Population dynamics

Model structure

Five size class model

One – 30.0 cm or less

Two – 30.1 to 35.0 cm

Three – 35.1 to 40.0 cm

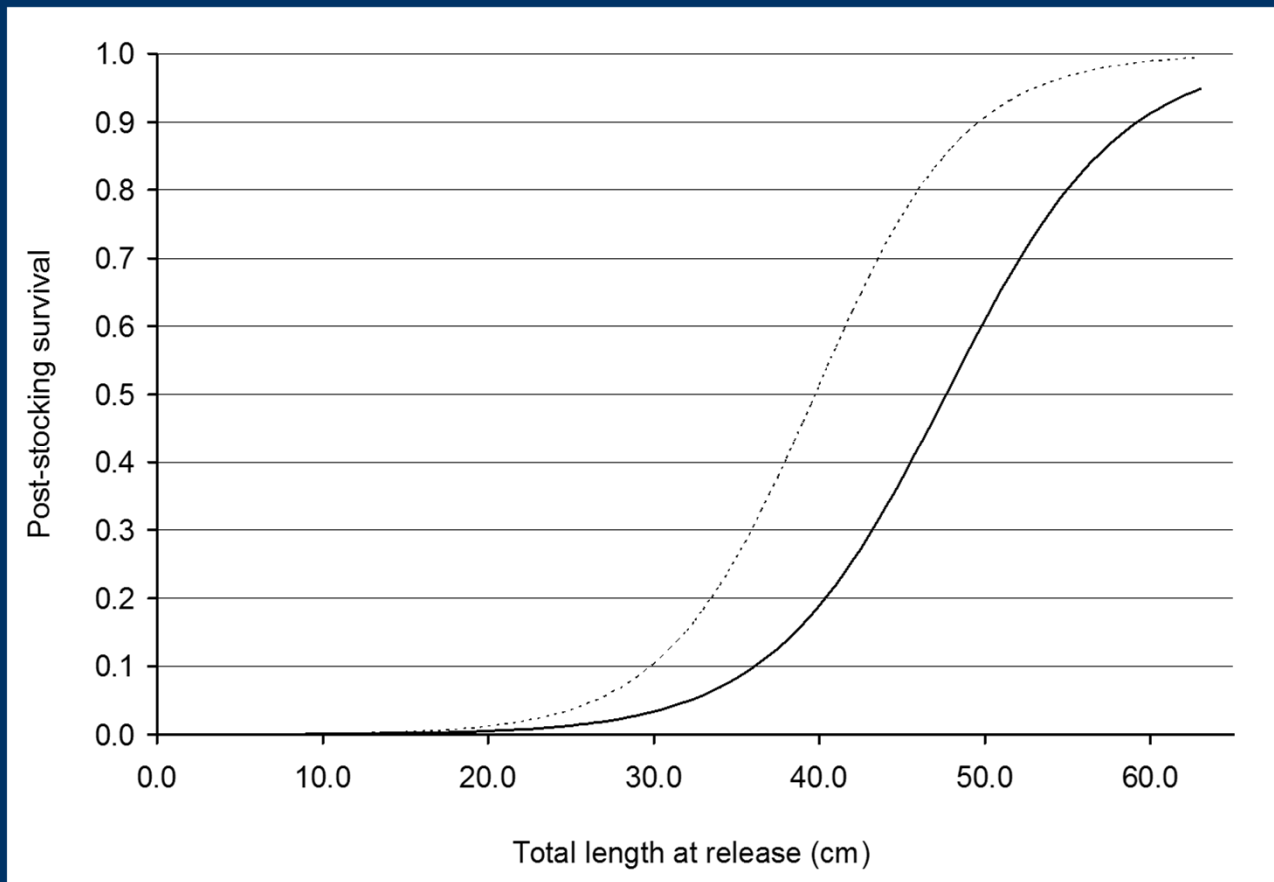

Four – 40.1 to 45.0 cm

Five – 45.1 cm or more

Model structure

Post-stocking survival based on size-survival relationship

Model structure

Growth from one size class to another based on NFWG database

Size Class	One	Two	Three	Four	Five
One	3	1	0	0	0
Two	14	24	0	0	0
Three	4	26	19	1	0
Four	1	4	7	18	0
Five	0	0	2	17	52

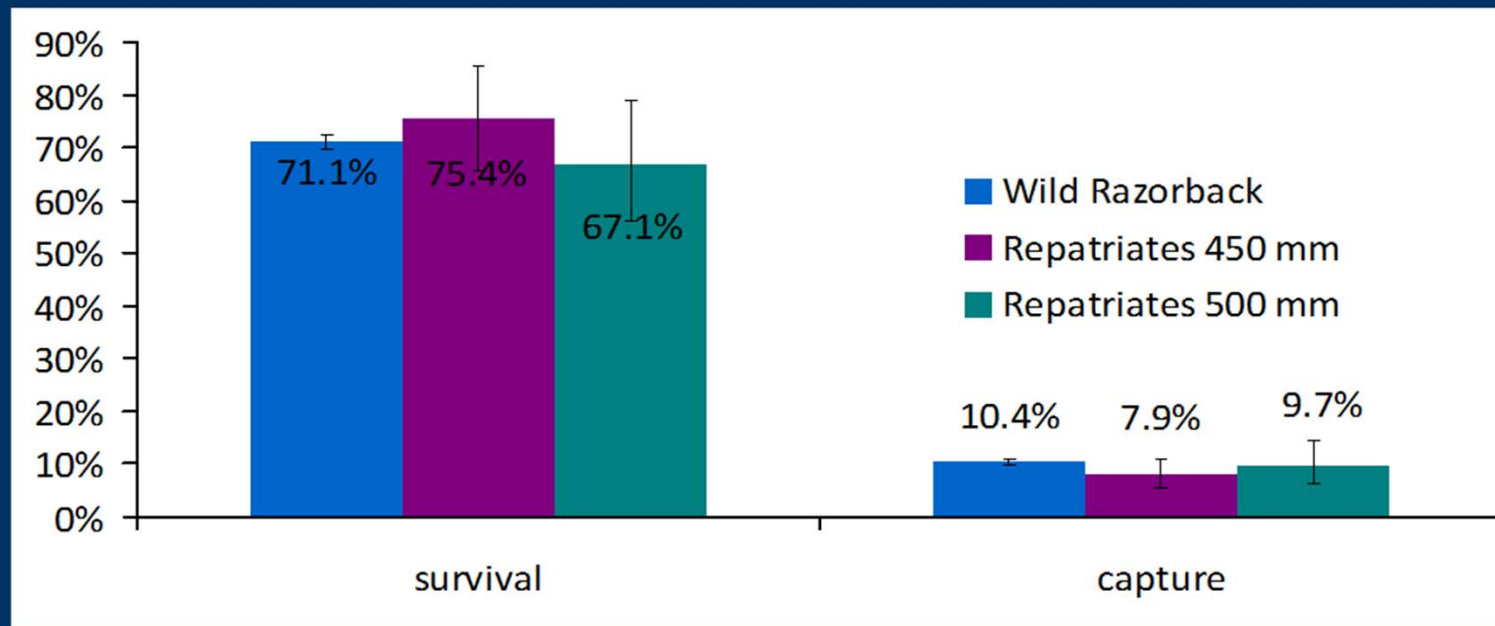

Size Class	One	Two	Three	Four	Five
One	0.14	0.02	0.00	0.00	0.00
Two	0.64	0.44	0.00	0.00	0.00
Three	0.18	0.47	0.68	0.03	0.00
Four	0.05	0.07	0.25	0.50	0.00
Five	0.00	0.00	0.07	0.47	1.00

Model structure

Three values of adult survival were tested

- 70, 75, and 80%

Model assessment

- Stocking records from 1992 – 2010 assigned to the five size classes
- Population size simulated based on model parameters of growth and survival
- Population estimates were not used to constrain the model

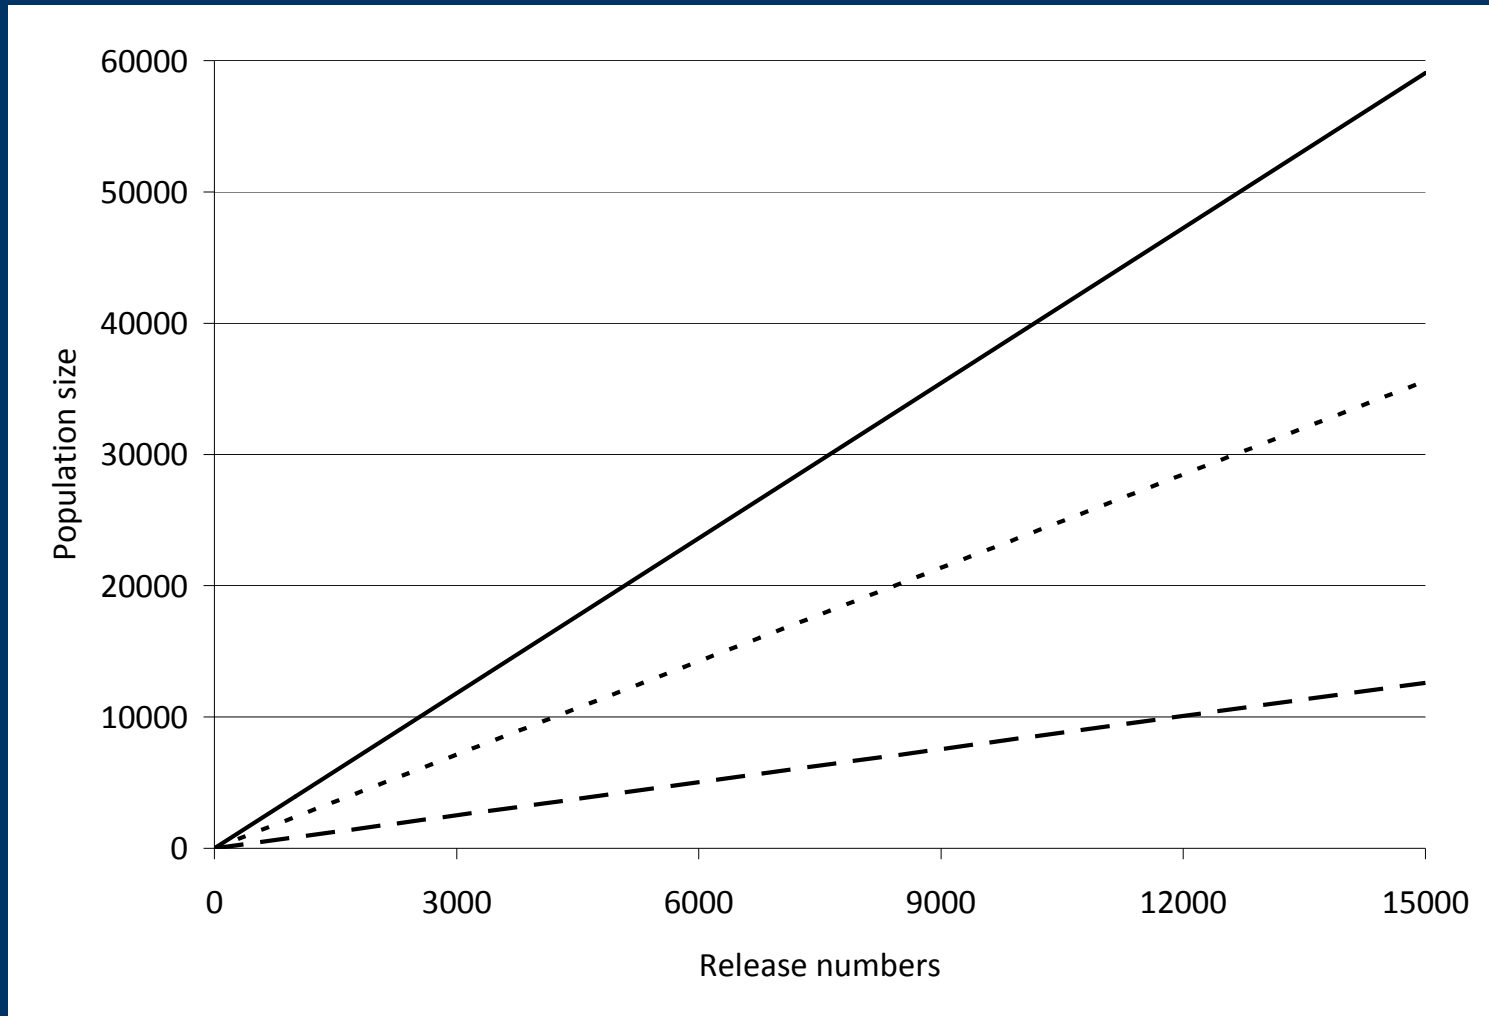

Stocking simulations

- Three different stocking regimes were simulated to estimate long-term stable population size
- Each stocking vector was based on an actual stocking year representing three target release sizes
 - 30 cm - 2002, 56% of razorback sucker stocked into Lake Mohave were larger than 30 cm
 - 35 cm - 2005, 69% of stocked razorback sucker were larger than 35 cm.
 - 50 cm - 2008, 56.5% of 978 fish stocked in 2008 were larger than 45 cm at release

Results

Results

Results

Simulations based on the updated size survival relationship the equilibrium population was always **8.3 times greater** for the 50 cm target than for the 30 cm target

Simulations based on the 2005 size-survival relationship the equilibrium for the 50 cm target was **4.7 times greater** than for the 30 cm target, cutting in half the benefit of annually stocking large fish
