feet on manufacturers' fleet average fuel economy and CO_2 levels" (NPRM p.74919), this is unrelated to the sound reasons they had previously offered for keeping the cutpoint at 66 feet. In particular, they previously noted that there is no safety-related reason to discourage downsizing of these large trucks. Indeed, given that vehicle compatibility is a major determinant of the severity of two-vehicle crashes, reducing the size and weight differential across the vehicle fleet should be a priority to improve highway safety. Thus, for environmental, energy, and safety reasons, the final rule should restore the 66 square foot cutoff for MY 2017-2025. [EPA-HQ-OAR-2010-0799-9528-A2, p.5]

Potential consequences of lenient standards for large light trucks

The agencies seek comment on whether their adjustments to the slope of the target curves "may encourage changes other than encouraging the application of technology to improve fuel economy and reduce CO_2 emissions" (TSD 2-27). The weakness of the standards at the large footprint end of the light truck spectrum not only will result in a direct loss in GHG reductions relative to what would have been saved with a uniform five percent annual emissions reduction across all classes, but also runs the risk of pushing production towards that larger end. Such a shift raises safety concerns as well. This concern applies across all large light trucks, including SUVs, even though difficulty in reducing emissions at a higher rate was alleged for large pickups only. According to agency projections (NOI TAR Appendix), pickups will account for only one-quarter of large truck sales in MY 2025. [EPA-HQ-OAR-2010-0799-9528-A2, p.5]

A recent analysis appearing in the journal *Energy Policy* concludes that the curves defining fuel economy standards for MY2011-2016 already create an incentive for upsizing, and as a result it will likely increase vehicle emissions by 5-15 percent (Whitefoot and Skerlos 2011). This analysis found that, assuming "consumer preferences for vehicle size, fuel efficiency, and acceleration performance are all at their midpoints," the slope of light truck curve for MY 2014 would need to be reduced by ½ to avoid promoting vehicle upsizing. This result suggests that the proposed light truck curve for 2025, for example, will provide a strong incentive to upsize and will lead to major losses in benefits for the program. In order to avoid this outcome, the curves for 2025 and earlier years would need to be much flatter. Figure 1 shows the MY2014 light truck target curve and the flatter curve (dotted blue) that the Whitefoot and Skerlos analysis indicates would be necessary to avoid upsizing. The red curves represent the proposed MY2025 targets and a curve (dotted red) scaled down from the adjusted MY2014 curve, which could reasonably be taken to approximate the slope necessary to avoid upsizing in 2025. The difference in slopes between the two 2025 curves is very large. [EPA-HQ-OAR-2010-0799-9528-A2, p.5] [For Figure 1 please refer to EPA-HQ-OAR-2010-0799-9528-A2, p.6]

The integrity of the analytical basis for the standard depends upon a clear and consistent basis for the treatment of all vehicles. In the case of large light trucks, we find that i) the deviations from the analytical approach previously adopted are not justified with data provided in the NPRM, and ii) the resulting ad hoc adjustments to the curve-fitting process detract from the agencies' argument for their proposals. Thus, in addition to reducing the fuel and GHG savings that the rule will bring, the weakening of standards for large light trucks undermines the technical foundation for the rule going forward. The treatment of this issue in the NPRM and related documents unfortunately gives the impression that the analytical components of the development the target curves are subjective and can be used to justify a very wide range of outcomes. Introducing this degree of subjectivity to the technical analysis invites unnecessary challenges to the standard-setting process. [EPA-HQ-OAR-2010-0799-9528-A2, p.6]

Regardless of whether the agencies change the truck curve in the final rule, we believe that adjusting the analytical approach to yield curves satisfying certain policy considerations is inadvisable. It would be preferable to choose the most robust analytical approach, and then to make exceptions as needed for a limited period to accommodate those policy considerations, and to explain the targets in those terms. [EPA-HQ-OAR-2010-0799-9528-A2, p.6]

Inflating the slope of the truck is counterproductive from a policy perspective as well. The domestic auto industry owes its strength today in part to its having been induced by the federal government to improve fuel economy, which in turn has enabled it to better compete with the other manufacturers. These same domestic manufacturers, by demanding lenient treatment for a subset of their products, are repeating their earlier mistake and will suffer the consequences in the long run of slowing technological improvement of their large light trucks. [EPA-HQ-OAR-2010-0799-9528-A2, p.6]

We strongly support the agencies' plan to revisit the choice of curve-fitting options in the final rule (TSD p.2-44). [EPA-HQ-OAR-2010-0799-9528-A2, p.6]

Recommendations

- Do not apply the density adjustment to the reference fleet data before fitting the light truck curve. If necessary to ensure that towing and hauling capability is maintained, revisit the process of adding technologies to the reference fleet to ensure that only technologies consistent with the functional requirements of the vehicle are added.
- Starting in 2017, apply the same annual percentage reduction to light trucks as to cars. Restore the 66 square foot cutoff for MY 2017-2025 (Figure 2, dotted green).
- If no such changes are possible in the final rule, introduce a provision to ensure the standards do not promote upsizing as follows: once sales of light trucks of 66 square feet and above in a given year reach MY 2008 sales of pickups 66 square feet and above, the upper bound for the light truck targets should be fixed at the 66 square foot target (Figure 2, dotted purple). This would ensure that automakers do not increase sales volume at this end by producing lower cost, inefficient vehicles. [EPA-HQ-OAR-2010-0799-9528-A2, pp.6-7] [For Figure 2 please refer to EPA-HQ-OAR-2010-0799-9528-A2, p.7]

Organization: American Honda Motor Co., Inc.

Honda is concerned that the relative stringency between small footprint light trucks and large footprint light trucks diverge dramatically from one another, and the stringency increases fall disproportionately on the smaller foot-print light trucks. One example is comparing the Omega package 807 and with package 1804. [See table on p. 1 of Docket number [EPA-HQ-OAR-2010-0799-9489-A1] [EPA-HQ-OAR-2010-0799-9489-A1, p. 1]

These similar technology packages respectively are applied to a small footprint light truck and a large footprint light truck. While the 2021 costs of these two package sets are relatively similar, with the cost/1% CO_2 reduction and flat costs both slightly higher for the smaller light truck, the increased stringency of the standards for these two vehicles are significantly dissimilar. A small footprint light truck such as the Honda CR-V (footprint of 44 square feet) has a proposed increased stringency of 18%, while a large truck, like a Ford F150 (footprint of 72.8 square feet) has a proposed increased in stringency of less than 5%. [EPA-HQ-OAR-2010-0799-9489-A1, p. 1]

This pattern repeats elsewhere within the light truck category, all showing that the stringency increases are falling disproportionately on small light trucks like the Honda CR-V and its competitors. [EPA-HQ-OAR-2010-0799-9489-A1, p. 2]

As noted above in #1, above, the stringency for the larger footprint light trucks is very low, compared to the smaller footprint light trucks. The combination of the lower stringency and the “game changing” credits cannot be justified as a matter of science, in furtherance of social goals and objectives or as a matter of simple fairness and equity. Not only are large footprint pick up trucks required to do very little (no stringency increase for a number of years), they are overly rewarded if they do increase their performance: in other words, required to do nothing, and highly rewarded for doing something. [This comment can also be found in section 5.1 of this comment summary.] [EPA-HQ-OAR-2010-0799-9489-A1, p. 2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 119-120.]

EPA and NHTSA propose for the 2017 to 2025 periods to radically alter the light-duty truck curves from their '12 to '16 slopes. The agencies have proposed dramatically increased stringency for the smaller footprint truck and little or no stringent increases for the larger footprint trucks. Honda previously shared data with the agencies indicating that if any change were to be made to the curves, it was more appropriate to flatten out the curves or moderate the increase in stringency for the smaller footprint trucks and to increase the stringency for the larger trucks. In other words, Honda believes that smaller light trucks are being unfairly singled out for increases in their standards, especially compared to the larger vehicles. This obvious -- this is obviously because the smallest trucks will have an annual increase of around 4 percent while the largest truck will have an annual increase of less than 1 percent.

Subsequent to the publication of the NPRM, on December 7th, 2011, the University of Michigan issued a study by Whitefoot and Skerlos. Honda agrees with their conclusion. And I'm quoting: 'In the near term, the analysis suggests that the slope of the function determining fuel economy targets based on vehicle footprint should be flattened for both passenger cars and light trucks and even further for light trucks.

Additionally, the agencies' own data show this to be true. Simply looking at the EPA's and NHTSA's estimates for the compliance cost differences between passenger cars and trucks, both agencies estimate lower compliance costs for trucks than passenger cars, and this is primarily due to an imbalance in the light truck slope and a much more stringent burden being placed on the lower sales volumes of the smaller light trucks and little to no additional stringency being put on the larger light trucks.

EPA and NHTSA believe that full-sized pickup trucks have unique challenges in improving fuel economy and GHG emissions due to payload and towing requirements. Honda believes that vehicles other than full-size pickup trucks should receive similar consideration in preserving their utility. SUVs and minivans, for example, are often fully loaded by families resulting in expectations or coming from expectations of 7- or 8-passenger seating capabilities while maintaining payload and towing functionality. Similarly situated vehicles ought to be treated the same.

Organization: Anonymous Public Citizen 1

Close the loophole for SUVs. This rule will be only very mildly effective without that loophole being closed. [NHTSA-2010-0131-0231, p.1]

Organization: Association of Global Automakers, Inc. (Global Automakers)

A. Lower “cutpoint” of light truck standard curve

We note that the lower “cutpoint” of the truck standards curve is set at the same footprint point (41 square feet) as the passenger car standard. In our view, it would be more appropriate to set that cutpoint at the same sales point (i.e., representing approximately 10 percent of sales) as the passenger car curve. In this way, the same portion of the respective fleets would fall within the flat portions of the footprint curves. The same arguments advanced by the agencies in support of the selection of the lower cutpoint of the passenger car curve apply as well to trucks (small market segment, minimal incentive to downsize, possible disincentives for manufacturers to offer small vehicles if the curve continues to slope downward at the low end). See 76 Federal Register (FR) 74919. We believe that this change should be made for consistency of methodology and that it should have minimal impact on the standards for light trucks. Therefore, we recommend that EPA and NHTSA incorporate this change in the final rule. [EPA-HQ-OAR-2010-0799-9466-A1, p. 2]

Organization: Capozzelli, J.

The proposed rules allow light trucks to increase their fuel efficiency at a much slower rate than cars. For many years; this problem led automakers to build bigger vehicles so they could take advantage of these weaker standards, which caused efficiency standards in the United States to stagnate. We should not make the same mistake twice, and should strengthen the standards for light trucks on par with cars. We cannot afford to skew the rules in favor of gas-guzzling SUVs. [NHTSA-2010-0131-0221-A1, p.1]

Organization: Center for Biological Diversity

In setting maximum feasible fuel economy standards, Congress instructed NHTSA to prescribe separate standards for passenger and non-passenger vehicles based on one or more vehicle attributes related to fuel economy and to express each standard in the form of a mathematical function.40 In the NPRM, the Agencies set forth separate targets based on vehicle size, or footprint. Using a projected make-up of the nationwide fleet, NHTSA estimates the average fuel efficiency for passenger cars and light trucks in each model year (MY).41 [EPA-HQ-OAR-2010-0799-9479-A1, p. 8]

[See Table 1 on p. 8 of Docket number EPA-HQ-OAR-2010-0799-9479-A1] [See Table 2 on p. 9 of Docket number EPA-HQ-OAR-2010-0799-9479-A1]

The fleet-wide fuel economy standards actually achieved in any year, however, depend on each individual manufacturer's choice of vehicles and production volume. Once a manufacturer determines its models and production volume for a MY, fuel economy standards for that manufacturer are determined using the attribute-based formula of the fleet that has been built during the year; every manufacturer must meet only the fuel economy standard that correlates to its own fleet mix. Because manufacturers control the size and number of the vehicles they produce, their choices also control their fuel economy targets, and the aggregate choice of all manufacturers determine the actual fleet-wide fuel economy achieved in any one year. [EPA-HQ-OAR-2010-0799-9479-A1, p. 9]

The proposed standards substantially and improperly favor light trucks, particularly the largest and least fuel efficient trucks, and they provide an economically compelling incentive to upsize vehicle footprint. Because the NPRM, without a backstop, creates a system that incentivizes manufacturers to produce larger, less fuel efficient vehicles, the Agencies' mileage projections – especially over a time span of a decade and a half – are likely to be wrong. These errors must be corrected in the final rulemaking. [EPA-HQ-OAR-2010-0799-9479-A1, p. 9]

1. The proposed increases for light trucks are back-loaded rather than ratable, contravening Congressional intent [EPA-HQ-OAR-2010-0799-9479-A1, p. 9]

As the tables above demonstrate, the standards the Agencies propose to set for light trucks are dramatically less stringent than the standards for passenger cars. While passenger cars' efficiency increases by 4.3% annually, the increase for light trucks is only 2.9%. In addition, the light truck standards increase at a significantly slower rate than the passenger car rate.44 Together, the minimal increases for light trucks for the first four years of the covered period and the overall decreased stringency exacerbate the historical "advantage" enjoyed by SUVs and pickup trucks, delay gains in fuel efficiency for the overall fleet, and incentivize gamesmanship and an ever-increasing SUV loophole. [EPA-HQ-OAR-2010-0799-9479-A1, p. 10]

Title 49 U.S.C section 32902 requires NHTSA to prescribe "annual fuel economy standard increases that increase the applicable average fuel economy standard ratably." 45 "Ratably" is defined as "in a proportional, well-proportioned or proportionate manner."46 In other words, the statute requires not only that fuel efficiency increase every year, but also that it do so proportionally. The legislative history of the provision demonstrates that Congress intended fuel economy standards to "make rapid and consistent annual progress."47 In requiring "ratable" increases, Congress sought "relatively consistent proportional increases in fuel economy standards each year."48 [EPA-HQ-OAR-2010-0799-9479-A1, p. 10]

Flatly contravening Congressional intent, the Agencies have proposed inconsistent, slow, and disproportionally small average fuel economy increases for light duty trucks during the first years of the covered period. They propose a mere .6 mpg average increase per year from 2017 through 2020. As further discussed below, this disproportionality is exacerbated by the fact that the heaviest "light" trucks are required to increase their fuel efficiency by the least amount. The increase then jumps to 2.1 mpg in 2021, a near four-fold increase, and stays in a higher range for the remaining rulemaking period – not coincidentally, the period when of time the Agencies propose for a de novo rulemaking review, an event that presents another chance for industry to convince the Agencies that the higher standards during the latter period of the rulemaking must once again be watered down. 49 These proposed average increases are neither rapid and proportional when compared to the increases proposed for passenger cars or to the later rulemaking period [see Tables 1 and 2] nor consistent given the sudden jump in 2021. The total percentage increase for trucks also is not consistent or proportional with the increase for passenger cars. Rather, light cars and trucks will be left even further behind passenger vehicles. The Agencies' own interpretation of "ratable" contradicts their proposed treatment of light trucks. They interpret "ratable" to mean that "annual increases should not be disproportionately large or small in relation to each other." Yet the Agencies propose minimal annual increases for the first part of the rulemaking, followed by a three- to four-fold jump after 2021. Rather than being rapid, consistent or proportional, the proposed light truck increases are overwhelmingly backloaded into later years. [EPA-HQ-OAR-2010-0799-9479-A1, p. 10]

The effect of allowing minimal efficiency increases early and demanding larger increases later is only to delay efficiency gains that could be achieved much sooner, at a much lower price. As we have frequently stated (see our comments to the DEIS), because greenhouse gases remain in the atmosphere for centuries and their warming effect is delayed for decades, it is essential to decrease their emissions as soon as possible; the benefits of avoiding the emission of a ton of carbon today by far exceed the benefits of avoiding the release of the same ton of carbon several years from now. The Agencies recognize this to some extent as they increase the social cost of carbon over time (though insufficiently so). Conversely, remedial efforts get more expensive the longer action is delayed. Even setting aside the triggering of catastrophic events by crossing tipping points and assuming arguendo that the social cost of carbon grows by no more than the Agencies currently assume, it is undoubtedly vastly preferable to remove a given ton of carbon in year 1 rather than year 4, when it has wrought that much more damage. From the CAFE perspective, something similar can be said: the longer vehicles retain the same, rather than increased, fuel efficiency standards, the more fuel, a finite commodity that Congress mandates must be conserved, is wasted. Thus, the Agencies' failure to comply with the Congressional mandate to devise ratable fuel efficiency increases, and its decision to backload achievable gains instead, has the additional pernicious effect of increasing the rulemaking's cost. [EPA-HQ-OAR-2010-0799-9479-A1, p. 11]

The Agencies seek to justify the anemic annual rate of improvement for trucks by referencing the "unique challenges in improving the fuel economy . . . of full-size pick-up trucks, while preserving the utility of these trucks." Specifically, they explain that due to characteristics such as 4WD and towing and hauling capacity, "the vehicles in the current light truck fleet are generally less capable of achieving higher fuel economy levels as compared to vehicles in passenger car fleet." While this reasoning may address the fact that stringency for trucks is currently lower than that of cars, it does nothing to explain the lack of the required ratable annual increases – i.e., increases that are proportional, lead to rapid and consistent progress, and do not create incentives to upsize cars to light trucks and lighter trucks to heavier ones. [EPA-HQ-OAR-2010-0799-9479-A1, p. 11]

In any event, the explanation lacks merit. Studies show that trucks are indeed capable of maintaining towing and hauling capacity with higher fuel economy standards.53 The claim that the "unique challenges" faced by trucks justify a slower and disproportional increase in fuel economy standards, or any of the other regulatory leniencies the Agencies provide for them in the NPRM, fails in light of the fact that technologies exist that fully enable trucks to improve fuel efficiency while retaining utilities like hauling and towing. [EPA-HQ-OAR-2010-0799-9479-A1, p. 11]

The Agencies also cite cost concerns as a reason for setting lower stringencies for trucks than for cars. This justification does not withstand scrutiny. It ignores that U.S. manufactured light truck models have been the most profitable vehicle for manufacturers since 1990. 54 Moreover, in general, because small cars cost almost as much as large cars to design, build and distribute, small cars generate small gross margins, while light trucks earn manufacturers greater profit.55 Ironically, the rulemaking demands the least from the most profitable segment of the automotive industry. This result is arbitrary and capricious, and contrary to law. [EPA-HQ-OAR-2010-0799-9479-A1, p. 11]

The Agencies further reason that the different standards for passenger cars and trucks will preserve consumer choice and "should not affect consumers' opportunity to purchase the size of vehicle that meets their needs."56 As discussed above, although the Agencies can consider consumer demand, "it would clearly be impermissible for NHTSA to rely on consumer demand to such an extent that it ignored the overarching goal of fuel conservation."57 The Agencies here have elevated purported consumer choice for larger, heavier, less efficient vehicles over energy conservation and thus violated Congressional intent. Moreover, this choice, improper in itself, cannot justify overriding the Congressional mandate to set fuel efficiency standards that increase ratably every year. As discussed below, manufacturers created consumer demand to use larger, less efficient, and more profitable light trucks as passenger vehicles,58 and a wide range of consumer options exist in this category. Consumers who desire to purchase the most fuel efficient and least polluting vehicles, on the other hand, are left with far fewer options, and the U.S. is left in last place in passenger vehicle and light truck fuel economy. [EPA-HQ-OAR-2010-0799-9479-A1, p. 12]

We note here the Agencies' assertion that the NPRM "will not create significant incentives to produce vehicles of particular sizes, and thus there should be no significant effect on the relative availability of different vehicle sizes in the fleet due to the proposed standards, which will help maintain consumer choice during the rulemaking timeframe." This assertion is insupportable. Lower efficiency standards for trucks have caused their manufacture and sale to balloon for decades, and these differences would be exacerbated by the proposed rule, which goes so far as to demand almost no increases of the most inefficient and polluting vehicles in the fleet. The fact that incentives for upsizing would be created simply cannot be disputed. The Agencies come close to admitting this fact: "[A] steeper slope [in compliance curves] relaxes the stringency of targets for larger vehicles relative to those for smaller vehicles, thereby shifting relative compliance burdens among manufactures based on their respective product mix." Indeed. And a further shift to the least efficient vehicles in the fleet is inevitable. [EPA-HQ-OAR-2010-0799-9479-A1, p. 12]

Moreover, we strongly disagree with the Agencies' belief that their regulatory efforts should have no effect (and have no effect) on consumer choice or market forces that drive auto sales in general. It is EPCA and EISA's very purpose to change those forces toward the conservation of energy. And, in the context of their safety discussion, even the Agencies admit that, "[f]or full size (i.e. 3/4- and 1-ton) pickups, risk increases as mass increases." Thus, the more heavy vehicles are built, the more risk. Far from having no effect on consumer choice and market forces, the NPRM proposes regulations that will create the market forces that drive increased production of the least energy efficient vehicles on our highways. [EPA-HQ-OAR-2010-0799-9479-A1, pp. 12-13]

Creating different (and for some years, next to no) efficiency standards for the heaviest trucks also plays havoc with the footprint-based attribute system the Agencies have, until now, staunchly defended. Tellingly, the Agencies admit as much – they state that they had rejected allowing different standards for light pickup trucks based on different attributes, such as power, because doing so would introduce' multi-attribute standards' that the Agencies had "judged . . . to be more subject to gaming than a footprint-only standard." Influenced by industry comments, they abandoned that previously-held line in the sand because the "challenges faced by manufacturers of large pickups currently outweigh[] these prior concerns." As shown above, however, the "challenges" allegedly facing these most profitable and least energy efficient vehicles in the fleet are bogus. If abandoning the footprint-based attribute system to create this loophole was a price for the "agreement" between the regulators and the regulated in July 2011, it was too high a price to pay. [EPA-HQ-OAR-2010-0799-9479-A1, p. 13]

The minimal increases proposed by NHTSA become even more problematic when combined with carry-forward credits. Congress allows manufacturers to utilize credits earned after model year 2010 for five subsequent years.63 There is a 1.5 mpg credit cap for model year 2017, and a 2 mpg credit cap for model years 2018 and beyond.64 Given the small increases proposed here, the amount of credit that can be carried forward by manufacturers is now greater than the average estimated increase for light duty trucks for the first years of the covered period. Accordingly, manufacturers with credits available from efficiencies obtained from other automobiles can use these credits to avoid implementing *any* fuel saving technologies on certain trucks with larger footprints. [EPA-HQ-OAR-2010-0799-9479-A1, p. 13]

Congress intended that use of credits "not in any way reduce the oil savings achieved by the standards set for any year."65 Light duty trucks, and particularly the largest trucks within this sector, consume the highest amounts of fuel. Setting minimal increases that can be satisfied with available credits provides a disincentive for manufacturers to design more fuel efficient trucks and runs counter to statutory mandates. [EPA-HQ-OAR-2010-0799-9479-A1, p. 13]

The Agencies' decision to backload increases in fuel efficiency for trucks – as well as for passenger vehicles, though to a lesser extent – is arbitrary and capricious. That trucks historically have been exempted from proportional efficiency increases does not justify continuing the practice and so as to exacerbate the efficiency inequality between the two types of vehicles throughout the covered period, providing even more incentive for manufacturers to produce more "light trucks." Moreover, letting consumer choice trump fuel conservation violates the statute. A ratable footprint curve for light trucks that contains proportional annual increases and is proportional to the passenger car curve is necessary to comport with Congressional intent. [EPA-HQ-OAR-2010-0799-9479-A1, p. 14]

2. The NPRM creates an SUV loophole that is contrary to Congress' purpose in enacting EPCA – energy conservation

The National Academy of Sciences ("NAS") found that from 1970 to 1982, CAFE standards helped contribute to a 50 percent increase in fuel economy for new light trucks.68 This progress soon stalled, however. Light trucks became ever more popular in the ensuing decades because less stringent CAFE standards for light trucks provided incentives for manufacturers to invest in vehicles like SUVs and minivans and to promote them to consumers.69 NAS found that this market shift had a "pronounced" negative effect on overall fuel economy.70 [EPA-HQ-OAR-2010-0799-9479-A1, p. 14]

The NPRM would continue and exacerbate this market shift. Light trucks are disproportionately favored in the NPRM; starting off with lower fuel efficiency targets, their targets increase at a lower rate than passenger cars, and the heaviest and dirtiest light trucks are near-exempt during the first two years of the covered period, making them even more profitable. The Agencies repeatedly claim that the attribute-based standards discourage changes in vehicle size.71 Focused on safety concerns that have now been largely dispelled, the Agencies state that attribute-based standards are laudable because they prevent manufacturers from gaming the system by building too many light vehicles.72 That concern, however, has no basis in fact: historically it is the SUV segment, not the segment for small and efficient cars, which has shown the largest growth. The manufacture of too many fuel efficient cars sadly has never been the problem. Instead, the NPRM incentivizes the manufacture of too many gas guzzlers. [EPA-HQ-OAR-2010-0799-9479-A1, p. 15]

3. The NPRM must require ratable fuel efficiency increases for all light trucks

As shown in the tables above, the Agencies provide an estimate of the average fuel economy standards per year for all light trucks. In fact, however, the Agencies are proposing the smallest increases for the largest and dirtiest trucks for the first two years of the covered period. 73 [EPA-HQ-OAR-2010-0799-9479-A1, p. 15]

Not only does this proposal quite obviously remove any incentive to improve the gas mileage of these largest vehicles, it may also result in an additional statutory violation. Given the long lead-time between the final rule and 2017, manufacturers have substantial time to adjust to this scheme by manufacturing larger light trucks with less stringent fuel economy standards. Because the actual national fuel efficiency level is determined not by the standards themselves but by what manufacturers decide to build, it is possible that this predictable shift toward larger, less fuel efficient cars could prevent the nationwide fleet from reaching the statutory minimum of 35 mpg in 2020.74 The near-exemption for larger trucks must be dropped for this reason alone. [EPA-HQ-OAR-2010-0799-9479-A1, p. 15]

4. The NPRM should tighten the definition of light trucks to prevent incentives to reclassify

As has been recognized for some time, because there are separate curves for passenger cars and light trucks, manufacturers have incentives to reclassify passenger cars as light trucks to render them subject to less stringent fuel economy goals.

The EPCA defines passenger automobiles as follows: [EPA-HQ-OAR-2010-0799-9479-A1, p. 15]

[A]ny automobile that the Secretary decides by regulation is manufactured primarily for transporting not more than 10 individuals, but does not include an automobile capable of off-highway operation that the Secretary decides by regulation –

(A) has a significant feature (except 4-wheel drive) designed for offhighway operation; and

(B) is a 4-wheel drive automobile or is rated at more than 6,000 pounds gross vehicle weight.75 [EPA-HQ-OAR-2010-0799-9479-A1, p. 16]

Light trucks are defined by exclusion as automobiles that are not passenger automobiles or work trucks.76 NHTSA has further defined light trucks as automobiles with greater cargo-carrying than passenger-carrying volume, and as automobiles that permit expanded use of the automobile for cargo-carrying purposes through removal of seats or stowing of foldable seats.77 [EPA-HQ-OAR-2010-0799-9479-A1, p. 16]

This statutory definition can already incentivize upsizing as it allows manufacturers to add 4WD technology plus any other “off-highway” feature to a vehicle to automatically fall within the less stringent light truck classification. The Agencies themselves recognize that this incentive exists if the fuel economy standard for a truck with a given footprint is less stringent than that for passenger car with the same footprint.78 The issue is particularly significant where a vehicle is built with both a 4WD and a 2WD version. The 2WD drive version, if it does not otherwise qualify as a truck, is subject to the passenger car curve. The same version with 4WD and some other off-road feature such as higher ground clearance, however, becomes subject to the truck curve. These circumstances create different fuel economy standards for vehicles with the same footprint. Manufacturers thus have incentive to redesign 2WD vehicles by adding 4WD and some off-road feature. The even greater disparity in mileage standards between trucks and passenger cars created by the NPRM provides even larger incentives for this type of abuse of the statutory scheme. [EPA-HQ-OAR-2010-0799-9479-A1, p. 16]

The Agencies have addressed this concern by noting that “despite comments in prior rulemakings suggesting that any vehicle that appears to be manufactured ‘primarily’ for transporting passengers must be classified as a passenger car, the statute as currently written clearly provides that vehicles that are off-highway capable are not passenger cars.”79 Congress, however, intended that “passenger automobiles be defined as those used primarily for the transport of individuals.” 80 And, as the Ninth Circuit noted, “many light trucks today are manufactured primarily for transporting passengers.”81 Indeed, “[c]onsumers use light trucks primarily for passenger-carrying purposes in large part because that is precisely the purpose for which manufacturers have manufactured and marketed them.”82 EPCA’s drafters surely never intended manufacturers to be able to manipulate their products for the sole purpose of escaping higher efficiency standards. Accordingly, the Agencies must remove the SUV loophole. Moreover, we urge the Agencies to create a single footprint for both passenger vehicles and light trucks because that change would eliminate the gamesmanship that has played out historically and is sure to continue without it. [EPA-HQ-OAR-2010-0799-9479-A1, pp. 16-17]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 214-216.]

Rather than promoting technological innovations, these rules rely on small improvements in existing technology. And, also, rather than pushing industry to make more efficient smaller vehicles, these rules create what we're calling an SUV loophole by incentivizing industry to build more trucks and SUVs that won't have to increase their fuel efficiency standards at the same rate as passenger vehicles. And those are our three very big points of concerns for us in these rules.

And the result of these problems with the rules are they actually could end up with an increase in overall greenhouse gas emissions from our transportation center rather than a decrease.

So in regards to what we would like to see done in the final rule, we would like to see these rules significantly strengthened.

One of our main concerns is the fact that the proposed rules allow light-duty trucks and SUVs to increase their fuel efficiency at a much slower rate and pace than cars, and for many years this problem has caused automakers to build bigger vehicles so they could take advantage of these weaker standards that have caused our efficiency to stagnate behind the efficiency across the world.

And we should not make the same mistake twice; we should strengthen those standards for light-duty trucks and put them on a par with cars, and we can't afford to skew the rules in favor of more gas-guzzling SUVs and light trucks.

Organization: Chrysler Group LLC

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 54.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 60-61.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 26.]

Chrysler agrees with setting the truck performance requirements based on the underlying physics of these types of vehicles. We believe the proposed 2017 through 2025 standards support this premise and correct the deficiencies in the 2016 model year rule, which overlooked these factors. The 2017 to 2025 truck standards are challenging while respecting the utility of these vehicles and their importance to the nation's economy.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 54.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 61.]

The truck standards for 2012 through '16 model year were not supported by fundamental science. Accommodating that science will seem to be restricted by statutory direction to not backslide on standards from previous years.

Organization: Consumers Union

It is counterintuitive and counterproductive to let the least fuel efficient models improve more slowly than more efficient models, and Consumers Union recommends that the light truck standard should be made more stringent, particularly in the cross-over range. A delta of 10-15 mpg by 2025 between passenger cars and light trucks of the same footprint is unreasonable, given the range of technologies and designs available for improving fuel economy. The gap in the proposed standards grows over time because light trucks are required to improve at a lesser rate, in addition to being subject to lower targets in absolute terms. [EPA-HQ-OAR-2010-0799-9454-A2, p.6]

IV. A stricter standard would deliver even greater consumer benefits

The proposed standards will likely save consumers billions of dollars and provide additional national security and environmental benefits. However, a higher CAFE target is achievable and would save consumers even more money on fuel at a reasonable investment cost. Especially given the regulatory flexibility and discrepancy between real-world and test results, a higher CAFE target is both achievable and desirable. [EPA-HQ-OAR-2010-0799-9454-A2, p.6]

As noted in prior comments, Consumers Union believes that allowing manufacturers to avoid stringent fuel economy standards by reclassifying passenger vehicles as light trucks as a way to game the system erodes consumer and oil saving benefits.[18] The current proposal's use of footprint-based curves that require vehicles of all size to improve in fuel economy is a significant improvement from letting light trucks off the CAFE hook. Indeed, vehicle "footprint" is a desirable attribute on which to base standards, for reasons noted in on pages 115-116 of NHTSA's Preliminary Regulatory Impact Analysis (PRIA). However, the gap between the curves is too large, especially in the cross-over SUV (approximately 42-50 sf) segment. [EPA-HQ-OAR-2010-0799-9454-A2, p.6]

There are several strong indicators that the gap between the curves is too large. First, the cost-per-vehicle to achieve the proposed standards is much lower for light trucks ($1,500) than for passenger cars ($1,950). This significant discrepancy indicates that light trucks have additional room for improvement at a reasonable cost. In addition, since passenger cars tend to be cheaper than light trucks, light trucks get off even easier in terms of compliance cost as a percentage of purchase price. [EPA-HQ-OAR-2010-0799-9454-A2, p.6]

Secondly, fuel economy savings are logarithmic, so allowing a lower percentage of improvement for vehicles that already have the lowest mpg is counterproductive for maximizing fuel savings and other benefits. The greatest potential for fuel savings is at the least efficient end of a fleet, but the vehicles at the bottom are provided the least stringent targets, even as a percentage of their current dismal performance. Third, the large gap provides a greater incentive to game the system by altering a vehicle to put it in the light truck category (increasing clearance or adding 4WD). For some vehicles, the compliance cost could be less than simply altering the vehicle to switch categories. Adding all-wheel or four-wheel drive does not generally warrant the extra leeway afforded under the proposed rules, especially in the cross-over market segment.[19] [EPA-HQ-OAR-2010-0799-9454-A2, p.7]

Negative consequences could result from the large gap. Cross-over vehicles are a growing market segment, and allowing cross-over vehicles to be counted in the light truck category significantly boosts a manufacturer's achieved CAFE average for light trucks. As a result, the larger and heavier vehicles will not need to make as much improvement as they would otherwise, even though the greater investment needed to make these improvements in the larger vehicles is the reason for a segmented standard in the first place. If the growing cross-over trend continues, the large gap between the curves will have deleterious effects on projected consumer savings and oil reduction.[20] [EPA-HQ-OAR-2010-0799-9454-A2, p.7]

As long as the light truck-passenger vehicle distinction remains in place, our recommended course of action is to alter the slope and floor values of the compliance curves so that there is less incentive to switch categories and to preserve the projected consumer savings. At the very least, the gap between the curves should be narrowed for the cross-over segment, and the gap should decrease, instead of increase, over time. The Union of Concerned Scientists has done extensive analysis on this topic, and we agree with their analysis and conclusion that a "backstop" would be an effective tool to preserve expected consumer savings and prevent exploitation of loopholes. If the agencies do not address this potential problem in the current rulemaking, we would urge them to perform rigorous analysis of this issue during the mid-term review to make sure that consumer benefits are indeed on track and that potential savings are not being squandered through manipulation of the standard. [EPA-HQ-OAR-2010-0799-9454-A2, p.7]

18 - See Appendix F: 'Comments of Consumers Union of the U.S., Inc. In response to Advance Notice of Proposed Rulemaking Docket No. 2003-16128 on Reforming the Automobile Fuel Economy Standards Program.'

19 - See Appendix G Comparison of Price and Operating Costs for 2WD and 4WD for real world examples of fuel economy differences between 2WD and AWD/4WD.

20 - NHTSA notes on page 71 of the PRIA that indeed, the market is expected to shift towards light trucks.

Organization: Ford Motor Company

The truck standards previously established for the 2012-2016 model years underestimated the unique challenges posed by the standards for the larger trucks, which have unique loadcarrying and towing capabilities that can be compromised by the fuel efficiency improvements more successfully applied on smaller vehicles. The current proposal will better enable manufacturers to develop and apply fuel economy technologies to light trucks without sacrificing the utility for which these vehicles are designed. [EPA-HQ-OAR-2010-0799-9463-A1, pp. 2 and 5]

Car and Truck Stringencies: The proposed fuel economy and GHG standards for 2017 and beyond take into account the particular attributes, needs and customer expectations for light trucks relative to passenger cars, and this must carry through to the final rule. [EPA-HQ-OAR-2010-0799-9463-A1, pp. 2 and 5]

Ford also believes that the relative stringency levels for the car and truck fleets, as proposed by the agencies, are appropriate. [EPA-HQ-OAR-2010-0799-9463-A1, p. 8]

Although the proposed 2017 – 2021 model year truck standards may appear to be less stringent than the car standards for the same years, this is not the case. In terms of the product actions necessary to comply, the proposed car and truck standards are roughly equivalent in stringency. This is attributable to the unique attributes expected from trucks—particularly the larger work trucks that constitute a significant portion of our full-line vehicle fleet offering—and also to the overly stringent standards imposed on light duty trucks in the 2012-2016 model year regulation. [EPA-HQ-OAR-2010-0799-9463-A1, p. 8]

Heavier pick-up trucks are expected to deliver even more cargo carrying and towing capacity not required from passenger vehicles. Such vehicles are used by consumers and small business owners for activities such as towing or hauling construction goods and machines, farm goods, landscape material, lawn maintenance equipment, home furnishings, animals, vehicles and trailers. Ford survey data shows up to 82% of F-150 customers use their vehicles for hauling. Up to 41% haul on at least a monthly basis; and 72% of F-150 customers use their vehicles for towing. Up to 28% tow on at least a monthly basis. [EPA-HQ-OAR-2010-0799-9463-A1, p. 8]

To achieve this capability, vehicles equipped with trailer tow packages include additional features that clearly distinguish them from passenger cars, and can negatively impact fuel economy:

- Auxiliary transmission oil coolers
- Upgraded radiators
- Trailer hitch connectors and wiring harness equipment
- Different steering ratios, upgraded rear bumpers and different springs for heavier tongue load (for upgraded 'max' trailer tow packages)
- Body on frame (vs. unibody) construction to support capability and an aggressive duty cycle
- Lower axle ratios for better pulling power/capability

in addition, vehicles with towing capability generally have increased aerodynamic drag caused by a modified frontal area, increased rolling resistance, and a heavier frame and suspension to support this additional capability.

We are seeing a continuing trend that our customers are purchasing these vehicles for work purposes. Based on 2011 segmentation models for our full size pick-up trucks, Business users account for approximately 30% of the market. The Business category includes fleet and work trucks (e.g. small business owner, farmer, foreman), as well as those customers who use their truck for occupational purposes during the week and personal use on the weekend. About 58% of the market is comprised of Recreational users, including hunters, boaters, fisherman, etc. These consumers rely on their vehicles for hauling and towing to support their recreational activities. Only a relatively small segment (12%) of the market is comprised of consumers who do not make significant use of the towing/ hauling/off-road capabilities of the truck. Based on the trends we have seen in the market, we fully anticipate that such buyers will continue to be a shrinking portion of our market. We believe that within a few years, the Business category will increase to over 40% of the market, and the combined Business/Recreational users will increase to over 90% of the market for full size pick-up trucks.

And to further demonstrate the importance of these vehicles to the American economy, the following graph demonstrates that new home construction, a key financial indicator, and the sales of the trucks needed to help this industry, go hand in hand. [EPA-HQ-OAR-2010-0799-9463-A1, p. 9]

In order to be fair to all manufacturers and avoid creating market imbalances, the stringency of the car and truck standards needs to be comparable in terms of the effort and level of investment necessary to comply. The imbalance in the relative stringency of the car/truck standards in the 2012-2016 rules needed to be corrected. In light of the above, we believe that the agencies' proposal with respect to car/truck stringency is sound and should be carried through to the final rule. [EPA-HQ-OAR-2010-0799-9463-A1, p. 10]

In the proposal, EPA makes reference to the fact that it “underestimated the impact of the different pickup truck model configurations” in the model year 2012-2016 rule, and that the “very largest light trucks have significant load-carrying and towing capabilities that make it particularly challenging for manufacturers to add fuel economy-improving/CO_2-reducing technologies in a way that maintains the full functionality of those capabilities." (76 Fed. Reg. 74919). We agree with this observation. The 2012-2016 truck standards did not fully account for the consumer-driven attributes of larger trucks, which, due to the technology trade-offs discussed above, created particular challenges for full-line truck manufacturers. [EPA-HQ-OAR-2010-0799-9463-A1, p. 10]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 45-46.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 35.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 87.]

In particular, EPA acknowledged it had underestimated the impact of the different pickup truck model configurations in the model year 2012 to 2016 rule. They further acknowledged that the 'very largest light trucks have significant load-carrying and towing capabilities that make it particularly challenging for manufacturers to add fuel economy-improving technologies in a way that maintains the full functionality of those capabilities.' We concur with the agencies' analysis and conclusions

Organization: General Motors Company

GM supports the target standard curve shapes, the relative car and truck stringency, and the statistical analysis used to analyze the fleet. [EPA-HQ-OAR-2010-0799-9465-A1, p.2]

GM also urges careful consideration of two key issues raised in the Alliance comments that would affect the implementation stringency of the proposal, namely whether NHTSA should change the current definition of what constitutes a passenger car and a light truck and whether NHTSA needs to further adjust the stringency of its proposed curves to more fully harmonize with the EPA proposed requirements and flexibilities. [EPA-HQ-OAR-2010-0799-9465-A1, p. 2]

Organization: Institute for Policy Integrity, New York University School of Law

The second justification offered is that a footprint-based approach will avoid negative safety impacts. To start, the footprint-based approach does not completely eliminate the incentive to build smaller cars to comply with the rule. The mathematical formulas that set the standards are only strictly increasing along the range from 40 square feet to either 55 square feet for cars or 75 square feet for trucks; at other points, the curve is flat. Admittedly, that central range covers most vehicle models.88 However, at least several dozen models (mostly subcompacts and sports cars) fall in the 30-40 square feet range,89 which are all subject to the same standards. At a minimum, the manufacturers of these models may have an incentive to decrease footprints as a compliance strategy, since doing so would not trigger more stringent standards. [EPA-HQ-OAR-2010-0799-9480-A1, p. 14]

Organization: Insurance Institute for Highway Safety (IIHS)

IIHS does have some concern regarding the “breakpoint” of the fuel economy curve at the lower extreme where footprint is the smallest (see Figure I-1 on page 74871 of the notice). This “breakpoint” is the leveling-off point on the fuel economy curve where the fuel economy requirement ceases to increase as footprint decreases. Moving this breakpoint farther to the left so that even smaller vehicles have increasing fuel economy requirements would reduce the chance that manufacturers would downsize the lightest vehicles for further fuel economy credits. [NHTSA-2010-0131-0222-A1, p. 1].

Organization: International Council on Clean Transportation (ICCT)

17. Separate footprint curves for cars and light trucks distort the requirements by making it easier for vehicle classified as light trucks to comply. Unlike the 20122016 requirements, the 2017-2025 rule increased the gap between cars and light trucks, providing stronger incentives for manufacturers to reclassify cars as light trucks and potentially undermining the benefits of the rule. A single footprint function would still give larger trucks a less stringent target to meet, while avoiding vehicle classification games. [EPA-HQ-OAR-2010-0799-9512-A1, p. 4]

The proposed 2022-25 standards would set consistent improvements for all cars and light trucks, with annual CAFE increases of 4.7% per year and annual GHG reductions of 5.0% per year. However, both EPA and NHTSA proposed a lower annual rate of improvement for light-trucks in the early years of the program. EPA is proposing an annual GHG reduction for cars of 5%, but only 3.5% for light trucks. Similarly, NHTSA is proposing an annual fuel economy increase of 4.3% for cars, but only 2.9% for light trucks. The required reductions for light trucks are also tilted, such that the smallest light trucks have larger increases (but still less than cars), while the larger light trucks have smaller increases. Figure 4 illustrates this effect. The annual fuel economy increases from 2016 to 2021 for cars is almost flat and ranges from 4.2% to 4.4%. The annual fuel economy increase for light trucks starts at 4.0% for the smallest trucks, drops to 2.3% for larger SUVs, and falls off to only 0.4% for the largest pickup trucks. Note that the 2012-16 standards also imposed smaller increases on the larger vehicles than they did on smaller vehicles. [Figure 4 can be found on p. 49 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, pp. 48-49]

Footprint systems are designed to encourage the use of lightweight materials (unlike weight-based standards) without affecting the mix of vehicles sold in the market. Under a footprint-based system, selling more small vehicles does not necessarily help manufacturers meet the standards, as smaller vehicles are subject to more stringent targets. However, the slope of the footprint curve and the difference between the car and light truck curves matter. The steeper the slope of the footprint curve, the more incentive manufacturers have to increase the size of their vehicles. And the larger the difference between the car and light truck curves, the more incentive a manufacturer has to add four-wheel drive and jack the vehicle up just enough to meet the ground clearance criteria so that the vehicle can be reclassified as a light truck. These are perverse incentives, as increasing the size of the vehicle or reclassifying cars as light trucks makes it easier for a manufacturer to meet the requirements while also increasing the fuel consumption and CO_2 emissions from the vehicle. [EPA-HQ-OAR-2010-0799-9512-A1, p. 49]

The tilt in the increase in light truck stringency, as illustrated in Figure 4, increases the incentive for manufacturers to increase the size of light trucks, especially pickup trucks. [Figure 4 can be found on p. 49 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 49]

More importantly, the lower requirements for all light trucks would increase the incentive to reclassify cars as light trucks. As illustrated in Figure 5, the 2012-2016 standards and the 2022-2025 standards have almost no impact on the relationship between the stringency of the car and the light truck targets. However, during the 2017 to 2021 timeframe, when the annual efficiency gains for light trucks are much lower than for cars, the difference in stringency between cars and trucks grows dramatically. As proposed, the 2017-2021 standards will increase the incentive to reclassify cars as light trucks, with a small additional incentive for the smallest cars and gradually increasing for larger cars. Fortunately, few cars have a footprint larger than about 54 sq.ft at present. [Figure 5 can be found on p. 50 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 50]

Single footprint curve

The proposed rule maintains separate footprint curves for cars and light trucks. This subjects light trucks with the same footprint to much less stringent standards and gives manufacturers a tremendous incentive to reclassify cars as light trucks. In the future it is likely to cause manufacturers to drop many 2wd versions of their small SUVs and make less efficient 4wd versions standard, so that they can be classified as light trucks instead of cars. This will actually increase overall real world fuel consumption and CO_2 emissions in two ways. First, it will increase 4wd installation and directly increase the fuel consumption of the fleet. Second, it makes it easier for manufacturers to meet the standards, so that they do not have to implement as much technology on other vehicles. [EPA-HQ-OAR-2010-0799-9512-A1, p. 50]

The large majority of light trucks today are based on car platforms with unibody construction. All minivans use unibody construction and cab-and-chassis construction for SUVs is rapidly disappearing. Except for pickup trucks, full-size cargo vans, and a few relatively low volume SUVs, such as the Jeep Wrangler and the Suburban, in the 2017-25 timeframe of the rule all light trucks will be based on car platforms. In addition, due to the empty pickup bed and empty cargo box, pickup trucks and cargo vans are considerable lighter than SUVs with the same footprint and fit well on a single footprint line. Thus, there is no technical reason to maintain separate footprint lines for cars and light trucks. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 50-51]

EPA recognized the importance of this issue when it established a single Tier 2 emission standard for all cars and light trucks. The issue here is just as important. It is time to begin the process to end this artificial distinction between cars and light trucks for fuel efficiency and greenhouse gas emissions. The ICCT recommends a single footprint function, which will still give larger trucks a less stringent target to meet, while avoiding vehicle classification games and helping to ensure fuel consumption and GHG emission goals are actually met. [EPA-HQ-OAR-2010-0799-9512-A1, p. 51]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 197.]

The separate footprint curve to cars and light trucks also distort the requirements by making it easier for vehicles classified as light trucks to comply. A single footprint function would still give larger trucks a less stringent target to meet while avoiding vehicle classification games.

Organization: Mass Comment Campaign (20,500) (Union of Concerned Scientists-3)

The proposed standards for light trucks are significantly weaker than for cars. In the past, automakers made vehicles bigger to qualify for weaker standards. Light truck standards should be strengthened to prevent automakers from gaming the system. [EPA-HQ-OAR-2010-0799-10166-A2_MASS, p.1]

Organization: Mass Comment Campaign (375) (Union of Concerned Scientists-2)

The proposed standards for light trucks are significantly weaker than for cars. In the past, automakers made vehicles bigger to qualify for weaker standards. Light truck standards should be strengthened to prevent automakers from gaming the system. [EPA-HQ-OAR-2010-0799-1246-A1_MASS, p.1]

Organization: Mass Comment Campaign (4,505) (Unknown Organization)

The proposed rules allow light trucks to increase their fuel efficiency at a much slower rate than cars. For many years, this problem led automakers to build bigger vehicles so they could take advantage of these weaker standards, which caused efficiency standards in the United States to stagnate. We should not make the same mistake twice, and should strengthen the standards for light trucks on a par with cars. We cannot afford to skew the rules in favor of gas-guzzling SUVs. [EPA-HQ-OAR-2010-0799-9595-A1_MASS, p.1]

Organization: Mass Comment Campaign (9,570) (Unknown Organization)

The proposed standards for light trucks are significantly weaker than for cars. In the past, automakers made vehicles bigger to qualify for weaker standards. Light truck standards should be strengthened to prevent automakers from gaming the system. [EPA-HQ-OAR-2010-0799-9578-A1_MASS, p.1]

Organization: National Association of Clean Air Agencies (NACAA)

First, NACAA understands that EPA and NHTSA are proposing that passenger cars have an average rate of improvement of 5 percent for MYs 2017 to 2025. However, light-duty trucks will start with an average rate of improvement of 3.5 percent for MYs 2017 through 2021 and 5 percent for MYs 2022 through 2025. These proposed rates of improvement are envisioned to result in an average CO_2 emissions rate of 163 grams per mile (g/mile) with an average fleet performance of 54.5 miles per gallon (mpg) if every manufacturer incorporates enhanced engine technologies. In addition, the proposal provides only a conditional approval of the standards by NHTSA for MY 2022 to 2025 vehicles. [EPA-HQ-OAR-2010-0799-8084-A1, p. 3]

NACAA supports EPA's and NHTSA's goal of a fleetwide performance that will result in 54.5 mpg fuel efficiency. We are concerned, however, that the approach taken in the proposal may undermine achievement of this goal. In fact, in a recently published study, researchers at the University of Michigan consider whether allowing a more lenient 3.5-percent rate of improvement requirement for larger vehicles creates an incentive for the manufacture of larger vehicles to the extent that it could lower the overall fleet performance standard by as much as four miles per gallon, thus undermining the goal of a 54.5-mpg fuel economy standard.[12] Accordingly, NACAA urges EPA and NHTSA to ensure that the full measure of the reductions envisioned by EPA and NHTSA is achieved. In addition, NACAA requests that EPA and NHTSA respond to the issues raised in the University of Michigan study. [EPA-HQ-OAR-2010-0799-8084-A1, p. 3]

Organization: Natural Resources Defense Council (NRDC)

NHTSA should revise truck definitions to reduce the incentive for cars to be reclassified as trucks and take advantage of a less stringent compliance regime. [EPA-HQ-OAR-2010-0799-9472-A2, p. 3]

2. Fuel Consumption and Pollution Reductions are Undermined by Large Gap between Car and Truck Curves; Agencies Should Revise Truck Definitions to Prevent Gaming

The large gap between the car and light truck curves creates an incentive that threatens to undermine the predicted oil and GHG reductions of the program. Automakers could have a strong incentive to modify vehicles classified as cars today to be reclassified as trucks because the truck curve has substantially less stringent compliance levels for the same footprint. NHTSA previously recognized that many crossover vehicles had been inappropriately classified as trucks. Starting with MY 2011, NHTSA required two-wheel drive crossovers that were previously subject to truck fuel economy standards to be shifted to the car fuel economy compliance requirements. NHTSA estimated that over a million vehicles required reclassification from trucks to cars.33 It is our concern that many automakers will modify vehicles or shift sales from crossovers currently on the car curve to the truck curve. [EPA-HQ-OAR-2010-0799-9472-A2, p. 10]

One way to make the curve shift is by the addition of four-wheel drive (4WD) capability. Adding four-wheel drive technology could classify a car into a truck yet have minimal impact on the actual fuel efficiency and emissions of the vehicle. By making the shift, a vehicle was previously complying with the car curve would immediately overcomply on the truck curve. The automaker’s decision to add 4WD capability will largely be influenced by whether or not the cost to add the 4WD technology is less than adding the fuel efficiency and emissions technology necessary to stay compliant on the car curve. [EPA-HQ-OAR-2010-0799-9472-A2, p. 10]

Consider the case of the popular Toyota RAV4 crossover and compliance with GHG emission standards. With a footprint of 44.6 square feet (ft2), the two-wheel drive RAV4 car requirement in 2016 is 223 g/mi. Adding 4WD will increase emissions by about 5 g/mi to 228 g/mi. If reclassified as a truck, the 4WD RAV4 would subject to less stringent compliance standards and at 228 g/mi, it would meet the meet the MY 2020 requirement for trucks at the 44.6 ft2 footprint. [EPA-HQ-OAR-2010-0799-9472-A2, p. 10]

By immediately complying with the MY 2020 standard, Toyota could avoid adding technologies to cut emissions from 2016 to 2020, and save approximately $1000. If Toyota can add 4WD technology for less than $1000, then they would have an incentive to shift RAV4 models from car classification to truck classification. The difference in MSRP between 2WD and 4WD models of the 2012 RAV4 is $1400 but actual costs could be less than $1000. [EPA-HQ-OAR-2010-0799-9472-A2, p. 10]

NHTSA and EPA should reduce the incentive to reclassify vehicles from the car to truck curves. The gap between the car and truck curves should be reduced, especially for footprints of crossovers similar to the RAV4. The emissions and fuel efficiency difference between 2WD and 4WD crossovers on the market today is often less than 10 g/mi yet the car and truck curves differ by over 40 g/mi. The agencies should also revise truck definitions to better distinguish truck-only capabilities. For example, trucks should be required to have technologies that are necessary for true off-road capability vs. typical all-wheel on-road driving. [EPA-HQ-OAR-2010-0799-9472-A2, p. 10]

Organization: Nissan North America, Inc.

The standards applicable to the light-duty truck fleet for MYs 2022-2025 are particularly challenging. Especially for automakers with more limited volumes in the light truck segment, the cost feasibility of implementing more advanced technology is limited. As manufacturers re-evaluate their commitment to these market segments, the broad industry-wide investment in truck technologies that can be spread through the industry is uncertain. Moreover, the willingness of the market to absorb substantial additional costs to ensure achieving the proposed standards is questionable as the light-duty truck segment is a cost-sensitive market. [EPA-HQ-OAR-2010-0799-9471-A1, p.8]

Organization: RVIA

Towing considerations for full size pickups

RVIA has commented in the past on the importance of considering towing when setting future GHG and CAFE standards for full size pickups. RVIA is pleased to see that the proposed standards for full size pickups do indeed take towing into consideration and we therefore support the standards proposed for the 2017-2021 model years. However, we are concerned that the costs associated with the standards proposed for the 2022-2025 model years could potentially hurt full size pickup truck sales. This would in turn have a negative effect on sales of towable RVs because when a person shopping for a new towable RV cannot afford to buy the vehicle capable of towing it, they will not purchase the RV. [EPA-HQ-OAR-2010-0799-9550-A2, pp.1-2]

Towing considerations for large passenger cars, small SUVs and crossover vehicles

With the price of gasoline hovering around four dollars per gallon today, consumers are buying SUVs that ride more like a car, get better fuel economy, but have a greatly diminished towing capacity. For example, the consumer who several years ago might have purchased a Chevy Tahoe (3 rows of seats and towing capacity of 8,500 lbs) might instead today purchase a Chevy Traverse which also has three rows of seats but has a maximum towing capacity of only 5,200 lbs. Similarly, consumers that previously might have purchased an SUV like a Volkswagen Toureg now consider smaller SUVs like the Tiguan, a minivan or even a station wagon. As this downsizing trend progresses, consumers (as they are already) will demand that these vehicles offer more towing capability than offered today. Therefore, we recommend that EPA and NHTSA closely examine whether they have appropriately considered this future light vehicle towing trend in setting standards for light duty passenger cars, cross-over vehicles, minivans and other vehicles that will be used by consumers to tow RV trailers, boats, ATVs, utility trailers, U-Haul rental trailers and the like. [EPA-HQ-OAR-2010-0799-9550-A2, p.2] [There are also images associated with this paragraph, please refer to EPA-HQ-OAR-2010-0799-9550-A2, pp.2-3]

Organization: Salinas, A.

SUVs are being allowed to improve gas-mileage standards later than passenger vehicles, and that has spurred the production of even more SUVs. These standards leave the United States behind Europe, Japan, and China in fuel efficiency. [EPA-HQ-OAR-2010-0799-7119-A1, p. 1]

Auto makers are being coddled into taking only baby-steps to improve already-existing technology. We are much better than that. At this pace, 2025 will not see much more fuel-efficiency than what some cars already have. By 2025 the United States should do better than the European Union, China and Japan, not continue to lag behind them. [EPA-HQ-OAR-2010-0799-7119-A1, p. 1]

We need better, stronger rules to make real progress in the fight to reduce greenhouse gas emissions and improve fuel efficiency, and we need for SUVs to be made adhering to the same standards as passenger vehicles. [EPA-HQ-OAR-2010-0799-7119-A1, p. 1]

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

Take steps to address weaker standards for light trucks: Closing the gap between cars and trucks has been a long-term concern for our organizations. We remain deeply concerned about the lower rate of improvement the light truck curve requires overall, driven by the much less stringent curve at the large footprint end of the light truck spectrum. The EPA is proposing lower annual emissions reductions of 3.5 percent per year for MY 2017-2021 light duty trucks. NHTSA is also proposing a low annual increase in fuel economy for light trucks for the first phase of standards which include MY 2017-2021 to be 2.9 percent per year on average (even lower for larger light trucks). The proposed rule presumes that additional increases will be achievable after 2021 – 5% emissions reductions for trucks and 4.7% annual efficiency improvements. This treatment results in the direct loss of greenhouse gas reductions relative to reductions that would have been achieved with a uniform 5% annual emissions reduction across all classes, and may undermine the benefits of the program. The lower rate of improvement in the early years could undermine the mid-term review and achieving the long term stringency of the National Program. [EPA-HQ-OAR-2010-0799-9549-A2, p. 6]

The agencies are continuing to use an attribute based curve for model years 2017-2025. While the car curve is the same as from the 2012-2016 standards, the agencies are changing the light truck curve. The proposed changes will increase the slope and extend the large footprint cut off point to larger footprints. By increasing the slope the rule will create an incentive to upsize vehicles that would continue through MY2025. The agencies consider this factor in the NPRM, noting that a “steeper footprint based standards may incentivize vehicle upsizing, thus increasing the risk that the fuel economy and greenhouse gas reduction benefits will be less than expected. Extending the slope part of the target curve will have adverse consequences for both emissions and safety. [EPA-HQ-OAR-2010-0799-9549-A2, p. 6]

We appreciate the agencies efforts to structure a program to encourage and reward application of “game-changing” hybrid technology to the largest pickups. To limit the impact of the proposed curves and treatment of light trucks, even with the incentive program in place, we recommend that the agencies provide an alternate emissions target for light trucks of 60 sq. feet and above that exceed the sales projected in the rule. This alternate emissions target will come into effect in the year that sales exceed the projected sales in the rule. By setting an alternate emissions target level representing a 4.8 percent annual reduction from the maximum 2016 truck target of 349 g of CO_2 per mile, automakers will be discouraged from increasing sales volumes at this end by producing lower cost and inefficient vehicles. [EPA-HQ-OAR-2010-0799-9549-A2, p. 6]

The gap between average car and truck emissions would widen due to the differing rates of improvements for cars and trucks under the proposed standards. This may further encourage manufacturers to reclassify certain large-footprint cars as trucks and/or change the balance of two-wheel drive and four wheel-drive SUV production, reducing the emissions benefits of the 2017-2025 standards. [EPA-HQ-OAR-2010-0799-9549-A2, p. 6]

In the past, the light truck loophole resulted in manufactures producing greater numbers of trucks. We are concerned that in the early years of the program automakers will take advantage of the weaker standards for light trucks, which will make it difficult to produce higher efficiency vehicles in the later years of the program setting automakers up for failure. [EPA-HQ-OAR-2010-0799-9549-A2, p. 7]

Automakers are already gearing up to take advantage of this loophole. A New York Times article reported in 2011 that sales of larger vehicles were up by 28.5% compared to an increase in car sales of 7% from 2010 sales in the same month.22 [EPA-HQ-OAR-2010-0799-9549-A2, p. 7]

Therefore we also urge the agencies to revisit the light truck definition as set by NHTSA in the 2011 fuel economy rule to further discourage reclassification of cars as trucks and substitution of two wheel drive with four wheel drive SUVs, simply to avoid the more stringent car standards. [EPA-HQ-OAR-2010-0799-9549-A2, p. 7]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 69.]

In addition, we want to emphasize that additional assurances are needed to ensure that the overall fleet performance of 5 percent is met. The proposal rule allows light-duty trucks produced in

2017 to 2021 to improve at a rate of only 3.5 percent. If sales of light-duty trucks during this time period exceeds expectations, then the overall fleet performance will be further reduced.

In addition, the use of early credits may lead to the production of light-duty vehicles that do not necessarily have to meet the 5 percent improvement rate.

Organization: Toyota Motor North America

While Toyota understands that the utility provided by larger trucks is a factor driving the lower overall target increases for trucks as a whole, and the lack of improvement required for larger trucks for 2017-2021 model years, the agencies must ensure that purchasers of affordable and fuel efficient smaller cars (and smaller trucks) do not bear a disproportionate burden as a result. As proposed, the standards may drive manufacturers of smaller footprint cars to add technology and cost to vehicles that are already among the most fuel-efficient and price sensitive in the market, while requiring little improvement of the largest vehicles on the road. This dilemma appears to be an unintended consequence of the shift to an attribute-based fuel economy and greenhouse gas regulation scheme and must be considered as standards are increased in this rulemaking and in the future. [EPA-HQ-OAR-2010-0799-9586-A1, p.2]

In particular, NHTSA should take steps to modify its target curves to account for the limited credit trading and transferring allowed under its authorizing statute. [EPA-HQ-OAR-2010-0799-9586-A1, p.2]

Nonetheless, we remain concerned about two aspects of the proposed standards. First, the targets for trucks require a lower average rate of improvement than for cars. And second, the targets for larger trucks require a lower average rate of improvement than smaller trucks. In fact, the target curves for the largest trucks remain flat for several years before increasing at all. This discrepancy is exacerbated by the availability of several credit opportunities - discussed later in these comments - that are applicable to certain large trucks at the exclusion of all other market segments. [EPA-HQ-OAR-2010-0799-9586-A1, p.5]

While Toyota understands that the utility provided by larger trucks is a factor driving the lower overall target increases for trucks as a whole, and the complete lack of improvement required for larger trucks for 2017-2021 model years, the agencies must ensure that purchasers of affordable and fuel efficient smaller cars (and smaller trucks) do not bear a disproportionate burden as a result. The target curves as proposed will drive manufacturers of smaller footprint cars to add technology and cost to vehicles that are already among the most fuel efficient in the market, and which are also among the most price-sensitive in the market, while requiring virtually nothing of the largest vehicles on the road. This dilemma appears to be an unintended consequence of the shift to an attribute-based fuel economy and GHG regulation scheme and must be considered as standards are increased in this rulemaking and in the future. [EPA-HQ-OAR-2010-0799-9586-A1, p.5]

Organization: Union of Concerned Scientists (UCS)

(b) Loss in Benefits from Increased Vehicle Size and Car/Truck Reclassification

In the proposed rule, the agencies project a sales mix in MY2025 of 66.9% passenger cars and 33.1% light trucks. This represents a significant consumer shift towards passenger cars from today's sales mix. While we agree that a variety of market and regulatory factors will move sales in this direction, the magnitude of this shift will strongly influence the actual outcome of these standards. This mix could shift for a host of reasons, including market forces, or because of compliance strategies adopted by automakers to either (a) reclassify cars as light trucks or (b) add size to vehicle footprints to qualify for weaker standards. According to the California Air Resources Board, "the extent to which the future fleet trends move toward larger average vehicle sizes and/or more trucks than projected in this analysis could significantly undermine the expected GHG benefits."29 CARB goes on to quantify how as much as a 16 percent loss in emissions reduction could result from even a modest shift to larger vehicles and an increase in market share of light trucks. And this concern is not without evidence. As Tom Cackette, Chief Deputy Executive Officer of the California Air Resources Board, noted at a recent public hearing, "We have some insight into the [auto industry's] business plans that suggest that we should worry about this."30 This concern is also consistent with past efforts by automakers such as Chrysler and Subaru to reclassify cars as "trucks" as well as the overall shift to SUVs during the 1990s as automakers took advantage of the significant difference in the car and light truck standards. [EPA-HQ-OAR-2010-0799-9567-A2, p. 7]

Modifying crossover-type vehicles currently defined as cars in order to qualify them as 'non-passenger vehicles' may pose an attractive strategy to automakers, as they could generate a windfall of credits due to weaker trucks standards. The fastest growing segment of vehicles over the past decade has been the crossover vehicle segment, growing from less than 5% in 2000 to nearly 25% of light-duty vehicles in 2010. The most popular of these vehicles are offered in 2wd and 4wd configurations, such as the Ford Escape, Toyota RAV4, and Honda CR-V. Consistent with current federal definitions, the 2wd variants of these vehicles are classified as cars while the 4wd versions are classified as light trucks. If the size of the gap between car and light truck standards at a given vehicle footprint is large enough, it alone can provide an incentive to automakers to modify the 2wd variant of crossover vehicles to meet the light truck definition. Today's popular 4wd versions of mid-size crossover vehicles emit 2 to 3 percent more global warming emissions than their 2wd counterparts. Yet the gap in the proposed standards between cars and trucks ranges from about 16 to 19 percent. This large gap presents a sizable loophole in the regulation and could result in a large loss in program benefits should manufacturers find it more economical to reclassify and migrate models to the less-stringent truck standard. [EPA-HQ-OAR-2010-0799-9567-A2, p. 8]

An even more troubling, though equally plausible scenario, is that a manufacturer could modify a halo vehicle to meet the truck definition with the express intent of minimizing obligations on the rest of its light truck fleet. At a January 19, 2012 public hearing in Philadelphia, PA on the proposed MY2017-2025 standards, a representative of Toyota Motor North America referred to the company's new Prius V as a crossover vehicle. This model is classified as a station wagon in EPA's fuel economy guide, and should be appropriately held to the more stringent passenger vehicle ('car') standard. However, if Toyota chose to apply a third row of seats, or to add a 4wd transmission and increase the vehicle's ground clearance, the Prius V would be close to, if not already, meeting the non-passenger ('light truck') definition. Doing so could have a profound effect on Toyota's remaining truck fleet. According to fueleconomy.gov, the Prius V's unadjusted 2-cycle fuel economy is 58.7 mpg; even assuming a 10 percent loss in (unadjusted) fuel consumption from applying 4wd and other modifications, the model would still achieve 53.4 mpg – more than 20 mpg over the 2017 target specified for the Prius V's 46.1 ft2 footprint. At a reasonable sales volume, this would create a massive windfall of credits, allowing Toyota to remain compliant while making very few improvements to the remainder of its light truck fleet. [EPA-HQ-OAR-2010-0799-9567-A2, p. 8]

With examples such as the one above, it is clear that the set of criteria used to differentiate passenger and non-passenger vehicles is inadequate, providing automakers ample opportunity to game the system and undermine the benefits of the program. One solution is to adjust the target curves, particularly in the 45 (+/- 3) ft2 footprint range seen by many crossover vehicles, to minimize the gap between car and light truck targets. [EPA-HQ-OAR-2010-0799-9567-A2, p. 8]

Though I strongly support these standards, I am concerned about possible loopholes that automakers could exploit. Specifically: The proposed standards for light trucks are significantly weaker than for cars. In the past, automakers made vehicles bigger to qualify for weaker standards. Light truck standards should be strengthened to prevent automakers from gaming the systems. [EPA-HQ-OAR-2010-0799-9713-A2, p. 2]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 218-219.]

We're also very concerned that significantly weaker standards for light trucks could give auto makers an incentive to reclassify passenger vehicles as non-passenger vehicles.

For example, the gap of roughly six to ten MPG exist between car and light truck target stringencies in the footprint range seen by many crossover vehicles.

This gap is much larger than the fuel economy loss a crossover would face from adding four-wheel drive, which could enable it to qualify it for a weaker standard as a non-passenger vehicle.

Gaming of the system like this will cut down on the anticipated program benefits giving the sizable and growing popularity of the crossover vehicle segment. The agencies cannot afford to dismiss this issue.

Organization: United Automobile Workers (UAW)

In particular the UAW supports the aspects of the proposals that recognize the importance of balancing the challenges of adding fuel-economy improving technologies to the largest light trucks with the need to maintain the full functionality of these vehicles across a wide range of applications. Second, the UAW believes that the agencies made reasonable determinations regarding the shape and slope of the curves that describe the proposed requirement for any particular size vehicle. Third, the UAW is pleased that the proposed CAFE regulations maintain the alternative minimum standard for domestically manufactured passenger cars. This requirement was maintained in EISA as an express mechanism to ensure a certain level of efficiency for the domestically-produced passenger car fleet. [EPA-HQ-OAR-2010-0799-9563-A2, p.2]

Organization: Volkswagen Group of America

Through these comments, Volkswagen will outline our main concerns and will define the implications of key elements which will lead to the inequitable treatment amongst manufacturers. Volkswagen will conclude the comments with a series of proposals aimed at improving the overall balance of the rule. [EPA-HQ-OAR-2010-0799-9569-A1, p. 3]

It was Volkswagens' position that all segments of vehicles within each compliance fleet should be capable of carrying an equitable burden in CO_2 reduction per year. [EPA-HQ-OAR-2010-0799-9569-A1, p. 5]

a. Equal stringency for cars and trucks in the range of 4%/year for 2017-2021

It was Volkswagen's position based on predictions for technical readiness and consumer affordability that an annual reduction in the range of 4% CO_2 promoted a balanced regulation for both cars and trucks for 2017-2021. An equal stringency equitably distributes the burden for reduction across all segments within the fleet. [EPA-HQ-OAR-2010-0799-9569-A1, p. 5]

Further, Volkswagen explained that there are many uncertainties regarding the market acceptance, cost and benefits of technologies such as hybrids, plug-in hybrids, lightweight materials and advanced combustion engines. It was also Volkswagen's position that stringency in the later phase of 2022-2025 could possibly be adjusted upward or downward following a midterm review that would provide more certainty over the cost, benefit and market forces surrounding more advanced technology. [EPA-HQ-OAR-2010-0799-9569-A1, p. 5]

In summary, Volkswagen's principles offered an equitable regulation driving aggressive reductions from the entire light-duty vehicle market. Importantly, the Volkswagen framework did not penalize an auto manufacturer who is more focused on the passenger car market versus large work trucks. We also believed that footprint curves based on equal stringency regardless of footprint size did not penalize smaller trucks. [EPA-HQ-OAR-2010-0799-9569-A1, p. 5]

Volkswagen contends that a regulation with equal stringency for both cars and trucks and with equal stringency across all footprints would result in a regulation that does not encourage manufacturers to increase footprint or change vehicle classifications. Achieving equal distribution would help assure that manufacturers focusing on passenger cars would continue to market or even expand this segment. Volkswagen also contends that a regulation structured in this manner does not place additional burden on affordable high volume vehicles that already save the most CO_2 per market segment. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 5-6]

a. Requires a stringency only for passenger cars that exceeds what Volkswagen predicted as a would be a both feasible and balanced requirement;

b. Fails to provide equal treatment for all vehicles by requiring higher stringency for cars and lower for trucks;

c. Continues with aggressive requirements beyond 2021 based on critical assumptions about the market and technologies which are simply too uncertain to appropriately comprehend; [EPA-HQ-OAR-2010-0799-9569-A1, p. 6]

With the publication of the SNOI and the subsequent NPRM, the agencies essentially followed the Volkswagen vision for reduced stringency in the first phase of the regulation (see Section 1.1a). However, this only applied to the highest CO_2 emitting segment of the light-duty fleet, trucks. Larger trucks in particular were provided with minimal CO_2 reduction requirements through the early years of the proposal. [EPA-HQ-OAR-2010-0799-9569-A1, p. 6]

The combination of lower stringency for larger trucks, combined with segment exclusive credit opportunities has the potential to distort the future light duty vehicle market. The agencies have disputed this claim, stating that work trucks have special needs and are challenged by the regulation even at the proposed stringency. In fact the agencies have contended that the work truck stringency is so great that even at the proposed levels they expect work truck manufacturers to earn credit in the passenger car segment and transfer that credit to the truck segment to assist truck segment compliance. If this is the case the agencies could have still created a regulation that was more equitable with equal stringency for cars and trucks. A regulation with stringency in the range of 4% for both segments would have resulted in extra credit in the passenger car segment that would have afforded work truck companies additional credit they could transfer to the truck category to offset the increased stringency of a balanced regulation compared to the lower stringency for trucks as proposed in the SNOI and NPRM. Volkswagen will expand on this argument in the comments that follow. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 6-7]

In summary, Volkswagen is concerned that the proposal will result in significant competitive inequity and will create market distortions affecting consumer purchase decisions. Furthermore, the proposal disproportionately impacts manufacturers who market primarily passenger cars while in turn benefitting producers of higher emitting large trucks. [EPA-HQ-OAR-2010-0799-9569-A1, p. 7]

Consumers ultimately will select a vehicle which best balances their needs and wants with affordability. The market has evolved to include a broad set of vehicles with a wide variety of features and emissions. In spite of the regulations, the choices people make when selecting a vehicle will have the most influence on the overall light duty carbon emissions. [EPA-HQ-OAR-2010-0799-9569-A1, p. 7]

Volkswagen understands that many consumers will continue to demand the utility provided by large trucks and pick-ups, either due to work or family requirements. Indeed, once again, two of the top-selling vehicles in the United States remain full-size pick-up trucks. Far into the future, the utility of these vehicles will continue to make them attractive to consumers. However Volkswagen feels that trucks and cars should be held to an equal percent burden for CO_2

reduction. Large trucks and pick-ups should not be singled out and provided a lesser requirement. [EPA-HQ-OAR-2010-0799-9569-A1, p. 7]

Volkswagen contends that the policy reflected in the NPRM may disproportionately drive cost into passenger cars versus trucks and may ultimately discourage customer consideration of lower CO_2 emitting passenger cars. Market segments should compete on the merits of their utility and affordability. Environmental regulations such as this CO_2 and fuel economy proposal should not at the very least create an unintended benefit for higher emitting trucks. This seems counterintuitive to environmental and energy goals. [EPA-HQ-OAR-2010-0799-9569-A1, p. 7]

Volkswagen will further expand upon our positions within these comments and will offer a series of amendments aimed at improving the overall framework of the proposal. Clearly, we would like to see a more balanced approach that equalizes the compliance burden across the industry. In addition we will offer proposals to modify the flexibilities to recognize a broader set of technologies and be available to other market segments. [EPA-HQ-OAR-2010-0799-9569-A1, p. 7]

As discussed previously, the Volkswagen Group maintains that the stringency and credit inequities within this proposal create a serious competitive disadvantage for Volkswagen. The framework of the proposal does not align with our key principles for a balanced program. [EPA-HQ-OAR-2010-0799-9569-A1, p. 7]

The following sections highlight the implications of such an inequitable proposal. Much of the competitive disadvantage for Volkswagen stems from the fact that Volkswagen as a group has the highest percentage car/truck split of any larger manufacturer (80% cars/20% trucks) in the US market. As a result, our fleet will be subjected to the most stringent standards, without the benefit of several key credits being offered to higher-emitting segments. This is in spite of the fact that due to the high percentage of passenger cars, Volkswagen has some of the lowest corporate emissions. Volkswagen remains unconvinced that a fleet composed primarily of lower-emitting passenger cars should be subjected to the most stringency standard, and carry such a disproportionate burden for CO_2 reduction. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 7-8]

Volkswagen is concerned that the differences in stringency levels between passenger cars and trucks as proposed within the NPRM creates an inequity in the projected corporate targets that each manufacturer must meet. What is immediately evident is that manufacturers who market a larger percentage of passenger cars versus light trucks will face a more challenging compliance outlook. The practical effect is that passenger car focused manufacturers will face a higher cost of compliance and will be at a price disadvantage in the marketplace. The resulting disparity amongst manufacturers is illustrated in some of the analysis included within the RIA. [EPA-HQ-OAR-2010-0799-9569-A1, p. 8]

Chapter 3 of EPA's RIA provides projections for car and truck targets for major manufacturers for the proposal and several other alternative scenarios. Volkswagen analyzed Table 3.8-3 from the RIA which provides EPA's projections through 2021. Disregarding several niche manufacturers (Aston Martin, Lotus, etc) it is apparent from the table that the proposal creates a higher burden on Volkswagen compared to many of the larger manufacturers, especially those with truck-centric fleets such as Ford or GM. [EPA-HQ-OAR-2010-0799-9569-A1, p. 8]

As shown below in Table 2-1, Volkswagen's 2021 car target is projected by EPA to be 167 g/mi CO_2 which is 6 g/mi less than the fleet average. When compared to manufacturers such as GM or Ford, Volkswagen's target is expected to be 9-10 g/mi more stringent. Volkswagen's truck target shows a similar situation. [See Table 2-1 on p. 8 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 8]

However analyzing the car and truck fleet separately does not show the full extent of the disparity. Table 2-1 also shows the combined sales weighted average target projected by EPA and further calculates the car/truck sales mixture. The car/truck split was not shown in the RIA, but can be derived from the individual compliance fleet and combined fleet target. [EPA-HQ-OAR-2010-0799-9569-A1, p. 8]

Table 2-1 shows Volkswagen having a combined sales weighted target of 184 g/mi. EPA is estimating Volkswagen to continue into the future with an 80% PC and 20% light truck share. This is consistent with Volkswagen's sales history and current projection. [EPA-HQ-OAR-2010-0799-9569-A1, p. 8]

Ford and GM are shown to have approximate sales weighted targets of 205 and 218 g/mi respectively. This is 21 and 34 grams less stringent when compared to Volkswagen. Furthermore, it appears that the combined fleet averages for these two OEMs were made assuming only 49% truck penetration for GM and 33% truck penetration for Ford. Volkswagen notes that these levels of truck penetration are far less than GM and Ford's current and historic sales split between PC and LT. For example, Ford's 2011 truck share was approximately 63% of their total sales, nearly one-third of which is the F150. GM's truck market share was estimated at 65% based on 2011 sales data. Projections for major manufacturers are illustrated below in Figure 2-1. [See Figure 2-1 on p. 9 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 8]

Volkswagen is concerned that the car/truck split assumed for different manufacturers may be unlikely to prove accurate. As illustrated in Table 2-2, had the EPA RIA calculation applied a truck estimate more consistent with market trends for both Ford and GM, the combined sales weighted fleet average would have approached 232 and 227 g/mi. This would further expand the disparity between corporate standards, resulting in Volkswagen being held to a 46 g/mi more stringent standard. This is 25% disparity in corporate target levels. This additional 46 g/mi translates into approximately 9 metric tons of additional CO_2 emissions per vehicle sold by these manufacturers than by Volkswagen. [See Table 2-2 on p. 9 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 9]

Volkswagen recognizes that the agencies are privy to confidential product plans supplied by manufacturers and that the agencies rely on this data to support future projections. However, the US has been averaging a near 50/50% split between cars and trucks for many years. Even at times of peak gasoline prices experienced during the past few years, interest in light trucks may have waned, however not to such a drastic extent as indicated by this radical shift in future product plans. Most disturbing is the recent trend back to light trucks even with fuel prices stabilizing near record highs. Volkswagen sees no evidence that would suggest a near 30% decline in truck market share from domestic OEMs. [EPA-HQ-OAR-2010-0799-9569-A1, p. 9]

Volkswagen is not privy to strategic plans by competitors, but we find it unlikely for OEMs historically focused on truck sales to so readily abandon what has proven to be a successful and profitable market segment. Dropping 30% truck share for a company like Ford would be equivalent to Ford cancelling their entire line-up of F150s, a vehicle which has remained a top, if not the top, seller in the US for many years. In addition, the proposals preferential treatment for large trucks and pick-ups further makes it unlikely that manufacturers would now prefer to market cars. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 9-10]

NHTSA states in the NPRM that 'the increases in technology application necessary to achieve the projected improvement in fuel economy will entail considerable monetary outlays'. Volkswagen agrees. NHTSA further estimates that the program will require a combined car/truck industry outlay of approximately $157 billion for 2017 through 2025. What is lost in the broad statement is the disparity in investment required for cars versus trucks. As shown in below in Table 2-3, the outlay for passenger cars far outweighs the investment required by light trucks. [See Table 2-3 on p. 10 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 10]

It is again important to stress that even within the truck segment, the stringency varies significantly. The investment data was not disaggregated to reflect investment requirements within the truck segment. Given the minimal requirement on larger trucks, Volkswagen must assume that the bulk of the truck investment shown in Table 2-3 is most likely concentrated amongst smaller trucks and SUVs. [EPA-HQ-OAR-2010-0799-9569-A1, p. 10]

The resulting cost increase disparity amongst manufacturers further illustrates the inequity of the program. As shown in Table 2-4, by 2021 the cost to Volkswagen per car as a result of the 2012-2016 and 2017+ regulation will exceed over $3300 per car. This is more than double the expected price increase for the fleet as a whole. [See Table 2-4 on p. 10 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 10]

Volkswagen continues to support a 4% per year stringency reduction from both passenger cars and light trucks as being the best balance between environmental objectives and market acceptance. However, given the commitments made by stakeholders to the overall framework provided within this proposal, Volkswagen offers the following amendments. [EPA-HQ-OAR-2010-0799-9569-A1, p. 26]

Volkswagen continues to support the concept that equal percent reductions in the order of 4% per year can be applied to both the car and truck fleet. In addition, the percent reduction for each fleet can also be equally applied across all footprint sizes. However, as mentioned above, given the extensive commitments made by stakeholders to the SNOI, Volkswagen finds it unlikely that the agencies will incorporate our principle for equal reductions from all cars and trucks. [EPA-HQ-OAR-2010-0799-9569-A1, p. 27]

Provide an alternative CO_2 reduction pathway for passenger cars which could provide needed flexibility and incentives to the segment of the fleet being most challenged with the highest annual CO_2 percent reductions (5% per year for Cars); [EPA-HQ-OAR-2010-0799-9569-A1, pp. 2 and 4]

The NPRM requires on average a 5% annual improvement in CO_2 emissions from passenger cars. This task is spread equitably across the footprint range of cars. Figure 2-2 illustrates yearly CO_2 targets for cars at the upper cut-point (56 ft2), lower cut-point (41 ft2) and EPA projected average car footprint (45 ft2). During the course of technical discussions with agency staff, Volkswagen supported a 4% annual percent reduction for passenger cars. Volkswagen based this position on both technical and market evidence. [See Figure 2-2 on p. 11 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 11]

EPA has predicted that over the lifetime of passenger cars covered by this rulemaking, the increasingly more stringent targets for cars will offset upwards of 1.2 billion metric tons of CO_2. Light duty trucks which on average face 3.5% annual CO_2 reduction will contribute approximately 800 million metric tons of reduction. [EPA-HQ-OAR-2010-0799-9569-A1, p. 11]

EPA predicts that during the 2017-2025 timeframe, the fleet will comprise of roughly 65% passenger car and 35% light truck. This is according to vehicle classification as defined by NHTSA. Figure 2-3 illustrates an example of EPA's projected MY2020 fleet distribution along with the accompanying CO_2 inventory by segment. [See Figure 2-3 on p. 12 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 11]

When normalized on a percent basis of per vehicle emissions (including VMT), passenger cars are expected to carry a higher burden of reduction as shown in Table 2-5. [See Table 2-5 on p. 12 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 12]

What is apparent in this data is that passenger cars are underweighted in emissions relative to their market share and trucks are overweighed in emissions. There is a value to the environment in promoting passenger cars and not incentivizing a move towards trucks. Incentivizing a shift away from cars and towards trucks will have a contradictory effect on the overall program GHG reductions. [EPA-HQ-OAR-2010-0799-9569-A1, p. 12]

The NPRM extends aggressive reductions for passenger cars into the 2017+ timeframe. Less demanding reductions are required for trucks. As discussed previously, Volkswagen contends that this will create market distortion and an incentive for a manufacture to reconsider future plans. In order to minimize the impact that this inequity could have within the market, an alternative pathway could be tailored to encourage manufacturers to continue offering cars, especially economy models which may otherwise have become less attractive in the marketplace. [EPA-HQ-OAR-2010-0799-9569-A1, p. 26]

Volkswagen proposes that EPA and NHTSA supplement the NPRM by including an alternative passenger car percent annual CO_2 reduction pathway. This pathway could consist of a series of annual reductions applied throughout the time period of the rule in lieu of the 5% per year currently proposed. Volkswagen believes that a combination of annual percent reductions can be determined which could help provide additional flexibility for passenger car fleets. [EPA-HQ-OAR-2010-0799-9569-A1, p. 26]

In principle, the concept of an alternative pathway would include a combination of lower percent reductions in early years coupled with increasing reductions in later years should technology and market factors make this feasible. Indeed this is similar to the treatment being afforded to the truck fleet. Volkswagen asks that a similar approach be offered for cars. [EPA-HQ-OAR-2010-0799-9569-A1, p. 26]

In addition to the alternative pathway being a compliance flexibility, Volkswagen believes it could also serve as an incentive to promote and provide support for the passenger car fleet. Volkswagen believes that a pathway could be developed which would provide support to low-emitting passenger cars to the same degree that other market segments, are being incentivized through their unique credit programs. As an example, the agencies could benchmark the degree of support being provided to full-size trucks. We contend that this is a reasonable approach and would not amount to an excessive 'loophole' or 'give-away' since it would be consistent with flexibilities found to be useful elsewhere. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 26-27]

d. Requires unequal % CO_2 reductions across the truck fleet --large trucks are benefited with minimal requirements; [EPA-HQ-OAR-2010-0799-9569-A1, p. 6]

Volkswagen maintains our original position that 4% per year for both cars and trucks has the most potential to create a balanced, effective proposal. Further, our suggestion is that the 4% reduction be equally applied to all sizes of vehicles within each compliance category. EPA claims that the average truck stringency for 2017-2025 is approximately 3.5% per year. This is less than the average reduction suggested by Volkswagen. In addition the 3.5% is a broad characterization of the burden being applied to the truck category as a whole. Volkswagen points out that upon closer examination the 3.5% is not equally applied across the whole category. As illustrated in Table 2-7, it is clear that large light trucks are provided significantly lower percent reduction stringencies when compared to the projected average sized truck, or a small truck with a footprint closer to the lower curve cut-point. [See Table 2-7 on p. 19 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 18]

This is especially evident within the first several years of the program when the stringency for larger trucks hovers around or even less than 1%. The least efficient vehicles offered in the market will be given at three years before any significant increases in efficiency are required. [EPA-HQ-OAR-2010-0799-9569-A1, p. 19]

The result is inequitable compliance obligations for various types of trucks. Figure 2-8 illustrates the decreasing CO_2 targets in g/mile CO_2 for trucks at the lower and upper footprint ranges. The dashed lines illustrate a forward trending projection of the 2012-2016 stringencies carried forward into the 2017-2025 timeframe. [See Figure 2-8 on p. 19 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 19]

In general for the smaller trucks, the reductions for 2017-2025 are roughly in line with the reduction trend from 2012-2016. However, for the larger light trucks, the proposed targets deviate away from the 2012-2016 trend line becoming less stringent on a percent basis. The blue shaded area is a representation of the pullback in the stringency provided for these vehicles. Further, the green shaded area in Figure 2-8 includes the additional credits available explicitly to 'game changing' full-size pick-up trucks that compose the majority of vehicles populating this footprint range, i.e. the full-size trucks credits. These credits further expand the area of the shaded region, increasing the gap between small and large trucks even further. [EPA-HQ-OAR-2010-0799-9569-A1, p. 20]

It is important to note that the top two selling vehicles for 2011, the Ford F150 and Chevrolet Silverado, with combined sales of nearly 1 million vehicles (approximately 8% of the entire US market light duty market) will be eligible to reside within the blue and green region of Figure 2-8. [EPA-HQ-OAR-2010-0799-9569-A1, p. 20]

The shaded region in Figure 2-8 not only represents competitive inequity, but also lost opportunity for CO_2 reduction from the very segment of the fleet with the highest emissions. Volkswagen acknowledges that vehicles within this footprint range may feature duty-cycles which may preclude adoption of certain fuel saving technologies or features, i.e. heavy duty towing or off-road capability. This however is not a unique challenge limited to vehicles with larger footprints. Smaller SUVs or trucks in some cases may feature near equal capability and consumers are no less demanding to this segment versus others. [EPA-HQ-OAR-2010-0799-9569-A1, p. 20]

Some stakeholders have claimed that the latter half of the 2012-2016 rule created an excessive stringency on larger light trucks, and that these vehicles were somehow more challenged than other vehicles. The lower stringency being proposed for 2017-2025 is intended to provide 'breathing room' to allow time for the larger trucks to catch up with the requirements. Volkswagen disagrees. We again refer to Table 2-7 which clearly shows for 2012-2016 that larger trucks already benefited from lower percent requirements compared to less-emitting smaller trucks and SUVs. In addition, the RIA indicates that a leading full-size truck already available in 2011 is close to being compliant with standards for the 2017+ timeframe. [EPA-HQ-OAR-2010-0799-9569-A1, p. 20]

Table 3.12-1 in the EPA RIA showcases vehicles which are at or near compliance with the 2017+ expected targets. Included in this list is a non-hybridized version of a large pick-up truck which remains the number one selling vehicle in the US, selling over 500,000 units per year. EPA’s data indicates that the 2011MY of this vehicle achieves 372 g/mi and has about a 4% gap from complying with its 2017 targets. EPA included assumptions regarding A/C credit usage in making this determination. [EPA-HQ-OAR-2010-0799-9569-A1, p. 20]

Volkswagen created an internal model to project the CO_2 performance of this vehicle. The model disaggregated the sales into various powertrain and wheelbase (affects footprint) combinations as shown in Figure 2-9. For simplification, all the pathways are not shown. The model then applies publically available EPA fuel economy and CO_2 emissions data for each of the resulting pathways and compares them with the resulting footprint target which varies based on wheelbase. Some of the combinations earn credits, while others earn debits. The compliance of the model as a whole was then determined assuming credit transfer amongst the powertrain/footprint combinations. [See Figure 2-9 on p. 21 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 20]

The RIA compares current model year performance with the expected footprint target for 2017 and beyond. For this sample vehicle, EPA claims that the truck will fall short of its target by 4%. This assumes that the vehicle receives no fuel saving technology upgrades from 2011 to 2017. Volkswagen's calculations confirms the claim that the stringency imposed on this vehicle by the 2012-2016 program indeed is challenging in the later years and results in a debit for 2015 and 2016. However, it should be noted that the vehicle earns credits in 2012 and 2013 sufficient to cover the debits in 2015 and 2016. Regardless, the credits would be consumed and the vehicle still faces a shortfall beginning in 2017. [EPA-HQ-OAR-2010-0799-9569-A1, p. 21]

What is important to consider is that the RIA shortfall assumes no application of fuel saving technology from 2011 to 2017, a full seven years. Volkswagen exercised the model by using two pathways to apply fuel saving technology. The first was to apply an average annual improvement for each model year, using the average of 1-2% per year as has been claimed in the past as a reasonable annual improvement in fuel economy. The other pathway recognizes that improvements may not necessarily be made on an annual basis and instead are applied in incremental steps at regular redesign intervals. For this pathway Volkswagen applied a suite of low-cost technologies4to the vehicle using EPA assumed costs and effectiveness and waited until 2017 to make the update. This provides a five year design cycle assuming the sample truck was potentially redesigned in 2011. An additional application of technologies is made in 2022, again providing for a 5-year design cycle. The approach results in an average year-over-year reduction of 1.2%. [EPA-HQ-OAR-2010-0799-9569-A1, p. 21]

Furthermore, Volkswagen refrained from assuming any adoption of HEV technologies for this vehicle. Assuming that the minimum deployment thresholds are met, this would have triggered the 'game changing' technology credit of 10 or 20 g/mi CO_2 depending on the degree of hybridization. Volkswagen did not include the HEV incentive because the model showed that the credits were simply not needed. Either of the conventional technology pathways provided significant compliance margins resulting in the pick-up truck generating credits throughout most of the 2012-2025 timeframe. The HEV incentive would have only 'piled on' to the credits being earned resulting in a windfall for this vehicle. Unless the credits were needed in another segment of the fleet, they would not be worth the investment required to earn them. [EPA-HQ-OAR-2010-0799-9569-A1, p. 21]

However, EPA has stated in the NPRM that it is their understanding that credits will only be transferred from cars to trucks and not vice-versa. Therefore, one can expect limited to no hybridization of this full-size truck. This does create doubt regarding the need to create the full-size truck credit incentive for 'game-changing' technologies. [EPA-HQ-OAR-2010-0799-9569-A1, p. 22]

Modest application of conventional technologies to full-size pick-ups, coupled with the benefit of low annual CO_2 reduction requirements, more than provides for a comfortable compliance margin for this segment of the fleet. Volkswagen questions why the other segments of the truck fleet, let alone the car fleet, must then be taxed with the role of carrying the more significant CO_2 reduction burden? [EPA-HQ-OAR-2010-0799-9569-A1, p. 22]

As discussed in Section 2.7, Volkswagen predicts that credits will be accumulated within the large truck and full-size truck segment due to the combination of lower stringency and segment exclusive benefits. Should this occur, then the fundamental premise upon which the reduced stringencies and unique credits are based will need to be reevaluated. [EPA-HQ-OAR-2010-0799-9569-A1, p. 27]

On the other hand, the NPRM and other stakeholders have claimed that large trucks face the most challenging reductions. Volkswagen disagrees. However, even if this proves to be true, then large trucks would be at or above their CO_2 g/mi targets, and would be mired in debits. Credits earned by this segment simply would not exist. Therefore there is no need for non-existent credits to be bankable or transferable to other segments. [EPA-HQ-OAR-2010-0799-9569-A1, p. 27]

Either way, large trucks, by claiming to be more uniquely challenged than any other segment of vehicles covered by this regulation are being afforded significant benefits not awarded anywhere else. It is therefore reasonable that the agency confine the reach of the benefit within the large truck segment which is demanding it. What is unreasonable is to claim such a degree of excessive hardship as to warrant less than one-fifth the stringency requirement of other segments and then expect that benefit to be transferable. [EPA-HQ-OAR-2010-0799-9569-A1, p. 27]

---

2 EPA projects the average footprint for trucks at approximately 53.5 sq-ft for MY2017-2025.

3 The upper cut-point of the Light Truck curve changes throughout 2017-2025, therefore VW used 72 sq-ft as a representation of vehicles near or above the upper cut-point. This is the footprint of a major large pick-up truck representative of vehicles within this class.

4 The technologies include electric power steering (EPS) + improved accessories (IAAC1) + aggressive shift logic (ASL-1) + low rolling-resistance tires (LRRT) + and low-drag brakes (LDB). Total cost was less than $300 and VW expects that this selection of technologies is neither complicated by synergy effects nor degrades towing and off-road capability, except possibly for the LRRT which may then be an option. MY2022 applies level-1 mass reduction (MR-1) and a high efficiency gearbox (HEG).

Organization: Weiner, L.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 107.]

Additionally, in the early years of the proposed standards, pickup trucks are not required to improve with the same rate as passenger cars, but there are incentives for manufacturers to apply advanced technologies to pickup trucks. So it's critical that the efficiency of the trucks not lag behind cars.

Organization: Whitefoot, K. and Skerlos, S.

To reduce the incentives to upsize the passenger car and light truck fleets, the slopes of the fuel economy curves for passenger cars and light trucks should be flattened with corresponding changes made to the CO_2 curves. [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

Our recent analysis (attached) suggests that manufacturers likely have a profitable incentive to upsize their vehicle fleets in response to the footprint-based standards, through a combination of adjusting prices to shift production to larger vehicles and increasing vehicle footprint during redesign. [See the attachment in Docket number EPA-HQ-OAR-2010-0799-9447-A2] [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

NHTSA and EPA should develop a model to analyze profitable incentives to upsize the vehicle fleet in response to the footprint-based standards. [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

The analysis also indicates that the incentive to upsize is greater for light trucks than for passenger cars, encouraging a further divergence of the sizes of these two classes. [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

The slope for the light truck curves should be flattened by a larger percentage than the slope of the passenger car curves to reduce the incentive to upsize light trucks to a larger extent than passenger cars. [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

Minimum standards for light trucks should be set at a high-enough level to ensure that fuel economy improvements in the total fleet are close to projected levels even if the production of light trucks increases relative to passenger cars. [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

NHTSA and EPA should conduct sensitivity analyses of consumer preference scenarios on projected improvements of fuel economy and GHG emissions. [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

Incentives to upsize the vehicle fleet

While we understand that NHTSA and EPA wish to reduce incentives to downsize the vehicle fleet, we believe that the proposed standards overshoot that goal and actually create incentives to upsize the fleet. We recently conducted an analysis, published in Energy Policy, which tests the hypothesis that the footprint-based fuel economy standards do not create a profit incentive for manufacturers to increase the average size of their vehicle fleet (attached). The analysis considered a very large range of average consumer preferences for vehicle size, fuel economy, and acceleration performance so that the set of plausible scenarios of consumer preferences are captured in the analysis. The findings indicate that the incentive for manufacturers to upsize their fleets exists over almost all of these scenarios. Only in the scenarios where average consumer preference for footprint is very low ($340 per sq ft) and average preference for acceleration performance is very high ($5,500 per 0.01 hp/lb) do the results indicate an incentive to slightly downsize the fleet. In all other scenarios, the incentive to upsize the fleet leads to substantially (5-15%) higher fuel consumption and GHG emissions than would have otherwise been achieved without an incentive to upsize the fleet. Furthermore, the analysis indicates that the incentive to upsize is larger for light trucks than for passenger cars, increasing the divergence of sizes of these two classes. This finding needs to be considered from the traffic safety perspective since the relative size of vehicles in collisions is an important risk factor. [See the attachment in Docket number EPA-HQ-OAR-2010-0799-9447-A2] [EPA-HQ-OAR-2010-0799-9447-A1, p. 2]

The results of our study suggest that the risk of backsliding during MYs 2017-2025 is substantial. Therefore, we encourage NHTSA and EPA to revise the standards to reduce the incentives to upsize the U.S. vehicle fleet. The slopes of the fuel economy curves for passenger cars and light trucks should be flattened (with corresponding changes made to the CO_2 curves) to reduce incentives for manufacturers to upsize their passenger car and light truck fleets. [EPA-HQ-OAR-2010-0799-9447-A1, p. 2]

Furthermore, the fuel economy curve for light trucks should be flattened to a larger extent than the passenger car curve to reduce the incentive to upsize light trucks even further than passenger cars, thereby increasing the divergence of vehicle size between these two classes. [EPA-HQ-OAR-2010-0799-9447-A1, p. 2]

Unfortunately, the proposed rule increases the risk of backsliding by making the MY2017-2025 light truck curves steeper than the MY2011-2016 curves. These steeper curves further raise the incentives to produce more light trucks overall (compared to passenger cars) and more large light trucks (compared to small light trucks). NHTSA and EPA state that the light truck curve was made steeper because large pickup trucks would be less capable of achieving further improvements in fuel efficiency without compromising load carrying and towing capacity. However, because the standards are fleet average standards, no specific vehicle must meet its target as specified by the curve. Therefore, efficiency improvements in smaller light trucks could offset the difficulties of improving fuel efficiency of larger light trucks. We encourage NHTSA and EPA to revise the light truck curves so that the risks of upsizing are reduced. [EPA-HQ-OAR-2010-0799-9447-A1, p. 2]

Improve analysis of incentives to upsize the vehicle fleet.

The risk of upsizing the vehicle fleet warrants a greater level of analysis. While NHTSA and EPA state that the fuel economy and CO_2 curves were chosen to minimize any incentive to increase or decrease vehicle size, no quantitative analysis is presented to support this. Potential incentives for automakers to upsize their vehicle fleet—by increasing sales of larger vehicles, or making vehicle models larger during redesign, or some combination—need to be carefully analyzed to ensure that the projected improvements in fuel economy and GHG emissions are realized. [EPA-HQ-OAR-2010-0799-9447-A1, p. 3]

NHTSA and EPA state that they do not consider any incentives to upsize the vehicle fleet in their analysis because they believe (1) that production shifts toward larger vehicles would run counter to market demand and (2) that redesigning vehicles to increase their footprint would be significant enough to be unattractive as a measure to take solely to reduce compliance burdens. However, the agencies do not provide any data to support that average vehicle footprint has been decreasing over time. By EPA's own data, production of small cars has been decreasing since the 1990's and production of large trucks has been increasing. 2 Furthermore, it is clearly difficult to predict future consumer preferences for vehicle size and other relevant vehicle attributes. Therefore, sensitivity analyses are needed to assess the impact of changes in consumer preferences on the projected improvements in fuel economy and GHG emissions. [EPA-HQ-OAR-2010-0799-9447-A1, p. 4]

We encourage NHTSA and EPA to develop a model to assess the risks of vehicle upsizing. The model should analyze manufacturers' profitable incentives to adjust vehicle dimensions as well as adjust the prices of their vehicles to shift production among their fleet. [EPA-HQ-OAR-2010-0799-9447-A1, p. 4]

---

1 Attribute-based standards can guarantee that the average fuel economy of the total fleet is at least as great as the lower-bound fuel economy of the light truck standard (the minimum fuel economy target assigned to any light-duty vehicle). However, in the proposed standards this value is only 25.25 mpg for MY2020. Requirements to set the standards such that they are technically feasible and economically practicable preclude raising this value to 35 mpg for MY2020. Therefore, the only way to ensure that the total fleet has a combined fuel economy average of 35 mpg by 2020 is to establish additional "backstops" in the standards.

2 U.S. Environmental Protection Agency. Light Duty Automotive Technology, Carbon Dioxide Emissions, and Fuel Economy Trends: 1975 through 2009. EPA420-R-09-014. pp. 23-24. Available at http://www.epa.gov/otaq/cert/mpg/fetrends/420r09014.pdf

Response:

EPA received a significant number of detailed comments on the shape of the curves – many of which questioned the relative stringency of the car and truck curves, and maintained that they favor trucks at the expense of cars. Others commented that the slope of the curves will create incentives for manufacturers to upsize the fleet, or that the location of cutpoints will encourage downsizing of the smallest vehicles. Descriptions of the agencies' methods for determining curve slope, cutpoints, and relative car and truck stringencies are provided in sections II.C.4 and 5, section III.B.2, and sections III.D.6 and 7 of the preamble, and chapters 2.4.2, 2.5.1, and 2.5.2 of the joint TSD. Detailed responses to most of the comments received on these topics are provided in these sections, while a summary of these responses, along with additional information, is provided below.

Response to comments that the curves are too steep

ACEEE objected to the agencies' adjustments to the truck curves based on density, which together with the revised curve-fitting methodology (revised from the MYs 2012-2016 rule) had the result of increasing the truck curve slope for this rule. The commenter further stated that in the proposal, the EPA did not provide evidence that load-carrying and towing capability of full-size trucks might be compromised. The agencies have added an in-depth explanation of the justification for revising the curve fitting methodology in chapter 2.4.2.4 of the Joint TSD and III.D.6.c. The main points of this explanation are summarized here: In discussions with large truck manufacturers prior to the proposal, they expressed their belief (and EPA agrees) that the light truck standard should be somewhat steeper after MY 2016, primarily because, after more than ten recent years of progressive increases in the stringency of applicable CAFE standards, manufacturers of large pickups would have limited options to comply with more stringent standards. Given the relatively few platforms which comprise the majority of the sales at the largest truck footprints, inappropriately stringent standards for this important segment of the truck fleet would require overly aggressive advanced technology penetration rates. See preamble Table III-35 , where under alternative 2, we project that 20% of the light truck vehicle fleet will be MHEV or HEV (the projection is 18% MHEV) in MY 2021; . By comparison, the final rule is projected to be 13% MHEV & HEV (11% MHEV). In MY 2025, the rate of strong hybrid (HEV) technology more than doubles in the 20g more stringent alternative standard compared to the final standard (Table III-37)., The agencies were concerned at proposal, and remain concerned, about issues of lead time and cost with regard to manufacturers of these work vehicles. EPA further believes that inappropriately stringent standards could create an incentive for these manufacturers to choose to downpower, modify the structure, or otherwise reduce the utility of these work vehicles. Therefore, the agencies revised the curve-fitting methodology, and thus changed the slope of the truck curve from the curve shape in the MY 2016 standards, in order to provide a clearer path toward compliance for manufacturers of these vehicles, and reduce the potential that new standards would compromise utility characteristics such as load-carrying and towing capability.

While the comments do not dispute the validity of the curve-fitting method, or the appropriateness of considering the unique requirements of trucks, ACEEE objected to the contribution that these analysis techniques make towards achieving a policy objective, stating "we believe that adjusting the analytical approach to yield curves satisfying certain policy considerations is inadvisable. It would be preferable to choose the most robust analytical approach, and then to make exceptions as needed for a limited period to accommodate those policy considerations, and to explain the targets in those terms." ACEEE also stated that "subjectivity to the technical analysis invites unnecessary challenges to the standard-setting process". EPA notes that a curve fitting process such as the one conducted for this rule will inevitably involve choices between various reasonable approaches. EPA maintains that the approach used for this rule is both reasonable and appropriate. EPA appropriately considered factors of technology cost, feasibility, lead time, and consumer acceptance in applying the density adjustment to the truck curve, in order to achieve the policy goal of avoiding incentives for manufacturers to reduce the utility of their work vehicles. A more detailed response to ACEEE's comments on this topic are provided in section II.C.4.d of the preamble and chapter 2.4.2.4 of the Joint TSD.

ACEEE requested further clarification on specific text in chapter 2.4.2.10 of the Joint TSD, stating "It is also puzzling that the agencies' analysis shows that trucks' HP-to-weight ratio increases only slightly with footprint (TSD p.2-17), yet "pick-up trucks must be more powerful, than their low 'density' nature would statistically suggest." If pick-up trucks have high horsepower and low weight, their HP-to-weight ratios should be especially high. An explanation of this apparent contradiction would be helpful". In response, EPA's statistical analysis does indeed show that the HP-to-weight rations are especially high. This is not in contradiction with the observation that pick-up trucks must be more powerful than would otherwise be expected for a low density vehicle.

Whitefoot and Skerlos submitted their findings supporting commenters' contention that the proposed (and now final) curve shapes create an inherent incentive to upsize the fleet (which would dilute the rules' benefits), and recommended that the curve slopes be flattened to reduce this perceived incentive. This paper was referenced by other commenters (ACEEE, CBD, NACAA, Honda) in support of their comments urging a flattening of the curves. EPA recognizes the significant amount of effort that went into the analysis of Whitefoot and Skerlos, and considers that the concepts presented have potential merit. However, EPA notes that the authors assumed different inputs than the agencies actually used in the MYs 2012-2016 rule regarding the baseline fleet, the cost and efficacy of potential future technologies, and the relationship between vehicle footprint and fuel economy. Were the agencies to use the Whitefoot and Skerlos methodology with the actual inputs to the MYs 2012-2016 rules, it is likely that different results would be obtained from those in the Whitefoot and Skerlos study. Whitefoot and Skerlos acknowledged the potential uncertainty when interpreting their results: "designing footprint-based fuel-economy standards in practice such that manufacturers have no incentive to adjust the size of their vehicles appears elusive at best and impossible at worst." EPA recognizes that based on economic and consumer demand factors that are external to this rule, the distribution of footprints in the future may be different (either smaller or larger) than what is projected in this rule. However, EPA continues to believe that there will not be significant shifts in this distribution as a direct consequence of this rule.

CBD, in addition to citing the Whitefoot and Skerlos study, commented that the previous shift in the fleet from cars to trucks was the result of previous difference in car and truck stringencies, and that in this rule, "the fact that incentives for upsizing would be created simply cannot be disputed". EPA disagrees. While no single vehicle need meet its emissions target, for manufacturers to comply with these standards, efficiency improvements will be required of all vehicles, cars and trucks, large and small. The current standards are different from previous standards in terms of stringency, the use of a footprint attribute, and the lack of a provision allowing manufacturers to pay a penalty for noncompliance. We therefore do not believe it is justifiable to draw conclusions about manufacturers' responses to this rule based upon responses to previous flat CAFE standards.

IPI also maintained that the standards would encourage upsizing, and proposed that the curves should be flat. IPI is therefore suggesting that the GHG standard should not be attribute-based, although they acknowledged that EPCA/EISA expressly requires that CAFE standards be attribute-based and defined in terms of mathematical functions. For purposes of harmonization (in addition to the reasons articulated in TSD 2.1 and 2.2), EPA has also issued an attribute based standard. The agencies have concluded that a properly designed footprint-based approach provides the best means of achieving the basic policy goals, as outlined in section II.C.2 of the preamble, while not creating inappropriate incentives to increase or reduce vehicle size in ways that could increase fuel consumption and GHG emissions, or impact overall safety.

Response to comments that the cutpoints should be adjusted

IIHS expressed some concern that the location of the cutpoint at the lower extreme curve where footprint is smallest would encourage manufacturers to downsize vehicles at or below the cutpoint in order to gain additional credits. The commenter proposed that the cutpoint be moved further to left to reduce the likelihood of this type of downsizing. Global Automakers proposed setting the cutpoint for the smallest light trucks at approximately ten percent of sales (as for passenger cars) rather than at 41 square feet. The comments from IIHS and Global Automakers represent two opposing positions on the placement of the left cutpoints. EPA agrees with IIHS that moving the 41 square foot cutpoint to an even smaller value would additionally discourage downsizing of the smallest vehicles. However, as discussed in section II.C.5.a of the preamble, EPA believes that consumer preferences are likely to remain such that manufacturers will be unlikely to deliberately respond to today's standards by downsizing the smallest vehicles. For manufacturers, very small footprint vehicles create additional design challenges for the packaging of components and occupants, as well as the need for additional safety equipment to compensate for reduced crush spaces. In EPA's judgment, placing the lower cutpoints at 41 square feet for both car and truck curves continues to strike an appropriate balance between (a) not discouraging manufacturers from introducing new small vehicle models in the U.S. and (b) not encouraging manufacturers to downsize small vehicles. EPA will review trends in footprint size in the car and truck markets and reassess the appropriateness of the lower cutpoint position during the mid-term evaluation.

Several commenters maintained that placing the right cutpoint for trucks at 74 square feet (compared to 66 square feet in the MYs 2012-2016 rule) would reduce stringency for these vehicles (ACEEE) and possibly encourage upsizing (Sierra Club, Volkswagen), even though there is no safety-related reason to discourage downsizing of these trucks. ACEEE went on to point out that in the MY2012-2016 rule, the agencies rejected requests to increase the cutpoint from 66 square feet. EPA agrees that the approach used in this rule is different from the curve fitting approach used in the MY2012-2016 rule. As a result of this revised curve fitting approach, we now account for more truck models that have footprints greater than 66 square feet. Specifically, as described in chapter 2.4.2.10 of the Joint TSD, some models of pickup trucks which, for example, are available in different cab configurations with different wheelbases, have been disaggregated for this rule and are represented individually, which leads to a slightly different outcome in the regression results than had they remained aggregated.

Two commenters suggested that the agencies provide an alternate emissions target for light trucks larger than 60 square feet (Sierra Club) or 66 square feet (ACEEE) that exceed the sales projected in the rule. In response, in EPA's judgement, there is minimal risk that manufacturers would respond to this upward extension of the cutpoint by deliberately increasing the size of light trucks that are already at the upper end of marketable vehicle sizes. Such vehicles have distinct size, maneuverability, fuel consumption, storage, and other characteristics, and are likely not suited for all consumers in all usage scenarios. Further, larger vehicles typically also have additional production costs that make it unlikely that these vehicles will become the predominant vehicles in the fleet. For this reason, and others described in section

II.C.5.b of the preamble and chapter 2.5.2 of the joint TSD, the EPA does not expect that gradually extending the cutpoint to 74 square feet will create incentives to upsize large trucks. Therefore, EPA does not believe that the suggested provision of an alternate emissions target for the largest light trucks that exceed projected sales is warranted.

Response to comments on the difference in car and truck stringencies

The comments on the relative car and truck stringency were largely divided between NGOs and OEMs that were concerned with the shape and relative rate of increase of the truck curve, and OEMs who expressed concern about their ability to comply with a large truck standard that continued to increase in stringency at the rate of the MY 2016 standard.

ICCT and CBD commented that the lower annual rate of improvement for light trucks from MYs 2017 to 2021 will potentially undermine the benefits of the rule. CBD went on to state that the consideration of the unique attributes of trucks "does nothing to explain the lack of the required ratable annual increases", and that "the rulemaking demands the least from the most profitable segment of the automotive industry". CBD further stated that there is no showing that light trucks, including pickups, cannot both preserve hauling and towing utility and achieve aggressive fuel economy. Toyota similarly commented the standards require "virtually nothing of the largest vehicles on the road". EPA disagrees with this assessment for the reasons below.

First, as explained in preamble section III.D.6.b, we project relatively little trading between the car and truck fleets (and vice versa). From the reference case emission level for combined car and truck fleets (sales weighted average of approximately 250 g/mile) to the control case (sales weighted average of approximately 163 g/mile) is a drop of approximately 90 g/mile. In this context, 4 g/mile of credits transferred from the truck fleet to the car fleet is relatively small. Disproportionate credit transfers would indicate a lack of balance in relative stringencies of the standards, but we see the opposite. This demonstrates an appropriate balance between car and truck stringencies. Moreover, in response to CBD, we agree that fuel economy, GHG emissions control, and preserving hauling and towing utility are not mutually exclusive. Indeed, EPA's methodology for assessing costs includes costs to preserve those utilities and to implement emission control/fuel economy technology. However, EPA remains concerned about adopting standards creating strong incentives for manufacturers to choose to reduce hauling and towing capacity as a compliance strategy. Of equal or greater significance, EPA has identified legitimate concerns with available lead time, especially through MYs 2017-2021, reflecting that the large truck segment is dominated by relatively few vehicle platforms with relatively large sales, and this limited number of vehicle platforms makes rapid technology changes a greater challenge than in other market segments. This is partly due to the lack of platform sharing, a flexibility that smaller vehicles have.[2] The pick-up trucks also tend to have longer redesign

[2] Although certain intermediate volume manufacturers, especially in the luxury car market, also have a relatively smaller number of platforms (relative to larger manufacturers), EPA believes the concerns are more acute with respect to work trucks, in part because these vehicles serve special needs (small businesses, ranchers, farmers, etc.) and that it is important

cycles, as discussed in section III.D.6.c of the preamble. The utility requirements of pick-up trucks relative to smaller vehicles results in longer development times for validation of a new platform. Pick-up truck product validation occurs across a broader range of gross vehicle weights for each platform due to a relatively large payload capacity and can include validation of trailer towing capability for multiple trailer configurations. There are also issues of consumer acceptance of the most advanced technologies in the larger light trucks. See generally preamble section III.D.6.

Second, as described in section III.D.6.c of the preamble, the year-to-year stringency of the standards were set with consideration of the technical challenges involved in applying efficiency technologies to these vehicles as well as lead time concerns in the early years of the programs. Additionally, even with these considerations, the trend of a gradually widening gap in the early model years of the rule is reversed during the MY 2021-2025 period, as described in detail in section III.D.7 of the preamble. EPA believes that the increase in stringency for the truck standard in the latter phase of the rule is a reasonable approach for avoiding a large gap between car and truck curves while also taking account of the challenges of implementing efficiency technologies in trucks during the first phase of the rule. Furthermore, the promulgated standards promote similar levels of emission reductions for smaller trucks and for cars of the same size. For example, the average year-to-year increase in the target level over the entire MY 2017-2025 period is identical for cars and trucks at the 41 sq. ft. curve cutpoint (5.1 percent per year), and is nearly the same over the initial MY 2017-2021 period (4.8 and 4.5 percent per year, for cars and trucks, respectively.) In addition, as shown in preamble Table III-57, by MY 2025 the gap for larger footprint vehicles is at levels similar to the MY 2012-2016 rule, while for smaller footprint vehicles, the gap is less than during the MY 2012-2016 rule.

ACEEE, citing Table III-53 in the NPRM, also questioned how the proposed standards, finalized by this rule, could be superior to the alternatives given the cost differential between cars and trucks in MYs 2017-2020. Similarly, Honda and Consumers Union cited the lower fleet average compliance cost for trucks as evidence that the truck standard is not stringent enough (or from Honda's comments, for large trucks, in particular).

EPA does not agree that it is necessarily preferable to have equal compliance costs for cars and trucks in each model year. EPA notes that while compliance costs are initially lower for trucks than for cars, the costs increase relatively faster for trucks in the latter phase of the rulemaking, as shown in Table III-56 and Figure III-5 of the preamble. The lower initial cost for trucks is a reflection of the lower initial stringency (relative to cars), which as discussed above, and in sections III.D.6.b and III.D.7 of the preamble, is due to considerations of the technical challenges and lead time concerns involved in applying efficiency technologies to these vehicles. As Ford Motor Co. noted in its comments: vehicles equipped with trailer tow packages include

---

that this basic market demand not be jeopardized. See International Harvester v. EPA, 478 F. 2d 615, 640 (D.C. Cir. 1973) (EPA required to consider issues of basic demand for passenger vehicles in making technical feasibility and lead time determinations; however, EPA need not accommodate every single model type) additional features that clearly distinguish them from passenger cars, and can negatively impact fuel economy:, including auxiliary transmission oil coolers, upgraded radiators, trailer hitch connectors and wiring harness equipment, different steering ratios, upgraded rear bumpers and different springs for heavier tongue load (for upgraded 'max' trailer tow packages), body on frame (vs. unibody) construction to support capability and an aggressive duty cycle, lower axle ratios for better pulling power/capability, and greater aerodynamic drag. Even for trucks with the same or similar footprint to cars, these features result in greater costs and technical challenges to apply GHG emission control/fuel economy technology.

Therefore, EPA does not agree with the commenters that lower compliance costs will favor manufacturers with a large proportion of trucks, noting that in the early years, these manufacturers will need to invest more in technology development, while in later years, compliance costs for trucks are similar to (or even slightly higher than) costs for cars. ACEEE requested that EPA provide these cost estimates for all years for each manufacturer's car and truck fleets. This information was available in chapter 5.1 of the draft RIA, and is also provided in chapter 5.1 of the final RIA.

Referring to the lower initial stringency for trucks, ACEEE expressed concern that that manufactures will use the initially lower truck standards to delay implementation of efficient technologies, and then use this circumstance to argue in the mid-term evaluation for relaxed standards. EPA does not believe this concern in justified. Manufacturers must comply with the standards on their entire fleet; thus a given vehicle is not required to meet any specific GHG standard. Therefore, delaying technologies on any portion of a full-line manufacturer's fleet will hurt their ability to comply across their fleet and thus be non-competitive in other portions of the market. Moreover, while we believe that the stringencies of the program can be met (and are thus feasible), EPA acknowledges that they will be challenging for all manufacturers and that they will all incur significant costs. The likelihood that a manufacturer will slow down the implementation of technology on a certain fraction of their (large sales) fleet just prior to entering the 2022-2025 period where stringencies are increasing at 5% per year, seems extremely unlikely. More likely, if there are cost effective technologies that have not yet been applied, the manufacturer will implement them in advance in order to earn credits for the 5%/yr period (this is the principle of "multi-year planning"). EPA will carefully monitor this issue during the mid-term evaluation.

Others commented more generally that throughout the rulemaking timeframe, the difference between car and truck curves is too large, which places manufacturers which mainly produce passenger cars at a disadvantage (Volkswagen, Toyota, Honda, and Mercedes). These comments are not supported by the analysis conducted for this rule. As just explained there are no indications in EPA's analysis that either the truck or car standards will encourage manufacturers to choose technology paths that lead to significant over or under compliance for cars or trucks, on an industry wide level. A consistent pattern across the industry of manufacturers choosing to under or over comply with a car or trucks standard could indicate that the car or truck standard should be evaluated further to determine if the relative stringency is appropriate in light of the technology choices available to manufacturers, and the costs of those technology choices. As detailed in section III.D.6.b of the preamble, that is not the case for the final car and truck standards, for which we project only a relatively small overall degree of net credit transfers from the truck fleet to the car fleet. EPA's evaluation of the alternative standards led to the same conclusions. EPA thus continues to believe that the relative stringency of the car and truck curves is reasonable and appropriate.

Several commenters maintained that the lower stringency of truck standards would encourage manufacturers to "game" the rule by adding features such as 4WD for the primary purpose of satisfying the requirements for classification as a truck (ICCT, NRDC, UCS). EPA recognizes that significant differences in the year-to-year stringency for cars and trucks could increase the incentives to reclassify cars as light trucks. However, this reclassification comes at significant cost to the manufacture, with added production and component costs, as NRDC acknowledged in their comments, and to the consumer in the form of reduced fuel savings and a higher purchase price (for example, NRDC quoted an additional cost of $1,400 for the 4WD option on the RAV4). EPA thus does not agree with these comments. In any case, EPA believes the car and truck curves appropriately reflect the differences in cost between the car and truck fleets for adding efficiency technologies, as supported by the analysis conducted for this rule.

In comments related to the topic of "gaming", CBD expressed concern that the difference in stringencies would encourage consumers to shift purchases from cars to trucks (as opposed to the comments addressed above that the standards create incentives for manufacturers to "game"). EPA does not believe the relative stringencies will result in a shift of this type, given the increased costs to the consumer mentioned above, and that the vehicle attributes associated with the truck classification may not be desirable to car buyers. Currently, there are many consumers that prefer the 2WD car version over the more costly and less fuel efficient 4WD truck version. EPA believes that manufacturers will continue to offer the variety of vehicles that satisfy the range of attributes that consumers demand, rather than limiting the choices (for example by only offering 4wd truck versions of a model), which could in turn lead to loss of customers and market share. At the same time, as discussed in the introductory text of section III.D of the preamble, EPA acknowledges that manufacturers may decide to alter the utility of the vehicles which they sell, but this would not be a consequence of the rule but rather a matter of automaker business choice. Finally, on the issue of "gaming", EPA plans to review trends in the fleet mix during the mid-term evaluation (see section III.B.3 of the preamble; see also RTC section 15.3 response to POP Diesel).

Honda commented about the relative stringencies of small and large footprint trucks, and proposed that "vehicles other than full-size pickup trucks should receive similar consideration in preserving their utility". EPA notes that the technology penetration analysis conducted for this rule considered the costs of preserving utility for not only full-size pickup trucks, but for vehicles of all footprint sizes. At the same time, EPA believes that pickup trucks are often used in ways that are fundamentally different from the typical use of minivans and smaller SUVs cited by the commenter. For example, Ford, in its comments, provided data for the usage of the F150: "up to 82% of F-150 customers use their vehicles for hauling. Up to 41% haul on at least a monthly basis; and 72% of F-150 customers use their vehicles for towing. Up to 28% tow on at least a monthly basis". The particular type of vehicle usage is significant, since the additional engine power requirements will be greater for vehicles intended to tow and carry heavy loads than for vehicles designed for high volume (but lower density) passenger spaces, such as an 8 passenger minivan.

Honda also commented on the cost per percent CO2 reduction of some of the vehicle technology packages in our proposal. Honda uses the comparison of packages to argue that we have been unfair to smaller footprint trucks relative to larger footprint trucks. However, the packages chosen by Honda were not really appropriate for the specific vehicle models compared by Honda—the packages that Honda thought represent the Honda CR-V and the Ford F150 (among other similar/competing models). Better vehicle types and package choices would have been those shown in the table below since, in our proposal, we placed the CR-V in vehicle type 7 and the higher sales F150s in vehicle types 10 and 14. As shown, the $/% CO2 reduction for the CR-V is far more favorable than the F150 at $41 versus $62-$67, respectively. Similarly, in our final rule where we place the CR-V in vehicle type 7 and the F150 in vehicle types 17 and 18, the $/% CO2 reduction is again far more favorable for the CR-V than the F150 at $39-$43 and $61-$64, respectively. This indicates that on a dollars per percent GHG reduction metric, it is more cost effective to add technology and improve efficiency on the smaller vehicle type 7 (small SUV and Multi-Purpose Vehicle) than the larger vehicle type 17 or 18 (pickup trucks).

ICCT commented that with the exception of pickup trucks, full size cargo vans, and a few SUVs, the construction of cars and trucks are similar, and there is therefore no technical reason to separate car and truck curves. EPA notes that ICCTs list of "exceptions" make up the majority of the truck market. However, we acknowledge that there are a number of vehicle nameplates that are classified as both car and truck and that their primary attribute difference is the 2WD vs the 4WD option (there are other attribute differences such as ground clearance, approach angles, etc.). As noted above, the 4WD attribute has a significant impact on fuel efficiency, cost, and consequently consumer choice. Ford provided an example of how towing requirements can result in differences in fuel efficiency and cost, commenting, "the Ford Edge and the Ford Taurus have the same footprint, but vastly different capabilities with respect to cargo space and towing capacity. Some of the key features incorporated on the Edge that enables the larger tow capability include an engine oil cooler, larger radiator and updated cooling fans."

The cost and efficiency differences that arise from differences in the utility of cars and trucks are real and measureable. Thus, at this time, EPA believes that the classification of these vehicles on two separate curves is justifiable and reasonable.

2.2.3. Backstop Standards

Backstop Standards [EPA-HQ-OAR-2010-0799-9487-A1, p.87]

The NPRM requests comments on whether minimum CAFE levels (so called “backstop standards”) should be adopted for import passenger car and light duty truck fleets. The need for backstop standards had been assessed during the MY 2012-16 GHG and fuel economy standards regulatory process. The agencies noted that substantial comments had been provided on both sides of the issue, but in the end determined that backstop standards would not be necessary. That decision was primarily based on the confidence the agencies had in their fleet modeling and the lack of incentives for manufacturers to “game” their product line-up in such a way to undermine the anticipated gains of the program. [EPA-HQ-OAR-2010-0799-9487-A1, p.87]

Concerns about backstop standards that were raised by the Alliance in the context of the MY 2012-2016 rules remain in place today. The concept of backstop standards is inconsistent with Reformed CAFE, which is intended to allow manufacturers to build the full range of vehicles that consumers demand. Backstop standards are unlikely to come into play in the first place, but if they did, they could have the effect of unduly limiting consumer choice and hampering the industry’s ability to achieve the goals of continuing the national program as cost-effectively as possible. Further, we continue to believe that NHTSA does not have legislative authority to adopt backstop standards for the import passenger car and light duty truck fleets. [EPA-HQ-OAR-2010-0799-9487-A1, p.87]

Notwithstanding NHTSA's previous decision to forego backstop standards, the question whether backstop standards should be reassessed in the context of the MY 2017-2025 rulemaking is raised on the basis that NHTSA “recognize[s] that given the time frame of the current rulemaking, the agency cannot be as certain about the unlikelihood of future market changes.” [EPA-HQ-OAR-2010-0799-9487-A1, p.87]

The Alliance concurs that there is increasing uncertainty with respect to market conditions, technological advances, consumer demand, etc., as we look further and further into the future. It is this uncertainty that gave rise to the mid-term evaluation provisions, which we believe are an essential element of the MY 2017-2025 National Program rules. Any necessary adjustments to the standards based on market shifts or other unforeseen developments should be addressed pursuant to the mid-term evaluation process (for EPA) and the concurrent process of setting final, enforceable CAFE standards (for NHTSA). Apart from that, it is not helpful or desirable to layer additional requirements on top of the Reformed CAFE standards, since this would only serve to reduce flexibility and add complexity to the manufacturers' product planning efforts. We therefore oppose any consideration of additional backstop standards at this time and recommend that the agencies rely on the mid-term evaluation and the CAFE standard-setting process as their primary means for making any necessary adjustments to the stringency and structure of the program. [EPA-HQ-OAR-2010-0799-9487-A1, pp.87-88]

Organization: Center for Biological Diversity

D. NHTSA Should Adopt a Backstop to Ensure the Nationwide Fleet Moves Towards Greater Fuel Efficiency.

As noted above, the rulemaking is currently structured so that the fuel economy standard actually reached in each MY depends entirely on each manufacturer’s fleet mix during that year. If manufacturers shift towards a greater percentage of light trucks, or increase the size of their vehicles to trigger less stringent fuel economy standards, the overall fuel efficiency of the nationwide fleet will decrease. But Congress tasked NHTSA with prescribing ratable fuel economy standards for passenger automobiles and light trucks, not with merely estimating them. Attribute-based standards “plus a backstop would prevent manufacturers from upsizing their vehicles or producing too many large vehicle footprint vehicles, if the backstop were set high enough.”83 We believe that, without a backstop, the NPRM does not comply with the statutory mandate to prescribe ratable increases, particularly given the free pass for the largest trucks and the added incentive to shift toward the least efficient vehicles. The Center proposes that the Agencies adopt a backstop to rein in shifts towards manufacturing larger vehicles and to ensure the standards continue to move the nationwide fleet towards energy conservation. [EPA-HQ-OAR-2010-0799-9479-A1, p. 17]

NHTSA has resisted adopting a backstop for years, despite losing the argument in Center for Biological Diversity v. NHTSA. In that case, the court observed, “Petitioners raise well-founded concerns (given the historical trend) that a floating feet mix-based standard would continue to permit upsizing – which is not just a function of consumer demand, but also a function of manufacturer’s own design and marketing decisions.” 84 The court found that NHTSA had not considered fuel conservation in deciding not to adopt a backstop, and had not shown that a backstop would be either technologically infeasible or economically impractical. It remanded the rulemaking with instructions for NHTSA to “reconsider under the proper standard whether to adopt a backstop based on the factors in the statute.”85 [EPA-HQ-OAR-2010-0799-9479-A1, p 17]

In subsequent rulemakings, NHTSA justified its continuing refusal to set a backstop based on various reasons, including its belief that it could successfully prognosticate fleet mix shifts, that its footprint attribute-based standard would prevent gamesmanship and backsliding, that the lack of lead time and a growing preference for smaller cars weighed against adopting a backstop, and that backstops created inequitable burdens on manufacturers who exceeded the backstop.86 However, the Agencies did recognize the potential need for a backstop in the current NPRM: "[W]e recognize that given the time frame of the current rulemaking, the agency cannot be as certain about the unlikelihood of future market changes. Depending on the price of fuel and consumer preferences, the 'kind of industry-wide situation' described in the MYs 2012– 2016 rule is possible in the 2017–2025 time frame, particularly in the later years."87 [EPA-HQ-OAR-2010-0799-9479-A1, pp 17-18]

The Agencies are correct. They cannot possibly predict future market changes or "consumer preference" with any degree of certainty over a period spanning some 14 years. Moreover, the justifications NHTSA provided in the MY 2011 and MY 2012-2016 final rules for failing to adopt backstops are incorrect or no longer apply, and do not in any event consider the relevant statutory factors as required by CBD v. NHTSA. [EPA-HQ-OAR-2010-0799-9479-A1, p 18]

First, the hypothesis that the attribute-based system does not provide an incentive to increase the size of vehicles has been refuted by studies showing the opposite. In fact, considering multiple variables, including consumer preferences, a recent study of the MY 2012- 2016 final rulemaking concluded that under most scenarios, the attribute-based standards "create an incentive to increase vehicle size that undermines gains in fuel economy."88 In all but two simulations, "the sales-weighted average vehicle size increases by 2–32%, undermining gains in fuel economy by 1–4 mpg (0.6–1.7km/L). Carbon-dioxide emissions from these vehicles are 5–15% higher as a result . . . which is equivalent to adding 3–10 coal-fired power plants to the electricity grid each year. Furthermore, results suggest that the incentive is larger for light trucks than for passenger cars, which could increase traffic safety risks."89 Moreover, the same study found that the incentive to increase vehicle size is greater for light trucks than for passenger cars due to the larger impact of the CAFE standards for light trucks on manufacturers' profits: "Because the light truck standard causes larger profit losses than the passenger car standard, firms increase the sales-weighted average footprint of light trucks more than passenger cars." 90 Thus, the Agencies' claim that the attribute-based standards serve as backstops and prevent backsliding is simply incorrect. The already existing incentives to upsize would now be substantially increased. Without a backstop, it is not credible to assume that the fleet will not shift to lower efficiency vehicles. [EPA-HQ-OAR-2010-0799-9479-A1, p 18]

Second, the claim of insufficient lead time to adjust to backstops is inapplicable to the MY 2017-2025 NPRM. Manufacturers will have unprecedented lead time to adjust their future fleets to the new regulations. The amount of lead time also refutes the argument that the backstop will create an inequitable burden on manufacturers currently above it: this problem can be remedied in the intervening years. [EPA-HQ-OAR-2010-0799-9479-A1, p 18]

Lastly, the Agencies have not based their refusal to implement a backstop on any analysis of the statutory factors they must consider: technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need for the

United States to conserve energy.91 We believe that none of the first three factors could be cited as a reason for foregoing a backstop, while the latter convincingly demands one. In short, the Agencies must supply annual or at least periodic backstops to comply with statutory mandates and dissuade manufacturers from “gaming” the attribute-based curves and avoiding implementation of fuel saving technology. [EPA-HQ-OAR-2010-0799-9479-A1, pp 18-19]

We also note that the NPRM allows manufacturers to rely on a variety of flexibilities and credits, discussed below, to meet annual fuel economy standards. The Agencies prognosticate that these features will decrease actually achieved mileage by less than 3 mpg by 2025 (see further discussion of credits below); but given the long time span covered by the rulemaking, this prediction is, by necessity, highly uncertain. A backstop would also ensure that the various credits and flexibilities will not be abused to the detriment of fuel conservation. [EPA-HQ-OAR-2010-0799-9479-A1, p 19]

We agree with the Agencies’ approach to extend exemptions only to small businesses as defined by the Small Business Administration and to limit the small volume manufacturers’ exemption to business with U.S. annual sales of less than 5,000 vehicles. Given the long lead times of the current rulemaking, no further exemptions are warranted. [EPA-HQ-OAR-2010-0799-9479-A1, p 19]

Congress has effectively set a backstop of 35 mpg in 2020 for the overall fleet. The Agencies’ estimated fuel economy standards, however, demonstrate that the fleet can more than meet this standard; it can exceed it before 2020 even under the preferred alternative. In setting the maximum feasible standards, the Agencies should prescribe annual or at least periodic backstops designed to move the fleet to higher standards based on maximum feasible levels. [EPA-HQ-OAR-2010-0799-9479-A1, p 19]

Minimum 'Backstop' Standards for Imported Passenger Cars and Light Trucks

NHTSA once again raises the possibility of minimum 'backstop' CAFE standards for the imported passenger car and light truck compliance categories. Such 'backstop' standards, however, are both contrary to NHTSA's statutory authority and inconsistent with the Congressional mandate to regulate fuel economy through an attribute based program. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-18]

When amending the EPCA in 2007, Congress both mandated the use of an attribute-based program for the CAFE program and created a backstop for the domestic passenger car fleet. NHTSA construes the fact that Congress did not include the other compliance categories as legislative 'silence.' However, the fact that Congress included only the domestic passenger car fleet is determinative evidence that Congress intended not to allow a backstop to be applied to the imported passenger car fleet or the light truck fleet. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-18]

This is especially true where, as here, the imposition of a backstop is inherently inconsistent with attributes standards. The attribute based system was established as a replacement for a corporate average system with one numeric requirement. The proposed standards are aggressive and will require extensive technology adoption and market advancements for manufacturers to meet them. Manufacturers have no incentive to 'backslide.' The development of a trading market, moreover, creates a yet further incentive to continue to advance, especially in light of the overall stringency of the standards, because doing so creates a valuable and marketable asset. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-18]

There is no reason for the agencies to consider a backstop in the context of an aggressive and carefully constructed attribute based program. Congress continued the concept of a minimum standard for the domestic passenger car compliance category and made it clear through omission that such a backstop standard was not intended to be applied to the other compliance categories. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-18]

Organization: Natural Resources Defense Council (NRDC)

EPA and NHTSA should establish manufacturer-specific 'backstop' standards to ensure that environmental objectives are not undermined by shifts in sales mix and average vehicle size. [EPA-HQ-OAR-2010-0799-9472-A2, p. 4]

E. Compliance and Enforcement Requirements

1. GHG Standards Need 'Backstop' Standards to Ensure Environmental Objectives Are Not Undermined by Shifts in Sales Mix

The proposed GHG and fuel economy standards lack a regulatory 'backstop' mechanism to ensure that the 2025 fleetwide average emission level reaches 163 g/mi and that the targeted cumulative greenhouse gas and oil consumption reductions are met. Such mechanisms are necessary because under an attribute-based system that has separate car and light truck standards, the fleet sales mix could shift to larger, higher-emitting vehicles and to a greater proportion of light trucks, resulting in greater fleetwide emissions and oil consumption. [EPA-HQ-OAR-2010-0799-9472-A2, p. 17]

Achieving the pollution and oil reduction goals of the program are dependent on the overall market achieving the agencies' forecasted sales and size mixes. To reach a fleetwide average of 163 g/mi and 49.6 mpg in MY 2025, the agencies have set the individual car and light truck standards on the assumption of a specific car/light truck sales split. However, if the automakers shift their product mix to more light trucks or if they change the vehicle designs to classify fewer models as cars and more models as light trucks, this car/light truck split would be changed and the GHG and oil savings goals of the program would be undermined. [EPA-HQ-OAR-2010-0799-9472-A2, p. 17]

To prevent intentional and unintentional market shifts from undermining the environmental and oil savings benefits of the National Program, we recommend EPA and NHTSA adopt manufacturer-specific backstops on the combined car and light truck standards that bar an individual automaker from exceeding its forecast GHG emission levels by more than 2 gCO_2-equivalent/mi and forecast fuel economy levels by approximately 0.5 mpg. Manufacturer-specific backstop standards would ensure that specific manufacturers can be held accountable if the overall fleet emission targets are missed. A manufacturer should be allowed no more than three years to make up any exceedance in its manufacturer-specific backstop standard. [EPA-HQ-OAR-2010-0799-9472-A2, p. 17]

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

As we did in our comments on the 2012-2016 standards, we urge both agencies to consider including what we consider necessary "backstops" to the program. The draft rule fails to include measures sufficient to ensure that the fleet-wide targets in the rule are met. The draft rule relies upon attribute-based curves, whose efficacy will vary with the composition in the fleet. As currently written the draft rule would allow shifts in fleet composition to undermine greenhouse gas and oil reduction targets. A "backstop," in the form of a hard fleet-wide limit under-girding the attribute curves, should be incorporated in the final rule to insure that the program meets President Obama's stated goals. [EPA-HQ-OAR-2010-0799-9549-A2, p. 5]

Both NHTSA and EPA are granted broad authority and stern directives to incorporate backstop regulatory structures into fuel efficiency rules. For example, NHTSA is required to promulgate fuel efficiency regulations in terms of absolute standards, as opposed to mere targets that may or may not be by the regulatory program.15 Similarly, EPA is directed under the Clean Air Act to take measures to that pollution from vehicles is actually prevented.16 Rules promulgated under EPA authority, accordingly, should not be undermined by increasing vehicle footprint to dilute the overall intent and benefit of the standards. [EPA-HQ-OAR-2010-0799-9549-A2, p. 5] [EPA-HQ-OAR-2010-0799-9549-A2, p. 5]

Here, achievement of the target fuel economies and greenhouse gas reductions depend on the mix of vehicle classes on the road in the U.S. years in the future. The law governing both NHTSA and EPA requires that the uncertainty in those targets be resolved into enforceable standards through employment of a backstop. The draft rule should be revised to include such a backstop before it becomes final. Backstop mechanisms should be considered during the midterm review. [EPA-HQ-OAR-2010-0799-9549-A2, pp. 5-6]

Organization: Toyota Motor North America

Potential Expansion of Domestic Passenger Car Anti-Backsliding Standards [EPA-HQ-OAR-2010-0799-9586-A1, p.6]

Toyota opposes any expansion of anti-backsliding provisions beyond the domestic passenger car fleet in the CAFE program. The clear intent of Congress has been that NHTSA should only establish anti-backsliding standards for the domestic car fleet. As such, EPCA (as modified by EISA) requires NHTSA to establish anti-backsliding standards for domestic passenger cars and does not authorize NHTSA to establish additional anti-backsliding standards for import cars and trucks. [EPA-HQ-OAR-2010-0799-9586-A1, p.6]

In the case of EPA and the CAA, there is no explicit statutory authority that either compels or authorizes EPA to establish anti-backsliding standards for any class of light duty vehicles. While EPA's authority may be ambiguous, it is clear that any EPA-issued anti-backsliding standards would create new inconsistencies between the NHTSA and EPA programs, rather than support the goal of harmonization. NHTSA's anti backsliding standards are limited to domestic passenger cars, and the CAA cannot be used to duplicate a similar outcome since EPA's fleet definitions do not distinguish between domestic cars and import cars. The most 'harmonized' outcome is for NHTSA to proceed with the required domestic car anti-backsliding standard for the CAFE program, and for EPA to forego any attempt to set anti-backsliding standards under the CAA. [EPA-HQ-OAR-2010-0799-9586-A1, p.6]

Notwithstanding the legal constraints described above, Toyota outlined in its November 25, 2009 comments in response to the 2012-2016 model year rulemaking a variety of additional factors describing why anti-backsliding standards are unnecessary. Please refer to those comments. [EPA-HQ-OAR-2010-0799-9586-A1, p.6]

Organization: Union of Concerned Scientists (UCS)

Finally, the attribute-based system employed in the proposed rule does not guarantee that automakers will actually achieve the 163 g/mi and 49.6 mpg standard in MY2025. The agencies base these fleetwide projections on a variety of assumptions, including the vehicle footprint of future vehicles and the relative sales mix between cars and light-trucks. If these assumptions are wrong or if automakers adopt compliance strategies that either reclassify passenger cars as light trucks or add size to vehicle footprints in order to qualify for weaker standards, the projected benefits of the standards could be sizably eroded, particularly in the first five model years of the program, which have the largest gap in car/truck stringency. [EPA-HQ-OAR-2010-0799-9567-A2, p. 7]

In order to ensure that model year 2017-2025 vehicles yield anticipated consumer savings, oil savings and greenhouse gas reductions, the standards must include a backstop mechanism. Under the current attribute-based system, no mechanism exists to adjust individual manufacturers' fleet requirements in the event that product plans or manufacturer-specific performance diverges from anticipated levels. Because of these risks and because the model year 2017-2025 standards will be finalized before compliance data can be gathered under the new attribute-based system, it is critical to include a backstop mechanism to ensure that the fleet maintains its projected fuel economy and greenhouse gas emissions trajectory. A backstop could take numerous forms; UCS suggests one that includes an automatic re-computation or "ratchet" of stringencies for subsequent years, such that the National Program's cumulative emissions reductions and oil savings goals are fully achieved in 2025, even if falling short in early years of the program. [EPA-HQ-OAR-2010-0799-9567-A2, p. 7]

Finally, in addition to the gap between the car and truck standards, the relative stringency of the truck standards decreases as vehicle size increases. For the largest pickup trucks, total reductions in emissions required between 2016 and 2021 amount to less than 5% versus nearly 18% for the smallest trucks. Automakers may find it more economical to add footprint size to qualify for less stringent standards rather than add emission control technologies, further eroding benefits.

To prevent a loss in benefits, the agencies should adopt a backstop mechanism to ensure the anticipated global warming pollution reductions and oil savings benefits are achieved. [EPA-HQ-OAR-2010-0799-9567-A2, p. 8]

Organization: Whitefoot, K. and Skerlos, S.

Additional minimum fuel economy standards are warranted due to the substantial risks of backsliding. We encourage NHTSA to establish minimum standards across the combined fleet of passenger cars and light trucks to provide a limit to backsliding. [EPA-HQ-OAR-2010-0799-9447-A1, p. 1]

Below, we respond to NHTSA's request for comments on additional minimum standards and how they should be structured.

As NHTSA indicates in the proposed rule, the Energy Policy and Conservation Act of 1975 (EPCA), as amended by the Energy Independence and Security Act (EISA) of 2007 explicitly requires NHTSA to establish a minimum standard for domestic passenger cars but is silent as to whether the agency should or could establish other minimum standards. We believe that the requirement in EPCA (as amended by EISA) that the standards "achieve a combined fuel economy average for model year 2020 of at least 35 miles per gallon for the total fleet of passenger and non-passenger automobiles manufactured for sale in the United States" effectively requires NHTSA to establish additional backstops. This is because attribute-based standards (which are required by EPCA as amended by EISA) do not guarantee that any specific combined fuel economy average for the total fleet will be met in any year since the attributes of the fleet can change. 1 Therefore, additional minimum standards are needed to meet the requirement of reaching 35 miles per gallon by 2020. [EPA-HQ-OAR-2010-0799-9447-A1, p. 3]

The minimum standards for light trucks and imported passenger cars presented in the proposed rule for comment would help to limit the risk of backsliding and are warranted. However, these minimum standards do not reduce incentives to increase the production of light trucks relative to passenger cars, which would lead to higher fuel consumption and GHG emissions. We recommend that NHTSA establish a minimum standard across the combined fleet of passenger cars and light trucks for each year to limit incentives to increase production of light trucks in response to the regulation. Furthermore, we encourage NHTSA to establish minimum standards for light trucks at a high-enough level to ensure that fuel economy improvements in the total fleet are close to projected levels even if the production of light trucks increases. [EPA-HQ-OAR-2010-0799-9447-A1, p. 3]

Further backstops in the standards are warranted due to the substantial risks of backsliding during MYs 2017-2025. NHTSA has proposed minimum standards for domestically manufactured passenger cars in the proposed rule. We believe this is not enough to ensure that actual fuel economy improvements are close to the expected levels that NHTSA projects. [EPA-HQ-OAR-2010-0799-9447-A1, p. 3]

Response:

One undeniable feature of the footprint-based GHG emissions (and fuel economy) standard is that the fleet-wide GHG emissions reductions actually realized will depend on the average and distribution of vehicle footprint levels in future model years, and those footprint levels will not be known with certainty until months after the end of each model year. EPA projections of the average vehicle GHG emissions compliance level and societal GHG emissions savings in the future, for example, might prove to be either high or low depending on whether the average and distribution of vehicle footprint levels change relative to current projections. In response to the inherent uncertainty associated with footprint-based standards, one regulatory concept that has emerged is the concept of an emissions "backstop" that would move GHG emissions target values lower if vehicle footprint levels increase in the future. See 75 FR 25368-25370.

The agencies received comments both in support of and in opposition to the concept of a GHG emissions backstop.

The Center for Biological Diversity (CBD), Natural Resources Defense Council (NRDC), Sierra Club et al, Union of Concerned Scientists (UCS), and the researchers Whitefoot and Skerlos all supported the concept of a GHG emissions (and/or fuel economy) backstop. These commenters expressed concerns about vehicle footprint levels increasing ("upsizing") over time, as well as a future increasing truck market share. NRDC made a specific proposal for a manufacturer-specific backstop that would limit an individual manufacturer's combined car and truck CO_2 emissions level to no more than a 2 g/mi increase over that projected by EPA in this rulemaking. UCS supported an industry-wide "rachet" backstop approach that would build into the final regulations a provision for automatically making future years' CO_2-footprint curves more stringent if the data from early years shows higher footprint levels and higher average GHG emissions performance than projected by EPA. Other supporters strongly supported the concept of a GHG emissions backstop, but did not endorse specific designs. Whitefoot and Skerlos have published an academic study, using certain assumptions about key parameters, that projects that the MY 2014 footprint-based standards were likely to promote "upsizing" and therefore yield lower GHG emissions and oil savings than projected by EPA and NHTSA.

The Alliance of Automobile Manufacturers (AAM), Mercedes-Benz, and Toyota opposed GHG emissions (and/or fuel economy) backstops. AAM and Mercedes-Benz both stated that the concept of a backstop is inconsistent with an attribute-based standard, which by definition is intended to be flexible with respect to consumer demand, and AAM suggested that any necessary adjustments based on unforeseen developments should be addressed in the mid-term evaluation.

EPA is rejecting GHG emissions backstops in this final rule. Explicit and implicit in many of the comments is that there is an inherent tension between a footprint-based standard and certainty of GHG emissions reductions, and the agency recognizes this tension as well. The agency recognizes that factors related to specific design features of the final rule (shape of car and truck curves, relative stringency between car and truck curves) as well as factors unrelated to specific design features of this final rule (fuel prices, consumer preferences) could affect the average and distribution of vehicle footprint levels and therefore average GHG emissions requirements. Of course, footprint levels could increase or decrease relative to current projections, and GHG emissions reductions could therefore be either lower or higher than projected.

With respect to the design of the CO_2-footprint curves, EPA believes we have developed curves that maintain a reasonable level of neutrality with respect to technological feasibility across different vehicle classes and footprint levels. As discussed in Preamble Section III.D.6.b, EPA projects a relatively small overall net credit transfer from the truck fleet to the car fleet, which suggests that the relative stringency between the car and truck curves is relatively neutral. Accordingly, the agency believes that our projections of future footprint levels are reasonable, and that any future changes in average footprint or the distribution of footprint levels due to the design of the CO_2-footprint curves are not likely to lead to more than modest changes to projected GHG emissions reductions. See RTC Section 2.2.2 and joint TSD section 2,4 for a longer response to the Whitefoot and Skerlos study.

The agency believes it is more likely that changes unrelated to the design of this rule, such as fuel prices or consumer preferences, will affect future vehicle footprint levels and GHG emissions requirements. In this regard, we note that AEO2012 Early Release projects relatively stable gasoline prices over the next 13 years. The average actual price in the U.S. for the first four months of 2012 for regular gasoline was $3.68 per gallon[3] with prices approaching $4.00 in March and April.[4] The AEO2012 Early Release reference case projects the regular gasoline price to be $3.87 per gallon in 2025, only slightly higher than the price for the first four months of 2012.[5] As explained in preamble section III.D. 1.a, this factor strongly supports using a flat baseline (no significant voluntary GHG emissions improvement over the MY 2016 standard absent further regulation). However, for the same reason, this projection militates against the need for a backstop in this rule since no significant shift in fleet mix would be expected under these circumstances. Of course if oil prices were to drop to the levels of the 1990s, it is almost certain that vehicle footprint levels would rise and GHG emissions requirements would increase as well, while if oil prices were to increase significantly above today's level (and the level projected for MY 2025 based on AEO 2012 Early Release), it is quite likely that vehicle footprint and GHG emissions requirements would both decrease. (although no such decreases or increases are projected by AEO)

There are other drawbacks to adopting backstops (including backstops with ratchets, as UCS advocates). As explained in detail in the MYs 2012-2016 rule preamble, stringent backstops can compromise some of the advantages of attribute-based standards, especially with respect to manufacturers above a backstop, and especially under conditions where the entire industry's performance, taken as a whole, remains consistent with the emissions levels projected for the standards. See 75 FR at 25369; see also EPA Response to Comment Document for MY 2012-2016 rule at pp. 3-99 to 3-102. Under these circumstances, manufacturers would again (as under the flat CAFE regime) have the incentive to downsize as a compliance strategy, undermining the safety and across-all-footprint improvement objectives of an attribute-based standard. These concerns remain here. . EPA notes further that the questions about the potential need for a backstop, and if so, the best design of such a backstop, are very complex and difficult

[3] In 2012 dollars. As 2012 is not yet complete, we are not relating this value to 2010 dollars. See RIA 1 for additional details on the conversion between dollar years.

to assess as we are at the beginning stages of a 14-year program of more stringent GHG emissions standards

For all of these reasons, both related and unrelated to the CO_2-footprint curves in this final rule, EPA believes it unnecessary to establish a backstop in this rule. EPA commits to monitoring vehicle footprint data, and that data will form the basis for an analysis of the potential need for a GHG emissions backstop (or different GHG standards) in the mid-term evaluation.

2.3. Additional Flexibility for Intermediate Volume Manufacturers

Organizations Included in this Section

Alliance of Automobile Manufacturers
American Suzuki Motor Corporation
Fisker Automotive, Inc.
Jaguar Land Rover North America, LLC (JLRNA)
Natural Resources Defense Council (NRDC)
Porsche Cars North America, Inc. (PCNA)
Volkswagen

Organization: Alliance of Automobile Manufacturers

The program flexibilities in the Notice of Proposed Rulemaking (NPRM) will help manufacturers introduce new technologies that produce concrete environmental and fuel consumption benefits. The Alliance supports the flexibilities in the proposal and understands the needs of lower volume, limited line manufacturers. The program flexibilities in the NPRM will encourage early investment in technologies that produce concrete environmental and fuel consumption benefits that will be necessary to meet these challenging and increasingly stringent standards over the longer term. [EPA-HQ-OAR-2010-0799-9487-A1, p.4]

Organization: American Suzuki Motor Corporation

Suzuki is concerned, however, that the proposed standards do not adequately recognize the lead time needs of low-volume, limited-line manufacturers like Suzuki. [EPA-HQ-OAR-2010-0799-9523-A1, p.1]

California has long recognized that companies with small sales volumes and a limited number of models face unique challenges in complying with stringent standards that rely on the implementation of advanced technologies. As a result, California has created different manufacturer size categories[1], and has used these categories to provide additional implementation lead time for smaller-volume manufacturers. This approach helps to address, to some extent, the disadvantages that small-volume manufacturers have, compared to larger-volume manufacturers, in introducing advanced technologies across their product lines. Suzuki requests that the Environmental Protection Agency (EPA) and National Highway Traffic Safety Administration (NHTSA) adopt a similar approach in regulating GHG emissions and corporate average fuel economy. [EPA-HQ-OAR-2010-0799-9523-A1, p.1]

Suzuki Proposal

Suzuki proposes that EPA and NHTSA (1) establish a Limited Line Manufacturer (LLM) size category that approximates the California Small Volume Manufacturer (SVM) category scaled up to a national level, and (2) establish a three-year implementation lead time allowance for LLMs. [EPA-HQ-OAR-2010-0799-9523-A1, p.1]

Suzuki suggests that a national average annual sales volume such as 50,000 vehicles (calculated as a three-year average) would roughly approximate, on a national level, the threshold to qualify as an SVM in California. Suzuki proposes that LLMs be given a three-year implementation lead time allowance which does not require LLMs to comply with the 2017 model year standards until the 2020 model year, and requires LLMs to comply with the 2018-2025 model year standards in model years 2021-2028. Under this proposal, LLMs would meet the same GHG/fuel economy standards as large manufacturers, but with a moving three-year lead time allowance. [EPA-HQ-OAR-2010-0799-9523-A1, p.1]

Reason for Suzuki's Proposal

When small-volume manufacturers need to develop new technology and develop a new model/new engine to make the significant improvements necessary to comply with the proposed standards, the per-vehicle cost for the special development that is needed specifically for the U.S. market is much higher than for manufacturers with larger sales volumes. [EPA-HQ-OAR-2010-0799-9523-A1, p.2]

Adoption of Suzuki's proposal would have an insignificant impact on nationwide GHG emissions, as the combined GHG emissions from vehicles produced by small-volume manufacturers are an extremely small percentage of the fleet-wide total. [EPA-HQ-OAR-2010-0799-9523-A1, p.2]

Organization: Fisker Automotive, Inc.

Likewise, manufacturers seeking to participate in the expanded Temporary Lead-Time Allowance Alternative Standards (TLAAS) “must secure credits to the extent they are reasonably available from other manufacturers to offset the difference between their emissions reductions obligations under the base TLAAs program and the expanded TLAAS program.” Fisker Automotive strongly encourages EPA to hold to the spirit of these provisions. As the only entity with complete knowledge of every automaker’s credits and deficits, it is incumbent upon EPA to ensure that this provision is fairly enforced. [EPA-HQ-OAR-2010-0799-9266-A1, p. 4]

Organization: Jaguar Land Rover North America, LLC (JLRNA)

Jaguar Land Rover will meet the 2012-2016MY GHG program by a number of significant product actions and through use of the Expanded TLAAS program. [EPA-HQ-OAR-2010-0799-8102-A1, p. 1]

The Unique Challenge Facing Jaguar Land Rover in the Transition to the 2017MY Standard

Even though our company will make substantial CO_2 reductions during the 2012-2016MY period, the proposed 2017MY standard poses very significant challenges. First, as the Expanded TLAAS program comes to a close in 2016MY, companies which participated in this program will start 2017MY with either no CO_2 credits banked or CO_2 debits carrying forward. We understand the rationale in this structure but the resulting transition does not allow lower volume, limited line manufacturers the same flexibilities as afforded large volume manufacturers. [EPA-HQ-OAR-2010-0799-8102-A1, p. 1]

Given this situation, JLR requests that EPA consider a range of flexibilities aimed at creating a fair standard for lower volume, limited line manufacturers. Included amongst these ideas is a proposal to phase in the base standard for lower volume, limited line manufacturers toward full compliance in 2022MY. [EPA-HQ-OAR-2010-0799-8102-A1, p. 1]

As a result of this dramatic impact, JLR is inviting the EPA to consider phasing-in the GHG program for lower volume, limited line manufacturers, starting in 2017MY and ending with 2021MY production. We propose that manufacturers in this program be required to come into full compliance with the base program from 2022MY. [EPA-HQ-OAR-2010-0799-8102-A1, p. 2]

In the NPRM, EPA requested comments on additional lead-time for lower volume, limited line manufacturers. In response to this invitation, Jaguar Land Rover requests that EPA consider phasing in the 2017MY+ program for lower volume, limited line niche manufacturers when the Expanded TLAAS ends. This proposed alternative GHG standard would be designed to ensure fair but very stringent CO_2 reductions in excess of the industry average. [EPA-HQ-OAR-2010-0799-8102-A1, p. 2]

JLR will be delivering very significant CO_2 reductions well in excess of industry averages. However the required rates of reduction implied by the proposed NPRM curves between 2016MY and 2017MY are very challenging for lower volume, limited line manufacturers coming out of the Expanded TLAAS. JLR's fleet of passenger cars would be required to deliver circa **[ ]** CO_2 reduction as required by the NPRM. JLR's fleet of light trucks would be required to deliver circa **[ ]** CO_2 reduction as required by the NPRM. [Note: CBI information - **[ ] -** was omitted.] [EPA-HQ-OAR-2010-0799-8102-A1, p. 2]

Organization: Natural Resources Defense Council (NRDC)

4. Temporary Leadtime Allowance Alternative Standards Should Not be Extended to Model Years 2017-2025

NRDC agrees with the EPA proposal to end the Temporary Leadtime Allowance Alternative Standards with the 2016 model year. This exemption from the established 2012-2016 ramp-up—along with a generous early credit proposal, inclusion of FFV credits for MY 2012-2015, transferring credits between car and truck fleets, and 3-year carry forward of deficits—was provided so that all manufacturers had a pathway to comply with 2016 GHG standards. [EPA-HQ-OAR-2010-0799-9472-A2, pp. 13-14]

Organization: Porsche Cars North America, Inc. (PCNA)

Introduction:

On behalf of Dr. Ing, h.c. F. Porsche Aktiengesellschaft (“Porsche AG"), Porsche Cars North America Inc. (“PCNA," and, collectively with Porsche AG, "Porsche") is pleased to provide the following comments on the Notice of Proposed Rule Making (NPRM) regarding 2017 and Later Model Year Light Duty Vehicle GHG Emissions and CAFE Standards.

Porsche submits these comments in view of the fact that it has been recently announced that it is no longer realistic to achieve the once-planned merger between Volkswagen AG and Porsche Autornobil Holding SE (“'Porsche SE") within the framework and timeframe of the basic agreement from 2009. Porsche AG is a wholly owned subsidiary of Porsche Zwischenholding GmbH, which in turn is held by Porsche SE (50.1 percent) and Volkswagen AG (49.9 percent).

Nonetheless, Porsche SE and Volkswagen AG each also have reconfirmed their intention by some means to become part of an integrated automotive group. Both companies are currently examining whether alternatives to the measures provided for in the 2009 basic agreement are available. To the extent that such an alternative transaction is identified, and to the extent that such a transaction would materially change Porsche's status such that a supplement to these comments would be in order, Porsche reserves the possibility that it may do so.

2. Unequal burden: The goal of overall GHG reduction for the industry requires contribution from all manufacturers, but must account for the trajectory required for particular manufacturers. Transition from TLAAS to the base standards is a disproportionate burden for niche car makers. That transition cannot be accomplished by gradual incremental improvements. [EPA-HQ-OAR-2010-0799-9264-A1, p. 7]

3. Economy of scale: Porsche faces cost challenges due to its size (less than 0.25% of U.S. industry sales). Our development costs for new technology cannot be spread over a large fleet to take advantage of natural economies of scale. There is a disproportionate financial impact on small manufacturers, due to higher per unit cost. [EPA-HQ-OAR-2010-0799-9264-A1, p. 7]

4. Skewed competition: Porsche's positioning among our direct competitors in the sports car segment is a disadvantage. Our larger competitors can support sports car sales by fleet averaging over abroad range of products. EPA has also proposed that our smallest competitors can request alternate 'lowest feasible' CO_2 standards. Porsche cannot employ either of these options. Thus, the playing field is not level. [EPA-HQ-OAR-2010-0799-9264-A1, p. 7]

5. Availability of credits: We expect that many manufacturers will forego credit banking in order to expand sales of more profitable non-compliant models. Further, uncertainty will encourage other manufacturers to retain unused credits as insurance against the risk of catastrophic noncompliance in future years. Therefore, we believe it is unlikely that GHG credits will be readily available for sale on the open market. In fact, during the 2012-2016 GHG rulemaking, the Agencies acknowledged that experience shows that manufacturers do not sell credits. A business case cannot be built around such uncertainties that threaten our very existence. [EPA-HQ-OAR-2010-0799-9264-A1, p. 7]

In the absence of alternative standards, current TLAAS manufacturers would face a 25% reduction in GHG standards at the expiration of TLAAS following MY 2016. Due to Porsche's unique position in the market, we believe that those standards as proposed would create a hurdle that would drive us from the marketplace. We urge the agencies to consider alternatives which do not unjustly punish small specialty car manufacturers.

Porsche AG is a low volume manufacturer of premium high performance sports vehicles, targeted to a very small niche market. To assume that a performance car is in the same category as an economy sedan is to impose requirements that ignore the constraints of the laws of physics. It is certainly well accepted that it would be inappropriate for SUVs and light trucks to be subject to the same standards as passenger cars with similar footprints. Similarly, we believe it is not appropriate to set identical GHG standards for small economy vehicles and specialty performance machines, because of their vastly different design criteria and different market segments. [EPA-HQ-OAR-2010-0799-9264-A1, p. 7]

The consequence of setting uniform standards is illustrated in the following tables taken from the NPRM, showing technology penetration for Model Years 2021 and 2025, As these tables show, Porsche would be expected to employ far greater electrification than any other manufacturer. This absurd compliance path would place us at a severe competitive disadvantage with respect to development costs, and in the consumer market. [The tables can be found on p. 8 of Docket number EPA-HQ-OAR-2010-0799-9264-A1] [EPA-HQ-OAR-2010-0799-9264-A1, p. 8]

It is essential that a regulatory framework strive to accomplish its goals without interfering with natural free·market competition, Fair trade and free commerce demand a rule book that does not favor one business model over another. For the rules to be marketplace neutral, accommodation is needed for the unique challenge facing low volume niche manufacturers, yet without precipitating an unfair advantage over larger manufacturers who compete in those same niche markets. [EPA-HQ-OAR-2010-0799-9264-A1, pp. 8-9]

Porsche recommends three possible approaches for setting niche vehicle standards: fixed alternative standards, competitive standard setting, and alternate phase-ins. All three models would force Porsche to make significant GHG improvement equaling or exceeding the rest of the industry, but without imposing unrealistic targets likely to put us out of business.

<u>Alternative Standards</u>

Porsche suggests that a limited low volume alternative standards model similar to TLAAS is appropriate for the niche car market. We applaud the current TLAAS provisions, which require Porsche to make an annual GHG improvement comparable to the broader industry, without requiring wholesale restructuring of our market presence and without imposing an unfair competitive disadvantage either to us or to our competitors. [EPA-HQ-OAR-2010-0799-9264-A1, p. 9]

We estimate that the size of the industry's TLAAS fleet is on the order of 2% to 3% of total sales. The use of TLAAS standards at 125% of the base standards therefore has a minimal net effect on industry GHG performance in the 2012-2016 period. We believe that by further reducing the size of the TLAAS fleet (e.g., by 50% to 25,000 vehicles per manufacturer per year), the impact on industry-wide GHG would be negligible. A program like TLAAS is a sensible approach to achieving significant GHG benefits without interfering with the marketplace. We urge the agencies to continue to include alternative standards for the niche offerings of both small and large manufacturers. [EPA-HQ-OAR-2010-0799-9264-A1, p. 9]

Alternatively, we believe it would make sense to set GHG targets based on a sliding scale in proportion to market share / sales volume. This model would account for the relative ability of each manufacturer to weather increasing stringency, and to realize a return on the required technology investment. Conversely, as an OEM's sales and/or market share increase over time, it would make sense to adjust to more stringent GHG targets to reflect its increased capabilities. [EPA-HQ-OAR-2010-0799-9264-A1, p. 9]

Competitive Standard Setting

Standards for small volume niche manufacturers should not be more stringent than the GHG performance of their competitors' comparable models. Porsche proposes that small volume OEMs would have standards for each model set to the average GHG performance of competitor vehicles with similar horsepower, power/weight ratio, and type of technology employed (Diesel, Y-6 Turbo, conventional hybrid, PHEY, etc.). This will ensure a level playing field in competition with larger manufacturers which are using fleet averaging. [EPA-HQ-OAR-2010-0799-9264-A1, pp. 9-10]

This approach would be modeled after provisions for lower volume car makers described in California's LEY-II / Pavley I model, and in the successful "Top Runner' model used in other countries. It is an apples-to-apples variable standard that guarantees a neutral application of standards among all competitors. By definition, this strategy will force smaller manufacturers to make annual GHG improvements equaling or exceeding the improvement of comparable models, and without disrupting healthy competition. The following text outlines LEY-II provisions for lower volume manufacturers: [EPA-HQ-OAR-2010-0799-9264-A1, p. 10]

[§ 1961.1. Greenhouse Gas Exhaust Emission Standards and Test Procedures (D) Requirements for Small Volume Manufacturers and Independent Low Volume Manufacturers.

1..... [EPA-HQ-OAR-2010-0799-9264-A1, p. 10]

2. At the beginning of the 2013 model year, each small volume manufacturer and independent low volume manufacturer shall identify all 2012 model year vehicle models, certified by a large volume manufacturer that are comparable to that small volume manufacturer or independent low volume manufacturer's 2016 model year vehicle models, based on horsepower and horsepower to weight ratio. The small volume manufacturer and independent low volume manufacturer shall demonstrate to the Executive Officer the appropriateness of each comparable vehicle model selected. Upon approval of the Executive Officer, s/he shall provide to the small volume manufacturer and to the independent low volume manufacturer the CO_2- equivalent value for each 2012 model year vehicle model that is approved. The small volume manufacturer and independent low volume manufacturer shall calculate an average greenhouse gas emissions value for each its greenhouse gas vehicle test groups based on the CO_2-equivalent values provided by the Executive Officer. [EPA-HQ-OAR-2010-0799-9264-A1, p. 10]

3. In the 2016 and subsequent model years, a small volume manufacturer and an independent low volume manufacturer shall either: a. not exceed the fleet average greenhouse gas emissions value calculated for each GHG vehicle test group for which a comparable vehicle is sold by a large volume manufacturer, in accordance with section 1961. Hal(l)(D12: J [EPA-HQ-OAR-2010-0799-9264-A1, p. 10]

Porsche believes that such a standards framework upholds the spirit of worldwide GHG policy, in that all participants are expected to contribute to the overall emission reduction goals. Even niche players in the high powered sports car segment will contribute to innovation and efficiency improvement. Indeed, such a framework would ensure a thriving, competitive performance car segment, leading to innovations applicable to the entire industry. [EPA-HQ-OAR-2010-0799-9264-A1, p. 10]

Alternate Phase-In

If long-term alternate standards or competitive standards are unacceptable, we suggest an alternate phase-in to the base standards. This would mitigate the potential 25% drop in GHG standards at the expiration of TLAAS. It is important to consider that the length of Porsche's product cycles is 2- to 3- times the typical industry product cycle, in order to allow recovery of investment costs over small annual volume. An extended phase-in would be critical to Porsche's survival. [EPA-HQ-OAR-2010-0799-9264-A1, p.11]

The phase-in suggested below is a linear trajectory, starting from MY 2015 TLAAS, and ending at the MY 2025 base standards. This example illustrates GHG targets for one subset of Porsche's portfolio (small footprint sports cars). Similar curves can be drawn for other TLAAS products. [EPA-HQ-OAR-2010-0799-9264-A1, p.11]

It should be emphasized that this alternate phase-in would require an average 5.2% annual GHG reduction for these models, compared to 4.0% for vehicles which are already subject to the base standards in MY 2015. While such a phase-in would be a challenge, it does accommodate the long range planning needed to develop entire new product lines. [EPA-HQ-OAR-2010-0799-9264-A1, p.11]

Organization: Volkswagen

Volkswagen also submitted comments noting a gap in the MYs 2012-2016 TLAAS provisions involving a situation where TLAAS-eligible companies not participating in TLAAS merge with a TLAAS participant and the merged entities sales remain less than 400,000 units. VW requested that in such circumstances the companies should have the same administrative options as the rules provide for non-TLAAS participants merging with TLAAS participants where the merged entities sales exceed 400,000 units.

Response:

EPA did not propose to and is not extending the Temporary Leadtime Allowance Alternative standards (TLAAS) program per se. EPA received supportive comments regarding not extending TLAAS along the lines of the MYs2012-2016 program and received no comments recommending that the full-scale TLAAS program be extended.

EPA requested comments on whether there is a need to provide some type of additional lead time flexibility for intermediate volume, limited line manufacturers. EPA received supportive comments regarding providing some flexibility to intermediate volume manufacturers. Three manufacturers, Suzuki, Jaguar Land Rover, and Porsche provided specific recommendations and supporting rationale. EPA has carefully considered the comments regarding the need for additional flexibility for intermediate volume manufacturers. These manufacturers are eligible for the expanded TLAAS provisions in the MYs 2012-2016 rules which provide less stringent CO_2 standards through MY 2016 for manufacturers with U.S. sales below 50,000 vehicles. EPA understands the feasibility concerns raised by the manufacturers with regard to the significant increase in stringency represented by the change in standards under the TLAAS program in MY 2016 and the MY 2017 primary program standards. EPA is providing additional lead-time flexibility to these intermediate volume manufacturers through MY 2020 to help ease the transition to the MY 2017-2025 program. A more detailed review of the comments and EPA's response is provided in preamble Section III.B.6. The feasibility of the standards is discussed in Section III.D.6 of the preamble. As shown there, these intermediate manufacturers do face disproportionate compliance challenges in the early model years of this program. See Table III- 28 (JLR projected to require 23 % HEV, 2% PHEV, and 7% EV to meet MY 2021 combined fleet standard; these technology penetrations are considerably more challenging than for larger manufacturers; see also EPA RIA table 5.1.6 showing similarly disproportionate costs to meet the MYs 2019-2021 standards, even after the additional lead time afforded by the final rule.

Porsche notes that the company submitted comments under the assumption that they would remain independent from Volkswagen and that if the status of their relationship changed such that a supplement to their comments would be in order, Porsche reserved the possibility that it may submit such comments. On August 1, 2012, VW completed its acquisition of 100 percent of Porsche's automotive business.[6] While Porsche has not submitted follow-up comments, it is

[6] "Volkswagen and Porsche finalize creation of Integrated Automotive Group," Volkswagen news release, August 1, 2012.

EPA's expectation that Porsche will no longer be eligible for the expanded TLAAS program or the leadtime provisions discussed above since it will no longer be an intermediate volume manufacturer. EPA expects that Porsche's fleet will be absorbed into VW's fleet for purposes of determining compliance with the GHG standards. Nevertheless, EPA has considered Porsche's comments and recommendations with regard to intermediate volume manufacturers.

Fisker comments that manufacturers using the expanded TLAAS provisions are required to make a good faith effort to purchase credits and strongly encourages EPA to hold to the spirit of these provisions. In response, although the comments are on the implementation of the MY 2012-2016 program and not the MY 2017-2025 proposal, EPA understands the commenters concerns. The requirements for expanded TLAAS manufacturers to make a good faith effort to purchase credits remains in place as a regulatory requirement. EPA notes that the expanded TLAAS provisions will not be accessed by eligible manufacturers until the base TLAAS program maximum allowance has been reached. The base TLAAS program allows manufacturers to place a cumulative total of 100,000 vehicles into TLAAS in MYs 2012-2015.

Finally, EPA agrees with VW that the TLAAS provisions on mergers contain an inadvertent gap, and is clarifying those provisions in response to the comment. See preamble section III.E.7.h.

2.4. Mid-term Evaluation

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 66.]

As a contingency, if consumers in fact reject these vehicle offerings, it is my understanding the midterm review provides an opportunity to reset the goals if the needed technology cannot be provided at a reasonable price.

Organization: Alliance of Automobile Manufacturers

The Alliance supports the proposal to include an in-depth mid-term evaluation. [EPA-HQ-OAR-2010-0799-9487-A1, p.3]

This rulemaking reaches an unprecedented 13 years into the future. A mid-term evaluation process will allow the agencies to review a broad range of factors and make appropriate adjustments. It will provide better data and insight on a range of issues relevant to the appropriateness of the MY 2022-2025 standards, including consumers' willingness to buy the vehicles that are required to comply with the standards; future fuel pricing; and technology and raw materials costs. The Alliance comments on the mid-term evaluation include additional topics that the agencies should review. We recommend that, in addition to the proposed formal mid-term evaluation, the agencies continue their open dialogue and also conduct a series of smaller, focused technical evaluations - or “check-ins” - on the key assumptions of the proposal. The Alliance also requests a more specific description of the mid-term evaluation process and the specifics to be reviewed, including the timeline and procedures for assuring that the studies the agencies rely on are appropriately peer reviewed. [EPA-HQ-OAR-2010-0799-9487-A1, p.3]

The Alliance Supports the Proposal to Include an In-Depth Mid-Term Evaluation. [EPA-HQ-OAR-2010-0799-9487-A1, p.6]

The MY 2017-2025 GHG proposal includes provisions requiring EPA to conduct a mid-term evaluation of the MY 2022-2025 light-duty GHG standards to determine whether those standards remain appropriate in light of technological and other changes that may have occurred since the time of proposal. This evaluation process will be coordinated with NHTSA's effort to set final, binding CAFE standards for the 2022-2025 model years. The mid-term evaluation will include consideration of up to date information, a “holistic assessment of all of the factors considered by the agencies in setting standards” and the “expected impact of those factors on the manufacturers’ ability to comply.” To facilitate the evaluation, EPA (along with NHTSA and CARB) will publish a draft Technical Assessment Report (TAR), which will be peer-reviewed and made available for public comment. EPA also will request comment on whether the MY 2022-2025 standards remain appropriate under section 202(a) of the Clean Air Act (CAA) and whether the standards should be made more or less stringent. No later than April 1, 2018, EPA will make a final determination whether the MY 2022-2025 standards, as adopted in 2012, are appropriate. This process also is intended to guide NHTSA’s decision-making regarding its MY 2022-25 CAFE standards. If EPA concludes that the standards are not appropriate, the agency will then initiate a rulemaking to adopt standards that are appropriate under section 202(a). Both EPA and NHTSA have stated that that they would issue a joint rulemaking at least 18 months prior to the beginning of the 2022 model year, consistent with the statutory directive in the Energy Policy and Conservation Act of 2005 (EPCA). [EPA-HQ-OAR-2010-0799-9487-A1, p.6]

The Alliance consistently has advocated that a mid-term evaluation is more than just appropriate; it is a critical component of this rulemaking package if these GHG and CAFE standards are to be successful. This rulemaking will govern vehicle production 13 years from now, a particularly long time period when predicting technologies, costs, infrastructure, fuels and consumer behavior. It comes on the heels of a five-year rulemaking that will, according to the agencies, cost automakers almost $52 billion – the highest cost of any rulemaking imposed to date on the auto industry. The agencies estimate the additional GHG reductions and fuel economy gains from this rule will cost automakers an additional $133-157 billion, bringing the combined cost of the MY 2012-25 rules to somewhere between $185 and $209 billion. This unprecedented effort and expense will further our country’s energy and environmental goals, but only if consumers choose to purchase these fuel-efficient, climate-friendly vehicle technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.6]

By necessity, the GHG and CAFE standards proposed here are predicated on significant assumptions regarding the future - including such factors as the pace of technological innovation, deployment of supportive infrastructure for alternative fuels and advanced vehicles, rates of market penetration for new vehicle technologies, future costs of emerging technologies, fuel cost and availability and consumer acceptance. The agencies have attempted to make reasonable projections based on recent data. Nevertheless, the proposed standards cover an unusually long time horizon, governing the production of vehicles over a decade into the future. The mid-term evaluation will allow the agencies to determine whether the CAFE and GHG standards should be adjusted as a result of customers' willingness to buy vehicles that are required to comply with the standards, developments in technology, costs, safety, fuels, infrastructure and other relevant factors. [EPA-HQ-OAR-2010-0799-9487-A1, p.7]

Thirteen years into the future, consumer purchasing patterns will be the biggest unknown. Besides fuel economy, we know that consumers demand affordability, safety, convenience, performance and utility. One challenge we face is that fuel economy considerations often rank below these other attributes. Fuel prices, which are especially difficult to project, have a huge impact on how consumers weigh fuel economy at the dealership. All of this explains why the final rule should include a rigorous mid-term evaluation. [EPA-HQ-OAR-2010-0799-9487-A1, p.9]

Adherence to the Mid-Term Evaluation Process and Timing is Critical. [EPA-HQ-OAR-2010-0799-9487-A1, p.7]

EPA has proposed that the MY 2022-2025 GHG standards "will remain in effect unless and until EPA changes them by rulemaking." EPA has not specifically provided for expedited judicial review of the results of the final mid-term evaluation or any final rule setting revised MY 2022-2025 GHG standards. [EPA-HQ-OAR-2010-0799-9487-A1, p.7]

The Alliance would like to stress how important it is that both agencies follow the mid-term evaluation process laid out in the regulations, including strict adherence to the deadlines. Following the process as proposed should enable the agencies to consider all relevant issues, make an informed decision about the appropriateness of the MY 2022-2025 standards, and allow sufficient time for the promulgation of different standards and/or judicial review, if necessary. The purpose of the mid-term evaluation provision is to ensure that the assumptions underlying the MY 2022-2025 standards remain valid; to the extent that the assumptions are incorrect and the standards are inappropriate, the burden is likely to fall primarily on vehicle manufacturers. If EPA fails to follow the mid-term evaluation process or fails to meet the deadlines, it is probable that EPA will not have complied with the Section 202(a)(2) mandate to provide adequate time for the development and application of the technology required to comply with such standards. Moreover, failure to conduct the midterm evaluation or to meet the deadlines would constitute a failure to perform a nondiscretionary duty and/or final agency action. [EPA-HQ-OAR-2010-0799-9487-A1, pp.7-8]

In making this comment, we wish to stress that the Alliance does not assume that EPA or NHTSA intend to deviate from the mid-term evaluation process or ignore its deadlines. We believe that all parties, including the agencies, will work in good faith to follow the process. We merely wish to stress that the success of the mid-term evaluation depends on close adherence to the process and the deadlines. If anything is allowed to undermine or delay the process, it creates a significant potential for disputes and difficulties in the future, something we all hope to avoid. [EPA-HQ-OAR-2010-0799-9487-A1, p.8]

The Agencies Should Conduct Periodic Technical "Check-Ins." [EPA-HQ-OAR-2010-0799-9487-A1, p.8]

In the time leading up to the mid-term evaluation - and following the completion of the evaluation - the agencies should continue to check the validity of the assumptions upon which their standards are based. We suggest not only one formal mid-term evaluation, as the agencies have proposed, but also a series of smaller, focused, technical evaluations of, or "check-ins" on, the key assumptions of the proposal. These "check-ins" will allow the agencies to consider the latest relevant technical information, and thereby help the agencies keep the program on track and produce the best long term results. By having these "check-ins" the agencies will be better prepared to begin their formal mid-term evaluation and to make appropriate adjustments during the second half of the period covered by these regulations. [EPA-HQ-OAR-2010-0799-9487-A1, p.8]

The Alliance understands that EPA's mid-term evaluation will take place concurrently, and in conjunction with, NHTSA's process for setting final CAFE standards for MY 2022-2025. The agencies should jointly examine progress achieved towards compliance with the standards, and assess the latest information available on key assumptions and trends used to develop the standards, including the criteria set forth for determining maximum feasible fuel economy standards in 49 U.S.C. § 32902(f). Factors that should be considered include, but should not be limited to: [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Development of powertrain improvements to gasoline and diesel-powered vehicles; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Level of employment in U.S. automotive sector; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Availability and implementation of methods to reduce weight while assuring compliance with state and Federal safety, emissions and equipment laws and standards, and maintaining acceptable performance in consumer information crash testing and manufacturer due care testing; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Actual and projected combined sales of alternative fuel vehicles; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Actual and projected availability of public and private charging infrastructure for electric vehicles; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Actual and projected availability of low carbon and technology-enabling fuels and infrastructure, along with adoption and implementation of clean and renewable energy standards; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Costs, including average costs of technologies to ensure compliance with the standards, such as vehicle batteries and power electronics, mass reduction, and alternative fuels, and anticipated trends in these costs; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Current and expected availability of state and Federal incentives/subsidies for advanced technology vehicles; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Average payback periods for any incremental vehicle costs associated with meeting the standards, as well as up-front cost and impacts on consumer affordability; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Costs for gasoline, diesel fuel and alternative fuels; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Total light-duty vehicle sales and projected fleet mix; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Consumer demand for and customer acceptance of fuel-efficient technologies, and consumer valuation of fuel savings; [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

End-of-life costs associated with advanced technology vehicles; and [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Any other factors that may be deemed relevant to the review. [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Some recent studies attempt to identify opportunities for cost-effective near-term fuel economy improvements but also raise important questions about longer-term conditions. These questions call for information that is not yet available to EPA, NHTSA, the California Air Resources Board or any other party, including automobile manufacturers. The Alliance recommends that the mid-term evaluation focus on the issues as detailed below. During the evaluation, the agencies should seek expert peer-reviewed data and analysis, including the input of the National Academy of Sciences (NAS), to answer the following questions, among others: [EPA-HQ-OAR-2010-0799-9487-A1, p.17]

Given how little is known about the “energy paradox,” the Alliance supports NHTSA’s proposal to develop a Consumer Vehicle Choice Model to inform the mid-term evaluation. Such a model should also look at the other factors identified in the Preliminary RIA as having an impact on consumer purchasing decisions: sales taxes, insurance costs, the additional cost of auto loans and changes in resale value. To have credibility, the model needs to use real-world data, be developed in a transparent manner with full peer review, and should assess uncertainties in its predictions. [EPA-HQ-OAR-2010-0799-9487-A1, p.19]

Given the considerable uncertainty about future technology development, cost and consumer acceptability, the proposed mid-term evaluation is essential in order to assure that the maximum feasible fuel economy benefits are obtained in a cost-effective and safety neutral manner. [EPA-HQ-OAR-2010-0799-9487-A1, p.22]

Process for Conducting the Mid-Term Evaluation [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

The NPRM indicates that a draft Technical Assessment Report will be completed by November 15, 2017, and that EPA will make a final determination by April 1, 2018. The Alliance believes that a more detailed description of the process would be helpful. In particular, the final regulatory language should indicate that the agencies intend to perform a thorough analysis of consumer purchasing behavior, the single most important factor that will determine whether the goals of the program are being met. [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

The final regulatory language should also include the following important details: [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

start date of the evaluation and a schedule for major milestones to assure that the review is completed in time for EPA to make a fully informed regulatory determination; [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

specific studies the agencies plan to conduct; [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

details of the peer review process; [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

availability of a pubic docket; [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

role of NAS in the mid-term evaluation; and [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

roles of other departments and agencies that provide or regulate alternative fuels and emerging technologies. [EPA-HQ-OAR-2010-0799-9487-A1, p.24]

Further, the Alliance suggests that multipliers, like many aspects of the program, be reviewed during the mid-term evaluation. Should the mid-term evaluation reveal continuing market challenges with advanced technology vehicles, extending the multipliers beyond MY 2021 may be necessary to encourage fleet penetration. [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 96-97.]

That's why it's critical that the final rule include a rigorous mid-term review with a clearly defined process for its implementation.

During the review, the agencies should seek expert peer-reviewed information including the input of the National Academy of Sciences to answer these questions: Are the costs of advanced technologies declining as expected? Are researchers making the breakthroughs anticipated? What's happening with fuel prices, and how are consumers responding? What impact are the new requirements having on sales and on employment? How are the new rules impacting vehicle safety? What's happened with fuel quality? Will liquid fuels support the fuel-efficient technologies that have been introduced? Will the new charging infrastructure be available to enable plug-in hybrids, battery electric vehicles and fuel cell vehicles to penetrate the market at the levels predicted?

Organization: American Honda Motor Co., Inc.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 121.]

The proposed mid-term review seems appropriate to us and we believe it will be essential to checking progress and making necessary adjustments that cannot be foreseen from this early date.

Organization: American Medical Association of California

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 48.]

As well as to whether any midterm program review that may be viewed by some as an opportunity to weaken the standards previously agreed upon. The midterm review may have ramifications for the State of California and the programs in place here. It will align with the national standards, and it must remain clear that California maintains its own Clear Air Act authority to enact our own rules more stringent than the federal rules due to our extreme air quality challenges.

Organization: Association of Global Automakers, Inc. (Global Automakers)

For this reason, we support the proposed mid-term review to reassess the stringency of the standards, including technology penetration rates, fuel costs, and most importantly, consumer acceptance. [EPA-HQ-OAR-2010-0799-9466-A1, p. 1]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 66.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 50-51.]

Due to the many uncertainties that are implicit in the technical and economic assumptions that form the basis for the proposed standards, we support the proposed mid-term review of the standards. We also support the recommendation made at the Detroit public hearing that the final rule should specify a clearly defined process for the review, with a designated list of questions to be addressed. In addition, we agree with the recommendation (again at the Detroit public hearing) that the agencies consider a series of more narrow reviews of key aspects of the standards. [EPA-HQ-OAR-2010-0799-9466-A1, p. 9]

The need for a mid-term review finds ample support in both EISA and the Clean Air Act, as both statutes require the promulgation of regulations that are based on the most up-to-date information concerning the costs and benefits of the technologies required to meet the standards. Indeed, because EISA prohibits the promulgation of fuel economy standards past the MY 2021, a mid-term evaluation is required before final CAFE standards can be promulgated for the 2022 through 2025 MYs. EISA provides that the Secretary shall "issue regulations under this title prescribing average fuel economy standards for at least 1, but not more than 5, model years." 49 U.S.C. § 32902(b)(3)(b). Congress included the 5 year limit, in part, because it recognized that the factors NHTSA must consider in adopting fuel economy standards—technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy, see 49 U.S.C. §32902(f)—are fluid and vary over time. Consequently, any attempt to weigh these factors today for standards that would not apply until the 2022 MY would be fraught with uncertainty and inherently arbitrary. [EPA-HQ-OAR-2010-0799-9466-A1, pp. 9-10]

The current rulemaking being jointly undertaken by EPA and NHTSA encompasses nine model years (MYs 2017 through 2025). Under the plain terms of the statute, any final fuel economy standards that are issued now and are applicable to a model year after 2021 would be invalid. The Notice of Proposed Rulemaking recognizes this concern and therefore states "[t]he second phase of the CAFE program, from MYs 2022–2025, represents conditional proposed standards . . ." 76 FR at 74,859. NHTSA correctly recognizes that "conditional" rulemaking in this instance "means to say that the proposed standards for MYs 2022–2025 represent the agency's current best estimate of what levels of stringency would be maximum feasible in those model years, but in order for the standards for those model years to be legally binding a subsequent rulemaking must be undertaken by the agency at a later time." Id., n.7. According to NHTSA, "[t]he passenger car and light truck CAFE standards for MYs 2022–2025 will be determined with finality in a subsequent, de novo notice and comment rulemaking conducted in full compliance with EPCA/EISA and other applicable law . . ." Id. at 75,166. [EPA-HQ-OAR-2010-0799-9466-A1, p. 10]

Global Automakers supports the intent expressed in the Notice of Proposed Rulemaking concerning the mid-term evaluation. However, we are concerned that the actual language of the proposed regulations goes too far in adopting final regulations for MY 2022 through 2025. Proposed 49 C.F.R. § 531.5(c) provides that "[f]or model years 2012–2025, a manufacturer's passenger automobile fleet shall comply with the fleet average fuel economy level calculated for that model year according to Figure 2 . . ." and provides the parameters for the fuel economy targets through the 2025 MY. Viewed in isolation, this provision would constitute final fuel economy standards for the 2022 through 2025 MYs. The standards are ostensibly made conditional through proposed subsection (e), which provides: "For model years 2022–2025, each manufacturer shall comply with the standards set forth in paragraphs (c) and (d) in this section, if NHTSA determines in a rulemaking, initiated after January 1, 2017, and conducted in accordance with 49 U.S.C. 32902, that the standards in paragraphs (c) and (d) are the maximum feasible standards for model years 2022–2025. . . .” [EPA-HQ-OAR-2010-0799-9466-A1, p. 10]

Global Automakers believes that a mid-term evaluation of the GHG emission standards is likewise not only permissible under the Clean Air Act, but also required because of the uncertainties inherent in projecting regulatory requirements nine to twelve years into the future. First, Section 202(a) plainly provides EPA with the authority for a mid-term evaluation. See 42 U.S.C. § 7521(a)(1) (providing that “[t]he Administrator shall by regulation prescribe (and from time to time revise)” motor vehicle emission standards) (emphasis added). [EPA-HQ-OAR-2010-0799-9466-A1, pp. 10-11]

Moreover, a mid-term evaluation is required under the Clean Air Act in view of the proposed regulations’ long regulatory horizon. The Clean Air Act requires that standards “shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.” 42 U.S.C. § 7521(a)(2). EPA’s determination concerning the appropriate level of stringency for GHG emission standards must be based upon reliable and up-to-date information. [EPA-HQ-OAR-2010-0799-9466-A1, p. 11]

Given the extremely long time-horizon of these proposed mobile source regulations, EPA has conceded a number of uncertainties in the analyses that underlie its current rulemaking. See, e.g., 76 FR at 74,881 (recognizing the “uncertainties regarding the benefit and cost values presented in this proposal”). For example, the NPRM states that EPA and NHTSA “did not consider technologies that are currently in an initial stage of research because of the uncertainty involved in the availability and feasibility of implementing these technologies with significant penetration rates for this analysis. The agencies recognize that due to the relatively long time frame between the date of this proposal and 2025, it is very possible that new and innovative technologies will make their way into the fleet, perhaps even in significant numbers, that we have not considered in this analysis.” Id. at 74,922. Global Automakers believes that the converse may also be true, i.e., the proposed standards are based on assumptions concerning the availability and market penetration of technologies up to 12 years into the future that may not prove entirely accurate. Consequently, Global Automakers believes that it would have been arbitrary and capricious for EPA to promulgate GHG emission standards for model years as far into the future as MY 2022-2025 without providing for a mid-term evaluation. [EPA-HQ-OAR-2010-0799-9466-A1, p. 11]

Organization: BMW of North America, LLC

An in-depth mid-term review is extremely important in order to monitor the development of external factors such as customer acceptance of more fuel efficient vehicles. [EPA-HQ-OAR-2010-0799-9579-A1, p. 1]

Therefore, an in-depth mid-term review is an extremely important pillar in the proposed rule in order to monitor the development of external factors which are not under the manufacturer's direct control. This review is critical for reassessment of what technology can deliver and what consumers are willing to buy. [EPA-HQ-OAR-2010-0799-9579-A1, p. 3]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 78-79.]

Organization: Center for Biological Diversity

H. The Agencies' Proposed Interim Rulemaking Should, at a Minimum, Be Based on a Presumption that the Stringencies of the Standards Will Not Decrease

We have already commented on the Agencies' proposed mid-term review in our response to the DEIS. We add here that the Agencies' proposed method of undertaking this review is faulty. They state they intend the review to be based on "(1) a holistic assessment of all of the factors considered by the agencies in setting standards . . . , and (2) the expected impact of those factors on the manufacturers' ability to comply, without placing decisive weight on any particular factor or projection." To the contrary, as fully explained above, the Agencies must place decisive weight on energy conservation. Yet, by highlighting manufacturers' ability to comply in a separate category, the Agencies tip their hand about a very different, and improper, weighing of the statutory factors. We further note the irony of requests by automakers for "frequent evaluations" of the MY 2017-2025 standards in light of their insistence that "certainty" of standards and extreme lead times are needed if stringencies are to be increased.110 Efforts to water down already insufficient standards by any means must be resisted. [EPA-HQ-OAR-2010-0799-9479-A1, pp. 24-25]

---

110 See Jason Plautz, Fuel Economy: Automakers Urge Frequent Evaluations of 2027-2025 Program, GREENWIRE, Jan. 17, 2012. [EPA-HQ-OAR-2010-0799-9479-A1, p. 25]

Organization: Chrysler Group LLC

This rulemaking will affect vehicles over thirteen years into the future. Many key elements such as technology development, technology costs, fuel costs, and customer acceptance can be difficult to accurately predict. Therefore, Chrysler strongly supports the agencies' proposal to hold a formal mid-term review of the 2022-2025 model year standards and informal monitoring of industry progress towards meeting the National Program goals. [EPA-HQ-OAR-2010-0799-9495-A1, p. 2]

For this reason the proposed mid-term review of the 2022-2025 MY standards is critical. Chrysler strongly supports this provision and encourages EPA and NHTSA (collectively, the "Agencies") to also establish regular informal reviews leading up to and following the formal mid-term review. [EPA-HQ-OAR-2010-0799-9495-A1, p. 5]

Chrysler notes that the Agencies have a firm legal basis to conduct the mid-term evaluation. (Attachment 1)

The Agencies have legal authority to conduct a formal mid-term evaluation which can affirm or modify standards promulgated for the 2022-2025 model years. [EPA-HQ-OAR-2010-0799-9495-A1, p. 6]

EPA and NHTSA have a firm legal basis to conduct the mid-term evaluation

EPA and NHTSA have ample authority under Section 307(d) of the Clean Air Act and the Administrative Procedure Act to reconsider regulations based on new information. See, e.g., 5 U.S.C. § 553(e) (providing for petitions to issue, amend or repeal a rule); 42 U.S.C. § 7607(b) (allowing petitions for review of a Clean Air Act rule based on new information); 49 U.S.C. § 32902(c) (authorizing the Secretary of the Department of Transportation to amend CAFE standards following notice-and-comment rulemaking under 5 U.S.C. § 553 and allowing for oral, transcribed presentations). [EPA-HQ-OAR-2010-0799-9495-A1, p. 7]

As described in the proposed rule, "NHTSA has a statutory obligation to conduct a separate de novo rulemaking in order to establish final standards for vehicles for the 2022-2025 model years and would conduct a mid-term evaluation as part of that rulemaking." 76 Fed. Reg. at 74,861. Under the Energy Policy Conservation Act ("EPCA"), NHTSA must set fuel economy standards at least 18 months before the beginning of each model year, 49 U.S.C. § 32902(a), and "must issue regulations … prescribing average fuel economy standards for at least 1, but not more than 5, model years." 49 U.S.C. § 32902 (b)(3)(B). Since NHTSA must go through future rulemaking to establish the MY 2022-2025 standards, a full consideration of the standards based on the record at the time of the rulemaking is essential. [EPA-HQ-OAR-2010-0799-9495-A1, p. 7]

EPA proposed a commitment to undertake a similar mid-term evaluation under the Clean Air Act. See 76 Fed. Reg. at 75,370 (proposed to be codified at 40 C.F.R. § 86.1818-12 (h)) ("Mid-term evaluation of standards. No later than April 1, 2018, the Administrator shall determine whether the standards established in paragraph (c) of this section for the 2022 through 2025 model years are appropriate under section 202(a) of the Clean Air Act, in light of the record then before the Administrator. An opportunity for public comment shall be provided before making such determination. If the Administrator determines they are not appropriate, the Administrator shall initiate a rulemaking to revise the standards, to be either more or less stringent as appropriate.").

As it is, agencies m [EPA-HQ-OAR-2010-0799-9495-A1, p. 7]ay not violate their own rules and regulations to the prejudice of others. See United States ex rel. Accardi v. Shaughnessy, 347 U.S. 260, 267 (1954); Steenholdt v. F.A.A., 314 F.3d 633, 639 (D.C. Cir. 2003) ("The Accardi doctrine requires federal agencies to follow their own rules, even gratuitous procedural rules that limit otherwise discretionary actions."). [EPA-HQ-OAR-2010-0799-9495-A1, p. 7]

The factors to be considered at the mid-term evaluation are the same as those that the agencies are obliged to consider in initially setting standards under their respective authorities. See 76 Fed. Reg. at 75,370 (proposed to be codified at 40 C.F.R. § 86.1818-12 (h)) (listing factors EPA must consider, including cost to producers and purchasers, as well as the feasibility and practicability of the standards and the impact of the standards on the automobile industry). Under EPCA, the Secretary is to consider "technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy." 49 U.S.C. § 32902(f). [EPA-HQ-OAR-2010-0799-9495-A1, p. 7]

NHTSA has interpreted economic practicability to include consideration of consumer choice, economic hardship for the automobile industry, and vehicle safety. 76 Fed. Reg. at 74,897 (footnote omitted) (discussing NHTSA approach to economic practicability under EPCA and explaining: "Consumer acceptability is also an element of economic practicability, one which is particularly difficult to gauge during times of uncertain fuel prices."); see also CEI I, 901 F.2d at 120, n.11; Center for Auto Safety v. NHTSA, 793 F.2d 1322, 1340 (D.C. Cir. 1986). [EPA-HQ-OAR-2010-0799-9495-A1, p. 7]

Under Section 202 of the Clean Air Act, EPA emissions standards:

"shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period." 42 U.S.C. § 7521(a)(2). [EPA-HQ-OAR-2010-0799-9495-A1, p. 8]

EPA has also acknowledged, at least as to choices among vehicles, the relevance of consumer acceptance in evaluating these factors. See MY 2012-2016 Final Rule, 75 Fed. Reg. 25,324, 25,467 ("Consumer choice remains a pertinent factor for EPA to consider in balancing the relevant statutory factors," citing International Harvester Co. v. Ruckelshaus, 478 F.2d 615, 640 (D.C. Cir. 1973)). In International Harvester, the court of appeals, recognizing that "[a]significant decrease in auto production will have a major economic impact on labor and suppliers to the [automobile] companies," concluded that the Administrator is required to consider issues of basic demand for new passenger vehicles in making technical feasibility and lead time determinations. Id. at 641. [EPA-HQ-OAR-2010-0799-9495-A1, p. 8]

Under Section 202, EPA also must consider safety impacts:

"…[N]o emission control device, system, or element of design shall be used in a new motor vehicle or new motor vehicle engine for purposes of complying with requirements prescribed under this subchapter if such device, system, or element of design will cause or contribute to an unreasonable risk to public health, welfare, or safety in its operation or function." 42 U.S.C. § 7521(a)(4)(A) (emphasis added). [EPA-HQ-OAR-2010-0799-9495-A1, p. 8]

As it is, the factors of "the requisite technology" and "appropriate consideration to the cost of compliance within such period" encompass the issues related to infrastructure, technology cost, consumer acceptance, and the other factors that the proposed rule directs EPA to consider. [EPA-HQ-OAR-2010-0799-9495-A1, p. 8]

The mid-term evaluation contemplates coordination between EPA and NHTSA, just as they have coordinated in developing the MY 2012-2016 rule and in developing the MY 2017-2025 proposal. Indeed, the United States Supreme Court has recognized that while the agencies' "obligations may overlap, . . . there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency." Massachusetts v. EPA, 549 U.S. 497, 532 (2007). [EPA-HQ-OAR-2010-0799-9495-A1, p. 8]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 53.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 60.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 25-26.]

We believe the midterm review is critical to determining whether the customer's buying, and will continue to buy the technology packages needed to comply with the standards year over year. Efforts to search for parameters that measure potential customer acceptance must not lose sight of the most important question: Are they buying the product? Measuring whether consumers will buy what we offer next year is already challenging. Speculating as far as 13 years in the future holds significant uncertainty and risk. A midterm assessment of the underlying rulemaking assumptions provides a critical and equitable mechanism o adjust standards for future consumer and technology uncertainties and is a primary reason Chrysler supports this program.

Organization: Consumer Federation of America (CFA)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 91-92.]

And finally, sixth, the proposed rule recognizes the need to stay in touch with reality.

So we have this midterm review, which I fully support, as you've heard the auto makers insist on it. But I actually believe when we get to the midterm review, we're as likely to increase the standards as decrease.

Because, one, we've used the very low gasoline price. And so I think it will be higher when we get there.

And, two, historically we've seen that the original projections of the cost of meeting technologies in every major standard proposed by this agency and NHTSA have always been too high.

Organization: Ecology Center

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 189.]

While we do have some concerns about the proposed mid-term review providing an opportunity to slow progress, we understand the need for potential adjustments due to many unknowns that far into the future. We are hopeful that such a review will show that even more progress is achievable.

Organization: EcoMotors International, Inc.

NHTSA is obligated to conduct a separate de novo rulemaking in order to establish final standards for MYs 2022-2025 vehicles. The agencies are therefore proposing to conduct a comprehensive midterm evaluation to assess the appropriateness of the MY 2022-2025 standards, based on an updated assessment of all the factors considered in setting the standards and the impacts of those factors on the manufacturers' ability to comply.

The auto industry faces great uncertainty over future technology developments and costs, customer acceptance of new technologies, and fuel prices. Additionally, it will require more than just automotive production for emissions reductions from advanced technology vehicles to be realized. There must be a national fueling and service infrastructure available to support these technologies if they are to achieve significant market penetration. Developing and establishing this infrastructure for the nation and establishing consumer confidence in new technologies will take time. All of these factors make it critical that OEMs foresee the ability to cope with unexpected events and changes. Given the uncertainty inherent in setting standards over such a long time period, EcoMotors supports the agencies' plans to conduct a coordinated mid-term evaluation of the standards. [EPA-HQ-OAR-2010-0799-9594-A2, pp. 13-14]

- Specific Recommendation: Conduct a coordinated mid-term evaluation, as proposed.

We look forward to further developments in this rulemaking. [EPA-HQ-OAR-2010-0799-9594-A2, p. 14]

Organization: Ferrari

Finally, it is essential for EPA and NHTSA to conduct a comprehensive mid-term evaluation, taking into account the long period covered by the proposed regulations, regardless the legal obligations for NHTSA. [EPA-HQ-OAR-2010-0799-9535-A2, p.10]

Organization: Ford Motor Company

• Mid term Evaluation: The proposal provides for a thorough mid-term evaluation, by no later than April 2018, to assess the appropriateness of the targets for model years 2022 through 2025. This provision is essential and must be maintained in the final rule. The market success of our industry, and hence that of our new and innovative products, is dependent upon many factors outside of our control, such as the price of fuel, the state of the economy, or the availability of affordable technologies and materials (for example, to support electrification, or light-weighting). The further we look into the future, the more difficult it is to predict these factors with accuracy. This is why the proposed mid-term evaluation of the 2022-2025 model year greenhouse gas standards is vital to this joint proposal. The mid-term evaluation provides an essential checkpoint to ensure that the standards for those model years are consistent with evolving market conditions. [EPA-HQ-OAR-2010-0799-9463-A1, pp. 2 and 5]

Mid-Term Evaluation

The proposed rules include provisions for a mid-term evaluation of the appropriateness of the MY 2022-2025 GHG standards. This mid-term evaluation is to be conducted concurrently with NHTSA's actions in setting final, enforceable standards for MYs 2022-2025. Under the proposal, EPA and NHTSA, along with CARB, will jointly prepare a draft Technical Assessment Report ('TAR') on the appropriateness and feasibility of the MY 2022-2025 GHG and Corporate Average Fuel Economy (CAFE) standards and make the report available to the public no later than November 15, 2017. The agencies will receive public comment on the TAR as well as the standards themselves. EPA will then determine, by April 1, 2018, whether the MY 2022-2025 standards are appropriate, taking into account a number of factors, including but not limited to factors specified in the regulatory language. If EPA determines the MY 2022-2025 standards are appropriate, it will issue a final decision to that effect, which will be judicially reviewable. If EPA determines the MY 2022-2025 standards are not appropriate, it will initiate a rulemaking to adopt appropriate standards under Section 202(a) of the Clean Air Act, and any final rule resulting from that process would also be judicially reviewable. Any such rulemaking would be conducted jointly with NHTSA's de novo notice-and-comment rulemaking to set final CAFE standards for MYs 2022-2025. Both agencies would presumably issue final standards for MYs 2022-2025 on or before April 1, 2020, which would provide the minimum allowable lead time for the MY 2022 standards under the CAFE law. [EPA-HQ-OAR-2010-0799-9463-A1, p. 6]

Given the extended timeframe for the rules, the mid-term evaluation provisions are essential to Ford's support of this rulemaking package. The proposed standards for model years 2022-2025 are premised on projected developments in fuel economy technology, anticipated improvements in infrastructure to support new kinds of powertrains, the willingness of consumers to accept new technologies, and other factors. To the extent that these assumptions turn out to be incorrect, adjustments to the MY 2022-2025 standards may be necessary. The mid-term evaluation provides a vital checkpoint to ensure that the MY 2022-2025 standards are realistic and that the manufacturers have a workable pathway to compliance. It is also essential that the agency decisions emerging from the mid-term evaluation be judicially reviewable. While we think it is unlikely that the agency's mid-term evaluation determination will be challenged in court, the possibility of such a challenge helps to ensure that the evaluation process will be robust and that the agencies will give full consideration to all comments. [EPA-HQ-OAR-2010-0799-9463-A1, p. 6]

Ford supports the mid-term evaluation provisions as proposed by EPA. We also offer the following comments, which are fully consistent with the existing provisions: [EPA-HQ-OAR-2010-0799-9463-A1, p. 6]

- Timing. In conducting the mid-term evaluation, it is very important that the agencies meet (if not beat) the deadlines set forth in the proposed rules. The TAR must be issued on time to allow for a reasonable public comment period, and the public comment period must be completed in a timely fashion for EPA to meet its April 1, 2018 deadline for making its determination. That deadline, in turn, must be met in case EPA needs to undertake a joint rulemaking with NHTSA to set new standards for MYs 2022-2025 and complete that rulemaking by April 1, 2020, which is NHTSA's statutory deadline for setting MY 2022 CAFE standards. If the mid-term evaluation process is allowed to lag, stakeholders who are concerned about the appropriateness of the MY 2022-2025 standards may have little choice but to initiate 'deadline' litigation or take other actions they believe to be consistent with their interests. If this occurs, the goal of an orderly, thoughtful mid-term evaluation process could be thwarted. Adherence to the timing set forth in the proposal is critical. [EPA-HQ-OAR-2010-0799-9463-A1, pp. 6-7]

- Coordination between EPA and NHTSA. Closely related to the timing issue is the importance of close coordination between EPA and NHTSA during the mid-term evaluation process. Consistent with the overarching goals of the One National Program framework, the midterm evaluation process needs to result in a joint rulemaking with harmonized CAFE and GHG standards for MYs 2022-2025. The harmonized standards should enable manufacturers to comply with both their GHG and CAFE obligations by building one fleet of vehicles that can be sold nationwide. In order to accomplish this, the degree of coordination between EPA and NHTSA during the mid-term evaluation needs to be no less than the degree of coordination involved in the pending joint rulemaking. The mid-term evaluation should not be viewed as an opportunity for EPA and NHTSA to go in different directions with respect to the GHG and CAFE standards. [EPA-HQ-OAR-2010-0799-9463-A1, p. 7]
- Factors to be considered. The proposed mid-term evaluation provision states that '…the Administrator shall consider information available on the factors relevant to setting greenhouse gas emission standards under Section 202(a) of the Clean Air Act for model years 2022 through 2025, including but not limited to…' *emphasis added+. The provision goes on to list a number of specific factors that the Administrator must consider. In Ford's view, the 'including but not limited to' language is an essential part of the mid-term review provisions. The factors that turn out to be most important six years from now are not necessarily foreseeable today, and not necessarily the ones listed in the proposed rule. As we understand the language, EPA must be open to the consideration of relevant factors not specifically listed, including relevant factors that may be raised in public comments received by the agencies. We urge EPA to maintain this language in the final rule, so that the midterm evaluation is as robust and comprehensive as possible. [EPA-HQ-OAR-2010-0799-9463-A1, p. 7]
- Holistic View. As part of the mid-term evaluation, the Agencies should take a broad view of the opportunities for reducing transportation-related CO_2 emissions and fuel consumption, with an eye toward determining whether it may be necessary to implement measures external to the auto industry in order to support and complement the vehicle standards. A holistic approach to GHG reduction and fuel savings has the potential to be much more effective than a tunnel-vision focus on vehicles alone. Along these lines, we direct your attention to comments submitted by the University of Michigan (Chock, Gonzalez, Zeilinski) regarding the importance of considering the role of consumer fuel usage as part of any effort to establish policies and regulations related to GHG emissions. Ford has been, and continues to be, actively involved in dialogue with a variety of entities (including governments, academic institutions, and NGOs) on such subjects as urban

> planning, congestion reduction, fueling infrastructure, and connectivity technologies to facilitate more efficient public and private transport. The ability of manufacturers to achieve the proposed vehicle standards may in part depend on the degree of progress our society is able to achieve in one or more of these other areas. Also, market fuel quality, particularly octane level, can have a significantly positive impact on all on-road vehicles and should therefore be a key part of our national strategy to improve energy security. These issues need to be on the table as part of the mid-term evaluation. [EPA-HQ-OAR-2010-0799-9463-A1, p. 7]

On balance, we believe that the proposed mid-term evaluation provisions set forth a meaningful and reasonable process for revisiting the appropriateness of the proposed MY 2022-2025 standards, with the benefit of the information gathered in the intervening years. Ford supports the inclusion of these provisions in the final rule, and we pledge to work with the agencies in a constructive manner toward final MY 2022-2025 standards that are workable and appropriate. [EPA-HQ-OAR-2010-0799-9463-A1, p. 8]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 45.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 34.]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 86-87.]

This is why the proposed midterm evaluation of the 2022 to 2025 standards is so vital to this joint proposal. As proposed, the midterm evaluation provisions require EPA to make a fresh determination regarding the appropriateness of the post-2021 model year standards after considering a variety of factors and soliciting public comments. This process will take place concurrently with NHTSA's process for setting final standards for the 2022 to 2025 model years. The midterm evaluation is an essential checkpoint to ensure that the standards for these model years are consistent with evolving market conditions. The existence of a robust, meaningful midterm evaluation process is critical to Ford's support for this rulemaking package.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 44-47.]

The proposed rule extends to the 2025 model year which is an unprecedented time frame in the context of fuel economy regulations. This presents a significant challenge for manufacturers. While the establishment of longer-term standards provide manufacturers with targets for future product planning investment, the longer time frame leads to greater risk that the assumptions underlying the standards do not come to fruition.

Organization: General Motors Company

GM understands that the 2022-2025 standards will be evaluated further during the mid-term review. [EPA-HQ-OAR-2010-0799-9465-A1, p. 2]

GM supports an in-depth mid-term evaluation, and urges as well, a continuing open dialogue among industry and other affected parties, including a series of earlier, focused, technical evaluations, or “check-ins”, on the key assumptions upon which the proposed standards are based. [EPA-HQ-OAR-2010-0799-9465-A1, p. 2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 35-38, and 56.]

As this proposal makes many optimistic assumptions and sets goals all the way out to 2025, 13 years from today, it is imperative that we collectively check the validity of those assumptions as we move through that extended period of time. We suggest not only one formal mid-term review as the agencies themselves have planned for the proposal, but a series of smaller technical and detailed focused check-ins on the key assumptions contained in this proposal. These check-ins will allow the program to stay on track and lead to the best long-term results. Of course, the more formal mid-term review is also essential since NHTSA must itself conduct a separate rulemaking to set the requirements under the CAFE law for the final four years of this period.

But you have my commitment that we will provide whatever data, analysis, and input we can to help the agencies to make judgments and course corrections along the way.

Clearly this proposal represents a dramatic attempt to advance the mutual goals of CO_2 reduction and increased energy diversity. The mid-term review is essential to make sure that we also revisit the assumptions inherent in establishing these goals to make sure we have not overwhelmed technology development or the needs of consumers or their willingness to accept and pay for the associated changes in vehicles.

Organization: Honeywell International, Inc.

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 258.]

As the agencies recognize, turbo technologies will contribute significantly during the model years covered by this rulemaking, the agencies should commit during the mid-term review to evaluate the availability of more advanced turbo technologies and to ensure an equal production incentive as any ongoing incentive provided to battery technology.

Organization: Honeywell Transportation Systems

Honeywell also encourages the agencies to commit in the final rule to a detailed review of emerging boosting technologies that may considerably advance vehicle emissions and fuel economy performance during the later years of the rulemaking. The agencies have already committed within the mid-term review to consider powertrain improvements to diesel and gasoline powered vehicles. New, advanced turbo technologies can facilitate those improvements and may be ripe for regulatory consideration during the time when the agencies intend to conduct the mid-term review. [EPA-HQ-OAR-2010-0799-9474-A1, p.6]

Honeywell's research and development into turbo advancements continues. We expect to contribute significantly to support emissions and fuel economy improvements in both the light duty and heavy duty fleets during the upcoming model years. We are investing in yet more advanced approaches that we expect will allow diesel and gasoline vehicles to compete favorably in the marketplace while substantially advancing their environmental performance. While many of these technologies are not yet available for regulatory consideration, we anticipate that new, additional turbo technologies will be on the technology menu during the mid-term review. [EPA-HQ-OAR-2010-0799-9474-A1, p.6]

The agencies' consideration of additional flexibilities and credits in the mid-term review should include such technologies. While the agencies will reconsider the viability of any incentives provided to electric drivetrains in the upcoming final rule, the agencies at the same time should consider providing equal treatment to ICE vehicles incorporating the boosting technologies that may be ripe for emergence during the model year 2022-2025 timeframe. [EPA-HQ-OAR-2010-0799-9474-A1, p.6]

Honeywell also requests that the agencies commit to ensuring that future turbocharging technology be accorded full consideration and treatment analogous to electric drivetrain technology during the mid-term review. [EPA-HQ-OAR-2010-0799-9474-A1, [p.6]

Organization: House of Representatives, Congress of the United States

In addition, we were pleased that the Administration intends to include a 'midterm' review for the 2022-2025 requirements. This provides an opportunity for the last set of increases to be re-visited to see if the assumptions on technology, costs, fuel prices, consumer acceptance and vehicle prices still support the standards that will be proposed, or whether their stringency should be revised upwards or downwards. [EPA–HQ–OAR–2010–0799-1221-A1, p. 1]

Organization: Hyundai America Technical Center

The agencies are proposing a comprehensive mid-term review prior to the final adoption of the MY 2022-2025 standards by NHTSA. Hyundai supports the standards as proposed and appreciates the substantial lead time provided by the regulations which will provide stability for long-term product planning. At the same time, the proposal covers nine model years, out to MY 2025, which makes it difficult to make accurate assumptions due to market uncertainties such as the price and viability of different fuel types, infrastructure availability, technology availability, technology penetration rates and cost, and consumer acceptance of technology. Therefore, Hyundai supports the mid-term evaluation because it provides an opportunity to ensure that the details of the program are appropriate and that the requirements are sound closer to the time of implementation. [EPA-HQ-OAR-2010-0799-9547-A1, p.2]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 173.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 23.]

We agree with the comments by Global Automakers that the final rule should specify a clearly defined process for the mid-term review with a set of specific questions that should be addressed. Additionally, we also support additional informal periodic reviews to monitor areas such as the state of technology, the effect of the proposed incentives and the viability of testing methods. [EPA-HQ-OAR-2010-0799-9547-A1, p.2]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 173-174.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 24.]

Although we believe the proposed requirements are feasible, Hyundai recognizes that it is difficult to accurately predict out to the 2025 time frame the technologies and the cost and consumer acceptance of these technologies that will be necessary.

The mid-term review will help ensure that the requirements are sound closer to the time of implementation.

Organization: Institute for Policy Integrity, New York University School of Law

Factors for the Mid-Term Evaluation Should Specifically Include Benefit Estimate Revisions
The agencies should commit to developing better estimates of non-carbon dioxide benefits during the SCC revision process, ideally in time to incorporate such estimates in the final rulemaking.

Periodic review of ongoing regulations is a valuable check on efficiency,73 and the practice is now enshrined in executive order.74 The agencies' plan to conduct a mid-term evaluation of the rule in advance of model year 2022 is commendable. Unfortunately, EPA's list of relevant factors to consider during this review process lacks key elements. While there is a catch-all listing of "other factors," there is no specific mention of reviewing any changes in benefits estimates, such as any revised SCC values. The agencies should amend their list of factors to specifically reflect any potential changes to benefits estimates, in addition to changes to costs or the state of technology. [EPA-HQ-OAR-2010-0799-9480-A1, p. 11]

---

73 See Comments from Policy Integrity to EPA and DOT on Retrospective Review (Mar. 18, 2011, Apr. 1, 2011, June 27, 2011, July 3, 2011), available at http://www.policyintegrity.org.

74 Exec. Order 13,563 § 6.

Organization: International Council on Clean Transportation (ICCT)

10. ICCT enthusiastically supports a midterm review, as we believe it will find that costs have been significantly overstated. The criteria and analyses used for the midterm review should be similar to those used for any CAFE or greenhouse gas rulemaking process. EPA and NHTSA should also provide periodic status updates on technology progress and the results of additional benefit and cost analyses. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

10) Mid-Term Review

The ICCT enthusiastically supports a midterm review, as we believe the proposed rule significantly overstates the cost of compliance. Continued technology advancements will both increase the benefits of many technologies, such that not as much technology would need to be installed, and reduce the cost of technologies that are used. Capturing these future improvements in the midterm review will allow the agencies to increase the stringency of the 2022-2025 standards. [EPA-HQ-OAR-2010-0799-9512-A1, p. 22]

The process for the midterm review is critical to the 2022-25 standards. It is impossible to define all the criteria for the review at this time, just as it is not possible to define all of the criteria for any rulemaking process. EPA and NHTSA need latitude to apply their best analyses and base the requirements on the results of these analyses. The ICCT believes that the criteria and analyses used for the midterm review should be similar to those used for any CAFE or GHG rulemaking process. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 22-23]

The ICCT also recommends that EPA and NHTSA conduct periodic updates on technology progress and consider periodic status reports. Tear-down cost assessments should continue in order to assess the cost of newer technologies as they are introduced into the market. Simulation modeling also needs to be updated to keep pace with technology development. The scope and timing of reports should be up to the Agencies, but we see value in documenting progress in technology improvements and implementation. Manufacturers do not release details of their technology development, so periodic reports can summarize technology and cost developments and technology deployment for all interested parties, including other manufacturers. The ICCT also expects continued improvement in the science of assessing technology benefits and costs, which can be disseminated through the periodic progress reports. Forward-looking analyses would provide a better foundation going into the midterm review and should be updated as appropriate. [EPA-HQ-OAR-2010-0799-9512-A1, p. 23]

Organization: Johnson Controls, Inc.

Johnson Controls also supports the agencies' inclusion of a mid-term evaluation, which, as proposed, will provide all stakeholders with a comprehensive analysis so they may consider the current performance and ability to realistically deliver the MY 2017-2025 standards in the public docket. Long-term planning is an especially important factor in the battery industry as there are likely to be uncertainties in the product development cycle that could directly impact - positively or negatively - the commercial success of new products, as well as the return on investment required to expand the U.S. manufacturing base. Providing an opportunity for a thorough analysis is a critical and necessary component of this next National Program. [NHTSA-2010-0131-0253-A1, pp. 2-3]

Midterm Review should be supplemented by ongoing review and analysis during the course of the National Program. Midterm review is a critical component for this next National Program which covers eight years. Since the commencement of the midterm 'review is in the distant future, the industry encourages the agencies to be open to ongoing shared analysis and input to assess if the goals of the Program are being realized and/or if there are circumstances that drastically impact the marketplace or technology development. [NHTSA-2010-0131-0253-A1, p. 5]

Organization: Kia Motors

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 102.]

Kia appreciates these substantial lead times for these regulations which will provide stability in long-term planning. However, Kia believes it is important for the agencies to include mid-term evaluations to allow for revisions if some of the assumptions made in the drafting of the rule are not proven to be correct. Even though Kia supports the standards, Kia recognizes it is difficult to accurately predict the outcome -- to accurately predict how to deliver the 2025 technology in that time frame. Consumer acceptance of those technologies and costs will also be a challenge. The mid-term review will help us ensure that the standards are robust for all OEMs near to the time frame of implementation.

Organization: Marshall, C.

The idea of a review of the regulation in 2021 is a good concept but I think the lead-times for the vehicle manufacturing industry to retool are so long that I would suggest the review be held in 2019. [EPA-HQ-OAR-2010-0799-5917-A2, p. 1]

Organization: Mass Comment Campaign (20,500) (Union of Concerned Scientists-3)

The agencies are proposing a 'mid-term' review that would begin soon after the standards come into effect. In the past, automakers have abused similar programs--turning them into off-ramps as opposed to reviews. It is critical that this review does not undermine the program through 2025. [EPA-HQ-OAR-2010-0799-10166-A2_MASS, p.1]

Organization: Mass Comment Campaign (375) (Union of Concerned Scientists-2)

The agencies are proposing a 'mid-term' review that would begin soon after the standards come into effect. In the past, automakers have abused similar programs--turning them into off-ramps as opposed to reviews. It is critical that this review does not undermine the program through 2025. [EPA-HQ-OAR-2010-0799-1246-A1_MASS, p.1]

Organization: Mass Comment Campaign (9,570) (Unknown Organization)

The agencies are proposing a 'mid-term' review that would begin soon after the standards come into effect. In the past, automakers have abused similar programs--turning them into off-ramps as opposed to reviews. It is critical that this review does not undermine the program through 2025. [EPA-HQ-OAR-2010-0799-9578-A1_MASS, p.1]

Organization: Mercedes-Benz USA, LLC

The mid-term review is critical to ensuring that the program remains feasible and is achieving GHG and fuel economy reductions without creating unintended economic, market and/or safety consequences. DAG strongly endorses the comments of the Auto Alliance with regard to the mid-term review. In addition to the various 'unknowns' identified in the Alliance comments, the mid-term review is essential to evaluate the structure of the program as applied to companies needing to expand their product offerings beyond the addition of advanced technology vehicles. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-2]

DAG also encourages the agencies to engage in periodic evaluations, in addition to the more formal and comprehensive mid-term review, to appraise (1) the extent to which the market has sustained the continued growth of hybrid vehicles and has accepted electric vehicles, (2) the extent to which the infrastructure to support battery electric, fuel cell and CNG vehicles has grown, and (3) whether efforts to meet the standards have resulted in adverse market or economic losses or product withdrawals. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-2]

Organization: Mitsubishi Motors R&D of America, Inc. (MRDA)

Supports the inclusion of a mid-term evaluation as fundamental for setting realistic fuel economy and GHG stringency levels for MYs 2022 through 2025. Recommends that effects of consumer incentives and EV charging infrastructure must be considered in the mid-term evaluation. [EPA-HQ-OAR-2010-0799-9507-A1, p.2]

Mitsubishi Motors fully supports the mid-term evaluation, included in proposed language in Section 86.1818–12(h), in preparation for setting fuel economy and GHG standards for MYs 2022 through 2025. This is not only necessary, but fundamental to setting informed and practical standards that account for the realities of the U.S. market. Mitsubishi Motors believes the following factors must be considered and incorporated into the mid-term evaluation: [EPA-HQ-OAR-2010-0799-9507-A1, p.2]

- · What are fuel price trends as compared to what was projected? [EPA-HQ-OAR-2010-0799-9507-A1, p.2]
- · Are consumers buying more fuel efficient vehicles in general? [EPA-HQ-OAR-2010-0799-9507-A1, p.2]

- · Does sufficient EV infrastructure exist to support current and future EV adoption? Have consumers adopted EVs in the numbers as projected by the agencies in the analysis done for the NPRM? [EPA-HQ-OAR-2010-0799-9507-A1, p.2]
- · Have there been any significant industry-wide economic setbacks making EV and overall fuel economy targets as proposed in the NPRM impracticable? [EPA-HQ-OAR-2010-0799-9507-A1, p.3]
- · Are financial and non-financial incentives and compliance flexibilities still necessary to continue to advance adoption of EVs? [EPA-HQ-OAR-2010-0799-9507-A1, p.3]
- · Have there been significant advances in smart grid development, energy management and battery storage? [EPA-HQ-OAR-2010-0799-9507-A1, p.3]

This is not an exhaustive list. Given our significant investment and commitment to EV commercialization, these are important areas of concern for Mitsubishi Motors in the MY 2022 through 2025 timeframe. After a thorough analysis and consideration of all necessary factors, CAFE and GHG stringency levels for MYs 2022 through 2025 should be set accordingly. [EPA-HQ-OAR-2010-0799-9507-A1, p.3]

The agencies have never proposed fuel economy (or GHG) regulations that reach 13 model years into the future. Additionally, the agencies? target for finalizing this rule will be well before NHTSA?s statutory requirement of publishing finalized requirements at least 18 months prior to the beginning of a MY. This unprecedented lead time lends itself to more questions rather than providing certainty for OEMs. [EPA-HQ-OAR-2010-0799-9507-A1, p.3]

Additionally, the mid-term evaluation is necessary since the product plans for MYs 2016 through 2020 are not as well-defined as the product plans for MYs 2010-2015. And, no OEM has detailed product plans for MYs 2021 through 2025. Although the product cycle development begins nearly 10 years before the launch of a vehicle, the commitment to product plans does not happen 10 years in advance. Product plans are set in general for approximately five years at a time. Projecting beyond five years in the future presents incremental uncertainties that those projections can be fulfilled for a number of reasons. The mid-term evaluation will help ensure that substantive analysis, rather than incrementally uncertain assumptions, support progressive yet realistic targets for the later years of this rulemaking. [EPA-HQ-OAR-2010-0799-9507-A1, p.3]

Much of the uncertainty involves making realistic assumptions for consumer acceptance of alternative fueled vehicles (AFVs) for MYs 2022 through 2025. In order to make accurate assumptions for this timeframe, NHTSA and EPA must evaluate consumer choices made during MYs 2017 through 2021. Given historical adoption rates of advanced technology vehicles, there needs to be a thorough evaluation for an EV multiplier in MYs 2022 through 2025 in order to continue to advance EV market penetration. [EPA-HQ-OAR-2010-0799-9507-A1, p.3]

To spur EV industry investment, President Obama established a national goal of 1 million electric vehicles on the road by 2015. Localities like the twin cities of Bloomington and Normal in central Illinois are working with Mitsubishi Motors and the Eaton Corporation through the EV Task Force to educate consumers, install EV charging infrastructure and deploy 1,000 Mitsubishi “i”s by 2014. OEMs are planning for significant increases in consumer adoption rates of EVs and PHEVs. These progressive targets and plans are noteworthy and encouraging. Ultimately however, only consumers can fulfill these plans. EPA should account for uncertainty regarding consumer acceptance by extending the EV multiplier in MYs 2022 through 2025. This will help sustain progress towards establishing a mass EV market. [EPA-HQ-OAR-2010-0799-9507-A1, p.3]

Overall, NHTSA?s Preliminary Regulatory Impact Analysis (PRIA) suggests that this rulemaking is economically practicable for the industry as a whole. Yet, details in the PRIA indicate that manufacturers? costs to incorporate advanced technology in vehicles vary greatly. Specifically, Table VII-1a (estimated average cost per passenger car over the adjusted baseline for MYs 2017 through 2025) in the PRIA projects that Mitsubishi Motors? projected costs are higher than any other manufacturer. By 2025, they are projected to be more than three times greater than the average. [EPA-HQ-OAR-2010-0799-9507-A1, p.3]

It is evident and expected that some companies will be absorbing more incremental costs to remain price competitive, especially manufacturers with fewer product lines. Some increased material and component costs can be passed onto a consumer. However, Mitsubishi Motors strives to offer competitively priced vehicles, and like other manufacturers, endeavors to limit transferring costs to consumers. In addition, some manufacturers, because of size and product mix, continually face unique challenges. To that end, the agencies requested comments related to challenges that “intermediate volume limited line manufacturers” may face in meeting the fuel economy and GHG standards for MYs 2022 through 2025. As noted in the NPRM, these challenges include securing competitive supplier contracts and having limited product lines across which to spread costs. Mitsubishi Motors? light duty vehicle sales account for approximately 0.6% of the U.S. market. As a manufacturer with more limited resources than many others in the U.S. market, adding advanced technologies to all vehicle models simultaneously is not feasible or practical. The mid-term evaluation should include consideration of compliance options specifically for OEMs with limited product lines. [EPA-HQ-OAR-2010-0799-9507-A1, pp.3-4]

In the mid-term evaluation, the agencies should also review assumptions about EV market penetration based on the availability and effect of consumer purchasing incentives. Although outside the scope of this rulemaking, EV incentives will continue to be a pivotal factor in spurring EV growth towards a mass market option. Mandating fuel efficiency and GHG emissions standards will not guarantee that a consumer will choose an electric drive vehicle. Pricing and charging infrastructure availability will be the main drivers in purchasing an EV. Financial and nonfinancial consumer incentives at the federal/state/local levels are necessary in the early stages of introduction for a distinct and new technology for most customers. It should be noted that relying on government tax incentives is not and cannot be a part of a sustainable long-term business plan for OEMs selling electric drive vehicles. However, if this technology is to become a significant part of the overall fleet, then government tax incentives are necessary for the beginning stages of commercialization. [EPA-HQ-OAR-2010-0799-9507-A1, p.4]

The mid-term evaluation should also consider available EV infrastructure when assessing past and future assumptions of EV market penetration. As noted above, charging infrastructure availability is key to a consumer's decision to purchase an EV. Currently, there is no national plan for EV infrastructure development to compliment the federal government's efforts to support EV industry growth and consumer acceptance of EVs. A national plan would help develop regional targets to establish EV infrastructure. Specifically, Mitsubishi Motors believes that EV charging infrastructure should be developed and prioritized according to the following: [EPA-HQ-OAR-2010-0799-9507-A1, p.4]

1. Home charging is the top priority and permitting processes must be streamlined. [EPA-HQ-OAR-2010-0799-9507-A1, p.4]

2. Workplace charging is the next priority because this supports increased EV adoption and enables future Vehicle to Grid energy storage concepts. [EPA-HQ-OAR-2010-0799-9507-A1, p.4]

3. Public Charging, especially DC quick charging, encourages adoption of EVs with smaller-sized, more resource efficient battery packs by increasing a vehicle's effective daily range. [EPA-HQ-OAR-2010-0799-9507-A1, p.4]

OEMs must be able to innovate while complying with practicable federal fuel efficiency and GHG regulations to match the realities of the U.S. market. Mitsubishi Motors supports the inclusion of a mid-term evaluation in order to realistically evaluate the assumptions for setting fuel economy and GHG standards in MYs 2022 through 2025. [EPA-HQ-OAR-2010-0799-9507-A1, p. 6]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 96.]

Mitsubishi Motors urges the agency to work with stakeholders well in advance of the midterm evaluation to develop sound review process and framework.

Organization: Motor & Equipment Manufacturers Association (MEMA)

MEMA also strongly supports the agencies' inclusion of a mid-term evaluation. That way, all stakeholders can perform a comprehensive and transparent assessment to see if the goals of the Program are being realized and/or if there are circumstances that drastically impact the marketplace or technology development, which may call for appropriate revisions. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

Midterm Review is a key component of the National Program for MYs2017-2025. We support an assessment to ensure that the goals are being realized and/or to address any circumstances that drastically impact the marketplace or technology development to warrant revisions. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

MEMA strongly supports the agencies' inclusion of a mid-term evaluation, which, as proposed, will provide a complete comprehensive analysis for all stakeholders to consider the current state-of-play and practicability of the MY2017-2025 standards in the public docket. Long-term planning is an especially important factor in the motor vehicle industry as there are likely to be uncertainties in the product development cycle that could directly impact – positively or negatively – the commercial success of new products and the return on investment required to expand the U.S. manufacturing base. Outside of the formal midterm review, it seems reasonable that there should be an ongoing dialogue between all of the stakeholders leading up to the midterm review. [EPA-HQ-OAR-2010-0799-9478-A1, p.5]

MEMA supports a complete assessment of the Program to ensure that the goals are being realized and/or if there are any circumstances that drastically impact the marketplace or technology development to warrant revisions to the standards. Providing an opportunity for a thorough analysis is a critical and necessary component of this next National Program. [EPA-HQ-OAR-2010-0799-9478-A1, p.5]

Organization: National Association of Clean Air Agencies (NACAA)

Further, once this program is in place, it is critical that EPA and NHTSA closely track progress in meeting the standards. In addition, the mid-term evaluation to be conducted in the 2021-2022 timeframe should evaluate the use of credits by automobile manufacturers and the impact of credit use on average fleet performance. In particular, EPA and NHTSA should evaluate whether credit use is allowing the production of a greater number of vehicles that do not meet the 5-percent rate of improvement requirement. [EPA-HQ-OAR-2010-0799-8084-A1, p. 3]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 40-41.]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 35-36.]

Organization: National Association of Manufacturers (NAM)

The NAM submits these comments to address one specific substantive aspect of the proposed rule: the mid-term evaluation program. As described below, the NAM supports the inclusion of a mid-term evaluation cycle but has a number of concerns regarding the content of the review and the procedures through which it will be implemented. We urge the EPA to clarify the content of the evaluation and the procedural details of the evaluation and to add additional time to the review process so that the EPA can complete a revised rulemaking with sufficient lead time to allow regulated entities to achieve compliance. [EPA-HQ-OAR-2010-0799-9538-A2, p. 1]

The Agencies Should Adhere to the Mid-Term Evaluation Process to Ensure That Regulated Entities Are Not Subject to Inappropriate Standards

The Associations fully support the Agencies' proposal to complete a mid-term evaluation of the appropriateness of the Model Year 2022-2025 standards. Estimates and projections of future costs and the pace of technological development made more than 10 years in advance are fraught with uncertainty and the risk of significant deviation from those projections is high. Therefore, a mid-term evaluation is appropriate so that the Agencies can make necessary adjustments to the standards to ensure the standards are cost-effective and capable of implementation. The Associations generally agree with the proposed content of the mid-term evaluation, particularly its focus on the cost and availability of advanced technologies, the standards' impact on vehicle safety, the effect on the economic health of the automotive industry, and "other relevant factors." While the Agencies need not develop an exhaustive list of relevant factors in advance, they should include those factors that will necessarily impact the automotive industry's ability to achieve the standards. For example, the Agencies should expressly require consideration of consumer purchasing patterns and acceptance of new technologies, the availability of alternative fuel infrastructure, and government responses to declining gasoline tax revenue as a result of increased fuel efficiency. [EPA-HQ-OAR-2010-0799-9538-A2, p. 2]

The Associations also have a number of procedural concerns about how the mid-term evaluation and subsequent rulemaking will be conducted. First, the proposed timeline for the review and promulgation of new standards is compressed and delays in the review process may threaten the industry's ability to comply with revised standards once they are issued. The proposed rule requires the Agencies to make a final determination regarding the appropriateness of the existing standards a mere 4.5 months after issuing the draft Technical Assessment Report. In this short time period, the Agencies propose to complete a peer assessment of the draft report, solicit public comments on the draft report and the appropriateness of the existing standards, and respond to the peer assessment and public comments. The peer and public review are critical components of the mid-term evaluation and the Agencies must ensure that the comment process and their response are not rushed. If the Agencies find that the existing standards are inappropriate, they will have little more than two years to promulgate revised standards, leaving manufacturers with only 18 months to achieve compliance with the revised standards. While the schedule proposed by the Agencies will provide sufficient lead time to allow manufacturers to adjust to the revised standards, history has shown that rulemaking deadlines are often missed, meaning that manufacturers could be left with even less time to comply with the revised standards. As a result, we urge the Agencies to consider additional mechanisms to ensure that revised standards will be issued on schedule. For example, the Agencies could provide additional flexibility by beginning the review process earlier. To ensure the effectiveness of the review process, the Agencies should clarify and make judicially enforceable the proposed timeline and details of the public and peer reviews of the draft Technical Assessment Report. We also urge the Agencies to set a firm and judicially enforceable timeline (including a commencement date and intermediate milestones) for the development of the draft report to ensure that it is completed on schedule. With the addition of these procedural safeguards, we are confident that the Agencies will be able to complete the mid-term evaluation and subsequent rulemaking while adhering to the proposed timeline. [EPA-HQ-OAR-2010-0799-9538-A2, pp. 2-3]

Second, the Agencies should not take the default position that the existing 2022-2025 model year standards will remain in place unless changed by rulemaking. If the Agencies determine that the 2022-2025 standards are inappropriate, there is simply no reason to leave them in place during the subsequent rulemaking process. Instead the existing standards should be rescinded immediately upon a determination that they are inappropriate, leaving the 2021 standards in effect until revised standards are finalized. Otherwise, manufacturers would be required to comply with the inappropriate standards in the event that a subsequent rulemaking is not finalized by 2022. As noted above, there is always a risk that agencies will be unable to meet proposed timelines for review processes and rulemaking proceedings. Moreover, as EPA and NHTSA recognize, both the appropriateness determination and any subsequent rulemaking would be final agency action subject to judicial review. The proposed rule does not include an expedited review procedure and a challenge to either final agency action would add additional delay and threaten the Agencies' ability to complete a final rulemaking before 2022. In light of these risks, it would be arbitrary and capricious to leave the 2022-2025 standards in effect after they are determined to be inappropriate. [EPA-HQ-OAR-2010-0799-9538-A2, p. 3]

Organization: National Automobile Dealers Association (NADA)

The proposal contains a so-called 'mid-term evaluation' designed to allow for the reevaluation of the key regulatory assumptions. It defies logic that the proposal sets up the need for a 'mid-term evaluation' in the first place. In fact, NHTSA and EPA should not even be engaged in rulemaking at this time, so soon after having set standards for MYs 2012-2016, and before having had the benefit of learning from how those standards work in the real world. A prudent strategy would involve engaging in rulemaking in the calendar year 2014 time frame, aimed at setting standards for MYs 2017 through 2021 or 2022. Such a timetable would greatly reduce the likelihood that mandates will prove to be technologically infeasible or economically impractical. As evidenced by the truck emissions experience, NHTSA and EPA should strive to limit any risk of foreseeable harms and unforeseeable consequences. [EPA-HQ-OAR-2010-0799-9575-A1, p. 12]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 70.]

Sure, manufacturers need adequate time to achieve compliance. And as a businessman, dealers appreciate regulatory certainty, but we question whether setting fuel economy mandates so far out makes sense when critical variables like fuel prices, consumer behavior and creditworthiness are paramount. If anything, this contradicts Congress's intent that such standards be set in 5-year or fewer intervals. Moreover, any supposed certainty may be fleeting given the proposal's mid-term review could result in even stricter mandates for model years 2022 to 2025.

Organization: Natural Resources Defense Council (NRDC)

D. Mid-Term Evaluation Is Unnecessary but, If Used, Proposed Structure Is Appropriate

NRDC believes that the mid-term evaluation is unnecessary and potentially disruptive to automaker product planning. The mid-term review adds uncertainty to what is otherwise a nine-year planning horizon for the automakers. By cutting the planning time line roughly in half, the mid-term evaluation undermines investments in technology that will improve efficiency beyond 2021 required levels. The mid-term review could also disrupt the deployment of vehicle fueling infrastructure, for advanced vehicles such as plug-in electric vehicles and hydrogen fuel cell vehicles that may be on the verge of a rapid market growth in the post-2020 period. [EPA-HQ-OAR-2010-0799-9472-A2, p. 16]

As it is proposed, the mid-term evaluation follows an appropriate structure. There should be only a single mid-term evaluation to consider compliance with standards for just model years 2022 to 2025. The mid-term evaluation should consider the wide-range of factors that affect the automotive industry's ability to comply, including different technology pathways, credit mechanisms such as banking, trading and borrowing and market conditions. However, a decision to modify the standards should be based on weighing all factors and not mainly on a single factor, technology or market projection. [EPA-HQ-OAR-2010-0799-9472-A2, p. 16]

NRDC agrees that mid-term evaluation should occur as close as possible to the beginning of model year (MY) 2022 without violating the minimum 18 month leadtime. The close timing will ensure that recent advances in technology driven by the MY 2017-2021 standards will be considered in the evaluation. [EPA-HQ-OAR-2010-0799-9472-A2, p. 17]

We agree that an assessment of compliance and the development of a technical assessment report for the mid-term review should include the close coordination of all three regulatory agencies that have developed the National Program since 2009, including EPA, NHTSA and CARB. The evaluation should also be open for public participation and comment consistent with this proposed rule. [EPA-HQ-OAR-2010-0799-9472-A2, p. 17]

Organization: Nissan North America, Inc.

Mid-Term Review: Nissan's commitment to the program Is premised on a comprehensive mid-term evaluation for MYs 2022-2025. The standards are extremely aggressive, particularly with regard to the light truck fleet. The standards assume not only a significant amount of technology advancement, but also consumer acceptance and transformation of the vehicle fleet. For both the light truck and the passenger car fleets, the extent to which automobile manufacturers are able to meet these standards will depend not merely on their ability to cost-effectively incorporate additional and transformational technologies, but also on factors external to vehicle design and engineering. The mid-term evaluation is essential to ensuring that the standards remain technologically and economically feasible. A meaningful review, as set forth in the Notices of Intent and the proposal, to evaluate the full range of market, technology and regulatory factors for the later model years is not only essential, it is required by law. [EPA-HQ-OAR-2010-0799-9471-A1, p.2]

The Mid-Term Review is Essential to Ensure that the Assumptions Underlying the Proposal are Valid for the Later Model Years

The proposed standards are extremely ambitious. Success in meeting these standards will depend not only on the deployment of advanced technologies and materials, but also on consumer demand shifts and the economic vitality of the U.S. market. The technological and economic uncertainties inherent in setting standards so far into the future make a robust mid-term review an essential element of the program. Only through a commitment to a comprehensive mid-term evaluation will the government, industry and stakeholders have certainty that the goals established for MYs 2022-2025 remain appropriate and feasible. [EPA-HQ-OAR-2010-0799-9471-A1, pp.4-5]

Nissan will continue to provide a full range of vehicles, and to incorporate continuous improvements throughout its vehicle fleets. This includes advances in internal combustion engines (ICEs) as well as the continued deployment of electric drivetrains. Nissan also continues to explore appropriate opportunities for mass reduction. A comprehensive mid-term evaluation is critical to determining the extent to which the market accepts the additional costs associated with more advanced internal combustion vehicles, as well as the extent to which the advanced powertrain market develops. In addition, government regulatory programs involving both fuels and safety requirements will directly affect future feasibility and must be considered in any future review. [EPA-HQ-OAR-2010-0799-9471-A1, p.5]

Without a robust mid-term evaluation, manufacturers may face standards that have become infeasible in light of market movements or economic conditions beyond their control. Investment decisions will be focused on short term compliance rather than longer term technology advancements. The absence of a mid-term evaluation would subvert the framework embedded into the National Program and would create the uncertainty the agencies are trying to overcome by providing a starting point for regulatory review covering model years into the future. [EPA-HQ-OAR-2010-0799-9471-A1, p.5]

A comprehensive mid-term review is also necessary to review the extent to which the industry is able to meet the aggressive light truck standards set forth for MYs 2022-2025. Nissan anticipates that the level of improvement established for that vehicle segment will be extremely challenging, particularly for companies selling more limited volumes in those market segments or if companies curtail their offerings in the light truck fleet. The costs associated with the technologies necessary to meet the standards while still providing requisite consumer utility may render the light truck standards established for the later model years infeasible and require adjustment. [EPA-HQ-OAR-2010-0799-9471-A1, p.5]

Nor is it feasible to rely on credits generated in the car fleet to cover deficits in the truck fleet. While the GHG program properly allows for full credit transfers between the car and truck fleet, the ability to generate credits in the car fleet to cover the more challenging requirements in the truck fleet are statutorily limited in the CAFE program. It is imperative for the agencies to engage in a meaningful mid-term evaluation to ensure that the standards remain feasible for companies servicing this market with smaller volume light truck fleets. [EPA-HQ-OAR-2010-0799-9471-A1, pp. 8-9]

Both the Clean Air Act and the Energy Policy & Conservation Act require that the agencies make a determination that the standards can be met through cost-effective technologies. While NHTSA, subject to the five year limitation, will not yet formally adopt final regulations, consistent with the National Program the standards formally established by EPA will effectively be adopted later and applied to the CAFE program as well. A robust mid-term review is necessary to ensure that the standards remain consistent with the statutory underpinnings of both programs. [EPA-HQ-OAR-2010-0799-9471-A1, p. 9]

Accordingly, a robust and comprehensive mid-term review is legally necessary to ensure that the standards for the later model years are supported by substantial evidence and are not arbitrary and capricious. See Motor Vehicle Mfr's Ass'n v. State Farm, 463 U.S. 29, 42 (1983) (listing examples of arbitrary and capricious agency activity); Association of Data Processing Services Organization v. Board of Governors of the Federal Reserve System 745 F.2d 677, 683-84 (D.C. Cir. 1984). [EPA-HQ-OAR-2010-0799-9471-A1, p. 9]

Section 202(a)(2) of the CAA requires that standards promulgated under the Act 'shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.' 42 U.S.C. § 7521(a). Similarly, EPCA requires that CAFE standards be established at the 'maximum feasible' level taking into account, among other things, 'technological feasibility' and 'economic practicability.' 49 U.S.C. § 32902(f). [EPA-HQ-OAR-2010-0799-9471-A1, p.9]

The proposed standards assume a significant amount of market transformation, both within the ICE fleet and with regard to the penetration of new powertrains in order to be able to meet the levels established for the later model years. Unlike the situation in which the agencies establish aggressive requirements with long-lead times to allow technology and market development, the standards for MYs 2022-2025 follow a decade of increasingly stringent requirements already demanding substantial technological deployment and market penetration. This layering of new requirements renders it virtually impossible for the agencies to be able to determine with the requisite level of regulatory certainty that cost-effective, economically-practicable technology can be deployed into the fleet and enable compliance with these standards. [EPA-HQ-OAR-2010-0799-9471-A1, p.9]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 127-128.]

Nissan's commitment to the proposed rule is premised on a robust and comprehensive mid-term evaluation for the model years 2022 to 2025. The standards are extremely aggressive and extend beyond current development planning periods. The agencies have assumed a significant amount of technology advancement, consumer acceptance, and fleet shift during these model years covered.

The ability of auto manufacturers to meet these standards will depend not only on our commitment to incorporate additional and transformational technologies but also on factors external to vehicle design and engineering. The mid-term evaluation is essential to ensuring that the standards remain technologically and economically feasible during those time periods.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

EPA should continue to evaluate the GHG effects of these technology incentives to ensure preservation of the overall goals of the program. We also expect that EPA will monitor upstream emissions from the power grid to ascertain whether the improvements assumed to occur do in fact occur. In that regard, we strongly support the proposed mid-term review that will provide the opportunity to consider appropriate revisions to these incentives and to other aspects of the program. [This comment can also be found in section 4 of this comment summary.] [EPA-HQ-OAR-2010-0799-9476-A1, p. 2]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 74.]

Organization: Pew Charitable Trusts

While the proposed requirements set forth by EPA and DOT are aggressive and laudable, Pew strongly urges the agencies not to allow the final standards to be weakened during the midterm review period. Pew understands that fuel efficiency standards produced by DOT are limited by statute to five year increments, and also appreciates the value of technological and cost review to ensure that standards are achievable. However, we believe that federal fuel efficiency standards must remain strong in order to enhance American manufacturing competitiveness in the auto industry while protecting consumers and businesses from fuel cost volatility. [EPA-HQ-OAR-2010-0799-9496-A2, p. 2]

Organization: Porsche Cars North America, Inc. (PCNA)

Midterm Evaluation [EPA-HQ-OAR-2010-0799-9264-A1, p. 4]

Porsche strongly supports the proposed mid-term evaluation which will allow the Agencies to determine whether adjustment of fuel economy and GHG standards is warranted. The success of the program depends on customer acceptance, developments in technology, costs, safety, fuels, necessary infrastructure, and other relevant factors. Assumptions that informed the program model include significant uncertainties due to the length of time over which the standards apply. It is critical to evaluate whether those assumptions are still valid, and therefore whether the standards remain appropriate in light of technological and other changes that may have occurred since the initial setting of the standards. [EPA-HQ-OAR-2010-0799-9264-A1, p. 5]

In making this comment, we wish to stress that Porsche does not assume that EPA or NHTSA intend to deviate from the mid-term evaluation process or ignore its deadlines. We believe that all parties, including the Agencies, will work in good faith to follow the process, and will perform a serious assessment of the state of the program. But we wish to stress that the success of the mid-term evaluation depends on strict adherence to commitments and deadlines. Such adherence is essential in order to mitigate a significant potential for disputes and difficulties in the future. [EPA-HQ-OAR-2010-0799-9264-A1, p. 5]

Organization: RVIA

Therefore, we support the proposed mid-term review and we recommend that the agencies use the time leading up to the mid-term review to talk to consumers to better gauge what impact the increased costs will have on their new vehicle purchase decisions if prices are increased by the amounts projected by EPA and NHTSA. [EPA-HQ-OAR-2010-0799-9550-A2, p.2]

With regard to full size pickups, EPA and NHTSA should utilize the time leading up to the mid-term review to talk to consumers to better gauge what impact the increased costs will have on their new vehicle purchase decisions if prices are increased by the amounts projected by EPA and NHTSA for the 2022-2025 model year timeframe. [EPA-HQ-OAR-2010-0799-9550-A2, p.4]

Organization: Securing America's Future Energy (SAFE)

Midstream Review: The agencies have proposed standards that extend relatively far into the future. In contrast to the last round of regulations issued in 2011 that will affect cars that will enter the market within five years, these regulations will affect some cars that will not be manufactured for thirteen years. (Thirteen years ago, traditional hybrids were not yet on the market in the United States.) [EPA-HQ-OAR-2010-0799-9518-A1, p. 11]

The thirteen years over which these regulations will remain in effect will be a period of great uncertainty with respect to at least two factors that will have a substantial effect on the cost-effectiveness of more efficient vehicles, particularly if traditional hybrids, PHEVs or EVs are needed to meet the new standards: battery prices and oil prices. [EPA-HQ-OAR-2010-0799-9518-A1, p. 11]

It appears likely that automakers will have to rely on traditional hybrids, and to a lesser degree PHEVs and EVs, in order to meet the new standards. Throughout the period over which the standards will be tightening, the cost of these vehicles, and their overall cost-effectiveness, will remain a function of the price of large-format automotive grade batteries. In an area of such rapidly evolving technology, however, it is difficult to forecast with any degree of certainty what battery prices might look like in 2020, not to mention 2025. Higher battery prices will make it harder to meet the standards, just as lower battery prices will make it easier, perhaps supporting even tighter standards. [EPA-HQ-OAR-2010-0799-9518-A1, p. 11]

While battery prices are difficult to predict eight to thirteen years into the future, oil prices are difficult to predict even months in the future. As we prepare these comments, oil is selling for about $100 per barrel. But prices have been as high as $114 and as low as $34 over the past 36 months, and as low as $11.37 and as high as $145 over the past 13 years. Stated simply, given the uncertainty over oil prices of the time during which these rules will be in effect, and the consequences of oil prices for the cost-effectiveness of these rules, it is incumbent on the regulating agencies to carefully reevaluate the cost effectiveness of the standards in light of current oil prices and trends, and tighten or loosen the standards as appropriate at the midstream review. [EPA-HQ-OAR-2010-0799-9518-A1, p. 11]

Of equal importance is the possibility that technological innovation over the next several years will substantially alter the cost-effectiveness of increasing fuel efficiency or reducing oil consumption. For instance, the 2002 National Academies of Science study on fuel economy did not even mention plug-in hybrid technology, despite a detailed discussion of traditional hybrid technology, yet plug-in hybrids were on the road just eight years later. One can imagine that a newly developed battery chemistry, for instance, might substantially alter the cost-effectiveness of the regulations, allowing for an adjustment of the standards. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 11-12]

Not only do these regulations extend far into the future, and not only is there substantial uncertainty with respect to their cost-effectiveness, the regulations would require percentage increases in fuel economy that exceed previous increases, and may be more difficult to achieve as the lowest cost improvements in efficiency have already been made. We appreciate that the accelerated adoption of new technology may allow automakers to meet the proposed standards without any interruption in their product cycles, while delivering vehicles that consumers will purchase and enjoy. However, we also recognize that this question is fundamentally one of consumer acceptance that can be answered only once new more efficient vehicles are put into automobile retailers' showrooms. A midstream review will enable the agencies to examine the consumers' acceptance of new vehicles and adjust the standards upwards or downwards if and as appropriate. [EPA-HQ-OAR-2010-0799-9518-A1, p. 12]

Given the substantial uncertainty regarding the cost of batteries and oil, SAFE believes, that the midstream review should be a comprehensive review into which the agencies enter with an open mind. In support of that process, the agencies should prepare a new or updated technical support document and regulatory impact analysis. It should then affirm or adjust (upwards or downwards as appropriate) the standards based on the results of the analyses. [EPA-HQ-OAR-2010-0799-9518-A1, p. 12]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 152.]

Finally, I can't stress enough, as others have already said, the importance of a real midstream review. The fuel economy regulations have never been issued so far in advance and asked so much of automakers. We don't know where oil prices are going to be. We don't know where battery prices are going to be. And these are critical factors in trying to see what can happen. And just like it's possible that the rules may not prove cost-effective, it's possible that we may find that tightening is also inappropriate. So we stress the importance of having a real review.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

Remain strong throughout the program and not end with the midterm review and a backstop should be considered: Our transportation system drives our addiction to oil with cars and light trucks alone consuming more than 8 million barrels of oil every day. This addiction to oil spews out nearly 20% of US climate disrupting pollution. The proposed standards for 2017-2025 vehicles can help Americans avoid using as much as 1.5 million barrels of oil every day in 2030 and cut carbon emissions in that year by 280 million metric tons. A consumer who buys an average new vehicle in 2025 would keep more than $4,000 in their pocket rather than spending it on oil – even after paying for fuel savings technologies. [EPA-HQ-OAR-2010-0799-9549-A2, p. 4]

But to deliver these benefits the program must remain strong through 2025. The program as proposed includes a mid-term review that begins in 2017. While EPA's authority under the Clean Air Act permits it to propose and finalize a program for the full nine model years, NHTSA's authority is constrained. This factor among others created pressure for the mid-term review which appropriately will involve all three standard setting agencies: EPA, NHTSA and CARB. [EPA-HQ-OAR-2010-0799-9549-A2, pp. 4-5]

Automakers have suggested additional reviews in testimony at the public hearings the agencies held in January. We strongly urge that the final rule not open up additional reviews of the standards. As it stands, the mid-term review will occur just as this rule is taking affect and would therefore be based up on the successful implementation of the 2012-16 program. The agencies should ensure transparency and access to data that will allow the public to effectively and timely monitor compliance, trends and technology application. [EPA-HQ-OAR-2010-0799-9549-A2, p. 5]

In particular, the agencies should provide the public with data, including the following:

Credit use, current balance, and method of credit generation by manufacturer,

Technology penetration, both overall and by manufacturer

Sales by vehicle footprint

Car/truck mix, both overall and by manufacturer [EPA-HQ-OAR-2010-0799-9549-A2, p. 5]

We appreciate that the proposed rule as structured offers the opportunity for a full assessment of progress and technology development but it is necessary for mid-term review to be a check on progress and an opportunity to strengthen standards and not become and off-ramp or stop sign. [EPA-HQ-OAR-2010-0799-9549-A2, p. 5]

Organization: Toyota Motor North America

Also groundbreaking is the scope of the proposed regulations, covering cars and trucks the industry will be designing, manufacturing and selling up to 13 years in the future. The agencies have made a variety of assumptions underlying the proposed standards that may or may not prove accurate. These assumptions include the efficacy and pace of cost reduction for certain technologies, as well as consumers' willingness to pay for them. For this reason, Toyota fully supports timely completion of the proposed mid-term review to assess our progress toward these goals. [EPA-HQ-OAR-2010-0799-9586-A1, p.2]

Mid-term Review [EPA-HQ-OAR-2010-0799-9586-A1, p.7]

In proposing standards through 2025 model year, the agencies have made assumptions about numerous key factors including technology cost, technology performance, fuel prices, manufacturing efficiency, consumer adoption, and other factors that represent their best estimates of the future based on information available in 2012. The agencies acknowledge the significant uncertainty in many of these assumptions, and have proposed a mid-term evaluation of the 2022-2025 model year standards to determine whether those standards remain appropriate in light of changes that may have occurred since the time of proposal.[1] Toyota supports the mid-term review but, as discussed below, we request clarifications and additional details as to how the review will be administered. [EPA-HQ-OAR-2010-0799-9586-A1, p.7]

Key Factors/Assumptions [EPA-HQ-OAR-2010-0799-9586-A1, p.7]

The agencies proposed eight high-level areas of examination for the mid-term review and the preamble discusses additional factors to be evaluated. The Alliance of Automobile Manufacturers (Alliance) has submitted comments addressing the proposal, including a recommendation to expand the factors that should be included in the mid-term review. Toyota supports the Alliance comments in this area. Beyond the Alliance comments, the agencies should consider two additional issues in the mid-term review. [EPA-HQ-OAR-2010-0799-9586-A1, p.7]

First, the agencies must ensure that the proper baseline is used when determining the feasibility of the 2022-2025 model year standards. This issue is best explained with a simple example. Suppose the industry 'compliance level' at the time of the mid-term review (~2018 model year) is 38 mpg in CAFE space and the agencies determine that cost-effective technology exists to support a 4 percent annual improvement rate. A logical conclusion would be that 50 mpg (in CAFE space) is an appropriate standard for 2025 model year (a 4 percent annual compounded increase applied to 38 mpg for seven years). However, if industry has relied on credits to achieve the 38 mpg level, a 50 mpg target would effectively be higher than a 4 percent annual increase. In fact, if the industry relied on credits for just 2 mpg of compliance (resulting in a true technology baseline of 36 mpg), the annual improvement rate would be nearly 5 percent per year - or 25 percent higher than using the 38 mpg baseline. NHTSA is precluded by law from considering the availability of credits in establishing maximum feasible CAFE standards. Under current law, NHTSA will also be precluded from considering the availability of credits when it establishes 2022-2025 model year standards based on the mid-term review. While the CAA does not appear to specifically limit EPA's authority in this regard, the shared goal of harmonization would dictate EPA similarly not consider the availability of credits when determining the appropriateness of the 2022-2025 model year standards during the mid-term review. [EPA-HQ-OAR-2010-0799-9586-A1, p.7]

Second, in the course of the mid-term review the agencies should continue EPA's longstanding practice of treating vehicles and fuels as a system. While the proposed standards are based on currently available fuels, higher octane and/or reduced sulfur can enable additional greenhouse reductions and fuel economy improvements from several technologies. For example~ lower sulfur gasoline would allow the use of stratified lean-burn engines. Increasing octane in gasoline would enable engines to operate at higher compression ratios, and support technology approaches such as heavily boosted, downsized engines. Manufacturers may find these options increasingly necessary in the 2022 - 2025 model year time frame, and for that reason the role of fuels and fuel specifications should be included as part of the mid-term review. [EPA-HQ-OAR-2010-0799-9586-A1, p.8]

Process Details and Schedule [EPA-HQ-OAR-2010-0799-9586-A1, p.8]

The proposed regulation requires a Draft Technical Assessment Report to be completed by November 2017, and a final determination as to whether the 2022-2025 standards remain appropriate to be peer-reviewed and made available for public comment by April 1,2018. If the EPA determines the standards are not appropriate as promulgated in this rulemaking, EPA stated its intention in the preamble to establish by rulemaking new standards that are appropriate under section 202(a) of the CAA. In any case, NHTSA must formally promulgate standards for 2022-2025 model years by April 1, 2020. [EPA-HQ-OAR-2010-0799-9586-A1, p.8]

Toyota understands that soon after promulgating the 2017-2025 model year standards in this rulemaking, the agencies intend to begin an ongoing dialogue with the auto manufacturers, suppliers~ and other stakeholders about progress toward meeting the joint national standards. Toyota supports this type of information sharing because it will provide the agencies the most accurate sense of technology advancements, consumer preferences, and economic conditions as circumstances evolve. The information derived from this dialogue can serve as building blocks toward the mid-term review and afford the agencies and auto manufacturers timely course adjustments for items within their control. Toyota believes it would be helpful for the agencies to outline this process in as much detail as possible in the preamble to final rule. [EPA-HQ-OAR-2010-0799-9586-A1, p.8]

2022-2025 Model Year Default Standards [EPA-HQ-OAR-2010-0799-9586-A1, p.8]

Toyota appreciates the agencies' commitment to a mid-term review and EPA's stated intention to finalize any changes in its 2022-2025 model year GHG standards at least 18months prior to the beginning of the 2022 model year [2] (e.g. by April 1, 2020). Notwithstanding the good intentions of all parties involved to support timely completion of the mid-term review and timely rulemaking as needed, Toyota is concerned about what happens if the agency does not take a final agency action by April 1, 2020 to either validate the standards as originally promulgated or to revise the standards. As proposed by EPA, the 2022-2025 model year GHG standards would remain in effect unless and until EPA changes them by rulemaking. [EPA-HQ-OAR-2010-0799-9586-A1, p.8]

However, if EPA misses its self-imposed deadline for final agency action, it will not have met the requirement of Section 202(a)(2) of the CAA to provide adequate lead time for development of requisite technology for meeting emission standards. Further, given that EPA and NHTSA plan to work collaboratively on the mid-term review (with ARB) and to utilize the results to jointly assess the 2022-2025 model year standards, failure by EPA to take final agency action would likely indicate that NHTSA lacks sufficient information to promulgate its standards for 2022-2025 model year in a timely manner. In such a case, there would be no new NHTSA standards for 2022 model year, and NHTSA would presumably be forced to adopt the 2021 model year standards for 2022 model year. It is unclear what standards ARB would pursue for 2022 model year in this case. This would result in major differences between the EPA and NHTSA standards, and potentially different standards for ARB and Section 177 states, and would run completely contrary to the objective of a harmonized national program. [EPA-HQ-OAR-2010-0799-9586-A1, p.9]

For the reasons described above, Toyota requests that, in the event EPA does not take final agency action concerning the 2022-2025 model year standards by April 1, 2020, the 2021 model year GHG standards remain as the 'default' standards until such time as EPA does take final agency action providing at least 18-months of lead time prior to the applicable mode year. [EPA-HQ-OAR-2010-0799-9586-A1, p.9]

California Air Resources Board Participation [EPA-HQ-OAR-2010-0799-9586-A1, p.9]

Toyota fully agrees that ARB, as a signatory to the national program for GHG emissions and fuel economy standards, will be an important partner in the mid-term review process. We support the agencies' intention to coordinate the mid-term review with ARB and condition a waiver for their 2017-2025 model year standards on ARB accepting any adjustment to the EPA 2022-2025 model year GHG standards that result from the midterm review. [EPA-HQ-OAR-2010-0799-9586-A1, p.9]

---

1 - NHTSA's statutory authority prevents it from formally promulgating standards beyond 5-model years. Toyota's comments on the mid-term review generally refer the 'review' of the proposed EPA GHG standards, and to NHTSA's participation in, and use of, the mid-term review results as a basis for formally establishing for 2022-2025 model year CAFE standards. [EPA-HQ-OAR-2010-0799-9586-A1, p.7]

2 - NHTSA is required by law to finalize CAFE standards at least IS-months prior to the start of the model year. [EPA-HQ-OAR-2010-0799-9586-A1, p.8]

Organization: U.S. Chamber of Commerce

The Chamber supports reducing emissions from automobile tailpipes, and supports greater vehicle fuel economy when needed to address consumer demand. The Chamber is pleased that the automobile industry is receiving the regulatory certainty it needs for long-term planning purposes. However, given the costs the regulations will require to be built into all new vehicles to achieve these goals, a strong 2018 midterm review will be essential. [EPA-HQ-OAR-2010-0799-9521-A1, p. 1]

I. The 2018 Mid-Year Review Must Be Strong, Thorough and Realistic

The National Program for fuel economy proposed by EPA and NHTSA is very aggressive, and will test the limits of the automobile industry’s technological prowess. This is particularly evident in the last four years of the program (2021-2025), when the rate of increase in light truck fuel economy standards increases dramatically, from 3.5 percent per year to 5 percent per year. This portion of the proposal reaches so far into the future that EPA, NHTSA and automakers truly have no certainty as to how technologies will develop and what they will cost. However, at this early juncture, EPA seems to admit that they will cost the bulk of consumers more money. [EPA-HQ-OAR-2010-0799-9521-A1, p. 2]

Fuel economy matters to consumers, but car buyers historically have not valued fuel economy as highly as other key attributes such as affordability, safety, convenience and utility. A car buyer's perspective on fuel economy also fluctuates with fuel prices, which are very difficult to predict long-term. There is therefore a very real possibility that, for one or more reasons, consumers will not want to buy some of the new fuel-efficient vehicles that will have to be brought to market to comply with the 2017-25 rule. [EPA-HQ-OAR-2010-0799-9521-A1, p. 2]

Moreover, conditions beyond the control of automobile manufacturers will greatly affect automakers' ability to achieve aggressive new fuel economy standards. Gasoline prices are virtually impossible to predict long-term. Availability of critical minerals has already become an important issue to the automobile industry. The state of the economy certainly has an impact on consumers' car buying habits. And infrastructure for many of the new technologies being incentivized by the 2025 standards—such as electric vehicles, fuel cells and alternative fuels—must actually be built. [EPA-HQ-OAR-2010-0799-9521-A1, pp. 2-3]

It is therefore of utmost importance that any final rule include a rigorous midterm review in 2018, with a clearly defined process for conducting the review. If mainstream consumers are not buying the newer, fuel-efficient vehicles or are not likely to buy the significantly more efficient (and expensive) vehicles slated for the 2021-25 time frame, then the agencies must be able to change the rule.2 If conditions change that are outside the control of the automobile industry, Federal regulators must be willing and able to take a pragmatic view of the 2021-2025 time frame and revise the rule accordingly. [EPA-HQ-OAR-2010-0799-9521-A1, p. 3]

---

2 And if the agencies wish to change the rule downward, they should not be bound to the will of California, which has shown time and again that its fuel economy goals do not represent the national interest.

Organization: Union of Concerned Scientists (UCS)

(d) Mid-Term Evaluation

A great deal of attention to this proposal has been focused on the mid-term evaluation provision, and with good reason. Structured properly, it can provide assurance that the nine-year rulemaking is both equitable and based on the latest research. Structured improperly, however, it can create regulatory uncertainty, disturb the industry's product planning efforts, and impede technological development by undercutting industry investments in technologies slated to serve the post-MY2021 vehicle fleet. [EPA-HQ-OAR-2010-0799-9567-A2, p. 10]

According to UCS analysis, nearly 40 percent of the MY2017-2025 Program's 2030 oil savings and emissions reductions benefits would be lost if the mid-term evaluation foreclosed subsequent improvements to vehicle efficiency and GHG emissions reductions post-MY2021. Given what is at stake, it is imperative that the agencies structure the mid-term evaluation to ensure that the provision is used to support stronger standards moving forward, and not as an opportunity by the industry to stall or forego regulatory obligations. [EPA-HQ-OAR-2010-0799-9567-A2, p. 10]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 218.]

For example, the proposal's midterm evaluation provision must be structured to ensure that it is used to support strong standards moving forward, and not merely as an opportunity by the industry to stall or forego regulatory obligations.

Automobile manufacturers have publicly stressed the importance of tracking progress leading up to the mid-term evaluation. As UCS has stated in the past, the mid-term evaluation should occur only one time, and it should be conducted as closely to the first year in question (MY2022) as legally permitted, to most accurately capture the status of technology and the vehicle market for the model years in review. While EPA and NHTSA should remain up to date on technology developments, regularly scheduled “progress reports” between now and 2018, as suggested by some in industry, would be both time consuming and too premature to judge technology readiness of the Model Year 2022-2025 standards. Premature reports would increase speculation within the industry about “prevailing winds” of the mid-term evaluation, create unnecessary uncertainty, and undermine the intent and effectiveness of the provision itself.

That being said, UCS strongly supports the agencies continuing their work – for instance, the impressive teardown cost analysis conducted by EPA, and other assessments documented in the Joint Technical Support Document – during the next five years in order to feed those analyses into the formal mid-term evaluation. [EPA-HQ-OAR-2010-0799-9567-A2, p. 10]

When the mid-term evaluation is conducted to assess possible modification (up or down) of the 2022-2025 standards, it is critical that the entire suite of factors affecting manufacturers’ ability to comply be considered in their totality. UCS agrees that “a holistic assessment of all of the factors…without placing decisive weight on any particular factor or projection” is the correct approach in conducting the mid-term evaluation. Basing latter year feasibility on an isolated set of factors would be turning a blind eye to the reality that the industry has multiple options at its disposal in meeting the standards. [EPA-HQ-OAR-2010-0799-9567-A2, p. 10]

Finally, UCS agrees with the agencies that the mid-term evaluation be a closely coordinated process, conducted jointly by EPA, NHTSA, and CARB; that the evaluation be open to public participation; and that the agencies seek, consider and respond to public comment on its determination prior to invoking any final actions. [EPA-HQ-OAR-2010-0799-9567-A2, p. 10]

Though I strongly support these standards, I am concerned about possible loopholes that automakers could exploit. Specifically: The agencies are proposing a 'mid-term' review that would begin soon after the standards come into effect. In the past, automakers have abused similar programs-turning them into off-ramps as opposed to reviews. It is critical that this review does not undermine the program through 2025. [EPA-HQ-OAR-2010-0799-9713-A2, p. 2]

Organization: United Automobile Workers (UAW)

Finally, the UAW is pleased that EPA is proposing a mid-term review for the proposed standards for model years 2022–2025, and that NHTSA will perform a full rule making procedure for those years as required under its statutory authority to regulate fuel economy. Given the quickening pace of technical innovation and cost reductions in the auto industry, the UAW believes that it is wise to continue to evaluate the cost and effectiveness of fuel-saving technologies well in advance of the formal mid-term review. [EPA-HQ-OAR-2010-0799-9563-A2, p.4]

The mid-term review is a critical structural feature of the proposed unified national program, and a central reason the UAW can be so strongly supportive of the proposals by EPA and NHTSA. The UAW believes that the mid-term review should be conducted with the same type of broad stakeholder engagement and public participation that occurred in the development and presentation of the proposed regulations for 2017–2025. The proposed standards are stronger and more achievable because of this process, and they stand as a testament to how we can work together to address real issues of national importance. [EPA-HQ-OAR-2010-0799-9563-A2, p.4]

Organization: United States Senate

In addition, the 'mid-term' review for the model year 2022-2025 standards will require your agencies to evaluate whether the stringency required in the second phase of the program is still appropriate or whether the standards should be revised upwards or downwards. [NHTSA-2010-0131-0264-A1, p.1]

Organization: University of Michigan

A Call to EPA and NHTSA to Consider the Consumer Fuel Usage Reduction Options in the Mid-term Evaluation of the Greenhouse-Gas Emission and Corporate Average Fuel Economy Standards for Light-Duty Vehicles. [EPA-HQ-OAR-2010-0799-7986-A1, p. 1] [This comment can also be found in section 12 of this comment summary.]

As both the EPA and NHTSA will be undertaking the midterm evaluation of the GHG emission and the corporate average fuel economy standard for model year 2022-2025 vehicles in due course, we recommend that meaningful incentives for consumer fuel usage reduction be taken into consideration. [EPA-HQ-OAR-2010-0799-7986-A1, p. 2] [This comment can also be found in section 11 of Docket number EPA-HQ-OAR-2010-0799-7986-A1]

Organization: Volvo Car Corporation (VCC)

VCC is sympathetic to the numerous environmental challenges that impact the agencies in trying to reach their varied goals. However, it is of utmost importance that all agencies, as far as possible, collaborate to achieve common understandings, wherever possible. [EPA-HQ-OAR-2010-0799-9551-A2, p. 3]

VCC supports a mid-term evaluation. Amid-term evaluation will allow manufacturers and the agencies to consider whether the regulation is reasonable and on track in its assumptions. VCC supports a mid-term evaluation because it is very difficult to predict fifteen years into the future without making a vast number of assumptions. Customer acceptance, affordability (especially in light of the phase-out of many of the federal and state incentives), safety, convenience and utility should be examined in the mid-term evaluation. [EPA-HQ-OAR-2010-0799-9551-A2, p. 3]

It is therefore imperative that the industry and the agencies review and consider the outcomes of our work in 2012 in relation to the joint plan at the midpoint of the regulated period. With regard to the midterm evaluation, VCC emphasizes the needs and clarifications outlined in the Alliance comments. [EPA-HQ-OAR-2010-0799-9551-A2, p. 3]

For VCC, as an intermediate manufacturer, the common understanding and harmonization of approaches of the agencies is of great importance, and' ultimately leads to a very high level of administrative efficiency. It is critical for smaller manufacturers to reduce administrative costs in order to be able to focus on the relevant issues such as developing environmentally advanced technology. [EPA-HQ-OAR-2010-0799-9551-A2, p. 3]

The following criteria should be considered for the Mid-Term Evaluation:

• Are the costs of Advanced Technology Vehicles declining as predicted in the assessment in the NPRM?

• What impact will the new requirements have on sales of passenger cars and light duty trucks?

• How will the new rules impact vehicle safety?

• Is the needed fueling infrastructure available to enable PHEVs, BEVs and fuel cell vehicles to penetrate the market at the levels predicted?

• Are consumers purchasing the technologies needed to achieve the goals of the rulemaking?

• Multipliers for the period 2020-2025 need to be evaluated and reevaluated

• Off cycle technology - additional innovations identified between 2012 and 2018

• Harmonization between all agencies both regarding technology demands and administration - EPA, NHTSA and CARB [EPA-HQ-OAR-2010-0799-9551-A2, p. 3]

Organization: Weiner, L.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 107.]

So we ask that the midterm review be vigilant, and there should not be an opportunity to delay full compliance or, as has occurred occasionally in history, to dismiss part of the program. But we look at the mid-reviews to strengthen the compliance.

Response:

Section III.B.3. of the preamble provides a detailed discussion of the mid-term evaluation. As described there, the agencies are finalizing the mid-term evaluation and agency decision-making process as proposed. As stated in the proposal, both NHTSA and EPA will develop and compile up-to-date information for the mid-term evaluation, through a collaborative, robust and transparent process, including public notice and comment. The evaluation will be based on (1) a holistic assessment of all of the factors considered by the agencies in setting standards, including those set forth in this final rule and other relevant factors, and (2) the expected impact of those factors on the manufacturers' ability to comply, without placing decisive weight on any particular factor or projection. In order to align the agencies' proceedings for MYs 2022-2025 and to maintain a joint national program, if the EPA determination is that standards will not change, NHTSA will issue its final rule concurrently with the EPA determination. If the EPA determination is that standards may change, the agencies will issue a joint NPRM and joint Final Rule.

Overall support for finalizing the mid-term evaluation

Every automaker and associations representing either auto makers or suppliers who commented on the proposed mid-term evaluation indicated that this evaluation was essential to their support of the proposal and urged the agencies to finalize a comprehensive mid-term evaluation. These commenters included General Motors, Chrysler, Ford, Nissan, Toyota, Hyundai America Technical Center, Mercedes-Benz, Mitsubishi Motors, Volvo Car Corporation Porsche, Ferrari, KIA, the Alliance of Auto Manufacturers, the Global Automakers, the Motor & Equipment Manufacturers Association (MEMA), National Association of Manufacturers (NAM), EcoMotors International, Inc., and Johnson Controls, Inc. Two automakers, Chrysler and Nissan, specifically predicated their support of the MY2017-2025 National Program on the agencies finalizing the proposed mid-term evaluation. In addition, a number of other organizations including the United Auto Workers (UAW), the International Council on Clean Transportation (ICCT), U.S. Chamber of Commerce, Securing America's Future Energy (SAFE), as well as 112 members of the U.S. House of Representatives (in a letter to both agency heads) expressed strong support for finalizing the proposed mid-term evaluation.

Many environmental and consumer organizations, as well as many private citizens, both at the three public hearings and in written comments, expressed concern that the mid-term evaluation might be used as an opportunity to weaken the standards or to delay the environmental benefits of the National Program. Many stressed the expectation that the mid-term should be used as an opportunity to strengthen the MY2017-2025 standards. These commenters included the Pew Charitable Trust, Sierra Club, Union of Concerned Scientists (UCS), American Medical Association of California, the National Association of Clean Air Agencies (NAACA), Ecology Center and more 30,000 individual citizens who submitted letters to the docket. The ICCT expressed their strong support for the mid-term evaluation and

NESCAUM in discussing the need to evaluate technology incentives on the overall GHG goals of the program indicated their support of the mid-term evaluation for this purpose.

As discussed in section III.B.3 of the preamble, the mid-term evaluation will be a comprehensive and robust evaluation of all of the relevant factors. EPA is clear that any evaluation of the appropriateness of the standards and any decision to go forward with revising the standards will consider making the standards more or less stringent, whatever is most appropriate under the circumstances at that time. It would be inappropriate to limit EPA's consideration to either just increasing or just reducing the stringency of the standards. Instead, EPA will determine the appropriate course to follow based on all of the information, evidence, and views in front of it, including those provided during public notice and comment.

Two commenters opposed finalizing the mid-term evaluation. Natural Resources Defense Council (NRDC) stated that it was both unnecessary and potentially disruptive to automakers' product planning and would add uncertainty to a nine year period. The National Automobile Dealers Association (NADA) did not support the mid-term evaluation since it did not support the need for the underlying rulemaking "so soon after having set standards for MY2012-2016, and before having had the benefit of learning from how those standards work in the real world." EPA believes that the evaluation process will not be disruptive to the automakers product planning. Instead it provides a framework that allows manufacturers the certainty to go forward and prepare for these standards, as it both adopts them now as final standards and establishes a mechanism to evaluate and change them in the future, if appropriate. The common support from the manufacturers indicates that this is the case. The opposition by NADA is premised on their opposition to adopting standards in this rulemaking, which is addressed elsewhere.

Ensuring Coordination of Mid-term Evaluation

Ford, Toyota, NRDC and the UCS stressed the importance of a coordinated mid-term evaluation by EPA and NHTSA that should also include the California Air Resources Board (CARB). EPA agrees with this comment, as indicated by the discussion in section III.B.3 of the preamble. In adopting their GHG standards the California Air Resources Board (CARB), directed CARB's Executive Officer to, "participate in U.S. EPA's mid-term review of the 2022 through 2025 model year passenger vehicle greenhouse gas standards…" and to also, "continue collaborating with EPA and NHTSA as their standards are finalized and in the mid-term review."[7] In addition, the Board directed CARB's Executive Officer that "It is appropriate to accept compliance with the 2017 through 2025 model year National Program as compliance with California's greenhouse gas emission standards in the 2017 through 2025 model years, once United States Environmental Protection Agency (U.S. EPA) issues their Final Rule on or after its current July 2012 planned release, provided that the greenhouse gas reductions set forth in U.S. EPA's December 1, 2011 Notice of Proposed Rulemaking for 2017 through 2025 model year

[7] See California Low-Emission Vehicles (LEV) & GHG 2012 regulations approved by State of California Air Resources Board, Resolution 12-11 (March 22, 2012). Available at http://www.arb.ca.gov/regact/2012/leviiighg2012/leviiighg2012.htm (last accessed June 5, 2012)

passenger vehicles are maintained, except that California shall maintain its own reporting requirements." [8]

Clean Air Act Authority to conduct a mid-term evaluation

A number of auto manufacturers submitted comments agreeing that section 202(a) of the Clean Air Act (CAA) authorizes the proposed mid-term evaluation. Chrysler noted that the EPA had a "firm legal basis to conduct the mid-term evaluation under section 307(d) of the Clean Air Act (CAA) and the Administrative Procedures Act to reconsider regulations based on new information as well as under section 202(a) of the CAA under which EPA proposed the mid-term evaluation." The Global Automakers stated that a mid-term evaluation was, "not only permissible under the Clean Air Act, but also required because of the uncertainties inherent in projecting regulatory requirements nine to twelve years into the future," continuing that it "would have been arbitrary and capricious for EPA to promulgate GHG emissions standards for model years as far into the future as MY2022-225 without providing for a mid-term evaluation." Nissan indicated support for the views expressed by the Global Automakers and stated further that "a robust and comprehensive mid-term review is legally necessary to ensure that the standards for the later model years are supported by substantial evidence and are not arbitrary and capricious. (Citing Motor Vehicle Mfr's Ass'n v. State Farm, 463 U.S. 29,42 (1983) listing examples of arbitrary and capricious agency activity)."

EPA agrees that section 202(a) provides the agency with ample authority to undertake the mid-term evaluation. EPA does not agree that the mid-term evaluation is authorized under CAA section 307(d), as the mid-term evaluation is not a reconsideration of the standards under that provision. Instead the mid-term evaluation will be undertaken under EPA's general authority to establish emissions standards under section 202(a). EPA does not agree that the mid-term evaluation is legally required, or that the standards adopted today would be arbitrary and capricious or without substantial evidence to support them absent such a mid-term evaluation. The final rule and supporting information and analysis amply justify the reasonableness and appropriateness of the final GHG standards adopted by EPA, irrespective of the provisions for a mid-term evaluation. In any case, that issue is not before EPA as EPA is exercising its discretion to adopt provisions for a mid-term evaluation, for the reasons discussed above.

The Center for Biological Diversity (CBD) challenged the basis for the mid-term evaluation and specifically argued that any interim rulemaking should be based on a presumption that the stringencies of the standards will not decrease. As discussed above, the mid-term evaluation will be a robust and comprehensive evaluation, and it would be inappropriate to limit EPA's consideration to either just increasing or just reducing the stringency of the standards. Instead, EPA will determine the appropriate course to follow based on all of the information, evidence, and views in front of it, including those provided during public notice and comment. CBD also raised a concern that EPA would be applying a faulty weighting of the statutory factors under the CAA. CBD stated that highlighting the manufacturers' ability to comply was improper, and instead decisive weighting should be placed on energy conservation. EPA

[8] Id., CARB Resolution 12-11 at 20.

disagrees that it is improper to carefully consider the impact on manufacturers' ability to comply. When EPA conducts the mid-term evaluation, EPA will be evaluating standards that have already been adopted and for which manufacturers are required to comply. The ability to comply is an important part of determining the appropriateness of these standards. For example, ability to comply is directly tied lead time, a factor EPA is required to consider under section 202(a). EPA does not agree that it is appropriate to assign decisive weighting to any one factor, such as energy conservation. That is contrary to conducting a holistic assessment, where EPA carefully considers all of the relevant factors under section 202(a) and gives them the weight that is appropriate in light of all of the circumstances.

Recommendations for Additional “Check-ins” or Periodic Status Reports

Several automakers, auto suppliers and industry associations (General Motors, Chrysler, Daimler Automotive Group, Hyundai, Alliance of Automobile Manufacturers, Global Automakers, Inc and Johnson Controls) suggested that, in addition to the proposed formal mid-term evaluation, the agencies should also undertake a series of smaller, focused technical evaluations or “check-ins’ leading up to and potentially following the mid-term evaluation. Such check-ins, these commenters asserted, would allow the agencies to consider the latest relevant technical information, as well as other key issues. Several environmental organizations (Sierra Club, UCS, NRDC, and CBD) submitted comments opposing these focused technical evaluations or “check-ins,” arguing that these would be time consuming and too premature to judge technology readiness for the MY2022-2025 standards, and would undermine the intent and effectiveness of the mid-term evaluation. A number of environmental organizations also supported periodic updates on technology progress and compliance trends. The Sierra Club, while not supportive of the “check-in” concept, did urge agency transparency and access to data that would allow the public to “effectively and timely monitor compliance trends and technology applications.” The ICCT recommended that EPA and NHTSA conduct periodic updates on technology progress and consider periodic status reports in advance of the mid-term evaluation so that all interested parties could have access to key data that would be important in documenting progress in technology improvements and implementation.

As discussed above, the agencies will conduct a comprehensive mid-term evaluation and agency decision-making process for the MYs 2022-2025 standards as described in the proposal. The agencies expect to continue ongoing stakeholder dialogue, including in depth technical dialogue with automakers on their confidential technology development efforts and product plans for MYs 2022-2025. EPA does not believe that additional or more frequent reports, as suggested by some commenters would be an efficient way to prepare for the mid-term evaluation.

Timeline and Process for Mid-term Evaluation

Several auto companies including Ford, Toyota and Porsche noted the importance of the agencies meeting the proposed November 15, 2017, deadline for issuing the draft Technical Assessment Report (TAR) so that there is adequate time for a reasonable public comment period while still insuring that EPA meet its proposed April 1, 2018 deadline for determining whether the standards established for MY2022-2025 are appropriate under CAA section 202(a). The Alliance of Automobile Manufacturers, Global Automakers, and the National Association of

Manufacturers also expressed concern with the agencies' proposed schedule for undertaking the mid-term evaluation. These commenters recommended that additional details be written into the final regulatory text to provide more procedural certainty including: a start date for the evaluation, a schedule of major milestones, specific studies the agencies plan to conduct, and details of the peer review process. Toyota, Hyundai and Mercedes-Benz in their comments noted their support for these recommendations as well. Mitsubishi urged the agency to work with stakeholders well in advance of the mid-term to develop a sound review process and framework. Both the Union of Concerned Scientists and NRDC stated that the timing of the mid-term evaluation should be conducted as close as possible to the beginning of MY2022 so that the mid-term evaluation could most accurately capture the status of technology and the vehicle market for those model years under review.

EPA acknowledges the timing and other concerns raised by all commenters and continues to believe that the approach laid out in the proposal provides an appropriate balance between certainty and needed flexibility by providing end dates by which it must issue the draft TAR (November 15, 2017) and determine whether the MY2022- 2025 standards are appropriate under section 202(a) of the Clean Air Act (April 1, 2018). Additional regulatory details on the timing or content of the mid-term evaluation are not needed and would not be an efficient way to prepare for and conduct the mid-term evaluation.

Additional Evaluation Factors Should be Considered

In its proposal, EPA indicated that it would consider a range of relevant factors in conducting the mid-term evaluation, including but not limited to those listed in the preamble and proposed regulatory text. Quite a few commenters suggested that EPA expand the list of these high level factors. The Alliance of Automobile Manufactures recommended numerous additions to the list of factors including, "current and expected availability of state and Federal incentives/subsidies for advanced technology vehicles," "the end-of-life costs associated with advanced technology vehicles," and "consumer demand for and acceptance of fuel-efficient technologies, and consumer valuation of fuel savings." Honeywell encouraged the agencies to, "commit…to a detailed review of emerging boosting technologies that may considerably advance vehicle emissions and fuel economy performance during the later years of the rulemaking." The Institute for Policy Integrity commented that the agencies "should amend their list of factors to specifically reflect any potential changes to benefits estimates, in addition to changes to costs or the state of technology." Mitsubishi Motors commented that the mid-term factors must include an evaluation of the sufficiency of the EV infrastructure, including whether there have been any significant industry-wide economic setbacks making EVs and other overall fuel economy targets impracticable, consumer acceptance of EVs and a thorough evaluation of an EV multiplier in MYs 2022 through 2025 in order to continue EV market penetration. Also, Mitsubishi noted that the mid-term should include consideration of compliance options for OEMs with limited product lines. The National Association of Clean Air Agencies (NACAA) suggested that EPA evaluate the use of credits by automobile manufacturers and the impact of credit use on average fleet performance. The Clean Air Association of the Northeast States for Coordinated Air Use Management (NESCAUM) noted that it expected EPA to monitor upstream emissions from the power grid to determine whether the improvements assumed to occur were realized. Finally, the Sierra Club recommended that the agencies provide the public with data on credit use by manufacturers, technology penetration both overall and by manufacturers, and sales by vehicle footprints.

The Alliance for Automakers also indicated that the agencies should seek expert peer-reviewed information including the National Academy of Sciences to answer a number of questions associated with the Mid-term reviews.

A number of other commenters, including Ford, the UCS and ICCT supported the mid-term evaluation provisions as proposed by EPA. Ford commented that they believed the agencies had struck an appropriate balance between an exhaustive list and a high-level approach and pointed to proposed regulatory language "including but not limited to…" as critical language that should be maintained in final rule. Ford further noted that factors that turn out to be most important six years from now are not necessarily foreseeable today and not necessarily the ones listed in the proposed rule. The ICCT noted that "it is impossible to define all the criteria for review at this time…" And UCS agreed that "a holistic assessment of all of the factors… without placing decisive weight on any particular factor or projects" is the correct approach in conducting the mid-term evaluation."

EPA is finalizing the list of factors as proposed.[9] We believe these factors are broad enough to encompass all appropriate factors that should be considered during the mid-term evaluation, and provide the agency with an appropriate balance in that the list identifies major factors to consider and includes a clear provision for inclusion of other appropriate factors. This avoids trying to identify in detail at this time the myriad issues and factors that will be of concern in the mid-term evaluation. As in this rulemaking, in the mid-term evaluation EPA expects to place primary reliance on peer-reviewed studies. Additionally, as NAS reports are published, EPA will give careful consideration to reports and their findings as well as any reports and findings from other scientific and technical organizations.

As discussed above, the MY2022–2025 GHG standards will remain in effect unless and until EPA changes them by rulemaking. The National Association of Manufacturers (NAM) commented that EPA should not take the default position that the existing 2022-2025 model year standards will remain in place unless changed by rulemaking. Rather, they argued the existing standards should be rescinded immediately upon a determination that they are inappropriate, leaving the 2021 standards in effect until the revised standards are finalized. Another commenter, Toyota, requested that "in the event EPA does not take final agency action concerning the 2022-2025 model year standards by April 1, 2020, the 2021 model year GHG standards remain as the 'default' standards until such time as EPA does take final agency action providing at least 18-months of lead time prior to the applicable model year." EPA believes the appropriate approach is what was proposed; EPA is adopting the MY2022-2025 GHG standards at this time, and they will go into effect unless EPA revises them. The mid-term evaluation process is an effective and timely way to address any concerns that may arise in the future concerning the appropriateness of these standards. EPA believes this provides the right degree of certainty to the standards that are adopted today, along with a clear and effective mechanism

[9] See §86.1818-12 (h)

for the timely evaluation of the standards and their revision if EPA determines in the future that they are no longer appropriate based on the circumstances at that time.

2.5. Test Procedures

Organization: AAA

While it is clear that substantial progress is being made to improve the program, AAA continues to have concerns with the real world accuracy of the testing procedures utilized to determine the mileage ratings under CAFE. [EPA-HQ-OAR-2010-0799-9484-A1, p. 1]

With this said, AAA continues to have concerns with the testing procedures used to determine miles per gallon (mpg) ratings under the CAFE program. AAA maintains that there are existing tests that can be used to produce more accurate fuel economy ratings. CAFE ratings in particular continue to be based on testing methodology from the 1970s, even though it has been acknowledged to be inaccurate. [EPA-HQ-OAR-2010-0799-9484-A1, p. 1]

In 2008, EPA adopted new testing procedures with input from the Automobile Club of Southern California’s Automotive Research Center. These procedures combined the results of three new dynamometer tests to provide a more accurate method of estimating mpg and showed these new ratings to be at least 30 percent lower than the unadjusted test results. In 2011, AAA worked closely with EPA and NHTSA to develop new vehicle labels that provide consumers with the clear and accurate information regarding safety, fuel economy, and GHG emission scores necessary to facilitate informed vehicle purchase decisions. [EPA-HQ-OAR-2010-0799-9484-A1, p. 2]

Unfortunately, CAFE numbers do not reflect these new testing procedures. Until testing procedures are harmonized, the discrepancy between the two ratings will only increase. AAA is interested in working with EPA and NHTSA to find a solution that provides the most accurate consumer information possible. [EPA-HQ-OAR-2010-0799-9484-A1, p. 2]

AAA commends NHTSA and EPA for working diligently with auto manufacturers and other stakeholders to reach an agreement on the proposed new standards. Having safe, energy-efficient vehicles is in everyone’s best interest, but it is equally vital to ensure that the testing used to gauge efficiency provides accurate results. Thank you for your consideration of AAA’s views. [EPA-HQ-OAR-2010-0799-9484-A1, p. 2]

Organization: American Lung Association of the Mid-Atlantic

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 82.]

We also support changes to testing procedures and calculations that properly reflect actual experience.

Organization: Ferrari

2) Test procedures [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

We believe appropriate to continue to measure CO_2 emissions and fuel economy using the traditional test cycles city (FTP) and highway (HFET) for the present proposal. It is reasonable for EPA to address different test procedures in the context of a future rulemaking. Enough lead-time should be given in case of any change in the test procedure for manufacturers to make necessary changes to test equipments, carry out tests, and reflect the new procedures in their compliance plans. [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

We also support the proposal that the 5-cycle test procedures would remain the starting point for demonstrating off-cycle emissions reductions. [EPA-HQ-OAR-2010-0799-9535-A2, p.11]

Organization: Ford Motor Company

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 46.]

In general, we continue to encourage the agencies to take a holistic view of the transportation sector to encourage the implementation of technologies and strategies whose benefits might otherwise be reflected in the formal fuel economy test procedures.

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 35.]

With respect to our elements of the proposal, we will continue to work with the agencies to develop the test procedures necessary to validate off-cycle technology.

Organization: Johnson Controls, Inc.

Test cycles must be more reflective of the real-world. Johnson Controls is concerned that the proposed standards do not address one of the core problems with the standards - outdated city/highway drive cycle averages. Johnson Controls recognizes that the drive cycles must be a compromise between real world driving and testing workload/complexity. That said, the driving patterns and behaviors of American consumers have shifted dramatically in the past 40 years since the city/highway drive cycles were developed. The mere fact that the fuel economy labeling process for new vehicles has been adjusted twice since its inception is evidence that customer driving patterns are no longer properly reflected in the city/highway driving cycles. EPA's MOVES model includes an estimate that 13.5% of all driving (in terms of vehicle hours operating) nationwide is at idle. This is 50% more idling than the time weighted average idling time in the combined city/highway driving cycles of 9%. The Joint Technical Support Document (JTSD) issued with this NPRM offers giving 75% of theoretical difference in fuel economy benefit between MOVES and the city/highway drive cycles for start-stop technology as an off-cycle fuel economy and CO_2 credit. The rationale stated in the JTSD only offers 75% of the theoretical difference is due to engine warm-up characteristics and that start-stop functionality is disabled during that phase of the drive cycle. Johnson Controls believes this is a good start towards recognizing the benefit of start-stop technology. However, by placing a limit on the off-cycle credits that can be given to start-stop technology, the regulation may unintentionally place a limit on the level of innovation that could be employed to improve fuel economy, reduce the country's dependence on foreign oil. and reduce greenhouse gas emissions. While not directly involved in the business or technology of improving the warm-up characteristics of the engine, we do believe that innovations will continue to improve start-stop operation, consistency, and predictability. Customers recognize the tangible fuel savings benefits of start-stop technology since they can readily recognize the engine is not running and, therefore, not consuming fuel. This customer feedback to the OEMs will naturally drive technology and innovation to ensure that start-stop functionality is available under more operating conditions - including wider ambient temperature and wider engine operating temperature. Johnson Controls recommends offering more flexibility to the OEMs for off-cycle credits for start-stop technology if they can provide evidence of the operational characteristics of the technology performing better than 75% of the theoretical benefits. Johnson Controls also recommends the drive cycles be revisited and new drive cycles be developed which reflect the driving styles of today’s driver. To reduce workload, global harmonized drive cycles (aka WLTP proposed by the UNECE) should be considered. [NHTSA-2010-0131-0253-A1, pp. 3-4]

Organization: Manufacturers of Emission Controls Association (MECA)

Current U.S. light-duty CAFE/greenhouse gas emission requirements both use the FTP and highway fuel economy test cycles with specified weighting to determine a vehicle's fuel economy. The current weighting puts a larger emphasis on fuel consumption (or greenhouse gas emissions) during urban driving (FTP test cycle) than highway driving (highway fuel economy test cycle). EPA recently switched to a 5-cycle approach for light-duty vehicle fuel economy labeling. The rulemaking documents associated with EPA's new fuel economy label requirements provide important information and data that supports the choice of this 5-cycle approach as more representative of how vehicles are driven by U.S. vehicle owners compared to the current CAFE 2-cycle requirement. [EPA-HQ-OAR-2010-0799-9452-A3, p.3]

MECA believes that any regulatory requirements associated with greenhouse gas emissions should be based on real-world driving or usage patterns in order to ensure that regulatory standards reflect actual vehicle operations and deliver the greenhouse gas emission reductions that are needed. Vehicle manufacturers and emission control technology manufacturers need a valid test cycle for greenhouse gas emission to engineer and evaluate vehicles consistent with how they are used by the public. The weighting of the test cycle between urban and highway driving modes will have a significant influence on the choice and optimization of powertrain options that will be used to meet any future greenhouse gas emission or fuel economy standards. Work is already underway in Geneva, Switzerland under the United Nations GRPE harmonization umbrella to bring forward a new light-duty vehicle test cycle for use in quantifying real world greenhouse gas emissions. EPA and California should utilize test cycles for the purpose of measuring and controlling vehicle greenhouse gas emissions that are representative of real world driving patterns. [EPA-HQ-OAR-2010-0799-9452-A3, pp.3-4]

Organization: Marz, Loren C.

EPA needs to adjust the methodology for calculating 'combined' mileage for the purposes of CAFE. The 55% city/45% highway mix is apparently no longer representative based on the 43% city/57% highway mix EPA now uses in its MOVES model and also used in Argonne National Laboratory's GREET model. Furthermore, Bosch reports that based on a recent GPS study in California, the median driving intensity is between the highway (HWFET) and US06 cycles (http://www.erc.wisc.edu/documents/symp09-Freitag.pdf - slide #24). Having an unrepresentative drive cycle mix will skew how effective the results of proposed rule will be in the real world, and inappropriately favors hybrid/EV/PHEV/FCV technology in CAFE calculations. [NHTSA-2010-0131-0213-A1, p.5]

This is already becoming apparent based on a study by Oak Ridge National Laboratory (Lin, Z., and Greene, D. 'Predicting Individual Fuel Economy.' SAE Technical Paper #2011-01-0618) as the current 5-cycle fuel mileage values underestimate hybrid fuel mileage by an average of about 10%, while the fuel mileage of diesel vehicles is underestimated by an average of about 25%. EPA essentially acknowledged this trend in a 2006 publication ('Final Technical Support Document - Fuel Economy Labeling of Motor Vehicle Revisions to Improve Calculation of Fuel Economy Estimates', page 8). [NHTSA-2010-0131-0213-A1, p.5]

Organization: Motor & Equipment Manufacturers Association (MEMA)

Test procedures must be more reflective of the real-world. The current and proposed standards do not address one of the core problems with the standards – outdated highway/city drive cycle averages. Real-world benefits can only be achieved with real-world measures. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

The current and proposed standards do not address one of the core problems – outdated highway/city drive cycle averages (a split of 55 percent city and 45 percent highway). The EPA's own study illustrated the switch in driving behaviors since the original averages were set.2 Real-world benefits can only be achieved with real-world measures. Changing the approach could have profound effects on deployment of research funds and capital investment, on the choices of vehicle technologies, and on the real-world results for the consumer, emissions reduction, and fuel efficiency. Otherwise, the industry will make cost-benefit decisions on technologies to maximize the fuel economy numbers with a 55-city/45-highway split and will make long-term technology and capital decisions without an assurance that those decisions will produce real-world results for the consumer and the country. Moreover, by continuing to use outdated mileage formulas for current, real-world city/highway driving averages, the result is another unintended consequence of influencing the market toward "preferred technologies" (because it is slanted towards city-like driving). [EPA-HQ-OAR-2010-0799-9478-A1, p.4]

While new test procedures would be beneficial for real-world evaluation of CO_2 and fuel efficiency, until such time they are implemented, off-cycle credits are a good way to ensure manufacturers are encouraged to introduce technology(ies) that result in real-world improvements. Although, MEMA recognizes the challenges with the tall task of changing the FTP/HFET, we urge the agencies to continue to actively work on global harmonization efforts to develop test cycles that better reflect real-world driving habits and performance so that, ultimately, the root causes can be addressed, resolved and incorporated for future iterations of this Program. [EPA-HQ-OAR-2010-0799-9478-A1, p.4]

Test procedures must be more reflective of real-world conditions. [EPA-HQ-OAR-2010-0799-9478-A1, p.13]

Organization: National Automobile Dealers Association (NADA)

The final rule should be as performance-based as possible and, in doing so, treat all compliance technologies as fairly as possible. Unfortunately, the single CAFE test cycle inherently serves to disadvantage certain technologies over others to the extent that it fails to account for how those technologies are actually used. For example, vehicles with hybrid and plug-in technologies benefit from test cycles that emphasize city driving, vehicles with start-stop technologies benefit from test cycles with long idling periods, and vehicles with diesel engines benefit from cycles with a higher proportion of highway driving. To the extent allowed by law, where NHTSA and EPA have data showing that certain technologies are or will be used in a manner that varies from the CAFE test, or that are off-cycle, appropriate adjustments should be made. Moreover, appropriate adjustments should be made to the final rule to reflect that real world gasoline does not offer as much energy potential as the fuel used in the CAFE test. [EPA-HQ-OAR-2010-0799-9575-A1, pp. 10-11]

Organization: Necheles, L.

I am only a Juvenile Attorney so I honestly don't have a science background. What I am concerned about and can comment upon, as a lay person, is how the EPA calculates vehicle fuel mileage as seen on the stickers of new cars. 'EPA estimated fuel mileage.' [EPA-HQ-OAR-2010-0799-2487-A1, p. 1]

Based upon personal experience and observation, the current calculated gas mileage shown on stickers does not reflect reality. The Consumer Reports or Car and Driver 'observed' fuel mileage is the best indicator and predictor of fuel mileage that I have at my disposal. Please consider testing vehicles under real-world, reliable conditions. For instance, for Highway Driving: [EPA-HQ-OAR-2010-0799-2487-A1, p. 1]

1. Use ordinary fuel purchased from a local retailer-gas that might be contaminated with water or particles or may not be 87 Octane...fill the car with gas like an everyday consumer. 2. Drive the car at speeds of 70-75 miles per hour. 3. Use an intestate like the Pennsylvania Turnpike or Kansas Turnpike that contain hills. 4. Use full throttle at least once to simulate overtaking a truck. 4. Use the AC and CD player and a phone charger..load on the engine. 5. One tire at least 5 pounds under inflated. 6. 50 pounds of junk in the trunk....i.e. extra coolant, window washer fluid, jumper cables, tire inflator, flash light, groceries, kids toys, car seats, etc. (Items people lug around everyday) 7. Headwinds and cross winds of at least 10 mph should be factored in. 8. Slow down and speed up for 'construction zones' and make a full stop for a simulated rest room break:, 9. Use a front plate on the car. [EPA-HQ-OAR-2010-0799-2487-A1, p. 1]

Organization: Securing America's Future Energy (SAFE)

Vehicle Testing Procedure: The testing procedure that EPA uses to measure vehicle fuel economy is outdated, does not reflect actual driving patterns, confuses the public, undermines agency credibility, and ultimately discourages consumers from purchasing efficient and cost-effective vehicles. [EPA-HQ-OAR-2010-0799-9518-A1, p. 14]

For the purpose of measuring fuel economy for fuel economy and carbon emission regulations, EPA relies of two tests developed in the 1960s and 1970s that simulate urban and highway driving at relatively low speeds, in moderate weather, and without operating any vehicle accessories. In the 1980s EPA started adjusting the fuel economy measurements downward for the purpose of calculating the fuel economy that was placed on vehicle fuel economy labels so that the figure would more closely reflect actual driving experiences. As the gap between real world fuel economy and the figures on the label continued to grow, the Energy Policy Act of 2005 required EPA to revise its calculation for fuel economy labels again. Beginning with MY 2008 vehicles, EPA employed an updated test procedure which added three drive cycles to the calculation to evaluate fuel economy at high speeds, in cold weather, and in hot weather. Yet for fuel economy and carbon emission regulations, EPA continues to rely solely on the original drive cycles that are forty years old. They are estimated to overstate actual fuel economy by about twenty percent. [EPA-HQ-OAR-2010-0799-9518-A1, p. 14]

Yet in this proceeding, the characterization of fuel economy is more complex because in addition to calculations of fuel economy based on fuel consumption, the proposal reports calculations of fuel economy that are really fuel economy equivalents of emission standards. In the proposed rule and the accompanying announcements the agencies characterized the requirements that automakers will have to achieve by MY 2025 as "equivalent to 54.5 miles per gallon (mpg) if the vehicles were to meet this CO_2 level all through fuel economy improvements." It was this level of fuel economy that both agencies highlighted in their press materials and which was widely reported in the mainstream media. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 14-15]

In reality, all emission reductions will not be achieved through improvements in fuel economy. The agencies acknowledge this point, which is reflected in the fact that NHTSA stated that the fuel economy actually required pursuant to the rule would be 49.6 MPG. NHTSA then proceeds to explain that that estimate, however, also is overstated because it does not account for regulatory flexibilities that it is not allowed to consider in establishing the standards. NHTSA estimates that the achieved fuel economy under the proposed rule would yield a fleet average of 47.0 MPG. Yet even that estimate only reflects the estimated achieved fuel economy measured using the outdated test procedures. The 47 MPG estimate probably overstates the mileage that will be reflected on a vehicle's fuel economy label by about 20 percent, meaning that the fuel economy label would indicate a fuel rating closer to 38-40 MPG. And, even the figure on the label often overstates the vehicle's actual fuel economy, a point that contributed to a Honda Civic owner successfully suing Honda because her Civic Hybrid achieved far poorer fuel economy that indicated on the vehicle's label. [EPA-HQ-OAR-2010-0799-9518-A1, p. 15]

Therefore, in this instance, there may be as many of five different figures by which one could characterize the fuel economy requirements in the rule, enough to confuse most any consumer. [EPA-HQ-OAR-2010-0799-9518-A1, p. 15]

In the preamble to the rule, the agencies noted that consumers often choose not to make cost-effective investments in efficiency. The agencies identified several reasons why consumers might not purchase more fuel efficient vehicles that are cost effective, suggesting that consumers might be myopic, lack information to estimate the value of fuel savings, or might associate fuel efficiency with small poorly made cars, among other reasons. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 15-16]

The agencies should consider the extent to which multiple measures of fuel economy undermines confidence in the accuracy of the calculations, making it difficult for reasonable consumers to have any confidence in any single fuel economy number, or the calculations of cost-effectiveness based on them. SAFE believes that EPA should once again revise the test procedures to more closely reflect real world driving conditions and use the revised test in its carbon emission regulations. Likewise, NHTSA should use an updated test procedure for lightduty trucks, though it cannot adjust the test procedure for cars without Congress updating the statute. More importantly, however, EPA and NHTSA should work together to determine how to simplify the calculation of fuel economy so that it most accurately reflects real world conditions. They should then propose to Congress the appropriate changes to the law so that they may replace outdated and inconsistent test procedures with more accurate ones that will inspire confidence in the regulation system instead of undermining the public's confidence in it. [EPA-HQ-OAR-2010-0799-9518-A1, p. 16]

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

Take steps to address testing issues: Both agencies have recognized that the standards do not correlate with the mileage or emissions of vehicles consumers should expect to see in dealership showrooms or experience on the road. While the standards that are proposed for 2017-2025 vehicles are anticipated to yield a fleet of new vehicles in 2025 that averages 54.5 mpg (if all improvements are made through efficiency) and emits 163 g/mi of CO_2, there are various factors that reduce this standard to the much lower average of 37 miles per gallon that consumers will see on new vehicle labels. [EPA-HQ-OAR-2010-0799-9549-A2, p. 9]

In a report released last summer, Sierra Club detailed the history of CAFE standards and the testing regime that is used to set the standards and measure compliance. This testing regime remains as it was prescribed in the original fuel economy law. Testing for determining the mileage and now greenhouse gas information has gone through several updates with the goal of providing consumers shopping for new vehicles more accurate information. As a result of the divergent testing regimes, there is a confusing set of numbers - one for standards (i.e., the proposed 54.5 mpg and 163 g/mi CO_2 fleetwide average in 2025) and another that reflects the on-road impact of the program (i.e., consumers should anticipate vehicles averaging 37 mpg in 2025, not 54.5 mpg). Our report detailed how we ended up with a confusing set of numbers that persists with these proposed standards. [EPA-HQ-OAR-2010-0799-9549-A2, p. 9]

In the proposed and final rules for 2012-2016 vehicles both EPA and DOT recognized the disparity between standards and on-road mileage and pledged to address the issue before issuing further standards. The process for further standards launched within weeks of that those standards were final and the MPG values used to define the standards and the discrepancy between standards and labels is now further impacted by the accounting for AC and off-cycle reductions in the standard setting process. In the NPRM, the "on road fuel economy gap is recognized, and the agencies continue to apply a 20% discount to the standards to assess real world mileage and emissions and in calculating benefits associated with the standards. [EPA-HQ-OAR-2010-0799-9549-A2, p. 9]

The agencies are proposing in this rule to revise testing for purposes of measure compliance with the standards to account for some changes in air conditioning systems and some "offcycle" reductions, but this leaves the actual standards themselves still tied to outdated testing. As we noted in our report and in comments to the MY 2012-16 rule, steps could and should be taken to address the outdated testing used for setting the standards and to ensure that the public is fully and fairly informed. The fact remains that today's new vehicles average in the low 20 mpg range and new vehicles in 2025 will be nearly twice as efficient, on average. Consumers, however, who shop for a new vehicle in 2025 should seeing label values average around 37 mpg, not 54.5 mpg. While the proposed rule indicates that adjustments will be made for testing for compliance with fuel efficiency standards, we continue to urge both agencies to take steps to reform testing for setting the standards and to take steps to inform the public about the standards and what consumers should expect to see in dealerships. [EPA-HQ-OAR-2010-0799-9549-A2, pp. 9-10]

EPA versus NEDC Test Cycles

Regarding the relationship between NEDC and EPA test cycles please consider …

NEDC and fuel frugal diesels: Compare

http://www.autocar.co.uk/SpecsPrices/SpecsAndPricesEdition/Volkswagen-Jetta-2.0-TDI-140-SE-/62466/ at 58.9 mpg(Imperial) combined ==> converts

to ~49 mpg(US) to US Individual (user) MPG Estimates

http://www.fueleconomy.gov/mpg/MPG.do?action=mpgData&vehicleID=31577&browser=true &details=on at 45.5 mpg(US) with roughly 75% highway … with an EPA sticker of 34/42 mpg(US) combined/highway. [NHTSA-2010-0131-0240-A1, p.3]

Which better reflects US user estimated average experience, US sticker or the convert NEDC value? I believe you will find that the converted NEDC value (for diesels) more closely reflect USER Average experience. This appears to be relatively typical for Audi and VW's This tracking relationship between US user AVERAGE mpg experience and the converted NEDC combined mpg(Imperial) values seems to be relatively consistent for fuel frugal small displacement (Further, these VW/Audi vehicles are certainly NOT the best available diesel fuel economies in the world compared to 2.0~1.5 US gallons/100 miles that is more or less standard practice for significant portions of the > 49 mpg(US) combined EU offerings as demonstrated by Table 5 above… with diesel machines that look and function much like ones already in the US … EXCEPT for superior fuel economy. [NHTSA-2010-0131-0240-A1, p.3]

Organization: Tarazevich, Yegor

CAFE should be measured in EPA real world test numbers otherwise manufactures would continue to learn tricks to show even higher CAFE numbers which do not translate to real world numbers. 30 years ago CAFE MPG were very close to real world MPG but right now, CAFE 54.5 MPG in real world means only 40 MPG. Otherwise in 2025 CAFE 54.5 MPG could become EPA 35 MPG only. [NHTSA-2010-0131-0199, p.1]

Organization: U.S. Coalition for Advanced Diesel Cars

Emissions testing and calculations that: [NHTSA-2010-0131-0246-A1, p.2]

Use market fuel rather than higher energy content laboratory fuel; [NHTSA-2010-0131-0246-A1, p.2]

Employ real-world driving conditions; [NHTSA-2010-0131-0246-A1, p.2]

Accurately reflect the full environmental impact of each technology (not just at the vehicle's tailpipe); and [NHTSA-2010-0131-0246-A1, p.2]

The Coalition continues to advocate for fuel economy calculations that provide the clarity consumers require to make informed decisions and select a vehicle that best meets individual driving needs. This includes up to date calculations for real world driving and steps to limit the disparity between fuel economy measurements achieved in the laboratory and the real world. [NHTSA-2010-0131-0246-A1, p.10]

Real World Driving [NHTSA-2010-0131-0246-A1, p.10]

During the comment period for the MY 2012-2016 joint rulemaking on CAFE, the Coalition called attention to EPA and NHTSA's failure to utilize real world driving calculations. EPA's own data from a 2006 study confirms that the average American accumulates the majority of their miles at highway conditions. In spite of this, calculations that indicate drivers accumulate the majority of their miles in urban conditions were utilized for the MY 2012-2016 rule, and are again used in the MY 2017-2025 proposed rule. [NHTSA-2010-0131-0246-A1, p.10]

Interestingly, EPA is not using its own data and public information to calculate the most accurate fuel economy for CAFE despite the fact that it already utilizes the 2006 data to calculate the societal benefits resulting from the implementation of advanced vehicle technology. Because the calculations inaccurately reflect the driving patterns of the average American, EPA and NHTSA are causing automakers to disproportionately employ technologies that perform well in urban duty cycles in new vehicles, causing automakers to lean toward technologies that are not optimized for the needs of the average American driver. [NHTSA-2010-0131-0246-A1, p.10]

The NPRM states that EPA and NHTSA are considering significant changes to test procedures in response to the wide array of vehicle technologies available. The agencies have also stated that they lack the statutory authority to change some of these calculations. If EPA and NHTSA have determined that they lack the statutory authority to update the calculations to reflect the real world driving habits of the current American driver, the agencies should educate Congress on the impacts of this flawed statute and formally ask for the statutory authority from Congress to update the calculations. Instead, the current proposals risk yet another rulemaking process that will propagate the outdated and inaccurate 1975 calculations for the next decade and beyond. [NHTSA-2010-0131-0246-A1, p.11]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 248-249.]

By continuing to use outdated calculations, it may very well appear that manufacturers have reached the new fuel economy and emissions goals, but it is likely that the real-world impact will fall short of our nation's targets. Additionally, a significant disparity will continue between actual fuel economy and what consumers were expecting when they purchased their vehicles. This is evident from the recent class-action and small claims litigation by thousands of hybrid owners. In the Detroit Free Press on January 6, 2012, Neil Schmidt, a technical specialist for American Honda, explained the disparity between fuel economy on the sticker versus what the drivers were actually achieving. 'We have no choice. We have to put these numbers on the label.' He noted the small type on the label, which gave a listing of 41 to 57 miles on average, saying, 'This is more toward the real world.' The important point for this discussion is that government standards need to be consistently based on real-world driving patterns for the American consumer, and therefore optimized for highway driving, to achieve the greatest real world results. [NHTSA-2010-0131-0246-A1, p.11]

Organization: Volvo Car Corporation (VCC)

CC has put considerable time and effort into maintaining a high degree of accuracy by having well-developed arrangements to monitor calibrations, checks, and all critical processes in our emission laboratory. We work continuously to monitor and improve the correlation and repeatability of our test rooms. Thus, VCC realizes that test procedures, calibrations, and instrumentation must be regularly reviewed and renewed to meet new challenges. [EPA-HQ-OAR-2010-0799-9551-A2, p.13]

In the fall of 2011 EPA proposed, under TIER 3, to consolidate all test procedure requirements of Parts 86 into Part 1066 in order to improve their organization, including references to Part 600. In doing this, some test procedures will remain as they are, some will evolve, and new ones will be introduced. This will also come to affect procedures that involve CO_2 /FE. This has to be considered. [EPA-HQ-OAR-2010-0799-9551-A2, pp.13-14]

Along with the industry, VCC pointed out that close industry-EPA collaboration is critical to ensuring that test procedures are relevant, adequate, and meet the objective standards so that the tests can be reproduced and replicated. The initial EPA proposal would have required major investment from VCC, but based on current discussions there appears to be an understanding that there are other possible ways to address measurement. [EPA-HQ-OAR-2010-0799-9551-A2,p.14]

VCC has therefore been actively involved in addressing issues directly with the EPA and through the Alliance on the proposal that was presented by EPA in November 2011. Based on VCC's ongoing analysis of Part 1066, VCC believes that these proposed processes would benefit from thorough revision, in cooperation with the industry, to minimize the risk of creating processes that will add very little value to good repeatability and accuracy. EPA has recognized industry's challenges and therefore continues to work with industry on this issue. VCC would welcome CARB's participation in that dialogue. [EPA-HQ-OAR-2010-0799-9551-A2, p.14]

Currently there are crucial differences between CARB and EPA advanced technology vehicle test procedures that would benefit from harmonization. [EPA-HQ-OAR-2010-0799-9551-A2, p.14]

Hybrid Test Procedures

The hybrid test procedures need to be updated to reflect a common approach between EPA and CARB. EPA extensively refers to SAE J1711 test procedures updated during 2010. The J1711 test procedures are the result of many years of cooperative work between industry and government, which includes EPA and CARB. CARB's corresponding test procedures are based on J1711 of 2008/2009. There are several changes between these two versions which are going to generate extensive updating. If the harmonization does not occur, there will be unnecessary additional test burdens on the industry as a result of duplication of testing and uncertainty concerning the certification requirements. [EPA-HQ-OAR-2010-0799-9551-A2, [p.14]

Organization: Weiner, L.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 107-108.]

It's important that agencies develop new, precise test procedures that actively calculate the true mileage and not an overestimation, as has happened before.

Response:

EPA received a limited number of comments on test procedure changes being finalized by this rule, which are intended to account for impacts on fuel economy not currently included in the CAFE test procedures, as described in section III.B.10 of the preamble.

Several commenters noted that the test procedures used for this rule are different from those used for determining fuel economy label values, and requested that the methods be harmonized (AAA, U.S. Coalition for Advanced Diesel Cars). While EPA has broad discretion in our authority to calculate average fuel economy across manufacturers' fleets, we are required under EPCA 32904(c) to measure fuel economy for each car using "the same procedures for passenger automobiles the Administrator used for model year 1975 …, or procedures that give comparable results". In response to comments urging Congressional action, Congress was certainly aware of this issue in promulgating the EISA amendments to EPCA in 2007 and left this provision unamended. A more detailed discussion of the statutory authority is provided in section III.B.10 of the preamble. Although there is no outright legal bar to adopting a different test procedure for the other light duty vehicles (including MDPVs and light trucks), there are significant practical constraints. Virtually all data on control technology efficiency is based on performance over the CAFE two-cycle test procedure. See 75 FR at 25332, 25408 ("EPA simply lacks the technical basis to project the effectiveness of the available technologies over these three test cycles and therefore, could not adequately support a rule which set CO2 standards based on the five-cycle formulae.") In addition, having car standards based (for legal reasons) on two-cycle testing and truck standards based on five-cycle testing would raise obvious issues regarding implementation and harmonization (for example, crafting an ABT program, assessing costs, developing a proper relation between car and truck curves). As a result of these legal and practical restrictions, we are not adjusting the test procedures used in this rule to better reflect real-world driving. This is in contrast to the approach that EPA has taken for the fuel economy label, which is not subject to the same statutory restrictions. For the fuel economy label, EPA uses the five-cycle test procedure to better account for real-world driving conditions, and address issues similar to those expressed by commenter L. Necheles. EPA does not agree with the conclusion drawn in comments from SAFE that difference between test procedures for labeling and compliance will confuse consumers, noting that test results for individual models used to determine manufacturer fleet compliance are not widely publicized, and are likely to be unknown to the average consumer.

Furthermore, EPA does not believe the restrictions imposed by EPCA on test procedures will have any impact on the level of emissions reductions and fuel savings that will be achieved as a result of this rule. EPA notes that the car and truck standards in this rule were determined with consideration of cost, feasibility of technology adoption, lead time, and consumer acceptance. A change in test procedures for which the primary effect is a proportional decrease (or increase) in test values would alter the standard curves, but would not affect the level of adoption of efficiency technologies required to comply with the standards.

The proposed rules properly include various provisions offering manufacturers some flexibility in developing their plans to comply with the CAFE and GHG standards. Some of these provisions enable manufacturers to earn credits that can be used to satisfy part of their compliance obligations. While some may think the term 'credits,' as used here, connotes reduced stringency or even 'loopholes,' that is not the case. The objective of the CAFE and GHG standards is to reduce actual fuel consumption and actual GHG emissions from vehicles driven on American roads. In some cases, however, the laboratory testing used by the agencies to measure fuel economy and GHG emissions may not fully reflect the improvements built into a vehicle by the manufacturer, due to limitations of laboratory-based tests. And improvements to reduce MAC system refrigerant loss can reduce GHG emissions from vehicles while having little or no impact on fuel economy. It is important for the rules to properly account for such factors. Otherwise, manufacturers would be encouraged to focus solely on the test procedures, and opportunities for real-world GHG reduction and fuel economy improvement would be lost. The Alliance believes that the various credit provisions proposed by EPA and NHTSA are essential elements of the rulemaking package. Below we offer our specific comments on the details of these provisions. [EPA-HQ-OAR-2010-0799-9487-A1, p.10] [[This comment can also be found in Outline Heading 7.]]

Introduction [EPA-HQ-OAR-2010-0799-9487-A1, p.46]

The MAC credit provisions have become an essential piece of EPA’s GHG program. Rapid progress is underway as a result of the
MY 2012-2016 provisions to improve MAC efficiency, reduce refrigerant leakage, and switch to a new low global warming refrigerant. In order to maintain the progress made in improving MAC, as well as the overall integrity of the broader GHG program, the MAC provisions must be continued in MY 2017-2025 at unreduced credit levels. This was one of the foundations of the consensus to move forward toward the dramatic GHG reduction targets set through MY 2025, as the program stringency is designed on the basis of these alternative compliance mechanisms. Any obstacles that would prevent maximum attainment of MAC credits are therefore a

fundamental threat to the achievement of the overarching program goals. [EPA-HQ-OAR-2010-0799-9487-A1, p.46]

The Alliance comments are directed toward making a success of the MAC provisions through efficient crediting processes that achieve real-world GHG reductions, commensurate with the credit levels granted. The Alliance stands ready to work with the agencies to address the concerns outlined below. [EPA-HQ-OAR-2010-0799-9487-A1, p.46]

Organization: Association of Global Automakers, Inc. (Global Automakers)

The air conditioning system credits provide manufacturers flexibility in pursuing a variety of enhancements to system efficiencies and the use of advanced low global warming refrigerants. We see the flexibility mechanisms as an essential part of this program. [EPA-HQ-OAR-2010-0799-9466-A1, pp. 1-2]

[These comments were also submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 67.]

Organization: BMW of North America, LLC

Credit generation regarding direct (leakage) and indirect (fuel efficiency) emissions is generally supported. Details to be modified from our point of view are listed below. The aim is to ensure best objective methods as well as practicability and fairness. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 1]

Organization: Center for Biological Diversity

4. A/C credits should be eliminated

We support the use of all technologies that improve the efficiency of air conditioning systems and the employment of refrigerants with lower carbon footprints. However, these efficiency improvements and greenhouse gas reductions should not be approached by way of credits. The technology to accomplish them is or will be readily available and is economically feasible.105 Their use should be built into the standard rather than merely incentivized. [EPA-HQ-OAR-2010-0799-9479-A1, pp. 22-23]

105 As ICCT notes, vehicles with low greenhouse gas warming potential refrigerants are already being sold in Europe; it is preposterous to assume that the U.S. fleet cannot utilize them in all A/C systems by 2017. ICCT Comments at 42. [EPA-HQ-OAR-2010-0799-9479-A1, p. 23]

Organization: Ferrari

We agree with EPA's proposal that allows manufacturers to generate credits by reducing CO_2 equivalent emissions due to improved air conditioning systems, for reduced leakage (direct) and enhanced A/C system management with consequent reduced tailpipe CO_2 (indirect) emissions. This is consistent with the goal to reduce the greenhouse gases associated with vehicles regardless of the source. [EPA-HQ-OAR-2010-0799-9535-A2, p.13]

Organization: Ford Motor Company

Ford fully supports all aspects of the Alliance comments on Mobile Air Conditioning (A/C) credits. We believe these credits are an integral part of both the EPA and NHTSA programs. The stringency of the standards has been set using specific assumptions on a manufacturer's ability to make widespread use of this incentive program. It is therefore imperative that the agencies finalize requirements that allow companies who implement these technologies, which result in real world CO_2 reductions, to receive the appropriate benefit. In support of this overarching goal, Ford has the following comments: [EPA-HQ-OAR-2010-0799-9463-A1, p. 10]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 46-47.]

Manufacturers are developing more innovative in-vehicle systems such as more efficient air conditioning, use of refrigerants with lower global warming potential, and improvements in energy management and aerodynamics. These technologies provide a real-world benefit for drivers but are not fully reflected on the fuel economy label. We commend the agencies for acknowledging these technologies in the rulemaking.

Organization: Honeywell International, Inc.

Honeywell supports EPA and NHTSA's decision to continue and expand upon the A/C Credit Program to provide strong incentive to eliminate the emissions of greenhouse gases ('GHGs') from NC systems and improve energy efficiency in A/C operations to reduce fuel consumption. Consistency and technology neutrality are critical factors in designing regulations that enable businesses to invest in innovative technologies, systems, and controls. [EPA-HQ-OAR-2010-0799-9497-A1, p.3]

We believe that good regulatory approaches are performance driven, technology neutral, and provide some flexibility. They must accommodate for new developments and reflect the best available science and data. Honeywell believes that EPA should provide flexibility to accommodate for new developments in controls and test methods for measuring emissions and improvements in energy efficiency in A/C system programs. Incorporating the most up-to-date research and technical information will add further credibility to the A/C Credit Program by accounting accurately for emission reductions and energy efficiency attributable to alternative refrigerants. [EPA-HQ-OAR-2010-0799-9497-A1, p.4]

EPA and NHTSA must continue to maintain a clear regulatory approach that provides businesses across the life of a light vehicle's A/C system with the regulatory certainty to commercialize effectively and transition rapidly to low GWP refrigerants. This confidence in the regulatory system enables manufacturers such as Honeywell to take the risks necessary to innovate and solve our most pressing environmental and energy security challenges. Currently, markets for low GWP refrigerants are highly sensitive to standards, specifications, and incentives such as those established in the Proposed Rule. Continuation of the A/C Credit Program beyond 2016 based upon best available science clearly advances the goals and objectives of fuel economy and GHG emissions programs. [EPA-HQ-OAR-2010-0799-9497-A1, p.4]

In sum, Honeywell supports EPA and NHTSA's approach to continue and expand upon the A/C Credit Program beyond 2016, and the recognition of the important contribution that alternative refrigerants will make toward meeting both fuel economy and GHG emissions objectives. [EPA-HQ-OAR-2010-0799-9497-A1, p.12]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 206-210.]

Organization: United Automobile Workers (UAW)

The UAW also supports EPA's proposal for air conditioning improvement credits and so-called "off-cycle" credits. Air conditioning credits recognize real-world reductions in climate change pollution that occur through reduced leakage of chemicals with high global warming potential from air conditioning systems, the substitution of less harmful chemicals in air conditioning systems, and more efficient systems that draw less power from the engine and result in lower CO_2 emissions to run the compressor. [EPA-HQ-OAR-2010-0799-9563-A2, p.3]

Organization: Volvo Car Corporation (VCC)

In the GHG regulation for MY 2012-2016 EPA introduced the AC credits as an opportunity to achieve some flexibility in compliance with standards equivalent to the opportunity that exists within CAFE by paying fines for deviation. Hence rewarding the manufacturer who has a good engineering solution, the AC credit has become a very important part of the national GHG program. It is therefore important that this momentum is maintained. Also for this part of the program, it is critical that EPA and NHTSA interact with CARB in order to enable consistent design requirements and reporting requirements for maximum efficiency of both manufacturers and government. [EPA-HQ-OAR-2010-0799-9551-A2, p. 8]

Response:

EPA acknowledges comments of general support for the proposed program in the preamble to this rule, Section II.F.1. With regard to the comment from CBD that the standards should reflect the anticipated widespread use of A/C, we note that the GHG standards do exactly that (as a number of commenters, e.g. Ford, noted explicitly and correctly). See joint TSD section 2.5.3.2 (explaining how the target curves reflect use of A/C technology); preamble section III.C.3.

3.1. Credits Related to Reduced Leakage and the Use of Alternative Refrigerants

Organizations Included in this Section

Alliance of Automobile Manufacturers

Toyota Motor North America
Volkswagen Group of America
Volvo Car Corporation (VCC)

Organization: Alliance of Automobile Manufacturers

The Alliance does not support additional requirements on Low Global Warming Potential (GWP) refrigerant systems (i.e., the "high leak disincentive"). Some manufacturers have invested millions of dollars to redesign their vehicles and assembly plants for transitioning to new low-GWP refrigerants. These companies have counted on a specific level of credits in exchange for making this transition earlier than they might otherwise have done. This new proposal would potentially reduce the amount of credit, unfairly penalizing early adopters. [EPA-HQ-OAR-2010-0799-9487-A1, p.5]

Use of Updated SAE J2727 [EPA-HQ-OAR-2010-0799-9487-A1, p.59]

The Alliance supports the proposed adoption of the updated SAE J2727 procedure to calculate leak rates. However, at the time the NPRM was written, the updated SAE J2727 was still in draft form. Therefore, not all of the changes have been included in the NPRM. Now that the update is nearly approved, we recommend that it be fully incorporated into the final rule. Using a lower multiplier of 10 (instead of 125) for helium tested connectors makes sense to provide lower leak rates for tighter connectors. The Alliance also proposes that this methodology, along with all other SAE J2727 updates, be allowed for MY 2012-16 so that manufacturers will be encouraged to perform helium testing as soon as possible and develop testing methods in advance. This allowance will benefit the environment and support automakers ability to earn credits to meet the challenging standards of the future. [EPA-HQ-OAR-2010-0799-9487-A1, p.59]

Use of SAE J2064 [EPA-HQ-OAR-2010-0799-9487-A1, p.59]

The Alliance supports the adoption of the SAE J2064 procedure for MY 2017 and beyond for calculating hose leak rates. The Alliance also proposes to allow this calculation method for MYs 2012-16. [EPA-HQ-OAR-2010-0799-9487-A1, p.59]

High Leak Disincentive [EPA-HQ-OAR-2010-0799-9487-A1, p.59]

The Alliance does not support the proposal to reduce the MAC direct credits (up to 1.8 g/mile for cars and 2.1 g/mi for trucks) via the "high leak disincentive" if the refrigerant leakage rate is not reduced by half from industry average leak rates (in other words, generating debits if the MAC fails to achieve the low leak standards). Compared to the MY 2012-2016 regulation, an unreduced program for MAC credits was the basis for the consensus GHG targets set for MY 2017-2025. The major reasons why the high leak disincentive should not be implemented for MYs 2017-25 and beyond for the R1234yf refrigerant are: [EPA-HQ-OAR-2010-0799-9487-A1, p.59]

1) Manufacturers have invested millions of dollars to change the designs of their vehicles and their assembly plants to bear the added cost of the new refrigerant in order to earn these credits. This new proposal to potentially reduce the amount of credit from a switch in refrigerant changes the cost-benefit equation from making this switch. This unfairly penalizes early adopters by undercutting the value derived from the credits from their decisions to switch rapidly to a new refrigerant, when a slower changeover might have been preferred under the new proposed rules. [EPA-HQ-OAR-2010-0799-9487-A1, pp.59-60]

2) EPA is proposing the high leak disincentive should be implemented for a refrigerant that has a GWP below 150. R1234yf, the new refrigerant that many auto manufacturers plan to use in this timeframe, has a GWP of 4. The global warming impact of R1234yf is 0.0028 times that of R134a. [EPA-HQ-OAR-2010-0799-9487-A1, p.60]

The actual global warming impact of an average leak air conditioner vs. a low leak air conditioner is shown in the table below, where grams/mile of CO_{2e} are calculated based on the delta between average leak and low leak. The data suggests that the actual difference in global warming impact between a vehicle with an average leak and the same vehicle with a low leak air conditioner is 0.002 g/mile for cars and 0.003 g/mile for trucks on a CO_{2e} basis using the R1234yf GWP of 4. The high leak disincentives proposed by EPA are 1.8 g/mile for cars and 2.1 g/mile for trucks, which are not in line with the actual global warming impacts. The data below suggests that, assuming manufacturers report CO_2 emissions to the nearest tenth of a g/mile so in these terms, excess CO_{2e} emissions from these average leak vehicles will be 0.0 g/mile for cars and 0.0 g/mile for trucks. This analysis shows that the "high leak disincentive " proposed by EPA has no environmental basis, due to the de minimis environmental impacts of R1234yf leakage. [EPA-HQ-OAR-2010-0799-9487-A1, p.60] [For the table please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.60]

3) Refrigerant leak rates are historically low for modern MAC systems because automobile manufacturers have improved quality in order to meet rising customer expectations and reduce warranty expenses. There is no evidence that manufacturers will be backsliding on these leak rates to save costs. In fact, given the higher cost of R1234yf - up to ten times the price of R134a -

manufacturers have an increased incentive to further reduce leaks and thereby retain the expensive new refrigerant. [EPA-HQ-OAR-2010-0799-9487-A1, p.60]

4) EPA has expressed concern about refilling R134a refrigerant in place of the R1234yf refrigerant. However, this is not easily achieved, since the service port fittings installed on new vehicles with R1234yf refrigerant are totally different from those using R134a. [EPA-HQ-OAR-2010-0799-9487-A1, p.61]

5) It is also worth noting that the size of the proposed penalty greatly exceeds the actual scale of the GHG impact of potential leakage. Please also note that the closing bracket is placed at the wrong place in the formulas that calculate direct MAC credits in section § 86.1866-12.(b)(2)(i) & (ii), both for cars and trucks. We recommend that EPA make the correction of these closing brackets (as noted below) along with removing the HiLeakDis factor in both formulas. [EPA-HQ-OAR-2010-0799-9487-A1, p.61] [For the figure '(noted below)' please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.61]

Refrigerant Level Monitoring [EPA-HQ-OAR-2010-0799-9487-A1, p.61]

Emission warranty requirements are not appropriate for mobile air conditioners under the proposed rule. This is because in-use performance of MAC systems at levels comparable to a new vehicle is not needed to achieve the emission levels targeted by EPA. [EPA-HQ-OAR-2010-0799-9487-A1, p.61]

Warranty requirements were established for tailpipe pollutants, such as CO and NO_x, because emissions of those pollutants would rise significantly if the pollution control devices such as catalytic converters fail. This would typically not be the case for MAC components. First, consider the case of indirect emissions from fuel consumed to power the MAC. In the vast majority of MAC failure modes, the system stops cooling and ceases operation - either because the critical moving parts stop moving or because the system is switched off - thereby actually reducing the indirect CO_2 emissions. [EPA-HQ-OAR-2010-0799-9487-A1, p.61]

Emission warranties should not be required in relation to the indirect MAC emissions. The most significant item in EPA’s proposed warranty coverage, the compressor, can cost over $1,000 to replace. It seems paradoxical and disproportionate to impose such high costs in an emissions recall scenario to replace this component, and thereby actually increase indirect emissions. Although manufacturer warranties may typically already be longer than the two-year period proposed by EPA in this NPRM, in principle there is no sound basis for emission warranty coverage to safeguard indirect emission levels, since indirect emissions go down when the system fails. Finally, it is worth noting that proper functioning of these parts is not actually required to achieve the emissions levels set by EPA. [EPA-HQ-OAR-2010-0799-9487-A1, pp.61-62]

Regarding direct emissions of refrigerant, there is only a negligible environmental impact if refrigerants below a GWP of 150 are released from the system, even if the entire charge (typically between 1-2 pounds) is released. Therefore, emission warranty coverage of joints, hoses, seals, etc. is certainly not needed to protect the environmental gains from application of low-GWP refrigerants. While the ultimate cost of the new low-GWP refrigerant R1234yf (also known as HFO-1234yf)) is higher than the R134a, it is expected to be at a level that would severely discourage motorists from repeatedly recharging a system with significant unrepaired leaks (e.g., any cost of over $30 per pound). Therefore, there is no emission-based reason to mandate warranty coverage to prevent leaks on low-GWP systems, and the potential costs of an emission recall would be disproportionate to any environmental impact of leakage of these refrigerants. Any emission warranty requirements should specifically exclude emission warranty coverage for systems using a refrigerant with a GWP below 150. This is consistent with EPA’s position that no emissions warranty is required for zero emissions vehicles. The sole remaining MAC environmental impact would be from refrigerant leakage in the current R134a systems. Given the prospect for fairly rapid adoption of the low-GWP refrigerants in new vehicles during the time frame of this regulation, this would appear to be a very small basis on which to create an entirely new area of emissions warranty coverage and all the associated elements of an in-use program for air conditioners. EPA should not create a program of warranty coverage for MAC components in pursuit of such a small and temporary emissions impact. [EPA-HQ-OAR-2010-0799-9487-A1, p.62]

In conclusion, a properly structured MAC credit program can provide substantial low cost, near term GHG reductions. Our recommendations are provided to make the MAC program work as effectively as possible. [EPA-HQ-OAR-2010-0799-9487-A1, p.62]

Implementation of New Alternative Refrigerants [EPA-HQ-OAR-2010-0799-9487-A1, p.62]

As part of the Single National Program, the current regulations provide incentives to manufacturers to implement low-GWP refrigerants and reduce system leakage. Our members plan to make use of these incentives, with the degree of use depending on each manufacturer's model changeover plans, MAC technology implementation plans and capital investment schedules. In fact, we expect some automobile manufacturers to begin use of R1234yf on some models as early as 2013. Despite this promising news, there remain prohibitive barriers to achieving 100% use of low-GWP refrigerants. [EPA-HQ-OAR-2010-0799-9487-A1, p.62]

At this juncture, it would be premature for EPA to remove R134a from the list of acceptable substitutes for CFC-12 in MAC systems. We believe that the key to this transition is to instead continue the credits available under the MY 2012-2016 National Program for regulation of light-duty vehicle GHG and fuel economy. This approach would help ease the transition and encourage earlier action, to the extent that such action is achievable and cost-effective. It would encourage low-leak R134a systems, so long as R134a systems are allowed on new vehicles. It would also encourage accelerated introduction of new refrigerants if manufacturers were awarded credit for any usage of the new refrigerants in excess of mandated requirements. Should R134a become prohibited and R1234yf become mandatory for all vehicle MAC systems, it is critical that the MAC credits continue to apply throughout MY 2017-25, since these credits are an essential part of manufacturers’ compliance plans. [EPA-HQ-OAR-2010-0799-9487-A1, pp.62-63]

Refrigerant Availability [EPA-HQ-OAR-2010-0799-9487-A1, p.63]

Based on current knowledge, the best product that could meet a low-GWP requirement (at or below 150 GWP) would be R1234yf. This refrigerant is not yet available in commercial quantities, and it is unclear when a sufficient supply will be available in for the U.S. market or what the cost of this product will be. [EPA-HQ-OAR-2010-0799-9487-A1, p.63]

The single manufacturer of R1234yf – a joint venture of Honeywell and DuPont – recently announced that it would begin supplying the refrigerant in commercial quantities in the fourth quarter of 2012. According to current information, once production is permitted at pilot facilities at both Honeywell and DuPont, as well as an intermediate-scale facility in China at DuPont affiliate Changshu 3F Zhonghao New Chemical Materials, supplies likely will meet near-term EU requirements. A single world-scale plant is expected to follow at an undefined later date as demand grows. [EPA-HQ-OAR-2010-0799-9487-A1, p.63]

Current EU regulations mandate that automakers switch to low-GWP refrigerants by 2017. This EU mandate was phased in over a seven year period beginning in 2011. EU sales of nine million MAC-equipped vehicles filled with 600 grams of refrigerant equate to 5400 metric tons of refrigerant required for new production. Service and repair will require additional refrigerant. Since these regulations are already in place, the ramp-up of R1234yf production and system design is expected to fill the EU market first. The supply challenge is exacerbated by the fact that Honeywell and DuPont retain exclusive rights to the manufacture of R1234yf, thereby limiting the opportunity for other chemical manufacturers to supply the future demand for added manufacturing capacity. [EPA-HQ-OAR-2010-0799-9487-A1, p.63]

Engineering Resources Needed to Transition to R1234yf [EPA-HQ-OAR-2010-0799-9487-A1, p.63]

In evaluating this issue, the agencies should consider both the availability of the new refrigerant and the significant automaker resources needed to provide the engineering, logistics, training and roll-out. The deployment of these changes over 100% of vehicle models will present considerable challenge. In particular, all new systems will require complete revalidation using the new lubricants required for R1234yf. This will take time and strain the engineering resources throughout the MAC industry. [EPA-HQ-OAR-2010-0799-9487-A1, p.63]

In most cases, manufacturers will implement R1234yf with a revised component layout, including additional components that create packaging problems. Therefore, R1234yf is ideally implemented during vehicle major redesigns. Finally, there are significant changes to the assembly plants that are required to handle R1234yf (especially OSHA rules). These typically include relocation of the refrigerant charging area and relocation of refrigerant storage tanks. Extensive plant rearrangements such as this are very disruptive to plant operations, and are therefore typically performed as part of the changeover that occurs when new models are introduced, when extensive replacement of tooling and revised layout of production lines is typically required throughout the plant. [EPA-HQ-OAR-2010-0799-9487-A1, p.64]

Substituting R1234yf for R134a is fundamentally more complex than the change from R12 to R134a that was made during the 1990's, and the SNAP usage requirements are more significant.

The changes in the assembly plants will also be much more significant than were the case for R134a. [EPA-HQ-OAR-2010-0799-9487-A1, p.64]

For these reasons, EPA should not delist R134a from the approved SNAP list of automobile air conditioner refrigerants, nor should EPA establish other policies based on the assumption that a comprehensive changeover to new refrigerants can occur within the foreseeable future. [EPA-HQ-OAR-2010-0799-9487-A1, p.64]

Organization: Arkema Inc.

Arkema supports the EPA's focus on the use of more advanced components and technology to reduce the potential for refrigerant leakage and/or the use of alternative refrigerants. In fact, Arkema was and is an important contributor to the efforts to develop methods for leak-tight components and has an interest in the production of HFO-1234yf and/or other alternative refrigerants. The option of using air conditioning credits and the flexibility to choose leak-tight components or an alternative refrigerant should remain in the final rule. This choice gives flexibility to auto manufacturers, allows prioritization of improvements in vehicles, and acknowledges technological advancements that some auto manufacturers may have already implemented. For the consumer, the end result is the choice of the newest technology which could foster higher acceptance. Finally, for example, Arkema supports proper cooling load management to optimize the sizing of an air conditioning unit in motor vehicles. [EPA-HQ-OAR-2010-0799-9468-A1, p.2]

Arkema supplies a number of products into the automotive industry, which will help auto manufacturers achieve the proposed requirements. From coatings, refrigerants, plastics, polymers, and resins, Arkema serves a number of automobile parts suppliers and manufacturers to foster technological advancements for motor vehicles. [EPA-HQ-OAR-2010-0799-9468-A1, p.2]

However, as EPA considers which alternative refrigerants are eligible for use in mobile air conditioning systems, we believe that each potential, new refrigerant should be evaluated in terms of its full costs and benefits and effects on health, safety and the environment. Additional evaluation and information based on the above factors should be included in the final rule regarding alternative refrigerants. In addition, as alternative refrigerants play a key role in EPA's proposal, it is necessary to also more fully consider the availability, supply and competitiveness of such alternative refrigerants. Although potential supply issues are acknowledged in the NPRM, in light of other international regulatory efforts such as those previously undertaken by the European Union, for example, we believe additional analysis is needed by EPA to understand the potential costs and implications that could be posed by an adequate global supply of alternative refrigerants. Thus, a discussion on the acceptance of alternative refrigerants on a global scale should be included to benchmark other efforts in this area. EPA may also wish to consider delaying the use of alternative refrigerant incentives until relevant health, safety, environmental and supply issues can be fully and properly analyzed and/or until the mid-term evaluation process envisioned by the proposed rule. [EPA-HQ-OAR-2010-0799-9468-A1, pp.2-3]

c. Market Penetration of Alternative Refrigerants is the Best Way to Manage Existing Products [EPA-HQ-OAR-2010-0799-9468-A1, p.3]

Arkema supports EPA's proposed method of managing the transition to a new refrigerant as long as the use of particular refrigerants is not mandated by EPA and the market players have freedom of choice. This will ensure that there is adequate supply of the products and that the products will operate in a competitive marketplace. If the North American Proposal for HFCs (HFC Amendment to the Montreal Protocol) is successful, HFCs would be managed on a global cap and trade allocation basis and could still allow room for the market to govern the selection of materials. [EPA-HQ-OAR-2010-0799-9468-A1, pp.3-4]

EPA's potential Significant New Alternatives Policy (SNAP) rulemaking on HFC-134a is not consistent with the proposed method above or the HFC Amendment. The potential SNAP rulemaking to potentially de-list HFC-134a manages the process on a chemical by chemical basis and makes EPA the market regulator while the HFC Amendment allows competitive forces to make choices. [EPA-HQ-OAR-2010-0799-9468-A1, p.4]

Organization: Association of Global Automakers, Inc. (Global Automakers)

B. Availability of HFO-1234yf

As EPA is aware, manufacturers have been evaluating alternative refrigerants with low global warming potential (GWP) for many years. HFO-1234yf has emerged as a potential alternative that has the potential to be used in new vehicles in the near term. [EPA-HQ-OAR-2010-0799-9466-A1, p. 4]

However, while the outlook for the use of HFO-1234yf is promising, the availability of HFO-1234yf is still highly uncertain. With only two manufacturers and only one plant to produce this refrigerant at this time, there is not yet a guarantee that there will be adequate supplies for the U.S. vehicle market, especially since the European Union is moving ahead to adopt alternative refrigerants prior to the U.S. As part of the determination of the GHG standards, EPA accounts for the expected use of HFO-1234yf, and therefore the likely credits that would be obtained from this use, expecting 100% usage prior to 2025. The GHG standards were developed with these potential credits in mind. If for some reason HFO-1234yf does not reach commercialization, or adequate supplies are not available for all vehicle manufacturers, then it will be necessary for EPA to reassess the GHG standards, taking into account that a 100% usage rate will not be met. Global Automakers recommends that EPA continue to track the progress for HFO-1234yf and reevaluate the potential for 100% usage as part of the mid-term review. Again, if 100% usage is not feasible, then EPA should account for this shortfall through a revision of the standards following the mid-term review. [EPA-HQ-OAR-2010-0799-9466-A1, p. 5]

Organization: BMW of North America, LLC

From our point of view, the adequate availability of HFO-1234yf is highly questionable. Therefore, we greatly appreciate EPA's decision regarding the future ;:Adoption of this refrigerant. Currently, no one knows when the supply will be adequately established in the market. To assure that automakers will be able to continue to offer air conditioning to consumers in the future, the delisting of HFC-134a as an approved substitute would not be prudent at the present time. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 1]

Regarding leakage-related credits, we would like EPA to reconsider the so called 'Hi Leak Disincentive.' SAE J639 specifically requires unique service fittings for each refrigerant to prevent both accidental cross-contamination and intentional tampering by service technicians, and EPA's regulations currently do not allow the use of any unintended fluid or refrigerant in any A/C system. If someone does so, then it would violate the law. So the effects of illegal refrigerant charge cannot be influenced by the manufacturer. Furthermore, this disincentive provokes discussions to use unintended refrigerants. We do not expect that vehicle manufacturers will shift to higher potential leakage rates when using HFO-1234yf instead of HFC-134a; BMW would definitely not do so and our focus will remain on best quality refrigerant circuit tightness for any given refrigerant. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 2]

Organization: California Air Resources Board (CARB)

The California Air Resources Board (CARB) is supportive of the general structure of the motor vehicle air conditioning (AC) leakage credit program in the proposed United States Environmental Protection Agency (U.S. EPA) 2017-2025 MY light-duty vehicle greenhouse gas (GHG) rule. We believe the program will continue leading the automotive industry toward a more sustainable future by incentivizing the use of new refrigerants with low climate impact and superior refrigerant containment technologies. In the meanwhile, we have three specific comments on the U.S. EPA AC leakage credit provisions. The purpose of these comments is to accomplish three things:

- Correcting what appears to be an unintentional error in U.S. EPA’s proposed AC leakage credit formulas,
- Aligning U.S. EPA’s AC leakage credit formulas with the broad intent of the rule, and
- Fully aligning the U.S. EPA regulation and the CARB regulation with respect to AC leakage credit provisions.

The three specific comments are described in the attachment. [EPA-HQ-OAR-2010-0799-9491-A1, p. 1]

Attachment. Specific Comments on AC Leakage Credit Provisions in U.S. EPA’s 2017-2025 MY Light-duty Vehicle GHG Rule

Comment 1 refers to portions of subsections (i) and (ii) in §86.1866-12(b)(2). [EPA-HQ-OAR-2010-0799-9491-A1, p. 3]

Comment 2 refers to portions of subsections (i) and (ii) in §86.1866-12(b)(2). [EPA-HQ-OAR-2010-0799-9491-A1, p. 4]

Comment 3 refers to portions of subsections (i) and (ii) in §86.1866-12(b)(2). [EPA-HQ-OAR-2010-0799-9491-A1, p. 5]

[See pp. 3-7 of Docket number EPA-HQ-OAR-2010-0799-9491-A1 for specific comments on AC Leakage Credit Provisions.]

Organization: Chrysler Group LLC

The updated SAE J2727 and J2064 procedures and their bearing on EPA air conditioning system leakage calculations;

Opposition to EPA's proposed "high leak disincentive";

Refrigerant level monitoring;

And low-global warming potential ("GWP") refrigerant availability and the resources necessary to transition from R-134a systems to Low-GWP refrigerants. [EPA-HQ-OAR-2010-0799-9495-A1, p. 10]

Organization: Ford Motor Company

Ford also supports the continuation of the existing A/C leakage credit opportunities and offers the following comments about the proposed program for 2017-2025 MYs. [EPA-HQ-OAR-2010-0799-9463-A1, p. 14]

We believe that the current design-based "menu" approach to quantifying leakage credits is effective and should be retained. We also agree with EPA's proposal to adopt the latest version of SAE J2727 for calculating leak rates, including the lower multiplier for helium tested connections as well as all other updates incorporated into the SAE standard at the time the final rule is published. In addition, Ford supports the adoption of the hose permeation rates calculated from SAE J2064 as part of SAE J2727. For consistency and to encourage helium leak testing, we propose that EPA also allow these updated methodologies to be used for 2012-2016 MY vehicles. [EPA-HQ-OAR-2010-0799-9463-A1, p. 14]

Ford supports the mechanisms in place to incentivize the introduction of new low global warming potential (GWP) refrigerants, such as R-1234yf. Use of such refrigerants directly reduces the climate effects of A/C system leakage. As detailed in the Alliance comments and the NPRM preamble, there are still a number of obstacles that must be overcome before new low-GWP refrigerants can be used widely throughout the industry. These include, but are not limited to, refrigerant availability and cost, required A/C system hardware updates and testing, and assembly plant facility upgrades. Nonetheless, manufacturers are working to pursue this as a viable option to directly reduce GHG emissions in the future. Ford believes appropriate credit levels must continue through 2025 MY in order to incentivize the introduction of these new refrigerants. [EPA-HQ-OAR-2010-0799-9463-A1, p. 14]

Related to credit amounts, Ford does not support the introduction of the “high leak disincentive” proposed in the 2017-2025 MY program for low-GWP refrigerants. This revision makes it impossible for manufacturers to obtain the maximum leakage credit amounts for these refrigerants, unless they implement a system that achieves the minimum leakage score. Credits may be reduced by as much as 1.8 g/mile for cars and 2.1 g/mile for trucks. As detailed in the Alliance comments, Ford does not believe that the introduction of R-1234yf will encourage backsliding on leakage rates. Retention of the new, more costly refrigerant should serve as an incentive to improve or maintain leakage levels. We also have no indication that customers will commonly choose to recharge with R-134a or higher-GWP refrigerants. As required by the SNAP rule and SAE J639, we will engineer our systems and port fittings to avoid the possibility of this occurring. Finally, we do not believe it is appropriate to introduce a disincentive that would impact all systems that do not achieve the minimum leak score. This goes above and beyond the goal of discouraging backsliding and significantly infringes on manufacturers’ ability to obtain the full benefit of introducing low-GWP refrigerants. To encourage implementation of the new refrigerants, Ford recommends that the “high leak disincentive” be removed from the leakage credit equations. If such a “disincentive” value is retained, Ford believes the score levels used in the equation to calculate the value should be re-evaluated to ensure that it accomplishes the stated goal of minimizing backsliding. [EPA-HQ-OAR-2010-0799-9463-A1, pp. 14-15]

Outside the scope of this NPRM, we understand that a petition has been filed and separate regulatory workstreams are in process to potentially remove the current predominant refrigerant, R- 134a, from the list of acceptable substitutes for CFC-12 in mobile A/C systems. Due to the impediments to R-1234yf introduction described above, Ford does not support efforts to delist R-134a. Should R-134a be delisted for new vehicles, or R-1234yf become required in the future, the credit opportunities for low-GWP refrigerants should remain in place through 2025 MY. In determining the stringency of the GHG standards, EPA assumed manufacturers would make widespread use of the alternative refrigerant credits (especially during the later years of the program). Therefore, this incentive opportunity must continue through the duration of the entire 2017-2025 MY rule. Ford believes that removal of this flexibility would necessitate a modification to the overall stringency of the GHG targets. [EPA-HQ-OAR-2010-0799-9463-A1, p. 15]

Organization: Honeywell International, Inc.

Continuation of the A/C Credit Program beyond 2016 will accelerate the transition to low global warming potential ('GWP') refrigerant technologies and provide clear market signals to manufacturers as they incorporate cleaner technologies into their vehicles. [EPA-HQ-OAR-2010-0799-9497-A1, p.3]

The A/C Credit Program offers a valuable tool to comply with the fleet-wide CO_2 emission requirements and corporate average fuel economy standards by providing vehicle manufacturers with the flexibility necessary to continue to move ahead on a specific compliance pathway. [EPA-HQ-OAR-2010-0799-9497-A1, p.3]

Innovation means investment. In response to the European Union's call for a more environmentally friendly refrigerant for cars, Honeywell's team of world-class scientists launched an accelerated effort to develop a next generation air conditioning refrigerant. The result: Solstice™ 1234yf, a product that not only exceeded the goals set politically, but one that represents a long-term, global, and energy-efficient solution. [EPA-HQ-OAR-2010-0799-9497-A1l, p.3]

EPA and NHTSA properly acknowledge that the large number of light duty vehicles with A/C in use today has a substantial impact on the amount of energy vehicles consume and on the amount of refrigerant leakage that occurs due to their 'significant use.' With forecasts predicting more than 90 million light vehicles to be built per year by 2019, Solstice™ 1234yf mobile refrigerant can serve as an important component in global climate protection. [EPA-HQ-OAR-2010-0799-9497-A1, p.4]

With the development of Solstice™ 1234yf refrigerant, Honeywell is investing in making modern life more comfortable, cost- and energy efficient, and safer. [EPA-HQ-OAR-2010-0799-9497-A1, p.4]

Honeywell supports EPA's proposal to continue to allow auto manufacturers to generate credits for employing technologies that reduce A/C leakage emissions ('Leakage Credits') that may be used for compliance with vehicle emissions standards. The Leakage Credit program can be improved upon and Honeywell offers recommendations for EPA to incorporate the best available science in its analysis of average leak rates across the life of a vehicle. [EPA-HQ-OAR-2010-0799-9497-A1, p.4]

EPA explains that its proposed Leakage Credit is based on the SAE 12727 method. This standard does not adequately reflect leakage over the lifecycle of the vehicle. In the Draft Joint Technical Support Document ('TSD'), EPA states that it considers SAE J2727 to be an appropriate method for quantifying the expected yearly leakage rates from A/C systems, despite EPA's recognition that SAE 12727 is a 'surrogate for in-use emissions' and is 'not necessarily an accurate representation of real-world emissions Honeywell agrees that the test is appropriate for calculating leakage from new, properly constructed vehicles, but this test fails to account adequately for the increased leakage as vehicles age. [EPA-HQ-OAR-2010-0799-9497-A1, p.5]

Several recent studies indicate that emissions rates in older vehicles are much greater than the J2727 scores represent. For example, one study found that the average leakage rate of mobile A/C systems that are 1 to 6 years old is 52.4 g/year ± 4.6 g/yr. Another indicates that new compressors leak at a rate between 5 and 40 g/year and that aged compressors leak at rates from 97 to 1800 g/year when pressurized with refrigerant.[EPA-HQ-OAR-2010-0799-9497-A1, p.5]

Given that SAE 12727 does not account fully for leakage of refrigerants over the life of a vehicle, Honeywell proposes that companies seeking to obtain leakage credits be allowed the opportunity to design a component test based on SAE Standard 12763, Test Procedure for Determining Refrigerant Emissions from Mobile Air Conditioning Systems. Honeywell suggests that the use of SAE Standard 12763 test protocols provides a true indication of the correct selection of leakage reduction components and also allows for the development of additional credit goals for manufacturers to reduce the overall leakage rate. [EPA-HQ-OAR-2010-0799-9497-A1, p.5]

Honeywell is committed to put in place capacity in the United States to produce Solstice™ 1234yf consistent with the requirements of the US automobile manufacturers to meet GHG emission and fuel economy standards in the current regulations and the Proposed Rule. [EPA-HQ-OAR-2010-0799-9497-A1, p.5]

Compared to other alternative refrigerants referenced in the Proposed Rule, Solstice™ 1234yf has the most favorable climate footprint over its entire life cycle, and transition to Solstice™ 1234yf will require relatively few changes to existing air conditioning systems. [EPA-HQ-OAR-2010-0799-9497-A1, p.5]

Solstice™ 1234yf refrigerant has a 99.7 percent lower global warming potential than R134a (4 versus 1430) and breaks down and disappears from the atmosphere within 11 days compared to the 13 years that R134a stays in the environment. [EPA-HQ-OAR-2010-0799-9497-A1, p.5]

A major part of a refrigerant's global warming potential is due to indirect emissions: CO_2 emissions, caused by increased fuel consumption needed to power the air conditioning system. NC systems using Solstice™ 1234yf refrigerant generally burn less fuel than other low GWP technologies. For example, air conditioners equipped with Solstice™ 1234yf refrigerant use markedly less fuel and produce 20 to 30 percent fewer emissions than CO_2 used as a refrigerant in hot climate zones. These efficiencies offer OEMs additional benefit in meeting the underlying fuel economy standards in the Proposed Rule. [EPA-HQ-OAR-2010-0799-9497-A1, p.6]

Adoption of Solstice™ 1234yf will require few changes to existing NC systems. The operating system pressures of Solstice™ 1234yf are similar to the most popular current refrigerant, R134a. This allows for re-use of the recent manufacturing technology advancements that will continue to make NC systems affordable into the next generation of Solstice™ .1234yf refrigerant systems. Conversely, CO_2 A/C systems require completely new equipment designs that would require significant investment in resources to implement. [EPA-HQ-OAR-2010-0799-9497-A1, p.6]

In the Proposed Rule, EPA and NHTSA generally provide a clear and appropriate process for alternative refrigerants with low GWPs to qualify for credits that may be used by OEMs for compliance with GHG emission requirements. The agencies also present some plausible scenarios for the transition toward commercialization and broad market acceptance of alternatives to the status quo refrigerant, R134a. Honeywell appreciates and supports the Proposed Rule's recognition of the dual benefits of alternative refrigerants in meeting our climate change and energy independence objectives and the incentives to enable the transition to low GWP refrigerants. [EPA-HQ-OAR-2010-0799-9497-A1,p.6]

Honeywell Agrees with EPA's Leakage Credit Equation to Determine the Net Fleet Effect of Direct Emission Due to Refrigerant Leakage.

Honeywell supports the continuation of credit opportunities for low leakage technologies and suggests that to the maximum extent possible the credit program should reflect accurately leakage rates in vehicles over time. As vehicles age, the following conditions cause leakage rates to increase: seasonal, daily, and in operation thermal cycles; vibrations; hardening of hoses and o-rings; drying out of the shaft seal due to non-operation (or continuous operation for clutchless models); collisions; service (engine or mobile A/C system); and corrosion leaks. [EPA-HQ-OAR-2010-0799-9497-A1, p.6]

Honeywell agrees that the assumed emissions leakage rates of 16.6 and 20.7 g/year are representative of refrigerant emission rates for new motor vehicle A/C systems. Honeywell also concurs that the MaxCredit term reflects a correct order of magnitude to account for fleet aging through the vehicle lifetime. Last, Honeywell agrees that the GWP Refrigerant term accounts for the GWP impact of alternative refrigerants compared to the current R134a refrigerant, which has a GWP of 1430. In sum, Honeywell concurs with EPA's emission equation to determine the net fleet effect of direct emissions due to refrigerant leakage. [EPA-HQ-OAR-2010-0799-9497-A1, pp.6-7]

EPA HiLeakDisincentive Term Is Not the Best Approach to Prevent Against Backsliding to Higher GWP Refrigerants and Increase GHG Emissions During Ale System Retrofit and Recharge.

EPA proposes to add to the existing credit calculation a HiLeakDisincentive term with the intention of preventing GHG emissions from systems designed to operate on low GWP refrigerants but which potentially could be recharged with a higher GWP refrigerant. This method is neither effective nor appropriate for two reasons: it provides an advantage to high GWP refrigerants and it raises the cost of credits far vehicle manufacturers without delivering demonstrated GHG emissions or fuel economy improvement. [EPA-HQ-OAR-2010-0799-9497-A1, p.7]

First, if the HiLeakDisincentive term is to account for the loss of efficiency as systems leak, then it should apply to all refrigerants and not just refrigerants with a GWP less than 150. EPA proposes that the HiLeakDisincentive term for refrigerants with a GWP higher than 150 will automatically be zero, regardless of the A/C system's efficiency. Conversely, for lower GWP refrigerants, EPA proposes that the term account for A/C system efficiency loss due to leakage. Honeywell argues that the disparate treatment of low GWP refrigerants compared to high GWP refrigerants for purposes of the HiLeakDisincentive term is inequitable because both high and low GWP refrigerant systems sustain some amount of leakage before system performance is affected. [EPA-HQ-OAR-2010-0799-9497-A1, p.7]

SAE Standard 12765:2008 provides a chart, shown below, that demonstrates this point. Conventional systems such as R134a and future systems that utilize low GWP fluids in subcritical system design both have optimum charge plateaus, representing a range of refrigerant charges where system efficiency is largely independent from system refrigerant amount. Typically, auto manufacturers will charge to the right side of the plateau to allow for some system leakage before system efficiency is affected. Although the chart below represents a theoretical bench top system, it demonstrates that a charge amount of nearly 400 grams may be lost before the leakage affects system efficiency. [EPA-HQ-OAR-2010-0799-9497-A1, p.7]

The HiLeakDisincentive term should account for this standard leakage, regardless of the refrigerant's GWP. Honeywell recommends that EPA either remove the default value of zero for refrigerants with GWP higher than 150 or raise the MaxCredit term by an equal amount for refrigerants with a GWP lower than 150. Unfortunately, subcritical systems for CO_2 do not have a charge plateau, and system efficiency correlates directly with refrigerant leakage. Consequently, the performance loss disincentive for these systems should be based on the science of the system design, rather than a set term.

Second, EPA's proposed HiLeakDisincentive term will raise production costs for vehicle manufacturers without reciprocal GHG benefits, penalizing them for the potential actions of others without creating any additional efficiency. In order to avoid the HiLeakDisincentive penalty in the credit calculation, OEMs must not only purchase more costly low GWP refrigerants, but also the more expensive high-efficiency components. One of the strengths of the current A/C Leakage Credit system is that it provides OEMs with flexibility to meet fleetwide GHG emission requirements. [EPA-HQ-OAR-2010-0799-9497-A1, p.8]

The high efficiency components will only render a meaningful fuel savings if the vehicle owner and repair shop chooses to recharge the vehicle with a low GWP refrigerant. Honeywell believes that the regulations should not penalize OEMs for decisions that they are unable to control, such as recharging and retrofitting A/C systems. Instead, Honeywell proposes to collaborate with EPA and NHTSA to develop an alternative mechanism to prevent backsliding, including providing certain incentive for recharging with low GWP refrigerants, discussed further in Part IV. [EPA-HQ-OAR-2010-0799-9497-A1, p.8]

Anti-Backsliding

As discussed in Part II.B., above, the use of low GWP refrigerants brings new challenges in developing regulations to prevent backsliding to a higher GWP refrigerant during recharging of a low GWP refrigerant system. EPA and NHTSA acknowledge in the Proposed Rule that repeated recharging of A/C systems could lead some consumers and/or repair facilities to recharge a s1stem designed for use with a low GWP refrigerant with a cheaper high GWP refrigerant. Unfortunately, EPA and NHTSA have not set out a strong enough legal case to assure against such backsliding. [EPA-HQ-OAR-2010-0799-9497-A1, p.11]

The agencies' statement that 'recharging with a refrigerant different from that already in the A/C system is not authorized under current regulations' is not correct. Per the authority granted to EPA under Section 612(c) of the Clean Air Act, the Significant New Alternatives Policy (SNAP) Program, it may identify acceptable and unacceptable substitutes for ozone-depleting substances, including R-12 (Freon). The SNAP program has identified alternatives to R-12 and has granted them New system (with or without restriction) or Retrofit (with or without restrictions) status. The common refrigerant R -134a is now the focus of the instant rulemaking. SNAP granted R-134a both New and Retrofit status for R-12 for its automotive application, including the use restriction that the vehicle charging ports should be modified to allow technicians to service that vehicle once a retrofit has been carried out. [EPA-HQ-OAR-2010-0799-9497-A1, p.11]

SNAP has only granted HFO-1234yf new system status, with certain restrictions regarding proper vehicle design for the use of a mildly flammable refrigerant, as a replacement to R-12 systems. The SNAP program has not granted Retrofit status to HFO-1234yf because of the design practices of current R-134a systems and do-it-yourselfer ('DIYer') use of the product is the subject of current and active judicial matters. One may argue that SNAP approved HFO-1234yf as a replacement for R-134a and not R-12 and thus that new vehicles using HFO-1234yf cannot be recharged with R-134a. As such, SNAP's approval of HFO-1234yf would not have been necessary because R-134a is not an ozone depleting substance and SNAP would not have had to exercise its authority under the Clean Air Act to name its acceptable substitutes. Thus, because they are both acceptable substitutes for R-12, the reverse retrofit of a system designed and filled by a vehicle manufacturer with HFO-1234yf and recharged by a service garage or DIYer with R-134a may be considered a legal conversion. [EPA-HQ-OAR-2010-0799-9497-A1, pp.11-12]

Given that lack of existing legal mechanisms to prevent against backsliding to higher GWP refrigerants during retrofit and recharge, we support regulatory measures that protect against reverting to higher GHG emissions over the life of a vehicle. We recommend that EPA and NHTSA provide incentives for the aftermarket industry to assure use of compliant, low GWP refrigerants. [EPA-HQ-OAR-2010-0799-9497-A1, p.12]

In sum, Honeywell supports, and is willing to assist, EPA and NHTSA in developing a clear and appropriate approach to assure the use and maintenance of low GWP refrigerants in the aftermarket. [EPA-HQ-OAR-2010-0799-9497-A1, p.12]

Honeywell appreciates EPA's and NHTSA's recognition of the meaningful contribution that refrigerants like Solstice™ 1234yf offer to carmakers to comply with the Proposed Rule's GHG emission and fuel economy requirements throughout the life of the program. Assuring a rapid and smooth transition to low GWP refrigerants such as Solstice™ 1234yf will deliver comparable cooling in all climates while saving time, costs, and environmental impact for years to come. Solstice™ 1234yf will serve as a valuable tool for automakers to achieve the GHG emissions and fuel economy requirements while advancing our nation's clean energy and environmental objectives. [EPA-HQ-OAR-2010-0799-9497-A1, p.12]

Solstice™ 1234yf will contribute significantly to the US economy throughout the life of the Proposed Rule. Honeywell is committed to put in place capacity in the United States to produce Solstice™ 1234yf consistent with the requirements of the US automobile manufacturers to meet GHG emission and fuel economy standards in the current regulations and the Proposed Rule. Building this new capacity will create large numbers of construction, engineering, and manufacturing jobs. In addition, plants like a Solstice™ 1234yf facility typically require significant local contractor support for maintenance and other ancillary services and create substantial indirect employment in the local community. [EPA-HQ-OAR-2010-0799-9497-A1]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 207-210.]

Organization: Hyundai America Technical Center

HFO-1234yf: EPA has specifically requested comment on the implications for a market transition to the new HFO-1234yf refrigerant and the factors that may affect the industry demand for refrigerant in the U.S. and internationally. Hyundai agrees with EPA that while the technology is very promising, there is uncertainty as to the widespread availability of HFO-1234yf. Hyundai believes the A/C credits for HFO-1234yf create an incentive to move toward this refrigerant and a phase-out of HFC-134a will ultimately be unnecessary. The uncertainty of the availability of HFO-1234yf coupled with a phase-out of HFC-134a could create a market distortion. However, Hyundai is not opposed to phasing-out HFC-134a once there is full-scale availability of HFO-1234yf and recommends that the agencies wait until this time to take any action. [EPA-HQ-OAR-2010-0799-9547-A1, p.6]

There is a minor typographical error in the calculation of leakage credit on pages 76 FR 75373 & 75374. The closing bracket is missing in the calculation. We believe the calculation should read as follows with the red bracket in the correct position: [EPA-HQ-OAR-2010-0799-9547-A1, p.8]

Leakage Credit =MaxCredit x [1-(leakScore/16.6)x(GWPref/GWPHFC134a)]-HileakDis [EPA-HQ-OAR-2010-0799-9547-A1, p.8]

Organization: International Council on Clean Transportation (ICCT)

A/C alternative refrigerant credits

The ICCT supports the agencies' proposal to issue credits for alternative refrigerants, which can dramatically reduce the potential for greenhouse gas emissions from servicing, leaks, and end-of-life disposal. We commend EPA for tying the leakage credit to the refrigerant being used in the vehicle. A flat leakage credit would have potentially overstated or underestimated the climate benefit of the intervention, depending on the refrigerant contained in the vehicle. We also commend EPA for including a disincentive for systems that utilize a low GWP refrigerant but do not also adopt low leakage equipment. [EPA-HQ-OAR-2010-0799-9512-A1, p. 39]

We also agree with US EPA and NHTSA that the credits should account for the possibility of dropping in higher GWP refrigerant such as HFC-134a (GWP 1430) as a replacement for 1234f in use.[69] This potential for backsliding is not fully addressed in the proposed rule. High prices for alternative refrigerants will very likely encourage vehicle owners to use lower cost but higher GWP replacements. EPA estimates that 49 percent of direct refrigerant leakage occurs during servicing and maintenance and nine percent occurs during end of life. This suggests the possibility for continued release of these higher GWP refrigerants, particularly among poorly maintained vehicles. Meanwhile, EPA assumes in its credit calculation that low GWP refrigerant will be used throughout the full life of the vehicle. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 39-40]

To address this concern in part, EPA has proposed to reduce the eligible credit available to the manufacturer when low-leak hoses and valves are not incorporated into the system (p 75002). While we strongly support this proposed anti-leak credit and agree that it may reduce the rate of servicing and maintenance, we remain concerned that poorly maintained vehicles or 'super emitters' will be re-charged with high GWP refrigerant and contribute substantial emissions over the course of the vehicle life. [EPA-HQ-OAR-2010-0799-9512-A1, p. 40]

The ICCT recommends that the credit be further modified to reflect the likelihood of the use of higher GWP refrigerant. Currently, the credit assumes that low GWP refrigerants will be used throughout the life of the vehicle, such that accidental releases during service events and disposal will be releases of only low GWP refrigerant. EPA should instead assume this only for systems where manufacturers demonstrate designs that cause the system to fail to operate when recharged with higher GWP refrigerants. [EPA-HQ-OAR-2010-0799-9512-A1, p. 40]

EPA should require manufacturers to demonstrate applicability to this criterion. When the criterion isn't met, EPA should reduce the amount of the credit to a level that represents only the share of total refrigerant consumption represented by the first initial charge of a new vehicle.

This approach may only apply to HFO 1234yf at the moment, since HCF-134a is essentially a drop-in replacement. Other systems like HFC-152a and CO_2 may not suffer this weakness. For HFO 1234yf, automakers would receive credit only for the refrigerant they put in the vehicle. [EPA-HQ-OAR-2010-0799-9512-A1, p. 40]

In our view, it is not enough to say that SAE design standards are being met. Additional measures are needed to encourage chemical manufacturers and auto manufacturers to find solutions that will more reliably deliver climate benefits. Such measures could be patterned after the requirements for approval of low viscosity and low friction oils for vehicle testing.[71] In this way, EPA would further ensure that design and operational limitations adopted by manufacturers fully realize the A/C emission reduction credits. [EPA-HQ-OAR-2010-0799-9512-A1, p. 40]

Credit Continuity with 2012-2016 Final Rule

EPA describes in the draft TSD that: [EPA-HQ-OAR-2010-0799-9512-A1, p. 40]

EPA made the policy decision to maintain continuity with the 2012-2016 FRM analysis, and is proposing to incorporate this level of the credit in the standard setting process. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 40-41]

This was done despite new information that suggests a need to revise the emissions inventory and the leakage credits derived from this. The reason for continuing the previous leakage credits is:

'A reduction in A/C credits would artificially increase the stringency of the standard for those manufacturers who generated leakage credits in 2016 ... alternatively, the stringency of the 2017 standards would have to be relaxed.' '...need for stability for the standards...'. [EPA-HQ-OAR-2010-0799-9512-A1, p. 41]

We understand the need for stability of the standards for those manufacturers who generate leakage credits in 2016. However, the proposed rule acknowledges that the credits do not represent the emission reductions they are designed to represent. We strongly urge that this approach be re-evaluated in order to provide manufacturers who generate leakage credits in 2016 a means to generate alternative emission reductions equivalent to those represented by the credits based on the latest understanding of the emissions inventory. [EPA-HQ-OAR-2010-0799-9512-A1, p. 41]

We are concerned that the proposed policy may stimulate manufacturers to pursue these credits more aggressively as a means to avoid on-cycle reductions. We recommend that staff quantify the differences between a revised leakage credit based on a revised TAR inventory, and the credits being proposed, so as to justify the continuation of the existing leakage credits. If the differences are considerably larger, we recommend reconsideration of the proposed credits. But if they are small, then it is justifiable to maintain the credits as is. [EPA-HQ-OAR-2010-0799-9512-A1, p. 41]

Lead Time for Low-GWP Refrigerant Penetration

EPA assumes a long lead time for penetration of low GWP refrigerants, claiming that automakers expect a full re-design to be necessary. However, automakers in Europe are already selling vehicles with low GWP refrigerant. For example, EPA assumes 20 percent penetration in 2017, while Europe will be requiring 100 percent penetration that year. In addition, some refrigerant options like 1234yf require only minor changes to the refrigerant system. EPA cites confidential discussions with vehicle manufacturers who say 'it may be possible to modify the hardware for some alternative refrigerant systems between redesign periods.' Thus, the ICCT strongly recommends harmonization with the European rule. At a minimum, EPA should explain its expectation of 20 percent penetration in 2017 and 20 percent additional penetration in each subsequent year through 2021. We feel the long lead time is unjustified and recommend that EPA expect full adoption of low GWP refrigerant along a more accelerated time frame. [EPA-HQ-OAR-2010-0799-9512-A1, p. 41]

Refrigerant OBD Monitoring

In its 2012-2016 rulemaking, EPA considered additional leak credits for systems that monitor refrigerant charge on-board the vehicle, but these ultimately were not adopted. EPA is again opening the door to this type of monitoring, considering that most A/C systems contain sensors that detect low refrigerant pressures. The ICCT would be supportive of a refrigerant OBD monitoring credit in principle, although it would be challenging to accurately model and estimate the emissions benefits of OBD monitoring. Despite this, we think providing such information to the vehicle owner would cause many owners to seek repair and maintenance of the A/C system. In light of the potential benefits and the difficulty in estimating a credit, the ICCT recommends that EPA require such on-board monitoring. Another approach might be to estimate the proportion of time that owners would have the A/C system repaired in response to a Malfunction

Indicator Light (MIL) illumination and multiply this percent by the calculated amount of leakage used for other A/C refrigerant credits. [EPA-HQ-OAR-2010-0799-9512-A1, p. 42]

Vehicles without air conditioning

The proposed crediting system is designed to mitigate the rather significant climate impacts of the air-conditioning unit, based upon both its efficiency and its refrigerant emissions. Based on this perspective, a vehicle without an air-conditioning system would have fundamentally lower climate impacts, as no refrigerant would be consumed and emitted and no energy would be required to operate the A/C system. [EPA-HQ-OAR-2010-0799-9512-A1, p. 42]

A potential concern is aftermarket installation of air conditioning systems, especially kits provided by OEMs and installed by dealers at the time of purchase. The ICCT recommends that vehicles without air conditioning systems be given an appropriate amount of credits, provided that the manufacturer commits to monitoring and reporting on dealer-installed AC systems. [EPA-HQ-OAR-2010-0799-9512-A1, p. 42]

---

69 ICCT recognizes that HFC-132 phase-out would diminish the potential for 1234f replacement with HFC132a.

71 EPA guidance letter CISO-08-11;Use of OW Multi-grade Engine Oils in Gasoline Fueled EPA Test Vehicles, Sept. 18, 2008. EPA guidance letter CCO-04-7; Use of GF-4 Engine Oil in EPA Test Vehicles, March 2, 2004

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

The inclusion of credits for air conditioning system improvements provides an opportunity for the program to effectively address emissions of hydrofluorocarbons that have a very high global warming potential. [EPA-HQ-OAR-2010-0799-9476-A1, p. 3]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 72.]

In addition, the inclusion of credits for air-conditioning system improvements provides an opportunity for the program to address emissions of a class of high global warming potential refrigerants, the hydrofluorocarbons.

Organization: Toyota Motor North America

Air Conditioning (A/C) Leakage Credits [EPA-HQ-OAR-2010-0799-9586-A1, p.14]

High Leak Disincentive: Toyota does not agree with EPA's proposal to impose a high leak disincentive for refrigerants with a GWP below 150. EPA's proposal will compromise a manufacturer's ability to maximize credits~ when the manufacturer elects to utilize a global A/C system design. To obtain maximum credit, the system would unnecessarily need to be modified for the US market, incurring additional expense and resource requirements for no additional environmental benefit. Toyota thinks that EPA~s tampering concern, where R134a would be refilled in place of R1234yf, is unfounded because the service port fittings for the two refrigerants are incompatible which makes tampering highly improbable. Additionally, Toyota believes that appropriate measures are already in place that should be used to address any attempted tampering that were to occur in the field. [EPA-HQ-OAR-2010-0799-9586-A1, p.14]

Organization: Volkswagen Group of America

Volkswagen contributed to and supports the comments submitted by the Alliance of Automobile Manufacturers (Alliance) regarding Mobile Air Conditioning (MAC) system credits. [EPA-HQ-OAR-2010-0799-9569-A1, p. 30]

Volkswagen continues to make significant investments in deploying advanced MAC systems incorporating low-leak components and advanced low-GWP refrigerants. The successful market introduction of these advanced MAC systems relies to a great degree on the treatment of these systems within the GHG and CAFE program. [EPA-HQ-OAR-2010-0799-9569-A1, p. 30]

HIGH-LEAK DISINCENTIVE

Volkswagen is concerned by the EPA proposal to add a so called 'High Leak Disincentive'. There are two main reasons: Firstly our company as a major EU manufacturer is obliged by European law to change to refrigerants <150 GWP. Thus if we make significant investment and adapt our systems early to integrate low-GWP refrigerants, we would be penalized as fast mover. Secondly, Volkswagen maintains that refilling an updated system with older refrigerant is unlikely or even impossible due to differences in the filling systems. Therefore, Volkswagen recommends EPA to remove the 'High Leak Disincentive' factor. [EPA-HQ-OAR-2010-0799-9569-A1, p. 30]

LEVEL MONITORING

Volkswagen believes that additional refrigerant level monitoring obligations are not appropriate for mobile air conditioning systems. As discussed within the Alliance comments, in the case of MAC failure modes, the system simply stops operating thereby eliminating indirect CO_2 emissions. Figure App-0-1 shows that in case of refrigerant losses the power consumption of the A/C system would decrease as well. [See Figure App-0-1 on p. 32 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 31]

Organization: Volvo Car Corporation (VCC)

VCC continuously develops the climate system in order to reduce AC natural losses and improve durability. The strategy is to keep the rate of natural losses low and also to design the AC-system to prevent uncontrolled refrigerant losses during the full vehicle service life. [EPA-HQ-OAR-2010-0799-9551-A2, p. 9]

According to VCC the revised SAE J2727, which is a major improvement compared to the version of 2008, does get closer to a real world refrigerant loss rate than the previous version. At the assembly of the systems, VCC is testing all components and connections of the AC system with Helium to find any leakage before filling of refrigerants. However, VCC believes that the actual measured natural losses (according to SAE J2763) could be lower than the calculated natural losses, according to SAE J2727: [EPA-HQ-OAR-2010-0799-9551-A2, p. 9]

• SAE J2727 does not reflect all existing designs and technologies. VCC assumes that the reason for this is that such an expansion of the standards would make it very complex to use from a practical point of view. [EPA-HQ-OAR-2010-0799-9551-A2, p. 9]

• VCC uses a 'soft nose' concept of AC-connectors. The VCC technical solution has a low loss rate due to: [EPA-HQ-OAR-2010-0799-9551-A2, p. 9]

o Special rubber material used for the o-rings, a special variant of HNBR, specifically formulated for this application, where low permeation is one of the more prominent characteristics.

o The geometry of the outer, axially sealing o-ring where the two halves of the blocks are clamped together with zero clearance between these two surfaces, minimize the possible losses. [EPA-HQ-OAR-2010-0799-9551-A2, p. 10]

• The service valves cap in the VCC AC technology solution are equipped with a special seal that functions independent of the torque applied. The sealing properties are not a function of torque as it is with the standard cap more commonly used. SAE J2727 only includes the standard cap. The Standard industry cap seals properly if tightened by 0, 8 - 1, 2 Nm - too loose causes leak, and too tight causes seal damage. The service valve cap used by VCC has strong sealing capability at 20x of that torque. [EPA-HQ-OAR-2010-0799-9551-A2, p. 10]

• The part of the total natural losses coming from the compressor is too large according to independent measurements made by Ecoles des Mines in Paris (ordered by ACEA in Brussels). According to SAE J2727 natural losses of the compressor is 67%. Independent measurements indicate that the natural losses from the compressors, depending on brand and actual design} are in the range of 40-60%. VCC, therefore, believes that the calculated natural losses from the compressor are too large. [EPA-HQ-OAR-2010-0799-9551-A2, p. 10]

VCC performs physical tests in a mini-SHED according to the test method prescribed as F-gas directive 706/2007/EC. VCC strongly believes that physical measurements reflect real vehicle emissions more accurately than calculations and estimations. The proposed natural losses measurement standard SAE J2763 (Test procedure for determining R134a natural losses rates of Mobile Air Conditioning systems in a mini-SHED) is equal to the 706/2007/EC directive. VCC considers that natural losses rates < 10 gram/year are possible to measure in a mini-SHED. [EPA-HQ-OAR-2010-0799-9551-A2, p. 10]

CARB and the state of Minnesota allow physical measurements as an alternative to SAE J2727 calculations. [EPA-HQ-OAR-2010-0799-9551-A2, p. 10]

VCC would also like to point out that CARB has identified the possibility of physical measurements as a possibility. VCC supports CARB's intent to allow, as expressed in the draft's Appendix D, paragraph 2.5.6.3,l physical measurements of refrigerant leakage as an alternative to the latest version of SAE J2727. High Leak Disincentive [EPA-HQ-OAR-2010-0799-9551-A2, p. 10]

VCC does not support the EPA's proposal to reduce the AC direct credits via the 'high leak disincentive, if the refrigerant leakage rate is not reduced by half from industry average leak rates. This is a major change compared to the 2012-2016 program and reduces the value because it alters the rules of the game by adding low GWP for manufacturers considering early adoption. [EPA-HQ-OAR-2010-0799-9551-A2, p. 10]

Response:

Most commenters from the auto industry generally supported the proposed process for generating direct A/C credits by using SAE J2727 refrigerant leakage values. Most industry commenters, as well as Honeywell, opposed the "High Leak Disincentive" relating to A/C leakage credits; ICCT commented in favor of this provision. EPA's responses to these comments are presented in Section III.C.1.a.i of the preamble. EPA is retaining the provision, with some revisions. In regard to Honeywell's comment that the disincentive is not applied to HFC-134a and HFO-1234yf refrigerants in an equitable manner, as we discuss in TSD 5.1.2.3.2.5, the disincentive for low-GWP refrigerants only is intended to reduce the probability that the A/C system will be recharged with a high-GWP refrigerant.

EPA responds to comments related to EPA use of the updated SAE J2727 procedure in quantifying A/C leakage credits in the Joint TSD, Section 5.1.2.3. EPA is maintaining the use of this procedure as the basis for it leakage credits.

EPA responds to comments related to the expected transition to one or more alternative A/C refrigerants, including the potential pace of that transition and refrigerant availability, costs, vehicle technical issues, and manufacturing issues, in Section III.C.1.a.ii of the preamble. EPA continues to believe that the major transition to alternative refrigerants will primarily occur beginning around MY2017 and continue at a pace that we approximate by a 20% per year conversion through MY2021, based on the typical 5-year vehicle redesign cycle.

EPA responds to comments on the concept of monitoring refrigerant levels in Section 5.1.l.2.7 of the Joint TSD.

Regarding the comments from the California Air Resources Board, we have corrected the error in the High Leak Disincentive formula that CARB identified. In response to CARB comment 2), we have adjusted the threshold for incurring a High Leak Disincentive to lower values. (Specifically, we will reduce the threshold from 16.6 g/yr to 11.0 g/yr for systems with refrigerant charges equal to or less than 733g, and reduce the threshold by 1.5%/yr for systems with charges greater than 733g). In response to CARB comment 3), electric compressor systems should have a very low leak score, so we believe that incurring a High Leak Disincentive should not be an issue for systems incorporating this technology, and we have not further adjusted the proposed values.

Regarding concerns about the SAE J2727 procedure failing "to account adequately for the increased leakage as vehicles age," J2727 was correlated to JAMA and ACEA vehicle field test results (vehicle/shed test results are ~5 g/yr lower than what J2727 predicts. but the trends are identical). In addition, the SAE-IMAC study that formed the basis of J2727, "seasoned" the systems (10-day static soak at 36 deg C, and 30 minutes of system operation at 23 deg C ambient temp), so the components were broken-in, but not new. We continue to believe that deterioration of leakage emissions is adequately accounted for in J2727, and that basing leakage credits on those values is appropriate. We are also continuing to use a Global Warming Potential of 150 to determine whether an alternative refrigerant requires a manufacturer to consider the High Leak Disincentive term in the equation, consistent with other programs (CARB and Europe) that distinguish higher and lower GWP refrigerants.

Regarding the comment from ICCT about how to treat vehicles without A/C systems installed at the factory, we believe that if someone orders a vehicle without A/C, they aren't doing it to reduce GHGs - they're doing it because it's a feature they don't need (and consequently, don't want to pay for). Further, the use of aftermarket A/C systems in modern vehicles, which have tightly-packaged underhood and underdash environments, is highly unlikely. Therefore, as proposed, the program will not provide credits for vehicles without factory-installed A/C systems. In addition, in response to ICCT's comment regarding a requirement that the HFC-1234yf A/C systems "fail to operate" when recharged with another refrigerant, we know of no cost-effective, feasible technology that would allow us to incorporate such a requirement, and we are not pursuing this concept in this rule. Regarding the comment from Volvo about the option to use a "mini-SHED" procedure to establish leakage credits, the new February 2012 version of J2727 allows the use of a mini-SHED approach. We are incorporating the new J2727 by reference.

We acknowledge Honeywell's request for new regulatory measures to protect against parties reverting to higher GWP refrigerants over the life of a vehicle. It is true that EPA has found HFO-1234yf acceptable for use in new systems and not for retrofit in motor vehicle air conditioning systems under the Significant New Alternatives Policy (SNAP) program. It is also true that EPA has found HFC-134a acceptable for use both in new systems and for retrofit in motor vehicle air conditioning systems. However, we disagree that this means that users may retrofit a system designed for HFO-1234yf with HFC-134a. First, the SNAP listings, both for HFO-1234yf and for HFC-134a, are for use as a substitute for CFC-12. The SNAP listings do not say that different substitutes are interchangeable, as the commenter implies. Second, the regulations for the SNAP program at appendix D to subpart G of 40 CFR part 82 state, "No substitute refrigerant may be used to 'top-off' a system that uses another refrigerant. The original refrigerant must be recovered in accordance with regulations issued under section 609 of the CAA prior to charging with a substitute." Thus, it is not permissible to add HFC-134a to an MVAC system that contains HFO-1234yf, as may well occur if a consumer were to service his or her own car's AC system without refrigerant recovery equipment. Third, the regulations at appendix D to subpart G of 40 CFR part 82 and the listings for HFO-1234yf and HFC-134a require use of a unique set of fittings for a specific alternative refrigerant. The SNAP regulations in appendix D also state, "Using an adapter or deliberately modifying a fitting to use a different refrigerant is a violation of this use condition." The SNAP requirements for unique fittings do not prohibit retrofitting of vehicles using CFC-12, and appendix D to subpart G of 40 CFR part 82 sets out the conditions for such retrofits.

3.2. Credits Related to Improved A/C system Efficiency

Organizations Included in this Section

Alliance of Automobile Manufacturers
Delphi Corporation

Motor & Equipment Manufacturers Association (MEMA)
Toyota Motor North America

Organization: Alliance of Automobile Manufacturers

The performance-based Mobile Air Conditioning (MAC) efficiency test needs additional technical analysis and testing, and the Alliance stands ready to work with the agencies to address these concerns. The proposed MAC efficiency test is likely to interfere with the achievement of maximum credit levels for improved system efficiency that were fully included in the agencies' feasibility analysis. The Alliance comments describe these concerns in depth and suggest that the test not be established as a strict requirement. Instead, we propose that the agencies continue to allow use of the credit menu, and that manufacturers work with EPA and NHTSA to provide "reasonable verification" of this progress through selected vehicle testing and other methods. Such verification will show that the menu amounts are appropriate, and that commensurate real-world progress is achieved. [EPA-HQ-OAR-2010-0799-9487-A1, p.5]

Organization: Delphi Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 110.]

Fourth, the air conditioning system is the highest ancillary load on the system. We highly support the EPA's proposed credit system to incentivize energy-efficient HVAC technology that can reduce the fuel needed for the air conditioning system by 40 percent.

Organization: Ford Motor Company

Ford supports the continuation of the A/C efficiency credit program into the 2017-2025 MY rule. [EPA-HQ-OAR-2010-0799-9463-A1, p. 10]

In addition, Ford supports the differentiation in credit levels for cars and trucks that are being proposed for 2017-2025 MY, based on the simulation work conducted by the EPA (TSD 5-32). [EPA-HQ-OAR-2010-0799-9463-A1, p. 14]

We support the proposed addition of the A/C efficiency benefits into the CAFE program which brings the NHTSA program one important step closer to harmonization with the EPA GHG program. [EPA-HQ-OAR-2010-0799-9463-A1, p. 14]

Organization: General Motors Company

GM supports the Mobile Air Conditioning (MAC) provisions included in the proposal. However, we, like the Alliance, have concerns regarding the performance-based MAC efficiency test and request that cooperative technical work continue - potentially as part of one of the mid-term review “check-ins” - to address the concerns with testing burden and reasonable verification of efficiency improvements. [EPA-HQ-OAR-2010-0799-9465-A1, p. 3]

Organization: Honeywell International, Inc.

Honeywell commends EPA and NHTSA for recognizing the measurable contribution that energy-efficient A/C systems and components can have in reducing CO_2 emissions and fuel consumption attributable to A/C operation. We support the agencies' proposal to allow auto manufacturers to generate fuel consumption improvement values for purposes of CAFE compliance by using technologies that enable A/C systems to run more efficiently. Honeywell offers that incorporating the most up-to-date research and technical information will add further credibility to the A/C Efficiency Credit by accounting accurately for the reduced emissions and energy efficiency attributable A/C system components. [EPA-HQ-OAR-2010-0799-9497-A1, p.9]

EPA and NHTSA Should Provide Flexibility in the A/C Efficiency Credit Program to Include New Performance-Based Test Methods That May Become Available Prior to 2026

EPA and NHTSA propose to allow auto manufacturers to generate credits for employing more energy efficient A/C component technologies ('A/C Efficiency Credits'). Honeywell encourages EPA and NHTSA to provide flexibility in the A/C Efficiency Credit program to accommodate new performance-based tests that may be developed during the life of program. EPA and NHTSA state in the Preamble that although they would ideally award A/C Efficiency Credits using a performance test, there currently is no reliable performance-based procedure capable of accurately quantifying efficiency credits. [EPA-HQ-OAR-2010-0799-9497-A1, p.9]

Organization: Hyundai America Technical Center

A/C Credits: [EPA-HQ-OAR-2010-0799-9547-A1, p.6]

1) Hyundai supports the use of the A/C menu for determining air conditioning system credits and supports an increase in the maximum amount of credits that will be permitted if we are able

to demonstrate an emission reduction greater than what is available in the menu. [EPA-HQ-OAR-2010-0799-9547-A1, p.6]

Organization: International Council on Clean Transportation (ICCT)

16. The ICCT strongly supports off-cycle credits in principle, as they can reduce compliance costs and increase benefits. However, the credits must avoid double counting and must be valid and verifiable. ICCT has provided detailed suggestions on how to improve the off-cycle credits so they are verifiable and do not inadvertently weaken overall standard stringency. [EPA-HQ-OAR-2010-0799-9512-A1, p. 4]

A/C off-cycle efficiency credits

ICCT appreciates US EPA and NHTSA's efforts to thoroughly document the potential benefits of A/C off-cycle credits based on both testing and engineering studies for each of the potential A/C technologies. While we have not fully reviewed the test data and studies for each type of credit, overall the agencies' basis for inclusion of credits for A/C system efficiency, leak reduction and alternative refrigerants is well documented. [EPA-HQ-OAR-2010-0799-9512-A1, p. 37]

Our primary concern with the air conditioning credits calculation is that methodology changes are needed to avoid double-counting the benefits from A/C load reductions and A/C system efficiency improvements. Currently, the efficiency credits and the load reduction credits are calculated independently. This is not appropriate. The efficiency reductions and the load reductions must be treated as a system to avoid double-counting.

To avoid double-counting, the ICCT recommends a multiplicative approach to A/C credit generation. Following is how the credit calculations should be done in concept:

A/C efficiency credits (CO_2 g/mi) = baseline A/C indirect emissions (CO_2 g/mi) improved A/C indirect emissions (CO_2 g/mi), where A/C indirect emissions are calculated as: A/C indirect emissions (CO_2 g/mi) = cooling load (degrees) x efficiency (kwhr/degree cooling) x engine CO_2/kWh [EPA-HQ-OAR-2010-0799-9512-A1, p. 38]

The baseline calculation is done using the baseline cooling load and A/C efficiency and the improved calculation is done using the improved values for cooling load and A/C efficiency. Note that the improved cooling load should include the impacts of solar reflective paint, window glazing, and active and passive ventilation, if these technologies are being counted towards off-cycle credits. [EPA-HQ-OAR-2010-0799-9512-A1, p. 38]

This approach should apply across the A/C system efficiency credits and the load reduction credits contained on the menu of non-A/C default credits. For instance, if an OEM claimed a 30% improvement in A/C system energy efficiency and a 40% reduction in solar load, the new energy consumption rate would be 42% of baseline (70% times 60%) for a total benefit of 58% times the engine CO_2/kw-hr, rather than a benefit of 70% times the engine CO_2/kw-hr. This multiplicative assessment should also hold true for determining the cumulative effects of individual A/C system efficiency improvement technologies. In addition, future engine efficiency should be verified as proposed including advanced engine technologies such as hybrids that may operate the A/C system with the internal combustion engine entirely turned off during idle. [EPA-HQ-OAR-2010-0799-9512-A1, p. 38]

US EPA and NHTSA should also account for the system efficiency impact of alternative refrigerants. In particular, any system efficiency disbenefit with a new refrigerant should offset either any alternative refrigerant credit or A/C system efficiency credit in this case. [EPA-HQ-OAR-2010-0799-9512-A1, p. 38]

Organization: Johnson Controls, Inc.

Specifically, we support the inclusion of fuel consumption reductions resulting from air conditioning improvements [NHTSA-2010-0131-0253-A1, p. 2]

Organization: Kia Motors

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 102.]

Additionally, Kia requests the industry -- for industry consistency that EPA set more detailed guidelines for the framework to prove out the A/C system durability. It's unclear how A/C system durability is defined.

Organization: Motor & Equipment Manufacturers Association (MEMA)

1. Oil Separators [EPA-HQ-OAR-2010-0799-9478-A1, p.5]

In the NPRM, there is a credit of 0.5 to 0.7 g CO_2/mi proposed for an oil separator in the A/C system. This credit is for either an internal or external oil separator and “the baseline component for comparison is the version which a manufacturer most recently had in production on the same vehicle design or in a similar or related vehicle model.” MEMA asks the agencies to clarify by changing this to read: “the baseline component for comparison is the version which a manufacturer most recently had in production without an oil separation feature on the same vehicle design or in a similar or related vehicle model.” [EPA-HQ-OAR-2010-0799-9478-A1, pp.5-6]

2. Improved Condensers / Evaporators [EPA-HQ-OAR-2010-0799-9478-A1, p.6]

In the NPRM, the credit listed for improved condensers and/or evaporators ranges from 1.0 to 1.4 gCO_2/mi. The conditional requirement for this credit is “system analysis on the component(s) indicating a coefficient of performance improvement for the system of greater than 10 percent when compared to previous industry standard designs.” Based on this prerequisite, MEMA believes that early adopters of high performance heat exchangers will not receive the incentive for their proactive behavior. Therefore, MEMA recommends that standards for heat transfer and pressure drop – at fixed air inlet conditions (temperature, humidity, flow rate) and refrigerant inlet conditions (temperature, pressure, flow rate) – be the prerequisite for the credit. This will help prevent content regression and provide equitable treatment to both early and later adopters. [EPA-HQ-OAR-2010-0799-9478-A1, p.6]

3. Internal Heat Exchanger [EPA-HQ-OAR-2010-0799-9478-A1, p.6]

There are no conditional requirements listed in the NPRM for the Internal Heat Exchanger credit. Similar to the improved condensers and evaporators, MEMA recommends that the agencies include a performance threshold for the credit. We note that both the heat transfer and the vapor side pressure drop are critical attributes of the internal heat exchanger to improve the energy efficiency of the A/C system. A standard for heat transfer performance and vapor side pressure drop at fixed inlet refrigerant conditions (temperature, pressure, flow rate) should be set to ensure actual improvement in system coefficient of performance. The graph below highlights the importance of vapor side pressure drop. [EPA-HQ-OAR-2010-0799-9478-A1, p.6] [For the associated graph please refer to EPA-HQ-OAR-2010-0799-9478-A1, p.6]

Organization: Toyota Motor North America

EPA is proposing to allow manufacturers to generate credits for improvements to air conditioning systems that reduce GHG emissions. In the CAFE portion of the joint proposal, NHTSA is proposing to allow fuel consumption reductions equivalent to the GHG credits allowed by EPA that would be applicable for the credit menus provided for MAC efficiency and the use of off-cycle technologies. Toyota believes that the proposals are appropriate and fully supports the Alliance comments that address the details of the provisions. However, Toyota offers additional comments and concerns on several issues below. [EPA-HQ-OAR-2010-0799-9586-A1, p.13]

Response:

EPA acknowledges the general support for credits related to improved A/C system efficiency and the use of a new test cycle to provide “reasonable verification” (Alliance of Automobile Manufacturers) that the efficiency-improving technologies and methods employed produce quantifiable reductions in GHG emissions. EPA responses to comments related to the A/C efficiency credit program are found in Section II.F.1 and Section III.C.1 of the preamble to the rule, as well as in Section 5.1 of the joint TSD.

Regarding the comment from ICCT that a “multiplicative approach” should be used to avoid double-counting the credits (i.e. where A/C load reductions show up as ‘credits’ as well as on the 5-cycle emissions result), we disagree that our approach will lead to double-counting. Since tailpipe CO_2 emissions standards are based on a 2-cycle test (FTP and HWY cycles) where the A/C system is turned off, the reduction in engine load due to A/C efficiency improvements (whether direct A/C compressor load reduction, or system load reduction due to improved solar and cabin ventilation technologies) is not measured, and therefore cannot be double-counted. We believe that technologies that reduce the cooling load on the vehicle’s A/C system (e.g. glazing, cabin ventilation, solar reflective paint, etc.) are best addressed using the off-cycle credit provisions of this rule (see preamble Section III.C.5 and TSD Section 5.2).

Regarding the comment from MEMA that we incorporate specific language to define the components and common test conditions to quantify their benefits, in order to generate credits for oil separators, improved condensers/evaporators, and internal heat exchangers, we cannot incorporate proscriptive language regarding these technologies, as the implementation of these technologies is manufacturer-specific. In addition, we do not believe that setting a common set of test conditions for demonstrating their performance characteristics or introducing common descriptive language regarding their design are is feasible at this time. Should industry organizations adopt common methods and procedures regarding the performance of A/C technologies, we could consider them in future rules. But until such methods are available, we will require manufacturers to demonstrate the effectiveness of these components on a case-by-case basis during the certification process, as proposed.

Idle Test [EPA-HQ-OAR-2010-0799-9487-A1, p.46]

The MY 2012-2016 EPA GHG program uses a menu of credits for application of various MAC efficiency technologies. However, beginning in MY 2014, an “idle test” requirement is superimposed on the credit menu, such that certain emissions thresholds must be achieved on the idle test before credits can be granted for application of the technologies on the menu. The Alliance, as well as individual manufacturers, supported the credit menu, but commented during that rulemaking process on the inadvisability of superimposing the idle test. [EPA-HQ-OAR-2010-0799-9487-A1, p.46]

One key concern was that the most promising real-world MAC efficiency technologies - those that reduce compressor workloads at moderate ambient temperatures - would not have sufficient time to show their benefits during the idle test procedure. Although the idle test is not performed at a high ambient temperature, the idle test procedure calls for the systems to be operated as if they were responding to high ambient temperatures. Automatic systems are set to 9oF below the 75oF ambient temperature. Thus, in order to get to the unrealistically low 66oF interior setting required by the test procedure, the automatic systems work at maximum cooldown through much of the 10-minute MAC-on portion of the test. Manual MAC systems are tested at maximum cooldown for ten minutes (as if responding to a high ambient temperature) and at a low fan setting for ten minutes. [EPA-HQ-OAR-2010-0799-9487-A1, p.46]

The SAE IMAC study, which was a major basis for EPA's idle test thresholds, demonstrated a 30% lifecycle energy efficiency improvement for a nationally representative mix of high, moderate and light MAC loads. But the energy efficiency improvements came primarily from better moderate temperature technologies. At moderate and light loads, efficiency improvements of 40% or more were recorded. An energy efficiency improvement of only 5% to 10% was measured at high ambient temperatures. [EPA-HQ-OAR-2010-0799-9487-A1, pp.46-47]

Since the development of the MY 2012-2016 regulation, many idle tests have been run in automobile manufacturer laboratories, and the anticipated concerns, as well as other problems, have been confirmed. [EPA-HQ-OAR-2010-0799-9487-A1, p.47]

One of the most prominent issues identified for the idle test is that smaller displacement engines will receive significantly less EPA CO_2 credit for the same HVAC technology content, compared to larger displacement engines. [EPA-HQ-OAR-2010-0799-9487-A1, p.47]

Manufacturer testing also shows that on small engines, even the most sophisticated MAC systems will probably receive little EPA CO_2 credit because of their idle test results, thereby sharply reducing the incentive to apply MAC efficiency technologies to these vehicles. [EPA-HQ-OAR-2010-0799-9487-A1, p.47]

Test-to-test variability is large relative to the scale for getting credit, creating an additional element of regulatory compliance planning uncertainty, resulting in an additional barrier to MAC efficiency technology implementation. High variation is inherent in this test, in part due to the higher CVS dilution (low CO_2 concentrations) of tailpipe exhaust gases for a vehicle at idle, which makes CO_2 measurement highly variable being close to the limit of detection of the analyzer. [EPA-HQ-OAR-2010-0799-9487-A1, p.47]

Many of these preliminary idle test results and their implications have been communicated to EPA over the past two years, and these issues are discussed by EPA in the NPRM. Although the idle test has some relationship to MAC efficiency, it does not sufficiently get at the most important area for improvement, the moderate load technologies, since much of the idle test is conducted as if the vehicle were in a high ambient temperature, with corresponding high demands placed on the MAC system. The thresholds for obtaining full credit were established by EPA based on the premise of a 30% efficiency improvement over baseline MAC technologies. This is a challenging hurdle that can only be met if moderate and light load technologies are allowed to demonstrate their benefits to a substantially greater extent than the idle test allows. Based on the tests reported to EPA, no vehicle with an engine below approximately 2.5 liters in displacement would receive full credit for its MAC technologies, due to the idle test results (e.g., TSD p. 5-40). Unmodified, the idle test poses a potentially insurmountable obstacle to MAC improvements for credits on many vehicles, especially those with small engines which are anticipated to be predominant in the future. [EPA-HQ-OAR-2010-0799-9487-A1, p.47]

The test-to-test variability is an additional obstacle, since it introduces inherent uncertainty as to whether technology additions will ultimately result in credits. MAC operation is a fraction of overall vehicle fuel consumption, and the fuel consumption difference between a good, advanced technology MAC system and a bad MAC system is a matter of only a few grams of CO_2 per mile (or per minute). On the idle test scale, the total range from maximum credit to no credit is only 6.4 g CO_2/minute. Thus, significant test-to-test variation (even as low as a gram or two) carries the potential to negate a large portion of the planned credits for any program to improve MAC efficiency technology or to move the vehicle to the next level of credits. In testing reported at the United States Council for Automotive Research (US CAR), standard deviations of over 1.0 gCO_2/minute were consistently found from repeated idle testing on the same vehicle. Statistically, this shows that inherent test-to-test variation could negate a substantial portion of the MAC indirect credits for any vehicle. [EPA-HQ-OAR-2010-0799-9487-A1, pp.47-48]

Idle Test Temperature and Humidity Tolerances [EPA-HQ-OAR-2010-0799-9487-A1, p.48]

The Alliance supports EPA's effort to broaden the ambient air temperature and humidity specifications for the idle test and the optional idle test, from the current requirements for humidity levels of 50 ± 5 grains/pound, average temperature 75 ± 2 °F and instantaneous temperature: 75 ± 5 °F. We also support the EPA proposal to relax temperature and humidity requirements in order to use test cells designed for FTP testing. The data that manufacturers shared with EPA on June 30, 2011 (EPA Ann Arbor Meeting) showed that some tests run at a manufacturer's lab failed/exceeded these stringent specifications defined for the idle test on temperature and humidity. Automaker emission test facilities are not all designed for tight temperature and humidity controls such as are required for SC03 test chambers. Since the idle/optional idle test will not require solar loads, these tests will probably not be performed in SC03 solar test cells. The non-solar test cells are designed to run standard emission tests such as the FTP (EPA75), Highway Fuel Economy (HWFET) and US06 tests, where temperature and humidity specifications are less stringent as compared to the current A/C SC03 test specifications. If the temperature and humidity range is not widened, it will cause a large percentage of void tests that the manufacturers will be forced to repeat simply because of seasonal temperature and humidity variation or because the original specifications of test cell HVAC system were not designed around the idle test limits. This will add to the manufacturer testing burden and costs without any significant benefit to the accuracy of the test results. Therefore, the Alliance encourages EPA to widen these temperature and humidity specifications limits on the idle/optional idle tests, as proposed, so that they can be performed in the non SC03 chambers without added testing and cost burdens on manufacturers. [EPA-HQ-OAR-2010-0799-9487-A1, p.48]

The Alliance recommends the following humidity and temperature tolerances: [EPA-HQ-OAR-2010-0799-9487-A1, p.48]

(1) Ambient humidity within the test cell during all phases of the test sequence shall be controlled to an average of 50 ± 10 grains of water/pound of dry air. [EPA-HQ-OAR-2010-0799-9487-A1, p.48]

(2) Ambient air temperature within the test cell during all phases of the test sequence shall be controlled to 75 ±5 °F on average and 75 ±10 °F as an instantaneous measurement. Air temperature shall be recorded continuously at a minimum of 30 second intervals. [EPA-HQ-OAR-2010-0799-9487-A1, p.48]

Idle Test Engine Size Adjustment [EPA-HQ-OAR-2010-0799-9487-A1, p.49]

To partially address these concerns, EPA proposes an optional revised set of thresholds for performance on the idle test beginning in 2014. The revised thresholds are adjusted for engine size, so that smaller engines receive better scores and more ability to earn credits from application of MAC technologies on the credit menu. Although we believe all the idle test requirements should be discarded from the MAC program, if the idle test is kept, then it is useful to add this optional engine-size adjusted set of thresholds. [EPA-HQ-OAR-2010-0799-9487-A1, p.49]

Adding the engine size adjustment option to the MAC program is an improvement, but it does not solve the most fundamental problems with the idle test. The most important technologies for real-world energy savings, the moderate load technologies, would continue to show little benefit on the idle test, and the test-to-test variability would remain inherently high. We therefore believe that both the idle test and the engine size-adjusted idle test contribute little toward the goal of ensuring real-world greenhouse gas reduction, and that they will do little to encourage improved MAC technology implementation. [EPA-HQ-OAR-2010-0799-9487-A1, p.49]

Reasonable Verification [EPA-HQ-OAR-2010-0799-9487-A1, p.49]

The Alliance supports the EPA goal stated in the NPRM of “reasonable verification” that the technologies receiving credit from the credit menu are actually producing commensurate levels of GHG reduction. Chrysler, Ford and GM have worked with EPA and CARB over the past several months at USCAR to evaluate procedures for MAC efficiency testing. This work has identified several key criteria and issues for MAC testing that directly relate to the goal of reasonable verification. This research has resulted in the draft “AC17” test procedure discussed in the NPRM. [EPA-HQ-OAR-2010-0799-9487-A1, p.49]

Since the creation of the EPA MAC program, automobile manufacturers have believed that the MAC technology improvements on the EPA credit menu will result in actual GHG emission reductions that significantly surpass the amounts of the credits on the menu. This stems from the methodology used to quantify credits on the menu. EPA began with an overall inventory of estimated fuel consumption from MAC operation, then apportioned improvements from that inventory to the percentage improvements identified for various prominent MAC efficiency technologies, especially those used by the SAE IMAC cooperative research program. EPA estimated that MAC operation accounted for 14.3 g CO_2/mile on average for each vehicle, representing 3.9% of national light duty vehicle GHG emissions. The cap of 5.7 g CO_2/mile was derived as 40% of the 14.3 g CO_2/mile total, and the credit for each technology was roughly calculated as a percent improvement of the 14.3 g CO_2/mile total. [EPA-HQ-OAR-2010-0799-9487-A1, pp.49-50]

Automobile manufacturers commented at that time that the EPA inventory of fuel consumed for MAC operation was at the low end of the range of estimates by various researchers, such as studies by the National Renewable Energy Laboratory (NREL) and
Northeast States Center for a Clean Air Future (NESCCAF)/CARB. For example, NREL estimates were that MAC usage consumed 5.5% of national light duty fuel usage. NESCCAF and CARB together estimated that MAC operation accounted for 5.3% of a vehicles fuel usage. These alternative estimates are at least 70% higher than the 14.3 g CO_2/mile figure ultimately used by EPA. In the MY 2012-2016 Regulatory Impact Analysis, there is a complicated comparison of these studies, and EPA made numerous adjustments and assumptions in arriving at its ultimate figures, noting numerous uncertainties along the way. Without fully replaying that debate, suffice it to say that automobile manufacturers believed MAC compressors were engaged much more often and used more total fuel than EPA estimated, and that the higher estimates from relatively sophisticated analyses by NREL and NESCCAF/CARB were closer to the real-world MAC energy consumption. [EPA-HQ-OAR-2010-0799-9487-A1, p.50]

If the higher amounts of baseline MAC fuel consumption were used, the reductions from each MAC efficiency technology would be expected to be much greater than the figures used in the EPA credit menu. EPA finalized the regulation using its own (low) estimate of total MAC fuel consumption, resulting in credits on the menu that should be very conservative compared to actual vehicle usage, as measured by other researchers and industry data, and as used in the SAE IMAC program. This should be kept in mind when considering the need for thorough and precise verification procedures, since EPA’s very conservative methodology in creating the credits results in a huge margin before real-world emissions reductions might fall short of the credited amounts. [EPA-HQ-OAR-2010-0799-9487-A1, p.50]

AC17 Test [EPA-HQ-OAR-2010-0799-9487-A1, p.50]

The auto industry has shared EPA and CARB’s interest in furthering understanding of these issues, and the draft AC17 vehicle test procedure that we jointly developed through USCAR is a significant step to aid future research. We therefore strongly support adding an option to use the AC17 procedure as a reporting-only alternative to the idle test to demonstrate that a vehicle’s MAC system is delivering the efficiency benefits of the new technologies from the credit menu in MY 2014-2016. [EPA-HQ-OAR-2010-0799-9487-A1, p.50]

During the development of the AC17 procedure, it was shown that a very complicated and elaborate procedure would unavoidably be needed to accurately measure MAC energy consumption. A high level of vehicle instrumentation is needed, in part to understand what is happening throughout the test and identify voided tests where the procedure may have gone wrong. A high number of voided tests are to be expected. Also, the procedure cannot be conducted in a standard FTP test cell, but needs a climate controlled chamber with solar lamps that meets SC03 test specifications. At least four hours is needed for the test, due to the desire to include solar soak periods that attempt to comprehend the benefits of reduced thermal load technologies. In addition, even with the improved repeatability and added instrumentation of the AC17 test, testing has shown that a single AC17 test may not demonstrate the benefit of a single or a bundled set of technologies. In order to statistically verify the benefit, multiple tests may need to be run and statistically analyzed. [EPA-HQ-OAR-2010-0799-9487-A1, pp.50-51]

In total, although this test is unlike any other used for emission certification (or any other regulatory certification program), the high level of complexity was arrived at and determined to be necessary in pursuit of the goals of an accurate, reproducible test that could distinguish a good MAC system from a bad one under representative ambient climate conditions, and which could validate the benefits of the technologies on the EPA credit menu. [EPA-HQ-OAR-2010-0799-9487-A1, p.51]

EPA proposes testing with the relevant technologies turned “on” then turned “off” in order to validate the improvements that are awarded from the credit menu. We agree with the principle of validating the menu credit amounts through actual vehicle testing, but note the difficulty of doing this on a comprehensive basis for every model of vehicle. In actuality, there is typically no baseline vehicle and baseline MAC system that is engineered and built without the improved MAC technologies for true apples-to-apples comparison of tests with the MAC technologies turned “on,” and then turned “off.” For example, if a variable compressor with the associated computer controls is engineered for a vehicle platform, it is typically applied across-the-board on that platform, and no systems are built with a fixed compressor or with the computer controls that would be necessary to get optimized performance from this fixed compressor. [EPA-HQ-OAR-2010-0799-9487-A1, p.51]

The exercise suggested by EPA is more appropriately viewed as a research exercise, rather than a traditional vehicle emissions certification program. For example, the IMAC program tested a baseline Cadillac vehicle, and then added various new MAC technologies, including new, smarter computer controls that improved vehicle integration. The improvements from each added new technology were measured as the IMAC program progressed. However, IMAC was a research program that cost hundreds of thousands of dollars, involved experts from approximately 40 corporations, government labs and agencies, and spanned approximately two years. To expect such a complicated procedure to validate the menu credit amounts for a large number of vehicles is simply not feasible and would violate the boundaries of “reasonable verification.” [EPA-HQ-OAR-2010-0799-9487-A1, p.51]

In some circumstances, it may be possible to obtain (or build) baseline vehicles which approximate the apples-to-apples technology “on” versus technology “off” comparisons that EPA seeks. A research program would seek to identify the best of these vehicle opportunities and, on a selected basis, use them to answer the research questions that are to be studied. Such a program would allow for multiple repetitions of the test to be run on the selected vehicles to statistically verify results. There are only approximately eight efficiency technologies on the MAC credit menu (including the two levels of reduced reheat). This is a manageable number of technologies to assess using the AC17 test (or other methods) in a detailed way in order to validate the amount of credits provided by the menu. On a survey basis, it can also be used to show that the credit amounts from the menu are being consistently achieved, but it is not reasonable to require that this be tested on every model or platform. [EPA-HQ-OAR-2010-0799-9487-A1, pp.51-52]

Due to the complexity of the required tests, the rarity of good baseline comparison opportunities, and the overall high test burden of this program in comparison to the amount of credits involved, the Alliance recommends that EPA to utilize the AC17 test solely to validate menu credit amounts and monitor progress on a sample basis, rather than as a mandatory certification test that must be run on every vehicle model or platform in order to achieve MAC efficiency credits. [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

AC17 Thresholds [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

EPA raises the possibility of setting an absolute required threshold for the AC17 test, as was done in 2014 with the idle test, rather than comparing improvements to case-by-case baselines. This raises a host of complex issues. Establishing these standards would be a very complex exercise, and two key issues emerge that show this to be a bad idea, even before entering into the particular issues related to the standard setting process. [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

First, the test burden would be overwhelming. The AC17 test is much longer and more complicated than other emissions tests, and it cannot be used in the same way. [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

Second, the planning uncertainties and implementation difficulties from such a complex program would become an insurmountable obstacle to getting better MAC technologies implemented. Rather than speeding progress in this area, the tests would slow or stop the progress that is being made. [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

AC17 Corrections and Clarifications [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

We note the need for the following minor technical corrections and clarifications in the AC17 procedure written in the NPRM: [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

During the soak that occurs between the preconditioning and test cycle (for both the solar-on and solar-off portions of the test) we believe that instead of turning the cooling fan off, it should be set to 4 mph. The low wind level is a more representative real-world condition. Maintaining that fan speed impacts solar glazing technology. This change would impact 40 C.F.R. §86.167(f)(8). [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

A solar load tolerance of 850 W/m2 +/- 45W/m2 should be allowed, and the procedure should specify 'solar off' for the MAC off test. [EPA-HQ-OAR-2010-0799-9487-A1, p.52]

If windows are partially cracked during the test in order to accommodate wiring or other test instrumentation, a piece of foam or other flexible insulation should be used to keep a tight seal when the window should be closed or when wires are inserted through the gap. (Without this, the gap is too large where the various cords run through the window and the vehicle will not heat up consistently during the solar soak.) [EPA-HQ-OAR-2010-0799-9487-A1, pp.52-53]

In the test procedure flow chart on p. 75359 of the NPRM the word “Nominal” should be added to “Time (Minutes)” [EPA-HQ-OAR-2010-0799-9487-A1, p.53]

AC17 Test Vehicle Selection [EPA-HQ-OAR-2010-0799-9487-A1, p.53]

Because the AC17 test is so long, expensive and complicated, the number of tests should be minimized to a manageable level, no matter what the ultimate purpose of the test. These tests must be done in climate-controlled SC03 chambers, not in regular FTP test cells, and test capacity is very limited in SC03 chambers. MAC systems generally have consistent designs and specifications on each vehicle platform (except that some platforms now have hybrid powertrain models, which would usually have a very efficient MAC electric compressor), so performing one test per vehicle platform would give a good overview of MAC efficiency performance. However, vehicle platforms usually have multiple engine and transmission combinations available, so the number of tests would escalate rapidly if various engine and transmission combinations require testing. [EPA-HQ-OAR-2010-0799-9487-A1, p.53]

For example, for 2012 model certification, one manufacturer, GM, tested and certified approximately 20 vehicle platforms. There were approximately 85 GM platform/engine combinations, and this number then approximately doubles if transmission combinations are included. Clearly, if various engine/transmission combinations required testing, the MAC testing program would surpass the number of tests performed for tailpipe certification, which violates the standard of “reasonable “verification,” considering the relatively small environmental impacts of MAC indirect GHG emissions. [EPA-HQ-OAR-2010-0799-9487-A1, p.53]

We therefore object to the criteria for test vehicle selection proposed in the NPRM, which defines a platform as “a group of vehicles with common body floorplan, chassis, engine and transmission.” We propose the following “platform” definition, which is adapted from the current EPA definition for a “carline”: [EPA-HQ-OAR-2010-0799-9487-A1, p.53]

Platform means a group of vehicles within an OEM which has a degree of commonality in construction (e.g., body, chassis). Platform does not consider the model name, brand or marketing division, does not consider any level of decor or opulence and also does not consider characteristics such as roof line, number of doors, seats, or windows. A platform may include vehicles from various fuel economy classes, including both cars and trucks. [EPA-HQ-OAR-2010-0799-9487-A1, p.53]

This definition provides the flexibility to combine the large variations which occur within platform families that use the same MAC architecture. Intra-platform variation is based on "floorplan" such as two-door, four-door and wagon/crossover variants or SUV/pickup variants, as well as powertrains. However, the benefit of the menu technologies should not be significantly affected by body style or powertrain. We recommend that wherever the term "platform" is used in MAC regulations, it be based on the flexible and inclusive definition proposed above by the Alliance. [EPA-HQ-OAR-2010-0799-9487-A1, pp.53-54]

In addition, in 40 C.F.R. 86.1866-12(c)(6)(iii), EPA proposes that the highest selling sub-configuration within each platform be tested in the first model year for which a MAC system is expected to generate credits and then one additional sub-configuration must be tested in each subsequent model year until all sub-configurations within the platform have been tested. Given the fact that a platform will contain tens, if not hundreds, of sub-configurations, this proposal essentially eliminates the possibility for a manufacturer to "carryover" representative data from a prior model year and unnecessarily increases a manufacturers overall testing burden. Therefore, we urge EPA to allow the use of good engineering judgment when selecting a representative test vehicle for each platform and when determining whether carryover of data is appropriate. Also, if EPA were to persist on having sales figures be a part of the basis for test vehicle selection, sales projections should be clearly allowed as the basis for these test vehicle selections rather than waiting for actual sales figures to be finalized at the end of the year. [EPA-HQ-OAR-2010-0799-9487-A1, p.54]

Finally, we believe that 40 C.F.R. §86.1866-12(c)(6)(iv) is redundant to 40 C.F.R. §86.1866-12(c)(6)(iii) and should be removed. [EPA-HQ-OAR-2010-0799-9487-A1, p.54]

AC17 Test Burden [EPA-HQ-OAR-2010-0799-9487-A1, p.54]

The AC17 test takes approximately four hours, which is eight times as long as the idle test. Further, AC17 requires more technician time to set up the elaborate instrumentation, and it requires SC03 climate-controlled test cells. More voided tests are also expected with AC17, due to all the complications. The following are specific recommendations to reduce test burden: [EPA-HQ-OAR-2010-0799-9487-A1, p.54]

86.167-17 (a) Overview. [EPA-HQ-OAR-2010-0799-9487-A1, p.54]

The reference for humidity should be changed from "…50 percent relative humidity…" to "…69 grains of water / pound of dry air…" to be consistent with our recommendation for test cell ambient conditions (please see our next recommendation). [EPA-HQ-OAR-2010-0799-9487-A1, p.54]

86.167-17 (c) Test cell ambient conditions. [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

The proposed A17 test procedure limits are extremely stringent. SC03 test facilities were not designed to operate at 77 °F at 69 grains of water/pound of dry air humidity at 850 W/m2 solar load. We recommend that the tolerances be widened to minimize test voids without significantly impacting testing accuracy as described below: [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

§ 86.167–17 (c) Test cell ambient conditions. [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

The test cell ambient temperature and humidity recorded values should lie within the specifications at least 95% of the time [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

(1) Ambient Air Temperature (i) Temperature = 77 ± 3 °F air temperature on average and 77 ± 5 °F air temperature instantaneous [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

(2) Ambient Humidity (i) Humidity = 69 ± 5 grains of water/pound of dry air on average and 69 ± 10 grains of water/pound of dry air instantaneous [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

§ 86.167–17(d) Interior temperature measurement. [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

A thermocouple location tolerance should be added to (d) Interior temperature measurement. The current requirement is too restrictive for high volume production testing (language implies a location of exactly 30mm and 330 mm). The word “nominally” should be added before each measurement tolerance and OEM’s should not be required to validate exact physical location by documenting dimensions. Also there may be some vehicles (like 2 seat sports cars or pickup trucks) where the distance below the roof or behind the headrest is not achievable due to physical constraints of vehicle (example; rear deck lids or window). In these cases language should be added to allow OEM’s to use “good engineering judgment” to get a close as possible to these prescribed physical locations. [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

§ 86.167–17(e) Air conditioning system settings. [EPA-HQ-OAR-2010-0799-9487-A1, p.55]

The requirement for “6 volts at the motor” is too unwieldy a specification to be reliably executed in high volume testing and may not even be achievable, given varying motor voltage configurations such as vehicles with systems other than 12-volt. We recommend that it be reduced to the setting closest to “6 volts at the motor” or the blower switch position at 50% of maximum blower speed, or immediately below 50% if there are an odd number of positions. For example, position 2 if the maximum is position 4, or position 3 if the maximum is position 7. Also, the word “nominal” should be added to the requirement “…to provide 55 degF…” since (1) this temperature may change with different segments of the test (idles, accelerations, cruses, decelerations) or (2) with some vehicles may not achievable or stable at this idle period, and (3) implies a tolerance of ±0.49 degF which may be difficult to set in such a short period of time. Finally, on vehicles that 'default to recirculated air above 75 °F,' the OEM should have the option to let this feature function as intended and not be required to start in recirculated air and change to outside air at the first idle of the SC03. [EPA-HQ-OAR-2010-0799-9487-A1, pp.55-56]

§ 86.167–17(f)(8) Procedures following the preconditioning cycle. [EPA-HQ-OAR-2010-0799-9487-A1, p.56]

Following the preconditioning cycle, the test vehicle and cooling fan(s) are turned off, all windows are rolled up, and the vehicle is allowed to soak in the ambient conditions of paragraph (c)(1) of this section for 30 ±1 minutes. The solar heat system must be turned on and generating 850 W/m2 within 1 minute of turning the engine off. [EPA-HQ-OAR-2010-0799-9487-A1, p.56]

This requirement implies that the solar heat system must be turned on and achieves 850 W/m2 within 1 minute of turning the engine off. This takes four events to accomplish: (1) turn engine off, (2) turn solar lamps (heat) load on, (3) set pyrometers up near the vehicle, (4) solar load lamps warm up to produce 850 W/m2. One minute (total) is insufficient time to accomplish these tasks as just item #4 can take more than five minutes to achieve (produce 850 W/m2). Since this short time requirement of one minute is really not a critical element to the test, we recommend changing it to: [EPA-HQ-OAR-2010-0799-9487-A1, p.56]

The solar heat system must be turned on within one minute of turning the engine off. The 30 minute soak starts immediately after the solar load has achieved 850 ± 45 W/m2. Facility calibration data on solar lamp warm-up can be used to establish the start of solar soak time. Total soak time would be time to turn on the lights (e.g., one minute) plus lamp warm-up time (from calibration data) plus 30 minute solar soak. For example if the facility calibration demonstrates the lamps reach 850 W/m2 within two minutes, the soak time can be standardized at 33 minutes after engine off for that facility. [EPA-HQ-OAR-2010-0799-9487-A1, p.56]

§ 86.167–17(f)(10) “Air conditioning off” test. [EPA-HQ-OAR-2010-0799-9487-A1, p.56]

The air conditioning off test is identical to the steps identified in paragraphs (d)(1) through (9) of this section, except that the air conditioning system and fan speeds are set to complete off or the lowest. It is preferred that the air conditioning off test be conducted sequentially after the air conditioning on test, following a 10–15 minute soak.” We believe this to be a typo, “…set to complete off or the lowest (setting).” Also during this SC03 and HFET portion of the air conditioning off test, (f)(8) requires “…all windows are rolled up…”. Provisions need to be made to allow the driver to get sufficient cooling, such as allowing the windows to be partially or fully opened during the “air conditioning off” portion of the test. [EPA-HQ-OAR-2010-0799-9487-A1, p.56]

The MY 2014-2016 regulation currently allows substantial flexibility based on good engineering judgment to limit idle testing to one worst-case vehicle per platform, and carryover data could be used from one year to the next if no changes are made to a platform. Under the current regulation, although initially all platforms would need testing, over time, the regular cadence of vehicle changes over (typical) five-year program lives would mean that only 20% or so of each manufacturer’s platforms would need testing in any year. [EPA-HQ-OAR-2010-0799-9487-A1, pp.56-57]

In contrast, the new proposal requires AC17 testing in each year on each platform that receives credit. Beginning in 2017, carryover data is effectively disallowed, since a different sub-configuration within the platform must be tested each year. Also, the technology “on” and technology “off” testing effectively doubles the number of tests. Thus, the high test burden from attempting to test every platform every year with the AC17 test exceeds the objective of reasonable verification, since the test burden has grown exponentially from the original idle test. Disallowing carryover data effectively raises the number of tests approximately five-fold, the technology “on” versus “off” requirement then doubles the number of tests, and the AC17 test is at least eight times longer than the idle test. Although this is very rough math, it shows that the proposed approach would require approximately 80 times more test hours. [EPA-HQ-OAR-2010-0799-9487-A1, p.57]

The objectives of menu validation and monitoring real-world progress can be achieved with a much lower test burden than this. In view of the complexity of the AC17 test in comparison with the idle test as well as other emission certification tests, no manufacturer should be required to conduct AC17 testing on more than four platforms in any year. [EPA-HQ-OAR-2010-0799-9487-A1, p.57]

Bench Testing [EPA-HQ-OAR-2010-0799-9487-A1, p.57]

SAE procedures have been developed for bench testing of MAC systems at a range of steady-state speeds and for the calculation of the Lifecycle Climate Change Performance of the system using the steady-state results as input data. These methodologies were used for some analyses within the IMAC program. [EPA-HQ-OAR-2010-0799-9487-A1, p.57]

These procedures have strengths as well as weaknesses. The bench test data is accurate and reproducible, although the full battery of SAE tests is very expensive to run (e.g., $80,000 per model), and automobile manufacturers are not currently set up to run these tests. Importantly, the integration of the MAC system with the vehicle is not comprehended in a sophisticated manner by these procedures. Thermal load technologies could not be directly evaluated. As computer controls grow more sophisticated, they have become a major factor in reducing energy consumption of MAC systems, while also meeting acceptable levels of performance in other vehicle parameters. The bench test procedure does not include sophisticated consideration of these computer control algorithms, and it would not be a simple task to include this important variable. [EPA-HQ-OAR-2010-0799-9487-A1, p.57]

The bench test methodology would be no better than the AC17 methodology in achieving the EPA goal of reasonable verification, and it would probably have deficiencies compared to AC17. The bench test methodology was considered within USCAR, but a vehicle test approach was selected instead because it was more comprehensive and the OEMs had facilities and experienced staffs in place for vehicle testing. Since the AC17 test has shown positive early results, it is preferred over bench testing as the basis for future work on these issues. [EPA-HQ-OAR-2010-0799-9487-A1, pp.57-58]

Once again, even using a bench test approach, the questions to be examined more closely resemble a research program than a traditional vehicle emissions certification program. If necessary, reasonable verification of the menu credit amounts could probably be achieved by a research program using bench test data, and sample-based verification could be used to validate that real improvements were occurring on new vehicles. However, comprehensive testing of every platform or model using this approach would be enormously burdensome, and the bench test approach does not solve the problem of defining baseline performance or standards. Since bench testing offers no clear advantages, we recommend AC17 as the basis for future progress on MAC performance. [EPA-HQ-OAR-2010-0799-9487-A1, p.58]

Conclusion [EPA-HQ-OAR-2010-0799-9487-A1, p.58]

EPA set the stringency of the overall GHG standards based on maximum achievement by the industry of 5.0 g CO_2/mile MAC efficiency credits for cars in 2017, followed by maximum achievement of the 7.2 g CO_2/mile MAC efficiency credits by trucks in 2019. Clearly, this is an ambitious forecast, since it requires that no manufacturer encounter obstacles that preclude achievement of the maximum credit on any of its vehicles. However, the proposed efficiency tests have a high potential to interfere with the achievement of these maximum credit levels. In testing thus far, vehicles with engines below 2.5 liters in displacement have consistently shown only partial achievement of the idle test thresholds. It is not yet clear what achievement levels can be attained on the AC17 test, or how that test may be used. The potential testing burden and/or the planning uncertainties created by these tests may by themselves be sufficient to prevent maximum achievement of these credits. [EPA-HQ-OAR-2010-0799-9487-A1, p.58]

In view of these considerations, we ask that achievement of certain levels on the MAC efficiency tests not be established as a strict requirement in order to gain credits from the MAC technology menu. The credit menu is working, and we expect it to continue to generate significant progress, provided that these test requirements are not allowed to interfere. We will work with EPA and NHTSA to provide “reasonable verification” of this progress through selected vehicle testing and other methods to show that the menu amounts are not overstated, and that commensurate real-world progress is achieved. The mid-term review and the 'check-ins' prior to the mid-term review will provide an opportunity for EPA to review whether a “reporting-only” AC17 test (instead of an AC17 test with thresholds) continues to be adequate. However, the number of tests to achieve this should be far less than proposed in the NPRM. [EPA-HQ-OAR-2010-0799-9487-A1, p.58]

NHTSA should adopt regulatory language that provides equivalent levels of MAC efficiency credits in the CAFE program. We note, however, both the difficulty and the importance of keeping the EPA and NHTSA programs aligned. NHTSA CAFE standards will also be based on maximum achievement of these credits, while the ability to earn other compliance credits to offset MAC efficiency shortfalls will not be the same. [EPA-HQ-OAR-2010-0799-9487-A1, p.59]

Finally, we support including MAC credits in fleet averages in a manner consistent with the proposal for off-cycle credits. [EPA-HQ-OAR-2010-0799-9487-A1, p.59]

Organization: American Honda Motor Co., Inc.

5. A/C 17 Test Concerns

“Baseline vehicle” – In section III. C. 1. b) of the preamble, the AC17 test procedure is described as requiring an OEM “To determine whether the efficiency improvements of these technologies are being realized on the vehicle, the results of an AC17 test performed on a new vehicle model would be compared to a “baseline” vehicle which does not incorporate the efficiency-improving technologies.” Honda believes this is problematic for the following reasons: [EPA-HQ-OAR-2010-0799-9489-A1, p. 4]

- Comparator - It may be impossible to re-create a vehicle without the new technology, and secondly, all-new and completely re-designed vehicles may not have a proper comparison vehicle.
- Fairness – early efficiency is not rewarded, because the prior model (where one exists) is the basis for establishing improvements. If prior models are extremely efficient, only relative improvements are rewarded.
- Test integrity – Test repeatability is yet to be assured. EPA says that OEM only needs to pick one model from vehicles that share common platform. Test result, however, is easily affected by vehicle design, such as window size and design, test cell condition (blower setting, humidity level control), resulting in test result variability. Thus test method that use baseline vehicle cannot be accepted. [EPA-HQ-OAR-2010-0799-9489-A1, p. 4]

AC17 Test Repeatability – In the preamble, the agencies claim that the AC17 test shows good repeatability, however, there were limited laboratories used and limited models. Honda proposes a solution to this issue. Recognizing that the idle test does not have good repeatability, and that the AC17 test data points are not as substantial as they need to be, the agencies could allow OEMs to provide AC17 test data during the MY12 – MY16 period, in lieu of the idle test (with its questionable repeatability) and the threshold concern. AC17 test data would allow OEMs to take advantage of the menu-based credits. This will enable EPA to quickly develop a large dataset of AC17 test results, which will accelerate the adoption of performance-based criteria for AC credits. [EPA-HQ-OAR-2010-0799-9489-A1, p. 4]

The agencies seek comment on the threshold criteria for the AC17 test. Unfortunately, Honda doesn’t have any test data or experience at this point. The previous proposal (allowing AC17 test in lieu of idle test during the MY12- MY16 period) would provide EPA with enough data to make a good determination. Additionally Honda proposes that EPA work with SAE Interior Climate Control Committee to establish appropriate thresholds values. [EPA-HQ-OAR-2010-0799-9489-A1, p. 4]

Organization: Association of Global Automakers, Inc. (Global Automakers)

EPA proposes to use a new air conditioning test procedure (AC17) to evaluate potential credits for system efficiency improvements by manufacturers. However, it is clear that there could be problems resulting from the use of the new test. EPA states that “the appropriateness of the test is still being evaluated” and “EPA believes that more testing and development will be necessary before the new test could be used directly …” See 76 FR 74938, 74940. Global Automakers has several concerns with AC17 test procedure, which we recommend that EPA address before the test procedure is required by the regulations. For instance, it is not clear if the precision of the AC17 test procedure is high enough to differentiate between the baseline vehicle and the vehicle enhanced with A/C energy saving technologies. If the total precision of the vehicle test is 2 g CO_2/mi and the enhanced vehicle has A/C-related technologies with menu credits worth that amount or less, the benefit may not be identifiable at all on the vehicle test. Moreover, it is not clear that it would be practicable to use the AC17 test to compare the performance of certain vehicles with and without the individual efficiency improvements from the EPA menu installed, as proposed by EPA. This would be a problem in particular for vehicles that incorporate efficiency improvements as part of a major redesign or full model change. In those situations, it may not be possible to provide a comparable vehicle having an air conditioning system without the efficiency improvements installed. Another issue may result from the comparison of A/C systems when the “baseline” system is already efficient. It may be difficult to demonstrate improvements between two efficient systems, and it is not clear how to obtain credits for changes that resulted in the improved efficiency for the “baseline” system. [EPA-HQ-OAR-2010-0799-9466-A1, p. 4]

We understand the goal of ensuring that credits given on the menu system for A/C technologies actually translate into real-world emissions reduction and fuel savings on the vehicle. There are different methodologies to evaluate the improvement from A/C technologies including menu systems, bench testing, simulation, and vehicle testing. Each of these has its own merits and challenges. One possible improvement that can be made in the current menu system is to put technical specifications relating to efficiency for the individual component technologies. Other options may also be appropriate. Nevertheless, the test procedure concerns should be addressed before implementation. [EPA-HQ-OAR-2010-0799-9466-A1, p. 4]

Due to these potential problems, we urge the EPA to collaborate with the SAE Interior Climate Control Committee to evaluate options to improve the test procedure and to reassess the test procedure as part of the mid-term review. In the interim, we recommend that EPA include in the final rule an “off-ramp” procedure to allow the determination of air conditioning credits without using the AC17 test procedure. [EPA-HQ-OAR-2010-0799-9466-A1, p. 4]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 51.]

Second, the agencies should carefully consider the relationship between the creation of incentives under the new standards and the development of alternative test procedures to assess the incentivized technologies. Global Automakers strongly supports incentivizing technologies whose potential benefits are not fully measured under the 1975 CAFE test procedure. Air conditioning efficiency, off-cycle, and advanced technology incentives are justified based on their potential long term, real world benefits. Such incentives will typically take the form of compliance credits that are assessed using alternative test procedures. In developing incentives for the final rule, the agencies need to carefully consider how to reconcile these incentives with the testing procedures required by law. [EPA-HQ-OAR-2010-0799-9466-A1, p.2]

[[This comment can also be found in Outline Heading 7.4.]]

Organization: BMW of North America, LLC

Regarding fuel efficiency credits, we provide the following comments and recommend some specific changes.

• AC-idle:

- We support the review of AC-idle judgment limits as a function of engine displacement.

- This also supports implementing fuel efficient technologies in smaller vehicles even when fuel consumption improvements which definitely have positive effects during overall typical driving conditions - are not fully visible during small engine idling. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 2]

• AC17 Test and Evaluation:

- We carried out our own AC17 tests after the publication of the NPRM. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 2]

- In our opinion, the AC17 test conditions do not reflect typical average or moderately increased air conditioning loads. In particular, the solar load is too high. According to a FAT study, the average North American sun load is around 310 Wfm2 already taking into account that driving time periods are variable during a day (e.g. less driving at night). We therefore would expect a maximum value of around 350 Wfm2 to 400 Wfm2 (instead of 850 Wfm2) for the AC17 test. Some of the powerful measures to lower all-the-year fuel consumption also can't be evaluated at the currently suggested AC17 test load - e.g. significant reduction of reheat. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 2]

- Reliability of test data is expected to be not better but similar to the AC-idle-test.

- Definition of platforms or carlines could be adopted according to the Alliance proposal. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 2]

- We are also concerned about determining fuel consumption improvements and credit calculations depending on baseline test results. The generation of baseline car results needs to be properly defined. BMW does not have baseline cars - especially focused on 2017 – they have to be designed and built up for this single test. Therefore, we propose to test a baseline car once for each platform - according to the Alliance carline definition - and the use of these baseline results should be allowed during the entire model year 2017 to 2025 timeframe. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure pp. 2-3]

• AC17 Test Procedure:

- During the 30 minute soak, it is quite difficult to control temperature and humidity properly. A wider tolerance range in this phase of the cycle would help. Even more critical for some modern full automatic test benches is the combination of engine off and 4 mph wind speed because this has significant impact on exhaust gas analysis measurement devices. We would prefer a soak definition with a wider tolerance range of temperature and especially humidity and a speed definition of maximum 4 mph (instead of exactly 4 mph). [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 3]

- Solar load during MAC off phases causes extreme temperature exposure to test drivers. These working conditions are unacceptable and will lead to poor accuracy when trying to meet the given drive cycle requirements. We suggest running MAC off phases without solar load. As MAC is turned off, this has no impact on MAC off fuel consumption. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 3]

- Drive cycle definitions should be fully equal to currently used cycles (e.g. some seconds time shift @ HWFET). This would help to keep accuracy and test quality high and to avoid mistakes. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 3]

Organization: Chrysler Group LLC

Air conditioning system efficiency improvements differ between passenger cars and light-duty trucks. It is appropriate to establish separate credit levels for the passenger car and light-duty truck fleets. The Agencies have developed this split in an environmental and fuel consumption neutral manner. [EPA-HQ-OAR-2010-0799-9495-A1, p. 6]

The air conditioning efficiency idle and AC17 test procedures; [EPA-HQ-OAR-2010-0799-9495-A1, p. 10]

Chrysler supports the Agencies' development of separate passenger car- and light-duty truck-specific credits for air conditioning system efficiency improvements.

In the DJTSD, the Agencies derive passenger car and light-duty truck specific greenhouse gas and fuel consumption benefits associated with air conditioning load demand. Chrysler believes that it is a reasonable approximation that opportunities for improvement on passenger cars will differ from those on light-duty trucks. Therefore, the Agency's proposal to establish separate air conditioning system efficiency improvement credits for passenger cars and light-duty trucks is appropriate. [EPA-HQ-OAR-2010-0799-9495-A1, p. 11]

Organization: Enhanced Protective Glass Automotive Association (EPGAA)

4. EPGAA supports the proposal to add the AC17 test procedure with certain modifications. EPGAA advocates migration toward incorporation of AC load into drive cycles or test procedures which can be determined to produce reasonable correlation with real world performance. While credits are a good first step to recognizing the untapped benefits of heat load reduction, the reality is that the imposed caps and generality of credits will not allow full recognition of the potential benefit. To this end EPGAA acknowledges the proposed AC17 test cycle as a potential good advancement. There is always some question as to the validity of sun lamps to simulate true solar load due to incident angle and emitted spectra variances. However, it is also recognized that a repeatable outdoor test, which would be the ideal solution, is difficult to

achieve. Regarding the specifics of the AC17 proposed test protocol, EPGAA would like to offer the following comments: [EPA-HQ-OAR-2010-0799-9301-A1, p. 2]

a. EPGAA suggests that the solar soak period time be increased from 30 minutes to 40-45 minutes. Studies have shown that consumer do indeed leave their vehicles parked for longer than 30 minutes, and thermal modeling of some typical passenger vehicles with RadTherm software shows that at 30 minutes there is still a fairly steep slope of cabin temperature increase occurring in many cases. This slope does tend to taper after about 45 minutes. [EPA-HQ-OAR-2010-0799-9301-A1, pp. 2-3]

b. EPGAA supports the test condition of a 72 degree set point for automatic climate control systems but has concerns regarding the control logic for manual systems. Any protocol selected for the manual systems should be validated by testing a similar or same vehicle configuration equipped with an automatic system and subsequently with a manual system and confirming that both procedures provide the same or similar results. Regarding the proposed manual system procedure, EPGAA agrees that the test should begin at full output with recirculation and also agrees that at some reasonable time period the fan speed should be moderated. It is also agreed that the recirculation mode should be defeated after the vehicle attains a comfort level. It is EPGAA's recommendation that this adjustment point should be triggered by internal cabin temperature rather than simply based on time. Using the temperature control to moderate air supply temperature seems flawed as most manual temperature controls when in fresh air mode moderate supply temperature by adjusting a mixing damper to introduce partial reheat through the heating coil. This will not necessarily result in a true reduction of AC load or hence measurement of the attainable efficiency. The AC compressor in most systems will cycle based on evaporator coil temperature. Introducing mixed air will ultimately increase evaporator sensible load to remove the reheat energy resulting in a poor measure of any heat load reduction improvement as the compressor will not shut off as often as was possible without reheat. In this scenario, any technology which reduces heat load in the cabin will trigger a response to increase the temperature setting which will simply increase the amount of reheat energy. EPGAA suggests that for the above reasons, the temperature control must remain in the full cold position during the test cycle and cooling air supply should only be regulated via fan speed. The fan speed should be adjusted as required at intervals to hold an interior temperature. Furthermore, EPGAA suggests that the adjustment should be based on a breath level cabin temperature reading, rather than the supply air temperature at a duct outlet, since this will be more representative of the usage by an actual driver. [EPA-HQ-OAR-2010-0799-9301-A1, p. 3]

Organization: Ferrari

To reduce the certification test burdens for small-volume manufacturers, we request that the A/C Idle Test could be used (instead of the new AC17 test) beyond MY 2016. At least, the transition from the A/C idle test to the AC17 should be smooth. [EPA-HQ-OAR-2010-0799-9535-A2, p.13]

Organization: Ford Motor Company

We also support proposed changes to the program for 2014-2016 MYs that will allow manufacturers to earn credits by reporting results from the new AC17 test, which Ford helped to develop jointly with industry (USCAR), EPA and CARB. This option has two primary benefits. First, it provides a rich source of data for evaluating the new AC17 test, prior to its proposed 2017 MY implementation. Second, it provides an alternative to the Idle Test, which has several shortcomings, as detailed in the Alliance comments as well as in the NPRM preamble and Technical Support Document. [EPA-HQ-OAR-2010-0799-9463-A1, pp. 10-11]

Ford also supports the introduction of the AC17 test procedure as a means of validating credit values for the 2017-2025 MYs. As mentioned, Ford has worked with industry and the agencies to develop this procedure and will continue to work with these groups in the future to conduct additional prove-out on this test. We do however, have some concerns with the 2017-2025 MY test requirements, as proposed: [EPA-HQ-OAR-2010-0799-9463-A1, p. 11]

While the AC17 test is much improved over the Idle Test, we believe that the addition of this test is more suited for a research program to validate menu levels, rather than a certification-type test requirement. Variability with this test has been reduced, but remains a concern. The charts below show that using a single baseline and demonstration test may not always successfully show the technology benefit. On the left side of the first chart, test data from a base test, without recirculation, and two tests with recirculation technology are shown. On the right side of that chart, the difference in CO_2 emissions between the base test and the two recirculation tests are provided. Based on this data, one of the recirculation tests does not show an improvement over the baseline. If this single test were run for certification, no credit would have been earned for a technology that clearly should provide a benefit. This shows the importance of running multiple repeats when demonstrating the benefits of these technologies. The second chart below shows that when multiple baseline and "with technology" tests are averaged and compared, the benefit of the recirculation technology is seen and can be quantified. This shows that reliance upon one test point may not adequately demonstrate an accurate credit level, nor does it allow for acceptable credit planning assessments. Without the ability to reliably estimate credit levels during the planning process, decisions to introduce these beneficial technologies will be jeopardized. [EPA-HQ-OAR-2010-0799-9463-A1, p. 11]

For certification, the concept of comparison testing a vehicle containing the A/C new technology with a similar "baseline vehicle" without the technology will be difficult to accomplish in practice. When manufacturers introduce new A/C technology, these changes typically take place when other updates are being made to the vehicle. As a result, a comparison of the older baseline vehicle to the new vehicle may be influenced by factors other than simply the A/C system changes. In general, it is also not rational to test a vehicle with the A/C technologies deactivated as a baseline. In many circumstances this is impossible, or would require a great deal of effort to accomplish, and would not be optimized for performance. Therefore, it may be difficult to identify reasonable baseline vehicles, especially given the large number of tests that are proposed to be required for each model year. In the interest of validating menu levels, a more limited number of comparison tests should be conducted to evaluate the different A/C technologies, with multiple test runs to statistically verify results. This could be done as a research program using industry and agency data collected prior to 2017 MY. Once that work is complete, we recommend that credit levels be awarded on the basis of that validated menu (similar to the current process, as well as the proposed off-cycle pre-approved technology list). Additional testing should then be limited to survey or confirmatory purposes or for the evaluation of new technologies. [EPA-HQ-OAR-2010-0799-9463-A1, p. 13]

Ford believes the testing burden associated with the new requirements is excessive, as proposed. EPA acknowledges that the AC17 test requires a significant amount of time, using expensive SC03-capable facilities, and therefore suggests this testing should be conducted on a limited subset of vehicles. The proposal indicates that one vehicle (plus the baseline) per platform must be tested. Based on the proposed platform definition, this is problematic because each platform is required to have a common body floor plan, chassis, engine and transmission. Ford’s product line-up would result in an extremely large number of required tests. For example, using the proposed definition on Ford's 2012 MY line-up would result in up to 63 platforms. For 2013 MY, the number of platforms increases to 66. We do not expect elements like powertrain and transmission to have any significant impact on the benefits of the A/C technologies and therefore believe the scope of the platform definition should be narrowed. If testing requirements are determined on a platform-basis, we agree with the definition proposed in the Alliance comments, included below for reference: [EPA-HQ-OAR-2010-0799-9463-A1, p. 13]

Platform means a group of vehicles within an OEM which has a degree of commonality in construction (e.g., body, chassis). Platform does not consider the model name, brand or marketing division, does not consider any level of decor or opulence and also does not consider characteristics such as roof line, number of doors, seats, or windows. A platform may include vehicles from various fuel economy classes, including both cars and trucks. [EPA-HQ-OAR-2010-0799-9463-A1, p. 13]

Using this updated definition would reduce Ford’s platform counts to 10 and 9 for the 2012 and 2013 MYs, respectively, which is much more reasonable than the number that would be required using the definition proposed in the NPRM. [EPA-HQ-OAR-2010-0799-9463-A1, p. 13]

Ford also requests the option of allowing manufacturers to use additional instrumentation for collecting PCM and other A/C control data during the AC17 testing to study parameters and better understand what occurs during the test. This should be an allowable option, but not a requirement for recording or reporting. [EPA-HQ-OAR-2010-0799-9463-A1, p. 13]

Ford also supports all of the suggested technical corrections and recommended test procedure and tolerance updates to the Idle Test and AC17 Procedures in sections 40 CFR § 86.165-12 and § 86.167-17, as detailed in the Alliance comments. [EPA-HQ-OAR-2010-0799-9463-A1, p. 14]

To summarize, Ford believes the inclusion of the new AC17 test is a major step in the right direction for helping to quantify A/C technology benefits. As indicated by the above comments, additional work remains to resolve various technical and logistical issues for using this test to validate credit levels. Ford is committed to continuing our cooperative work with industry and the agencies to make the use of this test a success and allow for proper credit achievement with planning certainty. As that development work continues, we urge the agencies not to finalize a rule that will establish overly burdensome test requirements or thresholds for achieving maximum credit levels that have not yet been fully proven out. [EPA-HQ-OAR-2010-0799-9463-A1, p. 14]

Organization: Guardian Automotive Products, Inc.

Guardian advocates migration toward incorporation of AC load into drive cycles or test procedures which can be determined to produce reasonable correlation with real world performance. While credits are a good first step to recognizing the untapped benefits of heat load reduction, the reality is that the imposed caps and generality of credits may not allow full recognition of the potential benefit. Nonetheless, the proposed AC17 test cycle appears to be a step in the right direction. Sun lamps in test chambers do not represent an ideal duplication of real world solar load; however, they are perhaps the best available compromise given the difficulty of establishing a repeatable outdoor test. Guardian offers the following specific comments regarding the proposed AC17 cycle: [EPA-HQ-OAR-2010-0799-9299-A1, p. 2]

• The solar soak period time should be increased from 30 minutes to 40-45 minutes. Thermal modeling of various passenger vehicles with RadTherm software demonstrates that at 30 minutes there is still in many cases a fairly steep slope of cabin temperature increase. This slope tends to taper only after about 45 minutes. [EPA-HQ-OAR-2010-0799-9299-A1, p. 2]

• We understand the rationale behind the proposed test condition of a 72 degree set point for automatic climate control systems left to operate during testing in fully automatic mode. However, we have concerns regarding the proposed control logic for manual systems. Any protocol selected for manual systems should be verified by testing a similar or same vehicle configuration equipped with an automatic system to ensure that the manual system results are similar to those of the automatic system. Regarding the proposed manual system procedure, Guardian agrees that the test should begin at full output with recirculation and that at some reasonable time period the fan speed should be moderated. We also agree that the recirculation mode should be defeated after the vehicle attains a comfort level, but this adjustment point should be triggered by internal cabin temperature and not a set time period. Using the temperature control to moderate air supply temperature seems flawed as most manual temperature controls when in fresh air mode moderate supply temperature by adjusting a mixing damper to introduce partial reheat through the heating coil. This will not necessarily result in a true reduction of AC load or, therefore, measurement of the attainable efficiency. The AC compressor in most systems will cycle based on evaporator coil temperature or humidity level. Introducing mixed air will ultimately increase evaporator sensible load to remove the reheat energy resulting in a poor measure of any heat load reduction improvement as the compressor will not shut off as often as was possible without reheat. In this scenario, any technology which reduces heat load in the cabin will trigger an operator response to increase the temperature setting which will simply increase the amount of reheat energy. Guardian suggests that for the above reasons the temperature control must remain in the full cold position during the test cycle and cooling air supply should only be regulated via fan speed. The fan speed should be adjusted as required at intervals to hold an interior temperature. Furthermore, Guardian suggests that the adjustment should be based on a cabin temperature reading near one of the headrests rather than the supply air temperature at a duct outlet since this will be the control input temperature for an actual driver. [EPA-HQ-OAR-2010-0799-9299-A1, pp. 2-3]

Organization: Honeywell International, Inc.

Consequently, the agencies propose to require manufacturers to use the new Air Conditioning, 2017 ('AC17') tests to demonstrate that new or improved A/C technologies actually result in efficiency improvements, while continuing to use the menu-style approach to determine credits and fuel consumption improvement values. [EPA-HQ-OAR-2010-0799-9497-A1, p.9]

Honeywell agrees that a performance-based test is preferable to the proposed menu-style approach because it could quantify more accurately the degree of improved efficiency resulting from an A/C system, thus providing a more precise measurement of GHG emissions reduction and CAFE fuel consumption value. Honeywell believes that by locking in the vehicle menu approach for the next 13 years, EPA and NHTSA could prevent the use of new and improved performance tests developed during the life of the Proposed Rule. Although EPA and NHTSA are obligated to conduct a separate rulemaking for MY 2022-2025 standards, Honeywell maintains that the proposed midterm review is still too far into the future to exclude new performance tests and recommends providing opportunity for more frequent updating in the final rule. [EPA-HQ-OAR-2010-0799-9497-A1, p.9]

Honeywell offers that EPA and NHTSA should not require manufacturers to use the AC17 test to demonstrate the effectiveness of their A/C efficiency technologies until that test has been thoroughly evaluated. It is our understanding that EPA and NHTSA propose the use of the four-part AC 17 performance-based test to quantify efficiency improvements as a prerequisite for access to the credit menu. However, EPA and NHTSA note that they are not proposing to replace the credit menu with the AC 17 test because the test 'is still being evaluated.' Although Honeywell generally prefers the use of a performance-based test when practicable, Honeywell discourages the required use of a new test until the agencies can verify the test's accuracy and reliability. Honeywell suggests that EPA and NHTSA either conduct more frequent reviews or develop a method to evaluate industry suggestions for potential performance tests and to incorporate them as they deem appropriate. [EPA-HQ-OAR-2010-0799-9497-A1, pp.9-10]

Honeywell Agrees with the Use Of SAE Standard J 2765 to Establish the Credit for Improved Evaporators and Condensers, which EPA Required Specifically for MY 2012·2016 Vehicles, and Suggests that EPA Expressly Require Its Use for MY 2017·2025 Vehicles as well [EPA-HQ-OAR-2010-0799-9497-A1, p.10]

EPA and NHTSA propose an A/C Efficiency Credit for the use of improved evaporators and condensers. EPA and NHTSA state in the TSD that the credit will be based upon SAE Standard 12765 - Procedure of Measuring System Coefficient of Performance of a Mobile Air Conditioning System on Test Bench Honeywell agrees that Standard J 2765 is the appropriate method for showing improvements in the energy efficiency and cooling capacity of systems. EPA and NHTSA do not specify, however, in the Proposed Rule, as EPA did in final rule establishing vehicle emissions and fuel economy standards for MY 2012-2016 vehicles, that the credit for improved condensers and evaporators must be determined using the bench test procedures described in SAE 12765. To ensure compliance with this requirement, Honeywell suggests that EPA and NHTSA specify expressly in the rule, in addition to the TSD, that the credit shall be determined using the SAE 12765 bench test procedures. [EPA-HQ-OAR-2010-0799-9497-A1, p.10]

Honeywell proposes that EPA employ SAE Standard J 2765 for calculation of the oil separators credit [EPA-HQ-OAR-2010-0799-9497-A1, p.10]

EPA and NHTSA propose a credit for manufacturers if they prevent oil from circulating throughout the A/C system due to inefficiencies resulting from heat transfer effectiveness. Honeywell agrees that large amounts of oil circulating throughout the system can negatively impact the efficiency of a system, but we disagree that adding an oil separator will necessarily improve efficiency. For example, an improperly designed oil separator could negatively impact the system's efficiency by restricting the flow of refrigerant through the device, resulting in increased pressure losses. [EPA-HQ-OAR-2010-0799-9497-A1, p.10]

Relying on the SAE IMAC team, EPA and NHTSA estimate a standard credit of 0.6 gram/mi CO_2. Instead, Honeywell suggests that the efficiency improvements of oil separators can be measured identically to evaporators and condensers by using SAE Standard 12765 - Procedure of Measuring System CO_2 of a Mobile Air Conditioning System on a Bench Test. Using SAE Standard 12765 will enable manufacturers to more accurately determine the overall efficacy and resulting credit of their component technology. [EPA-HQ-OAR-2010-0799-9497-A1, p.11]

Organization: Hyundai America Technical Center

However, Hyundai has concerns with the new AC17 A/C test procedure that allows manufacturers to evaluate potential credits for A/C efficiency improvements. Since the new AC17 test procedure has not yet been fully developed, Hyundai recommends that EPA retain the idle test as an option until the AC17 procedure has been proven to be reliable rather than requiring the use of AC17 procedure beginning in 2017. [EPA-HQ-OAR-2010-0799-9547-A1, p.6]

2) Hyundai questions the requirement that automakers conduct back-to-back tests with and without the credit-generating technologies to determine potential credits. There may be a number of scenarios which make it impossible to test without the credit-generating technologies, particularly on a full model changeover. For this reason and for consistency, the baseline vehicle should be clearly defined. Unless the baseline is defined, some manufacturers could be comparing their new A/C technologies against a highly efficient system and generate minimal credits while another could be comparing against a less efficient system and show greater improvement. Hyundai supports the recommendation made in the Global Automaker's comments which would be to rely on the Society of Automotive Engineers (SAE) Interior Climate Control Committee to determine the appropriate baseline A/C systems and address any test procedure concerns prior to implementation of requirements. [EPA-HQ-OAR-2010-0799-9547-A1, p.7]

Organization: International Council on Clean Transportation (ICCT)

ICCT also supports combining the menu of credits for specific A/C technologies with manufacturer performance testing to justify application of these credits. Creating a menu of credit values will help quantify emission reductions for components/technologies that may be hard to quantify through testing individually, while performance testing will verify that an effective overall package meets the minimum threshold for improvement and achieves the claimed emissions reductions. We encourage US EPA's continued work to improve the A/C test procedures in parallel with the rulemaking effort. [EPA-HQ-OAR-2010-0799-9512-A1, p. 37]

We note that the USEPA/NHTSDA November 2011 draft TSD (page 5-51) suggests that only one or two vehicles per year may be tested per manufacturer on average. Given the wide range of changes in new product offerings, engine technology, A/C system operations, and alternative refrigerants, we believe that each significantly changed model should be tested. We recommend deleting this statement in the final TSD. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 37-38]

Organization: Kia Motors

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 101-102.]

Kia supports the use of A/C menu for determining air conditioning system credits but supports an increase in the maximum amounts of credits permitted if we were able to demonstrate an emission reduction greater than the items provided in the menu. However, since the new AC17 test procedure has not yet fully been developed, Kia recommends that EPA retain the idle test as an option until the AC17 has been proven to be more reliable rather than requiring the use of the AC17 procedure at the beginning of 2017.

Organization: Mercedes-Benz USA, LLC

In particular, we endorse the concept of reviewing the A/C idle values with regard to small displacement engines, where fuel consumption improvements may be less visible during idling. With regard to the proposed A/C 17 test, DAG is concerned that the test conditions do not reflect typical, or even moderately elevated, A/C loads. For example, a 2008 German study of vehicles in over 3200 counties in the United States found that the average solar load in the U.S. is below 350 W/m2 rather than the 850 W/m2 . DAG is concerned that, given these more typical loads, the most effective ways to reduce annual MAC fuel consumption may not be recognized or evaluated through the proposed A/C 17 test procedure.[6] [EPA-HQ-OAR-2010-0799-9483-A1, p. A-3]

DAG has a number of additional suggestions with regard to the proposed test procedures. These include wider tolerances for the climate parameters during the soak period, as it is difficult to maintain temperature and humidity within the proposed tolerances. A wider tolerance range can be provided without impacting results. A wind speed lower than 4 mph should also be established since such a wind speed would improve the accuracy of the exhaust gas measurement. Drive cycle definitions should also be consistent with currently used cycles to retain accuracy and reduce failures. Correction factors should be applied to retain accuracy. First, a correction factor is necessary to overcome the fact that fuel consumption from the MAC system is calculated as the difference between two measured values that are approximately an order of magnitude larger than the MAC fuel consumption value. Second, the expected efficiency differences related to technical measures, component enhancements and refrigerant circuit optimization would fully be hidden by the effect of ambient and operating conditions deviations. Therefore, correction factors are needed to recognize ambient enthalpy, system settings and driving variations. We also propose that the HVAC system be adjusted at the beginning of the preconditioning stage of the MAC test cycle, that target temperatures be defined to meet the target temperature and mass air flow values, that A/C recirculation be allowed if recirculation is the default, and that the settings of all vent flaps be specified. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-3]

Rather than attempting to correlate the cabin volume and the cabin temperature level during the test, DAG suggests that a correction factor be deduced based on vehicle size and later applied to the measured MAC fuel consumption. This would allow consideration of vehicle cabin sizes and allow all vehicles to be tested with the same MAC settings. Finally, we suggest that the Tts value for each glazing plane be calculated in accordance with ISO 13837. This allows glazing quality and angle to be accounted for in the Tts value. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-4]

We look forward to working with the agencies as the A/C 17 test procedure is further refined and fully support the effort to promote more efficient MAC systems. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-4]

---

6 We are also concerned about unacceptable work place conditions for the test bench personnel due to solar radiation during that portion of the MAC test conducted with the A/C off. We therefore recommend that the MAC test be conducted without solar radiation during both the A/C off and the A/C on portions of the test.

Organization: Mitsubishi Motors R&D of America, Inc. (MRDA)

Recommends the AC17 test on a reporting only basis to verify air conditioning (A/C) efficiency improvements as an option in MYs 2014 through 2016, and after MY 2016, as a replacement for the A/C Idle test. [EPA-HQ-OAR-2010-0799-9507-A1, p.2]

Organization: Pittsburgh Glass Works (PGW)

3. PGW supports the proposal to add the AC17 test procedure to enable an actual measurement of the impact rather than a model-based calculation. PGW recommends certain minor modifications to the proposed AC17 test procedure. The AC17 test procedure calls for a 30 minute soak. PGW recommends a 45 minute soak to better account for “real world” conditions. Cabin temperature after 30 minutes is still deviating between cars with heat load technologies compared to those without. In addition, solar lamps located overhead do not necessarily provide adequate simulation of real world conditions where the sun moves across the horizon over the day. The heat load in the mornings and evenings can be very different from the mid-day sun.

Therefore, PGW recommends that test chambers be modified to include solar lamps on the sides as well as above the vehicle. Finally, the test procedure for cars with manual air conditioning should be modified to require changing the air flow with the cabin temperature rather than temperature of the vent air. A simple procedure could be to measure air temperature at a few locations (three at a minimum – driver breath, passenger breath, and rear seat breath) and use that air temperature to control the air conditioning system. This would be a better simulation of the actual air conditioning use by a consumer. [EPA-HQ-OAR-2010-0799-9300-A1, pp. 2-3]

Organization: Toyota Motor North America

Air Conditioning (A/C) Efficiency Credits [EPA-HQ-OAR-2010-0799-9586-A1, p.13]

Idle Test Thresholds - EPA has proposed to modify the Idle test thresholds from a flat threshold to a function of engine displacement. Toyota recommends that an additional threshold be considered for dual A/C systems. Under the proposed threshold, it will be difficult for a dual A/C system employing state of the art high efficiency technology to comply. Toyota recommends that the threshold for vehicles equipped with dual A/C systems be increased to a value of 19 g/minute. [EPA-HQ-OAR-2010-0799-9586-A1, p.13]

AC17 Test General- Toyota appreciates EPA's flexibility in allowing manufacturer's to run the AC17 test for 2014-2016 model years as a reporting option, in lieu of the Idle test requirements~ while still allowing credits to be generated from the menu. However, EPA has proposed AC17 testing be required to generate credits starting with the 2017 model year. Toyota remains concerned with the proposed AC17 test because its complexity will require 8 hours from set-up to completion. In addition, the proposed AC17 testing for 2017 model year requires testing in each year and on each platform that would receive credit, which would quickly create an inordinate test burden. In order to reduce this burden, Toyota requests that EPA consider flexibility when addressing carry over allowances, test group configurations, and testing requirements. [EPA-HQ-OAR-2010-0799-9586-A1, p.14]

Technical Recommendation -Toyota supports the corrections and clarifications provided in the Alliance comments. In addition~ per AC17 test procedure §86-167-17 (e)(2) regarding manual A/C systems, a manufacturer must manually adjust the airflow setting to 'outside-air' at the first idle period of the SC03 drive cycle, even if the airflow setting is automatically set to "recirculated-air" by systems having automatic recirculation control technology. Toyota requests to add the option that if the system is equipped with automatic recirculation control~ then it is not necessary to change the airflow setting to 'outside-air' at the first idle period of SC03 drive cycle in AC17 test. Toyota thinks this recommended option would be consistent with EPA's current consideration for A/C systems. As an example, EPA currently allows 'default to recirculated air with closed-loop control of the air supply whenever the outside ambient temperature is 75F or higher' as an efficiency improvement to current A/C systems. [EPA-HQ-OAR-2010-0799-9586-A1, p.14]

Organization: Volkswagen Group of America

CREDITS FOR EFFICIENCY IMPROVEMENTS

Volkswagen disagrees with the agencies modifications to the credit levels available for efficiency improvements within the 2017-2025 proposal. Previously in 2012-2016, both cars and trucks were eligible for up to 5.7 g/mi CO_2 credit. Within this proposal, the agencies have decreased the maximum level of car credit to 5.0 g/mi and increased the maximum truck credit to 7.2 g/mi. Volkswagen understood that it was the intention of the agencies to continue the base flexibilities from 2012-2016 into the 2017-2025 timeframe. The decrease in passenger car and increase in truck credits contrasts with this understanding. [EPA-HQ-OAR-2010-0799-9569-A1, p. 30]

It is Volkswagen's position that A/C loading is a function of vehicle attributes rather than compliance category. Vehicle mass, interior volume, glazing, etc will determine loading requirements and the effects of efficiency improvements rather than whether the vehicle is a car or truck. In some cases the exact same A/C system between related or similarly sized cars and trucks. Improvements made to particular A/C system would then be integrated into both the car and truck at the same point in production. [EPA-HQ-OAR-2010-0799-9569-A1, p. 30]

Efficiency is a reduction in energy use which is independent of the type of vehicle. Trucks will feature greater total lifetime CO_2 reductions due to the expected higher VMT, however in terms of rate (g/mi) there may not be any difference between cars or trucks. [EPA-HQ-OAR-2010-0799-9569-A1, p. 30]

We simply fail to see enough technical evidence to broadly apply a 2.2 g/mi difference, especially for two vehicles in different categories which have the same A/C system. Volkswagen proposes that the maximum credit levels for cars and trucks are equalized at 7.2 g/mi. As an alternative, an average g/mi reduction could be calculated for the fleet as a whole and applied equally for cars and trucks. [EPA-HQ-OAR-2010-0799-9569-A1, p. 30]

IDLE TEST CONDITIONS

As stated within the Alliance comments, the idle test procedure requires the air conditioning system to be operated as if they were working at a high ambient temperature. Thus the air conditioning system will work at maximum 'cool down' for a majority of the testing time. These temperature conditions are unrealistic and prevent the test from reflecting efficiency gains possible at moderate and light load. As demonstrated by the SAE/IMAC study, the efficiency improvements at moderate and light loads are 40% or more. The idle test conditions should be adapted to include efficiency gains at moderate and light loads within the overall result. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 30-31]

Volkswagen maintains that there are significant test-to-test repeatability issues with the idle test due to test cell influences (air movement, etc). Volkswagen requests that EPA provide more clearly defined testing parameters to improve the repeatability of the test. Volkswagen has conducted internal evaluations of the idle test and would welcome the opportunity to provide input on how to improve the definition of these test parameters. [EPA-HQ-OAR-2010-0799-9569-A1, p. 31]

IDLE TEST ENGINE DISPLACEMENT FACTOR

EPA has included within the proposal an idle test threshold adjustment based on engine displacement. Volkswagen supports the overall comments from the Alliance on the minimal contribution of this change to the higher level goals of real world GHG reductions. Volkswagen considers this option as a transitional provision until the AC 17 test will be used to quantify MAC system efficiency. Volkswagen seeks to clarify that the optional use of this provision is at the discretion of the manufacturer, e.g. by model type. [EPA-HQ-OAR-2010-0799-9569-A1, p. 31]

AC 17 TESTING AND VEHICLE SELECTION

Volkswagen fully supports the concerns over the complexity, length and therefore time and costs to run the AC 17 test. Furthermore, there may be difficulties in establishing baseline results from which to compare a vehicle equipped with a new A/C system. It is often the case that a new A/C system will be integrated into a vehicle which has also undergone a significant refresh, or even a complete redesign. In this case, it will be difficult to implement an 'old' baseline A/C system in a 'new' redesigned car in order to properly establish before/after results. Therefore Volkswagen agrees with the alliance proposal to utilize the AC17 test solely to validate menu credit amounts and monitor progress. Another option would be to consider the possibility of establishing an industry baseline value. [EPA-HQ-OAR-2010-0799-9569-A1, p. 31]

Volkswagen proposes the following definition of a 'vehicle platform' and to restrict the required testing to a platform. [EPA-HQ-OAR-2010-0799-9569-A1, p. 31]

Platform means a group of vehicles within an OEM which has a degree of commonality in construction (e.g., body, chassis). Platform does not consider the model name, brand or marketing division, does not consider any level of decor or opulence and also does not consider characteristics such as roof line, number of doors, seats, or windows. A platform may include vehicles from various fuel economy classes, including both cars and trucks. [EPA-HQ-OAR-2010-0799-9569-A1, p. 31]

Volkswagen supports the concept of eventually allowing the use of detailed simulation as an accepted analysis tool in helping to determining credit levels. Simulation tools are broadly applied within the vehicle development process and have proven valuable in both enabling faster analysis and lower costs. We request EPA to consult with SAE in order to fully explore this route. [EPA-HQ-OAR-2010-0799-9569-A1, p. 31]

Organization: Volvo Car Corporation (VCC)

VCC supports the use of the complete vehicle test cycle AC17 instead of the A/C Idle ON/OFF test, but would like to see a harmonization of the complete vehicle test cycle AC17 (within the US) and the European MAC efficiency test cycle. VCC proposes this to keep the number of tests at a minimum because these tests are very resource demanding. [EPA-HQ-OAR-2010-0799-9551-A2, p. 8]

The new GHG regulations have led to substantial enhancements of several test procedures, all to achieve more real and credible results. However, it is important that EPA and NHTSA, in cooperation with CARB, also realize that these complex test procedures may result in excessive costs for manufacturers. VCC therefore asks that EPA and NHTSA, in cooperation with CARB, recognize that the SC03 test is a much more complex test format and requires a unique test facility, and that manufacturers today have limited capacity. Consideration also should be given to how critical these tests are, with a view to limiting the number of tests that are required, while achieving quality results in order to identify the efficiency of AC systems. [EPA-HQ-OAR-2010-0799-9551-A2, p. 8]

The AC17 test is a long, expensive and complicated test, so it is essential that the number of tests should be kept to a reasonable and manageable level. The AC17 test takes approximately four hours, which is eight times as long as the AC Idle test. The AC17 test requires more technician time to set up the elaborate instrumentation, and it requires SC03 climate-controlled test cells. [EPA-HQ-OAR-2010-0799-9551-A2, p. 9]

For future technologies, VCC supports the utilization of a system bench test to measure energy efficiency of an AC system. In future advanced technology vehicles, active AC cooling of the battery pack could be necessary. Therefore, for this type of vehicle a complete vehicle test such as the AC17, could prove to be difficult to achieve the necessary repeatability, because it would require keeping track of the environment of the battery pack during the test. [EPA-HQ-OAR-2010-0799-9551-A2, p. 9]

VCC supports the new method for attaining efficiency credits. VCC thinks that the so-called credit menu for energy efficient AC system components is somewhat misleading. VCC considers that a combination of different technologies in the credit menu could give advantages or disadvantages in AC system efficiency depending on how the combination is made. [EPA-HQ-OAR-2010-0799-9551-A2, p. 9]

VCC's opinion is that the amount of credits should be a result of a suitable full vehicle test or bench test. [EPA-HQ-OAR-2010-0799-9551-A2, p. 9]

Response:

EPA acknowledges the general support for a more comprehensive vehicle-based test for generating A/C efficiency credits, AC17, instead of the Idle Test. We also recognize the manufacturer and industry concerns regarding the burden and accuracy of such a test. As such, we have incorporated changes regarding ambient temperature and humidity tolerances the environmental test chamber (see TSD Section 5.1.3.6). Modifications regarding the tolerances for test cell ambient conditions on the Idle Test have been incorporated as well (see TSD Section 5.1.3.5). Regarding the burden of the AC17 test, we have implemented a program where a maximum of one AC17 test per vehicle platform will be required in a given model year, with the ability to carry forward the AC17 test result and A/C credits to future model years. We believe that this revision addresses concerns about the number of tests that will need to be performed in order to generate credits, while appropriately ensuring sufficient testing to confirm that new technologies are reducing CO_2 emissions as expected. The details regarding the determination of how many AC17 tests a manufacturer will need to submit upon certification (see preamble Section II.F.1.b.ii and III.D and TSD 5.1.3.8).

In response to comments concerning the accuracy (and test-to-test repeatability) of the AC17 test, EPA believes that our testing of production vehicles has shown that with proper control of the test cell conditions, the AC17 test cycle is capable of producing results that can demonstrate differences in A/C load, which are then reflected in tailpipe CO_2 emissions. Our analysis of these test results is found in TSD 5.1.3.7. In addition, our memo to the docket (see Docket Number EPA-HQ-OAR-2010-0799) describing the results of USCAR testing -- in which the effect of specific A/C technologies are evaluated relative to a baseline technology -- also supports our position that the AC17 test is capable of quantifying the effect of efficiency-improving technologies. While the USCAR test results may lack the number of repeat tests necessary to establish a reduction in CO_2 emissions, these preliminary and developmental results serve to demonstrate that the effect of the efficiency-improving technologies is always in the direction of lower A/C-related CO_2 tailpipe emissions relative to a baseline technology.

In regard to comments which suggested different A/C system control settings or adjustment of control settings based on actual interior temperature readings, we believe that such changes would add complexity to the test and could result in greater test-to-test variability, as interior temperatures can be airflow- and vehicle-dependent, and language to define precise, repeatable positioning of vents (which would affect the interior temperature reading) is not feasible at this time. As such, we are finalizing the A/C system control settings that were specified in the NPRM (see TSD Section 5.1.3.6).

Organization: Alliance of Automobile Manufacturers

Automakers should not be required to account for utility GHG emissions. The proposed rule indicates that the agencies expect electric vehicles to become an increasingly large part of the car park. Yet the rule leaves open the possibility of requiring manufacturers to account for upstream emissions from electricity generation in the event that the Administration is unable to control these emissions through other channels. In other words, automakers may now be called on to not only make an unprecedented investment into vehicles with lower GHG emissions, but to also fill the void between this rulemaking and a comprehensive national energy policy. If Americans agree that programs to address upstream GHG emissions are appropriate, then such programs should be put in place through appropriate regulation of electricity generators, not by imposing additional burdens on vehicle manufacturers. [EPA-HQ-OAR-2010-0799-9487-A1, pp.4-5]

Dual Fuel Plug-In Hybrid Electric Vehicles (PHEVs) [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

The Alliance supports the continued use of the Society of Automotive Engineers (SAE) cycle-specific utility factor approach for PHEV compliance and label emissions calculations. This utility factor approach provides a method for predicting the fractions of total distance driven in each mode of operation. In this case the modes of operation would be wall electricity from the grid or conventional liquid fuel such as gasoline. [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

Automakers Should Not be Required to Account for Utility GHGs. [EPA-HQ-OAR-2010-0799-9487-A1, p.76]

EPA requests comments on several aspects of its proposal regarding accounting for the carbon emissions from the use of electricity. These include the conversion process, tons accounting, a phase out, costs, the timing, etc. The Alliance strongly recommends that all upstream carbon emissions from the use of electricity be quantified as zero for the purposes of automotive GHG emissions regulations. This should be the case for all model years and for all vehicle volumes. [EPA-HQ-OAR-2010-0799-9487-A1, p.76]

In the NPRM, EPA notes, [EPA-HQ-OAR-2010-0799-9487-A1, p.76]

The tailpipe GHG emissions from EVs, PHEVs operated on grid electricity, and hydrogen-fueled FCVs are zero, and traditionally the emissions of the vehicle itself are all that EPA takes into account for purposes of compliance with standards set under Clean Air Act section 202(a). [EPA-HQ-OAR-2010-0799-9487-A1, p.76]

The Alliance agrees with this statement and further notes that EPA should, in fact, maintain this same logic when dealing with current and future GHG emissions. [EPA-HQ-OAR-2010-0799-9487-A1, p.76]

EPA further states, [EPA-HQ-OAR-2010-0799-9487-A1, p.76]

Focusing on vehicle tailpipe emissions has not raised any issues for criteria pollutants, as upstream emissions associated with production and distribution of the fuel are addressed by comprehensive regulatory programs focused on the upstream sources of those emissions. At this time, however, there is no such comprehensive program addressing upstream emissions of GHGs, and the upstream GHG emissions associated with production and distribution of electricity are higher, on a national average basis, than the corresponding upstream GHG emissions of gasoline or other petroleum based fuels. [EPA-HQ-OAR-2010-0799-9487-A1, p.76]

Again, the Alliance maintains that simply because EPA does not currently regulate upstream emissions at the source, this is not reason enough to inappropriately attempt to control them via automakers. Clearly automakers have no control over the feedstock's that power plants use to create electricity, nor do we have control over the conversion or transportation processes, or where and when a vehicle owner recharges a vehicle. [EPA-HQ-OAR-2010-0799-9487-A1, pp.76-77]

Further, EPA states, [EPA-HQ-OAR-2010-0799-9487-A1, p.77]

Manufacturers are unlikely [to invest in PHEVs and EVs] if vehicles with these technologies are treated for compliance purposes to be no more advantageous than the best conventional hybrid. [EPA-HQ-OAR-2010-0799-9487-A1, p.77]

EPA Data Supports the Alliance Position [EPA-HQ-OAR-2010-0799-9487-A1, p.77]

The agencies' own analysis and data prove that if upstream carbon emissions from electricity are accounted for in automakers compliance calculations, a PHEV or EV costs three to four times more than a strong hybrid for the same reduction benefit. While the Alliance is not indicating agreement with the agency's analysis and data, we do believe it is helpful to use that analysis and data to show how it supports the Alliance position. [EPA-HQ-OAR-2010-0799-9487-A1, p.77]

Table 3.12-1 of EPA's Draft Regulatory Impact Analysis (EPA RIA) shows several 2011 model year vehicles with associated data. The table includes manufacturer, vehicle name, footprint, unadjusted fuel economy, tailpipe CO_2 and powertrain type. In addition to the data in this table, for select models, below we have also included the associated unadjusted electrical consumption and the cost from other sources within the joint TSD and the EPA RIA. Finally, for the analysis, we included data from a baseline small car (4-cycle, 6-speed at 41 mpg (216.8 g/mile)) from the TSD for comparison purposes. [EPA-HQ-OAR-2010-0799-9487-A1, p.77] [For the table please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.77]

Leaf mpg value is mpge [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

** Costs from EPA documents below: [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

P2 from Table 1.2-7 Costs for P2-Hybird Technology (pg 24 of 377 of the EPA RIA), large car at 10% mass reduction [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

PHEV40 from Table 1.2-9 Costs for Plug-in Hybrid Technology with 40 Mile EV Range, (pg 25 of 377 of the EPA RIA), small car at 15% mass reduction [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

EV75 from Table 1.2-10 Costs for Full Electric Vehicle Technology with 75 Mile Range, or EV75, (pg 25 of 377 of the EPA RIA), small car at 10% mass reduction [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

PSHEV from Table 3-46 Costs for Power-Split Hybrids, small car [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

* 260 w-hr/mi is back-calculated from pg 294 of 893, 'example, as shown in the Regulatory Impact Analysis, today's Nissan Leaf EV would have an upstream GHG emissions value of 161 grams per mile based on national average electricity' [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

* 251.9 Whr/mi is the unadjusted combined electric consumption rate for the Volt as report in certification documentation for the 2011MY Chevrolet Volt [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

From this EPA data, a "grams per unit" benefit (with the 0.0 g/mile incentive in place) can be calculated, compared to the baseline, for each technology. For example, to improve the performance of his fleet, if a manufacturer chose to replace a baseline small car in its fleet with an EV75, it would replace a 216.8 g/mile unit with a 0.0 g/mile and have a 216.8 g/unit benefit. Similarly, if the manufacturer chose to replace the baseline car with a P2HEV, the benefit would only be 46.5 g/unit (216.8-170.3). [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

Further, by dividing EPA's cost by the calculated gram per unit benefit, we can determine the cost per gram of improvement for the manufacturer's potential choices. For example, while replacing a baseline small car with an EV75 gains the manufacturer 216.8 g/unit of benefit, it comes at a cost of $57.7/gram ($12,508/216.8). It is interesting to note, before moving on to these same calculations without the 0.0 g/mile upstream incentive in place, that a PSHEV (i.e., a strong hybrid that does not use grid electricity) is more effective on a $/gram basis than either PHEV40 or an EV75. [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

The next step in the analysis is to determine both the gram/unit and $/gram values for both the PHEV40 and EV75 if the 0.0 g/mile upstream emissions incentive is removed and automakers are required to account for power plant emissions. EPA outlines how this calculation is to occur, proposing a 4-step methodology for calculating the GHG emissions compliance value for vehicle production in excess of the cumulative production cap for an individual automaker.[6] For example, for an EV in MY 2025, this methodology would include the following steps and calculations: [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

Measuring the vehicle electricity consumption in watt-hours/mile over the EPA city and highway tests (for example, a midsize EV in 2025 might have a 2-cycle test electricity consumption of 230 watt-hours/mile). [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

Adjusting this watt-hours/mile value upward to account for electricity losses during electricity transmission (dividing 230 watt-hours/mile by 0.93 to account for grid/transmission losses yields a value of 247 watt-hours/mile). [EPA-HQ-OAR-2010-0799-9487-A1, p.79]

Multiplying the adjusted watt-hours/mile value by a 2025 nationwide average electricity upstream GHG emissions rate of 0.574 grams/watt-hour at the power plant (247 watt-hours/mile multiplied by 0.574 grams GHG/watt-hour yields 142 grams/mile). [EPA-HQ-OAR-2010-0799-9487-A1, p.79]

Subtracting the upstream GHG emissions of a comparable midsize gasoline vehicle of 39 grams/mile to reflect a full net increase in upstream GHG emissions (142 grams/mile for the EV minus 39 grams/mile for the gasoline vehicle yields a net increase and EV compliance value of 103 grams/mile). Using this methodology and the data in table 3.12-1, a g/mile value without the 0.0 g/mile upstream emissions incentive for both the Volt and Leaf can be determined. The Leaf's compliance value without the 0.0 g/mile upstream emissions incentive is 121.5 g/mile while the Volt's is 141.3 g/mile. [EPA-HQ-OAR-2010-0799-9487-A1, p.79] [For the table referenced please refer to EPA-HQ-OAR-2010-0799-9487-A1, p.79]

Applying the same gram/unit and $/gram values for both these values for Leaf and the Volt results in: [EPA-HQ-OAR-2010-0799-9487-A1, p.80]

Model Year Vehicle	Grams/unit benefit NO 0.0	$/gram NO 0.0
2011 Small Car		
2011 Leaf	95.3	131.3
2011 Volt	75.4	155.0 [EPA-HQ-OAR-2010-0799-9487-A1, p.80]

On a dollars per gram of benefit basis, using EPA's own data, an EV75 or PHEV40 costs three to four times as much as a strong hybrid (i.e., $43.1/gram for a strong hybrid versus $131.3/gram for an EV75). Automakers are businesses, and with the 0.0 g/mile upstream electricity emissions incentive, an EV75 or PHEV40 make only marginal business sense. Without the zero upstream emissions factor, both an EV75 and a PHEV40 - all PHEV/EV variants for that matter - make no business sense. The Alliance strongly recommends that EPA finalize the 0.0 g/mile quantification incentive for the purposes of automotive GHG emissions regulations, for all model years, and for all vehicle volumes. [EPA-HQ-OAR-2010-0799-9487-A1, p.80]

Additional Comments Related to Upstream Emissions [EPA-HQ-OAR-2010-0799-9487-A1, p.80]

The Agencies request comment on whether or not the 0.0 g/mile value should phase out completely in MY 2022 or instead decay at half value or some other rate. They also ask for comment regarding the 200,000 unit cap (or 300,000 if certain conditions are met) for MYs 2012-2016. Consistent with our above comments, upstream electricity emissions should be counted at 0.0 g/mile for auto manufacturers for all years - MYs 2012-2025 - with no sales volume limits. [EPA-HQ-OAR-2010-0799-9487-A1, p.80]

The entities with control over those emissions are the federal and state agencies that regulate power plant operation and performance, the power companies that buy and sell power from different energy sources, and the vehicle operators who decide when to recharge their vehicles -- not the manufacturers who produce the vehicles. Assigning upstream emissions factors to grid-powered vehicles would be economically inefficient. The entity to regulate is the utility, not the downstream user. [EPA-HQ-OAR-2010-0799-9487-A1, p.80]

Finally, making vehicle manufacturers responsible for emissions over which they have no control is contrary to the Clean Air Act. Section 202(a) of the Act gives EPA authority to set 'standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines.' Upstream emissions are not emissions 'from' vehicles or engines; they are emissions from power plants and other facilities involved in generating energy used for many purposes, such as powering vehicles. And even if such legal authority existed, with no sound method for assessing comparative upstream emissions effects from grid-powered electric vehicles, and significant regional variations in upstream GHG emissions, the attribution of upstream emissions impacts to grid-powered vehicles alone would be arbitrary, capricious and an abuse of discretion. [EPA-HQ-OAR-2010-0799-9487-A1, p.80]

The Alliance supports the advanced technology volume multipliers as proposed in the NPRM. [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

In addition, the Alliance would support NHTSA’s further evaluation of such multipliers, as their inclusion in the NHTSA requirements would help to further harmonize the two programs. [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

Also, the agencies proposed minimum electric or equivalent all-electric range for the definition of a PHEV for use of this advanced technology volume multiplier. The agencies specify that to qualify, a PHEV must “…be required to be able to complete a full EPA highway test (10.2 miles), without using any conventional fuel, or alternatively, have a minimum equivalent all-electric range of 10.2 miles as measured on the EPA highway cycle.” [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

The Alliance supports this metric and definition. [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

Additional Attribute(s) for PHEV Incentive Multipliers [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

EPA requests comment on whether PHEV incentive multipliers should vary based on range or on another PHEV metric such as battery capacity, or ratio of electric motor power to engine or total vehicle power. [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

Basing PHEV incentive multipliers on factors such as battery capacity or power has potential unintended consequences. These types of metrics encourage manufacturers to install battery capacity or power not demanded by customers thereby increasing vehicle costs. [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

Given the potential unintended consequences of adding additional attributes to determine PHEV incentive multiplier credits, the Alliance recommends that a single multiplier be used for all PHEVs. [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

Dual Fuel Vehicle CAFE Calculations for MY 2020-2025 [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

EPA requests comment on several aspects of dual fuel vehicle CAFE calculations for MY 2020 and later, including how to weight alternative and conventional fuel use and whether to continue use of the petroleum equivalency factor for PHEV equivalent fuel economy and the 0.15 divisor for dual fuel vehicles. [EPA-HQ-OAR-2010-0799-9487-A1, p.82]

EPA proposes to weight dual fuel (but not flexible fuel vehicle) conventional and alternative fuel use by applying the SAE-based utility factor approach. This approach equitably weights the expected fuel use on conventional and alternative fuels based on national driving pattern surveys, and is supported by the Alliance. [EPA-HQ-OAR-2010-0799-9487-A1, p.83]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 98.]

Second, the rule needs to fit into comprehensive energy policy. For instance, the proposed rule indicates that the agencies expect electric vehicles to become an increasingly large part of the car market; yet, the rule leaves open the possibility of requiring manufacturers to account for upstream emissions -- this is what Mike Robinson spoke about -- from electricity generation in the event that the Administration is unable to control these emissions through other channels. If programs to address upstream emissions are needed, then let's put them in place with appropriate upstream regulations, not by imposing additional burdens on automakers.

6 - Id. at 75014. The Alliance is using EPA’s methodology only for the sake of analysis. The Alliance is not stating it is in agreement with EPA’s methodology. [EPA-HQ-OAR-2010-0799-9487-A1, p.78]

Organization: American Clean Skies Foundation (ACSF)

In the Proposed Rule, EPA plans to allow a '0 grams per mile' incentive to EVS. This incentive is subject to certain per-manufacturer and industry-wide production caps. The decision to calculate the upstream emissions of EVs at 0 grams per mile (g/mi) is combined with the above multiplier incentive to create undue and discriminatory benefits for EVS. For the reasons stated above, ACSF believes that the 0 g/mi incentive is inappropriate and it should be eliminated. The 0 g/mi is anticompetitive and unnecessarily favors one class of lower carbon vehicle platforms at the expense of others. [EPA-HQ-OAR-2010-0799-9464-A1, p. 11]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Treatment of EVs and PHEVs

ACEEE has previously expressed to the EPA its view that the treatment of EVs and PHEVs in the GHG emissions program should be based on emissions performance, both to maximize benefits of the rule and to help put plug-in vehicles on a sound environmental footing. Treating EVs as zero-emissions vehicles allows unearned increases in emissions from gasoline vehicles, thereby undercutting the GHG reductions achieved by the rule. We have also previously recommended that, if some EVs are to be treated as zero-emissions vehicles in the 2017-2025 period, the number of such EVs should be capped at 2 million, based on considerations of annual sales volumes and battery cost reductions. The caps on zero-emissions EV proposed in the NPRM far exceed our recommendations. In fact, no cap is proposed for the period 2017-2020. [EPA-HQ-OAR-2010-0799-9528-A2, p.8]

Most important, however, is that a zero-upstream treatment of plug-in vehicles not be continued indefinitely, and that full upstream accounting be applied to these vehicles by a date certain. EPA's proposed treatment of EVs largely accomplishes this, so we strongly support that aspect of the proposal. [EPA-HQ-OAR-2010-0799-9528-A2, p.9]

Recommendations

- In calculating UFs for PHEVs, apply the appropriate shortfall to fuel economy test values in charge-depleting mode. Use Fleet UFs, rather than the MDIUFs, for labeling purposes.
- Make UF values for PHEVs publically available, along with other fuel economy and emissions performance data for individual vehicle models.
- Begin using UFs to calculate the fuel economy of PHEVs in 2017. EPA-HQ-OAR-2010-0799-9528-A2, p.9]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

Compliance calculations should be transparent and should not include inappropriate incentives or credits. [EPA-HQ-OAR-2010-0799-9485-A1, p.8]

EPA proposed temporary incentives for EVs, PHEVs, and FCVs for MYs 2017-2025 (76 FR 75012). The first is to allow EVs, plug-in hybrid electric vehicles (PHEVs, electric operation), and fuel cell vehicles (FCVs) to use a GHG compliance value of 0 grams per mile, even though upstream GHG emissions for electricity generated by a coal-fired powerplant without carbon capture and sequestration or for hydrogen generation can be very high. The second proposed alternative is a multiplier for all EVs, PHEVs and FCVs which would allow each of these vehicles to “count” as more than one vehicle in the manufacturer’s compliance calculation. AFPM objects to these proposed temporary incentives as they distort real world impacts and paint a false picture of the proposed fuel economy standards. [EPA-HQ-OAR-2010-0799-9485-A1, p.8]

These proposed incentives are inappropriate and very misleading considering the current extent of electricity generation by coal-fired powerplants without carbon capture and sequestration and unknown processes for generating hydrogen. These proposed temporary incentives will not result in a substantial reduction in lifecycle GHG emissions if recharging uses coal-fired powerplants without carbon capture and sequestration. It is certainly not evident that hydrogen will be produced on a low-carbon lifecycle basis. Conversion of fossil fuels like natural gas to produce hydrogen results in carbon emissions until carbon capture and sequestration is commercialized and deployed. [EPA-HQ-OAR-2010-0799-9485-A1, p.8]

Organization: American Honda Motor Co., Inc.

EPA requests comment the multiplier incentives, as proposed in Table III-15, for EVs, PHEVs and FCEVs. Honda supports these multipliers. EVs, PHEVs and FCVs are expensive technologies that hold promising environmental benefits. Honda generally supports incentives that are proportionate to the benefits. Alternative fuel vehicles and advanced technologies face unique challenges in coming to market; developing appropriate infrastructure and overcoming initial consumer resistance to new, unfamiliar technologies. Incentives that are limited in time and appropriately phased-out can help accelerate the introduction of these vehicles. [EPA-HQ-OAR-2010-0799-9489-A1, p. 2]

EPA proposes to set the upstream portion of EVs, PHEVs and FCEVs to zero grams/mile. EPA requests comments on this approach. Honda believes that EPA should separate incentives and credits from the measurement of emissions. Honda believes that without accounting for the upstream emissions of all fuels, inaccurate comparisons between technologies will take place. Relying upon EPA’s regulation, policy makers – in the U.S. and around the world – may make unfavorable technology comparisons and set mis-directed policies as a result. [EPA-HQ-OAR-2010-0799-9489-A1, p. 3]

A compelling example exists. According to DOE’s GREET model, the upstream emissions of a Toyota Prius are 46 grams/mile, and the tailpipe emissions are 198 grams/mile, for a total of 244 grams/mile. By contrast, the GREET model estimates the average upstream emissions of a comparably sized Battery Electric Vehicle (BEV) are 256 grams/mile. Without commenting on the merits of creating incentives for electric vehicles, it is clear that zero grams/mile for the BEV would lead one to believe that BEVs have a clearly superior greenhouse gas profile compared to similarly sized hybrid gasoline vehicles. [EPA-HQ-OAR-2010-0799-9489-A1, p. 3]

EPA's regulations need to be comprehensive and transparent. By zeroing out the upstream emissions, EPA is conflating incentives and credits with proper emissions accounting. In discussions with EPA staff, the question of "double counting" arose. This argument points out that electric power generation is under its own regulations, and including the upstream emissions in this regulation would result in "double counting." Honda observes that upstream emissions are necessarily correlated with the intensity-based emissions regulation of light duty automobiles. In the case of petroleum refineries, significant increases in fuel economy on the part of automobile manufacturers could result in a "windfall" for the refineries' if their tonnage caps were not adjusted accordingly. These two arguments suggest that not only the upstream emissions of electricity but the upstream emissions of all fuels ought to be included in EPA's regulation. [EPA-HQ-OAR-2010-0799-9489-A1, pp. 3-4]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 116-118.]

Honda has long advocated for technology-neutral performance-based standards. These are important principles for several reasons. First, technology-neutral is important because these standards would be in place for more than a dozen years into the future. It is impossible to predict the potential advances that would be made over this time in each and every technology. Technology-neutral standards help to assure that favoritism in 2012 does not lead to failure in 2020. And just as importantly, each OEM will have different capabilities with respect to each technology, and favoritism for a technology necessarily results in, intentionally or not, favoritism for an OEM.

Secondly, performance-based standards are the best way to assure that regulations result in the greatest advance possible for our social goals.

In the 2012 to '16 regulation EPA set the CO_2 value for the electric portion of the plug-in electric vehicles and battery electric vehicles to zero as an incentive for OEMs to bring these relatively expensive vehicles to market. This incentive was capped both in terms of volume and timing. These constraints have been weakened by their extension through 2025. Honda believes that this policy is misguided and creates significant incorrect perceptions about the relative merits of these technologies. We agree with most of the environmental community that the social benefits must be understood and measured on a well-to-wheel basis. It is clear that there are no special virtues to be associated with tailpipe greenhouse gas emissions if the well-to-tank emissions are high.

Additionally, without a comprehensive well-to-wheel assessment of greenhouse gases, EPA and others who rely on EPA's assessments will improperly favor or signal preferred technologies rather than providing technology-neutral standards.

We think the solution to quantify well-to-wheel greenhouse gas emissions is already within the government's grasp. The Department of Energy uses a respected, widely accepted model called GREET, and the NGOs, academics and the federal government itself use GREET to model policy choices when considering light-duty vehicles and their impact on the greenhouse gas emissions. We believe it makes sense for EPA to adopt DOE's GREET model in order to evaluate the well-to-wheel impact on various technologies.

EPA has solicited comments on its proposal for advanced technology multipliers as a means to facilitate market penetration of the most advanced vehicle technologies as rapidly as possible. Honda supports the proposed multipliers for EV, PHEV, and fuel cell technologies. EPA requested comment on the idea of including natural gas vehicles in the technology multipliers. Natural gas vehicles can reduce CO_2 as much as 25 percent simply through changing the fuel from gasoline to natural gas. In addition, there is a new-found abundance of this clean domestic fuel. Together these attributes mean it makes sense to include natural gas vehicles in the advanced technology multiplier.

Organization: American Petroleum Institute (API)

While API has no comment on the stringency of the proposed fuel economy and CO_2 standards, we are concerned that the proposal provides a number of incentives that appear to reflect an attempt to pick winning and losing technologies in the marketplace, an action which could potentially limit consumer choice and increase societal costs. [This comment can also be found in sections 5.1 and 6 of this comment summary.] [EPA-HQ-OAR-2010-0799-9469-A1, p. 1]

Incentives for Electric Vehicles, Plug-in Hybrid Electric Vehicles, and Fuel Cell Vehicles— EPA is proposing an extra credit incentive multiplier for CO_2 compliance purposes to promote early market penetration for all electric vehicles (EVs), plug-in hybrid electric vehicles (PHEVs), and fuel cell vehicles (FCV) sold in MY 2017 through 2021. EVs and FCVs would start with a multiplier value of 2.0 in MY 2017, phasing down to a value of 1.5 in MY 2021. PHEVs would start at a multiplier value of 1.6 in MY 2017 and phase down to a value of 1.3 in MY 2021. The multiplier is 1.0 for MY 2022-2025 vehicles. [EPA-HQ-OAR-2010-0799-9469-A1, p. 1]

For EVs, PHEVs (electricity usage) and FCVs, EPA is proposing to set a tailpipe-only CO_2 compliance value of 0 g/mi. Beginning from MY 2022, the 0 g/mi limit would only be allowed up to a per-company cumulative sales cap, above which manufacturers would be required to account for the net upstream GHG emissions for the electric portion of operation, using accounting methodologies set out in the rule. [EPA-HQ-OAR-2010-0799-9469-A1, p. 1]

As EPA and NHTSA staff should be aware, the history of government agency efforts to dictate the pace of technology development and utilization in the market place is usually unsuccessful, to the detriment of US taxpayers and, ultimately, consumers. The recent bankruptcy filing of the solar panel firm, Solyndra Corp after having received over a half billion dollars in US government loan guarantees is one example.3 Continuation of a mandate to force the use of millions of gallons of cellulosic biofuels (when the current production is zero) is another.4 EPA's faith that NO_x adsorbers will be the predominant technology to meet the heavy-duty diesel engine emissions standards is a third.5 The incentive to use an artificial 0 g/mi lifecycle GHG value for EVs, PHEVs and FCVs and to count this value as much as twice for compliance purposes for a period of time is potentially a fourth example. [EPA-HQ-OAR-2010-0799-9469-A1, p. 2]

API opposed the use of multipliers and 0 g/mi lifecycle GHG scores for advanced technology vehicles in comments filed on the corporate average fuel economy/GHG rulemaking for MY 2012 – MY 2016 passenger cars and light trucks, and our opposition remains unchanged.7 Ignoring the significant contribution of (and extensive compilation of published literature on) upstream CO_2 emissions from electricity generation, defies principles of transparency and sound science and distorts the market for developing transportation fuel alternatives. It incentivizes the electrification of the vehicle fleet with a pre-defined specific and costly8 set of technologies whose future potential is not measured with the same well-to-wheels methodology against that of advanced biofuels or other carbon mitigation strategies. Furthermore, when used in conjunction with the car/light truck trading flexibilities proposed for the automakers, this incentive could potentially yield unintended consequences that run counter to the intent of the rule to reduce GHG emissions attributable to light-duty vehicles. [EPA-HQ-OAR-2010-0799-9469-A1, pp. 2-3]

Although battery electric vehicles (BEVs) and hydrogen fuel cell vehicles (HFCVs) have zero tailpipe emissions, they will have significant upstream emissions. Despite the proposed per-company cumulative production cap on the numbers of BEVs and HFCVs that will qualify for the zero emissions compliance incentive, the effect of ignoring upstream GHG emissions yields a substantial incentive for these qualifying vehicles as we demonstrate below. [EPA-HQ-OAR-2010-0799-9469-A1, p. 3]

Upstream emissions, coupled with the incentive multipliers described above, will allow well-to-wheels (WTW) carbon dioxide equivalent (CO_2e) emission rates for BEVs and HFCVs that are clearly greater than the gasoline vehicles they would replace for model years 2017 to 2021, even though they are counted as zero for compliance purposes. Even for model years 2022 to 2025, neither BEVs nor HFCVs have a WTW emission rate markedly lower than the gasoline target. These results, which are based on the published fuel economy performance and specifications (i.e., footprint) of the Nissan Leaf (BEV) and Honda FCX Clarity (HFCV), are shown in Figures 1 and 2, respectively. Appendix A summarizes the details regarding the calculation of the estimated WTW CO_2e gram-per-mile emission rates shown in these figures, which reflect U.S. average electricity emission rates and hydrogen produced from natural gas via steam methane reforming. [Figures 1 and 2 can be found on p. 4 of Docket number EPA-HQ-OAR-2010-0799-9469-A1.] [Appendix A can be found on pp. 14-18 of Docket number EPA-HQ-OAR-2010-0799-9469-A1] [EPA-HQ-OAR-2010-0799-9469-A1, p. 3]

Regulatory agencies should not be in the business of promoting investments and innovations in government-selected technologies applied to government-selected vehicle categories. Regulators should instead set broad, performance-based targets that reward innovation directed at achieving outcomes, not the implementation of specific technologies. The market, via consumer choice, should then be allowed to select the winners and losers. In short, the proposed 0 g/mi CO_2 compliance values and multipliers for EVs, PHEVs and FCVs should be removed. [EPA-HQ-OAR-2010-0799-9469-A1, p. 3]

Calculation of Upstream GHG Emissions

EPA argues that electricity and hydrogen can be produced from renewable resources with very low carbon emissions (e.g., wind energy for electricity and use of that electricity for electrolysis of water to H2). The contribution of these carbon-free electricity feedstocks (to the extent that they are dedicated to the production of transportation fuels in the timeframe of the proposed rule) should be calculated as a percent of their overall contribution to the electricity grid. [EPA-HQ-OAR-2010-0799-9469-A1, p. 5]

EPA is requesting comment on the appropriate electricity upstream GHG emissions factor or rate to use in future projections of EV/PHEV emissions based on the net upstream approach outlined in the proposed rule. The Agency is proposing to use a CY 2025 nationwide average electricity GHG emissions rate (power plant plus feedstock extraction, transportation, and processing) of 0.574 grams GHG/watt-hour, based on simulations with the EPA Office of Atmospheric Program's Integrated Planning Model (IPM) in the calculation of upstream GHG emissions for EVs and PHEVs. API concurs with the EPA's observation that there is significant regional as well as temporal variation in the fuels and equipment used for electric power generation. Consequently, a more robust analysis and representation of upstream electricity GHG emissions that incorporates this regional and temporal variability is preferable if the ultimate objective is to reflect real-world fuel usage patterns. [EPA-HQ-OAR-2010-0799-9469-A1, p. 5]

EPA notes that the emission factor for electricity was adjusted upwards by 6 percent in order to properly capture GHG emissions associated with the feedstock gathering that occurs upstream of the power plant. This adjustment apparently was based on the GREET Model Version 1.8.c.0 and was carried over from the analysis used to support the MY 2012-MY 2016 Final Rule.10 Using the most recent version of GREET (version 1_2011) yields an adjustment factor of 9.2% for the average US electricity mix in calendar year 2020, calculated as shown in Appendix B of these comments. However, this revised adjustment factor from GREET masks a wide range of uncertainty in the underlying data used in the model – a fact recently acknowledged in print.11 If EPA continues to rely on GREET for upstream emissions calculations, this further heightens the need for the Agency to conduct a more robust and rigorous analysis (as discussed above) to increase confidence in the accuracy of the model results. [Appendix B can be found on p. 19 of Docket number EPA-HQ-OAR-2010-0799-9469-A1.] [EPA-HQ-OAR-2010-0799-9469-A1, pp. 5-6]

• The government should not pick technology winners - Regulatory agencies should not promote investments and innovations in government-selected technologies applied to government-selected vehicle categories. Regulators should instead set broad, performance-based targets that reward innovation directed at achieving outcomes, not the implementation of specific technologies. The market, via consumer choice, should then be allowed to select the winners and losers. The proposed production and compliance incentives - particularly those for plug-in hybrid electric vehicles (PHEVs) full electric vehicles (EVs) fuel cell vehicles (FCVs) and dual-fueled vehicles should be removed. [EPA-HQ-OAR-2010-0799-9469-A2, pp. 1-2]

• The proposal distorts the market and ignores real environmental impacts - Allowing plug-in hybrid electric vehicles, full electric vehicles and fuel cell vehicles to certify to a 0 g/mi CO_2 standard does not properly reflect the full well-to-wheels contribution of these technologies to the GHG inventory. By not counting the real contribution of upstream CO_2 emissions from electricity generation, the proposal distorts the market for developing transportation fuel alternatives. The 0 g/mi CO_2 compliance values for EVs, PHEVs and FCVs should be dropped from the proposal. [EPA-HQ-OAR-2010-0799-9469-A2, p. 2]

Organization: Association of Global Automakers, Inc. (Global Automakers)

EPA has proposed company specific caps on the 0 grams per mile emissions rate for electric and fuel cell vehicles beginning with MY 2022. Global Automakers recommends that EPA reconsider the need for these caps as part of the planned mid-term review of the standards. If EPA decides to adopt company-specific caps, we recommend that it adopt a simple linear function based on vehicle sales levels to establish the caps, rather than using the proposed two-step approach. [EPA-HQ-OAR-2010-0799-9466-A1, p. 7]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 66-67.]

Advanced technology credit provides an incentive for manufacturers to continue to develop and market these technologies which have the potential for substantial long-term improvements in fuel efficiency and emission performance.

Organization: BMW of North America, LLC

Regarding electric vehicles, automakers can influence tailpipe emissions but not power plant emissions. [EPA-HQ-OAR-2010-0799-9579-A1, p. 1]

We acknowledge that the upstream impact of electricity generation needs to be addressed in order to ensure the credibility of a policy supporting the electrification of road transport; therefore, 0g/mi upstream emissions can be the goal. However, as automakers, we accept the responsibility for vehicle efficiency, but we have no control over the carbon content of electricity generation and cannot be held responsible for energy mix decisions made decades ago. Automakers can influence tailpipe emissions but not power plant emissions. [EPA-HQ-OAR-2010-0799-9579-A1, p. 3]

Multipliers encourage automakers to pull-ahead early generation low CO_2 technologies such as BEV, PHEV and FCV. Multipliers should be applied on advanced technologies with significant GHG reduction potential (which are much more expensive than mature gasoline technologies). Therefore, they are a motivation for automakers to move forward with cost-intensive technology (low volume, high investments) to reach full market economic viability. Multipliers are a key issue because significant market penetration of electric vehicles is needed for compliance with the proposed standards. The mid-term evaluation should also reassess the further need of multipliers, based on the current market penetration of electric vehicles. BMW is supportive of the proposed multipliers and recommends the inclusion of BEVx with a pro-rated multiplier in line with the recent CARB proposal. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 3]

Projections by US authorities for overall standard achievement and projections for each OEM are all based on the assumption of a 0g/mi upstream approach. It is fundamentally unfair to punish the auto industry for power plant decisions made decades ago. Further, public utility commissions do not consider electric vehicles when they make decisions. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 4]

The proposed cap for MYs 2022-25 may serve to slow the U.S. market penetration of electric vehicles as described below:

• Situation 1: A significant market penetration of E-mobility is needed for compliance with the proposed standards through MY2025 (i.e., industry must undertake extensive efforts). If E-mobility does not develop as expected today or as projected in the joint draft Technical Support Document (TSD), automakers will need to compensate the missing E-mobility contribution through the introduction/penetration of additional cost-intensive advanced technologies, thereby creating a disadvantage for automakers. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 4]

• Situation 2: If E-Mobility shows a higher success than assumed, then industry will be punished for their efforts by inclusion of upstream emissions but without a corresponding correction of the standards. This increases the stringency of the standards, again disadvantaging automakers. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 4]

• Result: The inclusion of upstream emissions, even with the proposed exemption for MYs 2022-25, creates a strong disincentive for future E-mobility activities from automakers. Automakers do not control the electric power grid mix and have absolutely no ability to influence upstream emissions. Therefore, 0g/mi upstream emissions should be set for electric vehicles without caps or other conditions for the duration of the rule and beyond. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 4]

However, if the proposed cap for MYs 2022-25 is retained, BMW recommends the adoption of the following for the treatment of upstream emissions when the cap is exceeded:

• Manufacturers are responsible for vehicle energy consumption only.

• Therefore, the regulation of energy efficiency should be taken into account by converting the electric energy consumed during the cycle into fuel efficiency- or CO_2- equivalent by means of a MJ based conversion from electricity to gasoline CO_2 content. [EPA-HQ-OAR-2010-0799-9579-A1, enclosure p. 5]

Organization: Borg Warner, Inc.

In reviewing the proposal we are concerned that the rules contain a lot of language and incentives to steer the technologies used to achieve the goals. We feel the rules should focus solely on setting the standards and let the marketplace decide which technologies are best to meet the consumer needs. [EPA-HQ-OAR-2010-0799-9320-A1, p. 1]

The inclusion of performance based credits offered for any vehicle that achieves a rating above the standard is the right approach and we commend the EPA and NHTSA for this. However, we see no need to also offer credits based on simply using a certain technology regardless of its credits for incorporating a technology regardless of the contribution that technology has made in improving CO_2 performance, and plug-in electric, plug-in hybrid electric and fuel cell vehicles that are rated at 0 g/mi CO_2 and also receive an inflationary multiplier to vehicle volumes when calculating corporate averages. In today's atmosphere of limited capital this approach to drive a certain technology mix could also impede the development and market introduction of more conventional, cost-effective solutions that utilize existing infrastructure in large volumes resulting in better real-world results. All technologies need to be on equal ground and evaluated/incentivized based on their real-world performance. [EPA-HQ-OAR-2010-0799-9320-A1, pp. 1-2]

Organization: Center for Biological Diversity

1. The electric vehicle credits must be removed

The Center supports the development of all forms of non-fossil-fuel based vehicles, including electric vehicles (EVs), battery electric vehicles (BEVs), fuel cell electric vehicles (FCEVs) and plug-in hybrid electric vehicles (PHEVs). Although these vehicles are likely to have tremendous advantages in the form of energy conservation and greenhouse gas emissions reductions over conventional vehicles and play a critical role in weaning the transportation sector off fossil fuel use, those benefits can be lost if manufacturers are given credits for them that exceed the actual improvements they bring. In addition, credits lead to lower fuel efficiency standards overall if used to evade other efficiency technologies that would otherwise be installed. [EPA-HQ-OAR-2010-0799-9479-A1, p. 21]

For this reason, it is imperative that the Agencies complete full life-cycle analyses of the greenhouse gas emissions of each of these vehicles, accurately account for them in the overall vehicle fleet, and limit credits for these vehicles based only on actual emission reductions they achieve. We also believe the two “bonus credits” the NPRM envisions for EVs are inappropriate.100 These credits are (1) a default greenhouse gas compliance value of zero g/mi for BEVs, FCEVs and PHEVs, and (2) a multiplier system that lets manufactures count each EV as more than one vehicle in the earlier years of the rulemaking. [EPA-HQ-OAR-2010-0799-9479-A1, p. 21]

While we believe that credits may have provided a valuable incentive for electric vehicles during the 2012-2016 rulemaking to encourage this relatively new technology, such concerns are now misplaced. The 2017-2025 rulemaking years no longer constitute a start-up period for these vehicles. Allowing their lifecycle greenhouse gases to be ignored may well lead to substantial unintended consequences, encouraging forms of technologies that actual do not reduce greenhouse gases to the extent envisioned. Only full, transparent, and accurate accounting can guard against this clear possibility, including full modeling of regional variations in grid electricity carbon intensity. As pointed out by ICCT, the use of multipliers and windfall credits for vehicles required under the California ZEV mandate is particularly problematic and should be eliminated, and we incorporate ICCT’s comment on this subject here by reference. 101 ICCT calculates that these two forms of credit would eliminate the reduction of 80 to 110 million metric tons of greenhouse gases from the MY 2017-2025 rulemaking period.102 This is clearly contrary to the statutes’ intent, and we urge the Agencies to remove these credits from the final rulemaking. [EPA-HQ-OAR-2010-0799-9479-A1, p. 21]

100 We agree with the Agencies’ assessment that the credits for electric vehicles already included in 49 U.S.C. § 32904(a)(2)(B) precludes additional incentives beyond those already provided for by Congress. NPRM, 76 Fed. Reg. 74878 n.56. [EPA-HQ-OAR-2010-0799-9479-A1, p. 21]

101 ICCT Comments at 29-34. [EPA-HQ-OAR-2010-0799-9479-A1, p. 21]

102 Id. [EPA-HQ-OAR-2010-0799-9479-A1, p. 21]

Organization: Center for Sustainable Systems, University of Michigan

We recognize that electrified vehicles, including battery electrics (EVs), and plug-in hybrids (PHEVs), have the potential to reduce GHG emissions from the light-duty vehicle fleet. In low carbon grid scenarios electrified vehicles have been shown to have a lower emissions profile than conventional gasoline and diesel powered vehicles (CVs).[1] However, the GHG emissions attributable to electrified vehicles charged on the current U.S. electric grid, are significant.[2] The proposed 2017-2025 GHG emission standards neglect to count these important upstream sources. This may result in unintended consequence by incentivizing electrified vehicles which may be charged in regional grids of high carbon intensity. Vehicles charged in these grids may do little to reduce the total new vehicle fleet GHG emissions, without a significant change in the electric grid. [EPA-HQ-OAR-2010-0799-9493-A1, p.1]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 190-191.]

in particular the incentives for electric vehicles, plug-in electrics and fuel cell vehicles.

As I stated earlier, support for these emerging technologies is critical if we are to maintain U.S. leadership and encourage new manufacturing opportunities here at home. We do agree, however, that the incentives should be phased out over time so the full emissions of these vehicles can be accounted for. We, therefore, support the decrease in the incentive multiplier and the proposed manufacturer caps on the 0-gram per mile value for upstream emissions.

Organization: EcoMotors International, Inc.

II. Proposed Incentives for EVs, PHEVs, and FCVs

In developing the proposed standards, the agencies have considered and accounted for a wide range of technologies which they believe are, or will be available for manufacturers to reduce GHG emissions and improve fuel economy. These technologies specifically include advances in gasoline engines and transmissions - technology already familiar to, and accepted by the vast majority of consumers. However, in the Proposed Rule the agencies have chosen to limit valuable industry incentives for meeting these standards to a small, select group of vehicles. [EPA-HQ-OAR-2010-0799-9594-A2, p. 3]

While we agree that including credit mechanisms in the National Program is necessary and appropriate, such provisions should not undercut the primary objectives of the program, namely achieving significant reductions of GHG emissions and improving fuel economy in the light vehicle fleet. Favoring a handful of vehicle technologies over other competing technologies with equal or better performance is counter to the intent of the Proposed Rule. EcoMotors urges EPA and NHTSA to adopt a significantly more technology-neutral and attribute-based program that provides greater opportunities and incentives for OEMs to take advantage of a broader range of technologies to meet federal standards. [EPA-HQ-OAR-2010-0799-9594-A2, p. 4]

A. EPA's Proposed Multiplier Incentive for EVs, FCVs and PHEVs

In order to encourage commercialization of EVs, FCVs and PHEVs, EPA is proposing an incentive multiplier for all EVs, PHEVs, and FCVs sold in MYs 2017-2021. Each EV/PHEV/FCV would 'count' as more than one vehicle in a manufacturer's compliance calculation. EPA is also considering providing similar multiplier incentives to dedicated and/or dual fuel compressed natural gas vehicles. [EPA-HQ-OAR-2010-0799-9594-A2, p. 4]

EcoMotors endorses EPA's institution of temporary regulatory incentives that will promote commercialization of game-changing advanced vehicle technologies. However, as drafted, the regulations would result in OEMs and consumers being force-fed a select group of costly vehicles at the expense of technology neutrality. Other less-costly and equally energy efficient and environmentally beneficial vehicle technologies - available today - should be afforded equally beneficial regulatory incentives. [EPA-HQ-OAR-2010-0799-9594-A2, p. 4]

EPA has been very candid about the significant consumer barriers facing EVs, FCVs and PHEVs in the Proposed Rule. While it 'remains optimistic' about consumer acceptance of these vehicles in the long run, it acknowledges that it is 'less certain' about their near-term market acceptance. The unease expressed by the agency is not unfounded. A 2010 study by J.D. Power and Associates concluded that the significant obstacles faced by hybrid electric vehicles and battery electric vehicles make it unlikely that global demand for these vehicles will reach the levels predicted for the industry. The study determined that sales of these advanced vehicles are expected to account for only slightly more than 2.2% of global passenger-vehicle sales in 2010, and will only account for 7.3% of global passenger-vehicle sales in 2020.6 [EPA-HQ-OAR-2010-0799-9594-A2, p. 4]

The Proposed Rule, if implemented, will clearly diminish the incentive for automotive manufacturers to invest in a range of other technologies that can dramatically reduce GHG emissions and improve fuel economy. Yet, as the Boston Consulting Group recently noted, '[a]dvanced ICE technologies [which include gasoline- or diesel-based direct injection, reduction of engine displacement by turbocharging and reduction of internal engine resistance] will be the most cost-effective way to reduce CO_2 emissions on a broad scale.' 7 Near-term development and commercialization of advanced ICE technologies, such as the opoc engine and other advanced vehicle technologies, remains an extremely important path for emissions reduction and fuel economy improvements and should be encouraged by national policy, particularly considering the challenges that must still be overcome for widespread market acceptance of EVs, FCVs and PHEVs. [EPA-HQ-OAR-2010-0799-9594-A2, p. 5]

Other hybrids, such as hydraulic hybrids, should also be targeted for regulatory incentives. Certainly EPA's partnership with the Chrysler Group, LLC to apply EPA's hydraulic hybrid technology to LDVs is a clear indication that EPA is very optimistic about the GHG and fuel economy benefits of this cutting-edge technology. The Final Rule should include language broad enough to encompass, and grant incentives to hydraulic hybrid vehicles, as well as all mechanical hybrids. [EPA-HQ-OAR-2010-0799-9594-A2, p. 6]

- Specific Recommendation: EcoMotors strongly encourages EPA to extend comparable EV/PHEV/FCV multiplier incentives to OEMs that manufacture mechanical hybrid vehicles, hydraulic hybrid vehicles, and similar advanced technology hybrid vehicles during MYs 20172021. This would place other significant, game-changing vehicle technologies -like the dual-module opoc engine - on a level playing field with EVs, PHEVs and FCVs, and continue to encourage innovation in our struggling auto industry. EcoMotors stands ready to assist the agencies in crafting appropriate language to embrace a range of advanced technology hybrid vehicles. [EPA-HQ-OAR-2010-0799-9594-A2, p. 7]

EPA is proposing a 0g/mile tailpipe compliance value for all EVs, PHEVs (electricity usage) and FCVs in MYs 2017-2021. In MYs 2022-2025, 0g/mi would only be allowed up to a per-company cumulative sales cap, established on a tiered basis. EPA proposes to phase-in the change in compliance value, from 0g/mile to a net upstream accounting, for any manufacturer that exceeds its cumulative production cap for EV/PHEV/FCVs. Not until MY 2022 would the compliance value for EVs, FCVs, and the electric portion of PHEVs in excess of individual automaker cumulative production caps begin to be calculated according to a methodology that accounts for the full net increase in upstream GHG emissions relative to that of a comparable gasoline vehicle. [EPA-HQ-OAR-2010-0799-9594-A2, p. 9]

The EPA proposal to specify 0g/mile for these vehicles' tailpipe emissions continues to completely ignore the fact that electric vehicles draw some or all of their fuel from the grid which is not GHG free.13 Yet EPA has repeatedly acknowledged that 'the upstream GHG emissions associated with production and distribution of electricity are higher than the corresponding upstream GHG emissions of gasoline or other petroleum based fuels.” The Proposed Rule even notes that 'today's Nissan Leaf EV would have an upstream GHG emissions value of 161 grams per mile based on national average electricity, and a value of 89 grams per mile based on the average electricity in California, one of the initial markets for the Leaf.' Other significant studies, such as the National Academy of Sciences' report, 'Hidden Costs of Energy-Unpriced Consequences of Energy Production and Use,' have also recently drawn attention to the hidden life-cycle costs associated with electric vehicles - including those associated with energy- and material-intensive battery and electric motor production. [EPA-HQ-OAR-2010-0799-9594-A2, p. 9]

An accurate assessment of the environmental benefits of fuel/propulsion system options requires a complete 'well-to-wheels' analysis. The CO_2 value for these vehicles should be based on a sound scientific approach. [EPA-HQ-OAR-2010-0799-9594-A2, p. 10]

The impacts on GHGs and other pollutant emissions from electric vehicles are significant and should be quantified by EPA to the extent possible for purposes of this rulemaking. The emissions associated with EVs, PHEVs and FCVs should not be ignored for several more years. Commencing with MY 2017, EPA should set aside all incentives that falsely suggest that there are no environmental repercussions associated with the use of these vehicles. Furthermore, when combined with the incentive multipliers proposed for EVs, PHEVs and FCVs (discussed above), allocating a 0g/mile emissions value to these vehicles is clearly excessive. EPA is promoting these vehicles well beyond their environmental merits. This is inherently inequitable to other less-costly and even more environmentally-beneficial vehicle technologies available today -like EcoMotors' opoc MDH engine. [EPA-HQ-OAR-2010-0799-9594-A2, p. 11]

- Specific Recommendation: EcoMotors encourages EPA to drop the 0g/mile tailpipe compliance value for EVs, PHEVs (electricity usage) and FCVs and to calculate and include the full 'well-to-wheels' upstream emissions from fuel production and distribution in their CO_2 emissions commencing in MY2017 in order to achieve equity across different vehicle technologies. [EPA-HQ-OAR-2010-0799-9594-A2, p. 11]

---

6 J.D. Power and Associates, 'Drive Green 2020: More Hope than Reality?' (November 2010). The MIT Electric Vehicle Team has identified significant limitations for electric vehicles in each of the following areas: energy and power density, battery charging, lifetime performance, and system costs, and recently cautioned: Existing internal combustion powertrains are remarkable in that they provide excellent performance... We can drive our cars for more than 300 miles, fill lip anywhere in 5 minutes. When treated well, these vehicles can last a decade and travel hundreds of thousands of miles before they finally fall apart. This sets quite a high bar for the new EV market entrants. Power and Associates, supro, p. 68 ('[I)n order to safeguard the environment today, it will remain important to pursue continuous improvements in ICEs and allow time to map out the future.')

13 EcoMotors commends the agency for attempting to fully account for the upstream GHG emissions associated with all electricity used by EVs and PHEVs (and any hydrogen used by FCVs) in its regulatory projections of the impacts and benefits of the program, and in all GHG emissions inventory accounting.

Organization: Edison Electric Institute (EEI)

More than most other technologies or policy options, EVs offer the U.S. the capability to substantially reduce, if not end, its dependence on petroleum fuels. EEI’s comments focus on EPA’s regulatory incentives to foster widespread commercial deployment of EVs. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 1-2]

I. Executive Summary

Electric vehicles "have significant transportation GHG emissions and oil consumption gamechanging potential in the long-run." Increased deployment of EVs will increase fuel efficiency and reduce dependence on petroleum. Increased EV deployment also will reduce emissions of GHGs and criteria air pollutants from the transportation sector. These environmental benefits will be compounded by the continued reductions in emissions of both GHGs and criteria air pollutants related to the generation of the electricity that will fuel EVs. [EPA-HQ-OAR-2010-0799-9584-A2, p. 2]

EEI supports the decision to use 0.0 g/mile for the EV (and PHEV in all-electric mode) compliance value for MY 2017-2021 and to provide a multiplier for manufacturers who produce these zero-emitting vehicles. EPA should not "discount" EV incentives for MY 2022-2025 to reflect specific upstream GHG emissions related to electricity production. If EPA decides to discount EV incentives in the later years of the proposal, the Agency should not calculate an upstream electricity GHG emissions factor today for standards that will not take effect for nearly 10 years. Given the limits of EPA's modeling and uncertainties about the fuel and emissions profile of electric generation in 10 years, there is no way that any emissions factor for MY 2022 calculated today would bear a reasonable relationship to actual future emissions. [EPA-HQ-OAR-2010-0799-9584-A2, p. 2]

Moreover, EPA's proposed approach to assessing upstream GHG emissions in the power sector is inappropriate, unfair and based on incorrect data and assumptions. By focusing only on upstream electricity GHG emissions and not upstream emissions related to other fuels, EPA is not fairly comparing the overall well-to-wheels emissions of EVs with those of conventional vehicles. When compared on a well-to-wheels basis, EVs have lower emissions than conventional vehicles. If EPA continues to focus on upstream electricity GHG emissions, the Agency's analysis must be based on the most accurate and timely information about the makeup of the electric generating fleet and must consider regional variation in generation portfolios, particularly in those areas that are likely to be earlier adopters of this important technology. If EPA does not revise this approach, the Agency will continue to overestimate EV emissions as compared to emissions from conventional fuels, underestimating the environmental, economic and energy security benefits of EVs are realized. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 2-3]

II. EPA and NHTSA Should Incentivize the Production of All Types of Electric Vehicles for All Model Years Covered by the Proposed Rule.

EEI applauds EPA's determination that incentives are needed to ensure the commercial success of electric vehicles because they "have significant transportation GHG emissions and oil consumption game-changing potential in the long-run." 75 Fed. Reg. at 75011. Increased deployment of EVs will increase fuel efficiency and reduce dependence on petroleum, consistent with the goals of the Energy Independence and Security Act of 2007. Increased EV deployment also will reduce emissions of GHGs and criteria air pollutants from the transportation sector. These environmental benefits will be compounded by the continued reductions in upstream emissions of both GHGs and criteria air pollutants related to the generation of the electricity that will fuel EVs. See upstream emissions discussion in section III, infra. [EPA-HQ-OAR-2010-0799-9584-A2, p. 3]

At present, as EPA notes in the proposed rule, the missing link between the potential environmental and energy independence benefits of EVs and achieving these benefits is the widespread deployment of this new technology. See 76 Fed. Reg. at 75011. EPA's proposed incentives for EVs will help forge this link. EEI supports providing EV incentives in the context of CAFE and GHG vehicle standards, as discussed below. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 3-4]

A. EPA Should Finalize the EV Incentives for MY 2017-2021 as Proposed.

EPA proposes different incentives for the different types of electric vehicles and for different time periods covered by the MY 2017-2025 standards. For MY 2017-2021, EPA proposes two incentives: 1) allowing EVs, including PHEVs in all-electric mode, to use emissions of 0.0 g/mile for compliance purposes; and 2) providing a multiplier that allows EVs to "count" as more than one vehicle in a manufacturer's compliance calculation. The proposed multiplier for PHEVs is discounted, presumably to reflect operations not in all-electric mode. 76 Fed. Reg. at 75012. [EPA-HQ-OAR-2010-0799-9584-A2, p. 4]

EPA considers counting EV emissions (and PHEV emissions when operating all-electric mode) as 0.0 g/mile an "incentive" because of concerns related to the upstream GHG emissions associated with electricity production. See upstream emissions discussion, section III, infra. While EEI appreciates EPA's efforts to foster increased EV manufacturing and deployment, it must be emphasized that this is not an "incentive" but a recognition of actual EV emissions, which are 0.0 g/mile when measured at the tailpipe, the proper point at which to measure compliance with vehicle emissions standards. [EPA-HQ-OAR-2010-0799-9584-A2, p. 4]

Nonetheless, these MY 2017-2021 incentives represent a welcome improvement and departure from EPA's more limited approach to EV incentives for MY 2012-2016, which placed a production cap on the number of vehicles for which manufacturers could use 0.0 g/mile for compliance purposes and provided no multipliers. See 75 Fed. Reg. 25324 (May 7, 2010). EEI supports the broader "incentives" for MY 2017-2021 proposed by EPA as tools necessary to encourage the increased manufacture and ultimate deployment of EVs and PHEVs. EPA should finalize these incentives as proposed. [EPA-HQ-OAR-2010-0799-9584-A2, p. 5]

B. EPA's Approach to Incentives for MYs 2022-2025 Is Fundamentally and Technically Flawed and EPA Should Wait to Finalize These Incentives.

For MY 2022-2025, EPA proposes only one "incentive" for EVs: Manufacturers can use 0.0 g/mile for EVs (and PHEVs in all-electric mode) when calculating compliance averages, but this is limited by a manufacturer-specific production cap. The production cap is tiered to provide greater incentives to those manufacturers that invest in EV technologies earlier. See 76 Fed. Reg. at 75013. EPA states that the production cap also is necessary as a way to limit "the overall decrease in program GHG emissions reductions associated with the incentives." Id. [EPA-HQ-OAR-2010-0799-9584-A2, p. 5]

In the alternative, EPA is considering an industry-wide production cap to provide greater certainty as to the number of EVs deployed and the overall impact on GHG emissions. See id. EPA suggests that a 2-million vehicle cap would limit the "maximum decrease in GHG emissions reduction to about 5 percent of total program GHG savings." Id. EPA would allocate the cap to individual automakers in calendar 2022 based on cumulative EV/PHEV/FCV sales in MYs 2019-2021. Id. [EPA-HQ-OAR-2010-0799-9584-A2, p. 5]

For vehicle production that exceeds the cap, EPA proposes that compliance values for EVs and PHEVs be "calculated according to a methodology that accounts for the full net increase in upstream emissions relative to that of a comparable gasoline vehicle." Id. EPA proposes a methodology for making this calculation, based on estimated future projections of upstream GHG emissions associated with the grid electricity used to charge EVs and PHEVs. See id. at 75014. [EPA-HQ-OAR-2010-0799-9584-A2, p. 6]

In order to discount the incentive for any sales above the manufacturer-specific (or industrywide) cap for MY 2022-2025, EPA proposes a four-step methodology, which would require, among other things, measuring EV electricity consumption in Watt-hours/mile and then multiplying this figure by an already pre-determined 2025 nationwide estimated average electricity upstream GHG emissions rate of 0.574 grams/Watt-hour. See 76 Fed. Reg. 75014. EPA would use a similar approach for PHEVs. See id. [EPA-HQ-OAR-2010-0799-9584-A2, p. 6]

EEI opposes the use of any upstream GHG emissions factor. EV tailpipe emissions are 0.0 g/mile, and this is the value that should be used for compliance purposes for all time periods covered by the proposed vehicle standards. EPA should not "discount" this compliance value to reflect upstream GHG emissions related to electricity production. After all, EPA does not calculate any value for upstream emissions rates for conventionally-fueled vehicles.3 [EPA-HQ-OAR-2010-0799-9584-A2, p. 6]

In addition to EEI's general objection to estimating any discount factor based on upstream electricity GHG emissions, there are several issues with EPA's proposed approach to estimating an appropriate discount factor. If EPA persists in using a discount factor, the Agency must address these issues. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 6-7]

First, it is inappropriate for EPA, now in 2012, to calculate any upstream electricity GHG emissions rate for 2025, as there is no way that this value could reasonably approximate actual electric generating unit (EGU) emissions 13 years in the future. The current version of EPA's Integrated Planning Model (IPM), which is used to generate electricity generation emissions data, relies on certain assumptions about the current national electric generating unit (EGU) fleet and incorporates some, but not all, regulations affecting EGUs in the near term. The version of IPM used for the proposed vehicle standards does not, for example, include EPA's recently promulgated hazardous air pollutant regulations, nor does it include any regulations that are not currently on the books, but expected to be final and effective well before MY 2025. These include GHG new source performance standards (NSPS) for both new and existing EGUs, new effluent guidelines for EGUs, new regulations for EGU cooling water intake structures and new regulations affecting the disposal of coal combustion residuals. These regulations will dramatically change the makeup of the current EGU fleet, as many coal-based units will retire rather than incur the substantial costs associated with air, water and solid waste pollution control retrofits. If these units are replaced by those using renewable fuels, or even natural gas, their GHG emissions will be much lower than those of existing units. Because no one knows how many units will be retired and replaced by cleaner fuels, it is impossible for the 2012 version of IPM to predict with any accuracy an upstream electricity GHG emissions rate for 2025. [EPA-HQ-OAR-2010-0799-9584-A2, p. 7]

EPA notes that it is considering running IPM with "more robust" vehicle and vehicle charging specific assumptions to generate a "better" electricity upstream emissions factor for the final rule. Id. Unless EPA dramatically changes its assumptions about the makeup of the generating fleet in 2025 to better reflect current and expected regulations, any additional IPM runs – even those using updated vehicle and charging assumptions – will be equally unable to provide an upstream electricity GHG emissions rate that has any relationship to actual emissions in 2025. If EPA does decide to conduct additional IPM runs for the final rule, the Agency must do more than update vehicle and charging assumptions, and any and all changes in the assumptions must be subject to notice and comment. A discussion of appropriate assumptions related to EV upstream emissions is included in section III, infra. [EPA-HQ-OAR-2010-0799-9584-A2, p. 8]

If EPA persists in using an upstream electricity GHG emissions rate, there is no regulatory purpose served by calculating a 2025 rate that is, on its face, inaccurate now. The Agency would be better served by waiting until MY 2021 to estimate upstream GHG electricity emissions, using actual emissions data and the most up-to-date information about the EGU generating fleet. EPA easily could conduct this analysis concurrently with the planned midterm evaluation of the vehicle standards necessary to support NHTSA's required, separate rulemaking to establish CAFE standards for MY 2022-2025. See 76 Fed. Reg. at 74879. [EPA-HQ-OAR-2010-0799-9584-A2, p. 8]

III. EPA's Approach To Upstream EV Emissions Related To Electricity Generation Is Flawed And Must Be Revised.

The tailpipe emissions of EVs (and PHEVs operating in an all-electric mode) are 0.0 g/mile, for both GHG emissions and criteria air pollutant emissions. Despite this, EPA asserts that it must consider the upstream GHG emissions related to the grid electricity and that these upstream emissions are higher than those associated with the production and distribution of gasoline. See 76 Fed. Reg. at 75010. [EPA-HQ-OAR-2010-0799-9584-A2, p. 9]

Upstream GHG emissions related to electricity production are only part of the analysis, however, and by focusing on upstream emissions only for EVs, EPA underestimates the overall environmental benefits of EVs. Upstream electricity GHG emissions are only relevant to the extent that EPA considers all upstream emissions from all fuels, which EPA does not do. When compared on a well (EGU)-to-tailpipe basis, EV GHG emissions are less than those of conventional vehicles. [EPA-HQ-OAR-2010-0799-9584-A2, p. 10]

Contrary to EPA's assertions, expanded introduction of EVs into all classes and categories of vehicles will serve to reduce GHG emissions significantly from the transportation sector, not dilute vehicle emissions standards, as EPA asserts. See Electric Power Research Institute (EPRI)-

National Resourced Defense Council, Joint Technical Report, Environmental Assessment of Plug-in Hybrid Electric Vehicles, Vol. 1: Nationwide Greenhouse Gas Emissions.6 In the Draft Environmental Impact Statement (EIS) (at 6-22), NHTSA concludes that the literature review reveals an overarching conclusion about the GHG emissions from EVs compared to conventional vehicle: "[E]ven in modeled scenarios in which EVs charge from a carbonintensive grid mix (i.e., electricity generated mostly from coal power plants), the vehicle lifecycle emissions from EVs are less than conventional gasoline vehicles." [EPA-HQ-OAR-2010-0799-9584-A2, p. 10]

Even if EPA were to compare the overall emissions of conventional vehicles and EVs fairly, EPA first would have to revise its assessment of EV emissions. EPA's current approach to EV emissions is unfair, inappropriate, and based on flawed data and assumptions. If EPA believes that upstream emissions must be discussed in the context of vehicle standards and decides to consider all emissions from all fuels, EPA must revise the final rule to provide a full and accurate discussion that leads to a fair comparison of the upstream emissions for all vehicle fuels and recognizes the environmental benefits of EV deployment. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 10-11]

A. EPA Has Failed To Consider the Transition of the Generating Fleet in Response to Environmental Regulations.

For many reasons, the U.S. electric generating fleet in MY 2025 will be significantly cleaner than the fleet of 2012: [EPA-HQ-OAR-2010-0799-9584-A2, p. 11]

Increased regulation of criteria air pollutant emissions, via more stringent standards under the CAA to address national ambient air quality standards for sulfur dioxide, nitrogen oxides, particulate matter; new hazardous air pollutant regulations addressing mercury, acid gases, non-mercury metals and other pollutants; new standards to address the interstate transport of air pollution; and more stringent standards to address ozone and opacity.

Regulation of GHG emissions from new sources and the existing fleet under two separate

CAA programs, NSPS and the new source review/prevention of significant deterioration pre-construction permitting programs.

Regulation of coal combustion residuals.

More stringent effluent guidelines and cooling water intake structure regulations.

Increased deployment of high-efficiency natural gas combined cycle units to provide additional generating capacity and replace retired coal units.

Increased deployment of renewable generation to comply with state renewable portfolio standard (RPS) or renewable electricity standard (RES) requirements. [EPA-HQ-OAR-2010-0799-9584-A2, p. 11]

These trends towards increasingly clean generation are evident in the recent projections from the Energy Information Administration (EIA) in its Annual Energy Outlook 2011. In EIA's Reference Case, average emissions intensity, per unit of electricity generated, for the U.S. electric power sector is projected to fall between 2010 and 2020 by 40.4 percent for sulfur dioxide, 26.5 percent for nitrous oxide, 36.9 percent for mercury and 7.9 percent for carbon dioxide.7 And because EIA's Reference Case generally assumes that current laws and regulations remain unchanged throughout the projections, these calculated improvements would likely be greater if EIA took into consideration all of the air quality rules that have been finalized in recent years and are expected to be finalized in the next several years, as well as clean energy technology improvements and cost reduction. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 11-12]

EPA also states that it is appropriate to consider upstream EV emissions because currently there is no national, comprehensive program addressing GHG emissions from the electric sector. See 75 Fed. Reg. at 75010, 75011. EPA's focus on the existence of a "current" national regulatory program addressing GHGs related to electricity production and distribution is not appropriate in the context of vehicle rules covering MY 2017-2025. But, there are no comprehensive GHG emissions control programs for any fuel sector today. [EPA-HQ-OAR-2010-0799-9584-A2, p. 12]

Moreover, it appears that the electric sector will become subject to GHG regulations sooner than other fuel sectors. Under the terms of a settlement agreement signed in late 2010, EPA is in the process of designing proposed GHG NSPS for all fossil fuel-based EGUs. These standards will apply to new units and major modifications, as well as the existing fleet. While EPA has missed the original deadline for proposing the GHG NSPS, at least the new and modified source parts of the rule are expected to be released imminently. The entire GHG NSPS program is expected to be in place within the next few years, well before the MY 2017 standards take effect. In the proposed rule, EPA fails to acknowledge these standards and their effect on electricity generation during the time period covered by the proposed MY 2017-2025 standards. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 12-13]

B. Unless EPA Considers the Upstream Emissions Related to Other Fuels, EPA Cannot Purport to Compare EV and Conventional Vehicles.

Moreover, EPA asserts that the "overall GHG emissions" associated with the generation and distribution of electricity are higher than the upstream emissions associated with the production and distribution of gasoline. See 75 Fed. Reg. at 75010, 75011. Not only is this statement unsupported by any facts or analysis, but it difficult to see how EPA can make such a comparison when the Agency has failed to include, by its own admission, an examination of the overall GHG emissions related to the production and distribution of other transportation fuels. In the proposed rule, the Agency acknowledges that 20 percent of the GHG emissions from traditional fuel vehicles are related to upstream fuel production and distribution, see id., but provides no evidence that these emissions were considered when making comparative statements about the upstream emissions for EVs. This undermines EPA's determination that considering upstream GHG emissions related to electric vehicles is appropriate because of the "higher" upstream GHG emissions associated with electricity production and distribution. See id. EPA cannot compare upstream emissions of the various vehicle fuels unless that comparison is a fair comparison – and EPA has acknowledged that it is not. At minimum, if EPA is going to consider upstream emissions, the Agency should not make broad statements purporting to compare the "overall GHG emissions" related to electricity with the "overall GHG emissions" of other fuels unless and until the Agency's analysis includes upstream emissions related to conventional fuels. [EPA-HQ-OAR-2010-0799-9584-A2, p. 13]

C. EPA Does Not Use Recent Electricity Emissions Data and Has Failed to Consider Regional Variation in Electricity Generation and Likely EV Charging Timing Patterns.

Even if EPA were to conduct a fair comparison of the upstream GHG emissions between EVs and conventional vehicles, EPA first would have to revise significantly how the Agency estimates upstream emissions related to electricity generation. EPA's assumptions about the upstream emissions related to the grid electricity that will be used to charge MY 2017-2025 are based on outdated and incomplete electricity generation data; do not address regional variability in the generating fleet or likely EV charging patterns; and do not take into consideration the expected composition of the electric generating fleet during the periods covered by the proposed standards. Unless and until EPA revises these assumptions, any comparison between the upstream emissions of EVs and conventional vehicles is fundamentally flawed and cannot serve as the basis for reasonable regulatory action. [EPA-HQ-OAR-2010-0799-9584-A2, p. 14]

First, EPA has used outdated data to support its assessment of the upstream GHG emissions related to EVs. EPA used eGRID2007 emissions factors, which contains electric generation emissions data from calendar year 2005. See 76 Fed. Reg. at 75012. Using 2005 data quite clearly skewed the national average electricity upstream GHG emissions rate that EPA calculated for comparative purposes. For example, according to EIA, total carbon dioxide emissions from electric generation were 8.6 percent lower in 2009 compared to 2008 (and declined by nearly 10.8 percent between 2005 and 2009).8 [EPA-HQ-OAR-2010-0799-9584-A2, p. 14]

But even if EPA used 2011 emissions data, the more current data have no bearing on the GHG emissions from electricity production in MY 2017 and beyond. As noted, the electric generation in the U.S. has and will continue to become cleaner over time. This results from many factors, including renewable energy policies enacted by many states, more stringent EPA regulation, and even the low cost of natural gas, which has been displacing coal in many markets. EPA's analysis fails to recognize these changes in the electric generation fleet. At a minimum, EPA should wait until the Agency can more reasonably obtain data for the period covered by the vehicle standards, considering all environmental requirements that will be in effect, as well as fuel generation patterns, as discussed above. [EPA-HQ-OAR-2010-0799-9584-A2, p. 15]

Second, EPA's creation and use of a national average electricity upstream GHG emissions rate fails to account for significant regional differences in electricity generation. Emissions associated with the generation of electricity vary significantly from utility to utility—with nuclear, wind, solar, geothermal and hydroelectric power sources emitting extremely low or no GHGs or criteria air pollutants. Any meaningful estimates of upstream emissions associated with electricity as a transportation fuel would need to be tailored not only to reflect regional variations in current electricity baseload (and peak load) generation and expectations for marginal electricity generation mix, but also developments in usage and recharging of the vehicle (as more "smart meters" and "smart chargers" are installed), as well as state and federal electric generation policies (such as state RPS and RES requirements)9 and state and regional/federal GHG emissions limits and reductions programs (e.g., California's A.B. 32, the New England Regional Greenhouse Gas Initiative and the federal CAA). [EPA-HQ-OAR-2010-0799-9584-A2, pp. 15-16]

In the proposed rule, EPA acknowledges that there is "significant regional variation with upstream GHG emissions associated with electricity production and distribution." See 76 Fed. Reg. at 75010 n.280. Accordingly, given this recognition, it is unreasonable for EPA to continue to use a nationwide average emissions rate. Any analysis of upstream electricity GHG emissions methodology for estimating upstream emissions rates must take the significant orders of magnitude of regional variability into account. [EPA-HQ-OAR-2010-0799-9584-A2, p. 16]

Regional variations in generating resources must be considered, especially with respect to the areas of the country with the highest expected near-term EV deployment rates. For example, California's average upstream GHG electricity emissions rate is significantly lower than that of other parts of the country, as EPA recognizes in the proposed rule. See 76 Fed. Reg. at 75011. California also is expected to have one of the highest rates of EV adoption.10 In 2011, California residents purchased more than 60 percent of the Nissan Leafs and about 30 percent of the Chevrolet Volts sold in the U.S.11 California also recently adopted aggressive regulations that are intended to put 1.4 million EVs, PHEVs and hydrogen vehicles on the state's roads by 2025.12 As a result, any analysis that uses national average upstream electricity GHG emissions to estimate the environmental impacts of early EV deployment is, by definition, overestimating these emissions. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 16-17]

A recent graphic from the California Air Resources Board (CARB) report demonstrates the superior emissions benefits of EVs and PHEVs in California.13 [See figure on p. 17 of Docket number EPA-HQ-OAR-2010-0799-9584-A2.] [EPA-HQ-OAR-2010-0799-9584-A2, p. 17]

In addition, using nationwide average upstream GHG emissions would be inconsistent with previous Agency action to address fuel economy labels for LDVs. In that rulemaking, EPA concluded that "[d]ue to different electric generation fuels and technologies, this level of [regional generation] variation is significant; from one region to another, the highest-to-lowest upstream average GHG emission ratios are roughly 3-to-1. If examined from a utility-by-utility perspective, the ratio is even greater, at 75-to-1. For a national label to present a single national average would be misleading and inaccurate given such a wide range." Revisions and Additions to Motor Vehicle Fuel Economy Labels, 76 Fed. Reg. 39478, 39493 (July 6, 2011). [EPA-HQ-OAR-2010-0799-9584-A2, p. 18]

Finally, EPA must also take into consideration the effects on upstream emissions rates of expected EV charging patterns. EV charging is likely to take place at night,14 when overall national GHG emissions related to electricity generation are lower because most wind power is generated at night15 and because baseload nuclear generating units do not cycle and are always operating.16 Electric utilities also are incenting night EV charging through time-of-day electricity rates and separate EV rates, which are significantly lower at night when overall electricity demand is lower. In addition, increased installation and use of smart meters in the coming years, funded in large measure with stimulus funds administered by DOE, also will help to facilitate charging EVs at home at night. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 18-19]

IV. Conclusion

EEI appreciates EPA's efforts to incentivize the manufacture and deployment of EVs and EPA's recognition of the potential for EVs to revolutionize the transportation sector by reducing GHG and other criteria pollutant emissions and reducing U.S. dependence on imported oil. EPA's overall assessment of the environmental impacts of EVs is flawed, however, and should be revised. If EPA's assumptions about the upstream GHG emissions related to the generation of the electricity that will be used to power EVs were consistent with scientific literature, used appropriate and accurate information about the current and future generating fleet and recognized regional variability in electricity generation and expected charging timing patters, EPA would conclude that increased EV deployment will enhance GHG reductions in the transportation sector. [EPA-HQ-OAR-2010-0799-9584-A2, p. 19]

---

3 Upstream emissions related to oil production have been a central part of the debate over the Keystone pipeline.

4 See Department of Energy, Alternative Fuels & Advanced Vehicles Data Center, Natural Gas Emissions, available at: http://www.afdc.energy.gov/afdc/vehicles/natural_gas_emissions.html.

5 For an assessment of the upstream emissions related to natural production and transportation from the Center for Transportation Research, Argonne National Laboratory, see A. Burnham et al., Life-cycle Greenhouse Gas Emissions of Shale Gas, Natural Gas, Coal and Petroleum, 46 Envtl. Sci. & Tech. 619 (2012), available at: http://www.transportation.anl.gov/pdfs/EE/797.PDF.

6 Available at: http://my.epri.com/portal/server.pt?Abstract_id=000000000001015325. It is important to note that the EPRI-NRDC study focused on PHEVs and did not include EVs. If it had included EVs, its conclusions about reduced GHG emissions would have been even more robust.

7 EIA, Annual Energy Outlook 2011 (Apr. 2011), Reference Case Scenario ref2011, Datekey d0202011a, compiled from Tables 8, 18, available at: http://eia.gov/forecasts/aeo/excel/yearbyyear.xls.

14 Researchers at the Department of Energy's (DOE) Argonne National Laboratory used data from the 2001 National Household Transportation Study to determine likely charging scenarios. They found that more than 60 percent of vehicles end their last trip after 5 p.m. and 70 percent after 4 p.m. More than half of these vehicles begin their first trip between 6 and 9 a.m. See A. Elgowainy, et al., Well-to-Wheels Analysis of Energy Use and Greenhouse Gas Emissions of Pug-In Hybrid Electric Vehicles, Energy Systems Division, Argonne National Laboratory, ANL/ESD/10-1 (June 2010), available at: http://www.transportation.anl.gov/pdfs/TA/629.PDF.

15 See K. Coughlin & J. Eto, Analysis of Wind Power and Load Data at Multiple Time Scales, Environmental Energy Technologies Division, Lawrence Berkeley National Laboratory, LBNL-4147E, 4 (Dec. 2010) (noting the "common features of wind power: regular diurnal pattern with stronger winds at night…"), available at: http://www.ferc.gov/industries/electric/indusact/ reliability/analysiswindpowerload.pdf. Indeed, NHTSA's analysis also fails to consider how EVs, especially PHEVs, can help better integrate more variable resources, like wind, into the grid, further de-carbonizing electricity generation. See, e.g., F. Tuffner & M. Kintner-Meyer, Using Electric Vehicles to Meet Balancing Requirements Associated with Wind Power, DOE, PNNL-20501 (July 2011), available at: http://energyenvironment.pnnl.gov/pdf/PNNL-20501_Renewables_Integration_Report_Final_7_8_2011.pdf.

16 Nuclear power plants essentially run continuously. This is because their power output cannot be ramped up and down readily on a daily and weekly basis. As a result, at night, when electric demand is lower, nuclear units continue to run and other forms of generation are backed off. See the World Nuclear Association's website for more information: http://world-nuclear.org/.

Organization: Electric Drive Transportation Association

While EDTA supports the overall direction of the proposed regulations, EDTA has three significant concerns with the proposal:

First, EDTA opposes the proposal to include upstream emissions when determining the "compliance value" for light-duty vehicles pursuant to these regulations. The proposal to include upstream emissions exceeds EPA's authority under Title II of the Clean Air Act. This proposal also lacks a rational basis because of the inherent uncertainties involved in calculating upstream emissions, and is arbitrary because it does not adequately account for the upstream emissions of conventionally fueled vehicles. [EPA-HQ-OAR-2010-0799-9449-A1, pp. 1-2]

Second, EDTA opposes the automatic phase-out of the multiplier for electric drive vehicles. The phase-out schedule in the proposed regulations is predicated on the assumption that the multiplier will become unnecessary by the year 2022. While it is possible that electric drive vehicles will gain widespread adoption by that year, the pace of adoption is uncertain and will be impacted by economic factors outside of the control of vehicle manufacturers, such as the price of conventional motor fuels. Given the inherent uncertainty in predicting the underlying economic trends that affect this industry, EDTA recommends that the multiplier be established for the full period covered by this rule (through 2025), subject to modification in a separate rulemaking following a mid-term review. [EPA-HQ-OAR-2010-0799-9449-A1, p. 2]

Third, EDTA opposes NHTSA's determination that it lacks authority to include a multiplier as part of its CAFE standards under EPCA and EISA. While these statutes do provide for certain incentives, they do not preclude NHTSA from establishing additional incentives, such as a multiplier. Adoption of a multiplier in NHTSA's rule would promote the fundamental policy of developing a harmonized national system in which EPA and NHTSA establish consistent regulatory requirements. [EPA-HQ-OAR-2010-0799-9449-A1, p. 2]

In addition, while we support the use of the utility factor methodology developed by the Society for Automotive Engineers (SAE), we encourage EPA to ensure the manufacturers are given an adequate opportunity to participate in determining the utility factor for each vehicle model. We also encourage EPA to ensure that its approach to determining the utility factor is harmonized with the ongoing efforts of the California Air Resources Board. [EPA-HQ-OAR-2010-0799-9449-A1, p. 2]

1. Upstream Emissions.

EPA's proposed rule would provide a temporary incentive for (EVs), plug-in hybrid electric vehicles (PHEVs), and fuel cell vehicles (FCVs) – that is, electric drive vehicles – by allowing manufacturers to use a compliance value of 0 grams per mile (g/mile) when calculating GHG emissions for those vehicles. This provision will allow the 0 g/mile compliance value to be used for an unlimited number of vehicles in MY 2017-2021. But from 2022 onward, there would be a cap on the number of vehicles that could qualify for the 0 g/mile assumption. If sales exceed the cap in MY 2022 and afterward, the GHG emissions calculation for those vehicles would be required to include an amount equivalent to "net upstream emissions." [EPA-HQ-OAR-2010-0799-9449-A1, p. 2]

EDTA supports the proposal to establish a zero-emission compliance value for MYs 2017-2021, but opposes the proposal to include upstream emissions in the compliance values for vehicles above the cap in MY 2022 and beyond. Upstream emissions should not be included in determining the compliance value because (1) EPA has authority under Title II of the Clean Air Act only to set emissions standards based on emissions from the vehicle itself, not upstream emissions; (2) EPA has not established an accepted methodology for calculating upstream emissions for individual makes and models of light-duty-vehicles; (3) it is arbitrary to include upstream emissions for electric drive vehicles, when such emissions are not regulated for other types of vehicles; and (4) any method for allocating the proposed cap could create uncertainty and adversely affect competition among vehicle manufacturers. [EPA-HQ-OAR-2010-0799-9449-A1, p. 2]

a. EPA Lacks Authority to Include Upstream Emissions.

The proposed GHG emission standards are based on EPA's authority to regulate motor vehicle emissions under Section 202(a) of the Clean Air Act, 42 U.S.C. § 7521(a). Section 202(a) gives EPA authority to set "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines …." Id. (emphasis added). The plain language of Section 202(a) authorizes EPA to set emission standards applicable to emissions "from" a vehicle – i.e., tailpipe emissions. There is nothing in Section 202(a) that states or implies that EPA can set emission standards for a vehicle based on emissions that come from power plants or other upstream sources and are not "from" the vehicle. [EPA-HQ-OAR-2010-0799-9449-A1, p. 3]

This reading of Section 202(a) is supported by other provisions in Title II of the Clean Air Act. For example, Section 206 provides for the testing of vehicles to determine whether they conform to the emission standards established by EPA. Section 206 states that EPA "shall" test or require to be tested any new motor vehicle or engine upon request of a manufacturer, and "shall" issue a certificate of conformity to the manufacturer if the vehicle or engine conforms to the regulations issued under Section 202(a). This provision makes clear that EPA is required to issue a certificate of conformity for a vehicle if the emissions from the vehicle comply with the EPA-prescribed emissions test. Section 206 does not give EPA discretion to establish an emissions test that imputes to a vehicle emissions that do not come from the vehicle itself, nor does it give EPA discretion to deny a certificate of conformity for a vehicle that passes the emissions test. Similarly, Section 207 authorizes EPA to establish the emissions test that is used for determining "whether, when in actual use throughout its warranty period, each vehicle and engine … complies with the emissions standards" set in the regulations issued under Section 202. This language in Section 207 requires the emissions test to be based on emissions from the vehicle itself, and leaves no discretion for EPA to establish an emissions test that imputes to a vehicle emissions released by power plants or other sources. [EPA-HQ-OAR-2010-0799-9449-A1, p. 3]

The overall structure of the Clean Air Act also confirms that Title II only gives EPA authority to set standards for emissions that come directly from motor vehicles. Congress created a comprehensive scheme to regulate emissions from a wide range of sources. Title I authorizes EPA to set emissions standards for stationary sources; Title II authorizes EPA to set emissions standards for mobile sources.1 There are many end-users of electricity whose activities could be associated with "upstream" emissions from power plants, but to date EPA has not sought to impute the power plants' emissions to the end-users of the power generated by those plants. Rather, EPA has interpreted the statutory scheme to require regulation of power plant emissions at the source, not at the end-user. This approach is not only consistent with the structure of the Act; it also makes practical sense, because end users have no ability to control upstream emissions. [EPA-HQ-OAR-2010-0799-9449-A1, p. 3]

Notwithstanding the plain language of Section 202(a) and the structure of the Clean Air Act, EPA asserts in this rulemaking that it has authority to include upstream emissions when establishing the compliance value for light-duty vehicles. The proposed rule itself does not articulate the legal basis for this assertion of authority. In its previous rulemaking for MYs 2012-2016, EPA asserted in response to a comment that it has “broad discretion” to set GHG emission standards for light-duty vehicles under Section 202, including the authority to base compliance values on an assumed level of upstream emissions. (See 75 Fed. Reg. 75437). We respectfully disagree with that conclusion because it is contrary to the language and intent of the Clean Air Act. For the reasons stated above, Title II of the Act only gives EPA authority to set standards governing emissions “from” the vehicle itself. [EPA-HQ-OAR-2010-0799-9449-A1, pp. 3-4]

b. EPA's Proposed Methodology for Estimating Upstream Emissions is Arbitrary.

Even if EPA were authorized to include upstream emissions when setting standards for vehicle emissions under Title II, such a requirement would be permissible only if EPA could articulate a non-arbitrary basis for estimating the upstream emissions for each vehicle model covered by the regulations. The “four-step methodology” proposed in this rule falls far short of this requirement. Rather than describing a methodology for estimating the upstream emissions associated with each vehicle, the proposed rule requires a single national average to be used as the basis for estimating upstream emissions for all vehicles. (76 Fed. Reg. 75014) (requiring use of “2025 nationwide average electricity upstream GHG emissions rate of 0.574 grams/watt-hour at the powerplant”). [EPA-HQ-OAR-2010-0799-9449-A1, p. 4]

This national average – or any national average for that matter – fails to take into account the wide variation in actual “upstream emissions” among different regions, demographic groups, and vehicle types. The fundamental point is that average GHG emissions from electricity generation are not necessarily representative of the incremental emissions resulting from the charging of a particular vehicle or vehicle model. The additional emissions associated with charging a particular vehicle or vehicle model will depend on many factors. First, any estimate of upstream emissions would need to take into account the geographic distribution of the users of the vehicles, since the electricity generation mix varies considerably by region. In addition, it would need to take into account the expected driving habits and charging habits of those users, which could vary significantly for different vehicle models. It also would need to take into account a host of capital investment and operational decisions made by electric utilities and grid operators, including decisions about the electricity generation mix for both base load and peak load that are made on a daily basis in managing the grid, and over time, in planning the energy inventory of a service territory. [EPA-HQ-OAR-2010-0799-9449-A1, p. 4]

To avoid arbitrariness, any calculation of upstream emissions would need to be customized to reflect these factors with regard to each vehicle model in a manufacturer’s fleet. To date, no such methodology has been developed, and indeed it may not be possible to credibly do so. In the absence of a statistically reliable methodology for calculating upstream emissions for each vehicle model, it would be arbitrary for EPA to require upstream emissions to be included as part of the compliance value for electric drive vehicles. [EPA-HQ-OAR-2010-0799-9449-A1, p. 4]

c. EPA's Proposal is Also Flawed Because it Would Not Apply Equally to All Vehicle Types.

An additional flaw in the proposed rule is the fact that it requires upstream emissions to be included for electric drive vehicles in spite of the fact that this has never been done for conventionally fueled vehicles. Even if EPA were authorized to regulate upstream emissions under Title II, any such system would need to apply evenhandedly to all categories of vehicles, including those that use petroleum fuel. [EPA-HQ-OAR-2010-0799-9449-A1, p. 4]

The proposed regulations seek to address this concern by requiring the upstream emissions for a "comparable midsize gasoline vehicle" to be deducted from the upstream emissions for an electric drive vehicle. (*See* 76 Fed. Reg. 75014.) This methodology would mitigate, but not eliminate, the arbitrariness inherent in requiring upstream emissions to be included for some vehicles but not others. By EPA's own logic, this methodology would understate the GHG emissions of *both* gasoline vehicles and electric drive vehicles.
In short, we see no justification for imposing this upstream emission requirement on electric vehi cles alone. [EPA-HQ-OAR-2010-0799-9449-A1, pp. 4-5]

d. Allocating a Cap Could Create Uncertainty and Adversely Affect Competition.

Finally, the proposed methods for allocating a cap would create uncertainty among manufacturers and could distort competition. An industry-wide cap is especially problematic, because each manufacturer's cap would depend on that manufacturer's relative share of the market, not its absolute sales volume; a cap based on relative share is very difficult for a manufacturer to predict, because it is tied to decisions made by other manufacturers. The proposed company-specific cap would provide greater certainty, but it has drawbacks as well. Any company-specific cap is potentially market-distorting, because it could enable a manufacturer to lock in a multi-year competitive advantage (in the form of a much higher cap) based on that manufacturer's sales of electric drive vehicles in the years immediately following adoption of these regulations. While advantageous to that manufacturer, such a system would conflict with the goal of free and open competition. These practical difficulties with allocating a cap provide a further basis for eliminating the cap and instead allowing all vehicles to qualify for the zero-emissions compliance value.

For all of these reasons, EDTA recommends that the rule provide a zero-emissions compliance value for electric drive vehicles for the full period covered by this rule, MYs 2017-2025. [EPA-HQ-OAR-2010-0799-9449-A1, p. 5]

2. Phase-Out of Multiplier for EVs, PHEVs, and FCVs.

For MY 2017-2021, EPA is proposing an incentive multiplier for all electric drive vehicles to facilitate market penetration of the most advanced vehicles as rapidly as possible. This multiplier approach means that each EV, PHEV, and FCV would count as more than one vehicle in the manufacturer's compliance calculation. For EVs and FCVs, the multiplier would be 2.0 from MY 2017 to MY 2019, at which point it will be phased down to 1.75 in 2020 and 1.50 in 2021; in 2022 and later, it would be 1.0 (i.e., no multiplier). For qualifying PHEVs, the multiplier would be 1.6 from 2017-2019, 1.45 in 2020, 1.3 in 2021, and 1.0 from 2022 onward. To qualify for the multiplier, a PHEV would need to complete a full EPA highway test (10.2 miles), without using any conventional fuel, or alternatively, have a minimum equivalent all-electric range of 10.2 miles as measured on the EPA highway cycle. [EPA-HQ-OAR-2010-0799-9449-A1, p. 5]

The rationale for the multiplier, as described in the proposed rule, is that a multiplier is needed as an incentive to accelerate the commercialization and widespread adoption of EVs, PHEVs, and FCVs. EDTA concurs that this incentive is needed, but opposes automatic termination of this incentive in 2021. There is significant uncertainty in making multi-year market predictions; in this case, the uncertainty is compounded by the fact that electric drive technology and markets are just emerging. Moreover, expanding electric drive vehicle capacity will require substantial investments and long-term planning by manufacturers and other industry participants. The incentive to encourage those investments should be similarly long-term and not subject to an arbitrary time limit. [EPA-HQ-OAR-2010-0799-9449-A1, p. 5]

For these reasons, EDTA recommends that the multiplier be extended at its initial level throughout the full time period covered by these regulations (through MY 2025), subject to mid-term review. If EPA determines through its mid-term review of actual market conditions that the incentive is no longer needed or should be reduced, it could make that change through a separate rulemaking. [EPA-HQ-OAR-2010-0799-9449-A1, pp. 5-6]

In short, rather than arbitrarily building in a phase-out schedule, the rule should include a trigger for a new rulemaking to reduce the multiplier *if* EPA determines – based on sales volumes of electric drive vehicles – that the multiplier is no longer needed. This approach will ensure that the multiplier remains in effect as long as it is needed, while also providing a mechanism to reduce or eliminate the multiplier when it is warranted. [EPA-HQ-OAR-2010-0799-9449-A1, p. 6]

3. NHTSA Authority to Establish a Multiplier.

EDTA also objects to NHTSA's determination that it lacks authority to establish a multiplier in the fuel economy regulations under EPCA and EISA. The preamble to the proposed rule states that: "NHTSA currently interprets EPCA and EISA as precluding the agency from offering additional incentives for EVs, FCVs and PHEVs, except as specified by statute, and thus is not proposing incentive multipliers comparable to the EPA incentive multipliers described above." (76 Fed. Reg. 74878). This statement is accompanied by a footnote, which states that: [EPA-HQ-OAR-2010-0799-9449-A1, p. 6]

Because 49 U.S.C. 32904(a)(2)(B) expressly requires EPA to calculate the fuel economy of electric vehicles using the Petroleum Equivalency Factor developed by DOE, which contains an incentive for electric operation already, and because 49 U.S.C. 32905(a) expressly requires EPA to calculate the fuel economy of FCVs using a specified incentive, NHTSA believes that

Congress' having provided clear incentives for these technologies in the CAFE program suggests that additional incentives beyond those would not be consistent with Congress' intent. Similarly, because the fuel economy of PHEVs' electric operation must also be calculated using DOE's PEF, the incentive for electric operation appears to already be inherent in the statutory structure.(76 Fed. Reg. 74878, at footnote 56). [EPA-HQ-OAR-2010-0799-9449-A1, p. 6]

EDTA disagrees that these statutory provisions preclude NHTSA from including an incentive multiplier for EVs, PHEVs, and FCVs in its CAFE regulations. As NHTSA acknowledges in the proposal, "the President's National Fuel Efficiency Policy announcement of May 19, 2009…called for harmonized rules for all automakers…." (76 Fed. Reg. 75164). Consistent with this directive, NHTSA should, wherever possible, interpret its authority in a manner that is consistent with the establishment of a single, consistent national program, with requirements that parallel those established by EPA. [EPA-HQ-OAR-2010-0799-9449-A1, p. 6]

The interpretation of EPCA and EISA offered in footnote 56 falls short in this regard. 42 U.S.C § 32904(a)(2)(B) merely directs NHTSA to "include" equivalent petroleum-based fuel economy values in its calculation of average fuel economy for electric vehicles. This section contains no "exclusivity" language, nor does it even imply an intent to preclude other incentives. From a practical standpoint, there is nothing that prevents NHTSA from complying with this statutory directive and also promulgating a regulatory incentive multiplier to harmonize with EPA's program. The same holds true for 42 U.S.C. § 32905(a), which directs NHTSA to use a specific equivalency factor for liquid alternative fuel. This language does not otherwise constrain NHTSA's authority; NHTSA can comply with this statutory directive *and* comply with the President's directive to harmonize the CAFE and GHG programs. EDTA strongly encourages NHTSA to reconsider its interpretation of its governing statutes in light of the President's harmonization policy. EDTA does not believe that EPCA or EISA presents a barrier to the adoption by NHTSA of an incentive multiplier for advanced technology vehicles, consistent with EPA's proposal. [EPA-HQ-OAR-2010-0799-9449-A1, p. 6]

---

1. In the proposed rule, EPA implies that it needs to address upstream GHG emissions from motor vehicles as part of the emission standards under Title II of the Clean Air Act because that "[a]t this time ... there is no such comprehensive program addressing upstream emissions of GHGs." (See 76 Fed. Reg. at 75010). In fact, EPA has taken several steps to regulate the GHG emissions of stationary sources, including rulemakings under the Prevention of Significant Deterioration and Title V Operating Permit programs and the upcoming New Source Performance Standard for electric generating units. These programs directly regulate the GHG emissions of power plants. The fact that EPA is already regulating upstream GHG emissions contradicts the rationale offered in this rulemaking for addressing those emissions through the emission standards for motor vehicles.

Organization: Ferrari

We concur with EPA that believes it would be appropriate to provide an incentive to encourage the introduction of advanced technology vehicles (Electric Vehicles, Plug-in Hybrids, and Fuel

Cells), FFV and AFV vehicles and off-cycle technologies and that a credit mechanism is an effective way to do this. [EPA-HQ-OAR-2010-0799-9535-A2, p.14]

Organization: Fisker Automotive, Inc.

Fisker's solution to this conundrum is the electric vehicle with extended range (EVer), a powertrain that enables all-electric driving while eliminating the range anxiety that presents a hurdle to some buyers. We are proud to offer the Karma as the first electric vehicle with extended range in the premium luxury sedan segment. Not only does the Karma offer a world-class combination of style and luxury, but the Karma would allow Fisker to comply with the greenhouse gas standards proposed in this rulemaking for 2025 – today. [EPA-HQ-OAR-2010-0799-9266-A1, pp. 1-2]

As stated in the preamble to this rule, plug-in vehicles are one of the technologies that "have significant transportation GHG emissions and oil consumption game-changing potential in the longer run, and that also face major market barriers in entering a market that has been dominated by gasoline vehicle technology and infrastructure for over 100 years." Fisker Automotive is bringing to market today the type of vehicle that this rule is designed to support. [EPA-HQ-OAR-2010-0799-9266-A1, p. 2]

Encourage re-consideration of upstream emissions in the future

One of the rationales for accounting for upstream emissions (for those vehicles not subject to the incentive) is that "there is currently no program in place to reduce GHG emissions from electric powerplants." However, in the recently adopted amendments to California's GHG program for light-duty vehicles, the Air Resources Board (ARB) continued to hold automakers responsible for upstream emissions even in the context of a cap-and-trade program in that state to control GHG emissions from powerplants. As automakers have no control over the GHG intensity of electricity generation, we encourage EPA to consider a pathway in which tailpipe emissions and upstream emissions are controlled separately. For instance, if a national cap-and-trade program or other GHG control regulation is in place at the time of the proposed mid-term review, we would encourage both EPA and NHTSA to reconsider its treatment of upstream emissions. [EPA-HQ-OAR-2010-0799-9266-A1, p. 4]

Support incentive program for electric vehicles, plug-in hybrid electric vehicles, and fuel cell vehicles as proposed

In the absence of a means of controlling GHG emissions upstream, Fisker supports the 0 g/mi upstream emissions incentive and the multipliers for years 2017-2021 as proposed. We believe the requirement that a PHEV be required to complete a full EPA highway test without using any conventional fuel – essentially a 10.2 mile All Electric Range (AER) – is an appropriate threshold to place for participation in the incentive program. [EPA-HQ-OAR-2010-0799-9266-A1, p. 5]

Organization: Ford Motor Company

Production Volume Multipliers: To promote the research, development and manufacture of advanced technology vehicles, Ford supports the proposal to provide production volume multipliers for electrified vehicles (full battery electric and plug-in hybrid electric vehicles) and fuel cell vehicles, at the levels proposed. As noted in the preamble, it is likely that these technologies will become increasingly important toward meeting the aggressive standards, and we further recommend that the continuation of the multipliers beyond 2021 model year be considered during the mid-term evaluation. [EPA-HQ-OAR-2010-0799-9463-A1, p. 18]

Upstream Emissions: Ford also supports the continuation of the accounting of the electric drive portion for battery electric and plug-in hybrid electric vehicles in the GHG equation as 0 grams/mile. However, just as traditional vehicles are certified based on their measured tailpipe emissions over the federal test procedures, without regard to the source of the gasoline on which they are operated, we do not believe it is appropriate to include upstream (e.g., utility) emissions in the vehicle greenhouse gas compliance calculation for electrified products. Therefore, the production volume caps, adopted for 2012-16 model years as well as those proposed for the 2022-2025 model years should be eliminated. [EPA-HQ-OAR-2010-0799-9463-A1, p. 19]

Auto manufacturers have no control over the emissions of the utility industry, but unique solutions for electric vehicles are being investigated which allow the customer to further reduce the “carbon footprint” of these vehicles independent of the local energy supply. For example, Ford has announced a partnership with SunPower to provide a high-efficiency rooftop solar system that could provide Focus Electric owners enough renewable energy production to offset the energy used for charging. Ford also has an established a partnership with Microsoft to develop technology that will allow the customer to easily charge vehicles when electricity rates are lowest, which typically corresponds to when the utilities have excess capacity in their system. Balancing utility load in such a manor improves the overall utility industry carbon footprint. Requiring manufacturers to bear the burden of another industry’s greenhouse gas emissions is not only inappropriate, it could potentially disincentivize innovations like these which provide a real world benefit. [EPA-HQ-OAR-2010-0799-9463-A1, p. 19]

Ford supports the comments provided by the EDTA, which raises the additional issues regarding EPA’s authority to include upstream emissions in a vehicle requirement and the proposed methodology for estimating the upstream emissions. [EPA-HQ-OAR-2010-0799-9463-A1, p. 19]

Definition of PHEV: EPA has proposed that a plug-in hybrid vehicle must meet a minimum “all electric range” limit of 10.2 miles in order to be eligible to utilize the production volume multiplier, and requested comments on this threshold and whether a different PHEV metric (such as battery capacity, ratio of electric motor power to engine, or total vehicle power) would be appropriate. Ford supports the minimum range requirement both as the appropriate metric for defining a PHEV for the purpose of the use of a volume multiplier, and at the level proposed (10.2 miles). Further, we support the proposal, as stated by EPA, that the minimum electric range may be optionally measured as equivalent all-electric range as measured on the EPA highway cycle. [EPA-HQ-OAR-2010-0799-9463-A1, p. 19]

NHTSA Incentives for Electric Vehicles, Plug-in Hybrids, and Fuel Cell Vehicles

NHTSA has also expressed the view that it lacks authority to establish an incentive multiplier for EVs, PHEVs, and FCVs, comparable to the one proposed by EPA, in the fuel economy regulations under EPCA and EISA. In this case, we disagree with NHTSA's interpretation of EPCA and EISA. In our view, the law does not address this issue, either directly or indirectly. Moreover, the President has directed EPA and NHTSA to coordinate and harmonize their regulations as much as possible. Consistent with that directive, the agencies should interpret statutes so as to optimize the degree of harmonization between the GHG program and the CAFE program. Thus, if one agency incorporates a program flexibility into its rules, the other agency should adopted a corresponding program flexibility unless expressly prohibited by law. We refer the agencies to the comments of EDTA on this point, which we support and incorporate by reference. [EPA-HQ-OAR-2010-0799-9463-A1, p. 21]

Organization: General Motors Company

GM supports the advanced technology volume multipliers as proposed, as well as the proposed definitions and metrics for electric, fuel cell and plug-in vehicles. GM recommends that all aspects of the advanced technology program should be fully examined in the mid-term review, and updated as appropriate. [EPA-HQ-OAR-2010-0799-9465-A1, p. 3]

GM does not believe that requiring automakers to account for upstream electricity carbon emissions should ever become a part of the agencies' vehicle regulatory programs. Vehicle compliance has been, and should continue to be, regulated at the vehicle emissions and consumption level. For the purposes of calculating a manufacturer's fleet average performance, GM strongly recommends that all upstream carbon emissions from the use of electricity be quantified as zero, for all model years, and for all vehicle volumes. [EPA-HQ-OAR-2010-0799-9465-A1, p. 3]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 36-37.]

Finally, a specific concern that we have with the proposal is related to the treatment of so-called upstream electricity emissions. EPA has couched the quantification of upstream emissions at 0.0 grams per mile as a 'flexibility' for automakers. This characterization is really inappropriate and could lead EPA at some point to reduce or eliminate this so-called flexibility. At its core, the problem is that the word flexibility suggests some measure of choice or control. However, automakers control neither the feedstocks nor the conversion processes for generating and creating electricity. Suggesting that at some point we could or should be responsible for these emissions is worrisome to us. To the degree that these emissions are going to be addressed by government, legislators and regulators need to create a program to do so directly, not indirectly through further restrictions on vehicles. With due respect, we have a tough job ahead of us as it is.

Organization: Growth Energy

Although not required by Congress in EISA or in the other statutes governing this rulemaking, the proposed standards in the Joint NPRM place great reliance on the production, sale and use of vehicles powered from the electrical grid, far exceeding any prior federal regulatory program. As noted above, the success or failure of the regulations that the Agencies are proposing will ultimately be determined by the consumer market for new motor vehicles. Insofar as the Agencies' program is based on regulatory templates from California, which has attempted for more than 20 years to implement requirements for widespread sale and use of pure electric vehicles, there is reason for great skepticism about the Joint NPRM's view that grid-powered electric vehicles (pure electric vehicles and plug-in hybrid vehicles) can provide a "game-changing" strategy to reduce GHG emissions and dependence on foreign oil. [EPA-HQ-OAR-2010-0799-9505-A1, p. 2]

This Attachment to the Comments of Growth Energy explains why EPA needs to reconsider its analysis of the electric vehicle component of the Joint Notice of Proposed Rulemaking (Joint NPRM). [EPA-HQ-OAR-2010-0799-9505-A1, p. 7]

As part of the Joint NPRM, EPA includes incentives for electric vehicles (EVs), plug-in hybrid electric vehicles (PHEVs), and fuel cell vehicles (FCVs) intended "To facilitate market penetration of the most advanced vehicle technologies as rapidly as possible…" EPA goes on to provide the following rationale for providing these incentives:

EPA has identified two vehicle powertrain-fuel combinations that have the future potential to transform the light-duty vehicle sector by achieving near-zero greenhouse gas (GHG) emissions and oil consumption in the longer term, but which face major near-term market barriers such as vehicle cost, fuel cost (in the case of fuel cell vehicles), the development of low-GHG fuel production and distribution infrastructure, and/or consumer acceptance.

- Electric vehicles (EVs) and plug-in hybrid electric vehicles (PHEVs) which would operate exclusively or frequently on grid electricity that could be produced from very low GHG emission feedstocks or processes.
- Fuel cell vehicles (FCVs) which would operate on hydrogen that could be produced from very low GHG emissions feedstocks or processes. [EPA-HQ-OAR-2010-0799-9505-A1, p. 7]

EPA believes that these advanced technologies represent potential game-changers with respect to control of transportation GHG emissions as they can combine an efficient vehicle propulsion system with the potential to use motor fuels produced from low-GHG emissions feedstocks or from fossil feedstocks with carbon capture and sequestration. [EPA-HQ-OAR-2010-0799-9505-A1, p. 8]

However, EPA also notes that during the 2017 to 2025 time frame that the production of the electricity and hydrogen required to power these vehicles:

…will decrease the overall GHG emissions reductions associated with the program as the upstream emissions associated with the generation and distribution of electricity are higher than the upstream emissions associated with production and distribution of gasoline… [EPA-HQ-OAR-2010-0799-9505-A1, p. 8] and quantifies the magnitude of these lost emission reductions as between 80 million and 120 million metric tons of CO_2 over the period from 2017 to 2025 alone. According to EPA, the loss in benefits associated with EV, PHEV, and FCV incentives equals 4 to 5% of the total GHG reductions expected from the proposed rule. [EPA-HQ-OAR-2010-0799-9505-A1, p. 8]

Given that EPA admits that the incentives it is providing for EVs, PHEVs, and FCVs will undermine the goal of the GHG regulation at least during the period from 2017 to 2025, the obvious question is why are these incentives being provided? The answer to this question is that as indicated above, EPA believes these advanced technologies are potential game-changing technologies. As discussed in detail below, not only does EPA overstate the potential GHG benefits of EVs, PHEVs, and FCVs, but the Agency fails to accurately address the serious challenges facing these vehicle technologies. As a result, EPA's decision to incentivize these technologies seems completely at odds with the goal of the proposed rule, which is to lower GHG emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 8]

In contrast, the proposed rule ignores the fact that vehicles designed to operate on ethanol-blended fuels are truly "…potential game-changers with respect to control of transportation GHG emissions…" Given this, EPA must modify the proposed rule to provide incentives that will ensure that vehicles capable of operation on ethanol blends continue to enter the vehicle fleet in substantial numbers so that the tremendous "game-changing" GHG benefits of ethanol-blended fuels can be realized in the real world. [EPA-HQ-OAR-2010-0799-9505-A1, p. 8]

Another major factor with respect to vehicle costs for EVs, PHEVs, and FCVs are the durability of batteries and fuel-cells. Most analyses of EVs, PHEVs, and FCVS, including that associated with CARB's recent rulemaking (which used the same data that supports the NPRM) are based on two highly uncertain assumptions which are: [EPA-HQ-OAR-2010-0799-9505-A1, pp. 11-12]

1. The useful lives of EVs, PHEVs, and FCVs will be the same as conventional vehicles in terms of miles travelled; and

2. Vehicle owners will not have to replace batteries or major fuel cell system components over the course of a vehicle's useful life. [EPA-HQ-OAR-2010-0799-9505-A1, p. 12]

Obviously if either shorter vehicle life or the need to incur replacement costs for batteries or fuel cell systems occurs, the costs associated with EV, PHEV and FCV will be even higher than described above making these vehicles even less likely to provide "game-changing" reductions in GHG emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 12]

In supporting the proposed credits for EVs and PHEVs, EPA notes that "…electricity is considerably cheaper, on a per mile basis, than gasoline." While that may be true at present for electricity from the existing electrical grid and generation mix, it is not at all clear that will be the case for the electricity produced "…from low- GHG emissions feedstocks or from fossil feedstocks with carbon capture and sequestration" that EPA makes clear will need to be used to power EVs and PHEVs in order for them to provide "game-changing" reductions in GHG emissions. Generation costs for electricity from low-GHG sources or fossil-fired sources with carbon sequestration may be far higher than current generation costs and need to be carefully considered by EPA to the extent that decisions to provide incentives to EVs and PHEVs are based on the premise that electricity costs less than gasoline. Evidence that generation costs for low-GHG sources are likely to be higher than for existing plants can be seen, for example, in substantially higher capital cost estimates for those sources. Again, construction and operation of these low-GHG electricity sources are a necessary condition that must be met in order for EVs and PHEVs to provide “game-changing” reductions in GHG emissions. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 12-13]

The situation with respect to fuel costs for hydrogen is far less clear than for electricity. Hydrogen dispensed as a transportation fuel for use in FCVs is currently more expensive than gasoline and even in large scale wide spread production, the cost of low-GHG hydrogen is going to be considerably higher than that of central steam reforming of natural gas. Therefore, there will likely be substantial cost premiums associated with low GHG hydrogen that will have to be paid in order for FCVs to provide “game-changing” reductions in GHG emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 13]

In order to put the fuel cost issues for EVs, PHEVs, and FCVs into perspective, the “Payback Calculator” developed by CARB for its recent rulemaking was used to estimate the prices at which fuel costs for EVs and FCVs would equal those for gasoline vehicles based on low and average gasoline price forecasts which range from about $3.10 to $4.10 from 2017 to 2025. Using this CARB spreadsheet and its optimistic assumptions regarding EV and FCV energy efficiency, the electricity price at which electric vehicle fuel costs equal those for gasoline ranges from about $0.36 to $0.45 per kilowatt-hour while the hydrogen price ranges from about $7.50 to $9.00 per kilogram. [EPA-HQ-OAR-2010-0799-9505-A1, p. 13]

Although these prices for electricity and hydrogen may seem high relative to current electricity prices and prices for hydrogen produced using steam methane reforming at centralized plants, it should be recalled that they have to be compared to the prices that will be associated with electricity from marginal new ultra-low GHG generation capacity that would not otherwise be built and hydrogen production using ultra-low GHG processes. Given this, it is not at all clear that when proper cost accounting is made for ultra-low GHG electricity and hydrogen production that EVs, PHEVs, and FCVs will provide any meaningful fuel costs savings relative to conventional vehicles which in turn will create yet another hurdle to their ever providing “game-changing” reductions in GHG emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 13]

Although it might seem that the situation would be similar with respect to the distribution of electricity for use by EVs and PHEVs, that is in fact not the case. First, there are direct costs associated with residential charging equipment (referred to as electric vehicle service equipment or EVSE) which EPA has estimated range from about $1,300 to $1,500 for equipment and installation labor over the 2017 to 2025 period with the lower end of the range applying in the later years. These costs must be added on top of the already large incremental purchase prices of EVs and PHEVs. [EPA-HQ-OAR-2010-0799-9505-A1, p. 14]

Next there is the possibility that additional costs will be incurred to develop public EV and PHEV recharging infrastructure. While it is not clear that this infrastructure will be necessary, CARB will be studying the need for it and may at some point mandate its construction, and EPA may have to follow suit in the remainder of the nation. Again, to the extent that public EV and PHEV recharging infrastructure does have to be constructed to improve the viability of these vehicles those costs will obviously also have to added to the ledger. [EPA-HQ-OAR-2010-0799-9505-A1, p. 14]

Another potentially substantial cost associated with the deployment of EVs and FCVs is the need to upgrade the existing electrical transmission and distribution system. This is a problem that is already facing California that will almost certainly have to be dealt with across the country before EVs and PHEVs could even be hoped to provide “game-changing” reductions in GHG emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 14]

FCVs face even more serious issues with respect to the development of refueling infrastructure. First, refueling stations will either have to be located in reasonably proximity to existing hydrogen production facilities and receive hydrogen by truck or pipeline or utilize expensive onsite hydrogen generation capability. In addition, there may be significant facility siting and permitting issues and concerns regarding the high pressures and special equipment required for FCV refueling. [EPA-HQ-OAR-2010-0799-9505-A1, p. 14]

Although EPA has not attempted to analyze the costs associated with the development of the hydrogen refueling infrastructure that will be required to support FCVs regardless of how the hydrogen they use is produced, CARB has performed an analysis that likely represents a “best case” scenario. This analysis includes numerous optimistic assumptions regarding hydrogen station costs as well and assumes both that stations can be carefully located using knowledge of where FCVs will be sold and in general 100% utilization rates for hydrogen refueling stations. Even with these very optimistic assumptions, the direct capital costs for refueling stations amount to about $1,700 per FCV over roughly the same period as the 2017 to 2025 period considered by EPA. Again, these costs have to be added on top of the already large incremental purchase costs for FCVs and must be incurred before it can even be hoped that FCVs will provide “game-changing” GHG reductions. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 14-15]

To summarize, EPA has proposed to provide incentives under the GHG regulation for EVs, PHEVs, and FCVs because according to EPA these vehicles have the potential to yield “game changing” reductions in GHG emissions. However, in order for those reductions to be realized the following things all have to occur:

1. The public (directly or indirectly) must be willing to pay substantially higher prices for these vehicles;

2. The public (directly or indirectly) must be willing to pay substantial costs in order to develop the infrastructure required to provide fuel to these vehicles;

3. The public must be willing (directly or indirectly) to pay the costs associated with low-GHG electricity and/or hydrogen, which are not likely to be substantially lower than the costs for petroleum based fuels. [EPA-HQ-OAR-2010-0799-9505-A1, p. 15]

Organization: Honeywell Transportation Systems

EPA and NHTSA have historically refrained from adopting prescriptive policies favoring technologies, instead aiming to implement regulations favoring innovation and preserving the ability of industry to develop new technologies while also encouraging enhancements to current technologies. The Council of Economic Advisors has strongly endorsed technology neutrality, making clear that "the difficulty in promoting technology adoption through subsidies and other tools lies in designing policies that are neutral across all alternative technologies. Weighting the size of a subsidy by the degree to which each technology reduces environmental and security concerns would help to ensure that the Government is not in the position of picking winners. [EPA-HQ-OAR-2010-0799-9474-A1, p.3]

The agencies have proposed various incentive programs. Incentives for electric drivetrains take the form of both credit multipliers and a focus on tank-to-wheel emissions rather than accounting for the full well-to-wheel emissions of those vehicles. [EPA-HQ-OAR-2010-0799-9474-A1, p.4]

Organization: Hyundai America Technical Center

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 23.]

For example, some OEMs are focusing resources on electric vehicles, and they are receiving credit multipliers for expanding that technology.

EPA Should Move Quickly Toward Fully Counting Upstream Emissions from Electric Vehicles [EPA-HQ-OAR-2010-0799-9480-A1, p. 11]

In the proposed rule, EPA continues its practice of incentivizing electric vehicle technology by treating such vehicles as producing zero emissions and by letting manufacturers apply a multiplier when counting electric vehicles in their fleet averages. Yet, as EPA knows, electric vehicles are not responsible for zero greenhouse gas emissions: electric vehicles run on energy from the electric grid, produced largely by carbon-emitting combustion. EPA's program in essence allows for a triple undercounting of greenhouse gas emissions—once by not accounting for emissions from electric cars, twice by counting electric cars more than once when averaging, and finally by allowing the credits to be traded to other manufacturers—and allowing for increases in greenhouse gas emissions at every step. Any form of subsidization of new technology should be neutral with respect to greenhouse gas emissions; it should definitely not contribute to their increase. Although it may be a valid policy goal to incentivize new technology, EPA should achieve this goal by providing grants and subsidies to manufacturers and scientists exploring all promising emission-reducing technologies. By giving inflated regulatory incentives to a certain type of technology rather than allowing manufacturers to find the most efficient and effective solution, EPA will disincentivize other forms of technology that may be more cost-effective at reducing greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-9480-A1, pp. 11-12]

Fortunately, EPA at least plans to limit these distorting credits starting with model year 2022, dropping the multiplier and capping the number of cars that can be counted as having zero emissions; any remaining electric vehicles will be assigned their net upstream emissions. The agency asks for comments on whether there should be an interim period where only half of upstream emissions are counted, whether any changes should be made to the current electric vehicle incentive program, and whether similar incentives should be extended to other specific technologies. For the reasons given above, EPA should either eliminate these incentives, or at least move as quickly as possible toward fully accounting for the upstream emissions of alternative fuel vehicles. [EPA-HQ-OAR-2010-0799-9480-A1, p. 12]

Organization: International Council on Clean Transportation (ICCT)

13. While the ICCT strongly supports development of electric and fuel cell vehicles, one of our core principles is that efficiency and greenhouse gas emission standards should be technology neutral. Default zero upstream electric and fuel cell vehicle credits and multipliers violate this principle and reduce the benefits from the rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 3]

The provision will also give windfall credits to vehicles required by the CA ZEV mandate, reducing benefits from the rule without any additional advanced vehicle sales. Electric and fuel cell vehicle credits should at least be limited to vehicles that are additional to those required by the ZEV mandate. A proposed system that strikes a balance between providing appropriate incentives for advanced vehicles and maintaining the effectiveness of the standards is detailed in our comments. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 3-4]

13) Upstream Plug-in and Fuel Cell Vehicle Credits

The ICCT was founded around the Bellagio Principles37, set forth in 2001 by regulators from the largest car markets around the world to help guide the future of worldwide motor vehicle technology and transportation fuels. A key principle states: 'Policymakers must...base policies solely on performance compared to societal objectives, and not give special consideration to specific fuels, technologies, or vehicle types.' [EPA-HQ-OAR-2010-0799-9512-A1, p. 25]

Technology-neutral standards have a number of advantages over policies that specifically target distinct technologies. Picking the right 'winners' is challenging, and the wrong choices may hinder technologies that could have had the greatest potential benefit over the long run. Technology-specific bonuses reduce transparency and at the same time introduce opportunities for windfall credits at the expense of alternative technology development, consumer cost savings, and GHG reductions. [EPA-HQ-OAR-2010-0799-9512-A1, p. 25]

EPA has proposed two electric vehicle (EV) technology-specific bonus credits:

1. A default GHG compliance value of zero g/mi for battery electric vehicles (BEVs), fuel cell electric vehicles (FCEVs), and the electric operation fraction of plug-in hybrid electric vehicles (PHEVs). [EPA-HQ-OAR-2010-0799-9512-A1, p. 25]

2. A system of multipliers that allows manufacturers to count EVs as more than one vehicle in manufacturers' compliance calculations during the 2017 to 2021 model years. [EPA-HQ-OAR-2010-0799-9512-A1, p. 25]

The ICCT strongly agrees with the need to commercialize BEVs, FCEVs and PHEVs. These technologies are key components needed to meet the ambitious 2050 GHG reduction targets necessary to avert the worst impacts of climate change.39 To promote these vehicles without violating the principle of technology neutrality, ICCT is proposing an alternative accounting method for EV upstream fuel cycle GHG emissions that strikes a balance between providing advanced vehicle credits and maintaining technology-neutral standards. We also propose eliminating or restricting the use of multipliers and eliminating windfall credits for vehicles that are required under the California ZEV mandate. This would appropriately reward benefits inherent to EV technology, while also encouraging a number of other technology options to further improve EV efficiency. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 25-26]

The NPRM estimates that the two credit types proposed in the rule would erode 80 to 110 million metric tons of benefits from the MY 2017-2025 GHG standards. Our detailed comments below describe the benefits of ICCT's proposed technology-neutral EV emissions accounting system, contrasting them with the large windfall credits and unfavorable cost/benefit ratios that would result from the currently proposed EV incentives. [EPA-HQ-OAR-2010-0799-9512-A1, p. 26]

Electric Vehicle Net Upstream Fuel Cycle GHG Emissions Accounting

There are a number of compelling reasons why the regulatory proposal should properly account for the EV fleet's upstream GHG emissions from grid electricity and/or hydrogen. First, such a system would achieve all of the benefits of a technology-neutral standard. As noted earlier, transparency would increase and windfall credits would be avoided. Windfall credits are discussed in further detail later. [EPA-HQ-OAR-2010-0799-9512-A1, p. 26]

In addition, full EV upstream net-GHG emissions accounting would incentivize efficiency improvements and fully legitimize, for EVs, the application of many important and desirable off-cycle incentives proposed by the US EPA. ICCT expects that EVs can earn low or zero g/mile compliance values (as shown in Table 4) both because of intrinsic advantages to electric drive technology and the ability to capitalize on other improvements such as:

• Inherent efficiency advantages over petroleum combustion engines

• Further efficiency improvements through lightweighting, aerodynamics, and low rolling resistance tires

• Displaced petroleum upstream emissions

• Reduced air conditioning GHG emissions through low Global Warming Potential (GWP) refrigerants, low-leak technologies and/or improved AC system efficiency

• Other off-cycle credits, when justified [EPA-HQ-OAR-2010-0799-9512-A1, p. 26]

We recommend that the net EV emissions be calculated in the same way as the example for BEVs provided by US EPA, with the explicit addition of off-cycle credits: [EPA-HQ-OAR-2010-0799-9512-A1, pp. 26-27]

net upstream EV emissions = fuel carbon intensity x vehicle efficiency - off-cycle credits - displaced petroleum upstream emissions [EPA-HQ-OAR-2010-0799-9512-A1, p. 27]

EVs with specific technologies not reflected on FTP/HWFET test cycles, upon meeting specific criteria, would receive credit for displacing off-cycle internal combustion engine (ICE) GHG emissions. As opposed to giving credit for avoided BEV upstream emissions only (based on displaced upstream), this approach would not understate the overall BEV benefit compared to a conventional ICE. [EPA-HQ-OAR-2010-0799-9512-A1, p. 27]

In response to US EPA's request for comments on FCEV hydrogen carbon intensity, we recommend using California's expected carbon intensity values as a default at least until the mid-term review of the national GHG standards. California cumulative FCEV deployments are expected to reach more than 50,000 by 201742 and California is currently establishing hydrogen stations through the use of incentives and regulations.43 We encourage US EPA to establish an initial California transportation hydrogen carbon intensity placeholder value based on 67% steam methane reformer (SMR) hydrogen production (a widespread method of production in the United States today) and 33% hydrogen production from renewable resources. This would be reflective of California's approach and could be updated over time as FCEVs spread to other states. [EPA-HQ-OAR-2010-0799-9512-A1, p. 27]

We encourage US EPA to model regional variations in grid electricity carbon intensity, as suggested in the NPRM. Potential reductions in grid carbon intensity, changing over time due to mandatory state renewables or other carbon-reduction standards, should be accounted for as well. In the meantime, California has conducted extensive analysis estimating electricity carbon intensity for 2020, including imported electricity, which could be used for a substantial portion of US BEV and PHEV placements. As this information is currently available, US EPA could establish an interim California value of270 g/kw-hr44 along with a parallel aggregate value for the remaining 49 states. We agree with US EPA's proposed inclusion of transmission and distribution losses, as well as upstream fossil fuel production emissions. [EPA-HQ-OAR-2010-0799-9512-A1, p. 27]

Table 4 provides an example of the ICCT's recommended emission calculations, using a 2020 BEV fueled by projected California or US average 2020 electricity. We would encourage US EPA to determine a similar example with a 49-state electricity carbon value.45 This example is not intended to predict future vehicle emissions, but rather to illustrate the methodology explained above and show the potential for 'earned zero' net g GHG/mile ZEV compliance values. [Table 4 can be found on p. 28 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, pp. 27-28]

Windfall Credits for Mandatory ZEV Deployments and Lost Benefits

We agree with the importance of EV technology deployment. However, we emphasize that EV credits should be earned based on performance, rather than awarded, independent of performance, for the production of a certain vehicle type. [EPA-HQ-OAR-2010-0799-9512-A1, pp. 28-29]

The ICCT has two significant issues related to (a) the proposed EV multipliers (also referred to as 'supercredits') and (b) the concept of giving vehicles a default zero gram per mile compliance score:

1. Large windfall credits for mandatory ZEV deployments.

2. High costs in terms of lost consumer savings and GHG benefits, even for vehicle deployments beyond mandatory levels. [EPA-HQ-OAR-2010-0799-9512-A1, p. 29]

Incentive programs are normally structured to avoid rewarding activity that is already otherwise required.47 The NPRM itself cites this principle, noting in the discussion of off-cycle credits that 'EPA would not provide credits for a technology required to be used by Federal law, such as tire pressure monitoring systems, as EPA would consider such credits to be windfall credits (Le. not generated as a results of the rule),'48 We agree with this principle, and in these comments we discuss how it can be applied to EV incentives. [EPA-HQ-OAR-2010-0799-9512-A1, p. 29]

The California Air Resources Board and Section 177 states have adopted the Zero Emission Vehicle program, requiring that manufacturers deploy large numbers of EVs.49CARB has forecast vehicle deployments out to 2025, although in terms of vehicle numbers the deployments are not specific regulatory targets due to flexibilities included in the ZEV rule. US EPA projections imply that for model years 2017 through 2025, deployments of BEVs and FCEVs mandated under California's ZEV rule are likely to account for 85 to 90+% of such vehicles nationally, whereas CARB forecasts show that PHEV deployments would be much higher than the US EPA's projection, as shown below in Table 5. Thus the vast majority of 'supercredits' generated under the proposed multipliers would likely be awarded to vehicles that manufacturers will be required to build even in the absence of the incentive. Furthermore, the total allocation of windfall credits seems likely to exceed the high-end scenario considered by US EPA in determining potential emission detriments stemming from the multiplier. [Table 5 can be found on p. 30 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 29]

While manufacturers receive benefit from bonus GHG credits, as noted below, ICCT finds that the societal costs of 'supercredit' multipliers and related default zero g/mi compliance values would be significantly greater than any potential incentive to manufacturers. Excess GHG credits allow manufacturers to decrease fuel efficiency across non-EVs in the fleet, and the resulting increase in overall fuel consumption and expenditures is the main factor responsible for this result,52 [EPA-HQ-OAR-2010-0799-9512-A1, p. 30]

Higher fleetwide fuel consumption along with related costs are shown in Table 6 below. Increased petroleum fuel costs range from $17,200 in MY2017 to $9,400 in MY2021 (in 2009$) at a 3 percent discount rate per EV from the proposed excess credits. We also estimate that fleetwide CO_2 would increase significantly per incremental EV due to the excess credits. Results for PHEVs would be scaled down based on different multipliers and the electric fraction of mileage. [Table 6 can be found on p. 31 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 30]

Table 7 shows two potential scenarios for the magnitude of the potential incentive manufacturers would see from the multiplier and zero upstream credits. ICCT selected scenarios of $25 and $35 per g CO_2/mi for illustrative purposes in Table 7 to represent a range of estimates of the potential marginal cost to move below 2020 emission levels for a midsized vehicle.57 As noted in several of our earlier comments, we believe that technology development will tend to result in lower costs than these estimates, reducing the potential value of bonus credits to manufacturers. ICCT used assumptions from NHTSA to calculate the reduction in a manufacturer's sales price for less efficient vehicles, which would reduce the net value of a GHG credit to a manufacturer.58 [Table 7 can be found on p. 33 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, pp. 31-32]

In all of these cost scenarios, the societal cost of the proposed EV incentives (as shown in Table 6) is significantly higher than the net benefit incentivizing the manufacturer (as shown in Table 7). We also note that the net manufacturer cost savings in these scenarios is less than the incremental cost of producing a BEV or FCEV in 2020, which is estimated by ARB to be $12,400-$12,900.59 The magnitude and uncertainty of this benefit is such that the EV bonus credits are unlikely to be effective in the absence of other types of consumer benefits, incentive programs, or manufacturer priorities. [Tables 6 and 7 can be found on pp. 31 and 33 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 32]

We also find that the system proposed in the NPRM could create confusion in the minds of consumers by creating a linkage between EV purchases and increased overall GHG emissions. Surveys show that drivers in the US, Canada, and 11 other countries overwhelmingly would want to know the source of electricity for a plug-in vehicle, and in the US 43% of respondents said that the source of electricity would affect their decision of whether to purchase the vehicle or not.60 While drivers were not directly asked whether indirect CO_2 increases linked to an EV purchase would discourage them from buying an EV this could be an unintended side-effect of these bonus credits. [EPA-HQ-OAR-2010-0799-9512-A1, p. 32]

Alternative Recommendation

If US EPA chooses not to eliminate MY2017-2021 multipliers and does not require EV fuel cycle net GHG upstream accounting, we would strongly encourage two modifications to the NPRM. First, EV incentives should be eliminated for all mandated vehicles. Direct coordination with CARB and Section 177 states would be the preferred approach, or an acceptable alternative would be to set a corresponding minimum deployment floor below which vehicles would not qualify for the incentives. Table 8 shows a potential scenario of ZEV and PHEV sales in California and Section 177 states as a percentage of national passenger vehicle sales, by model year. [Table 8 can be found on p. 34 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, pp. 33-34]

In addition, we would also recommend setting ambitious performance requirements to restrict eligibility for multipliers to the top performers. Real world range is a key determinant of environmental impact (due to gasoline vehicle miles displaced) as well as consumer acceptance, and could be used to establish performance criteria for each of the multiplier ratios that US EPA is considering. An example of this concept is shown in Table 9.64 [Table 9 can be found on p. 34 of Docket number EPA-HQ-OAR-2010-0799-9512-A1] [EPA-HQ-OAR-2010-0799-9512-A1, p. 34]

Finally we would also encourage US EPA to add a cap on incentives offered for MY 2017MY2021, and to generally set these caps for those model years as low as possible. In the proposed rule, the lack of a cap for MY 2017-2021 leaves open the possibility of significant foregone emission reductions in the event that electric vehicle sales greatly exceed US EPA's expectations. If such high sales levels occur, then presumably the technology is succeeding beyond expectations and the incentive is either unnecessary or excessive. We recommend establishing caps, with eligibility on a 'first come-first served' basis, even if US EPA initially gives each manufacturer credit eligibility for a minimum number of vehicles in order to encourage broader adoption of EV technology. [EPA-HQ-OAR-2010-0799-9512-A1, p. 35]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 197.]

One of ICCT's guiding principles is that standards should be technology neutral. The proposed provisions to assign zero carbon emissions to electric-only operation and for artificial credits for certain pickup truck technologies distort the compliance system and reduce the overall benefits of the program.

37 Bellagio Memorandum on Motor Vehicle Policy, Principles for Vehicles and Fuels in Response to Global Environmental and Health Imperatives, Consensus Document: 19-21 June, 2001, Bellagio, Italy

39 See for example California Air Resources Board. 2011 Staff Report: Initial Statement of Reasons, Advanced Clean Cars, 2012 Proposed Amendments to the California Zero Emission Vehicle Program Regulations; Vehicles.' (ZEV ISOR)

42 Source: CARB. 2011. Initial Statement of Reasons, Advanced Clean Cars 2012 Proposed Amendments to the Clean Fuels Outlet Regulation. (CFO ISOR) November. p12. Available at http://www.arb.ca.gov/regact/2012/cf02012/cfoisor.pdf. last accessed 2-6-2012. Note that factors

such as transportation hydrogen station infrastructure deployment and the Zero Emission Vehicle regulation will favor FCEV deployments in California initially.

43 CARB. 2011. Initial Statement of Reasons for Proposed Rulemaking, Public Hearing to Consider the 'LEV III Amendments' (LEV III ISOR) etc. p 136. CARB expects that California's 33% renewable transportation hydrogen requirement (California Senate Bill 1505 of2006) will be effective in the 2017-2025 timeframe

44 CARB LEV III ISOR. 2011. p136

45 us EPA us EPA Draft Regulatory Impact Analysis: Proposed Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse gas Emission Standards and Corporate Average Fuel Economy Standards (DRIA) RIA p4-31 and 4-32 and Federal Register Volume 76, Number 231, '2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards; Proposed Rule', p75014.

47 See for example the California Carl Moyer Memorial Air Quality Standards Attainment Program, which 'provides incentive grants for c1eaner-than-required engines, equipment and other sources of pollution providing early or extra emission reductions'. (emphasis added)

49 Currently, there are 10 states which have adopted the California ZEV regulation: Connecticut, Maine, Maryland, Massachusetts. New Jersey. New Mexico, New York, Oregon. Rhode Island, and Vermont CARB, 2011. ZEV ISOR.BEVs and FCEVs are mandatory, and PHEVs can be used to partially satisfy the mandate.

52 The zero g/mi compliance value and related multipliers applied to ZEVs allow a de facto increase in the fleet average GHG standard that must be met by the conventional (non-ZEV) portion of the fleet. Thus each ZEV deployed results in a small increase in allowable emissions from the remainder of the fleet, and a related small decrease in mandated fuel economy.

57 As a first-order approximation, ICCT estimated an average cost of $29 per g/mile for midsize car technology packages. excluding AC reduction, to reduce emissions from the level of the 2020 standard. Technology package costs are from the CARB LEV IlIlS0R p124. LEV IlI1S0R technology costs generally listed in 2009 dollars, see for instance ES-12. Some packages would cost more while others less.

59 CARB. 2011. ZEV ISOR, p. 62.

60 Accenture. 2011. 'Plug-in electric vehicles: Changing perceptions, hedging bets'. http:jjwww.accenture.comjus-enjPagesjinsight-plug-in-electric-vehicles-changing-perceptions-summary.aspx last accessed 10-13-2011. pp. 5, 17. 1,000 of 7,000 surveys were conducted in the US, 500 in Canada, and 3,502 in Europe.

64 1.45 and 1.5 multiplier categories merged for simplicity. Note that while this suggested table would not provide an additional timing incentive, early deployments would generally receive

greater credits through a more favorable credit due to the higher level of the standards in earlier years.

Organization: Jackson, F.W.

Comments:

1. Impressive claims appear based on 'faulty' EPA analyses, see references 2 & 3. Ref 2 page 4 - 32 claim in error. Claims Leaf CO_2/mile at 161 g/mile by using average grams CO_2 per Kw-hr (0.632) but this is a marginal problem and has to use marginal analyses which as documented in ref 1 table 3-15 & 3-16 calcs to 1.267 gCO_2/added (marginal) Kw-hr. So using the correct marginal rate the Leaf g CO_2/mile would be 323 g CO_2/mile. This should be immediately corrected by EPA in their documentation, to not do so raises the question: where else in EPA's documentations are they using incorrect analyses & assumptions & methods & credits & multipliers to promote a more favorable, albeit incorrect, number. And using the official label's 0.34 Kw-hrs per mile yields 431 g CO_2/mL [EPA-HQ-OAR-2010-0799-8041-A1, p. 1]

2. Additionally, the claimed (Ref. 2 on page 4 - 32) for the Leaf of 0.34 Kw-hrs/mile, or at 3412 btu/Kw-hr yields 1160 btu/mile electrical energy to plug, or at 115,000 btu per gallon gasoline makes vehicle mpgge (miles per gallon of gasoline equivalent) at 99 mpgge. However, with overnight coal generating & distribution & conversion net efficiency at 28% coal fossil fuel to plug Kw-hrs reality is system fossil fuel mpgge is at 28 mpgge. While vehicle performance is interesting to make the vehicle go it has to have the fuel, thus information on all it takes to make the vehicle go a mile has to be counted, Le., moving the Leaf a mile using overnight coal generated Kw-hrs calcs to 28 mpgge fossil fuel (not 99 mpgge) and produces CO_2 emissions of 431 g/mile (not 161)! And at significantly more cost per vehicle mile, so why is Govt promoting these expensive to Nation poor system performance vehicles? [EPA-HQ-OAR-2010-0799-8041-A1, p. 1]

'Faulty' PHEV & BEV & corn ethanol Promotional analyses often used by others corrected for in my data: [EPA-HQ-OAR-2010-0799-8041-A1, p. 5]

1. Failure to assess all results at National and Consumer/Taxpayer level (all consequences of action including taxes & inflation & credits & multipliers & passthroughs impact; all important measures)

2. Use of average vs. reality (gCO_2 per overnight added/removed Kwhr)

3. pre-2017; classifying Plug-in miles as zero emissions, when they, at National system level, are not; and using elec miles to 'allow' vehicles with gas mpgg not meeting CAFE to be sold!

4. benign miles/Kwhr vs real world miles/Kwhr (environment cabin/battery conditioning/performance)

5. Need full & accurate upstream CO_2 & oil & E6Btu & $s & lifestyle accounting, use of current/future HEV upstream vs. CV upstream and some reduced upstream gasoline CO_2 & fuel could be nonUS

6. PHEV vs. CV instead of PHEV vs. HEV; obscures the Plug-in stand alone consequences

7. failure to show all consequences of CAFE credit (cost,CO_2,gasoline,E6Btu).

8. failure to evaluate all possible actions, e.g., Mid/Max *eft* ICE or HEV or PHEV or less ethanol, i.e., pick 'poor' competition and not look for most improvement for $:lifestyle, CO_2, gasoline, E6Btu

9. failure to account for Business/Govt pass throughs, i.e., inflation/taxes (I believe very significant, albeit not included in most of my above data). e.g., assuming for every consumer vehicle business+Govt also have some then the delta cost (all factors included) would be an increase to consumers/taxpayers. [EPA-HQ-OAR-2010-0799-8041-A1, p. 5]

Organization: Johnson Controls, Inc.

Standards must be technology-neutral and performance-based. Johnson Controls believes that, in some ways, this proposal inadvertently imposes 'preferred technologies' and, in so doing, does not consider the full range of technologies available to allow for a fully competitive marketplace. [NHTSA-2010-0131-0253-A1, p. 3]

Organization: Magna E-Car Systems

Magna E-Car Systems is engaged in the supply and manufacture of high quality components and systems for hybrid and electric vehicles. We at Magna E-Car Systems view our work as central to the innovation that automakers will require to reach the 54.5 mpg fuel economy standard proposed by the EPA and NHTSA. But more importantly, we view hybrid and electric vehicle technology as imperative to the continued growth and reinvention of the automotive industry in the United States.[EPA-HQ-OAR-2010-0799-9263-A1, p. 1]

Hybrid and electric vehicles will help automotive manufacturers reach their 54.5 mpg target for their corporate average fuel economy. That's good news for the American economy and workers. Already, Magna E-Car Systems manufacture these technologies at our new hybrid and electric vehicle development facility in Holly, Michigan. Magna E-Car Systems alone employs over 300 employees in Michigan. [EPA-HQ-OAR-2010-0799-9263-A1, pp. 1-2]

Organization: Marz, Loren C.

However, I do not support the 'Incentives for Electric Vehicles, Plug-in Hybrid Electric Vehicles, and Fuel Cell Vehicles' unless diesel technology is also included in some fashion. [NHTSA-2010-0131-0213-A1, p.1]

Another National Academies report concluded...

'...Electric vehicles and grid-dependent (plug-in) hybrid vehicles showed somewhat higher nonclimate damages than many other technologies for both 2005 and 2030. Operating these vehicles produces few or no emissions, but producing the electricity to power them currently relies heavily on fossil fuels; also, energy used in creating the battery and electric motor adds up to 20 percent to the manufacturing part of life-cycle damages....' [NHTSA-2010-0131-0213-A1, p.7]

Source: National Academies, 'Hidden Costs of Energy: Unpriced Consequences of Energy Production and Use.'

This is supported by GREET1_2011 which shows that WTW emissions of particulate matter (PM) are higher for EV, PHEV, and FCV technology, all of which are proposed to receive special incentives under the proposed rule, than 'clean diesel' technology. Based on the default 'mid-sized' car assumed in GREET for the year 2020... [NHTSA-2010-0131-0213-A1, p.7]

WTW PM_{10} (diesel) = 0.009 (Feedstock) + 0.013 (Fuel) + 0.030 (Vehicle Operation) = 0.052 g/mi

WTW PM_{10} (EV) = 0.355 (Feedstock) + 0.017 (Fuel) + 0.021 (Vehicle Operations) = 0.393 g/mi

WTW PM_{10} (FCV) = 0.001 (Feedstock) + 0.059 (Fuel) + 0.021 (Vehicle Operations) = 0.081 g/mi

WTW $PM_{2.5}$ (diesel) = 0.005 (Feedstock) + 0.007 (Fuel) + 0.016 (Vehicle Operations) = 0.028 g/mi

WTW $PM_{2.5}$ (EV) = 0.089 (Feedstock) + 0.009 (Fuel) + 0.007 (Vehicle Operations) = 0.119 g/mi

WTW $PM_{2.5}$ (FCV) = 0.001 (Feedstock) + 0.031 (Fuel) + 0.007 (Vehicle Operations) = 0.039 g/mi

All of these values are based on the U.S. electric generation mix assumed in GREET in 2020. These values are graphically depicted more or less in a presentation of a previous version of GREET at http://www.iom.edu/~/media/Files/Activity%20Files/Environment/EnvironmentalHealthRT/WangGREETPresentationtoInstituteofMedicine1107REVISED.ashx - slides 24-25. [NHTSA-2010-0131-0213-A1, p.8]

Vehicle assumptions in GREET1_2011...

Diesel = 120% mpgge of baseline gasoline car

EV = 375% mpgge of baseline gasoline car

FCV = 237% mpgge of baseline gasoline car

Exhaust PM from the diesel car = 0.009 g/mi (PM_{10}); 0.0084 g/mi ($PM_{2.5}$).

Based on certified emissions of the 1996 VW Passat TDI (example of an 'old tech' diesel car), exhaust PM emissions = 0.06 g/mi (http://www.arb.ca.gov/msprog/onroad/cert/pcldtmdv/1996/volkswagen_pc_a0070189_1d9_1_diesel.pdf). [NHTSA-2010-0131-0213-A1, p.8]

0.06 - 0.009 = 0.051 g/mi more exhaust PM for the 'old tech' diesel than that assumed for 'clean diesel' in GREET.

0.052 g/mi + 0.051 g/mi = 0.103 g/mi WTW PM_{10} for the 'old tech' diesel car, still far less than 0.393 g/mi WTW PM_{10}, and significantly less than the WTW $PM_{2.5}$ from EV even assuming all PM from 'old tech' diesel exhaust is $PM_{2.5}$ (0.079 g/mi vs. 0.119 g/mi). [NHTSA-2010-0131-0213-A1, p.8]

'Old tech' diesel vehicles have been effectively banned for many years under Tier 2/LEV II regulations, to EPA's and CARB's credit, yet special incentives are being proposed for vehicle technology (e.g., EV) which may actually increase PM emissions from a WTW perspective above 'old tech' diesel engine technology. EPA acknowledges in the Draft RIA for this proposed rule that all $PM_{2.5}$ is treated as equally potent in causing premature mortality regardless of source (page 6-35 of the Draft RIA), even specifically mentioning $PM_{2.5}$ from diesel engine sources. So there appears to be no valid reason from a public health perspective to displace the reduction in $PM_{2.5}$ emissions from diesel engines with increased $PM_{2.5}$ emissions from power plants to support EV/PHEV/FCV technology. The regulatory push for these 'advanced technologies' defies logic from an emissions perspective. [NHTSA-2010-0131-0213-A1, pp.8-9]

It should also be noted that WTW SO_x emissions would also be higher for EV/PHEV/FCV, as would WTW NO_x emissions for EV/PHEV, than the default diesel car, according to GREET. [NHTSA-2010-0131-0213-A1, p.9]

A massive shift to EV/PHEV/FCV technology could risk offsetting gains made by EPA from diesel PM emission reduction mandates, more than offsetting it in the case of EV, and potentially reverse downward trends in the National Emission Inventory of PM_{10} and $PM_{2.5}$ emissions recently highlighted by EPA. Based on this analysis, a massive shift to these 'advanced technologies' would not only not be desirable, it may actually be environmentally detrimental, and incentives for these technologies are dubious. [NHTSA-2010-0131-0213-A1, p.9]

Organization: Mercedes-Benz USA, LLC

DAG endorses many aspects of the proposal, including in particular the agencies incentivizing advanced technologies such as electric and fuel cell drivetrains and off-cycle technologies. [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

DAG's future products will incorporate all aspects of advanced technologies. DAG will offer in the United States electric vehicles, plug-in hybrid vehicles, hybrid vehicles, fuel cell vehicles and potentially dedicated CNG vehicles as well. [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

• DAG strongly endorses the incentives for electric and fuel cell vehicles. Fuel cell vehicles, in particular, offer considerable long term advantages, and yet enjoy less short term public and private financial support than electric recharging infrastructure. The agencies should ensure that fuel cell vehicles remain a feasible option in the future by increasing the multiplier for fuel cell vehicles to 4. In addition, the agencies should provide a multiplier of 3 to dedicated CNG vehicles in light of the barriers these vehicles face and the significant role they can play in the fleet. [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

DAG strongly endorses the proposed incentives for battery-powered vehicles. The potential for battery technology in the United States and throughout the world remains strong, with a hesitant consumer market beginning to consider advanced technology vehicles. The four major market hurdles for battery-powered vehicles are: (l) public perception of electric vehicles as having limited range and functionality; (2) attacks based on upstream emissions pending change in the electricity supply towards renewable energy sources; (3) battery costs; and (4) limited infrastructure. EPA's conclusion that the market requires support to grow consumer confidence, build the refueling and servicing infrastructure and reduce battery costs recognizes the difficulties of building and sustaining support for 'game-changing' technologies with transformational long-term potential. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-5]

The concept of providing breathing room within a regulation to help nascent technology overcome short-term barriers is not novel.[9] EPA, for example, granted waivers through a relaxation of the NO_x standards in the 1980s in order to encourage diesel vehicles, and diesel sales soared. DAG's diesel sales during that period were substantial. More recently DAG introduced diesel BlueTEC technology to the United States. Other manufacturers have also introduced diesel passenger vehicles to the U.S. market. Public demand for clean diesel vehicles is growing.[10] The electric vehicle segment is particularly well-suited to such support. The credits associated with each type of battery technology should reflect the technology's potential to eliminate fossil fuel dependence and the level of the barriers that must be overcome for the technology to gain a strong foothold in the consumer marketplace. Thus, EPA has proposed that the credit multiplier for plug-in hybrids be somewhat less than the credit multiplier for full battery electric vehicles. Plug-in hybrids, while certain to playa significant role in building public confidence in electric vehicles, continue to have some limited ability to emit greenhouse gases. Full battery electric vehicles require a slightly higher incentive because they emit no greenhouse gases but will require more infrastructure and further technological advancement and more public experience to overcome initial skepticism. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-5]

Fuel cell vehicles are at the ultimate end of the spectrum. Fuel cell vehicles are able to support full functionality and dispense with range anxiety. They supply emissions free urban transportation as well as the capacity for long distance and interurban driving. Fuel cell vehicles can support a wide range of renewable fuels to generate hydrogen and electricity. Advances in battery technology will have a synergistic effect, because they will promote fuel cell batteries, as well as BEYs and PHEYs. DAG believes that with supporting government incentives, economies of scale, and advances in module strategies, fuel cell technology can be made cost competitive with diesel-hybrid vehicles. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-6]

Support for fuel cell infrastructure in the United States, however, lags behind that for electric vehicles. To be sure, California has moved towards revamping the Clean Fuels Outlet to promote fuel cell refueling stations.[11] The CFO proposal, however, links infrastructure support to the volume of fuel cell vehicles in California. Production incentives are therefore especially important to sustain the California effort and to ensure that a fuel cell market begins to take root and can ultimately grow in California and then spread throughout the United States. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-6]

Accordingly, DAG urges EPA to expand the credit multiplier applicable to fuel cell vehicles from 2.0 to 4.0. While PHEYs and BEYs are important, fuel cell technology represents the best opportunity over the long term to transform the personal transportation system entirely, to eliminate tailpipe greenhouse gas emissions and to service the full range of functionality and range demanded in the U.S. market. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-6]

---

9 EPA has long supported advanced diesel technology. While diesel engines expand fuel economy range over gasoline engines, they suffer from the carbon penalty when applied in the GHG program. This creates an inherent inconsistency between the CAFE and the GHG programs. A product with growing public support and the capacity to enhance fuel efficiency, reduce dependence on foreign oil and promote the economy provides a substantial compliance benefit in CAFE but goes largely unrecognized in the GHG program. This fundamental inconsistency creates a public policy disconnect with Europe and penalizes companies, such as DAG, that invested substantially in developing advanced diesel technology for the world market as well as the additional technology necessary to meet U.S. requirements.

10 Indeed, DAG has found that consumer prefer advanced diesel engines to hybrid vehicles with comparable fuel economy performance, at least as applied to DAG's luxury car offerings.

11 A nationwide effort is also underway in Germany to create a refueling network to support fuel cell vehicles.

Organization: Minnesota Department of Commerce

The proposed rule provides Electric vehicles (EVs) with preferential treatment compared with conventional or alternative fuel vehicles by means of a "credit" mechanism. The "credit" system proposed in the rule does not use life cycle assessment (LCA) methods commonly used for evaluating greenhouse gas emissions. Absent use of LCA, the proposed rule grants EVs zero greenhouse gas emissions even though U.S. DOE National Energy Technology Laboratory (NETL) studies show that electricity produced from fossil fuel may result in higher LCA vehicle emissions per mile than produced from gasoline (E10) hybrid electric vehicles. [EPA-HQ-OAR-2010-0799-7363-A1, p. 1]

Assure that the rule drives innovation so that diverse vehicle propulsion and fuel technologies can compete to achieve the goal. [EPA-HQ-OAR-2010-0799-7363-A1, p. 1]

Electric motors have no GHG emissions at point of use. A federal rule that only includes "tail pipe" –rather than life cycle emissions – effectively requires electric vehicles for the U.S. market. Rather than mandating a technology, the rule should motivate all propulsion and fuel technologies to compete to provide diverse, technical and economically optimal solutions for the Greenhouse Gas Emissions and Corporate Average Fuel Economy Standard. [EPA-HQ-OAR-2010-0799-7363-A1, p. 1]

Use LCA methodology for evaluating greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-7363-A1, p. 1]

Organization: Mitsubishi Motors R&D of America, Inc. (MRDA)

Supports the inclusion of an EV multiplier for MYs 2017 through 2021, and recommends that an EV multiplier be extended for MYs 2022 through 2025. [EPA-HQ-OAR-2010-0799-9507-A1, p.2]

Supports the 0 gram per mile compliance value for EVs, and the electric portion of PHEVs for MYs 2017 through 2021, and recommends that this compliance value continues in MYs 2022 through 2025. [EPA-HQ-OAR-2010-0799-9507-A1, p.2]

Mitsubishi Motors fully supports EPA's decision to provide an EV multiplier "to facilitate market penetration of the most advanced vehicle technologies as rapidly as possible". (76 FR 74878) This decision accurately reflects the current status of the EV industry relative to the U.S. market. During commercialization, an EV multiplier helps justify necessary capital investments to enable, deploy, and advance EV technologies before recouping these costs from vehicle sales. These capital investments are in addition to ongoing investments in traditional internal combustion engine technologies. As stated earlier, Mitsubishi Motors encourages the agencies to extend the EV multiplier in the later years of this rulemaking. Extending the multiplier will continue to make costs more reasonable and further promote EV technologies, allowing even greater GHG emission reductions to be realized. [EPA-HQ-OAR-2010-0799-9507-A1, p.4]

Mitsubishi Motors capital investments have led to global commercialization of the i-MiEV and to the development of quick charging technology. Specifically, we are a founding member of the CHAdeMO Association, a private industry association which aims to increase EV infrastructure worldwide and to internationally standardize the CHAdeMO protocol for DC quick charging of electric vehicles. As of February 2012, 1011 CHAdeMO quick chargers have been installed worldwide -- 835 in Japan and over 176 in Europe, Australia and North and South America. One of these quick chargers, certified for U.S. sale and public utility, was installed in our solar-powered charging station at our corporate headquarters in Cypress, California. [EPA-HQ-OAR-2010-0799-9507-A1, p.4]

Some of our continued and future capital investments are in the area of innovative charging techniques and energy storage management. Currently in Japan, Mitsubishi Motors is collaborating with wireless charger manufacturing and technology companies to develop EV charging systems enabled through electromagnetic induction. Mitsubishi Motors is also researching methods for capitalizing on i-MiEV batteries' storage capability for non-vehicle applications. Later this year, the Smart Grid Demonstration Project (the „V2X? concept) will begin at Mitsubishi Motors R&D headquarters in Okazaki, Japan. In the V2X project, electricity produced by solar panels will be stored in solar batteries, as well as i-MiEV batteries, and will be distributed to the factory power grid. All of these examples demonstrate our ongoing commitment and investment in EV vehicles and associated applications. An EV multiplier helps companies to sustain this type of research and investment before the establishment of a mass market for EVs. [EPA-HQ-OAR-2010-0799-9507-A1, pp.4-5]

Zero gram per mile compliance value [EPA-HQ-OAR-2010-0799-9507-A1, p.5]

Mitsubishi Motors fully supports EPA's decision to assign a zero gram per mile compliance value to EVs and the electric portion of PHEVs without company level caps for MYs 2017 through 2021. EPA's decision is sound public policy and recognizes that geography and regional economic factors determine the amount of renewable energy used to generate electricity. OEMs do not control these factors. Moreover, stationary source emissions are directly controlled by EPA under Title 5. Assigning power generation emissions to vehicles would lead to double counting – this is unprecedented and introduces an artificial burden on emerging technologies. Historically, fuel production ("well-to-tank") emissions were never assigned to the vehicle utilizing the fuel. Vehicle emissions are currently measured and regulated by the amount of compounds directly emitted by the vehicle. Given EVs and the electric portion of PHEVs do not emit CO_2, the proposed zero gram per mile compliance value is appropriate. [EPA-HQ-OAR-2010-0799-9507-A1, p.5]

The factors determining the amount of renewable energy used to generate electricity will not change. Therefore, the zero gram per mile compliance value as discussed above should remain in place for MYs 2022 through 2025. The regulatory cost of requiring the accounting of upstream emissions could create a barrier that would prevent manufacturers from producing and introducing newer, more efficient EVs and PHEVs. Furthermore, a company cap as proposed on the amount of vehicles that can use the zero gram per mile compliance factor is an unnecessary regulatory limitation, and we recommend that this requirement be removed. A cap could prevent a true and effective market penetration rate of these technologies. [EPA-HQ-OAR-2010-0799-9507-A1, p.5]

The EV multiplier compliance incentive is absolutely necessary to promote EV adoption during this rulemaking, and should be extended into the later part of this rulemaking. We support the zero gram per mile compliance value for EVs and the electric portion of PHEVs, which reflect the real-world GHG emissions at the vehicle level- a factor OEMs can control. Furthermore, this compliance value should continue into the later years of the rulemaking without limitations on usage. [EPA-HQ-OAR-2010-0799-9507-A1, p. 6]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 95-99.]

Automotive OEMs have little control over the source of electricity. Therefore, like was said before, they should not be subject to arbitrary emissions regulations on electric vehicles. These need to be accounted for in separate regulations of those regulated industries. And in absence of comprehensive national energy policy, Mitsubishi Motors recognizes the challenges and the associated risks of developing practical federal and fuel economy and greenhouse gas standards for light-duty vehicles. Mitsubishi Motors believes continued inclusive process to develop fuel economy and greenhouse gas standards is a realistic goal.

Organization: Motor & Equipment Manufacturers Association (MEMA)

Standards must be technology-neutral and performance-based. The proposed rule inadvertently imposes “preferred technologies” and, in so doing, does not consider the full range of technologies available to allow for a fully competitive marketplace. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

Fuel efficiency and GHG emissions standards must be technology-neutral and performance-based. Undoubtedly, the standards proposed by the agencies are well-intended and will continue to compel the automotive industry to reach these goals by incorporating a full range of technological innovations. No specific vehicle technology will meet all of our nation’s driving needs. All options must be made available in order to achieve the overall objectives to reduce fuel consumption and emissions. Despite the agencies’ assurances that they are not influencing the availability of certain vehicles, the proposal inadvertently influences “preferred vehicle technologies.” Thus, it constrains the full field of advanced technology vehicles that are available to meet the overarching fuel consumption and emissions reduction goals. A solution of today may not necessarily be the solution of tomorrow. Unintentionally driving technologies down a few narrow paths could possibly set us up for long-term failure to realize the nation’s goals. Moreover, such inadvertent preferences stifle technology innovation and constrain the competitive marketplace. [EPA-HQ-OAR-2010-0799-9478-A1, p.3]

Other potential consequences are non-market based imbalances and preferential treatment to certain vehicle manufacturers (depending on their use of “preferred technologies” in their fleet mix), ultimately picking "winners and losers." Restricting incentives to specific technologies could present a market where such vehicles are produced, but not purchased because these vehicles may not meet consumers' needs or value expectations. Again, this may result in less-than-needed fleet penetration in order to impact the emissions and fuel consumption and meet the goals of the Program. [EPA-HQ-OAR-2010-0799-9478-A1, p.3]

Benefits of these technologies should be considered from a well-to-wheel, fuel lifecycle perspective. Without this type of comprehensive assessment, the agencies consequently improperly favor preferred technologies rather than providing truly technology-neutral standards. MEMA would recommend using the existing well-to-wheel assessment of the GREET (Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation Model) that is used by the U.S. Department of Energy. GREET has been used to shape policy choices that impact emissions and evaluates the well-to-wheel impact of various technologies. [EPA-HQ-OAR-2010-0799-9478-A1, p.3]

In the NPRM, EPA discusses two alternatives for the calculation of CAFE for dual fuel vehicles for MY2020 and beyond after the expiration of the calculation currently in effect through MY2019 (as specified in 49 U.S.C. 32905). EPA has invited comment on both approaches. [EPA-HQ-OAR-2010-0799-9478-A1, p.12]

Organization: National Association of Clean Air Agencies (NACAA)

Third, we recognize that this program, proposed by EPA under section 202(a) of the Clean Air Act, is a vehicle tailpipe emissions control program. As such, it is appropriate to assign a tailpipe emissions level of 0 g/mile CO_2 for all electric vehicles (EVs), plug-in hybrid electric vehicles (PHEVs) and fuel cell vehicles (FCVs), as EPA does for MYs 2017 through 2021 with a per-company cumulative sales cap for 0 g/mile for MYs 2022 through 2025. [EPA-HQ-OAR-2010-0799-8084-A1, p. 4]

We are pleased that, as EPA states, this program's focus on vehicle tailpipe emissions does not raise issues relative to criteria pollutants because "upstream emissions [of criteria pollutants] associated with production and distribution of the fuel are addressed by comprehensive regulatory programs focused on the upstream sources of those emissions." In addition, we appreciate the agency's statement that because "upstream GHG emissions values are generally higher than the upstream GHG emissions values associated with gasoline vehicles, and because there is currently no national program in place to reduce GHG emissions from electric power plants, EPA believes it is appropriate to consider the incremental upstream GHG emissions associated with electricity production and distribution." But, we also believe it is an appropriate position to encourage the initial commercialization of EVs, PHEVs, and FCVs while monitoring the status of upstream emissions. [EPA-HQ-OAR-2010-0799-8084-A1, p. 4]

[These comments were also submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 36-37.]

Organization: National Corn Growers Association et al.

Only vehicle tailpipe emissions are counted toward compliance with GHG standards rather than including complete life cycle emissions, excluding emissions generated in the production and delivery of the fuel whether electricity, gasoline, natural gas or a renewable fuel such as ethanol. As a result, all types of electric vehicles would have “zero” emissions during electric operation when this is clearly not the case when electricity production emissions are included. This method unfairly advantages electrically fueled vehicles over other technologies, and does not allow for a comparison of true emission performance among various propulsion technologies and fuels. For example, a BEV generates no tailpipe emissions, but an FFV fueled with E85 might compare very favorably to the BEV if GHG emissions were evaluated on a life cycle basis[3] as they should be in evaluating their contribution to the air. By structuring credits to favor one technology over another, the agencies are picking winners and losers rather than allowing technologies to compete on a level playing field against a performance standard[4] . In addition, the fact that EPA chose tailpipe instead of life cycle emission standards for the CAFE/GHG rule is inconsistent with EISA and with RFS2 GHG performance threshold standards[5]. [EPA-HQ-OAR-2010-0799-9565-A1, p.3]

3 - “Well-to-Wheels Analysis of Advanced Fuel/Vehicle Systems — A North American Study of Energy Use, Greenhouse Gas Emissions, and Criteria Pollutant Emissions”, May 2005, Figure 4-5. [EPA-HQ-OAR-2010-0799-9565-A1, p.3]

4 - The favoring of EV technology over renewable fuels is especially evident in the specific denial of credits for FFVs in the proposed rule, Sec. III.C, p311. [EPA-HQ-OAR-2010-0799-9565-A1, p.3]

5 - “EISA required EPA to apply lifecycle greenhouse gas performance threshold standards to ensure that each category of renewable fuel emits fewer greenhouse gases than the petroleum fuel it replaces.” From http://www.epa.gov/otaq/fuels/renewablefuels/ [EPA-HQ-OAR-2010-0799-9565-A1, p.3]

Organization: National Propane Gas Association (NPGA)

Government Agency Consistency

The Department of Energy is currently seeking to adopt the recommendation of the National Academy of Sciences (NAS) that “DOE shift over time to use of a FFC measure of energy consumption for assessment of national and environmental impacts, particularly GHG for establishing appliance efficiencies.” In doing so, the NAS also recommended providing more comprehensive information to the public through labels and/or other means, such as an enhanced website. [EPA-HQ-OAR-2010-0799-9482-A1, p. 6]

NPGA believes any final rule reducing CAFE and GHG standards for light-duty vehicles for the years of 2017 through 2025 absent FFC measurement would easily provide automakers of advanced technology vehicles an unfair market advantage for their vehicles. Without FFC analysis, using electricity as the dedicated vehicle fuel gives the impression that its use in light-duty vehicles is 100 percent efficient with zero end-use emissions. This conclusion is erroneous and analogous to the DOE promulgating energy efficiency standards for building appliances finding no GHG emissions associated with turning on a light bulb. Further conveyance of this logic will have a compounding effect for any and every year the EPA/NHTSA carries it forward through the year 2025. [EPA-HQ-OAR-2010-0799-9482-A1, p. 6]

Rulemaking that focuses on point-of-use energy creates and maintains an unfair market advantage for technologies that already have lower full-fuel-cycle efficiency and higher GHG emissions. The overall FFC efficiency for electricity typically results in only about 30 percent of usable energy at the point-of-use. However, FFC analysis recognizes the efficiency of the autogas delivery process resulting in approximately 87% of the energy produced being delivered as usable energy. For these and other reasons, we propose that GHG emissions especially as they relate to emissions for electric vehicles, fuel cell vehicles, and the electric portion of plug-in hybrid electric vehicles be accounted for immediately upon the final rule's effective date. [EPA-HQ-OAR-2010-0799-9482-A1, p. 7]

Organization: National Wildlife Federation (NWF)

In principle, we also support incentives for plug-in hybrid electric and electric vehicle technology and for real off-cycle CO_2 reductions, and we look forward to continuing to work with automakers, the agencies and consumers to maximize the effectiveness of these credits and other measures which enable rapid adoption of new technology, and to optimize short and long term emissions impacts. [EPA-HQ-OAR-2010-0799-9887-A2, p. 4] [[This comment can also be found in Outline Headings 5. and 7.]]

Organization: Natural Resources Defense Council (NRDC)

EPA should include emissions associated with upstream electricity or hydrogen production for plug-in electric or hydrogen fuel cell vehicles in the emission scoring. If incentives remain that discount upstream emissions, the structure should be strengthened to ensure greater environmental certainty of the incentives and minimize losses of emission reduction benefits. [EPA-HQ-OAR-2010-0799-9472-A2, p. 3]

B. Program incentives

1. Treating Plug-in Electric and Hydrogen Fuel Cell Vehicles as "Zero" Emissions Undermines Pollution and Technology Benefits of Program

In the proposal, EPA acknowledges that awarding plug-in electric vehicles an emissions rate of 0 g/mi inaccurately reflects their real-world impact and reduces the potential GHG reductions of the program by up to 5.4 percent.34 Automakers can comply by producing advanced technology vehicles such as plug-in electric or hydrogen fuel cell vehicles which then allows them to apply less technology to their conventional vehicle fleet which, in turn, results in a higher average fleet emissions rate. To avoid this loss in emissions and fuel savings benefits, NRDC believes that the emissions associated with upstream electricity or hydrogen production should be included in the compliance scoring. [EPA-HQ-OAR-2010-0799-9472-A2, p. 11]

However, if the agencies proceed with their proposed 0 g/mi treatment, other incentives, such as off-cycle credits, should not be available for the portion of an advanced vehicle's driving range that is powered by grid electricity or off-board hydrogen. No vehicles should be allowed to have negative emissions. For plug-in hybrid electric vehicles, the benefit of additional incentives should be calculated based on the emissions or efficiency benefit achieved for only the gasoline or diesel operation of the vehicle. [EPA-HQ-OAR-2010-0799-9472-A2, p. 11]

NRDC believes EPA underestimates the potential losses in GHG reductions due to plug-in electric vehicles. The California Zero Emission Vehicle (ZEV) program, the latest version of which was recently authorized by the California Air Resources Board (CARB), is expect to encourage higher sales volumes nationally than those predicted by EPA. EPA estimates up to 2.8 million vehicles (plug-in electric and fuel cell vehicles) will be sold from 2017 to 2025. According to CARB, the ZEV program could result in 1.4 million sold in California during the same period.35 Additionally, CARB has estimated that the states which have adopted the ZEV program (under Section 177 of the Clean Air Act) could have electric vehicle sales that are twice the California level, or 2.8 million vehicles.36 It is also reasonable to assume that another 10 percent of vehicles would be sold in non-ZEV states as many automakers are focusing sales nationally or at least in some states in addition to 177 states. In total, national electric vehicle sales could be 4.6 million, or 65 percent greater than EPA's highest estimate. [EPA-HQ-OAR-2010-0799-9472-A2, p. 11]

To limit the loss of GHG benefits, EPA should modify the cap on the number of vehicles eligible for 0 g/mi treatment. NRDC recommends that EPA adopt an industry-wide cap following the structure described in the NPRM as the alternative to the proposed manufacturer-specific cap. NRDC recommends the industry-wide cap because it ensures the environmental benefits of the program. If set appropriately by considering the higher potential sales as described above, the industry-wide cap could ensure that no more than 5 percent of the program GHG reductions are lost. NRDC recommends that the industry-wide cap be set based on cumulative plug-in electric vehicles produced beginning in 2012 because even these early volumes will help pave the way for electric vehicle production cost reductions and greater market acceptance. While 0 g/mi treatment could be applied for model years 2017 to 2021, as EPA has proposed, the post 2021 cap of no more than 2 million vehicles would be lowered by the cumulative sales that occurred before 2022 to reflect the technology advancement in the early years of the program. [EPA-HQ-OAR-2010-0799-9472-A2, pp. 11-12]

If EPA maintains the manufacturer-specific cap, NRDC believes it should be lowered from the proposed 600,000 for each manufacturer that sells at least 300,000 from 2019-2021 to ensure that no more than 5 percent of the GHG reductions are lost when considering sales volumes in excess of 4 million vehicles from 2017-2025. [EPA-HQ-OAR-2010-0799-9472-A2, p. 12]

NRDC opposes any weakening or removal of the cap on 0 g/mi treatment that exists for model years 2012-2016. [EPA-HQ-OAR-2010-0799-9472-A2, p. 12]

NRDC supports the requirement of a minimum all-electric range of at least 10 miles for a vehicle to be eligible for 0 g/mi treatment. NRDC also agrees that the 0 g/mi treatment should only apply to operation on grid-supplied electricity in plug-in hybrid electric vehicles. The use of a utility factor is a reasonable allocation of the 0 g/mi treatment. [EPA-HQ-OAR-2010-0799-9472-A2, p. 12]

We also welcome further discussions with EPA on the details of setting upstream emissions accounting. EPA notes that there are several factors to consider including marginal versus average power plant emissions rates, regional variability and how to project emission rates for vehicles that are charging over many years. NRDC provided comments in the 2012-2016 GHG proposed rule along these lines and we recognize that on-going analysis could be appropriate to most accurately quantify electric vehicle emission rates for real-world operation. [EPA-HQ-OAR-2010-0799-9472-A2, p. 12]

---

35 CARB, Staff Report: Initial Statement Of Reasons, Advanced Clean Cars, 2012 Proposed Amendments To The California Zero Emission Vehicle Program Regulations, December 7, 2011. [EPA-HQ-OAR-2010-0799-9472-A2, p. 111]

36 Ibid [EPA-HQ-OAR-2010-0799-9472-A2, p. 13]

Organization: Nissan North America, Inc.

Support for Electric Vehicles: The proposal represents a significant leap forward in advancing environmentally friendly vehicles and zero emissions transportation. Battery electric technology has the ability, over time, to reduce substantially reliance on foreign oil and to provide vehicles capable of running on renewable energy sources. While automobile manufacturers cannot control the source of fuel, the industry can develop and market vehicles supporting clean energy use and can ensure that tailpipe emissions are diminished, or-as in the case of the Nissan LEAF-eliminated completely. [EPA-HQ-OAR-2010-0799-9471-A1, p.2]

Credit Multiplier: The proposed credit multiplier for battery electric vehicles (EVs), plug-in hybrid electric vehicles (PHEVs) and fuel cell vehicles (FCVs) is critical to the Widespread deployment of these advanced powertrain technologies. The adoption of these alternative powertrains, beyond their initial purchasers, hinges on significant investment by automobile manufacturers in research and development, the appropriate amount of time to create an effective deployment strategy, and marketing initiatives that are tailored to new technology deployment. Past experiences have shown that regulatory programs that support new technologies Increase the availability and rate of adoption of new technologies, making it more likely that new technologies reach a critical mass of consumers. [EPA-HQ-OAR-2010-0799-9471-A1, p.2]

Measuring Tailpipe Emissions: Nissan supports EPA's proposal to use a greenhouse gas emissions compliance value of 0 grams per mile for EVs, FCVs and the electric portions of PHEVs in MYs 20172021 (and certain vehicles in MYs 2022-2025). The compliance value of these vehicles should always be measured at zero grams per mile. Including upstream emissions in the compliance calculation will cause confusion in the marketplace and will detract from the agencies' support for the deployment of battery powered vehicles. The agency should, as a matter of public policy, continue to promote the advancement of zero and low-emission vehicles while separately focusing on the development of renewable and/or low emission power sources. This is not only the best policy decision to promote EV deployment and increase their rate of adoption, it is also legally required. [EPA-HQ-OAR-2010-0799-9471-A1, p.3]

While advancements in petroleum powered vehicles are essential to improving fuel efficiency and necessary to achieve immediate goals, battery electric technology offers the promise of yet more substantial reductions-and even the elimination-of tailpipe emissions. Nissan anticipates that battery electric and plug-in hybrid vehicles can achieve a significant market share if supported by government programs and incentives, and if the industry is provided with the necessary incentives to invest in the technology. [EPA-HQ-OAR-2010-0799-9471-A1, p.10]

Other automakers are also entering the market for battery electric vehicles and plug-in hybrids. Most, however, are doing so more cautiously than Nissan and continued investment will depend largely on the extent to which consumers adopt the technology and infrastructure is built to support the vehicles. As set forth in more detail below, government incentives and support are essential to ensuring manufacturer investment and widespread consumer adoption of these technologies. [EPA-HQ-OAR-2010-0799-9471-A1, p.10]

The credits proposed for electric drivetrains and the continued focus on tailpipe emissions when calculating GHG emissions are critical to promoting the government's long term policy initiatives. Without the incentives and continued focus on tailpipe emissions when calculating GHG emissions, as explained more fully below, consumers will be slower to adopt these advanced technologies and continue to rely on traditional internal combustion vehicles, which will result in higher overall greenhouse gas emissions long term. It is not until consumers adopt these technologies that the United States can realize the benefits of these transformational, 'game changing' vehicle technologies. [EPA-HQ-OAR-2010-0799-9471-A1, p.10]

As EPA recognizes, the proposed regulatory incentives for electric vehicles are 'justified by promoting technologies that have significant transportation GHG emissions and oil consumption game-changing potential in the longer run, and that also face major market barriers in entering a market that has been dominated by gasoline vehicle technology and infrastructure for over 100 years.' See 76 Fed. Reg. 74,854, 75,011 (Dec. 1, 2011) ('Proposed Rule'). Meaningful market penetration of these advanced powertrains hinges not only on increased consumer demand and continued infrastructure development, but also on significant investment by automobile manufacturers. [EPA-HQ-OAR-2010-0799-9471-A1, pp.10-11]

Automobile manufacturers face an increasingly competitive market, short-term economic uncertainties and increasing regulatory costs. Nissan and other automakers must invest in a range of technologies to provide certainty in their ability to meet the proposed standards. While Nissan remains committed to the promise of battery electric vehicles, the proposed incentives provide the requisite support to the industry as a whole to make the early investment required to create a more robust market for battery electric vehicles and to spur their adoption rate. [EPA-HQ-OAR-2010-0799-9471-A1, p.11]

In order for new a technology--especially technologies that disrupt the status quo-to be adopted on a meaningful scale, it is essential that the new technology be adopted by a critical mass of consumers. While some new technological innovations diffuse from first use to widespread adoption in a matter of years, others may level out at less than 2 percent. See generally Everett M. Rogers, Diffusion of Innovations 219 (Free Press 5th ed. 2003) (1962). [EPA-HQ-OAR-2010-0799-9471-A1, p.11]

A widely used depiction of the technology adoption curve is the 'Innovation Adoption Lifecycle' developed by Joe M. Bohlen, George M. Beal, and Everett M. Rogers at Iowa State University: [EPA-HQ-OAR-2010-0799-9471-A1, p.11] [For the graphic referenced (technology adoption curve) please refer to EPA-HQ-OAR-2010-0799-9471-A1, p.11]

See Diffusion of Innovations at 281.[6] As the bell curve shows, new technologies begin with a relatively small number of 'Innovators,' then move to 'Early Adopters' before possibly finding acceptance within the pragmatic majority of consumers. Most of the variance in the rate of adoption of innovations is explained by five attributes: relative advantage, compatibility, complexity, trialability, and observability. Jd. at 221. [EPA-HQ-OAR-2010-0799-9471-A1, pp.11-12]

As applied to many consumer markets, a disruptive technology is likely to displace more traditional technology as it moves along the adoption curve to reach the pragmatic majority of consumers. However, as applied to the motor vehicle market, the goal is not for electric drivetrains to displace ICE vehicles, but rather for electric vehicles to gain enough of a foothold in the marketplace to be able to share the market with more traditional drivetrain technology. [EPA-HQ-OAR-2010-0799-9471-A1, p.12]

A disruptive technology has the best chance of broader adoption when 'opinion leaders adopt, which usually occurs somewhere between 3 and 16 percent adoption in most systems.' Jd. at 223. The Early Adopters are the opinion leaders in communities, and potential adopters of a new technology look to them for advice and information. Jd. at 283. Consistent with this well-developed theory of technology adoption, the agency has recognized that 'consumer interest in EVs is likely to change over time, as early adopters share their experiences.' Proposed Rule at 75,117 (emphasis added). [EPA-HQ-OAR-2010-0799-9471-A1, p.12]

The Innovation Adoption Lifecycle represents what is necessary to enable EVs to move from Innovators to Early Adopters in order to gain enough of a foothold to, over time, find acceptance amongst early members of the more pragmatic majority. In this context, government production incentives are imperative to ensure that electric drivetrains are able to make the critical move from the approximate 2.5% of the market where Innovators are willing to experiment with the new technology to the next group of consumers where Early Adopters showcase the practical use of the technology and begin the process of incorporating the technology into the broader market. [EPA-HQ-OAR-2010-0799-9471-A1, p.12]

Since the motor vehicle market needs to be supported by substantial infrastructure and involves substantial investment and up-front costs, movement along the technology adoption curve is substantially slower and more precarious. Hybrids, for example, while gaining general acceptance as a viable drivetrain, have only just reached a consumer market share where they have transgressed beyond innovative consumers to more widespread early adopters. [EPA-HQ-OAR-2010-0799-9471-A1, p.13]

The chart on the following page depicts the rate of HEV sales from when they were first introduced in 1999 through 2007, and also depicts where EVs are on that same production schedule: [EPA-HQ-OAR-2010-0799-9471-A1, p.13] [To view the chart please refer to EPA-HQ-OAR-2010-0799-9471-A1, p.14]

The first hybrid Honda Insight was introduced in the U.S. in 1999 and the first Toyota Prius was introduced in the United States in 2000. HEVs comprised only about 0.5% of new car sales during the first generation of these vehicles; and, as of2004, only five HEV models were available. HEVs reached a key tipping point, increasing their U.S. light-duty vehicle market share by 250%, between 2004 and 2005 when multiple automobile manufacturers entered the market offering a variety of HEV models. This tipping point coincided with the second generation Prius. Yet, today hybrids have just reached a 2.5-3% market share. [EPA-HQ-OAR-2010-0799-9471-A1, p.14]

The hybrid experience represents the extreme challenges of introducing transformational drivetrain technology into the new motor vehicle fleet. EVs must not only travel the same early-stage adoption path as HEVs (which still rely on petroleum), but also face more substantial market barriers, such as concerns over range and the need to develop support infrastructure. As reflected on the graph, the EV market is only in its infancy. It will require substantial support to overcome the barriers to broad market penetration and to ensure a solid and long-lasting foothold in the automotive marketplace. [EPA-HQ-OAR-2010-0799-9471-A1, p.14]

The projected market penetration rates for EVs and PHEVs vary significantly, demonstrating the market uncertainty surrounding these technologies. The Boston Consulting Group projects that EVs and PHEVs could make up 2% of new light-duty vehicle sales in 2020. A study conducted by Google.org using McKinsey & Company’s Low Carbon Economics Tool, on the other hand, projects that EVs and PHEVs could make up as much as 70% of new light-duty vehicle sales by 2030. The Google Study projection assumes rapid decreases in battery costs and increases in energy density by 2030, to enable the production of electric vehicles with 300-mile range and a total cost of ownership lower than that of conventional gasoline vehicles. See Google Study at 12. Without a breakthrough in battery technology, however, the Google Study concludes that it will be 'much harder for EVs to reach scale.' Id. [EPA-HQ-OAR-2010-0799-9471-A1, pp.14-15]

The HEV experience and the EV market forecasts reflect the uncertainties surrounding the successful deployment of transformational drivetrain technologies beyond market innovators. 'Diffuser incentives'-incentives provided to manufacturers to produce a new technology and to persuade consumers to adopt that technology-will provide a strong foundation upon which to base that deployment and to redress the market barriers that may otherwise stall or limit a more expanded market for advanced vehicle technologies. The proposed production incentives are imperative for that technology adoption to occur. [EPA-HQ-OAR-2010-0799-9471-A1, p.15]

Indeed, compliance incentives historically have been successful in generating production and creating a market for new light-duty vehicles. When, for example, EPA provided an incentive for diesel vehicles in the 1980s through a relaxed NO_x standard, the production and sale of diesel vehicles rose considerably.[11] As evidenced in the graph below, diesel vehicles saw their best sales during those years. For the period during which the waivers were in effect, the percentage of new light-duty vehicle sales was approximately four times higher than it was in the immediately preceding years: [EPA-HQ-OAR-2010-0799-9471-A1, p.15] [To view the graph please refer to EPA-HQ-OAR-2010-0799-9471-A1, p.16]

The experience with light-duty diesel vehicles demonstrates the successful use of compliance incentives to generate the manufacture and marketing of advanced and innovative technology in the light-duty vehicle market.[13] [EPA-HQ-OAR-2010-0799-9471-A1, p.16]

The Proposed Incentives Will Encourage State and Local Governments and Private Firms to Stay the Course, and Continue to Promote Advanced Vehicle Technologies [EPA-HQ-OAR-2010-0799-9471-A1, p.16]

The successful development of an EV market depends upon the simultaneous growth of vehicle production, consumer demand and infrastructure. The proposed incentives offered to manufacturers will result in increased production and availability of EVs and PHEVs. They will complement an existing array of federal and state consumer incentives and public funds for infrastructure and charging[14] that have created a viable market in the key and early markets, and a budding consumer interest in additional markets throughout the nation. Private investment in EV infrastructure is being made as well[15], and utilities are offering time-of-use incentives which make owning and operating a battery electric vehicle easier.[16] [EPA-HQ-OAR-2010-0799-9471-A1, pp.16-17]

Public and private investment, however, remains uncertain as budget constraints present challenges to the federal, state and local governments. Private firms, moreover, must see strong government support for electric vehicles to justify investment in electric vehicle infrastructure. The proposed incentives will encourage state and local governments and private firms to stay the course, and continue to promote advanced vehicle technologies. [EPA-HQ-OAR-2010-0799-9471-A1, p.17]

The experience to date shows that the market will respond best with a combined support of incentives, infrastructure and vehicle availability. The deployment of the Nissan LEAF has been initiated in 'waves'. The waves reflect the markets that Nissan considered to be more market ready in terms of both consumer demand and local government support. The initial wave (Wave 1) began in late 2010 and included San Francisco, San Diego, Sacramento, Los Angeles, Honolulu, Portland, Seattle, Phoenix, Nashville, Dallas, Houston and Austin. The Nissan LEAF was introduced in other cities in additional waves throughout 2011. Nissan anticipates a nationwide rollout of the Nissan LEAF in 2012. [EPA-HQ-OAR-2010-0799-9471-A1, p.17]

Focusing on the Wave 1 markets where data is more readily available, Nissan has analyzed the factors necessary to convert general consumer interest in electric vehicles to the ultimate purchase of a Nissan LEAF. Consumer interest in the Nissan LEAF begins with 'Handraisers,' those who sign up (bye-mail or otherwise) to receive information about the Nissan LEAF. Handraisers can then take the next step and make a 'Reservation,' a refundable $99 deposit that will reserve the consumer's place in line when Nissan LEAFs are made available in the consumer's market. Once they are, the consumer can request a quote (RAQ) from a dealer. Ultimately, if the consumer decides to purchase the Nissan LEAF, this will lead to an order or sale (collectively 'Orders'). [EPA-HQ-OAR-2010-0799-9471-A1, p.17]

The Wave 1 markets demonstrate the importance of consumer incentives. Providing direct consumer benefits such as access to HOV lanes and financial support for home electric vehicle supply equipment (EVSE) installation significantly increase EV interest and sales. Data from Wave 1 of the Nissan LEAF shows that consumers eligible for the EV Project (a public-private partnership funded in part by the Department of Energy), through which they would receive residential EVSE installation at no cost, were twice as likely to purchase an EV as those who did not. Moreover, in states with one monetary consumer incentive, internal data shows that people were 216% more likely ultimately to order a Nissan LEAF. In states with two or more consumer incentives, data shows that people were 300% more likely ultimately to order a Nissan LEAF. [EPA-HQ-OAR-2010-0799-9471-A1, p.18]

Further, markets with more substantial installed and planned infrastructure exhibit a higher level of conversion from Reservations to Orders (35-40%) than those with less infrastructure (23-30%). The amount of infrastructure needed in the remaining markets, however, remains considerable and Nissan's data suggests that a combination of increased vehicle availability and growth in infrastructure will combine to increase demand for battery electric vehicles. [EPA-HQ-OAR-2010-0799-9471-A1, p.18]

In sum, the proposed incentives will complement an existing array of consumer incentives and infrastructure development to enable EVs to overcome near-term market barriers, resulting in an accelerated tipping point for EV adoption. [EPA-HQ-OAR-2010-0799-9471-A1, p.18]

Upstream Emissions Should Not be Considered When Calculating Greenhouse Gas Emission Compliance Values [EPA-HQ-OAR-2010-0799-9471-A1, p.18]

Nissan has long endorsed measuring the greenhouse gas emissions from EVs, PHEVs and FCVs from the tailpipe, and not including the upstream emissions associated with the generation of the electricity that powers these vehicles. EPA endorsed this approach in the previous rulemaking governing MYs 2012-2016 (up to a specific amount of vehicles), in the labeling rule and has proposed that approach for certain EVs, PHEVs, and FCVs in this rulemaking as well. The proposal to focus on tailpipe emissions is consistent with the policy objective of fostering electric vehicles and with the fact that automobile manufacturers only control tailpipe emissions and have no control over the fuel source for electric power. [EPA-HQ-OAR-2010-0799-9471-A1, p.18]

Moreover, any non-regulatory consumer information provided by website, label or otherwise, must present any upstream emissions information to consumers in a consistent fashion so that consumers will see not only the upstream emissions associated with electric vehicles but also the upstream emissions associated with other types of vehicles. The agencies should not provide any upstream emissions information to consumers based on a net adjustment for electric vehicles because such an approach unfairly suggests that ICE vehicles involve no upstream emissions and creates unnecessary confusion over the question of upstream emissions. If the agencies were to provide this information to consumers, the information should reflect the upstream emissions associated with each vehicle type and should further provide consumers with insight into how their region or location may differ from the national average. [17] [EPA-HQ-OAR-2010-0799-9471-A1, pp.18-19]

Policy Considerations Mandate Against Including Upstream Emissions [EPA-HQ-OAR-2010-0799-9471-A1, p.19]

In the prior rulemaking, EPA acknowledged that including consideration of upstream emissions would detract from the strong public policy support for encouraging the development of an electric vehicle market to enable the long term emissions reductions opportunities associated with electric vehicles. See 75 Fed. Reg. 25,323,25,341 (May 7, 2010). EPA stated that the agency would reassess the issue of how to address upstream emissions associated with EVs and PHEVs for MYs 2017-2025 based on: (1) 'the status of advanced technology commercialization,' (2) 'the status of upstream GHG control programs,' and (3) 'other relevant factors.' Id While the final rule was issued only twenty months ago, in May 2010, the same considerations leading to a focus on tailpipe emissions in that rule are equally applicable to the current proposal. [EPA-HQ-OAR-2010-0799-9471-A1, p.19]

The electric vehicle market remains embryonic and, as the experience with hybrid vehicles shows, will still be in its infancy when the proposed standards go into effect. Disparaging the substantial benefits associated with EVs, PHEVs and FCVs by focusing on the upstream emissions of the utilities that provide electric power detracts from the public policy of fostering the manufacture and sale of vehicles capable of emitting little or no tailpipe emissions. The proposed standards, furthermore, are aggressive and will require complex compliance planning for manufacturers, particularly in light of uncertain economic conditions and the need to invest in a variety of technologies; including within the compliance calculation a factor that is beyond the control of the automobile manufacturer inserts unnecessary ambiguity into that process. [EPA-HQ-OAR-2010-0799-9471-A1, p.19]

Indeed, EPA's proposal to use a national average does not account for the substantial regional differences-up to 3 times as much in the highest regions as compared to the lowest regions. Proposed Rule at 75,010, n. 280. EPA properly notes the unfair impact on the Nissan LEAF, which, using 2007 data, would have an upstream GHG emissions value of 161 grams per mile based on national average electricity, and a value of 89 grams per mile based on the average electricity in California, one of the initial Wave 1 markets for the Nissan LEAF and the state with the most Nissan LEAF sales to date. Id. at 75,011. [EPA-HQ-OAR-2010-0799-9471-A1, pp.19-20]

That disparity, moreover, may be greater in MYs 2017 and beyond. EPA is proposing to use national average GHG emissions rate of .574 grams/watt-hour for MYs 2017 and beyond. [18] Based on the EPA RIA upstream calculation method, the Nissan LEAF's upstream GHG emissions would be about 146 grams per mile during that period. Under CARB's recently adopted regulations, the Nissan LEAF's upstream GHG emissions value in MYs 2017 and beyond would be about 64 grams per mile. Thus, instead of the national average resulting in

GHG value 1.8 times higher than it actually is (based on 2007 data), use of the national average proposed by EPA projects to result in a GHG value 2.28 times higher than it actually is in MYs 2017 and beyond. [19] [EPA-HQ-OAR-2010-0799-9471-A1, p.20]

California is not the only initial Nissan LEAF market with comparatively low electricity GHG emissions; in fact, most initial Nissan LEAF markets have lower-than-average electricity GHG emissions. By accounting for upstream emissions using a national average, electric vehicle manufacturers would be penalized because their compliance standard will not be reflective of actual upstream emissions. [EPA-HQ-OAR-2010-0799-9471-A1, p.20]

The agencies have recognized the need to consider the vitality of the electric vehicle market during the mid-term review. At that time, the growth and potential for battery electric vehicles to reach critical mass will be better known. While it may remain necessary to continue to encourage electric vehicles through further incentives, the current status of the market compels continuation of the policy and program elements put into place just 20 months ago. [EPA-HQ-OAR-2010-0799-9471-A1, p.20]

Another factor weighing in favor of continued focus on tailpipe emissions is the upcoming regulation of greenhouse gas emissions from electric utility steam generating units. Although EPA has stated that 'there is currently no national program in place to reduce GHG emissions from electric powerplants,' the current proposal and the opportunity to focus on utilities between now and the model years covered by this proposal suggest that the agency should not force vehicle manufacturers to carry the burden of utility generators. Id. (emphasis added). Rather, the agency should ensure that each producer is responsible for the emissions it can control and cost-effectively reduce. [EPA-HQ-OAR-2010-0799-9471-A1, pp.20-21]

Not only is EPA's proposal to measure EVs as zero grams per mile the best policy decision to promote EV deployment, it is also legally required. EPA and NHTSA have chosen to utilize the current federal test procedure for measuring fuel economy in vehicles. Significantly, those procedures were designed to measure the tailpipe emissions from ICEs and provide for electric vehicles to be assigned a measure according to a petroleum equivalency factor. The testing and calculation procedures to be used in the CAFE and GHG programs do not account for upstream emissions in the production, refining or delivery of petroleum to vehicles operating on petroleum. [EPA-HQ-OAR-2010-0799-9471-A1, p.21]

In its previous rulemaking, in response to Nissan's suggestion that excluding upstream GHGs is legally required under Section 202(a)(l), EPA stated that Section 202(a)(l) granted it 'broad discretion in setting emissions standards,' and that this discretion 'included adjustments to compliance values adopted in final rule, the multipliers [EPA] proposed, and other kinds of incentives.' 75 Fed. Reg. at 25,437. Nissan agrees that Section 202 gives EPA discretion to incentivize new technologies, but Section 202 does not give EPA the authority to consider non-vehicle related emissions when setting compliance standards. Doing so would disrupt the careful structure of the CAA. [EPA-HQ-OAR-2010-0799-9471-A1, p.21]

The CAA governs emissions from both stationary and mobile sources. Specifically, Title I of the CAA regulates stationary sources, while Title II of the CAA regulates mobile sources.

Regulation of stationary sources is primarily left to the states, whereas the federal government sets nationwide emissions standards for mobile sources. See Jensen Family Farms, Inc. v. Monterey Bay Unified Air Pollution, 644 F.3d 934, 938 (9th Cir. 2011). EPA relies on Section 202 of the CAA-located in Title II-as the basis of its authority to regulation upstream emissions. See 75 Fed. Reg. at 25,437. Congress never intended that Title II encompass consideration of upstream emissions, however, nor has EPA ever considered these emissions. See Proposed Rule at 75,010 ('[T]raditionally the emissions of the vehicle itself are all that EPA takes into account for purposes of compliance with standards set under Clean Air Act Section 202(a).'). [EPA-HQ-OAR-2010-0799-9471-A1, p.21]

Section 202(a)(l) states that 'the Administrator shall by regulation prescribe (and from time to time revise) ... standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles . .., which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.' 42 U.S.C. § 7521(a) (emphasis added). That is, Title II is limited to consideration and regulation of emissions from the vehicle, not any other source. The House Committee report on Title II of the Clean Air Act similarly indicated that Section 202 requires the Secretary to promulgate standards applicable 'to the emission of substances from new motor vehicles or new motor vehicle engines.' H.R. Rep. No. 89-899, at 9 (1965) (emphasis added). Nowhere in Title II of the CAA or its legislative history does it indicate that EPA can take into account the upstream emission associated with a motor vehicle when establishing compliance values under Section 202. Doing so would undermine the careful structure of the CAA, which leaves stationary source regulation primarily to the states. Jensen Family Farms, Inc., 644 F.3d at 938. Consideration of upstream emissions from EVs would amount to an indirect regulation of stationary sources under Title I, which is impermissible. [EPA-HQ-OAR-2010-0799-9471-A1, pp.21-22]

Further, to the extent that EPA does decide to revise its testing procedures and consider upstream emissions associated with EVs-which it legally cannot-it is arbitrary to consider the upstream emissions associated with one type of vehicle and not the other. As Nissan noted in its comments on the previous greenhouse gas rulemaking, when regulating products, 'the overriding principle of fairness is always the same: the government must govern with an even hand.' us. v. Undetermined Quantities of an Article of Drug Labeled as Exachol, 716 F. Supp. 787, 795 (S.D.N.Y. 1989) (holding that the FDA applied an 'uneven regulatory policy' by not treating one product like similar situated other product). It is well-established that an agency cannot treat similarly situated parties differently without a reasoned basis for doing so. See, e.g., Burlington Northern and Santa Fe Ry. Co. v. Surface Transp. Bd., 403 F.3d 771, 776-777 (D.C. Cir. 2005) ('Where an agency applies different standards to similarly situated entities and fails to support this disparate treatment with a reasoned explanation and substantial evidence in the record, its action is arbitrary and capricious and cannot be upheld.'). There is no rational basis for EPA to discriminate in the regulatory program based on the form of fuel used, especially when doing so would hold manufacturers of advanced powertrains accountable for emissions they cannot control. [EPA-HQ-OAR-2010-0799-9471-A1, p.22]

In sum, the federal test procedure, which measures emissions from a vehicle's tailpipe, measures battery electric vehicle GHG emissions at zero grams of CO_2 per mile. See Proposed Rule at 74,964 ('The 0 gram per mile value accurately reflects the tailpipe CO_2 gram per mile achieved by [EVs, FCVs and the electric portion of PHEVs].'). Therefore, the compliance value of these vehicles should always be measured at zero grams per mile. EPA should not-nor does it have the authority to-increase this value based on consideration of upstream emissions associated with EV, PHEVs and FCVs, but not other vehicles. [EPA-HQ-OAR-2010-0799-9471-A1, p.22]

Additional Issues Relating to Upstream Emissions [EPA-HQ-OAR-2010-0799-9471-A1, p.23]

I. To the Extent Upstream Emissions Are Considered, EPA Should Adopt an Industry Wide Cap to Reward Early Investors in Advanced Vehicle Technologies [EPA-HQ-OAR-2010-0799-9471-A1, p.23]

Although Nissan strongly supports the exclusive focus on emissions from the tailpipe, EPA requests comment on elements of the proposed cap structure to the zero grams per mile standard for MYs 2022-2025, and in particular on the benefits of an industry wide cap versus a per-company cap. The two-tier, per-company cap would allow manufacturers that sold 300,000 or more EVIPHEV/FCVs combined in MYs 2019-2021 a cumulative production cap of 600,000 in MYs 2022-2025, and manufacturers that sold less than 300,000 EV/PHEV/FCVs combined in MYs 2019-2021 a cumulative production cap of200,000. Proposed Rule at 75,013. The industry-wide cap would place an industry-wide cumulative production cap of 2 million EV/PHEV/FCVs eligible for the zero grams per mile standard in MYs 2022-2025, which would be allocated to individual automakers in calendar year 2022 based on cumulative EVIPHEVIFCV sales in MYs 2019-2021. Id EPA notes that a small portion of the industry-wide cap may be reserved for manufacturers that sold zero EV/PHEVIFCVs in MYs 2019-2021. Id [EPA-HQ-OAR-2010-0799-9471-A1, p.23]

Any regulatory cap should be industry based in order to encourage investment in electric powertrains now for use in the coming model years, and the cap should not reserve any volume for manufacturers selling zero electric vehicles in MYs 2019-2021. Although the per-company cap encourages manufacturers to sell at least 600,000 advanced technology vehicles in MYs 2019-2021, the industry-wide cap will encourage manufacturers to exceed that total to maximize its share of the zero grams per mile standard in MYs 2022-2025. [EPA-HQ-OAR-2010-0799-9471-A1, p.23]

The per-company cap would also have the perverse effect of rewarding manufacturers that are lagging behind and not fully committed to investing in these game-changing technologies by allowing a guaranteed amount of vehicles to benefit from the zero grams per mile standard in MYs 2022-2025, regardless of whether the manufacturer sold any EVs, PHEVs or FCVs in MYs 2019-2021. [EPA-HQ-OAR-2010-0799-9471-A1, p.23]

The purpose of the proposed incentives is to encourage manufacturer investment in potentially game-changing technologies now to accelerate their adoption rate. Adopting an industry-wide cap will serve that purpose. [EPA-HQ-OAR-2010-0799-9471-A1, p.23]

II. PA's Proposed Phase-in Approach to Measuring Upstream Emissions Beyond the Cap will Incentivize Advanced Vehicle Investment and Increase Their Rate of Adoption [EPA-HQ-OAR-2010-0799-9471-A1, p.24]

EPA also requests comment on various approaches for phasing in from a 0 grams per mile value to a full net increase in upstream emissions value. Proposed Rule at 75,013. Nissan supports EPA's phase-in proposal, both for production beyond the cumulative cap in MYs 2022-2025, as well as production beyond the cumulative cap for MYs 20122016. The interim period between a zero grams per mile compliance value and full net increase in upstream emissions value should be equal to the number of vehicles each manufacturer can assign a zero grams per mile compliance value for MYs 2022-2025, and the interim period compliance value should be one-half of the net increase. Nissan supports a similar approach for MYs 2012-2016 (i.e., the number of vehicles subject to the phase in will be equal to the number of vehicles each manufacturer can assign a zero grams per mile standard in MYs 2012-2016). This approach would further incentivize manufacturers to invest in EVs and other advanced powertrains, increasing the rate of adoption of these technologies. [EPA-HQ-OAR-2010-0799-9471-A1, p.24]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 129-130.]

The production credits in the proposed rule are essential to incentivizing continued manufacturer investment in these advanced technologies, increasing their rate of adoption and the rate by which the United States will realize a zero emission society.

We also understand that certain groups have raised concerns about upstream emissions from energy-producing facilities that power the grids that charge the vast range of consumer goods including electric vehicles. The solution to the issue of emissions from energy production facilities is not to discourage the proliferation of electric vehicles or other consumer goods by devaluing their contribution to a cleaner environment. Discouraging that fleet by diminishing the way in which the environmental benefits are presented to the public will only serve to reduce the market for electric-powered vehicles, delay further serious advancements in low emissions electricity and perpetuate the domination of emission-producing internal combustion engines. We support the continued focus on tailpipe emissions in this program. While we have no control over the energy production facilities or their emissions, we also support public and private efforts to move the power supply towards renewable energy sources.

---

6 - The theories presented in Diffusion of Innovations are widely accepted. Indeed, Diffusion of Innovations is 'the second most-cited work in social science after Cook and Cambell's (1979) treatise on quasi-experimentation.' Arvind Singhal & Sweety Law, A Research Agenda for Diffusion of Innovations Scholars in the 21st Century: A Conversation with Everett M Rogers, 8 J. Develop. Comm. 39, 39 (1997). The various editions of Diffusion of Innovations have received numerous awards. 'In 1990, the Institute for Scientific Information designated Diffusion of Innovations as a 'Citation Classic' on the basis of the large number of citations (approximately 7,000) that it received in articles published in social science journals. This book was selected by Inc. magazine in 1996 as one of the ten classic books in business and in 2000 was designated as a 'Significant Journalism and Communication Book of the Twentieth Century' by Journalism and Mass Communication Quarterly. It was also awarded the first Fellows Book Award in the Field of Communication by the International Communication Association's fellows in 2000,' Diffusion

of Innovations at 551. Diffusion of Innovations has also been cited in two administrative reports from the Federal Communications Commission. See In Re: International Comparison Requirements Pursuant to the Broadband Data Improvement Act, 26 F.C.C.R. 7378, 7393 n.108 (May 20, 2011); Connecting America: The National Broadband Plan, 2010 WL 972375, *151 n. 29 (F.C.C. Mar. 16,2010). Finally, a Westlaw.com search of all law review articles and treatises revealed 93 law review articles that cite Diffusion of Innovations.

11 - Section 202(b)(6)(B) of the Clean Air Act (CAA) provided that upon the petition of a manufacturer, the EPA Administrator could waive the then-existing 1.0 grams per mile (gpm) NO_x standard to a level not to exceed 1.5 gpm for diesel-powered light-duty vehicles and engines manufactured in MYs 1981-1984. Upon receiving several manufacturer petitions in 1980, EPA granted waivers permitting emissions up to 1.5 gpm for MYs 1981-1982 diesel-powered light-duty vehicles manufactured by GM, Daimler-Benz, Volkswagen, Volvo, and Peugeot. See 45 Fed. Reg. 5,480 (January 23, 1980); 45 Fed. Reg. 34,719 (May 22, 1980).

13 - The proposed incentives, moreover, do not favor one technology over another to achieve compliance. Traditional ICE vehicles will remain a majority of the fleet and will continue to gamer significant investment in improved and advanced technologies. The incentives for electric drivetrains instead recognize the existing market barriers and will justify private investment in a longer-term, transformational solution to yet more substantial environmental benefits in the future.

14 - Examples of local governments supporting EV infrastructure development include Chicago's 'sip and gulp' approach will made available both a limited supply of direct connect charging stations and a more expansive number of Level 2 public charging stations. In addition, San Francisco recently placed in 20 city-owned garages throughout the city, which are free to use through 2013. See Cars.com, Chicago Plans Most-Electrified City in the us. (Feb. 8,2011), available at http://blogs.cars.com/kickingtires/20 1l/02/chicago-ev-stations.html (last visited January 5, 2012); Smartplanet.com, San Francisco will charge your electric car for free until 2013 (May 9,2011), available at http://www.smartplanet.comlblog/transportation!san-francisco-wi Il-charge-your-electric-car-for- free until- 2013/380 (last visited January 5,2012).

15 - Walgreens, for instance, has installed or plans to install approximately 800 EV charging stations across the country. See Walgreens Newsroom, First Walgreens Electric Vehicle Charging Station in Orlando Unveiled (Oct. 12, 2011), available at http://news.walgreens.com /article_display.cfm?article_id=5482 (last visited January 5, 2012).

16 - Examples include: Georgia Power offers a Plug-In Electric Vehicle time-of-use electricity rate for residential customers who own an EV or PHEV. The Indianapolis Power & Light Company offers special plug-in electric vehicle charging rates, including year-round time-of-use based options, for residential and fleet customers who own a licensed EV or PHEV. Louisville Gas & Electric offers a pilot Low Emission Vehicle time-of-use electricity rate for residential customers who own an EV or PHEV (limited to 100 customers). DTE Energy (in Michigan) offers a reduced electricity rate to qualified residential customers for charging EVs and PHEVs during off-peak hours. Nevada Energy (NV Energy) offers discounted electricity rates to residential customers in their Northern and Southern Service Territories who charge EVs or

PHEVs during off-peak hours. See Department of Energy, Alternative Fuels & Advanced Vehicles Data Center, available at http://www.afdc.energy.gov/afdc/laws/ (last visited January 5, 2012).

17 - The most recent labeling rule, which applies to MY 2013 and later vehicles, is limited to tailpipe-only GHG emissions. 76 Fed. Reg. 39,478, 39,492-93 (July 16, 2011). The labels for EVs, however, will include a clarifying statement, 'Does not include emissions from producing electricity,' and vehicles fueled without grid electricity will include the statement 'Producing and distributing fuel also creates emissions; learn more at fueleconomy.gov.' Id. For PHEVs, the text '& electricity' will be added after the word 'fuel.' Id. The website will offer detailed information on upstream emissions, including regional-specific values, where appropriate. ld. Nissan supported this approach in the labeling rulemaking, and continues to do so. If EPA were to consider listing the upstream emissions associated with an EVon the vehicle label itself, however, it must do the same for all vehicles to prevent consumer confusion.

18 - Given the uncertainties associated with the electricity GHG emissions rate in MYs 2017 and beyond, EPA should reassess the appropriateness of the GHG emissions rate of .574 grams/watt-hour during the mid-term review, and revise it as appropriate.

19 - Upstream emissions vary not only by region, but also by service territory. For example, the utility company Seattle City & Light uses a combination of hydroelectric power and carbon offsets for 100% carbon free electricity, unique to the Pacific Northwest Region. Upstream emissions also vary by customer. For example, LEAF customers in a coal-heavy region that install solar technology on their roof will have an inaccurate measure for upstream GHG emissions.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

Technology Incentives

NESCAUM supports EPA’s proposed zero gram per mile incentive for EVs and PHEVs as a reasonable short-term accommodation that recognizes the initial barriers to adoption of these technologies. While the zero emission factor for electricity used to power these advanced vehicles does not account for upstream emissions from electricity generation, application of this zero factor for MY 2017-2021 will provide auto manufacturers with greater incentives to deploy these technologies. We in turn support, in principle, EPA’s proposed sales cap, above which upstream emissions are included for MY2022-2025. The sales cap will help the program to achieve greater GHG emission reductions in the long term. [EPA-HQ-OAR-2010-0799-9476-A1, p. 2]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, pp. 72-73.]

EPA should continue to evaluate the GHG effects of these technology incentives to ensure preservation of the overall goals of the program. We also expect that EPA will monitor upstream emissions from the power grid to ascertain whether the improvements assumed to occur do in fact occur. In that regard, we strongly support the proposed mid-term review that will provide the opportunity to consider appropriate revisions to these incentives and to other aspects of the program. [This comment can also be found in section 2.4 of this comment summary.] [EPA-HQ-OAR-2010-0799-9476-A1, p. 2]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 73.]

While for this time frame we support the concept to forego accounting for net upstream electric power generation emissions, we in turn support in principle EPA's proposal for sales cap above which upstream emissions are included in model years 2022 through 2025.

Organization: Pennsylvania Department of Environmental Protection

Eliminate the Two-for-One Incentive Multiplier. EPA should not increase the manufacturers' sales incentives for EVs, plug-in hybrid electric vehicles (PHEVs) or fuel cell vehicles (FCVs) by including a 2-for-1 incentive multiplier. EPA is proposing that a manufacturer of EV s, PHEVs, or FCVs will receive a 2-for-1 incentive multiplier starting in 2017 that will decrease over time to 1-for-1 in 2025 for each EV, PHEV, or FCV sold. No cap on the number of vehicles sold would exist until 2022. By developing a new sales incentive solely for electrically powered vehicles, EPA is creating a disadvantage for vehicles powered by natural gas. In fact, vehicles powered by natural gas could have fewer emissions of GHG and have an overall smaller environmental footprint than vehicles powered by electricity in some, if not most, parts of the country. Congress recognized this fact and provided incentives in the CAFE program to manufacturers of all alternately fueled vehicles. In addition, the 2-for-1 incentive would appear either to be inconsistent with, or exceed the intent of, Congress as reflected in the CAFE· program. EPA has no legal or practical basis for providing this excessive incentive for EVs. We believe that the 2-for-1 incentive multiplier offer to manufacturers should be withdrawn, but if the incentive multiplier is not withdrawn, then gaseous alternative fuel vehicles should also be included in this incentive mechanism. [EPA-HQ-OAR-2010-0799-7821-A1, p. 4]

In addition, EPA needs to treat all alternative fuels as alternatives and not support EVs over vehicles alternatively fueled with gaseous fuels. [EPA-HQ-OAR-2010-0799-7821-A1, p. 5]

Organization: Pew Charitable Trusts

The proposed joint rule for model years 2017 to 2025 incentivizes the introduction of advanced technologies that seek to decrease U.S. dependence on foreign oil. Incentives designed to spur deployment of electric and hybrid vehicle technologies in the U.S. light duty fleet provide a clear path for auto manufacturers to invest in research, development, and production, which can improve the competitiveness of U.S. manufacturing and enhance exports to nations with growing demand. Investment in the research, development, production, and deployment of advanced vehicle technologies will help vehicle manufacturers located in the United States achieve the proposed standards, and present an opportunity for the U.S. to lead in new markets such as advanced batteries, which experts predict could be a $100 billion global industry annually by 2030. Pew is a strong advocate for the deployment of electric and hybrid vehicles and the necessary charging infrastructure, which could significantly reduce oil consumption and consumer fuel costs. [EPA-HQ-OAR-2010-0799-9496-A2, pp. 1-2]

[These comments were also submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2009-2010-11788, pp.18-19.]

Organization: Plant Oil Powered Diesel Fuel Systems, Inc.

2. The Proposed GHG Standards are arbitrary and capricious because their exclusive consideration of tailpipe GHG emissions fails to take into account the relative life cycle contribution to GHG emissions of various engine technologies and the energy sources that make them run. The analysis of the wells-to-wheels energy inputs associated with various technologies and fuels set forth herein demonstrates that the Proposed Regulations' apportionment of GHG credits to various technologies and fuels is irrational because it considers only tailpipe emissions. [EPA-HQ-OAR-2010-0799-10337-A2, p. 2]

c. re-do the weight the Agencies give to various alternative technologies and fuels according to a wells-to-wheels approach that corresponds more accurately with their relative contribution to and mitigation of atmospheric greenhouse gas accumulation; [EPA-HQ-OAR-2010-0799-10337-A2, pp. 2-3]

The Proposed Regulations base the GHG accounting primarily on tailpipe emissions. The Agencies, therefore, deem all electric vehicles to have zero emissions of CO_2 and zero fuel consumption. 76 Fed. Reg. at 74878. Through model year 2021, electric vehicles, hybrid electric vehicles, and hydrogen fuel cell vehicles receive a multipliers of between 1.3 to 2.0 times the amount of tailpipe CO_2 emissions reduced by the technology as compared to the same engine or vehicle without the alternative technology installed. Id. [EPA-HQ-OAR-2010-0799-10337-A2, p. 5]

A. Electric and Electric Hybrid Vehicles [EPA-HQ-OAR-2010-0799-10337-A2, p. 6]

The GHG theory behind electric vehicles is that they eliminate GHG emissions from the tailpipe and transfer any such emissions to less onerous upstream electricity production. The fallacy underlying this theory is stated in the Preamble to EPA's Proposed Regulations, as follows: [EPA-HQ-OAR-2010-0799-10337-A2, pp. 6-7]

At this time [], there is no [] comprehensive program addressing upstream emissions of GHGs, and the upstream GHG emissions associated with production and distribution of electricity are higher, on a national average basis, than the corresponding upstream GHG emissions of gasoline or other petroleum based fuels. [cite omitted] In the future, if there were a program to comprehensively control upstream GHG emissions, then the zero tailpipe levels from these vehicles have the potential to contribute to very large GHG reductions, and to transform the transportation sector's contribution to nationwide GHG emissions (as well as oil consumption). [EPA-HQ-OAR-2010-0799-10337-A2, p. 7]

76 Fed. Reg. At 75010 (emphasis added). It makes no sense to give electric vehicles any credit, much less a 100 percent credit, when "the upstream GHG emissions associated with production and distribution of electricity are higher, on a national average basis, than the corresponding upstream GHG emissions of [] petroleum based fuels." Id. [EPA-HQ-OAR-2010-0799-10337-A2, p. 7]

Even comparing solely tailpipe emissions, "[t]he energy efficiency assigned to electric vehicles [] does not account for the inefficiency associated with generating electricity from the combustion of fossil fuels." National Energy Technology Laboratory, "Battery-Powered Electric and Hybrid Electric Vehicle Projects to Reduce GHG's: A Resource Guide for Project Development" (July 2002), n. 119 (Exhibit 3). Research conducted by Argonne National Labs found that, "to achieve significant reductions in GHG emissions, [plug-in and battery-powered electric vehicles] must recharge from a generation mix with a large share of non-fossil sources (e.g., renewable or nuclear power generation)." A. Elgowainy, et al., "Well-to-Wheels Energy Use and Greenhouse Gas Emissions Analysis of Plug-in Hybrid Electric Vehicles," Argonne National Laboratory Report ANL/ESD/09-2 (Feb. 2009). Renewable sources contributed 10 percent of U.S. electricity generation in 2009. U.S. Energy Information Administration ("EIA"), "How much of our electricity is generated from renewable sources?" (Web: Feb. 11, 2012) (http://www.eia.gov/energy_in_brief/renewable_energy.cfm). In 2010, 45 percent of U.S. electricity was generated from coal. EIA, "What is the role of coal in the United States?" (Web: Jan. 30, 2012) (http:// www.eia.gov/energy_in_brief/role_coal_us.cfm). The combustion of coal produces 25 to 50 percent more CO_2 emissions than petroleum. Id. [EPA-HQ-OAR-2010-0799-10337-A2, pp. 7-8]

In the absence of a program to transform emissions from the upstream production of electricity to less carbon intensive sources, conferring on electric vehicles and hybrid electric vehicles a preference is irrational. It only encourages the introduction to the market of electric and hybrid vehicles that will contribute net more overall GHG emissions. Since a transforming upstream program is within EPA's authority under the Clean Air Act, the Proposed Regulations' favoring electric and hybrid electric vehicles is illogical and contradicts EPA's mission under the Clean Air Act. [EPA-HQ-OAR-2010-0799-10337-A2, p. 8]

B. Hydrogen Fuel Cells [EPA-HQ-OAR-2010-0799-10337-A2, p. 8]

The manufacture and sequestration of hydrogen to power a fuel cell requires an energy input and engenders some loss of energy content. EIA, Office of Integrated Analysis and Forecasting , Office of Coal, Nuclear, Electric and Alternate Fuels ("EIA OIAF-OCNEAF"), "The Impact of Increased Use of Hydrogen on Petroleum Consumption and Carbon Dioxide Emissions," at ix (Sept. 2008) (Exhibit 4). Reliance on hydrogen to power a mobile engine carries with it the same drawback of electricity: "[t]he main sources of hydrogen currently are hydrocarbon feedstocks, such as natural gas, coal, and petroleum, all of which also produce CO_2." Id., at xi (Exhibit 4). "Significant technical and infrastructure challenges" remain for the development of a large market for hydrogen fuel cell vehicles. Id., at ix (Exhibit 4) [EPA-HQ-OAR-2010-0799-10337-A2, pp.8-9]

In contrast, as set forth below, POP DieselTM has overcome the technical obstacles to the use of 100 percent plant oil and low-cost infrastructure that is independent of petroleum infrastructure is at hand. [EPA-HQ-OAR-2010-0799-10337-A2, p. 9]

Organization: Porsche Cars North America, Inc. (PCNA)

Porsche supports the proposed provisions for *advanced* technology multipliers. However, we believe that larger multipliers are justified, as an incentive for faster penetration of these technologies and to offset the significant development costs. The long-range GHG benefits of faster penetration far outweigh the effect on short term GHG fleet averages. We also propose that there should be no phase-out of AT multipliers for the duration of this rule. Each new application of a particular *advanced* technology requires significant development cost and time. It is not appropriate to assign an incentive to development projects over one 5-year period, and provide no incentive in the next. [EPA-HQ-OAR-2010-0799-9264-A1, p. 6]

In addition, we believe it is not appropriate to include upstream emissions in Light Duty GHG calculations for electric and plug-in hybrid vehicles. These emissions are not under the control of the automakers. We believe that the provisions for zero gram/mile upstream emissions for electric vehicles and plug-in hybrids should be made permanent. [EPA-HQ-OAR-2010-0799-9264-A1, p. 6]

Organization: Renewable Fuels Association (RFA)

EPA/NHTSA also propose significant incentives for certain dedicated (i.e. single-fueled) vehicles, which effectively creates an un-level playing field for FFVs. Specifically, EPA/NHTSA propose a GHG emissions compliance value of 0 for EVs, PHEVs (for the portion of operation that is electric), and fuel cell vehicles (FCVs). This proposal implies that operating one of these vehicles results in no GHG emissions whatsoever, despite EPA/NHTSA's acknowledgement that "[d]epending on how the electricity and hydrogen fuels are produced, these fuels can have very high fuel production/distribution GHG emissions (for example, if coal is used with no GHG emissions control)…" Indeed, on a full lifecycle basis, production of average electricity for use in EVs and PHEVs actually generates nearly 30% more GHG emissions per unit of energy delivered than petroleum.[3] [EPA-HQ-OAR-2010-0799-9490-A1, p.4]

EPA/NHTSA also propose providing a multiplier for all EVs, PHEVs, and FCVs, which would allow each of these vehicles to "count" as more than one vehicle in the manufacturer's compliance calculation. The agencies' reasoning for offering such a multiplier is that these vehicles, in their view, offer "the potential for game-changing GHG emissions and oil savings in the long term." We agree that EPA/NHTSA have a role in encouraging the production of vehicles that potentially reduce GHG emissions and oil consumption, but we believe favorable treatment under the rules should be afforded consistently to all vehicles that offer such potential. [EPA-HQ-OAR-2010-0799-9490-A1, pp.4-5]

While we strongly agree with EPA/NHTSA that automakers should be encouraged to produce vehicles that "[r]educ[e] petroleum consumption to improve energy security", "save the U.S. money" and "[r]educe climate change impacts," we believe incentives to stimulate the production of such vehicles should be constructed fairly and consistently. With regard to utility factors for fuel economy calculations and emissions compliance values, EPA/NHTSA should be consistent in the treatment of all dual-fueled vehicles. [EPA-HQ-OAR-2010-0799-9490-A1, p.5]

A. To ensure consistent treatment of vehicle/fuel options, EPA/NHTSA should consider basing emissions compliance values on direct "well-to-wheels" lifecycle GHG emissions. [EPA-HQ-OAR-2010-0799-9490-A1, p.5]

In order to accurately portray the GHG emissions impacts of various fuel/vehicle combinations when determining emissions compliance values, EPA/NHTSA should consider including upstream ("lifecycle") emissions that are directly related to the production and use of the fuel. This is particularly important for electricity because, as EPA/NHTSA acknowledge, "…there is currently no national program in place to reduce GHG emissions from electric powerplants." As proposed, compliance values would be based on an incomplete accounting of the vehicle's actual GHG impacts. While the bulk of lifecycle emissions for petroleum fuels occur at the tailpipe (i.e., as hydrocarbons are combusted in the internal combustion engine), the bulk of direct lifecycle emissions for EVs and the electric operation portion of PHEVs occur upstream and are associated with the production of electricity. For biofuels, the bulk of net lifecycle emissions also occur upstream during biomass production and conversion, as the principles of lifecycle accounting hold that biogenic CO_2 emissions at the tailpipe are equivalently offset by the CO_2 that was removed from the atmosphere by the biofuel feedstock during growth. Basing compliance values on full direct well-to-wheels lifecycle emissions would allow for "apples-to-apples" treatment of the GHG emissions associated with different fuel/vehicle options, whereas the use of tailpipe-only emissions provides only a partial picture of the GHG impacts of various platforms. Impartial GHG accounting misrepresents the true climate impacts of the CAFE/GHG program. [EPA-HQ-OAR-2010-0799-9490-A1, p.5]

---

3 - Lifecycle analysis conducted by the California Air Resources Board for the Low Carbon Fuels Standard found the well-to-wheels GHG emissions associated with "California average electricity" are 124.1 grams of CO_2-equivalent per mega joule (g/MJ), compared to 95.85 g/MJ for gasoline. In CARB's analysis, electric vehicles offer GHG savings relative to gasoline only after "Energy Economy Ratios" are applied to EVs and PHEVs to account for energy efficiency differences between electric drivetrains and internal combustion engines. http://www.arb.ca.gov/fuels/lcfs/022709lcfs_elec.pdf

Organization: Securing America's Future Energy (SAFE)

Upstream Emissions: In the proposed rule, EPA is proposing to account for carbon emissions from a limited number of EVs, PHEVs, and fuel cell vehicles (FCVs), by assigning to then a carbon emission value of zero grams per mile, with no limit on the number of vehicles eligible for such treatment, through MY 2021. Between model years (MYs) 2022 and 2025, EPA will assign a zero grams per mile value to the first 600,000 vehicles for companies that sell 300,000 EVs, PHEVs, and FCVs in MYs 2019–2021 and 200,000 vehicles for all other manufacturers. EPA believes that approximately 2 million cars will benefit from this treatment through MY

2025. For additional vehicles, EPA proposes to calculate upstream emissions (using the average carbon emissions per kWh of power generated), as estimated by EPA's Office of Atmospheric Programs' Integrated Planning Model. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 7-8]

SAFE believes that upstream emissions resulting from the operation of EVs, PHEVs and FCVs should not be attributed to the vehicles, even after MY 2021. For its entire 35-year existence, the fuel economy program at NHTSA, and the GHG emission program at EPA that has been incorporated into the fuel economy framework in recent years as part of the national program, has regulated only the direct consequences of operating a vehicle, whether the volume of fuel that the vehicle actually burned or the emissions directly emitted from the vehicle. Automakers have never been held responsible for the energy required to produce, process, and transport the fuel their vehicles consumed or that was consumed in the process of manufacturing the vehicles or any of their parts. Likewise, they have never been held responsible for the upstream emission of other regulated pollutants attributable to the production of fuel consumed by vehicles that they sold. [EPA-HQ-OAR-2010-0799-9518-A1, p. 8]

At the most fundamental level, automakers cannot reasonably be held accountable for the upstream consequences of power generation for any pollutant. These are emissions that they do not cause and over which they have absolutely no control. The emissions will vary for a wide range of reasons, from utility to utility, hour of day to hour of day, and customer to customer, even more so if a customer purchases "green power," a decision over which the automakers have no influence or control. EPA should consider carefully whether, and the extent to which, it is appropriate to hold automakers responsible for other parties' emissions that they cannot control or affect. [EPA-HQ-OAR-2010-0799-9518-A1, p. 8]

Doing so, in fact, would be a sharp departure from how EPA has typically regulated pollution. In each of its major programs, EPA has regulated polluters, and subjected them to regulatory requirements or penalties as a result of their direct actions. Power plants are responsible for their air emissions, water treatment plants for their effluent, and landfills for their leakage. We are unaware of other situations in which EPA regulates anyone other than the generator of pollution, even if other parties ultimately bear the financial costs of EPA's regulations. For example, water treatment facilities' customers are not responsible for compliance with the Clean Water Act, individuals whose trash haulers dispose of trash in landfills are not responsible for the landfill's compliance with the Resource Conservation and Recovery Act, and consumers of power are not held responsible for power plant emissions. Yet in this instance, the regulated party would be even further removed from the activity causing the regulated harm. The agency would be regulating Party A (automakers) for producing a device whose use by Party B (drivers) caused Party C (generators) to create carbon emissions. That would be akin to imposing responsibility for carbon emissions on Carrier, Dell, and Thermador because their HVAC systems, computers, and electric ovens and stoves consumed power whose generation was responsible for carbon emissions. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 8-9]

While we appreciate the difficulty of regulating carbon emissions from power plants in the absence of an economy-wide scheme to regulate carbon emissions, we do not believe that the political challenge that EPA faces in regulating carbon emissions from power plants should be used to justify deviating from its longstanding approach to regulating pollution. [EPA-HQ-OAR-2010-0799-9518-A1, p. 9]

EPA also should consider the extent to which regulating upstream emissions would conflict with future prospects of developing an economy-wide GHG regulatory system. Once some carbon emissions are regulated downstream, at the appliance level, it would be very difficult to regulate the remainder of emissions upstream, because of the inherent difficulty in separating upstream emissions that were attributable to regulated downstream activities from upstream emissions that were attributable to unregulated downstream emissions. Moreover, SAFE believes that attributing upstream emissions to the downstream product is a short term approach that will complicate EPA's long-term efforts to develop an approach to economy-wide regulation of carbon emissions. [EPA-HQ-OAR-2010-0799-9518-A1, p. 9]

Finally, if EPA decides to regulate upstream emissions from PHEVs, EVs, or FCVs, it also should regulate upstream emissions from all other vehicles to put all vehicles on an equal footing. If EPA's goal is to attribute all emissions resulting from the operation of a vehicle to the manufacturer of that vehicle, then that general principle should be fairly and equitably applied across all vehicles regardless of technology. [EPA-HQ-OAR-2010-0799-9518-A1, p. 9]

Multiplier Credit: To help promote the adoption of EVs, PHEVs, and FCVs, EPA's proposal creates an incentive multiplier for qualifying vehicles sold in MYs 2017 – MY 2021. The multiplier would treat each qualifying vehicle as more than one vehicle in the compliance calculation. The value of the multipliers is stated in Table 1. [Table 1 can be found on p. 9 of Docket number EPA-HQ-OAR-2010-0799-9518-A1] [EPA-HQ-OAR-2010-0799-9518-A1, p. 9]

SAFE believes that the multiplier is a valuable incentive to help promote the adoption of electric drive vehicles. Further, we believe the incentive is justified because of the critical contribution that the technology employed in the qualifying vehicles can make in improving our economic and national security. For the vehicles to achieve their potential, however, they will need incentives of sufficient size and duration for the vehicles to achieve scale, reduce costs, and penetrate the mainstream market. [EPA-HQ-OAR-2010-0799-9518-A1, p. 10]

The agencies' forecasts regarding the vehicle sales between MYs 2017 and 2021, indicates that they do not expect PHEVs and EVs to achieve significant market penetration over this time period. Through MY 2021, the agencies forecast cumulative sales of 381,160 EVs and PHEVs. If we generously assume that every one of those vehicles were an EV that consumed no gasoline, and each one replaced a vehicle with an internal combustion engine that travelled 15,000 miles a year and achieved 30 miles per gallon, the vehicles would reduce oil consumption by 12,400 barrels of oil a day out of nearly 20.63 million barrels per day of liquid fuel that EIA forecasts the United States will consume in 2021. Stated simply, this is a modest contribution to our economic and energy security, reflecting the fact that EVs and PHEVs will need more time to penetrate the marketplace. [EPA-HQ-OAR-2010-0799-9518-A1, p. 10]

If the agencies want to provide a sufficient level of assistance to help achieve an important national goal, SAFE believes that rather than phasing the vehicle multiplier out before it can help

EVs and PHEVs penetrate the mainstream marketplace, that EPA should keep it in place at the initial rate of 2.0 for EVs and 1.6 for PHEVs until the midstream review. At that time, the agency can evaluate its efficacy, and adjust it for the period through MY 2025 as appropriate. [EPA-HQ-OAR-2010-0799-9518-A1, p. 10]

However, SAFE also believes that EPA's proposed application of the multiplier credit to PHEVs is too narrow. EPA stated that for a PHEV to qualify for the multiplier, the vehicle must be able to complete a full 10.2 mile EPA highway test without using any conventional fuel, or have a minimum equivalent all-electric range of 10.2 miles as measured on the EPA highway cycle. SAFE believes that EPA could simplify this requirement, allowing a PHEV to qualify for the multiplier credit if it incorporates a battery with at least 4kWh of storage capacity. A midsize PHEV that travelled 2.5 miles per kWh of power would have about 10.2 miles of range. Moreover, Congress has determined that the use of PHEVs with a 4kWh battery is of sufficient national importance that it is deserving of substantial incentives, in the form of a federal tax credit. Changing the criteria to a simple minimum battery size requirement will simplify the regulation, and maintain consistency with EPA's overall goal and the national interest. It also would give appropriate credit to a PHEV whose design yielded substantial fuel savings even if it operated in a blended mode that made it difficult to travel 0 miles without using any liquid fuel. Alternatively, EPA could add a minimum battery size requirement as an alternative qualifying criterion that would allow vehicles to qualify for treatment as PHEVs based on a clear, simple, and objective criterion. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 10-11]

PHEV Utility Factors: While calculation of energy consumption by a single fuel vehicle is somewhat straightforward, calculation of fuel consumption of a dual fuel vehicle is more complex because one must estimate the amount of each fuel used in the operation of the vehicle. To calculate vehicle emissions and fuel consumption, EPA proposes relying on the use of "utility factors," which are ratios or percentages that indicate how much energy used by a PHEV comes from the grid and how much comes from onboard fuel. Because the operating cost for PHEVs are typically lower than liquid fueled vehicles and their emissions profile is typically better, utility factors that are too low will result in an overstatement of emissions, liquid fuel consumption, and operating costs. [EPA-HQ-OAR-2010-0799-9518-A1, p. 12]

The utility factors that the agencies used in the proposal are based on a standard developed by the Society of Automobile Engineers, SAE-J2841. The standard is based on data about daily vehicle miles traveled for about 32,000 days of vehicle travel. Briefly, to calculate a utility factor, the standard divides the sum of the number of miles each vehicle in the dataset traveled that would have been charge-depleting miles by the total vehicle miles traveled for a particular sized battery. [EPA-HQ-OAR-2010-0799-9518-A1, p. 13]

This approach makes sense on its face. Yet, SAE likely underestimated the utility factor for two separate reasons. First, SAE assumed that people who drive PHEVs will have similar driving patterns as those who drive traditional vehicles. SAE acknowledged the issue, even noting in an update of the standard that its initial calculation was "highly weighted towards [vehicles making] long distance trips." Second, the SAE standard also assumed that consumers will charge their PHEVs only once a day. [EPA-HQ-OAR-2010-0799-9518-A1, p. 13]

PHEVs carry a premium purchase price in exchange for lower operating costs. Customers who are willing to pay the premium for the vehicle, a substantial one at first, and one that they can only hope to recover by driving “electric miles” will have a strong incentive to drive “electric miles,” either by using the vehicles for commutes that are largely within their “electric range” or by midday charging, usually at work. The first point suggests that people who purchase PHEVs are likely to drive fewer miles per day than the average vehicle in the whole fleet, because drivers whose driving patterns can maximize the value of the PHEV powertrain are its most likely customer. The second point suggests that many PHEVs whose average daily vehicle miles travelled exceeds the electric range of the vehicle will have a strong inventive to charge their vehicles at work or elsewhere, and that the average driver of a PHEV is likely to charge their vehicle more than once a day. [EPA-HQ-OAR-2010-0799-9518-A1, p. 13]

SAE’s approach fails to recognize this high likelihood of these sales and usage patterns. To the extent that EPA’s calculation of utility factors relies on SAE’s methodology, EPA’s use of utility factors is flawed. [EPA-HQ-OAR-2010-0799-9518-A1, p. 13]

SAFE believes that it is reasonable to truncate the data set and eliminate from it trips that exceed either an absolute distance or a distance that is some function of the charge depleting range of the battery. SAFE also believes that a more appropriate utility factor methodology would recognize that some portion of the vehicles that travel more than the electric range each day will be charged more than once a day, generally (but not exclusively) at work. Doing so would more accurately portray how the PHEVs are likely to actually be used by the people who purchase them. [EPA-HQ-OAR-2010-0799-9518-A1, pp. 13-14]

If the agencies choose not to adjust the utility factor calculation at this point in time, SAFE believes that the agencies should commit to evaluating the actual usage patterns of PHEVs within the next two years of the issuance of the final rule, and update the calculation of utility factors to reflect the manner in which the actual vehicles are really being used. Many of the vehicles and charging facilities used collect extensive data about vehicle usage, energy consumption, and charging patterns, which is being collected by automakers, charging infrastructure providers, and the Department of Energy. The data required to perform such analysis should be readily available. As part of that reexamination of utility factors, EPA and NHTSA should commit to examining how often PHEV owners charge their vehicles to determine if the assumption that they will only charge once a day is appropriate or needs updating. [EPA-HQ-OAR-2010-0799-9518-A1, p. 14]

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 150-152.]

That the plug-in vehicles offer these great benefits to the nation justifies the incentives for this rule. The multiplier for EVs, for instance, will be an important incentive. We believe, however, it should not be phased down, as proposed. 10 years after entering the market the, 2.1 -- 1.9 million hybrid vehicles on the road represent about 2.1 of the new-car market. Yet if they are getting an average of 35 to 45 miles per gallon, they are saving the nation about 15- to 25,000 barrels a day out of the diet of 19 million barrels a day.

Plug-in vehicles have an opportunity to make a much greater contribution than traditional hybrids, but they are going to need some incentives in the meantime so that consumers can overcome their concerns about them, help bring demand up, get to economies of scale and bring the price down.

Secondly, we believe the upstream emissions should not be attributed to the plug-in vehicles. Until this proposal, cars had always been responsible for what comes out of the tailpipe, not the fuel that goes into the car. If automakers are held responsible for upstream emissions, they'll be unique in the economy as compared to manufacturers of other power-consuming appliance, such as air conditioners, well pumps or electric ovens. They cannot control upstream emissions, which will, in any event, vary from region to region, from consumer to consumer and over time. And in regulating total emissions, it will make it infinitely more difficult to later have a cap and trade program that incorporates emissions without endangering the whole count.

If, however, you do decide to regulate upstream emissions, they should be regulated for all vehicles, including petroleum-powered vehicles.

Organization: Sierra Club, Environment America, Safe Climate Campaign, and Clean Air Council

Address emissions associated with Electric Vehicles: Sierra Club believes that electric vehicles can and will play a critical role in providing Americans with oil free transportation. Automakers are bringing electric and plug in vehicles to the market and consumers are eager for the chance to drive without oil. Consistent with our position in the prior standards, we continue to have concerns with the impact failing to account for the emissions associated with EVs has on the overall emissions reductions benefits of the program. [EPA-HQ-OAR-2010-0799-9549-A2, p. 7]

The proposed rule accounts for electric vehicles as "zero-emission" in tabulating fleet-wide averages. While electric vehicles do not have tailpipe emissions, they do draw energy from the electrical grid, and the majority of electrical energy generation in the United States involves emissions of greenhouse gases.27 Thus, electric vehicles - unless powered by carbon-neutral sources of electricity, such as wind or solar - still contribute some amount of greenhouse gas emissions. By excluding these emissions, as the proposal does, along with a multiplier, the proposed rule gives a distorted and overstated picture of the reductions in greenhouse gas emissions flowing from the rule. [EPA-HQ-OAR-2010-0799-9549-A2, pp. 7-8]

EPA and NHTSA should revise the final rule to account for emissions associated with electrical generation to charge electric vehicles. In the alternative, the number of electric vehicles considered as "zero-emission" for the purpose of calculating fleetwide averages should be capped initially, and phased out over the course of the program. This would ensure that the final does not deliver distorted "reductions" in greenhouse gas emissions. [EPA-HQ-OAR-2010-0799-9549-A2, p. 8]

In this proposal, EPA has adopted an approach of applying a multiplier for MY 2017-2021 while capping the quantity of vehicles eligible for 0g/mi accounting in MY 2022-2025. The tiered approach proposed by the EPA represents additional sales volumes of vehicles eligible for the 0 grams per mile credit as this credit already exists under the 2012-2016 standards. No more than 1 million electric vehicles should be treated as zero grams per mile vehicles in 2017-2025 to limit the pollution that would result from this incentive. Although the cumulative reductions in greenhouse gas pollution benefits from 2017-2030 is 4.3% at 1 million EV sales, it is even greater at higher sales volume. [EPA-HQ-OAR-2010-0799-9549-A2, p. 8]

We support the transition to accurate upstream accounting for any manufacturer that exceeds its cumulative production cap for EVs and urge that the final rule effectively limit the loss of emissions benefits of the program. [EPA-HQ-OAR-2010-0799-9549-A2, p. 8]

Although an incentive multiplier was proposed for EVs in the 2012-2016 standard it was not finalized as this incentive coupled with a zero emissions treatment would have reduce the greenhouse gas benefits of the standard. However, in the 2017-2025 standard to facilitate market penetration of advanced vehicle technologies as soon as possible, the EPA is again proposing an incentive multiplier for compliance purposes for electric vehicles sold in MY 2017 through 2021. EPA is proposing that EVs start with a multiplier of 2.0 in 2017 and phase down to 1.5 in MY 2021. EPA is proposing this multiplier as it deems EVs are necessary for compliance with standards. [EPA-HQ-OAR-2010-0799-9549-A2, p. 8]

We recommend a floating industry wide cap for number of EV sales eligible for zero emissions treatment in 2022-2025 be set at 1 million minus cumulative sales in 2017-2021 rather than the 2 million vehicle cap in the proposed rule. If sales exceed 1 million units, the zero emissions treatment would discontinue in 2021. There are several ways the agencies can allocate the industry wide cap among manufacturers, including an equal distribution among manufacturers and weighted allocation based on product plans, or a first come, first served approach. EPA proposes to phase-in an emissions factor for electric vehicles after 2022 for automakers that exceed their cumulative caps. The agency could phase-in the emissions factor sooner to avoid erosion of the overall program benefits. [EPA-HQ-OAR-2010-0799-9549-A2, pp. 8-9]

Plug-in hybrids should be counted in units of full plug-ins, in the same ratio as the fraction of miles they are assumed to operate on electricity from the grid. Plug-in hybrids would be required to achieve the same minimum all electric range as in relevant CARB regulations for its Zero Emission Vehicle program. [EPA-HQ-OAR-2010-0799-9549-A2, p. 9]

In sum, a strong final rule should ensure that greenhouse gas benefits of the program are maximized and the impact of the compliance flexibility afforded by the proposed EV credits should be minimized. [EPA-HQ-OAR-2010-0799-9549-A2, p. 9]

27 See U.S. Energy Information Agency, Electric Power 2010, Table ES1, Summary Statistics for the United States, 1999 through 2010 (Nov. 2011), available at http://www.eia.gov/electricity/annual/pdf/tablees1.pdf (showing that in 2010 approximately 70% of U.S. electrical generation was derived from combustion of coal, oil, or natural gas). [EPA-HQ-OAR-2010-0799-9549-A2, p. 8]

Organization: South Coast AQMD

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 69-70.]

To help alleviate these concerns, the South Coast AQMD staff strongly supports incentives for the purchase of light-duty vehicles that are cleaner than the applicable standards in as early as possible time frame. Increasing the penetration of cleaner vehicles will not only provide additional assurances that the fleet performance will be met, but also help reduce the overall cost of the cleaner vehicles in future years. This South Coast AQMD staff welcomes the opportunity to work with U.S. EPA and NHTSA on mechanisms to incentivize greater penetration of cleaner vehicles, especially zero and near-zero emission and alternative fuel vehicles.

Organization: Tesla Motors, Inc.

• EPA and NHTSA must enact a final rule that incentivizes EV technology but without detracting from development through consideration of issues outside the scope of this rulemaking. [EPA-HQ-OAR-2010-0799-9539-A2, p. 1]

In particular, Tesla agrees with EDTA’s position that upstream GHG emissions should not be included as a part of this rulemaking. In enacting the Clean Air Act, Congress expressly set forth a structure of emissions regulation that would address the individual sources of air pollution. The so-called “upstream sources” EPA would propose to include in this rulemaking are more appropriately regulated under Titles I and V of the Act, with the former establishing stationary source limits of air pollutants and the latter establishing a highly structured permitting framework under which compliance can be regulated. In fact, EPA has already signaled its intent to enact GHG regulation for stationary sources in future rulemakings. Addition of such emission sources in the current mobile source rulemaking would be an *ultra vires* application of the Agency’s authority to regulate tailpipe emissions. Such an extension of authority was not contemplated by Congress and could otherwise result in the dual regulation of a single source. EPA should, instead, focus on regulating GHG from stationary sources under the appropriate provisions of the Clean Air Act and limit application of this rulemaking to mobile sources only. [EPA-HQ-OAR-2010-0799-9539-A2, p. 6]

In addition, Tesla notes that despite the difficulty recognized by EPA in establishing single unified value for GHG emissions from electricity generation in the U.S. for EV’s, the Agency is proposing to do so through application of upstream emissions to motor vehicles. However, application of a nationalized figure fails to account for regional variability in electricity production, as well as the diverse distribution and use of various vehicle types throughout the United States. Moreover, such an approach fails to take into account the continuous improvement in emissions from major power generators. Accordingly, the attempted “one-size-fits-all” approach is neither appropriate nor accurate. [EPA-HQ-OAR-2010-0799-9539-A2, p. 6]

Tesla also takes issue with the method by which EPA attempts to count upstream emissions for internal combustion engines. While Tesla appreciates the Agency’s consideration of our comments to the Notice of Intent to Conduct Rulemaking for Model Year 2017 and Higher

Motor Vehicles where Tesla noted the failure to account for upstream GHGs for internal combustion engines, EPA's proposed solution is far from complete. Specifically, consideration of GHG emissions from refineries accounts for only a part of the emissions. To obtain a true accounting in a "wells-to-wheel" manner, EPA must also look to the emissions profile of oil exploration, production and transport. Regardless, such efforts are neither necessary nor appropriate. Instead, EPA should remove consideration of upstream emissions in a regulation enacted under Title II of the Clean Air Act, which should and must address tailpipe emissions only. [EPA-HQ-OAR-2010-0799-9539-A2, p. 6-7]

Tesla also supports the EDTA statements regarding EPA's proposed automatic termination of the credit multiplier for advanced technology vehicles in MY 2021, as well as challenging NHTSA's legal authority to enact such multipliers. Without providing a full restatement of the EDTA arguments, Tesla notes that incentives such as credit multipliers not only serve to accelerate the commercialization and widespread adoption of advanced technology vehicles like, EVs, they provide support for the businesses seeking to introduce such technology. [EPA-HQ-OAR-2010-0799-9539-A2, p. 7]

Tesla Motors has developed a business model that seeks to introduce EVs in the classic Silicon Valley fashion – namely, introducing low volume, high priced new technology with a unique value proposition and then rapidly moving down the cost curve by capturing increasing economies of scale. Much as the $5,000 cell phone of the 1980's demonstrated the capability of the then nascent cellular network, Tesla demonstrated that long-range, high performance EVs were possible utilizing lithium ion technology in a sports car package. This had the desired effect of catalyzing a competitive response from major automakers like General Motors. In order to continue that mission and move down the cost curve while ramping up the production curve, Tesla funneled the profit from Roadster sales into the Model S design and development. This alone, however, was insufficient to move to our next vehicle, the Model S. Accordingly, the Company was also able to generate additional capital from a variety of sources – including through the sale of credits earned under California's Zero Emissions Vehicle program. By being able to monetize ZEV credits, Tesla was able to generate additional capital enabling more rapid execution of the Company's business plan to Model S. [EPA-HQ-OAR-2010-0799-9539-A2, p. 7]

Like the California ZEV program, GHG and CAFE credits earned from production and sales of EVs like the Model S will allow Tesla to generate revenue for more rapid EV development and production. This will, in turn, speed the introduction of the next generation of EVs at higher volumes and lower price points (i.e., the Gen III). In addition, this will also assist in support of Tesla's power train business as well. EPA's automatic elimination of the credit multiplier and NHTSA's refusal to consider a CAFE multiplier will only delay the otherwise rapid deployment of EV technology not only by Tesla, but others as well. Accordingly, Tesla encourages EPA not to automatically eliminate the credit multiplier, but commit, instead to reviewing whether the multiplier is still needed as part of the mid-point review already proposed. Similarly, Tesla encourages NHTSA to revisit its authority to enact a CAFE multiplier for the reasons provided in EDTA's comments.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, pp. 94-95.]

And second, with respect to the consideration of upstream emissions, we believe that if this were to -- number one, it's adequately covered under Title V of the Clean Air Act. Moreover, pursuing this, this provision, could result in double counting. But in any event, if this were pursued, that we would encourage the agency to consider methodology on a well-to-wheel basis as opposed to simply stopping at the point of generation.

Organization: Toyota Motor North America

It is unclear that EPA has authority under Title II of the Clean Air Act to regulate upstream emissions from mobile sources. To the extent EPA is concerned with upstream emissions in power generation or fuel production resulting from potential expansion of electric and hydrogen fueled vehicles, it should regulate those sectors directly under other parts of the Act. [EPA-HQ-OAR-2010-0799-9586-A1, pp.2-3]

Advanced Technology Vehicle Credits [EPA-HQ-OAR-2010-0799-9586-A1, p.19]

EPA has proposed incentives to promote the commercialization of electric vehicles, fuel cell vehicles, and plug-in vehicles. The agency believes these technologies warrant incentives because they have the potential to nearly eliminate GHG emissions and petroleum use from vehicles, but face significant barriers today in terms of costs, infrastructure, and market acceptance. The first incentive allows an unlimited number of these vehicles to use a GHG emissions compliance value of 0 grams per mile (only during electric operation for PHEVs) through the 2021 model year, at which point upstream emissions are counted when production thresholds are exceeded. The second allows these vehicles to count as more than one vehicle for the purpose of calculating compliance with the fleet average CO_2 standards. The incentives are proposed to sunset after the 2021 model year. Toyota generally supports the intent to incentivize advanced technology vehicles, but has some concerns that are outlined below. [EPA-HQ-OAR-2010-0799-9586-A1, p.19]

Upstream Emissions Accounting [EPA-HQ-OAR-2010-0799-9586-A1, p.19]

Toyota opposes any requirement for automakers to account for upstream emissions in determining the compliance level of vehicles. First, automakers have no control over the level of upstream emissions and thus no ability to reduce such emissions to enhance compliance. Second, it is unclear that EPA has authority under Title II of the CAA to regulate upstream emissions from mobile sources. To the extent EPA is concerned with upstream emissions in power generation or fuel production resulting from potential expansion of electric and hydrogen fueled vehicles~ it should regulate those sectors directly under other parts of the CAA. Third, if EPA decides to include such emissions, there could be no end what other emissions automakers will be asked to account for~ including steel production emissions, rubber production emissions for tires, and so on. Clearly, Title II of the CAA was never intended extend the responsibility to automakers for these various emission sources. Finally, as the agencies recognized in the preamble, 'manufacturers are unlikely [to invest in PHEVs and EVs] if vehicles with these technologies are treated for compliance purposes to be no more advantageous than the best conventional hybrid'. [EPA-HQ-OAR-2010-0799-9586-A1, pp.19-20]

Organization: U.S. Coalition for Advanced Diesel Cars

To accomplish these goals, the Coalition supports technology-neutral regulations that create an environment of stability and predictability for auto makers and their suppliers. [NHTSA-2010-0131-0246-A1, p.1]

Our comments below assert that technology neutral policies and consumer acceptance are the only proven methods for the automotive industry to move forward with certainty and with the flexibility to seek and strive for new innovations that will dramatically improve fuel economy and reduce emissions. [NHTSA-2010-0131-0246-A1, p.1] [This statement also cross-referenced with section 18.1]

Members of the Coalition invest in every advanced automotive technology – not just diesel technology. We believe, therefore, that changes to Corporate Average Fuel Economy (CAFE) regulations should not be aimed at steering automakers to produce specific types of vehicles. Instead, the Environmental Protection Agency (EPA) and the National Highway Transportation Safety Administration (NHTSA) should employ technology-neutral policies that are outcome and performance based. Without such policies, EPA and NHTSA will be picking winners and losers, stifling innovation, limiting consumer choice, preventing significant increases in fuel economy today and potentially stunting job growth. [NHTSA-2010-0131-0246-A1, pp.1-2]

In 2009, the Coalition stated in response to the MY 2012-2016 joint rulemaking that the best way to drive innovation and achieve the desired outcomes of reduced petroleum consumption and lower greenhouse gas emissions is to provide automakers with regulations that are technology neutral. The “2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards Proposed Rulemaking” (NPRM) falls short of giving automakers a pathway to innovation as EPA and NHTSA clearly attempt to steer future vehicle production into technologies that, although promising in the future, will prevent American’s from maximizing improved fuel economy and reducing their greenhouse gas (GHG) emissions in the near- and medium-term. [NHTSA-2010-0131-0246-A1, p.2]

The auto industry cannot afford to make investment decisions based on inaccurate EPA testing data and inaccurate modeling. This is in stark conflict with President Obama’s call for rules that will “give our auto companies some long overdue clarity, stability and predictability.” See, Pres. Obama (press release) September 15, 2009. [NHTSA-2010-0131-0246-A1, p.3]

The Coalition urges EPA and NHTSA to refrain from expanding the system of CAFE credits based on specific technologies and instead offer manufacturers ONYLY performance-based credits. By supporting only performance-based credits, the agencies will have a greater role in incentivizing fuel economy improvements and GHG reductions with improvements in Internal Combustion Engine (ICE) vehicles. As ICEs are expected to dominate new car sales well beyond 2025, the agencies are more likely to accomplish their mission in reducing the nation’s dependency on foreign oil and dramatically reducing GHG emissions. [NHTSA-2010-0131-0246-A1, p.5]

Specific Technology Incentives are Unnecessary: The Coalition disagrees with the agencies' commentary about specific technologies. As stated previously, the goal of EPA and NHTSA should not be to identify or incentivize "advanced technologies." Instead, the focus should be solely on advanced fuel savings and GHG emission reductions. [NHTSA-2010-0131-0246-A1, p.5]

In stark contrast to the EPA's findings, researchers have affirmatively stated that technology specific incentives are not necessary. Researchers at the University of Michigan's Energy Institute & School of Natural Resources and Environment have stated that substantial opportunities exist for ongoing fuel economy gains through evolutionary technology change. [NHTSA-2010-0131-0246-A1, p.5]

"…but technology neutral policy provides the best benefit/cost ratios for consumers, industry and society. Even over a long-term time horizon — looking at 2025 as a milepost on the road to future GHG reduction needs — there is no scientific justification for favoring grid-connected vehicle electrification." (John M. DeCicco, Univ. of Michigan's Energy Institute & School of Natural Resources & Environment.) [NHTSA-2010-0131-0246-A1, pp.5-6]

Performance Based Standards Will Lead to Better Market Penetration: New technologies, changes to the driving habits of Americans and many other factors will make acceptance of certain technologies difficult to predict. We currently have advanced technologies that are readily available, reasonable priced and already accepted by consumers that can dramatically improve fuel economy and reduce emissions, without the need for infrastructure investment. [NHTSA-2010-0131-0246-A1, p.6]

In fact, a performance-based standard could achieve a remarkably higher effect on the environment than rules that steer towards certain technologies. What is clear is that the percentage of new vehicles sold in 2025 will be powered by internal combustion engines (ICEs). Incentivizing alternative technologies like hybrid, EVs and PHEVs will overlook common-sense improvements to the powertrain that will remain dominant in the marketplace throughout the course of the NPRM. A truly performance-based standard for credits will likely increase improvements to the ICE segment. These improvements will lead to greater fuel economy and lower emissions much faster than incentives limited to such a small percentage of cars. [NHTSA-2010-0131-0246-A1, p.6]

Expand Incentives to Advanced Technologies for ICEs: As stated in the NPRM, "EPA is not expanding the list of eligible advanced vehicle technologies primarily because all of these technologies utilize internal combustion engines, which have dominated the personal vehicle market for the last 100 years and do not present the same level of market challenges to automakers as EVs, PHEVs and FCVs." The goal of CAFE regulations and the Clean Air Act is not to overcome market challenges for alternative vehicle technologies. The Coalition requests that EPA and NHTSA expand incentives that seek to expand market penetration for all advanced vehicle technologies in order to achieve the nation's goals. [NHTSA-2010-0131-0246-A1, p.6]

In the current proposed rulemaking, production multipliers for each EV, PHEV and FCV are again proposed. These multipliers are distortive to the marketplace. Each of the "phantom" vehicles allowed under a multiplier scheme will result in less technology implementation on a real vehicle in the fleet; meaning more fuel consumption and more GHG emissions. The CAFE program is intended to control the fuel consumption of vehicles that are actually manufactured and sold into commerce, not to create market and competition distorting accounting methods that have government picking winners and losers. [NHTSA-2010-0131-0246-A1, p.8]

A strictly performance based credit system would allow manufacturers the flexibility to innovate and create a vehicle fleet that best suits their vision and customer base. Best of all, the manufacturers will be focused on looking at all available options to achieve the higher incentive levels with all available technologies. [NHTSA-2010-0131-0246-A1, p.8]

Of additional concern to the Coalition is EPA and NHTSA's decision to not calculate upstream emissions when determining incentives (credits) associated with all vehicle technologies. Such a decision is clear evidence that the agencies do not intend to proceed in a technology neutral manner. Under Section III of the NPRM, the agencies acknowledge the existence of upstream emissions but chose to only focus on GHG emissions at the tailpipe. (The NPRM justifies this calculation by identifying electric (EV), plug-in hybrid electric (PHEV), and fuel cell (FCV) vehicles as "game-changers.' [NHTSA-2010-0131-0246-A1, p.8]

As in the 2012-2016 rule, EPA is proposing temporary regulatory incentives for the commercialization of EVs, PHEVs, and FCVs. EPA believes that these advanced technologies represent potential game-changers with respect to control of transportation GHG emissions as they can combine an efficient vehicle propulsion system with the potential to use motor fuels produced from low-GHG emissions feedstocks or from fossil feedstocks with carbon capture and sequestration. EPA recognizes that the use of EVs, PHEVs, and FCVs in the 2017-2025 timeframe, in conjunction with the incentives, will decrease the overall GHG emissions reductions associated with the program as the upstream emissions associated with the generation and distribution of electricity are higher than the upstream emissions associated with production and distribution of gasoline. EPA accounts for this difference in projections of the overall program's impacts and benefits (see Section III.F). [NHTSA-2010-0131-0246-A1, p.8]

The tailpipe GHG emissions from EVs, PHEVs operated on grid electricity, and hydrogen-fueled FCVs are zero, and traditionally the emissions of the vehicle itself are all that EPA takes into account for purposes of compliance with standards set under Clean Air Act section 202(a). Focusing on vehicle tailpipe emissions has not raised any issues for criteria pollutants, as upstream emissions associated with production and distribution of the fuel are addressed by comprehensive regulatory programs focused on the upstream sources of those emissions. At this time, however, there is no such comprehensive program addressing upstream emissions of GHGs, and the upstream GHG emissions associated with production and distribution of electricity are higher, on a national average basis, than the corresponding upstream GHG emissions of gasoline or other petroleum based fuels. [NHTSA-2010-0131-0246-A1, p.9]

Stated more simply, EPA acknowledges that: [NHTSA-2010-0131-0246-A1, p.9]

EVs and PHEVs are responsible for more upstream GHG emissions than ICEs; [NHTSA-2010-0131-0246-A1, p.9]

New vehicles traditionally have their emissions regulated only at the tailpipe; [NHTSA-2010-0131-0246-A1, p.9]

The NPRM doesn't need to regulate EV and PHEV upstream criteria emissions because other regulations will do so; and [NHTSA-2010-0131-0246-A1, p.9]

No other program actually exists to account for upstream GHG emissions. [NHTSA-2010-0131-0246-A1, p.9]

Despite the conclusions of the agencies regarding upstream emissions, the Department of Energy's Energy Information Administration (EIA) disproved the conclusions of the EPA and NHTSA in January of 2009. In response to a Congressional inquiry, the EIA compared the well-to-wheel GHG emissions of a variety of light duty vehicles. The report clearly compared the GHG emissions of different advanced vehicle technologies and proved that the GHG emissions of several widely available technologies compare very favorably to EVs, PHEVs and FCVs. According to the EIA study in 2009, a well-to-wheel comparison of different vehicle technologies ranks electric vehicles, diesel and turbocharged gasoline engine vehicles within a 10% to 15% performance band. [NHTSA-2010-0131-0246-A1, p.9] [There is an associated figure, please refer to NHTSA-2010-0131-0246-A1, p.10]

The study compared vehicles on an equal footing: size and performance were held constant and only the powertrain was changed. The performance improvement of the next generation of internal combustion engines (ICEs), hybrids and EVs was calculated, and fuel economy and emissions were simulated on the usual U.S. standard test cycles. [NHTSA-2010-0131-0246-A1, p.10]

The need to meet aggressive national goals regarding our energy independence should not overshadow the reality of today's limitations faced by many advanced technologies. Primarily, car and light truck buyers will buy the vehicles that best meet their needs. We will achieve dramatic, game changing fuel savings and emission reductions by providing an evolutionary pathway for the advanced technologies that have proven market acceptance and are available today. This will provide the opportunity for new technologies to continue to develop into reliable, cost effective options that meet consumer needs. [NHTSA-2010-0131-0246-A1, p.13]

The investment in future technologies, such as vehicle electrification, go well beyond the engine bay to include sourcing and developing raw materials, complex vehicle integration and development, infrastructure support on a national level and increased costs for consumers forced to the cutting edge of what is still a boutique technology. [NHTSA-2010-0131-0246-A1, p.14]

Embracing a strictly performance-based standard will allow America to achieve the fuel savings and emissions reductions promised in the NPRM by the end of 2025. [NHTSA-2010-0131-0246-A1, p.14]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 242-243.]

Federal government's favoritism of hybridization and electrification continues in EPA and NHTSA's joint NPRM with two areas of particular concern to the Coalition. First, the NPRM presents a process of incentivizing specific technologies by establishing and awarding credits for 'game changing technologies,' such as a hybrid trucks and electric vehicles. Additionally, the NPRM continues to ignore the EPA and NHTSA's own data that shows the majority of miles traveled by the average American are on highway conditions instead choosing to favor and reward a technology that is best suited to city driving and start/stop conditions. The Coalition continues to advocate for policies that incentivize game-changing fuel savings by rewarding outcomes, not implementation of a specific technology.

Organization: Union of Concerned Scientists (UCS)

(c) Electric Drive Vehicle Incentives

Under the current federal vehicles greenhouse gas standards, models relying partially or completely on electricity or hydrogen receive significant extra credit towards meeting those standards. These extra credits do not represent actual reductions in greenhouse gas emissions, but rather were created as incentives for automakers to sell electric-drive vehicles. [EPA-HQ-OAR-2010-0799-9567-A2, p. 9]

In the 2017-2025 proposed rule, EPA is proposing compliance ledger accounting of EVs and FCVs (and partially for PHEVs) at zero grams per mile (g/mi) through model year 2021, well below the 103 g/mi the agency specifies a midsize EV would emit under a 2025 grid mix. Above and beyond that, the agency is proposing an additional “incentive multiplier” for EVs, FCVs, and PHEVs sold in MYs 2017 through 2021, whereby an advanced technology vehicle sold would count as more than one vehicle in the manufacturer’s compliance calculation. [EPA-HQ-OAR-2010-0799-9567-A2, p. 9]

UCS strongly opposed these incentives during the 2012-2016 rulemaking on the grounds that they do not reflect real emissions reductions and thus erode the benefits of the National Program and that there are other, more effective ways of accelerating the market for electric cars (e.g. the California ZEV program, federal tax credits, loan guarantees, and other state and local incentives). We continue to oppose them here for the same reasons, and express grave concern that they, like many auto industry incentives over the years, will again be extended and continue to undermine the goals of the program they serve. [EPA-HQ-OAR-2010-0799-9567-A2, p. 9]

UCS is particularly disappointed by the agency’s proposal on incentive multipliers, given its intellectual inconsistency with an EPA determination on the very same issue made only a year and a half earlier. As the agency noted in its May 2010 final rule on MY2012-2016 vehicle standards, “EPA is not finalizing a multiplier based on the concerns potentially excessive credits using that incentive [sic]. EPA agrees that the multiplier, in combination with the zero grams/mile compliance value, would be excessive.” 32 [EPA-HQ-OAR-2010-0799-9567-A2, p. 9]

EPA acknowledges this inconsistency in the proposed 2017-2025 rule, and offers up the following as an explanation: "While the Agency rejected a multiplier incentive in the MYs 2012-2016 final rule, we are proposing a multiplier for MYs 2017-2021 because, while advanced technologies were not necessary for compliance in MYs 2012-2016, they are necessary, for some manufacturers, to comply with the GHG standards in the MYs 2022-2025 timeframe." [EPA-HQ-OAR-2010-0799-9567-A2, p. 9]

This rationale is not supported by EPA's arguments. First, EPA's new interest in incentive multipliers is, by its own admission, rooted in catering to the industry's least-capable manufacturers. As noted throughout the proposal, numerous compliance pathways exist for meeting standards (including trading of credits between manufacturers, which alone should more than address the challenge cited by EPA above). EPA should not design and incorporate program loopholes to accommodate industry laggards when many other flexibility mechanisms already exist. Second, EPA states these multipliers are necessary for certain manufacturers to comply "in the MYs 2022-2025 timeframe," yet EPA is proposing that the multiplier incentive expire at the end of MY2021. Logically, this means that either (a) industry laggards expect the agencies (or will lobby them) to extend this incentive beyond the proposed 2017-2021 time frame, allowing even more time for all manufacturers to take advantage of the multipliers through 2025, further eroding National Program benefits; or (b) the industry laggards' only plan for complying with 2022-2025 standards is by using banked, inflated credits generated in 2017-2021, and are not planning for a technology pathway that will allow them to achieve 2025 standards. Concrete product plans for MY2022-2025 vehicles have yet to even begin; EPA should not endorse these industry arguments and weaken its program by introducing loopholes that either have the potential to balloon beyond proposed levels, or that encourage some in the industry to slow-walk fuel-saving technology deployment. UCS calls upon EPA to exclude the multiplier incentive in the final rule, on the "excessive" grounds noted previously by the agency, as well as to ensure that 0 g/mi treatment of these vehicles does not extend beyond MY2021. [EPA-HQ-OAR-2010-0799-9567-A2, pp. 9-10]

Though I strongly support these standards, I am concerned about possible loopholes that automakers could exploit. Specifically: The proposal largely ignores the pollution released from power plants when electric cars are recharged. The EPA should require automakers to fully account for their vehicles' pollution--whether from petroleum or power plants. [EPA-HQ-OAR-2010-0799-9713-A2, p. 2]

---

32 Federal Register Vol. 75, No. 88, p. 25401 [EPA-HQ-OAR-2010-0799-9567-A2, p. 9]

Organization: United Automobile Workers (UAW)

Likewise, the UAW supports the proposal by EPA to count each electric, plug-in hybrid and fuel cell vehicle as more than one vehicle in the manufacturer's compliance calculation for model years 2017–2021. The UAW is in strong agreement with EPA's proposal to assign a value of zero grams per mile for these vehicles when operating on electricity for the same model years 2017–2021. The UAW believes that zero grams per mile are the most faithful representation of the tailpipe pollution for a vehicle that in many cases has no tailpipe. Accordingly, while the UAW believes that the proposed caps for zero gram per mile treatment by the EPA for model years 2022–2025 are likely adequate to avoid assigning upstream emissions to large numbers of these vehicles, we urge the EPA to reconsider its stance that the emissions of electricity producers should be assigned to the products that use electricity. The proper place to measure and regulate these emissions is of course where the electricity is produced and the grid system that distributes electricity. [EPA-HQ-OAR-2010-0799-9563-A2, pp.3-4]

At the same time, we believe it is important to understand the changes in electricity sector emissions that will be caused by the addition of significant numbers of electric-drive vehicles to the fleet, and to be able to account for the net change in emissions in the switch from liquid fuels to electricity. To that end, the UAW encourages the EPA to continue to study how real-world electric vehicle use impacts the emissions of electricity producers. The efficiency of electric-drive vehicles in converting energy stored as electricity into distance traveled by the vehicle can and should be evaluated and eventually regulated. The efficiency of the charging systems for electric vehicles should also be measured and eventually regulated, perhaps as an appliance under existing Department of Energy authority. Improving the overall efficiency by charging an electric vehicle and converting that energy to miles driven will lead to the most effective and lowest cost scheme for realizing the most emissions reduction from increased adoption of electric-drive vehicles. [EPA-HQ-OAR-2010-0799-9563-A2, p.4]

Organization: Volkswagen Group of America

- Expand the range of technologies (beyond only electrification) which would qualify for emission incentives within the regulatory program in order to promote a broader set of fuel saving, low-CO_2 emitting options for consumers, i.e. alternative fueled vehicles, advanced combustion engines, etc. [EPA-HQ-OAR-2010-0799-9569-A1, p. 4]

Volkswagen proposes that the agencies expand the assortment of technologies credited within the regulatory program. As we understand, the intention of technology credits are to promote market availability of fuel saving and low-emission options for consumers. Currently the program achieves this for electrification and for technologies applied to full-size pick-up trucks. It is Volkswagen's position that a general expansion of the technology awarding credits could drive a greater number of technologies into the field and into vehicles other than just full-size trucks. [EPA-HQ-OAR-2010-0799-9569-A1, p. 28]

Organization: Volvo Car Corporation (VCC)

Also, the agencies proposed minimum electric or equivalent all-electric range for the definition of a PHEV for use of this advanced technology volume multiplier. [EPA-HQ-OAR-2010-0799-9551-A2, p. 12]

VCC supports the Alliance position that, upstream emission should be counted as 0 g/mile for the period 2012-2025. [EPA-HQ-OAR-2010-0799-9551-A2, p. 14]

VCC supports the advanced technology volume multipliers as proposed in the NPRM. VCC also suggests that the proposed multiplier be reviewed during the mid-term evaluation and potentially approved for continued use post 2021. [EPA-HQ-OAR-2010-0799-9551-A2, p. 12]

Organization: Weiner, L.

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p. 107.]

The cap on electric vehicles should be strong so automakers cannot produce less efficient vehicles in other parts of their fleet yet still meet overall standard. Not that it would happen, but we want to make sure that no one games the system.

Response:

Introduction

EPA received a very large number of comments with respect to the proposed incentives for electric vehicles (EVs), plug-in hybrid electric vehicles (PHEVs), and fuel cell vehicles (FCVs). Most of the comments in this section addressed the same fundamental set of issues associated with incentives for EVs, PHEVs, and FCVs. The reader should note that most of the comments related to electricity are addressed in this section, while most of the comments related to diesel, compressed natural gas, ethanol, and other alternative fuels are in RTC Section 6. Many comments raise issues relevant to both this section and Section 6, sometimes even in the same sentence, so readers interested in a comprehensive treatment of comments on alternative fuel vehicles should read the comments and responses in both sections. In addition, comments related to gasoline fuel quality in general, and to ethanol/gasoline blends in particular, are addressed in RTC Section 11.

EPA rationale for temporary regulatory incentives for EV/PHEV/FCVs

There was a wide spectrum of comments on the overall appropriateness of regulatory incentives, ranging from complete opposition to any incentives whatsoever to support for stronger incentives than proposed.

EPA believes that temporary regulatory incentives are permissible under CAA section 202 (a), and justifiable here. These incentives promote the commercialization of technologies that have, or of technologies that can be critical facilitators of next-generation technologies that have, the potential to transform the light-duty vehicle sector by achieving zero or near-zero GHG emissions and oil consumption, but which face major near-term market barriers. [10] As such, the incentives are part of the process of determining the "period … necessary to permit the

[10] As BMW stated in its comments, "Multipliers encourage automakers to pull-ahead early generation low CO_2 technologies such as BEV, PHEV and FCV. Multipliers should be applied on advanced technologies with significant GHG reduction potential (which are much more expensive than mature gasoline technologies). Therefore, they are a motivation for automakers to move forward with cost-intensive technology (low volume, high investments) to reach full market economic viability"

development and application of the requisite technology" (section 202 (a)(2)) by creating regulatory incentives to shorten the time for "development and application". Although providing temporary regulatory incentives for certain advanced technologies will decrease the overall GHG emissions reductions associated with the program in the near term, EPA believes it is worthwhile to forego modest additional emissions reductions in the near term in order to lay the foundation for the potential for much larger "game-changing" GHG emissions and oil reductions in the longer term (EPA has adopted this strategy in previous mobile source rulemakings, such as its Tier 2 Light-Duty Vehicle, 2007 Heavy-Duty Highway, and Tier 4 Nonroad Diesel rulemakings, as well as the MYs 2012-2016 light duty vehicle GHG rule and the MYs 2014-2018 heavy duty vehicle and engine GHG rule). This objective is again fully in accord with the pollutant emission reduction goals of section 202(a). EPA accounts for the higher real world GHG emissions and lower GHG emissions reductions associated with these temporary regulatory incentives in all of our regulatory analyses.

Some proponents of incentives questioned EPA's legal authority to include upstream emissions in any compliance calculation under section 202(a), maintaining that section 202 (a) authorizes EPA to regulate only emissions "from … any motor vehicle[e]" and that upstream emissions are not from the vehicle (EDTA comment). EDTA also points to other provisions in Title II (sections 206 and 207) which, in the commenter's view, rest on the same predicate of control of tailpipe emissions only. The Alliance and other auto manufacturers argued that by including upstream GHG emissions in compliance calculations for EVs and PHEVs de facto requires automakers to meet utility GHG standards. A number of commenters also maintained that EPA was arbitrary in including upstream emissions in compliance calculations for electric vehicles but not for non-electric vehicles.

EPA disagrees with these commenters. Section 202(a) states that EPA must adopt "standards applicable to the emission of any air pollutant from any class of new… motor vehicle…." The provision does not directly address what the "standards applicable to" the emissions must be, or how those standards are to be measured. It does not specify how or what mechanisms EPA may reasonably use in applying a standard to vehicle emissions. This leaves EPA with discretion to develop both elements of the standards and the means of measuring compliance with them. See 75 FR at 25437.[11] EPA has done so in this rule, developing compliance values for use in meeting the attribute-based standards that recognize the overall GHG impacts of electric vehicles. Put another way, where appropriate, the standard applicable to emissions from electric vehicles reasonably can include use of a compliance value that better reflects the overall emissions impact of the vehicle, and this can include net upstream GHG emissions attributable to use of the fuel that powers the vehicle. The standard employs a compliance value to reflect those emissions when production exceeds the per-company production caps.

EPA has long interpreted section 202(a) as providing EPA the discretion to develop appropriate compliance calculations that in some cases differ from the actual tailpipe or leakage values for a vehicle. For example, a multiplier or other incentives for EVs are an adjustment to

[11] CAA sections 206 and 207, also referred to by the commenter, refer back to the section 202 regulations, and so do not provide any additional support for the commenters' argument.

the compliance calculation that does not reflect literal tailpipe emissions. EPA has authority to apply such adjustments where they are an appropriate mechanism to promote the overall emissions reductions achieved by the motor vehicle standards. Likewise, the use of a net upstream compliance value for EVs is an adjustment to the compliance calculation that appropriately reflects the overall emissions impact of the motor vehicle standards. Both of these kinds of adjustments fall within EPA's broad discretion to determine how a standard should be applied to emissions from motor vehicles. In the case of a multiplier for EVs, the standards are applied by artificially adjusting the number of times the tailpipe emissions level for an EV is used in the compliance calculation. In the case of the net upstream compliance value for EVs, the level of the tailpipe emissions are adjusted for use in the compliance calculation. In both cases, these adjustments to the actual tailpipe levels reflect reasonable and appropriate policy responses that further the emissions goals of the section 202(a) standards. Ironically, if the commenters were correct, EPA would have no authority to assign a multiplier or other incentives for EVs, since these multipliers also do not reflect literal emissions from a vehicle.

EPA does not believe that in doing so it is requiring auto manufacturers to control GHG emissions from utilities. As EPA explained when discussing this issue in the MYs 2012-2016 light duty vehicle GHG rulemaking, "EPA is not directly regulating upstream GHG emissions from stationary sources, but instead is deciding how much value to assign to a motor vehicle for purposes of compliance calculations with the motor vehicle standard. While the logical place to start is the emissions level measured under the test procedure, section 202 (a)(1) does not require that EPA limit itself to only that level." 75 FR at 25437.

Nor is EPA arbitrary in including upstream emissions in the compliance calculation for the standard applicable to the emissions from electric vehicles. As shown in preamble Table III-16 , upstream GHG emissions attributable to increased electricity production to operate EVs or PHEVs currently exceed the upstream GHG emissions attributable to gasoline vehicles. See preamble section III.C.2.c.v at n. 499; see also 75 FR at 25437. Moreover, as EPA found in the MYs 2012-2016 light duty vehicle rulemaking, the difference in upstream GHG emissions for both diesel fuel from oil and CNG from natural gas are relatively small compared to differences associated with electricity. 75 FR at 25437.

EPA thus believes that although section 202 (a)(1) of the Clean Air Act does not require the inclusion of upstream GHG emissions in these regulations, the discretion afforded under this provision allows EPA to consider upstream GHG emissions, particularly when such emissions from new technologies are higher than those from conventional vehicles. There is consequently a rational basis for EPA to account for this net difference.

Opponents of incentives emphasized three primary arguments: 1) that regulatory incentives are not technology neutral and therefore pick "winners and losers" among various advanced technologies, 2) that such incentives reduce the GHG benefits of the program, and 3) that incentives are no longer needed for technologies such as EVs.

EPA believes that the issue of technology neutrality is a much more complex issue than some commenters suggest when they advocate for a "level playing field," suggest that a level playing field is best achieved by no incentives, and that incentives cannot be "scientifically justify[ed]." Given that internal combustion engines and petroleum-based fuels have dominated the U.S. light-duty vehicle market for 100 years, with massive sunk investments, there are major barriers for new vehicle technologies and fuels to be able to gain the opportunity to equitably compete on any type of level playing field. For example, consider a hypothetical new vehicle/fuel technology that could be superior to conventional technology from a consumer perspective if, and only if, the vehicles and fuels could be produced at similar economies of scale. But, it is very possible that such a hypothetical new technology would never get the opportunity to compete at equivalent economies of scale, because of the very large investments that are needed, up front, to support the research and development, parts and vehicle production facilities, and fuel infrastructure, none of which are needed for conventional technology as these investments have been made in the past. In this context, temporary regulatory incentives do not so much "pick winners and losers" (as an inefficient or unattractive technology is not going to achieve long-term market success based on temporary incentives) as to give new technologies more of an opportunity to compete with the established technologies.

The agency agrees that the temporary regulatory incentives will slightly reduce the short-term benefits of the program and in fact the Agency accounts for the lower benefits in all of our regulatory analyses. But, as noted above, EPA believes that it is worth a limited short-term loss of benefits to increase the potential for far-greater game-changing benefits in the longer run. EPA also believes that temporary regulatory incentives may help bring some technologies to market more quickly than in the absence of incentives.

Finally, EPA disagrees that such incentives are no longer needed for EVs. Although it is true that several EV and PHEV models are now on the U.S. market, sales of EVs and PHEVs amounted to less than 0.2% of all sales in 2011.[12] Alternatively, vehicles with internal combustion engines that operate primarily on petroleum-based fuels continue to account for over 99% of all light-duty vehicles sold in the U.S.

At the same time, EPA believes there must be limits on the use of such incentives. For example, while temporary incentives can be justified as allowing a new game-changing technology, the opportunity to compete in the initial stages of technology commercialization when economies of scale are poor, permanent incentives are very different in that they would tilt the market even after a new technology has overcome the initial low economies of scale. In this case, the agency believes that temporary regulatory incentives best balance our dual objectives of achieving near-term GHG emissions reductions and promoting game-changing technologies that could provide even greater GHG emissions reductions in the longer-term.

Design of incentive multiplier for EV/PHEV/FCVs for MYs 2017-2021

Public comments on this topic mirrored those of incentives in general, i.e., those commenters that opposed incentives in general almost always opposed the proposed incentive multiplier for EV/PHEV/FCVs, while those commenters that supported the concept of incentives

[12] Total 2011 U.S. light-duty vehicle sales were 12.8 million (see http://online.wsj.com/article/SB10001424052970203513604577140440852581080.html, last accessed on July 10, 2012). Total 2011 U.S. EV/PHEV sales were less than 20,000 (see http://www.plugincars.com/nissan-leaf-sales-trump-chevy-volt-2011-111308.html, last accessed July 10, 2012, for total Leaf EV plus Volt PHEV sales of 17,345).

generally supported the proposed approach. Only a few commenters suggested a different multiplier design, i.e., higher multiplier levels or longer duration.

EPA disagrees with the comment by the Union of Concerned Scientists of "intellectual inconsistency" with the MYs 2012-2016 standards. In that rule, EPA did not project that advanced technologies like EVs and PHEVs were necessary to meet the MY 2016 standards so that no further incentive was needed. In contrast, EPA projects here that, for some manufacturers, EVs and PHEVs are in fact projected for meeting the much more stringent MY 2025 standards. As EPA stated in the proposal, providing multipliers for MYs 2017-2021 can lay the foundation for commercialization of these technologies that can then contribute toward compliance with standards in MYs 2022-2025. 76 FR at 75012. On the other hand, EPA disagrees with those commenters that support higher multipliers and/or multipliers of longer duration, as we believe that such incentives could lead to a significant reduction in program GHG savings, particularly if the incentives were to remain in effect past MY 2021 and if EV/PHEV/FCV sales increase significantly after that year. EPA believes it has struck a reasonable balance in finalizing the proposed multipliers for EV/PHEV/FCVs for MYs 2017-2021 (multipliers for CNG vehicles are discussed in Section 6). EPA reiterates that it is both reasonable and appropriate to accept some short-term loss of emissions benefits in the short run to increase the potential for far-greater game-changing benefits in the longer run. The agency believes that these multipliers may help bring some technologies to market more quickly than in the absence of incentives. In addition, the agency agrees with the Alliance of Automobile Manufacturers about the possible unintended consequences of a variable multiplier (e.g., based on electric range or battery capacity which, as the Alliance reasonably points out could encourage manufacturers to install battery capacity or power not demanded by customers thereby increasing vehicle costs), and is finalizing a fixed multiplier for all PHEVs that meet the eligibility requirements discussed below.

PHEV eligibility requirements

EPA received only a few comments related to eligibility requirements for PHEVs to be able to use the incentive multiplier. EPA agrees with Securing America's Future Energy that a 4 kilowatt-hour minimum battery energy storage requirement would be a reasonable approach, but because the Agency prefers performance-based metrics when possible, we are finalizing the proposed 10.2 miles all-electric or equivalent all-electric range that was supported by the Alliance of Automobile Manufacturers and Ford comments.

0 gram/mile compliance treatment for EV/PHEV/FCVs with MYs 2022-2025 per-company cap and net upstream GHG emissions compliance beyond cap

A large number of the above commenters addressed the related issues of the appropriateness of the proposed 0 grams/mile (g/mi) compliance treatment for EV/PHEV/FCVs, and of the proposed cumulative per-company vehicle production cap for this compliance treatment in MYs 2022-2025.

For an extensive summary of the key comments and EPA's response to the key comments, see Preamble Section III.C.2.c.v. As proposed for EV/PHEV/FCVs, EPA is finalizing the 0 g/mi compliance treatment with a cumulative per-company vehicle production cap for MYs 2022-2025, and net upstream GHG emissions compliance for production in excess of the cap. The cumulative per-company vehicle production cap for MYs 2022-2025 is 600,000 EV/PHEV/FCVs for those manufacturers that sell at least 300,000 such vehicles in MYs 2019-2021, and is 200,000 EV/PHEV/FCVs for all other manufacturers.

Methodology for determining net upstream GHG emissions compliance for EV/PHEVs beyond the MYs 2022-2025 per-company vehicle production cap

EPA proposed a relatively simplistic approach for calculating the net upstream GHG emissions compliance values for EVs and the electric portion of PHEVs, but signaled its intention to consider a more technically robust approach in the final rule. EPA received a few comments, which directly or indirectly supported a more sophisticated modeling approach based on better projections of the future electric power sector, a plausible regional distribution of plug-in electric vehicles, etc.

See Preamble Section III.C.2.c.vi for an extensive discussion of the key comments and multiple changes that EPA is finalizing, based on new work that EPA has carried out with the EPA Integrated Planning Model, a state-of-the-art electric power sector model. The results are new projections for the average GHG emissions factor for electricity used to support EV/PHEVs in the future, as well as for the multiplicative factor used to project the additional GHG emissions associated with electricity feedstocks.

The Edison Electric Institute commented that it would be better for EPA to wait until the midterm evaluation to adopt an electricity upstream GHG emissions factor. EPA disagrees with this comment. EPA believes it is critical to provide the automobile manufacturers, for their long-term compliance planning, a value that we expect to be used for compliance purposes in MYs 2022-2025, for those manufacturers who exceed their vehicle production caps for EVs and PHEVs since this value will become a part of their standard. We understand that there are many factors that could lead to an electricity upstream GHG emissions factor for EVs and PHEVs that may be higher or lower than our latest projection, such as future regulations, market forces, regional distribution of EV/PHEV sales, and vehicle charging patterns. EPA will continue to evaluate these factors, including in the mid-term evaluation.

Applicability of other program credits for EV/PHEV/FCVs

The Natural Resources Defense Council commented that, if necessary, other program credits should be limited such that no vehicle would effectively have a “negative” compliance value. EPA is finalizing, as proposed and consistent with the MYs 2012-2016 program, no restrictions on the use of GHG emissions credits for those vehicles eligible for the 0 g/mi GHG emissions compliance treatment, i.e., EV/PHEV/FCVs can earn air conditioner efficiency, air conditioner refrigerant, and off-cycle credits. EPA will be accounting for these credits at the manufacturer fleet level, not at the individual vehicle model level, though we accept the point by NRDC that, in effect, if one were to assess the actual credits earned on a per vehicle basis, the overall compliance value would appear to be negative. Because of the relatively small number of EV/PHEV/FCVs expected during MYs 2017-2025, EPA expects the fleetwide impact of these additional credits to be very small, and EPA does not want to discourage improvements in air conditioner and other technologies for EV/PHEV/FCVs that provide real world GHG emissions benefits.

5. Advanced Technology Credits for Full-Size Pickup Trucks

The following comments address EPA's proposed changes to 40 C.F.R. §600.116-12(c) for determining the proportion of recovered braking energy for hybrid electric vehicles. In 40 C.F.R. §600.116-12(c)(1)(i)(A) and (B), it is unclear whether road load power and applied deceleration power are to be calculated from scheduled speed or measured speed. We recommend that Vmph, V and Vt+1 be defined as "measured velocity in miles/hour, rounded to the nearest 0.01 miles/hour…"

In 40 C.F.R. §600.116-12(c)(1)(C), EPA proposes to determine braking power by the following equation:

Pbrake = Paccel – Proadload

We recommend that the equation be changed to the following:

Pbrake = Paccel + Proadload and if Pbrake >0, set Pbrake = 0

The Proadload should decrease the magnitude of the Pbrake term. As it is currently written, the magnitude of Pbrake is not decreased by Proadload during deceleration. If Pbrake isn't decreased by Proadload, the Emax equation would assume that the roadload force could be recovered by regenerative braking, and this would cause the Emax calculation to give a higher value than is possible (thus lowering the eventual Energy Recovered %).

As can be seen in the following chart, the proposed equation would indicate that roadload during steady cruising would be able to be recaptured as regeneration (red line). The green line is Emax when you replace the "-" sign with a "+" sign in the Pbrake equation and revise the Pbrake = 0 criteria. [see figure on p.8, EPA-HQ-OAR-2010-0799-9487, Appendix 7]

Therefore, it would be more appropriate if the equation were written as Pbrake = Paccel + Proadload with the additional criteria that Pbrake = 0 whenever the calculation results in a positive value.

In addition, the following clerical errors were discovered during our review of the NPRM:

§600.116-12(c)(1)(i)(A): Road load equation has an extra “x” between 0.47704 and 4.448

§600.116-12(c)(3)(iii): “battery” is misspelled as “batter”

§600.116-12(c)(4)(3)(iii): Definition of Erec under the Energy Recovered % equation references paragraph (c)(2)(iii), should reference paragraph (c)(3)(iii) instead

§600.116-12(c)(4)(3)(iii): Conflicting nomenclature. Energy Recovered % equation uses Emax, which appears to be called Ebrake in the paragraph referenced by the Emax definition, §600.116-12(c)(2).

Further, prior to the final rule, we plan to engage the agency technical experts to ensure that the test procedure specifications and regulatory language for determining the proportion of recovered braking energy is clear, accurate and consistent with previous hybrid procedural guidance (e.g., SAE J1711, Part 86, Part 600), where applicable. [EPA-HQ-OAR-2010-0799-9487, Appendix 7, p. 7-9]

Organization: America's Natural Gas Alliance (ANGA) and American Gas Association (AGA)

“Game-Changing Pickup Technologies”

EPA has also proposed to “incentivize the penetration into the marketplace of ‘game changing’ technologies for full size pickups . . . [and] for that reason, EPA is proposing credits for manufacturers that hybridize a significant quantity of their full size pickup trucks, or use other technologies that significantly reduce CO_2 emissions and fuel consumption.” 76 FR 75016. If the agencies do not provide a multiplier incentive for NGVs as requested above, we ask that EPA clarify that natural gas-powered pickups would be able to qualify as a technology eligible for the proposed credits. [EPA-HQ-OAR-2010-0799-9548-A1, p. 8]

Assuming that NGVs are eligible for those credits, we note that for non-hybrid pickups to receive the proposed credits, they must achieve a “15 percent or 20 percent, respectively, better CO_2-reduction than their footprint based target in a given model year.” Id. at 75017. However, hybrid pickups do not have to meet any CO_2-reduction performance target in order to receive comparable credits, and we believe it would be appropriate and consistent to either apply identical performance targets to hybrids or, alternatively, eliminate the targets for “other technologies” that achieve equal or better GHG reductions. We also believe that the proposed thresholds (as a percentage of their full-size pickup production) that a manufacturer must meet before being able to receive these credits are way too high: starting at 15% in 2017, and ramping up to 40% in 2021 for the 15% CO_2-reduction credit and 10% for all model years for the 20% CO_2- reduction credit. Id. at 75017. If the goal of the incentive is to encourage deployment of these technologies, the initial levels should be far more modest. [EPA-HQ-OAR-2010-0799-9548-A1, p. 8]

Organization: American Honda Motor Co., Inc.

The preamble in the section titled “Incentives for “Game-Changing” Technologies Including Use of Hybridization and Other Advanced Technologies for Full-Size Pickup Trucks” notes that “the standards under consideration for MY 2017-2025 will be challenging for large trucks, including full size pickup trucks that are often used for commercial purposes and have generally higher payload and towing capabilities, and cargo volumes than other light-duty vehicles.” Honda believes that the same is true for minivans and SUVs and that these similarly situated vehicles ought to be treated in a similar fashion. Honda’s Pilot SUV and Odyssey Minivan are among the most popular vehicles in their segments. These vehicles have passenger load capabilities of up to 8 occupants and also are often used by families for the kind of high load usage described in the preamble. The 2012 Pilot 4WD, for example, is capable of carrying 8 occupants and also is capable of towing loads up to 4,500 lbs with the driver and one passenger. This kind of demanding use by consumers is similar in concept to the justification for the pick-up truck incentives proposed by the agencies. Honda believes that the incentives for “game changing” technologies be applied equally to 7 and 8 passenger vehicles with towing capabilities. [EPA-HQ-OAR-2010-0799-9489-A1, p. 2]

As noted above in #1, above, the stringency for the larger footprint light trucks is very low, compared to the smaller footprint light trucks. The combination of the lower stringency and the “game changing” credits cannot be justified as a matter of science, in furtherance of social goals and objectives or as a matter of simple fairness and equity. Not only are large footprint pick up trucks required to do very little (no stringency increase for a number of years), they are overly rewarded if they do increase their performance: in other words, required to do nothing, and highly rewarded for doing something. [This comment can also be found in section 2.2.3 of this comment summary] [EPA-HQ-OAR-2010-0799-9489-A1, p. 2]

Organization: American Petroleum Institute (API)

While API has no comment on the stringency of the proposed fuel economy and CO_2 standards, we are concerned that the proposal provides a number of incentives that appear to reflect an attempt to pick winning and losing technologies in the marketplace, an action which could potentially limit consumer choice and increase societal costs. [This comment can also be found in sections 4 and 6 of this comment summary.] [EPA-HQ-OAR-2010-0799-9469-A1, p. 1]

Incentives for Hybridization for Full-Size Pick-Up Trucks—EPA is proposing an additional CO_2 per vehicle credit for mild and strong hybrid electric (HEV) full size pickup trucks if this technology is utilized across a designated percentage of a manufacturers' full size pickup trucks. [EPA-HQ-OAR-2010-0799-9469-A1, p. 1]

Organization: American Public Gas Association (APGA)

With respect to pickup trucks, EPA also has proposed a special credit for pickup trucks that utilize GHG reducing technology. This credit would be worth 10 g/mi or 20 g/mi depending on the reductions. In order to get the 20 g/mi credit technology would have to provide a 20% reduction in GHG emissions. To qualify, technology would have to be used on at least 10% of full size pickups for manufacturers and credits limited to 5 MYs. APGA strongly supports this change and believes that it will be very beneficial in aiding the deployment of NGV pickup trucks and refueling infrastructure. [EPA-HQ-OAR-2010-0799-9448-A1, p. 3]

Organization: Association of Global Automakers, Inc. (Global Automakers)

The advanced technology credits provide an incentive for manufacturers to continue to develop and market these technologies, which have the potential for substantial long term improvements in fuel efficiency and emissions performance. [EPA-HQ-OAR-2010-0799-9466-A1, p. 1]

Global Automakers supports the inclusion of advanced technology incentives as an integral part of the MY 2017-25 standards program. As stated in the agencies' proposal, such vehicles have the potential to achieve major emission reductions and improvements in fuel efficiency, but face near-term market barriers relating primarily to price and fueling infrastructure. The incentives proposed by EPA provide a bridge to overcome these near-term obstacles. [EPA-HQ-OAR-2010-0799-9466-A1, p. 7]

The agencies also propose an incentive for "game-changing" technologies used in large pick-up trucks. Also provided as an incentive for larger trucks are certain adjustments to the slope of the truck curve, to reduce the stringency of standards for those vehicles. The agencies justify these incentives based on what they see as special compliance burdens of these vehicles, including "generally higher payload and towing capabilities and cargo volumes than other light duty vehicles." See 76 FR 74944. In our view, other classes of vehicles may face similar compliance obstacles, or obstacles that, while different in nature, are still significant. [EPA-HQ-OAR-2010-0799-9466-A1, pp. 7-8]

We urge the agencies to consider extending "game-changing credits" to other vehicle classes, such as minivans or SUVs with towing capabilities. These credits should also be reassessed as part of the mid-term review process, to determine whether they should be modified. [EPA-HQ-OAR-2010-0799-9466-A1, p. 8]

Organization: Center for Biological Diversity

In addition to the improper credits discussed below, the NPRM contains yet another sweetener that cannot but lead to even more pickup trucks used as passenger vehicles. EPA is seeking comment on changing the definition of a full-size pickup truck by reducing the minimum wheelhouse width requirement from 48 inches to about 42 inches, as long as the vehicle remains capable of towing at least 6,000 lbs. Such a redefinition is entirely inappropriate. The Agencies provide no reasonable basis for this request, and entirely overlook the fact that it would enable virtually every pickup truck to fall into the full-sized pickup truck definition and escape higher fuel efficiency standards. The Agencies must not take this step backward. [EPA-HQ-OAR-2010-0799-9479-A1, p. 14]

2. The pickup truck credits must be eliminated

As yet another preference for the dirtiest vehicles in the fleet, the Agencies propose a credit of 10 g/mile for each pickup truck that either has mild hybrid technology or achieves an emission rate 15% higher than the standards in any year from MY 2017 to 2021 (if certain minimum production rates are met); and a credit of 20 g/mile for each pickup truck that is either uses strong hybrid technology or achieves an emission rate 20% higher than the standard for that year (if minimum production rates are met). [EPA-HQ-OAR-2010-0799-9479-A1, p. 22]

This give-away is ill-conceived for a number of reasons. First, hybrid technology is one of the most effective technologies to improve these vehicles' fuel efficiency. It is both technologically and economically feasible,103 and failing to require – rather than to incentivize – its use is contrary to statutory intent. In fact, none of the factors the Agencies must consider in setting standards argues for anything other than immediate and mandatory application of this technology across the entire fleet as quickly as possible. In addition, as with all other credits, it would displace the implementation of other fuel efficiency measures such as stronger hybrids or EV vehicles. Moreover, the Agencies admit that these credits do not correspond to the actual improvements obtained.104 [EPA-HQ-OAR-2010-0799-9479-A1, p. 22]

---

103 Ford and Toyota have already announced a joint venture to develop the systems for pickup trucks. ICCT Comments at 36. The profitability of trucks, discussed above, nullifies any cost concerns, even when the hundreds of billions in other benefits flowing from increased fuel efficiency standards are disregarded. [EPA-HQ-OAR-2010-0799-9479-A1, p. 22]

104 NPRM, 76 Fed. Reg. 74879. [EPA-HQ-OAR-2010-0799-9479-A1, p. 22]

Organization: Chrysler Group LLC

Chrysler agrees with the Agencies' support for "game-changing" full-size pickup truck technology and recommends improvements for its regulatory implementation. (Attachment 3)

Chrysler agrees with the Agencies expectation that the proposed standards will be challenging for fullsize light-duty trucks. The proposed rules will provide additional incentives to manufacturers for early development of the technologies which will be needed to meet 2022-2025 MY light-duty truck standards. Chrysler recommends that the agencies retain as much flexibility as possible both for which light-duty trucks will qualify and for how those light-duty trucks are defined. The proposed definitions for qualifying vehicles need to be defined so as to capture the intended population of vehicles. Also, establishing minimum penetration rate thresholds is an unnecessary additional constraint on the use of these incentives. [EPA-HQ-OAR-2010-0799-9495-A1, p. 6]

Chrysler supports EPA's proposed incentives for "game-changing" technologies on fullsize pickup trucks and other high-utility light-duty trucks.

Full-size pickup trucks are frequently purchased by customers who need varying combinations of payload, trailer towing, four wheel drive, and passenger carrying capability. These utility-adding features enable Chrysler's customers to satisfy their transportation, business, and recreational needs. However, adding features to enable increased cargo and trailer tow capabilities can challenge high-utility vehicle energy efficiency. [EPA-HQ-OAR-2010-0799-9495-A1, p. 12]

Some "game-changing" technologies already exist, or are under development, but such technologies come at a cost-premium and may compromise vehicle utility. For example, vehicle hybridization and advanced diesel engines are significantly more expensive than conventional gasoline powertrains. These technologies also increase vehicle curb weight, thereby reducing payload and towing capability unless further modifications are made to the vehicle. [EPA-HQ-OAR-2010-0799-9495-A1, p. 12]

It is appropriate to encourage "game-changing" technologies in this segment and help to minimize the tradeoffs between efficiency and utility. [EPA-HQ-OAR-2010-0799-9495-A1, p. 12]

The definitions for a "full-size" vehicle should capture the intended vehicles both now and in the future.

The automotive market continues to evolve. Given that this regulation will affect vehicles produced far into the future, the agencies should strive to leave vehicle-based definitions as broad as possible. Establishing narrow definitions for what vehicles qualify for "full-size" game-changing technology incentives may lock manufacturers into producing vehicles within these design constraints instead of creating innovative ways to provide similar or better utility and game-changing fuel economy for future customers. [EPA-HQ-OAR-2010-0799-9495-A1, p. 12]

Chrysler agrees that the definitions which qualify light-duty trucks for "game-changing" technology incentives should reflect utility-adding features.

Chrysler agrees that payload and towing capability are two key utility-adding features. EPA and NHTSA recognized these features as “work-based attributes” in their medium- and heavy-duty truck greenhouse gas and fuel efficiency rules for heavy-duty pickup and van standards. The use of payload and towing capability to define a higher utility light-duty truck is a logical extension of the reasoning provided by EPA and NHTSA therein. [EPA-HQ-OAR-2010-0799-9495-A1, p. 13]

Light-duty trucks which meet minimum payload and/or towing capability should qualify for the “full-size” hybrid and performance-based incentives - an open cargo box should not be required.

EPA and NHTSA are proposing that these incentives be applicable only to full-size pickup trucks, with one qualification being an “open cargo box”. However, large light-duty trucks without open cargo boxes include many of the same utility-adding features as full-size pickup trucks. For example, a number of Chrysler’s Dodge Durango and Jeep Grand Cherokee variants meet or exceed the capabilities of full-size Ram 1500 pickup trucks, as shown in Figure 1 below. [See Figure 1 on p. 13 of Docket number EPA-HQ-OAR-2010-0799-9495-A1] [EPA-HQ-OAR-2010-0799-9495-A1, p. 13]

These higher utility vehicles are purchased by customers not only for their passenger-carrying capability, but also for their payload and towing utility. Many of Chrysler’s customers desire vehicles which can transport both a family and commercial or recreational trailers. [EPA-HQ-OAR-2010-0799-9495-A1, p. 14]

These utility requirements can create the same vehicle efficiency challenges in these other large light-duty trucks as they do in full-size pickup trucks. In incentivizing technology which causes “game-changing” vehicle efficiency improvements while maintaining vehicle utility, non-pickup large light-duty trucks should also be encouraged to make similar improvements. Therefore, Chrysler recommends that any light-duty trucks which meet minimum payload or towing capability requirements qualify for these incentives. [EPA-HQ-OAR-2010-0799-9495-A1, p. 14]

If finalized, open cargo box requirements should allow greater flexibility in dimensions and “open” criteria; Chrysler recommends reducing minimum box size requirements and permitting greater flexibility in bed area coverage.

The agencies propose to set minimum open cargo box dimensions which appear to be based on today’s largest pickup trucks. By setting the minimum dimensions to today’s largest pickup trucks, the agencies drive the unintended consequence of also incentivizing manufacturers to design to these dimensions. If the agencies were to instead reduce or eliminate the minimum dimensions of an open cargo box, manufacturers would have more freedom to invent new designs which could satisfy customer cargo carrying needs in a more efficient manner. [EPA-HQ-OAR-2010-0799-9495-A1, p. 14]

The agencies also propose that a full-size pickup include an “open box”, defined as “a vehicle where the cargo box does not have a permanent roof.” The restriction that the roof not be permanent is a distinction that may encourage manufacturers to make use of potentially less aerodynamically efficient designs to qualify a vehicle for the “game-changing” technology incentives. In contrast, keeping the "open box" definition flexible, for example to allow a design with a permanent pickup truck cap (extending the roofline of the cab to rear of the box) could be an aerodynamic improvement if designed properly. Chrysler recommends that if the "open cargo box" requirement is finalized, the definition also include that "a covered box not readily accessible from the passenger compartment will be considered an open cargo box for the purposes of this definition". [EPA-HQ-OAR-2010-0799-9495-A1, p. 14]

Chrysler recommends that the Agencies set the minimum payload capacity at 1,300 lb. and the minimum towing capacity at 3,500 lb.

The agencies propose to limit applicability of "game-changing" full-size pickup truck incentives to vehicles which meet a minimum payload capability of 1,700 lb. or which meet a minimum towing capability of 5,000 lb. The Agencies intended that these limits would qualify larger pickup trucks while excluding smaller pickup trucks.17 However, these limits exclude a number of Chrysler's full-size 2012 MY Ram 1500 pickup truck variants, (as demonstrated in Figure 2), that were designed to meet customer utility requirements, and therefore which should not have be excluded from the "game-changing" technology incentives. [EPA-HQ-OAR-2010-0799-9495-A1, p. 14]

Chrysler notes that virtually none of the 2012 MY full-size Ram 1500 pickup trucks are capable of meeting the minimum payload requirements as proposed, even though these full-size trucks provide significant payload carrying capability and are designed to meet the utility needs of our customers. We recommend lowering the minimum payload capability requirement to 1,300 lb. [See Figure 2 on p. 15 of Docket number EPA-HQ-OAR-2010-0799-9495-A1] [EPA-HQ-OAR-2010-0799-9495-A1, p. 14]

Similarly, Chrysler recommends that the minimum towing capability be lowered to 3,500 lbs if the proposed towing capability definition is finalized. Under the proposed definition, certain current and potential future Ram full-size trucks with maximum trailer capacities greater than or equal to 5,000 lb. are excluded. An alternative to lowering the minimum towing capability would be to strike the proposed definition of trailer tow capability (GCWR – GVW) and to define towing capability as meaning "the value specified by the manufacturer as the maximum towable trailer weight, consistent with good engineering judgment. For example, compliance with SAE J2807 is generally considered to be consistent with good engineering judgment." [EPA-HQ-OAR-2010-0799-9495-A1, pp. 14-15]

Minimum penetration rate requirements increase uncertainty for manufacturers and are an unnecessary constraint. [EPA-HQ-OAR-2010-0799-9495-A1, p. 15]

The agencies propose that to qualify for the "full-size" hybrid and performance-based incentives, a manufacturer must meet a minimum penetration rate. These minimum penetration rates add a level of uncertainty for manufacturers and are an unnecessary additional constraint for incentives offered on a per-vehicle basis. [EPA-HQ-OAR-2010-0799-9495-A1, pp. 15-16]

Minimum penetration rates add a level of uncertainty for manufacturers. If a manufacturer invests in the technologies necessary to hybridize a full-size vehicle, or to significantly over-perform to a vehicle's footprint-based target, it still may not meet the required minimum penetration rate if market demand is not sufficient. For example, manufacturers could choose to invest in the necessary technologies, but if market demand is only 9% against a required 10% penetration threshold, those investments would not generate the credits expected by a manufacturer. Before approving funding for such investments, manufacturers need certainty that their investment will realize expected benefit of making those investments. Introducing the uncertainty of minimum penetration rate requirements creates a disincentive to adoption of game-changing technologies until market demand is proven. [EPA-HQ-OAR-2010-0799-9495-A1, p. 16]

Minimum penetration rate requirements are also an unnecessary additional constraint on the proposed incentives. Because the incentives are offered on a per vehicle so-equipped basis, manufacturers are incentivized to apply game-changing technologies as broadly as market demand allows. Technologies with lower penetration rates will produce less credit than those with higher penetration rates. This approach also provides a level playing field for all manufacturers. Further discouragement of technologies based on penetration rates actually works against the intent of early adoption of game changing technologies. [EPA-HQ-OAR-2010-0799-9495-A1, p. 16]

Chrysler supports broad technology definitions for mild and strong HEV technology

Given the long-term timeframe of this rulemaking, Chrysler supports maximum flexibility in the definition of hybrid technology. [EPA-HQ-OAR-2010-0799-9495-A1, p. 16]

The definitions of mild and strong hybrids should not use technology-specific terms; Chrysler recommends that the term "mild hybrid vehicle" be used instead of "mild hybrid gasoline-electric vehicle" and "strong hybrid vehicle" be used in place of "strong hybrid gasoline- electric vehicle". [EPA-HQ-OAR-2010-0799-9495-A1, p. 16]

The agencies refer to mild and strong hybrid technologies which qualify for "game-changing" technology credits using the term "gasoline-electric". The use of this term implies that the only hybrid technology acceptable is a gasoline and electric powertrain combination. Not only are other fuels possible (e.g. E85, diesel, and CNG), but other "hybrid" types other than electric are also possible (e.g. hydraulic hybrids and flywheel energy storage systems). The agencies should strive for both fuel and hybrid technology neutrality in this rulemaking and provide this incentive to any system that can capture a minimum fraction of otherwise wasted energy and convert it to tractive power. [EPA-HQ-OAR-2010-0799-9495-A1, p. 16]

The required energy recovery rate definition for full-size strong hybrids should be reevaluated.

EPA proposes that a "strong" hybrid must recapture at least 75 percent of available braking energy over the Federal Test Procedure. This target may be appropriate for passenger cars, but is very aggressive for full-size trucks. For example, hybrid systems for full-size truck applications may have difficulty in meeting the proposed 75% energy recovery rate because of the need to design the braking system for maximum payload and trailer capability while maintaining drivability in the absence of these loads. Chrysler recommends reducing the requirement to 50%.

This value will help maintain the distinction between strong and mild hybrids, but recognizes some of the design constraints for large high-utility vehicle hybrid systems. [EPA-HQ-OAR-2010-0799-9495-A1, p. 16]

Performance-Based Incentive

Chrysler supports the tiered incentive system based on varying levels of over-performance.

The agencies propose to offer two levels of performance-based incentives, with a greater incentive offered for greater levels of performance. This methodology incentivizes manufacturers to maximize the fuel economy performance of full-size trucks and to take additional incremental steps if possible. [EPA-HQ-OAR-2010-0799-9495-A1, p. 17]

Chrysler supports the agencies' proposal to base the credit on over-performance in the first year of production.

The agencies propose to begin the performance-based incentive in the model year of introduction and to extend that incentive for up to five years. Chrysler agrees with this approach. Requiring the vehicle to make continuous improvements to maintain its original over-performance to a standard would not respect automotive design cycles and the resources required to make significant improvements. [EPA-HQ-OAR-2010-0799-9495-A1, p. 17]

Organization: Clean Energy

Advanced Pickup Truck Credits [EPA-HQ-OAR-2010-0799-9511-A1, p.6]

For 2017-2025, EPA and NHTSA have proposed special credits for pickup trucks. There is a credit for mild and also for strong-hybrid pickups, and a separate credit for pickups that are able to meet prescribed GHG reductions. The description in the proposed rule appears to indicate that hybrid pickups and pickups that satisfy the GHG performance criteria will earn GHG and FE credits. We recommend that the agencies also consider and include additional credits for dedicated, dual-fuel and hybrid NGV applications on pickup trucks. Clean Energy would be happy to work with the agencies to develop credits that fully recognize the benefits that natural gas can provide on these trucks. [EPA-HQ-OAR-2010-0799-9511-A1, pp.6-7]

Organization: Eaton Corporation

• Provides incentives to promote the adoption of advanced vehicle technologies that over comply with the targets set forth in the rule while not pre-selecting winners and losers in the marketplace. [EPA-HQ-OAR-2010-0799-9494-A1, p. 2]

The rule has the potential of accelerating adoption of game-changing technologies that otherwise would not have been adopted. However, we offer the following comments to recommend that the concept of 'technology neutral' is adhered to in the Light-Duty Truck Program. [EPA-HQ-OAR-2010-0799-9494-A1, p. 2]

'Game Changing' Technology Credits for light Duty Trucks

We applaud the inclusion of a credit program that includes mild hybrids. Mild hybrid technologies show great promise for cost-effective fuel consumption and GHG reductions. [EPA-HQ-OAR-2010-0799-9494-A1, p. 2]

Eaton recommends that the definition of hybrids and mild-hybrids under the 'Game Changing' Technologies for Full-Size Pick-up Trucks be technology neutral. The phrase 'gasoline-electric' is too narrow and would eliminate other non-battery internal combustion based technologies from being considered. All full-hybrid and mild-hybrid technologies should qualify for credits. Also, the penetration rate thresholds for full-size pick-up trucks should be significantly reduced or eliminated so that market and economic uncertainties do not prevent innovation from being introduced. [EPA-HQ-OAR-2010-0799-9494-A1, pp. 2-3]

Organization: EcoMotors International, Inc.

EPA is proposing CO_2 credits for manufacturers that hybridize a significant quantity of their full-size pickup trucks, and the agencies are also proposing that manufacturers be able to include 'fuel consumption improvement values' equivalent to EPA CO_2 credits in the CAFE program. Access to the incentives is conditioned on a minimum penetration of mild and strong hybrid electric vehicle (HEV) technologies in an OEM's full-size pickup truck fleet. [This comment can also be found in section 8 of this comment summary.] [EPA-HQ-OAR-2010-0799-9594-A2, p. 8]

EcoMotors endorses the agencies' incentives to promote the use of advanced vehicle technologies in both full-size and smaller size pick-up trucks. However, for all of the reasons noted above, other less-costly and equally energy efficient and environmentally beneficial vehicle technologies - available today - should be afforded equally beneficial regulatory incentives. Near-term development and commercialization of advanced ICEs, such as the dual-module opoc engine performing as a mechanical hybrid, remains an extremely important path for emissions reduction and fuel economy improvements in pick-up trucks and should also be encouraged by national policy. In a dual-module, mechanical hybrid configuration, the EM100 base opoc engine would provide fuel savings exceeding 45%. [EPA-HQ-OAR-2010-0799-9594-A2, p. 8]

EcoMotors believes that the market penetration requirements established for the hybridization incentives should be removed in the Final Rule. New technologies typically take years to prove themselves and attain significant market penetration. In the past, it has taken a decade for a technology to prove itself and attain a sales fraction of 40-50%, and has taken as long as another 5-10 years to reach maximum market penetration. Thus, establishing a 30% market penetration rate threshold for MY2017 (mild HEV pickups) is unrealistic. Even the 10% annual market penetration suggested for strong HEV pickups is problematic. It will likely be necessary to provide incentives to OEMs just to get within reach of these thresholds. [EPA-HQ-OAR-2010-0799-9594-A2, p. 8]

- Specific Recommendation: EcoMotors strongly encourages the agencies to extend CO_2 and fuel economy credits to OEMs that manufacture mechanical hybrid pick-up trucks, hydraulic hybrid pick-up trucks, and similar advanced technology hybrid pick-ups. This would place other significant, game-changing vehicle technologies -like the dual-module opoc engine - on a level playing field with HEVs. EcoMotors also encourages the agencies to completely eliminate the market penetration requirements established for the credits, to better reflect historic market penetration issues facing new technologies. [EPA-HQ-OAR-2010-0799-9594-A2, p. 8]

EPA is proposing performance-based incentive credits and equivalent fuel consumption improvement values for CAFE for full-size pickup trucks that achieve an emission level significantly below the applicable CO_2 target. The performance-enhancing technology must be used on a minimum percentage of a manufacturer's full-size pickup trucks. [EPA-HQ-OAR-2010-0799-9594-A2, p. 12]

EcoMotors strongly endorses this technology-neutral incentive to promote the use of advanced vehicle technologies in both full-size and smaller-size pick-up trucks. By establishing performance-based incentives, the agencies are enabling OEMs to choose their own cost-efficient path for achieving CO_2 reductions and fuel economy improvements, consistent with their specific product plans. [EPA-HQ-OAR-2010-0799-9594-A2, p. 12]

EcoMotors encourages the agencies to remove the market penetration requirements established for the credits, to better reflect historic market penetration issues facing new technologies. As discussed above, new technologies typically take years to prove themselves and attain significant market penetration. Thus, even the lowest rate associated with this incentive - 10% - is likely set too high for OEMs to secure these credits. [EPA-HQ-OAR-2010-0799-9594-A2, p. 12]

- Specific Recommendation: EcoMotors supports the agencies' performance-based incentive program for full-size pick-ups and encourages the agencies to extend it to somewhat smaller pickups as well. EcoMotors encourages the agencies to remove the market penetration requirements established for the credits in order to better reflect historic market penetration issues facing new technologies. [EPA-HQ-OAR-2010-0799-9594-A2, p. 12]

Organization: Encana Natural Gas Inc.

Advanced Pickup Truck Credits

For 2017 - 2025, the EPA and NHTSA have proposed special credits for pickup trucks. There is a credit for mild and also for strong hybrid pickups, and a separate credit for pickups that are able to meet prescribed GHG reductions. The description in the proposed rule appears to indicate that hybrid pickups and pickups that satisfy the GHG performance criteria will earn GHG and FE credits. [EPA-HQ-OAR-2010-0799-9585-A2, p. 6]

First, we offer the following comments with respect to the hybrid credits. like other credits proposed in the rulemaking, the mild and strong hybrid credits are not tied to specific GHG or FE performance metrics but rather attempt to incentivize a specific type of technology in order to encourage manufactures to sell such vehicles. Encana recommends an approach that regulates all alternative fuel technologies equally. In order to provide equitable treatment, the proposed rule should provide similarly strong incentives for NGVs. We have outlined the types of incentive we believe are necessary to encourage the development and sale of light duty NGVs. Encana believes that it is appropriate to provide incentives like those proposed for hybrid trucks as long as similarly strong incentives are provided for other technologies. [EPA-HQ-OAR-2010-0799-9585-A2, p. 6]

Second, with respect to the performance-based credits provided for pickup trucks, we offer the following comments. We agree that all technologies should have the opportunity to earn credits under this provision. Also, we believe that, if specific credits are provided elsewhere in the rules for NGVs, that such vehicles, like hybrids, should not earn double credits under those provisions and also under the pickup truck credit provision. If no additional credits, as described earlier in our Public Comment letter, are provided for NGVs, then they should have the potential to earn credits under the Advance Pickup Truck Credits provisions. [EPA-HQ-OAR-2010-0799-9585-A2, p. 6]

We also believe that targets for introduction are simply too high with respect to NGVs and that the EPA and NHTSA should amend the proposal to provide a lower-threshold. In the Proposed Rule, the EPA and NHTSA provide a 10 g/mi GHG credit if advanced pickup truck production is at least 15% of a company's full sized pickup production in MY 2017 with a ramp up to at least 40% in MY 2021. Additionally, a 20 g/mi credit is provided if advanced pickup truck production is at least 10% of a company's full sized pickup production in each year over the model years 2017-2025. These proposed production goals are unattainable for NGVs and simply precludes NGVs from receiving this incentive. [EPA-HQ-OAR-2010-0799-9585-A2, p. 6]

The US Energy Information Administration - AEO 2011 projects sales of alternative fueled vehicles[2]. At no time during the 2017·2025 time period does the EIA project light truck sales to exceed even 0.1% of total new light truck sales (sic). Encana proposes that there should be no production minimum for MYs 2017 through MY 2020. For MYs 2021 and beyond, a meaningful stretch goal would be 0.5% of production. [EPA-HQ-OAR-2010-0799-9585-A2, pp. 6-7]

Encana appreciates the opportunity to provide public comment on this rulemaking. Encana requests that the EPA and NHTSA incorporate the additional incentives described in this letter for natural gas vehicles. The following summarizes the additional incentives Encana believes will provide fair and equitable treatment of NGVs: [This comment can also be found in section 6.2 of this comment summary] [EPA-HQ-OAR-2010-0799-9585-A2, p. 7]

• Modify the Advanced Pickup Truck Credit provisions to include NGVs. [EPA-HQ-OAR-2010-0799-9585-A2, p. 7]

[2]http://www.eia.gov/oiaf/aeo/tablebrowser/#release=AEO2011&subject=0-AEO2011&table=48-AEO2011®ion=1-0&cases=ref2011-d020911a

Organization: Ford Motor Company

- Auxiliary transmission oil coolers
- Upgraded radiators
- Trailer hitch connectors and wiring harness equipment
- Different steering ratios, upgraded rear bumpers and different springs for heavier tongue load (for upgraded 'max' trailer tow packages)
- Body on frame (vs. unibody) construction to support capability and an aggressive duty cycle
- Lower axle ratios for better pulling power/capability [EPA-HQ-OAR-2010-0799-9463-A1, p. 9]

In addition, vehicles with towing capability generally have increased aerodynamic drag caused by a modified frontal area, increased rolling resistance, and a heavier frame and suspension to support this additional capability. [EPA-HQ-OAR-2010-0799-9463-A1, p. 9]

We are seeing a continuing trend that our customers are purchasing these vehicles for work purposes. Based on 2011 segmentation models for our full size pick-up trucks, Business users account for approximately 30% of the market. The Business category includes fleet and work trucks (e.g. small business owner, farmer, foreman), as well as those customers who use their truck for occupational purposes during the week and personal use on the weekend. About 58% of the market is comprised of Recreational users, including hunters, boaters, fisherman, etc. These consumers rely on their vehicles for hauling and towing to support their recreational activities. Only a relatively small segment (12%) of the market is comprised of consumers who do not make significant use of the towing/ hauling/off-road capabilities of the truck. Based on the trends we have seen in the market, we fully anticipate that such buyers will continue to be a shrinking portion of our market. We believe that within a few years, the Business category will increase to over 40% of the market, and the combined Business/Recreational users will increase to over 90% of the market for full size pick-up trucks. [EPA-HQ-OAR-2010-0799-9463-A1, p. 9]

And to further demonstrate the importance of these vehicles to the American economy, the following graph demonstrates that new home construction, a key financial indicator, and the sales of the trucks needed to help this industry, go hand in hand. [EPA-HQ-OAR-2010-0799-9463-A1, p. 9]

Game Changing Technologies for Full Size Pick-up Trucks

Ford supports the agencies' proposal to provide additional "game changing technology" incentives for full-size pick-up trucks. We agree with the agencies' statement that this incentive

"…provides the opportunity to begin to transform the most challenging category of vehicles in terms of the penetration of advanced technologies, which, if successful at incentivizing these ''game changing technologies,'' should allow additional opportunities to successfully achieve the higher levels of truck stringencies in MYs 2022–2025." (76 Fed. Reg. 74879) [EPA-HQ-OAR-2010-0799-9463-A1, p. 21]

As noted previously, weight-based vehicle attributes such as payload and towing capability are key among the parameters that characterize differences in the design of these work vehicles, as well as differences in how the vehicles will be utilized. Vehicles with towing capability generally have increased aerodynamic drag caused by a modified frontal area, increased rolling resistance, and a heavier frame and suspension to support this additional capability. Manufacturers are faced with the challenge of applying technologies to significantly improve fuel economy without sacrificing the utility required by our customers. [EPA-HQ-OAR-2010-0799-9463-A1, p. 21]

- Pick-up Truck Definition: The current proposal for cargo box size, towing capability and payload capability encompasses the majority of full-size pick-up trucks on the road today. While it is difficult to forecast future customer needs and expectations for vehicles that we will be building 10 years from now, Ford believes the proposal incorporates the appropriate size and work factor related attributes to define a full-size pickup truck. [EPA-HQ-OAR-2010-0799-9463-A1, pp. 21-22]
- Hybrid Electric Vehicle Pick-up Truck Definition: Ford supports the proposed performance-based definitions for both mild and strong HEV pick-up trucks, which provide manufacturers flexibility in technology deployment, taking into consideration customer expectations, while still providing the anticipated efficiency benefit. We also support the comments provided by the Alliance on proposed changes to 40 CFR § 600.116-12 for determining the proportion of recovered braking energy for hybrid electric vehicles. However, in addition to those recommendations, we also believe the definition of a strong hybrid should be expanded beyond the currently proposed energy recovery methodology, which does not allow braking energy to be easily segregated from other battery charging sources, such as the engine. As proposed, we believe there is a potential for gaming that could allow a mild hybrid to qualify as a strong hybrid. Also, the level of capture of regenerative energy is only one of the important functional elements delivered by a strong hybrid system. As such, Ford recommends the following improvements to the proposed methodology, including the addition of a new metric, fedrive, the fraction of electric driving. [EPA-HQ-OAR-2010-0799-9463-A1, p. 22]

1. Calculate E_{rec} using the proposed formula, only during deceleration.
2. Calculate E_{brake_max} using the proposed formula, from the measured speed trace, in lieu of using the scheduled speed trace.
3. Calculate the energy recovered percentage using the values from (1) and (2), as proposed.
4. Calculate a new metric, the percent fraction of electric drive, $f_{edrive,}$ using the formula:

$$f_{edrive} = 100 \times \frac{E_{e-tractive, P_{accel}>0}}{E_{tractive, P_{accel}>0}}$$

$E_{tractive,\ Paccel>0}$, the total tractive energy under positive acceleration conditions is equal to the sum over the FTP cycle of the absolute values of P_{accel}+$P_{roadload}$ for the condition P_{accel}>0 divided by 36,000 and rounded to the nearest 0.01 kW-hr.

$E_{e\text{-}tractive}$, $P_{accel>0}$, the total electric drive tractive energy under positive acceleration conditions is equal to the sum over the FTP cycle of the absolute values of $P_{accel}+P_{roadload}$ for the conditions $P_{accel}>0$ and engine speed = 0 divided by 36,000 and rounded to the nearest 0.01 kW-hr.

To qualify as a strong hybrid, Ford recommends that the following thresholds be used:

Energy Recovered % ≥ 40%
$f_{edrive} \geq 10\%$

[See calculations on p. 22 of Docket number EPA-HQ-OAR-2010-0799-9463-A1]

Based on the recommended change to measure E_{rec}only during deceleration, only braking energy will be included in the calculation, as opposed to including energy from the engine or other sources. As a result of this procedural revision, the threshold to qualify as a strong hybrid must be reduced. Ford believes that 40% is an appropriate level for full size pickup trucks because the higher weight of such vehicles and rear wheel braking stability constraints will limit braking energy recovery potential. In addition, wheel-to-traction motor losses will be larger for feasible full size pick-up truck strong hybrid system architectures compared with smaller front wheel drive passenger cars. We also believe setting the fedrive metric at 10% should allow all applicable strong hybrids to achieve the credit, but would prevent any mild hybrid from being able to meet that target. [EPA-HQ-OAR-2010-0799-9463-A1, p. 23]

Further, from a technical perspective, certain sections of the proposed regulation were written in an inconsistent manner. 40 CFR § 600.116-12(c)(3)(ii) and (iii) reference a confusing mix of incompatible units (e.g. "…current in Watt hours…" "….the total *energy* recovered by the hybrid battery system, in kilowatt hours, is the sum of the positive *current* values…"). The equation given for dSOC is also incorrect. The equation as shown represents change in energy, not state of charge. Further, battery current in A is measured directly in the test, not state of charge (SOC). [EPA-HQ-OAR-2010-0799-9463-A1, p. 23]

To correct this, we recommend revising 40 CFR 600.116-12(c)(3)(ii) to specify clearly that the recovered braking energy should be determined from an integration of the battery charge power during decelerations over the course of the drive cycle where the battery charge power is the product of measured current and voltage at the battery terminals, i.e.: [See calculation on p. 23 of Docket number [EPA-HQ-OAR-2010-0799-9463-A1]

In addition, for nominal voltage, Ford requests that the definition of "nominal" be published within the regulations to avoid confusion and the usage of differing methodologies for its determination. [EPA-HQ-OAR-2010-0799-9463-A1, p. 23]

As noted above, the specific technical details of the voltage and current measurements and the subsequent calculations with consistent units need to be worked out with appropriate industry and EPA technical experts. The goal will be to define test procedure specifications and regulatory language for determining the recovered braking energy that are clear, accurate, and consistent with previous hybrid procedural guidance (e.g. SAE J1711, Part 86, Part 600). Ford plans to discuss these recommendations with the agencies in more detail and would be happy to provide additional input to help develop the procedure and appropriate metrics for this important regulatory flexibility. [EPA-HQ-OAR-2010-0799-9463-A1, p. 23]

- Performance Based Incentives: Other technologies are available beyond hybridization to provide game changing greenhouse gas reduction and fuel economy improvement, for full-size pick-up trucks. The performance based incentive offers a technology neutral alternative to pursue these other strategies. The provision of the 5 model year carry-over of the credit will encourage earlier adoption of these technologies. [EPA-HQ-OAR-2010-0799-9463-A1, p. 23]
- Incentive Levels: The proposed incentive levels are aligned with the anticipated development and implementation costs, as well as the expected benefits, associated with implementing game-changing technologies on the full-size pick-up trucks. [EPA-HQ-OAR-2010-0799-9463-A1, p. 24]
- Minimum Penetration Thresholds: The thresholds proposed pose a significant concern. The intent of the credit is to drive advanced technologies that are typically more challenging in heavy truck applications, giving manufacturers the opportunity to gain experience with these applications and giving consumers the chance to become more accustomed to certain advanced technologies in pickup trucks. As these are achieved, the expectation is that the technology penetrations will increase and high fuel efficiency can be affordably implemented amongst the heavier trucks. [EPA-HQ-OAR-2010-0799-9463-A1, p. 24]

However, the aggressive, minimum penetration rates actually thwart that attempt. First, because significant early investment is required to develop and implement the “game changing technologies”, manufacturers will need the certainty that the credit will be achievable when the product goes to market. The uncertainty of the market acceptance, and affordability of the subsequent products make it difficult, if not impossible, to establish the necessary assurance that there will be a return on investment. If, for example, we plan on a 10% market penetration of full size hybrid pick-up trucks, but external conditions result in a 9% acceptance rate, our investment will not have yielded the anticipated credit and could threaten an otherwise compliant strategy. [EPA-HQ-OAR-2010-0799-9463-A1, p. 24]

Similarly, the aggressive year over year increases in the fleet thresholds for mild hybrids and performance based technologies do not align with typical product plans and strategies. For example, a particular truck platform/engine may be better suited for the application of the game changing technology, but requiring large year over year volume increases would require those same technologies applied to a broader range of products – some or many of which may not be suited to those particular advanced technologies. Again, without assurance that the credits can be achieved, the decision to proceed with the development of these game changing technologies may not be supportable in a sustainable business strategy. [EPA-HQ-OAR-2010-0799-9463-A1, p. 24]

Organization: General Motors Company

GM supports the proposed methodology to incentivize hybridization of pickup trucks. Additional supporting information and some technical suggestions are provided in the Appendix of these comments. [EPA-HQ-OAR-2010-0799-9465-A1, p. 3]

Pickup Truck Credits

General Motors supports the agencies' proposal to provide additional "game changing technology" credits for pickup trucks. We agree with the agencies' assessment, as noted in the Technical Support Document, that the proposed standards are most challenging to the larger trucks. Consumers use these vehicles for a wide variety of work purposes and expect them to provide durability and reliable towing and hauling capability. [EPA-HQ-OAR-2010-0799-9465-A1, p. 6]

Weight-based vehicle attributes such as payload and towing capability are key among the parameters that characterize differences in the design of these work vehicles, as well as differences in how the vehicles will be utilized. Vehicles with towing capability generally have increased aerodynamic drag caused by a modified frontal area, increased rolling resistance, and a heavier frame and suspension to support this additional capability. Manufacturers are faced with the challenge of applying technologies to significantly improve fuel economy without sacrificing the utility required by our customers. The incentives proposed by the agencies will encourage the development of innovative and more expensive technologies, to achieve breakthroughs in fuel consumption improvement on these products. These credits are consistent with the agencies' objectives to foster new and cost-effective technologies to achieve environmental benefits. [EPA-HQ-OAR-2010-0799-9465-A1, p. 6]

Pickup Truck Box Definition

As discussed in the draft Joint TSD (Section 5.3.1) as well as the Section III of the NPRM, EPA is seeking comment on expanding the scope of the hybridization credit to slightly smaller pickups (with a minimum distance between the wheel wells of 42 inches), provided they have the towing capabilities of the larger full-size pickups (for example a minimum towing capacity of 6,000 pounds). GM agrees with EPA that this could incentivize hybridization on pickups which offer much of the utility of the larger pickups, but overall have lower CO_2 emissions. GM agrees that providing an advanced technology incentive credit for a slightly smaller boxed, but greater towing capacity vehicle, would promote the overall objective of the proposed standards. [EPA-HQ-OAR-2010-0799-9465-A1, p. 6]

Pickup Truck Utility Definition

The current proposal for towing capability and payload capability include the key parameters to define a work vehicle and are appropriate. While it is difficult to forecast future customer needs and expectations for vehicles that we will be building 13 years from now, GM supports the agencies reliance upon utility-adding features such as towing or payload capability and agrees with the agency's direction to set these thresholds at a level representing significant utility capability. Further, we believe that the methodology for calculating the appropriate parameters should be tied to SAE J2807. It is also appropriate for these parameters to be evaluated at the mid-term review. [EPA-HQ-OAR-2010-0799-9465-A1, p. 6]

Hybrid Electric Vehicle Pickup Truck Definition

GM supports the proposed hybrid system definitions for both mild and strong HEV pickup trucks. We believe they are technically sound and reasonable. [EPA-HQ-OAR-2010-0799-9465-A1, p. 7]

Minimum penetration thresholds

The purpose of the "game changing" incentive provisions in the proposed rule is to encourage early introduction of advanced technologies. However, the proposed minimum volume thresholds for mild hybrid incentives are overly aggressive and may well significantly out-pace market demand for these technologies. The proposed minimum penetration rates for mild hybridization are not aligned with a historic rate of customer acceptance of any new and/or advanced technology. An alternative minimum penetration rate for mild hybrid incentives, which is still quite aggressive, but more respectful of historic technology penetration phase-in rates, is that which EPA proposed for the performance based incentives in Section II. F. 3 of the proposal on page 74,945. [EPA-HQ-OAR-2010-0799-9465-A1, p. 7]

GM recommends that the agencies harmonize the mild hybrid incentive rates with those proposed for the performance based incentives. Further, GM recommends that both the incentive level and the appropriate penetration rates be evaluated at the mid-term review. [EPA-HQ-OAR-2010-0799-9465-A1, p. 7]

Organization: Honeywell Transportation Systems

The agencies have proposed various incentive programs. Credits for hybridizing full-size pickup trucks are also proposed. The truck program also includes an incentive applicable to full-size pickup trucks where a credit of either 10 g/m (0.001125 gal/m) or 20 g/m (0.002250 gal/m) applies to those vehicles achieving 15 percent or 20 percent better CO_2 performance than their footprint based target once a fleet penetration target is reached. [EPA-HQ-OAR-2010-0799-9474-A1, pp.4-5]

Should the agencies finalize any of the proposed incentives for electric drivetrains, the agencies should also include an incentive for ICE vehicles that achieve substantially better CO_2 performance than their footprint based target as measured by the fuel economy test cycles. For purposes of this incentive, Honeywell suggests that micro-hybrid technology such as start/stop technology not preclude application of the incentive since that technology is available for an off-cycle credit regardless of the applicable drivetrain.4 The agencies have offered as much as 10 g/m for adding off-cycle technologies to vehicles. An OEM should similarly be able to obtain 5 or 10 g/m (and the equivalent value in the CAFE program) for ICE vehicles that perform 15 percent or 20 percent better than their applicable footprint-based target. [EPA-HQ-OAR-2010-0799-9474-A1, p.5]

An incentive for high performing ICE vehicles would encourage manufacturers to improve their vehicles beyond what is necessary for compliance alone and would help to detract from any reliance on the EV credit multipliers for fleetwide compliance. In addition, further improvements made in an effort to gain these credits can proliferate beyond the individual vehicle and, as a result, improve the performance of the fleet overall. [EPA-HQ-OAR-2010-0799-9474-A1, p.5]

The performance credit proposed for full-size pickup trucks presents a model to promote technology neutrality in the remainder of the fleet as well. [EPA-HQ-OAR-2010-0799-9474-A1, p.5]

Organization: Hyundai America Technical Center

The agencies have provided two incentives for full size pick-up trucks recognizing it will be challenging for manufacturers of these vehicles to meet the proposed targets and because they want to incentivize 'game-changing' technologies. One is a technology-based CO_2/mpg credit for manufacturers that hybridize full-size pick-ups. The other is a performance-based CO_2/mpg credit for full size pick-up trucks that exceed their applicable target. Hyundai supports technology-neutral and performance-based incentives for large pick-up trucks. However, Hyundai questions the need for both types of incentives as we believe the performance-based incentives achieve the same objective as hybridization incentives. Additionally, Hyundai asks that the agencies consider extending the performance-based incentives for pick-up trucks to all classes of vehicles. If the agency truly wants to incentivize performance and 'game changing' technologies, it makes sense that the agency would support game-changing technology for any class of vehicle. [EPA-HQ-OAR-2010-0799-9547-A1, p.3]

Starting in MY 2017, if a full-size pickup truck achieves either a 15 or 20% fuel efficiency/GHG improvement, the agencies will provide credits equivalent to approximately 2 mpg or 4 mpg, respectively. The 4 mpg credit would be available from MY 2017 through 2025 as long as the fuel efficiency of the first year is maintained. In addition to maintaining the first year's fuel efficiency over the entire nine year period in order to be eligible, Hyundai suggests that the agencies also consider the possibility of fuel efficiency/GHG improvement during that period. (The current proposal requires only increased penetration rates of the fuel efficiency/GHG improvement for a model) Additionally, Hyundai notes that if automakers are capable of exceeding large truck fuel efficiency targets by 15 or 20%, this will be valuable information to the agencies at the time of the mid-term review. [EPA-HQ-OAR-2010-0799-9547-A1, p.3]

Finally, while we support performance-based incentives, we do acknowledge that it is possible that these incentives could shift the fleet mix toward the full-size truck segment, thus reducing the overall benefits of the proposed requirements. [EPA-HQ-OAR-2010-0799-9547-A1, p.3]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 173.]

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 23.]

Others are improving the fuel efficiency of cargo-carrying larger pickup trucks, and the agency is providing incentives to provide that technology.

Organization: International Council on Clean Transportation (ICCT)

14. Similarly, the full-size pickup truck credits also violate the principle that efficiency and greenhouse gas standards should be technology neutral, and reduce the benefits from the rule. As a minimum, the credits should only be given if the sales targets are met each year and the credits should be phased out in the final rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 4]

15. Full-size pickups have been defined by the ability to fit four foot wide construction materials between the wheel wells at least since the introduction of the F-series pickup in 1948. The full-size pickup truck credits should not be expanded to pickups with less than 48 inches wheelhouse width. [EPA-HQ-OAR-2010-0799-9512-A1, p. 4]

14) Pickup Truck Credits

A second type of technology-specific bonus credit currently in the proposed rule applies to full-size pickup trucks. For the same reasons we expressed in the last section on upstream credits, the ICCT encourage US EPA to eliminate the proposed bonus credits for pickup trucks. [EPA-HQ-OAR-2010-0799-9512-A1, p. 35]

The NPRM proposes two types of pick-up bonus credits. First, the NPRM proposes a bonus credit of 10 g/mile for each full-sized pickup truck that is either equipped with mild hybrid technology, or achieves an emission rate 15% better than the standard in any year from MY2017 to MY2021 (assuming minimum fleet deployment rates are met). Second, the NPRM proposes a bonus credit of 20 g/mile for each full sized pickup that is either equipped with strong hybrid technology, or achieves an emission rate 20% better than the standard in any year (assuming certain fleet deployment rates are achieved). [EPA-HQ-OAR-2010-0799-9512-A1, p. 35]

These proposed credits are not related to any additional fuel or CO_2 reductions and could hinder, rather than promote, additional technology advancement for two reasons. First, there is no inherent reason why hybrid systems for pickup trucks would be different from hybrid systems for other vehicles. Even if hybrid development proceeded initially on other vehicles, it could easily be spread to pickup trucks when it is ready. In fact, Toyota and Ford have already announced a joint venture to develop hybrid systems for pickup trucks.[65] [EPA-HQ-OAR-2010-0799-9512-A1, p. 35]

Second, OEMs could use the bonus credit to delay introducing this technology on other models and/or delay introduction of stronger hybrids, zero tailpipe emission vehicles, and other superior technologies. In addition, once a vehicle qualifies in a given year, future production of the model can also qualify for the 10 g/mile credit up until 2021, even as the expected benefit over the standard shrinks toward zero. [EPA-HQ-OAR-2010-0799-9512-A1, p. 35]

Technology-neutral standards, without the 10 g/mile and 20 g/mile pick-up credits, would best achieve the valuable benefits of this rulemaking. [EPA-HQ-OAR-2010-0799-9512-A1, p. 35]

As a minimum, OEMs should be required to achieve a performance standard of 15% (10 g/mile credit) or 20% (20 g/mile credit) better than the compliance curve for a given model in each year that the credit is awarded to that model. In addition, the pickup truck credits should be phased out in the final rule and not be allowed to continue indefinitely. [EPA-HQ-OAR-2010-0799-9512-A1, p. 36]

15) Pick-up Truck Definition

For the purposes of the full size pickup truck hybrid technology incentive credit or the full size pickup truck performance-based incentive credit, EPA is seeking comment on expanding the definition of a full-size truck by reducing the minimum wheelhouse width requirement from 48 inches to a value around 42 inches, provided the vehicle is able to tow at least 6,000 lbs. Note that this is 1,000 lbs higher than the requirement for 48 inch wide pickup trucks. [EPA-HQ-OAR-2010-0799-9512-A1, p. 36]

It is inappropriate to expand the definition of full size pickup trucks to include trucks with less than 48 inches between the wheelhouse. The ability to haul standard four foot wide building sheets, such as plywood and drywall, between the wheelhouse has been the marketing definition of a full size pickup at least since the introduction of the F-series pickup in 1948. Reducing the wheelhouse width to 42 includes will allow virtually all pickup trucks to qualify for the artificial pickup truck credits, further distorting technology requirements and reducing the benefits of the rule. [EPA-HQ-OAR-2010-0799-9512-A1, p. 36]

ICCT strongly opposes expansion of the full size pickup credits to pickups with less than 48 inches wheelhouse width. [EPA-HQ-OAR-2010-0799-9512-A1, p. 36]

Organization: Marz, Loren C.

However, I do not support the 'Incentives for Advanced Technologies Including Hybridization for Full-Size Pick-Up Trucks' unless diesel technology is also included in some fashion. [NHTSA-2010-0131-0213-A1, p.1]

Organization: Mercedes-Benz USA, LLC

• DAG supports credits applicable to the hybridization of vehicles with footprints less than 40 square feet. Additional credit opportunities would provide significant assistance in overcoming the cost-benefit barriers to investment in hybrid powertrains in this market segment. [EPA-HQ-OAR-2010-0799-9483-A1, p. 2]

DAG proposes that EPA provide a further credit to assist manufacturers in hybridizing smaller vehicles, i.e., those 40 square feet or less. This category would currently include approximately

14 vehicles, including the smart car, the Mini Cooper, the Ford Fiesta and the Toyota iQ.[29] Only Honda is offering hybrid vehicles in this size category.[30] [EPA-HQ-OAR-2010-0799-9483-A1, p. A-15]

Vehicles within this category generally achieve EPA-combined fuel economy in the range of 30-35 mpg, primarily by virtue of their size and weight. In comparison, however, hybridization is more cost-effective for vehicles in larger segments. Larger vehicles with hybrid engines, such as the Prius and the Honda Civic hybrid, achieve substantially greater EPA-combined fuel economy, in the range of 40-50 mpg. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-15]

For small-size cars, however, the barriers to hybridization include architecture and cost impediments to hybridizing smaller vehicles.[31] Indeed, press reports indicate that while companies have explored hybridizing in this category; as of yet, however, only Honda has thus far decided to offer hybrid vehicles in this segment. The vast majority of companies appear to have determined that it is not commercially feasible to hybridize in this category. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-15]

Hybridizing this market segment, however, could garner significant benefits. The fuel efficiencies of smaller vehicles are generally associated with steady state driving, mostly on highways and in rural areas. The power-to-weight ratio of vehicles in this class are typically 15-20% worse than the next larger vehicle class. As a result, fuel efficiency in fact suffers in smaller vehicles when driven in urban settings because in that setting they are being driven outside their most fuel-efficient envelopes. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-15]

Urban city modes tend to impose greater transient demands on the engine. On urban expressways, extended higher-rpm acceleration is often required. Hybrid vehicles offer the opportunity to enhance fuel efficiency by supplanting, with hybrid propulsion, the power required for acceleration which would otherwise occur at a less than optimum efficiency. Outside of urban areas, the hybrid propulsion can serve as a range extender during steady state cruising to supply power at times, such as long grades, that would otherwise require the engine to operate at less than optimal fuel consumption. As a result, hybridizing smaller vehicles would offer substantial fuel efficiency gains and CO_2 reductions while providing enhanced consumer functionality in both urban and highway settings. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-15]

DAG proposes a credit of 10 g/m, consistent with the credit proposed for hybridizing larger trucks, for hybrid vehicles in this class once a penetration rate of 10% is reached. The application of a penetration rate recognizes that there may be individual companies that are able to invest in particular models, but that for most manufacturers investment in this segment is not feasible or likely to provide enough benefit to justify the costs. A 30% penetration rate ensures that the incentive is in fact encouraging investment. A substantially higher penetration rate requirement would render the incentive infeasible. [EPA-HQ-OAR-2010-0799-9483-A1, pp. A-15-A-16]

29 The category would also include the Chevrolet Aveo, the Fiat 500, the Toyota Yaris, the Mazda2, the Honda Fit, the Hyundai Accent, the Kia Rio, the Ford Fiesta, the Scion xD and the Chevrolet Spark 2013. The list is based on EPA's 'small size' car list for MY 2012.

30 Honda currently offers the hybrid CR-Z and has announced plans to offer the hybrid Honda Fit. We do not believe other companies will follow in the absence of a government production incentive to do so. The Mitsubishi i-MiEV also falls within this size range, but is a full electric vehicle.

31 Hybridization in this context should refer to regenerative braking and/or electric motor drive assist.

Organization: Motor & Equipment Manufacturers Association (MEMA)

Incentives for “game changing” technologies performance for full-size pickup trucks including hybridization is too limiting and requires revisions. These incentives should not be limited to this vehicle segment. Also, incentive metrics for hybrids need to be based on vehicle performance, not architecture; other technical possibilities for full-size pickup truck hybrids should be considered; and, the penetration rate requirement should be eliminated. [EPA-HQ-OAR-2010-0799-9478-A1, p.2]

Essentially, any technology that is “game changing,” as stated in the NPRM, should qualify for the same incentives. The quantification of significant improvement is a reasonable definition of “game changing,” and should therefore apply to any technology and vehicle segment. No one vehicle segment should be the beneficiary of “game-changing” technologies. Such focus on one segment could also have unintended consequences. As a hypothetical example, if the OEM concentrates their efforts on full-size pickup trucks and thereby generates a large number of credits, there is a possibility they may not apply advanced technologies to large SUVs. Instead, they may use those credits from the pickup trucks to offset their SUVs that do not meet the standard. Thus, the overall effect on emissions and fuel consumption goes in the wrong direction. [EPA-HQ-OAR-2010-0799-9478-A1, p.3]

Second, with respect to full-size it is our understanding, that if full-size pick-ups demonstrate a 15 or 20 percent performance improvement pre-MY2017 (i.e. during MYs2014, -15, -16) then those vehicles would not be eligible to be pulled through as a carry-forward credit in the form of a full-size pick-up performance improvement credit post-MY2017. Under this scenario, MEMA asks that the agencies clarify if these full-size pickups would instead be eligible for an early compliance credit. This important point needs to be clarified primarily because the multiplier for early credit and the performance improvement credit for this vehicle class would be different (flat 1 versus 1.5). If these pickups would not be eligible as a performance improvement credit and carried forward as such, then there may not be as large of an incentive to research, develop, produce and implement technologies more rapidly. [EPA-HQ-OAR-2010-0799-9478-A1, pp.9-10]

A. “Game Changing” Technologies Should Apply to All Vehicle Segments [EPA-HQ-OAR-2010-0799-9478-A1, p.10]

As MEMA stated earlier in Section II, the credits for “game changing” technologies should not be limited to just full-size pickup trucks. Any technology that is “game changing” should qualify for the same incentives and have the same hurdles to meet. No one, single segment should be the beneficiary of “game changing” technologies. For example, systems like Higher Voltage Stop-Start/Belt Integrated Starter Generator (BISG), can be utilized in other vehicle categories. If there is a technology that improves any vehicle segment by a given percentage or target (performance-based criteria) and subsequently the criterion is exceeded, then an incentive/credit should apply across the board. [EPA-HQ-OAR-2010-0799-9478-A1, p.10]

By making this change, these “game-changing” technologies can be implemented to other vehicles, such as large SUVs. In many ways, large SUVs face some of the same challenges as full-size pickup trucks. It would be prudent for the agencies to treat all vehicle segments equally so that the rule does not drive certain types of vehicles to be made available to consumers. Such a constraint not only influences and favors vehicle “winners and losers” and prescribes a technology pathway, but also influences the offsets for those vehicles that may not meet the standard. This direction is counter to the intent of the Program’s goals. All opportunities to improve real-world emissions and fuel consumption should not be limited exclusively to any one vehicle segment. Therefore, MEMA urges the agencies to consider applying “game changing” performance-based improvements to all vehicle segments and not just full-size pickup trucks. [EPA-HQ-OAR-2010-0799-9478-A1, p.10]

B. Mild and Strong Hybrids Should be Based on Vehicle Performance, Not Architecture [EPA-HQ-OAR-2010-0799-9478-A1, p.10]

If the agencies will not apply “game changing” technologies to all vehicle segments, MEMA urges that changes are made to the treatment of mild and strong hybrids in the rule. In the NPRM, hybrid electric vehicles have been categorized as “mild” or “strong” in a manner based more on hybrid architecture than on any specific performance definition. There are many different architectures employed using single, dual, or multiple electric motors performing various functions including traction drive, power generation (both while driving and braking), and battery charging. These electric drive systems cover a continuum of power levels.[EPA-HQ-OAR-2010-0799-9478-A1, p.10]

In real-world driving, regenerative braking efficiencies can be similar for both mild and strong hybrids when the driver coasts to a stop. A strong hybrid is capable of a higher regenerative braking level and the vehicle will coast to stop sooner. Thus, the regenerative braking efficiency is not a representative metric when classifying mild or strong hybrids. It is recognized that when following a defined deceleration rate on a specific driving cycle there will be differences in regenerative braking energy levels between mild and strong hybrids. [EPA-HQ-OAR-2010-0799-9478-A1, p.10]

If regenerative braking efficiency is used as a metric for incentives, then vehicle manufacturers will focus on this and not the goal of maximizing fuel efficiency at an affordable cost. An architecture that could maximize regenerative braking efficiency and meet the 75 percent breakpoint is one that uses four-wheel motors. This is unlikely to be used in mass-market vehicles due to the high cost of implementation. On a full-size pickup truck with rear-wheel drive, optimum regenerative braking could use an electric motor on the front axle, commonly referred to as a "through-the-road" hybrid. Typical vehicle braking is done with 70 percent on the front and 30 percent on the rear, which also provides stability under braking. [EPA-HQ-OAR-2010-0799-9478-A1, p.11]

Hybrid architectures for large pickup trucks – both mild and strong – more typically provide electrical boost through the drivetrain to the rear wheels. This configuration is able to employ regenerative braking on the rear and friction braking on the front to retain vehicle safety and stability. In this architecture the system is incapable of meeting a 75 percent regenerative braking efficiency, as defined in the NPRM, whether or not it is a mild or strong hybrid. Drivetrain losses and engine pumping losses also reduce the amount of recovered energy. [EPA-HQ-OAR-2010-0799-9478-A1, p.11]

For these reasons, MEMA urges that the calculated incentive be based on vehicle performance (i.e. the improvement in fuel efficiency of the hybrid compared to a conventional vehicle) and using a formula that provides a continuous value that does not require a breakpoint and a definition of "strong" versus "mild." MEMA further recommends that this incentive is calculated using the "Autonomie" modeling and simulation program developed by Argonne National Laboratory. This program is widely recognized for its ability to model different architectures to determine vehicle performance, including fuel efficiency. [EPA-HQ-OAR-2010-0799-9478-A1, p.11]

In this same section, § 86.1866–12 (e) Paragraph (2) (i) and (ii), the proposal defines penetration rate thresholds for full-size pickup trucks.[11] Based on current penetration rates of light-duty hybrid vehicles of 2.4 percent in 2010 and 2.2 percent in 2011, the proposed threshold penetration rates are unlikely to be achieved. Further, there is close correlation between the number of hybrid vehicles sold and the price of gasoline. MEMA recommends that the penetration rate thresholds be eliminated because these factors are impossible to predict. Therefore, the credit should be given according to the actual number of vehicles actually produced. [[EPA-HQ-OAR-2010-0799-9478-A1, pp.11-12]

Incentives for "game-changing" technologies should available to all vehicle segments, not just full-size pickup trucks. [EPA-HQ-OAR-2010-0799-9478-A1, p.13]

Metrics and terminologies for hybrids should be modified. [EPA-HQ-OAR-2010-0799-9478-A1, p.13]

Organization: National Wildlife Federation (NWF)

NWF supports provisions in the rule that encourage more rapid adoption of the most fuel efficient technology at scale – especially the incentive for "game changing" technologies for full size pickup trucks. [EPA-HQ-OAR-2010-0799-9887-A2, p. 4]

In principle, we also support incentives for plug-in hybrid electric and electric vehicle technology and for real off-cycle CO_2 reductions, and we look forward to continuing to work with automakers, the agencies and consumers to maximize the effectiveness of these credits and other measures which enable rapid adoption of new technology, and to optimize short and long term emissions impacts. [EPA-HQ-OAR-2010-0799-9887-A2, p. 4] [[This comment can also be found in Outline Headings 4. and 7.]]

Organization: Natural Resources Defense Council (NRDC)

2. Incentives for Full-Size Pickup Trucks Should Require Wide Scale Technology Deployment and Phase Out during Model Years 2017-2025

NRDC agrees that the proposed truck incentives should be limited to just full-size pickups. While full size pickup trucks may often be used for the main purpose of transporting just passengers, these trucks are the most likely light-duty vehicles to have legitimate non-passenger applications such as handling large and heavy cargo payloads and/or towing. NRDC believes that known technologies can be applied to address the payload needs while also significantly improving fuel efficiency and reducing GHG emissions. However, these technologies only deserve special incentives if they can be scaled up for widespread application. [EPA-HQ-OAR-2010-0799-9472-A2, p. 12]

NRDC supports the proposed requirement that manufacturers reach minimum volume levels in order to be eligible for the full-size pick truck incentives. The minimum volumes require a commitment from manufacturers for wide scale production and deployment. [EPA-HQ-OAR-2010-0799-9472-A2, p. 12]

Among the truck incentives being proposed, NRDC appreciates the inclusion of a technology-neutral, performance-based credit structure. Performance-based targets allow for new innovation but can also bring uncertainty in the verification of real-world results. Due to the uncertainty, NRDC supports constraining the credit allowance to truck credit to no more than five consecutive model years or until emissions increase. [EPA-HQ-OAR-2010-0799-9472-A2, p. 13]

NRDC agrees that vehicles receiving the performance-based credit be prohibited from receiving hybrid truck credits. [EPA-HQ-OAR-2010-0799-9472-A2, p. 13]

NRDC also agrees that the mild hybrid truck incentive be no more than 10 g/mi. When analyzing the effectiveness of the mild hybrid technology—which EPA notes has not been done for the NPRM—EPA should consider reducing the maximum credit available to be consistent with the analysis. [EPA-HQ-OAR-2010-0799-9472-A2, p. 13]

Organization: NGV America

Advanced Pickup Truck Credits

For 2017–2025, EPA and NHTSA have proposed special credits for pickup trucks. There is a credit for mild- and also for strong-hybrid pickups, and a separate credit for pickups that are able to meet prescribed GHG reductions. The description in the proposed rule appears to indicate that hybrid pickups and pickups that satisfy the GHG performance criteria will earn GHG and FE credits. The descriptions of the incentives contained in the proposals are reprinted here:

As with the HEV-based credit, the performance-based credit/value requires that the technology be used on a minimum percentage of a manufacturer's full-size pickup trucks. That minimum percentage for the 10 g/mi GHG credit (equivalent to 0.001125 gal/mi fuel consumption improvement value) would be 15 percent of a company's full sized pickup production in MY 2017 with a ramp up to at least 40 percent of production in MY 2021.

The minimum percentage for the 20 g/mi credit (equivalent to 0.002250 gal/mi fuel consumption improvement value) would be 10 percent of a company's full sized pickup production in each year over the model years 2017–2025.

First, we recognize that pickup trucks are among the most challenging in terms of meeting aggressive future requirements. As a result, we recommend that the agencies provide the broadest array of credits for game changing technologies implemented on these vehicles. The agencies have proposed credits for either hybridizing these vehicles or providing superior emissions performance. We recommend that the agencies also consider and include additional credits for natural gas applications on pickup trucks. We would be happy to work with the agencies to develop credits that fully recognize the benefits that natural gas can provide on these trucks. We have outlined earlier the types of incentive we believe are necessary and appropriate to encourage the development and sale of light-duty NGVs.

Second, with respect to the performance-based credits provided for pickup trucks, we offer the following comments. We agree that all technologies should have the opportunity to earn credits under this provision, and we expect NGVs will qualify based on the performance levels proposed. Also, we believe that, if specific credits are provided elsewhere in the rules for NGVs, that such vehicles, like for gasoline-hybrids, should not earn double credits under those provisions and also under the pickup truck credit provision. If no additional credits are provided for NGVs, then they should have the potential to earn credits under this program. Regardless, we believe that the proposed targets -- 10% - 15% of production -- for introduction are simply too high with respect to NGVs, and that EPA and NHTSA should amend the proposal to provide a lower threshold. We propose that a more reasonable target for NGVs would be tied to penetration of the commercial and public fleet market as opposed to the overall market for trucks since NGVs and other alternative fuel vehicles likely will be targeted mostly to fleets during their initial introduction for a number of reasons. [EPA-HQ-OAR-2010-0799-9461-A1, pp. 13-14]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

NESCAUM supports EPA's proposal to include flexibility mechanisms to provide manufacturers with the means to incorporate a range of technologies to meet the requirements of the proposed standards. [EPA-HQ-OAR-2010-0799-9476-A1, p. 2]

Organization: Toyota Motor North America

The agencies have proposed to provide 'credits' for deployment of hybrid electric technology on full-size pick-up trucks (FSPUs). Toyota appreciates and supports the agencies' objective to promote hybrid electric technology in vehicle segments that have proven difficult to penetrate, but numerous market segments currently have a lower penetration rate of hybrid electric technology than does the FSPU segment. Therefore, limiting the proposed credits to FSPUs appears arbitrary. [EPA-HQ-OAR-2010-0799-9586-A1, p.2]

Full Size Pick Up (FSPU) Credits [EPA-HQ-OAR-2010-0799-9586-A1, p.14]

The agencies have proposed incentives for the adoption of 'game changing' technologies that could provide significant environmental and energy benefits for full-size pick-up trucks (FSPUs) while preserving their utility characteristics. Two specific credit incentives are proposed; (1) for FSPUs that perform 15-20 percent better than the vehicle's CAFEI CO_2 attribute targets regardless of the technology used on the vehicle~ and (2) for FSPUs using hybrid technology once certain sales thresholds are met. As proposed, a given FSPU could not qualify for both of these credits. [EPA-HQ-OAR-2010-0799-9586-A1, pp.14-15]

Toyota appreciates the challenge of reducing emissions and improving the fuel economy of FSPUs. However, as explained in more detail below, Toyota has concerns about both of these provisions. [EPA-HQ-OAR-2010-0799-9586-A1, p.15]

Credit for FSPUs Achieving 15-20 Percent Better than Target [EPA-HQ-OAR-2010-0799-9586-A1, p.15]

The agencies have proposed a variety of reasonable and necessary flexibilities related to advanced technology vehicles that span all vehicle segments, including FSPUs (for example, sales multipliers for plug-in hybrids, electric vehicles and fuel cells). The agencies have also proposed credits for FSPU hybrids (discussed below). Therefore, it remains unclear to Toyota why the credit provision for 15-20 percent above target is needed for the FSPU segment. Toyota requests that, based on the myriad other proposed flexibilities available for this segment, and the generally less stringent target curves proposed for large trucks, the agencies drop this provision. [EPA-HQ-OAR-2010-0799-9586-A1, p.15]

Scope of the FSPU Hybrid Technology Provision [EPA-HQ-OAR-2010-0799-9586-A1, p.15]

The agencies appear to have arbitrarily limited which trucks are eligible for hybrid credits. While Toyota appreciates and supports the agencies' objective to promote hybrid technology in vehicle segments that have proven difficult to penetrate, numerous market segments currently have a lower penetration rate of hybrids than does the FSPU segment. According to EPA-published data for 2010 model year4 shown in Appendix 2, the FSPU segment is not unique in terms of low hybrid penetration. In fact, a number of car and truck segments have an even lower penetration than the 'large' pick-up truck segment. Among all truck segments, hybrid share for 2010 model year was only 1.6 percent industry-wide. Clearly, hybrid penetration is an issue for the entire car and truck fleet, and particularly so for the truck fleet. Toyota's own data supports this view as well. For the 2011 model year, hybrids comprise 1.5 percent of Toyota's entire light-duty truck product line, which is an order of magnitude less than the 15.6 percent penetration rate for Toyota passenger cars during the same model year. [EPA-HQ-OAR-2010-0799-9586-A1, p.15]

Toyota requests that the credit for hybrid FSPUs be extended to all truck segments. Notwithstanding this request, the comments below address specific details of the proposed FSPU hybrid credit. [EPA-HQ-OAR-2010-0799-9586-A1, p.15]

Minimum Sales Volume Threshold for FSPU Hybrid Credits [EPA-HQ-OAR-2010-0799-9586-A1, p.15]

The agencies are proposing minimum sales percentages of a manufacturer's full-size pick-ups be equipped with hybrid technology before credits can be generated. These minimum sales percentages vary by model year, and whether the hybrid system is 'strong' or 'mild'. As explained previously for off-cycle technology credits, arbitrary sales thresholds, absent market demand, will do nothing to speed deployment. The likelihood of falling short of the sales thresholds are far greater for hybrids compared to off-cycle technologies given the higher cost of hybrid technology and the higher minimum sales percentages required. We again refer the agencies to Appendix 1, which contains analysis of technology penetration rates. For additional reference, Toyota has only reached 1.5 percent hybrid penetration rate for trucks after nearly 8 years of marketing hybrid trucks in the U.S. [EPA-HQ-OAR-2010-0799-9586-A1, pp.15-16]

We understand the agencies' goal for the thresholds is to reward meaningful hybrid technology deployment. However, we are concerned that thresholds will be counterproductive to achieving this goal. In fact, a maximum threshold appears more appropriate than the proposed minimums because commercially viable technologies eventually attain a level of market acceptance where incentives are no longer necessary. The proposed minimum thresholds would guarantee credits for extremely high penetration rates that clearly no longer warrant incentives. [EPA-HQ-OAR-2010-0799-9586-A1, p.16]

Hybrid Credit Technical Issues [EPA-HQ-OAR-2010-0799-9586-A1, p.16]

To ensure that participating manufacturers employ hybrid technology that meets the intent behind the incentives, EPA is proposing definitions of 'mild' and 'strong' hybrid. Toyota supports EPA's intention to distinguish between strong and mild hybrids for the purpose of awarding FSPU credits. After careful analysis of EPA's metrics being proposed to define strong and mild hybrids, Toyota would like to offer the following comments based on our hybrid experience and expertise which would enhance the technical accuracy and robustness of this proposed FSPU provision. [EPA-HQ-OAR-2010-0799-9586-A1, p.16]

(i) Total Braking Energy (reference Chapter 5 of the TSD, section 5.3.3.2). The equation for determining Ebrake_max is incorrect. Specifically, EPA is proposing: [EPA-HQ-OAR-2010-0799-9586-A1, p.16] [There is an associated figure, please refer to EPA-HQ-OAR-2010-0799-9586-A1, p.16]

Toyota recommends the following revision: [EPA-HQ-OAR-2010-0799-9586-A1, p.17] [There is an associated figure, please refer to EPA-HQ-OAR-2010-0799-9586-A1, p.17]

(ii) Measurement of Recovered Braking Energy (reference TSD, section 5.3.3.1). EPA proposes to incorporate a metric - the total percentage of available vehicle braking energy recovered over the test cycle (T]recovery) - as a way to define levels of hybrid vehicles. Toyota agrees that this metric can be a way to simplify the characterization of a hybrid as a 'mild' or 'strong' hybrid because batteries and motors will increase in scale to recover the relative braking energy. EPA's metric involves calculating the available braking energy on the FTP city cycle and comparing the actual energy recovered by the vehicle during FTP city cycle testing. The measured energy into the battery is divided into the total calculated braking energy to determine if the vehicle is a mild or strong hybrid. For a mild hybrid, EPA is proposing that the recovered energy must be greater than 15 percent and less than 75 percent of the calculated available braking energy. For a strong hybrid, EPA is proposing that the recovered braking energy must be greater than 75 percent of the calculated available braking energy. Toyota is providing specific comments on three particular aspects of the metric being proposed by EPA: [EPA-HQ-OAR-2010-0799-9586-A1, p.17] [There is an associated figure, please refer to EPA-HQ-OAR-2010-0799-9586-A1, p.17]

(A) EPA's definition of the Erecovered term does not match the equation. Toyota believes that Erecovered should be calculated based on charging energy recovered only when the vehicle is in deceleration mode. As is currently proposed, EPA's method incorrectly includes battery charge energy supplied by the engine. Toyota recommends that EPA revise the methodology to include the condition of 'onlv during deceleration' for the Erecovered calculation. [EPA-HQ-OAR-2010-0799-9586-A1, pp.17-18]

(B) EPA's equation for Ebrake_max is calculated by integrating required braking power at each point in the FTP test cycle, over the entire test. For technical accuracy, Toyota recommends that Ebrake_max be calculated from the measured vehicle speed trace instead. [EPA-HQ-OAR-2010-0799-9586-A1, p.18]

(C) In concert with adoption of the technical change recommended in paragraph (A), EPA's strong hybrid threshold of 75 percent would need to be revised because this threshold would be too high to be met only by battery charging during regenerative braking. Toyota's assessment of future concept hybrid systems shows an energy recovery efficiency threshold (T'\recovery) to be within the range of 35- 48 percent. Toyota's analysis shows that 11recovery becomes less as the vehicle weight increases. This reduction in recovery efficiency is because the traction motor cannot absorb all of the braking energy and the wheel-to-motor losses will increase for heavier vehicles. As a result, Toyota recommends that an appropriate threshold for 11recovery >40 percent. [EPA-HQ-OAR-2010-0799-9586-A1, p.18] [There is an associated figure, please refer to EPA-HQ-OAR-2010-0799-9586-A1, p.18]

(iii) Additional Metric Needed. Toyota remains concerned that the proposed llrecovery metric and associated thresholds would not be sufficiently robust in distinguishing between strong and mild hybrids. To clearly identify a strong hybrid system, Toyota supports inclusion of an additional metric, fedrive, to clearly distinguish between strong and mild hybrids. The fe_{drive} metric would represent the amount of tractive effort a vehicle can achieve with electric drive only. A description of this metric and appropriate threshold value is provided below. [EPA-HQ-OAR-2010-0799-9586-A1, pp.18-19] [There is an associated figure, please refer to EPA-HQ-OAR-2010-0799-9586-A1, p.19]

Organization: U.S. Coalition for Advanced Diesel Cars

The Coalition embraces the Obama Administration's support for investments in technologies that, in the future, will lead to the wide-spread adoption of new "Game-Changing" technologies. Still, these technologies, will not significantly penetrate the marketplace until well beyond 2025 - the timeline for this rulemaking. This is why the Coalition strongly urges EPA and NHTSA to focus more on incentivizing "Game-Changing" fuel savings based on the ability of automakers to incorporate as many existing and developing technologies that can have the broadest impact for fuel economy for model years 2017 and 2025. [NHTSA-2010-0131-0246-A1, p.2]

Only a performance-based system for awarding credits to manufacturers – specifically with regard to full-sized pickup trucks – that is consistent across all technologies; [NHTSA-2010-0131-0246-A1, p.2]

The Coalition opposes EPA and NHTSA's intention to offer manufacturers incentives for hybrid technology utilized in the full-sized pickup truck market. The Coalition supports a single performance-based credit and argues that a separate hybrid credit is unnecessary and poorly conceived. [NHTSA-2010-0131-0246-A1, p.3]

Specifically, incentives, in the form of credits, will be offered in one of two ways - to manufacturers that produce hybrid electric vehicle (HEV) pickup trucks and to those that produce pickup trucks that meet a performance based standard. As stated earlier, the Coalition opposes any credit that is used to incentivize a particular technology in a specific vehicle class as opposed to incentives based solely on fuel economy increases and GHG emission reductions. [NHTSA-2010-0131-0246-A1, p.3]

In its current form, the hybrid full-sized pickup truck credit should be revised or eliminated from the Final Rule for the following reasons. [NHTSA-2010-0131-0246-A1, p.3]

GHG Reduction Target for Full-Sized Pickup Trucks' HEV Credit: The NPRM's description of the HEV pickup truck credit does not carry any CO_2 reduction requirements whatsoever. Although the agency outlines the dimensions of a pickup truck that can qualify for the credit, to the NPRM does not mention the volume of CO_2 or gallons of fuel these HEV trucks are supposed to save for the consumer and for the nation. Furthermore, at no point in the NPRM or the Draft Joint Technical Standards Document do the agencies support the need for a separate HEV incentive from the Performance Based Incentive. [NHTSA-2010-0131-0246-A1, p.3]

The Credit Does Not Include a Minimum Fuel Economy Threshold Provisions: While EPA specifies the amount of recovered break-energy these HEV trucks must achieve, EPA does not specify how that recovered energy should be used to benefit the environment or reduce national petroleum consumption. The proposed rule is void of any language that communicates anti-backsliding provisions that were once at the core of EPA's mobile source rulemaking. Under the language of this proposal, a "horsepower war" in the full size pickup truck market could emerge as long as these trucks carry a battery pack. EPA's authority should be used to ensure reduced emissions and fuel consumption without ambiguity. [NHTSA-2010-0131-0246-A1, pp.3-4]

Larger GHG Footprint and Decreased Fuel Economy: EPA is proposing a 20 g/mile credit for hybrid pickup trucks without requiring any GHG reduction or fuel economy improvement over the baseline foot print target. Without prescribing technology performance benefits, EPA's proposal could incentivize vehicles that undermine, rather than advance, the nation's policy objectives. As such, the Coalition requests that EPA and NHTSA require qualifying vehicles to actually reduce CO_2 and petroleum use in the real-world by 20 percent below the footprint target. [NHTSA-2010-0131-0246-A1, p.4]

Furthermore, the EPA and NHTSA identify the need that these vehicles have for more power based on traditional towing and hauling needs yet fail to clarify how the traditional drive cycle of the full-sized pickup truck driver would benefit from the hybridization of these vehicles. Assuming the need for more towing power and use at highway speeds, these owners will not enjoy any improved fuel economy or GHG reduction as a result of the hybridization. While other technologies added to the truck may improve fuel economy at highway speeds, there is no indication that GHG reductions from the hybrid credit will be "Game-Changing." [NHTSA-2010-0131-0246-A1, p.4]

As such, the Coalition requests that EPA or NHTSA publish any real-world data that indicates drivers of full-sized pickup trucks predominately are used in a stop and go driving pattern or that the credit as offered will be designed to significantly improve fuel economy and GHG emission reductions at highway speeds. [NHTSA-2010-0131-0246-A1, p.4]

Erasing Market Challenges: EPA states that it intends to utilize "game changing credits" to overcome market challenges faced by hybrid pickup trucks. The agencies have cited the expense to bring this technology to the light truck segment. These credits, however, cannot guarantee demand. Hybrid powertrains have been available on pickup trucks in the U.S. market since MY 2005. Since that time, some hybrid variants have been dropped by manufacturers due to the lack of customer demand. By 2011, in fact, less than one-quarter of a percent (0.23%) of customers selected the hybrid pickup truck option where it was available as an option. In contrast, depending on the model, 15% to 50% of customers selected a diesel powertrain when such an option was offered. [NHTSA-2010-0131-0246-A1, p.4]

The Coalition does not believe that offering the full-sized pickup hybrid trucks a credit will overcome the enormous market challenges that these vehicles have faced for the last 7 Model Years. We see as evidence that even offering a $7,500 credit has not helped the electric vehicle market hit predicted sales targets. The Coalition urges EPA and NHTSA to focus solely on a performance based standard aimed at encouraging manufacturers to add all advanced technologies to this segment. A technology neutral credit will lead to faster adoption and greater fuel economy gains. [NHTSA-2010-0131-0246-A1, p.4]

Small Pickup Truck Market: The agencies have requested comments on expanding the scope of its performance credits to include somewhat smaller pickup trucks. The Coalition strongly supports expansion of this definition to encourage the broadest possible adoption rates for advanced, fuel saving technologies in the fleet, but ONLY under the performance-based rules where the vehicles that the EPA is incentivizing actually reduce emissions and fuel consumption. [NHTSA-2010-0131-0246-A1, p.5]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 243-246.]

In the NPRM, EPA and NHTSA outline proposals that offer manufacturers incentives to incorporate game-changing technologies into the full-sized pickup truck market. These incentives in the form of credits come in two forms. One will provide credits to manufacturers to produce hybrid electric pickup trucks, another will award credits to manufacturers that produce pickup trucks that meet a similar performance-based standard.

EPA and NHTSA argue the HEV technology in pickup trucks is an emerging technology that faces substantial challenges in gaining initial market penetration. The Coalition finds this argument tenuous on a number of levels. First, the Coalition believes the HEV technology, which has been on the market for over a decade, is not an emerging technology today, and certainly will not be an emerging technology in 2017 when these credits are set to go into effect. To the contrary, light-duty HEV's have been a viable option for a number of consumers, particularly those who drive in urban conditions. It might be considered an emerging application of an existing technology, but it certainly cannot be described as an emerging technology almost 20 years of being on the market, which will be the case when this rule goes into effect. In fact, the GMC Sierra and Chevy Silverado hybrid applications in the truck segment have been on the market for nearly a decade.

Second, EPA and NHTSA state that because of the substantial cost required to produce full-sized HEV pickup trucks, automakers have difficulty justifying the investments necessary to produce these vehicles without a government incentive. The Coalition believes that government incentives to create a market for specific technologies are the wrong path to achieve fuel efficiency gains and emissions reductions. Examining consumer acceptance of alternative vehicle technologies in light-duty vehicles where hybrid technology is already well established foreshadows the pratfalls of choosing a single technology winner for the full-sized pickup truck segment on a technology neutral approach that promotes all advanced technologies will achieve real results.

Despite inquiries to the agencies and with suppliers, we are unaware of any data that demonstrates that most full-sized pickup truck owners accumulate the majority of miles under urban conditions and duty cycles. Conversely, these light trucks will be burdened with carrying the significant weight of the battery technology at highway speeds while using a gasoline or a diesel-powered engine.

By driving conditions that do not utilize the benefits of hybridization, it is unclear that the fuel economy gains and emissions reductions have predicted to result from this game-changing technology are actually attainable.

The Coalition sees no benefit in maintaining a performance-based credit and a separate credit for full-sized HEV pickup trucks when the latter can, and should, qualify under a strictly performance-based structure. Instead of sending a strong signal to both manufacturers and consumers that hybrid trucks represent the best technology option, EPA and NHTSA should make the case for any technology that meets the aggressive guidelines set forth by the NPRM.

Organization: United Automobile Workers (UAW)

The UAW also believes that the agencies are wise to offer an incentivized path for the application of technologies other than hybridization for large pick-up trucks. This technology-neutral option offers CO_2 credits and fuel-economy calculation adjustments for vehicles that substantially over-comply with the applicable footprint-based target. The proposals take appropriate measures to prohibit double counting the available incentives for large pick-up trucks. [EPA-HQ-OAR-2010-0799-9563-A2, p.3]

The UAW is especially supportive of EPA and NHTSA's proposed incentives for the addition of advanced technologies to large pick-up trucks and the proposed performance-based credits for large pick-ups that significantly exceed the applicable footprint-based target. [EPA-HQ-OAR-2010-0799-9563-A2, p.3]

We believe the credits proposed by EPA and the fuel-economy calculation adjustments proposed by NHTSA for significant hybridization of a manufacturer's full-size pick-up fleet are worthwhile incentives that will quicken the pace of introduction of these advanced technologies in a market segment that faces unique challenges in improving efficiency while maintaining full functionality. The proposed incentives are sensible because these technologies can improve efficiency without compromising functionality, even though they will certainly be expensive in the early years of the proposed rule. The UAW believes that these incentives will hasten the transformation of the large pick-up segment, and will ultimately result in a full-size pick-up fleet that is significantly more efficient much sooner than would be the case without the additional incentive. [EPA-HQ-OAR-2010-0799-9563-A2, p.3]

Organization: VNG Co. (VNG)

Unlike electricity, natural gas is a viable option for the full range of vehicle c1asses including larger vehicles like pickups and other light trucks, which have vehicle envelopes that can easily accommodate CNG tanks. Given that light trucks account for slightly more than half of all US vehicle sales today (and 60 percent or more of Big Three sales),11 light-truck friendly NGV technology can play a major role in ensuring the 'economic practicability' of these rules. As defined in the NPRM:

'Economic practicality refers to whether a standard is one 'within the financial capability of the industry, but not so stringent as to lead to adverse economic consequences, such as a significant loss of jobs or the unreasonable elimination of consumer choice.'" [EPA-HQ-OAR-2010-0799-7941-A2, p. 4]

As discussed below, the Agencies have already acknowledged the importance of the pickup truck segment for meeting this economic practicality criterion with their proposal for special credits to encourage deployment of 'game-changing' technologies in these vehicles. By extension, the economic practicability of these and future regulations will be greatly enhanced if they provide appropriate, fair and consistent support for the production of NGVs, which will provide a much-needed long-term platform for reducing emissions and petroleum consumption for the entire light truck segment of the market. [EPA-HQ-OAR-2010-0799-7941-A2, p. 4]

• Incentives for 'game-changing' GHG-reducing technologies deployed in fullsized pickups could be a significant benefit to natural gas, which is the most viable alternative fuel for this critical vehicle segment; [EPA-HQ-OAR-2010-0799-7941-A2, p. 5]

Game-Changing Pickup Truck Credits

VNG understands the challenges that automakers face in terms of achieving the 2025 standards for full-size pickup trucks and we strongly support the Agencies' decision to provide special incentives to facilitate the adoption of advanced technologies in this segment. Moreover, we believe that the technology-neutral 'performance-based' credit, based on GHG emission reductions, is an important option for automakers that could help facilitate the production of significant numbers of natural gas-fueled pickups. [EPA-HQ-OAR-2010-0799-7941-A2, p. 7]

With tailpipe GHG emission reductions from CNG of 24 percent compared to gasoline,23 both dedicated and dual-fuel NGV pickups with significant range (assuming use of utility factor methodology) are likely to qualify for the 20 percent GHG reduction threshold. Moreover, unlike plug-in electric capability, which is not expected to be achievable for this segment due to 'tradeoffs in terms of cost, electric range, and utility,” dual-fuel natural gas capability is particularly well suited to pickups due to the relative ease of incorporating CNG tanks in large vehicle envelopes. Indeed, both GM and Chrysler have already announced plans to produce NGV pickup trucks this year.25, 26 Due to their significant fuel use and popularity as fleet vehicles, the pickup segment can be the base market for the broader development of NGVs. [EPA-HQ-OAR-2010-0799-7941-A2, p. 7]

Given the importance of the pickup truck segment to maintaining a full range of consumer choice, as well as the desirability of moving as many vehicles as possible towards the use of low-emission, alternative fuels, VNG supports the Agencies' consideration of expanding eligibility for these credits to include smaller pickup trucks with similar towing capacity. [EPA-HQ-OAR-2010-0799-7941-A2, p. 8]

We also believe that the minimum penetration thresholds (of 10 percent for the 20 g/mi credit and 15-40 percent for the 10 g/mi credit) for all of the game-changing pickup credits should be eliminated. Automakers should be encouraged to produce even limited quantities of these vehicles, which may be a necessary first step to test consumer acceptance in early years. [EPA-HQ-OAR-2010-0799-7941-A2, p. 8]

Finally, the Agencies offer no rationale for imposing a five-year limit on the performance-based 20 g/mi credit for a specific pickup model, where no such limit exists for equivalent hybrid-electrics. Given the similar impacts of both hybrids and performance-based credit pickups on emissions, as well as the broader importance of facilitating technological evolution in this segment, there is no justification for placing special limits on performance-based credits. Thus, the 5-year cap should be eliminated. [EPA-HQ-OAR-2010-0799-7941-A2, p. 8]

Organization: Volkswagen Group of America

Prescribe restrictions on the use of targeted, segment exclusive credits which we predict will provide a windfall for competitors marketing high-emitting large trucks and pick-ups. [EPA-HQ-OAR-2010-0799-9569-A1, letter p. 2]

Expand the range of technologies included within several flexibilities and incentives in order to promote the introduction of a broader set of fuel saving, low-emission options. [EPA-HQ-OAR-2010-0799-9569-A1, letter p. 2]

- Prescribe restrictions on the use of targeted, segment exclusive credits to avoid a windfall for competitors marketing high-emitting large trucks and pick-ups; and [EPA-HQ-OAR-2010-0799-9569-A1, p. 4]

c. Broad flexibilities and program credits available to all fleet segments

Continue to build upon the credits and flexibilities provided in the 2012-2016 regulatory program. Credits and flexibilities should be equal for passenger cars and light trucks due to similar requirements for investment and overall impact on CO_2 reduction. [EPA-HQ-OAR-2010-0799-9569-A1, p. 5]

Further the trading flexibility within and across compliance fleets should be sufficient to cover any vehicles with additional challenges in complying with 4%. [EPA-HQ-OAR-2010-0799-9569-A1, p. 5]

e. includes substantial compliance credits that are available for only a limited range of technologies, or are available only for specific segments (Full-Size Pick-Up Trucks); and

f. Fails to provide credit mechanisms that would have encouraged greater use of biofuels. [EPA-HQ-OAR-2010-0799-9569-A1, p. 6]

In addition, in contrast to Volkswagen's principle of equal credit opportunities across all segments, the proposal once again targeted benefits towards larger trucks by providing a significant credit opportunity only available to full-size pick-up trucks. Volkswagen contends and will describe below how this segment exclusive credit has the potential to create a windfall of excess truck credits that can then be transferred to the passenger car segment. [EPA-HQ-OAR-2010-0799-9569-A1, p. 6]

EPA is proposing a suite of CO_2 incentives exclusive to full-size pick-up trucks for 2017-2025. This flexibility provides 10 or 20 g/mi for hybridization and a separate 10 or 20 g/mi incentive for non-hybrid low emitting vehicles. Volkswagen opposes this provision within the NPRM. [EPA-HQ-OAR-2010-0799-9569-A1, p. 22]

First, as illustrated above in Section 2.6, it is Volkswagen's position that the full-size truck segment is not uniquely challenged by this proposal and that these vehicles do not face a disproportionately more stringent requirement than other segments. Again we refer to Table 2-7 above which summarizes the continuing minimal reduction requirements for large trucks. [See Table 2-7 on p. 19 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 22]

The Joint TSD indicates an approximate effectiveness for mild and P2 hybridization for large trucks on the order of 8-15%. Section 2.6 described an example full-size pick-up truck from the RIA (Chapter 3) which was 4% above its MY2017 target of 347 g/mi (72ft2 footprint target). This includes estimated A/C credits which according to Table III-2 in the NPRM amount to 12 g/mi. Strong hybridization would provide 56 g/mi (estimated TSD effectives of 15%) reduction captured in the two-cycle city/highway test used for compliance. According to the definition for Mild and Strong hybrid within the full-size truck credit section, these vehicles must be equipped with stop/start technology. Stop/Start technology is also being rewarded an additional 4.5 g/mi under the off-cycle technology 'list'. There is no stipulation in the rule that vehicles claiming the Full-size Truck hybrid credit cannot also claim the start/stop off-cycle credits even though one is required for the other. Therefore we must assume that the credit available is actually 14.5 or 24.5 g/mi. [EPA-HQ-OAR-2010-0799-9569-A1, p. 22]

As summarized in Table 2-8 this hybridized pick-up would earn upwards of 67.5 g/mi credits beyond its footprint target (0.3% stringency from 2016) which if transferred to the passenger car fleet would be inflated through VMT to upwards of 77 g/mi. [See Table 2-8 on p. 23 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 22]

This calculation does not include further conventional technology improvements which in Section 2.6 illustrated that hybridization would not even be necessary for this vehicle to comply. Hybridization of the truck would require a significant investment by the manufacturer and the reward in credits is warranted, however in this case the full-size truck credit (in addition to the accompanying stop/start credit) amounts to an excessive pool of credits that can be transferred to other market segments, including smaller trucks and/or passenger cars. This transfer of excess credits may result in a CO_2 disbenefit to the extent that the credit transfer reduces the need for other segments, many of which face more stringent reductions with fewer qualifying credits 6, to make improvements. [EPA-HQ-OAR-2010-0799-9569-A1, p. 23]

Figure 2-10 illustrates the transfer and maximum potential tailpipe emissions that a 45ft2 footprint passenger car could have and still remain compliant. Credit transfers will extend the reach of the large truck reduced stringency and full-size truck incentives to smaller trucks, or passenger cars. Manufacturers with significant quantities of large trucks may accumulate a windfall of credits which can then offset the CO_2 reduction obligations for their remaining smaller truck and car fleet. Companies that do not manufacture large pick-ups will be obligated to meet the passenger car targets without the benefit of these offsetting credits. [See Figure 2-10 on p. 24 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 23]

A car receiving the full transfer of credits from the full-size truck could theoretically retain tailpipe emission levels in excess of 300 g/mi. This is higher than 2012 MY standards by a significant margin. Even in a case where only the full-size truck credit and stop/start credit were transferred to the car fleet (28 g/mi VMT adjusted), the car's tailpipe level could reach 252 g/mi and remain compliant. This is less than the 2013 target. In this scenario the passenger car would be able to compete in the marketplace against other vehicles with a 40 g/mi investment advantage. This could result in that vehicle having a significant sales price advantage relative to other segment competitors. [EPA-HQ-OAR-2010-0799-9569-A1, p. 24]

This not only detracts from program CO_2 goals, but also amounts to an economic advantage for manufacturers of large trucks. The full-size truck credit does not represent real-world CO_2 reductions and in fact may offset real world CO_2 savings in other segments. [EPA-HQ-OAR-2010-0799-9569-A1, p. 24]

This means that the flexibility must be judged in light of the economics instead of environmental benefits. This is contrary to some of the other credits being offered within the program. Volkswagen does recognize that the same argument can be made with respect to credits being provided for electrified vehicles through the EV multiplier. However, in light of the economics context, we do note that EPA's cost estimates for plug-in electrification (either full EV or PHEV) far exceeds EPA's cost estimates for mild or even strong (P2) hybridization. The extent of investment needed to take advantage of the EV multiplier far outweighs the investment that would be required for a manufacturer to equip a vehicle with an open bed and regenerative braking. [EPA-HQ-OAR-2010-0799-9569-A1, p. 24]

In addition, EPA has cast the credit flexibility as incentivizing 'game-changing' technologies. Volkswagen disagrees with this notion and believes that this terminology is misleading. Hybridization of any vehicle remains an expensive and challenging technical endeavor, but we feel that this is equally true amongst all vehicle classes. Employing the term, 'game changing', leads one to believe that the technology has never before been attempted or that there has been a leap forward in capability to somehow make the technology significantly more effective in its application 7. We fail to see how regenerative braking on a vehicle with an open bed represents a "leap forward" in automotive technology, at least to the extent that it is awarded such a generous credit. [EPA-HQ-OAR-2010-0799-9569-A1, pp. 24-25]

As previously discussed in Section 2.6, Volkswagen's analysis of a market leading full-size truck indicated that the need to award additional, segment exclusive credits is unwarranted. Even without the available HEV incentive, a modest application of low-cost conventional technologies to this sample vehicle resulted in a significant pool of credits being generated. This is the simply the result of large trucks being provided with a low stringency. [EPA-HQ-OAR-2010-0799-9569-A1, p. 25]

EPA has stated that in the aggregate they predict the full-size truck credits will have around 1 g/mi impact on the overall industry truck compliance. However, Volkswagen is concerned with the effect that large truck credit windfalls may have when examining the implications at the manufacturer level. Although EPA's assessment at the industry level may seem insignificant, at the manufacturer level, the level at which we compete, the truck credits may provide significant company level advantages. Figure 2-11 shows the disparity in vehicle composition between competitors in the marketplace. The manufacturer on the left has a truck heavy fleet composed of upwards of 25-30% of a single full-size pick-up model. Clearly the full-size truck benefits would provide an economic and competitive benefit for this manufacturer. Volkswagen's fleet illustrated on the right side of Figure 2-11 is dominated by low-emitting small and medium sized passenger cars, both of which are subjected to the more stringent standard without the benefit of truck credits. [Figure 2-11 can be found on p. 25 of Docket number EPA-HQ-OAR-2010-0799-9569-A1] [EPA-HQ-OAR-2010-0799-9569-A1, p. 25]

In some cases, there are some manufacturers who sell more full-size pick-up trucks than passenger cars combined. In comparison, the majority of Volkswagen's sales are passenger cars. This segment faces the higher 5% stringency without the benefit of segment specific credits. In addition, the car segment is awarded fewer credits than trucks in A/C and off-cycle technologies. [EPA-HQ-OAR-2010-0799-9569-A1, p. 26]

It is not a stretch to imagine that manufacturers with pick-up focused fleets will easily be able to accumulate credits from both the lower stringency and available additional flexibilities. These credits can be transferred to offset investment in CO_2 reducing technologies for other segments, in turn reducing the price for consumers. This is not a transfer of real CO_2 from an over-compliant vehicle to under-compliant vehicle, but rather an economic transfer. Manufacturers who are not marketing full-size trucks will be offered no such economic benefit. Although Volkswagen understands that it is EPA's intention through this credit to help full-size trucks comply, we certainly do not believe it is EPA's intention to expand the number of OEMs marketing full-size pick-up trucks. Regardless that may very well be the result. [EPA-HQ-OAR-2010-0799-9569-A1, p. 26]

---

5 S/S is Off-cycle credit for stop/start technology. S/S is a necessary technology for qualification for Mild and Strong HEV under the full-size pick-up credits. Valued at 4.5 g/mi for trucks.

6 VW notes that not only are full-size trucks qualified for the 'game-changing' credits, but also qualify for higher credits under the A/C and off-cycle programs. This further compounds the inequity.

7 An immediate example of 'game changing' technology may be the introduction by Cadillac of the electric starter which opened up vehicle operation and ownership to people regardless of physical strength and free from the fear of injury.

Response:

Comments For and Against the Credit Program

Most of the commenters supported the large truck credit concept. ICCT, Volkswagen, and CBD opposed adopting the proposed incentive, arguing that this vehicle segment is not especially challenged by the proposed standards, that hybrid systems would readily transfer to it from other vehicle classes, and that the credit essentially amounts to an economic advantage for manufacturers of large trucks. CBD also commented that this credit should not be adopted, since they believe hybrid technology should be forced by aggressive standards rather than encouraged through regulatory incentives. Some environmental organizations also expressed concern about the real-world impacts of offering this credit, and suggested various ways to tailor it to ensure that fuel savings and emissions reductions associated with it are genuine.

Arguments made by commenters for not adopting the large truck technology credit are not convincing. Although there may not be inherent reasons for a lack of hybrid technology migration to large trucks, it is clear that this migration has nevertheless been slow to materialize for practical/economic reasons, including in-use duty demands and customer expectations. These issues still need to be addressed by the designers of large pickups to successfully introduce these technologies in these trucks, and we believe that assistance in the form of a focused, well-defined incentive program is warranted.

CBD expressed concern about how well the credits correspond to the actual improvements obtained. As in past EPA incentive programs aimed at encouraging advanced technology several years into the future, this is very difficult to assess quantitatively ahead of time. We discuss the value of incentive programs such as this one in response to comments regarding “level playing field” and short-term vs. long-term benefits of incentives in section 2 of this document, and in response to comments regarding the value of temporary regulatory incentives in section 4 of this document. We note too that, beyond its value in encouraging advanced technology in the full-size pickup truck sector, this credit program has added potential benefits because of the possibility of migrating the technology to even larger trucks. (See the heavy-duty vehicle GHG final rule for discussion of incentives to encourage the introduction of hybrid heavy-duty trucks—76 FR 57106, September 15, 2011.) The concerns expressed by Volkswagen and ICCT that the pool of credits generated by hybrid trucks will be excessive, and may result in an overall CO2 disbenefit and significant delay in technology introduction to other sectors, also seem unwarranted. The relatively small size of the full-size truck fleet compared to the rest of the light-duty sector, combined with our criteria for qualifying for the credits, limits the likelihood of a flood of market-shifting credits into the lighter vehicle sectors. Obviously, manufacturers who do not make full-size trucks will not be able to earn credits, but we believe the controls we are exercising in implementing the program (minimum production thresholds, truck definitions, limited model years, and performance criteria, etc.) serve to carefully target the incentives without creating undue advantages.

Our targeting this incentive program to full-size trucks is based on the challenge of applying the advanced technologies to them. As evidence that this challenge is substantial, we point to the fact that two companies ranking among the leaders in automotive hybrid technology, Ford and Toyota, have found it helpful to team up and work jointly on developing truck and

SUV hybrid technology over a multi-year span.[13] We also highlight Chrysler's comments that a major part of the challenge is applying advanced technologies in a way that preserves a truck's utility and accounts for added costs (as considered in the feasibility analysis for this rulemaking), both of which are critical for purchaser acceptance. The acceptance issues are especially important for large truck hybrids because the smaller engines that facilitate much of a hybrid's benefit are typically at odds with the importance some pickup truck buyers place on engine horsepower and torque, whatever the vehicle's real performance.

The U.S. Coalition for Advanced Diesel Cars questioned the granting of credits for hybrid technology, relying as it does on stop-start and regenerative braking technologies, in light of the lack of data on full-size pickup truck driving patterns. We agree that driving pattern data specifically for these large trucks are not plentiful, but do not agree with the implication that the trucks are driven extensively without sufficient braking and stopping activity so as not to warrant application of hybrid technology (and by extension that the credit would not reflect real-world environmental benefit). For example, many of these trucks are owned by urban and suburban small businesses engaged in construction, home maintenance, lawncare and the like, with daily travel activities involving frequent slowing and stopping. Full-size truck use on farms would also involve non-highway patterns requiring substantial braking. Furthermore, should hybrid technology, added at considerable cost, not yield real-world fuel consumption benefits for purchasers, it is doubtful that manufacturers would pursue it simply to gain credits.

By way of clarification prompted by the Coalition's comments, both the hybrid and performance-based credits are equally available for vehicles of all fuel types, including diesel. The Coalition also expressed concern that the program does nothing to discourage a "horsepower war" among the full-size truck manufacturers, exacerbated by the need for the trucks to carry the added weight of battery packs. In response we note that the standards remain on a gram per mile basis, so any future increases in horsepower for reasons related to curb weight or marketing will not make it easier to comply under our program— the footprint-based standard applies without regard to horsepower, and likewise the credit amount does not depend on horsepower.

Definition for Large Pickup Trucks and Extension of Credits to Smaller Vehicles

Some OEM commenters argued that these credits should be extended to other vehicles such as SUVs and minivans. We believe that doing so would greatly expand, and therefore dilute, the intended credit focus. The agencies do not believe it is necessary to provide such incentives for application of hybrid technology in these additional categories, beyond what is appropriate to account for off-cycle performance, or that the performance levels required of non-hybrid technologies eligible for credits are of such stringency that extending credits to all or most light-duty trucks would amount to anything more than a de facto lowering of overall program stringency. Although commenters rightly pointed out that some of these non-truck vehicles do have substantial towing capacity, most of them are not much used as towing vehicles, in contrast

[13] "Ford, Toyota to Collaborate on Developing New Hybrid System for Light Trucks, SUVs; Future Telematics Standards", http://toyotanewsroom.com/releases/ford+toyota+hybrid+trucks+suvs+telematics.htm, August 22, 2011.

to full-size pickup trucks that often serve as work vehicles.[14] Moreover, the smaller footprint vehicles fall on the lower part of the light-duty truck curve, and so have a higher rate of improvement (in stringency) than the larger trucks, thus making them more comparable to cars in terms of technology access and effectiveness. See preamble section III.D.7.

Mercedes-Benz suggested that the small car market (vehicles with footprints of 40 square feet or less) is also challenging for hybrid technology, for reasons of cost and architecture, and deserving of similar credit opportunities. Our expectation is that the primary barrier to hybrids in this market, the cost of hybrid technology compared to typical vehicle prices, is likely to diminish as battery costs decline over time. We do not believe that extension of the full-size truck credit program into this small car sector would be especially helpful in this regard. This differs from the large truck challenge where others factors such as preserving utility for work applications and purchaser acceptance are also key.

EPA sought comment on extending the pickup truck credits to smaller pickup trucks, specifically to those with narrower beds, down to 42 inches, but still with towing capability comparable to large trucks. This request for comment produced mixed reactions among truck manufacturers, and some argued that EPA should go further and drop the bed size limit entirely. ICCT and CBD strongly opposed any extension of the provision's scope to smaller bed trucks, arguing that adopting the 42" bed width criterion would allow virtually all pickup trucks to qualify, thereby distorting technology requirements and reducing the benefits of the rule. Beyond a general expression of support, there were no detailed comments backing the narrower bed width limit.

Chrysler commented that the proposed payload and towing capability minimums are too restrictive, making a sizeable number of Ram 1500 configurations ineligible to earn credits. However, the company provided no sales information to enable the agencies to reassess this issue. Moreover, the agencies did not premise the proposed incentive on every full-size truck configuration being eligible. Manufacturers typically offer a variety of truck options to suit varied customer needs in the work and recreational truck markets, and the fact that one manufacturer (or more) markets to applications lacking the towing and payload demands of the core group of vehicles in this segment does not, in the agencies' view, justify a revision of the hauling requirements that were a fundamental consideration in establishing the credit.

Definitions for Strong and Mild Hybrids

EPA received a number of manufacturer comments on these proposed definitions. Some industry commenters objected to EPA's characterization of the credit provisions as applying to hybrid "gasoline-electric" vehicles. We agree that this would be an overly narrow characterization, and are clarifying that the provisions also apply to non-gasoline (including diesel-, ethanol-, and CNG-fueled) hybrids. However, further extension to hybrids employing non-electric battery storage (including hydraulic-, capacitive-, and mechanical-energy storage), as urged by commenters such as EcoMotors, is complicated by the difficulty in developing regulatory procedures for all conceivable energy-storage media. We believe that these

[14] The 2011 segmentation and trend information provided in Ford's written comments demonstrates the ongoing trend toward greater use of full-size trucks for work purposes.

technologies are not hampered in participating in the large truck credit program because manufacturers using these technologies can utilize the alternative, performance-based pathway to gain the credits (assuming significant emissions reductions).

Ford, Toyota, and the Alliance of Automobile Manufacturers suggested improvements to the proposed procedure for determining whether hybrid technology is categorized as strong, mild, or having energy recovery too minimal to warrant credits. Most importantly, they argued that the proposed approach improperly integrated energy contributions over the entire city cycle FTP, thereby capturing more than just the intended recovered braking energy and creating an opportunity for gaming through tailoring of the direct addition of energy from the engine. They offered alternative procedures and corresponding recovered energy threshold levels based on energy input only during decelerations, with the recovery efficiency cutpoint between strong and mild hybrids correspondingly reduced from 75% to 40%. Chrysler maintained that a 75% energy recovery rate would be challenging for large pickups, even using the proposed procedure, because of the need to design the braking system for maximum payload and trailer capability while maintaining drivability in the absence of loads. Chrysler's specific recommendation was for a cutpoint of 50% energy recovery rate. Ford and Toyota also suggested an additional metric for qualifying strong HEVs – that at least 10% of the total tractive energy during positive accelerations on the FTP must be from the electric drive with the engine off.

As discussed in detail in section 5.3.3 of the TSD, we have evaluated these concerns and the suggested changes and have concluded that the proposed metric remains adequate for our purposes, and furthermore has the advantage of being simpler and easier to measure than other metrics. However, based on the comments received from Chrysler and follow-up testing described in section 5.3.3 of the TSD, showing that the only large hybrid truck currently marketed would not satisfy the proposed 75% metric, we believe that 65% is a more appropriate threshold for defining strong hybrid energy recovery, and so are adopting this threshold in the final regulations. We are retaining the proposed 15% threshold for mild hybrid energy recovery; we received no comments opposing this threshold.

Other commenters suggested dropping the hybrid-specific metric altogether, in favor of a CO2 performance-based metric instead, effectively removing the hybrid-specific credit. We favor retaining the hybrid-specific metric in addition to the more general performance-based credit option, because it more directly focuses the performance demonstration on the degree of hybrid technology utilization (a known technology with clear promise), while still making room for other technologies, including any innovations still beyond the horizon, through the performance-based credit option. In response to the Diesel Coalition's comments, the efficiency gains (which correspond to reductions in CO2 and fuel consumption) from hybrid vehicles are discussed in section 3.3.3 of the Joint TSD.

Ford, Toyota, and the Alliance of Automobile Manufacturers also recommended a number of edits and technical changes to the proposed hybrid procedures and equations: clarification of plus and minus current flows, dropping of incorrect use of battery state of charge, corrected references to other regulation paragraphs, spelling corrections, correction of conflicting nomenclature and units, and use of measured rather than scheduled speed traces. These changes are reflected in Section 5.3.3 of the Joint TSD and in the final regulatory text. Also, in response to comments requesting clarification of how nominal voltage is determined, we are defining nominal voltage as described in section 5.3.3 of the Joint TSD.

Volkswagen is correct that use of stop-start technology has significance under both the off-cycle and full-size truck credit provisions. However, each of these credit programs has its own additional criteria that must be met (such as proof of off-cycle performance, minimum hybrid sales thresholds, and demonstration of hybrid regenerative braking performance). Furthermore, the inclusion of stop-start capability in the hybrid pickup truck definition is intended to help distinguish what is and is not a hybrid. In this broad context it is not meant to be viewed in isolation, as though it justified a portion of the full-size pickup truck credit all by itself and could thereby be construed as double-counted. In fact, of the criteria for qualifying as a hybrid, it is of lesser importance than the recovered energy threshold. This contrasts with the focus of the off-cycle credit for stop-start technology which does not consider energy recovery and usage. Volkswagen also expressed the view that simply introducing regenerative braking on open bed trucks does not comprise a leap forward in automotive technology worthy of credits. We have taken care to adopt meaningful and verifiable criteria for hybrid performance, truck size, and market penetration, to ensure that the credits earned are justified by the technical and marketing challenges involved rather than a superficial offering of a niche product claiming to use hybrid technology.

We disagree with MEMA's view that the credit program's definitions of mild and strong hybrids are too dependent on hybrid architecture. We proposed and are adopting definitions that are not specific to hybrid architecture, and are intentionally kept as simple and technology-neutral as reasonably possible. More broadly, a number of commenters contended that our proposed hybrid credit program effectively amounted to picking technology or fuel-type "winners and losers". We believe that the above-discussed clarification regarding inclusion of non-gasoline hybrids, as well as the inclusion of the two performance-based credit options (with identical credit amounts as the hybrid provisions), delivers a program that is fundamentally fuel- and technology-neutral. We note in response to comments from the natural gas industry in particular that, in addition to the natural gas vehicle multiplier, full-size natural gas pickup trucks are eligible for both the hybrid and performance-based credits in the same way that gasoline vehicles are.

Minimum Market Penetration Thresholds

EPA received comments from NRDC in support of the proposed minimum penetration thresholds. Adverse comments came primarily from manufacturers arguing that the thresholds should be reduced or eliminated. These commenters felt that the requirements run counter to the agencies' goal of creating incentives for technology introduction, because they add uncertainty over whether the investment in a technology, a commitment that is made years ahead of time, will reap the credits if sales fall short of the minimum in a model year. These commenters also noted that new technologies are often phased in at rates lower than the proposed minimum penetration rates in order to gauge consumer interest and acceptance. GM specifically objected to the proposed rapid ramp up of the mild hybrid penetration rate as not being aligned with historic rates of customer acceptance of new and/or advanced technologies. GM requested that the levels be instead cut in half to match those proposed for the "15 percent better" performance-based credits.

Our reason for setting ambitious market penetration thresholds remains-- our goal is to create an incentive for manufacturers to commit to the large-scale application of hybrids and other advanced technologies in the challenging large truck sector and specifically that at least mild hybrid or comparable technology becomes a standard technology feature for large pickup trucks. Eliminating or greatly tempering the minimum penetration requirements might retain the incentive for niche applications but would lose any assurance of widespread "game-changing" technology introduction and substantial penetration. We do agree with comments that the ambitious penetration levels proposed for mild hybrid credits in the initial model years may be counter-productive, as launching a complex new technology on almost a third of first-year sales could be a risky business strategy in this highly competitive large truck market segment. As a result, we are scaling this requirement back to 20 and 30% in model years 2017 and 2018 (compared to the proposed levels of 30 and 40% in MY 2017 and 2018, respectively), to help facilitate the smooth introduction of mild hybrid technology. However, we are retaining the substantial penetration requirements that were proposed for later model years to maintain our focus on encouraging this technology to be more or less standard on large trucks. We note that a manufacturer that is unable to meet these penetration requirements may continue to generate credits through the 2021 model year for mild hybrid trucks under the performance-based credit option, assuming the less aggressive penetration threshold requirements for the performance-based credit provision are satisfied.

Concerns that consumer acceptance uncertainty existing today makes it challenging for manufacturers to plan for the sales ramp-ups required under the thresholds are reasonable, but the large ramp-ups are only required for the less risky credit options – mild hybrid and 15% performance improvement – and we feel that such widespread penetration of these more modest technologies is far from out of reach in this timeframe. The issue also tends to be self-limiting; that is, even if we were to entirely drop the thresholds, marginal sales would yield only marginal credit production and thereby make the credit program inconsequential for a manufacturer.

Toyota's view that *maximum* sales thresholds are more appropriate than minimum sales thresholds because credits are not warranted once a technology has largely phased in is, we believe, better addressed through the limiting of credit availability to certain model years, and to a shorter period (through MY 2021) for the less challenging credit options.

Credit Fungibility and Available Model Years

Volkswagen commented that any HEV or performance-based credits generated by large trucks should not be transferable to other vehicle segments, arguing that if compliance for the large truck segment is really as challenging as predicted, there should be no excess of credits to transfer anyway. This may be the case, but we do not agree that it argues for restricting the use of large pickup truck credits. We think the sizeable technology hurdle involved and the limited model years in which credits are available preclude the potential for credit windfalls. Furthermore, neither the size of the large truck market nor the level of the per-vehicle credit are so substantial that they could lead to a large pool of credits capable of skewing the competition in the lighter vehicle market. As described in Preamble Section III.D, EPA will continue to monitor the net level of credit transfers from cars to trucks and vice versa in the MYs 2017-2025 timeframe.

ICCT opposed allowing vehicle models that earn performance-based credits in one year to continue receiving them in subsequent years as the increasingly more stringent standards progressively diminish the vehicle's performance margin compared to the standard. We view the incentive over the longer term, as a multi-year package, intending it to encourage investment in lasting technology shifts. The fact that it is somewhat easier to exceed performance targets by 15 or 20% in the earlier years, when the bar is set lower, and, once earned, to retain that benefit for a fixed number of years (provided sales remain strong), works to focus the credit as intended—on creating an incentive for the introduction of new technology as early in the program as possible. The mild hybrid credit is available only through MY 2021 because the penetration threshold is high enough by then (80%) to essentially constitute fleetwide application of the technology.

VNG questioned the 5-year limit on availability of the 20 g/mi performance-based credit, given that the corresponding strong hybrid credit has no such limit. The 5-year limit is intended to deal with the general nature of the performance-based credit, which does not involve any requirement to identify what technology package is being applied to earn the credit. The vehicle design may evolve somewhat in this 5-year period (corresponding to a typical redesign cycle) without voiding the credit, unless CO_2 emissions increase. A major vehicle redesign triggers eligibility for a new 5-year eligibility period (but not past the 2025 model year). No such artificial construct is needed in the case of hybrids, as the "game changing" technology being introduced (hybrid-electric) is clear.

We agree with MEMA that, although full-size pickup truck technology credits are not available in model years 2014-2016, credit for "early compliance" is provided in that these pickups can still generate credits like any other vehicle in model years 2014-2016, and these credits can be carried forward and used in later model years.

6. GHG Emissions Compliance Treatment of Plug-In Hybrid Electric, Compressed Natural Gas, Ethanol, Diesel, and Other Alternative Fueled Vehicles, and CAFE Issues

Introduction

EPA received a very large set of comments with respect to issues associated with the compliance treatment for vehicles that can run on fuels other than gasoline. Section 4 addresses those comments that primarily focus on specific issues associated with GHG emissions incentives for EVs, PHEVs, and FCVs. This section addresses those comments that primarily relate to the use of utility factors for PHEVs, as well as all comments that primarily focus on compressed natural gas, ethanol, diesel, and other alternative fuels. In this section, the comments are divided into five sub-sections: PHEVs (6.1), CNG (6.2), ethanol (6.3), diesel (6.4), and other alternative fuels and miscellaneous comments (6.5). In addition, there is a sixth sub-section (6.6) that contains no unique comments, but which addresses issues that are relevant to multiple fuels, including CAFE issues (issues discussed here are often included in comments throughout the rest of this section). Many comments raise issues relevant to multiple sub-sections of this section as well as to Section 4, so readers interested in a comprehensive treatment of comments on alternative fuel vehicles should read the comments and responses in both sections, as well as the relevant preamble discussions. In addition, comments related to gasoline fuel quality in general, and to ethanol/gasoline blends in particular, are addressed in Section 11.

6.1. Plug-In Electric Vehicles

Organizations Included in this Section

American Council for an Energy-Efficient Economy (ACEEE)
American Petroleum Institute (API)
Electric Drive Transportation Association (EDTA)
Fisker Automotive, Inc.
Motor & Equipment Manufacturers Association (MEMA)

Organization: American Council for an Energy-Efficient Economy (ACEEE)

For PHEVs, EPA proposes to use cycle-specific utility factors (UFs) for determining electricity use (NPRM p.75018), which we support. EPA also references the fuel economy and environmental labeling rule in this context, which raises questions about the details of the approach. First, an important step in calculating realistic UFs is applying the shortfall correction to the fuel economy test values, or more specifically the miles traveled in charge depleting mode. While this is part of the calculation used for labeling purposes, EPA does not indicate in the NPRM that any such adjustment is to be made for purposes of the fuel economy and GHG emissions rule. While we understand that the EPA does not contemplate switching to “real-world" emissions rates for purposes of this rule, failure to adjust charge-depleting range will lead to utility factors that are far too high. Also, while the labeling rule uses Multi-Day Individual Utility Factors (MDIUFs), this rule should instead use the lower Fleet UFs, which will better capture the expected use of petroleum by the fleet of PHEVs. Information on the values of the UFs used to evaluate the performance of each PHEV model under the rule should be publically available. EPA-HQ-OAR-2010-0799-9528-A2, p.9]

EPA proposes a lower bound of 10.2 miles for the "all-electric range" of a PHEV to receive the special treatment accorded to EVs (for electric operation only). While we do not object to this proposal, we believe that, to be treated as an FFV for CAFE purposes prior to 2020, this range is not sufficient. A PHEV with an all-electric range of 10 miles has a UF of under 25 percent, yet would be treated for CAFE purposes as if it were driven half of the time on electricity. Moreover, CAFE credits generated by PHEV FFVs, unlike those generated by FFVs of other types, are not capped. Hence PHEVs should only be treated as FFVs if they can be expected to drive half the time on electricity. On the other hand, PHEVs that drive more than half the time on electricity would be disadvantaged by their treatment as FFVs. This problems would best be solved by advancing the use of UFs to determine the fuel economy of PHEVs to MY2017. EPA-HQ-OAR-2010-0799-9528-A2, p.9]

Organization: American Petroleum Institute (API)

Comments on the Proposed Approach to Measure Compliance with Fuel Economy and GHG Standards for Dual-Fuel CNG vehicles

EPA and NHTSA note that the statutory incentive for dual-fueled vehicles in 49 U.S.C 32906 and the measurement methodology specified in 49 U.S.C 32905 (b) and (d) expire in MY 2019 and request comment on proposed options going forward. The agencies are proposing to directly extend the PHEV utility factor methodology to dual-fuel CNG vehicles, using the same assumptions about daily refueling. Under the utility factor approach, the vehicle range on the alternative fuel would be used to estimate the fraction of average daily travel that the range represents based on SAE Standard J2841. For example, a plug-in hybrid electric vehicle (PHEV) with an all-electric range of 40 miles would be assigned a utility factor of 0.617, while a dual-fuel natural gas vehicle (NGV) with a range on natural gas of 150 miles would be assigned a utility factor of 0.925. [EPA-HQ-OAR-2010-0799-9469-A1, p. 7]

We have several concerns with this proposed approach. First, it relies on the implicit assumption that the driving behavior of owners/operators of PHEVs is identical to that of owners/operators of dual-fuel CNG vehicles; an assumption which we do not believe is (or has been) demonstrably supported by any underlying data, yet should be. (A related question is whether the driving behavior and vehicle use characteristics of that element of the population sometimes termed "early technology adopters" is similar to, or different than, the "national average" database of travel characteristics from which the Utility Factors were created.)13 Second, although the use of the utility factor is an improvement over the simple 50/50 split used previously, this approach inherently assumes that the vehicle begins each day with a full state of charge (PHEVs) or a full natural gas tank (NGVs). It is unclear that this will occur in practice, and it may significantly overestimate the calculated benefits of the alternative fuel. Additionally, the vehicle range on the alternative fuel is established based on 2-cycle testing (i.e., the FTP and the highway fuel economy test) that is used to determine compliance with the CAFE and GHG standards. This clearly overestimates the range on the alternative fuel, and the proposed rule should be revised to reflect real-world vehicle range based on 5-cycle test results or other data that better represent real-world performance. This is not at all inconsistent with the use of 2-cycle tests for CAFE and GHG emissions compliance, as the real-world range would only be used to establish the appropriate utility factor, which, in turn, was based on real-world driving statistics. [EPA-HQ-OAR-2010-0799-9469-A1, pp. 6-7]

Organization: Electric Drive Transportation Association (EDTA)

4. Use of SAE J2841 to Determine Utility Factor for PHEVs

EPA is proposing to use the utility factor methodology developed by the Society of Automotive Engineers (SAE) in the publication SAE J2841, “Utility Factor Definitions for Plug-In Hybrid Electric Vehicles Using Travel Survey Data”(Sept. 2010). EPA first adopted SAE J2841 in its July 2011 final rule on vehicle labeling requirements. [EPA-HQ-OAR-2010-0799-9449-A1, p. 7]

EDTA recognizes the need for a utility factor as a means of estimating the portion of the driving cycle that involves electric-only operation. EDTA supports using the utility factor methodology adopted by the SAE in the publication J2841. EDTA also supports use of a unique utility factor for each vehicle model, taking into account the characteristics of the vehicle and the expecting operating and charging behavior of the users of that type of vehicle. [EPA-HQ-OAR-2010-0799-9449-A1, p. 7]

EDTA urges EPA to ensure that each manufacturer is given an appropriate opportunity to provide input into the development of the utility factor for that manufacturer’s PHEV models, including notice of the proposed utility factor and an opportunity to submit comments prior to final adoption of that utility factor. [EPA-HQ-OAR-2010-0799-9449-A1, p. 7]

Organization: Fisker Automotive, Inc.

Support the continued use of the utility factor (UF) approach in calculating GHGs and support the adoption of this approach for CAFE calculation as proposed

Fisker believes the utility factor approach is a fair means of weighting the fraction of driving performed in electric and gasoline modes. We believe this approach is based on a more robust set of assumptions than the current 50-50 weighting in the dual-fuel vehicle approach used currently by CAFE standards, so we encourage the application of the utility factor to CAFE standards as soon as possible. [EPA-HQ-OAR-2010-0799-9266-A1, p. 5]

Organization: Motor & Equipment Manufacturers Association (MEMA)

On Page 75018, Col. 2 of the NPRM, “Based on this utility factor approach, EPA calculates the GHG emissions compliance value for an individual PHEV as the sum of (1) the GHG emissions value for electric operation … multiplied by the utility factor, and (2) the tailpipe CO_2 emissions value on gasoline multiplied by (1 minus the utility factor).” Please confirm in the final rule that where a PHEV has a diesel engine, that the calculation would also apply to diesel. In other words, it is not just limited to gasoline. If that is indeed the case, the agencies should consider revising that to read “gasoline/diesel.” (Please refer to Section VIII.C. for explanation.) [EPA-HQ-OAR-2010-0799-9478-A1, p.12]

Response:

Issues related to incentives for PHEVs are discussed in Section 4. This sub-section addresses issues related to EPA’s adoption of utility factors to weight electricity and gasoline GHG emissions in PHEV compliance calculations.

See Preamble Section III.C.4.a.i for a discussion of why the Agency is adopting the cycle-specific fleet-based utility factors as developed by the Society of Automotive Engineers (SAE). Commenters raised a few additional issues that were not addressed in Preamble Section III.C.4.a.i.

ACEEE and API suggested that PHEV utility factors should be based on 5-cycle range rather than 2-cycle range. EPA agrees that this would be a reasonable approach, but EPA is retaining the 2-cycle basis at this time because the limited real-world data on electricity and gasoline operation from the Chevrolet Volt suggests that the utility factors based on 2-cycle range appear to be closer to the real world experience than lower utility factors based on 5-cycle range. Range is just one of many assumptions involved in the utility factor methodology, and EPA commits to monitoring real world data from PHEV operation to evaluate the overall appropriateness of the SAE utility factors based on 2-cycle range.

EDTA suggested a notice and opportunity process for EPA calculation of PHEV utility factors. While EPA believes it is neither necessary nor efficient to implement a formal notice and opportunity process, EPA does commit to working closely with manufacturers to explain how we apply the utility factor regulations to individual vehicles.

Finally, in response to the MEMA comment, EPA will develop GHG emissions compliance values for all PHEVs the same way, regardless of whether the PHEV internal combustion engine operates on gasoline, diesel, or any other fuel.

6.2. Compressed Natural Gas Vehicles

Dual-Fuel CNG and LPG Gasoline Vehicles [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

CNG and LPG vehicles are another option that our country has to diversify the vehicle fleet and use a domestically available energy source. The Alliance supports the development of a utility factor approach very similar to the SAE standard mentioned above for PHEVs. The Alliance is also in favor of the option to allow manufacturers to use the proposed utility factor-based methodology as a “pull-ahead” option for MYs 2012-2015. [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

Based on the added cost of the vehicle technology and the cost advantage of using CNG and LPG fuel relative to gasoline, customers that purchase a dual-fuel CNG or LPG vehicle will, to the extent possible, use the intended alternative fuel. [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

Many companies may leverage global designs in developing dual-fuel CNG and LPG vehicles for the U.S. market. It is important that the variety of global design features available be allowed into the U.S. market. Rather than making specific design requirements in the rules, a better approach would be have these design features be factors in the calculation of the CNG and LPG utility factors. The Alliance would like to propose a work group to discuss the constraints mentioned in the NPRM for dual-fuel CNG and LPG vehicles. [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

In the NPRM, EPA specifically requested comments on the merits of providing sales multiplier (similar to the EV/PHEV incentives) for dedicated and/or dual-fuel compressed natural gas vehicles. The Alliance believes CNG and LPG technology also deserve multipliers. [EPA-HQ-OAR-2010-0799-9487-A1, p.69]

Organization: America's Natural Gas Alliance (ANGA) and American Gas Association (AGA)

I. NATURAL GAS VEHICLES FULFILL EACH OF THE GOALS OF THIS PROGRAM

The Presidential Memorandum calling for this program stated that its goals were “to improve fuel efficiency and to reduce greenhouse gas emissions of passenger cars and light-duty trucks of model years 2017–2025’’, and thus take advantage of an “opportunity to lead the world in the development of a new generation of clean cars and trucks through innovative technologies and manufacturing that will spur economic growth and create high-quality domestic jobs, enhance our energy security, and improve our environment.’’ Presidential Memorandum Regarding Fuel Efficiency Standards, May 21, 2010, as cited in 76 FR 74862. [EPA-HQ-OAR-2010-0799-9548-A1, p. 2]

Cognizant of this opportunity, EPA and NHTSA throughout the Light Duty Rule emphasize the importance of the economic impact of these regulations, noting, e.g., that they will “achieve important reductions in GHG emissions and fuel consumption from the light duty vehicle part of the transportation sector, based on technologies that either are commercially available or that the agencies project will be commercially available in the rulemaking timeframe and that can be incorporated at a reasonable cost.” 76 FR 74858. See also id. at 74859-60 (same); id. at 74962 (“This proposal provides important benefits to society and consumers in the form of reduced emissions of greenhouse gases (GHGs), reduced consumption of oil, and fuel savings for consumers, all at reasonable costs.”) Indeed, the agencies estimate that the benefits of this program outweigh the costs by hundreds of billions of dollars. Id. at 74890. [EPA-HQ-OAR-2010-0799-9548-A1, p. 2]

By requesting comment on incentives for natural gas vehicles (“NGVs”) (discussed more fully in Section II, below), the agencies seem to acknowledge that NGVs can meet the goals of reducing both GHG emissions and increasing use of alternatives, in addition to reduced emissions of criteria pollutants, while also serving to “spur economic growth” and “create high-quality domestic jobs” as the President called for. In fact, in his January 24, 2012 State of the Union address, the President repeatedly invoked both the environmental and economic advantages of domestic natural gas, e.g., “The development of natural gas will create jobs and power trucks and factories that are cleaner and cheaper, proving that we don’t have to choose between our environment and our economy.” [Section II can be found on p. 6 of Docket number EPA-HQ-OAR-2010-0799-9548-A1] [EPA-HQ-OAR-2010-0799-9548-A1, p. 2]

What the agencies may not have recognized is that NGVs are, in fact, both the single most cost-effective means of achieving these goals in the transportation sector and, if encouraged, will create more jobs and economic growth than any other proposed solution. [EPA-HQ-OAR-2010-0799-9548-A1, p. 2]

A. Natural Gas Vehicles Will Strengthen the U.S. Economy by Utilizing More Domestically Produced Resources and Creating Domestic Jobs

Increasing use of domestically produced natural gas is essential to help reduce U.S. dependence on foreign sources of energy from geopolitically unstable regions of the world. Despite 35 years of rising imports and the agencies' admission that "the need to reduce energy consumption is more crucial today than it was when the Energy Policy and Conservation Act was enacted in the mid-1970s" (Interim Joint Technical Assessment Report, "JTAR", p. 1-1), the Light Duty Rule continues to emphasize a policy of incremental improvements in fuel economy. Ignoring a domestically-produced transportation fuel in favor of marginal gains in petroleum fuel economy is a shortsighted energy security policy. As the U.S. Energy Information Agency points out, in 2035 the U.S. is still expected to import 16.71 QBtus of oil, down only 17% from the 20.14 QBtus imported in 2010. EIA, AEO 2012 Early Release Summary, Table AI, attached as Exhibit 1. Reducing imports by less than 1% a year is too little, too late. [EPA-HQ-OAR-2010-0799-9548-A1, p. 3]

These are the facts, and that means that fuel switching is the only realistic pathway to energy security. Each NGV totally displaces a gasoline vehicle's lifetime need for petroleum, and as the agencies acknowledge, "each gallon of fuel saved as a consequence of the GHG and fuel efficiency standards is anticipated to reduce total U.S. imports of petroleum by 0.95 gallon." 76 FR at 75135. And the most abundant, efficient and secure replacement fuel is natural gas. The U.S. and Canada supply 99% of U.S. natural gas demand, and U.S. gas reserves are growing. [EPA-HQ-OAR-2010-0799-9548-A1, p. 3]

U.S. Natural Gas Supplies

The U.S. has enormous natural gas supplies; as the President correctly pointed out in his State of the Union Address, "We have a supply of natural gas that can last America nearly 100 years." Indeed, multiple experts agree, the U.S. has enough natural gas to meet growing demand for generations to come.[1] [EPA-HQ-OAR-2010-0799-9548-A1, p. 3]

In its 2009 Report addressing the supply of technically recoverable natural gas in the United States, the Potential Gas Committee reported that the currently available total supply of natural gas was 1,836 trillion cubic feet ("Tcf"), which represented an increase of 39% (516 Tcf) over the Committee's year end estimate for 2006. Potential Gas Committee, Potential Supply of Natural Gas in the United States (December 31, 2008) (June, 2009). [EPA-HQ-OAR-2010-0799-9548-A1, p. 3]

The Potential Gas Committee is not alone in its estimates. MIT's Future of Natural Gas (Interim Report) also reviewed U.S. gas resource estimates from several sources, including the Potential Gas Committee, and assumed a mean remaining resource base of approximately 2,100 Tcf. Id., p. 9. This means that at current levels of consumption the U.S. has more than enough domestic natural gas to fuel the light-duty fleet. [EPA-HQ-OAR-2010-0799-9548-A1, p. 4]

The Economic Advantages of Natural Gas as a Transportation Fuel

Increasing our reliance on domestically produced sources of energy such as natural gas helps increase more than US energy security – it benefits our economy as well. According to the Department of Commerce, the U.S. trade deficit for 2011 was $558 billion, during which time the U.S. imported $432 billion of foreign petroleum. U.S International Trade Statistics, attached as Exhibit 2. [EPA-HQ-OAR-2010-0799-9548-A1, p. 4]

In contrast, producing and distributing natural gas as a transportation fuel means keeping this money at home and creating American jobs. In 2008, U.S. production of 20 Tcf of natural gas created more than 1.3 million jobs, and even a modest increase in demand for natural gas as a transportation fuel could create tens of thousands of additional jobs. "The Contributions of The Natural Gas Industry to the U.S. National and State Economies", IHS Global Insight, 2009, p.1, attached as Exhibit 3. The rapid growth in shale gas alone supported 600,000 jobs in 2010, a number expected to grow to nearly 870,000 in 2015. IHS Global Insight 2011, p. 1, attached as Exhibit 4. A significant push to increase NGVs in the U.S. also would create thousands of additional jobs related to manufacturing natural gas vehicles and building the relevant infrastructure. [EPA-HQ-OAR-2010-0799-9548-A1, p. 4]

Finally, we note that natural gas vehicles are just as available as natural gas itself. There are more than 12 million NGVs on the road worldwide, and a recent report forecast 28 million NGVs by 2015 (Global Industry Analysts, Inc.). Outside the U.S., NGVs are made by, among others, Ford, GM, Toyota, Honda, Nissan, Hyundai, Fiat, Volkswagen and Mercedes. Demand for U.S. NGVs would thus give domestic manufacturers a base upon which to build an export market. And another economic opportunity exists in converting existing petroleum vehicles to run on natural gas, yet another well-established technology that can further job creation here at home. [EPA-HQ-OAR-2010-0799-9548-A1, p. 4]

In sum, the only way to fulfill the statutory mandate of reducing U.S. dependence on foreign sources of energy is by beginning to move the U.S. light-duty vehicle fleet to natural gas as a complement to other advanced technology and alternative fuel vehicles, a policy which will also significantly assist the U.S. economy. [EPA-HQ-OAR-2010-0799-9548-A1, p. 4]

B. NGVs are the Most Cost-Effective Means of Reducing Light-Duty GHG Emissions [EPA-HQ-OAR-2010-0799-9548-A1, p. 4]

Each NGV not only utilizes a domestic alternative fuel source, but also has inherently lower GHG emissions. On a lifecycle basis (accounting for upstream emissions), NGVs have 30% lower GHG emissions than their gasoline-powered counterparts. California Energy Commission, Full Fuel Cycle Assessment, p. 30, attached as Exhibit 5. Apropos of lifecycle emissions, AGA and ANGA agree with EPA's position that full lifecycle accounting is necessary for determining both actual emissions reductions and vehicle compliance. 76 FR 75011. [EPA-HQ-OAR-2010-0799-9548-A1, pp. 4-5]

Moreover, natural gas is getting even cleaner, as renewable natural gas (biomethane from landfills and other sources) comes on line. Biomethane achieves nearly a 90 percent reduction in GHGs compared to gasoline, and U.S. biomethane production is increasing, with DOE's National Renewable Energy Laboratory estimating future production of up to 16 billion gasoline gallons equivalent. 74 FR 24982. [EPA-HQ-OAR-2010-0799-9548-A1, p. 5]

Not only will natural gas continue to reduce its GHG emissions, but the efficiency of natural gas vehicles will also continue to improve as the result of technological advances. In fact, NGVs will benefit equally from the very same technological advances the agencies say are available for gasoline vehicles to meet the proposed standards. The vast majority of these improvements, whether “vehicle technology”, “transmission technology”, “engine technology” or “vehicle electrification” can be used on NGVs to further lower their GHG emissions. Mass and drag reduction, low-friction lubricants, cylinder deactivation, variable valve timing, continuous variable transmissions, hybridization, etc., will have the exact same effect of reducing fuel consumption for NGVs as they do for petroleum ones. [EPA-HQ-OAR-2010-0799-9548-A1, p. 5]

Moreover, NGVs are not subject to the trade-off between greater fuel economy and lower safety considerations imposed by light-weighting or down-sizing vehicles. Of note, the JTAR presents mass reduction as the single largest component for increasing petroleum fuel economy and reducing GHG emissions (J-TAR Chapter 6, passim.) but at the same time admits that “the agencies believe that the effects of vehicle mass reduction on safety should be evaluated from a societal perspective (including an analysis of fatalities and casualties.)” JTAR 3-8. NGVs weigh somewhat more than comparable gasoline vehicles due to the weight of the CNG tanks, yet even with this weight penalty NGVs continue to reduce GHG emissions while utilizing an alternative fuel source. (Compare Honda CNG curb weight of 2,848 lbs with Honda Civic LX curb weight of 2721 lbs.) [EPA-HQ-OAR-2010-0799-9548-A1, p. 5]

II. INCENTIVES FOR NGVS

EPA has proposed not only extending the current incentives for electric vehicles (“EVs”), under which the agency deems them to have zero GHG emissions, but to add a second category of incentives for MY 2017-2021 under which each EV (and fuel cell vehicle) sold would be deemed to be equal to between 2.0 such vehicles (MY 2017- 2019) 1.75 vehicles (MY 2020), and 1.5 vehicles (MY 2021). Plug-in hybrid electric vehicles (“PHEVs”) would get similar, but smaller, multipliers: 1.6 for MY 2017-2019, 1.6 for MY 2020, and 1.3 for MY 2021. 76 FR 75013. EPA’s rationale for these incentives is that “it is appropriate to encourage the initial commercialization of EV/PHEV/FCVs as well, in order to retain the potential for game-changing GHG emissions and oil savings in the long term.” Id. at 75011. [EPA-HQ-OAR-2010-0799-9548-A1, p. 6]

EPA then asks for “comments on the merits of providing similar multiplier incentives to dedicated and/or dual fuel compressed natural gas vehicles”. Id. at 75013. While EPA proposes generous incentives for EVs and PHEVs because they represent “potential for game-changing GHG emissions and oil savings in the long term”, both dedicated and dual-fuel NGVs represent actual “game changing GHG emissions and oil savings” right now that justify comparable incentives. Moreover, considering NGVs superior cost-benefit performance in reducing GHGs compared to EVs, EPA should consider an even larger multiplier incentive, perhaps equal to the incentive Congress mandated for NGVs based on their oil-displacement performance. [EPA-HQ-OAR-2010-0799-9548-A1, p. 6]

According to EPA, the 2012 Nissan Leaf EV has upstream GHG emissions of 161 grams per mile. Id. at 75011. If the Leaf were gasoline-powered, the proposed 2017 GHG standard for it would be 210 g/mi.[2] Assuming, as EPA does (id. at 75011), a 20% upstream GHG value for gasoline vehicles (42 g/mi), this “gasoline Leaf” would have total GHG emissions of 252 g/mi. Thus the actual GHG emissions difference between the EV Leaf and the gasoline Leaf is 252-

161, or 91 g/mi. Using EPA's figures, simple math shows that the cost of this 91 g/mi advantage is a staggering $304 for each g/mi improvement over the comparable gasoline vehicle. [EPA-HQ-OAR-2010-0799-9548-A1, p. 6]

EPA expects that in 2016, the marginal cost of EV technology for a small size car (such as the Leaf) to be $27,628. Draft Joint Technical Support Document, Proposed Rulemaking to Establish Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, September 2009, p. 3-91. Conservatively assuming that the cost of EV technology in the 2012 Leaf is no more than EPA's estimate for 2016, $27,628 divided by 91 equals a cost of approximately $304 per g/mi of GHG reductions. [EPA-HQ-OAR-2010-0799-9548-A1, pp. 6-7]

In contrast, a 2011 Honda Civic NGV vehicle has tailpipe CO_2 emissions of 252 g/mi, and the comparable 2011 Honda Civic gasoline vehicle has tailpipe emissions of 306 g/mi. www.fueleconomy.gov. Even without including the NGV's smaller upstream GHG emissions, the NGV has 54 g/mi less GHG emissions than its gasoline counterpart, and costs $6,935 more. Thus the cost of achieving GHG reductions via an NGV is only $128 per g/mi. In other words, compared to electric vehicles, NGVs are close to three times more cost efficient in reducing GHG emissions. [EPA-HQ-OAR-2010-0799-9548-A1, p. 7]

Given this, AGA and ANGA believe that it would be reasonable for EPA to not only include incentives for NGVs, but to make them significantly larger than the ones proposed for EVs. Because the Light Duty Rule is a joint regulatory program designed to reduce both GHGs and oil dependency, the most logical basis for an incentive is the one Congress has already mandated for NGVs based on their displacement of oil imports. [EPA-HQ-OAR-2010-0799-9548-A1, p. 7]

In the Alternative Motor Fuels Act of 1988 ("AMFA"), Congress wrote a specific compliance metric favoring natural gas and other alternative fuels into the light-duty fuel economy statute. The Conference Report for AMFA could not have been clearer: "[t]he objective of both the House and Senate bills is to facilitate the development and use of alternative fuels in the United States for purposes of energy security" (House Report 100-929, 134 Cong Rec H 7732, September 16, 1988, p. 7736), and the first two legislative findings in the statute itself were "the achievement of long-term energy security for the United States is essential to the health of the national economy, the well-being of our citizens, and the maintenance of national security" and "the displacement of energy derived from imported oil with alternative fuels will help to achieve energy security and improve air quality." P.L. 100-494, Section 2. [EPA-HQ-OAR-2010-0799-9548-A1, p. 7]

Recognizing that every NGV increases utilization of a domestically produced alternative fuel, in AMFA Congress encouraged the production of natural gas vehicles by multiplying the fuel economy of an NGV relative to that of an equivalent gasoline-powered one. (AMFA Section 6(a), codified at 49 U.S.C. 32905(c), providing that in fuel-consumption calculations, "[a] gallon equivalent of gaseous fuel is deemed to have a fuel content of .15 gallon of fuel"; by multiplying natural gas volume by .15, the effect of this is to discount NGV fuel consumption by 85%.)

Based on the fact that NGVs are more cost-efficient than EVs in delivering GHG reductions, and that Congress mandated an incentive multiplier for NGVs of approximately 7 for their fuel-economy benefits, AGA and ANGA believe that an incentive multiplier that provides parity with electric and plug-in hybrid vehicles is justified for NGVs. [EPA-HQ-OAR-2010-0799-9548-A1, p. 7]

Using the equivalent multiplier for GHGs allows for full recognition of NGV fuel-economy benefits. However, any GHG multiplier that is less than the fuel economy one essentially negates the Congressional mandate in AMFA to the extent of that difference, a result at odds with the very purpose of this joint rulemaking. We strongly encourage EPA to take into account the fuel economy goals of this joint program in crafting their GHG standards, and the fact that NGVs are more cost-effective than EVs in reducing GHGs should allow for EPA to establish a GHG multiplier incentive equivalent to the Congressionally-mandated fuel economy incentive. [EPA-HQ-OAR-2010-0799-9548-A1, p. 8]

Dual-Fuel NGVs

As described in detail below, AGA and ANGA support EPA's proposal to "directly extend" to dual fuel CNG vehicles the PHEV utility factor methodology described in SAE J2841 ''Utility Factor Definitions for Plug-In Hybrid Electric Vehicles Using Travel Survey Data,'' September 2010. AGA and ANGA also support extending application of this utility factor methodology back to MY 2012-2016. [EPA-HQ-OAR-2010-0799-9548-A1, p. 9]

We agree with EPA's conclusion that "owners of dual fuel CNG vehicles will preferentially seek to refuel and operate on CNG fuel as much as possible" because, in part, "CNG fuel is considerably cheaper than gasoline on a per mile basis". 76 FR 75018. In fact, on a per-mile basis, CNG retails for approximately one-third to one-half the cost of gasoline. However, we note that another basis for EPA's conclusion ("because the owner paid a much higher price for the dual fuel capability", id.) is somewhat of a conjecture, as no manufacturer has yet to produce a duel fuel NGV. [EPA-HQ-OAR-2010-0799-9548-A1, p. 9]

AGA and ANGA also agree with EPA's observation, which further supports use of the SAE utility factor, that "many dual fuel CNG vehicles will likely have smaller gasoline tanks given the expectation that gasoline will be used only as an 'emergency' fuel". However, we believe that this is precisely what the market will produce, and thus do not believe that there is need for any of the agency's suggested "additional constraints on the designs of dual fuel CNG vehicles to maximize the likelihood that consumers will routinely seek to use CNG fuel", such as "placing a minimum value on CNG tank size or CNG range, a maximum value on gasoline tank size or gasoline range, a minimum ratio of CNG-to-gasoline range, and requiring an onboard control system so that a dual fuel CNG vehicle is only able to access the gasoline fuel tank if the CNG tank is empty." Id. at 75019. [EPA-HQ-OAR-2010-0799-9548-A1, p. 10]

EPA notes that the same SAE utility factor it proposes to apply to dual fuel NGVs is the one first developed for PHEVs, and that there are two potential differences which "might weaken the case for using utility factors for dual fuel CNG vehicles." AGA and ANGA addressed the first (relating to a dual fuel NGV running on gasoline when both fuels are available on board), above.

The second that “it may be much more inconvenient for some private dual fuel CNG vehicle owners to fuel every day relative to PHEVs, and there are many fewer CNG refueling stations than electrical charging facilities” is not the relevant consideration. Unlike PHEVs, CNG vehicles are exactly like gasoline vehicles insofar as they do not need to refuel every day. Based on NHTSA’s combined cityhighway fuel economy figure (31 mpg) and vehicle tank size, the driving range for the 2012 Honda CNG is 248 miles, which means that, like gasoline vehicles, it would only have to be refueled once every few days. [EPA-HQ-OAR-2010-0799-9548-A1, p. 10]

2 The GHG standard applicable to a vehicle is determined by its “footprint”, which is “the vehicle’s wheelbase multiplied by its track width”. 76 FR 74870. Multiplying the Leaf’s wheelbase of 106.3 inches by its track width of 60.6 inches (http://www.vehix.com/carreviews/2011/nissan/leaf/vehicle-specification) equals 6441.78 sq in, or 44.73 sq ft, and thus a GHG footprint of 210g/mi. Id. at 74873.

Organization: American Clean Skies Foundation (ACSF)

ACSF strongly supports the energy security and environmental goals underlying the Proposed Rule. However, the Foundation believes that these goals can best be met by adopting technology neutral incentives that enable natural gas vehicles (NGVs), as well as electric vehicles (EVs), to play a larger role. Both technologies can deliver similar well-to-wheel greenhouse gas (GHG) emission reductions. See Appendix 1. Accordingly, these comments propose several simple rule changes that EPA and NHTSA can make to establish a level regulatory playing field for advancing cleaner and more fuel-efficient vehicles, rather than arbitrarily providing incentives for selected vehicle powertrains, as the Proposed Rule now does. Consumers and the environment will benefit from competition across vehicle technologies. [Appendix 1 can be found on pp. 16-20 of Docket number EPA-HQ-OAR-2010-0799-9464-A1] [EPA-HQ-OAR-2010-0799-9464-A1, p. 1]

Given the Administration's recognition of the major energy security and emission benefits that NGVs can provide (See Appendix 2), we believe it is essential that any new vehicle standards adopted by EPA and NHTSA are consistent with that vision and, at a minimum, do not discriminate against NGVs or dual-fuel (natural gas/gasoline) vehicles. [Appendix 2 can be found on pp. 21-23 of Docket number EPA-HQ-OAR-2010-0799-9464-A1] [EPA-HQ-OAR-2010-0799-9464-A1, pp. 1-2]

I. Executive summary

The Proposed Rule has two overarching goals: to reduce GHG emissions and improve our nation's security. Encouraging the manufacture and use of more NGVs is one of the very best ways to achieve these goals because each new NGV will emit roughly 30% less GHG pollution than a gasoline vehicle and displace its lifetime consumption of imported petroleum. [EPA-HQ-OAR-2010-0799-9464-A1, p. 2]

The new rule will apply to vehicles manufactured in model years 2017 through 2025. This is a critical period for deploying alternative fuel vehicles, as it represents a key window of opportunity to make progress on environmental and security goals. Any new regulations that impact vehicle fuel choices and related infrastructure investments will also have far-reaching impacts on the country's transportation mix well before 2017 and after 2025. That is why it is so important that the proposed rule not handicap one category of oil-saving or lower carbon vehicle technologies versus another. [EPA-HQ-OAR-2010-0799-9464-A1, p. 2]

Unfortunately, however, in providing incentives for alternative fuel vehicles, the draft rule unduly favors EVs to the detriment of NGVs. This shortcoming can and must be addressed to create effective competition among alternative fuel vehicles and provide technology-neutral incentives. [EPA-HQ-OAR-2010-0799-9464-A1, p. 2]

To that purpose, ACSF recommends the following rule changes:

1. A technology-neutral pool of alternative fuel vehicle incentives should be created. All qualified alternative fuel vehicles, including EVs and NGVs, should qualify for these incentives which would use a multiplier to give extra credit for the emission reduction benefits of such vehicles in calculating each manufacturer's fleet averages. The incentive would be phased out when the annual sales of all qualified alternate fuel vehicles exceeds 10% of total vehicle sales, or roughly 1.5 million vehicles in 2017. [EPA-HQ-OAR-2010-0799-9464-A1, p. 2]

2. Because production volumes can be rapidly scaled-up, EPA should augment the near-term incentives for natural gas dual-fuel vehicles. As with hybrid electric vehicles, the increased production of NGVs that can run on both gasoline and CNG as 'dual-fuel vehicles' will significantly advance the objectives of the Proposed Rule. [EPA-HQ-OAR-2010-0799-9464-A1, p. 2]

3. Manufacturers producing NGVs and alternative fuel vehicles that use fuels having superior energy security benefits should be explicitly rewarded. Promoting the goal of energy security requires explicit targeted incentives. This might be done by using a common metric (e.g., imported oil reduced) to rank vehicles and/or fleets and provide a proportionate compliance benefit. [EPA-HQ-OAR-2010-0799-9464-A1, p. 2]

The rationale for these recommendations is discussed below. To provide context, we first provide an NGV 'technology overview' and review certain risks regarding EV deployment. We also briefly summarize the Proposed Rule's regulatory structure as it applies to alternative fuel vehicles. [EPA-HQ-OAR-2010-0799-9464-A1, p. 3]

II. Technology overview

A. The benefits and worldwide market acceptance of NGVs.

Only last month, President Obama used his 2012 State of the Union speech to call attention to America's 'nearly 100 year' supply of natural gas and the major role gas can play in enhancing our energy security and reducing GHG emissions. Later he challenged a Nevada audience to: [EPA-HQ-OAR-2010-0799-9464-A1, p. 3]

'Think about an America where more cars and trucks are running on domestic natural gas than on foreign oil. Think about an America where our companies are leading the world in developing natural gas technology and creating a generation of new energy jobs. . .. [L]et's get more of these natural gas vehicles on the road.” [EPA-HQ-OAR-2010-0799-9464-A1, p. 3]

We agree. That is why it is so important that the Proposed Rule promote the President's policy and be technology neutral so that the rules encourage manufacturers to produce more NGVs and dual-fueled vehicles (as well as EVs) capable of delivering similar environmental and security benefits. [EPA-HQ-OAR-2010-0799-9464-A1, p. 3]

NGVs provide a means to achieve the Proposed Rule's emission reduction and energy security goals with proven, cost-effective technology 5 that has been widely deployed around the globe. More than 12 million NGVs were in use worldwide as of 2010,6 far greater than EV deployment.7 In fact, a recent study by Harvard University noted that 'highway-capable BEVs [Battery-Electric Vehicles] are not yet in widespread use anywhere in the world.”8 [EPA-HQ-OAR-2010-0799-9464-A1, pp. 3-4]

In the United States, NGVs are widely recognized as providing 'game changing' opportunities today for vehicle fleets, reducing both costs and emissions and the use of foreign petroleum. There are now over 70,000 CNG vans, light duty trucks and cars in service, including more than 3,000 NGVs in AT&T's fleet alone.9 Moreover, states and local governments around the country are committed to expanded NGV roll outs. For instance, the governors of Colorado, Oklahoma, Pennsylvania, and Wyoming recently signed a memorandum of understanding to convert state fleets to CNG.10 [EPA-HQ-OAR-2010-0799-9464-A1, p. 4]

Of particular relevance to this docket, which targets incentives for the 2017-2025 time period, is the prospective build-out of a national NGV infrastructure and the availability of low cost home refueling appliances for NGVs. Last year, for example, several companies announced new financing commitments totaling $450 million to establish a coast-to-coast highway refueling network that, by 2014, could be capable of supporting tens of thousands of LNG-fueled trucks and CNG-fueled vehicles.11 By 2017, new 'brand name' home refueling appliances are expected to come to market, providing an affordable garage-based CNG option for over 65 million homes already connected to natural gas pipelines.12 [EPA-HQ-OAR-2010-0799-9464-A1, p. 4]

Beyond that, NGVs do not require the risky 'technological leaps' remaining for EVs and various alternative fuel technologies. In fact, most existing vehicles can be modified to utilize natural gas, as use of this fuel involves similar internal combustion components. In addition, the technological advancements (and associated fuel efficiency gains) that EPA and NHTSA predict for petroleum and diesel fueled engines are likely also to benefit NGVs.13 [EPA-HQ-OAR-2010-0799-9464-A1, pp. 4-5]

NGVs offer significant energy security benefits. As the President has noted, natural gas is an abundant domestic energy resource. The United States currently produces almost all of the natural gas that it uses and may actually be a net exporter of natural gas by 2021.15 Over 65 million homes are already connected to the local natural gas distribution network and expanding the delivery infrastructure may be more economical than developing similar infrastructure for electricity. For instance, a joint study by the Bonneville Power Administration and the Northwest Gas Association found that 'natural gas pipelines average between 50 and 60 percent of the cost of electric power transmission per unit of energy (or capacity) delivered."16 Additionally, adding new interstate natural gas pipeline capacity averages just three years from announcement date to commercial start of operations.17 [EPA-HQ-OAR-2010-0799-9464-A1, p. 5]

Finally, NGVs offer substantial GHG emission reduction benefits over conventional vehicles (those that use gasoline and diesel). Again, see Appendix 1. The natural gas-powered Honda Civic has regularly been recognized as among the 'greenest cars' on the road.18 While NGVs emit small amounts of methane, these emissions are more than offset by substantially reduced CO_2 emissions versus other vehicles.19 And in the future, larger amounts of bio-methane (a renewable fuel with a very low GHG footprint) may become available, further enhancing the emission benefits of NGVs.20 [Appendix 1 can be found on pp. 16-20 of Docket number EPA-HQ-OAR-2010-0799-9464-A1] [EPA-HQ-OAR-2010-0799-9464-A1, p. 5]

B. The Administration should not pick technology 'winners' and 'losers'.

In a market economy, it is an axiom of regulatory design that the government should avoid trying to favor competing technologies (or companies) by picking winners. Such decisions are best left to the private sector.21 This is especially true when the technology that may be favored faces large uncertainties in research or development for key components, materials supply risks in scaling-up production, billion dollar infrastructure hurdles and unproven consumer take up. [EPA-HQ-OAR-2010-0799-9464-A1, p. 6]

Qualified alternative fuel vehicles should all be given similar incentives so that they can compete on a level playing field in delivering the public benefits the Proposed Rule seeks. EVs may well have a very bright future. However, it is also possible that EVs may never be a widely-deployed technology. Unlike NGVs, EVs require technology advances in batteries and other components and have yet to be produced and deployed at scale.22 By comparison, NGVs utilize existing engine technology but merely burn a different fuel. Similarly, auto mechanics accustomed to working on typical internal combustion engines face a learning curve when asked to repair electric engines, which use a substantially different motor technology. [EPA-HQ-OAR-2010-0799-9464-A1, p. 6]

In short, the Administration should not create inefficient regulatory structures that pick technology winners and losers. That would be unlawfully arbitrary and capricious.23 Rather the Proposed Rule should be revised to establish a level playing field for alternative fuel vehicles. That is by far the most cost-effective and non-discriminatory way to achieve the rule's desired environmental and national security goals. [EPA-HQ-OAR-2010-0799-9464-A1, p. 6]

III. Regulatory structure of the Proposed Rule [EPA-HQ-OAR-2010-0799-9464-A1, p. 6]

The Proposed Rule consists of parallel standards issued by EPA and the NHTSA, which seek to accomplish similar goals through different regulatory mechanisms. In particular, EPA would impose a limit on vehicle GHG emissions pursuant to the Clean Air Act. More specifically, EPA's proposed standards require, on an average industry fleet-wide basis, an emissions standard of 163 grams/mile of CO_2e, which equates to 54.5 mpg, by 2025. Pursuant to CAA § 202, EPA has broad discretion to set emissions levels that are 'technology-based' and can be 'technology forcing.' Thus, EPA can use its standards to incentivize the deployment of advanced technologies such as EVs and NGVs. EPA proposes to include specific limits on three GHGs (CO_2, CH_4, N_2O), which can be met individually or through a combined CO_2-equivalent standard. [EPA-HQ-OAR-2010-0799-9464-A1, p. 7]

The NHTSA would increase the stringency of traditional mile-per-gallon (mpg) Corporate Average Fuel Economy Standards (CAFE). NHTSA proposes to tighten these CAFE standards pursuant to the Energy Independence and Security Act of 2007 (EISA), which amended the Energy Policy and Conservation Act of 1975 (EPCA). NHTSA considers four statutory factors in setting CAFE standards: technological feasibility, economic practicability, the effect of other Government standards on fuel economy, and the nation's need to conserve energy. NHTSA's proposal would require, on an average fleet wide basis, 49.6 mpg by 2025.24 [EPA-HQ-OAR-2010-0799-9464-A1, p. 7]

Because EPA and NHTSA both 'address the closely intertwined challenges of energy security and climate change,' they closely coordinated their GHG and CAFE standards development. Accordingly, both these EPA GHG and NHTSA CAFE standards are issued pursuant to this joint Proposed Rule, similar to the joint proposed standards that these agencies previously issued for light-duty vehicles for model years 2012-2016. [EPA-HQ-OAR-2010-0799-9464-A1, p. 7]

A. NHTSA alternative vehicle incentives. [EPA-HQ-OAR-2010-0799-9464-A1, p. 7]

Regarding EVs, NHTSA currently uses a statutorily-mandated petroleum equivalence factor (PEF) to convert the use of electricity into an equivalent 'miles per gallon.” The PEF for electricity includes an adjustment - that is, a discount - so that the mileage for EVs is calculated based on only 15% of the actual energy consumed. That adjustment provides a large benefit to EVs in calculating the average mileage for a manufacturer's fleet. Because Congress established this PEF incentive, NHTSA believes that it may not create additional incentives for EVs. EPA does not feel so bound, however, and proposes to create additional incentives for EVs in the Proposed Rule (as further described below). [EPA-HQ-OAR-2010-0799-9464-A1, pp. 7-8]

Under the current CAFE standards set by NHTSA, NGVs also receive similar benefits because the miles per CNG gallon equivalent are discounted by applying a 0.15 'divisor.' This incentive was created under the EISA, and the incentive is not scheduled for expiration. Under this incentive scheme, a 15 mpg dedicated alternative fuel vehicle is multiplied by 100/15 so that it would be rated as 100 mpg. The 'divisor' consequently has an impact equivalent to the PEF mentioned above for EVs. [EPA-HQ-OAR-2010-0799-9464-A1, p. 8]

B. EPA alternative vehicle incentives.

We come now to the nub of the discrimination and market inefficiencies that these comments are designed to rectify: Unlike the NHTSA rules, the EPA's new GHG standards contain additional EV-only incentives. These supplemental incentives arbitrarily and capriciously favor EVs over NGVS.31 For instance, EPA would continue the practice of considering EVs to be zero-emitting (up to certain production caps), even though EPA recognizes that generating electricity upstream creates substantial GHG emissions (particularly due to the emissions from coal-fired power plants). [EPA-HQ-OAR-2010-0799-9464-A1, p. 8]

EPA's proposal also includes a new incentive multiplier for EVs. Through this multiplier, EPA would allow a vehicle manufacturer to reduce its average fleet emissions by initially counting the lower emissions of each EV produced as two vehicles (i.e., using a 2 times multiplier). In addition, in the Model Year 2012-2016 rule, EPA utilized the same 0.15 'divisor' available in the CAFE rules (discussed above) in calculating GHG emissions compliance for NGVs. But, under the Proposed Rule, this incentive would expire. As a result, EPA's new rules would abolish the benefits NGVs gain under the NHTSA standards from the 0.15 'divisor' incentive. [EPA-HQ-OAR-2010-0799-9464-A1, p. 8]

C. Dual-fuel vehicle incentives. [EPA-HQ-OAR-2010-0799-9464-A1, p. 8]

The Proposed Rule also contains additional provisions that specifically address dual-fuel vehicles, including hybrid-electric vehicles and those that run on both CNG and gasoline. The Proposed Rule would change the assumption in both CAFE and GHG emissions regulations that alternative fuels are used 50% of the time in dual-fueled vehicles. Instead, the agencies would sensibly replace this 50/50 assumed fuel split with a 'utility factor'-Le., an approach that takes into account the actual percentage of alternative fuel use by the average driver. Thus, the Proposed Rule recognizes that 'CNG fuel is considerably cheaper than gasoline on a per mile basis,' and that CNG is likely to be used in a dual-fueled vehicle significantly more than 50% of the time. [EPA-HQ-OAR-2010-0799-9464-A1, pp. 8-9]

Dual-fuel vehicles also face discrimination related to the proposed use of the 0.15 'divisor.' Congress eliminated the 0.15 divisor incentive for non-electric, dual-fuel vehicles after 2019. The Proposed CAFE standards would continue the incentives for those dual-fueled vehicles after 2019. Again, however, EPA and NHTSA send a mixed message regarding CNG vehicles. Under EPA's proposal, dual-fuel CNG vehicles would see the 0.15 'divisor' eliminated from the alternative-fuel portion of a vehicle's emissions. By not utilizing the same incentive under its emissions standards, EPA limits the usefulness of NHTSA's incentives. [EPA-HQ-OAR-2010-0799-9464-A1, p. 9]

Finally, the Proposed Rule includes a significant focus on energy security concerns. We discuss these concerns-and how they might be better translated with a more effective set of vehicle incentives-at greater length below. [EPA-HQ-OAR-2010-0799-9464-A1, p. 9]

IV. Suggested Revisions to the Proposed Rule to Promote Technology-Neutral Benefits

A. A technology-neutral pool of alternative fuel incentives should be created. Vehicles in this pool, including NGVs, should qualify for the same incentives that are now only available to EVs, in particular the incentive 'multiplier.'

Rather than provide incentives to specific vehicle types, EPA should strive to be technology neutral in its efforts to reduce GHG emissions. In particular, the Proposed Rule offers two main incentives that currently favor EVs: the ability of manufacturers to count EV emissions at 0 grams/mile in calculating fleet averages; and an 'incentive multiplier' which begins by double-counting EVs in the overall fleet. This current incentive structure should be revised so that it is technology-neutral, and reflects life-cycle impacts, allowing NGVs-which provide comparable emission reductions and energy security benefits to EVs-to qualify for the same incentive available to EVs. [EPA-HQ-OAR-2010-0799-9464-A1, p. 9]

1. The incentive 'multiplier' should apply to NGVs and EVs. [EPA-HQ-OAR-2010-0799-9464-A1, p. 9]

The Proposed Rule provides a new incentive 'multiplier,' but as drafted would only allow this incentive for EVs. More specifically, this 'multiplier' allows manufacturers to multiply, by a determined factor, the number of EVs when calculating its fleet emissions profile. EVs would start with a multiplier value of 2.0 in Model Year 2017, phasing down to a value of 1.5 in 2021. [EPA-HQ-OAR-2010-0799-9464-A1, pp. 9-10]

By providing this incentive to EVs, while failing to provide a similar incentive to NGVs, the EPA has inappropriately picked EVs as 'the future' clean-car technology, thereby decreasing competition and incurring unnecessary program risks. This is unlawfully arbitrary and capricious. The GHG emission benefits on a life-cycle (well-to-wheel) basis are similar for EVs and NGVs. See Appendix 1. The EPA's current approach also harms consumers and cuts against the goals of the Proposed Rule because, as noted earlier, an NGV buyer likely can reduce her GHG vehicle emissions at a lower cost per unit than an EV buyer. [Appendix 1 can be found on pp. 16-20 of Docket number EPA-HQ-OAR-2010-0799-9464-A1] [EPA-HQ-OAR-2010-0799-9464-A1, p. 10]

The GHG emissions of NGVs are approximately 20-30% lower than for vehicles using gasoline. Furthermore, current technology can capture and utilize natural gas from renewable sources (e.g., landfills, farm animals). Natural gas from these sources (i.e., biomethane) has a carbon intensity approximately 85% less than gasoline.37 [EPA-HQ-OAR-2010-0799-9464-A1, p. 10]

All 'qualified' alternative fuel vehicles with a similar potential to reduce GHG emissions (on a well-to-wheel basis) should be eligible for a multiplier that encourages the production of these vehicles until annual vehicle sales reach 10% of total sales for all fleets combined.38 On this basis, the incentive would apply to approximately 1.5 million vehicles in 2017. The incentive could then be phased down by 2% annually so that it applies to a smaller number of qualified vehicles each year but affords a sufficient lead time for manufacturers to plan and begin deployment of these qualified vehicles. [EPA-HQ-OAR-2010-0799-9464-A1, p. 10]

Significantly, two other major federal programs for reducing the nation's GHG emissions treat the potential benefits of using NGVs and EVs in a similar way. The first provides for federal procurement for all qualified alternative fuel vehicles.39 The second, under Executive Order 13514, requires each federal agency to measure and report reduction targets for direct (Scope 1) and indirect (Scope 2) greenhouse gas emissions.40 Because the tailpipe emissions of the agency's vehicles are counted in Scope 1 and emissions from electricity used by the agency (including recharging EVs) are counted in Scope 2, both NGVs and EVs have emissions reflected in the relevant accounts. In addition, both types of alternative fuel vehicles contribute, on a technology-neutral basis, to achieving the two-percent annual reduction in petroleum consumption required in Section 2(a)(iii) of this Executive Order, and both types of vehicles are covered by Section 12's guidance to develop strategies on alternative fuel vehicles.41 [EPA-HQ-OAR-2010-0799-9464-A1, pp. 10-11]

Indeed, EPA acknowledges that the upstream GHG emissions of EVs are a significant negative factor and may be worse than gasoline vehicles. EPA states that EVs in the 2017-2025 period 'will decrease the overall GHG emissions reductions associated with the program as the upstream emissions associated with the generation and distribution of electricity are higher than the upstream emissions associated with production and distribution of gasoline.” [EPA-HQ-OAR-2010-0799-9464-A1, pp. 11-12]

On the other hand, the superior emissions benefits of NGVs over gasoline vehicles are thoroughly documented. 'The conclusion of recent studies such as those conducted by CARB and others is that, when used as transportation fuel, natural gas can reduce greenhouse gas emissions by 20 - 29 percent compared with diesel and gasoline fueled vehicles, respectively.”46 When compared to EVs, NGVs provide comparable emissions benefits (and NGVs can even provide superior emission reduction benefits to EVs depending on the extent to which coal-fired power is used to generate electricity for EVs). In addition, while EPA is counting on technological advancements to improve EVs, technology for NGVs will also advance if given the same opportunities. [EPA-HQ-OAR-2010-0799-9464-A1, p. 12]

The most effective and lawful incentive structure to promote vehicle emission reductions is a 'multiplier' incentive for all alternative fuel vehicles. Such a program would more strongly encourage manufacturers to develop cleaner vehicles through competition between EV and NGV technologies, and would allow the market to decide the extent of each technology's success. [EPA-HQ-OAR-2010-0799-9464-A1, p. 12]

3. The 0.15 divisor should continue for NGVs.

As noted above in the regulatory overview, in EPA's MY 2012-2016 GHG rule for light-duty vehicles, EPA utilized the same 0.15 'divisor' available in the CAFE rules in calculating GHG emissions compliance for NGVs. However, EPA has currently scheduled this incentive to expire in model year 2016, and the Proposed Rule does not renew this incentive. By not recognizing the 0.15 'divisor' incentive under its GHG regulations, EPA appears to be undercutting a statutorily-mandated incentive (for the CAFE rules) through its proposed GHG rules. By proposing GHG rules that work against the CAFE regulatory scheme, EPA is acting in a counterproductive way and hindering the development of cleaner technologies. [EPA-HQ-OAR-2010-0799-9464-A1, p. 12]

For the joint NHTSA and EPA rulemaking process to be effective, the agencies must work together so that the incentives provided by one agency are not limited by the regulations proposed by the other.47 Accordingly the 0.15 divisor for NGVs that exists under the CAFE rules should also be continued under EPA's GHG rules for light-duty vehicles. [EPA-HQ-OAR-2010-0799-9464-A1, p. 12]

B. Because of their potential for rapid scale-up, EPA should incentivize the deployment of CNG dual-fuel vehicles to the maximum extent possible. [EPA-HQ-OAR-2010-0799-9464-A1, p. 12]

Many CNG vehicles worldwide are equipped to run as dual-fuel vehicles. These vehicles can facilitate consumer acceptance of alternative fuel vehicles through the use of a small gasoline tank, thus reducing the 'range anxiety' that some consumers may have when choosing a vehicle that, as yet, has a limited fueling infrastructure.48 Dual-fuel CNG vehicles have the potential to be a 'game-changer' through rapid deployment. They also have a superior combination of reliability and the ability to use a domestic, clean-burning fuel, while reducing concerns about 'range anxiety.' Because CNG is 'considerably cheaper than gasoline on a per mile basis,' for dual-fueled vehicles the Proposed Rule includes a 'utility factor' approach that would 'result in a compliance assumption of about 95% operation on CNG and about 5 percent operation on gasoline' for CNG/gasoline dual-fueled vehicles.49 [EPA-HQ-OAR-2010-0799-9464-A1, p. 13]

The deployment of dual-fuel CNG vehicles should be encouraged by the agencies through the maximum use of incentives. Specifically, EPA should use a standard 'utility factor' that assumes these vehicles will run on CNG 95% of the time, as this reflects EPA's 'real-world' projection of these vehicles. This 95% figure should be a default value and not require a case-by-case review that might otherwise be required to determine the utility factor. [EPA-HQ-OAR-2010-0799-9464-A1, p. 13]

Furthermore, the incentive multiplier outlined above should apply to dual-fuel CNG vehicles as well. A multiplier is already allowed for PHEVs, which are operationally similar to CNG dual-fuel vehicles (in the sense that two sources of energy may operate the vehicle, in the case of PHEVs this being either electricity or gasoline). If PHEV's qualify for a multiplier, then so too should CNG dual-fuel vehicles. Finally, the 0.15 divisor should be available under both the CAFE standards and EPA's GHG rules for the portion of the vehicle's operation on natural gas. [EPA-HQ-OAR-2010-0799-9464-A1, p. 13]

C. The Proposed Rule should provide incentives for manufacturers producing NGVs and other vehicles that use fuels having superior energy security benefits.

'Energy security' is a central focus of the Proposed Rule. However, The Proposed Rule does not provide explicit incentives for manufacturing vehicles on the basis of energy security benefits. Nothing in either the EPA or NHTSA calculations explicitly considers energy security. By providing incentives for vehicles that enhance our energy independence, the agencies could ensure that manufacturers consider this factor. These incentives would also spur development and advance technology in the area of alternative fuel vehicles. [EPA-HQ-OAR-2010-0799-9464-A1, p. 13]

Because the comparative energy security benefits of different fuels can be readily ascertained an objective basis can be established for providing incentives. For example, a 'baseline' against which to assess energy security benefits could be tied to the current ratio of imported-to-domestic oil (which is used to make gasoline and diesel, the dominant fuels in light-duty vehicles). Thus, if the current ratio of imported-to-domestic gasoline/diesel used in fleets covered by the proposed rules is approximately 50-50, then covered vehicles that use a fuel with a higher percentage that is sourced domestically would be assigned a factor between 1 and 2. 51 A vehicle's multiplier could then be increased by this factor for the purpose of doing a fleet-wide compliance calculation. [EPA-HQ-OAR-2010-0799-9464-A1, pp. 13-14]

Alternatively, each manufacturer could have a fleet wide 'energy security' rating against which to measure the benefits/incentives it should receive. A manufacturer's ability to take advantage of its 'energy security' incentives could be dependent on its fleetwide GHG emission average: should a manufacturer's fleet meet the requirements for an 'energy security' benefit but not meet the applicable GHG standards, that manufacturer would be unable to utilize that benefit.52 [EPA-HQ-OAR-2010-0799-9464-A1, p. 14]

Various forms of 'revenue recycling' also could reward manufacturers who produce vehicles that enhance energy security. For instance, the revenue from fines collected under various motor vehicle regulations could be dedicated to enhance the use of fuels with energy security benefits. Since the implementation of CAFE standards, a total of nearly $795 million has been collected. In Model Year 2009, the last year data is available, the collected fines totaled approximately $9 million.53 In 2007, the total of collected fines was more than $37 million.54 [EPA-HQ-OAR-2010-0799-9464-A1, p. 14]

As noted above, NGVs offer significant energy security benefits. Utilizing natural gas as a fuel source is economical and wholly secure, as natural gas is an abundant domestic energy resource.55 Although the electricity used to repower EVs is domestic, the batteries on which EVs rely may be dependent on lithium and other scarce metals which must be imported from a limited range of nations.56 [EPA-HQ-OAR-2010-0799-9464-A1, pp. 14-15]

While EPA and NHTSA may take a variety of approaches in recognizing energy security benefits, what does seem clear is that these energy security benefits should be explicitly rewarded in order to further the stated energy security goals of the Proposed Rule. [EPA-HQ-OAR-2010-0799-9464-A1, p. 15]

V. Conclusion

Natural gas is an abundant domestic fuel that produces lower GHG emissions than gasoline and diesel on a lifecycle basis, and its use in vehicles involves widely-used, reliable engine technology. Encouraging the increased use of natural gas in vehicles will help to achieve EPA's goal of reducing GHG emissions from the nation's vehicle fleet. NGVs and dual-fuel CNG vehicles can also substantially improve our nation's energy security. Worldwide, millions of vehicles run on natural gas and the technology for NGVs is already available. Yet, despite the considerable benefits of NGVs, the Proposed Rule offers multiple incentives to EVs while overlooking the often superior benefits of NGVs. [EPA-HQ-OAR-2010-0799-9464-A1, p. 15]

The Proposed Rule must be revised so that its incentive structure for alternative fuel vehicles is technologically neutral and not anti-competitive. Failure of EPA and NHTSA to do so would be arbitrary and capricious. A technologically-neutral incentive scheme will unlock the full potential of our nation to utilize alternative fuels to meet both GHG reduction and energy security goals. [EPA-HQ-OAR-2010-0799-9464-A1, p. 15]

---

5 Based on the EPA's own data, from the consumer's standpoint, it is likely to be far cheaper-as measured in vehicle dollars spent to reduce a given amount of greenhouse gas per mile-for a driver to acquire a new NGV rather than an EV, given the substantially lower purchase cost of a CNG vehicle and the comparable full fuel cycle GHG reductions in emissions versus a gasoline powered vehicle. Small-sized EV sedans are expected to cost over $27,000 more in 2016; the additional cost for a CNG vehicle is likely to be under $2,500. See Draft Joint Technical Support Document, Proposed Rulemaking: Mode/ Year 2012-2016 Light-Duty Vehicle Greenhouse Gas Emissions Standards and Corporate Average Fuel Economy Standards, p. 3-91, available at www.epa.gov/otag/c1imate/regulations/420d09901.pdf.

6 International Natural Gas Vehicle Association, http://www.iangv.org/tools-resources/statistics.html. Companies that currently offer NGVs worldwide include Fiat, Chrysler, GM, Ford, Honda, and Mercedes.

7 A report from Pike Research notes that the 2011 sales of plug-in EVs and battery EVs totaled 'just under 114,000' worldwide. See http://www.pikeresearch.com/newsroom/cum ulative-plug-in-electric-vehicle-sales-to-reach-5-2million- worldwide-by-2017. By way of comparison, worldwide sales of NGVs in 2009 (the most recent worldwide data) were over 1.3 million vehicles. See http://www.iangv.org/tools-resources/statistics.html. See a/so, 76 Fed. Reg. 75,011 (noting that sales of the Nissan Leaf have been only approximately 8,000, and sales of the Tesla Roadster have been only approximately 1,500).

Furthermore, EVs are expected to 'have a significant impact on electrical grid strain.' See e.g., Nicholas DeForest, et aI., 'Impact of Widespread Electric Vehicle Adoption on the Electrical Utility Business - Threats and Opportunities,' Technical Brief, University of California, Berkeley Center for Entrepreneurship & Technology.

17 Implications of Greater Reliance on Natural Gas for Electricity Generation, American Public Power Ass'n, https://appanet.cms-plus.com/files/PDFs/lmplicationsOfGreaterRelianceOnNGforElectricityGeneration.pdf.

18 See the annual ratings issued by the American Council for an Energy Efficient Economy (ACEEE) at http://www.greenercars.org/highlights greenest.htm and http://www.honda.com/newsandviews/article.aspx?id=5904-enI noting that the CNG-powered Honda Civic GX was rated the 'greenest car in America' for eight years in a row (from 2003 to 2011).

19 The California Air Resources Board (CARB) has extensively analyzed this issue and found that CNG produces approximately 68 grams of CO_2 equivalent emissions per mega joule (MJ) burned. By comparison, gasoline and diesel produce approximately 94-95 grams of CO_2e/MJ.

These comparisons are based on well-documented, well-to-wheel analyses. Thus, natural gas can reduce GHG emissions by 28-29% compared with diesel and gasoline-fueled vehicles. See CARB Look Up Table, http://www.arb.ca.gov/fuels/lcfs/121409Icfs lutables.pdf

20 As detailed in Appendix 1, an NGV using even a 15% bio-methane blend would significantly reduce total GHG emissions. DOE's National Renewable Energy Lab has estimated future production of bio-methane will reach up to 16 billion gasoline gallons equivalent (GGEs). 74 Fed. Reg. 24,982. Bio-methane achieves approximately an 85 percent reduction in GHGs as compared to gasoline.

21 The federal government's track record in selecting clean energy winners has been questionable, at best. Over the last year, in addition to the well-publicized bankruptcy of the solar manufacturer Solyndra (which received a DOE loan guarantee of more than $500 million), a manufacturer of lithium-ion batteries for EVs, EnerDel, also filed for bankruptcy after receiving a $118 million grant from DOE. In 1971, significant federal funding was authorized for the Clinch River Breeder Reactor Project, which was considered to be 'revolutionary' at the time. Twelve years and $8 billion later, Congress pulled funding for the project, which was never finished. See e.g., http://www.nader.org/template.php?/archives/926-That-Clinches-lt-The-Breeder-Reactor-is-Dead.html.

22 See Lee & Lovellette, Discussion Paper, note 8, supra (noting that 'Batteries may become cheaper and lighter, and charging equipment can become more versatile; but these improvements are still developing').

23 See North Carolina v. EPA, 531 F.3d 896 (D.C. Cir. 2008) (holding that EPA's NO_x emissions trading program unduly favored coal-fired generation over natural-gas generation).

24 NHTSA is expressly prohibited from considering the availability of statutorily-established credits (such as for alternative-fueled vehicles) in determining its standards. Thus, NHTSA may not raise CAFE standards because manufacturers have enough of those credits to meet higher standards. By comparison, EPA's CAA authority does not have such a restriction, which allows EPA to set higher standards. 76 Fed. Reg. 75,341.

31 The Proposed Rule separately identifies electric vehicles (EVs) and plug-in hybrid electric vehicles (PHEVs). However, the regulatory benefits for both of these electric vehicle types are generally the same under the Proposed Rule. Therefore, 'EVs' in these comments should be understood to include both electric vehicles as well is plug-in hybrid electric vehicles, unless the context requires otherwise. Fuel cell vehicles also often share in comparable benefits, though because of the limited market deployment of these vehicles, they are not separately discussed herein.

37 Again examining CARB's look up table provides an approximate value of 94-95 gCO_2e/MJ for gasoline and diesel, while renewable natural gas has an approximate value of 11-13 gCO_2e/MJ. See CARB Look Up Table, note 19, supra.

38 'Qualified alternative fuel vehicles' should include only those vehicles that use an alternative fuel a minimum of 50% of the time (i.e., those vehicles that have a 'utility factor' equal to or greater than 50%). ACSF believes this qualification criteria is necessary to encourage the development of technologies that are truly 'alternative' with the potential to be 'game changing.' Thus, if forecast use of an alternative fuel is less than 50% (such as is the case with ethanol flex-fuel vehicles), then the vehicle class would not qualify for this incentive.

39 See EPA, 'Guidance for Implementing Section 141 of the Energy Independence and Security Act of 2007: Federal Vehicle Fleets and Low Greenhouse Gas-Emitting Vehicles' at 5 (Feb. 22, 2010).

40 Executive Order 13514, 'Federal Leadership in Environmental, Energy, and Economic Performance' Section 2(a) (Oct. 5, 2009), available at http:(/www.whitehouse.gov/assets/documents/2009fedleader eo rel,pdf.

41 See Federal Energy Management Program, 'Executive Order 13514: Federal Leadership in Environmental, Energy, and Economic Performance; Guidance for Federal Agencies on E.O. 13514 Section 12, Federal Fleet Management,' at 2 (Apr. 2010), available at http://www.gsa.gov/graphics/fas/ExecutiveOrder13514.pdf.

46 NGVAmerica, 'NGVs and the Environment,' available at http://www.ngvc.org/aboutngv/ngvenviron.html. Blending renewable sources of natural gas with traditional natural gas can further lower NGV GHG emissions.

47 Notably, the 'PEF' for EVs, which provides an equivalent benefit to the 0.15 divisor for EVs under the CAFE rules, continues to be in effect and is not impacted by the Proposed Rule.

51 With 1 being the baseline and 2 being equivalent to fuel that is 100% domestically sourced.

52 Another possible means of rewarding energy security is to make energy security benefits one of the 'gating' criteria for the existing vehicle multiplier, discussed above in section IVA For instance, to qualify for this multiplier EPA would need to determine that a certain minimum percentage of a vehicle's fuel is domestically sourced (say 75%), and that the vehicle drive-train technology does not require foreign-sourced materials that constitute more than a certain percentage of the drive-train's costs. 53 See Summary of CAFE Fines Collected, available at www.nhtsa.gov/staticfiles/rulemaking/pdf/cafe/CAFE fines collected summary.pdf.

54 As an example of statutory authority for revenue recycling, under 49 U.S.C. § 32912(e)(2), the Secretary of Transportation must use 50% of the fines collected 'to carry out a program to make grants to manufacturers for retooling, reequipping, or expanding existing manufacturing facilities in the United States to produce advanced technology vehicles and components.' Using the above 'energy security' factor, the agency could provide funds to manufacturers based upon the highest fleet wide 'energy security' factor to encourage development of vehicles that provide for a more secure energy future.

55 See EIA, 2012 Energy Outlook Early Release, Table A13, which finds that the 2012 supply of natural gas is in excess of 25 trillion cubic feet. Available at http://www.eia.gov/oiaf/aeo/tablebrowser/#release=EARLY2012 &subject:O-EARLY2012&tabIe:13EARLY2012& region=0-0&cases=fuI12011-d020911a,early2012-d121011b. See also Mass. Inst. of Tech., The Future of Natural Gas (noting that in the U.S., natural gas resources continue to grow, and the development of low-cost and abundant unconventional natural gas resources, particularly shale gas, has a material impact on future availability and price.), available at, www.cleanskies.org.

56 See http://www.minerals.usgs.gov/mineraI5/pub5/commodity/lithium/mcs-2011-lithi.pdf.

Organization: American Honda Motor Co., Inc.

Additionally, EPA requested comments about the inclusion of compressed natural gas vehicles (NGVs) in these incentives. NGVs have similar environmental and energy security benefits compared to EVs and PHEVs, and their marketing challenges (infrastructure and consumer acceptance) are similar, as well. Honda supports the addition of dedicated NGVs to the group of dedicated vehicle multipliers (EV and FCVs) and bi-fuel NGVs to the bi-fuel vehicle multipliers (PHEVs). A differential in the multiplier for dedicated and bifuel natural gas vehicles is fully justified because there is no guarantee that the latter will operate on natural gas all of the time. [EPA-HQ-OAR-2010-0799-9489-A1, p. 3]

Honda recommends revising Table III-15 as follows: [Table III-15 can be found on p. 3 of Docket number EPA-HQ-OAR-2010-0799-9489-A1] [EPA-HQ-OAR-2010-0799-9489-A1, p. 3]

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, pp. 118-119.]

However, EPA intends to use the SAE utility factor in calculating the contribution of each fuel in climate change in the future bi-fuel vehicle, which Honda believes will virtually eliminate any regulatory differentiation between a dedicated and the bi-fuel natural gas vehicle to detrimental effect. Therefore, Honda suggests that EPA instead add dedicated natural gas vehicles to the EV and fuel cell electric vehicle group of technologies and add bi-fuel natural gas vehicles to the PHEV group of technologies with respect to the multiplier.

Organization: American Petroleum Institute (API)

Comments on the Proposed Approach to Measure Compliance with Fuel Economy and GHG Standards for Dual-Fuel CNG vehicles

EPA and NHTSA note that the statutory incentive for dual-fueled vehicles in 49 U.S.C 32906 and the measurement methodology specified in 49 U.S.C 32905 (b) and (d) expire in MY 2019 and request comment on proposed options going forward. The agencies are proposing to directly extend the PHEV utility factor methodology to dual-fuel CNG vehicles, using the same assumptions about daily refueling. Under the utility factor approach, the vehicle range on the alternative fuel would be used to estimate the fraction of average daily travel that the range represents based on SAE Standard J2841. For example, a plug-in hybrid electric vehicle (PHEV) with an all-electric range of 40 miles would be assigned a utility factor of 0.617, while a dual-fuel natural gas vehicle (NGV) with a range on natural gas of 150 miles would be assigned a utility factor of 0.925. [EPA-HQ-OAR-2010-0799-9469-A1, p. 7]

We have several concerns with this proposed approach. First, it relies on the implicit assumption that the driving behavior of owners/operators of PHEVs is identical to that of owners/operators of dual-fuel CNG vehicles; an assumption which we do not believe is (or has been) demonstrably supported by any underlying data, yet should be. (A related question is whether the driving behavior and vehicle use characteristics of that element of the population sometimes termed “early technology adopters” is similar to, or different than, the “national average” database of travel characteristics from which the Utility Factors were created.)13 Second, although the use of the utility factor is an improvement over the simple 50/50 split used previously, this approach inherently assumes that the vehicle begins each day with a full state of charge (PHEVs) or a full natural gas tank (NGVs). It is unclear that this will occur in practice, and it may significantly overestimate the calculated benefits of the alternative fuel. Additionally, the vehicle range on the alternative fuel is established based on 2-cycle testing (i.e., the FTP and the highway fuel economy test) that is used to determine compliance with the CAFE and GHG standards. This clearly overestimates the range on the alternative fuel, and the proposed rule should be revised to reflect real-world vehicle range based on 5-cycle test results or other data that better represent real-world performance. This is not at all inconsistent with the use of 2-cycle tests for CAFE and GHG emissions compliance, as the real-world range would only be used to establish the appropriate utility factor, which, in turn, was based on real-world driving statistics. [EPA-HQ-OAR-2010-0799-9469-A1, pp. 6-7]

EPA and NHTSA Should Not Contravene the Will of Congress by Allowing an Unlimited Fleet Fuel Economy Credit for MY 2020 and Later Dual-Fueled Vehicles

EPA and NHTSA also are requesting comment on whether to continue to use the 0.15 divisor for CNG and ethanol, and the petroleum equivalency factor for electricity, both of which the statute requires to be used through MY 2019, for model years 2020 and later dual-fueled vehicles. The use of these factors in conjunction with the utility factor approach discussed above artificially and substantially inflates the fuel economy of dual-fueled vehicles and thus provides an incentive to the automakers to produce these for CAFE compliance purposes regardless of other consequences. In essence, the agencies are proposing that automakers may “…increase their calculated fleet fuel economy for dual-fueled vehicles by an unlimited amount using these flexibilities.”16 However, Section 32906 of the Energy Independence and Security Act of 2007 (EISA 2007) phased-out the maximum fuel economy credit attributable to dual-fuel vehicles (except electric vehicles) that could be taken by manufacturers of those vehicles such that the credit was reduced from 1.2 mpg in model year 2014 (and previous model years) to 0.2 mpg in model year 2019 to “0 miles per gallon for model years after 2019” (Section 32906(a)(7)). Clearly, the EPA and NHTSA proposed treatment of model year 2020 and later dual-fueled natural gas vehicles is overly generous and inconsistent with the intent and will of Congress. It should be set aside. [EPA-HQ-OAR-2010-0799-9469-A1, p. 7]

It is also useful to note that for the many years that this CAFE credit incentive has been in place, dual-fueled vehicles (particularly those using natural gas) have continued to remain a negligible fraction of the fleet. In other words, the presence of the incentive has not contributed to the influx of dual-fueled CNG vehicles. (In fact, there are no OEM dual-fuel CNG vehicles offered today; only a few after-market conversion models.) [EPA-HQ-OAR-2010-0799-9469-A1, p. 7]

---

13 Bradley, T.H and Quinn, C.W., Analysis of Plug-In Hybrid Electric Vehicle Utility Factors, Journal of Power Resources, 195 (2010) 5399-5408 [EPA-HQ-OAR-2010-0799-9469-A1, p. 6]

16 Note that E85 FFVs would need to demonstrate actual use of the alternative fuel to receive credit, via national average E85 and gasoline usage or manufacturer-specific data. [EPA-HQ-OAR-2010-0799-9469-A1, p. 7]

Organization: American Public Gas Association (APGA)

APGA also sincerely appreciates both agencies' efforts to make changes to the Greenhouse Gas/Corporate Average Fuel Economy Standards to further advance the development and deployment of alternative fueled vehicles (AFVs). However, APGA respectfully submits that both agencies consider changes to the NOPR (detailed below) to ensure that natural gas vehicles (NGVs) and infrastructure receive equal treatment to other AFV technologies. [EPA-HQ-OAR-2010-0799-9448-A1, p. 1]

Natural gas vehicles (NGVs) can play a critical role in reducing America's energy dependence on foreign oil, as well as reducing greenhouse gas emissions. The combination of a secure, domestic, affordable fuel source that can be used by existing technology makes NGVs the logical choice for replacing our transportation fleet.

In order to ensure that NGVs can make these critical contributions to U.S. energy and national security, APGA respectfully submits the following comments on: Current Law, the EPA/NHTSA Proposal for 2012-2015, and the Proposal for the 2016-2019 period. [EPA-HQ-OAR-2010-0799-9448-A1, p. 2]

2012-2015 Current Law: APGA believes that as structured under current law, dedicated and bi-fuel NGVs appear to receive significant NGV Fuel Economy (FE) and Greenhouse Gas Emissions (GHG) credits due to the .15 multiplier. However, because of the fact that E85 Flex Fuel Vehicles (FFVs) are eligible to receive these credits and because Original Equipment Manufacturers (OEMs) will likely not be required to have additional FE and GHG credits, they will be of little value to NGVs. [EPA-HQ-OAR-2010-0799-9448-A1, p. 2]

Additionally, APGA respectfully requests clarification on the following issues:

- Can GHG credits for dedicated and bi-fuel NGVs be carried forward?
- Can the bi-fuel FE credits be carried forward?

- Can the FE credits for dedicated vehicles be carried forward? [EPA-HQ-OAR-2010-0799-9448-A1, p. 2]

APGA respectfully requests that clarification be provided for each of these issues. [EPA-HQ-OAR-2010-0799-9448-A1, p. 2]

EPA/NHTSA Proposal 2012-2015:

Given the issues with current law, APGA respectfully requests that EPA and NHTSA to extend the incentives provided in 2012 – 2015 specifically for dedicated and bi-fuel NGVs until NGV sales hit a level demonstrating market acceptance or commercialization. APGA is open as to how to properly define this metric but suggests that perhaps a sales threshold of 250,000 dedicated NGVs per year is practicable. [EPA-HQ-OAR-2010-0799-9448-A1, p. 2]

Moreover, APGA also suggests that EPA and NHTSA establish a separate track for bi-fuel vehicles so that the credits for these vehicles are not overwhelmed by the FFV credits and subject to the caps of bi-fuel vehicles. APGA believes that the legal justification for this change is the same that they are offering for 2020 and beyond – i.e., the Utility Factor (UF) bases performance on real-world expectations not the seemingly arbitrary 50/50 allocation established in Energy Policy and Conservation Act (EPCA). [EPA-HQ-OAR-2010-0799-9448-A1, p. 2]

APGA also urges EPA to provide an incentive for OEMs like Ford and GM and others who are facilitating the development of the aftermarket industry by offering Natural Gas-ready engines and setting up Qualified Vehicle Manufacturer (QVM) programs. The aftermarket vehicles largely are not covered by GHG and FE rules so the OEMs should receive some credit for facilitating increased availability of aftermarket vehicles. [EPA-HQ-OAR-2010-0799-9448-A1, p. 2]

2016-2020 [EPA-HQ-OAR-2010-0799-9448-A1, p. 3]

APGA appreciates the changes the proposed rules make to current law. However, APGA does have two brief suggestions for improvement on two elements under EPA jurisdiction: the production multiplier and pickup truck rules. [EPA-HQ-OAR-2010-0799-9448-A1, p. 3]

EPA specifically solicited comments on whether it should provide a production multiplier for dedicated and bi-fuel NGVs for 2017 - 2021 – which would be a GHG credit. APGA strongly believes that this credit would be beneficial for NGVs if they are treated similarly under the rule as PHEVs. [EPA-HQ-OAR-2010-0799-9448-A1, p. 3]

Organization: Association of Global Automakers, Inc. (Global Automakers)

EPA invited comments on providing a multiplier incentive for dedicated and/or dual fuel compressed natural gas vehicles. Global Automakers supports such an approach, which would address the near term price and fueling infrastructure obstacles faced by these vehicles in a manner consistent with the approach taken for electric and fuel cell vehicles. Furthermore, Global Automakers supports the extension of multiplier incentives to other alternative fuels as well, such as liquid petroleum gas (LPG) or biodiesel. With regard to dual fueled vehicles in general, we urge the agencies to reconsider the treatment of these vehicles as part of the planned mid-term review of the standards, at which point the need for particular incentives would be clearer. Whatever approach is adopted, we urge that EPA and NHTSA agree on a single, harmonized set of incentives. [EPA-HQ-OAR-2010-0799-9466-A1, p. 7]

Organization: Boyden Gray & Associates PLLC

First, the joint proposal prioritizes CO_2 control at the expense of petroleum import reduction, which should be the paramount goal of these regulations. But the joint proposal fails to expressly acknowledge its preference; because of that lack of transparency, we fear that it will receive insufficient comment. [EPA-HQ-OAR-2010-0799-9506-A1, p. 1]

CO_2 VERSUS OIL IMPORT REDUCTION

In this joint rulemaking, both EPA and DOT go to considerable lengths to assert that although each agency is governed by different legislative authority, their proposals are for all relevant purposes similar in their requirements. Unfortunately this is not the case—the two agencies propose to impose fundamentally incompatible requirements. [EPA-HQ-OAR-2010-0799-9506-A1, p. 2]

Of course, similarity is not what one would expect from just a cursory familiarity with the underlying statutes—the Clean Air Act (CAA) and the Energy Independence and Security Act of 2007 (EISA)—and similarity is not in fact what results. The agencies acknowledge (fleetingly) the tradeoffs between climate control and oil import reduction, yet they fail to acknowledge the major contradictions that could easily develop under these joint proposed rules. [EPA-HQ-OAR-2010-0799-9506-A1, p. 2]

The easiest starting point for explanation is DOT's own description of the central intent of the authorizing 2007 energy legislation: "the overarching purpose of the statute is energy conservation and reducing petroleum usage." To that end, the statute provides for an alternative fuel "multiplier" that the 2007 Energy bill requires for model years to 2019 and which the agencies propose to continue well beyond. The multiplier—actually a 0.15 divisor—is a very powerful regulatory boost for domestically produced alternative fuels such as alcohols, natural gas or hydrogen. The mechanism works by dividing the miles per gallon (equivalent of gasoline) of the alternative fuel by 0.15, so that a car getting 15 miles per gallon on alternative fuel goes into the car company's fleet average as a 100-mpg vehicle. As the preamble to the proposed rules also explains, a typical compressed natural gas (CNG) vehicle that gets 25 miles per 100 cubic feet of gas goes into the average as a car getting 203 mpg. [EPA-HQ-OAR-2010-0799-9506-A1, p. 2]

These are big numbers with a potentially significant impact for lowering an automaker's fleetwide average fuel economy if the company sells more than a few alternatively fueled vehicles. Assume, for example, that a car company sells 30% of its vehicles to fleet operators (limousines, delivery vehicles, taxi cabs, etc.), and that the company decides to convert, by 2025, half of those cars (i.e., 15% of total sales) to natural gas.6 If 15% of the company's sales are

CNG-fueled, with a fuel economy of 203 mpg, the company could still achieve NHTSA's 2025 fuel economy requirement (49.6 mpg) so long as the remaining 85% of its sales were at least 43.77 mpg. Similarly, a car company could convert 15% of its total sales in 2025 to vehicles that run on E30—a blend of 30% ethanol and 70% gasoline that allows for some increased engine efficiency because of its high octane. Given growing awareness of the benefits of E30 as a sustainable and cleaner fuel choice, the administrator could grant a multiplier to E30 that functions in the same way as the current 0.15 multiplier for alternative fuels.8 A multiplier of 0.7 for E30, based on the 70% fuel content of E30, would allow the car company to meet NHTSA's 2025 requirement of 49.6 mpg with a fleet of cars that achieve only 47.4 mpg, so long as 15% of those vehicles were run on E30. These margins—6 mpg in the CNG example and 2.2 mpg in the E30 example—would provide car companies with flexibility to experiment with technological advances to satisfy consumer demand and reduce traditional pollution without fear of fines. That opportunity is precisely the type of incentive that the EISA, amending the Energy Policy and Conservation Act, was enacted to create: as NHTSA recognizes in its "portion" of the joint rulemaking proposal, EISA was enacted to promote fuel economy and displace foreign oil. It is irrelevant that companies may have made downsizing commitments in anticipation of continued high oil prices and may therefore never need the maximum leeway theoretically provided. The key is at the margins, and the need for car companies to steer clear of problems that cannot be anticipated, such as a changing consumer preferences and fluctuating oil prices. [EPA-HQ-OAR-2010-0799-9506-A1, pp. 2-3]

In practice, NHTSA's incentive structure is a mirage, because it is nullified in substance by EPA's greenhouse gas emissions regulations. Under the EPA's proposed rules, a car company could not fully utilize the 0.15 multiplier, as hypothesized above, to convert 15% of its sales to CNG, because the total emissions for all cars sold, including gasoline-fueled cars making up 85% of total sales, would far exceed EPA's maximum emissions limits. The company's total vehicle stock—15% CNG-fueled vehicles, with a statutory fuel economy of 203 mpg; and 85% gasoline-fueled vehicles, with a fuel economy of 43.77 mpg—would produce emissions averaging approximately 203 g/mi, 25% more than the EPA's proposed 2025 limit of 163 g/mi.10 Perhaps more to the point, today's CNG vehicles could not satisfy EPA's 2025 CO_2 requirements, despite the multiplier, even though CNG vehicles produce almost 30% less CO_2 emissions than gasoline vehicles do, because the EPA rules require a CO_2 reduction by 2025 larger than 30% (i.e., 163 g/mi verses 203 g/mi). Put another way, CNG vehicles alone would produce more CO_2 than a gasoline car that has been downsized and otherwise redesigned to meet a163 g/mi CO_2 rating.11 [EPA-HQ-OAR-2010-0799-9506-A1, p. 3]

In other words, the EPA's rules eliminate the flexibility that EISA, as implemented by NHTSA, is supposed to create for automakers. EPA's proposal caps car companies' ability to utilize NHTSA's 0.15 multiplier. EPA's proposal effectively repeals much of DOT's import-reduction efforts, and the 2007 statute on which DOT's efforts are based. [EPA-HQ-OAR-2010-0799-9506-A1, p. 4]

As noted above, the agencies cannot avoid this conflict by asserting that car companies are unlikely to want to utilize the 0.15 multiplier to an extent that would violate EPA's greenhouse gas limits. In fact, this scenario is much more likely than the agencies might admit, because the agencies own efforts to promote electric cars may be unrealistic. While the agencies presume that a significant segment of the market will move to hybrid and plug-in electric vehicles, actual electric car sales have fallen far short of the agencies' hopes; even going forward, electric vehicles' future is clouded by limited access to low priced rare metals essential to large scale battery production. Moreover, the future of solar and wind renewable energy is much less robust today than just a year ago, given the well publicized difficulties with solar investments and the very low price of natural gas. This could mean a much higher CO_2 profile for electric vehicles over the long haul (beyond the first 200,000 which are exempt from the life cycle analysis that applies to other alternative fuels). [EPA-HQ-OAR-2010-0799-9506-A1, p. 4]

Indeed, while market forces are making electric vehicles less attractive, market forces are making alternative-fueled vehicles more attractive. Natural gas vehicles will benefit from the low price of natural gas, which stems largely but not exclusively from the gas shale revolution. At the same time, biofuels will become more popular: ethanol produces less CO_2 than gasoline, on a life-cycle basis; but like natural gas, it still produces much more than a downsized gasoline car. It is not hard to envision a combination of natural gas and biofuel growth encouraged by the 2007 legislation that quickly challenges the CO_2 limits imposed by EPA. [EPA-HQ-OAR-2010-0799-9506-A1, p. 4]

Which regime takes precedence, EPA's or DOT's? The former is based on the Clean Air Act (CAA), the latter, on the 2007 EISA. The relevant CAA provisions were enacted as far back as 1970 and 1990, when climate change policy-making was in its infancy; there has been no relevant CAA legislation since 1990. If there is an irreconcilable conflict between the statutes, then the EISA will likely control the CAA, because the later enactment ordinarily displaces the earlier. [EPA-HQ-OAR-2010-0799-9506-A1, p. 4]

And in this case, the legislative history makes the EISA's displacement of the CAA even clearer. The Supreme Court ruled in Massachusetts v. EPA (2007) that CO_2 was a "pollutant" within the meaning of the CAA and thus subject to regulation upon a finding by EPA that CO_2 endangers the environment—a finding subsequently made by EPA that is now on appeal. In the Massachusetts v. EPA litigation, the EPA had argued that they could not regulate greenhouse gas emissions because doing so would be equivalent to regulating fuel economy, a subject committed to DOT's jurisdiction by the Energy Policy Conservation Act. The Supreme Court observed, without providing any details, that "there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency." That hypothetical co-existence might have been possible in 2006, but Congress's enactment of the EISA later that year ended any hope for co-existence. The EISA reaffirmed the 0.15 "multiplier," and it stated Congress's position that the country must "reduce the dependence of the United States on energy imported from volatile regions of the world that are politically unstable," and that "increased energy production from domestic renewable resources would attract substantial new investments in energy infrastructure, create economic growth, develop new jobs for the citizens of the United States, and increase the income for farm, ranch, and forestry jobs in the rural regions of the United States." [EPA-HQ-OAR-2010-0799-9506-A1, pp. 4-5]

As is often the case in state preemption and federal displacement cases, Congress did not address any possible conflict between the new CAFE statute and the much older CAA, which makes no mention of climate change or CO_2 regulation. But coming after the Supreme Court decision, there can be little question that if there is a conflict between the statutes, then the CAA must defer to the highly detailed 2007 legislation. At the very least, it is difficult to argue that EPA's CO_2 limits can be allowed to negate the multiplier. [EPA-HQ-OAR-2010-0799-9506-A1, p. 5]

Without acknowledging this potential conflict, EPA does request comment on whether natural gas vehicles should receive a CO_2 multiplier similar to that which EPA provides for electric vehicles. But EPA does not explain the basis for calculating the EV multiplier; it is therefore difficult to determine from the EV example how this should be done. An approach more clearly rooted in the statute would be to provide a CO_2 multiplier equivalent to the 0.15 multiplier EISA provides for alternative fuels, and make it similarly available to fuels like ethanol and natural gas. The result would be a CO_2 averaging number that companies could assign to non-petroleum cars in the same way that the 0.15 multiplier results in an mpg number for calculating a manufacturer's fleetwide average fuel economy. The agencies could in this way keep the two regulatory regimes from potentially troublesome legal conflict. [EPA-HQ-OAR-2010-0799-9506-A1, p. 5]

Organization: Chrysler Group LLC

Chrysler supports EPA's proposals regarding natural gas vehicles and recommends that the Agencies take steps to further harmonize the greenhouse gas and CAFE program treatment of the vehicles. (Attachment 4)

Current statutes and regulations limit the regulatory support for natural gas vehicles ("NGV"s). Chrysler recommends that the agencies establish a category of "extended-range" dual fuel NGVs which would be treated as dedicated NGVs. Chrysler supports EPA's proposal to weight dual fuel NGV fuel use using a utility factor-based approach. This approach is consistent with the expected real-world CNG utilization of this vehicle type. Given the additional expense of NGVs and the state of infrastructure development, Chrysler also supports EPA's proposed incentive multipliers for the production of these vehicles. [EPA-HQ-OAR-2010-0799-9495-A1, p. 6]

In his January 24, 2012 State of the Union Address, President Obama laid out a Blueprint for an America Built to Last, underscoring his commitment to an all-of-the-above approach that develops every available source of American energy. This commitment includes a plan to promote the safe, responsible development of the near 100-year supply of natural gas, supporting more than 600,000 jobs while ensuring public health and safety. Encouraging the development of the CNG refueling infrastructure and CNG vehicles supports this commitment. [EPA-HQ-OAR-2010-0799-9495-A1, p. 18]

Both dedicated and dual fuel compressed natural gas vehicles ("NGVs") represent a significant opportunity to reduce greenhouse gas emissions and to improve energy independence. The benefits of compressed natural gas include abundant domestic production, lower smog-forming and greenhouse gas emissions when burned, and a price advantage over gasoline. However, several roadblocks exist to the wide-spread adoption of NGVs. These include limited vehicle availability and a lack of public fueling infrastructure. [EPA-HQ-OAR-2010-0799-9495-A1, p. 18]

In the NPRM, the Agencies take positive steps towards enabling the successful deployment of NGVs, including the establishment of a utility factor-based method for dual fuel CNG vehicles. The Agencies can build on these positive first steps by developing a harmonized approach between the greenhouse gas and CAFE rules, extending EPA utilization of the NHTSA 15% fuel content factor under the greenhouse gas rules, and providing volume multipliers consistent with those proposed for electric and plug-in hybrid electric vehicles. [EPA-HQ-OAR-2010-0799-9495-A1, p. 18]

A special category of “extended-range” NGVs should be created

Chrysler believes that the creation of a special “extended-range” category for certain dual fuel NGVs would be helpful in encouraging manufacturers to produce NGVs while providing adequate reserve range where a re-fueling infrastructure is not readily available. This type of vehicle could provide significant CNG range, with a reserve of conventional fuel to reduce customer range anxiety. [EPA-HQ-OAR-2010-0799-9495-A1, p. 18]

Under current regulations, the incentives to undertake a dual fuel NGV are minimal for manufacturers which already meet the maximum dual fuel credit values through the production of dual fuel bio-fuel vehicles. If this special category of extended-range NGVs were treated, for regulatory purposes, as dedicated alternative fuel vehicles, this barrier would be removed and manufacturers would be incentivized to produce a greater number of NGVs, thereby also promoting infrastructure development. [EPA-HQ-OAR-2010-0799-9495-A1, p. 18]

Chrysler supports the proposed utility factor-based methodology to weight greenhouse gas emissions for dual fuel NGVs.

EPA proposes to apply a utility factor-based methodology to weighting greenhouse gas emissions on CNG and conventional fuel for dual fuel NGVs. Chrysler agrees that this approach is appropriate for this type of vehicle and will more accurately reflect the relative use of CNG and conventional fuels. As noted above, once the proportion of CNG to conventional fuel driving range exceeds a certain threshold, the Agencies should treat this type of vehicle as a dedicated alternative fuel vehicle. [EPA-HQ-OAR-2010-0799-9495-A1, p. 18]

The utility factor-based calculation should be made available for greenhouse gas and CAFE compliance purposes starting 2012MY.

Treatment of NGVs as Advanced Technology Vehicles

EPA requests comment on the merits of providing multipliers to NGVs similar to those for electric and plug-in hybrid electric vehicles. Chrysler supports this approach to providing regulatory incentives for this beneficial technology. Such an approach not only improves the business case for NGVs, but also provides a more technology-neutral approach to reducing greenhouse gas emissions and oil consumption. Chrysler recommends that dedicated and “extended-range” natural gas vehicles receive at least the same multipliers as electric vehicles, and that dual fuel NGVs receive at least the same multipliers as plug-in hybrid electric vehicles. [EPA-HQ-OAR-2010-0799-9495-A1, p. 19]

EPA is proposing “to allow the option, at the manufacturer’s discretion, to use the proposed utility factor-based methodology” for model year 2012-2015 greenhouse gas compliance calculations. Chrysler supports this proposal. [EPA-HQ-OAR-2010-0799-9495-A1, p. 19]

EPA further proposes to begin use of the utility factor-based approach for CAFE purposes starting in model year 2020. The goal of harmonizing greenhouse gas and CAFE compliance requirements would be best served if these vehicles were treated the same under both programs by using the utility factor-based approach in CAFE compliance calculations. [EPA-HQ-OAR-2010-0799-9495-A1, p. 19]

EPA should continue to apply the 15% fuel content factor to greenhouse gas emissions through 2025 model year.

Under current regulations, for model years 2012 through 2015, the greenhouse gas emissions for dual fuel NGVs are multiplied by a 0.15 fuel content factor, similar to their treatment in the CAFE program. In the 2016 and later model years, this fuel content factor is discontinued for greenhouse gas emission purposes, resulting in reduced harmonization with the CAFE program. To increase harmonization of the two programs, and to incentivize production of NGVs, EPA should extend this 0.15 fuel content factor through the 2025 model year, consistent with the CAFE program. [EPA-HQ-OAR-2010-0799-9495-A1, p. 19]

Organization: Clean Energy

PRESIDENT OBAMA'S COMMENTS ON NATURAL GAS VEHICLES ON JANUARY 26, 2012. [EPA-HQ-OAR-2010-0799-9511-A1, p.2]

On January 26, 2012, the President of our United States shared his views on the importance of natural gas use in vehicles at a Clean Energy refueling station serving the United Parcel Service in Las Vegas, Nevada. His remarks were so important, that we felt compelled to include them in our comments. Below is an important excerpt of his speech that day (emphasis in 'bold' added). [EPA-HQ-OAR-2010-0799-9511-A1, p.2]

Now, part of my blueprint and what I want to focus on a little bit today is for on economy built to last with American energy. That's why we're here. For decades, Americans have been talking about how do we decrease our dependence on foreign oil. Well, my administration has actually begun to do something about it. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

Over the last three years, we negotiated the toughest new efficiency standards for cars and trucks in history. We've opened millions of new acres for oil and gas exploration. Right now, American oil production is the highest that it's been in eight years. Eight years. Last year, we relied less on foreign oil than in any of lost 16 years. That hasn't gotten a lot of attention, but that's important. (Applause.) We're moving in the right direction when it comes to oil and gas production. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

And today, I'm announcing that my administration will soon open up around 38 million acres in the Gulf of Mexico for additional exploration and development, which could result in a lot more production of domestic energy. (Applause.) [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

But as I said on Tuesday, and as the folks here at UPS understand, even with all this oil production, we only have about 2 percent of the world's oil reserves. So we got to have an all-out, all-in, all-of-the-above strategy that develops every source of American energy - a strategy that is cleaner and cheaper and full of new jobs. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

Now, a great place to start is with natural gas. Some of you may not have been following this, but because of new technologies, because we can now access natural gas that we couldn't access before in an economic way, we've got a supply of natural gas under our feet that can last America nearly a hundred years. Nearly a hundred years. Now, when I say under our feet, I don't know that there's actually gas right here. (Laughter.) I mean in all the United States. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

And developing it could power our cars and our homes and our factories in a cleaner and cheaper way. The experts believe it could support more than 600,000 jobs by the end of the decade. We, it turns out, are the Saudi Arabia of natural gas. (Applause.) We've got a lot of it. We've got a lot of it. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

Now, removing that natural gas obviously has to be done carefully. And I know that there are families that are worried about the impact this could have on our environment and on the health of our communities. And I share that concern. So that's why I'm requiring - for the first time ever -- that aft companies drilling for gas on public lands disclose the chemicals they use. We want to make sure that this is done properly and safely. (Applause.) America will develop this resource without putting the health and safety of our citizens at risk. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

But we've got to keep at it. We've got to take advantage of this incredible natural resource. And think about what could happen if we do. Think about an America where more cars and trucks are running on domestic natural gas than on foreign oil. Think about an America where our companies are leading the world in developing natural gas technology and creating a generation of new energy jobs; where our natural gas resources are helping make our manufacturers more competitive for decodes. We can do this. And by the way, natural gas bums cleaner than oil does, so it's also potentially good for our environment as we make this shift. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

So lost April, we issued II challenge to shipping companies /Ike UPS. We sold if you upgrade your fleets to run on less oil or no oil at all, we're going to help you succeed. We wont to help you with that experiment. So we started out with five companies that accepted the challenge. And of course, UPS was one of the first. That's how they roll. (Laughter and applause.) [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

So less than a year later, we've got 14 companies an board, and together they represent 1 million vehicles on the rood. That's a lot of trucks. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

We should do more, though. And that's why we're here today. First, let's get more of these natural gas vehicles on the road. Let's get more of them on the road. (Applause.) The federal fleet of cars is leading by example. Tums out the federal government has a lot of cars. (Laughter.) We buy a lot of cars. So we've got to help not only the federal government but also local governments upgrade their fleet. If more of these brown trucks are going green, mare city buses should, too. There's no reason why buses can't go in the some direction. [EPA-HQ-OAR-2010-0799-9511-A1, p.3]

Second, let's offer new tax Incentives to help companies buy more clean trucks like these. (Applause.) [EPA-HQ-OAR-2010-0799-9511-A1, p.4]

Third, let's make sure all these new trucks that are running on natural gas hove places to refuel. That's one of the biggest impediments, is the technology. We know how to make these trucks, but if they don't have a place to pull in and fill up, they got problems. [EPA-HQ-OAR-2010-0799-9511-A1, p.4]

So we're going to keep working with the private sector to develop up to five natural gas corridors along our highways. These are highways that have natural gas fueling stations between cities, just like the one that folks at UPS, South Coast Air and Clean Energy Fuels are opening today between Las Angeles and Salt Lake City. That's a great start. (Applause.) So now one of these trucks can go from Long Beach all the way to Salt Lake City. And they're going to be able to refuel along the way. [EPA-HQ-OAR-2010-0799-9511-A1, p.4]

And finally, to keep America on the cutting edge of clean energy technology, I want my Energy secretary, Steven Chu, to launch a new competition that encourages our country's brightest scientists and engineers and entrepreneurs to discover new breakthroughs for natural gas vehicles. [EPA-HQ-OAR-2010-0799-9511-A1, p.4]

So we're going to keep moving on American energy. We're going to keep boosting American manufacturing. We're going to keep training our workers for these new jobs. But an economy that's built to last also means a renewal of the values that made us who we are: hard work, fair play and shared responsibility. [EPA-HQ-OAR-2010-0799-9511-A1, p.4]

The Proposed Regulatory Incentives for NGVs Do Not Reflect the President's Vision [EPA-HQ-OAR-2010-0799-9511-A1, p.4]

Clean Energy found that the incentives outlined in the proposed rule for NGVs are not adequate or consistent, especially when compared to electric vehicle incentives, to support greater natural gas vehicle adoption and advancement as the President urged his Administration to do last month. For dedicated NGVs after 2016, the 0.15 divisor would no longer be available, so GHG incentives for manufacturers would be negligible. For dual fuel vehicles, the use of the 0.15 divisor would end after 2015 - virtually eliminating the value of dual-fuel vehicle GHG benefits. [EPA-HQ-OAR-2010-0799-9511-A1, pp.4-5]

If the purpose of these regulations is to encourage manufacturers to produce vehicles that produce fewer greenhouse gases, this aspect of the proposed rules makes little sense. NGVs produce less GHGs than comparable gasoline vehicles - especially when the upstream emissions are considered. Without continued use of the 0.15 divisor for dual-fuel GHG calculations, the incentive for manufacturers to produce NGVs would be significantly reduced. [EPA-HQ-OAR-2010-0799-9511-A1, p.5]

Clean Energy's Recommends the Following Changes [EPA-HQ-OAR-2010-0799-9511-A1, p.5]

1. Provide Dual-Fuel NGVs a separate Track from E85 Vehicles [EPA-HQ-OAR-2010-0799-9511-A1, p.5]

The large number of E85 vehicles being manufactured, in effect, nullifies the value of other dual-fuel vehicle FE credits. Clean Energy recommends that the agencies develop a separate track for dual-fuel NGVs to make the incentives truly effective. Dual-fuel NGVs (and any other alternative fuel vehicles) certified under this track should earn unlimited (uncapped) FE and GHG credits. [EPA-HQ-OAR-2010-0799-9511-A1, p.5]

2. Apply the Utility Factor for Dual-Fuel NGVs for GHG and FE Credits In 2012 [EPA-HQ-OAR-2010-0799-9511-A1, p.5]

The utility factor (UF) should apply to dual-fuel vehicles beginning with MY 2012 for GHG and FE credits as the agencies have articulated sufficient legal justification for adopting the use of the utility factors for fuel economy for MY 2020 forward, and EPA has already proposed making the utility factors retroactive back to 2012 for GHG certification. This same rationale supports extending the utility factor to the FE calculations prior to 2020. Providing one credit but not the other is highly problematic and is not consistent with the intent of harmonization under one single national fuel economy/greenhouse gas program. That is why some credit provisions in the rules (e.g., FFVs, EVs, hybrid trucks) attempt to provide periods where both incentives overlap. Combining the incentives and providing consistent treatment of FE and GHG credits for dual-fuel NGVs is extremely important to ensure compliance with these extremely complex regulations. [EPA-HQ-OAR-2010-0799-9511-A1, p.5]

3. Apply the 0.15 GHG Divisor Beyond 2015 [EPA-HQ-OAR-2010-0799-9511-A1, p.5]

The use of the 0.15 divisor for GHGs for both dual-fuel and dedicated NGVs currently terminates after 2015 making them ineffective. These credits must be extended beyond 2015 so that manufacturers have sufficient time to respond to them and they should remain in place until a certain market penetration is achieved. Such a phase-out of incentives would be consistent with the approach taken with respect to electric drive vehicles. We believe that providing these credits until a manufacturer's sale of NGVs reaches several hundred thousand (300,000 in the case of EVs) is warranted. [EPA-HQ-OAR-2010-0799-9511-A1, p.5]

Sales Multipliers [EPA-HQ-OAR-2010-0799-9511-A1, p.6]

In its notices, the agencies have asked for comment on whether to provide a production or sales multiplier for dedicated and dual-fuel NGVs. The agencies have proposed adopting such multipliers for other technologies (e.g., a multiplier of 1.3-2.0 is proposed for EVs, FCVs, and

PHEVs) for 2017 - 2021. In order to ensure equitable treatment, the agencies should provide similar credits to NGVs. And since EVs and other electric-drive vehicles already receive extremely generous treatment in the rules, we believe that the provision of a sales multiplier for NGVs should be in addition to any other credits also provided for NGVs in order to further encourage manufacturers to offer such vehicles. In terms of credit values, we support NGV America's proposal that dedicated NGVs should be treated like EVs and that dual fuel NGVs should be treated like PHEVs. The result of this more equitable treatment would be to provide a level playing field to incentivize the manufacture of all alternative fuel vehicles and not favor one technology over another. Therefore, we support NGV America's proposed multiplier credits for NGVs: [EPA-HQ-OAR-2010-0799-9511-A1, p.6] [For the associated figure, please refer to EPA-HQ-OAR-2010-0799-9511-A1, p.6]

Clean Energy once again would like to thank EPA and NHTSA for the opportunity to provide comments on this important rule. While we certainly appreciate the inclusion of NGV incentives in the current proposal, we strongly believe that they need to be enhanced in order to be effective. Further, we believe it is in the agencies' best interest to do so as NGVs provide an opportunity to significantly displace foreign oil, harness a domestic resource that can help create American jobs and boost American businesses, while significantly reducing greenhouse gas emissions generated on American roads. [EPA-HQ-OAR-2010-0799-9511-A1, p.7]

Organization: Edison Electric Institute (EEI)

C. If Offered, Incentives for Compressed Natural Gas Vehicles Should Not Be “Equivalent” to Incentives for EVs. [EPA-HQ-OAR-2010-0799-9584-A2, p. 8]

EPA requests comment on the merits of providing similar incentives as proposed for EVs to dedicated and/or dual fuel compressed natural gas (CNG) vehicles. See 76 Fed. Reg. at 75013. EPA should not provide similar multiplier incentives for CNG vehicles. While CNG vehicles reduce GHG emissions from LDVs, when compared to traditional fuel vehicles, they do not reduce tailpipe emissions of all pollutants (GHGs and criteria air pollutants) to 0.0 g/mile.4 Accordingly, EPA should not allow manufacturers to count CNG emissions as 0.0 g/mile when calculating compliance averages. [EPA-HQ-OAR-2010-0799-9584-A2, pp. 8-9]

CNG vehicles could play an important role to play in the diversification of transportation-sector fuels, particularly in the fleet and medium-duty sectors. If EPA believes that some sort of incentive for CNG vehicles is necessary, EPA must take into consideration the fact that CNG is comprised primarily of methane, a GHG that has a 100-year global warming potential (GWP) 25 times greater than that of carbon dioxide. To the extent that EV incentives are discounted to reflect the upstream emissions related to electricity generation and transmission, any incentives for CNG vehicles also must be discounted to reflect not only methane’s higher GWP, but also the upstream emissions related to natural gas production and transportation.5 [EPA-HQ-OAR-2010-0799-9584-A2, p. 9]

Organization: Encana Natural Gas Inc.

Natural gas vehicles can play an important role in increasing fuel efficiency and reducing vehicle emissions. Compared with traditional and available alternative fuels, natural gas can deliver material emission reductions of greenhouse gases ('GHGs'), criteria pollutants and hazardous air pollutants. America's affordable, abundant natural gas resources can help the u.s. achieve greater energy independence in the transportation sector. [EPA-HQ-OAR-2010-0799-9585-A2, p. 1]

As one of the largest producers of natural gas in North America and a strong proponent of clean, abundant, affordable, and domestic natural gas. Encana is an example of an early mover by adopting natural gas vehicles ('NGVs') in our own fleet. At the end of 2011, Encana had 15% of its vehicle fleet transitioned to dedicated or bi-fuel natural gas, along with 6 CNG and 1 LNG fueling stations operating to service its own fleet, those of our contractors and the public. Encana intends to continue transitioning its fleet vehicles to CNG, as well as opening new stations for CNG and LNG. [EPA-HQ-OAR-2010-0799-9585-A2, p. 1]

Natural gas as a transportation fuel is not a new concept with growing utilization in U.s. fleet vehicles and wide acceptance internationally. Unlike other alternative vehicle technologies, natural gas vehicles are not in need of early stage technology support which has an inherently uncertain future. In fact, proven technology makes natural gas the recognized leader in affordable alternative fuels. To accelerate market acceptance, it is necessary to promote a clean domestic energy supply through production incentives. Incentives for Original Equipment Manufacturers ('OEMs') are critical to ensure market penetration of NGVs matches the pace of natural gas fueling infrastructure build-out. [EPA-HQ-OAR-2010-0799-9585-A2, p. 2]

As outlined in detail below, Encana respectfully requests that the EPA and NHTSA avoid picking technology winners and give all viable alternative fueled vehicles the opportunity for accelerated market acceptance. All alternative fueled vehicles should be treated equally. [EPA-HQ-OAR-2010-0799-9585-A2, p. 2]

GHG and Other Emission Benefits of Natural Gas Fuel

Clean burning natural gas offers many advantages over other fossil fuels such as gasoline and diesel. Natural gas is composed of nearly 100% methane, which has a simple molecular structure with one carbon atom per molecule. Due to this simple molecular structure, natural gas has the lowest carbon content of any of the commonly used fuels in the United States. Natural gas contains approximately 74% of the carbon content of gasoline per unit of energy produced (EPA 2010). As such, replacing traditional transportation fuels with natural gas can reduce GHG emissions by about 25%. [EPA-HQ-OAR-2010-0799-9585-A2, p. 2]

Additionally, natural gas combustion produces lower emissions of several other pollutants including sulfur dioxide, hazardous air pollutants, volatile organic compounds, and fine particulate matter. [EPA-HQ-OAR-2010-0799-9585-A2, p. 2]

Availability and Abundance of Natural Gas

As noted above, natural gas is an abundant resource in North America presenting over 100 years of supply at current consumption levels. The U.s. Energy Information Agency ('EIA') recognizes the significant new supplies of natural gas in the Annual Energy Outlook ('AEO') 2012 Early Release Overview forecasting greater demand for natural gas and lower prices over the same time period. Recent shale gas discoveries, technological innovation and the on-going expansion of the natural gas pipeline network are combining to make natural gas available throughout the continental United States. [EPA-HQ-OAR-2010-0799-9585-A2, p. 2]

According to the EIA AEO 2011, production from shale formations in the United States grew by an average annual rate of 17% per year from 2000 to 2006. While 17% is impressive for those years, in the years from 2006 to 2010, United States shale gas production grew by an average annual growth rate of 48%[1]. The natural gas industry will continue to find new shale gas resources and by using enhanced technologies such as horizontal drilling and hydraulic fracturing, this success rate will continue to outpace demand. [EPA-HQ-OAR-2010-0799-9585-A2, p. 2]

Affordability of Natural Gas [EPA-HQ-OAR-2010-0799-9585-A2, p. 2]

According to the AEO 2012 Early Release Overview, with increased domestic natural gas production, average annual wellhead prices for natural gas remain below $5 per thousand cubic feet (2010 dollars) through 2023 in the AE02012 Reference case. These projections are reflective of natural gas decoupling from international crude oil market prices. US consumers can now take advantage of the stable and low natural gas prices that will be realized through the life of this proposed rule. [EPA-HQ-OAR-2010-0799-9585-A2, pp. 2-3]

Advantages of a Domestic Fuel Supply

The US is in dire need of job growth to enable an economic recovery and the natural gas industry can provide a significant boost towards this end. In fact, during President Barak Obama's 2012 State of the Union Address, he highlighted a potential to grow 600,000 jobs producing domestic oil and gas in this decade alone. [EPA-HQ-OAR-2010-0799-9585-A2, p. 3]

Regulatory Incentives for 2012 2015

Under existing regulations, the EPA and NHTSA attempt to provide incentives to encourage manufacturers to produce dual-fuel NGVs in 2012 -2015 by providing favorable treatment of greenhouse gas GHG emissions and fuel economy ('FE') credits. This is done, in part, by using a multiplier (0.15) to compute GHG credits and a divisor (0.15) to compute FE levels. The use of the 0.15 divisor was first authorized for FE calculations as part of the Alternative Motor Fuels Act of 1988 (P. 1. No. 100-94). [EPA-HQ-OAR-2010-0799-9585-A2, p. 3]

As part of the current rulemaking, the EPA proposed modifying its regulations for MY 2012 and later years to improve the GHG credits provided for dual-fuel NGVs. The proposed change would include the use of a utility factor ('UF') to determine the percentage of time a vehicle is deemed to operate on alternative fuel. [EPA-HQ-OAR-2010-0799-9585-A2, p. 3]

Encana supports the EPA and NHTSA's previous decision to use the 0.15 factor to compute GHG and FE credits in MYs 2012 - 2015. We also support the proposal in this rulemaking to use

UFs to compute GHG emissions (and eventually FE-see below) for dual-fuel vehicles. [EPA-HQ-OAR-2010-0799-9585-A2, p. 3]

However, Encana wishes to point out several inconsistencies in the existing and proposed rules that undermine or eliminate the intended benefits of those rules. [EPA-HQ-OAR-2010-0799-9585-A2, p. 3]

First, the benefit of the FE credits is limited or non-existent since there currently are restrictions on the total amount of fuel economy credits manufacturers can use for dual fuel and flex-fuel vehicles. Federal law prescribes an upper bound on the maximum amount of fuel economy credit a manufacturer may earn and phases-out the credits after 2019 (although they are reinstated without a cap beginning 2020). Because of the significant number of E85 vehicles offered by manufacturers, it is expected that manufacturers will reach their fuel economy credit limit primarily via their E85 products. Any additional offerings of dual fuel NGVs will probably not earn the automakers any usable FE credits in MYs 2012 - 2015. There needs to be another avenue - not blocked by E85 vehicles - for manufacturers to take advantage of the FE credits generated by dual fuel NGVs. [EPA-HQ-OAR-2010-0799-9585-A2, p. 3]

Second, it is true that manufacturers that offer dual-fuel NGVs will earn enhanced GHG credits for MY 2012 - 2015 vehicles, and the value of these GHG credits will be further improved by the use of the proposed utility factors. However, manufacturers are unlikely to find these GHG credits sufficiently attractive to produce dual-fuel NGVs (even if the credits can be carried forward for use in later years) unless they can simultaneously earn enhanced GHG and FE credits. [EPA-HQ-OAR-2010-0799-9585-A2, p. 3]

It should be noted that, for 2012-2015, dedicated NGVs would continue to be of value to OEMs. They qualify for FE credits and there is no cap that limits the amount of the credits that manufacturers can use. The 0.15 factor also applies to dedicated vehicles' FE and GHG calculations. While we certainly support the proposed incentives for dedicated vehicles, it is also important to provide meaningful incentives for dual-fuel NGVs. Most consumers and even some fleets are likely to prefer dual-fuel vehicles over dedicated vehicles while natural gas fueling infrastructure continues to expand. [EPA-HQ-OAR-2010-0799-9585-A2, p. 4]

Regulatory Incentives for 2016 & Beyond

The incentives proposed for 2016 and beyond (as explained below) do not provide adequate or consistent incentives for NGVs (especially as compared to electric vehicles (EVs')) and, therefore, are unlikely to be adequately effective. [EPA-HQ-OAR-2010-0799-9585-A2, p. 4]

For dedicated NGVs, the proposed rules would continue to use the existing 0.15 FE divisor in 2016 and beyond (as required by law). For GHG calculations, after 2016, the 0.15 divisor would no longer be available, so GHG incentives for manufacturers are negated while EVs, hybrids during electric operation and fuel cell vehicles continue to enjoy a 0 g/mi tailpipe emission rate. [EPA-HQ-OAR-2010-0799-9585-A2, p. 4]

For dual fuel vehicles, the proposed rules would also continue to use the existing 0.15 divisor for FE in 2016 and beyond (as required by law). For FE purposes during 2016-2019, dual-fuel vehicles would be assumed to operate 50/50 on natural gas and petroleum. However, the need for FE credits, already limited by the cap and the production of E85 vehicles, would be further constrained by declining the cap. From 2020, the 50/50 rule would be replaced by the use of the UF. [EPA-HQ-OAR-2010-0799-9585-A2, p. 4]

For GHG emissions for dual fuel vehicles, the use of the UF also would replace the use of the 50/50 rule from 2012 and thereafter. However, the use of the 0.15 multiplier would end after 2015 - virtually eliminating the value of dual fuel vehicle GHG benefits. This aspect of the proposed rule fails to satisfy one of the primary drivers of the rule: to encourage manufacturers to produce vehicles that produce fewer GHGs. [EPA-HQ-OAR-2010-0799-9585-A2, p. 4]

Encana's Recommended Changes

1. Provide a Separate Track for Dual-fuel NGVs

As discussed above, the large number of E85 vehicles, in effect, nullifies the value of dual-fuel vehicle FE credits. Encana recommends that, in order to make the incentives for dual-fuel NGVs truly effective, the agencies should develop a separate certification and FE calculation track for these vehicles. Dual-fuel NGVs, and any other alternative fuel vehicles except E85 vehicles, certified under this track would earn unlimited and uncapped FE and GHG credits. [EPA-HQ-OAR-2010-0799-9585-A2, p. 4]

2. Apply the Utility Factor for Both GHG and FE Beginning in 2012 [EPA-HQ-OAR-2010-0799-9585-A2, p. 4]

The utility factors should apply to dual-fuel vehicles beginning with MY 2012 for GHG and FE credits. The agencies have articulated sufficient legal justification for adopting the use of the utility factors for fuel economy for MY 2020 forward, and the EPA has already proposed making the utility factors retroactive back to 2012 for GHG certification. This same rationale supports extending the utility factor to the FE calculations leading up to 2020. The EPA and NHTSA appear to understand that providing one credit but not the other is highly problematic. That is why some credit provisions in the rules (e.g., FFVs, EVs, hybrid trucks) attempt to provide periods where both incentives overlap. Combining the incentives and providing consistent treatment of FE and GHG credits for NGVs is extremely important in ensuring compliance with these extremely complex regulations and further promoting GHG reductions in the transportation sector. [EPA-HQ-OAR-2010-0799-9585-A2, pp. 4-5]

3. Continue the Use of the 0.15 GHG Multiplier Beyond 2015

As discussed above, the use of the 0.15 multiplier for GHGs for both dual fuel and dedicated NGVs currently terminates after 2015. But, these credits in order to be effective must be extended beyond 2015. OEMs have already made preparations for MYs 2012-2015 and are unlikely to have sufficient time to respond to these incentives in that short timeframe. Therefore, to encourage more NGVs, the EPA and NHTSA should extend the credits provided for NGVs until a certain market penetration is achieved. The phase-out of such incentives should be consistent with the approach taken with respect to electric drive vehicles. Enhanced credits for NGVs would only expire after reaching a certain level of market penetration. We believe that providing these credits until a manufacturer's sale of NGVs reaches several hundred thousand (300,000 in the case of EVs) is warranted. [EPA-HQ-OAR-2010-0799-9585-A2, p. 5]

4. Other Credit Provisions

In addition to urging the agencies to adopt the incentive described above, we offer the following comments with respect to several other incentives proposed as part of this rulemaking (i.e., the use of sales multipliers, and advanced pickup truck credits). [EPA-HQ-OAR-2010-0799-9585-A2, p. 5]

Sales Multipliers

In its notices, the agencies have asked for comment on whether to provide a production or sales multiplier for dedicated and dual fuel NGVs. The agencies have proposed adopting such multipliers for other technologies (e.g., a multiplier of 1.3 - 2.0 is proposed for EVs, FCVs, and PHEVs) for 2017 - 2021. These credits appear to be limited to GHG credits. In order to ensure equitable treatment, the agencies should provide similar credits to NGVs. We believe that a sales multiplier for NGVs should be in addition to any other credits also provided for NGVs in order to further encourage manufacturers to offer such vehicles. In terms of credit values, we believe that dedicated NGVs should be treated like EVs and that dual-fuel NGVs should be treated like PHEVs. Therefore, we propose the following multiplier credits for NGVs: [See table on p. 5 of Docket number EPA-HQ-OAR-2010-0799-9585-A2] [EPA-HQ-OAR-2010-0799-9585-A2, p. 5]

• For dual fuel NGVs, provide a separate certification and FE calculation track and allow unlimited and uncapped FE and GHG credits;

• Allow UF use for both GHG and FE calculations through 2019;

• Extend the 0.15 GHG multiplier beyond 2015 and provide a phase out that is similar to EVs;

• Provide Sales Multipliers for NGVs;

Encana appreciates the opportunity to provide public comment on this rulemaking. Encana requests that the EPA and NHTSA incorporate the additional incentives described in this letter for natural gas vehicles. The following summarizes the additional incentives Encana believes will provide fair and equitable treatment of NGVs: [This comment can also be found in section 5 of this comment summary] [EPA-HQ-OAR-2010-0799-9585-A2, p. 7]

Natural gas vehicles can play an important role in increasing fuel efficiency and reducing vehicle emissions. Accelerating NGV market acceptance by providing NGV incentives for the OEMs will aid our country's goal of energy independence in the transportation sector. Compared with traditional and available alternative fuels, natural gas can also deliver material emission reductions of GHGs, criteria pollutants and hazardous air pollutants. [EPA-HQ-OAR-2010-0799-9585-A2, p. 7]

---

1 The Annual Energy Outlook 2011 is used since the AEO 2012 Early Release does not provide this level of granularity.

Organization: Ford Motor Company

EPA further requested comment on the merits of providing similar multipliers for dedicated and/or dual fuel compressed natural gas vehicles. Ford supports providing multipliers for natural gas fueled vehicle, and further requests that the same multiplier be provided for dedicated and/or dual fuel liquefied petroleum gas vehicles. Both gaseous fuels provide substantial reductions in greenhouse gas emissions, as well as support the diversification of our energy supply, providing greater energy security. However, the vehicle technologies required to allow operation on these fuels is expensive, and the market availability of the fuel, similar to the availability of public charging stations for electric vehicles, remains very limited. Therefore, we believe that the multiplier is appropriate to encourage the investment in these technologies for broader new vehicles applications, and drive the volumes that will encourage greater investment in the necessary re-fueling infrastructure. We further recommend that the credit values for dedicated and bi-fuel gaseous vehicles be aligned with those provided for dedicated and bi-fuel electricity fueled vehicles. [EPA-HQ-OAR-2010-0799-9463-A1, p. 18]

Organization: Manufacturers of Emission Controls Association (MECA)

MECA also believes that EPA's proposed advanced technology vehicle credits should be expanded to include other ultra-low GHG vehicle technologies beyond battery electric vehicles, plug-in hybrids, and fuel cell electric hybrids. MECA believes that it is important for these advanced technology vehicle credits to be technology neutral in order to provide a more level playing field that encourages vehicle manufacturers to put into the market a range of technologies that can offer significant reductions in GHG emissions. Examples of other types of advanced vehicles that should also be considered for such credits are dedicated natural gas vehicles or vehicles that employ carbon emission capture strategies. MECA believes that it is too early in the development process for EPA to pick advanced technology vehicle "winners." MECA urges EPA to expand the vision of advanced technology vehicle credits in its final rule with a more technology neutral approach. [EPA-HQ-OAR-2010-0799-9452-A3, p.4]

Organization: Mercedes-Benz USA, LLC

DAG also suggests that EPA consider a multiplier for dedicated CNG vehicles. While electric and fuel cell vehicles are likely to dominate in the advanced technology vehicle space during this timeframe, both dual fueled and dedicated CNG vehicles take advantage of the United States' abundant supply of natural gas to provide an alternative energy source. As with battery electric and fuel cell vehicles, supporting CNG vehicles in the fleet will take substantial amounts of infrastructure development. The potential for CNG vehicles to contribute to the future U.S.

vehicle fleet should be supported along with battery electric vehicles. Incentives should not be limited to dual-fueled vehicles using CNG. An incentive program should be applied to dedicated CNG vehicles as well.[12] In light of the infrastructure needs to support these vehicles, DAG suggests that a multiplier of 3 be attached to dedicated CNG vehicles. [EPA-HQ-OAR-2010-0799-9483-A1, p. A-6]

---

12 Factory built CNG vehicles in the United States include the Honda Civic GX, the Chevy Express Van and the GMC Savanna Cargo Van. A number of vehicles are also supported by EPA Certified Conversion Kits, including the Dodge Ram 1500, Dodge Dakota, Chevy Impala, Chevy Silverado, Chevy Tahoe, Chevy Express, GMC Sierra, GMC Yukon, GMC Savanna, Cadillac Escalade, Ford Focus, Ford Transit Connect, Ford Fusion, Ford Expedition and Ford F-Series. These vehicles, and others, are candidates for factory built CNG support if provided with a GHG compliance credit.

Organization: National Propane Gas Association (NPGA)

NPGA believes it is imperative that the proposed rulemaking clearly establish parity among the various alternative vehicle fuels, including autogas, thereby removing any fuel bias or disincentive toward the production or sale of autogas fueled vehicles. We further believe that any manufacturing incentive such as a Gallon-Gasoline Equivalency (GGE) multiplying factor be implemented immediately and when authorized by statute, extended through 2025. A GGE value for autogas normalizes comparisons of fuel efficiencies[5]and reduced CO_2 emissions on a per mile basis for various alternative vehicle fuels. To this end, we believe the following discussion provides adequate substantiation to specifically codify a section in the final rule for autogas and its (GGE) value based upon energy density. [EPA-HQ-OAR-2010-0799-9482-A1, p. 3]

The need for a clearly codified GGE value and specific autogas provisions within the regulations is demonstrated by misleading government statistics comparing autogas to other alternative vehicle fuels. For example, the U.S. Energy Information Agency compares vehicle fuels in native units per fuel type[6]. Using estimates for native units per fuel type, autogas consumption for 2009 is found to be 175,177 thousand gallons and CNG is found to be 24,038 million cubic feet. However, using EIA's thousand gasoline-gallon equivalent values[7], autogas appears to have lost considerable market share disproportional to other fuels that have a GGE value. [EPA-HQ-OAR-2010-0799-9482-A1, p. 3]

The most dire consequence of omitting a GGE factor for calculating autogas CAFE credits results from the compounding effect realized when the Congressional allowance afforded alternative fuels to account for only 15% of fuel consumed is applied without the appropriate GGE value compensating for AFV energy densities. The 15% rule effectively increases the miles per gallon of autogas consumed by a factor of 6.67. And, applying the GGE factor to autogas miles per gallon produces a total CAFE credit equal to "miles per 9.2 gallons of propane (1.38 x 6.667)." For illustrative purposes, this means that for every dedicated propane vehicle that an OEM sells it would be able to claim a theoretical CAFE credit of 9.2 times the base vehicle's actual mpg. For every 20 mpg base-gasoline vehicle that an OEM manufactures using autogas, they receive a fleet credit of 6.67 miles per gallon of fuel consumed yielding an effective 133 mpg for their CAFE number. However, if the GGE factor of 1.38 is provided and applied for dedicated autogas fueled vehicles, the combined credits produce an effective CAFE credit of 184 mpg per vehicle. [EPA-HQ-OAR-2010-0799-9482-A1, pp. 3-4]

The following derivation compares autogas to gasoline on an energy content basis. Based upon the energy contents of autogas and gasoline, NPGA proposes that the CAFE standards specifically incorporate a GGE factor of 1.38 for autogas. [The derivation and Table 1 can be found on p. 4 of Docket number EPA-HQ-OAR-2010-0799-9482-A1] [EPA-HQ-OAR-2010-0799-9482-A1, p. 4]

The need to promote a GGE for propane is further supported by the similar approach for evaluating GHG emissions based upon energy density, i.e. “Carbon Equivalent Units” used by the U.S. Department of Energy’s Energy Information Administration[9]. [EPA-HQ-OAR-2010-0799-9482-A1, p. 4]

Full-Fuel-Cycle Analysis

NPGA believes it is imperative that the EPA/NHTSA establish principles implementing full-fuel- cycle (FFC) analysis consistent with accepted scientific findings and other government agencies. Evaluating GHG emissions from the vehicle’s tailpipe is consistent with current evaluation methodologies, but does little to accurately measure consumption of primary energy resources, emission of GHGs or smog forming pollutants attributable to the production of gasoline or the generation of electricity. Full-fuel-cycle measurement (well-to-wheels) captures the additional energy consumption and emissions derived from the extraction, processing, transportation, conversion, and distribution of energy to the vehicle. For electric and plug-in hybrid electric vehicles (EV and PHEV) that re-charge their batteries using power from the utility grid, point-of-use measurement such as a vehicle’s tailpipe misleads the consumer to believe the tailpipe is the only source of emissions and engine efficiency is the only source of energy consumption when, in fact, they are not. [EPA-HQ-OAR-2010-0799-9482-A1, p. 4]

NPGA commented on the EPA/NHTSA’s previous proposed rulemaking[10] on vehicle labeling discussing the positive attributes associated with using full-fuel-cycle energy metrics. We believe the EPA/NHTSA vehicle labels should provide consumers the more robust accounting of actual GHG emissions and energy efficiencies found with FFC measurement. We strongly believe to only present greenhouse gas performance values consistent with emissions measured at the tailpipe erodes any desired transparency of evaluating true fuel efficiencies and GHG emissions. In our opinion, to continue using point-of-use evaluations for vehicle emissions and fuel efficiencies is inaccurate and conveys only a partial story further promoting fuel biases. [EPA-HQ-OAR-2010-0799-9482-A1, pp. 4-5]

Scientific Findings

NPGA supports the use of the Source Energy and Emissions Analysis Tool[11] (SEEAT) developed by the Gas Technology Institute (GTI). This computer modeling tool calculates source energy and GHG emissions attributable to point-of-use energy consumption by vehicle fuel type.

SEEAT includes a source energy and carbon emission calculation methodology that accounts for primary energy consumption and related emissions for the full-fuel-cycle of extraction, processing, transportation, conversion, distribution, and consumption of energy. GTI researchers have calculated source-based fuel economies for various vehicle options and found more rational comparisons of vehicle efficiencies using ‘Source Fuel Economies’ than point-of-use fuel economies. [EPA-HQ-OAR-2010-0799-9482-A1, p. 5]

Another scientifically accepted modeling tool is the Greenhouse Gas, Regulated Emissions and Energy Use in Transportation (GREET) model developed by Argonne National Laboratory[12]. The GREET model estimates the upstream portion of the life-cycle GHG emissions of various vehicle fuels. This model calculates emissions in grams per million Btu, of multiple pollutants, including CO_2, CH_4, and N_2O to derive a total CO_2 equivalent. [EPA-HQ-OAR-2010-0799-9482-A1, p. 5]

NPGA supports the Department of Energy’s intended use of the GREET model to perform the national impact analyses and environmental assessments included in the review of proposed energy conservation appliance standards. Further affirming our support of the GREET model, the Propane Educational Research Council (PERC) conducted a study using the GREET model (version 1.8c) comparing autogas to other fuel sources. The study, titled “Propane Reduces Greenhouse Gas Emissions: A Comparative Analysis 2009” looked at thirteen (13) different applications where autogas was used including a GM 6.0L engine, Ford 150, Ford 250, school buses, forklifts, and commercial mowers. The comparisons looked at energy end-use and annual life-cycle GHG emissions for a variety of fuel sources. [EPA-HQ-OAR-2010-0799-9482-A1, p. 5]

A comparison by GTI found that the GREET and SEEAT vehicle source energy factors indicate excellent agreement between the two methodologies for both full-fuel-cycle efficiency factors and GHG emission factors. Minor differences appear to be based on underlying data sources and default values. Based on the national average fuel mix for electricity calculated using GTI’s SEEAT, the source energy conversion factor for electricity is 3.29 Btu/Btu. Conversion factors for fossil fuels directly consumed at the point-of-use are as follows: Natural gas: 1.09 Btu/Btu; Autogas: 1.12 Btu/Btu; Fuel oil: 1.13 Btu/Btu. [EPA-HQ-OAR-2010-0799-9482-A1, pp. 5-6]

It is NPGA’s contention that establishing a Gallon-Gasoline Equivalency for autogas, a clean burning alternative fuel, will provide automakers an incentive to manufacture autogas fueled light-duty vehicles. However, due to the lower energy density of autogas compared to gasoline, any legislation based upon “miles per gallon” obscures the positive benefits of using autogas. The CAFE standards provide a GGE value for CNG comparing equivalent energy densities instead of miles per equivalent volume of fuel and 49 U.S. Code 32905 provides gallon equivalents for gaseous fuels. In order to achieve parity among other alternative fuels, we believe that autogas should be treated comparably to CNG and other alternative fuels by providing its own unique section of regulation including its own GGE value based upon energy density. [EPA-HQ-OAR-2010-0799-9482-A1, p. 6]

NPGA respectfully requests the EPA/NHTSA codify by final rulemaking a Gallons of Gasoline Equivalency value of 1.38 for propane autogas establishing unambiguous parity among alternative light-duty vehicle fuels. [EPA-HQ-OAR-2010-0799-9482-A1, p. 6]

We also urge you to evaluate energy efficiency and GHG emission using FFC analysis thereby providing a complete and robust energy consumption and GHG emissions profile for all light-duty vehicles. Limiting emissions analysis to point-of-use metrics (tailgate emissions) ignores the fact that most energy losses associated with non-gaseous fuels, e.g. electricity, occur upstream and ignore greenhouse gas emissions. NPGA urges the EPA/NHTSA to account for upstream production and distribution emissions by applying readily available and scientifically accepted modeling technologies such as GREET and SEEAT. [EPA-HQ-OAR-2010-0799-9482-A1, pp. 6-7]

In today's world, consumers are repeatedly faced with making choices that are environmentally friendly and this observation is even more prevalent in the automotive industry. The shift by various federal agencies to a full-fuel-cycle analysis facilitates the ability of consumers to make informed decisions whom otherwise might not be aware of the environmental shortcomings of point-of-use energy analysis and labeling. Accurate and unbiased accounting of motor vehicle fuel efficiency and GHG emissions can be achieved today by using tools developed and accepted by the scientific community and readily available to the public. We believe these computer modeling tools should be harmonized across all federal agencies. And, to that end, we recommend that the promulgation of future GHG emissions and CAFE standards be established immediately recognizing FFC analysis and GGE energy values. [EPA-HQ-OAR-2010-0799-9482-A1, p. 7]

3. Dual Fuel Natural Gas Vehicles Require Further Constraints on Eligibility to Demonstrate Actual Natural Gas Use

NRDC believes that any emissions credits awarded to natural gas vehicles should be commensurate with real-world GHG reductions. Dual fuel natural gas vehicles that can be powered by onboard supplies of either natural gas or gasoline must have emission scores that reflect the actual use of each fuel. The use of a utility factor to represent the use of each fuel is a reasonable approach but further constraints on vehicle design on dual fuel natural gas vehicles must be included in the program for them to be eligible for separate natural gas and petroleum emissions accounting. If the design constraints are not met, the emissions ratings for dual fuel natural gas vehicles should be for operation only on gasoline. [EPA-HQ-OAR-2010-0799-9472-A2, p. 13]

The design constraints help ensure that the vehicle preferentially operates on natural gas. Dual fuel natural gas vehicles are powered by a combustion engine that can switch between gasoline and natural gas. If natural supplies are unavailable (or higher priced), then operation on gasoline might dominate. EPA has suggested several constraints that should be considered for adoption including “placing a minimum value on CNG tank size or CNG range, a maximum value on gasoline tank size or gasoline range, a minimum ratio of CNG-to-gasoline range, and requiring an onboard control system so that a dual fuel CNG vehicle is only able to access the gasoline fuel tank if the CNG tank is empty.”37 NRDC urges the agency to adopt some or all constraints before making dual fuel natural gas vehicles eligible for natural gas emissions ratings. The agencies should consider prioritizing a minimum requirement for natural gas-to-gasoline range of at least 80 percent on natural gas. [EPA-HQ-OAR-2010-0799-9472-A2, p. 13]

Organization: NGV America

These comments primarily focus on the incentives proposed in the rules. We strongly support the agencies’ efforts to craft incentives that will encourage automakers to accelerate the introduction of transformational technologies like natural gas vehicles (NGVs). In particular, we applaud the agencies for the incentives that have been proposed with respect to dedicated and dual-fuel NGVs. While much of the focus is on encouraging and facilitating the development of electric vehicles, the proposed rules do include some important, comparable provisions regarding the development of NGVs. We are encouraged by the inclusion of some incentives and the apparent recognition that natural gas fueled cars and trucks can and should be a part of transforming the U.S. automotive fleet. However, we believe that the incentives as proposed should be modified in order to be effective beyond the time period set out in the proposed rules and also to provide equitable treatment for NGVs. Given President’s Obama’s recent remarks concerning the benefits of NGVs and his desire to accelerate their use, we are extremely hopeful that the agencies will welcome the proposed changes we have offered here. [EPA-HQ-OAR-2010-0799-9461-A1, pp. 1-2]

At the outset it is important to clarify what we mean about transformational technologies. Transformational technologies in our view are those applications that have the potential to greatly change the transportation sector as it exists today. Any technology that has the ability to significantly reduce greenhouse gas and other emissions, lessen dependence on foreign oil, position the U.S. as an exporter of vehicle technology, and improve the economic well-being of our economy should be viewed as transformational. Natural gas and electric vehicles have these attributes As such, we believe any effort to stimulate the market for new technologies must be equitable in its treatment of natural gas and electric vehicles, and should not favor one over the other. [EPA-HQ-OAR-2010-0799-9461-A1, p. 2]

A. Benefits of Encouraging NGVs

An Abundant and Economical Domestic Resource

Reliance on foreign oil exacts a high toll on the U.S. in terms of direct economic costs and indirect energy security costs. During the three-year period from 2008 through 2010, the U.S. spent nearly $700 billion on imported petroleum. More recently, the cost of imported oil has been much higher as oil prices have once again exceeded $100 per barrel. In the coming decade, the U.S. Energy Information Agency (EIA) forecasts total expenditures for petroleum imports to top $3.3 trillion dollars.1 America's reliance on oil not only affects our trade balance but makes the U.S. vulnerable to price spikes and supply disruptions. And high oil prices results in a windfall for regimes that may not be friendly to the America. [EPA-HQ-OAR-2010-0799-9461-A1, p. 2]

Fortunately, the U.S. has an unprecedented opportunity to displace petroleum with domestic natural gas. As President Obama recently declared, the U.S. is "the Saudi Arabia of natural gas." The EIA, the Potential Gas Committee and other expert bodies now estimate that the U.S. has up to a 100 year supply of natural gas. The Potential Gas Committee's 2011 bi-annual report indicates that the U.S. now has a total future supply of 2,170 trillion cubic feet of natural gas. This is 89 Tcf more than estimated in the 2009 report. As was the case with the 2009 report, the 2011 report includes the highest resource estimate in the Committee's history. The availability of this significant domestic resource provides an unprecedented opportunity to solve a number of pressing national objectives like transforming the transportation sector. [EPA-HQ-OAR-2010-0799-9461-A1, pp. 2-3]

Increasing the use for natural gas in transportation will keep our economy growing by supporting new jobs and economic development. In 2008, U.S. production of 20 Tcf of natural gas supported nearly 3 million jobs.2 In his State of the Union remarks before Congress, the President indicated that new development of natural gas could result in 600,000 new jobs in this decade alone. Thus, increasing demand for natural gas as a transportation fuel will help put more people to work and ensure that we put this natural gas to good use. [EPA-HQ-OAR-2010-0799-9461-A1, p. 3]

Natural gas also benefits our economy because it is a low cost energy that helps businesses grow while at the same time controlling costs. Natural gas is priced much lower than petroleum. The two fuels no longer track one another -- and haven't for many years. The current contract price for natural gas (NYMEX) is trading at less than $3.00 per million Btu, and some analysts believe it could go below $2 per MMBtu. At $3.00 per MMBtu, the price of natural gas equates to a per-barrel of oil price of only $17.40 at a time when oil is trading near $100 a barrel. The low price of natural gas translates into significant savings for fleets and consumers who use natural gas to fuel their vehicles. In most areas of the country, natural gas sells at about a $1.50 discount compared to gasoline and diesel fuel. EIA's long-term forecast projects that differential between natural gas and petroleum fuels will remain as high as $2 per energy-equivalent unit. [EPA-HQ-OAR-2010-0799-9461-A1, p. 3]

Environmental Benefits

The same clean burning properties that make natural gas an excellent fuel for traditional applications like electricity generation, residential heating, and industrial applications, also make it an excellent fuel for transportation. Natural gas burns cleaner than gasoline and diesel fuel and most other transportation fuels as well. Not surprisingly, the first vehicles certified to the U.S. Environmental Protection Agency's (EPA) ultra-low emission, super-ultra low-emission and Tier 2/Bin 2 standards were NGVs. The natural gas-powered Honda Civic GX has won numerous awards for its outstanding environmental performance. In 2011, the Civic GX was rated the "Greenest Car in America" by the American Council for an Energy-Efficient Economy – for an amazing eight years in a row! It also was named the 2012 car of the year by the Green Car Journal. Compared to the gasoline Civic, the natural gas-powered Civic produces 95 percent fewer emissions of volatile organic compounds and 75 percent less emissions of nitrogen oxides – pollutants that contribute to ozone formation. [EPA-HQ-OAR-2010-0799-9461-A1, pp. 3-4]

The environmental benefits of NGVs are expected to continue to improve as new automotive technologies become available. EPA's own website describes natural gas as an inherently cleaner transportation fuel. That means that given the same amount of emissions control and technological advancement, natural gas should always produce lower emission than comparable gasoline and diesel-fueled vehicles. As long as the internal combustion engine is with us and as long as refinements to it are made, natural gas will be the cleanest transportation fuel to use in it. A National Academy of Science (NAS) report[3] that analyzed vehicle technologies as of 2005 and expected by 2030, projected that, with further expected improvements in vehicle technology and fuel efficiency, natural gas powered vehicles will provide superior benefits in terms of criteria pollutant reductions compared to nearly all other types of vehicles, even electric and plug-in hybrid electric vehicles. The reason, in part, is due to the fact that the internal combustion engine will continue to get much more fuel-efficient and cleaner, and internal combustion engines can always use natural gas. Electric vehicles sometimes use electricity produced from cleaner natural gas but they will likely continue to use electricity produced from coal, offsetting the benefits that otherwise would be provided by such vehicles. Electric vehicles also require more energy to produce them. [EPA-HQ-OAR-2010-0799-9461-A1, p. 4]

Natural gas vehicles will play a key role in reducing greenhouse gas emissions. Per unit of energy, natural gas contains less carbon than any other fossil fuel, and, therefore, produces lower carbon dioxide (CO_2) emissions per vehicle mile traveled. While NGVs do emit methane, another principal greenhouse gas, the increase in methane emissions is more than offset by a substantial reduction in CO_2 emissions compared to other fuels. The California Air Resources Board (CARB) has conducted extensive analyses on this issue, and has concluded that burning compressed natural gas produces about 22 percent less GHGs than burning diesel, and 29 percent less than burning gasoline.[4] The comparisons are based on well-to-wheels analyses, and include methane emissions. These reductions are equal to -- or better than -- some renewable liquid fuels. Most of the available studies show that given similar fuel efficiency, NGVs fueled by domestic natural gas will deliver about 20–30 percent improvement in GHG emissions. [EPA-HQ-OAR-2010-0799-9461-A1, p. 4]

Another important benefit of NGVs is that, in addition to the tailpipe reductions, they also provide upstream emission reductions of greenhouse gases. Therefore, any direct tailpipe reductions provided by introduction of NGVs resulting from this rulemaking will be increased by the additional emission offsets associated with upstream activities relative to petroleum upstream emissions, which these rules do not take into account. The fact that NGVs deliver these upstream emission reductions provides a rationale and quantifiable justification for providing additional emission reduction credits for NGVs in this rulemaking. These are real benefits that are provided not only by the NGVs incentivized by this rulemaking but also by NGVs sold after any incentives have expired. [EPA-HQ-OAR-2010-0799-9461-A1, p. 5]

The Potential for Natural Gas Vehicles

The current market for NGVs here in the U.S. is relatively small. Today, NGVs (and electric vehicles) are not yet economic for most owners of light-duty vehicles. The primary reason is that these vehicles have higher initial purchase costs than conventionally fueled vehicles, but are not driven enough miles or consume enough lower-cost fuel for the fuel cost savings that they offer to offset this higher purchase cost in a reasonable number of years. In fleet applications, however, where fuel consumption per vehicle is much greater, NGVs can be economically attractive to an increasing percentage of businesses and government agencies. [EPA-HQ-OAR-2010-0799-9461-A1, p. 5]

Outside the U.S., demand for NGVs is growing at a rapid pace, and much of this growth is in the light-duty vehicle market. In the last seven years, the global market for NGVs has more than tripled with a compound growth rate of over 17 percent per year. In fact, NGVs are the fastest growing alternative to petroleum vehicles in the world. In 2003, there were only about 2.8 million NGVs globally. Today, there are over 14 million NGVs in operation worldwide. This rapid growth points to the fact that rapid scaling up of NGVs is possible. The NGV Global (the international NGV association) forecasts that, by 2020, there will be 65 million NGVs on the world's roads. Unfortunately, the U.S. currently ranks fourteenth in the world in total number of NGVs – despite having more vehicles on the road than all the other fourteen countries combined. [EPA-HQ-OAR-2010-0799-9461-A1, p. 5]

As noted above, most of the new NGVs sold outside the U.S. are light-duty vehicles. Outside the U.S., tax and other government policies make NGVs even more economically attractive to consumers. As a result, in overseas markets, NGVs are now available from almost all major

OEMs, including: Ford, GM, Toyota, Honda, Nissan, Hyundai, Fiat, Volkswagen and Mercedes. In 2009, Fiat offered 14 separate NGV models, and more than 100,000 NGVs were sold in that year in Italy alone, comprising some 7 percent of the new vehicle market. Most U.S. manufacturers currently offer NGVs in Europe, South America and Asia, but only Honda currently offers a light-duty OEM NGV product in the U.S. -- the Honda Civic Natural Gas. [EPA-HQ-OAR-2010-0799-9461-A1, p. 5]

General Motor currently offers the GMC medium-duty Savana and Chevrolet Express vans as fully- backed, factory produced NGVs rated above 8,500 lbs. GVWR. And later this year, General Motors and Chrysler will begin offering factory built natural gas powered pickup trucks. As these offerings show, U.S. automakers certainly have the capability to produce NGVs – IF the proper incentives are in place. [EPA-HQ-OAR-2010-0799-9461-A1, p. 6]

Recent events are clearly pointing to a viable domestic market for light-duty NGVs. We are particularly encouraged by the unprecedented Memorandum of Understanding (MOU) concerning NGVs that has now been signed by ten state governors. The MOU urges U.S. automakers to expand their offerings of NGVs and attempts to stimulate the market for such vehicles by signaling the intent of these states to purchase NGVs. As noted above, in just the past two years, GM and Chrysler have announced plans to produce NGVs for the U.S. market. Honda also has expanded its production capacity for the Honda NGV offering, and is now marketing the car to consumers as well as fleets. Another telling factor is the significant growth in the aftermarket offerings here in the U.S., where nearly a dozen manufacturers offer systems to retrofit light-duty vehicles to operate on natural gas. These offerings include systems for the Fusion, Focus, Impala, Malibu, Milan, Transit Connect, in addition to a variety of popular pickup truck offerings. Ford, while not offering a factory NGV, has been working closely with the aftermarket industry to ensure that aftermarket systems offered for its vehicles meet its demanding standards for quality. These activities clearly show that there is very strong interest in bringing more NGV products to the U.S. passenger car and light-duty segment. [EPA-HQ-OAR-2010-0799-9461-A1, p. 6]

NGVAmerica believes that there could be a substantial market for NGVs in all applications, including the light-duty passenger car market. The most immediate opportunity for displacing petroleum and increasing the use of natural gas as transportation fuel lies with light-, medium- and heavy-duty fleets – especially trucks, buses and other heavier vehicles. America currently has a large selection of medium- and heavy-duty NGVs available in the U.S. and the market for natural gas trucks is beginning to ramp up. As a result, natural gas fueling infrastructure development is once again on the rise, recently exceeding 1,000 stations. More importantly, major industry players are now laying the groundwork for a national fueling infrastructure connecting major transportation routes across the country. Furthermore, President Obama's Blueprint for Energy, announced on January 26th, now calls for development of additional natural gas corridors. In that announcement, the President also called upon the Energy Department and national laboratories to focus their energies on bringing about technological breakthroughs in the use of natural gas as a transportation fuel. [EPA-HQ-OAR-2010-0799-9461-A1, p. 6]

These efforts will directly benefit the light-duty NGV market since increased fueling infrastructure is one of the key factors limiting the market for NGVs in the passenger car market. The economic outlook appears to be excellent. Lower natural gas prices and lower first cost premiums (brought about by mass production, economies of scale and more competition) mean that, in the future, even passenger cars could become economic. Adopting policies that encourage manufacturers to produce NGVs, just like policies that encourage manufacturers to offer EVs, are critically important. Tax policy certainly helps, and many in Congress -- as well as the President -- have indicated they support tax incentives for NGVs. But the Administration could do even more by adopting incentives for NGVs as part of this rulemaking. Just as with EVs, regulatory incentives combined with these other factors would help accelerate the introduction of NGVs into the light-duty passenger car market. [EPA-HQ-OAR-2010-0799-9461-A1, pp. 6-7]

Pathway to Hydrogen Fueled Vehicles

In addition to providing many near-term benefits, NGVs also likely will play an important role in facilitating the market penetration of fuel cell electric vehicles (FCEVs). Since the first wave of NGV adoption in the 1990s, the development of NGVs – and particularly natural gas refueling infrastructure – has long been recognized as a key bridge technology on a “path to hydrogen.”[5]Natural gas is largely composed of hydrogen, with four hydrogen atoms for every carbon atom in a molecule of methane. Due to the chemical and physical similarities of these two gases, they share a number of technology synergies, so that the proliferation of NGVs and natural gas fueling infrastructure will facilitate and accelerate deployment of FCEVs. Indeed, the development of the NGV market serves to reduce or eliminate all four of the near-term market barriers to FCEV adoption identified by the Agencies: [EPA-HQ-OAR-2010-0799-9461-A1, p. 7]

- Low-GHG Fuel Production and Distribution Infrastructure: NGV refueling infrastructure utilizes most of the same hardware (compressors, storage tanks, dispensers) that will be used to dispense hydrogen fuel, allowing natural gas refueling stations to be straightforwardly adapted for hydrogen dispensing. In fact, virtually all the hydrogen fueling component manufacturers are NGV fueling component manufacturers. Natural gas can also be used as a feedstock for hydrogen fuel production via distributed steam reforming at the refueling station, a fuel production pathway identified by the U.S. Department of Energy’s FreedomCAR & Fuel Partnership as the “most viable approach to begin building [the] hydrogen market in near term.” [6]Distributed steam reforming of natural gas for hydrogen production also yields just half of the lifecycle GHGs as production of hydrogen via electrolysis using grid electricity, according to Argonne National Laboratories’ GREET model.[7] [EPA-HQ-OAR-2010-0799-9461-A1, p. 7]
- Fuel Cost: Production of hydrogen from natural gas via distributed steam reformers also represents the “lowest current cost” hydrogen pathway compared to electrolysis and other methods, according to the FreedomCAR roadmap.[8] [EPA-HQ-OAR-2010-0799-9461-A1, p. 8]
- Vehicle Cost: NGV development will help reduce FCEV vehicle costs by advancing on-board gaseous storage and fuel management technologies, allowing more fuel to be stored safely with less weight and/or space. In a sense, the FCEV represents the ultimate

union of NGVs and EVs, with EVs providing the electric drive-train and NGVs ensuring the development of hydrogen storage technologies. [EPA-HQ-OAR-2010-0799-9461-A1, p. 8]

- Consumer Acceptance: By increasing familiarity and comfort with gaseous fuel vehicles and refueling, NGVs will help pave the way for consumer acceptance of FCEVs. NGV deployment will also serve the role of developing experience with gaseous-fueled vehicles for auto dealers, mechanics, and other important stakeholders that directly interface with consumers. [EPA-HQ-OAR-2010-0799-9461-A1, p. 8]

Thus, the market penetration of NGVs helps ensure that the necessary fuel and technologies will be in place for FCEVs, accelerating and lowering the costs of this transition. Much like the role that plug-in hybrid electric vehicles are playing in facilitating adoption of EVs, NGVs – and particularly dual-fuel NGVs (which mitigate “range anxiety” for early adopters) are essential for facilitating the market penetration of FCEVs. [EPA-HQ-OAR-2010-0799-9461-A1, p. 8]

B. Adopting Effective Regulatory Incentives

Regulatory Incentives for 2012 – 2015

Under the existing regulations, EPA and NHTSA attempt to provide incentives to encourage manufacturers to produce dual-fuel NGVs in 2012-2015 by providing favorable treatment of greenhouse gas (GHG) emission and fuel economy (FE) credits. This is done, in part, by using a divisor (0.15) to compute GHG and FE levels. The use of the 0.15 divisor was first authorized for FE calculations as part of the Alternative Motor Fuels Act (AMFA) of 1988 (P. L. No. 100-94). [EPA-HQ-OAR-2010-0799-9461-A1, p. 8]

As part of the current rulemaking, EPA also has proposed modifying its regulations for MY 2012 and later years to improve the GHG credits provided for dual-fuel NGVs, including the use of a “utility factor” to determine the percentage of time a vehicle is deemed to operate on alternative fuel. The current regulations calculate fuel economy and greenhouse gas emissions by assuming that dual-fuel vehicles operate only (and always) 50 percent of the time on conventional fuel and 50 percent of the time on alternative fuel. Like the 0.15 divisor, the 50/50 fuel consumption factor is prescribed in AMFA. The benefit of the proposed utility factor (UF)[9] is that, for most dual-fuel vehicles, the vehicles will be credited for operating more than 50 percent of the time on the alternative fuel. The UF takes into account typical consumer range requirements and a vehicles operational range on alternative fuel when calculating the percentage of time a vehicle is likely to operate on alternative fuel. The effect is that most dual-fuel natural gas vehicles will now be given credit for higher use of natural gas and lower GHG emissions. [EPA-HQ-OAR-2010-0799-9461-A1, pp. 8-9]

NGVAmerica supports EPA and NHTSA’s previous decision to use the 0.15 divisor to compute GHG and FE credits in MYs 2012 – 2015. We also support the proposal in this rulemaking to use UFs to compute GHG emissions (and eventually FE—see below) for dual-fuel vehicles. While the fuel economy program’s use of the 0.15 divisor are prescribed by federal law, the agencies apparently rely upon their general discretion to use the 0.15 factor to provide GHG credits for dual-fuel vehicles – and NGVAmerica supports that. [EPA-HQ-OAR-2010-0799-9461-A1, p. 9]

However, NGVAmerica wishes to point out several infirmities in the existing and proposed rules that undermine or eliminate the intended benefits of those rules. [EPA-HQ-OAR-2010-0799-9461-A1, p. 9]

First, in reality, the benefit of the FE credit is limited or non-existent since there currently are restrictions on the total amount of fuel economy credits manufacturers can use for dual fuel and flex-fuel vehicles. Federal law prescribes an upper bound on the maximum amount of fuel economy credit a manufacturer may earn and phases-out the credits after 2019 (although they are reinstated without a cap beginning 2020). Because of the significant number of E85 vehicles offered by manufacturers, it is expected that manufacturers will reach their fuel economy credit limit primarily via their E85 products. Any additional offerings of dual fuel NGVs will probably not earn the automakers any usable FE credits in MYs 2012–2015. There needs to be another avenue – not blocked by E85 vehicles – for manufacturers to take advantage of the FE credits generated by dual-fuel NGVs. [EPA-HQ-OAR-2010-0799-9461-A1, p. 9]

Second, it is true that manufacturers that offer dual-fuel NGVs will earn enhanced greenhouse gas emission credits for MY 2012--2015 vehicles, and the value of these GHG credits will be further improved by the use of the proposed utility factors. However, manufacturers are unlikely to find these GHG credits sufficiently attractive to produce dual-fuel NGVs (even if the credits can be carried forward for use in later years) unless they can simultaneously earn enhanced GHG and FE credits. [EPA-HQ-OAR-2010-0799-9461-A1, pp. 9-10]

It should be noted that, for 2012-2015, dedicated NGVs would continue to be of value to OEMs since they qualify for FE credits and there is no cap that limits the amount of the credits that manufacturers can use. (The 0.15 divisor also applies to dedicated vehicles' FE and GHG calculations.) While we certainly support the proposed incentives for dedicated vehicles, it is also important to provide useful and effective incentives for dual-fuel NGVs, too. Most consumers and even some fleets are likely to prefer dual-fuel vehicles over dedicated vehicles until the natural gas fueling infrastructure is significantly expanded. Dual-fuel vehicles will be a critical enabler to alleviate consumer concerns with range anxiety and will serve as an important vehicle option to help facilitate the transition to alternative fuel vehicles and spur consumer willingness to buy the types of vehicles that will be needed to comply with the new standards. [EPA-HQ-OAR-2010-0799-9461-A1, p. 10]

Regulatory Incentives for 2016 & Beyond

The incentives proposed for 2016 and beyond (as explained below) do not provide adequate or consistent incentives for NGVs (especially as compared to electric vehicles) and, therefore, are unlikely to be effective. [EPA-HQ-OAR-2010-0799-9461-A1, p. 10]

For dedicated NGVs, the proposed rules would continue to use the existing 0.15 FE divisor in 2016 and beyond (as required by law). However, for GHG calculations, after 2016, the 0.15

divisor would no longer be available, so GHG incentives for manufacturers would be negligible. [EPA-HQ-OAR-2010-0799-9461-A1, p. 10]

For dual fuel vehicles, the proposed rules would also continue to use the existing 0.15 divisor for FE in 2016 and beyond (as required by law). For FE purposes during 2016-2019, dual-fuel vehicles would be assumed to operate 50/50 on natural gas and petroleum. However, the need for FE credits, already limited by the cap and the production of E85 vehicles, would be further constrained by declining the cap. From 2020, the 50/50 rule would be replaced by the use of the UF. [EPA-HQ-OAR-2010-0799-9461-A1, p. 10]

For GHG emissions for dual-fuel vehicles, the use of the UF also would replace the use of the 50/50 rule from 2012 and thereafter. NGV America supports this. However, the use of the 0.15 divisor would end after 2015 – virtually eliminating the value of dual-fuel vehicle GHG benefits. If the purpose of these regulations is to encourage manufacturers to produce vehicles that produce fewer greenhouse gases, this aspect of the proposed rules makes little sense. As discussed above, NGVs produce less GHGs than comparable gasoline vehicles – especially when the upstream emissions are considered. Without continued use of the 0.15 divisor for dual-fuel GHG calculations, the incentive for manufacturers to produce NGVs would be significantly reduced. [EPA-HQ-OAR-2010-0799-9461-A1, p. 10]

NGV America's Recommended Changes

1. Provide a Separate Track for Dual-Fuel NGVs

As discussed above, the large number of E85 vehicles being manufactured, in effect, nullifies the value of other dual-fuel vehicle FE credits. NGVAmerica recommends that, in order to make the incentives for dual-fuel NGVs truly effective, the agencies should develop a separate track for these vehicles. Dual-fuel NGVs (and any other alternative fuel vehicles) certified under this track would earn unlimited (uncapped) FE and GHG credits. [EPA-HQ-OAR-2010-0799-9461-A1, p. 11]

2. Apply the Utility Factor for Dual-Fuel NGVs for Both GHG and FE Beginning in 2012

The utility factors should apply to dual-fuel vehicles beginning with MY 2012 for GHG and FE credits. The agencies have articulated sufficient legal justification for adopting the use of the utility factors for fuel economy for MY 2020 forward, and EPA has already proposed making the utility factors retroactive back to 2012 for GHG certification. This same rationale supports extending the utility factor to the FE calculations prior to 2020. EPA and NHTSA appear to understand that providing one credit but not the other is highly problematic and is not consistent with the intent of harmonization under one single national fuel economy/greenhouse gas program. That is why some credit provisions in the rules (e.g., FFVs, EVs, hybrid trucks) attempt to provide periods where both incentives overlap. Combining the incentives and providing consistent treatment of FE and GHG credits for dual-fuel NGVs is extremely important in ensuring compliance with these extremely complex regulations. [EPA-HQ-OAR-2010-0799-9461-A1, p. 11]

3. Continue the Use of the 0.15 GHG Divisor Beyond 2015

As discussed above, the use of the 0.15 divisor for GHGs for both dual-fuel and dedicated NGVs currently terminates after 2015. But these credits in order to be effective must be extended beyond 2015. Manufactures have already made preparations for MYs 2012-2015 and are unlikely to have sufficient time to respond to these incentives in that short timeframe. Therefore, to encourage more NGVs, EPA and NHTSA should extend the credits provided for NGVs until a certain market penetration is achieved. The phase-out of such incentives should be consistent with the approach taken with respect to electric drive vehicles. EPA and NHTSA have essentially proposed very generous treatment of such vehicles. Enhanced credits for such vehicles would only expire after these technologies reach a certain level of market penetration. We believe that providing these credits until a manufacturer's sale of NGVs reaches several hundred thousand (300,000 in the case of EVs) is warranted. Alternatively, EPA and NHTSA could establish one cap for all alternative fuel vehicles. [EPA-HQ-OAR-2010-0799-9461-A1, p. 11]

Other Credit Provisions

In addition to urging the agencies to adopt the incentive described above, we offer the following comments with respect to several other incentives proposed as part of this rulemaking:.

Sales Multipliers

In its notices, the agencies have asked for comment on whether to provide a production or sales multiplier for dedicated and dual-fuel NGVs. The agencies have proposed adopting such multipliers for other technologies (e.g., a multiplier of 1.3–2.0 is proposed for EVs, FCVs, and PHEVs) for 2017 – 2021. In order to ensure equitable treatment, the agencies should provide similar credits to NGVs. And since EVs and other electric-drive vehicles already receive extremely generous treatment in the rules, we believe that the provision of a sales multiplier for NGVs should be in addition to any other credits also provided for NGVs in order to further encourage manufacturers to offer such vehicles. In terms of credit values, we believe that dedicated NGVs should be treated like EVs and that dual-fuel NGVs should be treated like PHEVs. The result of this more equitable treatment would be to provide a level playing field to incentivize the manufacture of all alternative fuel vehicles and not favor one technology over another. Therefore, we propose the following multiplier credits for NGVs: [See table on p. 13 of Docket number EPA-HQ-OAR-2010-0799-9461-A1] [EPA-HQ-OAR-2010-0799-9461-A1, p. 12]

NGV America appreciates the opportunity to provide these comments. We applaud the agencies for the incentives that have been proposed for NGVs and other alternative fuel technologies. We urge the agencies to incorporate the changes we have proposed in our comments. The changes we have proposed will further stimulate the market for NGVs and other advanced technologies and provide significant economic, energy security and environmental benefits. We realize that this rulemaking is an enormously complicated and daunting undertaking and that EPA and NHTSA have a significant job ahead of them in terms of reviewing and evaluating the comments that have been submitted. We welcome the opportunity for additional dialogue and offer our assistance if necessary in understanding the proposals we have put forward in these comments. [EPA-HQ-OAR-2010-0799-9461-A1, p. 14]

9 Utility factors look at the driving range of vehicle on alternative fuel and assigns a utility factor for alternative fuel use (e.g., 70 miles on NG = 0.785 factor, 100 miles = 0.865, 150 miles = 0.925).

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

[These comments were submitted as testimony at the Philadelphia, Pennsylvania public hearing on January 19, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11788, p. 73.]

The NESCAUM states support EPA's proposal to calculate fuel economy for dedicated alternative fuel vehicles using only 15 percent of actual energy consumed as this provides a strong incentive for increased deployment of compressed national gas and fuel cell vehicles.

In the initial years of the standards, these vehicles will account for a very small fraction of overall sales and therefore own a small percentage of overall greenhouse gas emissions from the light-duty vehicle fleet.

Organization: Pennsylvania Department of Environmental Protection

Motor vehicles fueled by liquid petroleum remain a significant source of air emissions in Pennsylvania and this fact poses challenges to us in meeting and maintaining federal clean air standards. We are, however, seeing some promise from the dramatic increase in supplies and availability of domestic natural gas of swapping out our vehicle transportation fuel from imported foreign oil to domestic natural gas either directly or via electricity generated from domestic natural gas fuel. Indeed, this is the most significant opportunity we have had in our lifetime to clean our air, especially in urban areas where the burning of imported liquid transportation fuels is the most concentrated. This would dramatically improve the air quality of Pennsylvania and would, at the same time, significantly enhance our national security and energy independence to boot. We are encouraged by President Obama's statement made in January that natural gas could power America's long haul trucking fleet. Light-duty fleets could also benefit from the use of natural gas and we urge EPA to incorporate strategies in this regulation to promote natural gas light-duty vehicle development. [EPA-HQ-OAR-2010-0799-7821-A1, p. 1]

The Agencies Should Provide Similar Incentives to All Alternatively Fueled Vehicles.

We are concerned about the implications for provisions discussed below for encouraging the use of natural gas in light-duty vehicles. [EPA-HQ-OAR-2010-0799-7821-A1, p. 3]

Discard the Petroleum Equivalency Factor. The petroleum equivalency factor (PEF) should eventually be discarded in order that a fair and accurate accounting of GHG emissions be assessed among all vehicles so that the nation gets the most fuel efficient fleet possible. The agencies should work with Congress toward eliminating this statutory requirement. We recognize that the agencies are required by statute to count GHG emissions from electric vehicles (EV) using the PEF, which allows for only a partial counting of the actual GHG emissions produced by EVs. The PEF serves to incentivize manufacturers to produce more EVs. Discarding the PEF would level the incentive playing field among vehicles using different fuels, including natural gas, and allow for a more accurate accounting of GHG emissions. [EPA-HQ-OAR-2010-0799-7821-A1, pp. 3-4]

Organization: Plant Oil Powered Diesel Fuel Systems, Inc.

The Proposed Regulations assign to vehicles equipped to run on compressed natural gas ("CNG") a GHG emissions credit based on the amount of time the vehicle has been estimated by the Society of Automotive Engineers to run on CNG, as a function of the carbon emissions equivalency of this fuel as compared to petroleum. Id. [EPA-HQ-OAR-2010-0799-10337-A2, p. 6]

C. Natural Gas-Powered Vehicles

While natural gas produces less CO_2 per Btu than does coal or petroleum fuel oil, it entails the release into the atmosphere of fossilized carbon that constitutes a net addition to GHG's. EIA, "Natural Gas & the Environment," (Web: Feb. 3, 2012) (http://www.eia.gov/kids/energy.cfm?page=natural_gas_home-basics) (117 pounds versus 200 pounds versus 160 pounds, respectively). Proposed Regulations that encourage the use of a less-intensive GHG producing fossil fuel do not reduce GHG emissions going into the atmosphere; they only slow the pace of accumulation, still increasing Global Warming. Such incentives are, thus, contrary to the duty of EPA under the Clean Air Act to slow Global Warming. [EPA-HQ-OAR-2010-0799-10337-A2, p. 9]

Organization: Toyota Motor North America

ATV Multipliers [EPA-HQ-OAR-2010-0799-9586-A1, p.20]

EPA requests comment on extending to CNG vehicles a sales multiplier similar to those proposed for the advanced technology vehicles listed above. [EPA-HQ-OAR-2010-0799-9586-A1, p.20]

Toyota believes the primary consideration for including any technology in this provision should be its CO_2 reduction potential. The CAFE regulations already recognize the oil saving benefit of CNG vehicles by structuring the fuel economy calculations to provide a significant boost in their reported fuel economy. EPA's advanced technology provisions should be squarely focused on CO_2 benefits of a technology. [EPA-HQ-OAR-2010-0799-9586-A1, p.20]

Toyota opposes including CNG vehicles if it excludes other technologies that are more advanced and provide greater CO_2 reductions. While CNG vehicles typically emit about 20 percent less CO_2 compared to a convention gasoline engine, 'strong' gasoline electric hybrids typically emit 30 percent less. [EPA-HQ-OAR-2010-0799-9586-A1, p.20]

Toyota believes hybrid electric vehicles are a critical stepping-stone for the grid-connected technologies that are the focus of this proposed incentive. Hybrids share many of the same components as electric and plug-in hybrid vehicles (batteries, motors, and power electronics). Expanding hybrid vehicle penetration will help create economies of scale for these shared components while building manufacturing and supplier capabilities, ultimately supporting expansion of plug-in hybrid and electric vehicles. [EPA-HQ-OAR-2010-0799-9586-A1, p.20]

Therefore, if the agencies decide to grant CNG vehicles a multiplier under this proposed incentive, then hybrid vehicles should also be included and should be assigned a larger multiplier in recognition of their superior CO_2 reduction potential. Similarly, dual-fuel CNG systems should receive a lower multiplier than dedicated CNG systems based on expected real world CO_2 reductions. Finally, both the CNG and hybrid multipliers should be lower than those for plug-in hybrid electric vehicles. [EPA-HQ-OAR-2010-0799-9586-A1, p.20]

We also request the EPA revisit whether this provision should be continued beyond the 2021 model year as part of the mid-term review. [EPA-HQ-OAR-2010-0799-9586-A1, p.20]

Organization: Vehicle Production Group LLC (VPG)

Harmonization of Treatment of CNG Carbon Dioxide Emissions

Section 136 of the Energy Independence and Security Act of 2007 creates a government-backed loan program for the development of non-petroleum fuels for automotive applications. The Department of Energy administers this loan program through private banks. VPG was awarded a loan of approximately $50 million through this program for the development of our CNG offering. Among the benefits to OEM's responsible for compliance with CAFE regulations, and as a function of displacing the nation's dependence on foreign oil, there is a credit for the determination of the fuel economy of a dedicated CNG vehicle. [EPA-HQ-OAR-2010-0799-7985-A2, p. 3]

Congress has identified CNG for automotive fuel applications as strategically important to the extent that the above mentioned CAFE computation credit is granted, and government backed loans are offered for the development of CNG fueled vehicles; yet the carbon dioxide emissions from CNG fueled vehicles are handled in the same manner as CO_2 emissions from petroleum sources. Carbon dioxide emissions generated by VPG's gasoline and CNG vehicles as measured by the federal city and highway tests are detailed in Table 1. [See Table 1 on page 3 of Docket number EPA-HQ-OAR-2010-0799-7985-A2] [EPA-HQ-OAR-2010-0799-7985-A2, p. 3]

Since CO_2 emissions are essentially equivalent to fuel economy, and fuel economy of dedicated CNG fueled vehicles is adjusted to create a benefit for the CAFE calculation, VPG suggests the application of the same beneficial treatment of CO_2 generated from CNG as is given to fuel economy. The proposal forwarded by VPG shown in table 1 is an adjustment factor, consistent with the factor applied to fuel economy of dedicated CNG fueled vehicles in calculating CAFE. The adjustment is the use of a 0.15 factor applied to natural gas generated carbon dioxide emissions. [EPA-HQ-OAR-2010-0799-7985-A2, p. 3]

Organization: VNG Co. (VNG)

Section 1: Appropriate. Fair. and Consistent Incentives Are Needed for NGVs. [EPA-HQ-OAR-2010-0799-7941-A2, p. 1]

The success of VNG (and other fueling infrastructure providers) will thus be critical to achieving the Agencies' long-term environmental and energy security goals. However, the massive capital investments that will be required to build this infrastructure are dependent on automakers bringing substantial quantities of NGVs to market - and these production decisions are strongly influenced by the fuel economy and greenhouse gas ('GHG') regulations that are the subject of the present NPRM. [EPA-HQ-OAR-2010-0799-7941-A2, p. 2]

The Notice of Proposed Rulemaking ('NPRM') acknowledges the emissions and energy security benefits of NGVs and takes steps to support their production in ways that the Agencies do not in the current rules. As explained in more detail below, the NPRM includes several proposals that will benefit NGVs, including-

• Utility factors to determine natural gas fuel use for dual-fuel NGVs;

• Credits for deployment of 'game-changing' technologies for full-size pickups, potentially including NGV capability;

• Option to use new EPA rules for dual-fuel NGVs beginning in 2012; and,

• NHTSA's proposal for a strong regime for measuring fuel economy for dual-fuel NGVs after the expiration of statutory credits in 2019. [EPA-HQ-OAR-2010-0799-7941-A2, p. 2]

Despite these positive proposals, and despite the Agencies' desire 'to remain scrupulously neutral... to avoid picking technology 'winners',' electric vehicles ('EVs') receive far more consideration and incentives than NGVs under the NPRM. In order for the Agencies to facilitate the 'all out, all of the above' energy strategy advocated by the President in his recent State of the Union address,4 NGVs must also be provided with appropriate regulatory incentives relative to their unique benefits and contributions to near- and long-term emissions and energy security goals. Additional steps are required to establish appropriate, fair, and consistent incentives for NGVs:

• Multipliers for NGVs similar to those offered for PHEVs, EVs, and FCEVs;

• An extension of the current calculation of NGV GRG emissions as 0.15 times those of gasoline emissions (equivalent to CAFE credits), for a similar duration as the 0 g/mile emissions incentive for EVs; and,

• Appropriate fuel economy credits for dual-fuel NGVs between 2012 and 2019. [EPA-HQ-OAR-2010-0799-7941-A2, p. 2]

The long-term energy security, environmental, and technology innovation goals of the Agencies will have the greatest chance for success if the current NPRM establishes appropriate, fair, and consistent incentives for all alternative fuel vehicles, including NGVs, and refrains from picking 'winners.' Development of the NGV market is particularly important to the achievement of these goals because it serves two purposes: 1) NGVs are an essential technology to reduce emissions and replace petroleum consumption from ICE vehicles in the near term; and, 2) NGVs create a bridge to FCEV market development in the longer term. VNG urges the Agencies to consider their proposed rules and the following VNG comments in the context of this broader vision. [EPA-HQ-OAR-2010-0799-7941-A2, pp. 2-3]

Section 2: NGVs Will Benefit from New Economics of Natural Gas - But Require Appropriate Regulations to Meet Their Potential

The adoption of NGVs in the US will be driven by two core factors: consumer demand due to the new economics of natural gas in the US; and, regulations that recognize the ability of natural gas to address national environmental and energy security goals in both the near and long term. [EPA-HQ-OAR-2010-0799-7941-A2, p. 3]

The New Economics of US Gas: VNG - and increasingly, automakers - are optimistic about the future of NGVs in the United States due to the shale gas 'revolution.' The combination of established hydraulic fracturing techniques and new horizontal drilling technologies has been termed 'the biggest energy innovation of the decade' by energy expert Daniel Yergin for allowing drillers to economically access vast amounts of previously-untapped supplies of natural gas stored in shale rock formations.5 President Obama emphasized the importance of this new natural gas production for achieving US energy independence and environmental goals in his recent State of the Union, lauding a 'a supply of natural gas that can last America nearly 100 years."6 [EPA-HQ-OAR-2010-0799-7941-A2, p. 3]

This flood of new domestic natural gas has resulted in a surplus in the market and low prices, which are expected to remain much lower and more stable than oil for decades to come. Compressed natural gas (CNG) currently costs about $1.50 less per gasoline gallon equivalent (GGE) compared to gasoline,7 and according to forecasts from the Energy Information Administration (EIA), this pricing advantage is expected to grow to over $2 per GGE by 2020, and $3 per GGE by 2035.8 [EPA-HQ-OAR-2010-0799-7941-A2, p. 3]

This durable price advantage has the potential to drive widespread consumer adoption of NGVs, which automakers expect can be produced at an incremental cost of $3,000 or less.9 Presenting consumers with this favorable price-value proposition will require automakers to move from current small-volume, conversion kit production of NGVs to mass-produced, production line vehicles - a move that has been key to gaining market success in Europe. Before making necessary investments in mass-market NGV production, automakers will require assurance of fueling infrastructure availability and a regulatory framework that provides appropriate, fair and consistent incentives for NGVs. [EPA-HQ-OAR-2010-0799-7941-A2, p. 3]

Contributes to Energy Security and Environmental Goals: Natural gas is a 100 percent North American fuel that can directly replace imported oil in the transportation sector, in line with the energy security goals of the current rulemaking. Natural gas is also much cleaner burning than gasoline, making it well-suited to meet the environmental goals of the NPRM as well. Argonne National Laboratory's GREET model estimates that NGVs reduce GHG emissions by 24 percent compared to gasoline when fueled on conventional natural gas, and GHG emissions can be close to zero on a lifecycle basis when natural gas is sourced from landfills or other renewable, biogenic sources.10 [EPA-HQ-OAR-2010-0799-7941-A2, p. 4]

These benefits from natural gas operation will be in addition to the efficiency-related fuel economy improvements and emissions reductions achieved in the conventional gasoline-fueled vehicle fleet, since NGVs use the same ICEs. The added reductions in ICE petroleum use and emissions offered by natural gas operation will be valuable to automakers as they seek to comply with increasingly stringent future regulations. Although the US vehicle fleet may one day include large numbers of EVs and FCEVs, the vast majority of sales will be ICE vehicles for the foreseeable future, making it critical to ensure the viability of the natural gas compliance pathway for automakers. [EPA-HQ-OAR-2010-0799-7941-A2, p. 4]

Contributes to Other Regulations: NGV production and the development of natural gas refueling infrastructure can also facilitate compliance with other vehicle regulations. NGVs are well-suited to meet the Tier 3 emission standards under development by EPA due to low emissions for all criteria pollutants, and renewable biomethane can satisfy the advanced biofuels requirement of the EPA-administered Renewable Fuel Standard due to deep lifecycle emission reductions and use of non-food feedstocks.14 In California, NGVs qualify as an Advanced Technology Partial Zero Emission Vehicle under the Zero Emission Vehicle standard, 15 and CNG has one of the lowest carbon intensities of any fuel under the proposed Low Carbon Fuel Standard.16 [EPA-HQ-OAR-2010-0799-7941-A2, pp. 4-5]

Essential Bridge to Hydrogen: In the long term, NGVs will serve as an essential 'bridge' technology to FCEVs, which the Agencies recognize as one of the key technology pathways for achieving long-term energy and environmental goals. FCEVs and EVs can 'transform' the light-duty vehicle sector, but they face major market barriers including 'vehicle cost, fuel cost, the development oflow-GHG fuel production and distribution infrastructure, and/or consumer acceptance.' [EPA-HQ-OAR-2010-0799-7941-A2, p. 5]

The production of NGVs and development of natural gas refueling infrastructure directly address all ofthe 'major near-term market barriers' the Agencies identify for FCEVs. This critical context for understanding the importance of NGVs in achieving the country's long-term energy and environmental goals is summarized in Section 4, within a discussion of the advanced vehicle technology multipliers proposed in this NPRM. The role of NGVs as a 'bridge to hydrogen' is presented in much greater detail in the attached white paper entitled NATURAL GAS: An Essential Bridge To Hydrogen Fuel Cell Vehicles by clean transportation expert James Cannon. [The white paper can be found on pp. 19-35 of Docket number EPA-HQ-OAR-2010-0799-7941-A2] [EPA-HQ-OAR-2010-0799-7941-A2, p. 5]

• New rules for estimating the natural gas fuel use of dual-fuel NGVs developed by the Society of Automotive Engineers (SAE) - the 'utility factor' approach - will allow automakers to receive credit for the greater potential for alternative fuel use of NGV vehicles compared to dual-fuel ethanol (i.e., 'flex-fuel') vehicles; [EPA-HQ-OAR-2010-0799-7941-A2, p. 5]

• The option for automakers to use new EPA rules for dual-fuel NGVs beginning in 2012, which will allow these vehicles to be eligible for uncapped credits based on the utility factor methodology immediately instead of waiting until 2017; [EPA-HQ-OAR-2010-0799-7941-A2, p. 5]

• NHTSA's proposal for a strong regime for measuring fuel economy for dual-fuel NGVs after the expiration of statutory credits in 2019 - which represents an improvement over the current rules, since the removal of statutory caps will allow these vehicles to actually receive credits; [EPA-HQ-OAR-2010-0799-7941-A2, p. 6]

Utility Factors

In the same manner that PHEVs assuage EV owners' 'range anxiety' concerns, dual-fuel NGVs ameliorate 'range anxiety' that might discourage consumers from purchasing dedicated NGVs during the early years of natural gas refueling infrastructure build out. VNG therefore applauds and fully supports the use of the SAE 'utility factor' methodology to determine expected fuel use for both PHEV and dual-fuel NGVs. [EPA-HQ-OAR-2010-0799-7941-A2, p. 6]

The utility factors are a substantial improvement over the previous formula, which assumed that dual-fuel vehicles would only use natural gas for half of vehicle miles traveled. Instead, utility factors provide a more accurate calculation of usage because they compare the range of each specific natural gas vehicle to the daily travel needs of the average driver, resulting in a higher percentage of assumed natural gas fuel use for dual fuel vehicles with significant natural gas range. [EPA-HQ-OAR-2010-0799-7941-A2, p. 6]

VNG strongly supports the use of utility factors for dual-fueled NGVs for four reasons:

• Given the higher purchase price of an NGV and much lower fuel costs for natural gas compared to gasoline, drivers will fuel on natural gas as often as possible; [EPA-HQ-OAR-2010-0799-7941-A2, p. 6]

• The new economics of natural gas will support the build-out of a national, public NGV refueling infrastructure by VNG (and our competitors), giving dual-fuel NGV drivers widespread access to natural gas fuel; [EPA-HQ-OAR-2010-0799-7941-A2, p. 6]

• There is significant potential for overnight home natural gas refueling for NGVs, although the Agencies only acknowledge the potential for home charging for PHEVs in the NPRM. The combination of overnight horne refueling and fast 'on-the-go' fueling at public stations could ensure that the vast majority of daily travel for dual-fuel NGVs is fueled by natural gas; and, [EPA-HQ-OAR-2010-0799-7941-A2, p. 6]

• Adopting the utility factor approach is an important step towards correcting the current, statutorily-imposed rules that unfairly treat dual-fuel NGVs in the same fashion as E85 flex-fuel vehicles, despite the vastly greater potential for dual-fuel NGVs to make a significant impact on real-world petroleum consumption and GHG emissions. Treating dual-fuel NGVs similarly to PHEVs rather than FFVs is an important precedent that is also appropriate in the context of NGV multipliers, as discussed below. [EPA-HQ-OAR-2010-0799-7941-A2, p. 7]

Finally, in the event that the utility factors prove to be unrepresentative of real-world natural gas fuel use, the SAE and the Agencies will have an opportunity to adjust them appropriately during the midterm review period. [EPA-HQ-OAR-2010-0799-7941-A2, p. 7]

While VNG's business interest is for dual-fuel NGVs to fuel on natural gas as often as possible, we do not support the imposition of design requirements for dual-fuel vehicles based on tank size or other factors, a possibility the Agencies requested comments on in the NPRM. The utility factor approach itself incentivizes automakers to build vehicles with greater CNG range, since fuel economy and emissions calculations improve with tank size. However, specific range or design requirements would restrict the ability of automakers to design vehicles based on consumer preference - a particularly important concern in the early years of developing market acceptance of a new technology. [EPA-HQ-OAR-2010-0799-7941-A2, p. 7]

Consistent EPA Regime for Dual-Fuel Vehicles

EPA has proposed allowing automakers the option of moving immediately to the new regime for dual-fuel NGVs beginning in 2012, with no cap on emission credits, no CNG range minimum, and with utility factors to determine fuel use instead of the 50 percent natural gas fueling assumption. VNG strongly supports this proposal, as it will end discrimination against dual-fuel NGVs under the current rules, as discussed below. [EPA-HQ-OAR-2010-0799-7941-A2, p. 8]

In the prior rulemaking for light duty vehicles, EPA adopted the structure of dual-fuel vehicle incentives prescribed for NHTSA in the Energy Policy and Conservation Act ('EPCA') and

Energy Independence and Security Act ('EISA'), which assumed 50 percent alternative fuel use for dual-fueled vehicles and capped the total benefits to a given automaker's overall fuel economy calculation from all dual-fuel vehicles including dual-fuel NGVs and E85 'flex fuel' vehicles - at 1.2 mpg, declining to 0 in 2019. Because virtually all automakers have opted to produce a sufficient quantity of E85 flex-fuel vehicles to reach the maximum allowed credit,31 dual-fuel NGVs are effectively blocked from receiving their Congressionally authorized incentives. [EPA-HQ-OAR-2010-0799-7941-A2, p. 8]

Moreover, the statutory definition of dual-fuel NGVs within EPCA is unnecessarily restrictive. Dual-fuel NGVs are required to have a CNG-only range of at least 200 miles to qualify for the CAFE credit - a requirement equivalent to a 95.4% natural gas usage rate according to the utility factor methodology. This effectively results in vehicles expected to fuel on natural gas a large majority of the time - a vehicle with a IDO-mile CNG range is expected to fuel on CNG for 86.5% of total miles, for example - being treated as dedicated gasoline vehicles. The Agencies have implicitly acknowledged that this treatment of dual-fuel NGVs is unnecessary in this NPRM, as both EPA and NHTSA have opted not to adopt minimum range criteria except when required by EPCA. [EPA-HQ-OAR-2010-0799-7941-A2, pp. 8-9]

The Agencies' proposal to allow automakers to take advantage of the new EPA rules in 2012 is an important first step towards accelerating the production of dual-fuel NGVs, since NGVs can be added to automaker production plans with relatively short lead times and a low incremental cost (if automakers move from small-volume conversions to high-volume production line vehicles). As a result, NGVs can and should be encouraged to make a positive impact on energy security and environmental goals as soon as possible, during the 2012-2016 period. In fact, dual-fuel NGVs will have their greatest value during the early years of the build out of the natural gas refueling infrastructure due to their ability to eliminate range anxiety. [EPA-HQ-OAR-2010-0799-7941-A2, p. 9]

It should be noted, however, that this productive proposal by EPA is an incomplete solution to the unfairness of the current rules for dual-fuel NGVs. Until NHTSA's rules are revised to provide appropriate, fair, and consistent incentives for dual-fuel NGVs in 2012-2019 and beyond, these vehicles will continue to underachieve their potential and underserve the Agencies' objectives. In Section 4, below, VNG discusses ways in which NHTSA might make its rules more consistent with EPA's proposal. [EPA-HQ-OAR-2010-0799-7941-A2, p. 9]

Strong Post-2019 NHTSA Regime for Dual-Fuel NGVs

VNG strongly supports NHTSA's proposal for the treatment of dual-fuel NGVs after 2019. As the Agencies recognize, without credits for dual-fuel NGVs, automakers might only produce dedicated NGVs due to their ongoing regulatory incentives. This in turn could limit development of the market for NGVs, since many consumers may prefer a dual-fuel NGV as their first natural gas vehicle to eliminate 'range anxiety,' just as many consumers today may prefer PHEVs to dedicated EVs due to similar range and recharging concerns. NHTSA should thus continue using the Petroleum Equivalency Factor to calculate the fuel economy of dual-fuel NGVs, as with dedicated NGVs. [EPA-HQ-OAR-2010-0799-7941-A2, p. 9]

The use of utility factors to determine fuel usage and removing the previous statutory caps is also appropriate in the post-2019 period, given expectations for maximum possible natural gas fuel use by dual-fuel NGVs. Statutory minimums for CNG range for dual-fuel NGVs are also appropriately removed, in light of higher expected natural gas fuel use under the utility factor methodology as well as the structure of the utility factors, which give automakers greater incentives for vehicles with greater CNG ranges. These proposals are also consistent with the proposed treatment of dual-fuel NGVs under EPA rules, which will take effect beginning in 2012 under the NPRM. [EPA-HQ-OAR-2010-0799-7941-A2, pp. 9-10]

As discussed above, while the post-2020 regime for dual-fuel NGVs is excellent, the effectiveness of this post-2020 regime is severely curtailed by the fact that these vehicles are effectively blocked from receiving any incentives through 2019. [EPA-HQ-OAR-2010-0799-7941-A2, p. 10]

Section 4: Additional Steps Are Needed for Appropriate. Fair and Consistent NGV Incentives

Although the proposed rules provide increased incentives for NGVs, the overall regulatory regime for NGVs is substantially less favorable than the regime for PHEVs and EVs, particularly with regard to the EPA rules. Under proposed EPA rules, EVs will receive a 'double incentive' that includes both a 0 g/mi GHG incentive and multipliers that magnify the impact of each EV on a manufacturer's GHG compliance scores. NGVs do not receive comparable incentives in the NPRM, although notably the Agencies do request comments on NGV multipliers in the NPRM preamble. [EPA-HQ-OAR-2010-0799-7941-A2, p. 10]

The regulatory regime for NGVs is also fraught with inconsistency under both EPA and NHTSA rules. For example, EPA incentives are strong through 2015 but disappear in 2016, in contrast to the consistent 0 g/mi GHG incentive for EVs, which is retained through 2025 (although phased out for automakers producing large numbers of these vehicles starting in 2021). NHTSA incentives for dual-fuel NGVs are rendered effectively useless by statutory limits until 2020, after which time they become favorable. [EPA-HQ-OAR-2010-0799-7941-A2, pp. 10-11]

Without consistent incentives for NGVs, automakers will be less inclined to make investments in these vehicles since they will find it difficult to fit the benefits of these vehicles into their long-term compliance strategies. The Agencies' treatment of NGVs also stands in stark contrast to the consistent, long-term, favorable treatment given to EVs as well as the Agencies' goal of not 'picking technology winners.'38 The importance of establishing appropriate and consistent rules that allow all alternative fuels a fair chance to contribute to energy security and environmental goals is magnified by the particularly long duration of this rulemaking period compared to previous rulemakings. [EPA-HQ-OAR-2010-0799-7941-A2, p. 11]

VNG has several recommendations for providing more appropriate incentives for NGVs, which will ensure that consumers have a wide selection of low-emission alternative fuel vehicles and that the greatest number of such vehicles are produced and sold:

• Multipliers for dual-fuel NGVs on par with multipliers for PHEVs, and multipliers for dedicated NGVs equal to those for EVs;

• An extension of the current calculation of NGV GHG emissions as 0.15 times those of gasoline emissions (equivalent to CAFE credits), for a similar duration as the 0 g/mile emissions incentive for EVs. Measured emissions levels would similarly be phased in after 2022 on the same schedule that EV emissions begin to be measured according to their upstream emissions; and,

• Appropriate fuel economy credits for dual-fuel NGVs between 2012 and 2019. Dual-fuel NGVs expected to fuel predominantly on natural gas are effectively denied incentives under current statutory rules and treated like gasoline vehicles, which the Agencies acknowledge is an 'absurd result.' We encourage the Agencies to explore whether it is possible to provide appropriate fuel economy credits to these vehicles as soon as possible. [EPA-HQ-OAR-2010-0799-7941-A2, p. 11]

Multipliers for NGVs

EPA requested comments on 'the merits of providing similar multiplier incentives to dedicated and/or dual-fuel compressed natural §as vehicles' as those proposed for EVs, PHEVs, and FCEVs under the GHG program.3 These multipliers allow automakers to count each low-or-zero emission vehicle as more than one vehicle for the purposes of compliance calculations between 2017 and 2021, with the express purpose of facilitating market penetration of advanced technology vehicles.40 While EVs and FCEVs are expected to play crucial roles in achieving national energy and environmental goals in the long term, the multipliers are considered necessary in the NPRM to help surmount significant near-term market barriers they face, including: 'vehicle cost, fuel cost (in the case of fuel cell vehicles), the development of low-GHG fuel production and distribution infrastructure, and/or consumer acceptance." [EPA-HQ-OAR-2010-0799-7941-A2, pp. 11-12]

Both dedicated and dual-fuel NGVs should be eligible for similar multipliers as PHEVs and EVs. California already recognizes NGVs as an 'advanced technology' vehicle in its Zero Emission Vehicle (ZEV) regulation, as noted earlier in these comments. NGVs also contribute directly to the Agencies' own advanced technology goals, due to their essential role in facilitating the market penetration of FCEVs. Since the first wave of NGV adoption in the 1990s, the development of NGVs - and particularly natural gas refueling infrastructure - has long been recognized as a key bridge to hydrogen FCEVS.42 [EPA-HQ-OAR-2010-0799-7941-A2, p. 12]

Natural gas is largely composed of hydrogen, with four hydrogen atoms for every carbon atom in a molecule of methane. Due to the chemical and physical similarities of these two gases, they share a number of technology synergies, so that the proliferation of NGVs and natural gas fueling infrastructure will facilitate and accelerate deployment of FCEVs. Indeed, the development of the NGV market serves to reduce or eliminate all four of the near-term market barriers to FCEV adoption identified by the Agencies: [EPA-HQ-OAR-2010-0799-7941-A2, p. 12]

• Low-GHG Fuel Production and Distribution Infrastructure: NGV refueling infrastructure utilizes most of the same hardware (compressors, storage tanks, dispensers) that will be used to dispense hydrogen fuel, allowing natural gas refueling stations to be straightforwardly adapted for hydrogen dispensing. Natural gas can also be used as a feedstock for hydrogen fuel production via distributed steam reforming at the refueling station, a fuel production pathway identified by the Department of Energy's FreedomCAR & Fuel Partnership as the 'most viable approach to begin building [the] hydrogen market in near term.'43 Distributed steam reforming of natural gas for hydrogen production also yields just half of the lifecycle GHGs as production of hydrogen via electrolysis usin1 grid electricity, according to Argonne National Laboratories' GREET model.44 [EPA-HQ-OAR-2010-0799-7941-A2, p. 12]

• Fuel Cost: Production of hydrogen from natural gas via distributed steam reformers also represents the 'lowest current cost' hydrogen pathway compared to electrolysis and other methods, according to the FreedomCAR roadmap.45 [EPA-HQ-OAR-2010-0799-7941-A2, p. 12]

• Vehicle Cost: NGV development will help reduce FCEV vehicle costs by advancing on-board gaseous storage and fuel management technologies, allowing more fuel to be stored safely with less weight and/or space. In a sense the FCEV represents the ultimate union of NGVs and EVs, with EVs providing the electric drivetrain and NGVs ensuring the development of hydrogen fuel technologies. [EPA-HQ-OAR-2010-0799-7941-A2, p. 12]

• Consumer Acceptance: By increasing familiarity and comfort with gaseous fuel vehicles and refueling, NGVs will help pave the way for consumer acceptance of FCEVs. NGV deployment will also serve the role of developing experience with gaseous fuel vehicles for auto dealers, mechanics, and other important stakeholders that directly interface with consumers. [EPA-HQ-OAR-2010-0799-7941-A2, p. 13]

Attached to these Comments is a white paper NATURAL GAS: An Essential Bridge To Hydrogen Fuel Cell Vehicles authored by clean vehicle technology expert James Cannon, which provides detailed background on the synergies between NGVs and FCEVs in a number of key areas, including hydrogen production, distribution, storage, and fuel management systems, fuel dispensing, natural gas-hydrogen fuel blends, vehicle technologies, and safety standards and training. [The white paper can be found on pp. 19-35 of Docket number EPA-HQ-OAR-2010-0799-7941-A2] [EPA-HQ-OAR-2010-0799-7941-A2, p. 13]

In short, the market penetration of NGVs helps ensure that the necessary fuel and technologies will be in place for FCEVs, accelerating and lowering the costs of this transition. Much like the role that PHEVs play in facilitating adoption of EVs, NGVs and particularly dual-fuel NGVs, which mitigate 'range anxiety' for early adopters - are essential for facilitating the market penetration of FCEVs. [EPA-HQ-OAR-2010-0799-7941-A2, p. 13]

Thus, allowing dual-fuel NGVs to receive the same EPA multipliers as PHEVs - with every NGV counting as 1.6 vehicles in 2017, then declining to 1.3 vehicles in 2021 would help build a similar 'bridge' to the hydrogen future that PHEVs provide for EVs. Dedicated NGVs should be eligible for a multiplier level equivalent to EVs and FCEVs, of 2.0x in 2017, declining to 1.5x in 2021. [EPA-HQ-OAR-2010-0799-7941-A2, p. 13]

Our proposed multiplier values assume that the Agencies will also extend GHO incentives for NGVs in parallel with their proposed extension of the 0 g/mi GHG incentive for EVs, as we propose below - in effect, duplicating the 'double incentive' structure given to EVs. However, if the GHG incentive for NGVs is not extended, we would propose doubling all the proposed multipliers for NGVs and FCEVs in order to balance the EV 'double incentive' (in effect, a 'doubled single incentive' for NGVs). [EPA-HQ-OAR-2010-0799-7941-A2, p. 13]

Extended GHG Incentive for NGVs

Under the current rules, EPA will begin to count the emissions of vehicles operating on natural gas at their tailpipe value in 2016. While this value will recognize the real-world emission reductions of approximately 24 percent that natural gas provides compared to gasoline, it ends an emission incentive previously given to NGVs. Until 2016, EPA will count natural gas emissions as just 0.15 times the level of gasoline emissions, equivalent to the 'CAFE credit' approach of NHTSA's Petroleum Equivalency Factor. [EPA-HQ-OAR-2010-0799-7941-A2, p. 13]

Termination of the natural gas emissions incentive is premature - and disadvantages NGVs relative to EVs. The Agencies allowed automakers to count EVs and the electric portion of PHEVs as having emissions of 0 g/mi in the 2012-2016 rulemaking, and in this NPRM they propose extending this treatment to 2025. This incentive is given despite the Agencies' acknowledgement that the use of electric vehicles generates significant upstream emissions from power generation: [EPA-HQ-OAR-2010-0799-7941-A2, pp. 13-14]

'Because [EV] upstream emissions values are generally higher than the upstream GHG emissions values associated with gasoline vehicles, and because there is currently no national program in place to reduce GHG emissions from electric powerplants, EPA believes it is appropriate to consider the incremental upstream GHG emissions associated with electricity production and distribution.' [EPA-HQ-OAR-2010-0799-7941-A2, p. 14]

While the Agencies intend to eventually calculate EV emissions according to a formula that accounts for upstream GHGs, these values will not be phased in until the 2022-2025 period, and even then only for automakers that produce more than a specified number of vehicles. VNG does not object to this treatment of EVs: we recognize that incentives are needed to encourage automakers to take on the risks required to introduce new vehicle technologies. We simply believe that NGVs deserve similar treatment so that automakers will be given fair incentives and rewards for all clean alternative fuel technologies, instead of facing a regulatory landscape tilted towards one pathway. [EPA-HQ-OAR-2010-0799-7941-A2, p. 14]

Additionally, EPA's treatment of natural gas results in markedly inconsistent incentives between the Agencies. Under NHTSA's program, the fuel economy of natural gas will continue to be counted as 0.15 times the gasoline-equivalent fuel economy of the vehicle throughout the 2017-2025 program (although, as discussed below, dual-fuel NGVs may be limited in their ability to receive this incentive until 2020). The move away from the harmonized EPA/NHTSA incentive to a much lower incentive under the EPA program starting in 2016 will complicate and potentially limit the ability of automakers to incorporate NGVs into their compliance strategies. [EPA-HQ-OAR-2010-0799-7941-A2, p. 14]

In order to provide appropriate and fair treatment for NGVs under the EPA program, as well as maintain harmonized, consistent rules for automakers between the two Agencies for a longer period of time, the Agencies should extend the current GHG incentive for natural gas through 2025 under the same rules as the GHG incentive for EVs. This would entail continuing to count natural gas emissions as 0.15 times the level of gasoline emissions for all NGVs through 2021, and then phasing in the tailpipe emission level (e.g., -24 percent below gasoline) between 2022 and 2025 solely for manufacturers producing over 200,000 vehicles cumulatively over this period (or 600,000 vehicles for manufacturers producing over 300,000 vehicles cumulatively from 2017-2021). This is in keeping with the principle of fair, qualitatively similar incentives for both electric and gaseous-fueled vehicles while maintaining quantitatively differentiated incentives based on the characteristics of the technologies. [EPA-HQ-OAR-2010-0799-7941-A2, p. 14]

Appropriate NHTSA Credits for Dual-Fuel NGVs Between 2012 and 2019 [EPA-HQ-OAR-2010-0799-7941-A2, p. 14]

Due to their ability to alleviate 'range anxiety' for drivers, dual-fuel NGVs are a key transition technology for both dedicated NGVs as well as hydrogen FCEVs, in the same way that PHEVs are a key transition technology for dedicated EVs. VNG strongly supports all of the steps proposed by the Agencies to provide support for dual-fuel NGVs, and particularly the utility factor methodology for calculating dual-fuel NGV fuel use noted in Section 3. [EPA-HQ-OAR-2010-0799-7941-A2, p. 15]

However, there remains a major gap in the rules for dual-fuel NGVs due to the constraints of EPCA and EISA, which effectively prevent dual-fuel NGVs from receiving fuel economy credits for natural gas operation under the statutory program until 2020. The current NHTSA rules restrict dual-fuel NGV access to credits in two ways: [EPA-HQ-OAR-2010-0799-7941-A2, p. 15]

• Shared Cap With Ethanol Dual-Fuel Vehicles: Dual-fuel NGVs are grouped with dual-fuel E85 vehicles (also known as 'flex-fuel' vehicles) and placed under a cap that limits their combined statutory credits for automaker fuel economy calculations. Because dual-fuel E85 vehicles can be produced with minimal incremental cost, virtually all automakers have opted to produce enough of these vehicles to reach the maximum benefit allowed by statute, leaving no room under the cap left for dual-fuel NGVs. [EPA-HQ-OAR-2010-0799-7941-A2, p. 15]

• Excessively High Minimum CNG Range: Under the statute (49 USC 32901), in order to qualify as a 'dual fueled automobile' the vehicle must meet a prescribed minimum driving range of200 miles when driving on alternative fuel. Consequently, dual-fuel NGVs are required to have a CNG range of at least 200 miles to qualify for the statutory CAFE credit - a requirement equivalent to a 95.4% natural gas usage rate according to the utility factor methodology. No statutory credits are given for vehicles with less than a 200 mile CNG range, despite the fact that many of these vehicles would be expected to fuel on CNG the large majority of the time under the utility factor methodology. [EPA-HQ-OAR-2010-0799-7941-A2, p. 15]

Taken together, these restrictions will result in dual-fuel NGVs predominantly fueled on natural gas being treated as gasoline vehicles under NHTSA rules until the statutory credit program expires in 2019. This is unfair and counterproductive. Indeed, the Agencies recognize that this is an 'absurd result' in their rationale for providing dual-fuel NGVs with full access to the new utility factor-based rules starting in 2020:

'NHTSA and EPA believe that the expiration of the dual-fueled vehicle measurement methodology in the statute leaves a gap to be filled, to avoid the absurd result of dual-fueled vehicles' fuel economy being measured like that of conventional gasoline vehicles. If the overarching purpose of the statute is energy conservation and reducing petroleum usage, the agencies believe that that goal is best met by continuing to reflect through CAFE calculations the reduced petroleum usage that dual fueled vehicles achieve.” [EPA-HQ-OAR-2010-0799-7941-A2, p. 15]

Treating vehicles that will fuel predominantly on natural gas as gasoline vehicles is indeed an 'absurd' result that runs contrary to the purpose of the statute, and as noted in Section 3 we strongly support the steps taken by EPA and NHTSA to bridge this 'gap' fairly for the 2020-2025 period. However, because of the significant potential of dual-fuel NGVs to make an impact on petroleum reduction goals in the near term, it is also important and appropriate for the Agencies to attempt to address the gap in the 20122019 period to the extent possible. [EPA-HQ-OAR-2010-0799-7941-A2, p. 16]

For example, VNG believes that it may be possible for the Agencies to address the second barrier within the context of this rulemaking. The Agencies have implicitly acknowledged that this very high minimum range for dual-fuel NGVs is unnecessary in this NPRM, as EPA has not adopted a range minimum in its rules, and NHTSA has proposed discarding the range minimum beginning in 2020, after the expiration of the statutory dual-fuel regime.5 While NHTSA has previously determined that it lacked discretion to set a lower range for dual-fuel vehicles,52 the Agencies should consider whether it is possible to establish a new category of vehicle with less than a 200 mile range on an alternate fuel- not a 'dual-fueled' automobile as defined in the statutes, but not a dedicated gasoline automobile either - which can earn appropriate fuel economy credits throughout the period to be governed by the regulations.53 [EPA-HQ-OAR-2010-0799-7941-A2, p. 16]

Alternatively, the Agencies could explore the extent to which it could allow automakers to 'bank' credits that would otherwise be awarded to dual-fueled NGVs in the absence of the statutory limitations during the 2012-2019 period for use in 2020 and beyond.

VNG is fully cognizant of the challenges presented by these or other approaches, but nevertheless encourages the Agencies to explore all options for providing appropriate fuel economy incentives for dual-fuel NGVs prior to 2020. Even a partial solution would be a significant incentive for automakers to begin producing dual-fuel NGVs in the near term, and would harmonize NHTSA's rules with EPA's to the greatest extent possible for the 2012-2019 period. [EPA-HQ-OAR-2010-0799-7941-A2, p. 16]

Section 5: Ensuring a Fair Chance for NGVs and FCEVs is Essential to Achieving National Goals [EPA-HQ-OAR-2010-0799-7941-A2, p. 16]

The environmental and energy security risks posed by the transportation sector's dependence on oil are urgent challenges for the United States, and it would be a mistake for the Agencies to inadvertently and prematurely discourage the development of any promising technology that could help address these threats -let alone two technologies with the enormous potential of NGVs and FCEVs. In the near term, NGVs fueled by newly-abundant domestic natural gas supplies offer a unique combination of vehicle choice and affordability for consumers, low emissions, and replacement (not just reduction) of petroleum consumption. In the long term, NGVs are an essential bridge to the commercialization of FCEVs, which can provide the near-zero emission operation of EVs but with much greater range and much faster refueling. [EPA-HQ-OAR-2010-0799-7941-A2, pp. 16-17]

Despite the promise of both NGVs and FCEVs, the Agencies have not forecasted substantial adoption of either technology during the 2017-2025 period.54 While we believe this is due in part to flaws in the stakeholder consultation process,55 it also reflects the reality that the status quo will not change unless a robust, nationwide gaseous refueling infrastructure is developed. VNG believes that it and others can have this robust national natural gas refueling infrastructure in place by 2025 if the government broadly and the Agencies specifically support the deployment of NGVs with appropriate incentives, similar to EVs. Then, even if FCEVs are still a niche technology by 2025, this natural gas infrastructure will provide a foundation to incrementally provide hydrogen fuel going forward, ensuring that FCEVs do not encounter the extreme 'chicken and egg' dilemma that all alternative fuels currently face. [EPA-HQ-OAR-2010-0799-7941-A2, p. 17]

It is critical for the Agencies to provide appropriate support for the natural gas-to-hydrogen path so that both NGVs and FCEVs will be a viable option for consumers and automakers from 2017 to 2025, as well as during the post-2025 period as emission and fuel economy standards become ever more stringent. Keeping this gaseous fuel pathway 'open' to automakers is particularly important given the Agencies' acknowledged and well-founded concerns over the consumer acceptance of EV technology due to cost as well as range and refueling issues.56 It is, simply, too soon to put all of the Nation's eggs in the EV basket - and it would be a clear mistake to overlook the gaseous fuel pathway just as the supplies and economics of natural gas in the US are undergoing a historic transformation. Ultimately, both EVs and FCEVs will be necessary to achieve long-term environmental and energy security goals, and NGVs will play an essential role in reducing ICE vehicle emissions as well as enabling the transition to hydrogen. [EPA-HQ-OAR-2010-0799-7941-A2, p. 17]

To summarize, for the reasons explained in these Comments, VNG urges the Agencies to adopt the favorable NGV provisions proposed in the NPRM, including:

• Utility factors to determine natural gas fuel use for dual-fuel NGVs; [EPA-HQ-OAR-2010-0799-7941-A2, p. 17]

• Credits for deployment of 'game-changing' technologies for full-size pickups, potentially including NGV capability; [EPA-HQ-OAR-2010-0799-7941-A2, p. 18]

• The option for automakers to use new EPA rules for dual-fuel NGVs beginning in 2012; and, [EPA-HQ-OAR-2010-0799-7941-A2, p. 18]

• NHTSA's proposal for a strong regime for measuring fuel economy for dual-fuel NGVs after the expiration of statutory credits in 2019 VNG also urges the Agencies to incorporate the following provisions to provide more appropriate, fair, and consistent incentives for NGVs: [EPA-HQ-OAR-2010-0799-7941-A2, p. 18]

• Multipliers for dual-fuel NGVs on par with multipliers for PHEVs, and multipliers for dedicated NGVs equal to those for EVs; [EPA-HQ-OAR-2010-0799-7941-A2, p. 18]

• An extension of the current calculation of NGV GHG emissions as 0.15 times those of gasoline emissions (equivalent to CAFE credits), for a similar duration as the 0 g/mile emissions incentive for EVs. Measured emissions levels would similarly be phased in after 2022 on the same schedule that EV emissions begin to be measured according to their upstream emissions; and, [EPA-HQ-OAR-2010-0799-7941-A2, p. 18]

• Appropriate fuel economy credits for dual-fuel NGVs between 2012 and 2019.

We greatly appreciated having the time to meet last Thursday, and would like to provide more extensive comments on our core arguments for improved incentives for natural gas vehicles (NGVs) under the above-referenced rulemaking. As we discussed, natural gas can play an essential and *unique* role in achieving EPA's mandate for long-term reductions in transportation greenhouse gas (GHG) emissions, as well as the "All of the Above" energy strategy articulated by the President. Because NGVs face market barriers similar to other advanced technologies, particularly in terms of fuel distribution, we believe they merit a similarly structured set of incentives. [EPA-HQ-OAR-2010-0799-11797-A1, p. 1]

Natural gas has truly unique "game-changing" potential as an alternative fuel, playing a dual role by providing the lowest possible emissions for internal combustion engine (ICE) vehicles (and light trucks in particular) in the long term while also directly reducing barriers to commercialization for hydrogen fuel cell electric vehicles (FCEV): [EPA-HQ-OAR-2010-0799-11797-A1, p. 1]

Long-Term ICE Pathway: Thanks to plentiful domestic supplies and a robust long-distance pipeline distribution network, natural gas is the only alternative fuel capable of substantially reducing GHG emissions from ICE vehicles on a mass-market, nationwide basis. ICE vehicles will continue to dominate the market for the foreseeable future and will make major advances in fuel efficiency in the years ahead, making it important to ensure that these vehicles will have the opportunity to run on the cleanest fuel possible. In addition to 24% tailpipe reductions of GHGs today, natural gas emissions can be reduced even further through blending with biogas and/or hydrogen. In particular, NGV capability is very well suited to pickup trucks and other light trucks, vehicle classes that are critical to maintaining consumer choice (and thus the economic practicability of these regulations) and are unlikely to be a viable application for battery-based electrification. [EPA-HQ-OAR-2010-0799-11797-A1, pp. 1-2]

Bridge to Hydrogen: The deployment of NGVs and CNG refueling structure will directly reduce the market barriers to the commercialization of FCEVs. The gaseous fuel management and storage technologies used by NGVs are analogous to those that will be used by FCEVs – and, perhaps more importantly, the compressed natural gas (CNG) fueling infrastructure developed for NGVs can be used as a platform for the production and dispensing of hydrogen fuel. Thus, the investments made by companies like VNG for CNG fueling equipment today will directly reduce the costs and build-out time of a future hydrogen dispensing network. A transition to FCEVs can then proceed incrementally through the introduction of hydrogen-natural gas blends and hydrogen-fueled ICE vehicles. [EPA-HQ-OAR-2010-0799-11797-A1, p. 2]

This unique combination of two “game-changing” pathways for NGVs merits a unique set of incentives that recognize that, while NGVs are not the same as battery electric vehicles (BEVs) or FCEVs, they merit a similarly-structured program of consistent, meaningful incentives over the 2017-2025 period. As with BEVs and FCEVs, the NGV program should include: [EPA-HQ-OAR-2010-0799-11797-A1, p. 2]

Emission Incentive: An extension of the current incentive (0.15x gasoline equivalent) for measuring the GHG emissions of CNG through 2021, after which the incentive would be phased out on the same production volume basis as the 0 g/mi emissions incentive for BEVs and FCEVs. [EPA-HQ-OAR-2010-0799-11797-A1, p. 2]

While interest in NGVs is growing due to the increasingly compelling economics of U.S. natural gas, they face the same barriers to the market as other advanced technologies – particularly with regard to infrastructure costs. In referring to incentives for BEVs and FCEVs, the NPRM states: [EPA-HQ-OAR-2010-0799-11797-A1, p. 2]

EPA believes that the relatively minor impact on GHG reductions in the near term is justified by promoting technologies that have significant transportation GHG emissions and oil consumption game-changing potential in the longer run, and that also face major market barriers in entering a market that has been dominated by gasoline vehicle technology and infrastructure for over 100 years. [EPA-HQ-OAR-2010-0799-11797-A1, pp. 2-3]

Given the dual “game-changing” potential of natural gas, as well as the shared barriers posed by the historic dominance of gasoline, this rationale also justifies a similarly-structured program of incentives for NGVs. As with BEV and FCEV incentives, incentives for NGVs should be limited in duration, and these limits combined with the small proportion of NGVs likely to be produced compared to gasoline vehicles should ensure that the impact on GHG reductions from NGV incentives will also remain low. And, as we noted in our meeting, the mid-term review of the regulations in 2018 will also provide an opportunity for an “off-ramp” if unexpectedly rapid uptake of NGVs leads to a risk of “catastrophic success” in terms of impacts on the rule’s GHG reductions. [EPA-HQ-OAR-2010-0799-11797-A1, p. 3]

The following attachment will provide greater detail on these arguments. [EPA-HQ-OAR-2010-0799-11797-A1, p. 3]

[See Docket Numbers EPA-HQ-OAR-2010-0799-11797-A2 and EPA-HQ-OAR-2010-0799-11797-A3 for the above mentioned attachments.]

52 NHTSA may wish to reconsider this earlier decision in light of the changed circumstances since 1996 and the need to avoid an absurd result that Congress could not have intended and that

is contrary to the goals of the regulation. National Highway Traffic Safety Administration. Denial of Petition for Reconsideration in Docket 94-96, August 29, 1996, Federal Register Volume 61 Number 173, September 5, 1996.

53 As a practical matter, credits for this new category of vehicles could be administered under EPA's EPCA authority in the same fashion as NHTSA credits for improved air conditioner efficiency, 'game-changing' technologies for full-size pickups, 'off-cycle' technologies, and the post-2020 regime for NHTSA dual fuel NGV credits are proposed to be administered in this NPRM.

55 The Agencies' analysis for the rulemaking was driven by automakers' current production plans, which themselves are a reaction to previous rulemakings. While this focus is understandable, it is important for the achievement of the Agencies' goals, as well as the satisfaction of their responsibilities under the Administrative Procedure Act, that they give full consideration to all realistically viable alternatives that could playa significant role through 2025 and beyond - and not just those that enjoyed the most attention from automakers and regulators at the time of the rulemaking.

Response:

Arbitrary Distinction Between EVs/PHEVs and CNG Vehicles

A number of commenters argued that providing incentives for EV/PHEV/FCVs and not for CNG vehicles was arbitrary and capricious. EPA disagrees. First, EVs perform markedly better than CNG vehicles from a greenhouse gas emissions perspective, both on a tailpipe-only measurement, and when considering upstream plus tailpipe GHG emissions (see preamble Table III-16). For this reason, EPA does not consider CNG vehicles to be a long-term GHG emissions game-changer. Second, EVs/PHEVs face greater market barriers, including lower vehicle range, higher vehicle cost, and a much different refueling paradigm including a much longer refueling time, relative to CNG vehicles. In any case, the final rule provides an incentive, in the form of a multiplier, for CNG vehicles as explained immediately below.

Multiplier incentive for CNG vehicles for MYs 2017-2021

EPA did not propose, but did ask for comment on, incentives for dedicated and dual fuel CNG vehicles. A large majority of public commenters supported incentives for all CNG vehicles. EPA has finalized temporary incentive multipliers for all dedicated and dual fuel CNG vehicles for MYs 2017-2021 equal to those for PHEVs: 1.6 in MYs 2017-2019, 1.45 in MY 2020, and 1.3 in MY 2021. While EPA does not consider CNG vehicle technology to be a long-term GHG emissions game-changer, the Agency does believe that investments in CNG vehicle technology and refueling infrastructure could be valuable in helping to facilitate future commercialization of hydrogen fuel cell vehicles, which does have the potential to be a long-term GHG emissions game-changer. See Preamble Section III.C.2.c.iv for a much more extensive discussion of the GHG emissions benefits of current CNG vehicles relative to current gasoline and electric vehicles (see Table III-16), and why we believe CNG vehicle technology and refueling infrastructure can facilitate hydrogen fuel cell vehicle commercialization.

Toyota commented that, if CNG vehicles were to receive an incentive multiplier, then conventional hybrid electric vehicles should receive a multiplier as well. Although the Agency agrees with Toyota that conventional hybrids share many of the same electric drive components of EVs and PHEVs (e.g., batteries, motors, controllers), with respect to consumer acceptance and barriers to utilization, the Agency believes that conventional hybrids are much more similar to gasoline vehicles than they are to EVs, in that all of the propulsion energy comes from gasoline, vehicle range is improved, and hybrids need no new refueling infrastructure. As such there is not the same degree of market barriers inhibiting increased use of this technology. Accordingly, EPA is not adopting incentive multipliers for conventional hybrid vehicles. This final rule does provide a credit mechanism to encourage penetration of hybrid technology into the full-size pickup truck class.

See Section 6.6 for a discussion of why EPA is not using the 0.15 factor for GHG emissions compliance, but is adopting the 0.15 factor for the CAFE program beginning in MY 2020, for all nonpetroleum fuels.

<u>Adoption of utility factors for dual fuel CNG vehicles</u>

Commenters expressed widespread support for the EPA proposal to apply the PHEV-based utility factor methodology for weighting operation of natural gas and gasoline for dual fuel CNG vehicle compliance calculations. For a discussion of EPA's rationale for adopting utility factors for dual fuel vehicles, as well as the eligibility requirements that dual fuel vehicles must meet in order to use the utility factor approach, see Preamble Section III.C.4.a.ii.

Introduction and Request for Consideration

The 25x'25 Alliance, American Council on Renewable Energy, American Seed Trade Association, Association of Equipment Manufacturers, American Farm Bureau Federation, Biotechnology Industry Organization, National Association of Wheat Growers, National Farmers Union and National Sorghum Producers (hereinafter referred to as "25x'25 partners") seek leave to file late comments in the above-referenced dockets and respectfully submit such comments. These comments respond to the original notice of the proposed rule, 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, published in the *Federal Register* on December 1, 2011 (76 FR 74854). 25x'25 partners submit that the Environmental Protection Agency ("EPA") and the National Highway Traffic Safety Administration ("NHTSA") should accept and consider these comments, despite their late filing, for the following reasons:

- Additional comments are, as of this date, still being solicited and accepted electronically on the EPA website for this proceeding at http://www.nhtsa.gov/fuel-economy.
- In an earlier extension of the comment period in this proceeding issued on January 6, 2012, EPA and NHTSA stated that "NHTSA and EPA will consider all comments received before the close of business on the comment closing date, and will also consider comments received after that date to the extent practicable."
- 25x'25 partners submit that it is only in light of recent analyses of market trends and events that they could reasonably have understood the implications of the proposed rule as reflected in the comments submitted herein.
- 25x'25 partners have not submitted prior comments.
- 25x'25 partners accept the record as it is and do not seek any delay in the issuance of a final rule in this proceeding.
- 25x'25 partners have reviewed such submitted comments only insofar as necessary to discern whether other commenters have raised the substantive issues 25x'25 partners seek to have EPA and NHTSA consider.
- Consideration of these late-filed comments, to the extent practicable given the timing and the otherwise relatively complete state of the record, is therefore in the public interest.

25x'25 partners, representing a coalition of farm and related public policy organizations, understand the importance of flexible fuel vehicles and the greenhouse gas reduction potential of biofuels and offer the following comments on the following issues:

Background Information

The continued production of flexible fuel vehicles (FFVs) and the advancement of biofuels into the market are critical to expanding renewable fuel use, reducing greenhouse gas (GHG) emissions, and enhancing air quality. Today, nearly 12 million FFVs operate on American roadways. The use of midlevel ethanol blends and E85 in FFVs is a cost-effective and efficient way to help meet the agencies' ambitious standards for improving tailpipe emissions through biofuels utilization. Ethanol and other advanced biofuels such as biobutanol facilitate CO_2 emission reductions both within the vehicle, and, more importantly, throughout its production and combustion life cycle. Furthermore, increased biofuel use contributes to public health: Higher ethanol blends reduce emissions of hazardous air pollutants such as particulate matter (PM 2.5 and ultrafine particles) that result from the burning of aromatic hydrocarbons such as benzene, toluene, and xylene found in conventional fuels.

Despite the many benefits of biofuels, the proposed rule effectively eliminates statutory incentives intended to promote their use. Moreover, it appears to pick favorites by providing much more generous credits to other "advanced vehicle technologies," such as electric and plug-in hybrid vehicles. After a careful review of the proposed new rule in light of recent developments, we believe that the rule:

1. Does not sufficiently incentivize the production of FFVs; and

2. Does not adequately value the GHG reduction potential of biofuels.

Together, these oversights place the rule in conflict with other established national priorities, policies, and legislation (such as the federal Renewable Fuel Standard (RFS) and the Energy Independence and Security Act (EISA)) while ignoring the economic, public health, and environmental benefits that can be achieved through increased biofuel usage.

Rationale for Modification to the Rule

The automotive industry is a business characterized by high capital and development costs, and long vehicle development and life cycles. The proposed GHG standards are very stringent and will drive long-term change in the industry, requiring careful allocation of limited development and capital funds to produce the greatest reduction in GHGs. The proposed rule puts forward a common-sense approach to establishing the adoption of two selected technologies by making their future compliance value clear throughout the life of the rule, which states:

"EPA is proposing that CO_2 compliance values for plug-in hybrid electric vehicles (PHEVs) and bi-fuel compressed natural gas (CNG) vehicles will be based on estimated use of the alternative fuels, recognizing that, once a consumer has paid several thousand dollars to be able to use a fuel that is considerably cheaper than gasoline, it is very likely that the consumer will seek to use the cheaper fuel as much as possible. Accordingly, for CO_2 emissions compliance, EPA is proposing to use the Society of Automotive Engineers ''utility factor'' methodology (based on vehicle range on the alternative fuel and typical daily travel mileage) to determine the assumed percentage of operation on gasoline and percentage of operation on the alternative fuel for both PHEVs and bi-fuel CNG vehicles, along with the CO_2 emissions test values on the alternative fuel and gasoline." (*76 FR 74880)*

This approach of forecasting a high usage rate for the selected fuels and fixing the rate for the duration of the rules provides certainty as to the future CO_2 compliance value of these technologies. This certainty is needed by auto manufacturers to enable informed long-term investment trade-offs to be developed regarding these technologies.

However, EPA does not provide a similar level of certainty with regard to ethanol FFVs. Rather, it makes a backward-looking argument to estimate future E85 use. "Actual use," presumably after the fuel has been used, has been proposed as a way to calculate E85 CO_2 compliance values. EPA cites patterns of historical usage of E85 in FFVs, ignoring the rapidly increasing production of renewable fuels needed to comply with the RFS contained in the 2007 Energy Independence and Security Act (EISA). Most forecasts of the implementation of this act foresee significant increases in the usage of higher ethanol blends in flex-fuel vehicles, as opposed to past ethanol usage being constrained by the availability of higher blends than E10.

While the "actual use" approach that EPA proposes offers the hope that FFVs would be able to use the E85 CO_2 compliance values once these vehicles are designed, developed, and sold, this hope is a poor substitute for the certainty offered for PHEV and bi-fuel CNG vehicles. It is unlikely that automakers would invest in FFVs based on the uncertain prospect of a CO_2 compliance benefit when other technologies are certain to yield a CO_2 compliance benefit. The resulting shortage of FFVs will make EPA's implementation of the EISA more challenging.

Unlike natural gas and electricity, ethanol and other potential drop-in biofuels used in FFVs have inherent "lifecycle" CO_2 reduction benefits. As outlined in the EISA, ethanol must meet one of several GHG reduction targets. Taking only the currently predominant fuel, corn-based ethanol, EPA itself has found that, on average, corn-based ethanol meets the 20 percent reduction in GHG emissions required in the EISA.

Yet the proposed rule ensures that even if manufacturers could prove that their FFVs ran *solely* on ethanol, they would have no regulatory incentive to include such cars in their fleet. This is because the "0.15 divisor," a statutorily-mandated incentive that boosts the effective fuel economy of FFVs under the CAFE program, is omitted by EPA under the proposed CO_2 standards. Since fuel economy and CO_2 are directly correlated, the absence of an incentive in the EPA portion of the rule eliminates any benefit a manufacturer might gain from utilizing the incentive under the CAFE standards. In other words, the proposed rule not only fails to provide additional incentives for alternative fuel vehicles, it effectively eliminates existing incentives, thereby benefiting petroleum at the expense of cleaner alternatives. In the long run, the removal of a statutory incentive for alternative fuel vehicles will harm air quality, increase GHG emissions, and slow the development of clean alternatives to petroleum-based fuel.

Given the considerable influence the final CAFE-GHG rule will have on the synergistic relationship between fuels and vehicles between 2017 and 2025, and likely beyond, it is imperative the agencies give thoughtful consideration to how future fuels and vehicles can seamlessly and cost-effectively comply with the objectives of this rulemaking. With respect to biofuels, the use of E10 and E15 in legacy and newer vehicles between 2017 and 2025 will prove to be an inadequate substitute for the role FFVs can and should play. If FFVs are adequately incentivized in the final rule, use of E85 and other blends of ethanol in these vehicles will ensure compliance with the 2017-2025 rulemaking and fulfillment of the RFS by 2022 in a way that avoids the infrastructure costs, implementation hang-ups, and legal challenges that have surrounded the E15 waiver.

Recommended Changes to the Rule

The remedy for addressing the lack of parity for FFVs and biofuels is clear: The agencies can and should provide a level playing field for each vehicle technology. Further, the life-cycle CO_2 reductions that ethanol provides must be recognized, and the CAFE incentive for biofuels must be preserved in the combined EPA/NHTSA rule. To these ends, EPA should:

1. Either:

a. Use the Society of Automotive Engineers ‘‘utility factor’’ methodology (based on vehicle range on the alternative fuel and typical daily travel mileage) to determine the assumed percentage of operation on gasoline and percentage of operation on the alternative fuel. This will provide equity in treatment of alternative fuels and create a sensible incentive for continued production of FFVs.

Or:

b. Adopt the recommendation offered by the Alliance of Automobile Manufacturers to maintain meaningful FFV credits in the final rule. By using this alternative methodology based on E85 usage in FFVs to calculate GHG emission reductions, a sensible incentive for continued production of FFVs is created.

2. Add the life-cycle CO_2 reduction benefits of ethanol to the CO_2 compliance standards by providing a multiplier showing life-cycle CO_2 reduction, rather than simply measuring tailpipe CO_2 emissions, for all blends containing biofuels. This calculus must take into account *at least* the recognized minimum life-cycle CO_2 reduction of 20% for the biofuel portion of any fuel blend. This would be a conservative recognition of ethanol’s GHG benefits in light of the fact that future ethanol must meet the requirement of advanced biofuels and achieve a 50 percent GHG reduction.

3. At blends of E85 or higher, a 0.15 multiplier must be used for CO_2 calculations, in order to preserve existing statutory incentives for alternative fuels. The inclusion of this multiplier in CO_2 standards would align with EPA’s mandate to reduce emissions of GHG and other pollutants, because it will promote investment into alternative engines and fuels that reduce CO_2 on a life-cycle basis, while at the same time reducing a variety of other dangerous criteria pollutants.

These three changes would provide greater certainty in the manufacturing of FFVs and additional credit for biofuel usage based on sound science.

Conclusion

As written, the rule could have devastating economic consequences. Failure to meet the biofuel volume targets of the RFS due to an absence of vehicles, because of the lack of meaningful incentives for manufacturers to produce FFVs, would adversely impact America’s agricultural and rural economies and our national energy security. EPA’s Regulatory Impact Analysis of the RFS2, released in February of 2010, concluded that the implementation of the Renewable Fuel Program would, in the year 2022 (relative to 2007), increase farm income by $13 billion or 36 percent, improve energy security by $2.6 billion, and reduce our nation's expenditures on foreign oil by $41.5 billion. It would also reduce the cost of corn ethanol production by 13 cents per gallon and cut fuel costs by 2.4 cents per gallon for gasoline and 12.1 cents for diesel fuel. In addition, the monetized health benefits were estimated to be as high as $2.2 billion. This potential, as well as the many gains already made in moving toward the RFS goals, would be jeopardized by the proposed rule.

As noted earlier, the production of FFVs using ethanol and advanced biofuels is a cost-effective means for auto manufacturers to achieve GHG reductions. It is important to note that FFV incentives represent no cost to taxpayers or the government and no additional costs to consumers. Other vehicle technologies, such as natural gas, will require far more resources to establish the infrastructure necessary to enable them to have a meaningful impact on the market.

In summary, the proposed rule will become a self-fulfilling prophecy, one that will create negative outcomes both for consumers and for the environment. The rule presupposes that FFV owners will not elect to use biofuels on the assumption that ethanol fuel blends will remain as expensive as standard gasoline, without the same driving range. Drivers are therefore assumed not to take actual advantage of the potential GHG savings their vehicles make possible. There is also assumed to be no incremental push toward biofuel blends based on their ability to provide the higher octane required for better mileage with lower PM emissions than conventional gasoline despite accumulating evidence for major health problems from such PM emissions.

These assumptions drive the proposed rule to deny the credit for GHG savings that FFVs would deserve if they were used with biofuels. The problem is then compounded by the absence of *any* incentive for alternative fuels under EPA's CO_2 standards, even for dedicated vehicles, thus eliminating the benefit purportedly offered under the CAFE rules. This loss of credit ensures that vehicle manufacturers have no real world incentive to manufacture such vehicles, despite the modest incremental cost of making an FFV compared to a standard motor vehicle. The net effect will result in dramatic declines in FFV manufacture. The dramatic decline in FFV production will then ensure that customers will not be able to purchase FFVs even if biofuel blends are available in widespread locations or are available at costs considerably less than standard gasoline as a function of the major biofuels production scale-up the RFS calls for. Seeing the prospective loss of their major new market and the potential for very poor investment recovery, biofuel producers will simply not make the investments required to produce biofuels at scale.

As a result, the nation will fail to achieve the Renewable Fuel Standard, the rural American economy will lose its biggest opportunity for sustained economic health in generations, and the high-compression engines required to produce fuel economy will not have a high-octane fuel free of the toxic emissions that already comprise a major unaddressed health problem today. Only biofuel blends can provide the critical octane while decreasing PM emissions, but this rule will ensure it is not available for that purpose. And biofuels offer a better alternative for GHG reduction, both in use and in manufacture, than natural gas vehicles or electric vehicles powered by electricity generated – as 70 percent currently is – by fossil fuels, with the inherent GHG emissions and 33% average energy conversion efficiency of the electric grid.

In short, the proposed rule sets up a cascade of negative effects that will deprive biofuels of their opportunity to make a critical contribution to national policy only they can make, and it does so simply by embodying an implicit assumption that biofuels will not make that contribution because they have not already done so. 25x'25 partners appreciate the opportunity to submit late-filed comments on the proposed rule and urge their consideration to the extent practicable by EPA and NHTSA in adopting a final rule. Please feel free to contact us with any questions related to information contained within these comments. [EPA-HQ-OAR-2010-0799-11818]

Organization: Alliance of Automobile Manufacturers

In the final rulemaking for MY 2012-2016, EPA created regulations for MY 2016 ethanol flex-fuel vehicles (FFVs) that differed significantly from those provided for by EPCA. EPA ended the GHG emissions compliance incentives and adopted a methodology based on demonstrated vehicle emissions performance. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

For MY 2016, EPA proposed awarding CO_2 credits upon demonstration of actual usage of E85. EPA now proposes extending MY 2016 approach to MYs 2017-2025. In the MY 2012-2016 rulemaking, EPA offered two options for automobile manufacturers to consider:
(1) a default system based on 100% gasoline operation and (2) fuel economy weightings on national E85 use, or on manufacturer-specific data showing the percentage of miles that are driven on E85 versus gasoline for that manufacturer's ethanol FFVs. The Alliance supports the determination of CO_2 credits based on national E85 usage. The idea of actual national usage would be in conjunction with an early issuance of guidance to manufacturers indicating the value of the F-factor so that manufacturers can develop their vehicle portfolios and GHG compliance plans. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The "F factor" is used in the calculation of Carbon Related Exhaust Emissions (CREE) of flex-fuel vehicle and represents the relative usage of gasoline and E85. The calculation of "F" needs to take into account the following: [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The volume of ethanol used in motor vehicles. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The volume of ethanol available to the flex-fuel fleet. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The volume of E85 available to the flex-fuel fleet. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The fleet of active flex-fuel cars and trucks by model year. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The miles traveled by the fleet of active flex-fuel cars and trucks. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The total grams of CO_2 emitted by the fleet of active flex-fuel cars and trucks. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The CO_2 emissions of the flex-fuel fleet on E85. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

The proportion of the fuel used by the flex-fuel vehicle fleet that is E85. [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

Volume of Ethanol Used in Motor Vehicles [EPA-HQ-OAR-2010-0799-9487-A1, p.66]

EISA makes clear the volumes of renewable fuels that are to be used in the United States through 2022 and then maintains this proportion in 2023 and beyond. For example, the total renewable fuel requirement for 2016 is 22.25 billion ethanol equivalent gallons. EISA does not give guidance as to whether the fuels marketed or imported to meet these requirements will be ethanol, biodiesel or some other renewable fuel. Our recommendation is to use the Energy Information Agency Annual Energy Outlook Liquid Fuels Supply and Disposition forecasts volumes for ethanol, biodiesel and “other biomass-derived liquids.” The ratios between the three fuels can be used to determine the amount of ethanol to be used in any given year. For example, in 2016, the 2011 reference case forecast is 16.108 million gallons of ethanol, 1.381 million gallons of biodiesel and 307 million gallons of other biomass-derived liquids. This gives a ratio of 9.54 gallons of ethanol per gallon of other fuels. Assuming that both the biodiesel and other biomass-derived liquids have a RIN value of 1.5 and the ethanol has a RIN value of 1.0. The volume of ethanol required = 9.54 gallons of ethanol per 11.04 RINs (9.54+1.5) multiplied by 22.25 billion RINs or 19.23 billion gallons of ethanol. The corresponding volume of biodiesel plus other biomass-derived liquids would be 2.01 billion gallons. [EPA-HQ-OAR-2010-0799-9487-A1, pp.66-67]

Volume of Ethanol Available to the Flex-Fuel Fleet [EPA-HQ-OAR-2010-0799-9487-A1, p.67]

This is determined by subtracting the ethanol volumes used for gasoline blending from the total volume of ethanol. This is done by determining the total volume of hydrocarbons used in motor gasoline (this can be determined using the EIA AEO Liquid Fuels Supply and Disposition forecasts volumes) and dividing by 9 to determine the ethanol used for blending E10. For 2016, this is 14.30 billion gallons of ethanol used in gasoline blending. When this is subtracted from the 19.23 billion gallons of ethanol to be used, the resulting volume of ethanol to be used in the flex-fuel fleet is 4.97 billion gallons. [EPA-HQ-OAR-2010-0799-9487-A1, p.67]

Volume of E85 Available to the Flex-Fuel Fleet [EPA-HQ-OAR-2010-0799-9487-A1, p.67]

The volume of E85 available to the flex-fuel fleet is determined by dividing the volume of ethanol to be used by the flex-fuel fleet by the fractional ethanol content of the E85 certification fuel for the model year being evaluated (currently 0.85). [EPA-HQ-OAR-2010-0799-9487-A1, p.67]

Fleet of Active Flex-fuel Cars and Trucks by Model Year [EPA-HQ-OAR-2010-0799-9487-A1, p.67]

This can be done by obtaining vehicle registration data from a commercial company such as R. L. Polk and screening for flex-fuel vehicles. Alternatively, reported manufacturer FFV production by model year can be used, with the volumes reduced using vehicle survival rates from Table 4-3, “Survival Rates and Unadjusted Annual Miles Traveled (VMT) by Age for

Passenger Cars" and Table 4-4 "Survival Rates and Unadjusted Annual Vehicle-Miles Traveled (VMT) by Age for Light Trucks" from "Final Rulemaking to Establish Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards Joint Technical Support Document," April 2010 (2010 TSD). [EPA-HQ-OAR-2010-0799-9487-A1, p.67]

Miles Traveled by the Fleet of Active Flex-fuel Cars and Trucks [EPA-HQ-OAR-2010-0799-9487-A1, p.67]

Multiply the number of flex-fuel cars and trucks of each model year by the appropriate miles traveled per year for each model years' age obtained from Table 4-3, "Survival Rates and Unadjusted Annual Miles Traveled (VMT) by Age for Passenger Cars" and Table 4-4 "Survival Rates and Unadjusted Annual Vehicle-Miles Traveled (VMT) by Age for Light Trucks" from the 2010 TSD. [EPA-HQ-OAR-2010-0799-9487-A1, p.67]

Total Grams of CO_2 Emitted by the Fleet of Active Flex-fuel Cars and Trucks [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

Convert the average fuel efficiencies of U.S. light-duty vehicles (available from the Research and Innovative Technology Administration, Bureau of Transportation Statistics, table 4-23) to grams of CO_2 per mile using the conversion factor of 8,887 grams CO_2 per gallon of gasoline. For any model year too recent to be included in the Bureau of Transportation Statistics table, use the projected fleet-wide emissions compliance levels under the MY 2012-2016 or MY 2017-2025 final rules, as appropriate. Multiply the vehicle miles traveled for the cars and trucks of each model year by the CO_2 emissions per mile of the cars and trucks of each model year. Sum the CO_2 emissions for each model year of cars and trucks on the road. [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

CO_2 Emissions of the Flex-Fuel Fleet on E85 [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

Multiply the E85 volume available by the grams of CO_2 per gallon of E85 certification fuel for the model year being evaluated (currently 6,295). [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

Proportion of the Fuel Used by the Flex-fuel Vehicle Fleet That is E85 [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

Divide the CO_2 emissions of the flex-fuel fleet on E85 by the total CO_2 emissions of the flex-fuel fleet. This fraction is the value, F, used in the CREE calculation. [EPA-HQ-OAR-2010-0799-9487-A1, p.68]

Organization: American Council on Renewable Energy (ACORE) and Biomass Coordinating Council (BCC)

The proposed rules, NHTSA-2010-0131 and EPA-HQ-OAR-2010-0162, focus almost exclusively on automobile efficiency and largely neglect the crucial role of fuels. Considering the ambitious fuel efficiency targets proposed under the new GHG and CAFE rules (average US fleet fuel economy of 54.5 mpg by 2025), fuels are especially important and deserve inclusion in this legislation. If the automobile manufacturers are required to make all the changes necessary to meet these targets without any improvement in fuel quality, there is a serious risk that technologies will be implemented increasing fuel efficiency by sacrificing air quality, cost effectiveness, and consumer choices in terms of size, weight and power of the engine. [EPA-HQ-OAR-2010-0799-9593-A2, p. 1]

Octane enhancement is necessary for gasoline (refined from petroleum feedstock) to be used as a transportation fuel. Octane enhancement can be obtained from a variety of sources, including a wide range of domestically produced biofuels. Octane enhancing substances can also be produced from petroleum, through a further refining process. [EPA-HQ-OAR-2010-0799-9593-A2, p. 1]

The principle message of my letter is to submit that there appears to be little substantial rationale in continuing with high levels of fossil-based aromatic hydrocarbons (BTX-benzene, toluene and xylene) to meet octane needs of gasoline when renewable ethanol, less toxic and damaging to human health, is readily available at comparable prices, is domestic and renewable, and already used to boost gasoline octane – and can do more at higher blend levels. [EPA-HQ-OAR-2010-0799-9593-A2, p. 1]

A brief examination of the history of transportation fuels in America reveals that the petroleum and petroleum refining industries have exerted considerable effort to ensure that petroleum-based products are used to enhance the octane of gasoline. In the process, the domestic biofuels industry has been essentially sidelined and the US economy could become increasingly dependent on costly imported oil if the ethanol industry is further discounted. [EPA-HQ-OAR-2010-0799-9593-A2, pp. 1-2]

THE RECORD

- In 1864, there was a 9--million gal/yr ethanol industry providing fuel for the “Spirit Lamps” that replaced whale oil in oil lamps because of diminishing supplies and rising prices. [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]
- In 1865, oil was discovered in Titusville PA. There was no market for oil, so it was refined into kerosene to compete with ethanol in lamps. A $2.00 tax per gallon was levied on ethanol to help finance the Civil War. A $0.20 a gallon tax was imposed on Kerosene. The ethanol industry faded, over night, back into the cornfields. [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]
- In the 1920s, cars had advanced to the point where they needed more powerful engines with higher compression ratios. Henry Ford was promoting ethanol (113 octane) as the renewable fuel of the future. However, tetra ethyl lead (a known poison) was more profitable. For decades, lead was used and ethanol again faded. [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]
- In the 1970s, the huge human health impact of lead in gasoline became sufficiently clear to the public, and the environmental and public health communities. This, coupled with the advent of the catalytic converter (the key to cleaner air that is poisoned by lead)

finally, after nearly a half century of damaging public health, spelled the end of lead in gasoline. [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]
- Adding clean burning ethanol to meet octane needs in newer engines was the logical next step from environmental, human health and national security perspectives. However, profitability and market share prevailed; and methyl tertiary butyl ether (MTBE) was used to meet the required octane and oxygen needs. Ethanol was assigned a secondary role as an oxygenate to boost octane. [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]
- When MTBE turned out to be unacceptable in the U.S. market due to leaking underground storage tanks leading to ground water contamination, the oil industry turned to higher levels of aromatics to meet octane needs. Ethanol was again relegated to a secondary role in the octane market – a pattern that has been a part of America's transportation fuels history. [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]
- Controlled markets and profit driven forces in the transportation fuel sector have overpowered public health, environmental considerations and, too often, national/energy security issues – let alone the best interest of the nation. Without public involvement, history will likely repeat itself. [EPA-HQ-OAR-2010-0799-9593-A2, p. 2]

The Biomass Coordinating Council (BCC, of which I am the President) believes that domestically produced biofuels are a superior alternative to petroleum-based octane enhancers. Not only would the use of biofuels in place of BTX reduce air pollution and save billions of dollars each year in health care costs, they would take some of the burden of meeting the EPA's new fuel efficiency goals off the shoulders of automakers. Because the carbon footprint of biofuels is much lower than BTX, their use would effectively increase the fuel efficiency and decrease the carbon footprint of the cars and light trucks that run on them. Crucially, biofuels are now cost-competitive with BTX, and as the price of oil (from which BTX is refined) rises, so will the price of BTX. [EPA-HQ-OAR-2010-0799-9593-A2, p. 3]

Biofuels are superior to petroleum-based compounds for a host of reasons:

1. Use of biofuels enhances our energy security by insulating the economy from geopolitical shocks that have and will continue to adversely affect global oil markets. The oil crisis caused by the Yom Kippur War in the 1970s is a case in point, but more recent instances include last year's civil war in Libya and the current crisis in the Persian Gulf with Iran.

2. The production of biofuels here in the US creates jobs at a time when unemployment remains stubbornly high.

3. Every year, importing oil causes hundreds of billions of dollars to flow out of the US economy. Biofuel production would keep some of that money here at home.

4. In a global economy where research and innovation increasingly determine economic competitiveness, America must strive to remain at the forefront of renewable energy technologies. Investment in the domestic biofuels industry that has made steady progress in recent years would ensure a leading role for the US in this crucial 21st century industry.

5. In addition to producing biofuels, the growth of biomass acts as a carbon sink.

6. Biofuels burn more cleanly than petroleum-based octane enhancers, and do not produce harmful particulate matter that can cause serious health damage

7. Biofuels are cost-competitive with BTX. [EPA-HQ-OAR-2010-0799-9593-A2, p. 3]

It is imperative that the numerous advantages of clean, renewable, domestic octane enhancement be considered during the agencies' deliberations. [EPA-HQ-OAR-2010-0799-9593-A2, p. 3]

Over the course of ten successful years in advancing renewable energy, the American Council On Renewable Energy (ACORE) and the BCC have passionately advocated for all renewable energy but have taken no stance against any other form of energy. In addressing the issue of fuels, the BCC is for: [EPA-HQ-OAR-2010-0799-9593-A2, p. 3]

- Improvements to national and energy security and a reduction in the nation's dependence on oil through increased domestic biofuels production. [EPA-HQ-OAR-2010-0799-9593-A2, p. 4]
- First and second generation biofuels, ethanol and biodiesel, which have been steadily improving in terms of advanced farming practices to reach full sustainability; have increased feedstock yields and production volumes from these yields; have increased byproducts and the market value of these byproducts; have yielded less water and fossil fuel use; contributed to job creation; and have shown profitability without subsidies. All of these successes obviate the food versus fuel issue while internationally reducing the need for grain support programs to the advantage of farmers in developing countries. In short, grain, sugar and starch-based ethanol can compete in the transportation fuels marketplace, particularly with a "level playing field" and consideration given to their reduced carbon footprint. [EPA-HQ-OAR-2010-0799-9593-A2, p. 4]
- Biofuels from biowaste, cellulosic biomass, algae, and other forms of biomass that are now reaching the threshold of commercialization. These gains, coupled with continued advances in grain, sugar and starch-based ethanol, will meet the targets of RFS2 as now established. [EPA-HQ-OAR-2010-0799-9593-A2, p. 4]
- Discovering alternate markets for BTX displaced from the gasoline pool (such as high value petrochemical markets). [EPA-HQ-OAR-2010-0799-9593-A2, p. 4]
- Passage of the Open Fuels Standard, which will provide Americans more choice at the pump, and accelerated authority for the use of E-15 in later model automobiles to increase the number of jobs in domestic biofuel production. [EPA-HQ-OAR-2010-0799-9593-A2, p. 4]
- Increased Corporate Average Fuel Economy Standards, made possible by advanced engine designs with higher compression ratio engines and other breakthroughs in flexible fuel engines with improved efficiencies and greater variability of clean burning fuels. These advances will provide the public with greater choices in terms of bigger, safer, more powerful vehicles while still meeting high-mileage and environmental standards. [EPA-HQ-OAR-2010-0799-9593-A2, p. 4]

The BCC is particularly in favor of a systems approach in dealing with all of these opportunities that can be advanced in ways that improve our economy, create jobs, enhance our environment, and doing so cost effectively with open and unsubsidized market forces. [EPA-HQ-OAR-2010-0799-9593-A2, p. 4]

That systems approach involves four factors:

1. An expanding market for biofuels starting immediately to help steady the price of oil, maintain momentum in the biofuels market, and stimulate the production of cellulosic biomass and algae-based ethanol while encouraging the advance and use of other biofuels, methanol, electricity and hydrogen.

2. Rapidly speeding the production of flex fuel vehicles and refueling stations as called for by the Open Fuels Standard. [EPA-HQ-OAR-2010-0799-9593-A2, p. 4]

3. Reducing the level of aromatics (BTX) in gasoline to limit emissions of highly health-damaging particulate matter, especially ultrafine particulates. [EPA-HQ-OAR-2010-0799-9593-A2, p. 5]

4. Forming a working coalition of stakeholders representing the oil, refining and marketing industries; the auto manufacturers; the biofuels producers and other alternative fuel producers, including advanced biofuels, algae, methanol, natural gas, and hydrogen. This collaborative effort would serve the nation, the public, the environment, and the industries involved. The EPA and the NHTSA should also participate in this collaborative effort. [EPA-HQ-OAR-2010-0799-9593-A2, p. 5]

While the BCC appreciates the agencies' efforts to improve the fuel economy of the US car and light truck fleet, we regret that the current proposed rules focus almost exclusively on car manufacturers, neglecting fuel quality as an important part of the solution. We believe that automobiles and the fuels they consume must be regulated in tandem to allow gains in fuel efficiency to go hand in hand with improvements in air quality and public health. Replacing a portion of the BTX group compounds (aromatics) in gasoline with ethanol or other alcohols is in the interests of the public health, national energy security and the domestic economy. [EPA-HQ-OAR-2010-0799-9593-A2, p. 5]

Congress prudently allowed the Volumetric Ethanol Excise Tax Credit (VEETC) and the tariff on imported ethanol to expire at the end of 2011. The BCC supports unsubsidized transportation fuels markets (including subsidies for fossil fuels as well as biofuels) and therefore also supports the Open Fuel Standard. [EPA-HQ-OAR-2010-0799-9593-A2, p. 5]

Organization: American Forest and Paper Association & American Wood Council

Introduction [EPA-HQ-OAR-2010-0799-9537-A1, p.2]

EPA is proposing tailpipe emission standards that fail to distinguish between CO_2 emissions from cars using fuels derived from biomass ("biofuels") and CO_2 emissions from use of fossil fuels. Treating those two types of emissions the same is inconsistent with both international policies as well as existing EPA regulatory programs. EPA should consider modifying the proposed regulations so that the motor vehicle emissions from biofuels are not counted the same as emissions from fossil fuels in calculating grams of CO_2 emissions per mile, to reflect the role of the carbon cycle in biofuel production and combustion and to further encourage use of renewable fuels. This would (1) make the GHG tailpipe emission standards consistent with the endangerment that the standards are supposed to be mitigating and (2) encourage the substitution of renewable fuels for fossil fuels, which EPA already is seeking to accomplish through other provisions in the proposed GHG tailpipe standards. [EPA-HQ-OAR-2010-0799-9537-A1, p.2]

The Carbon-neutrality of CO_2 Emissions from Biofuel Combustion Is Widely Recognized [EPA-HQ-OAR-2010-0799-9537-A1, p.2]

Biomass CO_2 “neutrality” is an inherent property of biomass based on the natural carbon cycle. The carbon dioxide (CO_2) removed from the atmosphere during photosynthesis is converted into organic carbon and stored in biomass such as trees and crops. When harvested and combusted or left to die and decay, the carbon in the biomass is released as CO_2 to be reabsorbed by replanted trees and crops, thus completing the carbon cycle.[1] [EPA-HQ-OAR-2010-0799-9537-A1, p.2]

The neutrality of CO_2 emissions from biomass combustion has been repeatedly recognized for many years by an abundance of studies and is widely accepted by agencies, institutions, regulations and legislation. This is true not only of the IPCC Guidelines and Guidance for the UNFCCC reporting protocols, but of innumerable other agencies and institutions as well. [EPA-HQ-OAR-2010-0799-9537-A1, p.3]

The globally accepted accounting practice for sovereigns of the UN Framework Convention on Climate Change Treaty, of which the United States is a signatory, is developed in the IPCC Guidelines of 1996 and 2006 and the Guidance of 2003 for Land Use/Land Use Change and Forestry (LULUCF). Unequivocally, in the 2006 IPCC Guidelines, Volume 1, Section 1.2, IPCC states that “CO_2 from the combustion or decay of short-lived biogenic material removed from where it is grown, is reported as zero in the Energy, Industrial Processes Product Use (IPPU) and Waste Sectors.” EPA, in preparation and submission of the United States annual inventory of GHG emissions and sinks adheres to these guidelines and does not report CO_2 from biomass combustion based on the same neutrality principle and accounting best practices in order to avoid double counting. [EPA-HQ-OAR-2010-0799-9537-A1, p.3]

Similarly, other countries and regional entities follow the same best practices. For example, the European Union Climate Change Trade Scheme in its directive on carbon trading, the European Union Emissions Trading Scheme (EU ETS), the EU Commission 2004 regulation in Section 4.2.2.1.6, Emission Factors, states, “Biomass is considered as CO_2-neutral. An emission factor of 0 [t CO_2/TJ or t or m3] shall be applied to biomass.” [EPA-HQ-OAR-2010-0799-9537-A1, p.3]

EPA confirmed its position that the combustion of biomass should be considered as CO_2-neutral, regardless of the source of the biomass, in its final rule to implement the Energy Independence and Security Act of 2007 through a new Renewable Fuel Standard, RFS2 (75 Fed. Reg. 14,669 (March 26, 2010)). The preamble of the final rule includes that “[f]or renewable fuels, tailpipe emissions only include non- CO_2 gases, because the carbon emitted as a result of fuel combustion is offset by the uptake of biogenic carbon during feedstock production". 75 Fed. Reg. at 14,787. [EPA-HQ-OAR-2010-0799-9537-A1, p.3]

Further, because CO_2 emissions from combustion of biofuels are widely considered neutral, they are either not reported or reported separately for information purposes only in many protocols such as U.S. Department of Energy's 1605(b), World Resources Institute/World Business Council for Sustainable Development, International Standards Organization 14064, IPCC, Environment Canada, U.S. EPA Climate Leaders, Midwest Greenhouse Gas Reduction Accord Advisory Board recommendations, and the final EPA Mandatory GHG Reporting Rule. In its Mandatory Reporting of GHGs Rule, U.S. EPA makes clear the exclusion of biomass CO_2 emissions quantities for the calculation of thresholds for determining regulated facilities. [EPA-HQ-OAR-2010-0799-9537-A1, p.3]

Distinguishing Between CO_2 Emissions from Vehicles Burning Biofuels and Those Burning Fossil Fuels Would Be Consistent with EPA's Motor Vehicle Endangerment Finding [EPA-HQ-OAR-2010-0799-9537-A1, p.4]

As noted above, a statutory prerequisite for EPA to impose emission limitations on motor vehicles is a finding that emissions of the pollutant from domestic motor vehicles cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare. See CAA section 202(a). EPA proposed those findings on April 24, 2009 (74 Fed. Reg. 18,886), and AF&PA filed extensive comments on that proposal on June 23, 2009. As we stated in our comments, the proposed findings failed to distinguish explicitly between CO_2-neutral emissions from cars using biofuels and emissions from cars using fossil fuels, even though the emissions inventories that EPA relied on were for CO_2 emissions from fossil fuels. The fact is, however, that the effects that EPA projected in its findings of endangerment and causation are all based on increases in the concentration of the GHGs, and primarily in the concentration of CO_2, in the global atmosphere that EPA described and predicted based on combustion of fossil fuels. [EPA-HQ-OAR-2010-0799-9537-A1, p.4]

To the extent that a motor vehicle's CO_2 emissions merely return CO_2 to the global atmosphere that was removed when the organic compounds used to power the vehicle were produced through plant growth, that motor vehicle would not contribute to an increase in the concentration of CO_2 in the global atmosphere and could not be said to cause or contribute to the effects EPA described in its endangerment finding. Distinguishing between motor vehicle tailpipe emissions of CO_2 generated by combustion of biofuels would recognize that those emissions do not contribute to the harm EPA is attempting to mitigate. It also would further EPA's stated goals of increasing the use of renewable fuels and reducing our nation's dependence on foreign oil by creating an appropriate incentive for car manufacturers to accommodate and encourage the use of biofuels. [EPA-HQ-OAR-2010-0799-9537-A1, p.4]

The Proposed GHG Tailpipe Standards Could Be Modified To Differentiate Biofuel CO_2 Emissions [EPA-HQ-OAR-2010-0799-9537-A1, p.4]

Recognition of the fundamentally different nature, with respect to climate change, of combustion of biofuels in motor vehicles could be accomplished within the general regulatory framework

EPA has already proposed. AF&PA and AWC are not experts in EPA regulation of motor vehicle emissions, and we must defer to others as to the feasibility and appropriateness of the detailed requirements EPA has proposed. We can say, however, that recognition of the fundamental difference between CO_2 emissions from biofuels and those from fossil fuels would be consistent with provisions that EPA has included in previous GHG tailpipe standards and in the Proposed Fuel Economy and Tailpipe Standards. [EPA-HQ-OAR-2010-0799-9537-A1, p.4]

For example, for alternative-fuel vehicles up through MY2015, EPA proposed as an incentive, a method of calculating vehicle CO_2 emissions that in effect exempts 85% of the CO_2 emissions from use of alternative fuels such as biofuels or natural gas. See 74 Fed. Reg. at 49,531-32. This has the effect of understating the actual CO_2 emissions, in order to encourage use of alternative fuels. While we still maintain 100% of the CO_2 emissions from biofuels should be credited, it is illustrative of the mechanisms that can be adopted. There are various other incentives and credits, in the MY 2012-2016 light-duty vehicle GHG program and in the proposed MY 2017-2025 program, that are intended to encourage manufacturers to use technology, or implement it early, that will reduce CO_2 emissions by reducing the amount of [fossil] fuel used. Without necessarily endorsing any particular approach, we note that EPA could adapt one or more of those mechanisms to recognize the distinction, in potential effect on global climate, of CO_2 emissions from motor vehicles burning biofuels.[2] [EPA-HQ-OAR-2010-0799-9537-A1, p.5]

In summary, the Proposed Fuel Economy and Tailpipe Standards as written fail to distinguish between CO_2 emissions from the combustion of biofuels in light-duty motor vehicles and emissions from such vehicles burning fossil fuels, despite EPA's recognition of that distinction in other contexts, and the approaches followed by many international bodies. EPA should consider how to acknowledge the fundamentally different character of CO_2 emissions from use of biofuels when setting standards for emissions of CO_2 from motor vehicles. [EPA-HQ-OAR-2010-0799-9537-A1, p.5]

---

1 - From a technical or scientific perspective, biomass CO_2 neutrality is independent of any consideration of material sustainability of the sources of biomass – the CO_2 released back to the atmosphere is the same CO_2 that was just recently removed or "sequestered" from it. The carbon in biomass will return to the atmosphere regardless of whether it is burned for energy or allowed to biodegrade. When we burn biomass for energy we are simply inserting a step in the cycle that allows us to recover usable energy that can displace fossil fuels. [EPA-HQ-OAR-2010-0799-9537-A1, p.2]

2 - Some have suggested that burning biofuels may indirectly increase atmospheric concentrations of CO_2 because of loss of forests that may accompany increased demand for biomass for fuel or because of other indirect effects. As explained in footnote 1 above, such concerns, even if they have some basis, do not contradict the scientific fact that combustion of biomass fuel merely completes the carbon cycle and returns to the atmosphere CO_2 that was removed from the atmosphere by the plant. And in any event, EPA decided not to attempt to address a similar, but more directly related, issue in order to further its goal of reducing fossil-fuel consumption, by choosing to treat electric vehicles in most cases as having zero CO_2

emissions, disregarding that CO_2 may be emitted where the electricity is generated. See 75 Fed. Reg. at 25,341. [EPA-HQ-OAR-2010-0799-9537-A1, p.5]

Organization: American Honda Motor Co., Inc.

6. Testing Fuel – E0:

Current fuel economy and GHG testing are conducted with E0 fuels. We understand that it is EPA's intention in future rulemaking to adopt E15 as its test fuel. If and when EPA changes the certification fuel to E15, Honda believes it is essential that an adjustment factor be added to the GHG and CO_2 calculations so that it does not become a de facto fuel economy and GHG stringency increase. [EPA-HQ-OAR-2010-0799-9489-A1, p. 5]

Organization:	American Petroleum Institute (API)

Comment on the Impacts of Changing Fuel Composition on Costs, Benefits, and Emissions

The EPA and NHTSA point to an unintended consequence relating to the overlay of a regulation setting future light-duty vehicle Corporate Average Fuel Economy (CAFE) standards overlay on top of the separately imposed Renewable Fuel Standards (RFS) program: The cross-subsidization of costly renewable fuels could eventually result in a reduction of total fuel consumption. A CAFE- induced reduction in total fuel consumption will result in more costly cross subsidy per gallon of fuel. A reduction in total fuel consumption will lead to increased biofuel content (percent volume) which could change the timing and impact the severity of blend wall constraints. EPA should recognize that the CAFE standards potentially run counter to meeting RFS mandates. [EPA-HQ-OAR-2010-0799-9469-A1, p. 13]

Organization: Clean Fuels Development Coalition (CDFC)

RECOMMENDED ACTIONS. The Agencies have proposed a rule with multiple, and potentially competing, objectives. Increasing fuel efficiency and reducing transportation sector petroleum use and carbon emissions, without compromising urban air quality, requires a balanced approach to both fuels and vehicles. In order to enable the most cost effective compliance with these important objectives, we respectfully recommend the following changes to the rule as it now stands: [EPA-HQ-OAR-2010-0799-9574-A3, p. 1]

1. Provide automakers with sufficient incentives to commit to aggressive flex fuel vehicle (FFV) production schedules post-MY2016, with robust credit trading mechanisms among vehicle classes and among the manufacturers themselves. FFV incentives should be on par with those provided by the Agencies to other fuel options incented by this rule, such as electric, CNG, and fuel cell-powered vehicles. [EPA-HQ-OAR-2010-0799-9574-A3, p. 1]

2. Properly credit ultra-low emissions, high octane, low sulfur ethanol blends' (E30+ blends) higher octane; power density; reduced carbon; and RVP control benefits in calculating both

Petroleum Equivalency Factor (PEF) and carbon reduction credits. [EPA-HQ-OAR-2010-0799-9574-A3, p. 1]

3. Acknowledge the importance of octane in achieving both fuel efficiency and carbon/criteria pollutant reduction, and E30+ blends' unique ability to transform an 84 sub-octane gasoline blend-stock into a high-quality, clean-burning 94 octane (AKI) finished fuel. [EPA-HQ-OAR-2010-0799-9574-A3, p. 1]

4. Give full weight to E30+ blends' ability to substantially reduce both PM and $PM_{2.5}$ emissions, including the associated toxic PAHQ emissions, and thus fairly credit their ability to protect against unintended urban air quality impacts. [EPA-HQ-OAR-2010-0799-9574-A3, p. 1]

6. Recognize ethanol's cost advantages compared to gasoline Aromatic Group Compounds, and the sufficiency of E30+ ethanol supplies over the term of this rulemaking to both reduce Aromatics Group Compounds, and increase U.S. gasoline octane levels, while helping to reduce automakers' costs of compliance (see Attachment J). [This attachment can be found in Docket number EPA-HQ-OAR-2010-0799-9574-A14] [EPA-HQ-OAR-2010-0799-9574-A3, p. 2]

7. Develop commercially practicable methods to measure actual usage of E30+ blends post-MY 2019, whether it be on-board diagnostic reporting, or other predictable, and transparent, macro-accounting procedures. [EPA-HQ-OAR-2010-0799-9574-A3, p. 2]

BACKGROUND. Since the enactment of the 1990 Clean Air Act Amendments (1990 CAAA), U.S. policymakers have recognized that U.S. transportation fuels policy should strive to preserve a careful balance between vehicles and the fuels that power them, as they are synergistic pieces of an integrated system. Requiring automakers (original equipment manufacturers, or OEMs) to improve vehicle hardware and engine technologies without at the same time requiring fuel providers to improve fuel quality would be bad policy, and could result in adverse unintended consequences that will ultimately undermine the important objectives of this rule. In particular, failure to upgrade fuel standards to replace Aromatic Group Compounds with Clean Octane alternatives will compromise the nation's petroleum use and carbon reduction goals, potentially resulting in increased ambient particulate matter ($PM_{2.5}$, a currently regulated pollutant whose constituents include ultrafine particulates, or UFPs). We believe it is of paramount importance for the Agencies to ensure that the final rule properly recognizes intermediate ethanol blends' ability to enhance gasoline octane levels, and significantly reduce emissions of carbon and criteria pollutants. In order to take advantage of ethanol's unique qualities, the Agencies must revise their proposed rule to incent the manufacture of FFVs after MY2016 and require fuel quality improvements as Congress intended. This will be the best way to maximize cost effective compliance with both fuel efficiency and carbon reduction goals, enable the introduction of higher octane in-use fuels, prevent adverse urban air quality impacts, and protect the public health and welfare as new engine technologies come to market. [EPA-HQ-OAR-2010-0799-9574-A3, p. 2]

THE AGENCIES HAVE REQUESTED COMMENT ON A NUMBER OF IMPORTANT ISSUES. We commend the Agencies for requesting comment on a number of key issues that deserve careful consideration for shaping the final rule. Since we note that the Agencies project a fleet-wide penetration rate of only 1% for plug-in and electric vehicles (PHEVs and EVs) by 2021, and 7% for hybrid electric vehicles (HEVs), we believe that liquid fuel- propelled spark-ignition vehicles will continue to dominate the U.S. transportation fuels sector for many years, perhaps decades. A 2010 National Research Council (NRC) study was cited in a GM/Coskata paper as concluding that “PHEVs will have little impact on oil consumption before 2030 because there will not be enough of them in the fleet. More substantial reductions could be achieved by 2050 but will reduce oil consumption only slightly more than can be achieved by just the hybrid vehicles (HEVs).”12 Therefore, we will focus our comments on the important role we believe E30+ blends can play in down-sized GDI vehicles with bundled advanced technology packages. (The page numbers below identify where in the rulemaking the captioned issue is raised by the Agencies.) [EPA-HQ-OAR-2010-0799-9574-A3, p. 5]

- P. 75335, IMPORTANCE OF OCTANE. As mentioned previously, we believe that octane should play an extremely important role in meeting the nation‘s transportation fuels sector goals between now and 2025 and beyond. There are critical differences between the Aromatic Group Compounds (Dirty Octane) and Clean Octane alternatives, involving a range of considerations including legal/statutory authority, technical/performance, and environmental/health criteria. In the process of finalizing this rule, we strongly recommend that the agencies avail themselves of the extensive body of third party scientific literature, including recent Society of Automotive Engineers (SAE) and other credible work that has been done on performance and emissions effects of E30+ blends compared to the different types of in-use gasoline. [See Attachment C in Docket number EPA-HQ-OAR-2010-0799-9574-A6.] Well respected experts such as Honda Motors, Delphi Powertrain, Oak Ridge National Laboratories, and Southwest Research Institute have published findings that contradict many of the conventionally accepted assumptions about higher ethanol blends‘ performance based on testing that has historically been conducted primarily by petroleum interests or affiliated entities. In particular, E30+ blends can help the OEMs more cost effectively comply with the new fuel efficiency rules, reduce transportation fuel carbon intensity and CO_2eq tailpipe emissions, improve advanced engine design performance, and achieve significant reductions in harmful pollutants. [EPA-HQ-OAR-2010-0799-9574-A3, p. 5]
- P. 74878, PETROLEUM EQUIVALENCY FACTOR FOR E30+ BLENDS. The Agencies state in footnote #56 that EPA is required to calculate fuel economy using DOE‘s Petroleum Equivalency Factor (PEF). We are concerned that DOE‘s simplistic approach to ethanol‘s PEF based only on energy density comparisons (e.g., dividing gasoline‘s 115,000 BTUs into ethanol‘s 76,000 BTUs) significantly and incorrectly penalizes ethanol when it comes to both petroleum displacement and, by extension, carbon reduction credit calculations. It is important that the Agencies recognize at least three distinct facts about ethanol‘s unique octane enhancement properties: 1) it has an octane rating as high, or higher, than Aromatic Group Compounds, which means that ethanol can reduce the catalytic reformer‘s significant gasoline and other product yield losses sufficiently to entirely offset its lower energy density (confirmed by the 2008 NREL/McKinsey linear program study cited below);32 2) its power density, chemical octane, superior octane sensitivity, and charge cooling effects help to further compensate for its energy density (BTU) shortcomings; [See Attachment C in Docket number EPA-HQ-OAR-2010-0799-9574-A6] and 3) as ethanol volumes increase in the future in

response to market-based signals, OEMs can optimize advanced engine designs for higher compression ratios and other modifications to take even greater advantage of ethanol's unique performance benefits. Taken together, these benefits result in a greater than 1:1 displacement effect from E30+ blend substitution for Aromatic Group Compounds. Another important factor that must be considered in any recalculation of ethanol's PEF is for the Agencies to recognize that as ethanol concentration increases, e.g., E30+ blends, depending upon base gasoline properties, ethanol's naturally lower Reid Vapor Pressure (RVP)34 begins to take over, which allows refiners and blenders to more easily control for RVP (one of EPA's targets in the anticipated Tier 3 rulemaking). In any case, E30+ blends significantly reduce a wide range of tailpipe emissions, including NO_x, CO, VOCs, weighted average MSATs, and PM/PN that far outweigh any evaporative emission increases. [See Attachment C in Docket number EPA-HQ-OAR-2010-0799-9574-A6] [EPA-HQ-OAR-2010-0799-9574-A3, p. 9]

- ENSURE FULL-SCOPE COST-BENEFIT ACCOUNTING FOR REPLACING DIRTY OCTANE WITH CLEAN OCTANE. To our knowledge, the last time EPA did a cost-benefit analysis of reducing Aromatic Group Compounds was in the 2007 MSAT rulemaking. At that time, EPA's model used crude oil price assumptions of approximately $20 a barrel, which is of course 80% lower than current prices, making the analysis of little value. (Aromatics prices are tied directly to crude oil costs. As crude oil costs have soared in recent years, Aromatics Group Compound costs have also escalated rapidly.) Another major assumption that skewed the 2007 analysis against the potential of E30+ blends to replace Aromatic Group Compounds was EPA's adherence to conventional wisdom as far as penalizing ethanol for its energy density and RVP properties. This resulted in EPA assuming that it took approximately 1.6 barrels of ethanol to replace 1.0 barrels of aromatics. In fact, E30+ blends' superior octane enhancement effects, and the RVP control tendencies of higher blends—coupled with the offsets that should be credited to them for their substantial tailpipe emissions reductions—should result in E30+ blends being credited for at least a one for one displacement of Aromatic Group Compounds.36 In addition to the enormous health cost savings, there are at least two other costs-benefit considerations worth mentioning. The first is to recognize that commercial technologies exist to upgrade Aromatic Group Compounds and divert them from the gasoline pool to the value-added petrochemical market. [See Attachment H in Docket number EPA-HQ-OAR-2010-0799-9574-A12] The second consideration anticipates a predictable defense from refiners as to why the gasoline Aromatic Group Compounds cannot be reduced, whatever their costs or health risks: the catalytic reformer is not only the source of aromatics, but also provides off-gas hydrogen used for other operations, such as diesel fuel desulfurization. We believe that the best response to this specious argument can be found in the previously mentioned 2008 NREL/McKinsey linear program study of U.S. refiners, which specifically addressed the issue: "The [Linear Programming] model also calculated the input costs for each scenario to account for changes in inputs (e.g., as the reformer and isomerization unit throughputs are reduced, additional hydrogen will have to be purchased)…We also verified that increases in the inputs required, specifically hydrogen, could be met without driving up the prices of the inputs." (Emphasis added.)38 [EPA-HQ-OAR-2010-0799-9574-A3, pp. 9-10]

- P. 75103, GHG – CAFE RULEMAKING CAN/SHOULD COMPLEMENT TIER 3 RULEMAKING. We note EPA's statement that for this analysis, they assume "…no effect on volumes of ethanol and other renewable fuels because they are mandated under the Renewable Fuels Standard (RFS2)…However, as a consequence of the fixed volume of renewable fuels mandated in the RFS2 rulemaking and the decreasing petroleum consumption predicted here, we anticipate that this proposal would in fact increase the fraction of U.S. fuel supply that is made up by renewable fuels. Although we are not modeling this effect in our analysis of this proposal, the Tier 3 rulemaking will make more refined assumptions about future fuel properties, including (in a final Tier 3 rule) accounting for the impacts of the LD GHG rule." Inasmuch as EPA wants to reduce gasoline sulfur content, achieve RVP control, and establish a pathway to reducing PM emissions from gasoline-powered vehicles, it makes sense for EPA to also strive for "increasing the fraction of U.S. fuel supply that is made up by renewable fuels."39 However, we would point out that moving U.S. ethanol production and use to the next level faces many challenges, most of which will not be solved by simple reliance on RFS2 (the volume targets of certain categories of which can be, and often are, significantly reduced by EPA edict due to supply shortfalls). Private sector capital investment has dried up due to uncertainty driven largely by Blend Wall constraints and elimination of longstanding public sector support for new entrants. Now that the ethanol industry's tax incentives and other support has ended, what is most needed is regulatory policy that sends market-based, technology-neutral signals to investors that Clean Octane alternatives can compete on a level playing field with the entrenched, higher cost, higher carbon intensity, and highly toxic Aromatic Group Compounds. This is what the Congress intended in the 1990 CAAA, and it is what would be best for the nation's economy, energy security, environment, and public health and welfare. We strongly recommend that EPA fully consider the substantial benefits E30+ blends would bring in terms of: 1) reducing gasoline sulfur levels (a combination of refinery adjustments and the sheer dilution benefits of replacing Aromatic Group Compounds with 30+% low sulfur ethanol; 2) helping to control RVP, while achieving major reductions in a host of tailpipe emissions; and 3) substantially reducing PM, and especially $PM_{2.5}$, and their associated PAHQ toxic emissions, even as the use of GDI engine technologies increases in the future. For the OEMs, and the entire nation, to extract full benefit from the use of these high-performance, low carbon intensity E30+ blends, it is imperative that the OEMs are properly incented to manufacture FFVs after MY2016. While FFV cost differentials will be considerably lower than CNG alternative vehicles and/or EVs/PHEVs, the OEMs must receive fair and balanced treatment if they are to make the level of commitment needed to ensure that American motorists are able to exercise "consumer choice" at the pump. This means that, over time, all vehicles should be capable of running on no less than E30+ blends, i.e., all FFVS. In the future, as more volumes of ethanol enter the marketplace—from a diverse range of sources, feedstocks, and technologies—the OEMs will be able to achieve even greater mileage efficiencies, performance enhancements, and carbon, PM, toxics, etc. reductions by committing to higher compression engines and other forms of optimization. They will not be able to make such a transition, however, unless FFVs are replacing older legacy vehicles as the fleet turns over. [EPA-HQ-OAR-2010-0799-9574-A3, pp. 10-11]

- P. 74878, FAILURE TO EXTEND PARITY TREATMENT TO FFVs. Regrettably, we note that the Agencies fail to treat ethanol‘s many Clean Octane benefits equitably compared to other alternatives, and to offer the OEMs parity treatment as it relates to incentives to manufacture FFVs compared to other types of vehicles. The Agencies state: “To facilitate market penetration of the most advanced vehicle technologies as rapidly as possible, EPA is proposing an incentive multiplier for compliance purposes of all electric vehicles (EVs), plug-in hybrid electric vehicles (PHEVs), and fuel cell vehicles (FCVs) sold in MYs 2017 through 2021.” (The Agencies are relying on at least one questionable assumption to justify the EV incentives, in that they have elected to assume no upstream carbon emissions from electricity generating units.)40 CNG vehicles are also being incented in this manner. However, in stark contrast, EPA proposes no such incentive multiplier for FFVs, even as it also proposes to eliminate the Usage Factor for all FFVs after MY2016. Consequently, the OEMs have no incentive to manufacture FFVs in the future, which will effectively cap the ethanol industry at its current levels, and thus unnecessarily, and unwisely, prevent the realization of the enormous economic, environmental/health, and energy security benefits that would accrue from an aggressive E30+ Clean Octane program. [EPA-HQ-OAR-2010-0799-9574-A3, p. 11]
- P. 75126, CO_2 REDUCTION BENEFITS AND THE SOCIAL COST OF CARBON. The expanded use of E30+ blends between now and 2025 would achieve substantial reductions in mobile source carbon emissions. EPA has confirmed that Aromatic Group Compounds are 20% more carbon intensive than gasoline itself, and that based on their molecular formulas, ethanol‘s carbon share (% mass) is approximately 40% less than Aromatic Group Compounds.41 In addition, an accurate assessment of the carbon reduction impacts of a Clean Octane fuel reformulation program would have to recognize that the combustion of Aromatic Group Compounds emit orders of magnitude more carbon (see Southern California Particle Center chart, Attachment I). In its December 7, 2011 Technical Support document on PM, CARB provided reinforcement for this assertion: “…[B]ased upon the SPN-EC correlation observed in this study, it is likely that the inclusion of a strict SPN standard would lead to reductions in EC (i.e., BC) emissions.”42 In a recent paper on BC properties, Sierra Nevada Research Institute noted that PAH isomers are a major source of urban BC (EPA‘s draft 2011 Report to Congress on Black Carbon stated that mobile sources are the source of approximately 60% of BC emissions in the U.S.), and that automobiles are a major source of PAH isomers.43 As noted above, the Agencies are proposing to generously incent manufacturers to build FCVs, even though their commercialization is still many years away, because they can utilize hydrogen, which is a fuel that contains no carbon, and therefore would theoretically have no CO_2eq emissions. Using the same logic, the Agencies should be eager to incent the manufacture of FFVs, which can be mass produced today, and which are required to enable increased use of a fuel which contains at least 40% less carbon than the compounds it replaces, and which is available in large quantities today.44 By facilitating the widespread availability of FFVs, the Agencies can remove one of the most formidable barriers to E30+ blends‘ commercialization. Increased use of such blends would help the OEMs by reducing compliance costs in meeting the rulemaking‘s 2025 goal of 163 g/mile of CO_2eq emissions, due to a combination of their lower carbon molecular composition, as well as their ability to substantially reduce high carbon intensity combustion byproducts . We believe that this rulemaking fails to properly

identify, and credit, E30+ blends' cumulative carbon effect. The leading alternatives to the Aromatic Group Compounds all have a much lower carbon intensity index than the high carbon content they would displace, as suggested by the estimates in the table below. [See table on p. 12 of Docket number EPA-HQ-OAR-2010-0799-9574-A3] [EPA-HQ-OAR-2010-0799-9574-A3, pp. 11-12]

- P. 75070, TECHNOLOGY PENETRATION AND ADOPTION RATES. We have already noted that a range of experts—the NRC, the Agencies, and the OEMs themselves—predict that technology adoption challenges will limit the penetration of EVs, PHEVs, HEVs, and FCVs well into the future. Meeting this rule's important objectives will require primary reliance on liquid fuels to power mostly SI engines, equipped with advanced engine technologies. Many of the SI engine technology advancements are expected to be adopted rapidly. For instance, the Agencies project that GDI advances will be incorporated into 85% of new vehicles by 2016, and 100% by 2020 and beyond. Properly incentivized, the OEMs could make most of their light duty fleet flex-fuel capable within a comparable time frame, as the technology is readily available, and the costs are relatively low. There are at least two separate considerations involved here. The first consideration: whether or not the final rule properly recognizes the value of E30+ blends in meeting the petroleum and carbon reduction goals, and therefore sufficiently incents the OEMs by way of Incentive Multipliers and/or Utility Factors to produce the FFVs needed to use the fuel. The second consideration: whether the OEMs realistically expect that sufficient volumes of ethanol will be made available in the coming years to make it worth their while to produce such vehicles, especially since by MY2019 they must demonstrate that the ethanol is actually being used for their credits to be earned? Recognizing that current U.S. ethanol production capacity already stands at one million barrels per day (bpd), we believe that this second question can be answered affirmatively. Using U.S. Energy Information Administration (EIA) numbers, we can paint the following picture of U.S. transportation fuel demand by 2025: [EPA-HQ-OAR-2010-0799-9574-A3, pp. 12-13]

1. 2009, 245 million LDVs on U.S. roads

2. Based upon VMTs, each vehicle averages approximately 12,000 miles/year, and 22.5 mpg

3. Prior to the Great Recession, fleet turnover averaged 7%/yr. (e.g., entire fleet turns over every 14 years)

4. Assume only 5.5% replacement rate going forward, with fleet growth only 1%/year, effective 2013

5. Implies average new vehicles sales of 16.4 million vehicles/year

6. Assume new vehicles hit the 49.6 mpg target by 2025

7. Means that total U.S. LDV fleet would be 276 million vehicles, with an average fuel economy of 36 mpg

8. Equals 2.6 million bpd reduction in U.S. motor fuel consumption [EPA-HQ-OAR-2010-0799-9574-A3, p. 13]

If the EIA assumptions are anywhere near correct, the U.S. transportation fleet crude oil demand picture is in for a major transformation over the next 10 – 15 years. EIA numbers for 2010 show U.S. gasoline consumption at just short of 9 million bpd, which includes ethanol's 900,000 bpd. Adjusting the 2.6 mmbpd figure downward to net out diesel use yields a net reduction in mogas (motor gasoline) usage of approximately 2 mmbpd. That would make 2025 U.S. gasoline demand only 7 mmbpd, of which 1 mmbpd would be comprised of U.S. corn ethanol (capacity already in place), leaving a net total of approximately 6 million bpd of U.S. gasoline demand in 2025. [EPA-HQ-OAR-2010-0799-9574-A3, p. 13]

That means if the goal is to have a flex-fuel transportation system in place by 2025 that would accommodate a national average of E30+ blends, the U.S. would require only 2.1 million bpd of ethanol. This translates into an increase in ethanol supplies of only slightly more than double 2012's 1 million bpd of ethanol production capacity over a period of 13 years. To put this into perspective, the U.S. ethanol industry tripled its production capacity between 2005—the year RFS1 was signed into law—and 2011, or in only six years. Even with the recent elimination of ethanol tax incentives and import duty protections, the market-based signals of a properly drawn rule would unleash the private sector energies of scientists, investors, and feedstock producers to tap into a wide range of sources, technologies, and feedstocks. [See Attachment J in Docket number EPA-HQ-OAR-2010-0799-9574-A14] [EPA-HQ-OAR-2010-0799-9574-A3, p. 13]

The table in Attachment J provides a snapshot of how market-based regulatory signals could successfully balance a gradual reduction in gasoline Aromatic Group Compounds levels with a gradual ramp-up in ethanol levels, until the U.S. has reached a sustainable "equilibrium" of nationwide E30+ blends in 2025. [See Attachment J in Docket number EPA-HQ-OAR-2010-0799-9574-A14] [EPA-HQ-OAR-2010-0799-9574-A3, p. 13]

The graph attached to the table shows how U.S. fuel providers can actually REDUCE (Aromatic Group Compounds), REPLACE (with E30+ blends), and INCREASE (the U.S. transportation sector octane pool in the process). Such an outcome is achievable, so long as the Agencies adequately incent FFV manufacture in this rulemaking, and require higher quality fuel standards here and in the upcoming Tier 3 rule. [EPA-HQ-OAR-2010-0799-9574-A3, p. 14]

The primary assumptions are set out in the Key Market Driver Criteria column. They include the following:

- The fuel efficiency rules will reduce U.S. mogas consumption to 7 mmbpd by 2025
- This means that by 2025, U.S. ethanol use must reach approximately 2.1 mmpbd, or slightly more than double current production capacity of 1 mmbpd over the next 13 years
- That 84 sub-octane blend-stocks average approximately 10 volume % Aromatic Group Compounds
- That E30+ blends, when added to 84 sub-octane gasoline, result in a high quality finished gasoline of approximately 100 RON (for GDI engines)

- That ethanol will displace Aromatic Group Compounds on a one to one, gallon for gallon, basis, based upon its ability to reduce gasoline yield loss at the refinery; the RVP control benefits of higher levels of ethanol in E30+; the de minimus mileage penalty that could occur with E30+ blends (vs. E85), even before the OEMs are able to employ optimization techniques, such as increased compression; and the additional miscellaneous benefits of ethanol‘s increased power density, chemical octane response, and charge cooling effects. [EPA-HQ-OAR-2010-0799-9574-A3, p. 14]

Finally, we are also confident that the nation‘s fuel distribution infrastructure can keep pace with the FFV manufacturing schedule and the expansion of next-generation ethanol production. Based upon typical turnover rates for the nation‘s gasoline dispensers, if flex fuel dispensers were as a matter of course substituted as the obsolescent dispensers are phased out (such as has been proposed by Senate Energy and Natural Resources Committee Chairman Bingaman), the entire U.S. fleet and fuel dispenser system could be flex-fuel compatible by 2025. Consumers would be empowered to save billions of dollars on their fuel purchases by having the freedom to select which blend of gasoline and ethanol best suited their preferences, depending upon cost considerations, environmental impacts, and energy security concerns. Especially when compared to the formidable infrastructure and logistical challenges of some of the other alternatives, such as electric and CNG vehicles, transitioning to an ethanol flex fuel system can be done smoothly, cost effectively, and well within the time frame envisioned by the rule. [EPA-HQ-OAR-2010-0799-9574-A3, p. 14]

CONCLUSION. We respectfully urge the Agencies to make every effort to ensure that the final GHG – CAFE rule does not—in its pursuit of important petroleum and carbon reduction goals—inadvertently create air quality impacts that compromise the public health and welfare, especially that of our most vulnerable citizens living in our largest cities. Congressional intent in the 1990 CAAA is unmistakably clear: the U.S. transportation fuels sector must be managed as a synergistic whole, with vehicles and fuels carefully balanced and periodically aligned as the science advances and technological opportunities present themselves. This rule will shape the U.S. transportation fuels sector for decades to come and has the potential to make dramatic contributions to the nation‘s economic, energy security, environmental, and health and welfare goals. Failure to act now to match improved fuel standards with improved vehicle technologies will unnecessarily expose an entire generation of Americans to increased emissions, especially particle-bound toxics, substantially increase the nation‘s health care costs, and represent a missed opportunity of enormous proportions. In order to open the door to take full advantage of the many benefits of E30+ Clean Octane blends, it is imperative that the Agencies extend equal treatment to FFVs compared to electric, fuel cell, and CNG vehicles. The OEMs must be adequately incented to manufacture FFVs in the future. If they do not, ethanol use will be effectively capped at current levels, and the enormous benefits of a nationwide Clean Octane program will never be realized. [EPA-HQ-OAR-2010-0799-9574-A3, p. 14]

12 “Ethanol – the primary renewable liquid fuel,” Datta et al., J Chem Technol Biotechnol 2011; 86: 473-480.

32 http://www.nrel.gov/analysis/pdfs/44517.pdf, pp. 17 – 19. Specifically, as shown by the McKinsey linear program models, E30+ blends would provide sufficient octane clout to reduce refinery gasoline yield loss by approximately 9.9%, which effectively negates the mileage penalty predicted for E30+ blends. (The Agencies assume that E85 blends will result in 27% lower mileage, based on BTU calculations, although real-world mileage losses have been shown to be considerably lower. E30+ blends‘ mileage performance (assuming no engine optimization) should thus be approximately one-third of that, or 9 – 10% lower. See also Footnote #30.)

34 When not blended with gasoline, ethanol has an RVP of slightly more than two pounds.

36 For the reasons set forth in Footnote #25 above, we would respectfully suggest that now might be an excellent time for EPA to re-run the 2007 MSAT cost-benefit model using more current EIA oil price projections, and recognizing the 1:1 displacement factor for ethanol and Aromatic Group Compounds.

38 "2.4.2 Findings: As the percentage ethanol with which the CBOB will be blended increases, the share of naphtha in the CBOB increases, while the share of isomerate and reformate decreases…Overall, we found that refiners producing fossil gasoline for…E20 blending, the fossil gasoline yield goes up by…6.7 percent…we found that gasoline prices at the pump could fall to…2 to 5 cents… (Footnote 27: The increased gasoline yield is the result of reduced throughput in the reformer. A secondary effect of backing down the reformer is reduced production of hydrogen, which is required for desulfurization of diesel. For most refineries, this will not be a problem as they typically have access to hydrogen produced from natural gas.)" pp. 18-19. http://www.nrel.gov/analysis/pdfs/44517.pdf

40 A stark example of this unbalanced treatment is the EPA‘s provision of an advanced technology vehicle incentive in the form of a 0 g/mile compliance value for MYs 2017 and later electric operation. This 0 g/mile assumption was retained despite opposition from some quarters during the run-up to the proposed rule. In the September 2010 Interim Joint Technical Assessment Report for this rulemaking, the Agencies noted that "[s]ome environmental and public interest groups expressed concern that the 0 g/mi value does not adequately capture upstream emissions from the charging of electric vehicles, and believe an upstream emissions factor should be included." Pp.5-6. In contrast, the ethanol industry has been subjected to rigorous upstream and downstream lifecycle analyses, including applying international Indirect Land Use penalties, while other fuels, such as tar sands and oil shale, have been exempted from such considerations.

41 See "Final Rule for Mandatory Reporting of Greenhouse Gases," Technical Support Document, Climate Change Division, U.S. EPA, September 15, 2009, pp. 15, 32. http://www.epa.gov/climatechange/emissions/downloads09/documents/SubpartMMPr

42 http://www.arb.ca.gov/regact/2012/leviiighg2012/levappp.pdf, p. 126

43 "Black Carbon‘s Properties and Role in the Environment: A Comprehensive Review", Shrestha et al., Sustainability 2010, 2, 204-320;doi:10.330-/su2010294, p. 5.

44 Some experts have argued that next-generation cellulosic ethanol‘s reduced carbon footprints closely resemble the net carbon reduction benefits that have been attributed to the use of hydrogen in fuel cell-powered vehicles.

Organization: E100 Ethanol Group

[These comments were submitted as testimony at the San Francisco, California public hearing on January 24, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11787, p.202; pp. 204-206 and 226-227.]

In conclusion, our proposal: These standards for 2017-2025 are very strong and they are exceptionally well-written. We want to compliment the people who wrote the standards. So let's keep them in place exactly as written but apply them to only 50 percent of new light-duty vehicles.

For the other 50 percent, mandate E100 flex-fuel vehicles with strict mileage requirements.

Taking these two steps will assure complete independence of imported crude oil for the United States and lower greenhouse gas emissions far below the 2017 to 2025 standards.

What would be a viable strategy to make the U.S. independent of imported oil? E100 flex-fuel vehicles optimized to run on ethanol, not gasoline, are the most straightforward ways to do this.

Brazil did something similar to this several years ago and is now a net crude oil exporter, not an importer. The picture in front of you is of a pump at a Shell gas station in Sao Paulo, Brazil I took last April. Two grades of gasoline, regular and premium, and one grade of straight ethanol, no gasoline.

75 percent of the millions of light-duty vehicles in Brazil can burn this gasoline-free ethanol.

We use 140 billion gallons of gasoline per year. Roughly half, 66 billion gallons, come from imported crude oil. So to make the United States independent of imported oil, we need to replace 66 billion gallons of gasoline.

The fastest, lowest cost way to do this is to make ethanol a primary motor fuel in the United States, not a blend with gasoline, but a primary motor fuel for just half of all new vehicle inventory, 50 percent. E100 vehicles could still burn gasoline, but since ethanol would cost less than gasoline at the pump and since mileage would be better, consumers would flock to these vehicles.

E100 engines are applicable to all size vehicles, not just small ones. Cost may be $100 more per vehicle. The industry could easily be making 6.5 million such vehicles per year by January 1st, 2017. 10 years of doing this and now we have 65 million vehicles not burning gasoline, that makes a tremendous dent in the problem.

This ethanol will come from waste cellulose or municipal solid waste, not corn. The Department of Energy published a report that incontrovertibly proves that there is a billion tons of waste cellulose accessible every year in the Unites States.

Yield is 100 gallons per ton so we could make 100 billion gallons of ethanol without interfering with food production or agricultural exports. This is more than enough to provide crude oil independence. So for this and carbon already above ground to make this ethanol, not bringing up new carbon from underground, the net addition of CO_2 in the atmosphere with E100 is zero.

Basically what we're saying is at least mandate 50 percent of the vehicles run on straight ethanol; the other 50 percent continue with electric cars, fuel cells and everything.

We shouldn't just settle on gasoline and electric. It's too dangerous to put all our eggs in one basket.

Organization: Ford Motor Company

Flexible Fueled Vehicles: Consistent with the goals of helping America reduce its dependence on oil and reducing harmful pollution, incentives need to be continued for flexible fuel vehicles that can operate on alternative and renewable fuels. The federal 2007 Energy Independence and Security Act requires increasing use of renewable fuels through the Renewable Fuel Standard (RFS). While currently the volume requirements can be absorbed by blending up to 10% ethanol in the base gasoline available to conventional vehicles, very soon the mandated volume requirements will exceed that level as we proceed into next year. By 2022, the increasing RFS requirement will rely heavily on the ability of flexible fueled vehicles, capable of operating on gasoline blends containing up to 85% ethanol (E85), or other capable vehicles. These vehicles will be required in order to consume the mandated renewable fuel volumes that exceed what can be absorbed in the 10% ethanol blended gasoline, and which could be in excess of 20 billion gallons of ethanol, as demonstrated on the chart, below: [The chart can be found on p. 20 of Docket number EPA-HQ-OAR-2010-0799-9463-A1] [EPA-HQ-OAR-2010-0799-9463-A1, pp. 19-20]

The benefits of ethanol are well known. Argonne National Laboratory and EPA both show/confirm that on a Life Cycle Analysis basis, ethanol produces less GHG than gasoline (M. Wang, December 2010). Furthermore, cellulosic ethanol promises much larger CO_2 reductions. Based on these benefits, we strongly believe that the vehicles designed to operate on ethanol blends up to 85% should continue to receive an incentive to help offset the costs associated with the technology and calibration development. Therefore, we support the determination of credits based on national E85 usage. We look forward to working with the agencies to determine the most appropriate pathway forward to acknowledge the synergistic benefits of these technologies. [EPA-HQ-OAR-2010-0799-9463-A1, p. 20]

Organization: General Motors Company

GM supports the continuation of the quantification of CO_2 emissions reduction related to ethanol usage based on national E85 actual usage. We further urge the agencies to publish F-factor guidance, as suggested in the Alliance comments, as soon as possible to provide the basis for continued and further development of E85- capable vehicles. [EPA-HQ-OAR-2010-0799-9465-A1, p. 3]

Organization: Growth Energy

In the RFS 2 regulation, and consistent with EISA, EPA chiefly relies on the production and sale of domestically-produced ethanol and flexible fuel vehicles (”FFVs”) to meet the volumetric renewable fuels requirements now codified in section 211(o)(2)(B) of the Clean Air Act. The volumetric requirements were fully considered by Congress, were adopted by strong bipartisan majorities, and have been and remain provisions of the statute that representatives of the fossil fuel industry do their best to undercut. See, e.g., Nat'l Petrochemical & Refiners Ass'n v. EPA, 630 F.3d 145 (D.C. Cir. 2010) (denying petitions for review). EPA has a duty to carry out EISA’s mandates, and other federal agencies have provided strong financial support with public funds authorized by Congress to promote the development of biofuels. Growth Energy’s members have invested heavily in the production of renewable fuels, including cellulosic biofuels, and Growth Energy has been a staunch defender of the RFS requirements in EISA. [EPA-HQ-OAR-2010-0799-9505-A1, p. 3]

The GHG and fuel economy standards that the Agencies are now proposing will define, far more than any other step that the Agencies can take under federal law, the types of vehicles that the automobile industry will produce for many years into the future. EPA, however, has not reconciled the options presented for vehicle manufacturers under the regulations proposed in the Joint NPRM with the requirements of Title II of EISA and the strategy for achieving the volumetric requirements of Title II in the RFS 2 regulations. If the GHG reductions that FFVs can be expected to achieve when operated on renewable fuels are not translated into practical incentives for vehicle manufacturers to continue and expand production of FFVs, then the volumetric requirements in Title II of EISA will not be achieved. The Joint NPRM does not propose any program that provides vehicle manufacturers with the necessary incentives, and indeed seems to disfavor the use of ethanol as a vehicle GHG reduction strategy in comparison with a fossil fuel (natural gas) and electricity. This important issue is examined in Attachment 2 [pp. 16-21 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] to this letter, which also introduces concepts that could bring EPA’s vehicle-based GHG reduction goals back into line with EISA and the RFS 2 regulation. [EPA-HQ-OAR-2010-0799-9505-A1, p. 3]

The problem is not simply that EPA has neglected biofuels in the Joint NPRM. EPA and NHTSA are instead embarking on a course that will make the volumetric biofuels requirements of Title II in EISA unachievable. Vehicle manufacturers operate in a highly competitive environment, face a complex set of regulatory expectations from EPA, NHTSA, and the State of California, must plan their compliance strategies many years before the start of a given model year, and have no resources to waste on programs that will not help ensure regulatory compliance. The Joint NPRM is rooted in the policy preference of one State (California) for electric vehicles, and EPA has bifurcated this rulemaking from other emissions and fuels rulemakings. The Joint NPRM leaves no room for vehicle manufacturers to rely on biofuels and the mandates in Title II of EISA as part of an overall compliance strategy. [EPA-HQ-OAR-2010-0799-9505-A1, p. 3]

Notably, EPA does not try to explain in the Joint NPRM or in its regulatory support document why and how it thinks the program outlined in the Joint NPRM will ensure compliance with Title II of the 2007 Energy Act. Nor does the Agency claim, nor could it claim in light of the scope and duration of the standards outlined in the Joint NPRM, that any steps that EPA might take in future regulations under the Clean Air Act could address the conflict between its currently proposed prescriptions to the automobile the Joint NPRM, the guiding strategy appears to have been brokered with California, and not to have been based on the requirements of federal law. 1 If EPA does not correct the direction it is now setting for the automobile industry with respect to FFVs, there will be few FFVs produced after MY 2016. And, in the absence of a large and growing fleet of FFVs, the volumetric mandates in Title II of EISA cannot be met. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 3-4]

Given the neglect of the RFS 2 program in the current rulemaking, EPA appears to be setting the RFS 2 program on a course that is quite contrary to what Congress expected in EISA. That is completely unnecessary, because all EPA has to do in this rulemaking is to give vehicle manufacturers practical incentives for continued and expanded production and sale of FFVs that would be based on the volumes of biofuel required by Congress. EISA includes provisions allowing EPA to make adjustments in the RFS 2 program, if there are proper determinations of unforeseen, “severe” economic harm, “severe” unintended environmental impacts, or an “inadequate domestic supply” of biofuels. See 42 U.S.C. § 7545(o)(7)(A),(F). But those provisions merely provide narrowly-drawn “off-ramps” for the renewable fuels program to address paramount economic or environmental interests. They are hardly a license for EPA to set the RFS 2 program up for failure. It would be ironic in the extreme, and contrary to law, if regulations adopted by EPA in the exercise of administrative discretion, like the regulations in the Joint NPRM, were to deprive the nation of an adequate supply of biofuels, and thus to provide a pretext to abandon or curtail the requirements of Title II in EISA. [EPA-HQ-OAR-2010-0799-9505-A1, p. 4]

When it enacted EISA, Congress had lengthy experience with the efforts of the fossil fuel industry to retard the use of non-fossil fuels, and with the fossil fuel industry’s history of resistance to regulation under the mobile-source provisions of the Clean Air Act. Congress therefore spoke with clarity about its expectations for the volumetric requirements for biofuels in Title II of EISA. EPA was directed in mandatory terms to adopt regulations to “ensure” the sale of gasoline with the specified volumes of biofuels. See 42 U.S.C. § 7545(o)(2)(A) (the Administrator “shall” adopt regulations “to ensure” the use of specified volumes of biofuels). The only federal court that has needed to construe this provision has stated that the term “ensure” as used in EISA means “to make sure, [or] certain.” Nat'l Petrochemical & Refiners Ass'n, supra, 630 F.3d at 153 (internal quotation marks and citations omitted); see also Nat'l Treasury Employees Union v. Chertoff, 452 F.3d 839, 863 (D.C. Cir. 2006) (construing “ensure” under other statute as mandatory). Congress has left EPA no room to effect a de facto reduction in the domestic supply of biofuels when EPA adopts other regulations. EPA must “obey the Clean Air Act as written by Congress.” Natural Resources Defense Council v. EPA, 643 F.3d 311, 314 (D.C. Cir. 2011) (internal quotation marks and citation omitted). [EPA-HQ-OAR-2010-0799-9505-A1, p. 4]

As noted above, Attachment 2 to this letter provides further analysis of the treatment of FFVs in the current rulemaking. If EPA decides not to reform the program outlined in the Joint NPRM to conform with and to support the RFS 2 program, EPA must at a minimum address fully and in detail each of the following questions, in order to explain why it has not done so: [EPA-HQ-OAR-2010-0799-9505-A1, p. 4]

- EPA should explain how it expects the automobile industry and fuels providers to meet the RFS 2 requirements within the framework of the regulations contained in the Joint NPRM or in the Final Rule it adopts in this rulemaking;
- If EPA disagrees with Growth Energy's view that it is unrealistic to expect continued significant production of FFVs after model year 2016 if the Joint NPRM's provisions are adopted, the Agency should explain why;
- EPA should explain how it interprets the requirement to "ensure" the use of biofuels under the statutory text of EISA (see 42 U.S.C. § 7545(o)(2);
- EPA should explain how the vehicle production plans and strategies assumed in the regulatory analysis for the Joint NPRM will "ensure" that the country can meet the volumetric mandates for biofuels in Title II of the 2007 Energy Act;
- If EPA believes that it is not obligated in the current rulemaking to take account of and comply with its duty to ensure compliance with the biofuels mandate in EISA, EPA should explain why it is not required to do so.; and
- EPA should explain whether the absence of an adequate domestic supply of biofuels arising from reductions in the production and sale of FFVs could provide, in whole or in part, a basis of a waiver of any part of the biofuels mandate in EISA. [EPA-HQ-OAR-2010-0799-9505-A1, p. 5]

Because such an increase in octane cannot be accomplished by increases in gasoline aromatic content without compromising the control of emissions other than GHG emissions, EPA should evaluate increases in octane that rely on increases in ethanol content. Increased ethanol content for gasoline to obtain higher octane levels, implemented in a manner consistent with the product planning and validation cadences of the automobile industry and without disruption to existing liquid transportation fuels delivery systems, would have a number of benefits for the public. By enabling a greater mix of engine technologies to meet GHG reduction requirements on a fleet-wide basis, the automobile industry might be able to reduce the costs of GHG reductions. Carefully managed increases in ethanol content can also help reduce engine particulate emissions. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 5-6]

EPA's proposed greenhouse gas (GHG) emissions standard in the Joint Notice of Proposed Rulemaking provides incentives for electric vehicles (EVs), plug-in hybrid electric vehicles (PHEVs) and fuel cell vehicles (FCVs), but essentially eliminates incentives for flexible fuel vehicles (FFVs). The incentives have no clear foundation in a relative comparison of the overall GHG emissions or costs of each of these vehicles. EPA should undertake a thorough study of the lifecycle emissions and total costs, including the cost of the refueling infrastructure of these vehicles, in determining incentives. [EPA-HQ-OAR-2010-0799-9505-A1, p. 7]

The fact that vehicles operating on ethanol-blends can deliver significant GHG benefits can be seen in the results of numerous studies. One straightforward study is a summary of "well to wheels" analysis results published by the U.S. Department of Energy. Selected results from this publication are summarized in Table 1. [Table 1 can be found on p. 10 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, pp. 8-9]

There are several conclusions that can be drawn from the data shown in Table 1. The first of these is that the use of E85 derived from corn6 or from cellulosic materials will reduce GHG emissions by about 11% and 60%, respectively, relative to gasoline without the need for any substantial change in a given vehicle technology. The second is that the use of E85 in hybrid vehicles in the near term will result in substantially larger reductions relative to gasoline than will EVs, PHEVs, and FCVs. The third is that the use of E85 derived from cellulosic feedstocks in any FFV will yield larger reductions in GHG emissions than will be achieved with EVs, PHEVs, or FCVs. [EPA-HQ-OAR-2010-0799-9505-A1, p. 9]

These data and similar data from other related studies, clearly indicate the potential for ethanol-blends to provide "game-changing" reductions in GHG emissions without the need for the fundamental changes in vehicle technology associated with EVs, PHEVs, and FCVs or the fundamental changes in the technology used to generate electricity and hydrogen that would be necessary in order for these vehicles to provide meaningful GHG reductions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 9]

Further evidence of the inappropriateness of providing incentives for EVs, PHEVs, and FCVs while failing to do so for vehicles capable of operation on ethanol blends can be seen through even a cursory examination of the costs associated with these vehicles, their fuels, and the infrastructure required to supply those fuels. [EPA-HQ-OAR-2010-0799-9505-A1, p. 10]

Beginning with vehicle costs, as noted in the EPA proposal, "owners of ethanol FFVs do not pay any more for the E85 fueling capability" that affords the potential for "game-changing" reductions in GHG emissions. In contrast, although misguided subsidies and incentives may affect the prices consumers pay, the actual incremental costs at a retail cost level for EVs, PHEVs, and FVCs during the 2017 to 2025 time frame are expected to be thousands to tens of thousands of dollars. That this will be the case can be easily seen in Table 2 presented below which is taken (along with original footnotes) from a recently released California Air Resources Board (CARB) rulemaking document. As shown, incremental costs for even subcompact vehicles in 2025 are forecast by CARB to remain at levels from around $7,500 to $11,000. This means that unlike the case with vehicles capable of operation on ethanol-blends, substantial costs will have to be incurred before EVs, PHEVs, and FCVs can even be hoped to be capable of providing "game-changing" reductions in GHG emissions. [Table 2 can be found on p. 11 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, pp. 10-11]

Turning to the costs of fuel, the production costs of ethanol are well known for corn derived ethanol and production costs for much lower carbon intensity ethanol produced from cellulosic sources are ultimately expected to be similar or lower than those associated with production from corn. The price of E85 and gasoline is expected to be similar to or lower than those associated with petroleum based fuels over the 2017 to 2025 period based on the latest fuel price forecasts from U.S. Energy Information Administration (EIA). Therefore, it does not appear that there will be a significant fuel price related disincentive to operate FFVs on fuels other than E85. Moreover, as RFS volumes are ramped-up, as discussed in the next section, the additional ethanol beyond E10 will need to go into the available on-road FFVs. Therefore, ethanol vehicles do not have to overcome either vehicle price or fuel price barriers in order to provide "game-changing" reductions in GHG emissions. [EPA-HQ-OAR-2010-0799-9505-A1, p. 12]

Turning finally to the cost of refueling infrastructure, there will be costs associated with the development of a widespread distribution infrastructure for higher ethanol blends. However, that infrastructure will be integrated into the existing transportation fuel infrastructure in the U.S. and not require revolutionary changes to that infrastructure. Further, as ethanol blends will displace petroleum fuels, the capacity of the existing infrastructure will remain relatively constant. [EPA-HQ-OAR-2010-0799-9505-A1, p. 13]

In contrast, EPA has elected not to provide to incentives for vehicles capable of operating on ethanol blends despite the fact that they can provide "game changing" reductions in GHG emissions by being used in what are essentially conventional vehicles with little incremental cost for either the vehicles or the fuels using an existing refueling infrastructure that needs only to be modified to a fairly limited degree. [EPA-HQ-OAR-2010-0799-9505-A1, p. 15]

Given the above, it is clear that EPA's policy on providing incentives under the GHG regulation makes little sense and must be modified to provide incentives for the use of ethanol blends that are at least commensurate with those provided with much less certain and much more expensive technologies. [EPA-HQ-OAR-2010-0799-9505-A1, p. 15]

EPA's current GHG proposal would have the effect of eliminating any meaningful incentives for vehicle manufacturers to produce flexible fuel vehicles (FFVs) capable of operation on both gasoline and ethanol for the 2016 and later model years. FFVs are the backbone of the federal Renewable Fuel Standard (RFS), as they are expected to consume most of the ethanol that is produced to meet the RFS after the onroad fleet is all operating on E10, a blend of 90% gasoline and 10% ethanol by volume. One important goal of the RFS program is to help the United States do its part to control GHG emissions. If vehicle manufacturers stop selling FFVs after 2016, the GHG benefits of the RFS program will be lower than currently anticipated. To address this potential problem, Growth Energy recommends that EPA/NHTSA develop and permit the use of E85 "usage factors" for FFVs utilizing volumes of ethanol projected by the U.S. Energy Information Agency, so that vehicle manufacturers can decide when developing their product plans whether to provide FFVs, and to create incentives for the manufacturers to do so. In these comments, we lay out a reasonable method of projecting these usage factors. [EPA-HQ-OAR-2010-0799-9505-A1, p. 16]

FFVs typically have GHG emissions on E85 that are approximately 5% below the GHG emissions on E0, but this can vary between 3-6%. [EPA-HQ-OAR-2010-0799-9505-A1, p. 16]

Automakers currently sell FFVs because they receive fuel economy and GHG credits for these vehicles under EPA/NHTSA credit provisions, at least through model year 2015. Automakers can receive up to 1.2 miles per gallon in fuel economy credit against the applicable NHTSA

CAFÉ standards through 2014. After 2014, this credit declines by 0.2 mpg per year until it is fully phased out in 2020. [EPA-HQ-OAR-2010-0799-9505-A1, p. 16]

EPA's GHG emission standards between 2012 and 2015 are consistent with the NHTSA fuel economy credit. EPA's current rules for GHG emissions for 2016 model year FFVs, and its proposal for 2017 and later FFVs are found in the following discussion: [EPA-HQ-OAR-2010-0799-9505-A1, p. 16]

Beginning in MY 2016, EPA ended the GHG emissions compliance incentives and adopted a methodology based on demonstrated vehicle emissions performance. This methodology established a default value assumption where ethanol FFVs are operated 100 percent of the time on gasoline, but allows manufacturers to use a relative E85 and gasoline vehicle emissions performance weighting based on either national average E85 and gasoline sales data, or manufacturer-specific data showing the percentage of miles that are driven on E85 vis-à-vis gasoline for that manufacturers' ethanol FFVs. EPA is not proposing any changes to this methodology for MYs 2017-2025. [EPA-HQ-OAR-2010-0799-9505-A1, p. 17]

Regarding current national average E85 use by FFVs, EPA states:

The data confirm that, on a national average basis for 2008, less than one percent of the ethanol FFVs used E85. [EPA-HQ-OAR-2010-0799-9505-A1, p. 17]

The reason for the low adoption rate of E85 is that the E10 market was the first to consume all the available ethanol. Only now do we have more ethanol supply than is needed for E10 demand, so adoption rates should increase. [EPA-HQ-OAR-2010-0799-9505-A1, p. 17]

The vast majority of FFVs are sold to the general public (and not fleets that may have more control over fuel type), and it would be very difficult for manufacturers to determine the fraction of use on E85 for these vehicles. Under either current EPA requirements for 2016 vehicles or the proposed EPA requirements for 2017 and later vehicles, manufacturers would have to certify FFVs on 100% gasoline, or under the EPA proposal, use some national average E85 use, which as EPA indicates is still quite low. Since FFVs have a non-zero cost, but are assumed to have zero or very near zero benefit under either California or EPA requirements, the chances of automakers providing FFVs after 2016 is also zero, or near zero. [EPA-HQ-OAR-2010-0799-9505-A1, p. 17]

EPA expected that when they required model year 2016 FFVs to demonstrate use on E85, that this would provide incentive for automakers to optimize their FFVs on E85: However, if a manufacturer can demonstrate that a portion of its FFVs are using an alternative fuel in use, then the FFV emissions compliance value can be calculated based on the vehicle's tested value using the alternative fuel, prorated based on the percentage of the fleet using the alternative fuel in the field….EPA believes this approach will provide an actual incentive to ensure that such fuels are used. The incentive arises since actual use of the flexible fuel typically results in lower tailpipe GHG emissions than use of gasoline and hence improves the vehicles' performance, making it more likely that its performance will improve a manufacturers' average fleetwide performance. Based on existing certification data, E85 FFV CO_2 emissions are typically about 5 percent lower on E85 than CO_2 emissions on 100 percent gasoline. Moreover, currently there is little incentive to optimize CO_2 performance for vehicles when running E85. EPA believes the above approach would provide such an incentive to manufacturers and that E85 vehicles could be optimized through engine redesign and calibration to provide additional CO_2 reductions. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 17-18]

Manufacturers typically utilize at least a four-year lead-time in designing vehicles, therefore, in 2012 most manufacturers are working with the 2016 model year. While such an approach as outlined by the EPA above could provide incentive for manufacturers to optimize 2016 model year FFVs on E85, if they have no idea or guidance from the EPA what E85 use could be in 2016, and current use is close to zero, then it does not matter how much they optimize FFVs on E85, a larger GHG benefit times a current zero usage factor is still zero. [EPA-HQ-OAR-2010-0799-9505-A1, p. 18]

While current E85 refueling frequencies are quite low, EPA is counting on FFVs to use a significant amount of E85 due to the Renewable Fuel Standard requirements, which expand biofuel use in the U.S. to 36 billion ethanol equivalent gallons per year by calendar year 2022. EPA projected a range of ethanol volumes in the RFS, a “low”, “mid” and “high”. Figure 1.7-11 from the RFS Regulatory Impact Analysis shows necessary FFV E85 refueling rates in the future with the RFS. In 2016, FFV E85 refueling rates are between 38% and 55%, and increase to 40% to 70% by 2020. [EPA-HQ-OAR-2010-0799-9505-A1, p. 18]

The E85 refueling rates shown in Figure 1 were estimated by EPA with the 2012- 2016 GHG emission standards, but without the 2017-2025 GHG emission standards. If the 2017-2025 GHG emission standards were included, the E85 refueling rates would be higher than shown in Figure 1. For model year 2016, Figure 1 implies E85 usage factors of between 40-50%. The usage factors between for model years 2017-2020 would be higher because the fuel economy of the 2017-2020 model year vehicles would be higher than was used by EPA to produce Figure 1. [Figure 1 can be found on p. 19 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, p. 18]

Figure 2 shows the Energy Information Agency’s projection of ethanol volume in the AEO2011 forecast. We also show the ethanol volume predicted in the latest AEO2012 Early Release forecast. EIA’s 2011forecast is very close to EPA’s mid level case through 2023, and then goes much higher than the EPA mid case. The early release 2012 forecast is between the low case and the mid case prior to 2028, and higher than EPA’s mid case after then. [Figure 2 can be found on p. 20 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, p. 19]

Figure 3 shows FFV fractions of the national on-road car + LDT fleet from 2010 through 2030 with two assumptions – that FFV sales would continue at about 23% from 2012 on, and that FFV sales stop in 2016. In 2020, if FFV sales continue, then 25% of the on-road fleet would be FFVs. Alternatively, if FFV sales stop in 2016, then only 12% of the fleet would be FFVs in 2020. Clearly, if FFV sales stop in 2016, it may be difficult for the FFV fleet to absorb RFS ethanol volumes. [Figure 3 can be found on p. 21 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, p. 20]

EPA's RFS benefits analysis depends on E85 being consumed to claim GHG benefits under these rules. And yet, EPA is not rolling these use projections into its guidance on FFVs to the manufacturers so they can continue to build FFVs to support the RFS. Thus, EPA should either provide guidance to the manufacturers on likely E85 use in the 2016-2025 timeframe, or EPA should downgrade the GHG benefits of the RFS due to lack of availability of FFVs, and charge these benefit downgrades against their current GHG proposal. [EPA-HQ-OAR-2010-0799-9505-A1, p. 21]

Growth Energy therefore recommends that EPA develop new default projections of E85 use based on EPA's projections of overall ethanol volumes that will be required under EISA. These projections should also incorporate the Agencies' new fuel economy levels for 2017-2025. The projections should be provided to the auto industry as usage factors so that they can make a clear determination of whether to optimize FFVs on E85 and whether to continue building FFVs after model year 2015. A further projection to calendar year 2025 can be made around calendar year 2016. [EPA-HQ-OAR-2010-0799-9505-A1, p. 21]

Growth Energy's proposal would provide for a certification and in-use fuel for 2017 and later vehicles with an octane value of 94, accomplished with E30 instead of E10. This fuel would only be intended for the 2017+ vehicles, and not the legacy fleet (2016 and earlier), although legacy FFVs could also use it if doing so was consistent with the vehicle manufacturers' instructions or recommendations to owners and approved by the Agencies on that basis. The non-FFV legacy fleet (i.e., Tier 1, Tier 2, and LEVs in Section 177 states) would continue to operate on E10. [EPA-HQ-OAR-2010-0799-9505-A1, p. 22]

It is important that the increase in octane be accomplished with ethanol and not other gasoline blending components because of ethanol's many advantages relative to the other high octane blending components as explained below. Ethanol has a very high octane number relative to other gasoline hydrocarbons, has a lower carbon content than the gasoline components it generally replaces, and has many other benefits that assist in combustion to increase engine efficiency and reduce both tailpipe GHG and criteria pollutant emissions. The use of a 94 octane E30 blend for 2017+ vehicles would also provide additional GHG and PM emission reductions in the U.S., greater than could be achieved by the current Agencies' proposal. We note that some vehicle manufacturers have also requested that EPA study higher octane fuels as a part of the GHG program, and have also recommended continued control of multi-substituted alkyl aromatics, since they can lead to increased HC and PM emissions. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 22-23]

C. Increased ethanol use can decrease PM emissions

There is substantial evidence that increased ethanol use will reduce PM mass and number emissions from the vehicle fleet. Szybist et al., 2011 also summarize recent literature for ethanol effects in production engines:

A number of investigations have examined the effect of ethanol content on particle emissions in vehicles. Storey et al. found that blends of 10 and 20% ethanol in gasoline (E10 and E20) decreased particle number emissions during vehicle drive cycles, with the 20% blend decreasing particles by about 40% during the high-load US06 vehicle drive cycle. In comparison to gasoline, He et al. found a 20% reduction in particle emissions with E20 but no change with E10. Khalek and Bougher showed that E10 increased particle emissions compared to two different gasoline formulations, both with higher volatility than the E10. This work showed the importance of the hydrocarbon fraction of the E10 blend and suggests that the heavier hydrocarbons used to control vapor pressure of E10 may also increase particulate emissions. Aakko and Nylund found that the particle mass emissions from 85% ethanol (E85) were comparable to those with gasoline in a PFI vehicle but that DI (direct injection) fueling with gasoline produced particle emissions that were an order of magnitude higher. (reference numbers omitted) [EPA-HQ-OAR-2010-0799-9505-A1, p. 26]

The Szybist et al. study investigated the effects of fuel type, fueling strategy, and engine breathing strategy on particle emissions in a flexible spark ignited engine that was designed for optimization with ethanol. They report:

When DI fueling is used for gasoline and E20, the particle number emissions are increased by 1 to 2 orders of magnitude compared to PFI fueling, depending upon the fuel injection timing. In contrast, when DI fueling is used with E85, the particle number emissions remain low and comparable to PFI fueling. Thus, by using E85, the efficiency and power advantages of DI fueling can be gained without generating the increase in particle emissions observed with gasoline and E20. The main finding of the study is that use of E85 results in 1 to 2 orders of magnitude reduction in particle emissions relative to sDI (spray-guided DI) fueling with gasoline and E20. Furthermore, sDI particle emissions with E85 are similar to that for PFI fueling with gasoline. Thus, an increase in particle emissions beyond that of PFI engines can be prevented while gaining the efficiency of DI engines using E85. [EPA-HQ-OAR-2010-0799-9505-A1, p. 27]

Storey et al., 2010 characterized the emissions, including PM and aldehydes, from a U.S. legal stoichiometric direct injected spark ignited (DISI) vehicle operating on E0, E10, and E20. The PM emissions were characterized for mass, size, number concentration and OC-EC (organic carbon-elemental carbon) content. The DISI particle number-size distribution curves were similar in shape to light-duty diesel vehicles without Diesel Particle Filters, but had lower overall particle number and mass emissions. The aggressive US06 transient cycle had much higher PM mass emissions in comparison to the PM mass emission observed for the FTP. With respect to added ethanol, Storey et al. concluded: [EPA-HQ-OAR-2010-0799-9505-A1, p. 27]

Ethanol blends reduced the PM mass and number concentration emissions for both transient and steady-state cycles. By increasing the ethanol blend level from E0 to E20, the average mass emissions declined 30% and 42% over the FTP and US06, respectively. Measurements during hot cycle transient operation demonstrated that E20 also lowered particle number concentrations. The adoption of small displacement, turbocharged DISI engines into the U.S. fleet is likely to continue in the future, and the results of this study suggest that increasing ethanol blend levels in gasoline will lower DISI PM emissions. In addition, increasing ethanol content significantly reduced the number concentration of 50 and 100 nm particles during gradual and wide open throttle (WOT) accelerations. [EPA-HQ-OAR-2010-0799-9505-A1, p. 27]

Maricq et al., 2012 tested a light-duty truck equipped with a 3.5-L V6 gasoline turbocharged direct injection engine that is representative of current GDI products, but contained prototype elements that allowed changes in engine calibrations. Because PM formation in GDI engines is sensitive to a number of operating parameters, two engine calibrations were examined to gauge the robustness of the results. The study used four fuels: certification test gasoline (E0), a commercial E10 fuel similar to that expected for future certification, a commercial pump grade E10, and a commercial E100 fuel used for blending. E100 and E0 were splash-blended to produce E17, E32, and E45 fuels. Maricq et al. report: [EPA-HQ-OAR-2010-0799-9505-A1, pp. 27-28]

As the ethanol level in gasoline increases from 0% to 20%, there is possibly a small (<20%) benefit in PM mass and particle number emissions, but this is within test variability. When the ethanol content increases to >30%, there is a statistically significant 30%–45% reduction in PM mass and number emissions observed for both engine calibrations. [EPA-HQ-OAR-2010-0799-9505-A1, p. 28]

The results reported by Zhang are also particularly informative. The key results are shown in Figure 1 below. In this testing, a 2008 FFV was tested on a hot Unified Cycle on E6, E35, E65, and E85. Ethanol appears to have caused a large reduction in PM emissions (an particularly PN) from E6 to E35, with further PM reductions as ethanol concentration increased. However, the most significant PM and PN reductions are between E6 and E35. [Figure 1 can be found on p. 29 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, p. 28]

Thus, there are now a substantial number of studies showing that ethanol blends of 20% and higher reduce PM mass and number emissions in a variety of engines and vehicles. [EPA-HQ-OAR-2010-0799-9505-A1, p. 29]

In addition to the evidence that increased ethanol use will reduce PM mass and number, the Agencies acknowledge that the proposal will increase the fraction of the U.S. fuel supply that is made up of renewable fuels. The proposal indicates:

For the purposes of this emission analysis, we assume that all gasoline in the timeframe of the analysis is blended with 10 percent ethanol (E10). However, as a consequence of the fixed volume of renewable fuels mandated in the RFS2 rulemaking and the decreasing petroleum consumption predicted here, we anticipate that this proposal would in fact increase the fraction of the U.S. fuel supply that is made up by renewable fuels. [EPA-HQ-OAR-2010-0799-9505-A1, p. 29]

C. The Ramp-up of Low CI Ethanol and Additional GHG Reductions

For the RFS, EPA estimates that ethanol from cornstarch peaks at 15 bgy in 2014. Additional increases in ethanol volumes are projected to come from advanced ethanol and cellulosic ethanol. Advanced ethanol is required to have a 50% reduction in lifecycle GHG emissions from gasoline, and cellulosic ethanol is required to have a 60% reduction in lifecycle emissions from gasoline. These additional volumes currently are projected to go into FFVs. [EPA-HQ-OAR-2010-0799-9505-A1, p. 35]

The ethanol volumes produced above E10 level could go into the 2017 and later vehicle fleet as E30, and additional ethanol volumes (as E85 or E3), would go into FFVs. The amount of ethanol needed for the 2017 and later model year vehicles would slowly build as these vehicles are introduced. These advanced and cellulosic volumes would increase steadily until the on-road fleet is fully turned over to 2017 and later vehicles. [EPA-HQ-OAR-2010-0799-9505-A1, p. 35]

Figure 2 shows the allocation of ethanol into different fleet sectors, assuming the AEO2011 volumes. This figure was developed using a fuel consumption model for the passenger car and LDT fleet, which was adjusted to include the effects of the 2012-2016 regulations and the 2017-2025 proposed rule. The decision priority for the use of ethanol was: [Figure 2 can be found on p. 36 of Docket number EPA-HQ-OAR-2010-0799-9505-A1]

- E30 in 2017+ vehicles first
- E10 in legacy fleet, including FFVs
- E85 in FFVs (if E30 were used, refueling frequency with E30 would be higher) [EPA-HQ-OAR-2010-0799-9505-A1, p. 35]

During the 2005 to 2010 period, E10 is ramping up in the fleet. Between 2010 and 2015, E85 use starts to increase. In the 2015-2020 period, E30 use starts in the 2017 and later fleet. This directly affects the frequency of E85 use in the FFVs. E10 volumes start to decline because the fleet is more fuel efficient, and vehicles using E10 (2016 and earlier) are declining in population. Between 2020 and 2025, E30 use is expanding rapidly, and E10 and E85 use continues to decline (although E30 could be used in FFVs as well). In 2030, E30 use is still increasing, and E10 use and E85 use are low by comparison. [EPA-HQ-OAR-2010-0799-9505-A1, p. 36]

We performed the same analysis for the AEO2012 Early Release values, and the E30 fleet did not utilize all of the ethanol from the FFVs, indicating expected available supplies of ethanol. [EPA-HQ-OAR-2010-0799-9505-A1, p. 36]

The addition of 20% more ethanol into E10 to boost octane value is expected to reduce the price of the blend relative to regular E10, not increase it. Table 4 shows average octane values for three octane blending components (alkylate, toluene, and ethanol) averaged over the period from January 2007 through February 2012. These values are determined by the bulk market price (Gulf Coast) of each component divided the blending octane of each component. For example, if ethanol is priced at 26 cents over unleaded gasoline and ethanol has a 113 blending octane, then the octane value of ethanol would be 26 cents divided by 26 (113 ethanol octane less 87 unleaded gasoline octane) or 1 cent per ethanol octane number. [EPA-HQ-OAR-2010-0799-9505-A1, p. 36]

The results show that ethanol is the cheapest octane blending component, and that the addition of ethanol reduces the price of the blend, and does not increase it like the other blending components. [See chart on p. 37 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, p. 37]

In Figure 3 we evaluated Ethanol, Alkylate and Toluene as components in a gasoline blend. We focused on formula octane as the sole value of each component, similar to a refiner evaluation of a commercially available stream. The solid black line represents the commercial gasoline value of octane as represented in the market by the relative cost of premium 93 FON conventional gasoline versus regular 87 FON conventional gasoline in the Gulf Coast spot bulk market. This is a good benchmark of octane value to a refiner as they optimize the mix of premium versus regular gasoline they make relative to the properties of the blending components they produce or purchase. The remaining lines represent Alkylate, Ethanol and Toluene. Over the entire period, ethanol is the least expensive octane blending component. [Figure 3 can be found on p. 37 of Docket number EPA-HQ-OAR-2010-0799-9505-A1] [EPA-HQ-OAR-2010-0799-9505-A1, p. 37]

Ethanol has several properties that make it very desirable blendstock with gasoline. These were discussed in a paper referred to earlier. [EPA-HQ-OAR-2010-0799-9505-A1, p. 38]

The high octane of ethanol allows the use of higher compression ratios, particularly in dedicated ethanol vehicles. The high heat of vaporization produces a charge cooling effect, which is particularly effective with direct injection engines that can again allow higher compression ratios. This effect is enhanced by the increased volume of fuel that is required to compensate for the lower energy content of ethanol. Even when a vehicle is not optimized to take advantage of some of ethanol’s attributes, the higher octane and faster flame propagation speeds for ethanol result in increased efficiency (miles per BTU of energy present in the fuel used) for high ethanol blends relative to gasoline. [EPA-HQ-OAR-2010-0799-9505-A1, p. 38]

The paper goes on to show that there is an approximate 2% efficiency gain for E85 in 2010 FFVs on E85, which are not optimized on E85 but on E0, and some companies are able to do better than this across their portfolio. [EPA-HQ-OAR-2010-0799-9505-A1, p. 38]

A second study by Delphi examined changes in performance and efficiency on an engine equipped with gasoline direct injection and other control technologies at different gasoline/ethanol blend levels. The study investigated methods of improving fuel consumption when fueled with E85. [EPA-HQ-OAR-2010-0799-9505-A1, p. 38]

The benefit of the improved strategies for reducing the disparity between fuel consumption with gasoline and E85 is almost entirely offset on the FTP city cycle but is less effective as the demands of the driving conditions increase. At highway cruise speeds the shift schedule has no effect since the vehicles is in overdrive in all cases, only the benefits of the lower final driver ratio and the engine modifications are evident. [EPA-HQ-OAR-2010-0799-9505-A1, p. 38]

The paper then goes on to discuss the potential benefits of lower ethanol blends: [EPA-HQ-OAR-2010-0799-9505-A1, p. 38]

It is also important to consider that many of the techniques used to improve performance on E85 would also improve fuel consumption with gasoline or lower ethanol blends. Differences will show up more in performance and may need a shift schedule dependent on the ethanol blends torque capability. Ethanol blends from near E20 provide a good compromise, enabling most of the performance of an E85 blend with a significantly reduced energy penalty. Blends in this range would likely be able to offset the fuel density penalties with improved efficiency while providing superior performance to gasoline. [EPA-HQ-OAR-2010-0799-9505-A1, pp. 38-39]

The above discussions highlight the need to focus more on the power density of ethanol (power per unit volume) rather than the energy density (heat content per unit volume). When automakers can optimize on a particular ethanol blend, they are able to take increased advantage of ethanol's power density as opposed to its energy density, thereby improving vehicle fuel economy and extending vehicle range between refills. Much additional research is taking place in this area which will be released in the coming months. [EPA-HQ-OAR-2010-0799-9505-A1, p. 39]

---

1 California's own version of a biofuels strategy, its "low-carbon fuel standards" regulation, will be infeasible unless the California new-vehicle market can somehow absorb large numbers of pure electric and grid-connected hybrid electric vehicles.

6 The DOE values provided for corn ethanol did not include indirect land use effects. Growth Energy does not believe current analytical models and data permit reliable estimation of indirect land use effects for Midwest corn ethanol, particularly in regulatory settings. For purposes of this analysis, however, the values shown in Table 1 use the latest version of GREET (GREET2011) was used to estimate a lifecycle GHG emission rate for corn ethanol that included indirect land use effects, which was then used to adjust the DOE corn ethanol values relative to those for gasoline.

7 The 11% reduction using GREET is conservative. EPA, in its RFS RIA, estimated a 20% reduction for the average corn ethanol dry mill in calendar year 2022.

Organization: Minnesota Department of Commerce

However, I have serious concerns regarding unintended, yet detrimental consequences for the energy diversity and economic opportunity needed to most effectively accomplish stated goals.

The proposed rule is inconsistent with the 2007 Energy Independence and Security Act (EISA) which requires the use 36 billion gallons of renewable fuels by 2022 and the national Renewable Fuel Standard (RFS2). [EPA-HQ-OAR-2010-0799-7363-A1, p. 1]

The proposed rule, in effect, selects one technology pathway – vehicles powered by electric motors – as the national powertrain. 1) Due to difficulty anticipated for certifying use of renewable fuels in vehicles under anticipated new Tier III vehicle emission regulations; and 2) the elimination of vehicle use credits until renewable fuel use is increased by RFS2; 3) the opportunity to use renewable fuels as a means to reduce greenhouse gas emissions and reduce consumption of oil may be effectively eliminated. [EPA-HQ-OAR-2010-0799-7363-A1, p. 1]

In keeping with goal to and further reduce greenhouse gas emissions and reduce oil consumption, include the role of EISA and RFS2 in the proposed rule. [EPA-HQ-OAR-2010-0799-7363-A1, p. 1]

Organization: National Alliance of Forest Owners (NAFO)

While NAFO does not take issue with or seek to challenge the stringency of the actual fuel economy standards that the Agencies propose to impose on light-duty vehicles, NAFO does seek to ensure that government rulemakings reflect the role that woody biomass can play in achieving our nation's climate goals and appropriately encourage the use of this climate beneficial fossil fuel alternative. As described below, the climate benefits of woody biomass, which derive from the natural carbon cycle, are well-established and have already been recognized in a number of EPA policies. Moreover, woody biomass-based alternative fuels – and all biofuels – is an important part of this administration's "all-out, all-of-the-above strategy" to achieving energy security and energy independence. [EPA-HQ-OAR-2010-0799-9481-A1, p.2]

As the Agencies complete and ultimately implement this rulemaking, we urge them to seize opportunities to encourage the use of climate-beneficial woody biomass-based alternative fuels. Specifically, we urge the Agencies to 1) develop a science-based method for quantifying the climate benefits of woody biomass-based alternative fuels as compared to fossil fuels; and 2) apply the method immediately in model year 2017 or, alternatively, state in the preamble to the final rule that the Agencies will use the method in the mid-term evaluation following the completion of other ongoing assessments of the carbon benefits of biomass and biofuels. This will provide a credible approach for incorporating the carbon benefits of woody biomass-based alternative fuels into the Corporate Average Fuel Economy ("CAFE") Standard that does not presently appear to exist. [EPA-HQ-OAR-2010-0799-9481-A1, p.2]

I. Forest biomass is an important renewable fuel source leading to lower GHG lifecycle emissions than conventional fuels [EPA-HQ-OAR-2010-0799-9481-A1, p.2]

Wood from sustainably managed forests provides a renewable, low-carbon alternative to fossil fuels. According to U.S. Energy Information Administration ("EIA") data, biomass already supplies more than 50% of the nation's renewable energy.[1] Forests can provide ample sustainable, domestic supplies of biomass to produce liquid transportation fuels, electricity, thermal energy (heat and power for manufacturing and other industrial uses), and synthetic natural gas.[2] [EPA-HQ-OAR-2010-0799-9481-A1, p.2]

When evaluating the GHG emissions associated with fuels, a lifecycle analysis incorporates all steps in a "product system" to evaluate broader environmental impacts of products and processes. Using forest biomass as a renewable fuel source has significant carbon benefits because its lifecycle analysis GHG emissions are more favorable than those of petroleum and other fossil fuels. For example, the Department of Energy ("DOE") estimates that "[c]ellulosic ethanol use could reduce GHGs by as much as 86%."[3] In addition, EPA has determined, in conjunction with its Renewable Fuel Standard Program, that the lifecycle GHG emissions reductions associated with cellulosic ethanol may be as much as 92.7 percent.[4] Lifecycle analyses of biomass feedstocks used for electricity generation have produced similar results.[5]

Thus the prevailing science – in both the public and private sectors – acknowledges the significant carbon benefits of energy produced using renewable biomass from managed forests. [EPA-HQ-OAR-2010-0799-9481-A1, p.3]

II. The combustion of forest biomass is part of the ongoing carbon cycle [EPA-HQ-OAR-2010-0799-9481-A1, p.3]

The prevailing view in the science community is that, when forests are managed sustainably, CO_2 emissions from forest biomass are part of the natural carbon cycle and are balanced by carbon sequestration as forests grow. In other words the carbon that enters the atmosphere when forest biomass is combusted was previously absorbed from the atmosphere by the forest biomass and will be reabsorbed when new biomass is growth. [EPA-HQ-OAR-2010-0799-9481-A1, p.3]

As EPA has concluded, there is "[s]cientific consensus . . . that the CO_2 emitted from burning biomass will not increase total atmospheric CO_2 if this consumption is done on a sustainable basis."[6] Recognizing that CO_2 emissions from biomass combustion are inextricably tied to the forests where biomass is grown, EPA follows international convention and does not include emissions from biomass combustion in its national emissions totals.[7] Instead, EPA accounts for CO_2 emissions from biomass combustion by measuring changes in forest carbon stocks over time, recognizing that there is no net climate impact as long as forest carbon stocks are stable or increasing.[8] Similarly, DOE's Voluntary Reporting of Greenhouse Gases Program, authorized by Section 1605(b) of the Energy Policy Act of 1992, provides for exclusion emissions from the combustion of biomass fuels.[9] [EPA-HQ-OAR-2010-0799-9481-A1, pp.3-4]

More recently, EPA has affirmed the climate benefits of biomass energy combustion when compared fossil fuels by reconsidering its treatment of biogenic CO_2 emissions under the Prevention of Significant Deterioration ("PSD") and Title V Programs.[10] Recognizing that imposing regulatory burdens on the biomass energy sector would discourage development of this important renewable fuel supply, EPA has deferred regulation of CO_2 emissions from stationary sources for three years while it seeks to identify a method to quantify the climate benefits offered by biomass energy.[11] EPA has also convened a Biogenic Carbon Emissions Panel under the auspices of the Science Advisory Board to provide advice and recommendations as EPA completes the reconsideration process.[12] That process is ongoing, and NAFO is encouraged that the SAB will offer recommendations and conclusions that continue to affirm the strong climate benefits of biomass as a carbon neutral renewable energy source. [EPA-HQ-OAR-2010-0799-9481-A1, p.4]

EPA has consistently recognized the climate benefits of biomass energy and should remain committed to a regulatory approach that recognizes the climate benefits that bioenergy and biofuel producers provide in relation to fossil fuels. Similarly, EPA must ensure that the treatment of biofuels under this proposed rule is consistent with its overarching regulatory approach. [EPA-HQ-OAR-2010-0799-9481-A1, pp.4-5]

III. The promotion of renewable energy is a national policy that the Agencies must follow [EPA-HQ-OAR-2010-0799-9481-A1, p.5]

As described above, forests and forest products can play an important role in reducing and managing GHG emissions. Expanding the sources of renewable energy is a central feature of both national and international policy to reduce reliance on fossil fuels. [EPA-HQ-OAR-2010-0799-9481-A1, p.5]

EPA, in considering approaches toward addressing climate change, has long recognized that responsibly managed forests are considered one of five key "groups of strategies that could substantially reduce emissions between now and 2030."[13] Similarly, the United Nation's Intergovernmental Panel on Climate Change ("IPCC") report on mitigation technologies highlights forest management as a primary tool to reduce GHG emissions.[14] In fact EIA projects that biomass energy will account for 30% of the growth in electricity produced by renewable fuels between now and 2035.[15] [EPA-HQ-OAR-2010-0799-9481-A1, p.5]

President Obama has repeatedly emphasized that renewable energy derived from feedstocks such as forest biomass hold the key to transitioning the nation to a "sustainable, low carbon energy future."[16] Recognizing the benefits of all types of biomass, he recently stated that "another substitute for oil that hold tremendous promise is renewable biomass – not just ethanol, but biofuels made from things like switchgrass and wood chips and biomass."[17] And in last month's State of the Union Address the President advocated an "all-out, all-of-the-above strategy that develops every available source of American energy," specifically referencing a "clean energy standard" that would encourage the development of clean renewable energy including biomass fuels.[18] [EPA-HQ-OAR-2010-0799-9481-A1, pp.5-6]

With Presidential endorsement, if not direction, of national renewable energy policy and the role of biomass in that policy, the Agencies must conduct their programs in a manner consistent with that policy. In light of this policy, the Agencies must ensure that their regulations appropriately encourage the use of woody biomass-based fuels as clean, renewable alternatives to fossil fuels by distinguishing between GHG emissions from each source. While the proposed rule does provide preferential treatment to ethanol as an alternative fuel, the regulations would further benefit from the development of a science-based method that quantifies the climate benefits of woody biomass-based alternative fuels. [EPA-HQ-OAR-2010-0799-9481-A1, p.6]

IV. The Agencies should develop and implement a science-based method to account for the climate benefits of woody biomass-based alternative fuels [EPA-HQ-OAR-2010-0799-9481-A1, p.6]

Although the proposed fuel economy standards apply to manufacturer vehicle fleets and do not apply directly to consumers' fuel purchases, they can still reflect the climate-benefits of woody biomass-based alternative fuels, whether used in dedicated biofuel vehicles or in flexfuel vehicles. For example, as recognized in the proposed rule, the CAFE Standards calculations for flex fuel vehicles are currently governed by 49 U.S.C. § 32905, which assumes that alternative fuels are used 50 percent of the time in flex-fuel vehicles and treats each gallon of alternative liquid fuel as the equivalent of 0.15 gallons of gasoline. Thus, flex fuel vehicles – and ethanol-based fuels – are currently encouraged by discounting biogenic CO_2 emissions in comparison to fossil fuel CO_2 emissions. However, the 0.15 divisor applies equally to all alternative liquid fuels and is not directly related to the carbon benefits of the alternative fuel. Indeed, it may even underestimate the climate benefits of some alternative fuels such as cellulosic ethanol. [EPA-HQ-OAR-2010-0799-9481-A1, p.6]

As noted in the proposed rule, these special calculation procedures in 49 U.S.C. § 32905 are being phased out and will expire entirely for model year 2020 vehicles. We agree with the Agencies that the light-duty vehicle rule should continue to encourage the use of clean, renewable, alternative fuels such as cellulosic ethanol even after the statutory mandate expires in 2020. It should not treat woody biomass-based and fossil fuels equally. Thus we support the Agencies' proposal to continue to discount CO_2 emissions from alternative fuels as compared to fossil fuel CO_2 emissions. But rather than uniformly applying a 0.15 divisor to all alternative liquid fuels, the Agencies should develop a science-based method that quantifies the climate benefits of each alternative fuel and provide proper incentives for each alternative liquid fuel in comparison to traditional fossil fuels and each other. [EPA-HQ-OAR-2010-0799-9481-A1, pp.6-7]

To the extent that either Agency has the opportunity to deviate from the statutory requirements of 49 U.S.C. § 32905, now or in the future, it should adopt an approach that is grounded in science. Since the 0.15 divisor was enacted in 1994, there have been numerous studies of the climate benefits of biomass and EPA has engaged in efforts to quantity the climate benefits associated with biomass energy. Two recent examples include a life cycle analysis of cellulosic ethanol completed in conjunction with the RFS2 program and EPA's ongoing reconsideration of biogenic CO_2 emissions from stationary sources which is currently under review by the Science Advisory Board Biogenic Carbon Emissions Panel. Each of these programs offer a means to quantify the climate benefits of biomass energy as compared to fossil fuels. In order to aid the regulated community and provide consistency among regulatory program, the Agencies should adopt a harmonized approach to accounting for the climate benefits of biomass energy. We urge the Agencies to use the light-duty vehicle rule as a means to harmonize the findings of existing regulatory programs. [EPA-HQ-OAR-2010-0799-9481-A1, p.7]

Given the ongoing nature of EPA's reconsideration of biogenic CO_2 emissions from stationary sources and the continued applicability of 49 U.S.C. § 32905(a) to NHTSA's CAFE Standard calculations through model year 2019, the mid-term evaluation process already included in the proposed rule provides a means for EPA to harmonize is regulatory approaches to woody biomass-based fuels after having the opportunity to complete its scientific review of both mobile and stationary sources while allowing EPA and NHTSA to maintain uniform fuel economy standards for mobile sources. While a continuation of the 0.15 divisor may be appropriate today given NHTSA's statutory mandate and EPA's ongoing scientific reviews, EPA should use the intervening time before the mid-term review to synthesize its existing approaches to accounting for biogenic CO_2 emissions and develop a science-based method to account for the climate benefits of woody biomass-based alternative fuels as compared to fossil fuels. The EPA should then, at the earliest opportunity, apply the method in place of the generic 0.15 divisor and provide an exclusion, if appropriate, for vehicles that rely entirely on the combustion of woody biomass-based alternative biofuels. We thus urge the Agencies in the preamble to the final rule to recognize the opportunities that woody biomass-based alternative fuels can provide to reduce CO_2 emissions by committing to develop and apply a science-based method to quantify the climate benefits of woody biomass-based alternative fuels as part of their mid-cycle review. Organization: National Association of Convenience Stores (NACS)

CAFE and RFS Compatibility [EPA-HQ-OAR-2010-0799-9543-A1, p. 1]

In the Energy Independence and Security Act of 2007 (EISA), Congress revised the RFS to require that a minimum of 36 billion gallons of qualified renewable fuels be integrated into the motor fuels supply by 2022. This objective was expected to represent approximately 21% - 25% of the overall gasoline market (based upon 2007 gasoline consumption and assuming an annual increase in demand of up to 1%). However, the proposed CAFE revisions could dramatically reduce the amount of motor fuel consumed in 2022 and beyond, creating a situation in which renewable fuels will be required to represent a significantly greater share of the market than originally anticipated. [EPA-HQ-OAR-2010-0799-9543-A1, pp. 1-2]

To illustrate the challenge the two regulations present to the market, NACS has analyzed the Energy Information Administration's (EIA) 2011 Annual Energy Outlook. In this report, EIA evaluated two different CAFE scenarios - one factoring for an annual average fuel economy improvement of 3% and one factoring for an improvement of 6%. The current proposed rule calls for an annual improvement of 4.1% to 4.3%. Therefore, it is most sensible to use the more conservative model and evaluate market conditions under a 3% scenario. Please note that this analysis forecasts a market condition that is less extreme than what is likely to materialize under the proposed rule. [EPA-HQ-OAR-2010-0799-9543-A1, p. 2]

In creating this comparison, NACS has assumed that the RFS will be satisfied by blending renewable fuels with gasoline. The RFS requires a specific volume of bio-mass based diesel, but this is not a significant component of the program. Whether the renewable fuel brought to market is ethanol, butanol, or some other type of additive, it is likely to be optimized by blending with gasoline. [EPA-HQ-OAR-2010-0799-9543-A1, p. 2]

Therefore, NACS has compared EIA's projected finished gasoline volumes under a CAFE3 model with the mandated volumes of the RFS (less the biodiesel component). The following chart demonstrates the applicable blend rate required in this market scenario: [See chart on p. 2 of Docket number EPA-HQ-OAR-2010-0799-9543-A1] [EPA-HQ-OAR-2010-0799-9543-A1, p. 2]

Under a 3% annual improvement in fuel economy, compliance with the RFS will require a blend rate of 37.51% in 2022. This level of renewable fuels penetration in the market will impose significant economic burdens on the retail fuels market and consumers. [EPA-HQ-OAR-2010-0799-9543-A1, p. 2]

Organization: National Corn Growers Association et al.

The Energy Independence and Security Act (EISA) of 2007 called for the reduction of petroleum fuel use and greenhouse gas emissions (GHG), and it specified the use of 36 billion gallons of renewable fuels by 2022. In response, EPA promulgated the revised Renewable Fuel Standard (RFS2) that required increasing volumes of renewable fuels over a 10 year period from 2012 to 2022 to reach the 36 billion gallon statutory requirement. The renewable fuels specified in RFS2 were broken down into categories of conventional renewable biofuel (15 billion gallons), and advanced biofuels (21 billion gallons). Advanced biofuels were further divided into biodiesel, cellulosic biofuels and other advanced biofuels such as sugar cane ethanol. Each category or subcategory had its own requirement for GHG reductions; conventional renewable biofuels, primarily corn ethanol were required to reduce GHG by 20%, advanced biofuels by 50% and cellulosic biofuels by 60%. [EPA-HQ-OAR-2010-0799-9565-A1, p.2]

Due to substantial advances in crop production and energy efficiency improvements in ethanol production, corn starch ethanol significantly exceeds the 20% requirement on average. Indeed, the feasibility of meeting the 50% advanced biofuel requirement with corn ethanol has been demonstrated. EPA must fully account for these GHG reductions in RFS2 since January 1, 2008 and ensure that future GHG reductions for corn ethanol are fully credited as well. We further encourage EPA to perform a complete GHG inventory assessment of the RFS2 program through 2022. [EPA-HQ-OAR-2010-0799-9565-A1, p.2]

In its dual goals of reductions in petroleum fuel use and greenhouse gas emissions, EISA was concerned with addressing national energy security as well as greenhouse gas emissions concerns. Its requirement to displace about 25% of our national gasoline use with renewable fuels was a reasonable and effective means of addressing energy security by providing a diverse supply base. This diversity of supply is an important way to make the US economy more resilient to oil supply and price shocks since a vehicle population composed of sufficient numbers of Flexible Fuel Vehicles (FFVs) can easily and quickly switch to petroleum based fuel substitutes such as ethanol blends. In fact, vehicle fuel economy standards without petroleum fuel substitutes such as those required by EISA can do little to enhance oil security. [EPA-HQ-OAR-2010-0799-9565-A1, p.2]

We are concerned that the proposed CAFE/GHG rule is inconsistent with the RFS2 regulation and the EISA requirement to use 36 billion gallons of renewable fuel in 2022 in several areas. In other regulatory actions, EPA continues to express support for achieving the requirements of RFS2[1], yet there is no mention in the CAFE/GHG rule concerning the role of renewable alternative fuels in achieving the required GHG reductions. Many credits are provided in the rule that can be applied by vehicle manufacturers toward achieving the fuel economy and greenhouse gas emission requirements. [EPA-HQ-OAR-2010-0799-9565-A1, p.2]

Nearly all of these credits either directly or indirectly provide incentives for the production of electric vehicles including hybrid electric (HEV), plug-in hybrid electric (PHEV), fuel cell electric (FCEV) or battery electric (BEV) vehicles. For example, multiplier factors are provided for BEVs, PHEVs and FCEVs only, and electric propulsion for light duty trucks is favored over diesel or renewable alternative fuels. These credits which arbitrarily favor electric vehicle technology may interfere with RFS2 compliance strategies, and may send conflicting signals to the marketplace with unknown and potentially adverse economic impacts. [EPA-HQ-OAR-2010-0799-9565-A1, pp.2-3]

In the RFS2 regulation, EPA projects “Low”, “Mid” and “High” volume scenarios for ethanol use, and examines FFV fuel usage rates to consume these volumes[6]. The scenarios are built on the assumption that 15B gallons of ethanol would be consumed as E10. Under EPA’s Mid Volume scenario, 22.2 billion gallons of ethanol would be consumed by 2022 to comply with RFS2 requirements, FFV production by the Detroit 3[7] vehicle manufacturers would continue at a rate of at least 50% of annual production, 60% of FFVs would require “reasonable” access to E85 (24,000 refueling stations) and these FFVs would refuel with E85 at every opportunity. By EPA’s analysis, FFV production at a rate of at least 50% of vehicles produced would have to continue through 2022 in order to consume RFS2 volumes. A recent analysis by Air Improvement Resource examines EPA’s ethanol volume and FFV use scenario projections in detail[8]. It concluded that even if the EPA waiver for E15 were extended to all light duty vehicles, continued production of FFVs and higher level ethanol blends would be required in order to consume RFS2 volumes. [EPA-HQ-OAR-2010-0799-9565-A1, p.3]

A major inconsistency between the proposed CAFE/GHG rule and the RFS2 regulation is that the production of FFVs is discouraged by the proposed rule which would likely result in discontinuing FFV production after 2015. EISA extended fuel economy incentives for FFVs until 2020 because Congress wanted to encourage the continued production of vehicles that could use higher volume blends of ethanol up to E85. However, beyond 2015, EPA would require that the incentive be pro-rated based on use of the alternative fuel (E85 or ethanol blend greater than E15). Since E85 is dispensed at less than 2% of US fueling stations, it is not surprising that E85 use may still be less than 100 million gallons per year[9]. The result is that FFV production incentives would cease to exist as a practical matter after 2015. Congress expressed concern at a hearing in May 2011 that EPA chose to effectively eliminate FFV incentives after 2015 in the Supplemental Notice of Intent for the 2017 to 2025 CAFE/GHG rule.[10] [EPA-HQ-OAR-2010-0799-9565-A1, pp.3-4]

The purpose of the FFV incentives, sometimes referred to as CAFE credits created by the Alternative Motor Fuels Act of 1988 was to insure that an adequate number of FFVs were available in the fleet that could use E85 when it became available. Although E85 has not become widely available, the RFS2 regulation requires volumes of renewable fuels including ethanol that would require more FFVs than are currently available in the fleet. It is counter to the intent of EISA and the purpose of FFV credits to effectively phase them out just when FFVs are needed to consume RFS2 renewable fuel volumes. [EPA-HQ-OAR-2010-0799-9565-A1, p.4]

Although the proposed CAFE/GHG rule provides many credits for electric vehicles, it disallows credits for FFV technology on the basis of fuel cost. The concern for high relative cost of mid or high level ethanol blends does not seem to be justified in the term of the CAFE/GHG and RFS2 rules since at some point in the renewable fuel volume ramp-up of RFS2, market forces would result in competitive prices for ethanol and gasoline in order for the required volumes to be sold. As a result, the continuation of FFV incentives can be justified in order to consume the required RFS2 volumes of renewable fuels, and to be consistent with EISA’s intent. [EPA-HQ-OAR-2010-0799-9565-A1, p.4]

We recommend modifications to the proposed rule in the following three areas to achieve a more balanced, technology neutral approach to the control of fuel economy and GHG. [EPA-HQ-OAR-2010-0799-9565-A1, p.4]

Allow vehicle and fuel technologies to compete on a level playing field to meet fuel economy and GHG standards, rather than constructing credits to favor electric vehicle technology over renewable fuels. [EPA-HQ-OAR-2010-0799-9565-A1, p.4]

Provide flexibility within the rule and integrate RFS2 requirements such that renewable fuels can contribute to the greenhouse gas emission reduction requirements in the rule. [EPA-HQ-OAR-2010-0799-9565-A1, p.5]

Provide incentives for the production of FFVs that are needed to consume RFS2 renewable fuel volumes. [EPA-HQ-OAR-2010-0799-9565-A1, p.5]

We further believe that modifications in these areas would be more cost-effective and more consistent with EISA in addressing energy security, renewable fuel use and greenhouse gas emissions. We stand ready to convene a dialog with the agencies in this regard. [EPA-HQ-OAR-2010-0799-9565-A1, p.5]

9 - http://www.eia.gov/renewable/alternative_transport_vehicles/pdf/attf_c1.pdf [EPA-HQ-OAR-2010-0799-9565-A1, p.4]

10 - Congress did not add a fuel use requirement as a condition of extending FFV credits in EISA, and such a requirement appears to be inconsistent with Congress' intent. The following quotes are taken from comments by Congressman John Shimkus at a U.S. House of Representatives, Subcommittee on Energy and Power hearing on May 11, 2011 entitled, "The American Energy Initiative". Congressman Shimkus' comments are documented in an EPA response letter to Congress dated June 22, 2011. Congressman Shimkus: "Please provide this Subcommittee with a list of areas in the EPAINHTSA joint rulemaking of May 7, 2010 where EPA's rules are contrary to the program designed by Congress in EPCA as amended by EISA, and why EPA chose to substitute its judgment over the clear, specific policy preferences passed by Congress." "How can this rule be characterized as 'harmonized and consistent' if the way EPA treats FFV vehicles is markedly different than the way Congress mandated FFV credits be treated under CAFE?." [EPA-HQ-OAR-2010-0799-9565-A1, p.4]

Organization: Plant Oil Powered Diesel Fuel Systems, Inc.

Flex-Fuel Vehicles ("FFV's") equipped to run on 85 percent ethanol count as emitting only 15 percent of the GHG's that the same vehicle would emit without the FFV capability, even though the Agencies admit that, "[H]istorically consumers have only fueled these vehicles with E85 a very small percentage of the time." 76 Fed. Reg. at 74880. [EPA-HQ-OAR-2010-0799-10337-A2, pp. 5-6]

D. Ethanol

At present, the United States produces around 1.5 billion gallons of ethanol per year, approximately one-tenth of the 2022 goal for renewable fuels set by the Renewable Fuels Standard. U.S. Department of Energy ("DOE"), Office of Energy Efficiency and Renewable Energy, Freedom CAR & Vehicle Technologies Program, "Just the Basics: Ethanol" (Feb. 7, 2012) (www1.eere.energy.gov/vehiclesandfuels/pdfs/basics/jtb_ethanol.pdf). [EPA-HQ-OAR-2010-0799-10337-A2, p. 9]

Ethanol engenders agricultural practices, such as intensive use of fertilizer, that makes its increased use unsustainable for the environment. With Americans now farming more corn than in the past sixty years because of rising demand for ethanol derived from corn, nitrogen leaching from fertilized corn fields is a primary cause of hypoxia and fish kills in the Gulf of Mexico. S.D. Donner and C.J. Kucharik, "Corn-Based Ethanol Production Compromises Goal of Reducing Nitrogen Export by The Mississippi River," Proceedings of the National Academy of Sciences (March 18, 2008), at 1 and Abstract (http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2393748/). Expanding corn-based ethanol production would make controlling export of nitrogen to the Gulf practically impossible without large changes in food production and agricultural management. Id., Abstract. [EPA-HQ-OAR-2010-0799-10337-A2, pp. 9-10]

Organization: Renewable Fuels Association (RFA)

The proposal significantly discourages production of flexible fuel vehicles (FFVs) beyond 2016 by treating FFVs differently than other dual-fueled vehicles. The creation of incentives for certain dedicated alternative fuel vehicles also disadvantages FFVs. [EPA-HQ-OAR-2010-0799-9490-A1, p.1]

If implemented as proposed, the CAFE/GHG rule would frustrate the goals of the Energy Independence and Security Act of 2007 and significantly complicate compliance with the Renewable Fuel Standard (RFS). [EPA-HQ-OAR-2010-0799-9490-A1, p.1]

THE PROPOSAL SIGNIFICANTLY DISCOURAGES PRODUCTION OF FFVs BEYOND 2016 BY TREATING FFVs DIFFERENTLY THAN OTHER DUAL-FUELED VEHICLES. THE CREATION OF INCENTIVES FOR CERTAIN DEDICATED ALTERNATIVE FUEL VEHICLES ALSO DISADVANTAGES FFVs. [EPA-HQ-OAR-2010-0799-9490-A1, p.3]

In its final rule regarding MY2012-2016 CAFE/GHG standards, EPA promulgated provisions that, beginning in 2016, require automakers to demonstrate alternative fuel (i.e. E85) use in FFVs in order to generate fuel economy credits and determine emissions compliance values for those vehicles. The methodology established by these provisions assumes FFVs operate on gasoline 100% of the time, but allows a manufacturer to generate CAFE/GHG credits for its FFVs if it can document the percentage of miles driven on E85 versus gasoline for those vehicles. As discussed in comments from the stakeholders to EPA in response to the MY2012-2016 proposal, it is highly unlikely automakers have the resources or information necessary to provide proof of alternative fuel usage in the FFVs they manufacture. Thus, for all practical intents and purposes, fuel economy and emissions credits for FFVs cease to become relevant in MY2016 and automakers have no clear incentive to continue producing FFVs. In its current proposal for MY2017-2025, EPA/NHTSA state they do not intend to change the methodology for FFVs fuel economy calculations and emissions compliance values established in the rule for MY2012-2016. [EPA-HQ-OAR-2010-0799-9490-A1, pp.3-4]

One possible approach to determining utility factors for FFVs would be to base alternative fuel use on the levels of ethanol that FFVs will need to consume to comply with future RFS volume requirements. Notwithstanding the proposal's imbalanced application of utility factors, we do support EPA/NHTSA's proposal to continue the use of the 0.15 divisor for ethanol for MY2020 and later when calculating fuel economy. [EPA-HQ-OAR-2010-0799-9490-A1, p.4]

The Energy Independence and Security Act of 2007 substantially expanded the Renewable Fuel Standard originally enacted by Congress in the Energy Policy Act of 2005. The expanded RFS (known as RFS2) requires the consumption of 36 billion gallons of renewable fuels by 2022, and it is widely expected that the requirements will be met predominantly with ethanol. Indeed, in its Final Regulatory Impact Analysis for the RFS2, EPA analyzed a case where ethanol accounts for 33.2 billion gallons (92%) of the 36 billion gallon requirement in 2022. This amount of ethanol correlates to roughly 24% of expected gasoline demand in the 2022 timeframe.[7] [EPA-HQ-OAR-2010-0799-9490-A1, pp.5-6]

However, the amount of ethanol that can be used in the United States today is practically limited to 10% of the gasoline pool. This is because the Clean Air Act generally limits the amount of ethanol that can be consumed by conventional light-duty cars and trucks to 10%vol. (E10). EPA approved a waiver request allowing the use of E15 (15%vol. ethanol) for conventional light duty vehicles MY2007 or newer in November 2010. In January 2011, EPA extended the E15 waiver to MY2001. However, several additional regulatory and marketplace obstacles must be negotiated before significant volumes of E15 can realistically penetrate the marketplace. Thus, a maximum of roughly only 13-14 billion gallons of ethanol can currently be consumed by the conventional light-duty car and truck fleet at the E10 level, based on expected gasoline demand in the near term. Once E15 is broadly available in the marketplace, the conventional automotive fleet may be capable of consuming 18-20 billion gallons of ethanol, still far below the 2022 requirements of the RFS2. [EPA-HQ-OAR-2010-0799-9490-A1, p.6]

Based on the AIR study findings, we are confused as to how EPA/NHTSA reached the conclusion that the proposed CAFE/GHG emissions rule would have "no effect on volumes of ethanol and other renewable fuels," and we encourage the agency to revisit that portion of its analysis. [EPA-HQ-OAR-2010-0799-9490-A1, p.6]

Only FFVs may currently consume ethanol blends greater than E15. Thus, accelerated growth of FFVs will be necessary to consume the increasing ethanol volumes expected under the RFS2. The "Big 3" domestic automakers have committed to a goal of 50% of their new vehicles being FFV-capable in 2012 and thereafter. A 2011 study conducted for RFA by Air Improvement

Resource, Inc. (AIR) demonstrated that this commitment by the domestic automakers would technically enable the U.S. automotive fleet to consume 33.2 bg of ethanol by 2022 (Attachment A). The study also showed that a failure to ensure at least 50% of new vehicles are FFV-capable in 2012 and thereafter would result in falling short of long-term RFS2 volume requirements. [EPA-HQ-OAR-2010-0799-9490-A1, p.6] [For attachment A please refer to EPA-HQ-OAR-2010-0799-9490-A1, pp.9-54]

We are greatly concerned that by discouraging the continued production of FFVs beyond MY2016, the renewable fuel volumes required under the RFS2 likely cannot be consumed by the future U.S. automotive fleet. Thus, we encourage EPA to consider actions that place FFVs on a level playing field with other dual-fueled and dedicated alternative fuel vehicles for the purposes of complying with the proposed MY2017-2025 standards. [EPA-HQ-OAR-2010-0799-9490-A1, p.6]

Meanwhile, in regard to emissions compliance values and fuel economy calculations for plug-in hybrid electric vehicles (PHEVs) and dual-fueled compressed natural gas vehicles (CNGVs), EPA/NHTSA are proposing to allow the use of theoretical “utility factors” that assume PHEVs and CNGVs operate on gasoline only half of the time. EPA/NHTSA’s rationale for allowing the use of these utility factors for some dual-fueled vehicles but not for others is highly questionable. EPA/NHTSA state that PHEV and CNGV owners paid a premium for their vehicles and thus will seek out and predominantly use alternative fuels more frequently than they will use gasoline. EPA/NHTSA also assume the alternative fuels used by PHEVs and CNGVs will be cheaper than gasoline on a per mile basis. These assumptions do not take into account that refueling access for these vehicles may be limited or unavailable (EPA/NHTSA also assume, without basis, that PHEV drivers will always recharge once per day). Further, the cost per mile for these fuels may actually prove to be higher than gasoline, and prices may fluctuate as demand increases. If theoretical utility factors are to be applied to PHEVs and CNGVs, they should also apply to FFVs and any other dual-fueled vehicles. [EPA-HQ-OAR-2010-0799-9490-A1, p.4]

---

7 - The Energy Information Administration’s 2011 Annual Energy Outlook projects 2022 motor gasoline demand at 139.96 billion gallons.

Organization: Volkswagen Group of America

d. Credit mechanisms should be included to encourage greater use of biofuels in both spark ignited and compression ignition engines

Volkswagen explained that a bio-fuel credit mechanism would support the RFS II regulation and other complementary government policies regarding the reduced use of imported oil. [EPA-HQ-OAR-2010-0799-9569-A1, p. 5]

Response:

Basing the weighting of ethanol and gasoline use in an ethanol FFV on actual fuel use

Many of the above comments addressed this issue. Some commenters advocated for EPA to extend the utility factor methodology, adopted for PHEVs and dual fuel CNG vehicles, to ethanol FFVs. The agency disagrees with the objections raised by the Renewable Fuels Association and other commenters with respect to the selective use of utility factors for various dual fuel vehicles. EPA continues to believe that it is appropriate to assume that owners of some types of dual fuel vehicles, such as PHEVs and CNG vehicles, will preferentially seek to use the alternative fuel when the vehicle is much more expensive to purchase and much less expensive to operate on the alternative fuel—why else would the consumer pay more for the vehicle if (s)he did not intend to use the cheaper fuel? Similarly, EPA believes it is not appropriate to assume that ethanol FFVs will primarily use E85, as there is no extra vehicle cost to purchase an FFV (typically a consumer does not choose between an FFV and a non-FFV of the same vehicle model), E85 fuel is no cheaper and in fact usually more expensive per mile, and use of E85 reduces overall vehicle range since there is only one fuel tank (as opposed to PHEVs and dual fuel CNG vehicles which have two fuel storage devices and therefore the use of the alternative fuel raises overall vehicle range). Further, even with approximately 10 million ethanol FFVs in the US car and light truck fleet, fuel use data demonstrate that ethanol FFVs only use E85 less than one percent of the time. EPA considers the comment from the Renewable Fuels Association about relative fuel prices to be without merit. While it is true that prices of all motor fuels can be volatile, CNG prices are approximately one-half those of gasoline[15] (and electricity prices, per mile, are even lower), and expected to remain low for the foreseeable future (and, if CNG prices do rise, it would likely lead to lower dual fuel CNG vehicle sales since the primary reason for interest in dual fuel CNG vehicles is to take advantage of lower fuel prices).

Several automakers and the Alliance of Automobile Manufacturers asked for prospective guidance from EPA with respect to the relative weighting of gasoline and E85 emissions performance for future FFVs, and specifically recommended that EPA base the relative weighting of gasoline and E85 emissions performance on the projected national average use of E85 in ethanol FFVs that will be necessary to support compliance with the Renewable Fuel Standard in future model years. EPA plans to issue guidance, well in advance of each model year, but this guidance will be based on demonstrated E85 sales data from previous years, rather than projections of future E85 volumes. EPA believes that there is too much uncertainty associated with projections of future ethanol market share (vis-à-vis the market share for non-ethanol renewable fuels) in order to be able to base future FFV gasoline and E85 weightings on projections of how the Renewable Fuel Standard market will evolve. Our approach is responsive to comments from automakers, the 25x'25 Alliance, and the National Corn Growers Association, in that if actual use of E85 and other higher-ethanol blends increases, for example in response to future RFS requirements and/or due to more competitive pricing, then the regulations and guidance will allow automakers to apply a higher E85 weighting consistent with the greater use of the fuel.

No incentive multiplier for ethanol FFVs

A few commenters suggested that ethanol FFVs be provided the same incentives as EV/PHEV/FCV/CNG vehicles, such as the incentive multipliers. EPA believes it is not

[15] http://www.afdc.energy.gov/afdc/pdfs/afpr_apr_12.pdf

appropriate to adopt incentive multipliers in this rule for manufacturers of ethanol-capable vehicles. One, ethanol is not a vehicle GHG emissions game-changer—the tailpipe GHG emissions of ethanol FFVs when operated on ethanol are typically only slightly lower than GHG emissions from conventional vehicles (and those GHG emissions performance-based reductions would be accounted for in EPA compliance calculations based on actual ethanol use). Two, ethanol FFVs do not face the same consumer barriers as EV/PHEV/FCV/CNG vehicles—they are typically no more expensive than conventional vehicles, and they can, and most often are, operated on conventional gasoline-based fuels. Furthermore, there are approximately 10 million ethanol FFVs on the road in the U.S. today (far more than any other incentivized vehicle technology), and automakers produced approximately 2 million ethanol FFVs in MY 2011 alone. Although, as explained in the preceding response, the great majority of ethanol FFVs currently use gasoline, there is little reason to believe that automakers are not going to continue to produce ethanol FFVs, particularly if more ethanol FFVs begin to use E85 fuel to meet the RFS standards. Given the long history of federal incentives for ethanol FFVs, and the fact that ethanol FFVs can achieve GHG emissions credits after the GHG emissions incentives expire, the Agency believes that there is no need to provide additional incentives for ethanol FFVs in this rulemaking, beyond those already provided. Providing an additional incentive in the MYs 2017-2025 GHG program thus would not achieve any greater use of renewable fuels than is already required under the RFS program, and thus would not achieve any greater emissions reductions from the use of such fuel. Providing incentives would therefore only dilute the benefits of the GHG emissions program. Given that renewable fuel use is already required by and accounted for under the RFS program, it therefore would be inappropriate to provide additional incentives in the MYs 2017-2025 program.

Nevertheless, with future ethanol FFV credits tied to the actual use of ethanol fuel, there will be, for the first time, a motivation for automakers to encourage their customers to use ethanol in their FFVs. See Section 6.6 for a discussion of why EPA is not using the 0.15 divisor for GHG emissions compliance, but is adopting the 0.15 divisor for the CAFE program beginning in MY 2020, for all nonpetroleum fuels.

<u>No accounting of potential upstream GHG emissions benefits due to ethanol/biofuels</u>

Several commenters pointed out that cellulose-based ethanol and other renewable fuels have the potential to yield large lifecycle GHG emissions benefits due to the CO_2 uptake during plant growth, and recommended that such fuels be given credits, or have compliance measured, to reflect the upstream GHG emissions benefits. The use of biofuels with lower lifecycle GHG emissions is already required under the Renewable Fuel Standard (RFS) program, which is designed to achieve GHG emissions benefits through the required use of renewable transportation fuels that have better lifecycle GHG emissions performance than the gasoline or diesel fuel that they displace. EPA has already quantified the GHG emissions benefits associated with the RFS program. Therefore, as noted above, providing an additional incentive in the MYs 2017-2025 GHG program, which is focused on emissions from the vehicle and not lifecycle emissions, would not achieve any greater use of renewable fuels than is already required under the RFS program, and thus would not achieve any greater emissions reductions from the use of such fuel. Thus, providing an additional incentive, or using lifecycle emissions for compliance, would reduce the need to take other actions and thereby reduce the emissions benefits of the

MYs 2017-2025 light-duty vehicle GHG emissions program given that renewable fuel use is already required by and accounted for under the RFS program.[16]

Interaction between this rule and the Renewable Fuels Standard

Many commenters alluded to a potential conflict between the proposed CAFE/GHG standards and the RFS program

EPA sees no such conflict. The MYs 2017-2025 GHG program is designed to achieve GHG emission reductions from vehicle operation as measured at the tailpipe. It does this by reducing the amount of fuel that the vehicle consumes during operation. For conventional gasoline powered vehicles, the standard is based on a test procedure that uses gasoline without any ethanol as the test fuel. The GHG standards will require the manufacturers to produce vehicles that consume less fuel when operated on gasoline. These same vehicles will also be more efficient when operated on blends of gasoline and ethanol. The standards achieve greater efficiency in the consumption of the fuel, without affecting one way or the other how much renewable fuel is used by the operator. The RFS program is a separate, complementary program designed to increase the use of renewable fuels by operators and to achieve GHG emission reductions primarily through upstream emission reductions. It affects what fuels are produced and sold, but does not affect how efficient the vehicle is in consuming the fuel. The GHG standards affect the vehicles and improve their efficiency, while the RFS program achieves the goals of increased use of renewable fuels independent of the vehicle GHG standards. They are separate but complementary programs.

In addition, the RFS provisions themselves were drafted by Congress to include lifecycle GHG performance standards that were neutral to the type of fuel used to meet them. Other than subcategories for cellulosic biofuel and biomass-based diesel, EISA does not specify what types of renewable fuel must be used. Rather, it is structured to allow the free market to stimulate the development of a broad range of renewable fuels from an even broader range of feedstocks. We have already seen rapid growth in corn ethanol and soy biodiesel production, and by leveraging DOE and USDA programs we are now seeing billions of dollars spent in research, development, and now commercialization of “drop-in fuels” such as renewable diesel, biomass-to-liquids gasoline and diesel, and biobutanol, as well as biogas and bioelectricity. These fuels are and will be coming from an ever broader array of feedstocks, from municipal solid waste to corn stover to algae. EPA already has over 30 petitions for new fuel pathways under the RFS program that we are currently reviewing. These fuels are also finding markets beyond just cars and trucks, and are being introduced into planes, trains, ships, and home furnaces. In short, the opportunities for the use of non-ethanol renewable fuels that will meet the requirements of the RFS program are expanding quickly.

[16] The plant oil-based fuel produced by POP Diesel is not currently identified as an acceptable renewable fuel under the RFS program. EPA is currently considering the company’s petition seeking approval of its product under the RFS program. The RFS program established by Congress is the appropriate mechanism for evaluating the full lifecycle emissions impact of this type of biofuel use, rather than a program focused principally on vehicle tailpipe emissions.

The commenters focus narrowly on ethanol as the fuel to be used to meet the RFS standard, since ethanol has been the predominant renewable fuel used to date. Since the RFS standard increases over time, they then argue that EPA must provide additional mechanisms to ensure that gasoline blends with greater than 10% ethanol can be used in both conventional vehicles and flexible fuel vehicles. However, the commenters presume that additional EPA action is necessary in order for this to occur. While EPA has and will continue to take actions within its authority to help the marketplace achieve the RFS standards through the increased use of ethanol and all other renewable fuels, ultimately EISA places this responsibility on the parties obligated to do so under the RFS program. This makes sense, as the industry is not only capable of making all the changes necessary to accommodate both the CAFE/LDGHG standards and the RFS volume requirements, but is in the best position to do so in the most efficient manner. For instance, in addition to developing drop-in fuels, the marketplace has been also been finding ways to increase the use of ethanol. As a result of the commitment of the big 3 domestic vehicle manufacturers to the President several years ago, there are now over 10 million flexible fuel vehicles (FFVs) on the road capable of burning up to 85 percent ethanol. Similarly, hundreds of new retail outlets are being converted every year to market E85 to supply higher level ethanol blends to FFVs.

Thus, there are already a wide variety of solutions available to the market that will permit the increasing use of renewable fuels to meet the RFS standards. Many, if not all of these solutions will be implemented in the marketplace over the course of the next few years. By the time the CAFE/LDGHG standards will be implemented for MY2017 and later, the market will have sorted out the best mechanisms to expand the use of renewable fuels through both increased use of ethanol and non-ethanol renewable fuels. Given the long lead time for this rule, the long phase-in, and the long time it will take for the fleet to turn over, we have every confidence that the market will assure compliance with both the RFS standards and CAFE/LDGHG standards without the need of incentives in this rule.

Finally, while the current incentives for production of FFVs have not been effective at increasing the use of renewable fuels by FFVs, the provisions of this rule have the potential to provide an incentive for manufacturers to continue production of FFVs and to promote increased use of renewable fuels by operators of FFVs, which would help to achieve the RFS volume standards.

6.4. Comments Regarding the Treatment of Diesel-Fueled Vehicles

Organizations Included in this Section

Marz, Loren C.
Plant Oil Powered Diesel Fuel Systems, Inc.
U.S. Coalition for Advanced Diesel Cars
Volkswagen Group of America

Organization: BMW of North America, LLC

The joint draft TSD assumes almost negligible diesel market share in 2021 to 2025 (control case) which is in contradiction to increasing customer acceptance of diesel technology and automaker efforts to improve diesel technology. Clean diesel technology is a further option in the list of technologies with significant CO_2 reduction potential. Future diesel mix depends on factors such as incentives, customer acceptance, fuel price development, etc. [EPA-HQ-OAR-2010-0799-9579-A1, p.9]

Organization: Chrysler Group LLC

Diesel technology can provide significant greenhouse gas and fuel efficiency benefits.

We also request that the Agencies consider incentives for this technology such as volume multipliers, or credit for enabling the use of biofuel blends such as B10 or B20. [EPA-HQ-OAR-2010-0799-9495-A1, p.22]

Organization: Delphi Corporation

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 111.]

Second, Delphi has a proven track record in achieving energy and emissions reductions in diesel technology. Specifically, Delphi's direct injection fuel systems and linear oxygen sensors support diesel combustion with urea dosing systems, ammonia sensors and particulate matter or soot sensors help meet stringent emissions and on-board diagnostic requirements.

Organization: Manufacturers of Emission Controls Association (MECA)

[These comments were submitted as testimony at the Detroit, Michigan public hearing on January 17, 2012. See Docket Number EPA-HQ-OAR-2010-0799-11786, p. 181.]

Advanced diesel emission control technologies like particulate filters with lower backpressure characteristics, selected reduction catalysts with improved performance at lower exhaust temperatures and SCR catalysts coated directly on particulate filter substrates are examples of emerging diesel emission control technologies that will allow future diesel powertrains to not only be as clean as gasoline engines from a criteria pollutant perspective, but diesel powertrains will deliver improved fuel consumption characteristics and lower greenhouse gas emissions. The use of diesel particulate filters also delivers significant reductions in black carbon emissions from diesel engines, a combustion emission that also has important climate change impact.

Organization: Marz, Loren C.

The projected effectiveness of advanced diesel engine technology relative to advanced gasoline engine technology may potentially be underestimated. A cursory review of current diesel technology compared to current turbo-GDI technology in Europe reveals that diesel technology retains a significant fuel consumption advantage over identical vehicles with turbo-GDI technology in most cases. The following is a list of identical European-spec vehicles available with diesel and turbo-GDI technology at equivalent or nearly equivalent performance (based on 'combined' fuel consumption in the European test cycle (NEDC) and manufacturers' listed 1-100 km/hour times where those values were readily available (time in parentheses for each vehicle; diesel version listed first))... [NHTSA-2010-0131-0213-A1, p.1]

Audi A8 3.0 TDI – 6.6 l/100 km (6.1 sec) (27.5% lower Fuel Consumption)

Audi A8 3.0 TFSI – 9.1 l/100 km (6.1 sec)

MB S350 CDI BlueTEC L – 6.2 l/100 km (7.1 sec) (19.5% lower FC)

MB S350 CGI Blue Efficiency L – 7.7 l/100 km (7.1 sec)

MB C350 CDI Blue Efficiency – 5.9 l/100 km (6.0 sec) (15.7% lower FC)

MB C350 CGI Blue Efficiency – 7.0 l/100 km (6.0 sec)

MB C250 CDI Blue Efficiency – 4.8 l/100 km (7.1 sec) (28.4% lower FC)

MB C250 CGI Blue Efficiency – 6.7 l/100 km (7.2 sec)

Audi A3 2.0 TDI – 4.9 l/100 km (7.6 sec) (24.6% lower FC)

Audi A3 1.8 TFSI – 6.5 l/100 km (7.5 sec)

BMW 520d – 4.7 l/100 km (8-speed auto) (8.1 sec) (26.6% lower FC)

BMW 520i – 6.4 l/100 km (8-speed auto) (8.0 sec)

BMW X3 35d – 6.1 l/100 km (8-speed auto) (5.8 sec) (30.7% lower FC)

BMW X3 35i – 8.8 l/100 km (8-speed auto) (5.7 sec)

BMW 640d – 5.4 l/100 km (8-speed auto) (5.5 sec) (28.9% lower FC)

BMW 640i – 7.6 l/100 km (8-speed auto) (5.4 sec)

BMW 530d – 5.3 g l/100km (8-speed auto) (6.0 sec) (30.3% lower FC)

BMW 535i – 7.6 g l/100 km (8-speed auto) (5.9 sec)

MB E250 CDI Blue Efficiency – 4.9 l/100 km (7.5 sec) (25.8% lower FC)

MB E250 CGI Blue Efficiency – 6.6 l/100 km (7.7 sec)

BMW X5 40d – 7.5 l/100 km (8-speed auto) (6.6 sec) (25.7% lower FC)

BMW X5 35i – 10.1 l/100 km (8-speed auto) (6.8 sec)

Audi A8 4.2 TDI – 7.6 l/100 km (5.5 sec) (20.0% lower FC)

Audi A8 4.2 TFSI – 9.5 l/100 km (5.7 sec)

BMW 120d – 4.4 l/100 km (7.3 sec) (21.4% lower FC)

BMW 118i – 5.6 l/100 km (7.5 sec)

VW Golf 2.0 TDI – 4.8 l/100 km (manual) (9.3 sec) (22.6% lower FC)

VW Golf 1.4 TSI – 6.2 l/100 km (manual) (9.5 sec)

BMW 535d xDrive – 5.7 l/100 km (8-speed auto) (5.5 sec) (28.8% lower FC)

BMW 535i xDrive – 8.0 l/100 km (8-speed auto) (5.8 sec)

(ave. ~25.1% lower FC)
