

# Accuracy of the Data (2001)

## INTRODUCTION

The data contained in these Profiles and Summary Tables are based on the American Community Survey (ACS) sample interviewed in 2001. The ACS is designed to provide accurate estimates for the housing units and population of the sites participating in the 2001 ACS. The ACS, like any other statistical activity, is subject to error. The purpose of this documentation is to provide data users with a basic understanding of the ACS sample design, estimation methodology, and accuracy of the ACS data.

The “*Operational Overview of the 2001 American Community Survey*” provides information on the sites, data collection, and Master Address File.

## SAMPLE DESIGN

- Sites -- Thirty-six counties participated in the 2001 ACS. The primary sampling unit was the housing unit (HU), including all occupants. Persons living in group quarters (GQ) were **NOT** included in the sample.
- Sampling Rates -- In Fort Bend and Harris Counties, TX the overall HU sampling rate was 1 percent. In Broward, FL; Bronx, NY; Lake, IL; San Francisco, CA; and Franklin, OH the overall HU sampling rate was 3 percent. The remaining counties were sampled at 5 percent. The sampling rate within the county varied by the size of the governmental unit the housing unit was in. These sampling rates are provided under the section “ESTIMATION PROCEDURE”. A variable sampling rate was used for the purpose of providing relatively more reliable estimates for small areas.

## CONFIDENTIALITY OF THE DATA

- Confidentiality Edit -- To maintain the confidentiality required by law (Title 13, United States Code), the Census Bureau applies a confidentiality edit to the ACS data to assure that published data do not disclose information about specific individuals, households, or housing units. As a result, a small amount of uncertainty is introduced into the estimates of ACS characteristics. The sample itself provides adequate protection for most areas for which sample data are published since the resulting data are estimates of the actual characteristics. However, small areas require more protection. The confidentiality edit is implemented by identifying a subset of individual housing units from the sample data files as having a unique combination of specified person and household characteristics within a block group. The confidentiality edit is controlled so that the basic structure of the data is preserved.

## ESTIMATION PROCEDURE

The estimates that appear in this product were obtained from a raking ratio estimation procedure that resulted in the assignment of two sets of weights: a weight to each sample person record and a weight to each sample housing unit record. For any given tabulation area, a characteristic total was estimated by summing the weights assigned to the persons, households, families or housing units possessing the characteristic in the tabulation area. Estimates of person characteristics were based on the person weight. Estimates of family, household or housing unit characteristics were based on the housing unit weight.

Each sample person or housing unit record was assigned exactly one weight to be used to produce estimates of all characteristics. For example, if the weight given to a sample person or housing unit had the value 6, all characteristics of that person or housing unit would be tabulated with the weight of 6. The estimation procedure, however, did assign weights varying from person to person or housing unit to housing unit.

The estimation procedure used to assign the weights was performed independently within each of the 2001 ACS sites.

- Initial Housing Unit Weighting Factors - This process produced the following factors:
  - Base Weight (BW) - This factor was assigned to every housing unit based on its sampling stratum and was the inverse of the housing unit's sampling rate. The 2001 sampling rates are shown in the table below.

Type of Area	Fort Bend and Harris, TX	Broward, FL; Bronx, NY; Lake, IL; San Francisco, CA; and Franklin, OH	All Other Counties
Blocks in smallest governmental units (fewer than 800 HUs)	3%	9%	15%
Blocks in small governmental units (between 800 and 1200 HUs)	1.5%	4.5%	7.5%
Blocks in Large Tracts (more than 2001 HUs)	0.75%	2.25%	3.75%
All other blocks (including ungeocoded records)	1%	3%	5%

•CAPI Subsampling Factor (SSF) - The weights of the CAPI cases were adjusted to reflect the results of CAPI subsampling. This factor was assigned to each record as follows:

Selected in CAPI subsampling:  $SSF = 3.0$

Not selected in CAPI subsampling:  $SSF = 0.0$

Not a CAPI case:  $SSF = 1.0$

Some addresses were unmailable. A two-thirds sample of these were sent directly to CAPI and for these cases  $SSF = 1.5$ .

- Variation in Monthly Response by Mode (VMS) - This factor made the total weight of the Mail, Delivery, CATI, and CAPI records to be tabulated in a month equal to the total base weight of all cases originally mailed for that month. The value of VMS for all cases was determined as the weighted number of cases mailed out that month divided by the weighted number of cases received for that month.
- Noninterview Factor (NIF) - This factor adjusted the weight of all responding occupied housing units to account for both responding and nonresponding housing units. This factor was computed in two stages: NIF1 and NIF2. NIF1 was computed and assigned to occupied housing units based on the following groups.

County x Building Type (single or multi-unit) x Tract

After having adjusted each occupied housing unit for NIF1, a ratio adjustment NIF2 was computed and assigned to occupied housing units based on the following groups.

County x Building Type x Month

NIF was then computed for each occupied housing unit as the product of NIF1 and NIF2. Vacant housing units were assigned a value of  $NIF = 1.0$ .

Nonresponding housing units were now assigned a weight of 0.0.

- Noninterview Factor - Mode (NIFM) - This factor adjusted the weight of just the responding CAPI occupied housing units to account for both CAPI respondents and all nonrespondents. This factor was computed as if NIF had not already been assigned to every occupied housing unit record. This factor was not used directly but rather as part of computing the next factor: MBF. NIFM was computed and assigned to occupied CAPI housing units based on the following groups.

### County x Building Type x Month

Mail and CATI cases received a value of NIFM = 1.0. Vacancies received a value of NIFM = 1.0.

- Mode Bias Factor (MBF) - This factor made the total weight of the housing units in the groups below the same as if NIFM had been used instead of NIF. MBF was computed and assigned to occupied housing units based on the following groups.

County x Tenure (Owner or renter) x Month x Marital Status (married/widowed or other)

Vacant housing units received a value of MBF = 1.0.

- Housing control Factor (HPF1) - This factor made the total weight of all housing units agree with the county-level 2001 housing unit intercensal estimates.
- Person Weighting Factors - Initially the person weight of each person in an occupied housing unit was the product of the weighting factors of their associated housing unit (BW x . . . x HPF1). At this point everyone in the household would have the same weight. These person weights were then individually adjusted based on each person's age, race, sex, and Hispanic origin as described below.
- Person Post-Stratification Factor (PPSF) - This factor was applied to individuals based on their age, race, sex and Hispanic origin. It adjusted the person weights so that the weighted sample counts matched county-level 2001 intercensal population estimates by age, race, sex, and Hispanic origin.

This used the following groups:

County x Race (non-Hispanic White, non-Hispanic Black, non-Hispanic American Indian or Alaskan Native, non-Hispanic Asian, non-Hispanic Native Hawaiian or Pacific Islander, and Hispanic(any race)) x Sex x Age Groups .

- Rounding - The final product of all person weights (BW x . . . x HPF1 x PPSF) was rounded to an integer. Rounding was performed so that the sum of the rounded weights was within one person of the sum of the unrounded weights for any of the groups listed below:

County  
County x Race  
County x Race x Hispanic Origin  
County x Race x Hispanic Origin x Sex  
County x Race x Hispanic Origin x Sex x Age  
County x Race x Hispanic Origin x Sex x Age x Tract  
County x Race x Hispanic Origin x Sex x Age x Tract x Block

For example, the number of White, Hispanic, Males, Age 30 estimated for a county using the rounded weights was within one of the number produced using the unrounded weights.

- Final Housing Unit Weighting Factors - This process produced the following factors:
  - Principal Person Factor (PPF) - This factor adjusted for differential response depending on the race, Hispanic origin, sex, and age of the principal person in the household. The principal person was defined as the female spouse of the responding householder. If there was no such person, then the responding householder was the principal person. The value of PPF for a housing unit was the PPSF of the principal person.
  - Final Housing Unit Controls (HPF2) - The final product of the principal person weights ( $BW \times \dots \times HPF1 \times PPF$ ) was then assigned to the housing unit. The total number of weighted housing unit counts are then made to agree to the county-level 2001 housing unit intercensal estimates.
- Rounding - The final product of all housing unit weights ( $BW \times \dots \times PPF \times HPF2$ ) was rounded to an integer. Rounding was performed so that total rounded weight was within one housing unit of the total unrounded weight for any of the groups listed below:

County  
County x Tract  
County x Tract x Block

## ERRORS IN THE DATA

- **Sampling Error** -- The data in the ACS products are estimates of the actual figures that would have been obtained by interviewing the entire population using the same methodology. The estimates from the chosen sample also differ from other samples of housing units and persons within those housing units. Sampling error in data arises due to the use of probability sampling, which is necessary to insure the integrity and representativeness of sample survey results. The implementation of statistical sampling procedures provides the basis for the statistical analysis of sample data.
- **Nonsampling Error** -- In addition to sampling error, data users should realize that other types of errors may be introduced during any of the various complex operations used to collect and process survey data. For example, operations such as editing, reviewing, or keying data from questionnaires may introduce error into the estimates. These and other sources of error contribute to the nonsampling error component of the total error of survey estimates. Nonsampling errors may affect the data in two ways. Errors that are introduced randomly increase the variability of the data. Systematic errors which are consistent in one direction introduce bias into the results of a sample survey. The Census Bureau protects against the effect of systematic errors on survey estimates by conducting extensive research and evaluation programs on sampling techniques, questionnaire design, and data collection and processing procedures. In addition, an important goal of the ACS is to minimize the amount of nonsampling error introduced through nonresponse for sample housing units. One way of accomplishing this is by following up on mail nonrespondents during the CATI and CAPI phases.
- **Standard Errors** -- The standard error is a measure of the deviation of a sample estimate from the average of all possible samples. Sampling errors and some types of nonsampling errors are estimated by the standard error. The sample estimate and its estimated standard error permit the construction of interval estimates with a prescribed confidence that the interval includes the average result of all possible samples. The next section describes the method of calculating standard errors and confidence intervals for the estimates in this ACS product.

## CONTROL OF NONSAMPLING ERROR

As mentioned earlier, sample data are subject to nonsampling error. This component of error could introduce serious bias into the data, and the total error could increase dramatically over that which would result purely from sampling. While it is impossible to completely eliminate nonsampling error from a survey operation, the Census Bureau attempts to control the sources of such error during the collection and processing operations. Described below are the primary sources of nonsampling error and the programs instituted for control of this error. The success of

these programs, however, is contingent upon how well the instructions actually were carried out during the survey.

- Undercoverage -- It is possible for some sample housing units or persons to be missed entirely by the survey. The undercoverage of persons and housing units can introduce biases into the data. A major way to avoid undercoverage in a survey is to ensure that its sampling frame, for ACS an address list in each site, is as complete and accurate as possible.

The source of addresses was the Master Address File (MAF). The MAF is created by combining the Delivery Sequence File of the United States Postal Service, and the address list for Census 2000. An attempt is made to assign all appropriate geographic codes to each MAF address via an automated procedure using the Census Bureau TIGER files. A manual coding operation based in the appropriate regional offices is attempted for addresses which could not be automatically coded. The MAF was used as the source of addresses for selecting sample housing units and mailing questionnaires. TIGER produced the location maps for personal visit CAPI assignments.

In the CATI and CAPI nonresponse follow-up phases, efforts were made to minimize the chances that housing units that were not part of the sample were interviewed in place of units in sample by mistake. If a CATI interviewer called a mail nonresponse case and was not able to reach the exact address, no interview was conducted and the case was eligible for CAPI. During CAPI follow-up, the interviewer had to locate the exact address for each sample housing unit. In some multi-unit structures the interviewer could not locate the exact sample unit or found a different number of units than expected. In these cases the interviewers were instructed to list the units in the building and follow a specific procedure to select a replacement sample unit.

- Respondent and Interviewer Error -- The person answering the questionnaire or responding to the questions posed by an interviewer could serve as a source of error, although the questions were phrased as clearly as possible based on testing, and detailed instructions for completing the questionnaire were provided to each household. In addition, respondents' answers were edited for completeness, and problems were followed up as necessary.
- Interviewer monitoring -- The interviewer may misinterpret or otherwise incorrectly enter information given by a respondent; may fail to collect some of the information for a person or household; or may collect data for households that were not designated as part of the sample. To control these problems, the work of interviewers was monitored carefully. Field staff were prepared for their tasks by using specially developed training packages that included hands-on experience in using survey materials. A sample of the households interviewed by CAPI

interviewers was reinterviewed to control for the possibility that interviewers may have fabricated data.

- Item Nonresponse -- Nonresponse to particular questions on the survey questionnaire and instrument allows for the introduction of bias into the data, since the characteristics of the nonrespondents have not been observed and may differ from those reported by respondents. As a result, any imputation procedure using respondent data may not completely reflect this difference either at the elemental level (individual person or housing unit) or on average.

Some protection against the introduction of large biases is afforded by minimizing nonresponse. In the ACS, nonresponse for the CATI and CAPI operations was reduced substantially by the requirement that the automated instrument receive a response to each question before the next one could be asked. For mail responses, the automated clerical review and follow-up operations were aimed at obtaining a response for every question on selected questionnaires. Values for any items that remain unanswered were imputed by computer using reported data for a person or housing unit with similar characteristics.

- Automated Clerical Review -- Questionnaires returned by mail were edited for completeness and acceptability. They were reviewed by computer for content omissions and population coverage. If necessary, a telephone follow-up was made to obtain missing information. Potential coverage errors were included in this follow-up, as well as questionnaires with too many omissions to be accepted as returned.
- Processing Error -- The many phases involved in processing the survey data represent potential sources for the introduction of nonsampling error. The processing of the survey questionnaires includes the keying of data from completed questionnaires, automated clerical review, and follow-up by telephone; the manual coding of write-in responses; and the electronic data processing. The various field, coding and computer operations undergo a number of quality control checks to insure their accurate application.
- Automated Editing -- After data collection was completed, any remaining incomplete or inconsistent information was imputed during the final automated edit of the collected data. Imputations, or computer assignments of acceptable codes in place of unacceptable entries or blanks, were needed most often when an entry for a given item was lacking or when the information reported for a person or housing unit on that item was inconsistent with other information for that same person or housing unit. As in other surveys and previous censuses, the general procedure for changing unacceptable entries was to assign an entry for a person or housing unit that was consistent with entries for persons or housing units with similar characteristics. Assigning acceptable values in place of blanks or unacceptable entries enhances the usefulness of the data.

## CALCULATION OF STANDARD ERRORS

Direct estimates of the standard errors were calculated and reported for the estimates in this product. When reporting the standard error of a single line, we recommend that you use the direct standard error, which can be obtained from the published confidence interval using the steps in the next section.

For an estimate which combines more than one line - such as a sum, difference, or ratio - you may approximate the standard error using the direct standard error estimates or a generalized variance method. The parameters used in the generalized variances methods were obtained using the direct standard errors. Both methods are described in the sections below.

### Direct Standard Errors

**Methodology Used** -- Direct estimates of the standard errors were calculated for all estimates reported in this product. They are provided in the summary tables and profiles as 90 percent confidence intervals. The standard errors, in most cases, are calculated using standard variance estimation software using a methodology that takes into account the sample design and estimation procedures.

**Exceptions** -- There are seven cases for which the direct standard error estimates are not appropriate.

1. The estimate of the number or proportion of people, households, housing units or families in a geographic area with a specific characteristic is zero. A special procedure was used to estimate the standard error.
2. There are no sample observations available to compute an estimate of a proportion or other ratio or an estimate of its standard error. The estimate is represented in the tables by “-” and the lower and upper bounds of the 90 percent confidence interval by “\*\*”.
3. There are no sample observations available to compute an estimate of a median or an estimate of its standard error. The estimate is represented in the tables by “-” and the lower and upper bounds of the 90 percent confidence interval by “\*\*”.
4. Only a small number of identical values are reported and used to calculate an aggregate, mean, or per capita amount. In this case, there are too few sample observations to compute a stable estimate of the standard error. The lower and upper bounds of the 90 percent confidence interval are represented in the tables by “\*”.

5. The estimate of a median falls in the lowest interval or upper interval of an open-ended distribution. If the median occurs in the lowest interval, then a “-” follows the estimate, and if the median occurs in the upper interval, then a “+” follows the estimate. In both cases the lower and upper bounds of the 90 percent confidence interval are represented in the tables by “\*\*\*”.

6. The estimate of the number of people having a specified characteristic is controlled to be equal to an independently derived population estimate. For these cases the standard error is zero. The lower and upper bounds of the 90 percent confidence interval are represented in the tables by “\*\*\*\*\*”. (See “ESTIMATION PROCEDURE” for a further explanation.)

7. The estimate of the number of housing units is controlled to be equal to an independently derived housing unit estimate. For these cases the standard error is zero. The lower and upper bounds of the 90 percent confidence interval are represented in the tables by “\*\*\*\*\*”. (See “ESTIMATION PROCEDURE” for a further explanation.)

Calculating Standard Errors from the 90 Percent Confidence Interval -- In most cases you can calculate the standard error using the estimate and the upper bound. If the upper bound has been set to its largest admissible value (See Limitation 2. below) then the lower bound should be used instead of the upper bound.

Standard Error = ( upper bound - estimate ) / 1.65

or

Standard Error = ( estimate - lower bound ) / 1.65

- Sums and Differences of Estimates -- The standard errors estimated from these tables are for individual estimates. Additional calculations are required to estimate the standard errors for sums of and differences between two sample estimates. The estimate of the standard error of a sum or difference is approximately the square root of the sum of the two individual standard errors squared; that is, for standard errors  $SE(\hat{X})$  and  $SE(\hat{Y})$  of estimates  $\hat{X}$  and  $\hat{Y}$ :

$$SE(\hat{X} + \hat{Y}) = SE(\hat{X} - \hat{Y}) = \sqrt{[SE(\hat{X})]^2 + [SE(\hat{Y})]^2}$$

This method, however, will underestimate (overestimate) the standard error if the two items in a sum are highly positively (negatively) correlated or if the two items in a difference are highly negatively (positively) correlated.

- Ratios -- Frequently, the statistic of interest is the ratio of two variables, where the numerator *is not* a subset of the denominator. The standard error of the ratio between two sample estimates is approximated as follows:

$$SE\left(\frac{\hat{X}}{\hat{Y}}\right) = \frac{1}{\hat{Y}} \sqrt{[SE(\hat{X})]^2 + \frac{\hat{X}^2}{\hat{Y}^2} [SE(\hat{Y})]^2}$$

- Proportions/percents - The statistic of interest may be a proportion or percent, where the numerator *is* a subset of the denominator. Note the difference between the formulas for the standard error for proportions and ratios.

$$SE(\hat{P}) = \frac{1}{\hat{Y}} \sqrt{[SE(\hat{X})]^2 - \frac{\hat{X}^2}{\hat{Y}^2} [SE(\hat{Y})]^2}$$

## Generalized Standard Errors

There are three generalized variance procedures used to calculate standard errors based on the type of estimate. For most sample estimates of *totals* and *proportions* (*percentages*) we use a design factor approach; for sample estimates of *aggregates*, *population*, and *housing units* we use a method we refer to as a, b, & c parameters; and for sample estimates of *means*, *medians*, *per capita amounts*, and *ratios* (*other than proportions*) we use a method we refer to as a & b parameters. The generalized variance procedures provided here can be used when combining estimates from the tables.

### Design Factor Method

The information provided in Tables A-2001 through C-2001 can be used to approximate the standard errors of most sample estimates of *totals* and *proportions* in the Profiles and Summary Tables. Tables A-2001 and B-2001 give the basic standard error for an estimate of a characteristic that would result under a simple random sampling design. The estimates are for person, family, and housing unit characteristics. Design factors by site and subject are provided in Table C-2001. The term "subject" refers to a characteristic, such as age for persons and tenure for housing units. The design factors reflect the effects of the actual sample design and estimation procedures used for the 2001 American Community Survey. Details of the sample design and estimation procedures are provided elsewhere in this chapter.

To approximate the standard error of an estimate of a total or a proportion using Tables A-2001 through C-2001, follow the steps described later in this section. A proportion is defined as a ratio of two estimates where the numerator is a subset of the denominator. For example, the proportion of Black lawyers is the ratio of Black lawyers to all lawyers.

An inspection of the formulas used to calculate the simple random sampling standard errors suggests that when dealing with zero estimates or very small estimates of totals and percentages the standard error estimates approach zero. This is also the case for very large estimates of totals and percentages. Zero or small estimates, like any other sample estimates, are still subject to sampling variability and therefore an estimated standard error of zero or close to zero is not adequate.

- For Fort Bend & Harris Counties, TX, when an estimated total is less than 400 or within 400 of the total size of the tabulation area, use a basic standard error of 87. For estimated percentages that are less than 10 or greater than 90, use a value of 10 for  $\hat{p}$  in the formula below Table B-2001.
- For San Francisco County, CA; Broward County, FL; Lake County, IL; Bronx Borough, NY; and Franklin County, OH, when an estimated total is less than 100 or within 100 of the total size of the tabulation area, use a basic standard error of 44. For estimated percentages which are less than 2.5 percent or greater than 97.5 percent, use 2.5 as the value of  $\hat{p}$  in the basic standard error formula below Table B-2001.
- For all other counties, when an estimated total is less than 80 or within 80 of the total size of the tabulation area, use a basic standard error of 39. For estimated percentages which are less than 2 percent or greater than 98 percent, use 2 as the value of  $\hat{p}$  in the basic standard error formula below Table B-2001.

### Exception

There is one exception to the above method: when the denominator of a percentage is zero. (There are no sample observations available to compute an estimate of a proportion or an estimate of its standard error.) The estimate is represented in the tables by "-" and the lower and upper bounds by "\*\*\*".

### Use of Tables to Approximate Standard Errors

Tables A-2001 through C-2001 are used in the following manner to approximate standard errors:

1. Obtain the basic standard error from either Table A-2001 (for an estimate of a total) or Table B-2001 (for an estimate of a percentage) or use the formula given below the appropriate table. **Obtain the number of persons or number of housing units from Summary Table P001 or H001, respectively for the geography(ies) you are interested in. If the estimate is of families, households or housing units then use the number of housing units, otherwise use the number of persons.** Use these numbers to determine which column to look under in Table A-2001.

2. Use Table C-2001 to obtain the appropriate design factor for the characteristic; for example, educational attainment or ancestry. Multiply the basic standard error by this factor to get the ACS standard error estimate. If the estimate is a combination of two or more characteristics, then use the largest design factor for this combination of characteristics. **The only exception to this is for items crossed with race or Hispanic Origin, for an item(s) crossed with race or Hispanic Origin use the largest design factor not including the race or Hispanic Origin design factor.**

#### a, b, & c Parameter Method

The information provided in Table D-2001 can be used to approximate the standard errors for estimates of *aggregates*, *total population*, and *housing units*. Use Table D-2001 to obtain the appropriate a, b, & c parameters for the characteristic; for example, population or aggregate person income. To approximate the standard error use the following formula:

$$se(estimate) = \sqrt{a + b * estimate + c * estimate^2}$$

#### a & b Parameter Method

The information provided in Table E-2001 can be used to approximate the standard errors for estimates of *means*, *medians*, *per capita amounts*, and *ratios (other than proportions)*. Use Table E-2001 to obtain the appropriate a & b parameters for the characteristic; for example, mean family income or median value. To approximate the standard error use the following formula:

$$se(estimate) = \sqrt{a + b * LOG(N)}$$

Where: LOG is the natural log function and

N is the universe count for medians, or the denominator of the estimate for means, per capita amounts and ratios for the geography(ies) you are interested in.

## Exception

There is one exception to the above method: when the denominator of a mean, per capita amount, or other ratio is zero. (There are no sample observations available to compute an estimate or an estimate of its standard error.) The estimate is represented in the tables by "-" and the lower and upper bounds by "\*\*\*".

## Confidence Intervals

Confidence Intervals -- A sample estimate and its estimated standard error may be used to construct confidence intervals about the estimate. These intervals are ranges that will contain the average value of the estimated characteristic that results over all possible samples, with a known probability.

For example, if all possible samples that could result under the 2001 ACS sample design were independently selected and surveyed under the same conditions, and if the estimate and its estimated standard error were calculated for each of these samples, then:

1. Approximately 68 percent of the intervals from one estimated standard error below the estimate to one estimated standard error above the estimate would contain the average result from all possible samples;
2. Approximately 90 percent of the intervals from 1.65 times the estimated standard error below the estimate to 1.65 times the estimated standard error above the estimate would contain the average result from all possible samples.
3. Approximately 95 percent of the intervals from two estimated standard errors below the estimate to two estimated standard errors above the estimate would contain the average result from all possible samples.

The intervals are referred to as 68 percent, 90 percent, and 95 percent confidence intervals, respectively.

Lower and Upper Bounds -- The lower and upper bounds presented in the summary tables and profiles are the bounds based upon a 90% confidence interval.

Limitations -- The user should be careful when computing and interpreting confidence intervals.

1. The estimated standard errors included in this data product do not include all portions of the variability due to nonsampling error that may be present in the data. In particular, the

standard errors do not reflect the effect of correlated errors introduced by interviewers, coders, or other field or processing personnel. Thus, the standard errors calculated represent a lower bound of the total error. As a result, confidence intervals formed using these estimated standard errors may not meet the stated levels of confidence (i.e., 68, 90, or 95 percent). Thus, some care must be exercised in the interpretation of the data in this data product based on the estimated standard errors.

2. Zero or small estimates; very large estimates -- The value of almost all ACS characteristics is greater than or equal to zero by definition. For zero or small estimates, use of the method given previously for calculating confidence intervals relies on large sample theory, and may result in negative values which for most characteristics are not admissible. In this case the lower limit of the confidence interval is set to zero by default. A similar caution holds for estimates of totals close to a control total or estimated proportions near one, where the upper limit of the confidence interval is set to its largest admissible value. In these situations the level of confidence of the adjusted range of values is less than the prescribed confidence level.

3. Small tabulation areas -- Estimates for small tabulation areas (particularly small areas with high nonresponse rate) are based on small samples. Again, using large sample theory methodology to construct confidence intervals may result in values that are not admissible for the characteristic of interest or in overstating the confidence for a given range. The user should exercise caution in the analysis of data for these areas.

## EXAMPLES- STANDARD ERROR CALCULATIONS

We will present some examples based on 2001 to demonstrate the use of the formulas.

### Example 1 - Calculating the Standard Error from the Confidence Interval - Direct

The estimated number of males, never married is 8,085 from summary table P031 in Calvert County, Maryland. The lower bound is 7,427 and the upper bound is 8,743.

$$\text{Standard Error} = (\text{upper bound} - \text{estimate}) / 1.65 = (\text{estimate} - \text{lower bound}) / 1.65$$

Calculating the standard error using the upper bound we have:

$$SE(8,085) = (8,743 - 8,085) / 1.65 = 399.$$

### Example 2 - Calculating the Standard Error of a Sum - Direct

We are interested in the number of people who have never been married. From summary table P031 we have the number of males, never married is 8,085 with an upper bound of 8,743; and the number of females, never married is 6,807 with an upper bound of 7,399.

So the estimated number of people who have never been married is  $8,085 + 6,807 = 14,892$ . To calculate the standard error of this sum, we need the standard errors of the two estimates in the sum. We have the standard error for the number of males never married from example 1 as 399. The standard error for the number of females never married is calculated using the upper bound:

$$SE(6,807) = (7,399 - 6,807) / 1.65 = 359.$$

So using the formula for the standard error of a sum or difference we have:

$$SE(14,892) = \sqrt{399^2 + 359^2} = 537.$$

Caution: This method, however, will underestimate (overestimate) the standard error if the two items in a sum are highly positively (negatively) correlated or if the two items in a difference are highly negatively (positively) correlated.

To calculate the lower and upper bounds of the 90 percent confidence interval around 14,892 using the standard error, simply multiply 537 by 1.65, then add and subtract the product from 14,892. Thus the 90 percent confidence interval for this estimate is  $[14,892 - 1.65(537)]$  to  $[14,892 + 1.65(537)]$  or 14,006 to 15,778.

### Example 3 - Calculating the Standard Error of a Percent - Direct

We are interested in the percentage of females who have never been married to the number of people who have never been married. The number of females, never married is 6,807 and the number of people who have never been married is 14,892. To calculate the standard error of this sum, we need the standard errors of the two estimates in the sum. We have the standard error for the number of females never married from example 2 as 359 and the standard error for the number of people never married calculated from example 2 as 537.

$$\text{The estimate is } (6,807 / 14,892) * 100 = 45.7\%$$

So using the formula for the standard error of a ratio we have:

$$SE(45.7\%) = 100\% \times \frac{1}{14,892} \sqrt{359^2 - 0.457^2 \times 537^2} = 1.8\%.$$

To calculate the lower and upper bounds of the 90 percent confidence interval around 45.7 using the standard error, simply multiply 1.8 by 1.65, then add and subtract the product from 45.7. Thus the 90 percent confidence interval for this estimate is  $[45.7 - 1.65(1.8)]$  to  $[45.7 + 1.65(1.8)]$  or 42.7% to 48.7%.

#### Example 4 - Total Estimate - Generalized Variance

The estimated number of males, never married is 99,867, and females, never married is 86,150 from summary table P031 in Pima County, AZ, but we are interested in the total number of people who have never been married. So the estimate of never married people is  $99,867 + 86,150 = 186,017$ . To determine the basic standard error, we use the formula below Table A-2001. In this formula  $\hat{Y}$  is our estimate of 186,017 and N is determined from summary table P001 for Pima County to be 841,014.

$$\text{BasicSE}(186,017) = \sqrt{\frac{95}{5} * 186,017 * \left(1 - \frac{186,017}{841,014}\right)} = 1,659.$$

The design factor (from Table C-2001) for “Marital Status” for Pima County is 1.3. The approximate standard error estimate for the estimated number of never married people is determined by multiplying the basic standard error 1,659 by the design factor 1.3. This yields an estimated standard error of 2,157. (The level of precision on each calculation is the same as for the estimates.)

To calculate the lower and upper bounds of the 90 percent confidence interval around 186,017 using the final standard error, simply multiply 2,157 by 1.65, then add and subtract the product from 186,017. Thus the 90 percent confidence interval for this estimate is  $[186,017 - 1.65(2,157)]$  to  $[186,017 + 1.65(2,157)]$  or 182,458 to 189,576.

#### Example 5 - “Small” Total Estimate - Generalized Variance

The estimated number of people who used a taxicab to get to work from summary table P047 in Hampden County, MA is 48. Since this estimate is below the small estimate cutoff for Hampden County of 80, we use a basic standard error of 39.

The design factor (from Table C-2001) for “Means of Transportation to Work” for Hampden County is 1.7. The approximate standard error estimate for the estimated number of people who used a taxicab to get to work is determined by multiplying the basic standard error 39 by the design factor 1.7. This yields an estimated standard error of 66. (The level of precision on each calculation is the same as for the estimates.)

To calculate the lower and upper bounds of the 90 percent confidence interval around 48 using the final standard error, simply multiply 66 by 1.65, then add and subtract the product from 48. Thus the 90 percent confidence interval for this estimate is found to be  $[48 - 1.65(66)]$  to  $[48 + 1.65(66)]$  or -61 to 157, but since the lower bound cannot be negative as described in the Limitations section under Confidence Intervals, the lower bound is given a value of 0. So thus the confidence interval is 0 to 157.

#### Example 6 - Proportion or Percentage Estimate - Generalized Variance

The estimated percent of people 25 years or over with a bachelor’s degree or higher in Rockland County, NY is 39.7 from Table 2, Profile of Selected Social Characteristics and

the base of the estimated percentage is 180,381. Using the formula below Table B-2001 to obtain the basic standard error, we calculate:

$$\text{BasicSE}(39.7) = \sqrt{\frac{95}{5 * 180,381} * 39.7 * (100 - 39.7)} = 0.5.$$

The design factor for “Educational Attainment” for Rockland County, NY is 1.4. Multiply 0.5 by the design factor 1.4 to approximate the ACS standard error estimate. The standard error estimate is found to be 0.7.

To calculate the lower and upper bounds of the 90 percent confidence interval around 39.7 percent using the final standard error, simply multiply 0.7 by 1.65, then add and subtract the product from 39.7. Thus the 90 percent confidence interval for this estimated percentage is [39.7 - 1.65(0.7)] to [39.7 + 1.65(0.7)] or 38.5 to 40.9.

#### Example 7 - Median Estimate - Generalized Variance

The estimated median age for males is 32.3 from summary table P006 for Franklin County, OH. To determine the standard error, we use the formula given in the a & b Parameter Method section. The parameters a and b (from Table E-2001) for “Median Age by Sex” for Franklin County are: 10.720147 and -0.811279, respectively. In this formula, N (the total number of males) is determined from summary table P004 for Franklin County to be 510,700.

$$\text{SE}(32.3) = \sqrt{10.720147 - 0.811279 * \text{LOG}(510,700)} = 0.2.$$

To calculate the lower and upper bounds of the 90 percent confidence interval around 32.3 using the standard error, simply multiply 0.2 by 1.65, then add and subtract the product from 32.3. Thus the 90 percent confidence interval for this estimate is [32.3 - 1.65(0.2)] to [32.3 + 1.65(0.2)] or 32.0 to 32.6.

#### Example 8 - Ratio Estimate - Generalized Variance

The estimated average household size is 2.31 from summary table P009 for San Francisco County, CA. To determine the standard error, we use the formula given in the a & b Parameter Method section. The parameters a and b (from Table E-2001) for “Average Household Size” for San Francisco County are: 0.011787 and -0.000912, respectively. In this formula, N (the number of households) is determined from summary table P007 for San Francisco County to be 325,147.

$$SE(2.31) = \sqrt{0.011787 - 0.000912 * \text{LOG}(325,147)} = 0.01.$$

To calculate the lower and upper bounds of the 90 percent confidence interval around 2.31 using the standard error, simply multiply 0.01 by 1.65, then add and subtract the product from 2.31. Thus the 90 percent confidence interval for this estimate is [2.31 - 1.65(0.01)] to [2.31 + 1.65(0.01)] or 2.29 to 2.33.

#### Example 9 - Aggregate Estimate - Generalized Variance

The estimated aggregate household income in 2001 inflation adjusted dollars is 14,958,103,055 from summary table P071 for Multnomah County, OR. To determine the standard error, we use the formula given in the a, b, & c Parameter Method section. The parameters a, b, and c (from Table D-2001) for “Aggregate Household Income” for Multnomah County are: 1,521; 2,344,821.074810; and -0.000030; respectively.

$$SE(14,958,103,055) =$$

$$\sqrt{1,521 + 2,344,821.074810 * 14,958,103,055 - 0.000030 * 14,958,103,055^2}$$

$$= 168,409,411.$$

To calculate the lower and upper bounds of the 90 percent confidence interval around 14,958,103,055 using the standard error, simply multiply 168,409,411 by 1.65, then add and subtract the product from 14,958,103,055. Thus the 90 percent confidence interval for this estimate is [14,958,103,055 - 1.65(168,409,411)] to [14,958,103,055 + 1.65(168,409,411)] or 14,680,227,527 to 15,235,978,583.

- 1 To get a better approximation of the standard error of an estimated total use the formula below.

$$SE(\hat{Y}) = \sqrt{\frac{95}{5} \hat{Y} \left(1 - \frac{\hat{Y}}{N}\right)}$$

N = Size of geographic area

$\hat{Y}$  = Estimate of characteristic total

- 2 The population estimate of the tabulation area if the estimate is a person characteristic, or the estimate of housing units in the tabulation area if the estimate is a housing or family characteristic.

**Table B-2001. Unadjusted Standard Error in Percentage Points for Estimated Percentages**

[Based on a 5 percent simple random sample.]
