## CALIFORNIA ENERGY DEMAND 2008-2018 STAFF REVISED FORECAST

STAFF FINAL REPORT

NOVEMBER 2007 CEC-200-2007-015-SF2

Arnold Schwarzenegger, Governor

## CALIFORNIA ENERGY COMMISSION

Lynn Marshall Tom Gorin *Principal Authors* 

Lynn Marshall *Project Manager* 

Sylvia Bender Manager Demand Analysis Office

Sylvia Bender Deputy Director Electricity Supply Analysis

B. B. Blevins *Executive Director* 

#### DISCLAIMER

This paper was prepared by California Energy Commission staff. It does not necessarily represent the views of the Energy Commission, its employees, or the State of California. The Energy Commission, the State of California, its employees, contractors and subcontractors make no warrant, express or implied, and assume no legal liability for the information in this paper; nor does any party represent that the uses of this information will not infringe upon privately owned rights. This paper has not been approved or disapproved by the California Energy Commission nor has the California Energy Commission passed upon the accuracy or adequacy of the information in this paper.

## ACKNOWLEDGMENTS

The staff demand forecast is the combined product of the hard work and expertise of numerous staff members in the Demand Analysis Office. Andrea Gough ran the summary energy model and supervised data preparation. Glen Sharp prepared the residential sector forecast. Mohsen Abrishami prepared the commercial sector forecast. Lynn Marshall and Peter Puglia prepared the industrial forecast. Nahid Movassagh forecasted consumption for the agriculture and water pumping sectors. Mark Ciminelli forecasted energy for transportation, communication, and utilities. Mitch Tian prepared the peak demand forecast. Ted Dang prepared the historic energy consumption data. Tom Gorin prepared the demographic projections. Chris Kavalec developed the projections of commercial floor space, with contribution from Adrienne Kandel and Gary Ochiuzzio. Peter Puglia and Kate Sullivan compiled historic and projected economic data. Bill Wood of the natural gas unit provided the natural gas price projections.

# ABSTRACT

This document describes California Energy Commission staff's revised forecasts for 2008-2018 electricity, peak, and natural gas demand for each utility planning area in California and for climate zones within those areas. The staff *California Energy Demand 2008-2018* forecast supports the analysis and recommendations of the *2007 Integrated Energy Policy Report*, including electricity and natural gas system assessments and analysis of progress toward energy efficiency, demand forecasts for the respective territories of the state's three investor-owned utilities —Pacific Gas and Electric, Southern California Edison, and San Diego Gas & Electric —will be used in the long-term procurement process at the California Public Utilities Commission.

This forecast was produced with the Energy Commission demand forecast models. Both the staff revised energy consumption and peak forecasts are slightly higher than the previous Energy Commission 10-year forecast, prepared for the *2005 Integrated Energy Policy Report*, over the entire forecast period, primarily because both weather-adjusted peak and electricity consumption were slightly higher than previously forecasted. The revised energy forecast is unchanged from the staff draft forecast at the statewide level. The revised peak demand forecast is 1 percent higher than the draft forecast.

## **Keywords**

Electricity demand, electricity consumption, demand forecast, weather normalization, annual peak demand, natural gas demand, self-generation, conservation, California Solar Initiative.

# EXECUTIVE SUMMARY

## Introduction

This California Energy Commission staff report presents forecasts of electricity and end-user natural gas consumption and peak electricity demand for the State of California and for utility planning areas and climate zones within the state for 2008–2018. The staff *California Energy Demand 2008–2018* revised forecast supports the analysis and recommendations in the *2007 Integrated Energy Policy Report,* including the electricity and natural gas system assessments and renewable energy progress analysis.

## **Statewide Forecast Results**

**Table ES-1** compares the staff revised electricity consumption forecast with the staff draft forecast published in June 2007 and the final forecast used in the 2005 *Integrated Energy Policy Report.*<sup>1</sup> The revised forecast is slightly lower than the draft forecast in the beginning of the forecast period. Over the 10 year forecast period, it is projected to grow at a slightly higher rate (1.3 percent versus 1.2 percent) than the draft forecast. This results in the revised electricity forecast being about 0.3 percent higher than the draft electricity forecast by the end of the 10 years.

The revised peak forecast has the same starting point as the draft forecast and grows at a faster rate (1.4 percent versus 1.2 percent). This results in the revised peak forecast being about 1 percent (or 700 megawatts) higher than the draft peak forecast by the end of the forecast period. It is also about 3 percent higher than the September 2005 forecast, consistent with the increases seen in the 2006 and 2007 Energy Commission updates to the short-term peak demand forecast. The higher recorded peaks from those years represent the effect of higher saturations of residential air conditioning than was previously assumed. Peak demand is now projected to grow at an average of 1.4 percent annually. The peak demand growth rate is higher than electricity consumption growth because it is assumed the 2005 federal air conditioning standards have no impact on peak. While the 2005 standard's change to seasonal energy efficiency rating (SEER) of 13 is accounted for in the energy consumption projection, some analyses indicate uncertainty as to whether the move to a higher seasonal energy efficiency ratio actually reduces peak demand, therefore, no effects from the 2005 standards are included in the peak demand forecast.

<sup>&</sup>lt;sup>1</sup> The *California Energy Demand 2008–2018* revised forecast is referred to as the "revised 2008 forecast" or "revised forecast" throughout the report. The draft forecast published in June 2007 is referred to as the "draft 2008 forecast" or "draft forecast" throughout. The final forecast developed in support of the *2005 Integrated Energy Policy Report* and published in *California Energy Demand 2006–2016, Staff Energy Demand Forecast, Revised September 2005,* (publication no. CEC-400-2005-034-SF-ED2) is referred to as *CED 2006.*

# Table ES-1: Comparison of CED 2006 and Staff Draft andRevised Statewide Electricity Forecasts

Source: California Energy Commission, 2007

The growth of peak demand is offset slightly by a higher self-generation load forecast; the revised forecast includes staff's estimates of effects from the California Solar Initiative program and other programs to promote market penetration of photovoltaics. **Figure ES-1** graphically represents the peak forecast.

Figure ES-1 also shows the load factor for the state as a whole, as well as the estimated 1-in-10 peak temperature scenario. The load factor represents the relationship between average energy demand and peak; a high load factor means the peak demand is not much higher than average hourly demand. The

load factor varies with temperature: in extremely hot years (1998, 2006), actual peak demand shows a sharper increase than would be observed with average peak weather. The general decline in the load factor over the last 20 years represents a population shift to warmer areas and more homes and businesses with central air conditioning. The 1-in-10 temperature scenario estimate represents the projected peak given the 90<sup>th</sup> percentile of annual maximum temperatures. This is defined as a statewide weighted annual maximum temperature value, which theoretically would occur only 1 year out of every 10.

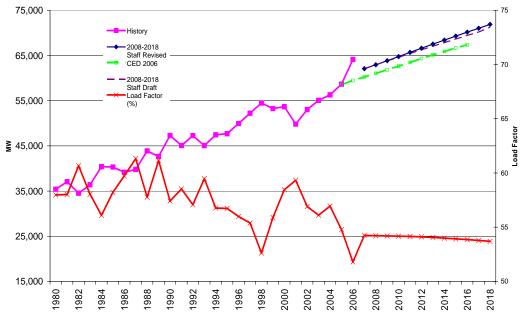

Figure ES-1: Statewide Non-Coincident Peak Demand

The overall increase in the statewide electricity forecast compared to the *CED* 2006 forecast reflects several factors. Higher-than-projected actual consumption in 2005 and 2006, adjusted for temperature, increased the starting point. Improvements to floor space estimation techniques led to increased floor space projections, which, accordingly, raise the forecast for commercial electricity consumption. Higher projections of personal income increase the forecasts of residential and commercial sector consumption. **Figure ES-2** shows the effect of these changes from the previous forecast.

Figure ES-2: Statewide Electricity Consumption

#### Summary of Revised Utility Area Forecasts

While the revised forecasts are not significantly different at the statewide level, the revised Department of Finance population projections had a noticeable effect for some individual utility areas. The Sacramento Municipal Utility District (SMUD) area forecast was revised downward 9 percent as population previously expected to locate in Sacramento County is now expected to locate in the surrounding areas not served by SMUD. The Southern California Edison (SCE) energy forecast increased by 2.5 percent and the peak forecast by 3.5 percent. The larger increase of the peak forecast reflects the change in population distribution. Within the SCE area, peak demand is projected to grow 2.3 percent annually in the Riverside-San Bernardino area, but less than 1 percent annually in the coastal areas. A similar pattern is evident in the Pacific Gas & Electric Company (PG&E) planning area. The energy consumption forecast was revised downward 1 percent because population projections are lower overall, but the peak forecast increases slightly because of growth in hotter areas served by PG&E and increased saturation of air conditioners in cooler areas that are used only during peak periods. Peak demand in the Sacramento Valley and foothills area is projected to grow by 2.4 percent annually, while the consumption in the East Bay and Central Coast area forecast is projected to grow at 1.3 percent. Demand in the Central Valley (excluding the Sacramento area) is projected to grow at 1.6 percent. Forecast results by climate zone are reported in the chapters on the SCE and PG&E forecasts. Another fast-growing area is that by served the Imperial Irrigation District (IID), with peak demand projected to grow 2.7 percent annually.

The revised annual consumption and peak forecasts for each utility area are shown in tables ES-2 and ES-3. The peak demand forecast for the California

Department of Water Resources (DWR) represents their peak demand on summer afternoons, assuming average water conditions.

#### Forecast of End-User Natural Gas Demand

The revised natural gas forecast, shown in Table ES-4, has a higher growth rate than the September 2005 forecast. However, revised historic consumption estimates makes the revised forecast about 4 percent lower than September 2005 at the beginning of the forecast period. The increased growth rate of the revised forecast relative to September 2005 is because of higher commercial floor space projections. In the revised forecast, the growth rate slows in later years because of rising natural gas prices which reduce commercial and industrial demand. This forecast includes natural gas demand for end use sectors, such as residential, commercial, and industrial, but not the natural gas used for electric generation.

#### Table ES-4: Comparison of *CED 2006* Forecast and Staff Draft and Revised Forecasts of Statewide End-User Natural Gas Consumption

### **Overview of Methods and Assumptions**

The staff revised demand forecast is the product of essentially the same methods used to prepare earlier long-term staff forecasts. The commercial, residential, and industrial sector energy models are structural models that attempt to explain how energy is used by process and end use. The forecasts of agricultural and water pumping energy demand are made using econometric methods. After adjusting for historical temperatures and usage, the annual consumption forecast is used to project annual peak demand.

#### **Economic and Demographic Assumptions**

Population growth is a key driver for residential energy demand, as well as for commercial growth and demand for water pumping and other services. This forecast uses the California Department of Finance's most recent long-term population forecast, published in July 2007. The draft forecast used the Department of Finance's May 2004 projections. Population is now projected to grow at about 1.2 percent annually. By comparison, statewide population growth an average of 1.3 percent annually from 1990 to 2000. The declining growth rates over the forecast horizon reflect lower rates of fertility and immigration as

the population of California ages. Other economic projections are from Economy.com.

#### **Electricity Rate Projections**

The 2005 forecast used rate projections developed by Energy Commission staff, which in general declined over time. For both this revised forecast and the draft forecast, the sector energy demand was forecasted with future real electricity rates held constant at their current levels. This change to higher forecasted rates, compared with those used in the *CED 2006* forecast, primarily affects commercial and industrial sector demand.

#### **Climate Zone Forecasts**

For the revised 2008-2018 forecast, the PG&E and SCE planning areas were forecast by several distinct climate zones. The PG&E planning area is divided into five zones and the SCE area into four. All other planning areas constitute one climate zone only. Historically the climate zones were used only to project energy use for heating and cooling equipment; all other end uses were assessed at the utility level. For this forecast, economic and demographic projections by climate zone were used to capture the effects of differential growth in households, income, commercial floor space, and industrial activity.

#### **Conservation Quantification**

This forecast report also includes estimates of conservation savings that are included in the baseline forecast. These estimates are made by broad program category. The estimates have been implicitly included in all of the previous forecasts but have not been explicitly identified since the 1990s era of demand forecasts.

## CHAPTER 1: INTRODUCTION AND STATEWIDE FORECAST

## Introduction

This California Energy Commission (Energy Commission) staff report presents revised 10-year forecasts of electricity and end-user natural gas consumption and peak electricity demand for California for each major utility planning area and for the climate zones within each area. The *California Energy Demand 2008–2018* forecast supports the analysis and recommendations of the 2007 Integrated Energy Policy Report (IEPR), including electricity and natural gas system assessments, energy efficiency and demand response progress analysis, and renewable energy goals.

The IEPR Committee conducted a workshop on July 10, 2007, to receive public comments on the staff draft forecast.<sup>2</sup> Staff has revised the forecast to address many of the comments received, as well the direction from the Committee. This report also presents quantification of energy conservation impacts included in the forecasts. After considering comments on this revised forecast, the Energy Commission may adopt this forecast.

The final forecasts will be used in a number of applications, including Energy Commission energy system assessments and the California Public Utilities Commission (CPUC) 2008 procurement process. The CPUC has identified the IEPR process as "the appropriate venue for considering issues of load forecasting, resource assessment, and scenario analyses to determine the appropriate level and ranges of resource needs for load-serving entities (LSEs) in California."<sup>3</sup> The final forecasts will also be an input to California Independent System Operator (California ISO) controlled grid studies and other transmission planning studies. The *California Gas Report* also uses Energy Commission demand and supply assessments.

#### Summary of Changes to Current Forecast

The previous long-term forecast, *California Energy Demand 2006–2016 (CED 2006)* was based on 2005 peak demand and 2004 total energy consumption. In June 2006, staff also published an updated peak demand forecast for 2007 summer peak demand.<sup>4</sup> That forecast, combined with the growth rates from the *CED 2006* 

<sup>&</sup>lt;sup>2</sup> The California Energy Demand 2008–2018 revised forecast is referred to as the "revised 2008 forecast" or "revised forecast" throughout the report. The draft forecast published in June 2007 is referred to as the "draft 2008 forecast" or "draft forecast" throughout. The final forecast developed in support of the 2005 Integrated Energy Policy Report and published in California Energy Demand 2006–2016, Staff Energy Demand Forecast, Revised September 2005, (publication no. CEC-400-2005-034-SF-ED2) is referred to as CED 2006.

<sup>&</sup>lt;sup>3</sup> Peevey, Assigned Commissioner's Ruling on Interaction Between the CPUC Long-Term Planning Process and The California Energy Commission Integrated Energy Policy Report Process, September 9, 2004, California Public Utilities Commission Rulemaking 04-04-003.

<sup>&</sup>lt;sup>4</sup> California Energy Commission, *Staff Forecast of 2007 Peak Demand*, staff final report, publication no. CEC-200-2006-008-SF, June 2006.

forecast, was used in many applications, such as the scenario studies for the 2007 *IEPR*. For the current forecast, staff added 2005 and 2006 energy consumption data to the historical series used for forecasting. The peak demand forecast also incorporates recent analysis of 2006 temperatures and peak demand, published in *Staff Forecast of 2008 Peak Demand*.<sup>5</sup>

Residential sector appliance saturations have been updated based on more current survey data. This update had the effect of increasing the saturation of homes with air conditioning but lowering some other electricity end uses. In the commercial sector, staff revised its estimates of existing floor space and projected new floor space using updated economic projections and a new econometric method. Both changes increase projected commercial electricity use. The energy and peak demand forecasts now include a projection of the impacts from penetration of rooftop solar photovoltaic (PV) systems as advanced through the California Solar Initiative (CSI).

#### **Changes from the Draft to Final Forecast**

For the first time, the entire electricity forecast was prepared by climate zone and sector. For forecasting purposes, the Energy Commission divides the state into 16 climate zones. Historically the climate zones were used only to project heating and cooling demand by climate zone; all other end uses were assessed at the utility planning area level. For this forecast, economic and demographic projections by climate zone were used to capture the effects of differential growth in households, income, commercial floor space, and industrial activity for both the PG&E and SCE planning areas.

The climate zone forecasts were then disaggregated to individual LSEs. As required by Public Resources Code Section 25302.5, staff assessed the extent to which load may be transferred among utilities and incorporated that analysis into the LSE forecasts. As part of this analysis, staff used information submitted to the Energy Commission by numerous LSEs based on their expected acquisition of existing customers from the investor-owned utilities (IOUs) and on load growth from areas newly incorporated in their service area.

For demographic projections, the revised forecast used the California Department of Finance's (DOF) new population projections, released in July 2007.<sup>6</sup> The forecast also used a new end-user natural gas price forecast from the Energy Commission's most recent natural gas assessment. This higher gas price forecast reduces commercial and industrial gas demand.

Since the draft forecast, staff reviewed energy intensity trends for each industry group and modified forecast assumptions to be more consistent with historical trends. Some changes were made to economic drivers based on staff's assessment

<sup>&</sup>lt;sup>5</sup> California Energy Commission, *Staff Forecast of 2008 Peak Demand*, staff final report, publication no. CEC-200-2007-006-SF, June 18, 2007.

<sup>&</sup>lt;sup>6</sup> State of California, Department of Finance, *Population Projections for California and Its Counties* 2000–2050, Sacramento, California, July 2007.

of their plausibility. For the construction industry, the forecast driver is now the UCLA Anderson School of Business projection of construction sector employment, weighted by the forecast of households in each climate zone. A number of parties commented on the plausibility of the declining use per square foot in the commercial sector predicted in the draft forecast. This decline is driven in large part by increasing efficiency in lighting as older systems were replaced. Based on information from the most recent commercial end-use survey, staff concluded that a high proportion of buildings have already retrofitted lighting systems. To more accurately model this trend, the lifetime of lighting equipment was reduced.<sup>7</sup> This change produced a greater reduction in lighting use in the historical period and less of a reduction in the forecast.

This report also presents estimates of residential and commercial energy conservation impacts. Detailed results for both natural gas and electricity impacts can be found in Appendix A.

## **Statewide Forecast Results**

**Table 1** presents a comparison of the revised and draft forecasts for select years with the *CED 2006* final forecast used in the *2005 IEPR*. Both the revised and draft energy consumption and peak forecasts are slightly higher than the *CED 2006* forecast over the entire forecast period, primarily because both weather-adjusted 2006 peak and electricity consumption were higher than forecasted in *CED 2006*. The draft forecast has a higher growth rate (1.3 percent versus 1.1 percent in *CED 2006*) because of higher projected demand in the residential and commercial sectors. The historical data used for this forecast differs from *CED 2006* because of revised data submitted by utilities and because a detailed review of self-generation consumption data found some data had been misclassified.

Statewide annual peak demand is projected to grow on average 890 megawatts (MW) per year for the next 10 years, or 1.4 percent annually. The peak forecast is about 2 percent higher than *CED 2006*, consistent with the increases made in recent updates in the short-term peak demand forecast. The higher recorded peaks represent the effect of higher saturations of air conditioning than was assumed in the *CED 2006* forecast.

The effect of population growth in the drier, warmer areas of the state increases peak demand—the highest hourly demand in each year—more than it increases annual energy consumption. Another reason for the higher growth rate of the peak forecast is the assumption that the 2005 federal air conditioning standards have no impact on peak because of their inefficacy in reducing California's peak demand.<sup>8</sup>

<sup>&</sup>lt;sup>7</sup> Commercial sector floor space is affected by Title 24 Building Standards when various remodeling activities take place. Equipment not yet at the end of its useful life may be replaced more quickly than originally planned.

<sup>&</sup>lt;sup>8</sup> Southern California Edison, *EER and SEER as Predictors of Seasonal Cooling Performance*, December 15, 2003.

The seasonal energy efficiency ratio (SEER) performance metric is based on outdoor temperatures far below California average annual maximum (peak) temperatures. Therefore, while the electricity consumption forecast accounts for the effects of the 2005 standard's change to SEER 13, impacts from the 2005 standards were not included in the peak demand forecast.

The higher growth in peak demand is somewhat offset by projected increases in the load served by self-generation, reflecting the penetration of rooftop solar PV by programs such as the CSI, the New Solar Homes Partnership, and the Self-Generation Incentive Program. The peak demand forecast represents the net amount of load the electric grid must serve so that demand by self-generation reduces the electric system peak. In the forecast, the growth in photovoltaic and other self-generation installations is assumed to reduce peak demand by 650 MW by 2018, based on current costs and program performance; if the installed cost of photovoltaic systems declines rapidly, this projection could easily be exceeded.

# Table 1: Comparison of CED 2006 and Staff Draft and Revised Forecasts of Statewide Electricity Demand

Source: California Energy Commission, 2007.

#### Annual Electricity Consumption

The revised statewide electricity consumption forecast, shown in **Figure 1**, is higher than the *CED 2006* forecast over the entire forecast period, although the projected annual growth rate is only slightly higher. The overall increase in the forecast reflects several factors. Higher-than-projected actual consumption in 2005, adjusted for temperature, increased the starting point. Also, the higher level of both projected commercial floor space and personal income increased demand projections.

Source: California Energy Commission, 2007.

Per capita electricity consumption, shown in **Figure 2**, is projected to remain relatively constant over the forecast period at just above 7,500 kilowatt hours (kWh) per person. This is about 150 kWh higher than the final *CED 2006* forecast. Per capita consumption has been relatively constant over the past 15 years, fluctuating between 7,200 and 7,800 kWh per person, depending on economic and annual temperature conditions. Per capita use in 2006 was 4.4 percent higher than in 1980, but 5.7 percent lower than usage in 2000. The revised forecast of per capita use has a lower starting point because actual use per capita in 2006 was lower than forecast.

**Figure 3** shows the current and previous forecasts of electricity consumption by the major economic sectors. From 1980-2000 the commercial sector has had the highest growth, followed by the residential sector. In the forecast period, the residential sector continues to grow at the historical rate (1.7 percent), while the commercial sector grows slightly slower (1.4 percent) than the historical rate. Both

the industrial and agriculture and water pumping forecasts are projected to be relatively constant over the forecast period.

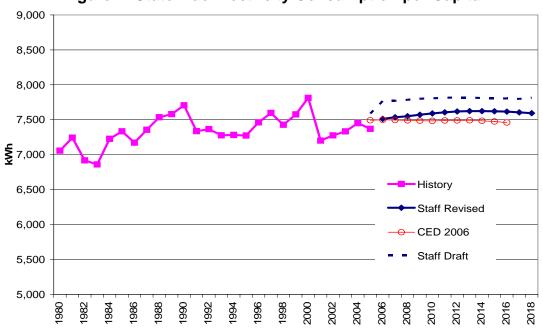

Figure 2: Statewide Electricity Consumption per Capita

Source: California Energy Commission, 2007.

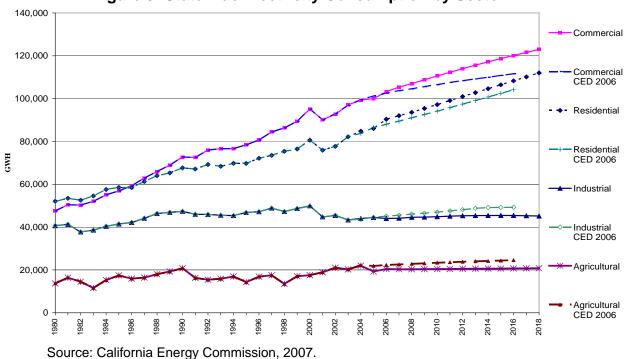

Figure 3: Statewide Electricity Consumption by Sector

The revised commercial sector forecast growth is higher than the *CED 2006* forecast because of staff's revised forecast of commercial floor space, discussed in the

methodology section of this chapter. The revised residential forecast is higher due to revised demographic projections by climate zone and a higher projection of personal income. The industrial forecast growth rate is lower because of slightly lower economic projections and because electricity rates are held constant in this forecast, while previously rates paid by industry were projected to decline. The agricultural and water pumping forecast is also reduced by the higher rates and because of apparent decreasing energy intensity in the agriculture sector.

To support electricity system analysis, staff disaggregates its planning area and climate zone forecasts to correspond to control areas and congestion zones. **Table 2** shows the forecast of electricity required to meet demand by control area and congestion zone. In the California ISO, demand is projected to grow about 1.4 percent annually over the next five years, with higher growth in the Southern California south of Path 15 area (1.5 percent).

### Statewide Peak Demand

Figure 4 compares the revised forecast of statewide non-coincident peak demand with the draft and CED 2006 forecasts. The revised forecast begins at a higher level than the CED 2006 forecast because the weather-adjusted peak in 2006 proved higher than previously forecast. This is in part because the saturation of air conditioning in recent years has proved to be higher than assumed in the previous forecast. Growth rates in the forecast period are very similar. Figure 4 also shows the load factor for the state as a whole. The load factor, defined as average demand relative to peak demand, measures the extent to which capacity is being used. A high load factor means the peak demand is not much higher than average hourly demand. A low load factor means there are very few high loads compared to the average, which is generally the case in California with air conditioners that are turned on when temperatures spike. The load factor varies with temperature patterns; in extremely hot years (1998, 2006) the peak demand is much higher than average demand. The general decline in the load factor over the last 20 years has been caused by a rising proportion of homes in warmer areas and more homes and businesses with central air conditioning. These trends are projected to continue over the forecast period. Energy efficiency measures, such as more efficient residential lighting, can also contribute to the declining load factor by reducing overall electricity

use while having a limited effect on peak. The forecast of per capita non-coincident peak, shown in Figure 5, is projected to increase slightly over the forecast period to 1.64 kilowatts per person in 2018.

Figure 5: Statewide Non-Coincident Peak Demand per Capita

**Figure 6** shows peak demand by the major economic sectors. As in the energy consumption forecast, residential demand grows fastest at 1.9 percent annually. Commercial sector peak demand grows at 1.3 percent compared to 0.9 percent in *CED 2006* because of a higher floor space forecast and reduced lighting impacts in the forecast period. Industrial peak demand grows at 0.3 percent annually, about the same as industrial energy growth.

**Table 3** shows peak demand for each control area in California. As in the electricity forecast, the central and southern parts of the state are growing fastest. The south of Path 15 zone of the California ISO is forecasted to add over 4,000 MW of load by the end of the forecast.

#### Natural Gas Demand Forecast

**Table 4** compares the staff revised forecast with the draft and *CED 2006* forecast of end-user natural gas consumption. This forecast does not include natural gas used for electric generation. The revised forecast has a slightly higher growth rate than the *CED 2006* forecast. Most of this increase is in the commercial sector because of the higher estimates of floor space and floor space projections. Higher saturations of gas appliances in the residential sector also increase the forecast. The revised forecast is lower than the draft because it incorporates a higher natural price forecast.

#### Methods and Assumptions

The revised and draft forecasts use essentially the same methods as earlier longterm staff demand forecasts. The specific data sources and assumptions used for this forecast and any changes to methodology since *CED 2006* are described here. A more detailed discussion of forecast methods and data sources is available in the *Methodology Report*.<sup>9</sup>

Models for the major economic sectors produce forecasts of annual energy consumption in each utility planning area. After adjusting for historical weather and usage, the annual consumption forecast is used to forecast annual peak demand.

<sup>&</sup>lt;sup>9</sup> California Energy Commission, *Energy Demand Forecast Methods Report*, publication no. CEC-400-2005-036, June 21, 2005.

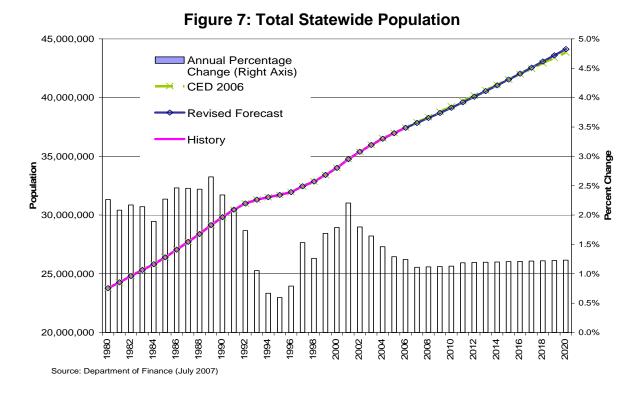

The commercial, residential, and industrial sector energy models are structural models that attempt to explain how energy is used by process and end use. Structural models are critical to enable forecasts to account for the impacts of mandatory energy efficiency standards and other energy efficiency programs that seek to force or encourage adoption of more efficient technologies by end users. This is especially true in the context of the major emphasis upon energy efficiency in California. The forecasts of agricultural and water pumping energy demand are made using econometric methods.

#### **Economic and Demographic Assumptions**

Broad economic indicators, such as population, personal income, and jobs, are translated into a variety of specific drivers for each economic sector that have been found to directly explain energy usage. Population growth is a key driver for residential energy demand, as well as for commercial sector growth and demand for water pumping and other services. This forecast uses the California Department of Finance's (DOF) most recent long-term population forecast, published in July 2007. The draft forecast used DOF's May 2004 projections.

**Figure 7** compares these two population projections. Population is projected to grow at about 1.2 percent annually. By comparison, statewide population grew an average of 1.3 percent annually from 1990 to 2000. The declining growth rates over the forecast horizon reflect lower rates of fertility and immigration as the population of California and other regions ages. Older-age cohorts have a lower propensity to immigrate.

Staff uses Economy.com as the source for many economic projections, including income, employment, and industrial output. In its May 2007 projections used for this forecast, Economy.com projects a slightly higher rate of growth than in the projections used for *CED 2006*. Personal income is projected to grow at 2.7 percent annually, compared to 2.5 percent in *CED 2006*. County-level economic projections are aggregated to climate zone or planning area for use in the sector energy forecasts. Economic projections for each utility area are presented in the respective utility forecast chapters.

#### **Electricity Prices**

The possible effects of future policy changes in energy efficiency, renewables, siting, or climate change on electricity prices paid by customers are highly uncertain. As in the draft forecast, sector energy demand was forecasted with future real electricity prices held constant at their current levels. The *CED 2006* forecast used price projections developed by Energy Commission staff based on data provided by utilities, which in general declined over time. At the July 10, 2007, workshop, most participants agreed that holding real prices constant was a more realistic assumption than declining prices. Staff used data provided by each of the major utilities on historical revenues and sales to estimate historical and current revenue per kilowatt hour for each economic sector or rate class. This change from the *CED 2006* forecast, to higher forecasted prices, primarily affects commercial and industrial sector demand.

#### **Residential End-Use Assumptions**

Since the *CED 2006* forecast, staff updated the appliance saturation estimates for all 24 end uses that comprise the residential sector to incorporate the findings of the *2004 Residential Appliance Saturation Survey*. "Saturation" refers to the percentage of homes that have a given end use.

The most dramatic effect of these saturation revisions concerns air conditioning, most specifically, central air conditioning. With the restructuring of the California electricity industry, end-user surveys and other data collection activities were not

funded for many years, and the Energy Commission experienced a 10-year hiatus in residential appliance saturation survey activity.

This lack of information meant that several cycles of staff forecasts failed to include a major period of retrofitting; many homes that formerly had either a room air conditioner or no air conditioning at all have since had a central system installed. For example, in recent previous forecasts of the Sacramento Municipal Utility District (SMUD) service territory, staff estimated that approximately 70 percent of single family homes had a central air conditioning system. Based on the new Residential Appliance Saturation Survey, staff now estimates that close to 95 percent of single family homes in the SMUD service territory, and many other parts of the Central Valley, have central air conditioning. Staff's corrected estimates drive an increase in forecasted peak load, due to the nearly complete saturation of air conditioning in warmer climates.

More temperate climates are becoming increasingly dependent upon air conditioning, too. Staff estimates that Pacific Gas & Electric Company's (PG&E's) Climate Zone 4, which surrounds San Francisco and includes Santa Rosa and San Jose, has a central air conditioning saturation of nearly 50 percent—double previous saturation estimates. More than 75 percent of new single family homes in Climate Zone 4 are projected to have central air conditioning.

This increase in electricity consumption from higher air conditioning activity is balanced somewhat by the effect of revised saturation estimates for natural gas appliances. The trend toward use of natural gas instead of electricity for cooking, water heating, and space heating produces a higher forecast of gas consumption in every utility service area.

# **Commercial Sector Assumptions**

Energy use in the commercial sector is modeled in terms of energy use, for each end use, per square foot for 12 different building types. A forecast of floor space in each county serves as the economic driver of demand trends. For this forecast, staff made significant changes to the methods and data used for forecasting floor space and vacancy rates.

The historical floor space stock estimates were revised based on analysis of the McGraw Hill database of permits for new buildings and floor space additions from 1970 through 2005, by county. Staff created a time series of floor space stock (rather than additions) by allowing additions to decay as they age, in concert with the logistic survival formula:

Survival (age t) = 
$$\frac{e^{v}}{1+e^{v}}$$
 where  $v = 6.912 \left(1 - \frac{t}{\text{median life}}\right)$ .

Logistic survival posits that few buildings are torn down in their early years and that tear-downs accelerate as buildings approach their average lifetime, then slow down again as fewer old buildings remain.

For *CED 2006*, the projection of future floor space additions was based on historical average growth in floor space. For the current revised and draft forecast, staff developed an econometric method for forecasting growth in floor space. For each building type, staff identified the economic or demographic variable that best correlates with energy use over time. Those variables are shown in **Table 5**. Since the draft forecast, the floor space forecast was re-estimated with the new DOF population projections.

Building Type	Variables
Small Office	Employment in finance, information, and government sectors;
	personal income; population
Large Office	Employment in finance, information, and government; personal
	income; population
Restaurant	Employment in services; per capita income; population

	population
Hotel	Employment in leisure activities; per capita income; population
Miscellaneous	Per capita income; personal income; population

### Table 5: Economic/Demographic Variables Specified for Each Building Type

Source: California Energy Commission, 2007.

To develop a relationship between floor space and the economic/demographic variables, changes in floor space from year to year for each building type and climate zone for the period 1980–2005 were regressed on three relevant economic/demographic variables, current and lagged, as follows:

$$\begin{split} \Delta FS &= a + b1 \Delta D1 + b2 \Delta D1 - 1 + b3 \Delta D1 - 2 + b4 \Delta D1 - 3 \\ b5 \Delta D2 + b6 \Delta D2 - 1 + b7 \Delta D2 - 2 + b8 \Delta D2 - 3 \\ b9 \Delta D3 + b10 \Delta D3 - 1 + b11 \Delta D3 - 2 + b12 \Delta D3 - 3 + \epsilon \end{split}$$

where  $\Delta$ FS is change in floor space from year t-1 to year t and  $\Delta$ D is the current or lagged annual change in an economic/demographic variable. Changes were used rather than levels to avoid autocorrelation problems. Lagged variables were included to account for time delay between a change in the state's economy and demographics and a response in terms of new construction.

Individual variables  $\Delta D$  were eliminated from the estimation if they did not reduce the regression's standard error. As an example, the change in hotel floor space in each climate zone was specified as a function of changes in projected leisure jobs, income per capita, and population (and their lags). After eliminating insignificant variables, the final regression for Climate Zone 2 included current per capita income

and population, per capita income lagged two periods, and population lagged three periods; for Climate Zone 3, the final regression included only current per capita income and population.

Using the regression results, floor space for each building type and climate zone was forecasted using economic and demographic projections from Economy.com and the California Department of Finance. Annual floor space additions were calculated by subtracting estimated building decay from year-to-year changes in projected floor space.

Vacancy rates for both historical and forecast years were estimated using data on office building vacancies by county for 1984–2005. Vacancy rates were specified as a function of the rate of net building additions and growth in employment in office related jobs (government, information, and finance). Regression yielded the following:

Vacancy rate(t) =  $14.66 + 42.27 \times \text{additions rate}(t) - 34.73 \times \text{employment growth}(t)$ 

with both explanatory variables statistically significant at a 95 percent confidence level. This estimated relationship was used to project vacancy rates for all building types, with employment growth in office-related employment replaced by a growth indicator relevant to the particular building type. For example, growth in projected retail employment was used in the case of retail buildings, and growth in school age population was used for schools.

Figure 8 shows the geographic definition of the climate zones used for forecasting.

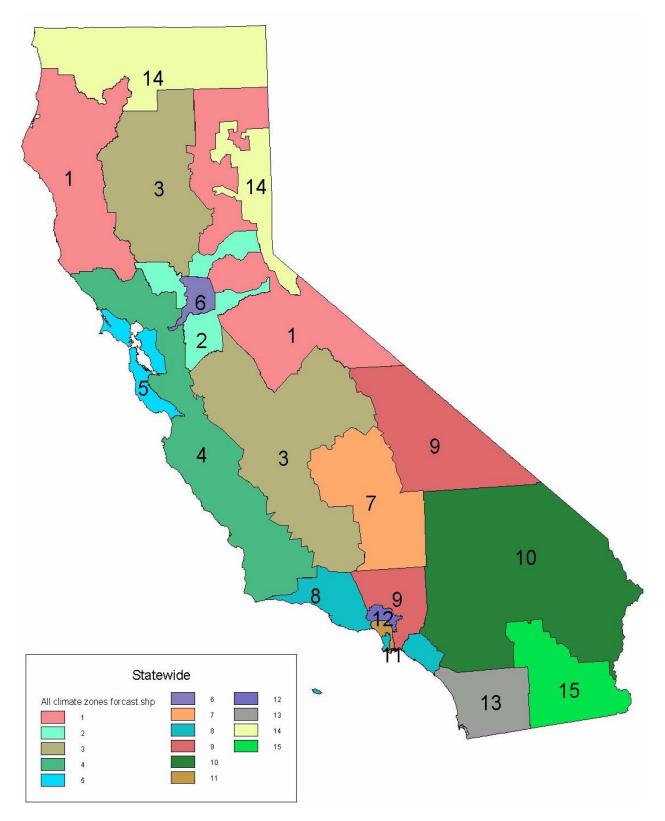

Figure 8: California Energy Commission Forecasting Climate Zones

# **Energy Conservation in Commission Demand Forecast Models**

Energy Commission demand forecasts seek to account for all conservation that is "reasonably expected to occur." Since the 1985 *Electricity Report*, conservation programs that are reasonably expected to occur have been split into two types: committed and uncommitted. This demand forecast continues that distinction. "Committed" programs are defined as programs that have been implemented or for which funding has been approved. While "conservation reasonably expected to occur" includes both committed and uncommitted programs, only the effects of committed programs are included in the demand forecast. The uncommitted demand side management (DSM) forecast of load impacts from programs or other actions is treated as a resource to allow comparison of DSM to other resource options. Longterm "stretch" goals for a series of programs that are not funded are considered uncommitted.

A difficulty arises in correctly projecting uncommitted impacts versus market effects. standards effect, and savings from public or utility programs that are captured in forecast models. Building and appliance standards are modeled within the residential and commercial forecast models. The models account for building decay, equipment replacement, and market-induced impacts. Some DSM programs sponsored by utilities, state government, local government, and other organizations are also modeled within the sector models. In addition, as models are calibrated to historical actual data, they implicitly account for the effects of many years of energy efficiency programs. Therefore, the forecasts may include some impacts associated with the historical and ongoing levels of programs to the extent they represent impacts associated with replacement of aging building stock and equipment or installation of new stock and equipment at efficiency levels that comply with current building and appliance standards. "Uncommitted effects" are thus defined as the incremental impacts of the level of future programs (for example, savings associated with new equipment that exceeds current standards or early replacement of existing stock), impacts of new programs, and impacts from expansion of current programs.

At the July 10, 2007, workshop, several utilities articulated the need to better understand the conservation embedded in the Energy Commission's forecast to avoid including in resource plans uncommitted savings that are already accounted for in the forecast. To address this issue, staff prepared estimates of conservation impacts for each utility planning area.

Attribution of savings from standards is guided by the principle that program savings are determined in the reverse order of introduction. This chronological sequencing approach requires that a series of model runs be made. For example, the effects of the 2005 building standards were calculated by comparing energy use with those standards in effect (the baseline forecast) to what energy use would have been under the prevailing 1998 building standards. The difference between the baseline forecast and a model run with the 2005 standards removed is the impact attributed to the 2005 standards. Similarly, the effect of the 1998 standards was calculated by comparing the energy use of buildings that comply with the standards to the

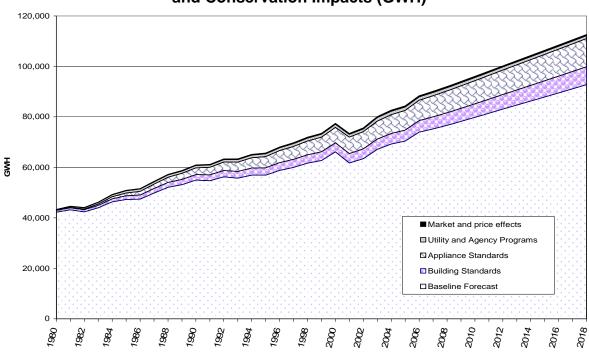

prevailing practice before their implementation. When all building and appliance standards are removed, only market or price effects remain. Finally, prices are held constant from 1977 forward, producing an estimate of demand with no standards or price effects.

A significant complication of implementing this convention is the attribution of savings to market forces, including direct consumer price response. Because the models runs which are used to quantify the effects of standards use fuel price assumptions from the baseline forecast, the estimated savings are conditional upon the market savings, which depend upon the fuel price assumptions of the baseline forecast. Changes in such fuel price assumptions, all other effects held constant, change the savings quantified for each program. High fuel prices lead to lower program savings and lower fuel prices lead to higher program savings.

The impacts from many utilities' and government programs are also estimated directly within the end-use models. However, because of the large number of programs and the extreme difficulty in attributing impacts to particular programs, no attempt is made to attribute impacts through an iterative process. Estimated savings by program are obtained directly from utilities and public agencies. At the aggregate, the utility and program estimates are used to gauge the impacts included within the end use models.

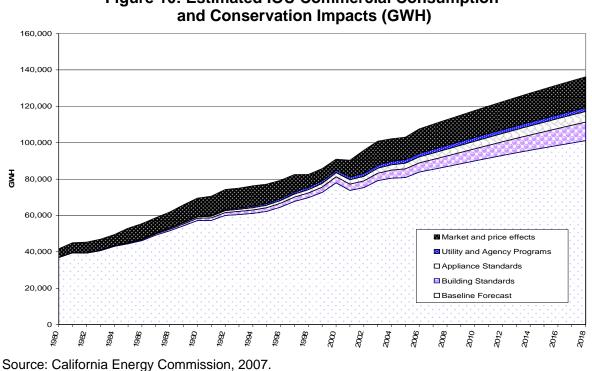

Estimates of impacts calculated outside the sector models are the product of a three step process. First, first-year impacts are assigned a useful measure life. Second, a degradation factor is applied to each year of the useful life to account for poor maintenance or equipment failure. Third, the final results are aggregated and provided to the summary model where they are used to evaluate the sector forecasts. Explicit adjustments are made only to those programs whose effects are not likely to be captured by other model effects.

**Figures 9 and 10** illustrate the commercial and residential results for the three IOUs combined. The bottom area represents the staff-revised demand forecast. Each area above the forecast represents the savings from that category—the amount by which it is estimated consumption would have increased if those requirements were eliminated. For example, the estimated impacts of residential building standards are over 7,000 GWH by 2018, meaning elimination of the standards from the residential forecast model increased projected consumption by that amount. The upper line represents estimated consumption when all standards and programs are removed from the model and electricity prices are held constant. Because of greater price elasticity, market effects are more significant in the commercial sector.

**Figure 9: Estimated IOU Residential Consumption** and Conservation Impacts (GWH)

Source: California Energy Commission, 2007.

**Table 6** summarizes the estimated residential and commercial conservation impacts for selected years for the three IOUs: PG&E, Southern California Edison (SCE), and San Diego Gas & Electric (SDG&E). Results for each utility can found in the planning area chapter. Tables presenting these impacts in more detail can be found in Appendix A.

 Table 6: Estimates of Commercial and Residential Conservation

 Impacts for PG&E, SCE, and SDG&E

Source: California Energy Commission, 2007.

These results represent impacts only in the residential and commercial sectors, about two-thirds of total consumption. The Energy Commission's industrial, agriculture, and other sector forecasts do not model conservation effects explicitly. In these models the forecast is driven by econometric or other statistical analysis of historical energy intensity trends. All conservation impacts through the last historical year are by definition accounted for, and the projected trends incorporate effects of past energy efficiency programs on usage, as well as price or market effects. The industrial sector overall has shown large decreases in energy intensity in many industries that far exceed utility estimates of program savings for that sector.

# Investor-Owned Utility Energy Efficiency Goals for 2006-2008

In decision D.04-09-060, the CPUC established numerical goals for electricity and natural gas savings for the IOUs for the period 2004–2013.<sup>10</sup> D.04-09-060

<sup>&</sup>lt;sup>10</sup> California Public Utilities Commission, *Interim Opinion: Energy Savings Goals for Program Year 2006 and Beyond*, D. 04-09-040, September 23, 2004, in Energy Efficiency Rulemaking 01-08-028.

implements a core component of the *Energy Action Plan*, which was earlier adopted by the CPUC, the California Energy Commission, and the California Consumer Power and Conservation Financing Authority. The decision translated that mandate into explicit, numerical goals for reducing electricity and natural gas consumption as well as peak demand. Savings from energy efficiency programs funded by the public goods charge and procurement rates will contribute to these goals, including those achieved through the Low-Income Efficiency Program. Committed conservation programs are those programs included in the 2006–2008 program plans approved in the CPUC Energy Efficiency Rulemaking Proceeding (R04-06-010) or in other CPUC decisions, and therefore <u>explicit</u> adjustments are made only for those programs.

To account for these goals in the forecast, staff used the impacts by sector or program category provided by each utility in its 2007 IEPR demand forecast submittal. The electricity program savings goals used for each IOU are shown in **Table 7**. The planned programs and estimated impacts are evaluated, and only the effects of those programs that are not already captured in the models are included in the forecast. The resulting forecast of efficiency impacts was then used to adjust the raw residential and commercial demand forecasts.

	PG&E		SC	E	SDG&E

# Investor-Owned Utility Energy Efficiency Goals for 2009 and Beyond

Because the post-2008 IOU program strategies are under development, they are not explicitly accounted for in this forecast. However, staff's assessment is that historically many of the effects of utility programs are indirectly accounted for in the models. For the programs implemented in 2006-2008, staff estimates that approximately 80 to 90 percent of the expected impacts are reflected in the models in other ways; the remainder is accounted for through direct adjustments. This assessment of significant overlap is specific to the 2006-2008 program mix which heavily targets end-uses also affected by codes and standards (such as refrigerators and commercial lighting). If the current program mix and level of effectiveness is unchanged, this level of overlap would be expected to continue in future years.

There are two important reasons why the explicit adjustment to the forecast is so small. First, much of this overlap is associated with effects that in staff's assessment are captured by other model assumptions. So the impacts are real, but they are attributed to standards, not programs. For example, in staff's commercial forecasting model, lighting intensity in large offices declines by 10 percent between 2009 and

2013 as standards are applied to buildings being replaced or retrofit. The current IOU program mix also emphasizes commercial lighting. In reality, lighting systems may be retrofit before the building reaches the model decay threshold, but this effect is not represented in staff's models. Also, the CPUC allows credit toward the goals of codes and standards compliance efforts by the IOUs. Finally, the process of calibration to historical data adjusts the forecast for actual impacts without attribution to any specific program or standard.

The second reason relates to projected program savings versus the actual net change in total consumption. Historically, verified program impacts have been found to be significantly less than projected program savings. Therefore, if actual utility savings have been, for example, 70 percent of planned savings, the forecast is calibrated to a trend with that lower level of impact (that is, a higher energy intensity trend), and the forecast assumes a similar trend for the future. If future programs are more effective, that will be an incremental reduction to the forecast. (This would also mean less cost-effective potential has been achieved, and therefore more remains available for the future). Futhermore, the net observed reduction in consumption may be reduced by offsetting behavior changes or incorrect assumptions about usage characteristics.

These overlaps would be expected to continue for post-2008 program expenditures, unless the post-2008 program designs change in substantial ways, for example by devising programs emphasizing measures that produce effects that are not captured currently within the forecasting models. The direction laid out in the October 18, 2007, CPUC decision<sup>11</sup> indicates a significant change of direction, targeting, for example, new construction and air conditioning rather than lighting. This change in program mix would translate to a greater explicit impact on the staff forecast. Also, the new structure of financial risks and rewards for IOUs presented in the CPUC's September 20, 2007, decision<sup>12</sup> could increase program effectiveness above historical levels. Also, future program strategies may place a greater emphasis on total long-term savings as opposed to near-term annual impacts, in which case the current annual targets are not a good indicator of the pattern of future savings.

The overlap between staff forecast assumptions and currently uncommitted program effects is likely to decrease in the post-2008 period but cannot be appropriately assessed until specific program plans are developed. Users of the forecast can assume it includes a level of future impacts consistent with the current program mix and effectiveness. As 2009-2011 program plans are developed and approved, staff will evaluate them and quantify appropriate adjustments to the forecast.

The use of Energy Commission forecasts in IOU procurement plans present several challenges. First, since the IOUs do not develop the forecasts, they have less insight

<sup>&</sup>lt;sup>11</sup> California Public Utilities Commission, Interim Order on Issues Relating To Future Savings Goals And Program Planning For 2009-2011 Energy Efficiency And Beyond, October 18, 2007.

<sup>&</sup>lt;sup>12</sup> California Public Utilities Commission, Interim Opinion On Phase 1 Issues:

Shareholder Risk/Reward Incentive MechanismFor Energy Efficiency Programs D.07-09-043, September 20, 2007.

into model characteristics. Second, the IOUs are directed to use targets developed several years ago. While the targets are valuable as a tool for directing policy, they do not correspond well to a forecast done in 2007. The analysis behind the targets did not account for 2005 building standards and used an Energy Commission forecast with different model assumptions (for example, lower saturations of air conditioning.) The CPUC declines to modify the targets at this time (except possibly for SDG&E's), suggesting that other energy efficiency opportunities are likely to have arisen to offset the decrease in potential now captured by standards. So the targets no longer embody a specific set of efficiency measures that can be compared to forecast assumptions. Third, the mandated approach of subtracting 100 percent of the targets from the demand forecast contrasts with Energy Commission approach of forecasting expected impacts. These issues can be addressed in part by staff providing the necessary analysis to identify the appropriate adjustment for a given energy efficiency program portfolio. Use of portfolio risk analysis can also account for the uncertainty of projected load impacts.

# **Self-Generation Program Impacts**

This forecast accounts for effects of two program areas designed to promote selfgeneration: the California Self-Generation Incentive Program (SGIP) and the CSI programs, including the CPUC-administered CSI, along with the Energy Commission New Solar Homes Partnership and the Emerging Renewables Program that has been administered by the California Energy Commission.

The general strategy of the Emerging Renewable Program and CSI programs is to encourage demand for solar photovoltaic (PV) arrays with financial incentives until the size of the market increases to the point where economies of scale are achieved and capital costs decline. As PV production capacity comes on-line in the next few years, production and hence the price of PV installations are expected to decline. However, the extent to which consumers see real price declines will depend on the interplay of supplier expectations, the future level of incentives, and demand as manifested by the number of states or countries offering subsidies for PV. For example, when the Emerging Renewables Program was established, the expectation was that the subsidy would be necessary only for a few years. Then Germany offered an incentive, driving up demand in excess of the production increase. Many states and nations currently have no solar programs; therefore, the possibility of similar future effects seems very possible. Given the uncertainty of the timing and magnitude of future PV price changes, staff assumed that the 2004-2006 rate of installations would continue through the forecast period. If the installed cost of photovoltaic systems declines significantly, either through reductions in component or installation costs or increases in federal/state tax credits, this projection could easily be exceeded.

Some technical assumptions about PV system performance were derived from the recent Energy Commission report, *Scenario Analysis of California's Electricity System* (*Scenario Report*).<sup>13</sup> Since the draft forecast, staff recalculated the

<sup>&</sup>lt;sup>13</sup> PV characteristics are described in Appendices E and G of the California Energy Commission

dependable coincident peak using the Energy Commission forecasting definition of peak: mid-June–mid-September. The factors used for the draft forecast used a longer definition of summer (May through October). Using the shorter summer definition results in higher expected peak impacts per kilowatt (kW) of installed capacity.

Assembly Bill 970 (Ducheny/Battin, Chapter 329, Statutes of 2000) required the CPUC to initiate load control and distributed generation program activities designed to produce significant public benefits. On March 27, 2001, the CPUC issued Decision 01-03-073, mandating a self-generation program in the service territories of California's investor-owned utilities. The SGIP offers financial incentives to customers of IOUs who install certain types of distributed generation facilities to meet all or a portion of their energy needs. The program began in mid-2001 and is scheduled to continue offering incentives for completed projects through the end of 2011.

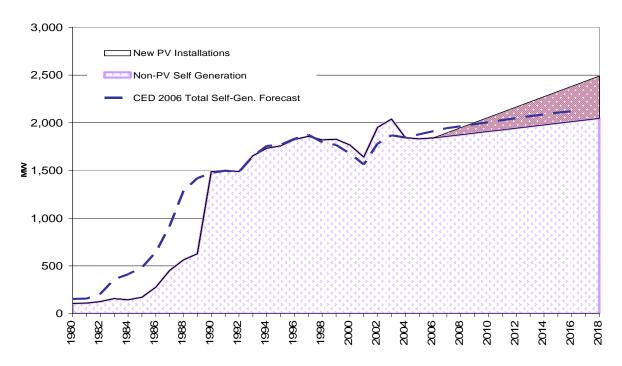

To forecast future self-generation load, staff used the IOU reports on completed new interconnections and pending applications to develop projections of capacity additions of new interconnections.<sup>14</sup> The interconnection reports provide a detailed picture of capacity addition trends. To translate self-generation capacity into effects on system peak demand requires assumptions about load shape, the coincidence of self-generation peak with system peak, and the extent to which self-generation units are operating during peak hours. Staff used the evaluation studies of the SGIP program for these assumptions.<sup>15</sup> For example, the 2004 study found that the load impact at the time of the 2004 California ISO peak was 58 MW out of 103 MW of installed capacity. As in the previous forecast, it is assumed that new additions will continue at the current rate through the life of the SGIP program. After 2011, self-generated loads are assumed to grow at the rate of the utilities' noncommercial sector. The revised forecast is slightly higher than in *CED 2006* with a peak impact of 2,048 MW by 2018.

**Figure 11** shows the combined impact of the SGIP and CSI forecasts. Together, they may serve load of 2,500 MW by 2018. These projections represent the available capacity at the time of the system peak.

# **Demand Response**

The term "demand response" encompasses a variety of programs, including traditional direct control (interruptible) programs and new price-responsive demand programs. A key distinction is whether the program is dispatchable. Dispatchable programs, such as direct control, interruptible tariffs, or demand bidding programs, have triggering conditions that are not under the control of and cannot be anticipated by the customer. Energy or peak load saved from dispatchable programs is treated as a resource and therefore not accounted for in the demand forecast. Nondispatchable programs are not activated using a predetermined threshold condition, and allow the customer to make the economic choice whether to modify its usage in response to ongoing price signals. Impacts from committed nondispatchable programs should be included in the demand forecast.

At this time, all of the existing demand response programs have some form of triggering condition. Although the utility or California ISO may not have direct control, the customer only has the opportunity to participate in the program when the program operator has called an event, whether because of high market prices or resource scarcity. Therefore, in this forecast, no demand response impacts are counted on the demand side.

# **Historical Electricity Consumption Estimates**

Energy Commission demand forecasting models are organized by sector according to economic activity (that is, commercial, industrial, agricultural, and so forth). Each of these forecasting models develops a forecast based on sub-activities within the sector (such as commercial building type or industrial activity). Under the Energy Commission's Quarterly Fuel and Reporting (QFER) regulations, each LSE is required to file monthly and annual reports that document energy consumption by activity group. In the past, this reporting was to conform to the Standard Industrial Classification (SIC) system. This system was revised to the North American Industrial Classification System (NAICS).<sup>16</sup> The switch to NAICS has caused some difficulty in identifying the appropriate economic classification of many energy users. The result of this change, along with the lack of reporting regulation adherence by various LSEs, is a lower quality of the Energy Commission's historical record of sector-specific consumption. Unclassified sales—consumption that the LSE has not identified by an NAICS category and that staff therefore cannot map to a customer sector—has become the fastest growing category of consumption reported to the Energy Commission.

The largest increase coincided with the advent of the restructured electric industry. Under current reporting requirements, the IOUs are required to identify the economic classification of direct access customers and provide that information to the direct access provider. Much of the increase in unclassified sales is among direct access customers identified by the IOUs as "unclassified." Staff allocated unclassified sales to economic sectors using professional judgment. In the current forecast, unclassified sales were allocated to sectors to adjust for unrealistic changes in historical consumption. The *CED 2006* forecast allocated unclassified sales in the summary model as a post-sector model adjustment. This change in allocation method has some impact on the commercial model results. If staff does not know more precisely how much electricity each economic sector is really using, it cannot correctly quantify the effects of energy efficiency programs or standards on demand or apply the correct load shapes for forecasting peak. The forecast may be over- or underestimating demand growth, depending on the true distribution of unclassified sale among sectors that have distinctly different underlying patterns of growth.

# **Climate Zone Demand Forecasts**

Many of the uses of demand forecasts require forecasts prepared at a finer geographic resolution than the planning area forecasts the Energy Commission has historically produced. Electricity system analysis requires identification of load by congestion zone or load pocket. Evaluation of progress toward renewable energy goals requires sales data by individual LSEs. Development of energy efficiency goals requires projections of per capita sales by LSEs. Controlled grid studies

<sup>&</sup>lt;sup>16</sup> As a result of North American Free Trade Agreement (NAFTA), the federal government replaced the SIC system with the NAICS system. In turn, the Energy Commission modified its regulations requiring utilities to classify all end users from SIC to NAICS to allow economic data to be matched to utility consumption data.

require forecasts for each LSE, sometimes with geographic subdivisions. To satisfy the needs of the California ISO, utilities, and Energy Commission studies, staff has been allocating planning area results to California ISO zones. To improve upon this, the fundamental basis for the forecast needs to be more geographically disaggregate. With this forecast cycle, the staff has begun the development of climate zone forecasts. The SCE planning area is composed of four distinct climate zones: Zone 7 (southern San Joaquin Valley); Zone 8 (coastal part of Los Angeles Basin served by SCE); Zone 9 (inland part of the Los Angeles Basin served by SCE); and Zone 10 (Inland Empire). The PG&E planning area is composed of five distinct climate zones: Zone 1 (North Coast and Eastern Mountain); Zone 2 (Sacramento area served by PG&E); Zone 3 (northern San Joaquin and northern Sacramento Valley); Zone 4 (East Bay/ Central Coast); and Zone 5 (San Francisco Bay). All other planning areas constitute one climate zone only.

The historical consumption and economic and demographic projections for the residential and commercial sectors were aggregated so that projected growth in each climate zone reflects the distinct economic trends and climate of that area. Because industrial sector is not weather-sensitive, economic drivers were developed for two regions each in the SCE and PG&E areas. For other sectors where the forecast is driven by household growth, a planning area forecast was distributed to each climate zone based on the projected share of households in each zone. Area forecasts for other sectors that are neither weather-sensitive nor driven by population trends, such as agricultural water pumping, were distributed to climate zones based on historical consumption.

To develop forecasts for specific control areas and congestion zones, the climate zone forecasts were then used to develop forecasts for LSEs by climate zone. Demand for individual LSEs is projected initially based on the sector growth rates of the climate zones in which they are located. The individual LSE forecasts were also adjusted to account for load migration (customers migrating from one service provider to another) and for areas newly incorporated as municipalities. Staff used data provided by numerous LSEs on expected migration. Where the raw forecast based on climate zone trends did not capture projected migration or municipalization, the gaining LSE's forecasted share of energy was increased, while the losing LSE's share of demand was decreased. The LSE-climate zone peak demand forecast was developed by applying climate zone load factors to the forecasted energy. Where the starting point of the forecast was inconsistent with staff's estimate of weather-adjusted 2006 peak demand for that LSE, the load factors for the LSEs were adjusted.

The statewide forms following this chapter include the forecast by climate zone, control area, and LSE. Subsequent chapters present the forecast for each of the major electric planning areas and for each climate zone and forms with detailed forecast results, followed by a chapter on the natural gas forecast. The planning areas used for this forecast are shown in **Table 8**.

# CHAPTER 2: PACIFIC GAS AND ELECTRIC COMPANY PLANNING AREA

The Pacific Gas and Electric (PG&E) planning area includes (1) PG&E bundled retail customers, (2) customers served by energy service providers (ESPs) using the PG&E distribution system to deliver electricity to end users, and (3) customers of publicly owned utilities, irrigation districts, and other load-serving entities (LSEs) in PG&E's transmission system, with the notable exception of the Sacramento Municipal Utility District (SMUD).<sup>17</sup> SMUD is treated as its own planning area and is discussed in a later chapter.

For this chapter, the PG&E planning area forecast includes the members of the SMUD control area, Modesto Irrigation District, Roseville, Redding, and directservice customers of the Western Area Power Administration (WAPA). The PG&E planning area also includes the Turlock Control Area. To support electricity and transmission system analysis, staff uses historical consumption and load data to develop individual forecasts for all utilities in the planning area. Those results are presented in Form 1.5a through 1.5c following Chapter 1. The results in this chapter are for the entire PG&E transmission planning area.

This chapter is organized as follows: first, forecasted electricity consumption and peak loads for the PG&E planning area are discussed; both total and per capita values are presented. The revised 2008-2018 values are compared to both the draft 2008-2018 and adopted *CED 2006* forecasts, with differences between the forecasts explained. The revised forecast for each of the five climate zones in the planning area is also presented. The forecasted load factor, jointly determined by the consumption and peak load estimates, is also discussed. Second, the chapter presents sector electricity consumption and peak load forecasts. The revised residential, commercial, industrial, and "other" sector forecasts are compared to the draft and *CED 2006* forecasts for the Self-Generation Incentive Program (SGIP) and the California Solar Initiative (CSI). Last, estimates of conservation savings from standards, utility and public agency programs, and market and price effects that are included in the baseline forecast are presented.

# **Planning Area Results**

**Table 9** presents a comparison of the revised 2008-2018 forecast with both the draft2008-2018 and CED 2006 electricity consumption forecasts.

<sup>&</sup>lt;sup>17</sup> The public utilities in the PG&E planning area are Calaveras Public Power Agency; Central Valley Project; Cities of Alameda, Biggs, Gridley, Healdsburg, Lodi, Lompoc, Palo Alto, Redding, Roseville, San Francisco, and Ukiah; Lassen Municipal Utility District; Merced Irrigation District; Modesto Irrigation District; Plumas-Sierra Rural Electric Cooperation; Shasta Dam Area Public Utility District; Silicon Valley Power; Tuolumne County PPA; and Turlock Irrigation District.

In the PG&E planning area, the revised electricity consumption forecast is about 1 percent lower than the draft forecast throughout the majority of the forecast period. This is primarily because of revisions to estimates of 2005 self generation, which lowered the starting point of the forecast. The post-2008 growth rates of the revised and draft forecasts are very similar. Both forecasts are higher than the *CED 2006* forecast because of revisions to economic and demographic projections.

**Table 10** presents a comparison of the revised 2008-2018 forecast with the draft 2008-2018 and *CED 2006* forecasts for selected years. The revised forecast is very similar to the draft forecast. Use of the new long-term Department of Finance (DOF) population projections shift more population to the hotter areas of the PG&E planning area so that the reduction in electricity consumption forecasts is not translated into a similar reduction in peak forecasts. Staff has increased its projection of 2007 and 2008 peak forecasts from the original projections made in 2005 for the *CED 2006* forecast based on actual temperatures and weather normalized load growth. The revised projections were vetted in public workshops and were adopted by the Energy Commission in June 2006 and 2007 for use in the CPUC Resource Adequacy process. The recently adopted 2008 peak is used as the starting point of both the revised and draft peak forecasts. The 2008–2016 growth rate of the revised peak forecast is slightly higher than the draft forecast.

 Table 10: PG&E Planning Area Peak Demand Forecast Comparison

Historic values are shaded

Source: California Energy Commission, 2007.

As shown in **Figure 12**, the revised electricity consumption forecast for the PG&E planning area is uniformly lower than the draft forecast. This is due to both the use of the revised DOF long-term population forecast and revision to starting point values caused by inclusion of 2006 Quarterly Fuel and Reporting (QFER) data and self-generation estimates. The growth rates of all three forecasts are very similar.

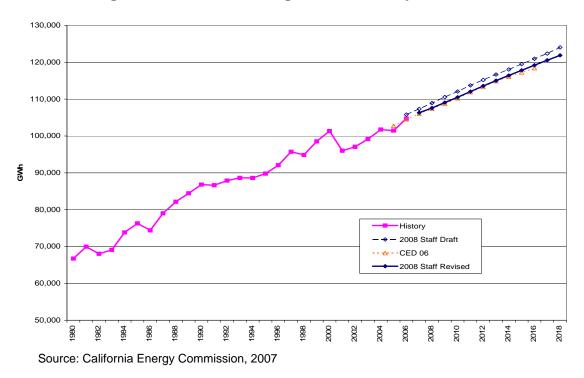

Figure 12: PG&E Planning Area Electricity Forecast

The revised PG&E planning area peak demand forecast, shown in **Figure 13**, is essentially the same as the draft forecast. Both the revised and draft forecasts are higher over the entire forecast period than the *CED 2006* forecast. This increase is due to the annual updates of the peak forecast described earlier in this chapter.

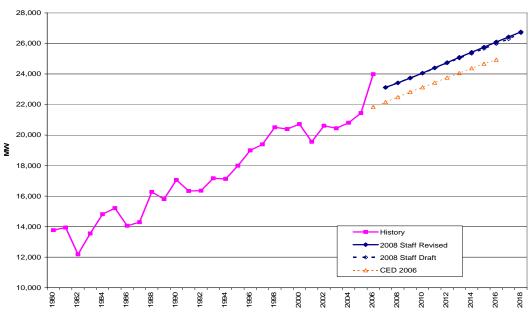

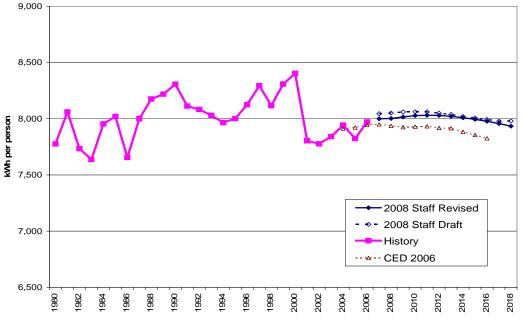

Figure 13: PG&E Planning Area Peak

Source: California Energy Commission, 2007

**Figure 14** provides comparisons of PG&E planning area per capita electricity consumption. Differences in per capita consumption are mainly in the assumed near-term level due to revisions of both consumption estimates and short-term population projections. All forecasts are relatively flat in the short- to mid-term forecast period and decline at the end of the period due to ongoing effects of efficiency improvements and declining industrial use. Evaluation of 2006 QFER data reduced the starting point differences somewhat. The level of per capita consumption projected in the revised forecast is still projected to be below preenergy crisis consumption levels.

### Figure 14: PG&E Planning Area Per Capita Electricity Consumption

Source: California Energy Commission, 2007

Revised per capita peak demand, shown in **Figure 15**, remains relatively constant throughout the forecast period. This level is slightly higher than the draft per capita peak demand caused by a greater shift of population to the hotter inland areas of the PG&E planning area than was projected in the previous forecasts. Both the revised and draft forecasts are higher than the *CED 2006* forecast consistent with the annual peak forecast updates described earlier. The revised level of per capita peak is now estimated to be at a level similar to the mid- to late-1990s, before the energy crisis.

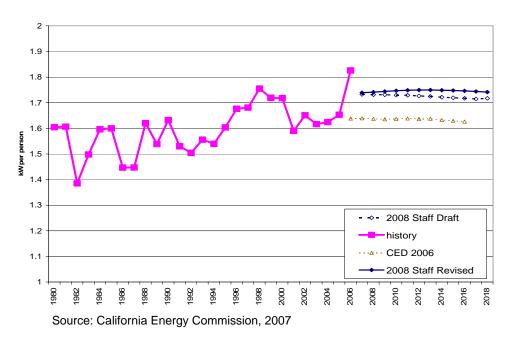

Figure 15: PG&E Planning Area per Capita Peak Demand

**Figure 16** provides a comparison of the implied forecast load factors. The load factor is a measure of the increase in peak demand relative to annual electricity consumption. Lower load factors indicate "a needle peak;" higher load factors indicate a more stable load. Actual data show a long-term downward trend as consumption shifts away from the industrial sector and toward the residential and commercial sectors. In the residential sector, more population and economic growth in the PG&E planning area is taking place in hotter inland areas, and there is an increasing saturation of central air conditioning equipment in the cooler Bay Area that is used on the few warm summer days. Both of these trends will cause a decline in the load factor compared to previous historical years. The revised load factor is on the low end of the range of annual load factors of recent history. Over the longer forecast period, the load factor declines slightly, which is consistent with higher weather-sensitive load growth in relation to baseload energy growth.

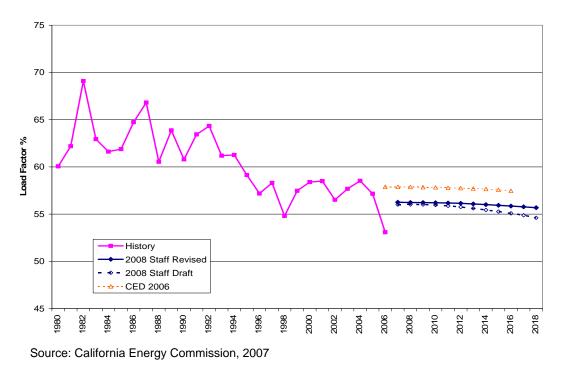

Figure 16: PG&E Planning Area Load Factor

In the staff forecasting models, the PG&E planning area is composed of five distinct climate zones: Zone 1 (North Coast and Eastern Mountain); Zone 2 (Sacramento area served by PG&E); Zone 3 (northern San Joaquin and northern Sacramento Valley); Zone 4 (East Bay/ Central Coast); and Zone 5 (San Francisco Bay). The purpose of presenting the revised staff forecast results by climate zone is to help plan for the differential growth patterns in the climate regions of the PG&E planning area. **Tables 11** and **12** present the PG&E planning area electricity consumption and peak demand forecast by climate zones. The highest growth in the forecast period is projected to occur in the hotter regions (Sacramento and Valley) of the planning area.

**Figures 17** and **18** present graphs of the revised electricity and peak demand forecasts, respectively, by climate zone. The fastest growing areas are the hotter inland regions followed closely by the East Bay region. The historical electricity values in Figure 17 are based on historical consumption by county aggregated to the climate zone level. Because the climate zone definitions do not necessarily correspond to specific physical subsets of the electric grid, no precisely comparable information exists to determine historical peak demand by climate zone. At this time

the historical peak estimates by climate zone are based on staff load model results, calibrated to individual load-serving entity historical loads to produce a forecast by load-serving entity and control area. Staff will investigate alternative strategies for calibrating the climate zone peak forecast.

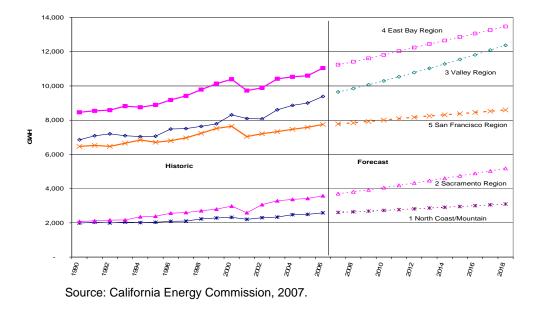

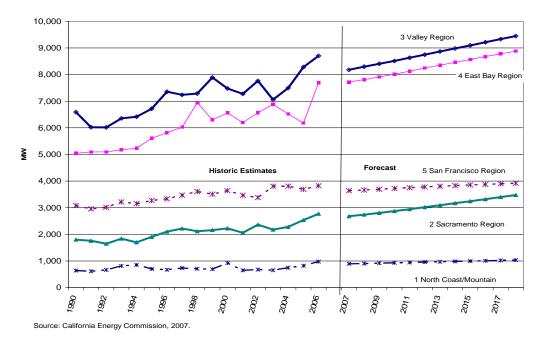

Figure 17: PG&E Planning Electricity Forecast by Climate Zone

## **Sector Level Results and Input Assumptions**

## **Residential Sector**

**Figure 19** provides a comparison of the revised 2008-2018 PG&E planning area residential forecast to both the draft 2008-2018 forecast and the *CED 2006* forecast. The revised forecast is lower than the draft forecast throughout the forecast period because of updated economic and demographic projections. The revised DOF long-term population forecast lowered population in the Bay Area where per capita income is higher and increased population in the inland valley areas where per capita and lower household income forecast. This also causes a slightly lower growth rate in the revised forecast compared to the draft forecast.

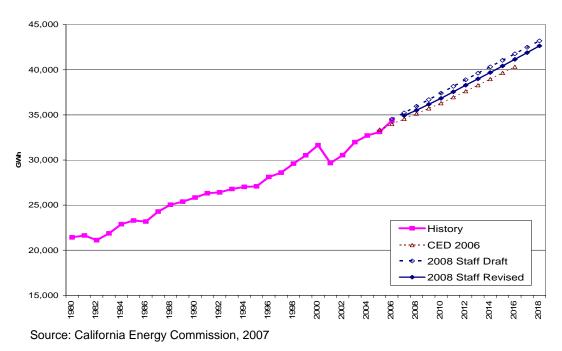

Figure 19: PG&E Planning Area Residential Consumption

**Figure 20** shows the revised forecast by climate zone for the PG&E planning area. While the East Bay region is still the largest area and continues to grow, the largest forecasted growth is coming from the Valley region. The electricity consumption forecast is consistent with the projected household growth by climate zone, shown in **Figure 21**.

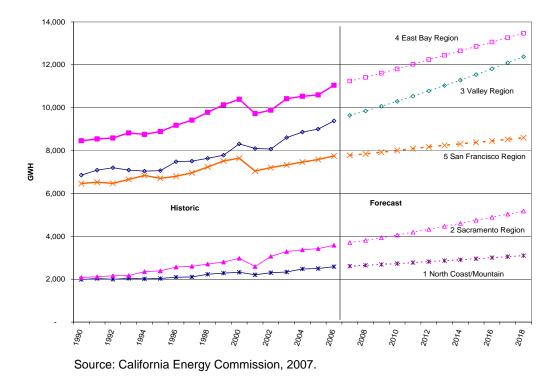

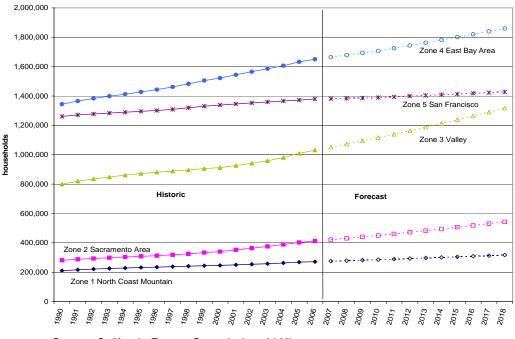

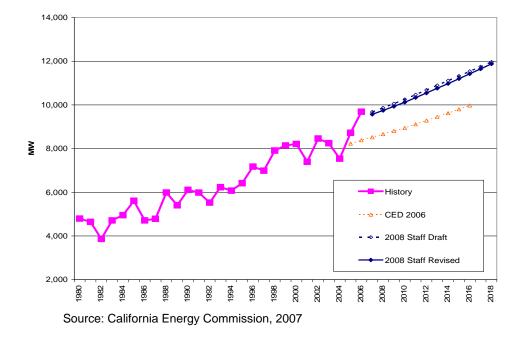

Figure 20: PG&E Planning Area Residential Electricity Forecast by Climate Zone

Figure 21: PG&E Planning Area Households by Climate Zone

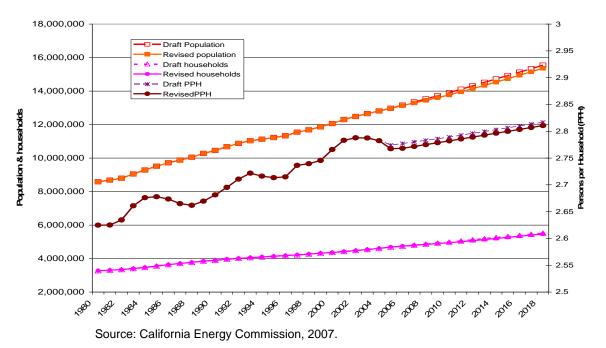

Source: California Energy Commission, 2007.

**Figure 22** provides a comparison of the revised and draft 2008 and *CED 2006* residential peak demand forecasts. As in the electricity consumption forecast, the revised residential peak forecast is slightly lower than the draft forecast. The difference between the revised and draft peak forecasts is slightly smaller than in the electricity forecast due to the shift of population to the hotter inland areas of the planning area. Also, savings from 2005 federal air conditioner standards are assumed to have an effect on annual electricity consumption but not on peak demand.

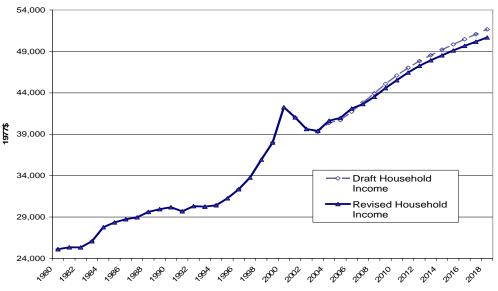

**Figures 23** and **24** provide comparisons of the residential drivers used in the revised forecast with those used in the draft forecast. Figure 23 provides comparisons of the total population, total households, and persons per household projections. The revised forecast of total population and households is slightly lower than in the draft forecast. The slightly lower revised household forecast is the net result of a lower population forecast and lower persons per household forecast. Figure 24 provides a comparison of household income (per capita income multiplied by persons per household) between the two forecasts. The revised estimate of household income is lower than that projected in the draft forecast partly due to the shift in population to locations in the planning area that have lower per capita income.

#### Figure 23: PG&E Planning Area Residential Demographic Projections

Figure 24: PG&E Planning Area Household Income Projections

Source: California Energy Commission, 2007.

**Figures 25** and **26** represent a comparison of electricity use per household between the revised forecast and the previous forecasts. Figure 25 is a comparison of annual use per household, and Figure 26 presents a comparison of peak use per household. The revised forecast of electricity use per household is lower than the draft forecast. This is caused by lower persons-per-household projections and a lower household income forecast. The difference is less pronounced in peak use per household due to a shift in households to the hotter inland climates. The growth rate of the revised electricity use per household forecast is similar to the draft forecast while the growth rate of the revised peak use per household is slightly higher than the draft forecast, reflecting growth in the hotter areas.

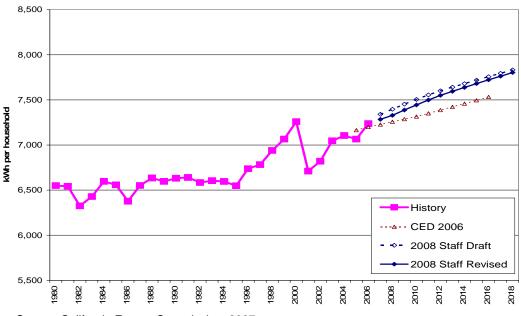

Figure 25: PG&E Planning Area Use per Household

Source: California Energy Commission, 2007.

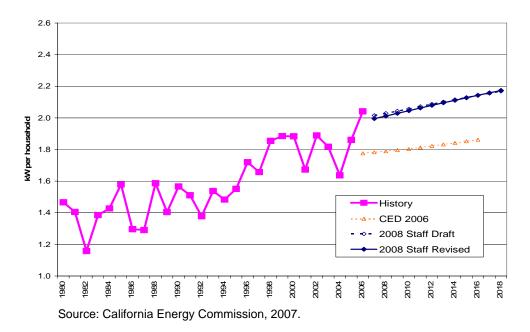

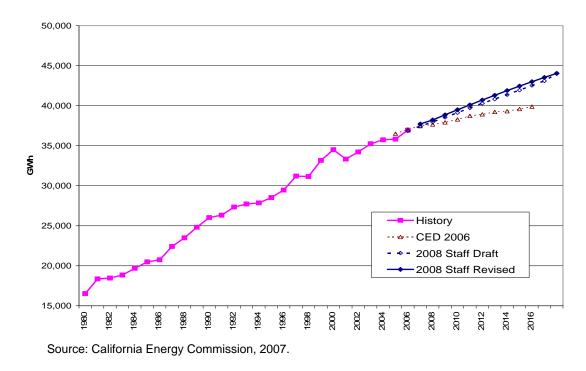

Figure 26: PG&E Planning Area Peak Use per Household

## **Commercial Building Sector**

**Figure 27** provides a comparison of the commercial building sector forecasts. The revised forecast is slightly higher throughout the forecast period than the draft forecast. This is caused by a slightly higher starting point of the commercial forecast due to inclusion of 2006 consumption data in the historical period. The growth rates of the revised and draft forecasts are similar as higher forecasted levels of lighting intensity are offset by a revised, lower forecast of floor space. Both forecasts are higher than the *CED 2006* forecast due to revised projection method of commercial square footage used in the current forecast cycle.

**Figure 28** shows the PG&E commercial electricity forecast by climate zone. For the commercial sector, the fastest growing regions are the East Bay, Valley, and Sacramento regions.

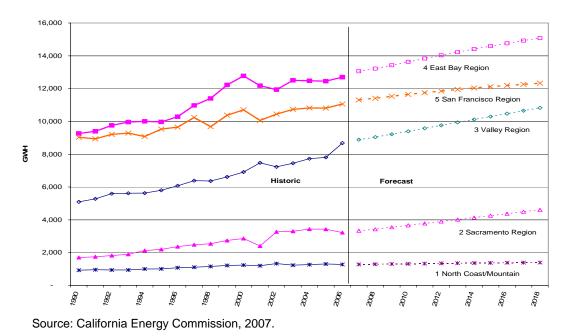

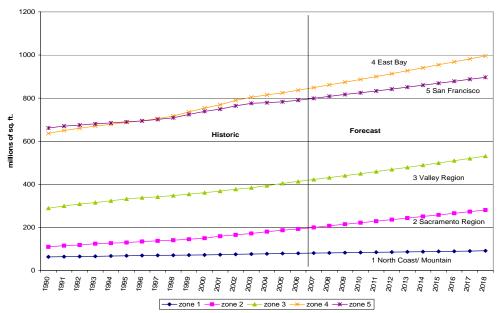

Figure 28: PG&E Planning Area Commercial Electricity Consumption by Climate Zone

**Figure 29** presents the revised forecast of commercial floor space by climate zone. Floor space in the East Bay region and Valley regions are growing at the fastest

Figure 29: PG&E Planning Area Commercial Floor Space by Climate Zone

Source: California Energy Commission, 2007.

rate.

**Figure 30** provides a comparison of the commercial peak demand forecasts. Forecast differences are driven primarily by the underlying electricity consumption forecasts and exhibit a similar pattern.

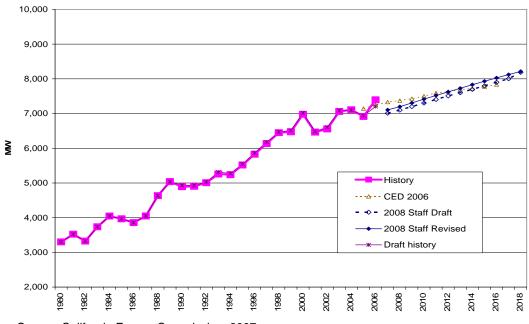

Figure 30: PG&E Planning Area Commercial Sector Peak

Source: California Energy Commission, 2007.

In staff's commercial building sector forecasting model, floor space by building type, such as retail, offices, and schools, is the key driver. **Figure 31** provides a comparison of total commercial floor space projections and historic estimates used in the two forecasts. In the latter part of the forecast period, the revised forecast is slightly lower than the draft forecast due to revisions in the economic and demographic projections used to derive commercial floor space estimates. Both of the recent forecasts are higher than the *CED 2006* forecast due to revisions in the estimation procedure described in Chapter 1 of this report.

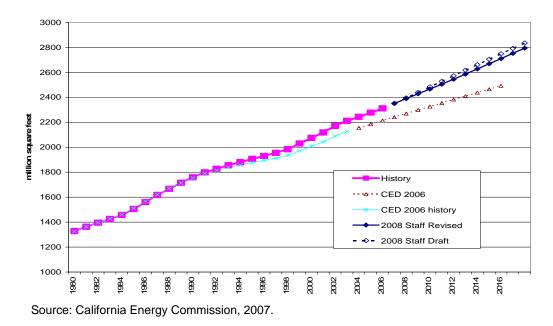

Figure 31: PG&E Planning Area Commercial Floor Space

Historical and projected commercial sector annual and peak use per square foot are shown in **Figures 32** and **33**, respectively. Historic differences in annual use per square foot are based on changes in historic floor space estimates and are also presented in Figure 32. Use per square foot in the revised forecast starts at a slightly higher value for both the electricity and peak forecasts. This is caused by revisions to both historical consumption and square footage estimates. The revised 2008-2018 forecast of annual use per square foot remains relatively constant in the first half of the forecast period and declines slightly in the second half of the forecast period due to effects of building and appliance standards and other conservation efforts.

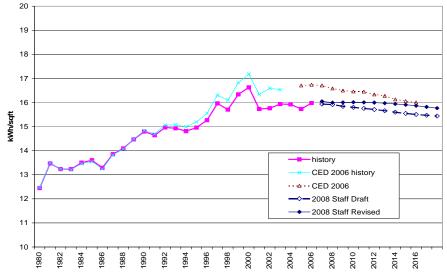

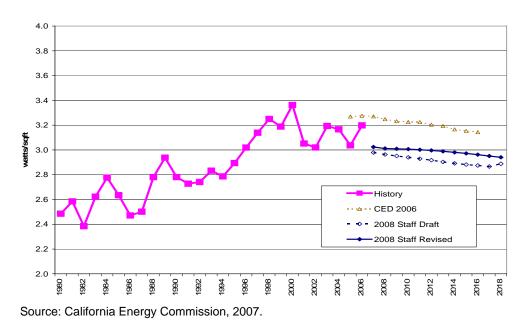

Figure 32: PG&E Planning Area Commercial kWh per Square Foot

Source: California Energy Commission, 2007.

## **Industrial Sector**

**Figure 34** provides comparisons of the PG&E planning area industrial sector electricity consumption forecasts. The revised industrial consumption forecast is lower than the draft forecast because of a lower assumed starting point. The projected growth in the revised forecast is also somewhat less than was projected in the draft forecast because assumptions about energy intensity trends were revised for each industry to be more consistent with recent historical patterns. The higher starting point of the draft forecast is, in part, a result of distributing previously unclassified consumption into the industrial sector based on revised QFER filings by various utilities.

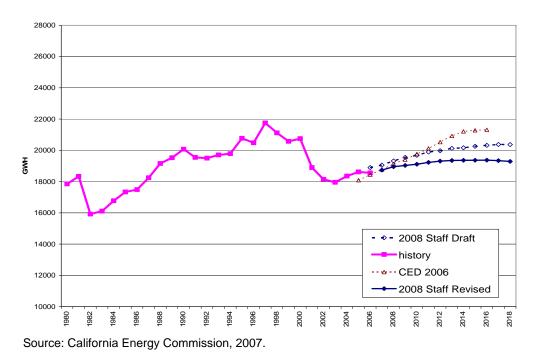

Figure 34: PG&E Planning Area Industrial Consumption

**Figure 35** presents the PG&E industrial sector forecast by climate zone. The industrial sector forecast slightly increases in the East Bay region. In all other regions the forecast is either constant or declining slightly.

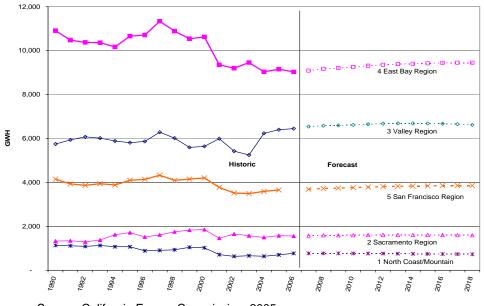

Figure 35: PG&E Planning Area Industrial Forecast by Climate Zone

Source: California Energy Commission, 2005.

**Figure 36** provides a comparison of the industrial sector peak forecasts. The revised peak forecast is lower than the draft peak forecast, which is consistent with the differences in electricity forecast.

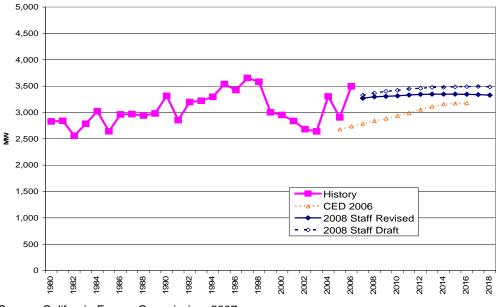

Figure 36: PG&E Planning Area Industrial Sector Peak

Source: California Energy Commission, 2007.

**Figure 37** provides a comparison of electricity use per dollar of industrial production value between the revised forecast and previous forecasts. In the revised forecast, industrial production drivers were developed for both inland and coastal regions to facilitate a climate zone specific industrial forecast for the PG&E planning area. The drivers in both regions now decline at a faster rate than was projected in the draft forecast. This is a continuation of the recent historical trend, which is in contrast to the rapid decline seen in the 1994–2000 period.

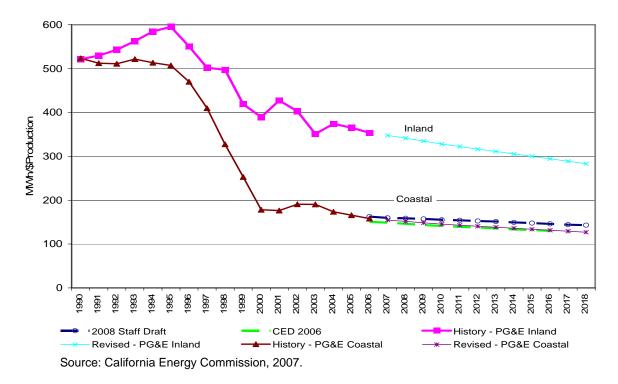

Figure 37: PG&E Planning Area Industrial Sector Use per Production Unit

## **Other Sectors**

**Figure 38** provides a comparison of the electricity consumption forecasts for the transportation, communication, and utilities and streetlighting sectors. The revised transportation, communication, and utilities and streetlighting forecast starts from a lower point than the draft forecast, but the projected growth is higher, resulting in a higher forecast in the latter portion of the forecast period. The starting point difference is a result of reallocation of previously unclassified consumption and revisions to estimates of historic self-generation.

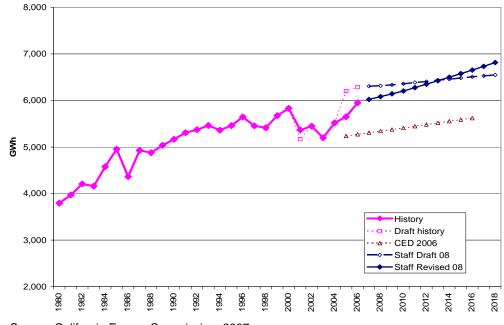

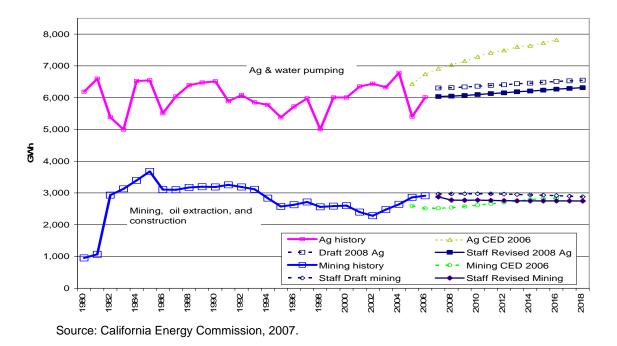

Figure 38: PG&E Planning Transportation, Communication, and Utilities and Streetlighting Sector Electricity Forecasts

Source: California Energy Commission, 2007.

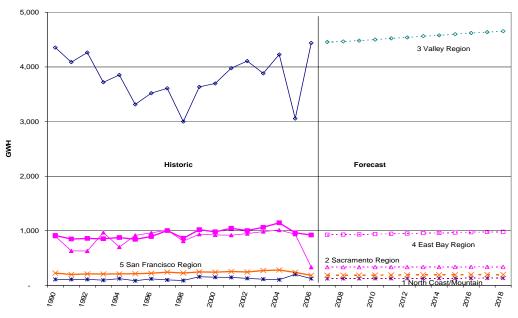

**Figure 39** provides a comparison of the electricity consumption forecasts for the agriculture and water pumping and mining and oil extraction sectors. The revised agriculture and water pumping forecast is lower than the draft forecast. This is caused by a decrease in the recent history of surface water pumping. This lower level of surface water pumping is expected to continue. The revised mining and oil extraction sector forecast is lower than the draft forecast based on revised energy intensity assumptions. The revised forecast is projected to remain fairly constant because of constraints on future capacity expansion.

Figure 39: PG&E Planning Area Other Sector Electricity Forecasts (Agriculture and Water Pumping and Mining and Oil Extraction)

**Figure 40** provides PG&E agriculture and water pumping forecast by climate zone. This sector is dominated by the inland valley region due to its agricultural base.

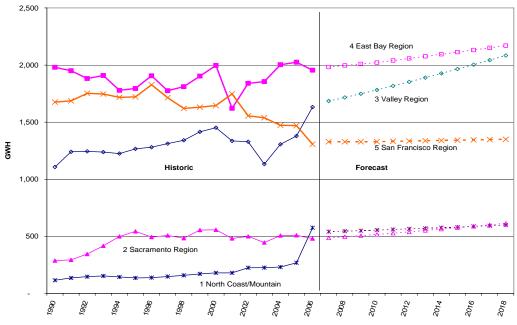

Source: California Energy Commission, 2007.

**Figure 41** presents the remainder of the Other sector (Transportation, Communication, and Utilities and Streetlighting forecast combined with the Mining and Oil Extraction forecast by climate zone) forecasts by climate zone. The forecast for Climate Zone 3 (Valley) is higher because of a projected increase of mining and oil extraction activity in that region.

#### Figure 41: PG&E Planning Area Other (Transportation, Communication, and Utilities; Streetlighting; Mining and Oil Extraction) Sector Electricity Forecasts by Climate Zone

Source: California Energy Commission, 2007

**Figure 42** provides a comparison combined peak forecast for these sectors. The revised forecast is lower over the entire forecast period than the draft forecast. This is caused by lower underlying electricity consumption forecasts.

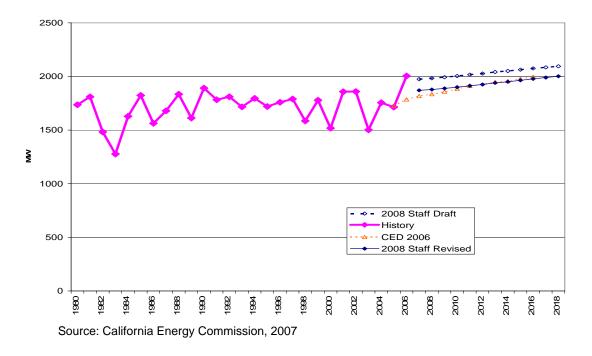

Figure 42: PG&E Planning Area Other Sector Peak

## **Electricity Prices**

As in the draft forecast, the revised 2008 forecast used prices that are held constant (in real terms) at the 2005 level for all sectors. This is in contrast to the declining price forecast that was used in the *CED 2006* forecast.

## Self Generation

As discussed in Chapter 1, the peak demand forecast is reduced by the projected effects of the SGIP, CSI, and other similar programs. The effects of these programs are forecast based on recent trends in installations. **Figure 43** shows the staff forecast of impacts from all non-PV and the incremental impact of new PV installations. Based on current trends, staff projects about 28 MW per year of additional peak reduction from self-generation, mostly from new PV systems.

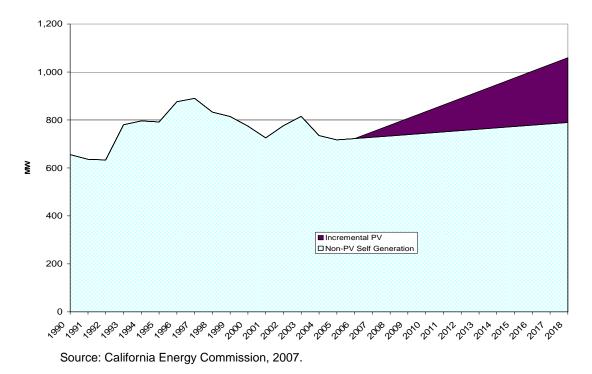

Figure 43: PG&E Planning Area Self-Generation Peak Forecast

### **Conservation Savings Embedded in the Forecast**

As discussed in Chapter 1, savings from building and appliance standards through 2005 are modeled in the Energy Commission residential and commercial demand forecast models. Savings from historical public agency and utility programs funded through 2008 are also included. To estimate the magnitude of these savings, the models are operated in a series of runs eliminating these programs in the reverse chronological order of the programs' occurrence. The savings are then calculated by subtracting the results of the run with the program in effect from the results without the program in effect. A condensed version of the results of this analysis is presented here as a partial estimate of conservation effects embedded in the revised forecast; see Chapter 1 for a detailed discussion of the relationship between forecast assumptions and utility program plans. **Table 13** presents electricity consumption savings, by broad program category, for selected years. **Table 14** presents similar estimates of peak savings. More detailed results can be found in Appendix A.

It should be noted that all savings are ultimately measured against a baseline before 1975, the year in which the first standards were introduced. For the PG&E planning area, in particular, this choice of base year produces a large volume of savings from price effects, as PG&E commercial prices increased significantly between 1975 and 1979. Savings from prices effects would be substantially lower if a more recent base year were chosen from which to measure savings.

### Table 13: PG&E Planning Area Electricity Conservation Savings Estimates

	1990	2000	2005	2008	2013	2018

# CHAPTER 3: SOUTHERN CALIFORNIA EDISON PLANNING AREA

The Southern California Edison (SCE) planning area includes: (1) SCE bundled retail customers, (2) customers served by energy service providers (ESPs) using the SCE distribution system to deliver electricity to end users, and (3) customers of the various Southern California municipal and irrigation district utilities with the exception of the cities of Los Angeles, Pasadena, Glendale, and Burbank and the Imperial Irrigation District.

This chapter is organized as follows. It first presents forecasted consumption and peak loads for the SCE planning area, including both total and per capita values. It compares the revised 2008-2018 forecast to both the draft 2008-2018 and *CED 2006* forecasts and explains differences between the forecasts. It also discusses the forecasted load factor, jointly determined by the consumption and peak load estimates. Next, the chapter presents the forecasts for the four climate zones that make up the SCE planning area. It then makes sector consumption and peak load forecasts comparisons for the residential, commercial, industrial, and "other" sector forecasts. This is followed by discussion of the forecasts for the Self-Generation Incentive Program (SGIP) and the California Solar Initiative (CSI) and followed lastly by estimates of conservation savings embedded in the revised forecast by sector and broad program category.

## **Forecast Results**

**Table 15** compares the revised electricity consumption forecast with the draft 2008-2018 and *CED 2006* forecasts. The revised forecast is higher than both of the previous forecasts over the forecast period. By the end of the forecast period, the revised forecast is about 2.5 percent higher than the draft forecast and 4.5 percent higher than the *CED 2006* forecast. The increase in the revised forecast results from incorporation of the new Department of Finance (DOF) long-term population projections. DOF raised its projection of population in the SCE planning area, particularly in the hotter Inland Empire region of the planning area.

**Table 16** presents a similar comparison for the peak demand forecasts. The increase in peak demand of the revised forecast is driven by the underlying changes in the energy consumption forecasts. The increase in the 2008–2016 growth rate of the revised forecast compared with the previous two forecasts is primarily driven by the revised DOF population forecast used in the revised forecast.

## Table 16: SCE Planning Area Peak Forecast Comparison

Source: California Energy Commission, 2007

As shown in **Figure 44**, the revised electricity consumption forecast starts at a point similar to the draft forecast. The revised forecast, however, grows at a faster rate over the forecast period than the draft forecast. This is mainly caused by revisions to the economic and demographic projections.

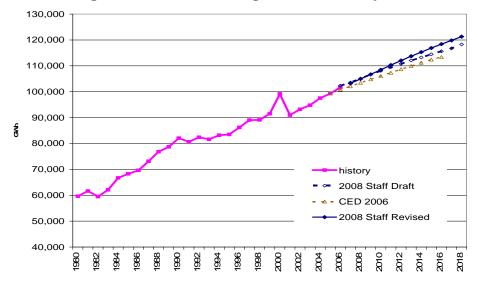

Figure 44: SCE Planning Area Electricity Forecast

Source: California Energy Commission, 2007.

The revised SCE planning area peak demand forecast, shown in **Figure 45**, also grows at a faster rate than the draft forecast. This is caused by the underlying electricity consumption forecast differences. The 2007 value of the revised 2008 forecast is based on normal weather assumptions. Load data to enable staff to develop a weather-adjusted 2007 peak value for the SCE planning area was not available at the time of the forecast. The temperatures in the SCE planning area on the 2007 summer peak day were substantially above normal, or "1-in-2" conditions, as were the temperatures in 2006, so the actual 2007 peak will be higher than what is estimated using normal weather.

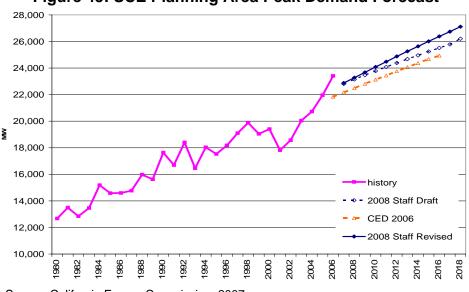

Figure 45: SCE Planning Area Peak Demand Forecast

Source: California Energy Commission, 2007.

As **Figure 46** shows, projections of per capita electricity consumption in the revised forecast are lower than in the draft forecast, but higher than the *CED 2006* forecast. This is in part because of inclusion of 2006 historical consumption data and revisions to the population forecast. The 2006 historical consumption data was lower than what was estimated in the draft forecast, and the revised population forecast is higher than what was used in the draft forecast. This yields a lower per capita consumption starting value and a somewhat lower forecast than was presented in the draft forecast. The decline of per capita consumption seen in the latter part of the revised forecast period is caused by declines in the growth rates of commercial and industrial sector consumption in the latter part of the forecast period, reflecting assumed savings from conservation programs and building and appliance standards effects, as well as a change in composition of industrial use. Per capita consumption in the revised forecast does not return to the pre-energy crisis levels until 2010 and remains well below the 2000 value throughout the forecast period.

**Figure 47** provides a comparison of per capita peak demand. The revised forecast of per capita peak demand is similar to the draft forecast and does not exhibit the reduction seen in the consumption forecast. This is caused by increased electricity consumption forecasts in both the residential and commercial sectors, which are more sensitive to peak demand.

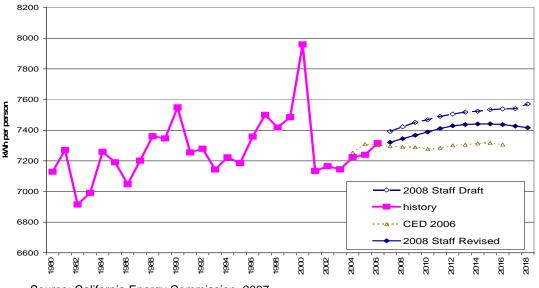

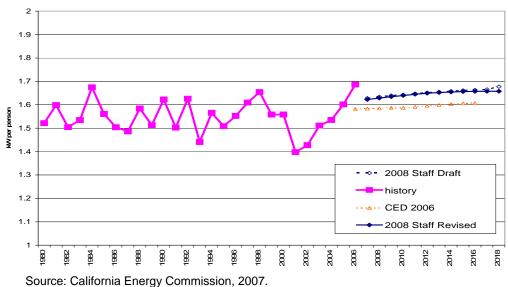

Figure 46: SCE Planning Area per Capita Electricity Consumption

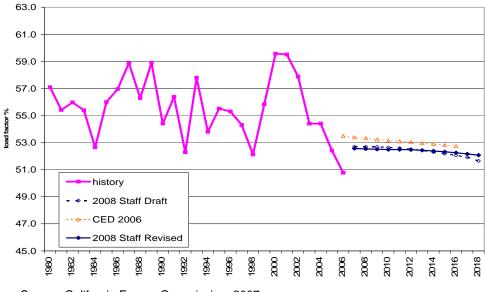

Source: California Energy Commission, 2007.

**Figure 48** compares load factors of the revised forecast with the two previous forecasts. The load factor is a measure of the relative increase in peak demand with respect to annual electricity consumption. Lower load factors indicate a sharper needle peak, and higher load factors indicate a more stable load. The revised forecast load factors are on the low end of the range of recent values and projected to decline slightly over the forecast period.

Over the forecast period, the revised load factor declines slightly, which is consistent with higher weather-sensitive load growth in relation to baseload energy growth. Consumption in the SCE planning area is shifting toward residential and commercial sectors and away from the industrial sectors. Growth is also increasingly taking place in hotter inland areas, leading to greater saturation of central air conditioning and greater use of air conditioning equipment compared to earlier concentrations in cooler coastal areas. Additionally, air conditioning loads are increasing along the coast as more households install air conditioning units for the few days they may be needed each year. This usage pattern adds to peak demand but adds very little to annual electricity consumption.

Source: California Energy Commission, 2007

## Forecast Results by Climate Zone

In the staff forecasting models, the SCE planning area is composed of four distinct climate zones: Zone 7 (southern San Joaquin Valley); Zone 8 (coastal part of Los Angeles Basin served by SCE); Zone 9 (inland part of the Los Angeles Basin served by SCE); and Zone 10 (Inland Empire). **Tables 17** and **18** present the electricity consumption and peak forecast by climate zones. The highest growth is projected to occur in both the Inland Empire (Zone 10) and southern San Joaquin (Zone 7) regions of the SCE planning area.

	Consumption (GWH)											
	Zone 7 Southern	Zone 8	Zone 9	Zone 10

**Figure 49** presents electricity forecasts by climate zone for the SCE planning area. The fastest growing region is the Inland Empire (Zone 10). The inland and coastal parts of the Los Angeles Basin are projected to grow at about one half the rate of the Inland Empire. **Figure 50** presents the peak forecast estimates by climate zone. Staff does not have reliable estimates of historical loads that translate well to climate zones, thus the historical peak estimates are developed from the staff model based on electricity consumption and calibrated to individual

LSE peak load data, where available. More geographically disaggregate load data are needed to make more accurate peak estimates by climate zone.

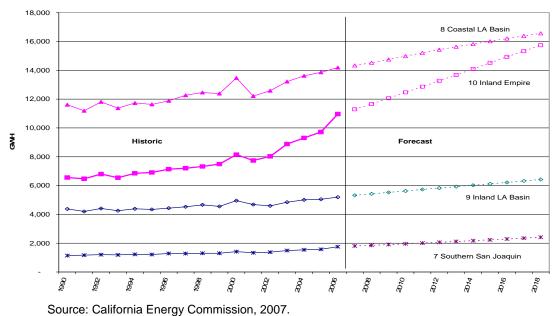

Figure 49: SCE Planning Area Electricity Forecast by Climate Zone

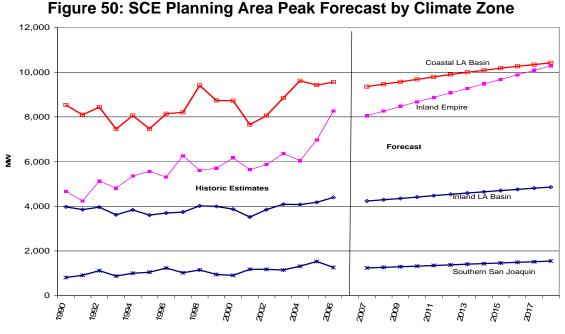

Figure 50: SCE Planning Area Peak Forecast by Climate Zone

Source: California Energy Commission, 2007.

# **Sector Level Results and Input Assumptions**

# Residential

**Figure 51** provides a comparison of the revised forecast of electricity consumption with previous SCE planning area residential forecasts. The revised forecast is higher throughout the entire forecast period. This is caused both by inclusion of actual 2006 consumption data in the historical period and use of the new Department of Finance long-term population projections. The inclusion of 2006 historic consumption raises the starting point of the forecast slightly, and the new population forecast increases the overall forecasted growth rate driven by increases in population projections in the Inland Empire, in particular.

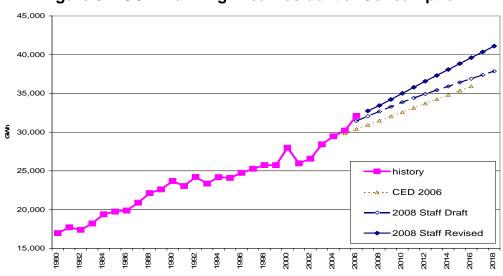

Figure 51: SCE Planning Area Residential Consumption

Source: California Energy Commission, 2007.

**Figure 52** presents the revised residential forecast by climate zone. The large projected growth in the Inland Empire is driven by increased population forecasts for that region. This can be seen in **Figure 53**, which presents the revised household forecast by climate zone.

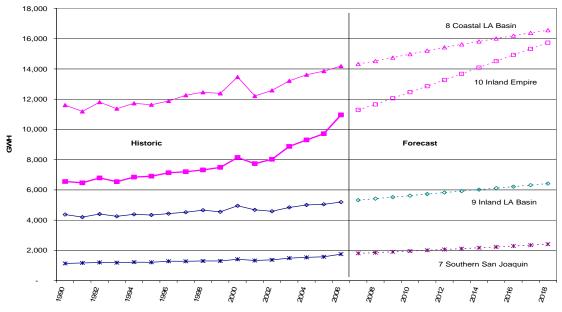

Figure 52: SCE Planning Area Residential Electricity Forecast by Climate Zone

Source: California Energy Commission, 2007.

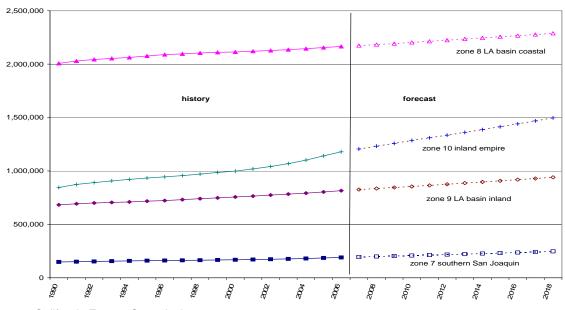

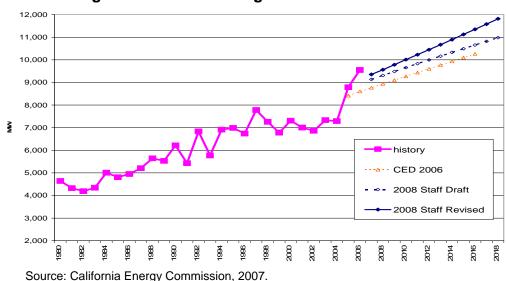

Figure 53: SCE Planning Area Household Forecast by Climate Zone

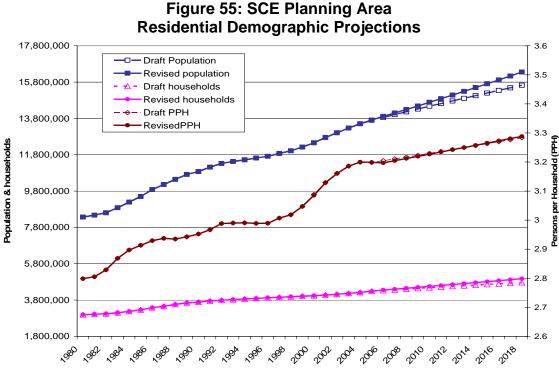

Source: California Energy Commission, 2007.

**Figure 54** provides a comparison of the revised residential peak demand forecasts with the previous forecasts. As is the case for residential consumption, the revised residential peak forecast is higher than both previous forecasts. The difference between the peak forecasts is similar to the difference in the electricity consumption forecasts.

Figures 55 and 56 provide comparisons of the residential drivers used in the revised forecast with those used in the draft forecast. Values used in the draft forecast were similar to those used in the CED 2006 forecast. Figure 55 provides comparisons of total population, total households, and persons per household projections. The revised forecast of total population is higher than the draft forecast. The revised Department of Finance long-term population forecast increased population projections for the SCE planning area. In addition, incorporation of recently updated historic estimates leads to a slight downward revision in projected persons per household estimates in the short term. However, the net impact yields an increase in projected household growth over the forecast period. The revised persons per household projections incorporate annual Department of Finance E-5A interim updates to county population and household estimates through 2006. Inclusion of these estimates slightly increases the growth in persons per household over the forecast period. The revised projected growth in persons per household per year is assumed to be half of the annual 1990-2006 growth.

Figure 54: SCE Planning Area Residential Peak

Source: California Energy Commission, 2007.

**Figure 56** provides a comparison of household income between the revised forecast and the draft forecasts. Household income is derived as the product of per capita income and persons per household. The revised projection starts from a slightly lower 2007 value but grows at a slightly higher rate in the short- to midterm because of continued optimism in the revised economic outlook for the SCE region. The higher growth continues through the forecast period so that by the last half of the forecast period, the revised forecast of household income is greater than that projected in the draft forecast. The higher household income growth serves to increase forecasted residential consumption.

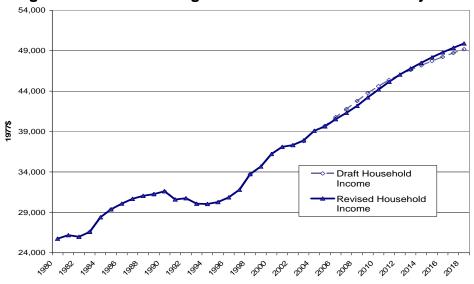

Figure 56: SCE Planning Area Household Income Projections

Source: California Energy Commission, 2007.

**Figures 57** and **58** present comparisons of energy use per household between the forecasts. Figure 57 is a comparison of annual electricity use per household, and Figure 58 is a comparison of peak demand per household. The revised forecast of energy use per household and peak use per household is somewhat higher than that projected in both of the previous forecasts. This is primarily due to higher short-term household income growth projections and higher persons per household estimates. The increased growth rate seen in the revised forecast is caused by the projected increase in population in the Inland Empire, where use per household is higher due to climate differences. Differences in peak use per household are primarily driven by the underlying consumption forecasts.

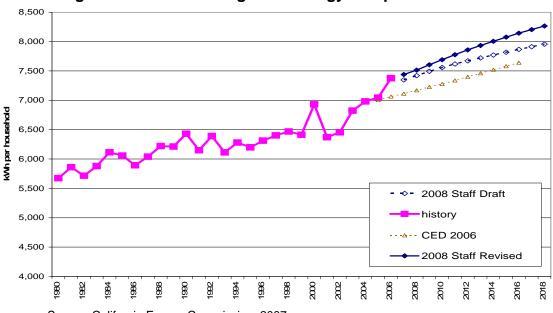

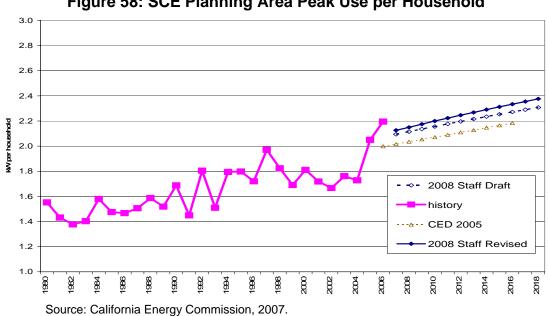

Figure 57: SCE Planning Area Energy Use per Household

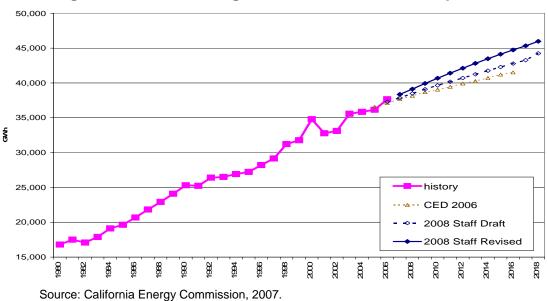

Source: California Energy Commission, 2007.

### Figure 58: SCE Planning Area Peak Use per Household

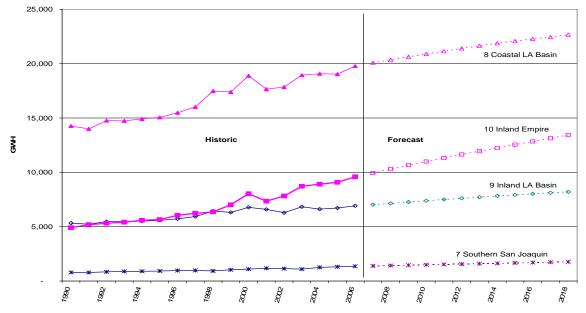

# **Commercial Building Sector**

Figure 59 provides a comparison of the commercial building sector forecasts. The revised forecast is higher than the previous forecasts throughout the entire forecast period. The forecast differences are driven by increased projections of commercial floor space. Revised floor space projections were updated using more recent demographic and economic projections.

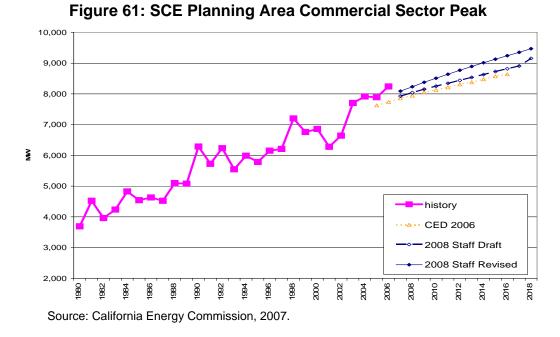

**Figure 60** presents the revised commercial forecast by climate zone. While the greatest growth is in the Inland Empire, it is not as fast as the residential sector growth.

**Figure 61** provides a comparison of the commercial peak demand forecasts. Growth in the commercial peak demand forecasts is driven primarily by the underlying electricity consumption forecasts. Therefore, the consumption and peak forecasts exhibit the same patterns.

Figure 59: SCE Planning Area Commercial Consumption

In staff's commercial building sector forecasting model, floor space by building type is the key driver for energy consumption and peak demand. **Figure 62** provides a comparison of total commercial floor space projections. The revised floor space projections are slightly higher throughout the forecast period than those used in the draft forecast because of updated economic and demographic projections. Both 2008 forecasts are higher than the previous forecast because of method changes, described in Chapter 1.

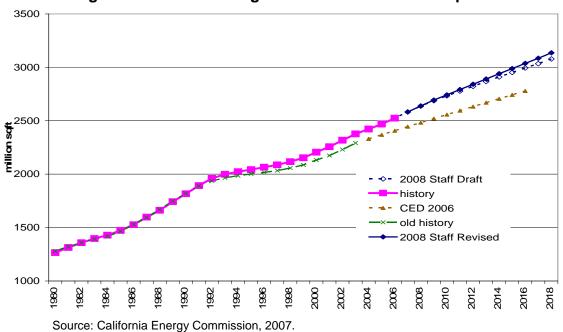

Figure 62: SCE Planning Area Commercial Floor Space

**Figures 63** and **64** show historical and projected commercial sector annual energy and peak use per square foot, respectively. Figure 63 presents changes in annual use per square foot based on historical floor space estimates. The projection of use per square foot in the revised forecast is relatively constant in the beginning of the forecast period and declines slightly toward the end of the forecast period. This is in contrast to the constant decline shown in the draft forecast period. A similar pattern can be seen in the projection of commercial peak use per square foot, shown in Figure 64. The higher starting values, in both instances, result from revised estimates of historic use. Both the energy and peak forecasts decline by the end of the forecast period due to projected impacts of commercial building and appliance standards.

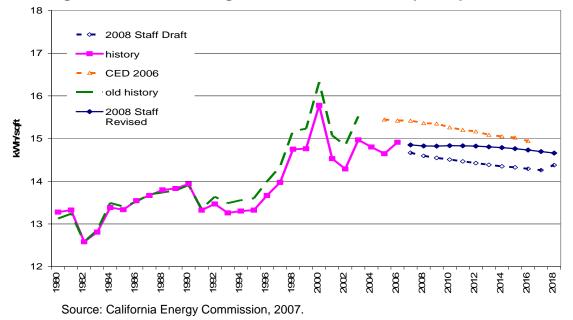

Figure 63: SCE Planning Area Commercial kWh per Square Foot

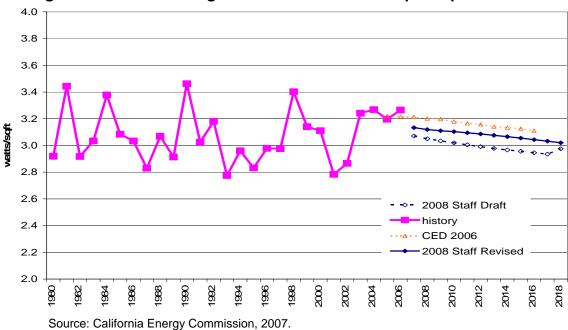

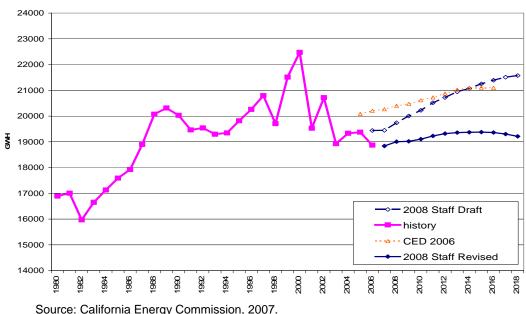

Figure 64: SCE Planning Area Commercial Watts per Square Foot

## **Industrial Sector**

**Figure 65** provides comparisons of the industrial sector electricity consumption forecasts for the SCE planning area. The revised forecast starts from a lower point than the draft forecast and grows at a slower rate over the forecast period. This produces a greatly reduced industrial forecast compared to the previous forecasts. The lower starting point is partly because historic "unclassified" consumption was allocated to the industrial sector at a lower level than previously. The lower forecasted growth rate reflects revised assumptions about energy intensity trends that are more consistent with historic energy use patterns.

Source: California Energy Commission, 2007. **Figure 66** presents the SCE industrial sector forecast by climate zone. The industrial sector forecast increases slightly in the southern San Joaquin region and is relatively flat in the remainder of the climate zones. **Figure 67** provides a comparison of the industrial sector peak forecasts. Re-estimation of the industrial sector peak caused the revised industrial sector peak to start at a somewhat lower value than in the draft forecast. Forecasted growth patterns are similar to those seen in the electricity consumption case.

Figure 65: SCE Planning Area Industrial Consumption

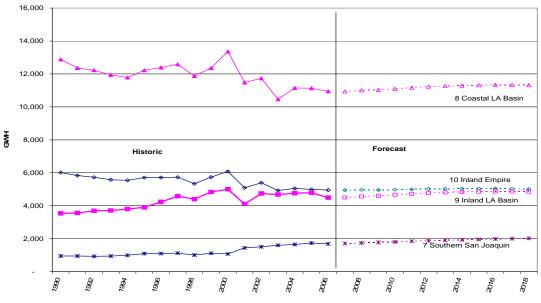

Figure 66: SCE Planning Industrial Electricity Forecast by Climate Zone

Source: California Energy Commission, 2007.

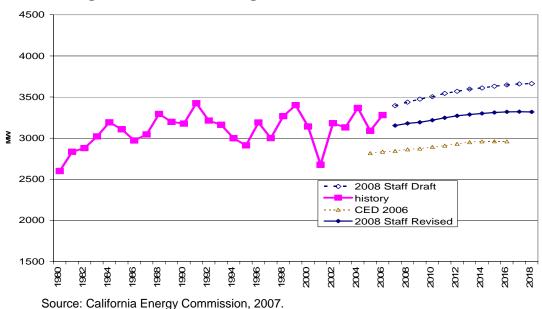

Figure 67: SCE Planning Area Industrial Sector Peak

**Figure 68** provides a comparison of electricity use per dollar of industrial production value between the revised forecast and previous forecasts. In the revised forecast, industrial production drivers were developed by coastal and inland zones to facilitate a climate region forecast for the SCE industrial sector. The revised forecast shows a greater decline in use per value added in the inland area than in the coastal zone.

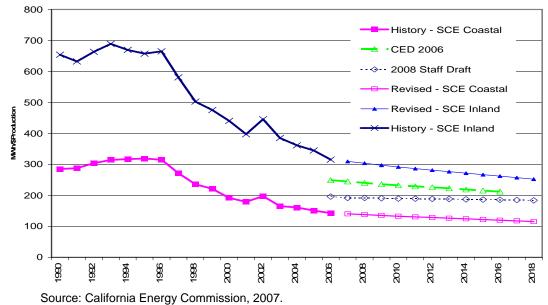

Figure 68: SCE Planning Area Industrial Peak Use per Production Unit

## **Other Sectors**

**Figure 69** provides a comparison of the electricity consumption forecasts for the transportation, communication, and utilities and streetlighting sectors. The revised transportation, communication, and utilities and streetlighting forecast is slightly higher than the draft forecast because of higher economic and demographic drivers.

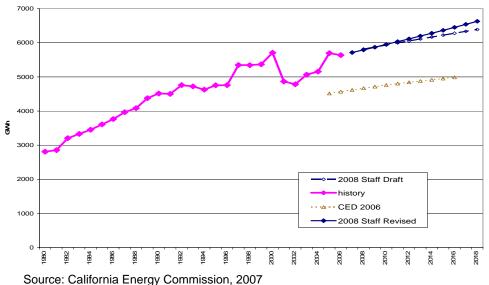

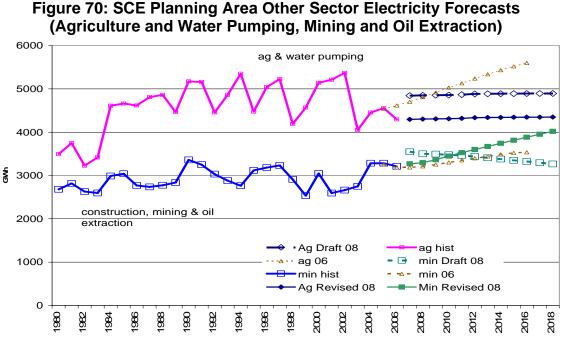

Figure 70 provides a comparison of the electricity consumption forecasts for the agriculture and water pumping and mining and oil extraction sectors. The revised agriculture and water pumping forecast is lower due to a lower starting point caused by inclusion of 2006 historical consumption estimates. The revised forecast growth rate is similar to the growth rate of the draft forecast. Both 2008 forecasts growth rates are lower than the CED 2006 growth rate due to a flatter trend projected in electricity used for urban water pumping.

The revised mining and oil extraction sector forecast is higher than the draft forecast because of increases in economic drivers used for that sector.

Source: California Energy Commission, 2007

Figures 71 and 72 present the remaining sector forecasts of electricity consumption by climate zone. Growth in the agriculture and water pumping sectors (Figure 71) is projected to be relatively constant by climate zone caused by a flat projection of electricity used for urban water pumping. Growth in the transportation, communication, and utilities and streetlighting sectors (Figure 72) mimics the population growth of the climate zones. Figure 73 provides a comparison of the combined peak for these sectors between the forecasts. The revised forecast starts from a lower initial point in 2007 but grows at a similar rate to the draft forecast.

Figure 72: SCE Planning Area TCU and Streetlighting Electricity Forecast by Climate Zone

Source: California Energy Commission, 2007.

#### Figure 73: SCE Planning Area Other Sector Peak

# **Electricity Prices**

As in the draft forecast, the revised 2008 forecast used prices that are held constant (in real terms) at the 2005 level for all sectors. This is in contrast to the declining price forecast that was used in the *CED 2006* price forecast.

# Self-Generation

**Figure 74** shows the revised 2008 forecast of demand served by self-generation. Based on recent patterns of growth reported under the SGIP, the ERP, and the CSI, the forecast assumes that an additional 20 MW per year of load will be served by photovoltaic or other self-generation technologies.

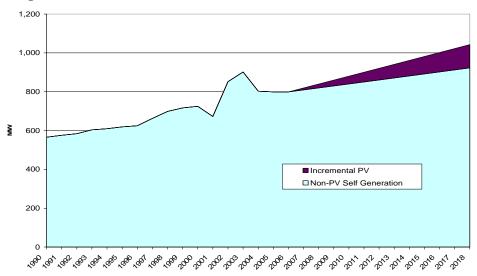

Figure 74: SCE Area Self-Generation Peak Demand Forecast

Source: California Energy Commission, 2007.

## **Conservation Savings Embedded in the Forecast**

As discussed in Chapter 1, savings from building and appliance standards through 2005 are modeled in the Energy Commission residential and commercial demand forecast models. Savings from historical public agency and utility programs funded through 2008 are also included. To estimate the magnitude of these savings, the models are run without these programs—in effect, in the chronological order of the program's occurrence. The savings are then calculated by subtracting the results of the run with the program in effect from the results without the program in effect. A condensed version of the results of this analysis is presented here as a partial estimate of savings that are embedded in the forecast. **Table 19** presents electricity consumption savings, by broad program category, for selected years. **Table 20** presents similar estimates of peak savings. More detailed results can be found in Appendix A. These tables do not quantify the effects of decreasing energy intensity (whether market or program driven) in other sectors.

# Form 2.2 - SCE Planning Area California Energy Demand 2008-2018 Staff Revised Forecast Planning Area Economic and Demographic Assumptions

# CHAPTER 4: SAN DIEGO GAS & ELECTRIC PLANNING AREA

The San Diego Gas & Electric (SDG&E) planning area includes (1) SDG&E bundled retail customers, (2) customers served by non-utility energy service providers (ESPs) using the SDG&E distribution system, and (3) customers served by the city of Escondido.

This chapter first presents forecasts of total and per capita consumption and peak loads for the planning area. It then compares the revised 2008-2018 forecast values to both the draft 2008-2018 and *CED 2006* forecasts. It also discusses the forecasted load factor, jointly determined by the consumption and peak load estimates. The chapter then presents sector consumption and peak load forecasts and compares them at the sector level to both previous forecasts. Finally, the chapter presents estimates of conservation savings embedded in the revised forecast.

# **Forecast Results**

**Tables 21** and **22** present comparisons of the planning area electricity consumption and peak demand forecasts for selected years. The revised electricity consumption forecast, presented in Table 21, is less than 1 percent higher than the draft forecast. This is caused by a revision to historical self-generation estimates that increased historical consumption values. The long-term growth rate of the revised forecast is virtually identical to the draft forecast.

Consumption (GWH)						
	CED 2006	Staff Draft	Staff Revised	Percent Difference Staff Revised/CED 2006	Percent Difference Staff Revised/Staff Draft	
1990	14,926	14,926	14,926	0.00%	0.00%	
2000	19,295	19,295	19,294	0.00%	0.00%

Historic values are shaded						

Table 22: SDG&E Planning Area Peak Forecast Comparison

Source: California Energy Commission, 2007.

As shown in **Figure 75**, the revised forecast is only slightly higher than the draft consumption forecast. Projected growth rates of the forecasts are essentially the same.

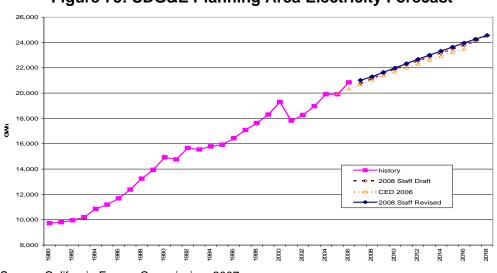

Figure 75: SDG&E Planning Area Electricity Forecast

Source: California Energy Commission, 2007.

**Figure 76** compares the various peak forecasts. The revised peak demand forecast has a similar growth rate as the draft forecast. The starting point of the revised forecast is consistent with the updated 2008 peak forecast adopted in June 2007.

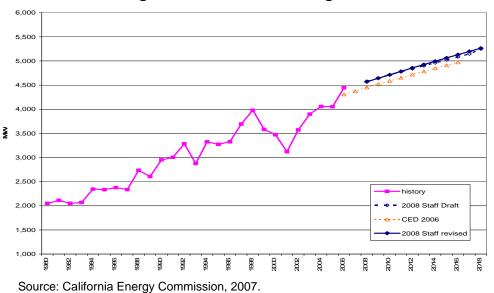

Figure 76: SDG&E Planning Area Peak

**Figure 77** compares forecasted per capita residential electricity consumption. Per capita consumption in the revised forecast is higher than in the draft forecast because of upward revisions to historical consumption estimates and higher projected growth in per capita income.

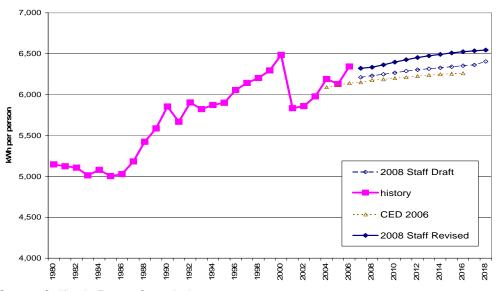

Figure 77: SDG&E Planning Area per Capita Electricity Consumption

Source: California Energy Commission, 2007.

Revised per capita peak demand, shown in **Figure 78**, grows at a slightly greater rate than in the draft forecast. This is caused by both a change in the mix of nonresidential sector consumption projections and an increase in the growth of per capita income over the forecast period. The projections of per capita peak demand still remain below pre-electricity crisis levels until the end of the forecast period.

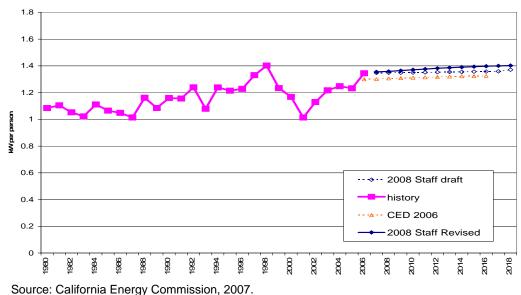

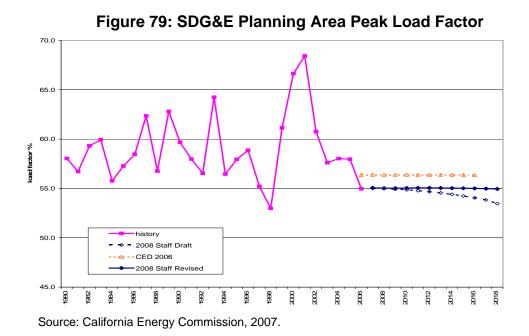

Figure 78: SDG&E Planning Area per Capita Peak Demand

**Figure 79** provides a comparison of the respective forecast load factors. High load factors observed from 1998 to 2005 are a product of lower-than-average temperatures reducing peaks compared with what would have been expected, and a reaction to the energy crisis when consumers voluntarily reduced their air conditioning usage. The projected load factor, based on higher, 1-in-2 peak temperatures and a return to normal air conditioning use patterns, should be lower than these recent values. The forecasted load factor is relatively constant at the lower end of the historical spectrum, reflecting an increase in air conditioning use in the SDG&E territory.

# **Sector Level Results and Input Assumptions**

# Residential

**Figure 80** provides comparisons of the residential electricity forecasts. The revised forecast is slightly lower than the draft forecast and slightly higher than the *CED 2006* forecast. These differences are caused by incorporation of the new DOF long-term population forecast for the SDG&E planning area. The new population forecast is slightly lower than the one used in both previous forecasts. However, the lower population forecast is partially offset by faster growth in the revised household income forecast. The draft forecast used December 2006 economic projections from Economy.com; the revised forecast uses their May 2007 projections.

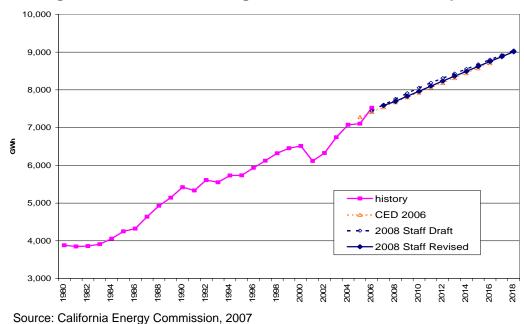

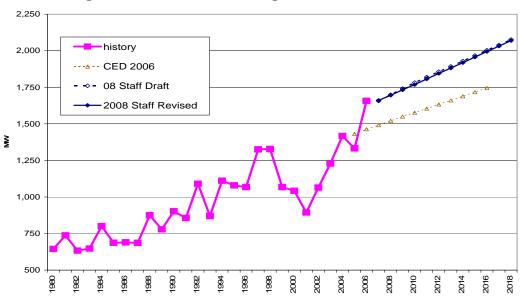

Figure 80: SDG&E Planning Area Residential Consumption

**Figure 81** compares the revised 2008-2018 residential peak demand forecasts with both the draft 2008-2018 and *CED 2006* forecasts. The differences in the respective electricity forecasts drive differences between the revised and draft forecasts.

**Figures 82** and **83** provide comparisons of the residential drivers used in the revised forecast with those used in the draft forecast. Figure 82 provides comparisons of total population, total households, and persons per household projections. The

Source: California Energy Commission, 2007

revised 2008 forecast of total population is slightly lower than the draft 2008 forecast. This produces a slightly lower revised household forecast.

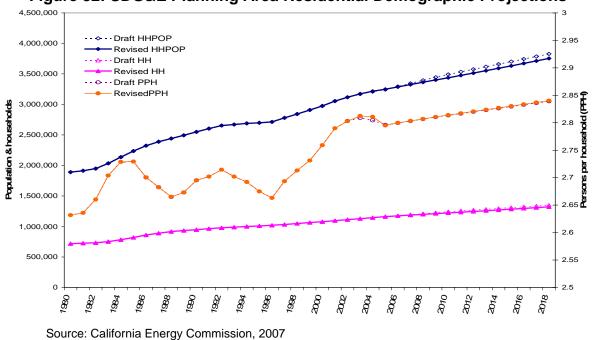

Figure 82: SDG&E Planning Area Residential Demographic Projections

Figure 83 provides a comparison of household income projections used in the revised forecast with those used in the draft forecast. The revised projection, using the May 2007 Economy.com forecast, is lower in the short term but grows at a faster rate over the forecast period than the December 2006 projection that was used in the draft forecast.

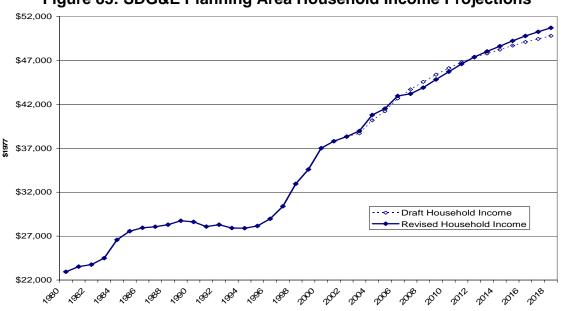

Figure 83: SDG&E Planning Area Household Income Projections

Source: California Energy Commission, 2007.

**Figures 84** and **85** present comparisons of use per household between the forecasts. Figure 84 is a comparison of annual electricity use per household, and Figure 85 is a comparison of peak demand per household. Both the electricity and peak revised forecasts of use per household are slightly higher than the draft projections, primarily because of higher household income growth projections.

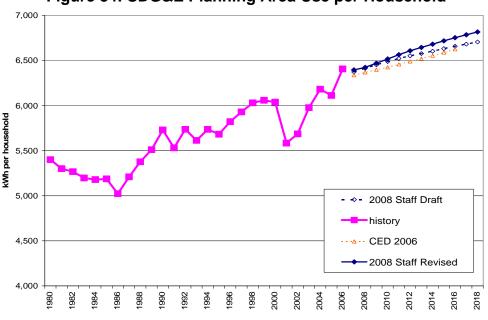

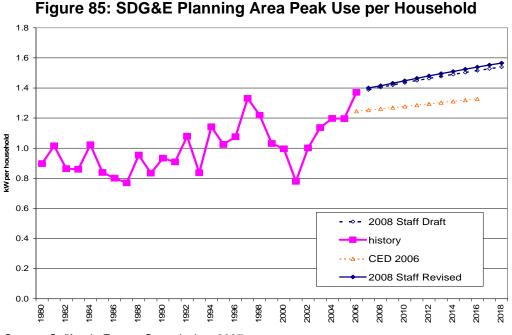

Figure 84: SDG&E Planning Area Use per Household

Source: California Energy Commission, 2007

Source: California Energy Commission, 2007

# **Commercial Building Sector**

**Figures 86** and **87** provide a comparison of the commercial building sector forecasts. The revised forecast is lower than the draft forecast. This difference is caused by lower estimates of historic consumption, provided by SDG&E, of both commercial retail sales and self-generation. The forecasted growth rates of the forecasts are essentially the same.

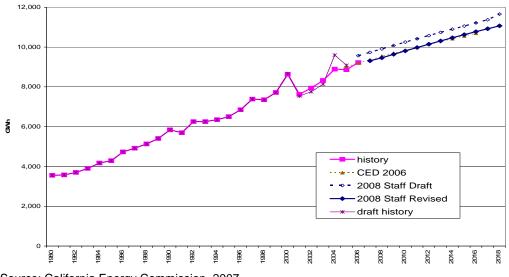

Figure 86: SDG&E Planning Area Commercial Consumption

Source: California Energy Commission, 2007.

Figure 87 provides a comparison of the commercial building sector peak demand forecasts. These differences mirror the differences in energy forecasts.

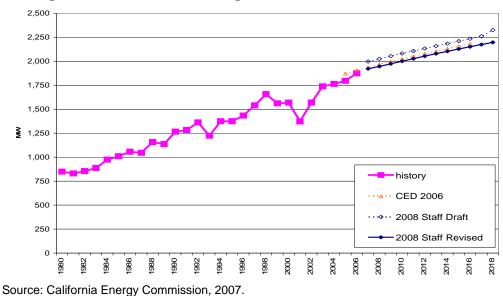

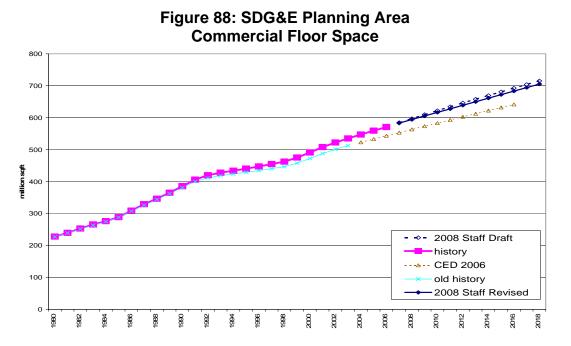

Figure 87: SDG&E Planning Area Commercial Sector Peak

In staff's commercial building sector forecasting model, projected floor space by building type, such as retail, schools, and offices, is the key driver of forecasted energy use. **Figure 88** provides a comparison of total commercial floor space projections. The revised 2008 floor space forecast is slightly lower than the draft 2008 forecast, primarily because of the lower population forecast.

Source: California Energy Commission, 2007.

**Figures 89** and **90** present historic and projected commercial sector annual and peak use per square foot, respectively. The lower values seen in the revised forecast is related to changes in historical commercial consumption estimates described previously. The revised annual use per square foot forecast, shown in Figure 89, is projected to decline at a slower rate than the draft forecast. However, the revised forecast of commercial peak use per square foot, shown in Figure 90, is projected to decline at a similar rate to the draft forecast. The energy and peak forecasts of use per square foot decline over the forecast period because of projected impacts of commercial building and appliance standards considered to be committed.

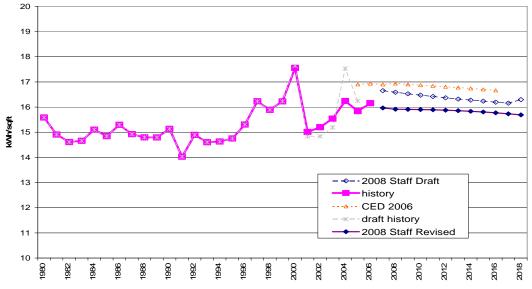

Figure 89: SDG&E Planning Area Commercial kWh per Square Foot

Source: California Energy Commission, 2007.

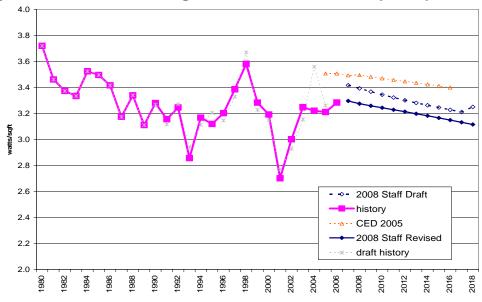

Figure 90: SDG&E Planning Area Commercial Watts per Square Foot

# **Industrial Sector**

**Figure 91** provides a comparison of the industrial sector electricity consumption forecasts for the SDG&E planning area. The revised forecast is lower throughout the entire forecast period than the draft forecast. This is caused by a lower 2006 starting point and revised estimates of energy intensity trends.

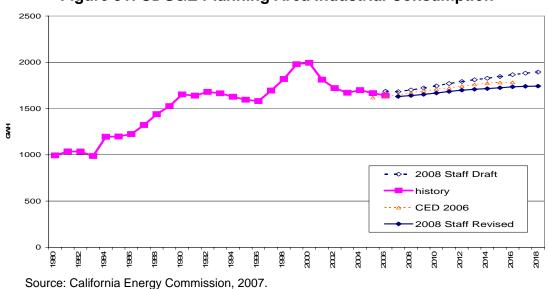

Figure 91: SDG&E Planning Area Industrial Consumption

**Figure 92** provides a comparison of the industrial sector peak forecasts. The peak forecast differences are driven by differences in the electricity consumption

Source: California Energy Commission, 2007.

forecasts. As was the case for industrial sector consumption, the revised growth rate of peak demand is slightly lower than that projected in the draft forecast.

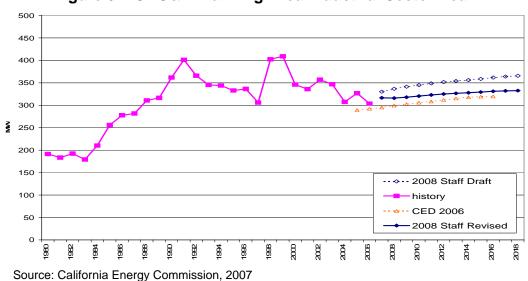

Figure 92: SDG&E Planning Area Industrial Sector Peak

**Figure 93** provides a comparison of use per dollar value of production between the forecasts. The difference in kWh per dollar of industrial value added in the forecasts is caused by different estimated starting points. The revised forecast of use per dollar of value added declines at a slightly faster rate than the draft forecast. Staff reviewed the historical energy use trends and revised the forecast model assumptions to be more consistent with observed patterns of declining use per dollar of production.

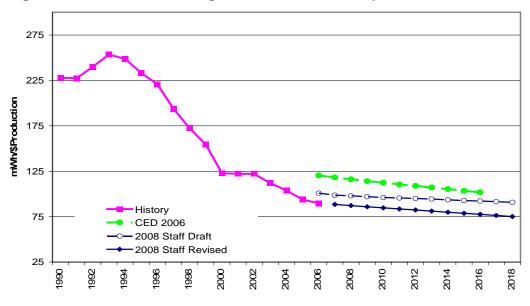

Figure 93: SDG&E Planning Area Industrial Use per Production Unit

Source: California Energy Commission, 2007

# **Other Sectors**

**Figures 94** and **95** provide comparisons of the remaining sector electricity consumption forecasts. Figure 94 provides a comparison of the transportation, communication, and utilities (TCU) sector forecasts. The revised forecast is higher than the draft forecast due to reallocation of additional historical consumption to the TCU sector based on estimates from SDG&E.

Figure 95 provides comparisons of the agriculture and water pumping and mining and oil extraction sector forecasts. The revised agriculture and water pumping forecast is higher than the draft forecast because inclusion of 2006 consumption data created a higher starting point. The revised mining and oil extraction forecast has a higher starting point because of changes in the unclassified consumption distribution. The lower growth rate of the revised forecast compared to *CED 2006* reflects the pattern of Economy.com's forecast of mining sector employment, which is used as the forecast driver.

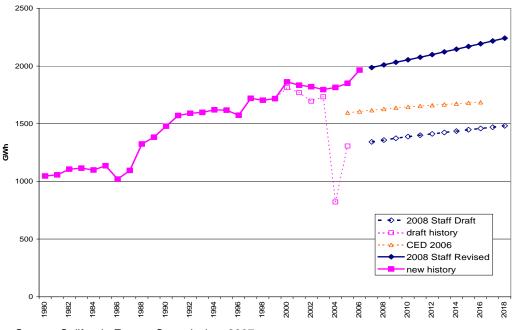

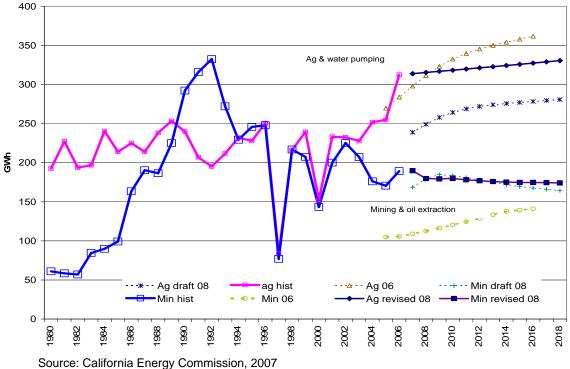

Figure 94: SDG&E Planning Area Transportation, Communication, and Utilities Sector Electricity Consumption

Source: California Energy Commission, 2007

**Figure 96** provides a comparison of the combined Other Sector peaks for the draft and revised 2008 forecasts and *CED 2006* forecast. The revised 2008 forecast starts at a higher level than the draft forecast, as does the consumption forecast, because of revised historic consumption data. Both forecasts have a similar growth rate.

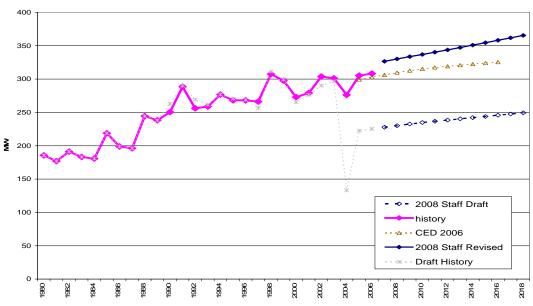

Figure 96: SDG&E Planning Area Other Sector Peak

Source: California Energy Commission, 2007.

# **Electricity Prices**

As in the draft forecast, the revised 2008 forecast used prices that are held constant (in real terms) at the 2005 level for all sectors. This is in contrast to the declining price forecast that was used in the *CED 2006* price forecast.

# Self-Generation

As discussed in Chapter 1, the peak demand forecast is reduced by staff's estimate of the effects of the Self-Generation Incentive Program and California Solar Initiative programs. Both programs are forecast based on the recent trend of installations. **Figure 97** shows the resulting forecast of cumulative peak impacts. Annual impacts are reported as "Private Supply" in Forms 1.2 and 1.4 following this chapter. Because the actual energy consumption and coincident peak impacts of PV are not reported to the Energy Commission, and therefore are not included in the consumption forecast, only the incremental impacts of new PV installations are forecast and subtracted from the peak demand forecast.

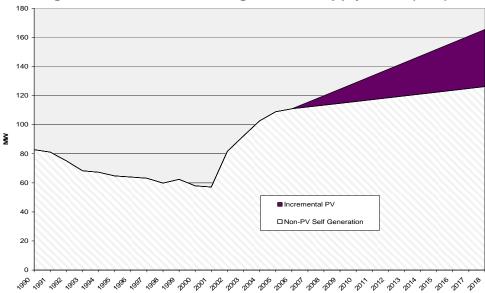

Figure 97: SDG&E Planning Private Supply Peak (MW)

Source: California Energy Commission, 2007.

# **Conservation Savings Embedded in the Forecast**

Savings from all building and appliance standards adopted through 2005 are accounted for in the Energy Commission residential and commercial demand forecast models. Savings from public agency and utility programs funded through 2008 are also included. However, there may be some overlap with effects embedded in the demand forecast with uncommitted program impacts; see Chapter 1 for a discussion of this issue. To determine the magnitude of these savings, the models are run without these programs in effect (in the chronological order of the programs' occurrence). The savings are then calculated by subtracting the results of the run with the program in effect from the results without the program in effect. A condensed version of the results of this analysis is presented here as an estimate of savings that are accounted for in the baseline forecast. Additional detail is shown in the tables at the end of this chapter. **Table 23** presents electricity consumption savings, by broad program category, for selected years. **Table 24** presents similar estimates of peak savings.

# CHAPTER 5: Sacramento Municipal Utility District Planning Area

Several alternative configurations of the loads served by various load-serving entities (LSEs) are useful for Northern California. Staff's Sacramento Municipal Utility District (SMUD) planning area includes SMUD retail customers but does not include the other members of the SMUD control area: Roseville, Redding, Modesto Irrigation District (MID), and some loads served by the Western Area Power Administration (WAPA). To support electricity system analysis, staff derives forecasts by control area and California ISO congestion zone from the planning area and climate zone forecasts. Individual LSE forecasts are prepared using weatheradjusted historic consumption and load data and use forecasted sector growth rates from the climate zone in which the LSE is located. The LSE forecasts are also adjusted to account for future migrating load or expansion of the LSE's territory. The WAPA, Roseville, Redding, and MID forecasts, included in the PG&E planning area definition, are added to the SMUD control area. Those results are presented in Chapter 1, Table 3, and in Form 1.5. The results in this chapter are for the SMUD planning area only.

This chapter first discusses forecasted consumption and peak loads for the SMUD planning area, presenting both total and per capita values. The revised 2008-2018 values are compared with both the draft 2008-2018 forecast and adopted *CED 2006* forecast; differences between forecasts are explained. The forecasted load factor, jointly determined by the consumption and peak load estimates, is also discussed. Second, the chapter presents sector consumption and peak load forecasts. It compares the residential, commercial, industrial and "other" sector staff-revised forecasts to previous forecasts and discusses differences among them. Third, the chapter presents the sector electricity prices used as inputs to the staff draft forecast. Fourth, the chapter briefly discusses self-generation included in the forecast and finally, presents and discusses estimates of conservation savings embedded in the revised forecast.

# **Forecast Results**

**Tables 25** and **26** present comparisons of electricity consumption and peak demand for selected years. The revised 2008-2018 electricity consumption forecast, presented in Table 25, is over 9 percent lower than the draft 2008-2018 forecast by 2016 and 11 percent lower by the end of the forecast period. This is caused by incorporation of the new July 2007 Department of Finance (DOF) long-term population forecast. The new long-term population forecast reduced population estimates for Sacramento County by 15 percent by the end of the forecast period. Clearly this is a major change.

The population decrease mostly affects the residential and commercial sector forecasts, which by 2018 are 13 percent lower in the revised forecast than in the draft. A lower population projection reduces the forecasted demand for services in

the commercial sector, such as grocery stores, retail, and schools, and therefore the commercial floor space forecast is lower. The effect of the population decrease is partially offset by higher persons per household numbers and a higher starting point reflecting higher actual consumption in the industrial, mining, and agriculture and water pumping sectors.

-----

The revised 2008-2018 SMUD peak demand forecast, presented in Table 26, is also lower than both the draft 2008-2018 forecast and the *CED 2006* forecast because of the revised population forecast.

**Figure 98** presents a graphical comparison of the revised 2008 electricity consumption forecast with the previous forecasts. Incorporation of the new DOF population forecast for the SMUD planning area causes the revised forecast to be lower over the entire forecast period than both of the previous forecasts. **Figure 99** presents a similar comparison of the respective peak forecasts. The differences in peak forecasts are caused by differences in the underlying electricity consumption forecasts.

### Figure 99: SMUD Planning Area Peak

Source: California Energy Commission, 2007

**Figure 100** compares the old and new per capita electricity consumption forecasts for the SMUD planning area. Projected per capita consumption in the revised 2008 forecast is higher than in the draft 2008 forecast. Part of the difference is caused by incorporating 2006 consumption data into the historical period. Industrial sector electricity consumption increased in 2006 over recent historical values. This had the effect of raising the starting level of per capita consumption slightly. Per capita consumption is projected to increase slightly in the SMUD planning area due to projected increases in use per household and higher projections of industrial consumption than were in the draft 2008 forecast.

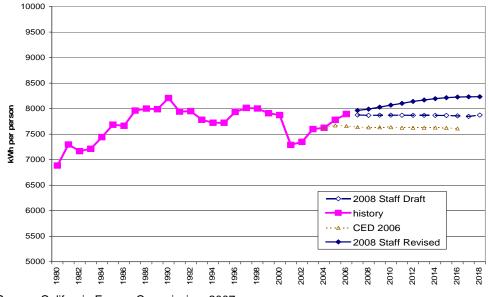

Figure 100: SMUD Planning Area per Capita Electricity Consumption

Source: California Energy Commission, 2007

Revised 2008 per capita peak demand, shown in **Figure 101**, increases over the forecast period at a slightly higher level than the draft 2008 forecast. The projections are higher than the draft 2008 forecast because of increases in the assumed starting 2007 weather normalized starting point. The level is slightly higher than the draft 2008 forecast but does not exceed levels seen in the mid- to late-1990s.

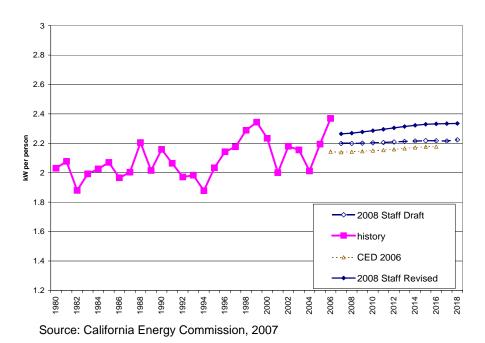

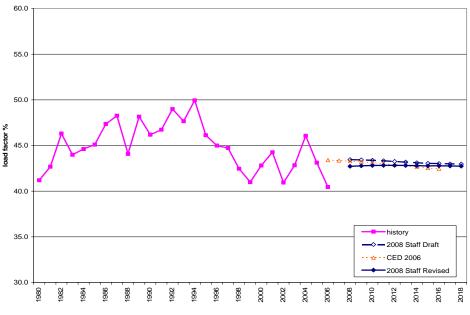

Figure 101: SMUD Planning Area per Capita Peak Demand

**Figure 102** compares the load factors of the forecasts. The load factor is a measure of the relative increase in peak demand with respect to annual electricity consumption. Lower load factors indicate a large difference between peak and average demand, while higher load factors indicate a more uniform load. Variation in historical load factors is caused in part by annual weather patterns. The SMUD load factor has been declining since the mid-1990s, as the residential sector—with a continually increasing use of air conditioning—grew faster than other sectors. The forecasted load factor is projected to remain relatively constant over the forecast period as central air conditioning in the SMUD planning area reaches full saturation.

# **Sector Level Results and Input Assumptions**

# Residential

**Figure 103** compares the revised 2008-2018 forecast with previous SMUD planning area residential forecasts. The revised forecast is substantially lower than both previous forecasts. This difference can be attributed to use of a new, lower long-term population forecast. The recent DOF long-term population forecast contained a reduction in SMUD planning area population of about 15 percent by the end of the forecast period.

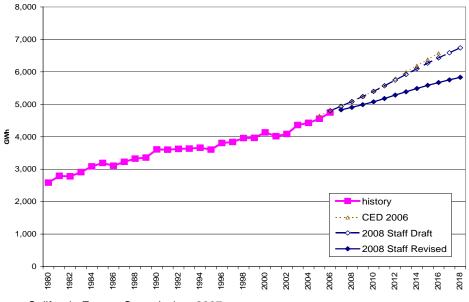

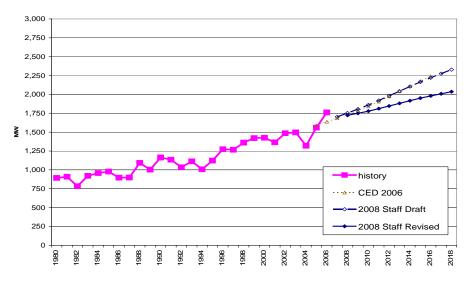

Figure 103: SMUD Planning Area Residential Consumption

Source: California Energy Commission, 2007

**Figure 104** provides a comparison of the revised residential peak forecast with the previous forecasts. The peak forecast differences follow the same pattern as differences in the electricity forecast and are also caused by decreased in the demographic forecast for the SMUD planning area.

### Figure 104: SMUD Planning Area Residential Peak

Source: California Energy Commission, 2007

**Figures 105** and **106** compare the residential drivers used in the revised forecast with drivers used in the draft forecast. Figure 105 compares total population, total households, and persons per household projections. The revised forecast has both lower population and persons per household projections. The reduction in persons per household projections the effect of lower population so that the decrease in households is a smaller reduction than the decrease in population.

Figure 106 compares income per household between the two forecasts. Household income is derived as the product of per capita income and persons per household. The revised projection is lower than the draft projection and grows at a slightly lower rate than the draft forecast.

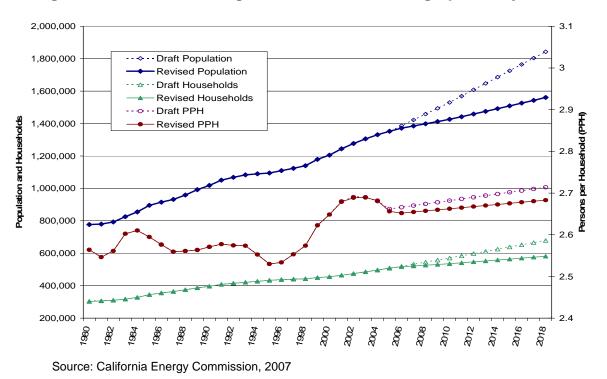

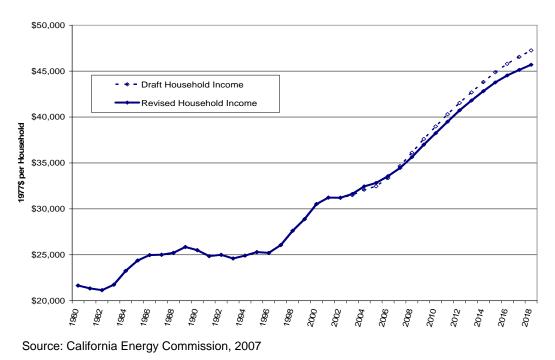

Figure 105: SMUD Planning Area Residential Demographic Projections

Figure 106: SMUD Planning Area Household Income Projections

**Figure 107** compares electricity use per household between the forecasts as well as with the 1980–2005 historical series. The revised use per household forecast is

similar to the draft forecast. The increase in revised peak use per household, as seen in **Figure 108**, is caused by adjustments made to the weather normalized starting point.

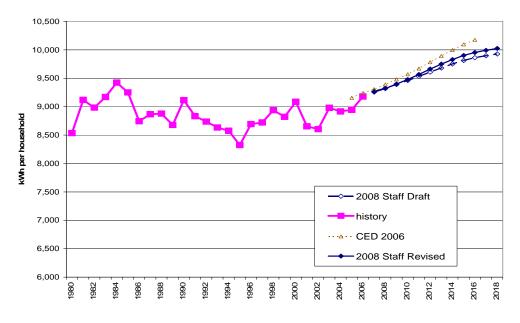

Figure 107: SMUD Planning Area Electricity Use per Household

Source: California Energy Commission, 2007

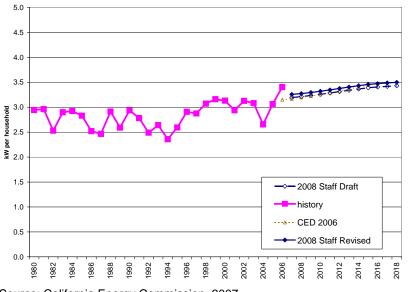

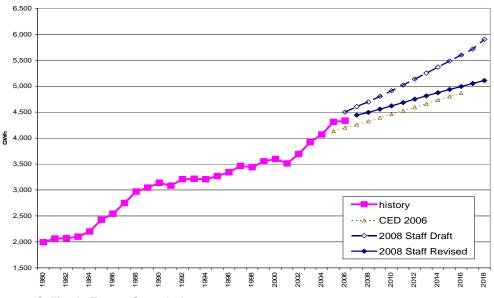

Figure 108: SMUD Planning Area Peak Use per Household

Source: California Energy Commission, 2007

# **Commercial Building Sector**

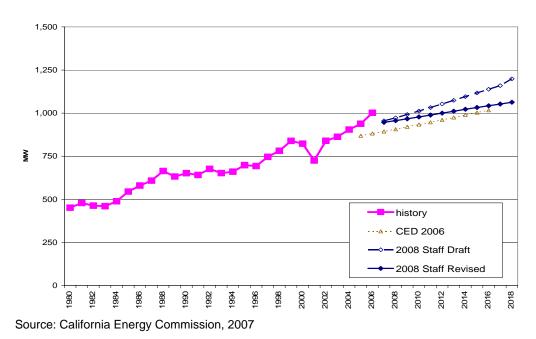

**Figure 109** compares the commercial building sector forecasts. The revised forecast starts at a lower value because of inclusion of 2006 historical consumption data. The revised forecast also grows at a lower rate than the draft forecast due to the revised commercial floor space projections based on the aforementioned lower demographic projections. The building types for which projected floor space decreased the most are large offices, warehouses, and hotels.

**Figure 110** compares the commercial peak demand forecasts. The revised commercial peak forecast is lower throughout the forecast period caused by a lower starting point and the difference in underlying electricity consumption forecasts.

### Figure 109: SMUD Planning Area Commercial Building Consumption

Source: California Energy Commission, 2007

### Figure 110: SMUD Planning Area Commercial Building Sector Peak

In staff's commercial building sector forecasting model, floor space by building type (for example, retail, offices, schools, and hospitals) is the key driver of electricity growth. **Figure 111** provides a comparison of total commercial floor space projections. The revised 2008 floor space projections are now lower over the forecast period than those used in the draft 2008 forecast.

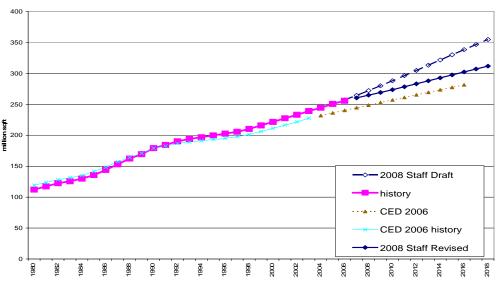

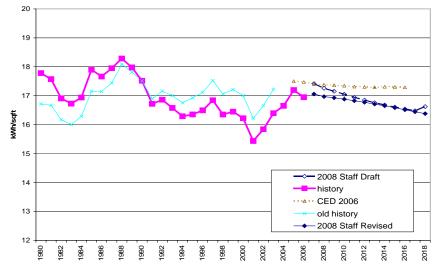

Figure 111: SMUD Planning Area Commercial Floor Space

Source: California Energy Commission, 2007

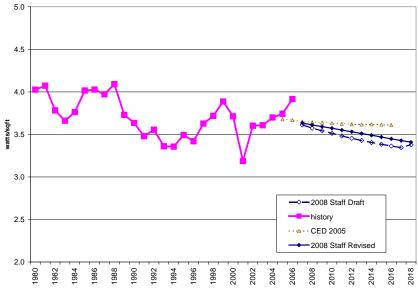

**Figures 112** and **113** present the use per square foot comparisons for both electricity consumption and peak, respectively. In both cases the revised values decline at a lower rate than in the draft forecast. Electricity use per square foot is lower in the short term because of inclusion of 2006 consumption data. Electricity consumption per square foot declines a lower rate because of the reattribution of lighting savings to earlier years as described in Chapter 1. This has a similar result on peak use per square foot.

### Figure 112: SMUD Planning Area Commercial kWh per Square Foot

Source: California Energy Commission, 2007

Source: California Energy Commission, 2007

# **Industrial Sector**

**Figure 114** compares the SMUD planning area industrial sector electricity consumption forecasts. The revised industrial electricity consumption forecast is higher than both of the previous forecasts due to revisions in the historic consumption data. Inclusion of 2006 historic consumption increased the starting point of the revised forecast. It appears that this increased consumption is because of under reporting in earlier years, not over reporting for 2006; therefore, staff is treating this increase as a permanent effect. Staff will develop correct historical data before the next forecast revision.

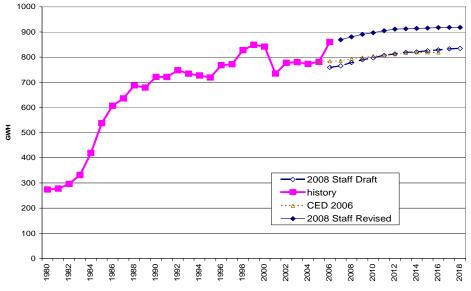

Figure 114: SMUD Planning Area Industrial Consumption

Source: California Energy Commission, 2007

**Figure 115** compares the industrial sector peak forecasts. The difference in the revised peak forecast is caused by the difference in the underlying electricity forecast.

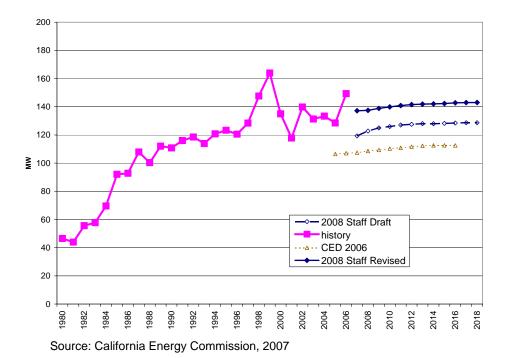

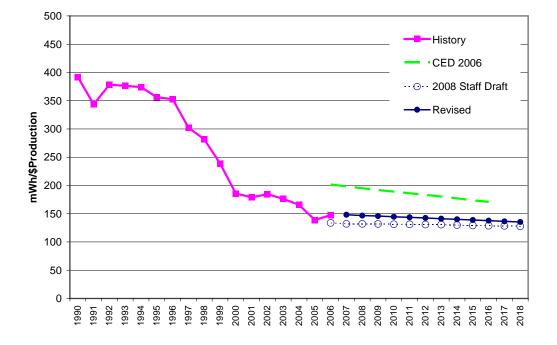

Figure 115: SMUD Planning Area Industrial Sector Peak

**Figure 116** compares use-per-dollar value of production among the revised and draft 2008 forecasts and *CED 2006* forecast. The revised forecast is slightly higher than the draft forecast. The difference in kWh per dollar of industrial value added is caused by the increase in consumption in the last historical year. The similar decline witnessed in both the revised and draft 2008 projections is less than was projected in the *CED 2006* forecast.

### Figure 116: SMUD Planning Area Industrial Use per Production Unit

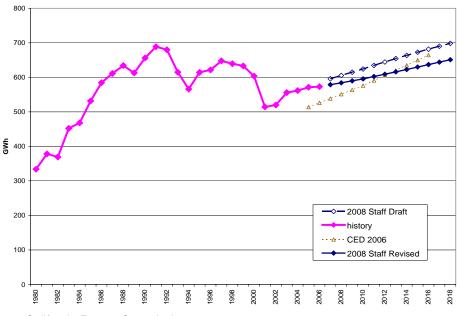

Source: California Energy Commission, 2007

# **Other Sectors**

**Figures 117** and **118** provide comparisons of the remaining sector electricity consumption forecasts. Figure 117 compares the transportation, communication, and utilities sector forecasts. The revised forecast is lower than the draft forecast because of lower economic and demographic drivers.

Figure 118 compares forecasts for the agriculture and water pumping and mining and oil extraction sectors. The revised agriculture and water pumping forecast starts from a higher point due to inclusion of 2006 consumption data but grows at a lower rate because of lower demographic projections. The net result is a forecast that is very similar at the end of the forecast period. After a decline in the first two years of the forecast, the revised mining and oil extraction forecast remains relatively constant over the forecast period. This results in a forecast that is similar to the draft forecast by the end of the forecast period.

Source: California Energy Commission, 2007

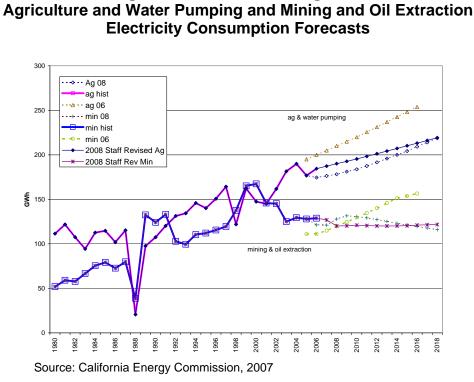

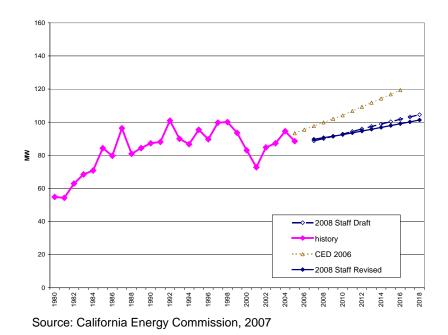

Figure 118: SMUD Planning Area

**Figure 119** compares the combined other sector peaks for the revised forecast with previous forecasts. The revised forecast is lower toward the end of the forecast period as a result of the lower growth in the corresponding electricity forecasts.

Figure 119: SMUD Planning Area Other Sector Peak

164

### **Electricity Prices**

As in the draft forecast, the revised forecast used prices that are held constant (in real terms) at the 2005 level for all sectors. This is in contrast to the declining price forecast that was used in the *CED 2006* price forecast. This change results in slightly lower demand in most customer sectors.

### Self Generation

As discussed in Chapter 1, the peak demand forecast is reduced by staff's current estimates of the effects of the Self-Generation Incentive Program, the California Solar Initiative, and similar programs. These programs are forecast based on the recent trend of installations. SMUD has had an aggressive solar program for many years, but the historical impacts have not been accounted for in staff's previous forecast or historical data. The forecast of peak impacts for the SMUD area represent incremental installations from 2007 forward. The forecast assumes about 800 kW of new installed capacity per year for a coincident peak reduction of about 500 kW per year. The cumulative forecast is shown in Forms 1.2 and 1.4 following this chapter.

### **Conservation Savings Embedded in the Forecast**

As discussed in Chapter 1, savings from building and appliance standards through 2005 are modeled in the staff residential and commercial demand forecast models. Savings from historical public agency and utility programs funded through 2008 are also included. To estimate the magnitude of these savings, the models are run without these programs—in effect, in the chronological order of the programs' occurrence. The savings are then calculated by subtracting the results of the run with the program in effect from the results without the program in effect. A condensed version of the results of this analysis is presented here as a partial estimate of savings, which are embedded in the forecast. **Table 27** presents electricity consumption savings, by broad program category, for selected years. **Table 28** presents similar estimates of peak savings. These tables do not quantify the effects of decreasing energy intensity (whether market- or program-driven) in other sectors.

### Form 2.2 - SMUD Planning Area California Energy Demand 2008-2018 Staff Revised Forecast Planning Area Economic and Demographic Assumptions

# CHAPTER 6: LOS ANGELES DEPARTMENT OF WATER AND POWER PLANNING AREA

The Los Angeles Department of Water and Power (LADWP) planning area includes LADWP bundled retail customers and customers served by any energy service providers (ESPs) using the LADWP distribution system to deliver electricity to end users.

This chapter is organized similar to previous chapters. First, forecasted consumption and peak loads for the LADWP planning area are discussed; both total and per capita values are presented. The revised 2008 values are compared to the draft 2008 and *CED 2006* forecasts, and forecast differences are discussed. The forecasted load factor, jointly determined by the annual energy consumption and peak load estimates, is also discussed. Second, sector consumption and peak load forecasts are presented. The residential, commercial, industrial, and "other" sector forecasts are compared to those in the previous forecasts. Third, the sector electricity prices used as inputs to the staff draft forecast are presented. Fourth, selfgeneration included in the forecast is briefly discussed, and finally estimates of conservation savings embedded in revised forecast are presented and discussed.

## **Forecast Results**

**Table 29** compares electricity consumption of the revised 2008 forecast with both the draft 2008 forecast and the *CED 2006* forecast. The revised 2008 forecast is very similar to the draft 2008 forecast. Both the revised and draft 2008 forecasts are higher than the *CED 2006* forecast. A slight decrease in the residential sector because of lower population projections is offset by an increase in industrial consumption. The draft forecast used Economy.com projections of industrial production, which in the LADWP area declined by 1.4 percent annually. This very pessimistic outlook appeared inconsistent with relatively flat consumption in the LADWP industrial sector; therefore, staff revised the economic drivers to a more moderate decline of 0.9 percent.

	Consumption (GWH)						
	CED 2006	Staff Draft	Staff	Percent	Percent

### Table 29: LADWP Planning Area Electricity Forecast Comparison

Source: California Energy Commission, 2007

**Table 30** compares the revised 2008 peak forecast with the previous forecasts. The revised 2008 forecast is about 100 MW (2 to 2.5 percent) lower than the draft 2008 forecast. The revised 2008 peak forecast is also lower than the *CED 2006* in the beginning of the forecast period, but by the end of the forecast period the two forecasts are the same.

Table 30: LADWP Planning Area Peak Forecast Comparison

Source: California Energy Commission, 2007

As shown in **Figure 120**, the revised 2008 electricity consumption forecast is essentially the same as the draft 2008 forecast. Both the revised and draft 2008 energy consumption forecasts grow at a faster rate than the *CED 2006* energy forecast.

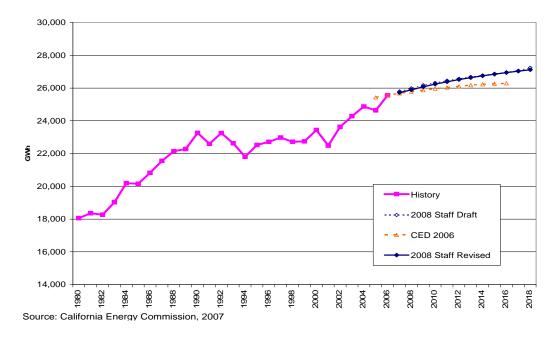

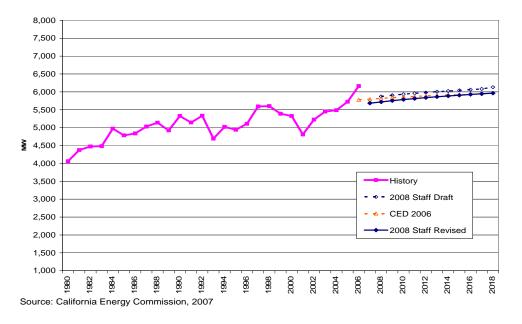

Figure 120: LADWP Planning Area Electricity Forecast

The LADWP planning area peak demand forecasts are shown in **Figure 121**. As opposed to the differences in electricity consumption forecasts, the revised 2008 forecast is lower than the draft 2008 forecast and is now very similar to the *CED 2006* forecast. This is caused by using a shorter calibration period for the peak forecasting model. The revised forecast was calibrated to 1990–2006; in the draft 2008 forecast the years 1980–2006 were used. The earlier period was dropped from calibration because of the shift to climate zone forecasts; historical data at climate zone level are not yet available for the 1980-1990 period. Also contributing to the difference is a slight shift in the sector composition of peak use.

### Figure 121: LADWP Planning Area Peak

**Figure 122** compares LADWP planning area per capita electricity consumption between the revised 2008 forecast and previous forecasts. Use of the new long-term Department of Finance (DOF) population forecast reduced projected population estimates for the LADWP planning area over the forecast period. This had the effect of raising per capita consumption in the revised 2008 forecast.

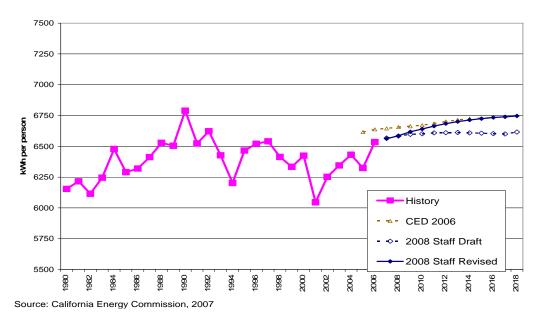

Figure 122: LADWP Planning Area per Capita Electricity Consumption

Per capita peak demand, shown in **Figure 123**, is slightly lower than projected in the *CED 2006* forecast. The draft 2008 projection remains constant over the forecast period.

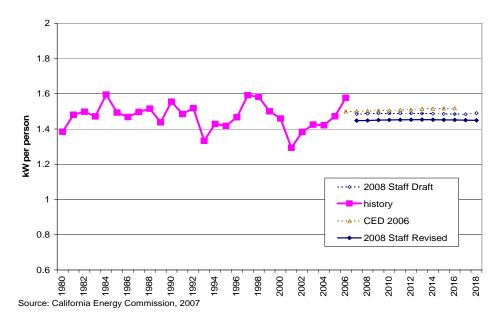

Figure 123: LADWP Planning Area per Capita Peak Demand

**Figure 124** provides a comparison of the respective load factors. The load factor is a measure of the relative increase in peak demand with respect to annual electricity consumption. The revised 2008 projected load factor is higher than the projected load factors of the previous two forecasts because of the shorter calibration period and because non-weather-sensitive end-use electricity is a higher percentage of total end-use load; commercial load is lower, while industrial is higher. The load factor is relatively constant over the forecast period. This trend is unchanged from the previous forecast.

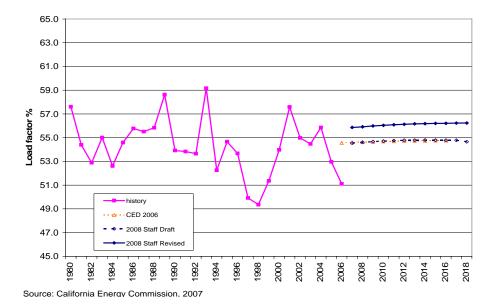

Figure 124: LADWP Planning Area Load Factor

## **Sector Level Results and Input Assumptions**

### Residential

**Figure 125** provides a comparison between the revised 2008 forecast and previous staff residential forecasts for the LADWP planning area. The revised 2008 forecast has a slightly higher starting point than the draft 2008 forecast but is projected to grow at a lower rate due to decreased economic and demographic projections. The result is a slightly lower forecast by the end of the forecast period. Both the revised and draft 2008 forecasts are higher than was projected in the *CED 2006* forecast.

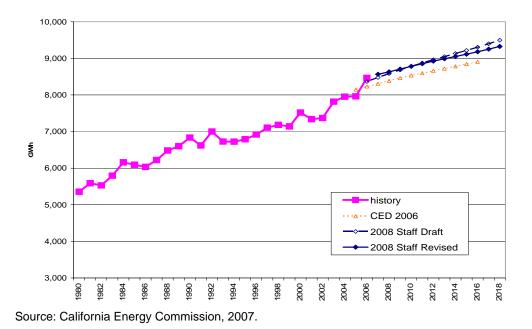

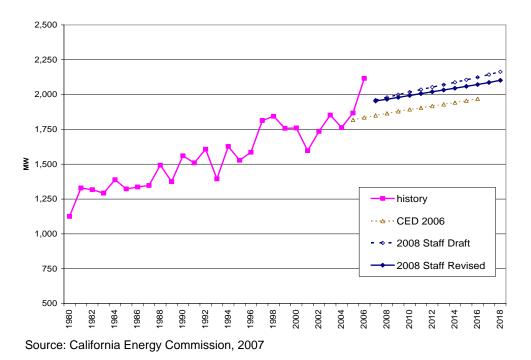

Figure 125: LADWP Planning Area Residential Consumption

**Figure 126** compares the revised 2008 residential peak demand forecast and previous residential peak demand forecasts. The peak forecast differences mirror the difference in electricity consumption forecasts. Unlike the electricity consumption forecasts, the revised and draft 2008 forecasts start from the same point. The revised 2008 forecast then grows at a slower rate resulting in a lower forecast by the end of the forecast period. Note that the 2007 peak projection is substantially below the actual 2006 peak value, which occurred during the July 2006 heat storm and was an all-time record for the LADWP planning area. The forecast for 2007 and future years assumes a return to average, or 1-in-2, peak temperature conditions.

### Figure 126: LADWP Planning Area Residential Peak

**Figures 127** and **128** compare the residential drivers used in the revised 2008 forecast with those used in the draft 2008 forecast. For both forecasts, staff revised the method for allocating Los Angeles County population, housing, and income data to the five utility service areas providing electricity within the county—SCE; the cities of Burbank, Glendale, and Pasadena; and LADWP. Previously unavailable sources of information, such as websites for the cities of Glendale and Los Angeles, and the county of Los Angeles, provided substantial insight into population shifts within the area. The result of this revision is to allocate slightly less of the county's population to LADWP but a higher proportion of homes to the warmer valley area and fewer in the coastal region. Also, a higher proportion of the county's personal income is assumed for the residents of Burbank, Glendale, and Pasadena than in previous staff forecasts.

Figure 128 provides comparisons of total population, total households, and persons per household projections. The revised 2008 forecast of total population is lower throughout the forecast period than the *CED 2006* forecast due to inclusion of the July 2007 DOF population forecast used as a new county control total in calculating the LADWP planning area population and household forecast.

For the draft forecast, staff reduced previous assumptions of increasing persons per household to a rate approximately half of the increase seen in the 1990–2000 period. Staff's revised 2008 projections of persons per household are higher than the draft 2008 forecast, based on 2005 and 2006 higher population and housing estimates provided by the DOF E5-A reports. This yields a forecast of household growth that is slightly lower than the draft 2008 forecast.

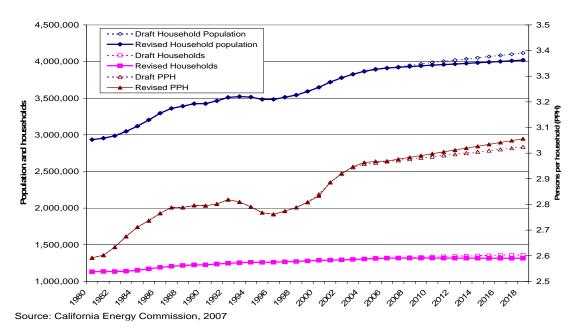

Figure 127: LADWP Planning Area Residential Demographic Projections

**Figure 128** provides a comparison of household income between the two forecasts. Household income is derived as the product of per capita income and persons per household. The revised 2008 projection is lower throughout the forecast period than the draft 2008 forecast. This is caused by both lower household projections described above and revised personal income projections, which are also slightly lower.

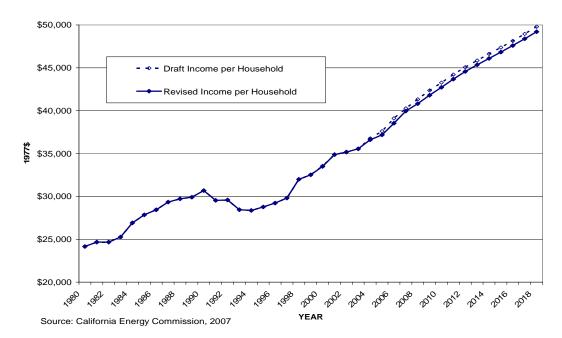

Figure 128: LADWP Planning Area Household Income Projections

**Figure 129** presents a comparison of electricity use per household between the forecasts as well as the 1980–2005 historic series. The revised 2008 forecast of use per household is higher than the draft 2008 forecast due to higher persons per household projections. However, there is no discernable difference in the revised and draft 2008 projections of peak use per household, as seen in **Figure 130**.

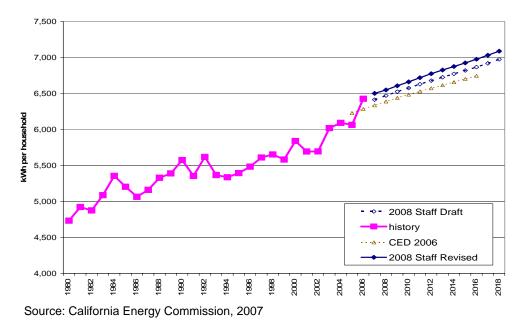

Figure 129: LADWP Planning Area Use per Household

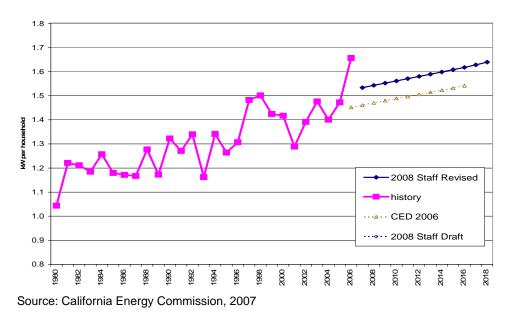

Figure 130: LADWP Planning Area Peak Use per Household

## **Commercial Building Sector**

**Figure 131** compares the commercial building sector energy consumption forecasts. The revised 2008 forecast is slightly lower at the beginning of the forecast, but grows at a faster rate than the draft 2008 forecast. This results in the two forecasts being almost identical by the end of the forecast period.

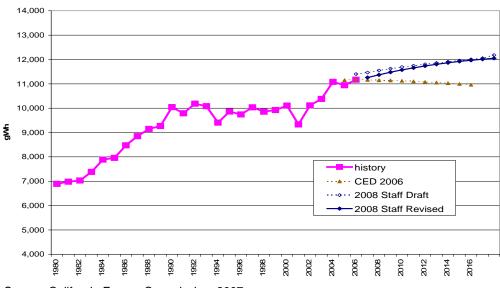

Figure 131: LADWP Planning Area Commercial Consumption

**Figure 132** provides a comparison of the commercial peak demand forecasts. The revised *CED 2006* forecast is lower throughout the forecast period due to a lower starting value. The difference in peak forecasts is primarily due to the difference in the periods used in calibration and the underlying electricity forecasts.

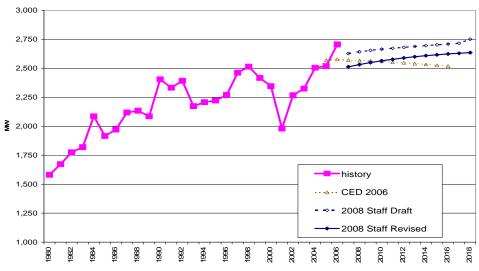

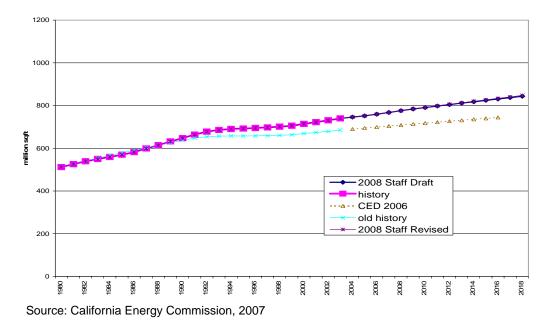

Figure 132: LADWP Planning Area Commercial Sector Peak

Source: California Energy Commission, 2007

Source: California Energy Commission, 2007

In staff's commercial building sector forecasting model, floor space by building type (for example, retail, offices, and schools) is the key driver of energy demand trends. The commercial building floor space forecast is based on the historic trend of additions in the LADWP planning area. **Figure 133** provides a comparison of total commercial floor space projections. For the LADWP planning area, the revised 2008 floor space projections are essentially the same as the draft 2008 forecast. Both forecasts are higher than the *CED 2006* floor space projections because of changes in estimation method.

Comparisons of use per square foot over the forecast period are shown in **Figures 134** and **135** for electricity consumption and peak, respectively. The revised 2008 forecast shows a decline in use per square foot in both electricity consumption and peak, although not as steeply as in the *CED 2006* forecast. This decline is a result of an increasing proportion of new floor space with more efficient end use intensities.

Figure 134: LADWP Planning Area Commercial kWh per Square Foot

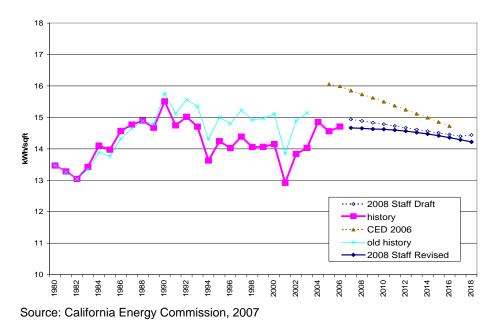

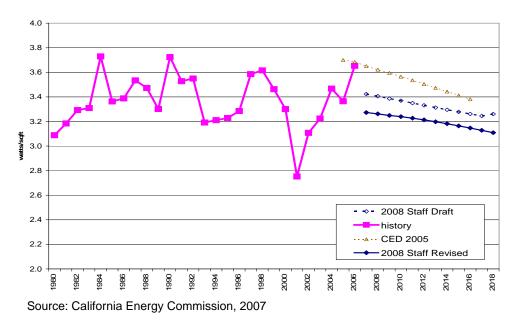

Figure 135: LADWP Planning Area Commercial Watts per Square Foot

## **Industrial Sector**

**Figure 136** compares the LADWP planning area industrial sector electricity consumption forecasts. The revised 2008 industrial electricity consumption forecast is higher than the draft 2008 forecast. The revised 2008 forecast also declines at a lower rate than the draft 2008 forecast because of the revised economic drivers discussed earlier. This produces a somewhat higher industrial forecast by the end of the forecast period. However, the revised 2008 forecast is still well below the *CED* 

2006 forecast. The growth rate of the *CED* 2006 industrial drivers was 0.7 percent, compared to -0.9 percent assumed in the revised forecast.

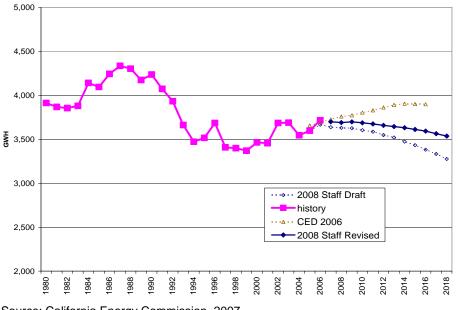

Figure 136: LADWP Planning Area Industrial Consumption

Source: California Energy Commission, 2007

**Figure 137** compares the industrial sector peak forecasts. The revised 2008 forecast starts from a slightly lower point due to revisions in calibration as noted earlier in this chapter. The revised 2008 forecast is more constant over the forecast period resulting in a higher forecast by the end of the forecast period.

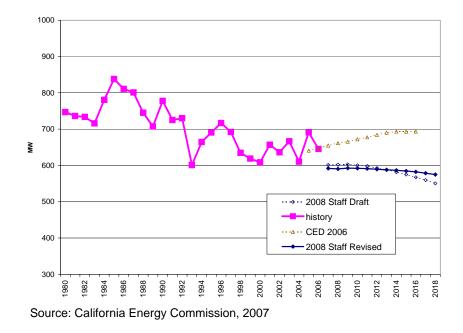

Figure 137: LADWP Planning Area Industrial Sector Peak

**Figure 138** compares use-per-dollar value of production between the revised 2008 forecast and previous forecasts. The revised 2008 forecast declines at a slightly lower rate than the draft 2008 forecast. Because of definitional changes in the sectors and revisions to historical data, the revised and *CED 2006* data are not comparable. However, it is the change in trend that affects the final calibrated forecasts.

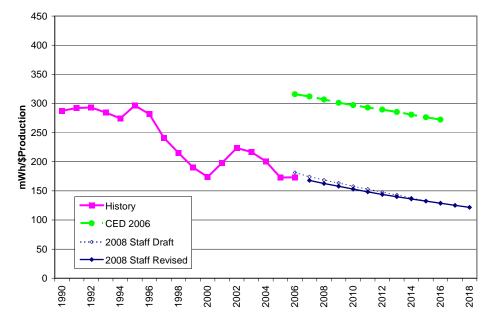

Figure 138: LADWP Planning Area Industrial Use per Production Unit

Source: California Energy Commission, 2007

### **Other Sectors**

**Figures 139** and **140** provide comparisons of the two remaining customer sector electricity consumption forecasts. Figure 139 compares the transportation, communication, and utilities sector forecasts. The revised 2008 forecast has a slightly higher starting point than the draft 2008 forecast because of the inclusion of 2006 consumption. This starting point is much higher than in the *CED 2006* forecast because unclassified sales were allocated to sectors differently in the current forecast. The growth rate of the revised 2008 forecast is lower than that of the draft 2008 forecast because of lower population projections used in the revised 2008 forecast. This results in the revised 2008 forecast being lower by the end of the forecast period.

Figure 139: LADWP Planning Area Transportation, Communication, and Utilities Sector Electricity Consumption

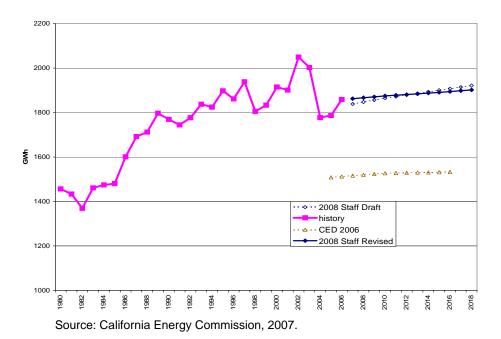

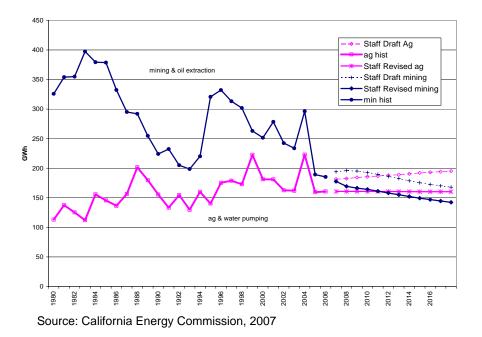

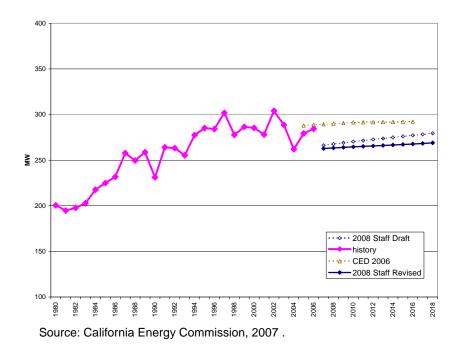

Figure 140 compares forecasts for the agriculture and water pumping and mining and oil extraction sectors. The draft 2008 mining and oil extraction forecast is projected to decline over the forecast period, while the agriculture and water pumping forecast is projected to increase. The decrease in the mining and oil extraction industry reflects projected decreases in production and changes in intensity assumptions. The increase in the agriculture and water pumping sector is caused by increased water demands. The previous forecasts had very different starting points because of the method of allocation of unclassified electricity sales to sectors.

### Figure 140: LADWP Planning Area Agriculture and Water Pumping and Mining and Oil Extraction Electricity Consumption Forecasts

**Figure 141** compares the combined peaks of other sectors. The revised 2008 forecast is slightly lower than the draft 2008 forecast. The lower growth in the revised 2008 forecast is caused by the growth of the underlying electricity forecasts.

Figure 141: LADWP Planning Area Other Sector Peak

## **Electricity Prices**

As in the draft forecast, the revised 2008 forecast used prices that are held constant (in real terms) at the 2005 level for all sectors. This is in contrast to the declining price forecast that was used in the *CED 2006* price forecast.

## **Self-Generation**

As discussed in Chapter 1, the peak demand forecast is reduced by the staff's estimate of the effects of programs to promote photovoltaic (PV) and other self-generation installations. The forecast of peak PV impacts, shown in **Figure 142.** represents incremental installations from 2007 forward. The forecast assumes about 1,200 kW of new installed capacity per year, for a coincident peak reduction of 675 kW per year. The cumulative forecast is shown in Forms 1.2 and 1.4 following this chapter.

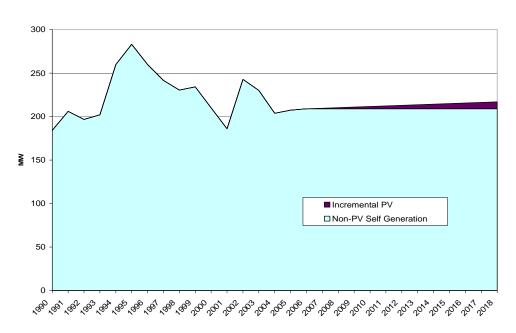

Figure 142: LADWP Planning Area Self-Generation Forecast

Source: California Energy Commission, 2007

### **Conservation Savings Embedded in the Forecast**

As discussed in Chapter 1, savings from building and appliance standards through 2005 are modeled in the Energy Commission residential and commercial demand forecast models. Savings from historical public agency and utility programs funded through 2008 are also included in the forecast. To estimate the magnitude of these savings, the models are run without these programs—in effect in the chronological order of the programs' occurrence. The savings are then calculated by subtracting the results of the run with the program in effect from the results without the program in effect. A condensed version of the results of this analysis is presented here as a

partial estimate of savings, which are embedded in the forecast. **Table 31** presents electricity consumption savings, by broad program category, for selected years. **Table 32** presents similar estimates of peak savings. These tables do not quantify the effects of decreasing energy intensity (whether market- or program-driven) in other sectors.

### Form 2.2 - LADWP Planning Area California Energy Demand 2008-2018 Staff Revised Forecast Planning Area Economic and Demographic Assumptions

# CHAPTER 7: END-USER NATURAL GAS DEMAND FORECAST

This chapter presents the staff-revised forecasts of end-user natural gas demand for the PG&E, Southern California Gas (SCG), and SDG&E natural gas planning areas. Staff prepares these forecasts in parallel with its electricity demand forecasts. The models staff uses are organized along electricity planning area boundaries. The gas demand forecasts presented here are the aggregate of gas demand in the corresponding electricity planning areas. These forecasts do not include natural gas used by utilities or others for electric generation or cogeneration. The projected demand for natural gas to generate electricity is presented in the *2007 IEPR Natural Gas Market Assessment*<sup>18</sup> and further explored further in the *2007 IEPR* scenario project.<sup>19</sup>

The revised forecast incorporates three changes compared to the draft forecast: 2006 actual consumption, the July 2007 Department of Finance (DOF) population projections, and a revised forecast of natural gas prices. The natural gas prices used in the revised forecast are those developed for Energy Commission staff's August 2007 *Natural Gas Market Assessment*. Prices used in the draft forecast were from the June 2005 assessment prepared for the *2005 Integrated Energy Policy Report*.<sup>21</sup> The base year of historic consumption in the draft forecast was 2005. See Chapter 1 for a discussion of economic and demographic assumptions.

## **Forecast Results**

**Table 33** compares the statewide revised and draft forecasts with the *CED 2006* forecast for selected years. The revised 2008 forecast has a lower starting point because recorded 2006 consumption was lower than previously forecast. The revised growth rate is slightly lower because of a higher natural gas price forecast.

 Table 33: Statewide Natural Gas Forecast Comparison

Source: California Energy Commission, 2007

**Figure 143** shows a comparison of the 2008 revised and draft statewide forecasts with the *CED 2006* forecast. Inclusion of the lower 2006 historic consumption reduces the 2008 starting point of the revised forecast back to the level of the *CED 2006* forecast but with a slightly higher growth rate than the earlier forecast.

### Figure 143: Natural Gas Demand Forecast

Source: California Energy Commission, 2007

**Figure 144** compares the previous and revised forecasts of per capita natural gas consumption. Historical per capita demand varies in response to annual temperatures and business conditions but has generally been declining over time. Projected per capita consumption in the revised forecast has now returned to the levels projected in *CED 2006*. All forecasts continue to project a steady decline in per capita consumption over the forecast period.

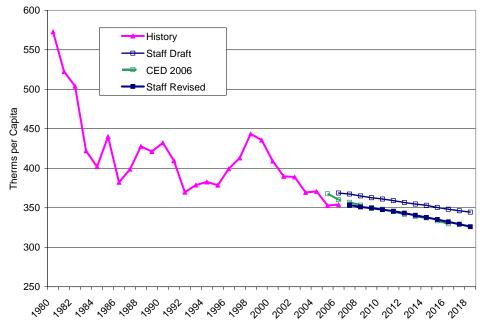

Figure 144: Statewide per Capita Natural Gas Consumption

Source: California Energy Commission, 2007

# **Planning Area Results**

# Pacific Gas and Electric Planning Area

The PG&E natural gas planning area is defined as the combined PG&E and SMUD electric planning areas. It includes all PG&E retail gas customers and customers of private marketers using the PG&E natural gas distribution system.

**Table 34** compares the PG&E planning area forecasts. Consumption in 2006 was somewhat lower than was projected in the draft forecast. Combined with the effects of higher gas prices, by the end of the forecast period, demand is more than 3.4 percent lower in the revised forecast than in the draft forecast.

 Table 34: PG&E Natural Gas Forecast Comparison

Source: California Energy Commission, 2007

**Figure 145** compares the revised 2008 forecast and previous PG&E planning area forecast for the residential sector. The revised forecast is lower throughout the entire forecast period, as actual consumption recorded in 2006 was lower than predicted in *CED 2006*, but all forecasts have similar growth rates.

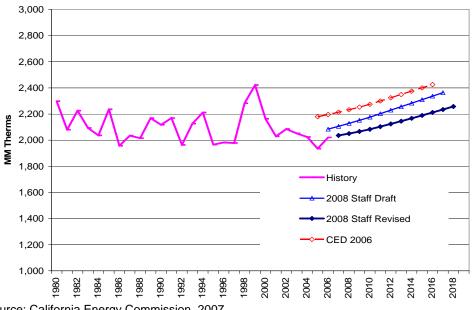

Figure 145: PG&E Planning Area Residential Consumption

Source: California Energy Commission, 2007.

**Figure 146** compares the revised 2008 commercial sector gas demand forecasts with the draft and *CED 2006* commercial sector gas demand forecasts. Commercial gas use is now expected to rise at a rate slower than that experienced in recent years of the historic period, continuing the changed growth pattern from the *CED* 

2006 forecast that first appeared in the draft forecast. New commercial floor space projections described in Chapter 1 are partially responsible for this change.

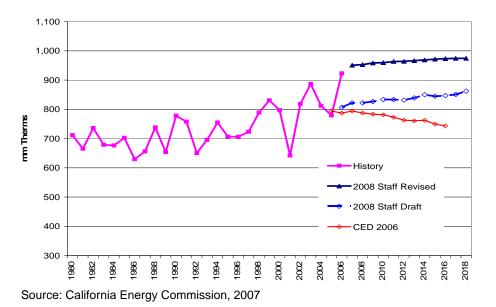

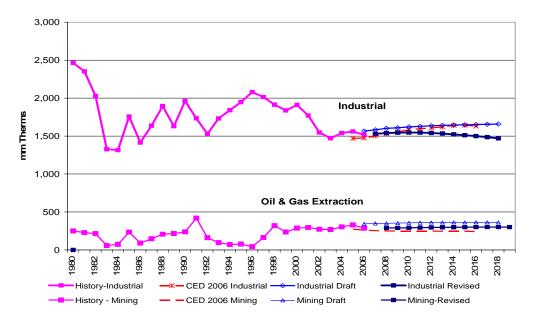

Figure 146: PG&E Planning Area Commercial Gas Demand

**Figure 147** shows the revised 2008 industrial forecast is relatively unchanged in the early years, but lower in later years, reflecting higher fuel prices. The revised 2008 oil and gas extraction forecast is relatively constant over the forecast period, similar to the draft forecast.

Figure 147: PG&E Planning Area Industrial Natural Gas Demand

Source: California Energy Commission, 2007

**Figure 148** compares prices used in the revised and draft forecasts by sector. Both the residential and nonresidential prices used in the revised forecast are higher in the long run than the prices used in the draft 2008 forecast.

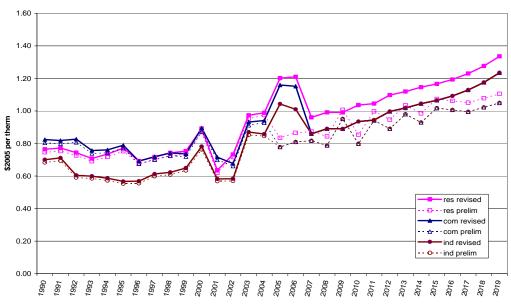

Figure 148: PG&E Planning Area Prices

Source: California Energy Commission, 2007

# Southern California Gas Company Planning Area

The Southern California Gas planning area is composed of the SCE, Burbank and Glendale, Pasadena, and LADWP electric planning areas. It includes customers of those utilities, plus customers of private marketers using the SCG natural gas distribution system.

**Table 35** provides a comparison of the SCG planning area forecasts. The revised 2008 forecast grows at a higher rate than the *CED 2006* forecast because of higher commercial floor space projections. The new DOF population projections increase residential demand directly and commercial demand indirectly as businesses serve population growth. Although total recorded gas use in the planning area was lower than projected, by the end of the forecast period the revised 2008 forecast is 1.4 percent higher than the *CED 2006* forecast.

# Table 35: SCG Natural Gas Forecast Comparison

Source: California Energy Commission, 2007

**Figure 149** compares the residential gas demand forecasts. The revised forecast is lower throughout the forecast period than the *CED 2006* forecast due to a lower starting point. The initial starting point of the revised forecast is also lower than the draft forecast, but higher growth, due to increased population projections for the SCG area, decreases the forecast differences slightly by the end of the forecast period.

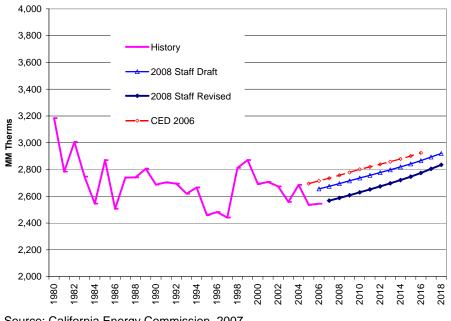

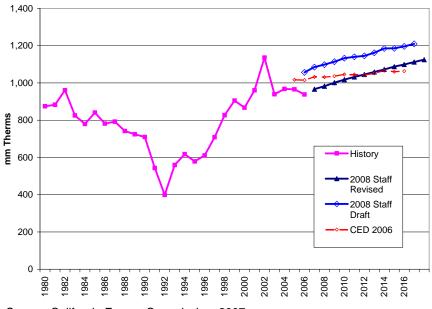

Figure 149: SCG Planning Area Residential Natural Gas Consumption

Source: California Energy Commission, 2007.

Figure 150 provides a comparison of the commercial sector forecasts, the revised 2008 forecast is now expected to increase at a higher rate than in the draft 2008 or CED 2006 forecasts because of faster population growth and floor space projections. The revised forecast also starts from a lower point than both the draft and CED 2006 forecast because historic consumption was lower than expected.

Figure 150: SCG Planning Area Commercial Natural Gas Consumption

Source: California Energy Commission, 2007.

**Figure 151** shows that the revised 2008 industrial forecast is slightly lower than the previous forecasts and is nearly flat throughout the forecast period. The mining sector (including oil and gas extraction) is now predicted to stay relatively flat instead of declining over the forecast period.

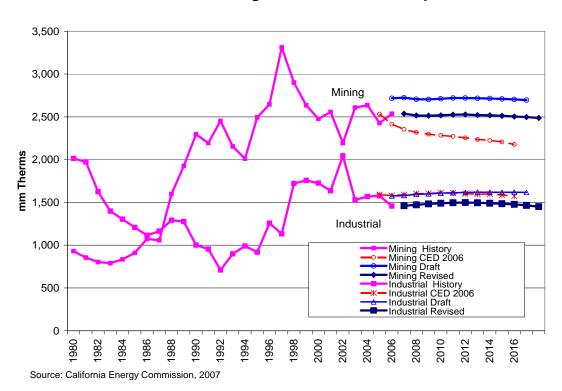

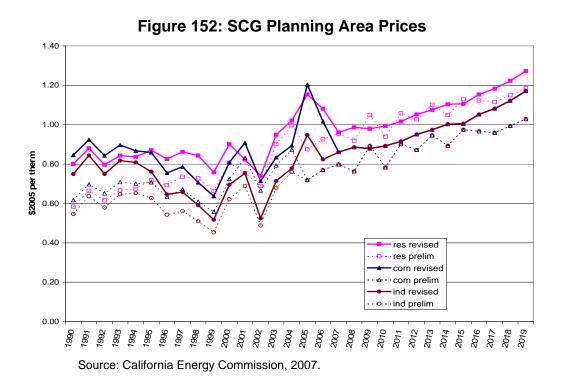

Figure 151: SCG Planning Area Industrial and Mining Natural Gas Consumption

**Figure 152** compares SCG sector natural gas prices used in the revised and draft forecasts by sector. Both the residential and nonresidential prices used in the revised forecast are higher in the long run than the prices used in the draft forecast.

# San Diego Gas & Electric Planning Area

The SDG&E planning area contains SDG&E customers and customers of private marketers using the SDG&E natural gas distribution system.

**Table 36** shows the SDG&E planning area forecasts to be very similar. The revised forecast is lower in the short term because of a lower starting point than was projected in the *CED 2006* forecast. The revised 2008 forecast is slightly higher than the draft forecast, primarily because of higher recorded 2006 consumption. This difference diminishes over time because of lower economic and demographic projections and higher natural gas prices.

	Con	sumption (I	MM Therm	s)	
				Percent	Percent

Table 36: SDG&E Natural Gas Forecast Comparison

Source: California Energy Commission, 2007

**Figure 153** provides a comparison of the SDG&E planning area residential gas consumption forecasts. The revised 2008 residential forecast is slightly lower than the draft 2008 forecast because of inclusion of 2006 historic data in the calibration procedure. The revised forecast grows at a lower rate, due to decreased population projections compared with those used in the draft forecast.

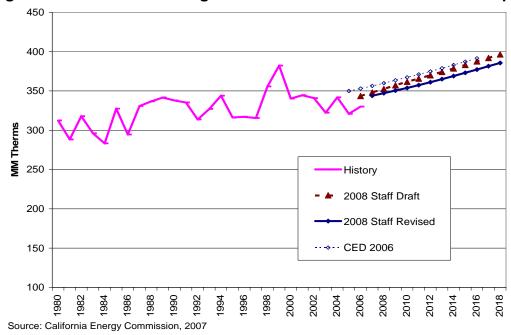

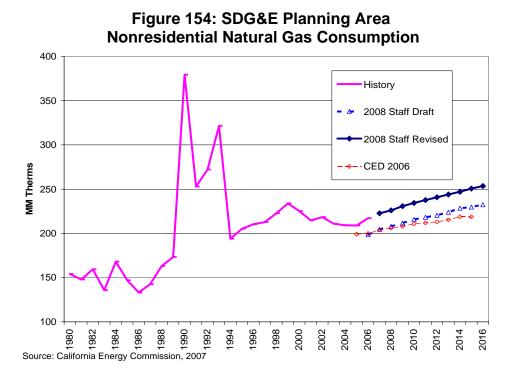

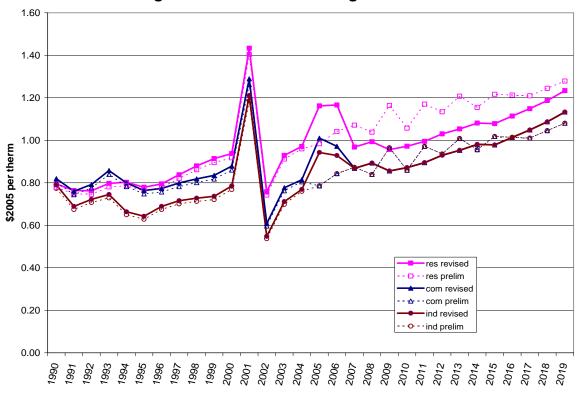

Figure 153: SDG&E Planning Area Residential Natural Gas Consumption

In the SDG&E nonresidential sector (**Figure 154**) the revised 2008 forecast grows at a rate similar to the draft 2008 forecast. However, the starting point is higher because actual consumption in the commercial sector was 6 percent higher than projected in 2006. Industrial sector historic consumption was also higher than projected, but the industrial sector in SDG&E area is very small, so the two sectors are combined for reporting purposes.

**Figure 155** compares SDG&E sector natural gas prices used in the revised and draft forecasts by sector. Residential prices are lower throughout the forecast period in the revised forecast. Commercial and industrial prices used in the revised forecast are similar to those used in the draft forecast until the latter part of the forecast period. In the latter part of the forecast period, the revised prices become higher than the draft prices.

# Table 41 - Statewide End-User Natural Gas Consumption Consumption by Sector (10^6 Therms)

# APPENDIX A: ELECTRICITY AND NATURAL GAS CONSERVATION IMPACTS

These tables present the annual estimated residential and commercial conservation impacts for individual vintages of building and appliance standards and for other types of conservation programs modeled in the residential and commercial sector models. Direct program adjustments are the effects of conservation programs which are accounted for in the summary model. Annual and peak electricity impacts are presented for the PG&E, SCE, SDG&E, SMUD, and LADWP electric planning areas. Natural gas impacts are presented for the PG&E, SCG, and SDG&E natural gas planning areas. See the section in Chapter 1 on "Energy Conservation in Commission Demand Forecast Models" for a discussion of the methods used to develop these estimates.
