Jean W. Gallagher, Editor

The Journal of Physical and Chemical Reference Data (ISSN 0047-2689) is published bimonthly by the American Chemical Society (1155 16th St., N.W., Washington, DC 20036-9976) and the American Institute of Physics (500 Sunnyside Blvd., Woodbury, NY 11797-2999) for the National Institute of Standards and Technology. Second-class postage paid at Washington, DC and additional mailing offices. POSTMASTER: Send address changes to *Journal of Physical and Chemical Reference Data*, Membership and Subscription Services, P.O. Box 3337, Columbus, OH 43210-0012.

The objective of the Journal is to provide critically evaluated physical and chemical property data, fully documented as to the original sources and the criteria used for evaluation. Critical reviews of measurement techniques, whose aim is to assess the accuracy of available data in a given technical area, are also included. Papers which report new estimation or prediction techniques and test these techniques against existing databases are also accepted. The journal is not intended as a publication outlet for original experimental measurements such as those that are normally reported in the primary research literature, nor for review articles of a descriptive or primarily theoretical nature.

Monographs are published at irregular intervals and are not included in subscriptions to the Journal. They contain compilations which are too lengthy for a journal format.

The Editor welcomes appropriate manuscripts for consideration as Journal articles or monographs. Potential contributors who are interested in preparing a compilation are invited to submit an outline of the nature and scope of the proposed compilation, with criteria for evaluation of the data and other pertinent factors, to:

One source of contributions to the Journal is The National Standard Reference Data System (NSRDS), which was established in 1963 as a means of coordinating on a national scale the production and dissemination of critically evaluated reference data in the physical sciences. Under the Standard Reference Data Act (Public Law 90-396) the National Institute of Standards and Technology of the U.S. Department of Commerce has the primary responsibility in the Federal Government for providing reliable scientific and technical reference data. The Standard Reference Data Program of NIST coordinates a complex of data evaluation centers, located in university, industrial, and other Government laboratories as well as within the National Institute of Standards and Technology, which are engaged in the compilation and critical evaluation of numerical data on physical and chemical properties retrieved from the world scientific literature. The participants in this NIST-sponsored program, together with similar groups under private or other Government support which are pursuing the same ends, comprise the National Standard Reference Data System.

The primary focus of the NSRDS is on well-defined physical and chemical properties of well-characterized materials or systems. An effort is made to assess the accuracy of data reported in the primary research literature and to prepare compilations of critically evaluated data which will serve as reliable and convenient reference sources for the scientific and technical community.

Foreword

As a spectroscopist with a long-standing interest in molecular hydrogen, I welcome, with enthusiasm, the publication of the vacuum ultraviolet emission lines of H_2 . This atlas will be of immense help to all of those who want to study further the H_2 spectrum in the VUV or identify it in observed spectra both in the laboratory and in space.

The authors have greatly increased the usefulness of the atlas by their simultaneous publications with colleagues of the detailed analysis of the Lyman and Werner bands. Further assignments of so far unassigned lines will be made much easier and will likely lead to many new results.

For a long time, this atlas will stand as the last word on the vacuum ultraviolet spectra of H_2 .

1. Introduction

Following the work of Schumann (1903), the first list of vacuum ultraviolet (VUV) spectral lines emitted by an electric discharge in molecular hydrogen (H_2) was published at the beginning of the century by Lyman (1904 and 1906). The spectrum was photographed at low resolution and no identification was possible at that time. Later on, Werner (1926) gave the first tentative classification of some lines. Other pioneering investigations were also performed, always at low resolution (Dieke and Hopfield, 1927; Hori, 1927; Hyman, 1930; Jeppesen, 1933). No rotational analysis was given yet in the list of characteristic band wavelengths of diatomic molecules published in 1952 by the "International Tables of Selected Constants" under the direction of Rosen (1952).

Although the absorption spectrum of H_2 has been extensively studied, relatively less study was done in emission at high as well as low resolution simply because the source of light used was an ordinary glow discharge, the pressure of which (about 100 Pa) was high enough to completely prevent emission at short wavelength by radiation trapping. Regarding absorption many references before 1977 can be found in Huber and Herzberg's table (1979). The most useful are Wilkinson (1968), Namioka (1964a and b), Dabrowski and Herzberg (1974), and Takezawa (1970).

The first VUV emission study of H_2 at high resolution was published by Herzberg and Howe (1959), concerning the Lyman band system $B\ ^1\Sigma_u^+ \rightarrow X\ ^1\Sigma_g^+$, down to 118 nm. These data were used by Junkes, Salpeter, and Milazzo (1965) to list about 1500 lines of the Lyman band system that they published, together with 32 lines of the Werner band system $C\ ^1\Pi_u \rightarrow X\ ^1\Sigma_g^+$ at wavelengths longer than 113.5 nm, in an atlas of VUV atomic emission lines. Pictures of high resolution spectra were also given.

In 1980 Larzillière, Launay, and Roncin (1980) published preliminary results about the $D\ ^1\Pi_u \rightarrow X\ ^1\Sigma_g^+$ band system at short wavelength around 80 nm. The spectrum was obtained at Meudon Observatory with a low pressure electric discharge where self-absorption is much reduced at short wavelength. It was the first observation of emission from levels above the ionization limit. Two spectrally more extended studies were reported in 1984. The first one, by Dabrowski (1984), was devoted to the analysis of the Lyman and Werner band systems down to 100 nm. The second one, by Roncin, Launay, and Larzillière (1984) and Larzillière, Launay, and Roncin (1985), extended the analysis of the four unperturbed band systems C , D , D' , and $D''\ ^1\Pi_u \rightarrow X\ ^1\Sigma_g^+$ down to 78 nm.

At first the analysis of the very crowded emission spectrum rested on absorption data and on calculations which did not take into account the rotational coupling. However, the temperature at which the emission spectrum occurs is much higher than that for the absorption spectrum, so that the emission spectrum exhibits lines of high rotational quantum number J impossible to ascribe unambiguously except for the lowest v' (unperturbed) bands of the Lyman system and the Q branches of the $^1\Pi_u \rightarrow X\ ^1\Sigma_g^+$ band systems.

From the theoretical point of view, Allison and Dalgarno (1970) first reported emission probabilities from each vibra-

tional level of the $B\ ^1\Sigma_u^+$ and $C\ ^1\Pi_u$ states towards all vibrational levels of the electronic ground state, neglecting the rotational coupling between B and C . In the mid-1970s, Julienne (1973) and Ford (1974 and 1975) performed the first calculations of line emission probabilities of the Lyman and Werner band systems of H_2 taking into account the rovibronic coupling between the excited states. But at that time no complete experimental high resolution emission spectrum was available to check the calculation so that the problem was passed over. Recently several refined calculations have been performed. Abgrall *et al.* (1987) calculated emission probabilities for the Lyman and Werner band systems and found very good agreement with intensity measurements. The method of calculation is what we call *semi-ab initio* in the sense that the potential energy curves were fitted to the experimental results for each (v' , $J=0$ or 1) before solving the system of two Schrödinger equations. An extended list of level energies and oscillator strengths has been subsequently published by Abgrall and Roueff (1989), while Senn, Quadrelli, and Dressler (1988) obtained level energies, up to $J=6$, of the B , B' , C , and D states, calculated completely *ab initio* by including the four excited states in the interaction. Finally a *semi-ab initio* calculation, including the four excited states, has allowed Abgrall *et al.* (1993a, 1993b, 1993c, and 1994) to publish a complete analysis of the Lyman, Werner, $B' \rightarrow X$, and $D \rightarrow X$ band systems.

2. Experimental

2.1. Photographic Recording

The spectra have been recorded by means of the Meudon Observatory Eagle mounting VUV 10-m spectrograph. The instrument is fitted with a concave ($R=10.685$ m), 3600 lines/mm Jobin-Yvon holographic grating which gives a plate factor of 0.026 nm/mm in the first order. The slitwidth was 30 μm , giving a resolving limit of 8×10^{-4} nm throughout the whole range of observation ($0.8\ \text{cm}^{-1}$ at 100 nm).

The presence of a magnetic field of about 0.1 tesla in the water cooled electric discharge lamp (ANVAR), made of a brass anode and two aluminum cathodes, makes it possible to run the source at a pressure as low as a few pascals, so that self-absorption is much reduced at short wavelength. With hydrogen flowing in the source, the lamp was operated at 350 V, 200 mA.

Exposure time on Kodak SWR plates varied from 5 mm to 13 h, depending on the spectral range photographed.

Reference lines (Cu II, Ge II, Si II and O I, N I, Cl I, Cl II as impurities) were obtained by flowing helium in an ancillary water cooled copper hollow cathode discharge lamp operated at 500 V, 200 mA. Small pieces of germanium and silicon were introduced inside the cathode.

Due to the difference of the grating illumination by the two lamps, one finds a random shift between the two spectra (Kaufman and Edlén 1974, Freeman and King 1977). For each plate the shift is determined by means of the impurity lines common to the spectra emitted by both lamps.

In the shortest wavelength range (78-89 nm), the hollow cathode spectrum was recorded in the same zone of the photographic plate as the H₂ spectrum, and extra Ar I reference lines were also obtained by flowing argon in the low pressure discharge lamp itself.

The plates were measured on the Meudon Observatory photoelectric comparator giving an accuracy of 1 μm on line position (Launay 1975). The measuring machine is now connected to a PC compatible micro-computer. The standard deviation of our polynomial fit for the hollow cathode reference lines is typically 7×10^{-5} nm and the wavelength accuracy of the hydrogen unblended lines is estimated to be $\pm 15 \times 10^{-5}$ nm.

2.2. Photoelectric Recording

Relative intensity measurements have been performed by replacing the plate-holder of the spectrograph by a scanning photoelectric device moving along the Rowland circle and including a slit and either a photomultiplier with a MgF₂ window (Hamamatsu R1459) or a channeltron (RTC X919BL), depending whether the measured range is above or below 120 nm. The width of entrance and exit slits was 30 μm.

A set of 29 scans was obtained, each section of the spectrum being scanned at least twice. The relative intensities derived from raw data were scaled in order to get a consistent set of values over the whole spectral range (100 nm) but the instrumental response was not taken into account.

3. Description of the Spectrum

The spectrum contains 12 265 lines, including impurity and reference lines, extending from 78.60 to 171.35 nm. It has been divided into 165 sections covering about 0.58 nm each. Each section comprises the following:

(i) A picture of the plate enlarged ten times where emission lines appear in white on the dark background. H₂ lines look always slightly broad due to the Doppler effect, whereas atomic lines are generally sharp and readily recognized. It has to be noted that, due to different exposure times, blackening varies from plate to plate so that it may happen that weak high-*J* lines show up on a plate, whereas strong lower-*J* lines of the same band are not seen on the next plate.

(ii) The corresponding microdensitometer trace in which the strong lines are saturated while even very weak lines show up. Each line is marked by a vertical tick below the trace. Longer ticks indicate lines whose number is a multiple of five, thicker ones those whose number is a multiple of ten. The numbering of the lines is marked above the trace every five lines. A wavelength scale in nanometers and a wavenumber scale in reciprocal centimeters are indicated at the bottom and at the top of the trace, respectively.

The appearance of the reference atomic lines on the microdensitometer traces depends on which part of the spectrum has been scanned. Plot of photoelectric recording would have been more realistic but more difficult to display due to the dynamic range of the existing data acquisition unit.

(iii) A table listing all the lines appearing in the corresponding picture and densitometer trace.

- In these tables, lines are numbered in the first column. A few atomic lines, and very close H₂ lines, appear in the table not in the same order as in the picture. This is because reference lines are not emitted by the same source as the H₂ lines so that they may be shifted with respect to the H₂ spectrum as explained in the experimental section. Sometimes a standard line appears twice in the list, which means that the line is emitted by both the low pressure discharge and the hollow cathode.
- The second column contains the relative peak intensities of H₂ lines, measured from photoelectric recording but not corrected for instrumental response. Intensities are reported for H₂ lines only. However no value of intensity is given for the shoulder lines indicated "sh" in the comment and also for the reversed lines, indicated "r" because for the latter lines the intensity depends strongly on the pressure in the source at the time of the recording. An intensity of zero is given to lines barely seen in the picture and the trace, for avoiding values smaller than one. It should also be remarked that, as intensities have been scaled throughout the spectrum, the figures given in the tables are rounded and may not correspond strictly to what is seen on the traces. Also the running conditions of the source may have been different at the time of the photoelectric recording from what it was when the picture was taken.
- The third and fourth columns display, respectively, the wavelength (in nm) in ascending order and the corresponding wavenumber (in cm⁻¹).
- The fifth column indicates the abbreviated assignment of H₂ lines. In the VUV range, H₂ emission lines can be ascribed to seven band systems, namely, $2p\sigma B \ ^1\Sigma_u^+ \rightarrow X \ ^1\Sigma_g^+$ (Lyman), $2p\pi C \ ^1\Pi_u^+ \rightarrow X \ ^1\Sigma_g^+$ (Werner), as well as $3p\sigma B' \ ^1\Sigma_u^+ \rightarrow X \ ^1\Sigma_g^+$ and $3p\pi D, 4p\pi D' \ ^1\Pi_u^+ \rightarrow X \ ^1\Sigma_g^+$. We have also tentatively identified a few lines of the band system $6p\pi \ ^1\Pi_u^+ \rightarrow X \ ^1\Sigma_g^+$. As all VUV transitions terminate on the ground state $X \ ^1\Sigma_g^+$ we have omitted *X* everywhere. For example, C2-7P5 designates the line *J*"=5 in the P-branch of the transition $C \ ^1\Pi_u \ (v'=2) \rightarrow X \ ^1\Sigma_g^+ \ (v''=7)$.
- The last column is devoted to the identification of reference and impurity lines and may contain comments about H₂ lines. For the self-reversed lines exhibiting clearly two components, the average wavenumber is repeated in the comments of the two components. Such a value is very accurate because the two components are always sharp. Finally "b" stands for blended lines, "d" for diffuse lines, and "s" for sharp unidentified lines.

Some molecular impurity lines due to N₂ and CO appear on a few pictures. Their wavelengths are indicated and they are identified in the comment.

At longer wavelengths, most of the unassigned lines have negligible intensities. They may be due to the presence of

some impurities. At shorter wavelengths a number of unassigned lines have appreciable intensities. Most of these are certainly due to transitions from still unidentified high- J levels of the states B' , D , B'' , D' , and D'' . These lines cannot be assigned because the calculation does not fit with the lines predicted from absorption data well enough for a few levels of B' and D , and no calculation is yet available for B'' , D' , and D'' .

For atomic lines appearing in the reference spectrum we have indicated only the wavelength unless the lines are good standards with 5 decimals. In this case we give only the literature wavelength, in the comment. All the wavelengths of reference atomic lines are extracted either from a paper by Kaufman and Edlén (1974) or from Kelly's table (1987). In the latter case the value is followed by Ke.

In a first stage of the work the lines could be identified from the values of level energies published long ago (Wilkinson 1968, Namioka 1964a and b, Dabrowski and Herzberg 1974, and Takezawa 1970), and from more recent identifications of small v' , high- J levels of the Lyman band system by Dabrowski (1984). The semi-*ab initio* calculations of Abgrall *et al.* (1993a, 1993b, 1993c, and 1994) give emission probabilities and wavenumbers of most lines to an accuracy of about 0.5 cm^{-1} . Such a calculation was necessary, in order to assign unambiguously many high- J lines. In that way about 96% of the lines have at least one assignment. The absence of most lines missing in the tables of Abgrall *et al.* (1993b, 1993c, and 1994) is well explained either by radiation trapping or a weak emission probability. Typical cases have been illustrated by Abgrall *et al.* (1993a). Most mistakes, but probably not all of them, have been tracked down by several error tests included in the file handling programs used for editing the tables of Abgrall *et al.* (1993b, 1993c, and 1994).

It has to be pointed out that, due to interactive work with theoreticians, the present atlas is more than a simple catalog of spectral lines, as 96% of molecular lines are identified, most of them for the first time. It is hoped that this book will be useful to scientists in many fields and particularly to:

- astrophysicists who study the interstellar medium as well as those who are receiving, from spacecrafts, VUV spectra emitted by planetary atmospheres where H_2 is the major constituent,
- physicists who study emission of H_2 excited by electron impact in connection with planetary atmosphere processes,
- laser physicists, who need a very good knowledge of molecular line wavelengths,
- theoreticians for testing any improvement of the model.

4. Acknowledgments

The present work is dedicated to Dr. Gerhard Herzberg, who did so much for the knowledge of H_2 and many other molecules. It was initially undertaken under the auspices of the International Tables of Selected Constants (Paris) and CNRS (Centre National de la Recherche Scientifique), which

provided useful advice and encouragement. Over the years, many people helped the authors to complete this long term project.

First of all credit must be given to Dr. Henri Damany for designing the low pressure gas discharge lamp, twenty five years ago, when he was at the Laboratoire des Hautes Pressions (Meudon-Bellevue). Thanks are due to Dr. Christian Jungen (Orsay, France) and to Dr. Michel Larzillière (University Laval, Québec, Canada) who contributed at the early stage of the work. We appreciated the help of Maurice Benharrou in taking pictures and photoelectric recordings. Microdensitometer traces were carefully done by Monique Clemeno. Professor Jean-Louis Subtil (University of Saint-Etienne) wrote the file handling software required by the great number of data. Rosario Battaglia assisted in entering and checking the data. We also acknowledge the help of Dr. Stéphane Mottin (University of Saint-Etienne) in the task of editing the tables in the proper format. The greatest contribution came certainly from Dr. Hervé Abgrall (Meudon Observatory), who performed the semi-*ab initio* calculations of emission probabilities and line positions that were so necessary to identify many features of the spectrum. Finally we would like to thank all of those who encouraged us to pursue this project in spite of the disregard of some people for what they term "grandpa's spectroscopy."

The American Institute of Physics was founded in 1931; it is chartered as a membership corporation with leading societies in the fields of physics and astronomy as members. The Institute combines into one operating agency those functions which can best be done by the societies jointly. Its purpose is the advancement and diffusion of the knowledge of physics and its application to human welfare. About 100 000 physicists belong to its ten member societies: The American Physical Society, Optical Society of America, Acoustical Society of America, Society of Rheology, American Association of Physics Teachers, American Crystallographic Associa-

tion, American Astronomical Society, American Association of Physicists in Medicine, American Vacuum Society, American Geophysical Union. In addition, there are 20 Affiliated Societies, 84 Corporate Associates, and 6500 members of the Society of Physics Students.

For itself and its member societies, AIP publishes 20 archival journals, 17 translated Soviet journals, a general interest journal, conference proceedings, handbooks, and bulletin-programs, as well as an integrated package of current awareness journals, magnetic tapes, and microfilm. AIP also serves the public by making available to the press and other channels of public information reliable communications on physics and astronomy and their progress; carries on extensive career planning and placement activities; encourages and assists in the documentation and study of the history and philosophy of recent physics; cooperates with local, national, and international organizations devoted to physics and the related sciences; and fosters the relations of the science of physics to other sciences and to the arts and industries.

The American Chemical Society was founded in 1876 as a scientific and educational society, and in 1937 was granted a national charter by an act of Congress. Its objectives include the advancement of chemistry, the promotion of research in science and industry, improvement of qualifications and usefulness of chemists, increased diffusion of chemical knowledge, and the promotion of scientific interest and inquiry.

ACS publishes 26 magazines, journals, and other scientific periodicals in addition to its participation in publication of the *Journal of Physical and Chemical Reference Data*. It also publishes books and other nonperiodical reports and operates the Chemical Abstracts Service, the key to the world's chemical literature. It pursues its objectives through its services to chemists and chemical engineers and to education, industry, and government.

National Institute of Standards and Technology

U.S. Department of Commerce
Gaithersburg, MD 20899-0001

U.S. Department of Commerce	Ronald H. Brown, Secretary
Technology Administration	Mary L. Good, Under Secretary for Technology
National Institute of Standards and Technology	Arati Prabhakar, Director

The National Institute of Standards and Technology (NIST), formerly the National Bureau of Standards, was established by an act of Congress 3 March 1901. NIST works to strengthen U.S. industry's international competitiveness, advance science and engineering, and improve public health, safety, and the environment. With an annual budget of more than \$350 million and about 3100 staff members, NIST conducts science and engineering research in commercially important fields such as advanced materials, information systems, bio-

technology, optoelectronics, computer-integrated manufacturing, and sensor technology.

NIST's laboratory research is designed to support development of critical emerging technologies and the new measurement methods and standards necessary to make them commercially viable. The ability of U.S.-based industries to exploit these new technologies determines in large part the health of the U.S. economy.

Several new NIST programs are designed to help spur innovation at U.S. businesses through seed money for development of generic technologies; grants to states for support of technology transfer programs; and financial and technical assistance to help small and mid-sized companies adopt more efficient manufacturing methods.

Throughout its history, NIST has helped industry to develop high-quality products and processes by supplying standard reference materials and data; by continuously improving technologies for precision measurements of mass, time, length, voltage, radiation, and other units; and through active participation in voluntary standards-setting bodies.
