The Salt River Bay Marine Research and Education Center (MREC) is a multidisciplinary partnership of academic, government and civic institutions working together to understand how to best protect, conserve and sustain tropical and subtropical marine ecosystems within the United States Virgin Islands and the Caribbean region.

The MREC, operated by a consortium of four public universities within a national park, provides the means for researchers, resource managers, educators and students to collaborate on issues affecting marine ecosystems, while increasing public awareness of the economic and cultural heritage through scientific studies, student education and science-based resource management.

The National Park Service (NPS) embraces the establishment of the MREC in the Salt River Bay National Historical Park and Ecological Preserve (SARI) to aid and support the park's mission to better understand and manage the over 30,000-acres of submerged lands within park management authority. The Joint Institute for Caribbean Marine Studies (JICMS) views the MREC as an opportunity to expand its research and education programs into the U.S. territory in the Caribbean, encourage collaboration among the JICMS universities and especially the host university, the University of the Virgin Islands, and support the science and research needs of its partners.

The MREC will provide a platform for the NPS and JICMS to conduct research and provide education programs in proximity to the resources being studied, and to do so in a campus environment that creates opportunities for synergies and collaborations among all of the researchers, educators and resource managers who will use the facility.

MREC project site

executive summary 1.2

The Salt River Bay National Historical Park and Ecological Preserve (SARI) is located on the north shore of St. Croix in the US Virgin Islands. The Park was created in 1992 in an effort to both protect the habitat within the park, as well as to study the resources within it; both natural and historical and from the ridge of the mountains to the deep water reef ecosystems. Located in SARI, the Marine Research and Education Center (MREC) will enable the NPS and its partner organizations to fulfill their mission to provide public educational opportunities about and in the marine ecosystems while engaging the local community. It will also allow for the study of the marine environment on a site that offers full immersion access to the fields of research. In 1989 Hurricane Hugo shut down the Fairleigh Dickinson University West Indies Lab (WIL) eliminating a functional center for long term research of the marine environment for academic and government studies. The MREC, through partnership, will provide this center for marine research to meet the National Park Service's goals of marine science research, education and stewardship. This partnership is made up of the National Park Service and four universities with world class marine research programs: University of the Virgin Islands, University of North Carolina Wilmington, University of South Carolina, and Rutgers University.

Of notable importance to the research capacity of the project and central to its research programs (and by extension its education programs) will be the presence of reliable power and high quality sea water. Together these combine to allow the core research to proceed.

The MREC's proximity to the marine resource for research and teaching, its small footprint on the land and its capacity to demonstrate sustainable construction make it an important resource itself. To this end, the project has been registered as a Living Buildings Challenge project, a rating system that aims to create regenerative buildings by requiring that buildings produce (or collect) at least as much water and electricity as they use, as well as other strict environmental impact requirements. The selected site on the east side of the Park offers abundant opportunity for the design of a project that is a national leader in sustainability. To start this process, for this Master Plan is only the first of many steps to bring the MREC to fruition, the NPS, JICMS and Office of Insular Affairs (OIA) have collaborated with the design team to fundamentally rethink what it means to build a building in a tropical climate for marine education and research. This process guestioned standard building and operational norms to achieve a Program and Master Plan that lays the ground work for a successful MREC that restores the site and minimally impacts the environment.

The Master Plan contains a summary of SARI's history and background information on the MREC, as well as the project goals by which the success of the project will be measured. A detailed site and climate analysis follows, putting in context the nature of the site, the environmental challenges it faces and the potential resources available on the site. Following the history and analysis, the body of the Master Plan contains a detailed program of the MREC and a functional analysis of the program. The Master Plan is then documented with both narratives and drawings. A proposed schedule and cost estimate follows this section.

site today (from hamilton drive)

2.1 salt river bay national historical park and ecological preserve

In 1992, Congress designated Salt River Bay National Historical Park and Ecological Preserve (SARI) to "preserve, protect and interpret ... nationally significant historical, cultural and natural sites and resources ... with particular emphasis on the preservation of both the cultural and natural resources and long-term scientific study of terrestrial, marine and archaeological resources" (Public Law 102-247).

The location and capabilities of the Salt River Bay Marine Research and Education Center (MREC) make it an important site from which to support research and monitoring in the parks. Research undertaken at the MREC will provide a rare opportunity to compare current ecosystem trends with the historic baselines of the coral reef research undertaken between the late 1960s and late 1980s.

SARI is a protected natural area that exhibits many of the region's important ecological relationships. Salt River Bay is an estuary, where fresh and salt waters mix. The diverse terrestrial environment is dominated by shrub land as a result of centuries of manmade alterations on the land, 2,000 years of human history, and non-native planting. Much of the flora is adapted to dry conditions. The mouth of the bay, with its undersea canyon and coral covered walls, opens to the sea, and falls away into the Virgin Islands Trough.

SARI contains a combination of marine, estuarine, and terrestrial habitats, including coral reefs, seagrass beds, an undersea canyon, and the largest remaining mangrove forest within the U.S. Virgin Islands.

The dynamic relationship between land and bay is ecologically important. Endangered hawksbill turtles feed and rest along the coral canyon walls. Snappers and grunts hide among coral reefs by day and feed in seagrass beds by night. Threatened green sea turtles and queen conch thrive on turtle grasses.

Coral reefs have built up in the Caribbean during the past 13,000 years. More than 400 species of reef fish are known in near-shore waters. Coral reefs may support one-third of all fish species globally and possibly a total of a half-million animal species.

Researchers at the MREC will provide the three existing NPS units on St. Croix, plus the proposed NPS units (Estate Castle Nugent, with four to five miles of shoreline on the south coast of St. Croix, and Hamilton Grange and Associated Sites) and The Government of the Virgin Island's (GVI) St. Croix East End Marine Park (the first marine park), with the capacity to study and respond to climate change, sea level rise, ocean acidification, coral diseases and other threats, and guide them in the recovery of threatened coral reef resources and fisheries restoration.

With the listing of elkhorn and staghorn coral as threatened species in 2006, Buck Island Reef National Monument (BUIS) provides more than 5,000 acres of critical habitat for these species, as well as critical foraging area and nesting beaches for the four species of sea turtle, including one of the few recovering hawksbill sea turtle nesting populations in the world.

The MREC will enable the St. Croix NPS units to fulfill their mission guided research management of critical resources and to provide public educational opportunities in the marine environment and engage the local community in this effort.

view across SARI to the west from proposed building site

project background and history 2.2

St. Croix, U. S. Virgin Islands (USVI) provides a rich environment for tropical marine research, especially on coral reef ecosystems.

Marine research activities began on St. Croix in the late 1960s, providing some of the oldest available data on coral reefs. Some of the world's leading marine researchers gathered these data at two former marine laboratories on St. Croix: Fairleigh Dickinson University's West Indies Laboratory (WIL) on the northeast end of St. Croix and the National Oceanic and Atmospheric Administration's (NOAA) National Undersea Research Program's habitats, first the "Hydrolab" and then the "Aquarius," which operated at Salt River Bay for more than 10 years.

The scientific records generated by investigators at these two facilities are rare for their duration, quality and documentation of reef conditions prior to the massive changes that occurred in this ecosystem beginning in the 1980s.

Under a cooperative agreement with NPS, WIL produced the first marine research and assessments at Buck Island, established in 1961. Through this agreement, WIL mapped, inventoried and investigated the ecology, function, status and trends of Buck Island marine resources, including its coral geology, reef fisheries, marine invertebrates, sea turtles, oceanography, and coral reef habitats. Over time, Buck Island Reef became one of the best documented and studied marine ecosystems in the Caribbean and a premiere field school for hundreds of WIL students each year.

This historic database provides an unparalleled record to guide, and against which to measure, present and future management actions. For example, WIL's documentation of the degradation of St. Croix's marine resources beginning in the 1980s was used in 2001 to support the expansion and designation of Buck Island Reef as a marine protected area.

The data are also invaluable in guiding the recovery of the acroporid corals, with 5,000 acres of coral reef designated as critical habitat. These examples illustrate just some of the significant ways in which NPS and the park units on St. Croix have benefited from the capacity to conduct marine research on the island.

The closure of both marine research facilities following Hurricane Hugo reduced the park's capacity to conduct marine research in the park and terminated some of the long-term marine research on St. Croix. Restoring this capacity will support the study and management of St. Croix's critical marine protected areas: serve NPS inventory, monitoring and research needs, and support science-based park management in St. Croix for over 30,000 acres of National Park submerged lands.

origin of partnership 2.3

In the wake of the closure of the WIL and NOAA facilities, the Department of the Interior (DOI), with staff from NPS Christiansted National Historic Site (CHRI), Buck Island Reef National Monument (BUIS), and Salt River Bay NHP & EP (SARI), the Office of Insular Affairs (OIA), and representatives of educational institutions that participated in research at WIL, recognized the need to restore St. Croix's marine research capability.

In 1999, the Department of the Interior (DOI) entered into a Memorandum of Understanding (MOU) with the Joint Institute of Caribbean Marine Studies (JICMS) to: (1) aid in the understanding of the marine environment, including coral reef ecosystems; (2) promote marine education and public awareness; and (3) assist in the development of appropriate public policy within the Caribbean.

NPS Outreach program in action

Through the MOU, the partners agreed to accomplish these goals by:

- Fostering collaborative research programs to understand and sustain management the coral reef ecosystems of the Caribbean;
- Providing support for marine education programs for school children and adults in the U.S. Virgin Islands;
- Fostering cooperation with other government, institutional and private organizations to better understand marine issues in the Caribbean; and
- Enriching the learning experiences and opportunities for the University of Virgin Islands and other university students.

The MOU documented the JICMS's desire to establish "a marine research and educational facility within the USVI, including research laboratories, classrooms, a lecture hall, teaching aquarium, boats and diving equipment, distance learning equipment, and housing for students, scientists and visitors." The facility would serve undergraduate and graduate students in a variety of marine education and research programs supported by the JICMS universities.

Initial efforts to develop the MREC focused on reestablishing a facility at the former WIL site, on what is now private property. When that effort failed due to land owner's lack of commitment to rebuild the facilities in 2000, other potential sites were explored, but land prices and the need for appropriate ocean access precluded acquisition. In 2001, NPS acquired 73 acres within the Salt River Bay NHP & EP. Also that year, Buck Island Reef National Monument (BUIS) was expanded from 880 to more than 19,000 acres and became one of the first fully protected ("no-take") marine protected areas (MPA) managed by NPS. These acquisitions further underscored the park's need for increased science-based marine resource management.

Given the combination of global and local threats to coral reefs and NPS's new management responsibilities, NPS approached the Office of Insular Affairs (OIA) and JICMS about partnering to build the MREC on the newlyacquired parkland at Salt River Bay.

Salt River Bay is a site of extensive cultural significance and is an important archaeological area for the indigenous prehistoric settlements, with remains of two pre-historic villages and a ball court established more than 2,000 years ago. On November 14, 1493, Christopher Columbus's party came ashore at Salt River Bay. It is the only site now in U.S. territory visited by Columbus's party during either voyage.

SARI is one of the few NPS units that are co-managed; NPS shares the management responsibilities with the Government of the Virgin Islands, an arrangement that includes oversight of more than 600 acres of mangrove estuarine bay, coral reefs, and a submarine canyon.

the partnership and local community

In 2003, St. Croix East End Marine Park was established as the Virgin Islands' first territorial marine park. It encompasses 60 square miles, including five square miles of no-take areas off the northern and eastern coasts of St. Croix and abuts the south side of BUIS. Combined with the NPS units, these marine park areas protect one of the largest coral reef ecosystems in the Caribbean.

In 2004, recognizing the many benefits of the marine laboratory and the value of locating it in the park, OIA provided a \$200,000 grant from its Coral Reef Program to conduct a Feasibility Study of sites around Salt River Bay that could support the MREC concept. The study, completed in 2006, found that the 73-acre site on the east side of the bay was the most feasible for this project. OIA subsequently awarded NPS an additional \$120,000 to conduct an Environmental Assessment of the preferred alternative, a document that was completed in June 2008, with a Finding of No Significant Impact (FONSI) signed in February 2009.

Following completion of the OIA- and NPS-funded assessment of the feasibility of the MREC from the park standpoint, the JICMS began working with NPS on all aspects of the project through the Partnership Construction Process. In 2009, the JICMS began to develop a Strategic Business Plan to define the MREC's programs and operations.

The MREC will provide the opportunity to expand and strengthen the University of the Virgin Islands' undergraduate and graduate marine studies programs by providing research and internship experiences for students that are not available currently on St. Croix. All of the educational programming at the MREC would help to support the training of the next generation of NPS staff and Virgin Islands resource conservation managers.

In 2009, OIA provided \$1.25 million to NPS and the JICMS to support the MREC project. This funding, augmented by the JICMS, will continue to support the project through pre-design.

vision and goals 2.4

The Joint Institute for Caribbean Marine Research is a consortium of four public universities that are combining resources in support of a research and education foundation that will operate the MREC in partnership with the National Park Service.

The JICMS was formed to address concerns over the future of coral reef ecosystems in the Caribbean, including:

- Population growth and its negative impact on the region's limited resources •
- Living resources that have been heavily affected by over-fishing and habitat destruction
- Declining coral reef ecosystems •
- Limited marine education programs •

vision

Although more than 4.2 million acres of coral reef submerged lands are under U.S. jurisdiction, few have been properly studied to assess their overall health, and evidence is overwhelming that coral reefs and associated ecosystems are deteriorating at a rapid rate throughout the world.

In response to these concerns, the JICMS seeks to:

- Foster understanding and proper management of coral reef and other tropical and sub-tropical marine • ecosystems by initiating a comprehensive long-term research and education program in the U. S. Virgin Islands;
- Foster public awareness of the importance of coral reefs and other marine ecosystems from economic, aesthetic ٠ and global health standpoints though educational programs for students and the general public;
- Share information and research and to form partnerships with other nations within the Caribbean and adjacent regions with common interests and problems in the marine environment;
- Support and expand research capacity within St. Croix and the USVI in archeology, anthropology, human • ecology, history, Caribbean studies and other fields.

goals

The project team early on in the programming process of the project collaborated on a list of goals for the MREC. These goals have been and will continue to be used to help determine future decisions and to focus the mission of the MREC. The list of stated goals is divided into two sections. The first list is overall project goals that include sustainability targets, educational ideals and overall project aspirations. The second portion of the list is a series of goals focused on the research portion of the project and what it will take to make the lab a unique and invaluable resource for the study of our marine environment.

overall goals

- The project shall support the marine components of the NPS/VI Vital Signs program.
- The project shall promote and support the SARI mission as defined in the legislation that created the Park.
- The project shall be constructed within the available construction funds.
- The project shall be designed as passively survivable (passively survivable should include storm surge, climate change, etc) and shall only have components necessary (dock, etc) in the 100 year flood plain.
- The project landscaping, siting and construction shall consider historic and prehistoric uses of the site.
- The project shall provide the Park and partners opportunity to conduct extensive landscape vegetation restoration as part of construction and infrastructure design, sustainability and planning.
- The structure shall be designed for a 49 year lifespan.
- The project shall be constructed with technologies that are appropriate for the remote nature of the site, its educational goals and to support the type of marine science being performed (more than a field station, less than a full institutional lab).
- The project shall serve to reenergize the scientific community in the Caribbean and give them a home base.
- The project shall provide a variety of housing types for the variety of long and short term stays to expose students to marine science.
- The project shall provide some storage for scientific and historical records/artifacts.
- The project shall be designed sustainably and shall exceed performance of a code compliant building by 50% and achieve 3 pedals of the Living Building Challenge certification system, including the Water and Energy Petals.

- The project shall be a local attraction and engage the local community.
- The project shall minimize the use of fossil fuel.
- The project shall reduce the construction impacts on energy use with local materials and modular construction.
- The project shall be constructed to minimize impact to the site.
- Create a unique facility.

lab goals

- The project shall enhance research collaboration, cooperation, coordination and capacity by sharing resources and personnel to meet St Croix greater marine research/monitoring goals.
- The project shall provide high quality sea water for lab use.
- The project shall be designed so that electricity is reliable and available.
- The project shall be designed to allow for a variety of research configurations and possibilities.

SALT RIVER BAY TODAY

existing conditions and resources 3.1

.1 process

A key goal of the MREC is the demonstration of environmentally-responsible, sustainable development. And a key element of sustainability is that a building should be 'of its site': the design should be developed in response to local environmental challenges and in harmony with local conditions.

A 2005 survey identified air quality and sewage as the environmental areas of greatest concern to St. Croix residents. St. Croix is home to the HOVENSA Refinery, the second largest oil refinery in the United States and among the 10 largest oil refineries in the world. Just this year, 2011, the EPA began a 3-month study of air pollution in response to community concerns about the health impacts of airborne chemical releases from the refinery. Additional air quality threats are posed by the Richmond power plant near Christiansted, which produces electricity using oil-fired generators.

Highly publicized raw municipal sewage discharges have caused periodic fish kills and beach closures. The majority of homes on St. Croix are served by septic systems. Due to poor soil conditions, steep slopes, and limited regulations, untreated effluent from failing septic systems also poses an environmental challenge, both to human health as well as the marine ecosystems that are the focus of the MREC.

Erosion and sedimentation resulting from stormwater runoff caused by poor soils, steep slopes, and conventional development further stress the marine ecosystem. And the services conventionally provided by municipal systems in other locations are much more expensive and less reliable on St. Croix. There is very limited freshwater supply from 'conventional' sources. There is little ground water and municipal water from a desalinization plant is energyintensive and expensive. Municipal electricity is among the most expensive in the United States, and the supply is unreliable with frequent, unpredictable interruptions which pose a particular challenge in a research environment where reliability is critical.

So an environmentally responsible facility on St. Croix should be designed to directly address the local environmental challenges of air pollution; water pollution (both from sewage and stormwater); limited water supply; and dirty, expensive, and unreliable electricity. This project aims to become an example of sustainability and conservation in practice for the territory.

HOVENSA Refinery

.2 location

St. Croix is part of the U.S. Virgin Islands located in the Caribbean Sea, approximately 1,135 miles Southeast of Miami, Florida and approximately 94 miles Southeast of San Juan, Puerto Rico with a tropical climate – both hot and humid. Two weather data stations were used for the climate analysis, one a buoy located in the bay off the coast of the project site in St. Croix and the other 41 miles North in St. Thomas.

.3 climate analysis

A sustainable building should respond to local environmental challenges and strive to harness the local climate conditions and cycles to meet building needs in an environmentally-responsible manner. An analysis of local weather data and trends to identify opportunities and challenges posed by the local climate.

temperature

The average dry bulb temperature of St. Croix is 82° F, with temperatures remaining relatively constant throughout the year with a typical swing of $\pm 10^{\circ}$ F. As shown in the Weekly Summary of Average Temperature graph for the site—which plots weeks of the year in the x-axis, time of day in the y-axis, and temperature in the z-axis—there is very limited seasonal variation in temperature with modest diurnal temperature swings (day-night).

humidity

The relative humidity in St. Croix also has fairly limited seasonal variation, averaging approximately 70-percent and generally staying between a low of about 60-percent and a high of 90-percent as illustrated in the plot of annual relative humidity (shown in green).

0-0.3%

wind

This wind rose diagram plots the annual frequency of wind speed and direction, with the prevailing winds predominantly from the east and southeast and velocities most commonly in the range of 3-6 meters/ second. Orienting openings to the east and west will provide the best opportunity for natural cross ventilation. This analysis also suggests that the frequency and velocity of the wind is substantial enough for the production of on-site wind energy, particulary from small-scale microturbines.

solar radiation

20

solar radiation and cloud cover

The solar radiation on site is relatively high, averaging 5.4 kilowatt-hours per square meter per day, with only 40-percent average annual cloud cover, which is conducive to collecting solar energy with both photovoltaics (solar-electric panels) and solar thermal technology (solar hot water), but will require proper building and sun shade orientation in order to avoid unwanted heat gain in the spaces.

16.9

To

20

100

116.4

50

40

5

4

50.8

less preferrable building orientation

preferrable building orientation

sun path and building orientation

Based upon the annual temperature and solar radiation data, and the annual sun path at the building site, a building oriented on an east-west axis will most effectively avoid undesirable solar heat gains. As indicated in the orientation analysis images, with minimal overhangs this orientation effectively shades the building facades, while a north-south orientation would result in greater solar heat gains. The ideal eastwest axis for passive solar is at variance with the ideal north-south axis for natural ventilation, and the ideal sustainable design solution will seek to balance these competing opportunities.

comfort analysis

Human comfort is governed by temperature, thermal radiation, humidity, and air speed. Buildings are designed to provide shelter and comfort; conventional building typically provides conditions for human comfort through heating, ventilation, and air conditioning system (HVAC) fed by fossil fuel energy, while a more sustainable building seeks first to maximize passive design opportunities through harnessing free local climatic resources.

A Psychrometric Chart provides a graphic representation of human comfort conditions, plotting dry-bulb temperature, wet-bulb temperature, and relative humidity. On the chart above, the annual hourly temperature and humidity conditions are represented by a dot, with those falling within the adaptive comfort zone—a comfort model which takes into account seasonal temperature variations and occupants tendency to adapt both expectations and clothing based on the outdoor temperature—shown in green and those falling outside of that zone, conditions which require cooling, heating, and/or dehumidification to meet thermal comfort, shown in red. In naturally ventilated spaces where occupants can open and close windows, their thermal response will depend in part upon the outdoor climate and will therefore have a wider comfort range than buildings with centralized HVAC systems and no operable windows.

As indicated, with the provision of operable windows for natural ventilation alone, comfort conditions are met by the local climate conditions approximately 68-percent of the time, and supplemental cooling and/ or dehumidification required during hotter periods which fall outside of comfort conditions.

With the addition of passive design strategies, such as proper building solar orientation, sunshading, and enhanced ventilation (such as ceiling fans) the building design can be optimized to essentially eliminate the need for supplemental heating and significantly reduce the need for energy-intensive dehumidification and supplemental cooling.

sustainable design opportunities

Based upon the local environmental challenges, the local climatic conditions, and the program requirements of the MREC, the following key regionally-appropriate sustainable design strategies were identified:

Cooling-load avoidance

B

50

So

116.4

50.8

68

2000

30

40

30

- Natural ventilation / multiple conditioning zones
- Passive solar heating
- Natural daylighting
- Onsite water collection and storage
- Onsite renewable energy and storage
- Solar hot water

20

Onsite wastewater and stormwater collection and treatment

0

thermal mass and shaded glass

 Historic vernacular design solutions (developed prior to the widespread use of fossil fuel energy, historic building precedents often provide successful precedents for regionally-appropriate design strategies)

project conditioning zones

One further strategy for reducing cooling and dehumidification energy requirements is the reduction of the amount of space within the facility requiring tight temperature and/or humidity controls through strategic programming. The MREC program contains both museum storage and laboratory spaces which have both temperature and maximum relative humidity requirements of 60 percent (i.e. requirements beyond occupant comfort), and dehumidification will require a large amount of the total project energy use to meet the requirements of these spaces.

above ground cistern

Rather than conditioning the entire project to meet the most restrictive requirements, three "Project Conditioning Zones" were developed based upon the unique temperature and humidity requirements for different program elements within the MREC, allowing a diversity of criteria:

Zone M: The most stringent requirements, required only for Museum Object Storage

- Temperature: ambient to 72° Fahrenheit, ±3° Fahrenheit (no heating)
- Humidity: 45% to 60% (dehumidification and cooling)
- Pressurization: positive
- Outside air: 5% fresh air (95% recirculated air)

Zone A: Controlled environment (labs, offices, theater, object cataloging, director's house, food storage and battery room)

- Temperature: ambient to 78 degrees Fahrenheit (no heating)
- Humidity: ambient to 60% (dehumidification and cooling)
- Pressurization: positive
- Outside air: 15% fresh air (85% recirculated air)

shading with pool to cool the air

Zone C: Environments with shading and screens or open environments (labs, lab support, meeting room, storage, classroom, lobby, reception, community space, touch tank, clean preparation, living accomodations, food preparation, boat dock/dive operations, maintenance, loading dock)

- Temperature: ambient (no heating or cooling)
- Humidity: ambient (no dehumidification)
- Pressurization: neutral (no directional airflow)
- Outside air: 100% fresh air (full natural ventilation)

.4 topographical analysis

16.9

Most of the site was disturbed during a 1960's development that was never completed. The eastern portion of the site which is above the flood plane is distinguished by a large hill on the eastern edge of the property with steeply sloping sides to the north and west, and a more gradual 'saddle' formed to the south and more gradual topography adjacent to the flood plain to the west. To minimize ecologically-intrusive (and expensive) grading activities required to develop steep slopes, efforts have been focused on development within the gently sloping areas adjacent to the flood plain and the saddle area to the south of the hill. The slopes support east-west building activities required. orientation well.

level

flood plain [in blue]

protected view zone [in yellow]

.5 protected areas/buildable limitations

The northeast portion of the site is a prominent hillside sloping to shore and part of a natural view shed which is to be preserved. The western portion of the site is largely within the flood plain and also features ecologically sensitive mangroves. This limits the desirable building area to the eastern portion of the site between the hill to the west and floodplain to the east.

.6 geotechnical analysis

Minimal geotechnical analysis is currently available (see landscape architecture portion of this report for detail). A thorough geotechnical analysis will be conducted during subsequent project phases.

mangroves

north

mangroves

invasive plant growth area

.7 vegetative analysis

The project site above the flood plain has been extremely degraded by invasive plant species. Restoration with native plants will offer an opportunity to not only reduce the negative impact of building but also provide a restorative ecological impact. Please refer to the landscape restoration section of the appendix for further detail.

development capacity of the site .8

B

.22

26.8

83

30

As the design team, the JICMS and the NPS analyzed the selected site for the MREC, a fundamental question needed to be addressed. What is the development capacity of the site? This question is important for many reasons: first, since the proposed site is within the boundaries of the SARI park, minimizing the impact to the Park is of great importance. Since the site was previously developed, it is considered a grey field (meaning a site that has had previous disturbance on it but has not necessarily been so polluted that it can be noted as a brown field site), so building on it in an appropriate way will be a restorative act and not a destructive one. This is especially true given the state of the site having been abandoned partway through the development of a commercial enterprise, prior to the formation of SARI as a National Park.

The second reason the development capacity of the site is important is the team needed to be sure that the site was capable of supporting the proposed program and population. The project's program is aligned with the SARI legislative mandate to study and preserve the historical and natural resources of the Park, and to further that mission the project has ambitious sustainability goals that include net zero annual electricity use and net zero water use (meaning the project produces and/or collects at least as much of each of these resources as it uses).

To evaluate if the proposed program exceeds the site's capacity, four criteria were assessed.

- Can the proposed student population be supported by the water available on site based on annual rain fall? Based on an average annual rain fall of 40.3" per year and a current program area of about 60,000 sf, the project can capture a total of 1.2 million gallons of water. The water use needs for the project show about 600,000 gallons of rain water capture are required based on the average daily usage. The USVI local code requires a minimum of 370,000 gallons. Based on this information, the site water capacity or the net zero water use goal are not limiting factors for the project at this time, but this is subject to the ultimate capacity of the cisterns.
- Can the proposed functions be accommodated reasonably with the amount of solar energy available for harvest on the site? Based on the current projection of 770,000 kWh per year of electricity being required and the available solar radiation on the site, photovoltaic panels covering about 30,000 sf will generate the required power. As such, we do not see power generation or net zero power consumption are not limiting the project at this time.
- Does the allowable population offer financial sustainability for the partner JICMS group to allow the project to sustain itself? Based on preliminary business plan models, the facility needs a minimum of 32 paying undergraduate students to keep the facility in good financial order, but the partner group had mentioned that more would be desirable. As such, the program shows 40 undergraduate students with the balance of the housing capacity being aimed at more senior groups (graduate students, post-doctoral researchers, etc). As such, this criterion allows for the business plan to function as adequate student populations are accounted for. The number of students could grow if needed, but the site impact and water and power impacts would need to be reviewed accordingly. 5
- Does the number of students needed for this financial sustainability prevent restorative action across a majority of the site? In looking at the East Site of SARI for the MREC, a 73 acre peninsula was selected because of its previously disturbed nature and its potential for access (please refer to the Environmental Assessment date June 2008 for the MREC for additional detail). The current proposed development impacts about 7 acres of this site allowing for restoration of a majority of the peninsula. In addition, due to the nature of the proposed construction, the area inside of the 7 acres will also be restorative with native vegetation and full storm water mitigation. This criterion is the most limiting of the 4, as enlarging the development footprint further would push the MREC to be bigger than the EA allotted for. As such, the development footprint should be considered the determining factor for maximizing the development of the site.

water supply cistern

.9 sustainable design metrics

Several of the overall goals articulated earlier in this report are related directly to sustainability. Design for passive survivability, restoration of the compromised landscape, and reduction in fossil fuel use, for instance, are project goals related to sustainability. Addressing local environmental challenges and designing in harmony with the local climate as outlined in the Existing Conditions and Resources section are also inherently sustainable approaches.

Beyond these more general goals and priorities, green building rating systems can provide an effective, holistic framework for both addressing the environmental impacts of building design and construction as well as setting concrete performance targets to inform the design. The now-familiar Leadership in Energy and Environmental Design (LEED) Rating System, and the emerging Living Building Challenge will be utilized to set specific sustainable design and high-performance metrics for the MREC project.

LEED rating system

The project will pursue Platinum level LEED certification under LEED for Building Design + Construction Rating System. This is this highest level of LEED certification attainable. The LEED Rating System is a point-based system with credits organized around 5 broad environmental categories: Sustainable Sites, Water Efficiency, Energy & Atmosphere, Materials & Resources, and Indoor Environmental Quality. The general methodology is to set a 'conventional practice' baseline for a given credit, against which performance over conventional practice is compared. For instance, water efficiency as measured against conventional practice. Aside from a limited number of prerequisites, credits are optional and project teams select the desired path to achieve a targeted score based upon project constraints and priorities. A LEED Scorecard outlining the preliminary strategy for platinum certification is included in the Appendix.

living building challenge

The Living Building Challenge takes an alternate approach to sustainability, emphasizing a 'do good' approach over a 'be less bad' approach. It is comprised of 20 "Imperatives" organized around 7 sustainability topics, or "Petals": Site, Water, Energy, Health, Materials, Equity, and Beauty. Unlike LEED's optional credits, the Imperatives, such as net zero annual energy use (the building must get by on its annual solar income), are selected with the intent of forcing designers and building owners to fundamentally rethink

stormwater collection cistern

the assumptions and processes of designing and the goal of creating deep green, 'living buildings' which do not exceed the carrying capacity of their site and which become a regenerative part of their ecosystems.

The project will utilize the Living Building Challenge as a design guideline with a sustainability target of achieving "Petal Recognition" for a minimum of three petals including the Water and Energy Petals. The project will collect all of its potable water from rainfall. The project will treat and reuse all waste water on site. The project will meet its energy needs with on-site generated renewable energy (photovoltaic, solar thermal, and wind) including back up to provide emergency power for critical operations and research. The project will create comfortable, productive spaces without conventional air conditioning systems using natural ventilation, dehumidification, and passive cooling design. The project will feature climatically- and culturally-appropriate design strategies which harness plentiful natural resources (sun and wind) while valuing limited resources (water). The project will serve as a model of regionally-appropriate sustainable design and construction for building occupants, visitors, and the broader community. The project will promote a car free living by using vans and buses only to leave the MREC and electric carts and walking to move around the site.

		MRI	EC Space Summary

4.1 design program space list

The space list summary displays spaces required to support minimum operation needs of the MREC with the net square footage (NSF) and gross square footage (GSF) totals for each of the eight building program categories as well as the two main site component categories.

Site Total:

Each of the eight building program categories is broken down to show the program spaces within each category and are color-coded to designate NPS, JICMS or shared spaces. This was determined through a collaborative effort between the JICMS, NPS and the design team. This includes the net square footage for each program space, the quantity of those spaces and the total net and gross square footage amounts for those spaces. Additionally, each program space has a conditioning zone specified, either A, C or M as defined on pages 18 and 19.

4.2 functional diagrams and adjacency studies

The functional diagram and adjacency study are illustrated in the diagram on the following page. Each large dashed circle represents a program category and holds each of the main program spaces within it. The spaces are associated either by a functional connection [close proximity is desired] or a direct, physical connection [adjacency required]. The program categories are linked to each other based on programmatic adjacencies, operational adjacencies, and social connections.

design solutions 4.4

.1 precedents

The study of precedent projects is an important component of any design project and in the case of the MREC offers the team a window into the past and present of tropical design solutions and ideas that can translate to architectural strategies for the site and building design of the MREC. The study of these other buildings offers insight into design solutions that have similar aspirations as the MREC; this can be seen from the cultural, sustainable and aesthetic perspectives. The design team looked at historical images of villages, the former WIL facility, other buildings in St Croix, colonial construction, local vernacular construction from housing to labs to institutional work. It was also gleaned from these studies the use of materials and empirically determine their susceptibility to the harsh marine climate on the site. Also included in the study is a series of projects that are in similar climates, but maybe located elsewhere to see what other cultures offer; to this end several buildings in Sri Lanka and Australia were reviewed. The design team has also reviewed some of their own work looking to past NPS projects as well as other work that has related program components. A photographic essay of images showing these precedents was compiled that focused on several key features that have become important to the MREC design.

- Siting buildings up on hills to take advantage of prevailing breezes and to build them above the flood plain.
- Grouping several smaller buildings together as a village or campus to maximize the potential for cross ventilation.
- Building into hill sides to work with and not against the site slope found on St Croix. Using this technique also allows the foundation cistern to be placed under buildings creating a cooled, protected and convenient storage location for collected rain water.

Using deep supported overhangs and colonnades to both protect the interior spaces from sun and rain, as well as allow the use this space as exterior circulation.

Using stone and concrete to create durable buildings that can withstand storms as well as harsh marine conditions. These materials also offer the benefits of thermal mass which helps keep spaces cool when used in conjunction with proper solar shading.

- The use of glued laminated timbers which offers a material of limited combustible nature, is resistant to salt corrosion and is made from smaller pieces of wood sourced from sustainable forestry practices.
- The use of shades that are oriented either vertically or horizontally (depending on exposure) that can become storm shutters or barriers when needed.
- The use of vertical elements that while historically used as chimneys can be effective in creating passive cooling techniques, such as solar chimneys.

04

.32

• The use of small interior courtyards that are shaded and offer occupants a shaded condition and allow for greater air movement through buildings as well as increasing access to natural light.

- The use of filtered light through diaphanous materials.
- The use of porous material in lieu of solid material to encourage air movement.
- The use of structural elements to create colonnades that define a rhythm across a site or building.
- Creating paths of protected movement to shield people from the sun and rain.
- Creating warm inviting spaces with large volumes to allow for passive cooling strategies such as stratification, effective daylighting and enjoyment of spaces.
- Not enclosing space (open air) where the program and climate allow.
- Siting buildings sensitively to work with the existing topography.
- To reveal the site in a controlled and designed entry sequence.
- Creating spaces that have an immediate and direct relationship to nature and the environment in which they are located.

Blue Ridge Parkway Destination Center Asheville, NC

Hawaii Preparatory Academy Hawaii, HI

The Nature Conservatory St. Croix St. Croix, USVI

Z

Three projects were selected to look at in greater depth for their relationship to the MREC and its program components. The three projects are:

- On-site Sewage Treatment
- Naturally Ventilated
- Thermal Mass
- Public Outreach/Education
- Colonnade
- Deep Overhang
- Solar Hot Water

.2 master plan

The organizing concept is to create a series of linked colonnades or passageways that tie the visitor and the resident experiences together as they move throughout the site as well as to provide shelter from the sun and rain as part of these paths. The colonnade evokes the rich architectural history of St Croix and the Virgin Islands; it mirrors the experience one has in Christiansted while allowing the development of the buildings to ultimately be of their own time. The colonnade concept also offers a direct strategy for connecting the buildings on the new campus and creating active points of interest along the way to spurn spontaneous interaction between disparate groups occupying the site including researchers, K-12 students and casual visitors.

Upon arrival at the site, the vehicular circulation moves around a constructed wetland that is the precursor to the forthcoming courtyards. This wetland is experienced using a bridge over the wetland offering educational opportunity as well as an informal but organized start to the entry sequence into the MREC. After crossing the wetlands, one follows a path to the east up to an entry pavilion that serves as the lobby and a central gathering space for the project. This space is open air, but has a rhythm of columns and beams overhead to define the space and provide shelter from the sun. Upon arrival at the entry pavilion, the site is revealed to you as the panoramic views from Buck Island and Christiansted in the east and Salt River to the west present themselves. Visitors and students from here have direct access to the Outreach and Education components of the project. To the north the pavilion opens onto the central courtyard where both sides are flanked with colonnades. The southern colonnade offers alternate entry to the Outreach and Education program elements.

parti

massing diagram

On the north edge of the courtyard, the spine of the center develops as a colonnade connects the courtyard, moving past the lab building connecting it directly to the maintenance building and further down the hill to the lagoon level elements and the dock. This colonnade creates a central location for movement between many of the project's key program elements helping to build a community and allow visitors to easily navigate.

The undergraduate housing units are arranged to define a dedicated courtyard space but leave the east view and windward direction open. Graduate and staff residences are located apart from the undergraduates for acoustic and other privacy reasons; they are higher on the hill. To bring these groups together, the dining pavilion is located centrally to all the housing and serves to help define the north edge of the central public courtyard. The lab colonnade terminates at this focal point for the site's residents and ties the whole site together.

project narratives 4.5

.1 site

site grading

The Salt River MREC site was dramatically altered during the 1960's and 1970's by failed hotel/condominium development leaving 26,000 square feet of unfinished structure, thousands of cubic feet of construction materials unnaturally sculpted contours and overgrown roads. Significant earthwork and grading will be required to develop the project site and restore the area to more natural topographical conditions.

Generally, the grading design will address vehicular and pedestrian areas, including ADA access requirements, proposed structure locations, stormwater management, and site restoration. The intent of the overall grading and drainage approach will be to utilize the existing topography to the maximum extent possible and provide the least site impact by disturbing only those areas proposed for new facilities or restoration. Because of the minimal amount of soil coverage and shallow underlying rock outcroppings, proposed excavation of existing grades will be minimized where possible.

The earthwork needed to construct desired project facilities will be limited to cut and fill operations, largely within 10 feet of existing grade, to create building foundations, roadway and parking areas, walkways and trails, and exterior common areas and park amenities. The need for excavation will include the burial of utility lines and preparation of building and structure foundations. Coordination of the overall site design will be important to maximize the co-location of facilities to further reduce the total area of disturbance and restore drainage and grades.

Additional earthwork will be necessary to perform restorative operations at the site. Previous development activities have degraded the natural landscape and altered the historic watershed characteristics. Over time this has contributed to erosion of the hillside and sedimentation buildup in the lowland areas (mudflats). Restoration of the site will include the reformation of the hillside to reflect historic contours and grading of the lowland areas to provide proper drainage of the affected basin.

A significant portion of the park property lies within the identified 100-year floodplain. Therefore, special considerations are warranted for the placement of facilities in this area. Additionally, any earthwork performed within this area will need to be compensated for to ensure there are no adverse impacts to floodplain capacity. By grading the site such that there is no net loss of flood water storage, associated development impacts will be avoided. Grading within the floodplain is anticipated, however, to support facilities proposed within its limits and provide the desired level of passive survivability.

MREC site looking southeast towards lagoon and SARI

stormwater management

There are no existing stormwater collection or conveyance systems at the MREC site.

New facilities will result in approximately 60,000 SF of new impervious area associated with building rooftop. Although this area will generate a significant volume of runoff, it will be directed to high capacity cisterns utilized for rain water storage and future use as potable water. Roof structures will be designed to maximize the collection of runoff as this will be the sole source of potable water for the development. It is anticipated, however, that roof collection systems will accommodate some level of first-flush bypass and/or overflow discharge flows. Flow rates and volumes from these sources are expected to be minimal but will contribute, at least occasionally, to the overall runoff from the developed portion of the site.

Another 50,000 SF of area may be needed for roadway, trails, parking, drive aisles, and other associated pedestrian and vehicular circulation facilities. The selection of pavement materials will dictate the level of runoff from these areas, with pervious or semi-pervious surfaces having reduced runoff rates and volumes compared to impervious surfaces. A maximized use of pervious surfaces through vegetated swales and rain gardens are encouraged due to the measurable benefit to runoff quantity and quality.

As stated above the intent of the overall grading and drainage design is to utilize the existing topography to the maximum extent possible to reduce the amount of earthwork needed for development and restoration. The sloping nature of the site combined with the limitations of shallow rock will steer the grading and drainage design away from traditional collection and conveyance systems which primarily utilize inlets and piping. The approach will be to collect and convey stormwater in swales prior to final treatment and discharge. Treatment will occur through the use of various Low Impact Development (LID) techniques including vegetated swales, rain gardens, off-line basins and other similar dry treatment facilities. The overall system will be designed to maximize on-site infiltration and evapotranspiration, while reducing runoff quantity and increasing water quality.

Salt River Bay is a Class B surface water per the U.S. Virgin Islands Water Quality Standards and is subject to Total Maximum Daily Load (TMDL) requirements associated with its current impairment for dissolved oxygen. The stormwater system will address these requirements while following the design direction dictated by the document Technical Guidance on Implementing the Stormwater Runoff Requirements for Federal Projects under Section 438 of the Energy Independence and Security Act. Utilizing Option 2 of this document, the stormwater system will ensure there are no post-development impacts associated with stormwater discharges to Salt River Bay. Berming around the proposed sanitary wetland treatment system will be required to prevent inadvertent discharges of this facility to the stormwater system during heavy rainfall events. Additionally, buffers will be provided around existing surface waters, wetlands, and mangroves to further protect these natural features.

A major constituent of the local soil is clay, which reaches its moisture capacity guickly after a rainfall event. This combined with large areas of steep slopes provides for a condition which results in significant sediment runoff to wetlands and coastal waters. Local residents have confirmed this condition citing the rapid change in surface water turbidity after significant rainfall events. The grading and stormwater management design will address existing conditions to control this impact. This is especially important during the project's construction phase. The Territorial Pollutant Discharge Elimination System (TPDES) Program requirements will be adhered to during construction for erosion and sedimentation control. Best Management Practices (BMPs) will be utilized to capture and control stormwater runoff to avoid impacts to sensitive coastal waters during construction. A Stormwater Pollution Prevention Plan (SWPPP) will also be developed for the site to describe in detail the means and methods of addressing erosion and sedimentation control for the property.

.2 landscape architecture

landscape components

The landscape components perform to achieve a harmonious relationship between form and function to articulate the needs of all users and site constraints. The goal is to stimulate the senses, facilitate human interaction, increase perception of natural habitat and thus, enhance the sequence of their daily routine.

The design of this site has high expectations because it will produce its own energy and water demand. All of these efforts and elements will be incorporated as an integral part of the landscape.

green parking

The parking is reached after an arrival sequence that should provide a sense of the place that will be visited or will become a temporary home for others. A native tree canopy will provide a visual focus and a marked change of scenery, atmosphere and scale from the road just left behind. The parking itself has a tree canopy that provides enough shade that shield the reflection of the sun and maintain a comfortable temperature.

The paving surface of the parking stalls will be a pervious and reliable vegetated surface that controls runoff and also maintains a comfortable temperature. The planting strips will not only screen with native shrubs the parking stalls to preserve the sense of place within a natural reserve, they will also filter runoff before it discharges into the estuary.

pedestrian path

The pedestrian path facilitates moving between different types of activities and the sequential transition between them. Typical design elements such as form, color, texture and visual focus will enhance this transition and Low Impact Development (LID) concepts will be used to reduce runoff velocity, promote infiltration and laminar flow with a minimum load of sediment.

landscape node

The Landscape Node is a confluence of paths that provides the opportunity of human interaction. It is a landscape component that has been highly stereotyped as the plaza or square. For this project it's interpreted as a place to leisurely meet and exchange ideas and or greetings essential for the marine laboratory campus program. The scale and design of these nodes will create the ultimate sense of place within a nature preserve.

This project will provide an opportunity where a plaza (node) functions both as a meeting place and a water reservoir, consistent with the sustainable site practices objectives.

For climate control where a tree canopy is not feasible, shade can be architecturally provided with a trellis and native vines or fruit plants.

native tree canopy

The final selection of natural site components such as vegetation will be derived from the detailed correlation and analysis of existing site conditions and design program variables such as NPS objectives and users' needs, hierarchy of circulation, functional relationships, site constraints and form determinants.

The selection and location of natural elements such as trees among other design objectives shall also consider: solar radiation utilization, energy conservation, relationship to the architecture and plantings that will not interfere with solar or roof water collection.

Trees can be generally categorized by scale and function into canopy trees and understory trees. The division is essentially made between those trees under 20 feet high and trees which are over 20 feet high.

A diverse variety of native trees will be used to provide the desired tree canopy. Consequent with the sustainable site objectives, they will also provide habitat.

native shrubs and ground cover

Shrubs may be	arbitrarily divide into 3 categories:
low	up to four feet high
medium	from four to eight feet
high	eight feet and over

The massing of shrubs and ground covers control circulation, define space, provide visual focus, form, color and texture. When selected to provide habitat, no intensive maintenance such as pruning will be recommended.

constructed wetland

The constructed wetland is an essential component to the sustainable site because it recycles wastewater to supply part of the demand of non-potable water. This is an odorless treatment sequence which produces a high quality effluent, a small percentage of which will be used for drip irrigation for new planting, the orchard and vegetable garden.

New planting always requires a minimum amount of water to become established. Especially so during their first year of growth. Conscious of the water limitation we recommend that new planting be established in a sequence of phases.

The selection of wetland plants is not directly related to the guality of the wastewater effluent because their roots only provide a host for the colonies of bacteria that decompose contaminants and are not really part of the wastewater treatment process. Therefore we recommend that the selection of wetland plants not be limited to native types because it provides an opportunity to incorporate a diverse

Examples of flowering wetland plants are: canna, heliconia, alpinia, hedichium, and iris among others.

plan.

The native shrub and ground cover edge is a landscape component that not only provides a barrier that defines borders between different functions and uses within the reserve, these edges also become a starting point of another restoration effort whose objective is to remove invasive species and restore native coastal ecosystems that include plants such as: Coccolobis uvifera, Chrysobalanus icaco, Argusia gnaphaloides and Suriana maritima among others.

The mangrove restoration strip is another landscape component we recommend be incorporated into the restoration efforts. Its objective would be to restore and or protect the basic three species of mangrove forest (Laguncularia racemosa, Avicennia germinans, Rhizophora mangle) and diversify the ecosystem by inserting a transitional area that includes species such as: Conocarpus erecta, Bucida buceras and the swamp fern Acrostichum danaeifolium.

variety of flowering plants whose fresh production could be sold to local hotels and restaurants.

orchard and vegetable garden

An area close to the kitchen and dining hall is reserved to provide fresh fruit and vegetable produce to add to the basic diet. We also recommend that selection of trees and vegetables not be limited to native materials. The final selection can be made depending on the area available and the recommendations of a nutritionist.

Native Shrub and Ground Cover Edge and Mangrove **Restoration Strip**

There are ongoing restoration concerns and efforts related to the site. One such example is the mudflat restoration

These landscape components shall be coordinated with the mudflat restoration plan because they are all directly interrelated to the Salt River Bay estuarine ecosystem.

.3 architecture

The buildings will sit on the site and take advantage of the positive climatic attributes discussed in the analysis section of the Master Plan. Buildings will be sited to maximize solar orientation and ensure that proper shading is possible on buildings to minimize the solar heat gain. Orientation will be important to allow even daylighting of spaces and avoid glare. In addition, since the domestic hot water and onsite power generation systems are all solar based, their orientation and location must be carefully considered in a final design solution. All of these criteria point to buildings that are generally long in the east-west axis to be sure the south and north facades are maximized, as these are easiest to control solar gain on and offer the best natural light.

In addition, the project's built components need to be configured to allow for cross ventilation and to take advantage of the easterly winds. One of the project's challenges then is the optimal orientation for solar and wind are contradictory; however we have determined that the solar issue should take precedent in the site design as other options are available to take advantage of prevailing winds. These opportunities include solar chimneys to take advantage of stack effects, proper cross ventilation to draw air across spaces, wind catchers to help direct the wind and open pavilions. These strategies could also be used in combination. For example, using thermal chimneys to help reduce fan usage in the exhaust stream of the labs is an idea that will be further explored during the next phase of design. Another example will be to use the building layouts as wind catchers. This is the intent of leaving the eastern ends of the courtyards open - which also provides great views - to allow air to move into the courtyards where it can aide in cross ventilation of the buildings creating that courtyard.

The buildings will be situated in the site to take advantage of the site slopes as well. Building on the moderate slopes of the site allows for views as buildings tier up the hill. In addition, the selected locations of most of the facilities allow for cistern foundations. This is the traditional location for rain water storage in St. Croix as the solution to limited fresh water.

Materials slated for campus buildings will be selected for long-term durability and compatibility with the marine environment. Flooring is scheduled to be sealed concrete (thermal mass), walls with epoxy paint, and no ceiling system (to avoid cavities without air movement). UV-tolerant materials (and service distribution means) will need to be considered. Glued laminated timbers offer great potential in this arena. They are resistant to the marine locale, can be easily fabricated from sustainable forest materials and offer warmth in their use as a visible structural system. Other material of interest include stone, which is guarried locally in St. Croix, and concrete for its durability.

shaded facades/walkways

durable building materials that are compatible with their environment

example of a teaching lab

.4 labs

description

The laboratory component of the Marine Research and Education Center (MREC) on St. Croix will support both marine research and teaching functions required of the Joint Institute of Caribbean Marine Studies (JICMS). Member schools, and perhaps other schools who may wish to participate, will offer courses at the campus which will be enhanced by what the facility offers, and by access to the marine environment.

The 15,000 gross square feet of laboratories will be designed to support a variety of marine research by both the JICMS and others of the campus facilities and marine environment. The two most critical components for long-term success of the project are reliable electrical power and quality seawater used in marine research and education programs.

program

The Research Labs will be easily divisible by visiting research teams, each with common layouts and service distributions. There will be 'core' labs which will be shared among the research teams; these will include Analytical Lab, Remote Operated Vehicle (ROV) Lab, an Equipment Room, Global Information Systems (GIS) Lab, Wet Labs, Sample Prep Labs, Materials Storage space and Field Lab space for biology, geology and archeology.

The Teaching Labs will be located both at the main lab facility as well as a component of the Boat/Dive operations area at the lagoon level. Space for marine biology, fisheries, geology, archeology, field operations and future expansion will be programmed and noted on the schematic design drawings.

Indoor spaces will be designed on an 11 ft. width by 33 ft. depth lab module, with structure, mechanical, electrical, plumbing, data distribution systems as well as sea water systems based on the module. The module is designed to be easily divisible for space assignment and for potential reconfiguration and repurposing as needed with program or project changes.

location on the site

The Lab component of the MREC requires functionally associating the Lab Building above the 20' contour line and the Boat Dock/Dive Locker facility at the lagoon level. This allows for the movement of samples from the field to the lab in the most efficient manner. As there are limited locations where this 20' contour approaches the lagoon at the inlet, options for locating these two critical components are limited. The space programmed for a future mariculture component is to be adjacent the Boat/Dive operations facility.

functional adjacencies

The Lab will be organized into blocks largely driven by functional adjacency requirements and by the need for associating spaces with similar environmental conditioning requirements. The ROV Lab and GIS Lab require Zone A conditioning, as do the Research Labs (assignable space) Analytical Lab (core) and Equipment Room (core). These labs will be a single 'block' within the larger lab volume. Other spaces - Teaching Labs, Wet Lab, Sample Prep Lab, Storage – are Zone C spaces and therefore may be associated in the most reasonable manner.

DISTRIBUTION PUMPS 1,3: PRIMARY, BATTERY POWER ELE PUMP (GENERATOR BACK-UP PUMP/CONTROLS), 300 GPM DISTRIBUTION PUMPS 2,4: BACK-UP, DIESEL POWER POMP (GENERATOR BACK-UP CONTROLS), 300 GPM SOURCE PUMPS 1, 3: PRIMARY, BATTERY POWER ELEC PUMP (GENERATOR BACK-UP PUMP/CONTROLS) 300 GPM SOURCE PUMPS 2,4: BACK-UP, DIESEL POWER PUMP (GENERATOR BACK-UP CONTROLS), 300 GPM

lab utility distribution diagram

Offices for administrators, researchers and shared space for agency staff will also be Zone A conditioned, and will be adjacent the lab block. See pages 18 and 19 for Zone definitions.

The Teaching labs in the main lab building will be functionally-associated with the Teaching labs at the Boat Dock/Dive operations facility. These labs will need to be placed reasonably close to the teaching classrooms on the site. The Teaching Labs at the Boat Dock/ Dive operations facility, at the lagoon level, will require minimal facilities for restroom and showers.

environmental conditions

The program calls for two environmental conditions for the Lab volumes. The 'core' Research Labs, Analytical Lab, Remote Operated Vehicle (ROV) Lab, an Equipment Room, and Global Information Systems (GIS) Lab will be maintained at 60% RH or less and from ambient temperature to 78 degree F (cooled, but unheated). These parameters have been established to meet the sustainability goals of the project, the targeted human comfort thresholds for those who may be working in the lab, and for establishing an environment conducive to the success of the research. Other spaces which will be a part of the lab can function appropriately as unconditioned space, which may be screened, shaded, or open. This open environment must consider the transfer of particulates (often wind-driven) and salt through the space, and the impact on comfort and research success.

The JICMS has confirmed that the use of chemicals, whether acid/base or solvent, will be limited to small volumes and will be dilute. As such, the labs are not required to meet the ASHRAE standard for lab ventilation requiring single-pass air.

access

Once the lab functional adjacencies are established, it is assumed that labs will be a linear assembly of the 11' by 33' modules, with each lab type (Research Lab, Analytical Lab, Remote Operated Vehicle (ROV) Lab, Equipment Room, Global Information Systems (GIS) Lab, Wet Labs, Sample Prep Labs and Materials Storage) accessible to the adjacent lab.

.48

Labs will be either temperature/humidity controlled, or open to the environment. Access into each conditioned lab space from the outside will be via an internal egress corridor. The ROV Lab will require an oversized door for bringing large equipment and carts; this access point may be shared by other Lab components.

materials of construction

Materials slated for the Labs will be selected for longterm durability and compatibility with the marine environment. Flooring is scheduled to be sealed concrete, walls with epoxy paint, and no ceiling system (to avoid cavities without air movement). Laboratory Casework will be thermoplastic; doors and frames will be fiberglass reinforced polyester. Fastener materials will be selected for their resistance to exposure in a salt environment. UV-tolerant materials (and service distribution means) will need to be considered.

service distribution

Power and data will be distributed to casework at the perimeter of the lab, likely via out-of-wall systems that can be reconfigured as needed without penetrating the walls. Power and data in the 'core' research lab will be delivered to the casework via either umbilicals at the ends of island assemblies (i.e. from above), or via overhead service drop locations. Power will be predominately 120V/20A 1phase service, with limited 208V/20A/1phase service. The lab plug load is targeted (preliminarily) at 3.5 W/sf.

Solar heated hot water and cold water (non-potable) will be delivered to lab sinks and to marine tank locations, as well as to locations required to service the seawater delivery system. Purified water (Lab grade) will also be owner-furnished, and will be assumed to be fed from the potable (house RO) filtered source.

lab lighting

Targets for lighting within the lab would be to use daylighting only during the majority of the day, and 50 footcandles (at the work surface) by zones during night use. The option of point-of-use task lighting will be considered. Shading will need to be considered to avoid glare and direct light strikes at the worksurfaces.

Surface treatments will be considered to enhance the distribution of natural light, and to reach daylighting targets for the labs.

lab equipment

The equipment which will remain on site will likely include a fume hood for mixing and dilution (and perhaps for dedicated lab ventilation). A biological safety cabinet (IIA) and -80C freezer(s) will be available for shared assignment. It is likely that a reasonable distribution of other lab equipment– analytical balances, centrifuge, microscopes – will be on-site for common use, as well as the consummables required for their operation.

lab waste

Water effluent from floor drains and from lab sinks will be directed to the facility wastewater system. Solid lab waste and liquid solvent waste will be collected and removed from the campus by a contracted vendor. Acid or base waste product will be neutralized, pH confirmed, and released to the facility wastewater system via the lab sinks.

Sea water rejected from marine tanks and aquaria will be released to either the inlet, bay, or ocean pending review of options by the research team currently considering the source water delivery system design and the authorities having jurisdiction.

lab storage

There will be limited square footage (unconditioned) available for storage of lab equipment and consumables in the project. The nature of the assignment of the Research Lab – short duration data collection, analysis and manipulation – will likely require research teams to return to their respective home bases for more in-depth review of data gathered on the island. As such, there is the reasonable expectation that these same teams will return for further rounds of work at the MREC, and that these teams might wish to leave equipment or research set-ups on the island. The Storage Facility at the MREC may have to consider this eventuality, and consider the capacity on-site versus storage at a bonded off-site storage facility, or make arrangements for storage (and perhaps sharing) at the University of the Virgin Islands campus.

seawater supply and delivery

One predominant Project Goal has been the consistent delivery of high quality seawater to the facility, in terms of availability, flow rates, storage capacity, temperature, salinity, turbidity, and the presence of limited amounts of other runoff contaminants. This system must be integrated with the proposed building campus design.

The initial specification for the system as defined by the JICMS Seawater System Advisory Team include the following parameters, with design team assumptions/clarifications/additions noted in italics:

- Two 3/16: mesh supply intake in a TBD location(s)
- Each of the two supply intakes will split into two Source Pumps at the Maintenance Building (Zone C unconditioned space), Primary and Back-up. The Primary pump will be 300 GPM electric-powered pump, with both pump and controls backed-up by a single diesel generator. The Back-up pump will be a 300 GPM diesel powered, with pump controls backed-up by the generator. On power loss, the Primary (electric-powered) pump will switch to the diesel pump fed by a local diesel tank. Loss of normal operation of this Back-up diesel pump will result in the generator driving the Primary electric-powered pump/controls into normal operation.
- One of the two redundant Source Pump systems described above will feed source water into an 8,000 Gallon conical Sediment/Degassing tank, conical at top and bottom for removal of sediment at the bottom and overflow near the top. Sediment and overflow will be routed back to the ocean.

- Seawater hereafter described as 'Raw Water for Distribution' will be decanted from the top of this conical tank, and delivered via redundant Distribution pumps (powered in the same manner as described for the Source pumps, redundant in the same way, with pumps and controls located in the Maintenance Building) to the Research/Teaching Lab Building, to the Dive Operations at the lagoon level, and to the Community Outreach facility, all locations where marine life will be housed.
- The other of the two redundant Source Pump systems described above will feed source water into a filter system composed of aggregate and sand, with backwash and overflow capability with lines routed back to the ocean. This seawater hereafter described as 'Filtered Water for Distribution' will be delivered to a storage tank designed to hold 300,000 Gallons plus, to be located beneath the unconditioned component of the Research/Teaching Lab. From this point the Filtered water for distribution will be routed via redundant Distribution pumps (powered in the same manner as described for the Source pumps,

redundant in the same way, with pumps and controls located in the Maintenance Building) to the Research/Teaching Lab Building, to the Dive Operations at the lagoon level, and to the Community Outreach facility, all locations where marine life will be housed.

- It is envisioned that the seawater exchange in the tanks located in the Research/Teaching Lab Building, in the Dive Operations at the lagoon level, and in the Community Outreach facility where marine life will be housed will be delivered at an exchange rate based on diversity. We are assuming a diversity rate for the flow of this water to be the following: 1/3 of the tanks flow at 25%, 1/3 at 35% and 1/3 at 50%.
- At those locations where marine life will be housed, both Raw water for distribution and Filtered water for distribution will be available. Heat exchangers will be available on a per outlet basis to adjust the feedwater temperature in a point*of-use, metered manner* between feedwater temperatures ranging from 20°C-30°C at marine tanks located in the Main

- •

For the purposes of the Master Plan deliverable prepared by the Design Team for the NPS, where the information noted in the April 2011 Report is in conflict with this Report, the Master Plan Report is the updated and agreed upon direction for the project.

Research/Teaching Building and at the future mariculture tanks adjacent the Dive Operations. The diversity calculated for this distribution will be 25% of the chilled seawater reduced to 20°C, with other 25% tiers at 25°C, 27.5°C, and 30°C. It is assumed that tanks requiring this level of cooling will require some type of insulative barrier between tank water and the environment to maintain these setpoints for supply water. This capability will not be required of tanks at either the Dive Operations at the lagoon level, or the Community Outreach facility, as these are not research functions. Effluent from all tanks will be routed back to the ocean. At all tank locations with marine life, individual tanks will have the ability to further filter either/both the Raw Water for Distribution and/or the Filtered Water for Distribution as needed.

At locations where marine life will be housed, a high-volume low pressure air system will provide Oxygenation to the tanks housing marine life. At locations where marine life will be housed, non-potable water from a facility cistern will be available for washing of marine tanks, Sediment/Degassing tank, Filter beds for Filtered Water for Distribution, and at locations where 'pigs' will be located for clean-out of lines.

It was noted that the 'Filtered Water for Distribution' storage tank 300,000 Gallons plus. An additional capacity to be delivered by source pumps, filtered and stored in this tank will be needed to provide 'Filtered Water for Distribution' required of the cooling needs of the Zone A space of the project. Zone A space will have in-slab cooling loops, and this medium will reject heat from the Zone A space to the Filtered Water for Distribution, which will be routed back to the ocean. The additional capacity and storage required of this Zone A heat exchange plan has not yet been determined, but has been estimated to provide minimal impact on overall water storage. It has also not been determined whether the source pump for supplying filtered water for distribution will be upsized to account for this added capacity, or whether a separate source pump/filter system will be required of this heat exchange system.

More specific requirements of the MREC Seawater Supply, Filtration, Storage, Control and Distribution System components, materials of construction, distribution, layout, cleaning, piping, control, filtration – are included in the appendix as the April 2011 Report prepared by the JICMS Seawater System Advisory Team (Bori Olla, Ron Moore, Dennis Allen, Robert Wicklund).

.5 mechanical

general hvac overview

The first and foremost priority of the design team will be to provide a HVAC system that meets or exceeds all of the requirements of the building users. Systems are designed to require minimum maintenance and to survive the hurricane conditions that the site will see over the life of the building. Minimum power use is critical since the building objective is to be net zero (ie, to export as much renewable electricity to the grid as is consumed from the grid for an annual net electricity use of zero), with all water and power provided by onsite systems.

There are three main types of areas in this project. The living accomodations will be designed to provide comfort with mostly passive systems – operable windows, exposed mass floor, and ceiling fans. The main lab areas will be provided with dehumidification and cooling to provide an indoor environment significantly cooler and dryer than outdoor conditions. Solar heated hot water will be the primary energy source to drive dehumidification, with a small traditional compressor based heat pump moving heat out via the seawater system providing additional comfort cooling. The final area is the small museum/archive space, which will be supplied with a small traditional mechanical system to ensure stable control. It is important to note that the museum/archive space is the only space with a set air temperature and humidity setpoint – the other two spaces need to provide comfort, which is only partly determined by air temperature.

The outflow from the seawater system will be used to reject heat as necessary. The system will emphasize use of equipment that requires minimal maintenance; this includes using hallways as plenums to distribute air instead of ducting, and a dehumidification system powered by simple solar hot water collectors and a desiccant wheel that can be literally hosed clean when required.

A high quality direct digital control (DDC) system will be used to operate the system. A modern DDC system allows for the greatest flexibility in scheduling and operating systems as well as the ability to remotely monitor system operation and provide a public reporting of campus efficiency with real-time power usage data.

living spaces

A number of traditional architectural approaches will be used to provide comfort in the residences. All living accomodations will have access to operable windows. A ceiling fan will be provided to increase air movement and the floor will be a high thermal mass material that helps even out the minor daytime temperature peaks. The typical residence on St Croix does not use air conditioning to maintain comfort and with careful design, these space should not require any either.

ASHRAE 55 Adaptive comfort range; mean monthly outdoor air temperature varies from 78-82 F on St. Croix

The living accomodations will be classified as naturally conditioned by ASHRAE standards. Evaluating the interior conditions that will make occupants comfortable falls under the Adaptive Comfort portion of Standard 55, the widely used method of predicting occupant comfort. Based upon thousands of surveys, it has been found that in naturally ventilated dwellings occupants adapt to the outdoor climate conditions and report comfort at higher temperatures than in a traditional sealed and mechanically cooled space. For the St Croix typical weather year, temperatures between 82-85F would be predicted to make 90% of occupants comfortable. By designing the spaces to be naturally ventilated and not concentrate solar heat (careful shading to avoid direct solar gains), comfort can be maintained for the majority of the year.

While these spaces will not have active mechanical systems, the design of passive features will emphasize proven features to provide comfort. The addition of a ceiling fan and thermal mass, common features of houses on the island, will be used to provide additional comfort and temper the highest temperature days. Breezes will be captured with an open, cross-ventilation design. And careful shading design will block direct solar from overheating occupants.

laboratory system overview

The conditioning system for the laboratory is summarized in the diagram below.

- A desiccant wheel removes humidity from incoming air. Cooling is still required, but with the wheel it can be provided by warmer water.
- 2. Outside air intake will be positioned to capture dominant winds across site, minimizing fan power and allowing some blow-through ventilation in case of system failure.
- 3. Solar hot water panels provide heat to regenerate the desiccant wheel dehumidification system.
- 4. An insulated tank stores solar hot water to provide desiccant regeneration during nighttime ventilation.
- 5. A titanium heat exchanger is used to reject heat from the heat pump into the seawater outflow.
- 6. High efficiency heat pump units provide 15C process cooling water to facility. Modular units are easily removed

(9) Humidity

Exhaust

and replace at end-of-life and essentially maintenance free (similar to a home refrigerator).

- 7. A radiant slab absorbs heat from the space; slab is cooled to a surface temperature of 21-23C using the process cooling water.
- 8. Process cooling water is supplied by a pipe loop with connection points available throughout the space for point-of-use water coolers, fan coils, or other equipment.
- 9. Humidity exhaust fan power usage can be reduced by incorporating a thermal chimney to create a heat-driven exhaust during peak solar time.
- Air distribution is primarily through the space, not ducts. An open plan lab facilitates this approach, although careful layout of hallways and small transfer fans for the few closed rooms are expected.
- 11. The fumehood will operate continuously, providing a minimum level of exhaust from the laboratory space and preventing humidity buildup from the tanks.
- 12. As required to control humidity and provide ventilation (primarily control to odors), additional air can be exhausted from the space via the outdoor air unit where it improves desiccant dehumidification effectiveness (latent cooling recovery).

Fumehood

Exhaust Air

process cooling (chilled) water generation system

To achieve the control desired in the laboratory spaces, some mechanical compressor based cooling will be required. While the conditioned areas will, by design, be habitable without mechanical cooling, the desired comfort control is simply not possible without it in this climate. To minimize the amount of mechanical equipment required and centralize it indoors and protected from the corrosive environment, a chilled water loop is recommended. A pair of water to water heatpumps will be used to create a process cooling water loop that will then be used to supply any cooling loads in the building. This cool water will also be supplied to the adjacent cooled office spaces. All cooling systems will be optimized to use 15C (60°F) water, a relatively high temperature for cooling water that significantly improves the heatpump units efficiency.

Heat will be rejected to the seawater system's outflow to the sea. Due to the low loads expected, the heat rejection will be insignificant to the volume of the bay, although the worst case heat rise in the rejection water (estimated to be 5F-8F over the intake temperature) should be determined and its acceptability verified. To ensure longevity in the harsh corrosive environment of seawater, a heat exchanger with pressed type titanium will be used in contact with seawater. There must be some method of rejecting heat to the environment, and this will provide a very reliable method of heat rejection that will not have the maintenance, hurricane vulnerability, and corrosion problems of a typical cooling tower or dry cooler (a radiator type fan and coil).

# lab requirement overview

The lab spaces need to provide a comfortable space for extended work. In particular, extended lab work in the high ambient humidity conditions is a comfort concern so some degree of air conditioning is required to provide a drier indoor environment. A space design criteria of 78F and 60% humidity is targeted. This is in line with the typical comfort envelope of 78F at 60%, and will meet the client's expectations for a space conditioned, but not to quite the same degree as a full featured, sealed traditional mainland laboratory.

There are three key elements to the laboratory: Ventilation, dehumidification, and sensible cooling.

Regeneration Side

Desiccant wheel with outdoor air dried on the top half and regeneration air on the bottom half

Displacement ventilation concept

Desiccant wheel dehumidification air handler

#### lab ventilation

Ventilation will use the constant volume laboratory fume hood as the primary exhaust fan. Constant volume exhaust hoods are very simple devices – just a constant speed fan. The disadvantage to constant volume hoods is that they cannot reduce the amount of air they are exhausting when not in use and exhaust air is energy intensive to replace. However, the labs require a certain level of continuous ventilation to control humidity. By utilizing an open floor plan for the lab that joins all the lab space into a single ventilation zone and minimizing the number of hoods, the constant airflow of the hood is less than the constant airflow required just to maintain humidity control. As long as an open floor plan is used for the majority of the lab space, constant volume hoods are not an energy penalty.

More airflow than used by the hood (or hoods) will draw out may be required for humidity control. To remove this air, a displacement approach will be used. Cool air naturally pools near the floor, in the occupied zone of the space, and is pulled towards thermal plumes, which are the updrafts of air around heat sources such as people or electrical equipment. This natural tendency can improve system efficiency if the system minimizes air motion in the space to allow for stratification and then pulls exhaust air out at the highest, warmest level. The exhaust air not used by the fume hood will be pulled from ceiling level back at the main desiccant air handler, where it will be used to help dehumidify incoming air before being exhausted.

#### lab dehumidification

Dehumidification is an energy intensive process that is traditionally done by using compressor based cooling to cool air down to around 6C, which is where enough water condenses out. Cooling air to that very low temperature is energy and equipment intensive. There is an alternative approach that uses a desiccant wheel and heat. Desiccant applied to a number of air passages through a wheel (a honeycomb pattern) absorbs water out of incoming air blown through the wheel. Then, the desiccant wheel rotates out of the incoming air stream and into a hot air stream, air hot enough to carry away the water from the desiccant. That hot air is passed through the moisture laden desiccant to dry it so it can be rotated back into the supply air and continue the dehumidification cycle. The hot air required to dry (regenerate) the desiccant will be generated by solar hot water panels supplying a heating coil.

The air leaving the wheel is dry but quite hot. Coils will be used to drop the air temperature, ideally with water cooled by the heatpump heat rejection loop that is cooled via a heat exchanger by spent seawater and then from the process cooling water loop if required. The ideal system concept is seen in the figure above (the energy model discussed later assumes both coils use process cooling water, a conservative worst case energy consumption assumption). A custom, or "built up", unit is recommended to allow for optimizing for minimal fan power, but there are some packaged units now available to provide this kind of operation.

The benefit of a desiccant system over a traditional dehumidification package is that no compressor based cooling is required for the dehumidification (but it is needed for final tempering of the delivered air) and solar heat can be used to power it. Solar heat will be produced by solar hot water panels at 160F and stored in an insulated tank to allow for night time operation. The wheel itself requires no complex maintenance – it can be cleaned by spraying with water and has little mechanical wear as it rotates at less than 1 RPM.

#### lab sensible cooling

With dry ventilation air controlling the space humidity, sensible cooling (temperature control) will be provided primarily by a radiant slab connected to the process cooling (chilled) water loop. A radiant slab is cooled by embedded plastic tubing that has cool water flowing through it. The cool slab absorbs heat from the space and ultimately transfers it to the process cooling water to be removed by the building heat pump. In this case, the process cooling water will be a relatively warm 15C (60F), or even higher if space loads are lower than expected.

Radiant slab systems have very low maintenance requirements, with the only moving part being a pump and control valve. The tubing encased in the slab is a very tough plastic material called PEX (crosslinked polyethylene) which is inert to any chemical reactions and able to bend and stretch without leaking. The main drawback to radiant is limited capacity; the floor surface cannot be cooled too far without risking condensation, limiting the maximum cooling available.

Radiant slabs are simple to control. The slab will be maintained at a set temperature between 20 C and 23 C. As the space temperature rises, the slab will naturally absorb more heat creating a self-regulating system. There are no ducts that can harbor mold. The cooling delivery device is the floor itself – an impermeable, washable surface.

Radiant tubing ready to have 3" thick topping slab poured over it to create a radiant slab floor

Radiant tubing ready to have structural concrete slab poured around it to create a radiante slab floor

A typical radiant manifold that distributes water into the slab tubing circuits

A mobile chilled water fan coil unit

# auxiliary cooling fancoils

In laboratories aiming to avoid oversizing their mechanical systems for cost and efficiency reasons, a fall back method of efficiently providing additional cooling if future usages required it is recommended. If future plug loads do exceed the design assumptions, portable fan coils that, by design, easily connect to the process cooling water loop that is accessible throughout the laboratory provide additional cooling as necessary. The portable fan coil would be on wheels, have internal controls, and connect by quick connects (leak free and simple, used often in industrial applications) to process cooling water connection points located throughout the lab. No ductwork is required with these spot cooling devices.

At least one fan coil would be included at building startup. Often, implementing a nominal cooling fee for use of a fan coil, enforced by submetering of plug load energy use/heat load per module, is more effective than any rarely-read facility efficiency policies in promoting the selection of more efficient lab equipment. Note that it is critical that this unit use the process cooling water loop, not an internal compressor – it should rely on the efficient building cooling water production system, with the unit itself providing only a fan, cooling coil, and thermostat controls.

# museum storage/archive space

The museum storage/archive space is more challenging due to the tight control requirements and constant dehumidification environment. A small, dedicated dehumidification unit will be provided to control the humidity and temperature in this space. Air will be dehumidified in the traditional manner, by using compressor based cooling to cool the air down to 55F to condense out water. As the design progresses, a desiccant wheel assisted unit should also be considered to improve efficiency. The volume of outdoor air introduced will be minimized to reduce the humidity load. In case of dehumidifier failure, outdoor air will be shut off entirely. The efficiency of this kind of system will be only standard, but it serves a very small space and load so the annual impact on energy use will be minimal. The highest priority is reliability and humidity stability.

# Energy model results by end use (kWh / yr)

#### energy modeling and budget - overview

To achieve a zero energy building requires an early and rigorous accounting of the building's energy requirements. The popular EQuest energy simulation package was used to perform an 8,760 hour analysis using Charlotte Amalie – Harry S Truman typical year weather data to estimate the energy use of the facility. A simplified block structure was used for the building since floor plans are undefined at this time, but program gross footages, expected daylighting harvesting, construction types, internal loads, orientation and other key features match the proposed plan for the campus.

Beyond the standard building loads, in this project there are a number of unusual loads including: SCUBA compressor load, electric vehicle charging, seawater system pumping, seawater system cooling, and laboratory equipment plug loads (both the direct electric consumption and the cooling of the resultant waste heat). All of these loads have been evaluated to a preliminary degree and input into the energy model.

#### energy modeling - scuba compressor system

To support research operations, approximately 120 SCUBA tanks per day will need to be filled. The compressed air to do this can be generated during the daytime, when the solar array will be producing the most power, and stored to provide SCUBA tank charging in the evening when the majority of divers will return. Shifting compressor operation to the daytime reduces concerns of compressor noise causing annoyance. An electric compressor will be used with an annual energy consumption of 31,000 kWh/yr included in the energy model.

#### energy modeling - seawater system

Total tank volume (including future)			132,000 Gallons	
Percent of tanks cooled	25%			
Total Cooled Tank Volume				33,000 Gallons
Quantity of Total Cooled Tank Volume at 20C	25%	8,250	Gallons total	
Quantity of Total Cooled Tank Volume at 23C	25%	8,250	Gallons total	
Quantity of Total Cooled Tank Volume at 25.5C	25%	8,250	Gallons total	
Quantity of Total Cooled Tank Volume at 28C	25%	8,250	Gallons total	
Daily tank turnover				50%
Annual Cooling Energy Cost Estimate			37,000 kWh	

Energy Usage	kWh / yr
SCUBA	31000
Seawater Pumping	18000
Seawater Cooling	37000
Electric Vehicles	10000
Plug Loads	385000
Heating	0
Cooling	165000
Pumping	30000
Fans	41000
Hot Water System	6000
Lighting	44000
Total	767000

Peak plug load initial survey result

A key component of the facility is reliable access to seawater. A continuous source of seawater from the ocean must be available at all times to support research tanks and aquaria. This system will be designed with redundant pumps and two separate intakes. All pumps will be equipped with variable speed drives to maximize system flexibility and efficiency.

There is an opportunity to recover energy by incorporating an electricity generating turbine in the seawater return pipe to the ocean. A turbine would generate power from the energy of the water falling down the hill from the laboratory back to sea level. Appropriate microturbine generators are available, but fouling and first cost are significant design challenges. In this environment, it is unclear if a microturbine would provide renewal energy at a lower cost than additional photovoltaic cells, but it should be analyzed further.

The electricity consumption for seawater pumping is estimated based upon an average daily seawater consumption of 100,000 gallons and a total system pressure drop (including filters) of 50 PSI. The annual seawater pumping energy use is estimated to be 17,000 kWh/yr.

The other energy aspect of the seawater system is the energy required to provide cool seawater. This energy is estimated based upon a cooling system efficiency of 1 kW/ton cooling (an EER of 12), an average water intake temperature of 29C and the estimates of the daily average amounts and temperatures of cooled tanks in the table on the left.

#### energy modeling - laboratory plug loads

It is assumed that every effort will be made to minimize internal plug loads. Selection of efficient equipment (particularly refrigerators, freezers, and compressors) has a significant financial savings with the high cost of power at this site (be it from the local utility or the photovoltaic array). To predict the plug load density of equipment in the lab, a list of typical equipment was created. The power consumption and heat load for the equipment was then determined from manufacturer's data, field measurement of similar equipment or estimates from the electrical circuiting data. The results of this preliminary survey are shown above (square footage is gross square footage of lab).

The peak calculated average plug load of 1.5 W/sf across the laboratory corresponds well with actual measured loads in operating laboratories. This load is far lower than the initial desired plug load capacity – again a common situation. Further plug load research, including more detailed equipment lists and spot power measurements on actual operating equipment, should be undertaken in later design stages. At this phase of the project, a significantly higher plug load than the 1.5 W/sf of the initial load survey was used for design due to uncertainty about the final equipment and future capacity required.

To account for uncertainly and future loads, the calculated plug load density of 1.5 W/sf was doubled and an additional 0.5 W/ sf was the added for the load of the low pressure compressed air system. The energy model uses the resulting 3.5 W/sf as the peak plug load; in the model, the laboratory space operates at peak load for 9 hours a day and drops down to 30% of the peak load at night. Note again that this plug load density was applied to the programmed gross square footage; another conservatism built into the calculations.

The largest area of power consumption based upon current estimates are the plug loads, followed by the cooling – which is driven largely by the need to remove plug load heat from the laboratory. It is critical that the design process both properly estimate plug loads and actively provide occupants the ability to manage them. During the design process, a detailed plug load study should be done. A design case equipment list should be defined and accurate heat load data collected for all the equipment, ideally by direct power measurement of the specific lab equipment. A reasonable future growth factor is prudent, but it should be clearly defined and applied.

The energy model results combined with an analysis of the renewable energy resources available at the site provide the analytical support for the feasibility of the net-zero goal.

# energy modeling results

The results of an energy model at this stage are useful for estimating the magnitude of energy consumption and the largest energy consumers on the project. They are expected to change as the design is refined and floor plans become set. Based upon reasonable and conservative estimates, the model energy usage results seen the table below form an energy budget to evaluate whether a net zero target is achievable.

The model results also offer a power insight into the aspects of the project that offer the most potential for energy savings as the design progresses. A simple pie chart of the Campus Annual Power Usage by Category offers guick insight into where the greatest energy reductions can likely be found.

The final design can incorporate a number of features to reduce plug load power consumption. For example, providing outlets that are controlled by occupancy sensors is a method of giving occupants an easy way to ensure non-critical equipment is shut off at night. Sub-metering power consumption on a per-module basis and charging the occupants based upon their actual power usage is a very effective way to encourage efficient equipment usage; to avoid insulting prize researchers, the same effect can be harnessed by not billing for power but rather providing refunds to the most efficient labs.

# solar system sizing and payback

At this site, the primary renewable energy source is solar. To evaluate the potential for solar, an hourly simulation tool called the System Advisor Model provided by the National Renewable Energy Laboratories (NREL) was used. Hourly weather data for a statistically typical weather year at the relatively nearby Charlotte Amalie – Harry S Truman airport provided the hourly solar radiation data required to model annual PV power production. The software also accounts for typical losses in inverters and annual performance degradation over time.

It is assumed that the photovoltaic modules will have a fixed mount pointed south at an angle approximately equal to the latitude of the site, about 18°. A high efficiency rigid panel module was chosen as the basis of design (the Sunpower SPR-315E-WHT) with performance as tested by Sandia National Laboratories. The target annual power production was set to the annual campus power consumption predicted by the energy model of 767,000 kWh/yr. Photovoltaic panel output degrades over time, (0.4% per year), so the array output in year 20 was used. Based on these assumptions, a 2,600 m2 (28,000 ft2) array of 1,600 modules with 34 inverter units is required to fully offset all site electricity usage and achieve net-zero operation.

Simple Payback	5.3 years		
Simple Payback is defined as the Year Zero impler rough measure of how quickly your investment is depreciation, competing investments, maintenance	mentation cost divided by the Year One cost savings. It is a recovered. It does not account for the effects of inflation, ce costs, nor does it ask if "do nothing" is an option.		
Relative Net Present Value (RNPV)	\$6,380,599		
Net Present Value is a time series of cash flows, both incoming and outgoing, and is defined as the sum of the present values of the individual cash flows. Both the baseline (purchase power from grid only) and the proper scenarios compared here have their own Net Present Value. The difference between these two NPVs is term the Relative Net Present Value. We present only the RNPV here, based on the differential costs.			
Internal Rate of Return (IRR)	24%		
IRR equals the percentage rate by which you have to discount the net benefits over our 20-year time period the point that they equal the initial costs. IRR is related closely to net present value. The discount rate you w need to apply to your benefits to obtain a net present value of zero is the rate of return calculated by IRR.			
Return On Investment (ROI)	632%		
Return On Investment is the ratio of money gainer relative to the amount of money invested. In this years in this analysis and a discount rate of 4%.	ed or lost (whether realized or unrealized) on an investment s analysis, we account for the effects of inflation. We use 20		

In the first year of operation, when the photovoltaic cells are at their newly manufactured efficiency, the campus will actually generate 50,000 kWh more than it consumes. That power will be provided back to the local power grid, making the campus not merely netzero, but net-negative. And the campus will remain a net power producer, for the first two decades of operation.

The high total cost of local electricity of \$0.49 per kWh (Atlanta, GA is about \$0.07 per KWh) makes the financial argument for onsite photovoltaic generation guite compelling. A simple payback of 5.3 years and a net present value of over \$6 million is the result of an initial financial analysis as summarized in the table to the left. The simple payback improves if the array is sized by its year one capacity.

A critical issue to consider when evaluating payback is the correct sizing of the photovoltaic array. Surplus energy generated by the array will provide green power back to the grid, but the money earned from generating more power than the campus uses on an annual basis is negligible. Extra generation capacity must be essentially given away, a benevolent gift of green power to the island; oversizing the array gains no financial benefits for the additional upfront cost. This makes the plug load estimate, the largest component of the annual energy consumption driving the array sizing, critical to achieving a cost effective netzero installation. For example, if the photovoltaic array is sized for a 6 W/sf plug load but the building only consumes 1.5 W/sf, as the initial plug load study and similar lab benchmarking suggests is possible, the simple payback is pushed back to 7.4 years.

The best payback will be achieved by installing exactly as much photovoltaics as required to produce the power used by the campus over the course of a year, no more. Accurate load estimates and modeling is required to achieve this, or a phased buildout of the photovoltaic array where a portion of the capacity is added after the campus is in operation and power usage is known.

A final design objective is to match the site electrical load profile over the day to the varying solar electricity production profile. In a typical building, this is difficult to do - the load (lights, cooling, fans, plug loads, etc) are instantaneous and cannot be shifted to other times. But at this site, a number of the process loads can be shifted. The seawater storage tank can typically be filled during sunny hours. Air can be compressed and stored for use in charging SCUBA tanks during the day (when noise is also less of a concern). And electric vehicle chargers can be set on timers to maximize daytime charging. These measures require design accommodations, but are feasible and can result in a peak day profile that approximates the solar production profile. This will minimize the sales required to the grid and makes the campus more robust to power outages, extending the hours that the solar array and small supporting battery room can support normal operation when the grid power is unavailable.

To allow the photovoltaic system to function as a reliable source of power for redundancy purposes, a moderately sized battery bank will also be provide. The battery bank will be sized to provide 8 hours of critical facility loads. Charged during the daytime, the battery bank will support critical systems during the hours when solar power is not

There is also opportunity for wind capture. There is a consistent wind across the site that could be captured to reduce fan power. The building structures can direct wind into building intakes to reduce fan power. It is also possible to incorporate airfoil shaped caps over stacks to create a windpowered suction to help ventilate the buildings, however it is a difficult design challenge to ensure they could survive hurricane conditions.

A final opportunity to save first cost and maintenance is to configure the site to allow for a gravity fed fire sprinkler system. This would require a fire water tank be located 30' or more higher than the ceiling in the highest sprinklered space. It would eliminate the need for fire water pumps. This is mostly a maintenance issue, since fire water pumps are only used in case of fire, so their annual energy use is hopefully negligible (just monthly test starts). The impact of elevation (a pumping cost) and siphoning (a pumping saver) on energy use at this site will be carefully considered throughout the system design as it impact the energy usage of many systems (seawater pumping, rainwater supply, waste treatment).

available and the grid is down. In normal use, the grid will be used at night with the kWhs used 'paid back' during the sunny daytime period. Battery bank usage will be minimized to maximize the life of the batteries and avoid the energy loss inherent in charging batteries.

# nontraditional opportunities

The use of solar photovoltaics to produce electricity is a mature technology and well suited to this site. Solar hot water is even more established and provides a lower cost and higher efficiency capture of solar energy. There are additional renewable energy opportunities that may not have as attractive a payback period but offer opportunities to diversify the site energy production (improving reliability) and/or serve as educational features.

One opportunity is to use a wind turbine to mechanically drive either a seawater pump or an air compressor. A direct drive system will be over 25% more efficient than photovoltaics producing electricity to drive electric motors. The SCUBA air supply system in particular is attractive for this approach since it will include a large storage tank that would easily accommodate the variable wind power production, compressing air when the wind blew.

Another renewable opportunity is to incorporate thermal stacks into the building structures to reduce the fan power required for ventilation air movement. The stacks could be designed to heat up by sun that falls on them, or assisted with a hot water coil located inside the stack and supplied by solar hot water. Such a stack is unlikely to entirely replace a fan in the critical fume hood application, but it could in less critical applications such as ventilation of visitor areas or classrooms.

# WATER DEMAND & SUPPLY

#### .6 water systems

#### overview

The focus of the plumbing system design shall be the supply of all domestic water needs from rainwater captured and stored onsite. All "waste" streams, including toilets, kitchen, and laboratory sinks, shall be treated onsite and the water recovered for appropriate secondary uses.

Drinking water will be provided from rainwater captured and stored onsite in cisterns primarily below grade under the buildings.

Low-flow fixtures will be used for all showers and lavatory sinks to reduce the domestic water load by a minimum of 40%. Standard flow toilets and urinals will be used, with ample flushing water available from reclaimed water produced by the onsite waste treatment system.

A small constructed wetlands will be part of the waste water treatment system. Local plants can be used in this lined gravel bed area; the primary purpose of the plants is to provide a root structure for the processing to take place in, so the specific plant type and biology is not critical.

The diagram above summarizes the basic water cycle on the site. Rainwater is the primary source of water, with all used water collected and treated to provide for flushing toilets and any irrigation needs on the site. Rainwater harvesting will provide all the water needs for this site.

### rainwater harvesting

As is common on the island, the only source of potable water shall be collection of rainwater. The US Virgin Islands require that all buildings include a cistern, with the size varying depending on the type of building. Based on the local code, Title 29 Chapter 5, a cistern of at least 370,000 gallons is required for this facility. This campus is likely

UV disinfection units - bulb(s) is in center, accessed from end; lower cost PVC units also available

Site water cycle summary

not bound by this code and a careful statistical analysis (gamma distribution based simulation) is required to determine the optimal size, but since site occupant capacity is limited by the water collection larger is advisable. To allow for process water usage and ensure capacity for dry seasons and potentially additional occupants, we recommend a size of 500,000 gallons at this stage of design. Ultimately, the system must be sized for the 1 in 10 drought year; only a full analysis can accurately size the cistern.

A reasonable starting assumption for occupant water consumption is 49 gallons a day. Typically, 21% of that consumption is used for flushing toilets, which in this case will be done with treated reuse water dropping the daily potable water requirement to 39 gallons per day. In the sample year shown in the graph below, there is plenty of water available with a catchment area of only 32,280 square feet provided the cistern is properly sized. This is a minimum amount of roof catchment area required; all roof area will serve as water catchment to improve resilience to dry conditions, provide a safety factor, and allow for future growth in residents or laboratory water consumption.

The construction of the cistern itself is primarily an architectural challenge influenced by the site layout and excavation conditions. Options range from buried fiberglass tanks to cast in place concrete tank to a flexible bladder tank with only a sunshade. From an energy standpoint, it is best if the tanks are located near but not above the elevation of the collection surfaces, to take advantage of gravity feeding to minimize pumping energy. To best align with local practice, concrete cisterns cast into the foundations are the current design recommendation. If this approach is found to be infeasible, fiberglass tanks are a reasonable alternative. A flexible bladder tank offers costs savings, but carries maintenance and higher failure risks.

The rooftops make the most natural collection surfaces, with collection from solar cells, standing seam metal roofs, or concrete all options. Due to storm damage concerns, eliminating exterior gutters and downspouts by design is attractive. One option is to have a controlled open cascade off the roof to courtyards below designed to serve as rainwater collection basins.

#### rainwater treatment

Because the cistern must hold water continuously, it will require treatment for grit, fine particles, algae, bacteria and some microinvertebrates that will enter or grow in the system. All of this is mostly harmless, but we are now used to pure drinking water so a treatment system will be provided.

Water for showering will receive a lower level of treatment, more comparable to the treatment level required for swimming pools. Treatment will consist of a filtration step followed by a UV light for disinfection. This offers a good level of treatment at a lower cost than the RO filtration used for drinking water. However, maintenance of UV can be higher than with RO.

Treatment for drinking water will be filtration followed by a point of use RO filter. The RO filter carries an energy cost due to the pumping power it requires, but reliably provides pure water using a common and widely supported technoloav.

Filter options

waste water treatment diagram

#### wastewater treatment

Onsite treatment of the wastewater is a critical leg of making the campus self sustaining. While there are many proprietary mechanical systems available that can do this task, a simple passive approach that needs nothing more complex than a standard well pump is recommended. The system provides enough treated water to supply all toilet flushing, reducing the demand on the rainwater system.

## primary treatment tanks

The passive approach utilizes a three step process to clean the water. The first step is the primary treatment tank. Waste water will be collected from all the site sources and pumped to the primary treatment tank where resident bacteria and organisms perform the first step in breaking down the waste. An ordinary tank of about 4000 gallons capacity is expected for this component to handle the waste from all campus sources. Maintenance requirements of this tank are the same as a standard septic tank.

primary treatment tank diagram

final sand filter treatment diagram

#### constructed wetlands

After the initial digestion in the primary tank, the waste water is pumped into a constructed wetlands. This wetlands is simply a carefully sized concrete lined depression filled with gravel that receives a wetland plant covering. It can be located almost anywhere on the site (although closer to the primary tank will reduce the already-small pumping energy consumption) and will have a footprint of around 1000 square feet. The specific type of plants used is not critical because it is their root structure that is important to provide the surface area and media to support a second stage of biological waste breakdown. It is most important to use native plants or other plants that will thrive in the local climate and environment, including tolerating hurricanes and salt mists.

# final sand filter treatment

The final stage is a sand filter, a simple workhorse filtration technology that is commonly used in municipal drinking water supplies. The sand filter has a foot print of about a quarter the constructed wetlands. A generic well pump is the most complex device in the system, allowing for very simple maintenance and local support. The water turbidity is tested via sensor at the final tank and simply recirculated through the system again automatically if it does not meet the desired standard.

Total residence time in the system is several days. A catastrophic accidental discharge into the system could be caught at the primary tank, pumped out, and the system restarted if necessary. However, the system is very robust and able to accommodate most foreseeable discharge events, with very high volume discharges (many gallons) of harsh cleaning chemicals such as bleach more likely to disrupt operation than any expected lab discharges or spills.

The final treated water will be disinfected by a UV light system and used for toilet flushing and subsurface irrigation. A 5 hp recycled water pump will be used to

pressurize a recycled water tank that will supply the water to the desired building fixtures. Overflow, if any, from the rainwater cistern will be piped to the on-site waste water treatment system.

All site water for toilet flushing will come from the treatment system, which will supply a surplus of water for this purpose so low water flow toilet technologies are not required. Excess treated water can be used for subsurface irrigation of plants or even crops, although it is recommended that as a fail-safe approach in case of a system failure edible plants should be chosen that do not contact the water directly (no tubers).

#### water systems - waste and supply flows summary

There will be three water harvesting streams from the building. They shall be defined as follows:

- Sanitary Waste & Vent To be routed to the onsite treatment system and treated for use in toilet flushing, irrigation and possibly for rinse down at dockside.
- Lab Waste The small volume of very hazardous chemicals used will be collected in containers for offsite treatment. Laboratory sink outflow will be benign acids and bases and routed to the onsite treatment system.
- Storm Water Rainwater captured from roofs is to be routed to a storage cistern and becomes the site • domestic water supply. With appropriate treatment (UV, point of use RO, ozone are options), it will be reused in the building for potable use. Overflow to the on-site waste water treatment system and ultimately site features such as bioswales.

There will be four water supply streams inside the building. The water supply streams shall be defined as follows:

- Domestic Water (Cold &Hot) Rainwater cistern will supply lavatories, showers, drinking fountains (cold only), kitchen sinks, emergency shower/eyewash stations with filteration, UV treatment and local RO for sinks.
- Industrial (Cold & Hot) Water Rainwater cistern will supply the laboratory sinks and all of the laboratory equipment with industrial water as required. The industrial water system is identical to the domestic water system, but with a double check backflow preventer to ensure no risk of backflow somehow contaminating the cistern.

example of constructed wetlands in campus setting

- Sea Water Supplied as required by separate seawater system.
- Treated Reclaim Water Water reclaimed by the treatment of sanitary and lab waste. To be used for toilet flushing and irrigation needs as required.

#### storm water (s)

Storm water from the building roof shall be discharged by gravity into the underground rainwater cistern. All rainwater is to be collected in the cistern until it is filled to the point of the provided overflow release.

#### laboratory waste and vent (lw and lwv)

The laboratory waste system shall include provisions for future installation of an in-ground neutralization tank with utility vault and remote monitoring system. If lab usage changes in the future, this will allow the lab waste to be easily separated from the other sources of waste water.

Piping material shall be mechanical-joint polypropylene for aboveground piping and schedule 80 PVC for underground piping.

# domestic cold water (dw)

Domestic cold water shall be connected restroom lavatories, showers, non-lab sinks, break room areas, kitchen sinks, and water fountains. Domestic water shall also be provided for the

emergency eyewash and safety showers. A separate industrial water system shall be designed for the industrial fixtures. Domestic water pipe material shall be type L copper above grade, type K copper underground. All buried domestic water pipe will be protected with 20 mil polyethylene tape and/or pipe sleeve.

#### domestic hot water (dhw)

Domestic hot water shall be supplied to the restroom lavatories, showers, non-lab sinks, break room areas, and kitchen sinks. The domestic hot water system shall be designed as an on-demand circulating system that shall provide hot water quickly and efficiently. The cold water supply line shall be used as the return leg of the recirculation system. This type of system shall also reduce the amount of water wasted down the drain while waiting for hot water to arrive.

Domestic hot water will be generated via solar and stored in an insulated tank to carry nighttime and early morning loads. The residence showers and lavatories will be provided with local solar hot water collectors with integrated tanks on each roof. Hot water to building plumbing fixtures will be 120 °F, but temperature and mixing valves will be provided that allow water storage temperature adjustment up to 150 °F. The higher storage temperature maximizes the amount of heat that can be stored for use during cooler nights and cloudy periods.

# industrial cold water (icw)

Industrial cold water shall be connected to the domestic water system through an approved reduced pressure type backflow pre. The industrial water systems shall be connected to all laboratory fixtures and equipment (except eyewash and safety showers).

Industrial water shall be designed to serve laboratory equipment. Industrial water pipe material shall be type L copper above grade, type K copper underground. All buried industrial water pipe will be protected with 20 mil polyethylene tape and/or pipe sleeve.

# industrial hot water (ihw)

Industrial hot water will be generated in the same manner as the building hot water via solar and supplied at the same temperatures.

# reclaimed water

Water".

Treated water pipe material shall be type L copper above grade, type K copper or PVC from a roll to minimize joints underground. All buried treated water pipe will be protected with 20 mil polyethylene tape and/or pipe sleeve. All treated water pipe and fittings shall be continuously wrapped with purple colored Mylar tape. This system is commonly referred to as a 'purple pipe' system.

#### fixtures

Low-flow plumbing fixtures shall be chosen for this installation that shall conserve water and meet the requirements of the client. These low-flow plumbing fixtures shall reduce the domestic water consumption by a minimum of 40%, reducing the rainwater cistern size requirement.

Solar-powered, sensor-operated faucets shall be installed at the restroom lavatories that provide water at 0.5 gpm. The Sloan Solis solar-powered faucet automatically operates in natural and artificial light. The restroom lavatories shall be supplied with hot and cold water.

Industrial hot water shall be supplied to the laboratory spaces including lab and other lab equipment as required. The industrial hot water system shall be designed as an on-demand circulating system that shall provide industrial hot water quickly and efficiently.

Waste water that has been treated utilizing the on on-site waste water treatment system will be used to supply water to toilets, urinals and subsurface irrigation as desired. Through the reuse of the sanitary waste water streams, the use of potable water for sewage conveyance will be eliminated completely.

All fixtures with treated water supply will be labeled "Non-Potable

#### .7 fire protection

#### fire suppression system

All sprinklered buildings will be provided with wet pipe sprinkler systems. The source of water for the fire suppression systems will be the rainwater cistern. A vertical turbine pump will draw water directly from the rainwater cistern and distribute water to each building through underground pipe.

All fire suppression systems will be hydraulically calculated. Each building will be provided with a sprinkler control valve, waterflow switch, and inspector's test/drain connection.

#### fire alarm system

An addressable fire alarm system will be provided in the Lab Building. A combination of addressable monitor modules, initiating device circuits, and conventional (non-addressable) detection devices will be utilized to provide detection in the outlying buildings. Total coverage smoke detection will be provided in all buildings. Occupant notification will be provided through the use of fire alarm horns and strobe lights.

.8 hazardous materials

The supply, storage, use and removal of hazardous materials are important issues that must be addressed as the design of the MREC moves forward. The identified hazardous materials include:

- Chemicals used in the research: the researchers will be required to provide MSDS material for all chemicals used on the campus. Included in information from the researchers will be how the material will reach the facility, how it will be stored at the site, and a plan for removing the material from the facility. The JCIMS will be responsible to follow-up on the required procedures for chemicals used in the research.
- Petroleum products: Several types of petroleum products will be utilized on the campus and protocols and procedures will be developed by the JCIMS to describe the appropriate methods for the storage, use, and the removal of waste materials. It is anticipated that there will be storage requirements for diesel fuel and gasoline and those requirements will be determined during the design phase. Needs for these petroleum based

battery bank

products include:

o Diesel fuel: outboard motors, emergency generator, service vehicles.

- o Gasoline: outboard motors, service vehicles
- o Lubricants: engines, equipment.

• Batteries and battery acid: an array of storage batteries will be required to support the "net-zero energy" concept for this complex and the storage and removal of this material is important to maintain the environment of the site. The decision on a centralized or decentralized storage system will be determined during the design phase of the project and that decision will drive the solution to the storage of the batteries. Procedures and protocols for the removal of used batteries and the acid will be developed by the JCIMS prior to the start-up of operations at the campus.

• Flammable gasses: a small amount of flammable gases will be required at the research labs for various analytical testing functions. These gasses will be stored in an appropriate manner and empty cylinders will be removed from the facility by a private vendor. A listing of the gasses required for the research will be provided by the JCIMS during the design phase of the project. The fuel type for cooking has yet to be determined, but the most efficient fuel for food preparation is a flammable gas, and a storage cylinder for propane maybe required. Private vendors will be responsible to supply appropriate vessels and remove empty cylinders from the campus.

All procedures and protocols for the procurement, storage, use and removal of any and all hazardous materials developed by the JCIMS must meet the requirements of the NPS and approved by the NPS prior to implementation. The operations manager must prepare and maintain an active hazardous materials plan, and an up to date inventory of all hazardous material used at the site.

# .9 electrical

# energy storage

Designing for passive survivability means supplying sufficient energy storage capacity such that essential functions are not impacted during power outages or natural disasters. The current storage options are batteries and compressed air, but additional storage media will be researched and likely a combination will be used.

The project will have the capacity to store electricity for times when the PV array is not active at night. While net metering allows use of grid sourced power at night, the unreliable nature of the grid mandates a storage capacity to address the potential gap left in service, while not necessarily having to rely on the back-up generator. Thus, an 8-hour battery bank is proposed to smooth over these grid outages and allow for overnight power should the grid be down for an extended period. A diesel generator will be provided for additional back up, the capacity of which will be determined during subsequent design phases.

#### building power distribution

Building power will be supplied from a combination of net metering with the local utility company, onsite renewable energy sources and roof mounted photovoltaic cells with 8 hours of battery storage capacity. The onsite solar and wind renewable energy can be gathered as either 208 Volt 3-phase or 480 Volt 3-phase electric power. Power will be supplied to the buildings at 208V, 3-phase unless the distance between the power source and building load is such that voltage drop becomes an issue at which point the building can be supplied with 480V, 3-phase power.

Both wind turbines and photovoltaics create DC that will have to be converted into AC for most equipment loads. The inverter that switches from DC to AC has an efficiency of 85%, so some energy will be lost in the conversion to AC. The use of DC power for lighting and other appropriate equipment will be investigated as a potential means of conserving the energy lost in the conversion from DC to AC power. Likely, a combination of both DC and AC power will be used on site.

Power in each building will be classified using the tiered system noted below and distributed throughout the building. Each panelboard will monitor its energy usage and report the information to a central network. Receptacles on each different power tier shall be independently color-coded to allow the users to distinguish between the different systems.

Tier 1 - Critical loads requiring 24/7 power and emergency generator back-up power. Includes essential loads such as life safety, saltwater pumps, lab freezers, museum storage, etc. Tier 2 - Normal loads requiring 24/7 power. Includes loads which require continuous or extended periods of power but no emergency back-up.

Tier 3 - Occupant or time controlled loads. Includes loads that can be shut off after a set period of time or when the occupants leave the space.

A diesel engine-generator will be provided as an emergency backup in cases where the onsite battery bank is not sufficient to handle the loads or outages are longer than the capacity of the battery bank.

# lighting

Daylighting will be used to the maximum extent possible as the primary light source with LED or fluorescent luminaires supplementing the daylight during overcast days and at night. Multiple daylighting strategies will be incorporated into the architectural design and include: light shelves, use of windows on both sides of the spaces, glare avoidance, and clerestories. The lighting will be designed such that the spaces are not overlit at night and with an avoidance of light pollution to promote views of the night sky and minimize the disturbance of sea turtles.

Illumination levels will be based on IESNA lighting standards for the appropriate task being performed in each space. Task lighting will be used to supply additional light for a minimum of 90% of the building occupants. The use of LED and fluorescent luminaires will be determined by a cost-benefit analysis in order to meet the lighting power density requirements set forth by the sustainable design goals of the project.

The lighting control system will be flexible to meet the lighting needs of the different spaces while reducing the overall energy use within the building. Dimmable or multi-level luminaires will be used in conjunction with daylight sensors to supplement the natural daylight within the space during overcast days and to reduce light levels at night. Occupancy sensors will be utilized to reduce the energy wasted by lights left on after the occupants have left the space.

Egress lighting and exit signs will be provided with integral battery back-up.

Site lighting will be minimal; only where required for footpaths and security. Site lighting will be designed to minimize light pollution and impact on local wildlife.

#### .10 exhibits

#### visitor experience tracks

The following types of visitor tracks have been identified by NPS for applicability at MREC:

Track 1: Self-guided outdoor experience consisting of trails and accompanying wayside interpretive stops that include information about what the MREC is accomplishing at the Salt River NPS site for St. Croix and the Virgin Islands.

Conditions:

- Open to visitors during daylight hours when the park is open.
- Does require a tour guide or docent
- Does not require access into the lab buildings or Education Center (with interactive exhibits)

Track 2: A guided tour including the Education Center (with interactive exhibits), MREC labs, and Park Trail.

Conditions:

- Expanded trail leading down to various outdoor research works in progress.
- Escorted trail option to include the archaeological field school. This would be a scheduled tour (3) times per week with a tour guide, NPS interpretive ranger, or science education student.

#### audience

The following four audience types have been identified by JICMS and NPS:

- College Students- undergraduate, graduates in residency at the MREC Campus for full semester.
- Faculty/Staff graduate, post-doctoral, professors, including scientists, administration, and maintenance. •
- Visiting Researchers / Federal Agency Researchers an integral part of the MREC operations and park mission goals for marine research/resource management activities in the parks.
- Local School Groups ages 10-18, Grades 5th to 12th.

In addition consideration should be made for casual visitors:

- Local Community those who are curious about the activities and opportunities at MREC
- Seasonal Residents/Tourists visitors who have sustained stays; visitors staying with family and friends •
- Organized Tour Groups–limited cruise ship groups

example of potential exhibit type

touch tank

#### core interpretive messages

The overarching theme is "Science in the Parks"– integrating research and resource management in the National Parks. The site-wide key messages are Sustainability, Change, Adaptation and Survival. In this instance Change is the relevant key message: the change of the landscape over thousands of years, and the changes brought about by natural phenomenon and human occupation. Adaptation is a secondary message: showing how plants and animals have adapted to the particular environmental conditions from the island's ridge to the reef.

The organizational diagram above shows the primary messages and their vital connections–between land and sea as well as where they intersect driven by *change* at the center.

# topics

The following is a preliminary list of topics:

#### change

Geological change: Salt River formed millions of years
 ago

- Environmental change: land and marine ecosystems are diminishing over time
- Human change: people have occupied this island from Pre-historic times through today

#### adaptation and survival

- Plants and animals have evolved adaptive
- characteristics to find water and nutrients
- People have used the natural resources of this island for thousands of years

#### sustainability

- This is one of the most biodiverse areas in the Caribbean but its biodiversity threatened by human interactions including global climate change
- The Park's landscape and biodiversity is being restored
- The new research center is environmentally
  responsible and resource-efficient in its design

#### visitor outcomes

#### about the education center complex

- Understand the reason for the Research Center is located here and who is sponsoring it
- Discover the type of research being performed (past and present); what the marine researchers, scientists and archaeologists do in their jobs and at this site
- Legacy of research at Salt River

# about the island

- Realize that from the mountain ridge to the reef there are diverse terrestrial and marine communities
- Realize human actions can have a positive or a negative impact on the environment
- Understand that this is a dynamic and changing landscape

# education center interior exhibits (preliminary)

# reception

A reception desk will face visitors as they arrive providing a welcome, orientation information, program and exhibit information. Trail maps and leaflets can be given to visitors from this location. These will be themed to allow exploration of different elements of the site, complementing content from the Education Center exhibits.

# lobby

A design feature marine or wetlands touch tank will punctuate the space making it as an inviting, public area. Consideration should be made to include a rotating exhibition of artwork by artists. Images that show the biodiversity of the area should be incorporated into the interior space as aesthetic design elements.

#### individual exhibits

#### what is this place?

An exhibit provides an orientation to this research facility and the restoration of the Marine Studies Program. Visitors will discover the long history of research at Salt River; understand why it is here, who is responsible for this facility; and why it is important to their lives.

#### who works here-what do they do?

An exhibit should enable young visitors to discover career opportunities that may be available to them in marine and ecological studies. Video diaries from staff enable visitors to hear about various restoration efforts or research projects, why they love what they do, and why it matters. (Oceanographer, marine biologist, field biologist, NPS Ranger, geologist, botanist, climatologist, archaeologist)

#### why is this area ecologically unique and significant?

Visitors will leave with an understanding as to why the geology of this area contributes to the ecological niches created from the ridge to the reef. Consider using a video format to tell this story in a theater environment.

#### what are the current threats?

Visitor will realize the current threats to the marine environment and plants and animals here. These exhibits could include threats from: climate change, ocean acidification, invasive species (Lion Fish), and feature threatened species such as sea turtles. Visitors will discover how this area can be protected, restored and preserved for the future. This will provide information on how through the MREC, the NPS and JICMS are addressing these threats with science and research management actions.

#### talk-back wall

Provide an area where visitors can express their point of view about the Education Center activities here and environmental challenges.

# FAQs

Provide an area where you answer visitors most frequently asked questions. Consider providing a QR code enabling visitors to find out more using their smart phones.

interactive touch-screen exhibit

display exhibit

interactive water-themed exhibit

#### education center exterior exhibits (preliminary)

#### entry plaza

A living mangrove model, located in the central plaza, illustrates the value of a mangrove, how it works as a natural system and restorations efforts and methods. This would be comparable to the one at Coral World. This living ecosystem exhibit could be in combination with a touch tank.

#### facility walking tour

To enable visitors to understand the purpose and the activities at the Research Center visitors can take a controlled walking tour. Labs are identified and graphics describe basic activities. A video flat panel enables visitors to "meet a researcher" or see a demonstration of scientific progress from "behind the scenes". This supplements those times when individuals are not in the lab and eliminates the need for researchers to be compelled to interact with visitors.

Lab facility interpretation will be located at:

- The wall of the main building along the visitor path
- The interior of the lab along the visitor path
- Along any outdoor test or demonstration areas

#### about the building walking tour

A self-guided walking tour explains the sustainable design features in the buildings and throughout the site.

It might include:

- How the areas are climate controlled
- How water is conserved on site to ensure a minimum necessary amount is used
- How waste is managed
- What makes a material green or considered sustainable

#### trails

Self-guided walking trails enable visitors to walk from the Education Center on the hillside to the water's edge. Interpretive wayside exhibits provide visitors with messages addressing the primary themes with an emphasis on the site's marine features, archaeological sites, and study programs. Visitors can see from the trails the bay, reef, canyon and ancient river channel.

These graphics should:

- Encourage visitors to explore and make discoveries
- Impress upon visitors the importance of respecting the site
- Demonstrate the uniqueness of this site and of the work that is being done
- Impress upon visitors the importance of site safety

#### 4.6 project schedule

The MREC schedule will be dependent on the fundraising schedule of the JICMS partner group. The schedule currently shows the fundraising effort commencing after the Master Plan and the associated fundraising images are completed. Thus, fundraising would start in earnest in August of 2011. It is anticipated that this will take no longer than 3 years, yielding an anticipated start of construction in 2014. It is anticipated that construction will take just under two years based on the complexity of the project and its remote location.

The design phases could begin as soon as funding is made available. It is anticipated that the project would take about 18 months to design, but this could be accelerated if necessary. Since momentum for the project is important to maintain to aid in fundraising and building public support for the project, it is desirable to start some early design activities during late 2011. This would leave a cushion post design before the anticipated completion of the fundraising and start of construction that will allow the design phases to float if necessary.

#### COST ESTIMATE

#### cost estimate 5.1

Class C estimates were created for each of the three alternatives that were evaluated during the CBA. As a result of that process, a hybrid preferred alternative was selected and a Class C estimate was created for it. The summary page of the estimate follows; please note that this is a construction estimate only and not a total project budget. It is therefore exclusive of design, scientific equipment, Owner contingencies and other costs that accompany the construction of complex projects. For further detail, please refer to the appendix for the full estimate.

The estimate is only conceptual given the level of design of the project and as such carries a design contingency as well as a bidding/procurement contingency. The costs have been adjusted based on a location factor from RS Means for San Juan Puerto Rico as RS Means has no documented factor for St Croix. Based on discussions with local experts and past experience with construction in St. Croix, a remoteness factor has been added to the costs.

Based on the anticipated fundraising duration, the costs have been escalated to 2014 dollars. Many of the onsite systems discussed elsewhere in this Master Plan have been included in the cost, such as on site power generation. However, some costs are unknown at this juncture; these include portions of the seawater system and full site restoration. With respect to the sea water system, the components that are on the site (piping and trenching) and portions that are directly linked to the buildings such as the storage cisterns are included. Since the location of the intake is unknown at this time (it is under study by a separate group) an allowance for this portion of the project has been included. This cost could vary widely depending on the depth, distance and route to the selected intake points. For site restoration, it is the intent of the Park that this work be performed outside of the costs of the MREC.

#### PLANNING TEAM AND ACKNOWLEDGEMENTS

#### planning team and acknowledgements 6.1

The Design Team would like to acknowledge local organizations in St Croix for their support and their on-going desire to improve the environment in which we all live. In addition, we would like to acknowledge the organizations identified on the following page for their contribution to this Master Plan and for their tireless efforts to make this the best project that it can be.

In addition, we would like to thank the following people specifically for their dedication to furthering the advancement of marine science and of our National Parks; without whom this project would not be possible:

Karen H. Koltes, Ph.D. Joel Tutein, Superintendant Zandy Hillis-Starr, Chief or Resources Stephen Meinhold, PH.D., Assoicate Dean of Research Michael Bayer, AICP Amy L. Sebring, Architect Andrea Lind, Landscape Architect Dennis McCarthy, Architect

O = Owner; A = Architect; C = Civil; M = Mechanical; E = Electrical; P = Plumbing; EM= Energy Modeler GC/CM = General Contractor/Construction Manager; CxA = Commissioning Agent; L = LEED AP; I = Interiors

Due to remote location, this credit is highly unlikely.

Will depend on the total amount of wood in the project and the cost impact of FSC products. Need to weigh carbon foot print of long travel against closer supplies.

Design natural ventilation systems to meet Carbon Trust "Good Practice Guide 237"; use an analytical model to demonstrate minimum ventilation rates required by ASHRAE 62.1-2007 for 90% occupied spaces; increase breathing zone OA ventilation rates by 30% above ASHRAE 62.1-2007

All spaces should be daylit (maybe minus theater) thin building to promote natural ventilation so 90% of occupied areas should be achievable

100% reduction in potable water for sewage conveyance Renewable energy accounts for 15% or more of annual building energy cost

Inspiration + Education

Υ

Project Name: NPS SARI Marine Research & Education Center Project Address: Salt River Bay, St. Croix, US Virgin Islands 00820

Y/?/N	Site Petal	?
Y	Limits to Growth	Projects may only be built on greyfields or brownfields that are not: wetlands, primary dunes, o prime farmland, or within the 100-year flood plain
?	Urban Agriculture	Must integrate opportunities for agriculture appropriate to scale and density of the project usi
Y Y	Habitat Exchange Car Free Living	For each hectare of development, an equal amount of land must be set-aside in perpetuity Contribute towards the creation of walkable, pedestrian-oriented communities that support a
Y/?/N	Water Petal	Targeting
Ŷ	Net Zero Water	100% of occupants water use must come from captured precipitation or closed loop water syst purified without the use of chemicals
Y	Ecological Water Flow	100% stormwater & building water discharge must be managed onsite
Y/?/N	Energy Petal	Targeting
Y	Net Zero Energy	100% of projects energy needs supplied by on-site renewables on a net annual basis
Y/?/N	Health Petal	Targeting
Y	Civilized Environment	100% occupiable space must have operable windows that provide access to fresh air and daylig with fume hoods are exempt
Y	Healthy Air	storage spaces must be separately ventilated and exhaust directly to outside; smoking prohibit air quality testing at pre-occupancy & 9 months after
Y	Biophilia	Designed to include elements that nurture the innate human attraction to natural systems and
Y/?/N	Materials Petal	?
?	Red List	Project cannot contain any of the red list materials or chemicals
Y	Embodied Carbon Footprint	Project must account for the total footprint of embodied carbon from its construction and do a
Y	Responsible Industry	Project must advocate for the creation and adoption of 3rd party certicied standards for sustain fair labor practices. Applicable raw materials include stone and rock, metal, and timber
?	Appropriate Sourcing	Project must incorporate place-based solutions and contribute to the expansion of a regional e practices, products and services
Y	Conservation & Reuse	All teams must strive to reduce or eliminate the production of waste during design, construction order to conserve natural resources; must create a materail conservation management plan an materials from landfills
Y/?/N	Equity Petal	Targeting
Y	Human Scale + Humane Places	Designed to create human-scaled rather than automobile-scaled places; there are specific maxi areas for each transect
Y	Democracy + Social Justice	ADA
Y	Rights to Nature	Project may not block access to, nor diminish the quality of fresh air, sunlight & natural waterw or adjacent developments
Y/?/N	Beauty Petal	Targeting
Y	Beauty + Spirit	Project must contain design features intended solely for human delight and celebration of cult

Initial Requirements and Design Parameters of the Seawater Supply, Filtration, Storage, Control and Distribution System for the Proposed Salt River Bay Marine Research and Educational Center (MREC) in St. Croix, USVI

### **APRIL 2011**

Prepared by the Joint Institute of Caribbean and Marine Studies Seawater System Advisory Team: Bori Olla Ron Moore Dennis Allen Robert Wicklund

### PREFACE

The dynamic nature of the marine environment in which seawater will be drawn presents a number of challenges in designing a seawater system for the proposed Salt River Bay facility. Through time, seawater will be used a multiplicity of ways. The main thread that transcends whatever way seawater is to be used is that the quality be consistent, especially in terms of salinity, turbidity and other runoff contaminants. Since the area in which water will be drawn is subjected to large and sometimes lengthy freshwater intrusions during major rain events, salinity may drop precipitously from freshwater runoff, which would also increase turbidity and the potential for contaminant enrichment. Wide swings in water quality such as these can have a devastating effect on marine organisms, the degree depending on species and life stage. To preclude what might translate into enormous losses in research investment, it is critical that the seawater system be designed to take ambient conditions into account. We therefore included some design parameters that, at least in part, deal with these potential problems by providing:

(1) inflow of seawater from the source at a rate sufficient to provide an adequate supply of water when environmental conditions cause water quality to be compromised, e.g. precipitous drops in salinity, and mandate that seawater be pumped only intermittently during any 24-hr cycle, e.g., certain periods of a flood tide;

(2) large seawater storage to mitigate the effects of intermittent source inflow so that seawater may still be supplied to researchers, albeit at a reduced level during non-intake periods.

Another critical and integral part of the design is concerned with back-up electrical power generation. Given the vagaries of power disruptions of the local electric grid, it is vitally important that emergency generation of power be included in the design. We have accounted for this in our report.

Joint Institute of Caribbean and Marine Studies: Seawater System Advisory Team:

Bori Olla Ron Moore Dennis Allen Robert Wicklund

### SEAWATER SUPPLY AND DELIVERY

Note: Due to the specialized nature of certain components of this design, specifications, in some instances, refer to various components by trade or manufacturer name. These are used for informational purposes to describe a standard of required function, dimension, appearance and quality and do not preclude other products as long as they are equivalent to those that are listed.

### STRUCTURES ASSOCIATED WITH THE SEAWATER DELIVERY SYSTEM

- 1. The intake pipes (two) shall be secured above the sea floor.
- assume that the delivery pumps will be in another environmentally controlled environment.
- all wet areas.
- degassing.
- 5. The filtration infrastructure needs to be in an environmentally controlled structure.
- weather.

### Seawater Source Piping

1. Two identical supply lines, each with the capacity to supply 300 gpm, will be needed to deliver from the source. These lines will terminate in a switching station where the water from whichever line is in service can be sent to both the filtered water and raw water branches. For the filtered water branch, two lines (redundancy, one in use at a time) will be available for delivery to the filter station. For the raw water branch, two lines (redundancy, one in use at a time) will be available for delivery to the settlement/degassing tank. All pipes shall be chemically inert to seawater (e.g. PVC) and of sufficient structurally integrity (not less than Schedule 80 PVC) to withstand the dynamic nature of the highly variable sea conditions.

2. Periodic cleaning the pipes requires back washing capabilities, and the use of "pigs" or some equally effective alternate to remove fouling organisms. Reasonably spaced cleanouts (Y-shaped couplings) will be required for long runs of pipe.

3. Screening for the supply end of the pipes shall consist of titanium of a mesh size of 3/16" with the final size to be determined by the seasonal water column debris field.

4. Foot valves, if required, shall be made of titanium.

5. All flanges, valves, Ts, or any other connectors should be of PVC or of an equivalent material inert to seawater.

### Seawater Supply Pumps

1. These pumps shall be functionally redundant, so that one is ready to take over immediately should the first one fail. They shall be self priming types equipped with capacitors and each must have the capability to supply 300 gpm. These shall be interfaced electrically to water level measurement and feedback control devices from the holding tank to insure a continuous and stable level of seawater delivery. One additional pump shall be available as a replacement should a pump fail.

2. Construction of internal parts such as the impellers or any surface that comes in contact with seawater should be made of titanium (coated), or inert plastic. Quality should be equal or exceed that of ITT Goulds Pumps of Seneca, New York.

2. The source water pumps need to be in a building/shed to minimize direct environmental assaults. We

3. A motor control center that comprises controls for all of the pumps needs to be physically separated from

4. The raw water needs to go into a tall tank (about 8000 gal.) to allow for sediment settlement and

6. The temperature controlling systems for the filtered water delivery system need to be protected from the

### RAW SEAWATER BRANCH

1. Two lines (redundant) will supply raw seawater from the switching station to an elevated cylindrical tank where sedimentation and degassing can occur.

2. The tank should have the capacity to allow a short turnover time between acquisition at the source and delivery to the tanks. We estimate that if the desired delivery rate at the tanks is 300 gal/min, the degassing tank should have a capacity of about 8000 gal.

3. The cylindrical tank shall be of fiberglass construction. The lower one third shall be cone-shaped bottom to allow for the collection and flushing of settled sediment. An overflow pipe at the top will allow for excess supply water to run off; this can be returned to the environment. The pipe for delivering water to the distribution pumps (as described below) shall exit the tank at the top of the cone.

### FILTERED SEAWATER BRANCH: FILTRATION AND CONTROL

General requirements: The specified level of filtration provides for a standard level of treatment. A higher degree of filtration can be achieved at the location of investigator specified needs. To insure that each item of apparatus is properly sized to perform with every other item, it is essential to use the filter manufacturer as a single source of supply for items of equipment as listed and described. The recommendation is that the equipment supplier be Neptune-Benson, Inc. of Coventry Rhode Island or a supplier of equal or superior quality.

### Fiberglass Filter Tanks

1. The filter tank shall be suitable for the working pressure of the system and hydrostatically tested to 75psi and designed with a 4:1 safety factor.

2. Saddle style bases shall be provided for tank support. Where stacked tanks become necessary, similar bases and mounting saddles should be provided for the upper vessel. Access to the tank(s) shall be provided with a manhole as large a possible to accommodate maintenance personnel with a two bolt, 4 point yoke. The manhole seal shall be complete with a one piece neoprene gasket and positioned so that the internal pressure from the filter will augment the seal. External bolt-on covers are not acceptable.

3. Drain out system shall consist of a 3/4" fiberglass coupling mounted to the tank bottom with each coupling fitted with a slotted PVC sand retainer. Air relief connection shall be a 3/4" coupling on top of the tank. Bulkhead fittings are not acceptable.

4. Each filter tank should be equipped with the necessary flanges and connections for the internal and external piping. Connections should be comprised of 1" minimum thickness fiberglass flanges. Connections requiring bolt-thru hardware are unacceptable.

5. The resin used in construction should be commercial grade, premium resistant vinylester that has been evaluated in a laminate by tests in accordance with ASTM C-581 in service comparable to the intended service. Other generic types of resin such as isophthalics or general purpose polyester resins are not acceptable.

6. The inner surfaces exposed to seawater shall be followed with a layer composed of vinylester resin, reinforced with non continuous glass filler strands applied to a minimum thickness of 0.100 to 0.130 inches and in no case be less than 0.100 inches.

7. Provisions need to be made for handling the backflushed water which can be returned to the environment.

### Filter Piping-Internal

1. The upper and lower internal distribution system shall be a horizontal header, lateral arrangement. Headers should be Schedule-80 PVC capped on one end and flanged on the other. Lateral connections shall be spaced no more than  $6^{"}$  on the centers with 1  $\frac{1}{2}$ " connections.

2. Under drain laterals shall consist of 1 ½" Schedule-80 PVC with machined double slotted openings on 1/8" centers. Machined openings shall be designed to retain all media particles as small as .30 mm particle size. Molded or drilled openings or retainer screens are not acceptable. Each lateral will be fabricated complete with a socket cap on one end and a male adapter on the other. Laterals shall be fitted with rubber o-rings to allow for proper positioning of the machined openings.

3. Upper laterals shall consist of 1  $\frac{1}{2}$ " Schedule-80 PVC with  $\frac{1}{2}$ " wide machined double slotted openings on 1 1/4" centers. These laterals shall be designed and sized at the factory so as to provide uniform distribution and unrestricted water flow during filter and backwash cycles. Laterals shall be fitted with a rubber o-ring to allow for proper positioning of the machined openings.

4. All hardware in wetted areas shall be inert in seawater.

### Face Piping

1. All external face piping shall be Schedule-80 PVC pipe and fittings. All fittings, including 10"-12" sizes shall be molded type. Fabricated or fiberglass wrapped fittings are not acceptable. Flanges should be located so as to allow for easy dismantling of face piping. All fittings shall be solvent cemented.

2. Standard accessory items shall include sight glass rated for 50 psi with polycarbonate glass, remote mounted gauge panel with two 4  $\frac{1}{2}$ " diameter pressure gauges, 1/4" peacocks, 1/4" poly vent tubing with PVC compression adapters.

### Automatic Air Relief Valve

1. A 1" valve shall be provided to automatically and continuously release air in each filter. This valve shall be fabricated of plastic with Buna-N seals. Also provided shall be two PVC ball valves to allow manual air relief and isolation of the automatic valves. Valves fabricated of cast iron, bronze or stainless steel shall not be acceptable.

### Valve Control Assembly

1. Simultaneous movement of valves that are operated by pilot actuated mechanisms using air or fresh water shall be required.

2. All linkage parts shall be 316L stainless steel.

### Automatic Controller

1. The operation of the filter system shall be governed by means of a programmable logic controller housed in a Nema 4x fiberglass polyester enclosure.

2. The controller should include at a minimum a 4 row x 24 character LCD display with 16 button numeric tactile feedback keypad and programmable function keys with LEDs. The unit will display system operations and status functions.

3. Included shall be 5 miniature plug-in double pole/ double throw relays and 4 quick disconnect fuse holders fully integrated to manage system functions.

report system σ Ð Na

4. A pressure switch shall be installed to sense and signal for backwash actuation based on preset pressure drops.

5. The controller shall provide the following operational features:

- A. Manual backwash initiation
- B. Automatic backwash initiation (pressure and/or time options
- C. Timer for time clock back washing
- D. Fixed backwash duration and delay features
- E. Real time clock with battery backup of data entry to maintain time during power outages
- F. Capability of controlling up to 4 or more filters

### Digital Management System

A computer-based management system needs to be incorporated so that basic functions of the system can be monitored and adjusted as necessary. The monitoring component shall track all water quality and performance variables including: water temperature, salinity, flow rates (supply pumps, post-treatment pumps), pressure on both sides of all pumps and filters, and storage and degassing tank water levels. The program shall provide the operator with capacity to adjust controls to achieve the desired level. Alarms must be a part of this system. The management system with its alarm system should include the capability for off-site monitoring and control through a web site.

### Filtrate Material

1. Gravel support media shall be of a coarse aggregate with a subangular grain shape with a particle size of 1/8"x1/4" and shall be placed by hand so as to avoid damage to the under drain system and leveled before the addition of the upper layer of filter media. Support media shall be provided in 100 lb bags for ease of handling and elimination of possible contamination. Media shall be free from minerals which could precipitate into the seawater supply.

2. Sand shall be a carefully selected grade of hard, uniformly graded silica material with naturally rounded particles of silica quartz. Particle size should be between .44mm and .55mm (#20). No more than 1.5% shall be allowed to pass through a #40 sieve (.0164"). Uniformity coefficient shall not exceed 1.53. Specific gravity must be not less than 22.5. Sand will be provided in 100 lb bags for ease of handling and elimination of possible contamination. It should also be free from minerals that may precipitate into the seawater.

### FILTERED SEAWATER SUPPLY STORAGE

1. The seawater supply storage capacity should be 300,000 gallons. The tank(s) shall be constructed of cement with epoxy coated rebar and be fully enclosed (vented).

2. Seawater exchanges in tanks at the delivery end of the system will need to be changed at rates that will vary from 20 to 50% per day, depending on the needs of the contained living materials. If the standing water capacity of all tanks in the facility amount to 200,000 gal., a 50% exchange rate would allow for a 3 day supply of filtered water from the 300,000 gal. storage tank.

3. High pressure water hose capability shall be available for cleaning out of each supply tank.

### HIGH VOLUME, LOW PRESSURE AIR SYSTEM

1. Ambient air needs to be delivered to all areas where running seawater is supplied. This is provided to supply airstones for both routine use and periods when seawater supply is unavailable or restricted.

2. All pressurized air lines, valves, and taps shall be PVC. Redundancy is necessary for the air pumps.

DISTRIBUTION PUMPS TO RESEARCH LABORATORY, TEACHING AREAS, EXHIBIT AREA, SEAWATER LAB, AND OUTDOOR RACEWAYS/TANKS

1. For each of the two delivery branches, raw and filtered, two centrifugal pumps will be needed with one operating at a time (redundancy). Each of these four pumps shall have the capacity to supply 300 gpm.

2. Construction of internal parts such as the impellers or any surface that comes in contact with seawater should be made of titanium (coated), or inert plastic. Quality should be equal to or exceed that of ITT Goulds Pumps of Seneca, New York.

3. Piping from the pumps shall be redundant with the potential to clean one while the other is operative.

### TEMPERATURE CONTROL

1. Following filtration, accommodation shall be made with regard to power requirements and seawater valving to a heat exchanger to maintain seawater at any chosen temperature (+/- 1°C) between 20 and 30°C at a flow rate of 100 gpm. This infrastructure will need to be available at each secondary distribution location (e.g. research lab, teaching area, exhibit area, seawater lab)

2. All internal exchanger parts shall be constructed of titanium or other inert to seawater material.

### BACKUP GENERATORS

1. Each of three backup generators shall have the power output capability to run all components of the seawater system in the event of loss of power from the grid.

2. Generators shall be redundant.

3. Startup shall be automatic.

4. Fuel storage shall be sufficient to operate at full power for thirty (30 days) and have an incorporated polishing system to maintain optimum quality.

### Michael and Steve,

I'd like to thank the Seawater team for pulling together the Initial Requirements and Design Parameters of the Seawater Supply, Filtration, Storage, Control and Distribution System for the Proposed Salt River Bay Marine Research and Educational Center (MREC) in St. Croix, USVI (Seawater Report). The effort was clearly substantial and will help the design team create an outstanding facility that will serve the JICMS's research needs and align them with the site constraints and budget. We have attached a copy of the report for everyone's reference.

In reviewing the Seawater Report, LAS would like to propose a series of recommendations. We have created a working lab diagram that outlines our understanding of the central seawater distribution system. Because the report had no drawings showing the desired locations of components (such as the settlement tank and the primary holding tank) we have attached this drawing for your review to ensure that we have properly understood the requirements; it is diagrammatic only.

Specific to some of the stated requirements in the report, we are planning to proceed with the following proposed system adjustments that in our experience will not compromise the quality or integrity of the system as outlined in the Seawater System Report:

Temperature Control: The report states several parameters for seawater temperature control that include providing the capacity to chill marine tank water to 20C. At face value, this request creates strain on the power infrastructure of the project. We propose adjusting the following base assumptions:

The seawater report states that chilled seawater is required at all seawater locations. We propose that chilled seawater is needed only for research use, not for education or touch tanks, etc. We propose to provide pointof-use heat exchangers at the filtered water outlets at each marine tank location in the main lab building on an as-needed basis to support the marine research. We are assuming that the marine tanks which will be located at the Dive/Boat Facility, and at the Outreach Building, will not require this feed water cooling functionality, as this is not a 'research function'.

The seawater report requests water chilling capacity to of 20-30 C. After reviewing the temperature data in and around St. Croix, this minimum temperature seems lower than needed, considering that the historical data suggests that at 10 meters the coldest water temperature ever recorded was 25.2 C in 1993 and in 2001 (with this temperature occurring once in 1993 and twice in 2001). We plan to provide filtered water cooling over a range of 22C-30C based on this historical data.

We have assumed that there would be some diversity in the temperature requirements. The report requests that seawater be available from 20-30C. See point above regarding overall recommended temperature ranges. Beyond this, some level of diversity is required, as not all the tanks will be at 22C all the time. Our diversity assumes 25% of the chilled seawater reduced to 22C, with other 25% tiers at 25C, 27.5C, and 30C. This translates to 4500 gallons of chilled water capacity at each of four temperature points, assuming research tanks only, and assuming the future capacity for the mariculture facility (80,000 gallons) will require a similar distribution of temperature (4 tiers of temperature capacity).

Water Volume Storage: The report requests filtered sea water storage of 300,000 gallons. Based on our calculations, this seems like an excessive amount of sea water storage. Our Seawater usage (worst case scenario) for the whole site is about 150,000 gallons; please see attached assumptions. This includes 80,000 gallons of future expansion for mariculture activities (about 5000 sf of site area used for this activity).

Assuming that the rate of replacement in all the tanks varies (diversity) based on use and research needs, the flow rates for these tanks could vary between 25% and 50%. Assuming that 1/3 of the tanks flow at 25%, 1/3 at 35% and 1/3 at 50% (a reasonable flow diversity), we have an average of 35% flow. Using our worst case scenario total volume, then a 3 day supply at full capacity is 150,000 gallons (1/3 of 150,000 times 3 days). A three day supply is what was requested in the Seawater Report.

At initial construction, without the mariculture program, even this capacity is double what should be needed based on the diversity and flow calculations since 80,000 of the 150,000 gallons of seawater projected use is for a future program.

The project currently is anticipating 600,000 gallons of fresh water storage for potable water but a reserve on this amount would be a benefit for the project. As such, we propose to plan the site for the full requested capacity (600,000+300,000=900,000 gallons) of 900,000 gallons. This would allow for 750,000 of fresh water and 150,000 of seawater. In addition, this capacity could be shared or interchangeable based on actual needs after construction since the cisterns need to be sub-divided for both utility and seismic reasons.

Power Supply: The report asks for quadruple redundancy of the power supply for the Seawater system (grid plus 3 generators). We propose the following power system set up which will offer triple redundancy from the most reliable sources available. Our primary supply will be solar (this is the primary supply for the whole project). The Seawater pumps will need to run only 2.5 -3 hours a day to meet the 50,000 gallon per day need, so it is reasonable that this could be done while the sun is up and the power availability is at its greatest. To back this system up at night, we will provide a battery bank.

The secondary power supply will be from the grid. We plan to net meter the project (this is a newer development) so we will have a power source in the event of a series of cloudy days or other similar event. In addition to these primary and secondary power supplies, we will provide a generator with sufficient capacity to power the seawater system as well as other functions that require emergency power giving us a third back up.

Please note that this is about the power supply, and not the pump redundancy which is a separate issue; we plan on proceeding as indicated in the Seawater report with primary and back-up pumps. Specifically we propose that the pumps will perform in the following manner:

- Two intakes of source water (redundant). .
- Each source water line split into two source pumps (primary source pump 1, redundant source pump 2).

. One set of source water pumps (primary source pump 1, redundant source pump 2) delivering raw water to a single sediment/degassing tank, and this water split into two distribution pumps (primary distribution pump 1, redundant distribution pump 2) delivering degassed raw water to all marine tank locations.

• The other set of source water pumps (primary source pump 3, redundant source pump 4) delivering raw water to a single filter system tank, and this filtered water delivered to a 150,000 Gallon storage; from storage it will be delivered to marine tanks via primary distribution pump 3 and redundant distribution pump

An additional TBD volume is noted for both cooling Zone A spaces and for point-of-use cooling marine tank exchange water.

Source pumps 1, 3, and distribution pumps 1, 3 will be battery-powered electric pumps, 300 GPM, with generator back-up for pumps and controls.

Source pumps 2, 4, and distribution pumps 2, 4 will be diesel-powered pumps, 300 GPM, with generator back-up for pumps and controls.

Please let me know if there are any questions concerning our recommended direction above. We look forward to seeing everyone next week. Thanks.

# **Bobendix** ⁶⁰ Seawater intake system report **6**

### Dear Joshua:

I appreciate the LAS team meeting with me last Friday to work out some of the sticking points on the proposed seawater system for the Salt River Bay Marine Research and Educational Center. It appears that, at least for this phase of the MREC facilities design, we agree on the basics of its onshore seawater system.

I want to reiterate that, although the Seawater System Advisory Team was not originally tasked with providing information regarding the onshore phase of the MREC design, as we proceeded with our development of the water quality protocol it became apparent that the expertise of the team could provide needed input to the onshore side of the design as well. It followed that during a meeting at UNCW in April we drafted the report "Initial Requirements and Design Parameters of the Seawater Supply, Filtration, Storage, Control and Distribution System for the Proposed Salt River Bay Marine Research and Educational Center (MREC) in St. Croix, USVI" and sent it to Michael Bayer for distribution. This report and your response are added as addenda to this letter.

Of paramount importance to the successful operation and support of marine science projects at the MREC is the recent change in how we approach the power requirements. We had been concerned from the beginning regarding the proposal to exclude the grid from the mix of power generating systems. Now, with the grid as primary and alternative systems tied in, the options for us are far greater. You assumed that we needed a quadruple power system which was just a miscommunication. Any combination of three -- primary, backup and second backup (generator[s]) -- is our recommendation which appears to fit your intentions. In terms of power and cooling of the seawater, again this was just a miscommunication. We recommend point-of-use heat exchangers, not cooling all the stored seawater.

You were concerned that providing a cooling range of 20-30 C would put too much strain on the power system and recommended 22-30 C instead. You based this on local history of temperature measurements at 10 meters offshore depth that never went lower than 25.2 C. Future research at MREC will include deep-water as well as local shallow-water species. Corals, sponges and many other important species live beyond 70 meters and some are much deeper. Also, since the research will occur in other places in the Caribbean, we may even be working in regions of upwelling. We agreed to leave the temperature range at 20-30 C for this phase of the design; however, there may be occasional requirements for seawater temperatures below 20C in the future and we can deal with that when it happens.

The assumption that the facilities at the dock area will not have a "research function" is incorrect. Support facilities necessary for science projects should include this area and we agreed on that at the meeting.

The assumption that mariculture and/or restoration of depleted reef species is off in the future and that the estimated 80,000 gallons of seawater storage should be deferred is unlikely and it is wholly possible that it may be one of the first projects started at MREC. For example, the grassbed ecology of the bay is conducive to research on restoring Nassau groupers to St. Croix waters. We strongly recommend that the seawater storage for mariculture be included in the original design.

To segue into the issue of seawater storage in general, your proposal includes 600,000 gallons of freshwater storage and 300,000 gallons of additional storage, which we recommend be used for seawater. However, of the 300,000 you propose to use 150,000 gallons for fresh- and 150,000 gallons for seawater storage, with 150,000 able to be used interchangeably as needed. As mentioned at our meeting, this seems to be an awkward approach and it could be not only a difficult logistical problem in terms of collecting fresh water during an unexpected rain event or making sure fresh water doesn't drain off roofs into tanks with seawater, but it may also leave one or the other with a shortage.

At least 300,000 gallons of seawater storage is of paramount importance for MREC to be able to provide successful support to marine research and to attract the best scientists in the world. We all saw that rain, sometimes heavy, fell the whole week we were in St. Croix. That illustrates how it is very possible we would not be able to pump good quality seawater for some time, perhaps for a week or longer. We can't rely on just averages; we must consider extremes. It is these periods of extremes that could leave scientists high and dry without a surplus to draw on.

Without a doubt MREC can be the best in the Caribbean and other tropic regions if there is a reasonable guarantee that our program can provide reliable power, full logistical support in terms of boats and other equipment, administrative and personnel support, and a reliable source of seawater for experiments. Anything less would put us in the category of just another substandard facility.

So, we continue to recommend in the strongest way possible that the MREC be designed to store all the fresh- and seawater it needs to be both a world-class research and educational facility and program, and as we discussed on Friday that would include a standing supply of 300,000 gallons of seawater.

Looking forward to reviewing the final design of MREC...if you have any further questions please contact me directly.

Bob Wicklund

### choosing by advantages

The design and owner teams gathered in May of 2011 to evaluate the progress of the project and to evaluate three site plan alternatives that had been developed to date. The three schemes were all conducive to the goals of the project and would have created a facility that allowed the project mission to prosper.

The Choosing By Advantages (CBA) process was used to evaluate the three alternates which proposed to solve the program in three different ways: the first proposed a colonnade to tie the buildings together and provide solar and rain protection, the second was focused on taking advantage of the views from the site by framing them with openings between buildings, the third was proposing to create a series of collegiate courtyards or quads which would anchor varying portions of the project. For additional detail and drawings of these alternates, please refer to the Master Planning Concept Options section of the report.

Each of these three alternates offered a different list of pro's and con's, and as such, the CBA process was used to evaluate them. Stakeholders from the local community and government joined the design team, OIA, NPS and JICMS in the evaluation and analysis of concepts resulting in a variety of positions and great feedback on the proposed MREC.

Through this 2-day workshop, it was agreed that the paramount advantage to be evaluated was the clarity of the entry sequence. Since this has an impact on visitors, operations and the enjoyment of the Park, everyone agreed that this was an appropriate paramount advantage. For further detail on the CBA, please refer to the appendix which details the discussions as well as the other major advantages that were reviewed.

In the end, it was Alternate 1 that was clearly the preferred alternative. Alternate 3 scored next with not too great a separation and Alternate 2 scored significantly weaker on the scorecard the team had created. Since Alternates 1 and 3 were both deemed to be advantageous, the group reviewed the options for moving certain components from one scheme to the other to create a hybrid that would offer even greater advantage. It was determined that the living accomodations, wet lab configuration, and maintenance facility location in Alternate 3 could be moved to Alternate 1 to create a hybrid that is the preferred alternative. Please refer to the following Design Solutions section for detail on the preferred alternative and the hybrid design.

Issue No.	DATE	Issue	DATE DUE STATUS
1	5/10/2011	Current Goal: Conceptual Approval from the NPS.	
2	5/10/2011	What is a CBA? Choosing by Advantages: assigning value to	
21	1271 - 2251 -	elements that are important to the mission of the project.	
3	5/10/2011	Project Overview: Site Location is near Salt River Bay at the	
		North end of Judith Fancy development in St. Croix, USVI	
4	5/10/2011	Climate & Site Considerations: All the elements that were taken	
		into consideration for the design so far such as: Average	
		temperature, solar radiation, Monthly Diurnal Averages, relative	
		humidity, wind velocity, frequency and direction, wind energy	
		potential, building orientation.	
5	5/10/2011	St. Croix Environmental Issues: There are five main	
		environmental issues that were taken into consideration. They are	
		air quality, sewage, erosion and sedimentation, limited fresh water	
2		and intermittent and expensive electrical supply.	
6	5/10/2011	There are three sustainability measuring sticks available for the	
		MREC. They are the Living Building Challenge, Island Green	
		Buildings Checklist (a.k.a. LEED "Tropical" formed by a group	
		in St. John), and LEED Platinum.	
7	5/10/2011	Deep Green – Concepts. The Living Building Challenge offers	
		the following concepts: Do good, not "less bad", requires Net	
		Zero energy use annually, requires Net Zero water use annually,	
		and forces designers and owners to fundamentally rethink	
2	25-15 12	assumptions and processes.	
8	5/10/2011	Deep Green – MREC Design: Project will collect all of its	
		potable water from rainwater. Project will treat all waste water	
		on-site and reuse it. All required power will be produced on-site	
		from Photovoltaic and Wind with battery backup power. It was	
		noted that net-metering was a more feasible option than earlier	
		investigations informed us – so the project will be net metered.	
		The project will create comfortable spaces without conventional	
		mechanical systems through natural ventilation and	
	F (10 (0011	denumidification.	
9	5/10/2011	Deep Green – MREC Strategies: The two main strategies are to	
8		create climatically and culturally appropriate designs that take	
		advantage of plentiful resources such as the sun and wind and	
	F (10 /0011	value the use of the precious ones such as water.	
10	5/10/2011	The project goals were read to the group again by Joshua.	
11	5/10/2011	Many attendees worked at the former West Indies Laboratory	
	5/10/2011	(WIL) and gave a brief history of the facility and provided useful	
		feedback on many meeting items	
12	5/10/2011	Former Senator Vernon Brown voiced concerns about code	
<del>and an</del> a s	-,,	compliance for cisterns. The design team has and will abide by all	
		codes for cistems and other elements of the facility.	
13	5/10/2011	Zone "M" Space – what is it and where will it be? The zone M	
	A DESCRIPTION OF A DESC	space will have the most stringent environmental control	
		(dehumidification, cooling). It will be housed in either the	
		Outreach Center or the Laboratory building. It will be an NPS-	
		managed space. The space will hold natural and cultural history	
		specimens. The purpose of the space is to be able to store St.	
		Croix specimens and artifacts in St. Croix for the students and	
		residents of St. Croix.

5/11/2011 The paramount advantages were discussed among the attendees and chosen based on their importance to the success of the project. Each scheme was then scored based on their advantage. A2. Labs: Solar Orientation to Minimize Solar Heat Gain and Optimize Daylighting.

- The scheme with the best orientation relative to the sun path will have the advantage because it will naturally be cooler while still allowing the optimum light into the space for lighting that will minimize electrical lighting.
  - Scheme 2 and Scheme 4 scored equally for the best orientation.
- A3. Housing: Access to Natural Ventilation.
  - Since the housing will rely on natural ventilation for cooling, the scheme with the best access to natural ventilation will have the most advantage.
    - Scheme 2 has larger undergraduate housing and therefore reduced cross ventilation.
    - Scheme 3 units have a better opportunity for cross ventilation than Scheme 2.
    - Scheme 4 has the best opportunity for cross ventilation based on building design and orientation on the site.
- C2. Housing: Foster Community through Shared Spaces.
  - The scheme with the greatest advantage would be the one that offered shared spaces that encouraged a sense of community for the people that used the housing.
    - Schemes 2 and 4 both offered courtyards in the housing are but Scheme 2 additionally offered a centralized location of the dining pavilion for good gathering opportunities and sense of community.
    - $\circ$  Scheme 2 has the greatest advantage.
- D1. Site: Clarity of Entry Sequence.
  - The clarity of entry sequence means that when a person arrives on-site it is very clear where they must go or enter the building and it is clear where they should not go.
    - Scheme 2 has a very clear entry sequence. It is easy to find the front door once you arrive in this scheme. The separation of the entry and postentry circulation is preferred.
    - Scheme 4 has a nice arrival sequence with a pedestrian bridge over a wetland – good educational opportunity.
    - Scheme 3 has a confusing entry sequence.
      Scheme 2 has the greatest advantage.
- E1. Labs: Lab/Dock/Maintenance Triangle Work Flow.
  - The researchers expressed importance that the laboratory, dock and maintenance facilities be as close to each other as possible. The reason is that each holds important components to the daily work flow. Researchers will be moving accessing elements from each of these locations daily.
    - Scheme 4 scored the lowest with no advantage because the work flow distances are the greatest.

	<ul> <li>Scheme 2 has some advantage facility locations needed to</li> <li>Scheme 3 has the greatest ad workflow triangle has the selab relationship to the main dock is the most critical.</li> </ul>

### master planning concept options

### .2 alternate 1: colonnade

The organizing concept of this alternate is to create a series of linked colonnades or passageways that tie the visitor and the resident experiences together as they move throughout the site as well as to provide shelter from the sun and rain as part of these paths. The colonnade evokes the rich architectural history of St Croix and the Virgin Islands; it mirrors the experience one has in Christiansted while allowing the development of the buildings to ultimately be of their own time. The colonnade concept also offers a direct strategy for connecting the buildings on the new campus and creating active points of interest along the way to spurn spontaneous interaction between disparate groups occupying the site including casual visitors, researchers and local k-12 students visitors.

Upon drop off or parking at the center, one follows a path to the east up to an open air entry pavilion that serves as the lobby and a central gathering space for the project. This space is open to the outside, but has a rhythm of columns and beams overhead to define the space and provide shelter from the sun. Upon arrival at the entry pavilion, the site is revealed to you as the panoramic views from Buck Island and Christiansted in the east to Salt River in the west present themselves. Visitors and students from here have direct access to the Outreach and Education components of the project. To the north the pavilion opens onto the central courtyard where both sides are flanked with colonnades. The southern colonnade offers alternate entry to the Outreach and Education program elements. On the north edge of the courtyard, the spine of the center develops as a colonnade connects the courtyard, moving past the lab building connecting it directly to the maintenance building and further down the hill to the water side elements and the dock. This colonnade creates a central location for movement between many of the project's key program elements helping to build a community and allow visitors to easily navigate.

The residences in this scheme for the undergraduates are housed in two linear buildings creating a residential courtyard between them. Graduate and staff residences are located apart from the undergraduates for acoustic and other privacy reasons; they are higher on the hill. To bring these groups together, the dining pavilion is located centrally to all the housing and serves to help define the east edge of the central public courtyard. The lab colonnade terminates at this focal point for the site's residents and ties the whole site together.

site parti

### .2 alternate 2: framed views

Alternate 2 is conceived to offer a sequence of framed views as one experiences the site which is rich with vistas in nearly all directions. To reinforce this idea, the building have been set in the site to offer views to their occupants, but more importantly, visitors and residents alike may move through the site where the buildings act as frames focusing one's experience on a particular view in a given direction.

Upon drop off at the site, one enters a forecourt that frames a view to the east of Buck Island framed between the Education and the Outreach components of the project. As visitors and residents move toward the lab buildings, they are again compressed between two buildings to reveal a view of Salt River Bay and the western side of the Park. Functionally speaking, placing the lab in this location also offers the closest proximity to the dock, easing the operations of the facility by keeping the dock, lab and maintenance buildings as close as the site allows.

The residences are arranged in a staggered pattern on the hill to allow each to have a view to the south and east. The dining pavilion is located high and to west above the labs. It thus becomes a central gathering space for all of the residents, as well as allowing it 270 degree panoramas as the apex of the framed view concept where the whole site is revealed and the frame is removed.

# **CBA** summary

courtyards connected

### .3 alternate 3: connected courtyards

The collegiate courtyard or quad is the conceptual and literal anchor for this alternate. The project lays out to create a series of 3 courtyards each with their own function and each becoming a part of a sequence of experiences as one moves through the project.

Upon arrival at the site, the vehicular circulation moves around a constructed wetland that is the precursor to the forthcoming courtyards. This one is experienced using a bridge over the wetland offering educational opportunity as well as an informal but organized start to the entry sequence into the MREC. The next courtyard is an entry and gathering space with the lab and outreach buildings creating is edges. Beyond this space is the central courtyard. This space is the central focus of the scheme with all occupants of the project present with the education, outreach, lab and dining pavilion all defining this courtyard.

The final courtyard is closer to an inner sanctum for the project, it is created by the undergraduate housing units as they are arranged to define the space but to leave the east view and windward direction open. Graduate and staff residences are located apart from the undergraduates for acoustic and other privacy reasons; they are higher on the hill. To bring these groups together, the dining pavilion is located centrally to all the housing and serves to help define the east edge of the central public courtyard.

Survey Miller

MREC site from across the bay, c1950

### landscape restoration plan

The Landscape demonstrates that the MREC can become an integral part of the natural reserve without interfering with its wildlife habitat and recreation potential.

The conceptual ideas we present dwell upon the interrelations of the marine, terrestrial and cultural environments we encounter on the site. These relationships are simplified in the typical description of the hydrologic cycle. They can be largely enhanced by the sensitivity we insert into the understanding and management of efforts to restore the hydrologic cycle of the two opposite flows typical to coastal areas where the land meets the sea, inland runoff flow and tidal flow.

To synthesize existing conditions we evaluated existing topography, hydrology and soil characteristics. Additional insight was provided by knowledge of ongoing concerns such as the plan to eradicate invasive species, restitute natural contours and the salt pond floodplain (mudflat) drainage.

The predominant landform is the hill which rises to 110 feet. The northeast and northwest slopes are a severe erosion hazard and have been designated as a natural contour restoration area. The natural slope can be identified by the soil type and a topographic plan. To achieve the natural non erosion slope we recommend bioengineering soil techniques such as the Filtrexx Compost Soxx. This is a system which doesn't requires heavy machinery, provides erosion control and native species re vegetation.

Basin A drains through an existing culvert at the southeast corner that eventually drains into the Caribbean Sea. It receives external offsite runoff contributions. A portion of Basin B will drain into a box culvert that is part of the proposed access road improvements. It also receives external offsite runoff contributions and drains into the Salt River Bay estuary. The remaining runoff of Basin B drains into the Salt River Bay estuary and the salt pond floodplain and will be subjected to the drainage runoff quantity and quality controls that will become an integral part of the MREC project. Basin C drains through a severe erosion hazard area of the hill because natural slope conditions have been significantly modified. It is the basin with the highest sediment runoff potential. Basin D drains almost directly into the Caribbean Sea.

views of existing site

The trails at the west of the hill provide an opportunity to incorporate runoff flow quality controls that filter sediment, avoid large concentrated flows and promote sheet or laminar flow, reduce velocity and restore natural time of concentration.

The flow quality control at the base of the hill also diverts runoff away from the archaeological site which facilitates future archaeological excavations. It also promotes sheet (laminar) flow and prevents the migration of excess runoff sediment to the mudflat floodplain. Natural capacity of sediment transport should be maintained because this is an area of great marine wetland habitat potential and sediments also transport elements that contribute to the ecological food chain wildlife support.

The mudflat drainage restitution is exemplified by an intermittent meandering stream. This stream has a dual function to restore drainage to the salt pond by controlling the frequency and detention time of floods and efficiently draining areas south to facilitate recreational activities and circulation consonant to the NPS site restoration objectives.

The meandering stream to restore mudflat drainage is the conceptual idea for the inland runoff flow. To enhance the opposite tidal flow influence of the salt pond we suggest modifying the eroded banks that are not productive to stimulate tidal flow and mangrove expansion.

Another possibility is to provide a connection between the salt pond and the Salt Ricer Bay. This may restore a hydrologic cycle and the tidal flushing capacities that could be beneficial to the marine wetland habitat. A hydrodynamic model and other studies will be needed to determine the benefits of this hydrological modification.

Basins A and B drain to existing or proposed box culverts which have been designed to manage quantity and not quality of runoff. We suggest inserting Flow Quality Controls previous to any of these two outfalls. The proposed box culvert of Basin B that discharges runoff from the proposed access road improvements provides another opportunity to further refine the quality of water draining into the Salt River Bay estuary, expand the tidal zone influence and redefine the already altered edges of this estuary.

### soil survey (soil conservation service)

Soil Series	Abb.	Soil Properties and Qualities
Cramer- Victory	CvC	clay. loam 2 to 12% slopes, very stony well drained severe erosion hazard 10 to 20 inches depth to bedrock
Pits, quarries	Pt	areas from which rock, gravel or sand have been removed for construction
Redhook	RdB	extremely stony sand 0 to 5% slope excessively drained, rarely flooded severe erosion hazard more than 60 inches depth to bedrock moderately saline
Salt flats, ponded	SaA	very poorly drained, strongly saline
Solitude	SoA	gravelly fine sandy loam 0 to 2% slopes, frequently flooded poorly drained more than 60 inches depth to bedrock Slightly to strongly saline
Southgate- Rock outcrop	SrF	gravelly loam and weathered igneous rock 40 to 60% slopes well drained severe erosion hazard 10 to 20 inches depth to bedrock
Usthortens	Us	areas that have been altered from their natural state by human activities
Victory- Southgate	VsC	loam, very stony 2 to 12% slopes well drained severe erosion hazard 20 to 40 inches depth to bedrock
Victory- Southgate	VsD	loam, very stony 12 to 20% slopes well drained severe erosion hazard 20 to 40 inches depth to bedrock
Victory- Southgate	VsE	loam, very stony

The site has a large variety of soil types (10) which in itself illustrates its rich environmental value. These soil types are differentiated according to the various landforms in the site and their topographic slope and relationship to the water.

The Southgate-Rock outcrop is the cliff that meets the sea surf in the north, northeast borders of the site.

The three Victory-Southgate soil types conform the hill that rises from 10 to 110 foot with slopes that range from 12 to 40%. All are extremely stony and an erosion hazard. The soil survey also indicates that a quarry was located in this hill.

The Solitude series is the floodplain which drains into the salt pond. It is an area with a high marine wetland wildlife habitat potential.

The Redhook series is the beach at the west edge of the site. The Usthortens series occupies an extensive part of the site and the whole edge with Salt River Bay, which testifies to some of the man made impact on the site. This is a very sensitive edge of the estuary which already has been altered from its natural state.

The Cramer-Victory series is located in the valley at the southernmost edge of the foot the hill. This soil series seems to be mostly located offsite.

### hydrology

The dominant landform in the site is the hill which has a ridge line that essentially divides the site into four basins that are identified as Basin-A, Basin-B, Basin-C and Basin-D in the Landscape Restoration Basins Delimitation Plan. Basins A and B are located within the proposed MREC site.

Basin A drains through an existing culvert at the southeast corner that eventually drains into the Caribbean Sea. It receives external offsite runoff contributions. A portion of Basin B will drain into a box culvert that is part of the proposed access road improvements. It also receives external offsite runoff contributions and drains into the Salt River Bay estuary. The remaining runoff of Basin B drains into the Salt River Bay estuary and the salt pond floodplain and will be subjected to the drainage runoff quantity and quality controls that will become an integral part of the MREC project. Basin C drains through a severe erosion hazard area of the hill because natural slope conditions have been significantly modified. It is the basin with the highest sediment runoff potential. Basin D drains almost directly into the Caribbean Sea.
