Vol. 28

Occupational Radiation Exposure at Commercial Nuclear Power Reactors and Other Facilities 2006

Thirty-Ninth Annual Report

AVAILABILITY OF REFERENCE MATERIALS IN NRC PUBLICATIONS

NRC Reference Material

As of November 1999, you may electronically access NUREG-series publications and other NRC records at NRC's Public Electronic Reading Room at www.nrc.gov/NRC/ADAMS/index.html. Publicly released records include, to name a few, NUREG-series publications; *Federal Register* notices; applicant, licensee, and vendor documents and correspondence; NRC correspondence and internal memoranda; bulletins and information notices; inspection and investigative reports; licensee event reports; and Commission papers and their attachments.

NRC publications in the NUREG series, NRC regulations, and *Title 10, Energy*, in the Code of *Federal Regulations* may also be purchased from one of these two sources.

1. The Superintendent of Documents
U.S. Government Printing Office
P. O. Box 37082
Washington, DC 20402-9328
www.access.gpo.gov/su-docs
202-512-1800
2. The National Technical Information Service
Springfield, VA 22161-0002
www.ntis.gov
1-800-533-6847 or, locally, 703-805-6000

A single copy of each NRC draft report for comment is available free, to the extent of supply, upon written request as follows:

Address: Office of the Chief Information Officer,
Reproduction and Distribution
Services Section
U.S. Nuclear Regulatory Commission
Washington, DC 20555-0001
E-mail: DISTRIBUTION@nrc.gov
Facsimile: 301-415-2289

Some publications in the NUREG series that are posted at NRC's Web site address www.nrc.gov/NRC/NUREGS/indexnum.html are updated periodically and may differ from the last printed version. Although references to material found on a Web site bear the date the material was accessed, the material available on the date cited may subsequently be removed from the site.

Non-NRC Reference Material

Documents available from public and special technical libraries include all open literature items, such as books, journal articles, and transactions, *Federal Register* notices, Federal and State legislation, and congressional reports. Such documents as theses, dissertations, foreign reports and translations, and non-NRC conference proceedings may be purchased from their sponsoring organization.

Copies of industry codes and standards used in a substantive manner in the NRC regulatory process are maintained at—

The NRC Technical Library
Two White Flint North
11545 Rockville Pike
Rockville, MD 20852-2738

These standards are available in the library for reference use by the public. Codes and standards are usually copyrighted and may be purchased from the originating organization or, if they are American National Standards, from—

American National Standards Institute
11 West 42nd Street
New York, NY 10036-8002
www.ansi.org
212-642-4900

The NUREG series comprises (1) technical and administrative reports and books prepared by the staff (NUREG-XXXX) or agency contractors (NUREG/CR-XXXX), (2) proceedings of conferences (NUREG/CP-XXXX), (3) reports resulting from international agreements (NUREG/IA-XXXX), (4) brochures (NUREG/BR-XXXX), and (5) compilations of legal decisions and orders of the Commission and Atomic and Safety Licensing Boards and of Directors' decisions under Section 2.206 of NRC's regulations (NUREG-0750).

ABSTRACT

This report summarizes the occupational exposure data that are maintained in the U.S. Nuclear Regulatory Commission's (NRC's) Radiation Exposure Information and Reporting System (REIRS). The bulk of the information contained in the report was compiled from the 2006 annual reports submitted by five of the seven categories¹ of NRC licensees subject to the reporting requirements of 10 CFR 20.2206. The annual reports submitted by these licensees consist of radiation exposure records for each monitored individual. These records are analyzed for trends and presented in this report in terms of collective dose and the distribution of dose among the monitored individuals. Because there are no geologic repositories for high-level waste currently licensed, and no low-level waste disposal facilities in operation, only five categories will be considered in this report.

Annual reports for 2006 were received from a total of **199** NRC licensees, of which **104** were commercial operators of nuclear power reactors. Compilations of the reports submitted by the 199 licensees indicated that **127,074** individuals were monitored, **64,743** of whom received a measurable dose (Table 3.1). The collective dose incurred by these individuals was **12,846** person-rem, which represents a **7% decrease** from the 2005 value. The number of workers receiving a measurable dose also decreased, resulting in an average measurable dose of **0.20** rem for 2006. The average measurable dose is defined as the total effective dose equivalent (TEDE) divided by the number of workers receiving a measurable dose.² The figures for commercial reactors have been adjusted to account for transient reactor workers.

In calendar year 2006, the annual collective dose per reactor for light water reactor (LWR) licensees was **106** person-rem. This represents a **4% decrease** from the value reported for 2005 (110). The annual collective dose per reactor for boiling water reactors (BWRs) was **143** person-rem, and, for pressurized water reactors (PWRs), it was **87** person-rem.

Analyses of transient worker data indicate that **27,799** individuals completed work assignments at two or more licensees during the monitoring year. The dose distributions are adjusted each year to account for the duplicate reporting of transient workers by multiple licensees. In 2006, the average measurable dose per worker for all licensees calculated from reported data was **0.15** rem. The corrected dose distribution resulted in an average measurable dose per worker for all licensees of **0.20** rem.

¹Commercial nuclear power reactors; industrial radiographers; fuel processors (including uranium enrichment), fabricators, and reprocessors; manufacturers and distributors of by-product material; independent spent fuel storage installations; facilities for land disposal of low-level waste; and geologic repositories for high-level waste. There are currently no NRC licensees involved in low-level waste disposal or geologic repositories for high-level waste.

²The number of workers with measurable dose includes any individual with a dose greater than zero rem and does not include doses reported as "not detectable."

EDITOR'S NOTE

Mr. Charles Hinson assisted in the preparation of this NUREG, serving as technical reviewer. The U.S. Nuclear Regulatory Commission welcomes responses from readers.

PREFACE

A number of U.S. Nuclear Regulatory Commission (NRC) licensees have inquired as to how the occupational radiation exposure data that are compiled from the individual exposure reports required by § 20.2206 are used by the NRC staff. In combination with other sources of information, the principal uses of the data are to provide facts regarding routine occupational exposures to radiation and radioactive material that occur in connection with certain NRC-licensed activities. These facts, as indicated below, are used by the NRC staff:

1. The data permit evaluation of trends, both favorable and unfavorable, from the viewpoint of the effectiveness of overall NRC/licensee radiation protection and as low as reasonably achievable (ALARA) efforts by licensees.
2. The external dose data assist in the evaluation of the radiological risk associated with certain categories of NRC-licensed activities and are used for comparative analyses of radiation protection performance: U.S./foreign, boiling water reactors/pressurized water reactors (BWRs/PWRs), civilian/military, facility/facility, nuclear industry/other industries, etc.
3. The data are used as one of the metrics of the NRC's Reactor Oversight Program to evaluate the effectiveness of the licensee's ALARA program and also for inspection planning purposes.
4. The data provide for the monitoring of transient workers who may affect dose distribution statistics through multiple counting.
5. The data help provide facts for evaluating the adequacy of the current risk limitation system (e.g., Are individual lifetime dose limits, worker population collective dose limits, and requirements for optimization needed?).
6. The data permit comparisons of occupational radiation risks with potential public risks when action for additional protection of the public involves worker exposures.
7. The data are used in the establishment of priorities for the utilization of NRC health physics resources: research, standards development, and regulatory program development.
8. The data provide facts for answering congressional and administration inquiries and for responding to questions raised by the public.
9. The data are used to provide radiation exposure histories to individuals who were exposed to radiation at NRC-licensed facilities.
10. The data provide information that may be used in the planning of epidemiological studies.

FOREWORD

Through this annual report, the U.S. Nuclear Regulatory Commission (NRC) supports openness in our regulatory process by providing the public with accurate and timely information about the safety performance of the NRC's licensees. Toward that end, NUREG-0713, Volume 28, summarizes the 2006 occupational radiation exposure data maintained in NRC's Radiation Exposure Information and Reporting System (REIRS) database. Seven categories of NRC licensees are required to report annually individual exposure in accordance with Title 10, Section 20.2206, of the Code of Federal Regulations (10 CFR 20.2206 Reports of Individual Monitoring). Specifically, these categories include commercial nuclear power plants; industrial radiographers; fuel processors (including uranium enrichment facilities), fabricators, and reprocessors; manufacturers and distributors of by-product material; independent spent fuel storage installations; facilities for land disposal of low-level waste; and geologic repositories for high-level waste. Because the NRC has not yet licensed any geologic repositories for high-level waste, and no NRC-licensed, low-level waste disposal facilities are currently in operation, this report considers only the first five categories of NRC licensees. As such, this report reflects the occupational radiation exposure data that the NRC received from 199 licensees, of which 104 were commercial operators of nuclear power reactors.

The data submitted by licensees consist of radiation exposure records for each monitored individual. In 2006, 127,074 individuals were monitored, and 64,743 received a measurable dose. This report analyzes and presents these records in terms of collective dose and the distribution of dose among the monitored individuals. During 2006, these individuals incurred a collective dose of 12,846 person-rem, which represents a 7% decrease from the 2005 value of 13,840 person-rem. The average measurable dose decreased from 0.21 rem in 2005 to 0.20 rem in 2006. The average measurable dose is the total collective dose divided by the number of workers receiving a measurable dose. This value can be compared to the 0.30 rem that the average person in the United States receives annually from natural background radiation. Worldwide annual exposures to natural radiation are generally expected to be in the range of 0.1 rem to 1.0 rem, with 0.24 rem being the current average worldwide value.

This annual report is useful in evaluating trends in occupational radiation exposure to assess the effectiveness of licensees' radiation protection programs to maintain exposures as low as reasonably achievable (ALARA). For example, the NRC staff uses the data presented in this report as one of the metrics of the NRC's Reactor Oversight Program to evaluate the effectiveness of licensees' ALARA programs.

Section 1

INTRODUCTION

1.1 BACKGROUND

One of the basic purposes of the Atomic Energy Act and the implementing regulations in Title 10, Code of Federal Regulations (CFR), Chapter I, Part 20, is to protect the health and safety of the public, including the employees of the licensees conducting operations under those regulations. Among the regulations designed to ensure that the standards for protection against radiation set out in 10 CFR 20 are met is a requirement that licensees provide individuals likely to be exposed to radiation with devices to monitor their exposures. Each licensee is also required to maintain indefinitely records of the results of such monitoring. However, there was no initial provision that these records or any summary of them be transmitted to a central location where the data could be retrieved and analyzed.

On November 4, 1968, the U.S. Atomic Energy Commission (AEC) published an amendment to 10 CFR 20 requiring the reporting of certain occupational radiation exposure information to a central repository at AEC Headquarters. This information was required of the four categories³ of AEC licensees that were considered to involve the greatest potential for significant occupational doses and of AEC facilities and contractors exempt from licensing. A procedure was established whereby the appropriate occupational exposure data were extracted from these reports and entered into the AEC's Radiation Exposure Information and Reporting System (REIRS), a computer system that was maintained at the Oak Ridge

National Laboratory Computer Technology Center in Oak Ridge, Tennessee, until May 1990. At that time, the data were transferred to a database management system and are now maintained at the Oak Ridge Institute for Science and Energy, which is managed by Oak Ridge Associated Universities. The computerization of these data ensures that they are kept indefinitely and facilitates their retrieval and analysis. The data maintained in REIRS have been summarized and published in a report every year since 1969. Annual reports for each of the years 1969 through 1973 presented the data reported by both AEC licensees and contractors and were published in six documents designated as WASH-1350-R1 through WASH-1350-R6.

In January 1975, with the separation of the AEC into the Energy Research and Development Administration (ERDA) and the U.S. Nuclear Regulatory Commission (NRC), each agency assumed responsibility for collecting and maintaining occupational radiation exposure information reported by the facilities under its jurisdiction. The annual reports published by the NRC on occupational exposure for calendar year 1974 and subsequent years do not contain information pertaining to ERDA facilities or contractors. Comparable information for facilities and contractors under ERDA, now the U.S. Department of Energy (DOE), is collected and published by DOE's Office of Corporate Safety Analysis, a division of Health, Safety and Security, in Germantown, Maryland.

³Commercial nuclear power reactors; industrial radiographers; fuel processors (including uranium enrichment as of 1997), fabricators, and reprocessors; and manufacturers and distributors of specified quantities of by-product material.

In 1982 and 1983, Paragraph 20.408(a) of Title 10 of the CFR was amended to require three additional categories of NRC licensees to submit annual statistical exposure reports and individual termination exposure reports. The categories were: (1) geologic repositories for high-level radioactive waste, (2) independent spent fuel storage installations, and (3) facilities for the land disposal of low-level radioactive waste. This document presents the exposure information that was reported by NRC licensees representing two of these categories, since there are no geologic repositories for high-level waste currently licensed.

This report and each of the predecessors summarize information reported for both the current year and previous years. More licensee-specific data for previous years, such as the annual reports submitted by each commercial power reactor pursuant to 10 CFR 20.407 and 20.2206 (after 1993) and their technical specifications (prior to Volume 20 of this report), may be found in those documents listed on the inside of the front cover of this report for the specific year desired. Additional operating data and statistics for each power reactor for the years 1973 through 1982 may be found in a series of reports, Nuclear Power Plant Operating Experience [Refs. 1–9].

These documents are available for viewing at all NRC public document rooms, as well as on the NRC public Web site (www.nrc.gov), or they may be purchased from the National Technical Information Service, as shown in the References section.

In May of 1991, 10 CFR 20 “*Standards for Protection Against Radiation; Final Rule*” was revised. The revision redefined the radiation monitoring and reporting requirements of NRC licensees. Instead of submitting summary annual reports (§ 20.407) and termination reports (§ 20.408), licensees are now required to submit an annual report of the dose received by each monitored worker (§ 20.2206). Licensees were required to implement the new requirements no later than January 1994.

Recommendations for further analysis or for different presentation of information are welcome.

1.2 RADIATION EXPOSURE INFORMATION ON THE INTERNET

In May 1995, the NRC began pursuing the dissemination of radiation exposure information via a Web site on the Internet. This site allows interested parties with the appropriate equipment to access the data electronically rather than through the published NUREG-0713 document. A Web site was created for radiation exposure and linked into the main NRC Web page. The Web site contains up-to-date information on radiation exposure, as well as information and guidance on reporting radiation exposure information to the NRC. Interested parties may read the documents online or download information to their systems for further analysis. Software, such as the Radiation Exposure Monitoring and Information Transmittal System, a software application designed to maintain licensee exposure records, and REIRView, a software package designed to validate a licensee's annual data submittal, are also available for downloading via the Web site. There are also links to other Web sites dealing with the topics of radiation and health physics. Individuals and organizations may also submit requests for dose records contained in REIRS on this Web site.

The NRC intends to continue pursuing the dissemination of radiation exposure information via the Web and will focus more resources on the electronic distribution of information rather than the publication of hard-copy reports.

The main Web address for the NRC is:

<http://www.nrc.gov>

The NRC radiation exposure information Web URL is:

<http://www.reirs.com>

Comments on this report or the NRC's radiation exposure Web page should be directed to:

Section 2

LIMITATIONS OF THE DATA

All of the figures compiled in this report relating to exposures and doses are based on the results and interpretations of the readings of various types of personnel-monitoring devices employed by each licensee. This information, obtained from routine personnel-monitoring programs, is sufficient to characterize the radiation exposure incident to individuals' work and is used in evaluating the radiation protection program.

Monitoring requirements are specified in 10 CFR § 20.1502, which requires licensees to monitor individuals who receive or are likely to receive a dose in a year in excess of 10% of the applicable limits. For most adults, the annual limit for the whole body is 5 rem, so 0.5 rem per year is the level above which monitoring is required. Separate dose limits have been established for minors and declared pregnant workers. Monitoring is also required for any individual entering a high or very high radiation area. Depending on the administrative policy of each licensee, persons such as visitors and clerical workers may also be provided with monitoring devices although the probability of their being exposed to measurable levels of radiation is extremely small. Licensees must report the dose records of those individuals for whom monitoring is required. Many licensees elect to report the doses for every individual for whom they provided monitoring. This practice increases the number of individuals that are considered radiation workers.

In an effort to account for this increase, the number of individuals reported as having "no measurable exposure"⁴ has been subtracted from the total number of individuals monitored in order to calculate an average dose per individual receiving a measurable dose, as well as the average dose per monitored individual (for example, see Table 3.1).

The average dose per individual, as well as the dose distributions shown for groups of licensees, also can be affected by the multiple reporting of individuals who were monitored by two or more licensees during the year. Licensees are only required to report the doses received by individuals at their licensed facilities. A dose distribution for a single licensee does not consider that some of the individuals may have received doses at other facilities. When the data are summed to determine the total number of individuals monitored by a group of licensees, individuals may be counted more than once if they have worked at more than one facility during the calendar year. These occurrences can also affect the distribution of doses because individuals may be counted multiple times in the lower dose ranges rather than one time in the higher range corresponding to the actual accumulated dose for the year (the sum of an individual's dose accrued at all facilities). This source of error has the greatest potential impact on the data reported by power reactor facilities since they employ many short-term workers. Section 5 contains an analysis that corrects for individuals' being counted more than once.

⁴The number of workers with measurable dose includes any individual with a total effective dose equivalent greater than zero rem. Workers reported with zero dose, or no detectable dose, are included in the number of workers with no measurable exposure.

Another fact that should be kept in mind when examining the annual statistical data is that all of the personnel included in the report may not have been monitored throughout the entire year. Many licensees, such as radiography firms and nuclear power facilities, may monitor numerous individuals for periods much less than a year. The average doses calculated from these data, therefore, are less than the average dose that an individual involved in that activity for the full year would receive.

Considerable attention should be paid when referencing the collective totals presented in this report. The differences between the totals presented for all licensees that reported versus only those licensees that are required to report should be noted. Likewise, one should distinguish between the doses attributed to the pressurized water reactors (PWRs) and the doses attributed to boiling water reactors (BWRs). The totals may be inclusive or exclusive of those licensees that were in commercial operation for less than one full year. These parameters vary throughout the tables and appendices of this report. The apparent discrepancies among the various tables are a necessary side effect of this endeavor.

The data contained in this report are subject to change because licensees may submit corrections or additions to data for previous years. For the 2006 report, data for prior years may have been updated to account for these corrections and additions. Users should be alert to these changes.

It should again be pointed out that this report contains information reported by NRC licensees and some Agreement State⁵ licensees who also have reported to the NRC. Since the NRC licenses all commercial nuclear power reactors, fuel processors and fabricators, and independent spent fuel storage facilities, information shown for these categories reflects all relevant activity in the United States. This is not the case, however, for the remaining categories of industrial radiography, manufacturing and distribution of specified quantities of by-product material, and low-level waste disposal. Companies that conduct these types of activities in Agreement States are licensed by the state and are not required to submit occupational exposure reports to the NRC. More than three times as many facilities are regulated by Agreement States than are licensed by the NRC. In addition, this report does not include compilations of nonoccupational exposure, such as exposure due to medical X-rays, fluoroscopy, and accelerators, received by patients.

All dose equivalent values in this report are given in units of rem in accordance with the general provisions for records, 10 CFR 20.2101(a). In order to convert rem into the International System of Units (SI) unit of sieverts (Sv), readers should divide the value in rem by 100. Therefore, 1 rem = 0.01 Sv. In order to convert rem into millisieverts (mSv), readers should multiply the value in rem by 10. Therefore, 1 rem = 10 mSv.

⁵Agreement states are states that have entered into an agreement with the NRC which allows each state to license organizations using radioactive materials for certain purposes. Currently, there are 34 Agreement States. (Minnesota became the 34th Agreement State on March 31, 2006).

Section 3

ANNUAL PERSONNEL MONITORING REPORTS - 10 CFR 20.2206

3.1 DEFINITION OF TERMS AND SOURCES OF DATA

3.1.1 Statistical Summary Reports

The total effective dose equivalent (TEDE) is summed per individual and tabulated into the appropriate dose range to generate the dose distribution for each licensee. The total collective dose is more accurate using this method because the licensee reported the dose to each individual, and the total collective dose was calculated from the sum of these doses and not statistically derived from the dose distribution (see Section 3.1.4). The TEDE includes the dose contribution from the committed effective dose equivalent (CEDE) for those workers who had intakes that required monitoring and reporting of internal dose.

3.1.2 Number of Monitored Workers

The number of monitored workers refers to the total number of workers that the NRC licensees (who are covered by 10 CFR 20.1502) reported as being monitored for exposure to external and internal radiation during the year. This number includes all workers for whom monitoring is required and may include visitors, service representatives, contract workers, clerical workers, and any other workers for whom the licensee determines that monitoring devices should be provided.

For licenses submitting under 10 CFR 20.2206, the total number of workers was determined from the number of unique personal identification numbers submitted per licensee. Uniqueness is defined by the combination of identification number and identification type [Ref. 10].

3.1.3 Number of Workers with Measurable Dose

The number of workers with measurable dose includes any individual with a TEDE greater than zero rem. This does not include workers with a TEDE reported as zero, not detectable (ND), or not required to be reported (NR) [Ref. 10].

3.1.4 Collective Dose

The concept of collective dose is used in this report to denote the summation of the TEDE received by all monitored workers and is reported in units of person-rem. Since 10 CFR 20.2206 requires that the TEDE be reported, the collective dose is calculated by summing the TEDE for all monitored workers. The phrase "collective dose" is used throughout this report to mean the collective TEDE, unless otherwise specified.

It should be noted that, prior to the implementation of the revised dose reporting requirements of 10 CFR 20.2206 in 1994, the collective dose was, in some cases, calculated from the dose distributions by summing the products obtained from multiplying the number of workers reported in each of the dose ranges by the midpoint of the corresponding dose range. This assumes that the midpoint of the range is equal to the arithmetic mean of the individual doses in the range. Experience has shown that the actual mean dose of workers reported in each dose range is less than the midpoint of the range. For this reason, the resultant calculated collective doses shown in this report for these licensees may be about 10% higher than the sum of the actual individual

doses. Care should be taken when comparing the actual collective dose calculated for 1994 to 2006 with the collective dose for years prior to 1994 because of this change in methodology. In addition, prior to 1994, doses only included the external whole-body dose with no internal dose contribution. Although the contribution of internal dose to the TEDE is minimal for most licensees, it should be considered when comparing collective doses for 1994 and later with the collective dose for years prior to 1994. One noted exception is for fuel fabrication licensees where the CEDE in some cases contributes the majority of the TEDE (see Section 3.3.5).

3.1.5 Average Individual Dose

The average individual dose is obtained by dividing the collective dose by the total number of workers reported as being monitored. This figure is usually less than the average measurable dose because it includes the number of those workers who received zero or less than measurable doses.

3.1.6 Average Measurable Dose

The average measurable dose is obtained by dividing the collective TEDE by the number of workers who received a measurable dose. This is the average most commonly used in this and other reports when examining trends and comparing doses received by workers in various segments of the nuclear industry because it deletes those workers receiving zero or no detectable dose, many of whom were monitored for convenience or identification purposes.

3.1.7 Number of Licensees Reporting

The number of licensees refers to the NRC licenses issued to use radioactive material for certain activities that would place the licensees in one of the seven⁶ categories that are required to report pursuant to 10 CFR 20.2206. The third column in Table 3.1 shows the number of licensees that have filed such reports during the last 10 years. All nuclear power plants, fuel processors and fabricators, and independent spent fuel storage facilities are required to report occupational exposure to the NRC, whether or not they are in an Agreement State. The other types of Agreement State licensees are not required to submit exposure reports to the NRC.

3.1.8 Collective TEDE Distribution by Dose Range

The United Nations Scientific Committee on the Effects of Atomic Radiation's (UNSCEAR's) 2000 report, entitled *Sources and Effects of Ionizing Radiation, United Nations Scientific Committee on the Effects of Atomic Radiation UNSCEAR 2000 Report to the General Assembly, with scientific annexes, Volume I*, [Ref. 11] recommends the calculation of a parameter, SR (previously referred to as CR or MR), to aid in the examination of the distribution of radiation exposure among workers. SR is defined as the ratio of the annual collective dose incurred by workers whose annual doses exceed a certain dose level to the total annual collective dose. UNSCEAR uses a subscript to denote the specific dose level in millisieverts. Therefore, SR₁₅ is the notation for the annual collective

⁶These categories are commercial nuclear power reactors; industrial radiographers; fuel processors (including uranium enrichment), fabricators, and reprocessors; manufacturers and distributors of by-product material; independent spent fuel storage installations; facilities for land disposal of low-level waste; and geologic repositories for high-level waste. There are currently no NRC licensees involved in low-level waste disposal or geologic repositories for high-level waste.

*These categories consist only of NRC licensees. Agreement State-licensed organizations are not required to report occupational exposure data to the NRC.

**As of 1999, there are no longer any NRC licensees involved in this activity. All low-level waste disposal facilities are now located in Agreement States and no longer report to the NRC.

***This category includes all LWRs in commercial operation for a full year for each of the years indicated. Reactor data have been corrected to account for the multiple counting of transient reactor workers (see Section 5).

dose above 1.5 rem divided by the total annual collective dose. The UNSCEAR 2000 report notes that the 1.5 rem dose level may not be useful where doses are consistently lower than this level, and UNSCEAR recommends that research organizations report SR values lower than 1.5 rem where appropriate. For this reason, the NRC has adopted the policy of calculating and tracking the collective TEDE distribution by dose range at dose levels of 0.10, 0.25, 0.50, 1.0, and 2.0 rem. The collective TEDE distribution by dose range values in this report was calculated by summing the TEDE to each individual who received a TEDE greater than or equal to the specified dose range divided by the total collective TEDE. In addition, the distribution is presented as a percentage rather than as a decimal fraction.

Figures 3.2, 3.3, 3.5, 3.6, 3.9, 3.11, and 3.12 show the collective TEDE distribution by dose range calculated in terms of percentage of the collective dose delivered above the specified dose levels for each of the categories of NRC licensee. Two properties of these graphs help to further reveal the nature of the distribution of dose and dose trends at NRC licensees. The first is that the percentage of dose in the higher dose ranges (i.e., above 0.50 rem) should be relatively small. This would indicate that fewer workers are exposed at these higher levels of individual risk. The second property is the ability to track the shift in dose over time. For a given dose value, a reduction in the percentage from one year to the next indicates that less dose is being received by workers above this value. Therefore, these graphs can be useful in qualifying the dose received in a given year and the trends in doses from year to year.

3.2 ANNUAL TEDE DOSE DISTRIBUTIONS

Table 3.2 provides a statistical compilation of the exposure reports submitted by six categories of licensees (see Section 3.3 for a description of each licensee category). The dose distributions are generated by summing the TEDE for each individual and counting the number of individuals in each dose range. In nearly every licensee category, a large number of workers receive doses that are less than measurable, and very few doses exceed 4 rem. Ninety-three percent of the reported workers with measurable doses (shown in Table 3.2) were monitored by nuclear power facilities in 2006, where they received 86% of the total collective dose.

Under the regulatory limits of 10 CFR 20.1201, annual TEDE in excess of 5 rem for occupationally exposed adults is, by definition, an exposure in excess of regulatory limits (see Section 6).

Table 3.3 gives a summary of the annual exposures reported to the NRC by certain categories of NRC licensees as required by 10 CFR 20.2206. Table 3.3 shows that approximately 95% of the exposures consistently remained <2 rem between 1968 and 1984. For the past 16 years, the percentage of workers with <2 rem has been greater than 99%. The number of workers receiving an annual exposure in excess of 5 rem has been <0.01% since 1985. No individual monitored at any of the six NRC licensee categories included in this report received a dose above the 5 rem annual TEDE limit during the past 3 years (see Section 6).

GRAND TOTALS	89,323	51,571	19,370	10,025	3,074	1,155	908	87	18	12			175,543	86,220	12,846,036	

*Dose values exactly equal to the values separating ranges are reported in the next higher range.

**There are no NRC licensees currently involved in this activity. All facilities are now located in Agreement States.

***This category includes fabrication, processing, and uranium enrichment plants (see Section 3.3.5).

****This category includes all reactors in commercial operation for a full year during 2006. Although Brown's Ferry 1 was placed on Administrative Hold in 1985, it remains in the count of operating reactors. These values have not been adjusted for the multiple counting of transient reactor workers (see Section 5).

2006	175,540	126,195	99.8% (204)	100% (0)	0

*Licensees required to submit radiation exposure reports to the NRC under 10 CFR 20.2206.

**This column lists the actual number of persons who may have been counted more than once because they worked at more than one facility during the calendar year (see Section 5).

***Data for 1977–2006 are based on the distribution of individual doses after adjusting for the multiple counting of transient reactor workers (see Section 5). The number of people exceeding both 2 and 5 rem are shown in parentheses from 1985–2006.

3.3 SUMMARY OF OCCUPATIONAL EXPOSURE DATA BY LICENSE CATEGORY

3.3.1 Industrial Radiography Licenses, Single and Multiple Locations

Industrial Radiography licenses are issued to allow the use of sealed radioactive materials, usually in exposure devices or “cameras,” that primarily emit gamma rays for nondestructive testing of pipeline weld joints, steel structures, boilers, aircraft and ship parts, and other high-stress alloy parts. Some firms are licensed to conduct such activities in one location, usually in a permanent facility designed and shielded for radiography; others perform radiography at multiple temporary sites in the field. The radioisotopes most commonly used are cobalt-60 and iridium-192. As shown in Table 3.1, annual reports were received for 69 radiography licensees in 2006. Table 3.4 summarizes the reported data for the two types of Industrial radiography licenses for 2006 and for the previous 2 years for comparison purposes.

The average measurable dose for workers performing radiography at a single location ranged from 12% to 15% of the average measurable dose of workers at multiple location facilities over the past 3 years. This is because it is more difficult for workers to avoid exposure to radiation at temporary sites in the field, where conditions are not optimal and may change daily. To view the contribution that each radiography licensee made to the total collective dose, see Appendix A, which presents a summary of the information reported by each of these licensees in 2006.

High exposures in radiography can be directly attributable to the type and location of the radiography field work. For example, locations such as oil drilling platforms and aerial tanks offer the radiographer little available shielding. In these situations, there may not be an opportunity to use distance as a means of minimizing exposure and achieving doses that are as low as reasonably achievable (ALARA). Although these licensed activities usually result

TABLE 3.4
Annual Exposure Information for Industrial Radiographers
2004–2006

Year	Type of License	Number of Licensees	Number of Monitored Individuals	Workers With Measurable Dose	Collective Dose (person-rem)	Average Measurable Dose (rem)
2004	Single Location	12	146	45	3	0.07
	Multiple Locations	87	3,114	2,785	1,592	0.57
	Total	99	3,260	2,830	1,595	0.56
2005	Single Location	9	55	22	2	0.09
	Multiple Locations	80	2,942	2,588	1,495	0.58
	Total	89	2,997	2,610	1,497	0.57
2006	Single Location	8	122	22	1	0.05
	Multiple Locations	61	2,096	1,807	1,039	0.57
	Total	69	2,218	1,829	1,040	0.57

in average measurable doses that are higher than those received by other licensees, they involve a relatively small number of exposed workers.

Figure 3.1 shows the number of workers with measurable dose per licensee, the total collective dose per licensee, and the average measurable dose per worker for both types of Industrial Radiography facilities from 1973 through 2006. While the number of workers with measurable TEDE per licensee decreased from 2005 to 2006, the average measurable TEDE remained at 0.57 rem. Figures 3.2 and 3.3 show the collective dose distribution by dose range (see Section 3.1.8) for single location and multiple location radiography licensees. These graphs demonstrate that multiple location licensees consistently have individuals receiving doses in the higher dose ranges and routinely have 25% to 35% of the collective dose delivered to individuals above 2 rem. For single location licensees, the percentage of individuals in 4 of the 5 dose ranges increased from the 2005 values. The percentage of the dose accrued to individuals above 2 rem in this category increased in 2006 after a decreasing trend for the past 4 years.

3.3.2 Manufacturing and Distribution Licenses, Type "A" Broad and Limited

Manufacturing and Distribution (M&D) licenses are issued to allow the manufacture and distribution of radionuclides in various forms for a number of diverse purposes. The products are usually distributed to organizations/companies specifically licensed by the NRC or an Agreement State. Type "A" Broad licenses are issued to larger organizations that may use many different radionuclides in many different ways and that have a comprehensive radiation protection program. Some Type "A" Broad license firms are medical suppliers that process, package, or distribute such products as diagnostic test kits; radioactive surgical implants; and tagged radiochemicals for use in medical research, diagnoses, and therapy. The Limited licenses are usually issued to smaller firms requiring a more restrictive license. Limited firms are suppliers of industrial radionuclides and are involved in the processing, encapsulation, packaging, and distribution of the radionuclides that they have purchased in bulk quantities from production reactors and cyclotrons. Major products include gamma radiography sources, cobalt irradiation sources, well-logging sources, sealed sources for gauges and smoke detectors, and radiochemicals for nonmedical research.

FIGURE 3.1. Average Annual Values at Industrial Radiography Facilities 1973–2006

FIGURE 3.2. Collective TEDE Distribution by Dose Range
Industrial Radiographer—Single Location Licensees
2002–2006

FIGURE 3.3. Collective TEDE Distribution by Dose Range
Industrial Radiographer—Multiple Location Licensees
2002–2006

Table 3.5 presents the annual data that were reported by the two types of licensees for 2006 and the previous 2 years. Looking at the information shown separately for the Type "A" Broad and Limited licensees, one can see that the values of collective and average measurable dose generally remain higher for the Type "A" Broad licensees. However, to examine trends in the data presented for this category of licensees, it should be noted that the types and quantities of radionuclides may fluctuate from year to year and even during the year. For this reason, some licensees may report dose data one year and not the next and may be included as a Type "A" Broad licensee one year and a Limited licensee at other times. Because the number of reporting licensees is quite small, these fluctuations may have a significant impact on the values of the parameters. Only two Type "A" Broad licensees reported in 2006.

Figure 3.4 shows the number of workers with measurable dose per licensee, the total collective dose per licensee, and the average

measurable dose per worker for both Type "A" Broad and Limited Manufacturing and Distribution facilities. Although the number of workers with measurable dose per licensee steadily increased between 1999 and 2004 and then dropped in 2005 and 2006, the collective TEDE per licensee has remained relatively level during this same time period. The figures for Type "A" Broad licensees are primarily attributed to Mallinckrodt, Inc., which accounted for 91% of the collective dose for this category of licensee in 2006. Figures 3.5 and 3.6 show the collective dose distribution by dose range (see Section 3.1.8) for Type "A" Broad and Limited Manufacturing and Distribution licensees. These graphs clearly show that, in past years, the Type "A" Broad licensees consistently have individuals receiving dose in the higher dose ranges. However, in 2005 and 2006, the percentages for Limited licensees in each dose range increased significantly and exceeded the values for the Type "A" Broad licensees for doses above 0.50 rem. The average measurable dose for Limited licensees more than doubled compared to the

TABLE 3.5
Annual Exposure Information for Manufacturers and Distributors
2004–2006

Year	Type of License	Number of Licensees	Number of Monitored Individuals	Workers with Measurable Dose	Collective Dose (person-rem)	Average Measurable Dose (rem)
2004	M&D - Type "A" Broad	3	448	339	158	0.47
	M&D - Limited	24	2,052	1,425	189	0.13
	Total	27	2,500	1,764	347	0.20
2005	M&D - Type "A" Broad	2	460	364	190	0.52

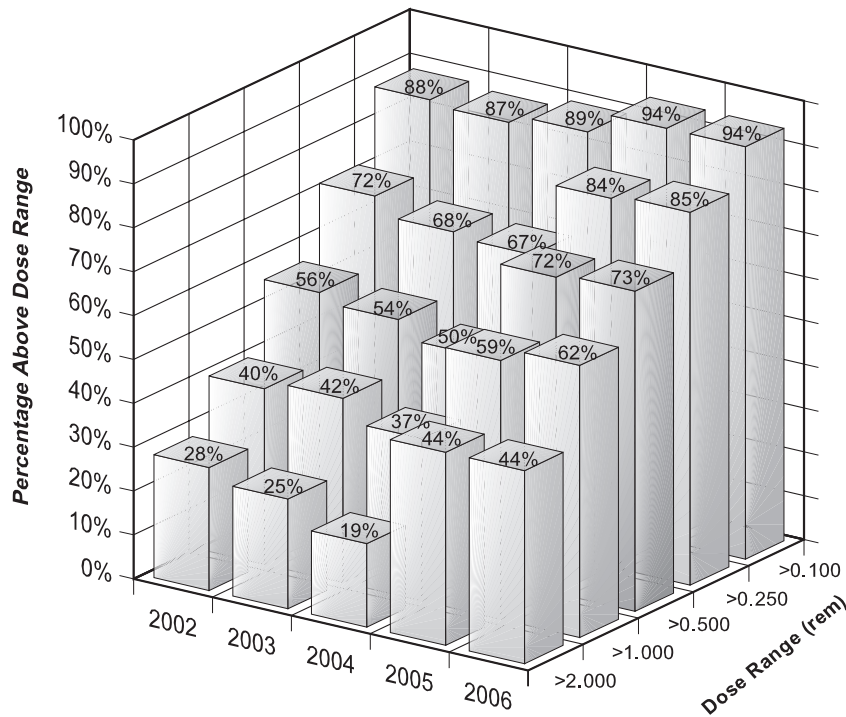

FIGURE 3.6. Collective TEDE Distribution by Dose Range Limited Manufacturing and Distribution Licensees 2002-2006

value for 2004. Most of the increases in this category for 2005 and 2006 were due to IBA Molecular, Inc. (formerly known as Eastern Isotopes). This licensee accounted for 86% of the collective dose in this licensee category in 2006. Appendix A lists the contribution that each of these licensees made toward the total values of the number of workers monitored, number of workers, and collective dose for 2006.

3.3.3 Low-Level Waste Disposal Licenses

Low-Level Waste Disposal licenses are issued to allow the receipt, possession, and disposal of low-level radioactive wastes at a land disposal facility. The licensee has the appropriate facilities to receive wastes from such places as hospitals and laboratories, store them for a short time, and dispose of them in a properly prepared burial ground. The licensees in this category are located in and licensed by Agreement States, which have primary regulatory authority over the licensees' activities. Since 1999, all licensees that have conducted these activities have been located in Agreement States; therefore, there are no licensees reporting radiation exposure data to REIRS. Figure 3.7 shows the number of workers with measurable dose per licensee, the total collective dose per licensee, and the average measurable dose per worker for low-level waste disposal facilities from 1982 through 1998.

3.3.4 Independent Spent Fuel Storage Installation Licenses

Independent Spent Fuel Storage Installation (ISFSI) licenses are issued to allow the possession of power reactor spent fuel and other associated radioactive materials for the purpose of storage of such fuel in an ISFSI. Here, the spent fuel, which has undergone at least 1 year of decay since being used as a source of energy in a power reactor, is provided interim storage, protection, and safeguarding for a limited time, pending its ultimate disposal.

The majority of ISFSI facilities are located on site at commercial power reactors. Since the doses from these ISFSI facilities are usually included with the doses reported to the NRC by the power reactors, the doses from these ISFSI facilities are not reported separately to the NRC. The doses from the two ISFSI licensees that are not associated with power reactors are reported here for 2006. One is the GE Morris facility located in Illinois, and the second is the Trojan ISFSI. The Trojan nuclear power plant is no longer in commercial operation and has been decommissioned and, therefore, no longer reports radiation exposure under a power reactor license. However, the ISFSI facility at Trojan remains in operation and occupational radiation exposure is, therefore, reported under the ISFSI license. Appendix A summarizes the exposure information reported by these licensees. (Note that from 1999 to 2003, the DOE facility in Idaho that stores fuel from Three Mile Island Unit 2 reported in this category.)

Figure 3.8 shows the number of workers with measurable dose per licensee, the total collective dose per licensee, and the average

FIGURE 3.7. Average Annual Values at Low-Level Waste Disposal Facilities 1982-1998

Note: As of 1999, there are no longer any NRC licensees involved in this activity. All low-level waste disposal facilities are now located in Agreement States and no longer report to the NRC.

FIGURE 3.8. Average Annual Values at Independent Spent Fuel Storage Facilities 1982–2006

measurable dose per worker for ISFSI facilities. The large increase in the collective dose per licensee and number of workers per licensee in 1994 was mainly because only one licensee reported separately for 1994 through 1998, rather than the two licensees that reported in prior years. The number of workers with measurable dose and collective TEDE per licensee have decreased between 2001 and 2006. Figure 3.9 shows the collective dose distribution by dose range (see Section 3.1.8) for ISFSI licensees from 2002 to 2006. The percentages for each dose range have generally decreased over the past 5 years, with an increase in the percentage above 0.10 rem and 0.25 rem ranges in 2006.

3.3.5 Fuel Cycle Licenses

Fuel Cycle licenses are issued to allow the processing, enrichment, and fabrication of reactor fuels. In most uranium facilities where light water reactor (LWR) fuels are fabricated, enriched uranium hexafluoride is converted to solid uranium dioxide pellets and inserted into zirconium alloy tubes. The tubes are fabricated into fuel assemblies that are shipped to nuclear power plants. Some facilities also perform chemical operations to recover the uranium from scrap and other off-specification materials prior to disposal of these materials. Starting in 1997, this category also includes the two uranium enrichment facilities at Portsmouth, Ohio, and Paducah, Kentucky. The regulatory oversight

FIGURE 3.9. Collective TEDE Distribution by Dose Range Independent Spent Fuel Storage Licensees 2002–2006

FIGURE 3.10. Average Annual Values at Fuel Cycle Licensees 1973–2006

for these facilities was transferred from DOE to the NRC in 1997. In 2005, a third uranium enrichment facility, the United States Enrichment Corporation (USEC), Inc., was added to this category.

Figure 3.10 shows the number of workers with measurable dose per licensee, the total collective dose per licensee, and the average measurable dose per worker for Fuel Cycle licensees. In addition to the TEDE collective and average measurable dose, the deep dose equivalent (DDE) collective dose and DDE average measurable dose are shown. Both doses are shown since the CEDE is a significant contribution to the TEDE for fuel fabrication facilities.

Figure 3.11 shows the collective dose distribution by dose range (see Section 3.1.8) for fuel cycle licensees from 2002 to 2006. From 2002 to 2005, there was a decrease in the percentage of the collective dose above each dose range, and in 2006, there was an increase in the next three dose ranges above 0.10 rem. Most of the increase in the higher dose ranges is due to Westinghouse Electric Co. at the Commercial Nuclear Fuel Division in South

Carolina, where the collective dose increased by 37% from 2005 to 2006. As shown in Table 3.6, the collective DDE increased by 19%, while the collective CEDE decreased by 8% in 2006.

Appendix A lists each of the licensees reporting in 2006, with the number of workers monitored, the number of workers receiving measurable external doses, and the collective dose for each licensee. Table 3.6 shows that there were nine licensed fuel cycle (fabrication and enrichment) facilities reporting in 2006.

Fuel Cycle Licensees
2002–2006

3.3.6 Light Water Reactor Licenses

LWR licenses are issued to utilities to allow them to use special nuclear material in a reactor that produces heat to generate electricity to be sold to consumers. There are two major types of commercial LWRs in the United States, PWRs and BWRs, each of which uses water as the primary coolant.

Table 3.1 shows the number of licensees, number of monitored individuals, number of workers with measurable dose, total collective dose, and average dose per worker for reactor facilities that were in commercial operation for at least a full year for each of the years 1997 through 2006. The values do not include reactors that have been permanently shut down or reactors that have not been in commercial operation for a full year. The figures for reactors have been adjusted for the multiple counting of transient workers (see Section 5).

The reported dose distribution of workers monitored at each plant site for the year 2006 is presented in alphabetical order by site name in Appendix B.

Figure 3.12 shows the collective dose distribution by dose range (see Section 3.1.8) for reactor licensees from 2002 to 2006. The distribution of collective dose has been fairly constant over the past 5 years, with a slight decrease noted from 2002 to 2006 in each dose range.

More detailed presentations and analyses of the annual exposure information reported by nuclear power facilities can be found in Sections 4 and 5.

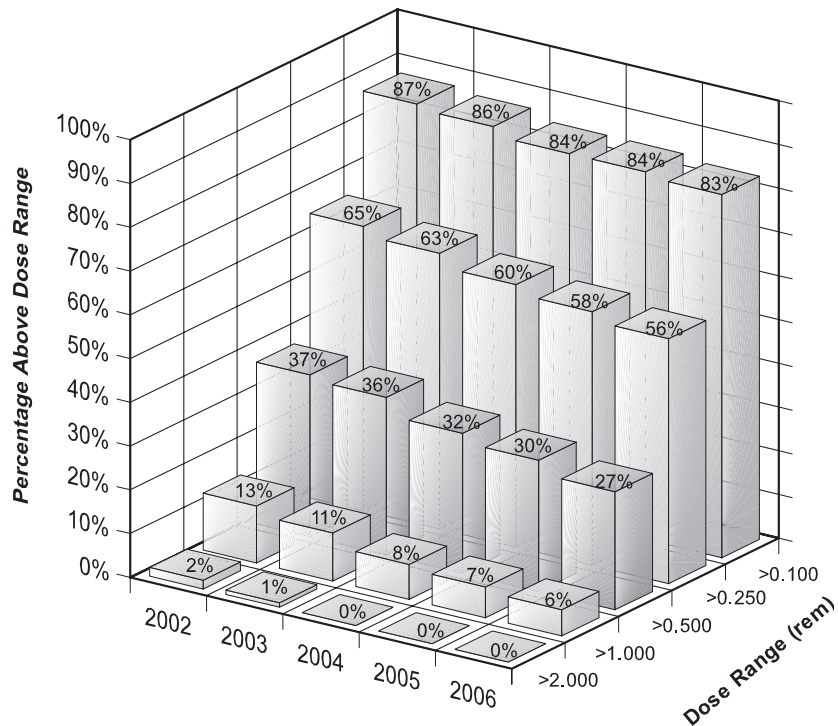

FIGURE 3.12. Collective TEDE Distribution by Dose Range
Reactor Licensees
2002–2006

3.3.7 Other Facilities Reporting to the NRC

For this year’s annual report, a listing has been added to the end of Appendix A that contains the dose distribution from additional facilities that reported occupational radiation exposure to the NRC in 2006. These facilities are not among the seven categories of licensees required to report to the NRC under 10 CFR 20.2206 (see Section 3.1.7) and are not included in the analysis presented in this report. However, these facilities may be of interest to researchers, and since they are not included in any other published reports, they are included here in the interest of completeness. The facility with the largest collective dose for these additional facilities reported under the category of Uranium Hexafluoride (UF6) Production Plants.

3.4 SUMMARY OF INTAKE DATA BY LICENSE CATEGORY

Licensees are required to list for each intake the radionuclide that was taken into the body, pulmonary clearance class, intake mode, and amount of the intake in microcuries. An NRC Form 5 report containing this information is required to be completed and submitted to the NRC under 10 CFR 20.2206. Tables 3.7 and 3.8 summarize the intake data reported to the NRC during 2006. The data are categorized by licensee type and are listed in order of radionuclide and pulmonary clearance class. Table 3.7 lists the intakes where the mode of intake into the body was recorded as ingestion and other means. Table 3.8 lists the intakes where the mode of intake was inhalation from ambient airborne radioactive material in the workplace. The pulmonary clearance class is recorded as F, M, S, D, W, or Y (fast, medium, slow, days, weeks, or years) corresponding to its clearance half-time from the pulmonary region of the lung into the blood and gastrointestinal tract. The amount of material taken into the body is given in microcuries, a

unit of measure of the quantity of radioactive material. For each category of licensee, the maximum number of intake records and the maximum intake are highlighted in the table in bold for ease of reference.

Table 3.9 lists the number of individuals with measurable CEDE, the collective CEDE, and the average measurable CEDE per individual for each licensee category. Fuel fabrication facilities have the majority of internal dose (over 99%) in 2006 and the highest average CEDE per individual. This is due to the worker's exposure to uranium during the processing and fabrication of the uranium fuel.

Table 3.10 shows the distribution of internal dose (CEDE) from 1994 to 2006 for licensees required to report under 10 CFR 20.2206. For the purposes of this table, the definition of a "measurable CEDE" is any reported value greater than zero. As noted above, the vast majority of the internal doses are received by individuals working at fuel fabrication facilities.

*Dose values exactly equal to the values separating ranges are reported in the next higher range.

Section 4

COMMERCIAL LIGHT WATER REACTORS – FURTHER ANALYSIS

4.1 INTRODUCTION

General trends in occupational radiation exposures at nuclear power reactors are best evaluated within the context of other pertinent information. In this chapter, some of the tables and appendices that summarize exposure data also show the type, capacity, amount of electricity generated, and age of the reactor. Exposure data are then presented as a function of these data.

4.2 DEFINITION OF TERMS AND SOURCES OF DATA

4.2.1 Number of Reactors

The number of reactors shown in Tables 4.1, 4.2, and 4.3 is the number of BWRs, PWRs, and LWRs, respectively, that had been in commercial operation for at least 1 full year as of December 31 of each of the indicated years. This is the number of reactors on which the average number of workers with measurable dose and average collective dose per reactor is based. Excluded are reactors that have been in commercial operation for less than 12 months during the first year and reactors that have been permanently defueled. This technique yields conservative values for many of the averages shown in the tables. The date that each reactor was declared to be in commercial operation was taken from Ref. 12.

Three Mile Island (TMI) 2 was included in the compilation of data for commercially operating reactors through 1988, even though the reactor was shut down following the 1979 accident, since TMI 2 was in the process of being defueled and decommissioned during those years.

TMI 2 has not been included in the data analysis since 1988. Data for this reactor, however, will be listed in Appendix B for reference purposes. The dose data presented in Appendix D for TMI include the dose data for Unit 2 prior to 1986.

There were no changes to the count of operating reactors in 2006. The number of operating BWRs remains the same as in 2006 at 35, and the number of operating PWRs remains the same at 69. The dose information for these reactors and for others that are no longer in commercial operation is listed at the end of Appendix B.

4.2.2 Electric Energy Generated

The electric energy generated in megawatt years (MW-yr) each year by each reactor is graphically represented in Appendix D. This number was obtained by dividing the megawatt hours of electricity annually produced by each facility by 8,760, the number of hours in the year, except for leap years, when the number is 8,784 hours. For the years 1973 to 1996, the electricity generated is the gross electricity output of the reactor. For 1997 to 2006, the number reflects the net electricity produced, which is the gross electricity minus the amount the plant uses for operations. This change is the result of a change in NRC power generation reporting requirements. The electricity generated (in MW-yr) that is presented in Tables 4.1, 4.2, and 4.3 is the summation of electricity generated by the number of reactors included in each year. These sums are divided by the number of operating reactors included in each year to yield the average amount of electric energy generated per reactor, which is also shown in Tables 4.1, 4.2, and 4.3.

*This column includes only those reactors that had been in commercial operation for at least one full year as of December 31 of each of the indicated years.

**Figures are not adjusted for the multiple reporting of transient individuals (see Section 5).

***Electricity generated reflects the gross electricity generated for the years 1973–1996. Beginning in 1997, it reflects the net electricity generated.

The number of megawatt hours of electricity produced each year was obtained from Ref. 12.

As shown in Table 4.3, there was a <1% increase in the net electricity generated at LWRs in 2006. Contributors to this increase included Callaway for PWRs and Perry for BWRs. These plants experienced the largest increases in power production (in MW-yr) from 2005 to 2006.

4.2.3 Collective Dose per Megawatt-Year

The number of MW-yr of electricity generated was used in determining the ratio of the average value of the annual collective dose (TEDE) to the number of MW-yr of electricity generated. The ratio was calculated by dividing the total collective dose in person-rem by the electric energy generated in MW-yr and is a measure of the dose incurred by workers at power plants in relation to the electric energy produced. For the years 1973 to 1996, the electricity generated is the gross electricity output of the reactor. For 1997 to 2006, the number reflects the net electricity produced. This ratio, calculated by year for BWRs, PWRs, and LWRs, is presented in Tables 4.1, 4.2, and 4.3. This ratio was also calculated for each reactor site (see Appendix C). The average collective dose per MW-yr for LWRs decreased to a value of 0.12 rem/MW-yr in 2006 from a value of 0.13 rem/MW-yr in 2005 due to a combination of the decrease in the collective dose and an increase in power production.

4.2.4 Average Maximum Dependable Capacity

Average maximum dependable capacity as shown in Tables 4.1, 4.2, and 4.3 was found by dividing the sum of the net maximum dependable capacities of the reactors in megawatts (net MWe) by the number of reactors included each year. The net maximum dependable capacity is defined as the gross electrical output as measured at the output terminals of the turbine generator during the most restrictive seasonal conditions less the normal station service loads. This "capacity" of each plant was found in Ref. 12.

4.2.5 Percent of Maximum Dependable Capacity Achieved

The percent of maximum dependable capacity achieved is shown for all LWRs in Table 4.3. This parameter gives an indication of the overall power generation performance of LWRs as compared to the maximum dependable capacity that could be obtained in a given year. It is calculated by dividing the average electricity generated per reactor by the average maximum dependable capacity for each year.

From 1973 to 1978 this indicator exhibited an increasing trend as a number of new reactors began producing power at higher efficiencies. Following the accident at TMI, reactor operations personnel concentrated on improving safety systems and complying with the new regulations for these systems. During this time period, from 1979 to 1987, the percent of maximum dependable capacity remained around 61%. Following the completion of most of these mandated repairs, reactors increased the percent of maximum dependable capacity from 62% in 1987 to 81% in 1996, a gain of nearly 20% in 10 years. The decrease in maximum dependable capacity from 1996 to 1997 was due to the change from measuring the gross electricity generated to the net electricity generated. The percent of maximum dependable capacity remained unchanged at 90% from 2005 to 2006.

4.3 ANNUAL TEDE DISTRIBUTIONS

Table 4.4 summarizes the distribution of the annual TEDE doses received by workers at all commercial LWRs during each of the years 1977 through 2006. This distribution is the sum of the annual dose distributions reported by each licensed LWR each year. As previously noted, the distribution reported by each LWR site for 2006 is shown in Appendix B. Table 4.4 shows the reported dose distributions corrected for the number of transient workers that were reported by more than one site (see Section 5).

Table 4.4 includes only those reactors in operation for a full year for each year presented in the table. The total collective dose decreased by 4% to a value of 11,021 person-rem in 2006. The PWRs with the largest decreases in the collective dose were Arkansas and St. Lucie. San Onofre experienced the highest increase in collective dose among PWRs. This was due, in part, to the fact that San Onofre 2 and 3 had no refueling outages in the previous year. The BWRs with the largest decreases in the collective dose were Quad Cities and Perry. Although Quad Cities experienced a large drop in collective dose in 2006, Quad Cities had six outages in 2006 to support a steam dryer replacement as part of a planned power uprate. The collective dose for Quad Cities 2 and 3 in 2006 was 559 person-rem. Clinton experienced the highest increase in collective dose among BWRs.

TABLE 4.4
Summary Distribution of Annual Whole-Body Doses at Commercial Light Water Reactors*
1977-2006

*Summary of reports submitted in accordance with 10 CFR 20.407 or 20.2206 by BWRs and PWRs that had been in commercial operation for at least 1 full year as of December 31 of each of the indicated years. Figures shown have been adjusted for the multiple reporting of transient individuals (see Section 5).

**Dose values exactly equal to the values separating ranges are reported in the next higher range.

***The collective dose, when not reported by the licensee, was calculated by the NRC staff using methods described in Section 3.1.4.

4.4 AVERAGE ANNUAL TEDE DOSES

Some of the data presented in Tables 4.1, 4.2, and 4.3 are graphically displayed in Figure 4.1, where it can be seen that the average collective dose and average number of workers per BWR have been higher than those for PWRs since 1974 and that the values of both parameters, in general, continued to rise at both types of facilities until 1983. Between 1983 and 2006, the average collective dose per LWR dropped by 86%. Between 2005 and 2006, the collective dose per reactor for PWRs increased by 10% to 87 person-rem. The collective dose per reactor for BWRs decreased by 16% to 143 person-rem from 2005 to 2006. The overall collective dose per reactor for LWRs decreased by 4% from last year's value to 106 person-rem in 2006. The number of workers with measurable dose per reactor increased to 976 for BWRs and increased to 668 for PWRs in 2006. The overall decreasing trend in average reactor collective doses since 1983 indicates that licensees are continuing to successfully implement ALARA dose reduction features at their facilities.

Figures 4.2 and 4.3 are plots of most of the other information that is given in Tables 4.1, 4.2, and 4.3. Figure 4.2 shows that in 2006 the net electricity generated increased to 89,990 MW-yr while the number of operating reactors

has remained constant for the past 8 years. The value for the total collective dose for all LWRs decreased by 4% from a value of 11,456 person-rem in 2005 to 11,021 person-rem in 2006. Together with the increase in the number of workers with measurable dose, this decline resulted in the average measurable dose per worker decreasing to 0.14 rem in 2006 (when not adjusted for transient workers).

The fluctuations in the parameters for the years following the accident at the TMI plant in 1979 may reflect some of the impact that this incident had on the nuclear power industry. The decrease seen in dose trends since 1983 may be attributable to several factors. Utilities have completed most of the tasks initiated as a result of the lessons learned from the TMI accident, and they are increasing efforts to avoid and reduce exposure. The importance of exposure control and the concept of keeping exposures to ALARA levels are continually being stressed, and most utilities have established programs to collect and share information relative to tasks, techniques, and exposures.

To further assist in the identification of any trends that might exist, Figures 4.4 and 4.5 together display the average and median⁷ values of the collective dose per reactor for BWRs and for PWRs for the years 1973 through 2006.

⁷The median is the value at which 50% of the reactors reported greater collective doses and the other 50% reported smaller collective doses.

The ranges of the values reported each year are shown by the vertical lines with a small bar at each end marking the two extreme values. The rectangles indicate the range of values of the collective dose exhibited by those plants ranked in the 25th through the 75th percentiles. Because the median values usually are not as greatly affected by the extreme values of the collective doses, they do not normally fluctuate as much from year to year as do the average values. The median collective dose for PWRs increased to 74 person-rem in 2006. At BWRs, the median fluctuates more from year to year. The median collective dose decreased from 153 person-rem in 2005 to 130 person-rem in 2006. Figure 4.5 also shows that, in 2006, 50% of the PWRs reported collective doses between 45 and 106 person-rem, while 50% of the BWRs reported collective doses between 97 and 214 person-rem. Nearly every year the median collective dose is less than the average, which indicates that the collective dose for most plants is less than the average collective dose per reactor (the value that is widely quoted).

4.5 THREE-YEAR AVERAGE COLLECTIVE TEDE PER REACTOR

The 3-year average collective dose per reactor is one of the metrics that the NRC uses in the Reactor Oversight Program to evaluate the effectiveness of the licensee's ALARA program. Tables 4.5 and 4.6 list the sites that had been in commercial operation for at least 3 years as of December 31, 2006, and show the values of several parameters for each of the sites. These tables also give averages for the two types of reactors.

Based on the 105 reactor-years of operation accumulated by the 35 BWRs listed, the average 3-year collective TEDE per reactor was found to be 157 person-rem, the average measurable TEDE per worker was 0.16 rem, and the average collective TEDE per MW-yr was 0.18 person-rem per MW-yr. The values for all three parameters decreased from 2005 to 2006.

Based on the 207 reactor-years of operation at the 69 PWRs listed, the average annual collective TEDE per reactor, average measurable TEDE per worker, and average collective TEDE per MW-yr were found to be 79 person-rem, 0.13 rem, and 0.09 person-rem per MW-yr, respectively.

The average 3-year collective TEDE per BWR for 2004 to 2006 is 4% less than the average for 2003 to 2005. The average 3-year collective TEDE per PWR for 2004 to 2006 is 2% less than the average for 2003 to 2005.

4.6 GRAPHICAL REPRESENTATION OF DOSE TRENDS IN APPENDIX D

Each page of Appendix D presents a graph of selected dose performance indicators from 1973 through 2006. The dose and performance indicators illustrate the history of the collective dose per reactor for the site, the rolling 3-year average collective dose per reactor, and the electricity generated at the site. These data are plotted, beginning with each plant's first full year of commercial operation and continuing through 2006. Data for years when a plant was not in commercial operation have been included when available. However, any data reported prior to 1973 are not included. The 3-year average collective dose per reactor data are included because they provide an overall indication of each plant's general trend in collective dose. The 3-year average collective dose per reactor is also one of the metrics used by the NRC in the Reactor Oversight Program to evaluate a plant's ALARA program. This average is determined by summing the collective dose for the current year and the previous 2 years and then dividing this sum by the number of reactors reporting during those years. Depicting dose trends by using a 3-year average reduces the sporadic effects on annual doses of refueling operations (usually an 18- to 24-month cycle) and occasional high dose maintenance activities and provides a more representative depiction of collective dose trends over the life of a plant. The annual average collective dose per reactor for all reactors of the same type is also shown on each graph.

Section 5

TRANSIENT WORKERS AND CAREER DOSES AT NRC-LICENSED FACILITIES

5.1 TERMINATION REPORTS

Under 10 CFR 20, licensees are required to submit NRC Form 5's to the NRC for each individual who is required to be monitored at the end of the monitoring year or upon the individual's termination of employment at the facility. The termination reports submitted in accordance with the old § 20.408, listing the individual's complete dose history during employment at the facility, are no longer required.

However, the Form 5's submitted to the NRC upon an individual's termination of employment serve the same function as the previous requirements with regard to the analysis of transient workers at NRC-licensed facilities. The following analysis examines the workers who had more than one Form 5 dose record at more than one NRC-licensed facility during the monitoring year. These workers are defined as "transient" because they worked at more than one facility during the monitoring year.

The term "monitoring year" is used here in accordance with the definition of a year given in § 20.1003, which defines a year as "the period of time beginning in January used to determine compliance with the provisions of this part. The licensee may change the start date of the monitoring year used to determine compliance provided that the change is made at the beginning of the monitoring/calendar year and that no day is omitted or duplicated in consecutive years."

5.2 TRANSIENT WORKERS AT NRC FACILITIES

Examination of the data reported for workers who began and terminated two or more periods of employment with two or more different facilities within one monitoring year is useful in many ways. For example, the number of transients and the individual doses received by them can be determined from examining these data.

Additionally, the distribution of the doses received by transient workers can be useful in determining the impact that the inclusion of these individuals in each of two or more licensees' annual reports has on the annual summary (as reported in Appendix B) for all nuclear power facilities and all NRC licensees combined (one of the problems mentioned in Section 2). Table 5.1 shows the actual distribution of transient worker doses as determined from the NRC Form 5 termination reports and compares it with the reported distribution of the doses of these workers as they would have appeared in a summation of the annual reports submitted by each of the licensees.

In 2006, over 99% of the transient individuals were reported by nuclear power facilities. For this reason, these data are shown separately in Table 5.1.

TABLE 5.1
Effects of Transient Workers on Annual Statistical Compilations
2006

Corrected Distribution (1-12-3)	61,769	35,194	13,713	8,480	3,370	1,670	1,798	172	20	12						126,198	64,429	12,846	0.20

*Dose values exactly equal to the values separating ranges are reported in the next higher range.

Table 5.1 illustrates the impact that the multiple reporting of these transient individuals had on the summation of the exposure reports for 2006. Because each licensee reports the doses received by workers while monitored by the particular licensee during the year, it is expected that a summation of these reports would result in individuals being counted several times in dose ranges lower than the range in which their total accumulated doses (the sum of the personnel monitoring results incurred at each facility during the year) would actually place them. Thus, while the total collective dose would remain the same, the number of workers, their dose distribution, and average dose would be affected by this multiple reporting. This was found to be true because too few workers were reported in the higher dose ranges. For example, in 2006, Table 5.1 shows that the summation of annual reports for reactor licensees indicated that 2 individuals received doses greater than 2 rem. After accounting for those individuals who were reported more than once, the corrected distribution indicated that there were really 84 transient workers who received doses greater than 2 rem. Correcting for the multiple counting of individuals also has a significant effect on the average measurable dose for these workers. The corrected average measurable dose for transient workers is twice as high as the value calculated by the summation of licensee records. The transient

workers represent 32% of the workforce that receives measurable dose. The correction for the transient workers increases the average measurable dose by a factor of 2 from 0.15 rem to 0.31 rem for the transient workforce for all licensees. It should be noted that this analysis of transient workers does not include workers who may have been exposed at facilities that are not required to report to the NRC's REIRS database (see Section 1), such as Agreement State licensees or DOE facilities.

One purpose of the REIRS database, which tracks occupational radiation exposures at NRC-licensed facilities, is to identify individuals who may have exceeded the occupational radiation exposure limits because of multiple exposures at different facilities throughout the year. The REIRS database stores the radiation exposure information for an individual by his/her unique identification number and identification type [Ref. 10, Section 1.5] and sums the exposure for all facilities during the monitoring year. An individual exceeding the TEDE 5 rem per year regulatory limit would be identified in Table 5.1 in one of the dose ranges >5 rem. In 2006, there were no individuals reported by NRC licensees that exceeded the 5 rem annual TEDE limit.

This page intentionally left blank.

Section 6

EXPOSURES TO PERSONNEL IN EXCESS OF REGULATORY LIMITS

6.1 CONTROL LEVELS

Exposures in excess of regulatory limits are sometimes referred to as “overexposures.” The phrase “exposures in excess of regulatory limits” is preferred to “overexposures” because the latter suggests that a worker has been subjected to an unacceptable biological risk, which may or may not be the case.

The implementation date for the revised 10 CFR 20 was January 1, 1994. Section 10 CFR 20 includes requirements for summing internal and external dose equivalents to yield TEDE and to implement a similar limitation system for organs and tissues (such as the gonads, redbone marrow, bone surfaces, lung, thyroid, and breast). Section 10 CFR 20.1201 limits the TEDE of workers to ionizing radiation from licensed material and other sources of radiation within the licensee’s control. Section 10 CFR 20 no longer contains quarterly exposure limits, but has reporting requirements for planned special exposures (PSEs)⁸. The annual TEDE limit for adult workers is 5 rem.

Sections 10 CFR 20.2202 and 10 CFR 20.2203 require that all licensees submit reports of all occurrences involving personnel radiation exposures that exceed certain control levels, thus, providing for investigations and corrective actions as necessary. Based on the magnitude of the exposure, the occurrence may be placed into one of three categories:

1. Category A
10 CFR 20.2202(a)(1)—a TEDE to any individual of 25 rem or more, an eye dose equivalent of 75 rem or more, or a shallow-dose equivalent to the skin or extremities of 250 rad or more. The Commission must be notified immediately of these events.
2. Category B
10 CFR 20.2202(b)(1)—a TEDE to any individual of 5 rem or more, an eye dose equivalent of 15 rem or more, or a shallow-dose equivalent to the skin or extremities of 50 rem or more in a 24-hour period. The Commission must be notified within 24 hours of these events.

⁸See 10 CFR 20.1206, 20.2204, and Regulatory Guide 8.35 for more information on PSEs and their reporting requirements.

3. Category C
10 CFR 20.2203—In addition to the notification required by § 20.2202 (Category A or B occurrences), each licensee must submit a written report within 30 days after learning of any of the following occurrences:
- a. Any incident for which notification is required by § 20.2202
 - b. Doses that exceed the limits in § 20.1201, § 20.1207, § 20.1208, and § 20.1301 (for adults, minors, the embryo/fetus of a declared pregnant worker, and the public, respectively), or any applicable limit in the license
 - c. Levels of radiation or concentrations of radioactive material that exceed any applicable license limit for restricted areas or that, for unrestricted areas, are in excess of 10 times any applicable limit set forth in this part or in the license (whether or not involving exposure of any individual in excess of the limits in § 20.1301)
 - d. For licensees subject to the provisions of the Environmental Protection Agency's generally applicable environmental radiation standards in 40 CFR 190, levels of radiation or releases of radioactive material in excess of those standards, or of license conditions related to those standards

6.2 LIMITATIONS OF THE DATA

It is important to note that this summary of events includes **only**:

- Occupational radiation exposures in excess of regulatory limits
- Events at NRC-licensed facilities
- Final dose of record assigned to an individual

It **does not** include:

- Medical misadministrations to medical patients
- Exposures in excess of regulatory limits to the general public
- Agreement State-licensed activities or DOE facilities
- Other radiation-related violations, such as high-dose rate areas or effluent limits
- Exposures to dosimeters that, upon evaluation, have been determined to be high dosimeter readings only and are not assigned to an individual as the dose of record by the NRC

Care should be taken when comparing the summary information presented here with other reports and analyses published by the NRC or other agencies. Various reports may include other types of "overexposure" events; therefore, the distinctions should be noted.

The analysis and summary of incidents presented here involving exposures in excess of regulatory limits represent the status of events as of the publication of this report.

Exposure events of this type typically undergo a long review and evaluation process by the licensee, the NRC inspector for the regional office, and NRC Headquarters. Preliminary dose estimates submitted by licensees are often conservatively high and do not represent the final (record) dose assigned for the event. It is, therefore, not uncommon for an exposure in excess of regulatory limits event to be reassessed and the final assigned dose to be categorized as not having been in excess of the regulatory limits. In other cases, the exposure may not be identified until a later date, such as during the next scheduled audit or inspection of the licensee's exposure records.

For these reasons, an attempt is made to keep the exposure events summary presented here current. An event that has been reassessed and determined not to be an exposure in excess of the limits is not included in this report. In addition, events that occurred in prior years are added to the summary in the appropriate year of occurrence. The reader should note that the summary presented here represents a snapshot of the status of events as of the publication date of this report. Previous or future reports may not correlate in the exact number of events because of the review cycle and reassessment of the events.

6.3 SUMMARY OF EXPOSURES IN EXCESS OF REGULATORY LIMITS

Table 6.1 summarizes the occupational exposures in excess of regulatory limits as reported by NRC licensees pursuant to 10 CFR 20.2202 and 10 CFR 20.2203 from 1994 to 2006. Table 6.2 shows the data reported under 10 CFR 20.403 and 10 CFR 20.405 for the period 1985 to 1993. Note that the categorization criteria changed effective with the revision of 10 CFR 20 in 1994.

For the period 1990 to 1993, Table 6.2 shows the number of individuals who exceeded various limits while employed by one of several types of licensees. For the period 1985 to 1989, only the exposures in excess of regulatory limits reported by licensed industrial radiography firms are shown separately. Most of the occurrences included in the "All Other" category come from research facilities, universities, and measuring and well-logging activities.

In 2006, there were no Category A, B, or C occurrences reported under the licensed activities included in this report.

^aOne of these individuals also received the extremity exposure as shown.

^bThis exposure was from a hot particle to a localized area of the skin.

^cThis exposure was from a hot particle to a localized area of the skin.

^dTwo of these exposures (230 rem and 342 rem) were the result of hot particles.

^eThis exposure was from a hot particle to a localized area of the skin.

^fThese exposures have been added due to a reassessment of extremity dose from the direct handling of vials containing Indium at a radiopharmaceutical manufacturing licensee.

^gThese exposures were received by the same individual.

^aSame individual exceeded 1.25 rem/qr limit twice during 1993.

^bThis 1992 exposure was reported in 1994.

^cThis individual received a whole-body dose of 24 rem in addition to a 6,000 rem skin dose.

^dOne of these individuals received a 9 rem whole-body dose in addition to a 1,070 rem extremity dose.

^eOne of these individuals exceeded the quarterly whole-body dose limits three times in one calendar year.

^fAn additional 1993 exposure was reported in 1994.

6.4 MAXIMUM EXPOSURES BELOW THE NRC LIMITS

Because few exposures exceed the NRC occupational exposure limits, certain researchers have expressed an interest in a listing of the maximum exposures received at NRC licensees that do not exceed the limits. This would allow an examination of exposures that approach, but do not exceed, the limits. Table 6.3 shows the maximum exposures for each dose category required to be reported to the NRC. In addition, the number of exposures in certain dose ranges is shown to reflect the number of exposures that approaches the NRC limits.

As shown in Table 6.3, few exposures exceed half of the NRC occupational annual limits. In 2006, only 14 individuals exceeded 75% of the TEDE dose limit. No individual exceeded the 5 rem TEDE annual limit or any other annual limit.

TABLE 6.3
Maximum Occupational Exposures for Each Exposure Category*
2006

Exposure Category**	Annual Dose Limit 10CFR20***	Maximum Exposure Reported (rem)	Max Dose Percent of the Limit	Number of Individuals with Measurable Dose	Number of Individuals $\geq 25\%$ of the Limit	Number of Individuals $\geq 50\%$ of the Limit	Number of Individuals $\geq 75\%$ of the Limit	Number of Individuals $\geq 95\%$ of the Limit	Number of Individuals $>$ Limit
SDE-ME	50 rem	47.462	95%	58,419	58	17	7	1	0
SDE-WB	50 rem	8.718	17%	63,849	-	-	-	-	0

CEDE		1.593		2,586					
CDE		13.277		2,498					
DDE		4.943		62,619					
TEDE	5 rem	4.943	99%	63,573	1,054	77	14	1	0
TODE	50 rem	13.425	27%	61,424	1	-	-	-	0

*Only records reported by licensees required to report under 10 CFR 20.2206 are included. Numbers have been adjusted for the multiple reporting of transient individuals.

**SDE-ME = shallow dose equivalent to the maximally exposed extremity

SDE-WB = shallow dose equivalent to the whole body

LDE = eye dose equivalent to the lens of the eye

CEDE = committed effective dose equivalent

CDE = committed dose equivalent

DDE = deep dose equivalent

TEDE = total effective dose equivalent

TODE = total organ dose equivalent

***Shaded boxes represent dose categories that do not have specific dose limits defined in 10 CFR 20.

Section 8

GLOSSARY

Agreement State: a state that has signed an agreement with the NRC under which the state regulates the use of byproduct, source, and small quantities of special nuclear material in that state.

As low as is reasonably achievable (ALARA): making every reasonable effort to maintain exposures to radiation as far below the dose limits in this part as is practical consistent with the purpose for which the licensed activity is undertaken, taking into account the state of technology, the economics of improvements in relation to state of technology, the economics of improvements in relation to benefits to the public health and safety, and other societal and socioeconomic considerations, and in relation to utilization of nuclear energy and licensed materials in the public interest.

Average measurable dose: the dose obtained by dividing the collective dose by the number of individuals who received a measurable dose. This is the average most commonly used in this and other reports when examining trends and comparing doses received by workers, because it excludes those individuals receiving a less than measurable dose.

Boiling water reactor (BWR): A reactor in which the water, used as both coolant and moderator, is allowed to boil in the core. The resulting steam can be used directly to drive a turbine and electrical generator, thereby producing electricity.

By-product material: any radioactive material (except special nuclear material) yielded in, or made radioactive by, exposure to the radiation incident to the process of producing or using special nuclear material (as in a reactor); and the tailings or wastes produced by the extraction or concentration of uranium or thorium from ore.

Collective dose: the sum of the individual doses received in a given period of time by a specified population from exposure to a specified source of radiation.

Committed dose equivalent (CDE): the dose equivalent to organs or tissues of reference that will be received from an intake of radioactive material by an individual during the 50-year period following the intake.

Committed effective dose equivalent (CEDE): the sum of the products of the weighting factors applicable to each of the body organs or tissues that are irradiated and the committed dose equivalent to these organs or tissues.

Exposure: being exposed to ionizing radiation or to radioactive material.

Independent Spent Fuel Storage Installation (ISFSI): a complex designed and constructed for the interim storage of spent nuclear fuel, solid reactor-related waste, and other radioactive materials associated with spent fuel and reactor-related waste storage. An ISFSI which is located on the site of another facility licensed by the NRC or a facility licensed under 10 CFR Part 50 and which shares common utilities and services with that facility or is physically connected with that other facility may still be considered independent.

Lens dose equivalent (LDE): the external exposure of the lens of the eye and is taken as the dose equivalent at a tissue depth of 0.3 centimeter.

License: a license issued under the regulations in 10 CFR parts 30 through 35, 39, 40, 50, 60, 61, 70, or 72.

Licensee: the holder of the NRC license.

Licensed material: source material, special nuclear material, or byproduct material received, possessed, used, transferred or disposed of under a general or specific license issued by the Commission.

Light water reactor (LWR): A term used to describe reactors using ordinary water as coolant, including boiling water reactors (BWRs) and pressurized water reactors (PWRs), the most common types used in the United States.

Measurable dose: a dose greater than zero rem (does not include doses reported as 'not detectable'.)

Megawatt-year: A unit of electric energy, equal to the energy from a power of 1,000,000 watts over a period of 1 year.

Mode of Intake: the manner of intake into the body; inhalation (H), absorption through the skin (B), oral ingestion (G), and injection (J).

Monitoring year: interval during which the radiation exposure monitoring was performed.

Non-reactor licensees: NRC licensees that are not commercial nuclear power reactors. These licensees are industrial radiographers, fuel processors, fabricators and reprocessors; manufacturers and distributors of by-product material; independent spent fuel storage installations; facilities for land disposal of low-level waste; and geologic repositories for high-level waste.

Number of individuals with measurable dose: the count of unique individuals that received measurable dose during the monitoring year. In some instances in this report, the number of individuals with measurable dose may include individuals that are counted more than once since they may be monitored at more than one licensee during the year. See Section 5 on the effect of transient individuals. Tables that have been adjusted for transient workers are noted in the appropriate footnotes to the tables.

Occupational dose: the dose received by an individual in a restricted area or in the course of employment in which the individual's assigned duties involve exposure to radiation and to radioactive material from licensed and unlicensed sources of radiation, whether in the possession of the licensee or other person.

Pressurized water reactor (PWR): A power reactor in which heat is transferred from the core to an exchanger by high temperature water kept under high pressure in the primary system. Steam is generated in a secondary circuit. The majority of reactors producing electric power in the United States are pressurized water reactors.

Pulmonary clearance class: a classification scheme for inhaled material according to its rate of clearance from the pulmonary region of the lung.

Radionuclide: a radioisotope.

REM: the special unit of any of the quantities expressed as dose equivalent. The dose equivalent in REMS is equal to the absorbed dose in rads multiplied by the quality factor (1 rem = 0.01 sievert).

Shallow dose equivalent, Maximum extremity (SDE-ME): the external exposure of an extremity and is taken as the dose equivalent at a tissue depth of 0.007 centimeter.

Shallow dose equivalent, Whole body (SDE-WB): the external exposure of the skin and is taken as the dose equivalent at a tissue depth of 0.007 centimeter.

Sievert: the SI unit of any of the quantities expressed as dose equivalent. The dose equivalent in sieverts is equal to the absorbed dose in grays multiplied by the quality factor (1 Sv = 100 rems).

Special nuclear material (SNM): plutonium, uranium-233, uranium enriched in the isotope 233 or in the isotope 235, and any other material that the Commission, pursuant to the provisions of section 51 of the Act, determines to be special nuclear material, but does not include source material.

Total effective dose equivalent (TEDE): the sum of the deep-dose equivalent (for external exposures) and the committed effective dose equivalent (for internal exposures).

Transient individual: one who is monitored at more than one site during the calendar year.

Unit availability factor: the unit available hours (the total clock hours in the report period during which the unit operated on-line or was capable of such operation) times 100 divided by the period hours

REACTORS NO LONGER IN COMMERCIAL OPERATION, REPORTED WITH OTHER UNITS																				
BROWNS FERRY 1**	BWR	Reported with Browns Ferry 2, 3																		
DRESDEN 1	BWR	Reported with Dresden 2, 3																		
THREE MILE ISLAND 2	PWR	Reported with Three Mile Island 1; estimated dose from Unit 2 is 0.372 person-rem.																		
TROJAN	PWR	Reported with ISFSI																		
Total Reporting***	12	2,270	561	116	57	19	2	11	-	-	-	-	-	-	-	-	3,002	797	72.992	

* Dose values exactly equal to the values separating ranges are reported in the next higher range.

** Browns Ferry 1 remains in the count of operating reactors, but was placed on administrative hold in June 1985.

*** These numbers are for the reactors no longer in commercial operation that report their doses separately (i.e., do not report their doses with other units).

Appendix C*

**PERSONNEL, DOSE, AND POWER GENERATION
SUMMARY**

1969–2006

* A discussion of the methods used to collect and calculate the information contained in this appendix is given in Sections 3.1 and 4.2.

⁴Dresden 1 has been shut down since 1978, and in 1985, it was decided that it would not be put in commercial operation again. Therefore, it is no longer included in the count of operating reactors. Parentheses indicate plant capacity when plant was operational.

¹³ San Onofre 1 was shut down in November 1992 and is no longer in the count of operating reactors. Parentheses indicate plant capacity when plant was operational.

¹⁴Three Mile Island 1 resumed commercial power generation in October 1985 after being under regulatory restraint since 1979.

¹⁵Three Mile Island 2 has been shut down since the 1979 accident, but was still included in the count of reactors through 1988 since dose was still being accumulated to defuel and decontaminate the unit during this time period. Parentheses indicate plant capacity when plant was operational. Since 2001, the dose breakdowns for Three Mile Island 2 have been reported with those for Unit 1.

¹⁶ Trojan ended commercial operation as of January 1993 and will not be put in commercial operation again. It is no longer in the count of operating reactors. Parentheses indicate plant capacity when plant was operational. As of 2005, Trojan no longer reports under its reactor license, but does report under its ISFSI license (see Appendix A).
