INTRODUCTION

SCOPE AND PURPOSE

The Hanford Site Waste Management Units Report (HSWMUR) has been created to meet the requirements of the Tri-Party Agreement (TPA) Action Plan, Section 3.5, which states: “The Hanford Site Waste Management Units Report shall be generated, in a format agreed upon by the Parties, as a calendar year report and issued annually by the DOE by the end of February of each year, and posted electronically for regulator and public access. This report shall reflect all changes made in waste management unit status during the previous year.”

This February 2012 version of the HSWMUR contains a comprehensive inventory of the 3389 sites and 540 subsites in the Waste Information Data System (WIDS). The information for each site contains a description of each unit and the waste it contains, where applicable. The WIDS database provides additional information concerning the sites contained in this report and is maintained with daily changes to these sites.

DEFINITIONS

The HSWMUR shows the classification and reclassification designations for each site. These designations are based on definitions in TPA procedure TPA-MP-14. Simplified definitions are provided below. Full definitions can be found in the procedure which is available at the following URL: <http://www.hanford.gov/files.cfm/TPA-MP14.pdf>.

Classification designations are as follows:

- Accepted – The site has been evaluated and found to be a waste management unit. For sites added to WIDS since February 2, 2007, the approval date for TPA-MP-14 Rev. 1, this evaluation has also been approved by the appropriate regulatory agency. Sites added prior to February 2, 2007 were classified as Accepted based only on a contractor review.
- Accepted (Proposed) – The site has been evaluated and tentatively identified as being a waste management unit, but this evaluation has not yet been approved by the appropriate regulatory agency.
- Rejected – The site has been evaluated and found not to be a waste management unit. This evaluation has been approved by the appropriate regulatory agency.
- Rejected (Proposed) – The site has been evaluated and tentatively identified as not being a waste management unit, but this evaluation has not yet been approved by the appropriate regulatory agency.
- Discovery - The site has not yet had the evaluation completed.

Reclassification designations are as follows:

- None – The site has not been reclassified.

- Rejected – The site does not require remediation based on qualitative information such as a review of historical records, photographs, drawings, walkdowns, ground penetrating radar scans, radiation surveys, and shallow test pits.
- No Action – The site does not require remediation based on an assessment of quantitative data (e.g. analytical samples) collected for the site.
- Closed Out – The site meets applicable cleanup standards or closure requirements.
- Interim Closed Out – The site meets cleanup standards specified in an Interim Action Record of Decision, but a Final Record of Decision has not been issued.
- RCRA Postclosure – The site is a TSD unit that has been closed with waste in place and postclosure care, including monitoring and institutional controls, is being implemented
- Consolidated – The site will be dispositioned as part of another WIDS site.
- Deleted from NPL – The site is deleted from the National Priorities List or included in a final action published in the Federal Register.

ORGANIZATION

The waste management units at the Hanford Site are grouped into operable units (OUs) or waste management areas (WMAs). The groupings may be based on geographic location, types of waste received, and/or the ability to achieve economies of scale during remediation. Sites flagged as TBD (To Be Determined) haven't been assigned to an OU or WMA. Sites flagged as Not Applicable do not fit the criteria to be assigned to an OU or WMA.

The HSWMUR organization is based on the waste site grouping within the operable units and waste management areas.

100-BC-1

Code: 100-B-2 **Classification:** Accepted

Names: 100-B-2; 181-B Backwash Trench; Backwash Trench; Miscellaneous Stream #73; Undocumented Liquid Waste Site **Reclassification:** No Action (11/18/2004)

Type: Trench **Start Date:** 1/1/1975

Status: Inactive **End Date:**

Description: The site is a trench that was constructed to receive backwash filter backflush from the 181-B Pumphouse. The trench was fed by a single 30 centimeter (12 inch) pipeline that originated at the backwash filter. The pipe is approximately 0.9 meters (3 feet) below grade and enters the trench from the west. Before construction of the trench, the backflush water was returned directly to the Columbia River.

Location: The site was located east of the 181-B pumphouse and outside the exclusion area perimeter fence.

Related Sites/ Structures: The site is related to the 181-B Pumphouse.

Waste Type: Water

Waste Description: The site received river screen backwash water effluent.

Code: 100-B-3 **Classification:** Accepted

Names: 100-B-3; Hot Thimble Burial Ground; Undocumented Solid Waste Site **Reclassification:** No Action (4/2/2003)

Type: Burial Ground **Start Date:** 1/1/1952

Status: Inactive **End Date:**

Description: The site has been remediated and reclassified.

Location: The site was located south of the 105-B Reactor and west of the southwest corner of the 115-B Building.

Waste Type: Equipment

Waste Description: A highly contaminated vertical thimble was removed from the 105-B Reactor Building in 1952 and temporarily buried in a trench. The thimble was later removed and taken to another burial ground. Radioactive contaminants may remain in the trench.

Closure Info: The 100-B-3 Hot Thimble Burial Ground requires no further action to meet the cleanup standards specified in the Interim Action Record of Decision for the 100-BC-1 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The calculation brief was based on a review of historical data and facility information, no sampling was necessary to confirm the status of this site because: original documentation explained that the vertical thimble was buried in 1952 and removed prior to 1956. Also that the contamination remaining in the excavation when the thimble was removed were short-lived radionuclides, all with half-lives of less than 5.27 years. After 10 half-lives have elapsed, a radionuclide is considered to have decayed away. A geophysical survey over a larger area showed no evidence of a remaining buried thimble or the conclusive location of an old burial site. Thus, while a possible location for the burial site can be estimated from old photographs,

the actual location is unknown. Test pit results, even if the correct location was sampled, would prove inconclusive since the thimble has been removed and the short-lived radionuclides have decayed.

The calculation brief demonstrated that, based on a preponderance of the information, the 100-B-3 Buried Thimble Site no longer exists. No concentrations of the potential contaminants of concern for this site could remain above the RAGS established in the approved ROD and Remedial Design Report/Remedial Action Work Plan for the 100 Area, RDR/RAWP due to decay of the short-lived radionuclides. These results also indicate that the site will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that the site poses no threat to groundwater or the Columbia River.

Code:	100-B-5	Classification:	Accepted
Names:	100-B-5; 105-B Effluent Vent Trench; 116-B-9; Effluent Vent Disposal Trench	Reclassification:	Interim Closed Out (9/11/2003)
Type:	Trench	Start Date:	1/1/1954
Status:	Inactive	End Date:	1/1/1956
Description:	The site has been remediated and closed out. The site was the result of leakage that occurred at a junction box [probably at the 0.61-meter (2-foot) vent pipe], where the 1.4-meter (54-inch) 100-B Reactor cross tie pipeline effluent joined the 1.7-meter (66-inch) 100-C Reactor pipeline effluent, resulting in contamination of the area (Dorian and Richards).		
Location:	The site was believed to be located east of the 105-B Reactor Building, west of the 100-C Reactor effluent pipeline, north of the 100-B Reactor effluent cross tie pipeline, and north of the junction box where the east-west 100-B effluent pipeline joined the north-south 100-C effluent pipeline. The site location was identified as site number 23 on site drawing H-1-4049.		
Process Description:	The junction box (part of site 100-C-6, 100-C Reactor Cooling Water Effluent Underground Pipelines, but pertinent to this site) was a concrete structure that was 5.6 meters (18.5 feet) long by 5.6 meters (18.5 feet) wide by 8.2 meters (27 feet) deep. The outer walls of the structure were 0.46 meters (1.5 feet) thick. Two sides of the structure were double-walled providing the structure with two chambers. The 1.4-meter (54-inch) 100-B Reactor cross tie pipeline (invert) entered from the west through a double concrete wall, while the 1.7-meter (66-inch) 100-C Reactor pipeline (invert) entered the structure from the south through a single concrete wall. A single 1.7-meter (66-inch) pipeline exited the structure to the north through the double walled portion of the structure. The interior of the structure was accessible via metal ladder rungs. The original structure had a 0.61-meter (2-foot) vent pipe. The vent pipe was located approximately 2.35 meters (7.7 feet) southwest of the southwest corner of the junction box. The vent was above grade 1.4 meters (4.6 feet) and had a valve on the top. A new 0.31-meter (12-inch) vent pipe was added later. The vent pipe was located approximately 2.3 meters (7.5 feet) south and 1.8 meters (6 feet) east of the southwest corner of the junction box. The vent was above grade approximately 1 meter (3.3 feet) (pipe + valve handle) and had a valve handle on the top. The effluent flowed out of the junction box via the 1.7-meter (66-inch) pipeline and downhill (gravity flow since there was no pump station at 100-B) to the retention basins. On the 100-C effluent pipeline north of the junction box about 80 meters (262 feet) was an inspection manhole. The manhole (riser) was marked "Confined Space 063" and "Fixed Contamination Area FCA-B-0003".		
Related Sites/ Structures:	Associated sites include the 100-C-6 and 100-B-8 Reactor Cooling Water Effluent Underground Pipelines.		
Waste Type:	Process Effluent		
Waste	The waste was process effluent contaminated soil. Sample numbers (Dorian and Richards) and		

Description: depths were: B - 4.6, 6.1, 8.4 meters (15, 20, 27.5 feet); C - 3.05 meters (10 feet); D - 4.6, 6.1, 8.4 meters (15, 20, 27.5 feet); E - 4.6, 5.3, 7.6 meters (15, 17.5, 25 feet); F - 4.6, 6.1, 8.4 meters (15, 20, 27.5 feet); H - 6.1 meters (20 feet). Samples were analyzed for plutonium-238, plutonium-239/240, strontium-90, hydrogen-3, europium-152, cobalt-60, europium-154, cesium-234, cesium-137, europium-155, and uranium.

Closure Info: Remedial action objectives (RAOs) and goals (RAGs) for the site were documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100 HR-1, 100 HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP). Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

For the respective points of compliance, remedial action goals (RAGs) were established to identify contaminants of concern (COCs). Waste site COCs identified through process knowledge for the 105-B and 105-C Reactor cooling water effluent pipelines are listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP). Additional pipeline COCs identified during remediation include lead, mercury, total chromium, and hexavalent chromium. Because the site was associated with leaks from the cooling water effluent pipelines, the site COCs and the pipeline COCs are the same. The COCs for the site consisted of the following: americium-241, cesium-137, cobalt-60, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, uranium-238, lead, mercury, total chromium, hexavalent chromium.

At the completion of the remedial action, the total excavation was approximately 4,450 meters squared (47,900 square feet) in area with a maximum depth of 8.5 meters (27.9 feet) below ground surface. Approximately 16,320 metric tons (17,950 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. In addition to the 100-B-5 site, the portions of the 100 B-8 and 100-C-6 Reactor cooling water effluent pipelines beneath the site were remediated with the 100-B-5 site. Cleanup verification of the rest of the adjacent large pipeline sites (100-C-6 and 100-B-8) will be included in the CVPs for those sites.

The CVP has demonstrated that remedial action at the site has met the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicated that the material from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site do not pose a threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The site has been verified to be remediated in accordance with the ROD and may be backfilled.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 100-B-8

Classification: Accepted

Names: 100-B-8; 100-B Reactor Cooling Water Effluent Underground Pipelines **Reclassification:** Interim Closed Out (4/20/2004)

Type: Radioactive Process Sewer **Start Date:** 1/1/1944

Status: Inactive **End Date:** 1/1/1968

Description: The site encompassed the underground 100-B Reactor cooling water effluent pipelines. These included the effluent pipelines that transported 118-B-8 (105-B Reactor) cooling water from the reactor core to the 116-B-11 (107-B) Retention Basin, and from the basin to the 116-B-7 (1904-B) outfall structure. This waste site included all associated expansion and valve boxes and excluded the retention basin, outfall structure, and those effluent pipelines that were within the confines of the 105-B Reactor Building or that run from the outfall structure to the bottom of the river. It also excludes all reactor influent pipelines that are upstream (untreated and treated water pipelines) of the 105-B Reactor Building.

Location: The site included of all the underground reactor effluent lines running from the 105-B Reactor Building to the Columbia River. This includes segments between the reactor building and the retention basin, and between the basin and the outfall structure. It excludes the reactor building (and a 7.6 meter [25 foot] buffer zone for the B Reactor Museum), retention basin, and outfall structure, each of which is treated as a unique waste site. Also included are the cross-tie underground lines (one north and one south) that connect the 100-B Reactor effluent system to the 100-C Reactor effluent system (100-C-6).

Process Description: Effluent water passed from the reactor rear face and gravity flowed through the underground effluent pipelines, junction boxes and diversion boxes to the retention basins where it was held up for a short period of time to allow thermal and radiological cooling before being released through the outfall structure to the Columbia River. During periods of reactor fuel cladding ruptures, some effluent was diverted to an open trench.

Related Sites/Structures: Related structures include the 116-B-11 (107-B) Retention Basin, the 116-B-7 (1904-B) Outfall, the 105-B Reactor, the 100-C-6 Effluent Pipelines, and the 100-B-15 River Pipelines.

Waste Type: Process Effluent

Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil. Reactor cooling water became radioactively contaminated as it passed through the reactor core. Activation products created in the water included calcium-41, chromium-51, and zinc-65. Activation products from the reactor core that were picked up and transported by the cooling water included tritium, carbon-14, cobalt-60, nickel-63, and europium-152/154/155. Fuel element fission products, such as strontium-90, and cesium-137, as well as transuranics such as plutonium-239/240 were introduced into cooling water due to fuel cladding failures. Concentrations of radionuclides in cooling water during normal reactor operations were approximately 0.2 microcuries/liter. Concentrations of radionuclides have built up in rust flakes and scale on the inner surfaces of the pipelines and in sludge in the diversion and junction boxes. Average beta-gamma concentrations for the effluent pipeline scale and junction/diversion boxes were 83,000 and 120,000 picocuries/liter, respectively. Average plutonium-239/240 concentrations were 66 picocuries/gram for the effluent pipeline scale and 720 picocuries/gram for the sludge at the bottom of the diversion and junction boxes. Direct readings of the bottom of the effluent pipelines averaged approximately 40,000 counts/minute with a Geiger-Mueller probe. Additional chemicals were added to the effluent for purposes of water treatment. These included aluminum sulfate (alum), with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter.

This Site has the Following SubSites:

Code: 100-B-8:1

Names: 100-B-8:1; 100-B Area South Effluent Pipelines

Code: 100-B-8:2
Names: 100-B-8:2; 100-B Area North Effluent Pipelines

Code: 100-B-8:1 **Classification:** Accepted
Names: 100-B-8:1; 100-B Area South Effluent Pipelines **Reclassification:** Interim Closed Out (4/20/2004)
Type: Radioactive Process Sewer **Start Date:**
Status: Inactive **End Date:**

Description: Cleanup Verification Package 2003-00022 (CVP) has documented completion of remedial action for the 100-B-8:1 subsite. The CVP demonstrated that remedial action at the 100-B/C south pipelines site had achieved remedial action objectives (RAOs) and goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

The site included the underground 105-B Reactor effluent pipelines running from within 7.5 meters (25 feet) of the reactor building north to B Avenue, including all associated expansion joints and valve boxes. Also included are the cross-tie underground lines that connected the 105-B Reactor effluent system to the 105-C Reactor effluent pipeline system. Sites that are excluded from the CVP are the associated retention basin and outfall structure, which was treated as unique waste sites. The 105-B Reactor effluent pipeline subsites (100-B-8:2) are located north of B Avenue and were addressed in a separate CVP.

Location: Subsite 100-B-8:1 includes the underground effluent pipelines surrounding the 105-B Reactor (excluding a 7.6 meter [25 foot] buffer zone around the reactor foundation), and running north from the reactor to B Avenue, including all associated expansion joints and valve boxes.

Waste Type: Not Specified

Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Closure Info: 100-B-8:1 and 100-C-6:1 were addressed as a group. The information below documents information for the group of sites.

Cleanup Verification Package 2003-00022 (CVP) has documented completion of remedial action for the 100-B-8:1 subsite and the 100-C-6:1 subsite. Also included are the cross-tie underground lines that connected the 105-B Reactor effluent system to the 105-C Reactor effluent pipeline system. The CVP demonstrated that remedial action at the 100-B/C south pipelines site had achieved remedial action objectives (RAOs) and goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Remedial action objectives and goals for the 100-B/C south pipelines site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. For the 100-B/C south pipelines site, these goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.

Waste site contaminants of concern (COCs) identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP). The original COCs

identified in the sampling and analysis plan for this site consisted of americium-241, cesium 137, cobalt-60, europium-152, europium-154, europium-155, plutonium-238, plutonium 239/240, strontium-90, and uranium-238.

Based on the results of sampling during 100-B/C pipeline and outfall remediation, lead, mercury, total chromium, and hexavalent chromium were added to the original COC list as contaminants of potential concern. Since in-process sample analyses returned detected results for all four analytes, they were retained and evaluated as COCs throughout the CVP. The final COC list for this site, therefore, consisted of the following: americium-241, plutonium-239/240, cesium-137, strontium-90, cobalt-60, uranium-238, europium-152, lead, europium-154, mercury, europium-155, total chromium, plutonium-238, hexavalent chromium.

Cleanup verification samples including QA/QC samples consisted of 50 shallow zone samples, 11 deep zone samples, 56 overburden samples. The final verification samples were collected between November 10, 2003, and concluded on November 19, 2004, and were analyzed for the established COCs. The numerous sample numbers were listed in appendix A of CVP-2003-00022 and also in the HEIS database.
100-B-8:1 and 100-C-6:1

At the completion of remedial action, the excavation was approximately 48,260 meters squared (519,466 square feet) in area. Approximately 244,656 metric tons (269,742 tons) of material, including soil, debris, and piping were removed from the 100-B/C south pipelines site and disposed of at the Environmental Restoration Disposal Facility.

The remaining soils at these sites have been sampled, analyzed, and modeled, while contaminated material has been excavated and disposed at ERDF. These results also indicated that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The site was verified to be remediated in accordance with the ROD and may be backfilled.

The SubSite is Part Of:

Code: 100-B-8

Names: 100-B-8; 100-B Reactor Cooling Water Effluent Underground Pipelines

Code: 100-B-8:2

Classification: Accepted

Names: 100-B-8:2; 100-B Area North Effluent Pipelines

Reclassification: Interim Closed Out (2/17/2004)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: Cleanup Verification Package 2003-00019 (CVP) documented completion of remedial action for the 100-B/C Effluent Pipeline subsites located north of B Avenue (100-B-8:2, 100-C-6:2, 100-C-6:3, and 100-C-6:4) (collectively referred to as the 100-B/C north pipelines site). The 100-B-8:2 subsite portion includes the 105-B Reactor effluent pipelines from B Avenue north to the 116-B-11 Trench (labeled as pipelines 3 and 4 in Figures 2 and 3 of the CVP), the pipelines from the 116-B-11 Retention Basin to the 116-B-7 Outfall (located just north of pipelines 3 and 4 terminations, Figures 2 and 3 of the CVP), and the east-west connecting pipeline from 100-B-8:2 to the diversion box for the 100-C-6 pipelines, which was just south of the 116-C-5 Retention Basin (labeled as pipeline 11 in Figures 2 and 3). It also includes the pipeline

connecting this diversion box to the 116-C-5 Retention Basin (labeled as pipeline 25 in Figures 2 and 3) and the northernmost section of pipe 11 (Figures 2 and 3) that drained into the 116-C-5 Retention Basin; these pipelines were removed and backfilled but not entirely sampled as part of the 116-C-5 remedial action (BHI 1997).

Cleanup verification for pipes 11 and 25 were conducted as part of CVP-2003-00019. Drawings identifying previous sampling locations were used to ensure that pipe 11 and pipe 25 corridors were excavated to below clean backfill elevations prior to verification sampling.

Location: These pipelines were north of the 105-B Reactor, north of B Avenue to the outfall structure.

Waste Type: Not Specified

Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Closure Info: 100-B-8:2, 100-C-6:2, 100-C-6:3 and 100-C-6:4 were addressed as a group. The information below documents information for the group of sites.

Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide contaminants of concern (COCs).

Waste site COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE RL 2001). The COCs identified in the sampling and analysis plan for this site consisted of americium-241, cesium 137, cobalt-60, europium-152, europium-154, europium-155, plutonium-238, plutonium 239/240, strontium-90, and uranium-238.

Based on verification sampling results from the 100-B/C outfalls site, total chromium, hexavalent chromium, lead, and mercury were added to the original COC list as contaminants of potential concern (COPC). Since verification sample analyses returned detected results for all four analytes, they were retained and evaluated as COCs.

Cleanup verification samples including QA/QC samples consisted of 193 shallow zone samples, 104 deep zone samples, 260 overburden samples, and 72 discovery area samples. The final verification samples were collected between August 12, 2002, and concluded on July 24, 2003, and were analyzed for the established contaminants of concern. The sample numbers are too numerous to list and as of March 2004 have not been reported to HEIS, however they are available in appendix A of CVP-2003-00019 .

At the completion of remedial action, the excavation was approximately 135,000 meters squared (443,000 square feet) in area with an average depth of approximately 7.5 meters (25 feet). Approximately 244,656 metric tons (269,742 tons) of material including soil, debris, and piping were removed from the 100 B/C north pipelines site and disposed at the Environmental Restoration Disposal Facility.

The CVP demonstrated that remedial action at the 100-B/C north pipelines site had achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1995), and in the RDR/RAWP (DOE RL 2002). The remaining soils at these sites have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-B-8:2, 100-C-6:2, 100 C-6:3, and 100-C-6:4 sites that contained COCs at concentrations exceeding RAGs have been excavated and disposed of at ERDF.

These results also indicate that residual concentrations in the shallow zone and discovery areas will support future land uses that can be represented (or bounded) by a rural-residential

scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

The SubSite is Part Of:

Code: 100-B-8

Names: 100-B-8; 100-B Reactor Cooling Water Effluent Underground Pipelines

Code: 100-B-10

Classification: Accepted

Names: 100-B-10; 107-B Basin Leak and Warm Springs

Reclassification: No Action (4/11/2002)

Type: Unplanned Release

Start Date: 1/1/1949

Status: Inactive

End Date:

Description: The site is an unknown location along the Columbia River shoreline. It was reported in February 1949 as a warm springs below the 116-B-11 Retention Basin, and was attributed to leaks in the wall of the north basin. This spring no longer exists and the precise location is unknown. The groundwater that fed the spring is a separate Operable Unit (100-BC-5).

Location: The springs were observed along the Columbia River below the 100-B Area Retention Basin (116-B-11).

Process Description: In 1991 in preparation for a spring sampling study, the entire shoreline of the River in the 100 Areas was searched for springs. Three were found at the 100-BC Area, all upstream (about 700 meters [2,300 feet] of the estimated location of this spring. No springs were found below the 116-B-11 Retention Basin. The reported spring is assumed to have stopped flowing after the basins were shut down.

Related Sites/ Structures: The springs were attributed to leaks in the walls of the north basin at 107-B (116-B-11).

Waste Type: Water

Waste Description: A sample of the water showed beta activity of 4E-03 microcuries/liter.

Code: 100-B-11

Classification: Accepted

Names: 100-B-11; 115-B Tank; 115-B/C Caisson Site; 115-B/C Caisson Valve Pit; 115-BC Drywell; 115-BC Sump

Reclassification: No Action (7/15/2004)

Type: Storage Tank

Start Date: 1/1/1944

Status: Inactive

End Date: 1/1/1969

Description: The site has been demolished and is no longer discernible from the surrounding area. The site was a steel pipe structure (caisson) about 1.2 meters (4 feet) in diameter and 1.5 meters (5 feet) deep with a bottom and a steel plate placed over the top. The site was self contained without any incoming or outgoing piping. This caisson was identified during a pre-demolition walk-through of the 115-B/C Gas Recirculation Building.

Location: The site was located just east of the 115-B/C Building Dryer Room #1 and approximately 60 meters (197 feet) south-southeast of the 105-B Reactor Building.

Release Description: The releases to the caisson are unknown. Sample results taken of soil from underneath and near the sides of the caisson were below Washington Administrative Code (WAC) limits for

chromium.

Related Sites/ Structures: The site was probably related to the 115-B/C Gas Recirculation Facility (132-B-5) that was demolished in 1989. The caisson was contaminated with sodium dichromate. Sodium dichromate was not normally used at the 115 B/C Gas Recirculation Facility.

Waste Type: Soil

Waste Description: Originally, the caisson contained a yellowish-colored soil which was sampled for pH and EP toxic metals. Sample results indicated a pH of 8 and 72,500 milligrams/liter of chromium. Additional samples were taken (after caisson removal) from soil directly underneath and around the outside of the caisson. Results from these samples showed chromium levels ranging from 0.08 milligrams/liter to 9.14 milligrams/liter. The caisson contained approximately 0.37 cubic meters (13 cubic feet) of chromate contaminated soil.

Closure Info: Confirmatory sample results taken September 2003 demonstrated that the site achieved remedial action objectives and remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units, commonly called the Remaining Sites Record of Decision (EPA 1999). These results show that residual concentrations will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations supported unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]), and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not have a deep zone, therefore, no deep zone institutional controls are required.

Code: 100-B-12 **Classification:** Accepted

Names: 100-B-12; Filter Box Radiological Materials Area (RMA) **Reclassification:** Interim Closed Out (5/31/2001)

Type: Storage **Start Date:**

Status: Inactive **End Date:**

Description: The location is a gravel field with sparse, weedy vegetation that matches the rest of the fenced 100-BC area. The site was a Radiological Materials area (RMA) with four metal boxes containing filters, that rested on shoring that sat on the bare soil. An additional six filter frames, marked as having fixed contamination, rested directly on the soil.

Location: The site is in the northwest corner of the 100-BC Area, at the approximate coordinates of 565000E and 144800N.

Waste Type: Equipment

Waste Description: The radiological contamination is fixed on the filter frames.

Closure Info: This site has been closed out. The filter boxes were removed, and the site was surveyed and downposted.

Code: 100-B-14 **Classification:** Accepted

Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines **Reclassification:** Interim Closed Out (3/1/2007)

Type: Process Sewer **Start Date:** 1/1/1944

Status: Inactive **End Date:** 1/1/1969

Description: The waste site encompassed pre-reactor underground process and sanitary pipelines and sewers, and was divided into seven subsites for decision-making purposes based on functional use and geographical location. The subsites included: 1) Main Process Sewer Collection Pipelines, 2) Sanitary Sewer Pipelines, 3) West Process Sewer Feeder Pipelines from 182-B and 183-B, 4) Cooling Water Pipelines and Tunnels from 190-B, 5) Sodium Dichromate and Sodium Silicate Pipelines, 6) Process Sewer Feeder Pipeline from 184-B and 184-B Ash Slurry Line, and 7) Process Sewer Feeder Pipelines from 185-B and 190-B.

Location: These pipelines were mostly north and west of the 105-B Reactor and north of the 183-B Filter House. Most joined to empty into the 116-B-7 Outfall. Others emptied into the 126-B-1 Power House Ash Pit, and the 1607-B2 and 1607-B7 Septic Systems. The sodium dichromate pipeline connected the 108-B Laboratory and the 190-B building, and the treated reactor cooling water ran from the 190-B Facility to the 105-B Reactor.

Process Description: These pipelines carried a variety of non-radioactive waste fluids, product (sodium dichromate), treated cooling water (pre-reactor), and sewage.

Related Sites/ Structures: Buildings associated with these pipelines included the 105-B Reactor, 190-B Facility, 108-B Laboratory, 182-B and 183-B Filter Buildings, 184-B Power House, 115-B Filter House, and 1700-Series support buildings.

Waste Type: Equipment

Waste Description: The waste site consisted of abandoned process and sanitary sewer pipelines, and residual chemicals remaining on the pipes. Chemical additives to the reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, the free chlorine residual was approximately 0.2 milligrams/liter, and sodium dichromate was added at a rate of about 2 milligrams/liter. One length of the product piping held undiluted sodium dichromate: the pipe from the 185-B/190-B to the 108-B Building (per drawing M2913, Sheet 5). This pipeline was in use only for a few years, until the sodium dichromate was added to the cooling water at the 185-B Building. (Note: Reference: WHC-SD-EN-TI-169 is for 100-F, and applies equally to 100-B).

This Site has the Following SubSites:

Code: 100-B-14:1

Names: 100-B-14:1; Main Process Sewer Collection Pipelines

Code: 100-B-14:2

Names: 100-B-14:2; Sanitary Sewer Pipelines

Code: 100-B-14:3

Names: 100-B-14:3; West Process Sewer Feeder Pipelines from 182-B and 183-B

Code: 100-B-14:4

Names: 100-B-14:4; Cooling Water Pipelines and Tunnels from 190-B

Code: 100-B-14:5

Names: 100-B-14:5; Sodium Dichromate and Sodium Silicate Pipelines

Code: 100-B-14:6

Names: 100-B-14:6; Process Sewer Feeder Pipeline from 184-B and 184-B Ash Slurry Line

Code: 100-B-14:7

Names: 100-B-14:7; Process Sewer Feeder Pipelines from 185-B and 190-B

Code: 100-B-14:1

Classification: Accepted

Names:	100-B-14:1; Main Process Sewer Collection Pipelines	Reclassification:	Interim Closed Out (2/22/2007)
Type:	Process Sewer	Start Date:	
Status:	Inactive	End Date:	
Description:	The main process line site consists of 1270 m (4166 ft) of pipe ranging from 0.3 m (12 in.) diameter vitrified-clay pipe to 1.82 m (72 in) diameter reinforced concrete pipe (RCP).		
Location:	The subsite consisted of the reinforced concrete process sewer main that formerly serviced the 105-B Reactor Building; the 108-B Chemical Pumphouse and Tritium Separation Facility; and 100-B water treatment facilities then discharged to the 116-B-7 Outfall Structure. Vitrified clay feeder pipelines associated with the 108-B facility were also included in the subsite.		
Waste Type:	Not Specified		
Waste Description:	The waste site consists of abandoned process and sanitary sewer pipelines, and residual chemicals remaining on the pipes.		
Closure Info:	Remedial action and evaluation of the 100-B-14:1 subsite has been documented in the Remaining Sites Verification Package (RSVP) (RSVP-2004-005). The subsite has met the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD).		

Remediation of the subsite was performed from January 2005 through April 2006 as part of the 100-B/C Area Remaining Pipes and Sewers remediation. In general, remediation of the pipelines consisted of the excavation and stockpiling (on-site) of overburden soils presumed to contain no residual contamination above cleanup levels; removal of soils around and approximately 0.3 meters (1 foot) below the pipelines; and disposal of the pipeline and suspect potentially contaminated soil at the Environmental Restoration Disposal Facility (ERDF).

Excavation at the upgradient (southeastern) end of the pipeline near the former 108-B facility was restricted within the shallow zone (less than 4.6 meters [15 feet] below ground surface [bgs]), and extended into the deep zone further downgradient, near the influent of the feeder line associated with the 105-B Reactor Building. The maximum depth of excavation was approximately 7.6 meters (25 feet) bgs, near the outfall of the pipeline at the northern end of the site. Due to co-location and concurrent remediation of differing functional pipeline groups, excavated and disposed material quantities could not be explicitly separated for the subsite. Following a determination that cleanup criteria had been attained, the excavation was backfilled with stockpiled overburden and borrow material. Railroad rails discovered and stockpiled during excavation of the site were also backfilled in the western portion of the excavation.

The Contaminants of Potential Concern (COPCs) for confirmatory sampling at the subsite were identified based on existing analytical data and process knowledge of the facilities serviced by the sewer system. The COPC list included metals, hexavalent chromium, semivolatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), and alpha-, beta-, and gamma-emitting radionuclides. Additional isotope-specific analysis was also performed for one confirmatory sample based on the results of initial radionuclide analyses.

The results of confirmatory sampling were used to determine the contaminants of concern (COCs) for verification sampling. Site COCs included carbon-14, cesium-137, cobalt-60, europium-152, europium-154, europium-155, and hexavalent chromium. Tritium was also included as a COC for the deep zone only because the process sewer formerly serviced the 108-B Tritium Separation Facility and this radionuclide was detected in a confirmatory sample

collected from the pipeline, but was mistakenly not included in analyses performed for underlying soils.

Initial cleanup verification sampling was conducted concurrently with variance sampling from May 30 to June 19, 2006. Additional verification sampling for carbon-14 in stockpiled overburden material was conducted from September 19 to 29, 2006. All verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency analytical methods as required per the Sampling and Analysis Plan (SAP). Based on process knowledge and the results of the confirmatory sampling activity for the subsite, this pipeline received radioactive waste stream discharges. Accordingly, the radioactive liquid waste effluent sites cleanup and closeout approach was implemented for the site, as described in the SAP.

Subsite Verification sample data were provided by the laboratories in 23 sample delivery groups (SDGs). The samples were listed by SDG in Table 8 of the RSVP. The SDGs K0388 and K0584 were submitted for third-party validation. No major deficiencies were identified in the analytical data set, all of which is acceptable for decision-making purposes. Samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency (EPA), and the results were compared against the cleanup criteria specified in the RDR/RAWP. The results were stored in the Washington Closure Hanford Environmental Restoration (ENRE) project-specific database prior to being provided to the Hanford Environmental Information System (HEIS).

Based on statistical evaluation of the resulting verification sampling data, the residual contaminant concentrations meet the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD.

The results of verification sampling illustrated that residual contaminant concentrations does not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. The acceptability of unrestricted exposure to deep zone portions of this site has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling/excavation are necessary.

The SubSite is Part Of:

Code: 100-B-14

Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-14:2

Classification: Accepted

Names: 100-B-14:2; Sanitary Sewer Pipelines

Reclassification: Interim Closed Out (3/21/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite includes septic sewer pipelines servicing several buildings and areas:

The 115-B Gas Recirculation sanitary sewer site consists of approximately 311 meters (1020 feet) of 20 centimeter (8 inch) vitrified clay sewer pipe;

The 190-B Pumphouse was serviced by 10, 15, and 20 centimeter (4, 6 and 8 inch) vitrified clay sewer pipes of various lengths;

The 183-B Water Treatment facility was serviced by a 200 meter (660 feet) long, 20 centimeter (8 inch) vitrified clay sewer pipe;

The 1700-B Series Support Buildings and 108-B Building were serviced by 15 and 20

centimeter (6 and 8 inch) vitrified clay pipes of various lengths.

Location: The pipelines in this subsite are located in four areas: east of the 183-B Clearwells; north and east of the 190-B Pumphouse; leaving the 115-B Gas Recirculation Facility and extending to the north on the east side of the 105-B Reactor; and at the 108-B Building and 1700-B Series support buildings about 150 meters (500 feet) north of the 105-B Reactor. The segments are mapped in the WCH Geographic Information System (GIS) database.

Waste Type: Not Specified

Waste Description: the waste is the sanitary sewer pipelines, pipeline contents, pipeline debris, and surrounding soils

Closure Info: 1607-B2 and 100-B-14:2 were addressed as a group. The information below documents information for the group of sites.

The Remaining Sites Verification Package (RSVP) 2006-055 for 1607-B2 and 100-B-14:2 has documented that the current site conditions supported a reclassification to interim closed out. Evaluations and verification sampling results for the RSVP demonstrated that the sites have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site (Remaining Sites ROD).

Remediation of the 100-B-14:2 and 1607-B2 waste sites was performed in stages from January 2005 through June 2006 as part of the 100-B/C Area Remaining Pipes and Sewers remediation project. All excavation was restricted within the shallow zone (less than 4.6 meters [15 feet] bgs), with an average depth of approximately 2.5 meters [8 feet] bgs, and a maximum depth of approximately 4 meters [13 feet] bgs at the septic tank. Excavation at the northern portion of the site continued to greater depth due to concurrent remediation of the underlying 100-B-14:1 process sewer. Excavated and disposed material quantities could not be explicitly separated for each site due to co-location and concurrent remediation of differing functional pipeline groups.

The SubSite is Part Of:

Code: 100-B-14

Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-14:3

Classification: Accepted

Names: 100-B-14:3; West Process Sewer Feeder Pipelines from 182-B and 183-B

Reclassification: No Action (6/4/2004)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The subsite consisted of the process sewer pipelines that exited from the 182-B reservoir and 183-B water treatment facilities. These process sewer lines were collected into a single 1.67 meter (5.5-foot) reinforced concrete box sewer that fed into the main process sewer collection line serving the 185-B/190-B Pumphouse, 105-B Reactor, and the 108-B Tritium Separation Facility. The basis for separating this subsite from the main process sewer line was that these lines carried effluent from facilities known to be potential sources of radioactive and chemical contaminants.

Location: These pipelines are located north of the 182-B and 183-B facilities, as well as between the 182-B and 183-B buildings, and east of the 183-B Clearwells. The individual pipeline segments are mapped in the WCH Geographic Information System (GIS) database.

Waste Type: Not Specified

Waste Description: The waste includes the pipelines and the contaminated scale contained within them.

Closure Info: A focused sampling approach was selected for this site, biased toward worst-case sample locations and locations that were accessible. Results of the sampling event were used to make decisions for reclassification of the site in accordance with the Waste Site Reclassification Guideline TPA-MP-14 (RL-TPA-90-0001).

Confirmatory sampling was conducted in October 2003. The sampling approach consisted of collecting three samples of pipe scale material from each of three manholes and one soil sample from below one manhole/pipe. The maximum detected results from the scale and soil samples were used to support waste site reclassification. A summary of the evaluation of the scale and soil sample results were compared against the applicable remedial action goals (RAGs).

The sample results demonstrated that the subsite has achieved the remedial action objectives and remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (commonly called the Remaining Sites Record of Decision). These results indicated that scale in the pipelines and associated residual soil concentrations support future unrestricted land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future use of vadose zone soil and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. Because all results attained the direct exposure remedial action goals (RAGs), deep zone institutional controls are not required.

The SubSite is Part Of:

Code: 100-B-14

Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-14:4

Classification: Accepted

Names: 100-B-14:4; Cooling Water Pipelines and Tunnels from 190-B

Reclassification: No Action (9/16/2004)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite included the pipes and tunnels from the 190-B Building to the road east of the 105-B Reactor. There were twin tunnels at each reactor. The tunnel dimensions varied, but were about 3.3 m wide by 3.6 m high (10 ft by 12 ft). They covered a distance of about 140.2 m (460 ft) from the pumphouses to the reactor. Each tunnel from the 190-C pumphouse held one 20.3 cm (8 in) steam line and three 61 cm (24 in) water pipes. Each tunnel from the 190-B pumphouse and annex held twelve 30.5 cm (12 in), and two 45.7 cm (18 in) pipelines for cooling water to the 105-B Reactor. The pipes from the edge of the road to the reactor should be included in 118-B-8, as they cannot be removed until the reactor is addressed.

Location: This subsite includes the pipes and tunnels from the 190-B Building to the road east of the 105-B Reactor, and from the edge of the road to the reactor.

Waste Type: Not Specified

Waste Description: The waste includes the pipelines, and their contents (scale, sediment).

Closure Info: The Cooling Water Pipe Tunnels Site meets the Remedial Action Objectives specified in the

Remaining Sites ROD, U.S. Environmental Protection Agency, Region 10, Seattle, Washington. The pipelines were removed and the tunnels collapsed in 1993 during deactivation and decommissioning of the 190-B pump house. There is no history of radiological contamination associated with the 100-B Reactor cooling water tunnels and no radiological contamination was detected during decommissioning of the tunnels. There were no known process incidents at 105-B Reactor that would have introduced radiological contamination from the reactor into the tunnels. Additionally, since the 105-B cooling water tunnels had the same source of water as the 105-C cooling water tunnels, the 105-B tunnels were analogous to the 105-C tunnels.

Historical sampling indicated that no unacceptable levels of residual hexavalent chromium existed in the 105-C tunnels. The pipelines were removed and the remaining concrete at the site was analogous to concrete in the 105-C cooling water tunnels. The 105-C tunnels have been determined to meet the cleanup criteria, therefore the site also meets the cleanup criteria and the remaining contaminant levels were protective of groundwater and the Columbia River. All samples were less than the criteria of 2.0 mg/kg for protection of groundwater and Columbia River.

The SubSite is Part Of:**Code:** 100-B-14**Names:** 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines**Code:** 100-B-14:5**Classification:** Accepted**Names:** 100-B-14:5; Sodium Dichromate and Sodium Silicate Pipelines**Reclassification:** No Action (6/3/2004)**Type:** Process Sewer**Start Date:****Status:** Inactive**End Date:****Description:** The subsite consisted of the sodium dichromate and sodium silicate product pipelines that transferred product from 108-B Building to 185/190-B facilities.**Location:** These pipes exit the northwest side of the 108-B Facility and connected to the north side of the 185-B Facility. The pipes make three 90-degree corners in a step like fashion with north-south and east-west sections. Exact depth below grade is unknown, but is believed to be within 3 m (10 ft) of the surface.**Waste Type:** Not Specified**Waste Description:** The waste includes the pipelines, and their contents (scale, sediment).**Closure Info:** Confirmatory sampling was conducted in October 2003. The original sampling approach consisted of collecting one sample of pipe scale and one soil sample from below each pipe at two sampling locations. Since no scale or sediment was found in the piping at the selected locations, two alternative soil locations along the piping were sampled. The maximum detected results from soil samples were used to support waste site reclassification.

The sample results demonstrated that the subsite has achieved the remedial action objectives and remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (commonly called the Remaining Sites Record of Decision). These results show that any residual soil concentrations support future unrestricted land uses that can be represented (or bounded) by a rural residential scenario. The results demonstrated that

residual concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]), and that contaminate levels remaining in the soil were protective of groundwater and the Columbia River. The site does not have a deep zone, therefore, institutional controls are not required.

The SubSite is Part Of:

Code: 100-B-14

Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-14:6

Classification: Accepted

Names: 100-B-14:6; Process Sewer Feeder Pipeline from 184-B and 184-B Ash Slurry Line

Reclassification: No Action (6/4/2004)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite included the process sewer pipelines from the 184-B Powerhouse, flowing north to the ash pit, and flowing east to the main trunk line (100-B-14:1) on both the north and south sides of the powerhouse. The underground piping for the 184-B Powerhouse included sanitary (clean) waterlines, a sanitary sewer line and process sewer lines. These pipelines consist of: Sanitary waterline pipelines: These pipelines consist of sanitary water pipelines, filtered water pipelines, and raw and condensor water pipelines. Proceeding from west to east along the south side of the building the pipelines include: 1607-B-3 Sanitary Sewer Pipeline: This piping is a 20.3 cm (8 in) diameter vitrified clay pipe that exited the northwest corner of the 184-B Powerhouse to the 1607-B-3 Septic Tank. 184-B Powerhouse Ash Pipeline: This pipeline is an 20.3 cm (8 in) diameter ashcolite pipe that was used to discharge coal ash that was mixed with raw water and sluiced from the 184-B Powerhouse to the 126 B Ash Pit. 184-B Process Sewer Pipelines: There are four locations where process sewer pipelines exit the 184-B Powerhouse and eventually discharge into the main 100-B-14 Process Sewer Pipeline connecting to the 116-B-7 Outfall. There is also a pipeline that discharges from the powerhouse blow-off tank into the 184-B Process Sewer Pipelines. These pipelines required confirmatory sampling and included: Two pipelines, a 15.2 cm (6 in) diameter vitrified clay pipe and a 20.3 cm (8 in) diameter vitrified clay pipe, both on the left south side of the building, that discharged into a 30.5 cm (12 in) diameter vitrified clay pipe and eventually into the main process sewer line. A 30.5 cm (12 in) diameter steel pipe near the center south side of the building that discharged into a 130.5 cm (2 in) diameter vitrified clay pipe and eventually into the main process sewer line. A 38.1 cm (15 in) diameter vitrified clay pipe on the north side of the building that discharged directly into the main process sewer pipeline.

Location: Process Sewer Pipelines exited the 184-B Power House and eventually discharged into the main 100-B-14 process sewer pipeline connecting to the 116-B-7 outfall.

Waste Type: Not Specified

Waste Description: The waste was the remaining pipelines and any potentially contaminated soil.

Closure Info: Confirmatory sampling was conducted in September and October 2003. The maximum detected results from the scale and soil samples were used to support waste site reclassification.

The Waste Site Evaluation for 184-B Powerhouse Pipelines sample results demonstrated that the site has achieved the remedial action objectives and remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington, commonly called the

Remaining Sites Record of Decision. These results indicated that scale and associated residual soil concentrations support future unrestricted land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual contaminant concentration supports unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]), and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

The SubSite is Part Of:

Code: 100-B-14

Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-14:7

Classification: Accepted

Names: 100-B-14:7; Process Sewer Feeder Pipelines from 185-B and 190-B **Reclassification:** No Action (6/3/2004)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite consisted of the pipelines that were used to control the temperature of process water used in association with the 185-B Deaeration Building and the 190-B Pumphouse. The pipelines were from the south side of the 185-B and 190-B facilities and ended at the sump on the southeast corner of 190-B. The subsite included the sump. The sump was a 14.3 m by 10.4 m by 4.6 m deep (47 ft by 34 ft by 15 ft deep) reinforced concrete reservoir, and was open to the environment. An 80 m (260 ft) long, 61 cm (24 in) diameter cast-iron pipe exited the south side of the 185-B Building and fed the sump. A 10 m (30 ft) long, 76 cm (30 in) diameter cast-iron pipe that exited the south side of the 190-B Pumphouse joined this pipe. The pipe entered the sump on the south side near the west corner at approximately 3 m (9 ft) below ground surface (coordinates N 144444.427; E 565173.872).

Location: These pipelines and sump are on the south side of the 185-B and 190-B facilities.

Waste Type: Not Specified

Waste Description: the waste is the pipelines, and their contents, and the 190-B sump.

Closure Info: Confirmatory sampling was conducted during October 2003. The contaminants of potential concern (COPCs) were identified based on existing analytical data, historical process information, and historical uses and practices associated with the 185 B/190-B sump and pipeline facilities. The COPCs included inductively coupled plasma (ICP) metals, mercury, and hexavalent chromium. At the location where a 46-centimeter (18-inch) pipe entered the sump, some suspect fibrous insulating material was observed. This fibrous material was sampled for asbestos analysis. The absence of radionuclide contamination was confirmed using gamma energy analysis (GEA) and gross alpha and gross beta analyses. On this basis, no radionuclide COPCs were identified for this site.

The Remaining Sites Verification Package (RSVP-2004-011) demonstrated that the site had achieved the remedial action objectives and remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, commonly called the Remaining Sites Record of Decision. These results document that pipe scale and associated residual soil concentrations supported future unrestricted land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual concentrations supported unrestricted future use of

shallow zone soil (i.e., surface to 4.6 meters [15 feet]), and contaminant levels remaining were protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

The SubSite is Part Of:

Code: 100-B-14

Names: 100-B-14; 100-B Area Process and Sanitary Sewer Underground Pipelines

Code: 100-B-15

Classification: Accepted

Names: 100-B-15; 100BC River Effluent Pipelines;
100BC River Lines

Reclassification: None

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This site includes the 100-B/C Area river effluent pipelines (river lines) that extend from each of the three outfalls into the main channel of the Columbia River.

Location: The river lines are located in the Columbia River, adjacent to the 100BC area. The lines extend north into the main channel of the river from three outfall structures located near the river shore.

Process Description: The river effluent pipeline from 116-B-7 (1904-B1) provided for the discharge of reactor cooling water and the B Area process sewers until 1955. After that time, it provided only for the discharge of B Area process sewers, and reactor cooling water was rerouted through a new, higher capacity 132-B-6 (1904-B2) pipeline. In 1952 the 1904-C pipelines (and the 132-C-2 outfall) discharged reactor cooling water for the new C Reactor and C Area process sewers. In the event any of the pipelines became plugged or had to be removed from service during operation, the effluent overflowed the effected outfall and entered the river via an attached spillway.

Related Sites/ Structures: The site is associated with the 116-B-7 (1904-B1 outfall), 132-B-6 (the 1904-B2 outfall), and 132-C-2 (the 1904-C outfall); the 100-B Reactor Cooling Water Effluent Underground Pipelines (100-B-8), the 100 B Area Process and Sanitary Sewer Underground Pipelines (100-B-14), the 100-C Reactor Cooling Water Effluent Underground Pipelines (100-C-6), and the 100-C Area Process and Sanitary Sewer Underground Pipelines (100-C-9); the 107-B Retention Basin (116 B-11), the 107-B Liquid Waste Disposal Trench (116-B-1), the 107-C Retention Basins (116-C-5), and the 107-C Liquid Waste Disposal Trench; and 100-B-24 (the 1904-B1 Spillway), 100-B-25 (the 1904-B2 Spillway), 100-B-26 (and the 1904 C Spillway).

Waste Type: Process Effluent

Waste Description: The waste includes the pipelines and the contaminated scale contained within them.

Contaminants of concern/potential concern are based on those for the outfalls themselves. They include americium-241, cesium-137, cobalt-60, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, tritium, uranium-234, uranium-235, uranium-238, hexavalent chromium, total chromium, mercury, and lead.

Code: 100-B-16

Classification: Accepted

Names: 100-B-16; Utility Poles and Fixtures Debris Pile

Reclassification: Interim Closed Out (6/29/2005)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: The site has been remediated and interim closed out.

Location:	(328 feet) west of Beaver Ave. The southern debris pile was directly south of Bell Ave. 90 meters (295 feet) and 95 meters (311 feet) west of Beaver Ave. Both areas were northwest of the 105-B Reactor.
Process Description:	The site consisted of four surface debris piles. Two piles were situated north of Bell Ave, the other two were directly south and across Bell Ave. The surface debris materials were composed of telephone poles (most of which were grouped together) and associated utility debris in piles adjacent to the telephone poles. Associated debris included unsheathed wire ropes, metal light poles, aluminum utility framing, rubber-insulated wires, ceramic insulators, broken light bulbs, light fixtures, lead bolts, and other wood pieces (including pressure-treated lumber).
Waste Type:	Misc. Trash and Debris
Waste Description:	The waste includes creosote-treated wood poles and cross beams, lead-tipped bolts and other debris. A few small boxes were seen that could be transformers. The possible transformers do not seem to be leaking any oil. Other debris included particle board, conduit, light fixtures, wire, insulators, junction boxes, chain link fencing and incandescent light bulbs.
Closure Info:	Remedial action activities for the site began November 11, 2004 until November 19, 2004. During remediation of the site all of the debris piles were removed. The material was collected, sorted, and disposed of at Environmental Restoration Disposal Facility. Following remediation, verification sampling was conducted on January 25, 2005.

Analytical results of the verification samples (J02FN3) collected in sample location 4 exceeded the asbestos criteria; consequently, additional remediation was warranted for this site. After additional remediation on March 7, 2005, a verification sample (J03034) was collected for asbestos analysis. Based on the samples and site visits, it was determined that the most effective approach would be to forego confirmatory sampling and remediate the debris piles.

Following remediation, verification sampling was conducted on January 25, 2005, and an additional sample was collected on March 7, 2005. A focused sampling approach was used and consisted of the collection of soil samples to a depth of 0.15 meters (6 inches) beneath the locations of the remediated debris piles.

The contaminants of potential concern (COPCs) for the site were identified based on the types of material present in the debris piles, which had been removed prior to sampling.

COPCs included semivolatile organic compounds, silver, arsenic, barium, cadmium, chromium (total), mercury, lead, selenium, polychlorinated biphenyls, and asbestos. Analytical results of soil samples for the site were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

In accordance with this evaluation, the sampling results supported a reclassification of this site to interim closed out. The current site soil conditions achieved the remedial action objectives and the corresponding remedial action goals established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (EPA 1999). These results also show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 100-B-18	Classification: Accepted
Names: 100-B-18; 184-B Powerhouse Debris Pile	Reclassification: Interim Closed Out (11/30/2007)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: The site consisted of a debris pile containing miscellaneous demolition waste from the decommissioning activities of the 184-B Building and the 184-B Power House.

Location: The 184-B surface debris pile was located northwest of the 184-B Power House. The coordinates at the center of the debris site were E 564449.562, N 144962.219.

Process Description: The 105-B Reactor operated between 1944 and 1968, and the 105-C Reactor operated between 1952 and 1969. Constructed in 1944, the coal-fired 184-B Power House provided steam and emergency electrical power for the secondary coolant system located at 181-B. The 184-B Power House also supplied office heat and other heating needs for 100 B/C Area facilities through overhead steam lines that looped through the 100 B/C Area. A small turbine generator in 184-B also supplied emergency electrical power for area building lights and motors. Soon after the 105-B and 105-C Reactors were deactivated in 1969, the 184 B Building and other ancillary facilities were gradually phased out. The 184-B Building was closed in the mid 1970s, and parts of the 184 B Power House and all of the equipment were removed in 1979. Demolition and removal of all above ground structures including the stack was complete in 1983, leaving the foundation slabs, footprints, tunnels, pits, and other associated concrete structures at or near grade level. During 1988, the foundation and the other below-grade features, including the salt dissolving pits, were demolished to at least 0.9 meters (3 feet) below grade, backfilled with rubble, and buried in situ. Four 184-B Process Sewer Pipelines exited the 184-B Power House and eventually discharged into the main 100-B-14 process sewer pipeline connecting to the 116-B-7 outfall.

Related Sites/ Structures: Some of the waste (especially corrugated ACM) at this site was similar to waste found at WIDS site 100-B-17, which was approximately 165 meters (541 feet) due north.

Waste Type: Misc. Trash and Debris

Waste Description: Suspect asbestos-containing materials such as siding, roofing, lagging, and wrapping were interspersed in the debris pile.

Closure Info: The Remaining Sites Verification Package for the 100-B-18, 184-B Powerhouse Debris Pile (Attachment to Waste Site Reclassification Form 2007-020), documents that the waste site verification sampling results support reclassification of the site to Interim Closed Out. The current site condition has met the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD).

Remediation of the site was begun on June 26, 2007, and July 16, 2007. Because the majority of the material to be disposed was inert demolition debris (e.g., concrete blocks and asphalt rubble), the Environmental Protection Agency (EPA) and the Department of Energy, Richland Operations Office (DOE-RL) agreed that site remediation would be accomplished by selective removal of suspect hazardous items (specifically, light ballasts and tar/mastic material) and potentially impacted . No cleanup action for the non-friable asbestos-containing material (ACM) was required because it did not present a potential release to the environment.

Remediation activities included the removal of 70 BCM (bank cubic meter) of tar/mastic material along with underlying soils. Although expected, no light ballasts were found during remediation. The numerous intact and broken fluorescent light tubes located at the site (approximately 50) were picked up and disposed. No other hazardous debris or stained soil

requiring remediation was identified at the site. The asphalt was not removed because it had been used for structural and construction purposes, therefore, it was excluded from consideration as a dangerous waste based on the Washington Administrative Code (WAC) 173-303-071(3)(e), it is listed as an inert waste in WAC 173-350-990(2)(b), and does not present a significant risk to human health or the environment

Verification sampling was performed concurrently with the remediation in June and July of 2007. The sampling approach was agreed to by the EPA and the DOE-RL. One focused sample, composed of 25 random aliquots and a duplicate, was collected of the soils underlying the removed tar/mastic debris. Ten focused samples were collected of the soils underlying the fluorescent light tubes. These samples were used to demonstrate that site remediation was complete and that the underlying soil met the remedial action objectives.

The analytical results for the verification samples indicated no elevated residual concentrations exceeding cleanup criteria, except antimony, barium, lead, mercury, zinc, and aroclor-1260. These constituents exceeded their respective groundwater and/or river protection remedial action goals, however, the results of vertical migration modeling predicted that none of these constituents would migrate to groundwater (and, thus, the Columbia River) within 1,000 years, and their residual concentrations were, therefore, protective of groundwater and the Columbia River. The verification sample analytical data have been stored in the ENRE project-specific database prior to being submitted for inclusion in the HEIS database. The data were also summarized in Appendix A of the RSVP-2007-020.

Because the majority of the material was inert demolition debris (e.g., concrete blocks and asphalt rubble), site remediation was accomplished by selective removal of suspect hazardous items (specifically, light ballasts and tar/mastic material) and potentially impacted soils. The asbestos-containing materials present at the site were in a non-friable form and did not present a potential release to the environment; therefore, no cleanup action was required.

Excavation was performed in June 2007 with removal of additional light tubes in July 2007. Seventy BCM (bank cubic meter) of tar/mastic material along with surrounding contaminated soils were disposal at the Environmental Restoration Disposal Facility (ERDF). Light ballasts were expected at the site, however, none were found. The numerous intact and broken fluorescent light tubes located at the site (approximately 50) were picked up and disposed. Inert debris material was left in-place at the site. No other hazardous debris or stained soil requiring remediation was identified at the site.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. Site contamination did not extend into the deep-zone soils; therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required.

Code: 100-B-19	Classification: Accepted
Names: 100-B-19; 100B/C Chemical Contaminated Surface Soil Areas; 100-B/C Stained Soil Sites	Reclassification: Interim Closed Out (1/13/2010)
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:
Description: Prior to remediation the 100-B-19 waste site consisted of six stained soil locations that were dispersed within the 100-B/C Area. They were created after a WCH 2004 orphan sites field visit	

of the 100-B/C Area. Three of the locations (SS-100BC-001, SS-100BC-002, and SS-100BC-003) contained reddish-to purple-colored coarse-grained garnet material on the surface. The other three locations (SS-100BC-004, SS-100BC-005, and SS-100BC-006) had yellow-stained surface soil that was ultimately determined to originate from sulfuric acid. An agreement was made among the Environmental Protection Agency (EPA), the U.S. Department of Energy, Richland Operations Office (DOE-RL), and the Environmental Restoration Contractor Team on May 5, 2005, that a general cleanup action to remove the garnet-like material and yellow-stained soils would occur at each of the six locations. Additionally, one multi-aliquot sample would be collected of the underlying soils at each of the six locations.

Location: Using handheld GIS equipment, coordinates were provided in Washington State Plane. (SS-100BC-001): Potential garnet material was found on the surface at coordinates E 566706.139, N 145169.459 in the northeast corner of the 100-B/C Area. (SS-100BC-002): Potential garnet grit-blasting material was visible on the soil surface at coordinates E 564420.28, N 144545.33 about 150 meters (475 feet) west of the southwest corner of the 182-B Reservoir in the 100-B/C Area. (SS-100BC-003): Potential garnet grit-blasting material was visible on soil surface at E 565968.41, N 144,046.68 about 32 meters (105 feet) northeast of the north boundary of the 128-C-1 WIDS waste site, which is east of the 105-C Reactor. (SS-100BC-004): This surface stained soil area was on the north side of the railroad tracks at E 564802.438, N 144346.781 (centroid). The north area was connected (by a clay pipe culvert under railroad tracks) to a soil stained area on the south side of the railroad tracks at E 564803.312, N 144327.703 (centroid). The pipe culvert was located between the head houses for the 183-B and 183-C Water Treatment Plants. The pipe culvert was about 175 meters (575 feet) west of the northwest corner of the 151-B Substation yard. The combined area was about 28 square meters (296 square feet). (SS-100BC-005): This surface stained soil area at E 564803.062, N 144144.156 (centroid) is located 135 meters (443 feet) north and 40 meters (131 feet) east of the 183-C Head House (center). The east-west centerline of the stained surface area runs parallel and about 6.6 meters (22 feet) north of the east-west paved road (center) between the 183-C Water Plant and the 151 B Substation. The total stained area is about 58 square meters (619 square feet). The area between the two locations (i.e., the culvert) is not included in the total area. If soil analyses for potential contaminants of concern for either or both areas indicate cleanup is required, then the culvert area should be included in the cleanup action. (SS-100BC-006): There is stained soil in a hole is about 0.7 meters (2 feet) in diameter and about 1.5 meters (5 feet) deep located at E 564804.06, N 144374.71. It is about 7.5 meters (25 feet) north of the east-west paved road (center) that runs between the 183-B Water Plant and the 151-B Substation.

Process Description: Garnet grit was commonly used in grit-blasting operations to clean the surface of metal components of rust, paint, or contamination. The garnet is not a hazardous substance, but there is a potential for contamination from the surface material that was cleaned by grit blasting. Analogous waste site information is available for WIDS site 100-K-29, a garnet grit blasting surface soil site in the 100-K Area that was remediated under the Remaining Sites Record of Decision. Yellow stains on soil in this area may be due to spills of concentrated sodium dichromate solution (hexavalent chromium) and/or concentrated sulfuric acid used at the water treatment plants for reactor coolant water cleaning and for corrosion control. These chemicals were received in railroad tank cars and in tanker trucks for off-loading to storage tanks at the 183-B, 185-B, 190-B, 183-C, and 190-C water plant facilities. Chemical spills and leaks to the surrounding soil are known to have occurred during loading and unloading operations and during equipment maintenance at the 100-K Area and similar problems likely occurred at the 100-B/C water plant facilities. Analogous hexavalent chromium waste sites include the 100-C-7 hexavalent chromium waste site for the sodium dichromate equipment area in the 183-C Filter House and surrounding soil. Hexavalent chromium on concrete, steel, and soil was successfully remediated for the 190 C Pump House and Water Tunnels (BHI 1997). Analogous concentrated sulfuric acid waste sites that have been remediated include the 100 K Area sulfuric acid storage tank sites (WIDS waste sites 100-K-30, 100-K-31, 100-K-32, and 100 K-33) associated with the water treatment plant for the 100-K Area. The contaminants of concern for

concentrated sulfuric acid are lead and mercury that were present as impurities in the acid.

Waste Type: Chemical Release

Waste Description: The waste is contaminated (stained) soil. Contaminants of potential concern (COPCs) include hexavalent chromium, lead, and mercury for yellow stained sites.

Closure Info: The Remaining Sites Verification Package (RSVP), RSVP-2009-051, for the 100-B-19 site has documented that the verification sampling results support a reclassification of the site to Interim Closed Out. The site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

An agreement was made between the EPA, DOE-RL, and the Environmental Restoration Contractor Team on May 5, 2005, that a general cleanup action to remove the garnet-like material and yellow-stained soils would occur at each of the six 100-B-19 locations. Therefore, confirmatory sampling was not required. The site was included in the Explanation of Significant Differences for the 100 Area Remaining Sites Interim Remedial Action Record of Decision, Hanford Site, Benton County, Washington (EPA 2009) as a waste site for remediation, treatment, and disposal.

Initial remediation of the 100-B-19 waste site was performed between June and October 2007. In total, approximately 11,390 metric tons (12,550 US tons) of material was excavated and disposed at the Environmental Restoration Disposal Facility (ERDF) from all locations in the entire waste site. All waste soils were directly loaded out, except at location SS-100BC-004, as discussed below. All remediation was guided by visual inspection, and, where applicable, X-ray fluorescence (XRF) field measurements.

Further remediation resulting in removal of approximately 1,150 metric tons (1,270 US tons) at locations SS-100BC-002 and SS-100BC-004 was performed in 2009. Remediation at location SS-100BC-002 was performed from February to May. Additional material removal revealed a more extensive subsurface lens of garnet mixed with soil, as was previously observed at locations SS-100BC-001 and SS-100BC-003. All visible garnet material was removed over an area of approximately 450 m² (4,800 ft²) to a maximum depth of approximately 1 m (3 ft) below original grade. Remediation was guided by visual inspection, and, where applicable, X-ray fluorescence field measurements. Approximately 650 bank cubic yards (500 bank cubic meters) of soil mixed with garnet grit was excavated and staged north of the site. Loadout of the material was completed in July 2009. A total of 12,540 metric tons (13,820 tons) of material from the six stained soil locations were disposed at ERDF.

The contaminants of concern (COCs) and contaminants of potential concern (COPCs) were identified based on process knowledge, in-process sample results, and sample results from other garnet grit-blasting and sulfuric acid waste sites in the 100-K Area. The COCs/COPCs include the expanded list of inductively coupled plasma metals (arsenic, antimony, barium, beryllium, boron, cadmium, total chromium, cobalt, copper, lead, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc), mercury, and hexavalent chromium.

Verification soil samples were collected in February 2008 from all remediation locations; the data showed exceedances of the direct exposure RAGs for arsenic at the SS-100BC-002 excavation and hexavalent chromium at the SS-100BC-004 staging pile footprint. Additional remediation resulting in removal of approximately 1,150 metric tons (1,270 US tons) at locations SS-100BC-002 and SS-100BC-004 was performed in 2009. Both statistical and judgmental sampling were performed to verify the completeness of remediation, and analytical

results for each of eight decision units were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. While a small portion of this waste site was excavated into the deep zone, the site is classified as interim closed based on shallow zone criteria; therefore, no deep zone institutional controls are required.

Code:	100-B-20	Classification:	Accepted
Names:	100-B-20; 1716-B Maintenance Garage Underground Tank	Reclassification:	Interim Closed Out (9/27/2006)
Type:	Maintenance Shop	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed. The site consisted of an underground gas and/or oil tanks near the garage. The garage was used for maintenance of 100-B area vehicles. The facility and tanks have been removed.		
Location:	The site was located approximately 300 meters (984 feet) northwest of the 105-B Reactor Building on the south side of B Avenue.		
Process Description:	The 1716-B Maintenance Shop was built in 1944 and provided automotive repair and light vehicle maintenance and lubrication service for 100-B/C Area vehicles until deactivation of B Reactor in 1968. Drawing H-1-10983 identified the building as a Bus Garage. Whalen noted the "lubrication of vehicles was accomplished from a grease pit dug in a high-bay area of the garage". Drawing HW-71669 references Drawing H-1-5055, Lube. Pit Lte. Electrical, which shows that 1716-D and 1716-F had lubrication pits, but there was no reference to one at 1716-B. The "L"-shaped 12.2 meter by 16.3 meter (40 foot by 53.5 foot), single-story, wood frame building, which measured approximately 167.2 square meters (1,800 square feet), contained one large rectangular room (high bay) and a small adjoining room (office). Drawing W-71300 shows two service bays that were large enough to accommodate buses. In 1979, the building was declared surplus, the equipment was excessed, and the entire facility was removed by a salvage operator. Removal of the gas and oil tanks nor the associated piping were mentioned.		
Waste Type:	Soil		
Waste Description:	While the records indicate that the underground gasoline tank was removed and no contamination was found in soil samples, no documentation of when the oil storage tank was removed could be found. Additional potential contamination sources include the former grease pit, lubricating fluids, battery acid in the high bay area, and asbestos shake siding.		
	Contaminants of potential concern (COPCs) would include total petroleum hydrocarbons (TPH) and polychlorinated biphenyls (PCBs).		
Closure Info:	The remedial confirmatory sampling results as documented in the Remaining Sites Verification Package (RSVP-2006-019) support a reclassification of this site to interim closed out. The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).		

The site was evaluated through field observations and focused sampling and analysis to determine if hazardous contaminants were present at the site. One test trench in the most likely location of the underground storage tank (UST) was excavated in sample area 1. The UST was discovered within the excavation trench at an approximate depth of 1.7 to 1.8 meters (5.5 to 6.0 feet) and consisted of two separate compartments, each of which contained waste material. The larger compartment had an approximate capacity of 946 to 1136 Liters (250 to 300 gallons) and contained 189 to 227 Liters (50 to 60 gallon) of sludge. The smaller compartment had an approximate capacity of 379 to 568 Liters (100 to 150 gallons) and contained 19 to 38 Liters (5 to 10 gallons) of a soil/water/diesel mixture.

The contaminants of potential concern (COPCs) for the waste site were identified based on existing historical information for the site and process knowledge of the 1716-B Maintenance Garage. The COPCs were associated with the petroleum storage during operation of the 454.2-Liters (120-gallon) UST, including arsenic, barium, cadmium, total chromium, lead, selenium, silver, mercury, total petroleum hydrocarbons (TPHs), semivolatile organic compounds, and polychlorinated biphenyls (PCBs). Although not included in the list of COPCs, antimony, beryllium, boron, cobalt, copper, manganese, molybdenum, nickel, vanadium, and zinc concentrations were evaluated by performing the expanded inductively coupled plasma (ICP) metals analyses. There were no radionuclides COPCs for this site.

Confirmatory sampling of the site was conducted on January 18 and 19, 2006. The objectives of the confirmatory sampling activities were to locate the UST, and assess the site soils for any unplanned releases from the tank to the environment. No reference was made in the RSVP regarding the associated pipelines that had been left in place.

The UST was unable to be sampled in place and was removed to gain access to the internal contents. A composite sample was collected from the material in the two compartments and analyzed for waste characterization purposes. According to remedial field notes the tank contents were removed, and the empty tank and waste contents were placed into a B-25 box. In addition to the tank removal, approximately 0.3 meters (1 foot) of soil was excavated from the location underlying the UST and placed into a second B-25 box. The contents of the B-25 boxes will be managed and disposed of separately in accordance with the Washington State Department of Ecology "Dangerous Waste Regulations" (Washington Administrative Code [WAC] 173-303) and as according to CERCLA requirements, the waste will be disposed at the Environmental Restoration Disposal Facility.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration project specific database prior to submitting for inclusion in the Hanford Environmental Information System and were presented in Appendix A of the RSVP.

The sampling results illustrated that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil [i.e., surface to 4.6 meters(15 feet)] and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

The depth of the oil tank was approximately 1.8 meters (6.0 feet) and the soils collected underlying the tank were at a depth of 2.1 meters (6.9 feet). The sample results at the boundaries of the excavation indicated that the remedial action objectives for the site have been met. No further excavation is required. As such, this site does not have a deep zone; therefore, no deep zone institutional controls were required.

Names: 100-B-21; 100-B/C Miscellaneous Pipelines **Reclassification:** Interim Closed Out (2/9/2010)

Type: Process Sewer **Start Date:**

Status: Inactive **End Date:**

Description: The site consists of a variety of underground pipelines that were uncovered during removal of the 100-B/C Reactor effluent pipelines and soils. The pipelines did not belong to previously-established waste sites, they have been grouped together based on the type of pipeline and potential closeout pathways for each.

Location: Locations were described in terms of easting (E), northing (N), and elevation (meters). Elevations are NAVD88.

Process Description: The pipelines in this waste site were uncovered during the removal of effluent pipelines and soils. As pipeline removal progressed, an effort was made to photograph, accurately locate (at least the exposed end), and in some cases perform limited chemical and radiological investigations of the pipelines. A number of the pipelines were not identified in drawings. Some of the pipelines were included in other waste sites, thus, gaps exist in the numbering of the pipelines included in this waste site. (DS = Discovery Structure, 100BC = Area, and 002 = next available number). Numbers (by themselves) (e.g., 26) were assigned to pipelines by the excavation subcontractor. Large-diameter pipeline generally means pipeline greater than 50.8 centimeters (20 inches).

Waste Type: Process Effluent

Waste Description: Contaminants of Potential Concern are listed only for sites known to have contaminants.

(DS-100BC-002) Contaminants of potential concern are asbestos, semivolatile organic analytes, phenanthrene, fluoranthene, pyrene, benzo (a, b, and k) anthracene, chrysene, mercury, and lead.
 (DS-100BC-016) The potential contaminants of concern are asbestos, lead, and arsenic.
 (DS-100BC-019) The potential contaminants of concern are americium-241, and asbestos.
 (DS-100BC-022) The potential contaminants of concern include asbestos.

This Site has the Following SubSites:

Code: 100-B-21:1

Names: 100-B-21:1; Steel Pipeline Segment

Code: 100-B-21:2

Names: 100-B-21:2; Asbestos/Tar Wrapped Pipeline

Code: 100-B-21:3

Names: 100-B-21:3; Asbestos Wrapped Steel Pipeline

Code: 100-B-21:4

Names: 100-B-21:4; Pipeline from the 105-C Reactor East to 116-C-2B Sump

Code: 100-B-21:1 **Classification:** Accepted

Names: 100-B-21:1; Steel Pipeline Segment **Reclassification:** No Action (2/14/2006)

Type: Process Sewer **Start Date:**

Status: Inactive **End Date:**

Description: Discovery pipelines that could not be associated with a previously-established waste site were grouped together into the 100-B-21 waste site based on the type of pipeline and potential closeout pathways for each. Two of these pipeline segments, (DS-IOOBC-016 and DS-100BC-022), were designated as subsite 100-B-21:1. The Remaining Sites Verification Package (RSVP) 2005-052 has demonstrated that the pipeline segments have met the objectives for

reclassification to "no action". The current site conditions have achieved the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD).

The evaluation of these pipelines included site histories, analytical data, process knowledge, and field observations based on field screening, and laboratory data.

The DS-100BC-016 pipeline segment consisted of a 20-centimeter (8-inch) diameter, east-west-running steel pipe found during excavation of waste site 100-C-6, the 100-C Reactor effluent underground pipelines. The pipe had an asbestos-containing tar-based spiral wrap. Where the pipeline crossed the excavation of the 100-C-6 pipelines, the pipeline segment was removed. The pipeline was left in place at coordinates, E 565473, N 144463, and elevation 145.194.

The DS-100BC-022 pipeline segment consisted of a 2.5-centimeter (1-inch) diameter pipeline discovered during the remediation of the 100-C-3 site. The pipeline was documented in an area to the southeast of the 105-C Reactor near the former location of the 119-C sample building. The pipeline connected to a larger 10.2-centimeter (4-inch) pipeline south of where the smaller section of pipeline was discovered. The larger pipeline was a water supply line, and no contaminants of potential concern were identified beyond the asbestos commonly found in the wrapping on this type of pipe. The small pipeline was considered analogous to the larger pipeline.

Location: The pipeline crosses along the east edge of 100-C-3. Coordinates are E 565396, N143951. The elevation is about 1.5 m (5 ft) below grade.

Waste Type: Not Specified

Waste Description: The waste is piping and potentially contaminated soil.

Closure Info: DS-100BC-016 : Approximately 50 meters (164 feet) of the pipeline was disposed at the Environmental Restoration Disposal Facility. The potential contaminants of concern were asbestos, lead, and arsenic. On 9/24/2003, samples J00YH1 (Chemistry) and J00YJ0 (Field Screening) were collected. The pipeline analytical data results detected total chromium (26.4-mg/kg)-and-lead-(48.4 mg/kg)-above-background-levels-and-confirmed-asbestos (4-8% chrysotile) in the pipe wrap. The total chromium and lead results were above background, but below direct exposure levels. RESidual RADioactivity (RESRAD) analysis illustrated that total chromium and lead will not reach groundwater or the river within 1,000 years, and, therefore, they are considered protective of groundwater and the river. The risk associated with asbestos was that of direct exposure to friable asbestos fibers. Because the asbestos on this pipe was suspended in a tar-based compound, it was considered nonfriable. The segment, therefore, does not require further remediation and was recommended for a no action decision.

DS-100BC-022 : A sample of the pipe wrap was taken and tested for asbestos. The analytical result confirmed 3% to 8% chrysotile in the tar wrap on the pipe. Again, the asbestos is in a nonfriable form and does not represent a risk warranting CERCLA action. The pipeline segment, therefore, does not require further remediation and is recommended for a no action decision.

Soil cleanup levels were established in the interim action ROD based on a limited ecological risk assessment. A baseline risk assessment for the river corridor portion of Hanford began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final ROD for the site.

The SubSite is Part Of:

Code: 100-B-21
Names: 100-B-21; 100-B/C Miscellaneous Pipelines

Code: 100-B-21:2 **Classification:** Accepted
Names: 100-B-21:2; Asbestos/Tar Wrapped Pipeline **Reclassification:** Interim Closed Out (6/16/2008)
Type: Process Sewer **Start Date:**
Status: Inactive **End Date:**

Description: The Remaining Sites Verification Package 2008-003 documents that the 100-B-21:2 subsite meets the objectives for Interim Closed Out as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites Rod).

The 100-B-21 :2 waste site consists of the discovery pipeline originally designated DS-IOOBC-002. When discovered, this pipeline was described as 2.5 cm (1-in.) diameter asbestos-wrapped metal pipe protruding 1.5 m (5 ft) horizontally from the bank of the Columbia River. The history of the 100-B-21:2 pipeline, prior to its discovery in 2003, is unknown. The pipeline did not appear on the historical construction drawings. The location and orientation of the pipeline suggested that it was associated with the 116-B-11 Retention Basin and discharged to the river embankment. It was smaller than most drain lines, suggesting it was a pressurized water pipe, though the exact purpose remained unknown. The northern end of the 100-B-21:2 pipeline, originally discovered at N145362, E565307, was located west of the 116-B-7 outfall structure and north of the 100-BC perimeter road. During remediation the pipeline was determined to extend due south, under the 100-BC perimeter road to the edge of 116-B-11 Retention Basin excavation boundary.

Location: The pipeline is north of the 100-B/C perimeter road and north of the former location of 116-B-11 Retention Basin. The location was measured at 30.5 m (100 ft) east of the 116-B-7 flume east edge and 34 m (111 ft) north of the road. The pipeline was sampled at coordinates E 565307, N 145362, and elevation 132.086 m.

Waste Type: Not Specified

Waste Description: The waste is a small diameter pipeline and potentially contaminated soil.

Closure Info: Remedial activities were conducted from June through September 2003 and included field screening, sampling, and geophysical investigations. An additional geophysical survey in March 2007 of the 100-B-21:2 pipeline segment was performed using ground penetrating radar with results similar to those found in 2003. The geophysical interpretation identified the pipeline and noted low amplitude anomalies (thought to be large boulders) in the subsurface. The pipeline, soil in contact with the pipe, and soil 0.3 meters (1 foot) below the pipeline were removed and disposed of at ERDF. A total of approximately 91 metric tons (100 US tons) of material was disposed at ERDF. No anomalies were discovered during the remedial action.

The COCs and COPCs as listed in The Work Instruction for Verification Sampling of the 100-B-21:2, Discovery Pipeline DS-IOOBC-002 included : europium-154, arsenic, barium, cadmium, chromium, lead, mercury, selenium, silver, hexavalent chromium, acenaphthene, anthracene, Bis(2-ethylhexyl)phthalate, carbaxole, dibenzofuran, fluorene, indeno(1,2,3-cd)pyrene, phenanthrene, pyrene. A characterization sampling event (J00YF7, J00YH7) occurred on September 3, 2003. The pipeline was severed 1.9 meters (6.2 feet) from its end, uplifted, and the scale dumped into a plastic bag. No elevated readings were discovered by an HPT who took direct readings of the scale.

The sampling results showed that residual soil concentrations supported future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future use and are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

The SubSite is Part Of:

Code: 100-B-21

Names: 100-B-21; 100-B/C Miscellaneous Pipelines

Code: 100-B-21:3

Classification: Accepted

Names: 100-B-21:3; Asbestos Wrapped Steel Pipeline

Reclassification: Interim Closed Out (5/7/2009)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The Remaining Sites Verification Package for the 100-B-21:3 (RSVP-2008-052) subsite has documented that the current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD).

Discovered in 2003, the DS-100BC-019 pipeline was described as a 20 cm (8-in.) diameter steel pipe with an asbestos-containing, tar-based spiral pipeline wrap and mechanical joints. This pipeline protruded from a sidewall of a railroad track bed cut, located just south of the 116-B-15 Percolation Pit, and ran in a north-south direction.

In June 2007, during remedial activities, it was discovered that the DS-100BC-019 pipeline and DS-100BC-016 pipeline were connected; therefore, the DS-100BC-016 pipeline was incorporated into the 100-B-21:3 subsite and both pipeline segments were removed. The DS-100BC-016 pipeline, mapped at Washington State Plane coordinates N 14463, E 565473, had been investigated separately and reclassified as No Action in the 100-B-21:1 subsite.

Location: The site is directly south of the 116-B-15 waste site;
DS-100BC-019 located at Washington State Plane coordinates N 144494, E 565528;
DS-100BC-016 located at Washington State Plane coordinates N 14463, E 565473.

Waste Type: Not Specified

Waste Description: The waste is piping and potentially contaminated soil.

Closure Info: In March 2007, geophysical surveys were performed over the site using ground-penetrating radar (GPR). A linear anomaly that was interpreted to be the target pipeline was oriented north-south and continued to the southern edge of the investigation area where it was obscured by a highly reflective horizon. It was uncertain whether the pipeline continued past the southern boundary of the survey area; however, during remedial activities it was verified that the pipeline extended past the boundary. In September 2007, GPR was used to trace the pipeline from the last exposed point in the excavation; the line was interpreted to bend to the west and extended approximately 60 m (200 ft) to the location of the DS-100BC-016 pipeline.

In June 2007, during remedial activities, it was discovered that the DS-100BC-019 pipeline and DS-100BC-016 pipeline were connected; therefore, the DS-100BC-016 pipeline was

incorporated into the 100-B-21:3 subsite and both pipeline segments were removed. The DS-100BC-016 pipeline, mapped at Washington State Plane coordinates N 14463, E 565473, had been investigated separately and reclassified as No Action in the 100-B-21:1 subsite.

The contaminants of potential concern (COPCs) for the subsite were identified in the Work Instruction for Verification Sampling of the 100-B-21:3, DS-100BC-019 Discovery Pipeline Waste Site and were listed in Table 1 of the RSVP. Asbestos and semivolatile organic compounds were included as COPCs based on positive sample results for asbestos and benzo(a)pyrene. The 100-B-21, 100-B/C Miscellaneous Pipelines Remove, Treat, and Dispose Report used process knowledge from other underground pipeline waste sites to include arsenic, barium, cadmium, chromium (total), hexavalent chromium, lead, mercury, selenium, and silver as COPCs. Gamma energy analysis (GEA) was requested due to the unknown nature of the pipelines. Although not considered COPCs, the expanded list of inductively coupled plasma (ICP) metals was also analyzed.

In October 2008, 10 verification soil samples and 1 field duplicate were collected from the excavated area. Three soil samples and one field duplicate were collected from the overburden stockpiles and staging pile area. These samples were analyzed for the COPCs.

Overburden soils were removed from above the pipeline and placed into two stockpile areas. A total of approximately 850 metric tons (940 US tons) of material was disposed at the Environmental Restoration Disposal Facility and consisted of the DS-100BC-019 and DS-100BC-016 pipelines, soil in contact with the pipelines, and soil 0.3 m (1 ft) below the pipeline. Photographs of remedial activities were presented in Appendix A of the RSVP.

A reclassification of Interim Closed Out for the subsite is supported based on site history, process knowledge, field observations, and laboratory data. Residual concentrations at the site support future unrestricted remaining sites land uses that can be represented (or bounded) by a rural-residential scenario and are considered protective of human health, groundwater, and the Columbia River. The site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

The SubSite is Part Of:

Code: 100-B-21

Names: 100-B-21; 100-B/C Miscellaneous Pipelines

Code: 100-B-21:4

Classification: Accepted

Names: 100-B-21:4; Pipeline from the 105-C Reactor East to 116-C-2B Sump

Reclassification: Interim Closed Out (2/9/2010)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The Remaining Sites Verification Package, RSVP-2009-041, has documented that the subsite has met the remedial action objectives (RAOs) and remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP)) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD).

The 100-B-21:4 subsite was located in the 100-BC-1 Operable Unit of the Hanford Site, and was previously classified as the DS-100BC-044 discovery pipeline segment. The 20-cm (8-in.) stainless steel, radioactive chemical waste pipeline was at a depth of 6.1 m (20 ft) below ground surface (bgs). The pipeline ran from the northwestern corner of the 105-C Reactor Building,

under the 105-C Metal Examination Facility (MEF), and discharged into the 116-C-2B Pluto Crib Pump Station. Although there is documentation of a smaller pipeline exiting the MEF and connecting to the DS-100BC-44 pipeline, this smaller pipeline or residual connection joints were not found during remediation, and they are assumed to have never been present. Drain lines from the MEF to the 116-C-2B sump and other facilities are believed to have been removed during decontamination and decommissioning activities at the 105-C Reactor Building or during field remediation of the 100-C-6:1 process effluent pipelines.

Location: The pipeline ran from the northwestern corner of the 105-C Reactor Building, under the 105-C Metal Examination Facility, and discharged into the 116-C-2B Pluto Crib Pump Station.

Waste Type: Not Specified

Waste Description: The waste is piping and potentially contaminated soil.

Closure Info: Remedial action at the waste site was performed in April 2009. The site was excavated to a depth of 7.5 m (25 ft), generating approximately 7,095 bank cubic meters (BCM) (9,280 bank cubic yards [BCY]) of overburden material stockpiled for evaluation for use as clean backfill. The excavation encountered and disposed of approximately 64 m (210 ft) of 20-cm (8-in.) stainless steel pipeline encased in concrete, and approximately 400 BCM (523 BCY) of debris and soil were sent for disposal at the Environmental Restoration Disposal Facility (ERDF).

The contaminants of potential concern (COPCs) for verification sampling of the waste site were identified based on existing historical information, in-process sampling results, and the contaminants of concern (COCs) for the 116-C-2A, B, and C sites. These COPCs included americium-241, cesium-137, cobalt-60, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, uranium-233/234, uranium-235, uranium-238, hexavalent chromium, total chromium, lead, and mercury. Although not considered COPCs, antimony, barium, beryllium, boron, cadmium, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc were analyzed as constituents of the expanded inductively coupled plasma (ICP) metals list.

The acceptability of direct contact with residual deep zone contamination has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required

The SubSite is Part Of:

Code: 100-B-21

Names: 100-B-21; 100-B/C Miscellaneous Pipelines

Code: 100-B-22

Classification: Accepted

Names: 100-B-22; 100-B Water Treatment Facilities, Pipelines, and Surrounding Soils

Reclassification: Interim Closed Out (3/22/2010)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: This site consists of the 100-B water treatment facilities, pipelines and associated soils. To facilitate remedial requirements and regulatory documentation, the site has been divided into subsites. Subsite 1 consists of the underground transfer piping that interconnected the 100-B Area Water Treatment Facilities and associated soils. Subsite 2 consists of the water treatment facility structures (183-B Filter House, 185-B Deaeration Building, 195-B Process Pump House).

Location: The water treatment facilities occupied an area approximately 275 meters (900 feet) wide by 365 meters (1200 feet) long and were 91 meters (300 feet) directly west of the 105-B Reactor

Building. The location of each facility follows: The 183-B Filter Plant structures were located along the centerline N144511 and between E564776 and E564846. The headhouse was located at E564781, N144511. The 12 flocculation basins were located at E564790, N144511. The 12 sedimentation basins were located at E564809, N144511. The filter building was located at E564839, N144511. Storage tanks were located at E565112, N144511. The process pump house was located at E565144, N144511.

Release Description: One dichromate release was noted as "a large spill in September 1966" (Gerber 1993), but was believed to have occurred on the north side of the 183-C Headhouse (discussion with J. J. Sharpe, September 2004). Unplanned releases are unknown.

Process Description: The 100-B Area Water Treatment Facilities were operated from 1944 until 1968, they provided large volumes of high-quality cooling water to the 105-B Reactor. The primary facilities (in the order of the treated water flow) included: 181-B River Pump House or Head House, Flocculation and Sedimentation Basins, Filter Building, 183-B Clear Water Reservoir (126-B-2) and Pump Room; the 185-B Deaeration Facility, the 190-B Process Pump House; and the 108-B Chemical Pump House (132-B-1). Water was removed from the Columbia River by pumps at the 181-B River Pump House and stored temporarily at the 182-B Reservoir. From 182-B, the water was pumped to the 183-B Filter House, where it was treated for use as process cooling water for the B Reactor. Here, chlorine was added to control algae, and sulfuric acid was added to lower the water pH to 7.5 for the coagulation and filtration process. Coagulants included alum, ferric sulfate, and Separan. Following coagulation and settling, the water passed through filters consisting of anthracite coal, sand, and gravel. After filtration, lime was added to raise the pH back to 7.8, and the water was stored temporarily in underground clearwells. The clarified water was next passed through the 185-B Deaeration Plant, where sodium dichromate was added at a rate of 2 parts per million. Until 1950 the sodium dichromate was mixed at the 108-B Chemical Pump House and sent via underground piping to storage tanks inside the 183-B Building. After 1950, sodium dichromate mixing was moved to 183-B. The actual injection points for the sodium dichromate were at the intake header for the storage tanks in the 190-B Process Pump House.

Related Sites/ Structures: 126-B-2 (183-B Clear Water Reservoir), 132-B-1 and 100-B-14 (108-B Chemical Pump House), 105-B Reactor

Waste Type: Soil
Waste Description: Fill material placed over potentially contaminated soil and demolished concrete structures.

The concrete flocculation and sedimentation basins were collapsed into themselves, and backfilled at least partially with waste material. No record has been found characterizing this waste material, nor has a record been found that any soil samples were taken.

Waste Type: Equipment
Waste Description: Best available information (Sharpe and Linville 2000, Plate 4) indicates that the underground piping connecting the 183-B Filter House and the 185-B/190-B Process Pump House is still in place. The lines are up to 600 meters (1,968 feet) long, and include reinforced concrete, cast iron, and steel pipes up to 137 centimeters (54 inches) in diameter. The paths of the lines are generally north of and parallel to an existing road, N144406; and south of and parallel to an existing road, N144631.

Waste Type: Soil
Waste Description: Contaminants of Potential Concern: Contaminants of potential concern (COPCs) include lead, mercury, hexavalent chromium, and polychlorinated biphenyls (PCBs).

Fill material was placed over potentially contaminated soil.
Sulfuric acid was added at the 183-B Head house for more than 20 years. Much of the sulfuric

acid was known to be contaminated with significant amounts of lead and mercury. The sulfuric acid was unloaded at the facility from two railroad car locations. It is reasonable to assume that, during the early hectic years of operation, some unplanned and unreported spills may have occurred. No record has been found that the soil in the area of the headhouse was sampled and tested for lead and mercury prior to backfilling.

Waste Type: Soil

Waste Description: Two 75,700 liter (20,000 gallon) acid storage tanks, believed to contain concentrated sulfuric acid, were located 12.2 meters (40 feet) south of the south end of the 185-B Deaeration Plant. Acid was unloaded from railroad cars near this location and acid was transferred from these tanks into the Deaeration Plant. The sulfuric acid was contaminated with significant concentrations of lead and mercury. It is prudent to assume unplanned and unreported leaks and spills of this acid may have occurred during the many years of operation of this plant. No records have been found to indicate that soil samples for lead and mercury were taken from this area during or after decommissioning. The tanks were located at E565113, N144451.

Waste Type: Soil

Waste Description: Concrete is located approximately 1 meter (3 feet) below clean fill material.

Description: Decommissioning of the 185-B Deaeration Plant, 190-B Process Pump House, and associated pipe tunnels, generally allowed any portion of a structure that was 1 meter (3 feet) below grade to be left in place. Foundation concrete for both buildings, as well as the demolished parts of the tunnels, remain underground, generally within the area bounded by E565103 and E565245, and N144444 and N144584.

This Site has the Following SubSites:

Code: 100-B-22:1

Names: 100-B-22:1; Piping Between 183-B and the 185-B/195-B Building(s)

Code: 100-B-22:2

Names: 100-B-22:2; 183-B Filter House, 185-B Deaeration Building, 195-B Process Pump House and Associated Soils; Water Treatment Facilities and Surrounding Soils

Code: 100-B-22:1

Classification: Accepted

Names: 100-B-22:1; Piping Between 183-B and the 185-B/195-B Building(s)

Reclassification: No Action (9/12/2006)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: Subsite 1 consists of the underground transfer piping that interconnected the 100-B Area Water Treatment Facilities and associated soils. The 100-B-22:1 Pipelines and Associated Soils waste site is limited to pipelines that interconnected the 183-B Filter House (including the 126-B-2 Clearwells), the 185-B Deaeration Plant, and the 190-B Process Pump House. All of the 100-B-22:1 pipelines are more than 0.15 m (6 in.) in diameter and were used for cooling water.

Location: The 100-B-22:1 pipelines are located in the 100-BC-1 Operable Unit in the 100-B/C Area of the Hanford Site just west of the 105-B Reactor.

Process Description: Process knowledge indicated that the pipelines were upstream of facilities where sodium dichromate was added to the process water and of the 105-B Reactor. The pipelines, therefore, would not have received discharges containing elevated levels of radionuclides or metals, including lead and hexavalent chromium. Originally, the sodium dichromate was brought into the 185-B/190-B Buildings as a concentrated solution through the sodium dichromate lines (100-B-14:5) that entered on the north side of the building. Cooling water pipelines between the 190-B Building and the 105-B Reactor were part of 100-B-14:4 waste site.

Waste Type: Not Specified

Waste Description: The waste is the underground piping and associated soils.

Closure Info: A reclassification to no action based on reviews of the site history, process knowledge, and field observations has been documented in the Remaining Sites verification Package 2005-042 (RSVP). The current site condition achieves the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The RSVP indicated that the only additives to the process water in the pipelines came from the 183-B facility. Chemicals added at the 183-B facility included chlorine, sulfuric acid, alum, ferric sulfate, Separan? (a coagulant), and lime. Sulfuric acid used for water treatment at the Hanford site, historically had lead and mercury contamination. Where sulfuric acid was spilled or otherwise allowed to collect, lead and mercury have been found above the remedial action goals. These areas were most commonly associated with the transportation and handling of concentrated sulfuric acid. Trace contamination from the sulfuric acid that was added to adjust the pH of the water, would be dilute in the cooling water. There was no evidence to suggest that the pipelines were ever a source of human health risk due to the addition of sulfuric acid.

Examination of excavated trenches as well as historical documents and drawings indicated that all of the pipelines were more than 0.15 meters (6 inches) in diameter and were used for cooling water not for the transfer of concentrated chemical solutions. Three small-diameter pipelines, used as chemical transfer lines, were found plumbed into the 183-B and 190-B Buildings. Two of these pipelines, the sodium dichromate and the sodium silicate pipelines (100-B-14:5) connected the 108-B Building to the 185-B/190-B Buildings. The third small-diameter pipeline has been identified as the sodium dichromate line designated as the 100-B-28 waste site. Remediation of the 100-B-28 site is expected in 2007.

The basis for the no action determination precluded the need for sampling at this site, and therefore a comparison between soil data and ecological screening levels was not necessary. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which included a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

Reclassification evaluations have illustrated that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The evaluations also demonstrated that residual contaminant concentrations support unrestricted future use and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

The SubSite is Part Of:

Code: 100-B-22

Names: 100-B-22; 100-B Water Treatment Facilities, Pipelines, and Surrounding Soils

Code: 100-B-22:2

Classification: Accepted

Names: 100-B-22:2; 183-B Filter House, 185-B Deaeration Building, 195-B Process Pump House and Associated Soils; Water Treatment Facilities and Surrounding Soils

Reclassification: Interim Closed Out (3/22/2010)

Type: Dumping Area

Start Date:

Status: Inactive**End Date:**

Description: The 100-B-22 waste site consisted of the former 100-B water treatment facilities, including pipelines between the facilities, and potentially impacted soils. The three former water treatment facilities are the 183-B Filter Plant, the 185-B Deaeration Plant, and the 190-B Process Pumphouse. These facilities were designed to supply, treat, store, and transport cooling water to the 105-B Reactor. They have been decommissioned and demolished to approximately 1 m (3 ft) below ground surface (Griffin 1988, Marske 1994). Subsite 2 consisted of the 183-B Filter House, 185-B Deaeration Plant, and 190-B Process Pumphouse footprints and associated soils. The 183-B clearwells are excluded from this waste site, as they are addressed separately as the 126-B-2 waste site.

A reclassification to Interim Closed Out for the 100-B-22:2 subsite is supported based on site history, process knowledge, field observations, and comparison of residual contaminant concentrations against RAGs. The Remaining Sites Verification Package (RSVP-2010-004) for 100-B-22:2 has documented that the site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units. (Remaining Sites ROD).

Location: The 185-B/190-B Building is about 100 meters (330 feet) west of the 105-B Reactor; the 183-B Building is about 400 meters (1/4 mile) west of the Reactor.

Process Description: The 105 B Reactor was a single-pass reactor, so cooling water was not recycled after its initial use. All water had to be treated and conditioned prior to use in the reactor to prevent pipes within the reactor from corroding and to prevent constituents dissolved in the water from precipitating and eventually restricting flow through the aluminum pipelines used for cooling the core of the reactor. Cooling water was pumped from the Columbia River via the 181-B river pumphouse into the 182-B reservoir. From the reservoir, water flowed into the 183-B Treatment Plant where it was treated with chlorine, sulfuric acid, and coagulants such as alum, ferric sulfate, and Separan. After flocculation, particle settling, and filtration, the clarified water was stored in large underground clearwells. From the clearwells, water flowed to the 185-B Deaeration Plant via the 100-B-22:1 cooling water pipelines. The 185-B Deaeration Plant was never used for deaeration as originally intended. It did, however, contain two 3,785 liters (1,000-gal) storage tanks where concentrated sodium dichromate solution was stored. Originally, the sodium dichromate solution was mixed and piped in from the 108-B Building. In the early 1950s, the sodium dichromate mixing was moved into the 185-B Building. The sodium dichromate solution was added to the cooling water lines at the common wall of the 185-B and 190-B facilities. Cooling water was stored in the 190-B Process Pumphouse in four 6.62 million liters (1.75 million gallons) tanks. Water stored in the 190-B Process Pumphouse was available for use in the 105 B Reactor on an as-needed basis via piping in underground tunnels (100-B-14:4 subsite).

Waste Type: Not Specified

Waste Description: The remaining footprint of these facilities contains inert concrete debris and structural material below 1 meter (3 feet) below ground surface, along with other clean fill used to bring the site to grade. Fill material placed over potentially contaminated soil and demolished concrete structures.

Closure Info: The entry points for process chemicals into the former facilities were targeted for visual investigation and focused sampling. Based on confirmatory sampling performed in 2007 and 2009 the results of this investigation, it was determined that remediation was required only for a small drain line associated with the 183-B headhouse.

Remediation was performed in May 2009, by excavating approximately 40 bank cubic meters (50 bank cubic yards) of pipe debris and soil and disposing it at the Environmental Restoration Disposal Facility.

Contaminants of potential concern (COPCs) for the 100-B-22:2 site were determined based on process knowledge. Hexavalent chromium and total chromium were considered COPCs due to past handling and usage of sodium dichromate at the facilities. Lead, mercury, and sulfate were included as COPCs due to past usage of sulfuric acid for coagulant preparation and pH modification. The bauxite used for alum generation contained naturally occurring radionuclides at higher levels than local background; therefore, gross alpha and beta proportional counting and gamma spectroscopy were also performed for selected samples.

Decontamination of facility interiors was performed as part of decommissioning of the 183-B, 185-B, and 190-B buildings (Griffin 1988, Marske 1994). The remaining footprint of these facilities contains inert concrete debris and structural material, along with other clean fill used to bring the site to grade. Therefore, in development of a confirmatory investigation strategy with the U.S. Environmental Protection Agency (EPA) and the Department of Energy, Richland Office (DOE-RL), it was decided that entry points for process chemicals into these facilities represented the worst case for potential remaining contamination. The Work Instruction for Confirmatory Sampling of the 100-B-22:2 Water Treatment Facilities identified three such locations for excavation of test pits and sampling. The laboratory-reported data results for all constituents were stored in the WCH ENRE project-specific database prior to provision to HEIS and are also presented in Appendices B and D of the RSVP.

The SubSite is Part Of:

Code: 100-B-22

Names: 100-B-22; 100-B Water Treatment Facilities, Pipelines, and Surrounding Soils

Code: 100-B-24

Classification: Accepted

Names: 100-B-24; 1904-B1 Spillway (Flume); 100-B-15:1 Flumes from Outfall Structures 116-B-7, 132-B-6 and 132-C-2

Reclassification: No Action (9/18/2006)

Type: Outfall

Start Date:

Status: Inactive

End Date:

Description: The site has been sampled and found to meet the requirements for reclassification to "No Action". The flume has been decommissioned and backfilled. The 100-B-24 Spillway (also referred to as a flume) was constructed of concrete and led from the 116-B-7 outfall structure to the river shoreline.

Location: The site was located northwest of 116-B-11 Retention Basin and upstream of the 132-B-6 Outfall. The remaining portion of the spillway is 18 meters (60 feet) downstream of, and parallel to, the river effluent pipeline.

Process Description: The spillway was an alternate discharge point for the 116-B-7 Outfall Structure. The spillway was to be for an emergency effluent release or if the 100-B-15 river effluent pipelines were blocked, damaged, or undergoing maintenance. There was no corroborated physical or historical evidence that the spillway was ever used.

Related Sites/ Structures: The site was associated with the 100-B-15 River Effluent Pipelines and the 116-B-7 Outfall Structure.

Waste Type: Construction Debris

Waste: No evidence has been found that the flume was ever put into service. If it had been used the

Description: COPCs for the 100-B-24 spillway would be the same as those for the 116-B-7 outfall structure, which are as follows: Americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, total chromium, hexavalent chromium, lead, and mercury.

Closure Info: During site evaluation for the Remaining Sites Verification Package 2006-051, (RSVP) results of confirmatory sampling conducted on January 17, 2006 supported a reclassification of the site to no action. The current site conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, (ROD).

The contaminants of potential concern (COPCs) for the site were identified based on the contaminants of concern (COCs) and COPCs identified for the 116-B-7 Outfall and were as follows: americium-241, cesium-137, cobalt-60, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, chromium (total), hexavalent chromium, lead, and mercury.

Further consideration of upstream processes resulted in the inclusion of polychlorinated biphenyls as a COPC. Although not considered COCs or COPCs, confirmatory sample analysis was performed for the expanded list of inductively coupled plasma (ICP) metals to include antimony, arsenic, barium, beryllium, boron, cadmium, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc. Results of the 1/17/06 focused confirmatory samples, collected from the concrete flume, exceeded the RAGs for soil. Because arsenic and other metals are commonly detected in concrete, studies have shown that the metals will not leach out in concentrations that are of concern to public health. their leachability from concrete has been repeatedly studied (PCA 1993) and is well documented. These studies have shown that metals will not leach out of concrete in concentrations that are of concern to public health (PCA 1995).

However, it was concluded that remedial action to remove the concrete had the possibility of destabilizing the riverbank. To avoid and minimize the impacts on the river and the local ecosystem of the release of soils and sediments into the river, it was reasonable to conclude that there was a greater risk posed to the river and the local ecosystem by a removal action than was posed by leaving it in its current state. The laboratory reported results for all analyzed constituents were stored in the WCH Environmental Restoration (ENRE) project-specific database prior to submitting the data for inclusion into the Hanford Environmental Information System (HEIS) and are also presented in Appendix A of the RSVP.

These results show that residual concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual contaminant concentrations supported unrestricted future use of shallow zone soil [i.e., surface to 4.6 meters (15 feet)]. Because the residual arsenic and other metals in the concrete were not available to human or ecological receptors, the site met the cleanup objectives for direct exposure, groundwater protection, and river protection. The site does not have a deep zone; therefore, no deep zone institutional controls are required. In accordance with this evaluation, the confirmatory sampling results support a reclassification of the site to no action.

Code: 100-B-25	Classification: Accepted
Names: 100-B-25; 132-B-6 Outfall; 1904-B2 Spillway; 100-B-15:1 Flumes from Outfall Structures 116-B-7, 132-B-6 and 132-C-2	Reclassification: Interim Closed Out (1/13/2010)
Type: Outfall	Start Date:

Status: Inactive

End Date:

Description: The site has been remediated and reclassified to Interim Closed Out. The site consisted of a Spillway (also referred to as a flume.) The spillway was constructed of concrete and led from the 132-B-6 outfall structure, via a heavy riprap extension on the end of the concrete spillway, to the river shoreline. During decommissioning projects in the 1980's, the spillway walls were collapsed and the structure was covered with clean soil.

Location: The site was located north of the northeast corner of the 116-B-11 (107-B Retention Basin) and downstream of 116-B-7 (the 1904-B1 Outfall).

Process Description: The spillway was an alternate discharge point for the 132-B-6 Outfall Structure. It was planned to be used only if the 100-B-15 river effluent pipelines were blocked, damaged, or undergoing maintenance. There is no corroborated historical information that the spillway was ever used.

Related Sites/ Structures: The site is associated with the 100-B-15 River Effluent Pipelines and the 132-B-6 Outfall Structure.

Waste Type: Demolition and Inert Waste

Waste Description: Possible chemical and/or radionuclide contamination (see Contaminants of Potential Concern).

No evidence has been found that the flume was ever put into service. If it had been used, the COPCs for the 100-B-25 spillway would be the same as those for the 132-B-6 outfall structure, which are as follows: Americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, total chromium, hexavalent chromium, lead, and mercury.

Closure Info: The Remaining Sites Verification Package (RSVP-2009-034) has documented that the 100-B-25 Overflow Spillway waste site has met the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units.

Excavation of the 132-B-6 Outfall sump in 2001 included removal of the upstream portion of the 100-B-25 spillway that was located within the excavation layback. Remedial action at the 100-B-25 waste site was performed between February 3 and March 14, 2009. Remediation encompassed the removal of a large volume of overburden that had been added in 2001, after the upper portion of the spillway was removed during the 132-B-6 Outfall remediation. The remaining spillway structure was unearthed and removed. Basalt rocks that formed the riprap on the slope to the Columbia River were removed for disposal due to elevated radiological readings.

The site was excavated to a maximum depth of approximately 5 m (16 ft) below grade, resulting in the removal of approximately 2,682 bank cubic meters (BCM) (3,504 bank cubic yards [BCY]) of material for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 4,991 BCM (6,521 BCY) of soil (overburden) was stockpiled for evaluation as clean backfill. Material awaiting disposal in the waste staging piles was removed and disposed at ERDF in July 2009.

Verification sampling was performed from July to September 2009. The samples were collected to determine if the remedial action goals (RAGs) for the site had been met. The contaminants of potential concern (COPCs) for verification sampling included americium-241, cesium-137, cobalt-60, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, chromium

(total), hexavalent chromium, lead, and mercury.

These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations supported unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and that contaminant levels remaining in the soil were protective of groundwater and the Columbia River. Site contamination extended slightly into the deep zone soils; however, the remediation footprint was evaluated against the more restrictive shallow zone criteria. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone were not required.

Code:	100-B-26	Classification:	Accepted
Names:	100-B-26; 1904-C Spillway; 100-B-15:1 Flumes from Outfall Structures 116-B-7, 132-B-6 and 132-C-2	Reclassification:	No Action (9/18/2006)
Type:	Outfall	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been reclassified to No Action. The riprap section of the spillway remains, with the upper portion covered by clean fill. A rudimentary road crosses the otherwise exposed lower riprap section.		
Location:	The site was located just north of 116-B-11 (the 107-B Retention Basin) and downstream of 132-B-6 (the 1904-B2 Outfall). The remaining portion of the spillway was along a centerline from E 565724, N 145498, a minimum of 7 meters (23 feet) due north to E 565724, N 145505. The top half of the remaining spillway was concrete, and the bottom half was heavy riprap.		
Process Description:	The Spillway (also referred to as a flume) was constructed of concrete and led from the 132-C-2 outfall structure, via a heavy riprap extension on the end of the concrete spillway, to the river shoreline. During decommissioning projects in the 1980's, the spillway walls were collapsed and the structure was covered with clean soil. The upper portion of the spillway was removed in 2001 as part of remediation of the outfall structure, and the remainder of the spillway/riprap was backfilled with clean soil. The spillway was an alternate discharge point for the 132-C-2 Outfall Structure. It was planned to be used as an alternate for effluent only if the 100-B-15 river effluent pipelines were blocked, damaged, or undergoing maintenance. There was no historical information that the spillway was ever used.		
Related Sites/ Structures:	The site was associated with 100-B-15 (the 100-B/C River Effluent Pipelines) and 132-C-2 (the 1904-C Outfall Structure).		
Waste Type:	Construction Debris		
Waste Description:	If ever put into service, the COPCs for the 100-B-26 spillway would be the same as those for the 132-C-2 Outfall, which are as follows: Americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, total chromium, hexavalent chromium, lead, and mercury.		
Closure Info:	During site evaluation for The Remaining Sites Verification Package it was determined that site reclassification to No Action posed less risk to human health and the environment than remediation. The remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD) have not been met. Confirmatory sampling results indicated that		

contaminant levels trapped in the soil beneath the riprap were more protective of groundwater and the Columbia River in their present state than they would be if released during remediation.

Confirmatory sampling of the waste site was conducted on January 17, 2006. Heavy equipment was used to excavate through the riprap, and the underlying soils were sampled. The sample results indicated that six constituents slightly exceeded remedial action goals for the protection of groundwater and the Columbia River. The residual contaminants within the spillway present little risk to human health and the environment compared to the effect remediating the spillway could have on the Columbia River and its shoreline.

The contaminants of potential concern (COPCs) for the 100-B-26 site were identified based on COPCs identified for the 132-C-2 outfall as follows: americium-241, cesium-137, cobalt 60, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, strontium-90, chromium (total), hexavalent chromium, lead, and mercury. Further consideration of upstream waste sites resulted in the inclusion of polychlorinated biphenyls (PCBs) as a COPC. Although not considered COPCs, confirmatory sample analysis was performed for the expanded list of inductively coupled plasma (ICP) metals to include antimony, arsenic, barium, beryllium, boron, cadmium, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc.

Samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The laboratory-reported results for all constituents have been stored in the Environmental Restoration (ENRE) project-specific database prior to submission for inclusion to the Hanford Environmental Information System (HEIS) and were included in Appendix B of the Remaining Site Verification Package, 2006-052.

The riprap section of the spillway remains, with the upper portion covered by clean fill. A rudimentary road crosses the otherwise exposed lower riprap section. The site was reclassified to no action because remediation to remove the riprap and underlying soils presented the possibility of destabilizing the riverbank and disturbing the existing ecosystem. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-B-27	Classification:	Accepted
Names:	100-B-27; Sodium Dichromate Spill	Reclassification:	Interim Closed Out (4/12/2010)
Type:	Unplanned Release	Start Date:	
Status:	Inactive	End Date:	
Description:	The site was an unplanned release of sodium dichromate that was discovered while removing the western staging pile associated with the cleanup of the 126-B-3 Coal Pit. Soil contamination associated with the spill consisted of a fairly narrow, near-vertical plume in the upper vadose zone (to approximately 11 m [36 ft] below ground surface [bgs]). Below this depth, the plume continued downward in a generally northeasterly direction. Soil contamination was found down to the groundwater table, located approximately 13.5 m (44 ft) bgs.		
Location:	The site was located 50 m (164 ft) due west of the former 126-B-3, Coal Pit.		
Process Description:	The source of contamination was unknown, but may have been related to a temporary receiving and storage warehouse that was located near the northern railroad spur. The warehouse was likely used for material offloading and storage from the railroad cars. Sodium dichromate was used in dry form at 100-B/C and transported via railroad until about 1955, when receipt of incoming sodium dichromate as a liquid solution began. The 100-B-27 waste site is believed to be associated with spillage and/or dumping of unknown amounts of sodium dichromate.		

Related Sites/ The site may be related to a temporary receiving and storage warehouse. The Plot Plan for 100-

Structures: B Area shows a material storage platform on the west end of the receiving warehouse. Initially, sodium dichromate was used in dry form thus, the platform was likely used for material offloading from railroad cars. A railroad spur left the main spur due north of the material handling platform and extended east 305 m (1000 ft) of track before it rejoined the main track. The site was associated with 126-B-3.

Waste Type: Chemical Release

Waste Description: The contaminant of potential concern is Cr6. Sample results for J030K6 show greater than 500 mg/kg total chromium (15,000 ug/L chromium by TCLP). Elevated chromium concentrations were also detected in waste characterization samples that were collected from segregated soil (J03CP6 and J03CP7).

The waste was soil contaminated with sodium dichromate. The suspected source of the sodium dichromate is consistent with handling and delivery of this material in bagged dry form. Sodium dichromate was delivered in dry form until about 1955 when modifications were made to use liquid sodium dichromate.

Closure Info: The Remaining Sites Verification Package (RSVP-2009-040) for the 100-B-27 has documented that the site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGS) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (ROD).

Initial remediation was performed from June 18 to 20, 2007, with excavation extending to approximately 4.6 m (15 ft) below ground surface (bgs) and removal of approximately 900 metric tons (1,000 U.S. tons) of contaminated material. Additional characterization showed that contamination extended to groundwater, so a decision was made to postpone remedial action until 2009.

Remediation resumed in February 2009 removing contaminated material to the groundwater table, encountered at approximately 14 m (46 ft) bgs. As remediation proceeded, rising Columbia River levels resulted in a rise in groundwater into the excavation, up to a maximum level of approximately 13.5 m (44 ft) bgs. Excavation activities were completed on June 9, 2009. A total of approximately 10,190 bank cubic meters (BCM) (13,330 bank cubic yards [BCY]) of contaminated soil and 40,180 BCM (52,550 BCY) of overburden/layback soil were excavated and disposed at the Environmental Restoration Disposal Facility.

The contaminants of potential concern (COPCs) were hexavalent chromium and total chromium, arsenic, antimony, barium, beryllium, boron, cadmium, chromium (total), cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc.

Following remediation, verification sampling was performed on August 3 through 10, 2009. The complete laboratory results were stored in the Environmental Restoration (ENRE) project-specific database prior to submitting to the Hanford Environmental Information System (HEIS) for archiving. They were also provided as an attachment to the 95% UCL calculation in Appendix C of the RSVP.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. Site contamination that extended into the deep zone soils was completely removed; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	100-B-28	Classification:	Accepted
Names:	100-B-28; 183-C Headhouse to 183-B Pumphouse Sodium Dichromate Transfer Pipeline	Reclassification:	Interim Closed Out (3/22/2010)
Type:	Product Piping	Start Date:	
Status:	Inactive	End Date:	
Description:	<p>This site consisted of an underground sodium dichromate pipeline from the 183-C Head House to the 183-B Filter Plant/Pump House. The pipeline was originally a soft water supply line from the 184-B Power House to the 183-C Head House. According to the RSVP in 1962, the pipeline was modified to transfer sodium dichromate from the 183-C Headhouse to the 183-B Filter Plant. The northern end of the waste site was located approximately 430 m (1,410 ft) directly west of the 105-B Reactor, and the southern end of the pipeline was 9 m (28 ft) northwest of the former 183-C Filter Plant (Figure 1). The remaining southern portion of the pipeline is considered within the footprint of the 100-C-7:1 waste site. The portion of the former soft water line leading to the 184-B Power House was confirmed to have been isolated during modification of the pipeline and was not associated with sodium dichromate transfer.</p>		
Location:	<p>The 7.6-centimeters (3-inches) steel line for supplying soft water from the 184-B Power House to the 183-C Head House was modified per the drawing (H-1-10350) at a point due east of the 183-B Filter Plant/Pump House in about 1962. The line from the 184-B Power House was blanked and a new line was run to the 183-B Filter Plant to allow use of the southern extent of the 3-inch steel line as a sodium dichromate transfer line from the 183-C Head House to the 183-B Filter Plant.</p>		
Release Description:	<p>Concentrated sodium dichromate solution was drained from the "softwater" pipeline (1,2) that was excavated and opened during July-August 2005 at the 100-C-7 waste site (dichromate unplanned release) north of the 183-C Head House. The piping drawing (3) indicates the 7.6-cm (3-in) softwater line was modified in 1962 to serve as a sodium dichromate solution transfer line from the 183-C Head House to the 183-B Filter Plant. The sodium dichromate solution was collected and disposed. The spilled material was contained within the existing 100-C-7 waste site (a sodium dichromate unplanned release waste site).</p>		
Process Description:	<p>Sodium dichromate solids and concentrated solutions were received, stored, and mixed with the reactor cooling water as a corrosion inhibitor for the reactor fuel and piping. Initially, granular sodium dichromate was mixed with water to prepare a 15 Weight Percent solution that was metered into the volute of the primary pumps in the 190-B Pump House to provide a 2 part per million (ppm) concentration of sodium dichromate in the reactor cooling water. Later, the solid sodium dichromate feedstock was replaced with a concentrated (70% by weight) sodium dichromate solution that was metered into the cooling water to produce the 2 ppm concentration of sodium dichromate. The southern section of the soft water line was isolated from the 184-B Power House supply line at a point east of the 183-B Filter Plant and the northern section was blanked. A new pipeline segment was installed to connect the southern section of the pipeline to the 183-B Filter Plant.</p>		
Related Sites/ Structures:	183-C Head House; 183-C Filter Building/Pump Facility; 184-B Power House		
Waste Type:	Abandoned Chemicals		
Waste Description:	<p>Concentrated sodium dichromate solution was drained from the converted softwater pipeline (1-3) excavated and opened at the 100-C-7 waste site (dichromate unplanned release) north of the 183-C Head House. The 7.6-cm (3-in) softwater line was modified in 1962 to serve as a sodium dichromate solution transfer line from the 183-C Head House to the 183-B Filter Plant</p>		
Closure Info:	The Remaining Sites Verification Package (RSVP-2009-057) has documented that the 100-B-		

CLOSURE IIIU.

28, 183-C Headhouse to 183-B Pumphouse Sodium Dichromate Transfer Pipeline site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGS) for Interim Closed Out as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD). The 100-B-28 waste site was included in the Explanation of Significant Differences for the 100 Area Remaining Sites Interim Remedial Action Record of Decision, (EPA 2009) as a waste site for remediation, treatment, and disposal.

Remedial action at the site was performed from February to April 2009. Remediation included removing and staging overburden material; hot tapping, draining, and collecting the pipeline liquid; size-reducing and removing the pipeline; and removing and staging contaminated material for disposal at the Environmental Restoration Disposal Facility (ERDF). Two sections of pipeline beneath active utility lines were grouted in-place to flush residual sodium dichromate liquid. The potential for pipe leakages beneath these sections could not be addressed while the utilities remain active. Therefore, in agreement with DOE-RL and EPA, these two sections will be administratively removed from the site and placed in a new waste site created to collect components from various waste sites that cannot be remediated while utilities remain active.

The grout-filling campaign for the two sections of pipeline that were left in place was initiated on April 13, 2009, and completed on April 14, 2009. The grout was pumped into the northern section of the 100-B-28 pipeline. This section of pipeline, approximately 26 m (85 ft) in length, was located beneath an active pipeline supplying water for fire suppression. During grout addition, approximately 76 L (20 gal) of sodium dichromate liquid was displaced, collected, and drummed. The second section of pipeline, approximately 26 m (85 ft) long, ran beneath the export water line located at the southern end of the excavation. Approximately 38 L (10 gal) of sodium dichromate liquid was displaced during grout addition and disposed in the same manner as described previously.

During the excavation of the southern portion of the site, discolored soil was encountered at the base of the 7.6-cm (3-in.) pipeline. The worst of the discolored material soil was sampled (J18N79) for ICP metals and TCLP metals. Data results showed TCLP values for chromium at 130 mg/L. The material was LDR, requiring treatment for disposal at ERDF. Sampling was not performed on the less-impacted soils; however, it was conceded the material would qualify as LDR material. Approximately 40 BCM (52 BCY) of material required treatment. During removal of contaminated soil and a concrete encasement surrounding the grout-filled pipeline, a 6.1-m (20-ft) section sheared off the end. This section was placed into an ERDF container with the rest of the pipeline designated for flood grouting.

The contaminants of potential concern (COPCs) for the site were determined based on available process information and field observations during remediation. The primary contamination at this site was related to sodium dichromate; therefore, the COPCs are hexavalent chromium and total chromium. Although not considered COPCs, analyses for the constituents of the expanded ICP metals list were also performed. This included analysis for arsenic, antimony, barium, beryllium, boron, cadmium, chromium (total), cobalt, copper, lead, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc.

One focused sample location included PAHs as the only COPCs due to the presence of benzo(a)pyrene and indeno(1,2,3-cd)pyrene detected in an in-process sample collected during remediation from the french drain location.

Following remediation, verification sampling was performed between August 24 and August 26, 2009. Based on evaluation of the final verification sampling results, the residual

contaminant concentrations meet the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. This site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

Code:	100-B-32	Classification:	Accepted
Names:	100-B-32; SCA #1; Soil Contamination Area Associated with Legacy Waste	Reclassification:	Interim Closed Out (1/13/2010)
Type:	Unplanned Release	Start Date:	1/1/2005
Status:	Inactive	End Date:	1/1/2009

Description: The site had been a Surface Contamination Area (SCA) found on the haul route from the 118-B-1 Burial Ground to the container transfer area. The area was previously posted as an SCA due to multiple locations of elevated radiological activity identified by LARADS. Field instrumentation indicated a location with approximately 3.4 million dpm/100 square centimeters beta/gamma activity at this spot. The hot spot measured approximately 25 square centimeters. The contamination at this location was matrixed with the asphalt and is believed to be a legacy of past practices and operations. Down-posting efforts following completion of remediation and closure activities in the area confirmed an area of significantly elevated radiological activity at the location listed. No other areas of significant elevated activity were identified along the posted haul route at the locations previously identified based on 2005 LARADS data.

Location: The site is located in 100-B/C Area, south of the 182-B Reservoir, just west of the intersection of Burnett Avenue and Bow Street, and on the southern portion of the roadway surface. The approximate Washington State Plane coordinates are E564738, N144362.

Related Sites/ Structures: 100-B-32 is associated with 118-B-1 Burial Ground.

Waste Type: Soil

Waste Description: The waste is contaminated soil and asphalt. The contaminants of potential concern are radiological contaminants. The source of this material is unknown.

Closure Info: The Remaining Sites Verification Package for the 100-B-32 Soil Contamination Area Associated with Legacy Waste, SCA #1, RSVP-2009-053, has documented that site verification sampling results support a reclassification to Interim Closed Out. The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 1004U-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

Remedial action activities were performed on July 28, 2009. Verification sampling was done on August 10, 2009. The Contaminants of Potential Concern (COPC) for the site were identified as beta/gamma emitters based on field detection instrumentation. The measured gross alpha and beta activity was consistent with background; therefore no further analysis was requested.

The laboratory-reported verification data results for all constituents were stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford

Environmental Information System (HEIS). A detailed sample summary was provided in Appendix A of the RSVP.

The waste site has been evaluated in accordance with the Remaining Sites ROD (EPA 1999) and the RDR/RAWP. Verification sampling was performed and the analytical results indicate that the residual concentrations of COPCs at this site meet the Remedial Action Objectives (RAOs) for direct exposure, groundwater protection and river protection. Site contamination did not extend into the deep zone soils; therefore no institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required.

Code: 100-B-33 **Classification:** Accepted

Names: 100-B-33; SCA #2; Soil Contamination Area 2 **Reclassification:** Interim Closed Out (1/13/2010)
Associated with Legacy Waste

Type: Unplanned Release **Start Date:**

Status: Inactive **End Date:**

Description: The site is a Surface Contaminated Area (SCA). The site was discovered during GPERS surface soil surveys of the north-east quadrant of the 100-BC Area in July - August 2007. The readings found showed an elevated area averaging 15,000 cpm over a 150 square meter area with a max reading of 93,000 cpm.

Location: The site is located in the north-east quadrant of the 100-B/C Area, north of the railroad tracks and east of the former 100-C-9 pipeline. The approximate Washington State Plane coordinates are E565557.125, N144949.672.

Waste Type: Soil

Waste Description: The waste is contaminated soil. The contaminants of potential concern are radiological contaminants. The source of this material is unknown.

Closure Info: Remedial action was performed from May to August 2009. Remediation consisted of removing soils with elevated radiological activity identified with field instrumentation. In total, approximately 310 bank cubic meters (410 bank cubic yards) of contaminated soil was excavated and staged on site before being disposed at the Environmental Restoration Disposal Facility.

The contaminants of potential concern (COPCs) for the site were determined using historical sampling data from adjacent structures (e.g., 116-C-5 Retention Basins) and the results of characterization samples J18N05 and J18N06. The COPCs for the site included: lead, mercury, chromium (total), carbon-14, cesium-137, cobalt-60, europium-152, nickel-63, plutonium-238, plutonium-239/240, strontium-90, tritium, uranium-233/234, uranium-235, and uranium-238. Although not considered COPCs, arsenic, antimony, barium, beryllium, boron, cadmium, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc were also evaluated by performing analyses for the expanded inductively coupled plasma metals list.

Following remediation, verification sampling was conducted in September 2009. The results indicated that the waste removal action achieved compliance with the remedial action objectives (RAOs) and remedial action goals (RAGs) for the site. The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to inclusion into the Hanford Environmental Information System. The sampling results data were presented in Appendix A of the RSVP. The verification sampling results support a reclassification of this site to Interim Closed Out. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 116-B-1 **Classification:** Accepted

Names: 116-B-1; Process Effluent Trench; 107-B Liquid Waste Disposal Trench **Reclassification:** Interim Closed Out (12/8/1999)

Type: Trench **Start Date:** 1/1/1950

Status: Inactive **End Date:** 1/1/1968

Description: The site has been remediated and closed out. The 116-B-1 Liquid Waste Disposal Trench was dug to receive effluent routed from 116-B-11 (107-B Retention Basin). The unit ran from southwest to northeast. The site included the 40.6 centimeter (16 inch) diameter steel piping from 116-B-11. Historical documents described the trench as a french drain or an excavation that was partly or completely filled with coarse gravel and had dimensions of 61 meters (200 feet) long by 9.1 meters (30 feet) wide by 4.6 meters (15 feet) deep. A geophysical investigation of 116-B-1 performed in November and December 1996 showed the trench was almost twice as long as indicated by historical information (see Dimensions). The Ground Penetrating Radar (GPR) survey identified a pipeline, labeled #10 in the survey report, entering the trench at its southwest end. No other pipelines were evident. A significant volume of buried debris was present in the northeastern half of the trench.

Location: The site was located east of the 107-B Retention Basin.

Related Sites/Structures: The site was associated with the 107-B Retention Basin and the 107-C Retention Basin.

Waste Type: Misc. Trash and Debris

Waste Description: Geophysical investigation identified a high concentration of subsurface debris in the northeastern half of the trench.

Waste Type: Process Effluent

Waste Description: The site received effluent from the 107-B Retention Basin at times of high activity due to fuel element failures. The fission products of 54 fuel ruptures were routed to this site.

Closure Info: The site has been excavated; the excavation floor was about 1,863 square meters (20,056 square feet or 0.46 acres) at a depth of 4.6 meters (15 feet). About 43,033 metric tons (47,436 tons) of material was disposed of in the Environmental Restoration Disposal Facility (ERDF).

The maximum dose rate (all pathways) predicted from the RESRAD dose assessment model is 5 mrem/year in 1999, and decreases to 0.014 mrem/year in 1,000 years, based on samples taken from the excavation walls and floor. Hexavalent chromium is the only non-radionuclide carcinogenic contaminant of concern; the risk value was three orders of magnitude below the individual and cumulative risk limits.

Code: 116-B-2 **Classification:** Accepted

Names: 116-B-2; B-Storage Basin Crib; 105-B Storage Basin Trench **Reclassification:** Interim Closed Out (2/24/2000)

Type: Trench **Start Date:** 1/1/1946

Status: Inactive **End Date:** 1/1/1946

Description: This site was remediated and closed out on February 24, 2000. It is no longer marked or posted. The trench was used one time to receive approximately 4E+06 liters (1.1E+06 gallons) of storage basin water that became contaminated when a fuel rod was accidentally cut in half. The trench was backfilled after use with clean dirt.

Location: The 116-B-2 site was located near the center of the 100-B Area, approximately 865 meters (2,838 feet) from the Columbia River and 76 meters (250 feet) northeast of 105-B Storage Basin.

Process: The trench was only used once in 1946 to receive contaminated basin water after a fuel element

Description: was accidentally cut in half in the 105-B Fuel Storage Basin.

Waste Type: Water

Waste Description: This unit was dug and used once after a fuel element was accidentally cut in half in the 105-B Storage Basin. Basin water was discharged to this unit in an attempt to remove radionuclides from the fuel storage basin cooling water for contamination control.

Closure Info: The site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the ROD (EPA 1995) and are summarized in the CVP along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 1998) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL 1998).

Excavation of the 116-B-2 site began on February 17, 1999, by removing the overburden materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. After completion of the initial excavation to design limits, several contaminated areas (i.e., plumes) were discovered. Each of the plumes was excavated and the new surfaces were screened for contamination. On May 20, 1999, the excavation had reached the final limit at El. 138.4 meters (454.2 feet). Cleanup verification sampling began on May 21, 1999, and was finished on June 24, 1999.

At the completion of the remedial action, the excavation floor area was approximately 459 square meters (4,940 square feet) at a depth of approximately 4.9 meters (16 feet), and approximately 9,393 metric tons (10,354 tons) of material from the site had been disposed of at ERDF.

As of February 2000, the excavation will be backfilled with clean fill materials to the reference grade of El. 143.3 meters (470.2 feet). Clean backfill may be taken from the clean overburden pile and other sources of clean material that have been verified clean in accordance with the SAP (DOE-RL 1998) and that are appropriate for use as backfill.

From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following: cesium-137, europium-152, europium-154, strontium-90, uranium-238, uranium-233/234, and hexavalent chromium (Cr+6).

The cleanup verification package (CVP) demonstrated that remedial action at the 116-B-2 site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and RDR/RAWP. Materials that contained COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in Section 4.2 of the CVP, assumes multiple exposure pathways (e.g., ingestion, inhalation, direct exposure) for shallow zone soils. (The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 meters (5 feet)] are required.) The verification package also demonstrated that residual COC concentrations pose no threat to groundwater or the Columbia River. Thus, the 116-B-2 site has been verified to be remediated and may be backfilled.

Code: 116-B-3	Classification: Accepted
Names: 116-B-3; 105-B Pluto Crib	Reclassification: Interim Closed Out (2/24/2000)
Type: Crib	Start Date: 1/1/1951
Status: Inactive	End Date: 1/1/1952

Description: The 116-B-3 Pluto Crib has been remediated and was closed out on February 24, 2000. It is no longer marked or posted. This unit was a wooden crib shored with railroad ties, filled with gravel and covered to grade with clean soil. A concrete marker indicates the position of the crib. Clukey (1954) indicates that the crib is a french drain, otherwise defined as a "tile or pipe buried vertically, sometimes gravel-filled". After its use, the crib was reportedly unearthed and shored with wooden ties.

Location: This unit was located within the 105-B Area exclusion fence, about 30 meters (100 feet) east of the 105-B Building and about 847 meters (2,780 feet) from the 100-year flood level of the Columbia River.

Process Description: This pluto crib received 105-B cooling water wastes that had been contaminated by cladding ruptures of fuel elements. Cooling water diversion occurred when a fuel element rupture was detected within a process tube. The water was diverted from the affected process tube through a valve on the rear of the reactor face known as a "pluto valve" and through rubber hose to the crib. The wooden crib was buried so that its upper surface was approximately at grade. A hatch on the upper surface was opened to receive the rubber hose and the crib was allowed to flood.

Waste Type: Water

Waste Description: The site received effluent from reactor tubes containing ruptured fuel elements.

Closure Info: The cleanup verification package (CVP-1999-00013) has documented that the 116-B-3 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision (ROD) (EPA 1995) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL 1998).

The remedial action excavation was conducted at this site beginning on February 17, 1999 and ending March 11, 1999. At the completion of the remedial action, the area of the excavation was approximately 112 square meters (1,209 square feet) at a maximum depth of approximately 4.6 meters (15 feet). Approximately 244 metric tons (269 tons) of material from the site were disposed at the ERDF. As of February 2000, the excavation is to be backfilled with clean fill materials to the reference grade of El. 143 meters (469 feet).

From process knowledge and identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-1998), contaminants of concern (COCs) included cesium-137, strontium-90, uranium-233/234, and hexavalent chromium.

The remaining soils have been sampled, analyzed, and modeled to show that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 meters (15 feet)] are required.) The verification package also demonstrated that residual COPC concentrations pose no threat to groundwater or the Columbia River. Thus, the 116-B-3 site has been verified to be remediated and may be backfilled.

square meters (11,433 square feet) at a depth of approximately 4.6 meters (15 feet), and approximately 8,700 metric tons (9,590 tons) of material from the site had been disposed at ERDF.

From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include cobalt-60, cesium-137, europium-152, europium-154, europium-155, and plutonium-239/240.

The cleanup verification package (CVP) demonstrated that remedial action at the 116-B-4 site has achieved the RAOs and corresponding RAGs established in the approved Interim Action ROD (EPA 1995) and RDR/RAWP (DOE-RL 1998). The remaining soils have been sampled, analyzed, and modeled to show that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 meters (5 feet)] are required.

Code:	116-B-5	Classification:	Accepted
Names:	116-B-5; 116-B-5 Crib; 116-B-5 Trench; 108-B Crib	Reclassification:	Interim Closed Out (1/14/1997)
Type:	Crib	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1968
Description:	The crib structure and its contents have been removed. The crib was constructed of concrete timbers and consisted of 12 rectangular cells in a single row. Each cell was partially filled with sandy gravel and had a separate concrete lid. For cleanup purposes, the cells were identified using the letters "A" through "L", with cell A being the southernmost cell.		
Location:	The crib was located approximately 46 meters (150 feet) north of the 108-B Building site (132-B-1) and east of the 108-B Ventilation Exhaust Stack Burial Ground (132-B-3).		
Waste Type:	Process Effluent		
Waste Description:	The site received liquid tritium wastes from the 108 Building. Only wastes of less than 1 microcuries/cubic centimeter were discharged to this unit.		
Closure Info:	In June 1995, the site was excavated as part of the 100-B/C Demonstration Project. Remedial action was accomplished by excavating approximately 300 cubic meters (10,600 cubic feet) of soil from the crib and demolishing the concrete crib structure, leaving an open excavation approximately 34 meters (112 feet) by 8 meters (26 feet) to a 5 meter (16 feet) depth. The soils within and surrounding the crib were sampled and analyzed. The soils from cells C and D containing levels of tritium above cleanup standards were taken to the Environmental Restoration Disposal Facility (ERDF). All other soils sampled were within cleanup standards.		

There were 137 samples taken during remediation activities. The samples are identified as follows: 116-B5-007, 116-B5-008, 116-B5A-10, 116-B5A-12.5, 116-B5A-14.5, 116-B5B-10, 116-B5B-12.5, 116-B5B-14.5, 116-B5C-6, 116-B5D-10, 116-B5D-12.5, 116-B5D-15, 116-B5E-10, 116-B5E-12.5, 116-B5E-15, 116-B5F-10, 116-B5F-12.5, 116-B5F-15, 116-B5G-10, 116-B5G-12.5, 116-B5G-15, 116-B5H-10, 116-B5H-12.5, 116-B5H-15, 116-B5I-10, 116-B5I-12.5, 116-B5I-15, 116-B5I-D, A_BTM, A_PILE, B_BTM, B0G7C2 through B0G7C9, B0G7C7ND, B0G7D0 through B0G7D9, B0G7F0 through B0G7F9, B0G7G0 through B0G7G3, B0G7G6 through B0G7G9, B0G7H0 through B0G7H9, B0G7J0 through B0G7J9, B0G7K0 through B0G7K9, B0G7L0 through B0G7L9, B0G7M0 through B0G7M5, B0G7N1 through B0G7N9, B0G7P1, B0G8Z4, B0G8Z5, CELL8TOP, CELLAPS1, CELLAPS2, CELLBPS1, H95023 through H95027, PIPELCA, and PIPELCB. A summary table showing

the samples results is published in the 100-B/C Demonstration Project Final Report (BHI-00752).

A "100 NPL Agreement/Change Control Form" documenting the close out of the 116-B-5 Crib was submitted on January 8, 1997 and signed by the Environmental Protection Agency Project Manager on January 14, 1997. The form also authorized the backfilling of the waste site.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code:	116-B-6A	Classification:	Accepted
Names:	116-B-6A; 111-B Crib No. 1; 116-B-6-1	Reclassification:	Interim Closed Out (5/17/2000)
Type:	Crib	Start Date:	1/1/1951
Status:	Inactive	End Date:	1/1/1968

Description: This site has been remediated and closed out.

Location: The site was located immediately north of the 111-B Building Site.

Process Description: The 116-B-6A Crib received radioactive liquid wastes from equipment decontamination performed in the 111-B Building, as well as from the decontamination of fuel element spacers.

Waste Type: Process Effluent

Waste Description: The unit received radioactive liquid wastes from equipment decontamination performed in the 111-B Building, as well as from the decontamination of fuel element spacers performed at the 111-B Building Decontamination Station.

Closure Info: 116-B-6A and 116-B-16 were addressed as a group. The information below documents information for the group of sites.

The cleanup verification package for the 116-B-6A Crib and 116-B-16 Fuel Examination Tank, because of their close proximity to each other and similar contaminants of concern (COCs), were excavated as one remedial action site and are hereinafter referred to as the 116-B-6A/116-B-16 site.

At the completion of the remedial action, the total excavation was approximately 603.5 meters squared (6,496 square feet or 0.15 acres) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 5,072 metric tons (5,591 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The excavation will be backfilled in the near future (written June 6, 2000) with appropriate materials to the reference grade El. 146 meters (479 feet).

Results of the sampling, laboratory analyses, and data evaluations for the 116-B-6A/116-B16 site indicate that all remedial action objectives and goals for direct exposure, protection of ground water, and protection of the Columbia River have been met. However, this site close out includes a deed restriction against drilling or digging into the deep zone soils (below 4.6 m [15 ft] depth).

Code:	116-B-6B	Classification:	Accepted
--------------	----------	------------------------	----------

Names: 116-B-6B; 111-B Crib No. 2; 116-B-6-2 **Reclassification:** Interim Closed Out (2/24/2000)

Type: Crib **Start Date:** 1/1/1950

Status: Inactive **End Date:** 1/1/1953

Description: This site has been remediated and closed out. The site was commonly known as the 116-B-6B Crib, although it has also been known as 111-B Crib No. 2 and as 116-B-6-2.

Location: The site is located approximately 9.2 meters (30 feet) southeast of the former 111-B Building site.

Process Description: The unlined crib received radioactive wastes from equipment decontamination performed in the 111-B decontamination station, as well as liquid wastes from the decontamination of fuel element spacers.

Related Sites/ Structures: The site was associated with the 111-B Building.

Waste Type: Process Effluent

Waste Description: The site received radioactive wastes from equipment decontamination performed in the 111-B Building as well as liquid wastes from fuel element spacer decontamination.

Closure Info: The Cleanup Verification Package (CVP-99-00017) demonstrates that remedial action at the 116-B-6B site has achieved the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the Interim Action ROD (ROD) (EPA 1995) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 1998).

The waste site contaminant of concern (COC) identified from process knowledge and listed in the sampling and analysis plan (SAP) is lead. Volatile organic compounds (VOC) were included as contaminants of potential concern; however, no VOCs were detected in the field. Therefore, VOCs were not addressed in the cleanup verification analyses for this site.

Excavation of the 116-B-6B site began on March 11, 1999, by removing the materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. On March 12, 1999, the excavation reached the design limits at El. 144.28 meters (473 feet) and cleanup verification sampling was initiated.

At the completion of the remedial action, the excavation floor was approximately 25 square meters (270 square feet) at a depth of 3 meters (9.8 feet). A total of approximately 263 metric tons (259 tons) of material were disposed at the Environmental Restoration Disposal Facility (ERDF). The excavation was to be backfilled with clean fill materials to the reference grade of El. 147.3 meters (483 feet).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 116-B-7 **Classification:** Accepted

Names: 116-B-7; 1904-B1; 1904-B-1 Outfall Structure **Reclassification:** Interim Closed Out (7/25/2002)

Type:	Outfall	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1972
Description:	The site has been remediated and closed out. The outfall was excavated, sampled and backfilled to match the surrounding grade.		
Location:	The site was located at the top of the river bank, northwest of 116-B-11 (107-B Retention Basin), upstream of 132-B-6 (1904-B2 Outfall).		
Process Description:	Outfalls were open, reinforced concrete structures that directed the water through either the river discharge pipelines or through spillways. The spillways were concrete flumes used when the river pipelines were blocked, damaged or undergoing maintenance. Cooling water released from the reactor went to a retention basin located between the reactor building and the river. Water retention permitted thermal cooling and decay of short-lived radioisotopes prior to river discharge. As reactor production increased, the hold-up period decreased. The basins also served to hold up flow of effluent with high radioactive isotope concentrations resulting from fuel element failure. This effluent was isolated and diverted, either by gravity or pumping, to an open pond area or crib. The pond or crib filtered the effluent through the ground. The cooling water discharged into the upper chamber of the concrete outfall structure, flowed through a bar grillwork and fell about 20 feet to the lower chamber of the outfall structure. The cooling water then overflowed from the lower chamber into the discharge pipe to the river.		
Related Sites/ Structures:	The site received effluent from the 100B process effluent lines (100-B-8), the 100B process sewer lines (100-B-14), and discharged effluent via the 100BC river effluent pipelines (100-B-15) and flumes (100-B-15:1).		
Waste Type:	Process Effluent		
Waste Description:	The outfall was originally used for both process sewer and reactor cooling water disposal until 1954 when it was used exclusively for process sewer disposal.		
Closure Info:	116-B-7, 132-B-6 and 132-C-2 were addressed as a group. The information below documents information for the group of sites.		

The cleanup verification package (CVP-2002-00003) for the sites, also referred to as B/C Outfall, has demonstrated that remedial action has met the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the approved interim action Interim Action Record of Decision (ROD) (EPA 1999) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17 Rev. 3).

Remedial action at the B/C Outfall site began on June 4, 2001. Excavation of the three outfall sites involved removing the overburden materials and debris, the contaminated structure, and underlying contaminated soil.

The COCs and COPCs for this site consist of the following: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, and strontium-90. Sampling and analysis during remediation indicated that additional COPCs should be identified. The additional COPCs are as follows: total chromium, hexavalent chromium, lead, mercury. Total chromium, hexavalent chromium, lead, and mercury were detected in cleanup verification samples and were therefore evaluated as COCs for the B/C Outfall site.

Cleanup verification sampling for the deep and shallow zones was done on January 14 and 15, 2002. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the SAP.

The sampling results indicate that residual concentrations in the shallow zone will support

future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

Institutional control (IC) information has been revised for 116-B-7, 132-B-6, and 132-C-2 as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including these, WIDS had shown that no IC restrictions were required but the sites were remediated with deep zone criteria so that Ics actually were required. The Ics for this site have been revised accordingly.

Code:	116-B-9	Classification:	Accepted
Names:	116-B-9; 104-B-2 French Drain	Reclassification:	Interim Closed Out (2/24/2000)
Type:	French Drain	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1954
Description:	The site has been remediated and closed out. The site is a french drain that was related to the 104-B-2 Tritium Laboratory (118-B-9). The site includes the feed pipeline that originated at the 104-B Building. The drain was not originally apparent from the surface. Ground Penetrating Radar (GPR) revealed an anomaly consistent with a french drain. Photo images #2 and #3 show the french drain.		
Location:	The site is located approximately 30 meters (100 feet) east of the 104-B-2 Storage Building (104-B2 Tritium Laboratory), northwest of the 108-B Tritium Separation Facility (132-B-1), and just inside the reactor exclusion area fence.		
Process Description:	The 104-B-2 building was associated with the P-10 project that involved tritium production. The 104-B-2 Building was used to store casks containing irradiated lithium targets for tritium production and product tritium. The facility contained an inspection laboratory and an annex on the east end that contained air sampling equipment.		
Related Sites/ Structures:	The site was associated with the 104-B-2 Building.		
Waste Type:	Process Effluent		
Waste Description:	The site received waste water from the P-10 Storage Building drain. Since the P-10 project involved tritium production, tritium may be a potential contaminant. The drain is not currently posted as being contaminated. An evaluation to determine potential contaminants for the 100 Area SAP resulted in four COPCs: coal-60, cesium-137, europium-152, and strontium-90.		
Closure Info:	Site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the Interim Action ROD (EPA 1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 1998) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL 1998).		

From process knowledge, there are no waste site contaminants of concern (COCs) identified in the SAP (DOE-RL 1998a). However, several contaminants of potential concern (COPCs) have been identified. These COPCs are cobalt-60, cesium-137, europium-152, and strontium-90.

Excavation of the 116-B-9 site began on March 10, 1999, by removing the overburden

materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. On March 11, 1999, the excavation had reached the design limit at El. 139 meters (455.8 feet). Cleanup verification sampling began on March 15, 1999, and was finished on April 23, 1999.

At the completion of the remedial action and removal of the engineered structure, the excavation area was approximately 51.5 square meters (554 square feet or 0.013 acres) at a depth of approximately 2.44 meters (8.0 feet). The excavation will be backfilled in the near future (as of February 2000) with clean fill materials to the reference grade of El. 141.1 meters (462.8 feet). Clean backfill may be taken from the clean overburden pile and other sources of clean material that have been surveyed in accordance with the SAP (DOE-RL 1998) and that are appropriate for use as backfill.

The CVP demonstrates that remedial action at the 116-B-9 site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and the RDR/RAWP (DOE-RL 1998). Materials that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual COC concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in the Cleanup Verification Package (CVP), assumes multiple exposure pathways (e.g., ingestion, inhalation, and direct exposure) for shallow zone soils.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 meters (15 feet)] are required. The verification package demonstrates that residual COC concentrations pose no threat to groundwater or the Columbia River. Thus, the 116-B-9 site is verified to be remediated in accordance with the ROD.

Code:	116-B-10	Classification:	Accepted
Names:	116-B-10; Quench Tank; 108-B Dry Well	Reclassification:	Interim Closed Out (2/24/2000)
Type:	Injection/Reverse Well	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1968
Description:	The site was remediated in 1999 and closed out in February 2000. It is no longer marked or posted. The site was a french drain with a metal manhole type cover and constructed of a 61-centimeter (24-inch) vitrified clay pipe on subsurface concrete slab. It was covered with a plywood cover and clean backfill material. A 3.8-centimeter (1.5-inch) drain line was added in the mid-50s that came from the experimental tube and other hardware decontamination facility. All piping leading into the drain was removed at the time of the 108-B demolition.		
Location:	The unit is located in the northwest corner of Room 15-C of 108-B Building.		
Process Description:	The quench tank was used to collect liquid decontamination wastes from the 108-B Tube Examination and Experimental Facility.		
Waste Type:	Process Effluent		
Waste Description:	This site received liquid decontamination wastes from the 108-B Tube Examination and Experimental Facility. During the tritium recovery programs, the site also received liquid decontamination wastes from the mask and small tool decontamination station located on the second floor and storm runoff from the fan room roof. The 108-B Building was involved with tritium recovery activities so tritium is a possible contaminant of concern.		
Closure Info:	The cleanup verification package (CVP-99-00010) has demonstrated that remedial action at the 116-B-10 site has met the Remedial Action Objectives (RAOs) and corresponding Remedial		

Action Goals (RAGs) as established in the approved interim action Interim Action Record of Decision (ROD) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

The site was remediated to meet the cleanup standards and closed out on February 24, 2000. The contaminants of potential concern (COPC) identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) include: cobalt-60, cesium-137, europium-152, europium-154, strontium-90, uranium-233/234, uranium-238, hexavalent chromium, and mercury.

Excavation of the site began on March 10, 1999. After completion of the initial excavation to design limits, several other contaminated areas (plumes) were discovered and also excavated. For this phase cleanup verification sampling began on May 20, 1999, and was finished on June 22, 1999.

At the completion of the remedial action, the excavation floor was approximately 153 square meters (1650 square feet) at a depth of 2.4 meters (8 feet), and approximately 692 metric tons (763 tons) of material were disposed at the Environmental Restoration and Disposal Facility (ERDF).

The remaining soils have been sampled, analyzed, and modeled to show that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in Section 4.2 of the CVP, assumes multiple exposure pathways (e.g., ingestion, inhalation, direct exposure) for shallow zone soils.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	116-B-11	Classification:	Accepted
Names:	116-B-11; 116-B-11 Retention Basin; 107-B Retention Basin	Reclassification:	Interim Closed Out (12/8/1999)
Type:	Retention Basin	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1968
Description:	The site has been remediated and closed out. It includes the retention basin and the two effluent pipes running parallel to, and adjacent to, the north side of the basins. These pipes were removed as part of the plume removal during the retention basin remedial action.		
Location:	The 116-B-11 Retention Basin lies near the northern edge of the 100-B Area and is located north of 116-C-5 (107-C Retention Basin).		
Process Description:	The 116-B-11 Retention Basin was constructed to hold cooling water effluent from the 105-B Reactor to allow for thermal cooling and radioactive decay prior to release to the Columbia River. This unit was a concrete-lined basin with wooden baffles. The basin was divided lengthwise into two halves designed to operate independently. The floor and walls consist of concrete slabs, their joints were originally closed with neoprene water seals. From the basin floor to approximately 3 meters (10 feet) above the floor, the walls sloped and were approximately 0.1 meter (4 inches) thick. The upper 3 meter (10-foot) sections of the walls were vertical and ranged in thickness from about 1.7 meters (5 feet 8 inches) at the bottom to 0.3 meter (1 foot) at the top. The unit was backfilled with soil to a depth of almost 1.2 meters		

(4 feet).

Related Sites/ Structures: The 116-B-11 Retention Basin is associated with the 105-B Reactor, the 116-B-1 Liquid Waste Disposal Trench, 116-B-7 (1904-B1 Outfall), and the 132-B-6 (1904-B2 Outfall).

Waste Type: Water

Waste Description: This unit received cooling water effluent from the 105-B Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Total radionuclide inventories in the vicinity of the unit ranged from 5 to over 400 curies. Eighty percent of the total radionuclide inventory is contained within the soil adjacent to the unit. Approximately 10 curies have leached into the concrete floor and walls.

Closure Info: The site has been excavated and remediated. Results of the sampling, testing, and analyses for the 116-B-11 site cleanup indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of surface waters (including the Columbia River) have been met.

The material removed from the site (approximately 165,178 metric tons [182,109 tons]) was disposed of in the Environmental Restoration Disposal Facility (ERDF). The excavation will be backfilled with clean material to the reference grade of elevation 132.5 meters (434.7 feet).

Code: 116-B-12	Classification: Accepted
Names: 116-B-12; 117-B Crib; 117-B Seal Pit Crib	Reclassification: Interim Closed Out (2/24/2000)
Type: Crib	Start Date: 1/1/1961
Status: Inactive	End Date: 1/1/1968

Description: This site has been remediated and closed out. The site was a crib with bottom measurements of 6.1 meters (20 feet) by 15.24 meters (50 feet).

Location: The site is located northeast of the 105-B Reactor Building. The site is adjacent to the 118-B-5 Burial Ground.

Process Description: The crib received drainage from the confinement system seal pits in the 132-B-4 Air Filtration Ventilation Building.

Related Sites/ Structures: The site was associated with the 117-B (132-B-4 Air Filtration Ventilation) Building, which has been demolished.

Waste Type: Process Effluent

Waste Description: The site received drainage from the confinement system in the 117-B Building seal pits. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP (DOE-RL 1998) include strontium-90, uranium-238, and hexavalent chromium (Cr+6).

Closure Info: This site was remediated to meet the cleanup standards and closed out on February 24, 2000.

Site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the Interim Action ROD (EPA 1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 1998) and are discussed in further

detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL 1998).

From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP (DOE-RL 1998) include strontium-90, uranium-238, and hexavalent chromium (Cr+6).

Excavation of the 116-B-12 site began on February 17, 1999, by removing the overburden materials and underlying contaminated soil. Based on field screening, materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On March 5, 1999, the excavation had reached the design limit at El. 139.93 meters (459.1 feet). Cleanup verification sampling began on March 15, 1999, and was finished on April 13, 1999.

At the completion of the remedial action, the excavation floor area was approximately 520.8 square meters (5,605.8 square feet or 0.129 acres) at a depth of approximately 4.6 meters (15 feet), and approximately 8,696 metric tons (9,586 tons) of material from the site had been disposed of at ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 144.5 meters (474 feet).

The Cleanup Verification Package (CVP) demonstrated that remedial action at the 116-B-12 site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and the RDR/RAWP (DOE-RL 1998). Materials that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual COC concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in the CVP, assumes multiple exposure pathways (e.g., ingestion, inhalation, and direct exposure) for shallow zone soils.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 meters (15 feet)] are required. The verification package demonstrates that residual COC concentrations pose no threat to groundwater or the Columbia River. Thus, the 116-B-12 site was verified to be remediated in accordance with the ROD.

Code:	116-B-13	Classification:	Accepted
Names:	116-B-13; 116-B-8; Basin Sludge Burial Pit; 107-B #2 Grave; 107-B South Sludge Trench	Reclassification:	Interim Closed Out (7/22/1999)
Type:	Trench	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1952
Description:	This site has been remediated, backfilled, and revegetated. It has been closed out.		
Location:	Historical documentation places the trench south of the southeast corner of the 116-B-11 Retention Basin.		
Process Description:	The 116-B-13 Sludge Trench was dug to receive sludge from the bottom of the 107-B Retention Basin (116-B-11).		
Related Sites/Structures:	The site was associated with the 116-B-11 (107-B) Retention Basin.		
Waste Type:	Sludge		
Waste Description:	The unit received low-level sludge waste from the bottom of 116-B-11 (107-B Retention Basin). During maintenance clean out operations, sludge was disposed of in the trench. There is no indication from available records that this site directly received any regular and/or high-		

volume effluent wastes.

Potential contaminants of concern included: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, uranium-238, total chromium, hexavalent chromium (Cr+6), mercury, and lead.

Closure Info: The cleanup verification package (CVP-1999-00002) has documented that the 116-B-13 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision (ROD) (EPA 1995) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17). 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).

Excavation of the 116-B-13 site began on August 7, 1998, by removing the overburden materials and underlying contaminated soil. On November 6, 1998, the excavation had reached the design limits at the base of the engineered structure, elevation 128.2 meters (421 feet) and cleanup verification sampling was initiated.

At the completion of the remedial action, the excavation footprint area was approximately 620 square meters (6,674 square feet) at a depth of 4.3 meters (14 feet), and approximately 6,340 metric tons (6,989 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled to the reference grade of elevation 132.5 meters (435 feet).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code:	116-B-14	Classification:	Accepted
Names:	116-B-14; 116-B-2; 107-B #1 Grave; 107-B Liquid Waste Disposal Trench No. 1; 107-B North Sludge Trench	Reclassification:	Interim Closed Out (7/22/1999)
Type:	Trench	Start Date:	1/1/1948
Status:	Inactive	End Date:	1/1/1948
Description:	The 116-B-14 site appears as an open field covered with cobbles and sparse vegetation. The site has been remediated and closed out.		
Location:	The 116-B-14 site is located immediately north of 116-B-11 (107-B Retention Basin) and is outside the exclusion area fence that encloses the 116-B-11 and 116-C-5 (107-C Retention Basin). The center line for the trench is believed to be approximately 12 meters (40 feet) north of the exclusion area fenceline. The exact locations of the site boundaries are uncertain.		
Related Sites/ Structures:	The site was related to 116-B-11 (107-B) Retention Basin.		
Waste Type:	Sludge		
Waste Description:	The unit received low-level sludge waste from the bottom of 116-B-11 (107-B Retention Basin). During maintenance clean out operations, sludge was disposed of in the trench. There is no indication from available records that this site directly received any regular and/or high-volume effluent wastes. After its use, the waste site was covered with about 1.8 meters (6 feet) of soil.		

Potential contaminants of concern included: americium-241, cobalt-60, cesium-137, europium-

152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, uranium-238, total chromium, hexavalent chromium (Cr+6), mercury, and lead.

Closure Info: The cleanup verification package (CVP-1999-00003) has documented that the 116-B-14 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision (ROD) (EPA 1995) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17). 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).

Excavation began on May 27, 1998, and reached the design limits below the base of the engineered structure (elevation 126.5 meters [415 feet]) on September 17, 1998.

At the completion of the remedial action, the excavation area floor was approximately 132 square meters (1,422 square feet) at a depth of 6 meters (19.7 feet), and approximately 3,795 metric tons (4,183 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled to the reference grade of (elevation 132.5 meters [435 feet]). Clean backfill was taken from the clean overburden pile and other sources of clean material (e.g., demolition rubble from the 108-F Building) that have been surveyed in accordance with the Sampling Analysis Plan (DOE/RI-96-22).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code:	116-B-15	Classification:	Accepted
Names:	116-B-15; 105-B Fuel Storage Basin Cleanout Percolation Pit; 105-B Fuel Storage Discharge Pond; 105-B Pond	Reclassification:	No Action (12/8/2003)
Type:	Pond	Start Date:	1/1/1984
Status:	Inactive	End Date:	1/1/1985
Description:	This site has been evaluated and determined to meet remedial action objectives. The evaluation and sampling results support the reclassification to No Action. The unit was a large, open, excavated pit, rectangular in shape. The site was used from November 1984 to December 1985.		
Location:	The site was located east of the 105-B Reactor Building.		
Process Description:	During the cleaning of the 105-B Fuel Storage Basin, the radiologically contaminated shielding water was processed through a system that utilized ion exchange columns. Before the water was discharged to this site, composite samples were taken to ensure that radionuclide concentrations were below release criteria.		
Related Sites/ Structures:	The site received processed water from the 105-B Fuel Storage Basin.		
Waste Type:	Water		
Waste Description:	The unit received processed water from the 105-B Fuel Storage Basin. During the cleaning of this basin, the radiologically contaminated shielding water was processed through a system that utilized ion exchange columns. Before discharging the water to the unit, composite samples were taken to ensure that radionuclide concentrations were below release criteria in Table II of DOE Order 5480.1. No known chemical substances were present in the water; however,		

chemical analysis during that period was not a standard practice, and there is no evidence that it was performed.

Closure Info: This site has been evaluated and determined to meet remedial action objectives. The "no action" reclassification was supported by a review of the site history, an extensive site evaluation, confirmatory soil sampling and the site reclassification form (control number 2003-052) with a supporting documentation package. The current site soil conditions achieve the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units.

Verification samples, including QA/QC samples were collected and analyzed for the established contaminants of potential concern (COPCs) on August 8, 2003. The COPCs consisted of metals, hexavalent chromium, polychlorinated biphenyls, and radionuclides.

Residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River.

Code: 116-B-16	Classification: Accepted
Names: 116-B-16; 111-B Fuel Examination Tank	Reclassification: Interim Closed Out (5/17/2000)
Type: Storage Tank	Start Date:
Status: Inactive	End Date: 1/1/1968

Description: This site has been remediated and closed out. The unit was a vegetation free, cobble-covered field located within a barricaded area at the former site of the 111-B Building. The floor, foundation, and tank were the only remaining portions of the building. The fuel examination tank was located along the west side of the barricaded area. A curved, capped ventilation pipe extended about 25 centimeters (10 inches) above ground just north and east of the tank location. The barricaded area was surrounded by light duty steel posts with light duty chain and has been posted with "Caution: Underground Radioactive Material" signs. The tank was constructed of concrete. It is believed that the tank was filled with either sand or concrete before the site was abandoned.

Location: The site is located below the northwest corner of the 111-B Metallurgical Examination Building floor, southeast of the 105-B Reactor Building, adjacent to 116-B-6A, and within the 105 B/C Exclusion Area.

Process Description: The 116-B-16 Fuel Examination Tank, was a low-level liquid waste disposal site that was operational during the lifetime of the 111-B Metallurgical Examination Building. The tank received liquid wastes from the decontamination of fuel element spacers and other equipment as well as from other 111-B Building activities.

Related Sites/ Structures: The site was associated with the 111-B Metallurgical Examination Building.

Waste Type: Process Effluent

Waste Description: The unit is believed to have received wastes similar to those identified in 116-B-6A (111-B Crib No. 1); i.e., radioactive waste from equipment decontamination, the 111-B Building, and liquid wastes from fuel element spacer decontamination.

Closure Info: 116-B-6A and 116-B-16 were addressed as a group. The information below documents information for the group of sites.

The cleanup verification package for the 116-B-6A Crib and 116-B-16 Fuel Examination Tank, because of their close proximity to each other and similar contaminants of concern (COCs), were excavated as one remedial action site and are hereinafter referred to as the 116-B-6A/116-B-16 site.

At the completion of the remedial action, the total excavation was approximately 603.5 meters squared (6,496 square feet or 0.15 acres) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 5,072 metric tons (5,591 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The excavation will be backfilled in the near future (written June 6, 2000) with appropriate materials to the reference grade El. 146 meters (479 feet).

Results of the sampling, laboratory analyses, and data evaluations for the 116-B-6A/116-B16 site indicate that all remedial action objectives and goals for direct exposure, protection of ground water, and protection of the Columbia River have been met. However, this site close out includes a deed restriction against drilling or digging into the deep zone soils (below 4.6 m [15 ft] depth).

Code:	118-B-5	Classification:	Accepted
Names:	118-B-5; Ball 3X Burial Ground	Reclassification:	Interim Closed Out (5/24/2004)
Type:	Burial Ground	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1953
Description:	The site has been remediated and interim closed out.		
Location:	The burial ground was located east of the 115-B Gas Recirculation Building.		
Process Description:	This burial ground received irradiated equipment and metallic wastes removed from the 105-B Reactor during the Ball 3X Project. The 118-B-5 (Ball 3X) Burial Ground contained one trench, which was covered with 1.5 meters (5 feet) of soil after its use was discontinued. The site appeared as a vegetation free "L" shaped mound of cobbles, about 0.9 meters (3 feet) high, that was surrounded by permanent concrete markers and was outside the reactor exclusion area. The long south side of the burial ground was about 4.6 meters (15 feet) from a section of the reactor exclusion area fence that ran from north to south. The west side was about 6.1 meters (20 feet) from the fence. The site was posted with signs reading "118-B-5 Ball 3X Burial Grounds".		
Waste Type:	Equipment		
Waste Description:	The unit received 40.00 cubic meters (1410 cubic feet) of highly contaminated metallic wastes, including thimbles and step plugs that were removed from the 100-B Reactor during the performance of work for the Ball 3X project. The Ball 3X project replaced the liquid boron system for emergency reactor control with a system using solid boron-steel and carbon-steel balls. Potential contaminants include: C-14, Co-60, Ni-63		
Closure Info:	The cleanup verification package (CVP), CVP-2004-00003, documented that the 118-B-5 Ball 3X Burial Ground site was remediated in accordance with the Interim Remedial Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units (100 Area Burial Grounds ROD) (EPA 2000) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 2002). The preferred remedy specified in the 100 Area Burial Grounds ROD and conducted for the 118-B-5 site was excavation, treatment as necessary, and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF).		

For the respective points of compliance, remedial action goals (RAGs) were established to

identify radionuclide and nonradionuclide contaminants of concern (COCs). Waste site COCs identified through process knowledge are listed in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (DOE RL 2001).

The COCs for this site consisted of the following: carbon-14, cobalt-60, nickel-63. Cleanup verification samples, including QA/QC samples, were collected and analyzed for the established contaminants of concern. Seven shallow zone samples (J01724 through J01729 and J01731) were collected on January 16, 2004. Seven Staging Area samples (J01718 through J01723 and J01730) were collected on January 16, 2004. All of the sample results are in the HEIS database.

At the completion of the remedial action, the total excavation was approximately 753 square meters (8,101 square feet) in area for the shallow zone and approximately 3,419 square meters (37,783 square feet) in area for the staging pile area, with a burial ground depth of approximately 4.8 meters (15.7 feet). Approximately 5,046 metric tons (5,563 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. Excavation during remediation of the site found only miscellaneous debris associated with the Ball 3X Project and lead solids.

Results of the sampling, laboratory analyses, and data evaluations for the 118 B-5 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

CVP-2004-00003 demonstrated that remedial action at the 118-B-5 Burial Ground has achieved the RAOs and corresponding RAGs established in the 100 Area Burial Grounds ROD (EPA 2000) and RDR/RAWP (DOE-RL 2002). The remaining soils at the 118-B-5 Burial Ground (including the staging pile area) have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 118-B-5 Burial Ground containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF.

The results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. Shallow zone soil cleanup criteria have been applied to the entire vadose zone underlying the 118-B-5 excavation; institutional controls against drilling or digging are not required for this site.

Code:	118-B-9	Classification:	Accepted
Names:	118-B-9; 104-B-1 Tritium Vault and 104-B-2 Tritium Laboratory; 104-B2 Storage Building	Reclassification:	No Action (7/15/2004)
Type:	Storage	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1955
Description:	The site is a gravel-covered field. The site consisted of two concrete masonry facilities identified as 104-B-1 Tritium Vault and 104-B-2 Tritium Laboratory. Both structures were demolished and their associated foundations removed to 1 meter (3 feet) below grade. The excavated areas were then backfilled and graded to match the existing terrain. Demolition took place beginning in mid-September 1996 and was completed in October 1996.		
Location:	The site was located in the extreme northwest corner of the 105-B Exclusion Area. The 104-B-2 Product Storage Building was located immediately northwest of the 91.4-meter (300-foot) 108-B Stack. The 104-B-1 Tritium Vault was located due north of the 103-B Building and just outside the fence for 103-B. Both structures have been demolished.		
Release Description:	There have been no known unplanned releases from these facilities.		
Process:	The 104-B-1 Tritium Vault had a concrete foundation and concrete block walls. The 104-B-2		

Process Description:	Tritium Laboratory was also a concrete structure with a small steel framed transite sided annex located on the east end. The Tritium Laboratory contained sixty-three (63) special cells recessed in the laboratory floor. These were used to store the vacuum casks which contained the irradiated target elements for the P-10 Project. The 104-B-2 Tritium Laboratory annex housed the air sampling equipment for the 108-B Stack. In the P-10 program, irradiation of lithium-aluminum fuel targets, took place in the 105-B, H and F Reactors. The irradiated fuel targets were put in special vacuum casks and taken to the 104-B-2 Tritium Laboratory where they were put into special storage wells. The vacuum casks were then moved to the 108-B Tritium Separations Facility and charged into a furnace with an inert atmosphere and a stainless steel furnace tube connected to a complex series of glass tubing and flasks fitted with palladium valves. As soon as the furnace was charged, the entire line was pumped down to an extremely high vacuum to remove impurities, and the furnace was out gassed to drive off absorbent gases. At that point, the actual extraction began. The furnace temperature was raised until all of the tritium gas had been driven from the irradiated targets, and the gas was drawn down the glass lines, through palladium valves, and collected in shipping flasks. These shipping flasks were stored in storage racks located on the north and south walls of the 104-B-1 Tritium Vault, prior to use. Prior to demolition, the laboratory had been deactivated, posted as radiologically contaminated, and used to store contaminated reactor refueling components from the 105-B and 105-C Reactors.
Related Sites/ Structures:	The two facilities (104-B-1 and 104-B-2) were related to each other (both supported the P-10 Project). The 104-B-2 Facility was related to 108-B, Tritium Separations Facility. The 104-B-2 Facility housed the air sampling equipment for the 108-B Stack. These two facilities were connected through a vent pipe leading from the 108-B Stack to 104-B-2 Tritium Laboratory (annex). Photograph (83E17058CN) 100 Area, 104-B-2, View of the 104-B-2 Tritium Lab from the roof of 108-B, shows the vent line that went from the 104-B-2 Tritium Laboratory to the 108-B, Tritium Separations Facility. A french drain, identified as the 116-B-9 French Drain, was associated with this unit (104-B-2). This site is located at the east end of the 104-B-2 Tritium Laboratory (the end containing the annex that housed the air sampling equipment for the 108-B stack). Drawing H-1-2659 shows a french drain associated with this facility. BHI-00835 states that no evidence of the french drain was found when the team performed the walkthroughs (prior to demolition of 104-B-2) or when the vent line from the storage cells to the 108-F Stack (demolished in the 1980's) was opened and surveyed. No french drain was identified during demolition. Ground Penetrating Radar (GPR) surveys were performed in 1994 and 1996 identified an anomaly consistent with the shape of a french drain. In preparation for sampling the french drain, the site has been located and uncovered. Site 116-B-9 has photo images (#2 and #3) of the exposed french drain. Early WIDS documentation states that the french drain was not visible from the surface
Waste Type:	Demolition and Inert Waste
Waste Description:	Following demolition activities, 0.7646 cubic meters (1 cubic yard) of miscellaneous metal from the two buildings was taken and staged with the 190-C recycle material.
Waste Type:	Demolition and Inert Waste
Waste Description:	Lead based paint was found on the roof trim, vents, and exterior doors. Following demolition activities, 0.7646 cubic meters (1 cubic yard) of lead base painted wood was disposed to an offsite vendor's container (where other 100-B/C small buildings hazardous waste was temporarily stored). This material was identified as number 200E-96-0015 and was packaged in a Laidlaw box and shipped offsite to Laidlaw Lone Mountain Facility on Manifest A6344 on 12/9/96.
Waste Type:	Demolition and Inert Waste
Waste Description:	The building was constructed of concrete block and the foundation was concrete. Following demolition activities, 110 cubic meters (144 cubic yards) of concrete rubble was disposed of in the 100-F Clearwell.

Waste Type: Demolition and Inert Waste

Waste Description: The facility (104-B-1) contained asbestos, consisting of caulking around exterior vents. Following demolition activities, 0.92 cubic meters (1.2 cubic yards) of non-friable cement asbestos board (CAB) were put into a dumpster and hauled away. The material was then shipped to Basin Disposal, Pasco for eventual disposal in the RABANCO landfill, Roosevelt, WA.

Total asbestos material identified was non-friable Category I: asphalt roofing 55 square meters (592 square feet), non-friable Category II: joint caulking 1.21 square meters (13 square feet), non-friable Category II: transite wall board 63.92 square meters (688 square feet). The total category I was 55 square meters (592 square feet) and Category I was 65.13 square meters (701 square feet).

Waste Type: Equipment

Waste Description: The unit (104-B-2) contained trace amounts of radioactive waste. It was used to store containers of reactor refueling components from 105-B and 105-C Reactors. No liquid contaminants were involved. Bird droppings were also found in small quantities.

Following demolition activities, two 1.2 by 1.2 by 2.44-meter (4 by 4 by 8-foot) plywood burial boxes equivalent to 7.25 cubic meters (9.5 cubic yards) were taken to a burial ground. The burial boxes have numbers 100B-96-0002 and 100B-96-0017 and were shipped on 12/3/96 to burial ground 218-W-5, trench 29.

Closure Info: The two facilities were characterized and a Final Characterization Report (Encke and Harris 1996) was generated to document the results. A Readiness Evaluation was conducted jointly for both buildings on August 19, 1996. A hazard classification determination was made of 'industrial' for both buildings (Little 1996; Larson 1996). A Cultural Resource Review (Teel 1996) was performed, as was a Biological Review (Teel 1996). Both showed no impact to the demolition process. Work was performed in compliance with National Environmental Policy Act (NEPA). A categorical exclusion was generated for 104-B-1 and 104-B-2 (BHI 1996). The two buildings were characterized, and a Final Characterization Report (Encke and Harris 1996) was generated to document the results. The structures were prepared for Decontamination and Decommissioning (D&D) by first removing all materials from within the buildings. Utility isolations for electrical, water, and phone were completed. The minor areas of radiological contamination were removed from the 104-B-2 Tritium Laboratory through use of nonintrusive means. The decontaminated areas were survey released. Nonfriable transite panels were removed intact and the waste generated was segregated. Lead-based painted building trim, wood and metal was removed from the buildings and segregated for separate disposal. A track-hoe was used to demolish the building structure, assisted by the use of a hydraulic impact hammer mounted on a tractor. Following sorting and segregation of the building debris, the building foundations were excavated and demolished to 1 meter (3 feet) below grade. Clean rubble from the structures and the associated foundations were then taken to, and disposed at the 100-F Clearwell on the Hanford Site. The lead-based painted wood was segregated from the rest of the debris and disposed by a subcontractor through the use of a "lugger", or dumpster.

During excavation of the foundations, courtesy surveys were made by the Health Physics organization to verify that no residual contamination existed in the footings or soil proximate to the foundations. No contamination was found.

The 2004 Remaining Sites Verification Package attached to the reclass form 2004-004 stated that the September 2003 confirmation soil sampling results supported a no action reclassification of the site.

The site sample results demonstrated that the site had achieved remedial action objectives and

remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units, commonly called the Remaining Sites Record of Decision (EPA 1999). These results showed that residual concentrations will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations supported unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]), and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not have a deep zone, therefore, no deep zone institutional controls are required.

Code: 118-B-10 **Classification:** Accepted
Names: 118-B-10; Ball 3X Storage Vault **Reclassification:** Interim Closed Out (5/24/2004)
Type: Storage Tank **Start Date:**
Status: Inactive **End Date:**

Description: The site has been remediated and interim closed out. Before remediation, the location of this burial ground showed as a concrete pad with a metal marker at the ground surface in a gravel field. It was otherwise unmarked. In November 2001 the site appeared as a vegetation-free area that had been covered with cobbles piled to 0.6 meters (2 feet) above grade. However, this location was wrong. As shown on Drawing H-1-19820 and confirmed by ground-penetrating radar (GPR), the mound of cobble is backfill over a process sewer that was constructed over the ventilation tunnel to 115-B. The pipeline had to be close to the surface because of the tunnel, so it was encased in concrete and covered with 18 inches of backfill.

Location: This site was south of the 105-B Reactor. See the photos for the top of this feature that is at ground level.

Process Description: The site was a metal tank used to store highly radioactive balls.

Waste Type: Equipment

Waste Description: The waste is a radioactive metal storage tank used to store radioactive boron balls from the ball 3X system.

Closure Info: The cleanup verification package (CVP), CVP-2004-00004, documented that remedial action at the 118-B-10 Burial Ground had achieved the RAOs and corresponding RAGs as established in the Interim Remedial Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units (100 Area Burial Grounds ROD) (EPA 2000) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL- 96-17, Rev. 4).

The site was remediated on December 1 and 2, 2003. Waste site COCs identified through process knowledge and listed in Appendix A of the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (DOE RL 2001) included: cobalt-60, nickel-63, arsenic, barium, cadmium, total chromium, mercury, selenium and silver.

Shallow zone verification samples were collected on January 14, 2004. Staging pile area samples were collected on January 14, 2004. Although lead was not a COC for the burial ground, lead solids were found during the excavation effort and a focused sampling effort was performed on January 19, 2004 to demonstrate that underlying soil had not been impacted. The focused sampling included analyses for several additional contaminants of potential concern (COPCs). None of these COPCs were encountered at concentrations above the RAGs. Therefore, they were not added to the list of COCs for the site.

At the completion of remedial action, the excavation was approximately 137 meters squared (1,475 square feet) in area with an average depth of approximately 3.21 meters (10.5 feet). Approximately 266 metric tons (293 tons) of material, including soil and burial ground debris, were removed from the site and disposed of at the Environmental Restoration Disposal Facility.

Results of the sampling, laboratory analyses, and data evaluations for the site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met. Shallow zone soil cleanup criteria have been applied to the entire vadose zone underlying the 118-B-10 excavation; therefore, no institutional controls against drilling or digging are required for this site.

Code: 120-B-1	Classification: Accepted
Names: 120-B-1; 105-B Battery Acid Sump	Reclassification: Interim Closed Out (9/25/2006)
Type: Sump	Start Date: 1/1/1944
Status: Inactive	End Date: 1/1/1969

Description: The site has been remediated and interim closed. The sump and underlying soils were removed on June 13, 2006. The site was backfilled with clean soil from the 100-B Area borrow pit.

Location: The site was located west of the 105-B Building adjacent to the main switchgear room.

Process Description: The battery acid sump was a standard limestone acid neutralization pit. It was used from approximately 1944 to 1969 to neutralize the spent sulfuric acid from lead cell batteries of emergency power packs and the emergency lighting system. The neutralized battery acid waste (containing calcium sulfate, metal sulfates, and water) was periodically jetted out to the process sewer. The sump was designed as a concrete box with hinged metal covers. During a site visit it was observed that concrete repairs had been made to each of the four corners. The repairs suggested that the integrity of the structure may have been compromised, creating the potential for leakage to the surrounding soils.

Related Sites/ Structures: The sump was located on the northwest corner of 118-B-8 (105-B Reactor).

Waste Type: Chemicals

Waste Description: The site contained unknown amounts of sulfuric acid from spillage during use and servicing of an emergency power battery bank inside the 105-B Building. The residual liquid and sludge were analyzed for heavy metals in 1986 using the EP Toxicity Test and chromium was found.

Closure Info: The Remaining Sites Verification Package (RSVP-2006-057) documents that the remediated waste site meets the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

When the sump was cleaned out in 1986, the residual limestone was removed and both the solution section (south end) and the solids (limestone) section (north end) were flushed with water and jetted out to the process sewer using the sump's water-operated eductor. Both sections of the concrete box were lined with acid-resistant brick including the partition between the two sections. The air and water supply to the sump (air sparger and water eductor) were shut off. The sump contained a 10-centimeter (4-inch) waste inlet pipe from the 105-B Building; it was located in the south wall of the sump about 50.8 centimeters (20 inches) below the metal access doors. The outlet pipe was located near the top of the west wall of the northern

section of the sump.

In support of confirmatory sampling, the sump was opened in March 2003. Standing water was observed in both sections of the sump. Due to the presence of corrosive water in the sump and the results of confirmatory sampling, it was determined that remedial action was necessary. The site was remediated to an approximate depth of 3 meters (10 feet) below grade in June 2006, sampled, and then backfilled with clean material. The inlet and outlet pipelines associated with the Sump were sampled but were not included as part of the closeout for the 120-B-1 waste site. The inlet and outlet pipelines were grouted and are included as a subsite within the 118-B-8, 105-B Reactor Building waste site.

Remedial contaminants of potential concern (COPCs) were identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP). They included silver, cadmium, total chromium, mercury, lead, selenium, and sulfate. Radionuclides were not listed as COPCs in the SAP; however, gross alpha, gross beta, and gamma spectroscopy analyses were performed on all samples because of the proximity of the battery acid sump to the 105-B Reactor Building.

Confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency, and the results were compared against the cleanup criteria specified in the RDR/RAWP. The results were stored in the Environmental Restoration (ENRE) project-specific database prior to submitting for inclusion in the Hanford Environmental Information System (HEIS) and were included in Appendix A of the RSVP. On June 1, 2006, the standing water present in the sump (approximately 6,400 Liters [1,700 gallons) was treated with lime to adjust the pH and removed.

On June 13, 2006, the remainder of the site (consisting of the sump structure) was excavated and removed along with a small volume of soil directly in contact with the sump. The site was excavated to a maximum depth of 3.0 m (10 ft) below ground surface in order to preclude any potential impact to the integrity of the 105-B Building walls and nearby transformer pad. The pipelines were removed to the extent of the excavation boundaries and grouted prior to backfilling. The site was backfilled immediately following the verification sampling with clean backfill material from the 100-B Area borrow pit. Approximately 32 bank cubic meters (42 bank cubic yards) of material was excavated and disposed at the Environmental Restoration Disposal Facility.

The results of verification sampling illustrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls were required. The pipelines associated with the battery acid sump were not included as part of the 120-B-1 waste site. Instead the pipelines were included as a subsite within the 118-B-8, 105-B Reactor Building, waste site.

Code: 126-B-2	Classification: Accepted
Names: 126-B-2; 183-B Clearwells	Reclassification: No Action (3/20/2007)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:
Description: The site has been evaluated and reclassified to No Action. The site consisted of two underground concrete reservoirs, or clearwells, separated in the center by the remains of a demolished pump room. A concrete piping structure was located above ground at the southeast corner of the clearwell site.	

Location: Facility and southeast of the 182-B Retention Basin.

Process Description: This site was part of the 100-B Water Treatment Facility. River water stored in the 182-B Retention Basin was transferred sequentially to the 183-B Head House for chemical additions, then to flocculation and sedimentation basins, through anthracite filters, and finally into the clearwells. The 183-B Filter Pump House then fed most of the stored potable water to the 185/190 B facilities, which provided final treatment and storage before use as cooling water for the 105-B Reactor. The pump room was constructed of concrete and was approximately 6.7 meters (22 feet) below grade. The remaining portion of the pump house contained debris from the demolition of the above-ground portion and was believed to include steel, concrete, and asbestos-containing siding (transite). The clearwells were each 1.9E+7 liter (5E+6 gallon) concrete rectangular boxes, with flat concrete roofs. The concrete roofs were surmounted by an above-grade water-resistant roof, which may have been made of asbestos-containing materials in asphalt-saturated board, covered by tarred felt. Water stored in the 183-B Clearwells would have contained additives from the flocculation and sedimentation steps that occurred at the 183-B facility. Chlorine, sulfuric acid, alum, ferric sulfate, Sepran® O 1 (a coagulant), and lime were used in the treatment process. After the filtration step, the additives and any trace contamination from the additives would have been very dilute in the treated water. The Clearwells were upstream of sodium dichromate additions and of the 105-B Reactor. There was no evidence to suggest that the water stored in the clearwells ever contained sufficient quantities of radionuclide or nonradionuclide hazardous chemicals to present a human health risk.

Related Sites/ Structures: This unit was part of the 100-B Water Treatment Facility.

Waste Type: Demolition and Inert Waste

Waste Description: No waste was deposited at the clearwells in the past. However, this unit is scheduled for future use as a disposal site for demolition and inert solid waste after the 126-B-3 Coal Pit and demolition landfill is closed. The remaining portion of the pumphouse currently contains waste from the demolition of the above ground portion. These wastes were believed to include steel, concrete, and asbestos transite.

Closure Info: Reclassification to No Action decision for the 126-B-2, 183-B Clearwells waste site was documented in the Remaining Sites Verification Package (RSVP) RSVP-2007-004. Evaluation of the site history and process knowledge, along with field observations of the site was used to make reclassification decisions in accordance with the TPA-MP-14 procedure. The current site conditions have also achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 1004U-6, and 200-CW-3 Operable Units, Hanford Site, (Remaining Sites ROD).

The No Action determination precluded the need for sampling at this site; therefore, a comparison between soil data and ecological screening levels was not necessary. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which included a comprehensive ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

On September 15, 2005, a meeting among the Washington Closure Hanford (WCH) Field Remediation Closure Project, the U.S. Environmental Protection Agency (EPA), and the U.S. Department of Energy, Richland Operations Office (DOE-RL) was conducted to discuss a path forward for the 126-B-2 Clearwells and the 100-B-22, 100-B Water Treatment Facilities and Surrounding Soils. Background information presented to facilitate the discussion included a description of the water treatment facilities, the 126-B-2 Clearwells, and current information from the 100-B-14 excavations occurring in the area. The status of pipelines in the immediate

area of the 126-B-2, 183-B Clearwells was also presented. The parties agreed that not all of the pipelines in the area were part of the 183-B Clearwells waste site. Their decision that the pipelines belonged to 100-B-14, the 100-B-28, or the 100-B-22:1 waste sites was based on the General Electric Drawing H-1-13050 and Hanford Engineering Works 1944 drawing W75014, Rev. 8.

It was further discussed that under the original and final configurations of the water treatment facilities, sodium dichromate was added to the process water downstream of the Clearwells in the 190-B facility. Therefore, water in the Clearwells would not have been expected to contain hexavalent chromium or radionuclides, even at low concentrations. The 100-B-28 pipeline appeared to have transferred sodium dichromate solution from the 100-C Area to the 183-B Pumphouse.

The evaluation concluded that no contamination or suspected contamination was associated with the waste site. No remedial action was required for this site. Based on remedial action objectives established in the RDR/RAWP and the Remaining Sites ROD, the evaluation does not preclude any future uses (as bounded by the rural-residential scenario) and allows for unrestricted use of shallow and deep zone soils; no deep zone institutional controls were required.

Code:	126-B-3	Classification:	Accepted
Names:	126-B-3; 184-B Coal Pit	Reclassification:	Interim Closed Out (8/8/2006)
Type:	Dumping Area	Start Date:	1/1/1943
Status:	Inactive	End Date:	1/1/1968
Description:	The site has been remediated and interim closed. The site consisted of a pit originally excavated to store coal for use in the 184-B powerhouse from 1943 through 1968. After coal storage was discontinued, the site was used as a demolition landfill.		
Location:	The site was located just west of the 184-B Power House (demolished) and northeast of the 182-B Pump House and Reservoir.		
Process Description:	The site was used for coal storage from 1943 to 1968. Beginning in the early to mid 1970's, the site was used as a dumping area (burial ground) for demolished 100B/C Area facilities. The decommissioning of the 108-B building was completed in May 1985. All the above-grade portions of the building were demolished to a minimum of 3 meters (10 feet) below grade. The clean rubble and debris were disposed in the 184-B Coal Pit.		
Related Sites/ Structures:	The site was associated with the 184-B Power House and 100-B-27 Chromium-contaminated Soil.		
Waste Type:	Demolition and Inert Waste		
Waste Description:	This unit contains waste from demolished 100-B Facilities. These include released portions of 108-B, 117-B, 117-C, 115-BC, and 184-B. This unit is likely to contain lead acid batteries. There are aluminum filter frames from the 117-B and 117-C Facilities on the surface on the south side. Steel staircases and ladders have been deposited on the surface on the northeast side of the site.		
Closure Info:	The Remaining Sites Verification Package, (RSVP-2005-028) documents that the waste site has met the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).		

A confirmatory focused sampling event was conducted in March 2003 to collect and analyze for contaminants of potential concern (COPCs). Initially, the COPCs were identified based on existing historical information. However, the 2003 confirmatory sampling of suspect hazardous materials and underlying soils detected asbestos, arsenic, barium, cadmium, chromium (total), lead, selenium, silver, mercury, pesticides, PCBs, SVOCs, volatile organic compounds (VOCs), and total petroleum hydrocarbons (TPHs). Multiple metals, pesticides, polycyclic aromatic hydrocarbons (PAHs), and TPH were also detected above direct exposure RAGs and/or soil RAGs for the protection of groundwater and/or the Columbia River in confirmatory samples. PCB-containing debris materials were also discovered in soil samples during excavation.

Initial remediation of the burn pit area was performed from September 4 to September 17, 2003; removing approximately 43,100 bank cubic meters (56,400 bank cubic yards) of material. The remediation consisted of the removal of suspect hazardous material and impacted soils within the disposal pit to depths of up to 7 meters (23 feet). Material removed included batteries, lead bricks, rubber gaskets, a compressor, metal scrap, concrete rubble, miscellaneous asbestos-containing material, ash, and contaminated soil.

After this remediation, an area of chromium-contaminated soil was identified in the northern portion of the western staging area. It was unrelated to waste staging or historical disposal activities at the site. This area was classified as a discovery site and designated as the 100-B-27 Chromium-Contaminated Soil waste site and was not considered within the closeout documentation of the 126-B-3 waste site.

Verification soil sampling within the remediation and staging pile footprints was conducted on April 15, 2005, and August 9, 2005. The results indicated that the waste removal action achieved compliance with the remedial action objectives for the 126-B-3 remediation footprint, but that additional material removal was required at the eastern staging pile footprint due to hexavalent chromium contamination. Following the removal of an additional 4,640 bank cubic meters (6,060 bank cubic yards) of material, including a suspect drywell discovered within the staging pile footprint, the additional removal brought the total material removed to approximately 47,740 bank cubic meters (62,440 bank cubic yards) of soil and debris disposed at the ERDF.

To verify the completeness of remediation, additional statistical and focused verification sampling was performed on February 7 and 14, 2006. Analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the verification sampling results support a reclassification of the site to interim closed out. The laboratory results were stored in the Environmental Restoration (ENRE) project-specific database prior to providing to the Hanford Environmental Information System (HEIS) and are summarized in Appendix A of the RSVP.

The results of final verification sampling illustrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural residential scenario) and allow for unrestricted use of shallow zone soils [i.e., surface to 4.6 meters (15 feet) deep]. Deep zone portions of this site meet the direct exposure cleanup criteria for the rural-residential scenario; therefore, no deep zone institutional controls are required.

Code: 128-B-2	Classification: Accepted
Names: 128-B-2; 100-B Burn Pit #2	Reclassification: Interim Closed Out (12/21/2005)
Type: Burn Pit	Start Date: 1/1/1948
Status: Inactive	End Date: 1/1/1968
Description: The site has been remediated and interim closed out. The site covers a large area, covered in	

places with gravel and vegetation.

Location: The site was located east of the northeast corner of the 100-B Area, north of Route 1. The site was on the north side of an east-west dirt road that connects to Route 1.

Waste Type: Misc. Trash and Debris

Waste Description: The site received nonradioactive, combustible materials. Old paint cans and sandblast sand can still be seen at the site. Office waste, paint waste, chemicals, and solvent were burned at this site. It appears that clean fill material has been added to the site, indicating that the site may have also been used as a solid waste landfill.

Closure Info: The REMAINING SITES VERIFICATION PACKAGE FOR THE 128-B-2, 100-B BURN PIT #2 WASTE SITE (Attachment to Waste Site Reclassification Form 2005-038) report demonstrated that the waste site has met the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999).

The 128-B-2 Burn Pit also referred to as 100-B Burn Pit #2, was historically used for the disposal of combustible and noncombustible waste. The operational use of the Burn Pit was not completely known it was used as a burn pit for office and paint wastes, chemicals, and solvents. Landfilled noncombustible material, including concrete and metallic debris, was also discovered during remediation of the site. The presence of garnet sand also suggests that sandblasting activities may have been performed at this site.

The contaminants of potential concern (COPCs) for the 128-B-2 site were identified based on existing historical information for the site. The COPC list identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) included polychlorinated biphenyls, pesticides, semivolatile organic compounds (SVOCs), total petroleum hydrocarbons (TPHs), volatile organic compounds (VOCs), asbestos, silver, barium, cadmium, chromium (total), hexavalent chromium, mercury, lead, and selenium. As a result of further evaluation of the site history, arsenic and asbestos were also included as COPCs. Gross alpha, gross beta, and gamma energy analyses were also performed on samples to evaluate the potential presence of radionuclide contaminants.

Confirmatory samples, too numerous to list, were analyzed and the results were compared against the cleanup criteria. The sample results are stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System and may be found in Appendix B of the RSVP 2005-038, including laboratory results for additional waste characterization analyses.

The results of the verification sampling illustrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 128-B-3	Classification: Accepted
Names: 128-B-3; 128-B-3 Burning Pit Site; 128-B-3 Coal Ash and Demolition Waste Site; 600-57; 100-B Dump Site	Reclassification: Interim Closed Out (11/17/2006)
Type: Burn Pit	Start Date: 1/1/1944

Status: Inactive**End Date:** 1/1/1968

Description: The site has been remediated and reclassified, however institutional controls are to be maintained on the river embankment area to prevent activities that would mobilize residual contaminants to travel to groundwater or the river. Institutional controls will be maintained until such time that the results of a baseline risk assessment can be considered (for a final site remedy, closure). The 128-B-3 Coal Ash and Demolition Waste Site is an area where dumping and burning of waste material had occurred. The site was visible in a 1968 aerial photo and appeared to have been divided into a construction debris dumping area to the south and a combustible waste burning area to the north. The site was separated into the two sections by an ash covered roadway. At the site's southern edge was an area of vegetation-free gravel, covered with what was described as a "white-colored spray".

Location: This site was northeast of the northeast corner of the 100-B perimeter road on the plateau above the river shoreline.

Waste Type: Misc. Trash and Debris

Waste Description: Coal ash, burning evidence, and demolition rubble can be seen at the surface of the site. A 1952 shop manual was found among the waste.

Closure Info: The Remaining Sites Verification package, (RSVP-2006-058) demonstrates that the 128-B-3 waste site has met the Remedial Action Objectives (RAOs) and Remedial Action Goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The waste site, located immediately adjacent to the Columbia River, was formerly used as a disposal site for the 100-B/C Area. Site history indicates that the site was used for the dumping and burning of miscellaneous wastes, including office waste, paints, solvents, coal ash, and demolition debris.

The COCs and COPCs for verification sampling were determined in consideration of in-process and waste characterization sampling results and the COCs/COPCs identified for similar burn pit waste sites. Residual concentrations of metals (including hexavalent chromium), SVOCs, chlorinated pesticides, TPH, PCBs, and asbestos within the remediation and general waste staging footprints were evaluated for site closure. The COCs/COPCs for the tar waste staging pile footprint were the same as for the remediation footprint, but COCs/COPCs at the lead and asbestos waste staging pile footprints were restricted to metals and asbestos, respectively. The process history for the 128-B-3 site does not suggest the presence of radiological contamination, and radiological activity was not detected by field screening during site remediation. Therefore, radionuclides were not considered COPCs for the site.

Remediation of the site was performed from November 2004 to May 2006, consisting of the removal of approximately 21,000 BCM (bank cubic meters) (27,500 BCY [bank cubic yards]) of material from four former disposal pits, the river embankment, and the upland surface to disposal at the Environmental Restoration Disposal Facility. Initial remedial efforts at the upland area of the site were extended to include the river embankment following the results of geophysical investigation and focused sampling of visible debris at the embankment. Multiple chemical contaminants were detected above action levels in the in-process and waste characterization samples, including metals, hexavalent chromium, polycyclic aromatic hydrocarbons, total petroleum hydrocarbons (TPH), pesticides, and polychlorinated biphenyls.

Following site remediation, final verification sampling of remediation and waste staging pile footprints was conducted from June 2006 to August 2006. The results indicated that the waste removal action achieved compliance with the RAOs and the Remaining Sites ROD, except at

the river embankment area. Residual concentrations of metals, TPH, and aroclor-1254 slightly exceeded soil RAGS for protection of groundwater and the Columbia River at this location. However, further remediation activities to remove trace remaining contamination are likely to inflict greater environmental damage than leaving said contamination in place. The results for the entirety of the site show that residual contaminant concentrations do not exceed cleanup levels for direct exposure (i.e., ingestion of the soil). Statistical and judgmental sampling to verify the completeness of remediation was performed, and analytical results for upland areas were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. Analytical results for the remediated river embankment were shown to meet the cleanup objectives for direct exposure and to not significantly exceed soil RAGs for protection of groundwater and the Columbia River.

Accordingly, an interim closure reclassification is supported for the site, with imposition of institutional controls on the river embankment area to prevent activities that would mobilize residual contaminants to travel to groundwater or the river. Institutional controls will be maintained until such time that the results of a baseline risk assessment can be considered (for a final site remedy, closure).

The remainder of the site does not have a deep zone or residual contaminant concentrations that would require any institutional controls. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 in [15 ft] deep). The results also demonstrate that residual contaminant concentrations are sufficiently protective of groundwater and the Columbia River to preclude further remedial action.

Code:	132-B-1	Classification:	Accepted
Names:	132-B-1; 108-B Tritium Separation Facility	Reclassification:	No Action (3/1/2004)
Type:	Process Unit/Plant	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1975
Description:	This site has been evaluated and determined to meet remedial action objectives. The evaluation and sampling results support the reclassification to No Action. The site is now a flat cobble field.		
Location:	The building was located north of 105-B.		
Related Sites/ Structures:	The 108-B Dry Well was left undisturbed. The drain line to the 108-B Crib was removed to a point south of the entrance road and capped.		
Waste Type:	Demolition and Inert Waste		
Waste Description:	The main radionuclide present at the site is tritium.		
Closure Info:	The Waste Site Evaluation for 132-B-1, 108-B Tritium Separation Facility (Calculation No. 0100B-CA-V0126) (BHI 2003), demonstrated that historical data was of sufficient quality and quantity to support a no action reclassification of the 132-B-1 site. The site achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 2002), and the Interim Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999).		

Verification samples of paint, floor tile, and concrete were collected and analyzed in June 16, 2003. All results were less than 20 pCi/g beta/gamma and less than 1pCi/g alpha.

Any residual concentrations will support future land uses that can be represented (or bounded)

by a rural-residential scenario, and that based on RESidual RADioactivity (RESRAD) modeling, residual concentrations at the site pose no threat to groundwater or the Columbia River.

Code: 132-B-3	Classification: Accepted
Names: 132-B-3; Ventilation Exhaust Stack Site; 108-B Tritium Pilot Facility; 108-B Ventilation Exhaust Stack Site	Reclassification: No Action (12/8/2003)
Type: Burial Ground	Start Date:
Status: Inactive	End Date:
Description: This site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification to No Action. The site consisted of a trench, which was used to bury low-level contaminated rubble from the demolition of the 108-B Ventilation Exhaust Stack, also known as the 108-B Tritium Pilot Facility Ventilation Exhaust Stack. The trench was 9.1 meters (30 feet) wide, 5.5 meters (18 feet) deep, and 76 meters (250 feet) long. The stack foundation was found to be free of contamination. It was destroyed separately, buried in place and covered with clean fill material. Although it was on the opposite side of the road, it was considered to be part of this site.	
Location: The burial trench was north of 105-B, west of 108-B Crib, across the road from the stack foundation site.	
Waste Type: Demolition and Inert Waste	
Waste Description: The 91-meter (300-foot) stack was demolished in 1983 and buried at this site. The stack was built of reinforced concrete and had a stainless steel liner. The total radionuclide inventory of the buried stack rubble is 21 millicuries.	
Closure Info: In 2003 a waste site evaluation (0100B-CA-V0127) was done. The evaluation and historical data support reclassification to "No Action" as documented in the attached reclass form, control number 2003-11. It was determined that the site had achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 2002) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (EPA 1999). Residual soil concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River based on RESidual RADioactivity (RESRAD) modeling.	

Code: 132-B-4	Classification: Accepted
Names: 132-B-4; 117-B Filter Building	Reclassification: No Action (4/2/2003)
Type: Process Unit/Plant	Start Date: 1/1/1961
Status: Inactive	End Date: 1/1/1968
Description: Historical data compiled for the Calculation Brief number 0100B-CA-V0128 was of sufficient quality and quantity to support reclassification of the site. The ventilation exhaust filter building housed blowers and particulate filters used to treat the ventilation exhausted from the B Reactor Building. Included in this site were the 117-B Building, the intake ventilation duct from the 105-D Reactor Building, and the exhaust ventilation ducts to the 116-B Reactor Exhaust Stack.	
Location: The site was located south of the 105-B Reactor, southwest of the 116-B Stack (132-B-2).	
Process The building and below grade duct work were made of reinforced concrete, 0.3 to 0.6 meters (1	

Description: to 2 feet) thick; above grade ducts were constructed of 10 gauge black steel. The building was 16.76 meters (55 feet) long, 7.01 meters (23 feet) wide, and 11.0 meters (36 feet) high with 2.4 meters (8 feet) above grade. A soil berm was built up around the building from grade level to the top of the structure. The building was divided into two large filter cells with a smaller operating area between them. The filter cells each held six filter frames (two wide and three deep). The filter frames were designed to hold twenty-eight filters that were 0.6 meters (2 feet) square by 0.3 meters (1 foot) thick. There were spaces between the frames to allow access for filter maintenance. The operating area between the two cells was divided into two levels. The upper level, called the access gallery had ten doors that lead from it. Four doors opened into each of the filter cells and the two other doors provided access to the intake and exhaust ducts. The operating gallery was located below the access gallery. A sump was located at each end of the operating gallery to collect incidental drainage from above. A large open area extended the full length of the structure above the access gallery and the filter cells. It ranged in height between 2.5 and 2.4 meters (8.1 and 7.8 feet) due to the structure's sloping roof. The space provided access to the cement cover blocks that were positioned over each of the filter frames. Before the filter building was used, unfiltered ventilation was exhausted directly from the reactor to the atmosphere. The reactor confinement system diverted the exhaust just before the stack and routed it to the filter building where it passed through a series of filters. The filtered exhaust was then routed back to the ventilation exhaust stack where it was discharged to the atmosphere. Sealwells within the filter building provided the ability to direct the exhaust into one or both of the filter cells.

Related Sites/ Structures: The site was associated with the 105-B Reactor (118-B-8), the 116-B Stack (132-B-2), the 119-B Sample Building, and the 117-B Seal Pit Crib (116-B-12).

Waste Type: Demolition and Inert Waste

Waste Description: The site contained radiologically contaminated debris. Total radionuclide inventory in this unit was estimated to be 92 nanocuries. The radionuclides comprising this inventory were tritium, carbon-14, cesium-137, strontium-90, and plutonium-239/240. Of these radionuclides, strontium-90 was the most restrictive in the allowable residual contamination level (ARCL) calculations. Cobalt-60, europium-152, europium-153, and europium-155 were not identified in any of the samples analyzed.

Closure Info: The Waste Site Evaluation for 132-B-4, 117-B Filter Building (Calculation No. 0100B-CA-V0128) (BHI 2003), demonstrates that the historical data available is of sufficient quality and quantity to support the no action interim closure. The site achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 2002), implemented for the Interim Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999).

The 117-B Filter Building and associated below-grade ductwork were demolished in two phases beginning in March 1985 and continuing through January 1988. Phase I included work necessary prior to demolition activities and included extensive radiological surveying and sampling, the removal of assorted equipment (e.g., HEPA filters) for disposal in the 200 West Area burial grounds, and decontamination and/or fixing contamination. As part of Phase I activities, a calculation methodology known as "Allowable Residual Contamination Level" (ARCL) was used to evaluate the potential radiological dose to a hypothetical, maximally exposed site resident if the site were released for unrestricted use after the demolition and burial in situ of the facility. The ARCL calculations were prepared in accordance with Allowable Residual Contamination Levels for Decommissioning Facilities in the 100 Areas of the Hanford Site (UNC 1983) and authorized by the U.S. Department of Energy, Richland Operations Office. The radionuclide inventories in the 117-B Filter Building and the inlet/outlet ducts were determined from radiological surveys, isotopic analyses, and from previously collected data that

are discussed in UNC (1978).

It has been determined that any residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that based on RESRAD modeling, residual concentrations at the site pose no threat to groundwater or the Columbia River.

Code:	132-B-5	Classification:	Accepted
Names:	132-B-5; 115-B/C Gas Recirculation Facility	Reclassification:	No Action (1/5/2004)
Type:	Process Unit/Plant	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1968
Description:	This site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification to "No Action". The unit consisted of a vacuum and pressure seal pit and tunnels. It was a single-story reinforced concrete structure with a basement. It was 6.1 meters (20 feet) above and 3.4 meters (11 feet) below grade, and the width ranged from 22 meters (72 feet) to 30 meters (98 feet).		
Location:	The site was located south of 105-B.		
Related Sites/ Structures:	100-B-11, 115-B/C Caisson Site		
Waste Type:	Demolition and Inert Waste		
Waste Description:	The resident radionuclides are tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and plutonium-239.		
Closure Info:	In 2003 the Waste Site Evaluation for 132-B-5, 115-B/C Gas Recirculation Facility (Calculation No. 0100B-CA-V0129) (BHI 2003) demonstrated that the site evaluation and historical data supported reclassification to "No Action" of the site. The site had achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 2002) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (EPA 1999). Residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River based on RESidual RADioactivity (RESRAD) modeling.		

Code:	132-B-6	Classification:	Accepted
Names:	132-B-6; 1904-B2; 1904-B-2 Outfall Structure Site; 116-B-8	Reclassification:	Interim Closed Out (7/25/2002)
Type:	Outfall	Start Date:	1/1/1954
Status:	Inactive	End Date:	1/1/1968
Description:	The site has been remediated and closed out. A dirt road leading to the site is crossed by a vegetation-free outfall structure wall that was left intact when the structure was backfilled to grade.		
Location:	The site is located north of the northeast corner of 116-B-11 (107-B Retention Basin) bank, directly north of the east end of 116-B-11 (107-B Retention Basin), and downstream of 116-B-7 (1904-B1 Outfall Structure), at the top of the riverbank.		
Related Sites/ Structures:	The site received effluent from the 100B process effluent lines (100-B-8), the 100B process sewer lines (100-B-14), and discharged effluent via the 100BC river effluent pipelines (100-B-15) and flumes (100-B-15:1).		

Waste Type: Process Effluent
Waste Description: The unit received and discharged reactor coolant effluent wastes to the river. The 1904-B2 Outfall received cooling water and process drainage from B Reactor and discharged through a 168-centimeter (66-inch) effluent line (100-B-15) to the middle of the Columbia River. A 1992 report states, "surface contamination is known to be present at the 132-B-6 spillway." Other documents reviewed provided no information about wastes or contamination.
Closure Info: 116-B-7, 132-B-6 and 132-C-2 were addressed as a group. The information below documents information for the group of sites.

The cleanup verification package (CVP-2002-00003) for the sites, also referred to as B/C Outfall, has demonstrated that remedial action has met the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the approved interim action Interim Action Record of Decision (ROD) (EPA 1999) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17 Rev. 3).

Remedial action at the B/C Outfall site began on June 4, 2001. Excavation of the three outfall sites involved removing the overburden materials and debris, the contaminated structure, and underlying contaminated soil.

The COCs and COPCs for this site consist of the following: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, and strontium-90. Sampling and analysis during remediation indicated that additional COPCs should be identified. The additional COPCs are as follows: total chromium, hexavalent chromium, lead, mercury. Total chromium, hexavalent chromium, lead, and mercury were detected in cleanup verification samples and were therefore evaluated as COCs for the B/C Outfall site.

Cleanup verification sampling for the deep and shallow zones was done on January 14 and 15, 2002. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the SAP.

The sampling results indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

Institutional control (IC) information has been revised for 116-B-7, 132-B-6, and 132-C-2 as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including these, WIDS had shown that no IC restrictions were required but the sites were remediated with deep zone criteria so that Ics actually were required. The Ics for this site have been revised accordingly.

Code: 1607-B1	Classification: Accepted
Names: 1607-B1; 1607-B1 Sanitary Sewer System; 1607-B1 Septic Tank System; 124-B-1	Reclassification: No Action (8/30/2007)
Type: Septic Tank	Start Date: 1/1/1944
Status: Inactive	End Date: 1/1/1960
Description: The site included a septic tank, tile field, and associated pipelines from the 1701-B badge house, 1720-B patrol building, 1709-B Fire headquarters, and the change rooms. The site currently appears as a vegetation and gravel covered area that is raised about 1.2 meters (4 feet) above the surrounding terrain. The septic tank is clearly marked on historical drawings in the location of the raised mound.	
Location: The site was located north of the 1720-B Building site near the entrance to the 100 B/C Area	

LOCATION:

Process Description: The septic tank was constructed of reinforced concrete and had a 125 person capacity (132 liters [35 gallons] per capita) or approximately 16,504 Liters with an average detention period of 24 hours. The walls and floor were 25 centimeters (10 inches) thick. The tile field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe or drain tile with a minimum of 2.4 meters (8 linear feet) per capita. The laterals were open-jointed and spaced 2.4 meters (8 feet) apart.

Related Sites/ Structures: The site received effluent from the change rooms, 1701-B Badgehouse, 1720-B patrol building, 1709-B Fire Station Headquarters.

Waste Type: Sanitary Sewage

Waste Description: According to documentation, the site received unknown amounts of sanitary sewage from the 1701-B Badgehouse (security checkpoint), the 1709-B Fire Station, the 1720-B Patrol Change Room, and offices.

Closure Info: The Remaining Sites Verification Package for the 1607-B1 Septic System has demonstrated that the site meets the objectives for reclassification to No Action. The remedial action objectives and the corresponding remedial action goals were established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

Excavation and confirmatory sampling at the site was conducted on May 21, 2007. Excavation began with a test pit at the suspected location of the septic tank. The septic tank was encountered less than 0.3 meters (1 foot) below ground surface (bgs). The top of the tank was found to have been entirely removed and the tank contained mostly soil backfill with small quantities of miscellaneous, nonhazardous debris (i.e., bollards, concrete debris, rebar, and VCP pieces). A single sample was collected from the bottom of the tank which was reached at 3.4 meters (11 feet) bgs. Excavation at the drain field revealed vitrified clay pipe containing no sediment. The rest of the samples consisted of soil underlying the tank, soil underlying pipelines, and the soil underlying the drain field.

The Contaminants of Potential Concern (COPCs) for the site were identified based on existing historical and analogous site information. Additional COPCs were identified and agreed upon as described in the site-specific sample design, they included the following: the inductively coupled plasma (ICP) metals, mercury, hexavalent chromium, pesticides, semivolatile organic compounds (SVOCs), and polychlorinated biphenyls (PCBs).

Radionuclides were not COPCs for this site; however, the presence of radiological contaminants was evaluated during excavation and sampling activities using field radiological survey instrumentation (capable of detecting alpha, beta, and gamma radiation). Although no elevated radiological activity was detected during field activities, samples were submitted for further radionuclide evaluation.

Field screening for volatile organic compounds using an organic vapor monitor was also performed during excavation and sampling activities. No elevated volatile organic readings were detected; therefore, volatile organic analysis was not included in the requested analyses. No oily soil, evidence of burning, or suspect asbestos-containing material was observed during field activities; therefore, additional analyses were not required. Confirmatory sampling was performed, and the analytical results indicate that the residual concentrations of COPCs at this site meet the remedial action objectives for direct exposure, groundwater protection, and river protection.

The analytical results were stored in the Environmental Restoration project-specific database prior to being provided to the Hanford Environmental Information System and were included in Appendix B of the RSVP.

In accordance with the RSVP, the confirmatory sampling results support a reclassification of the waste site to No Action. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	1607-B2	Classification:	Accepted
Names:	1607-B2; 1607-B2 Sanitary Sewer System; 1607-B2 Septic Tank System; 124-B-2	Reclassification:	Interim Closed Out (3/13/2007)
Type:	Septic Tank	Start Date:	1/1/1944
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed out. The site included a septic tank and drain field. See the subsites for detailed information. The site consisted of subsite 1) Septic drainfield and subsite 2) the septic tank and pipeline.		
Location:	The septic tank was located 390 meters (1280 feet) north of the 105-B Building. The drain field was located 240 meters (787.4 feet) northwest of the septic tank.		
Process Description:	The septic tank system received effluent from the 100-B/C Area office buildings, 105-B Reactor Building, and the 190-B Pumphouse. The septic tank had a capacity of 59,620.24 liters (15,750 gallons). The system had the potential to support 450 persons assuming input of 132.5 liters (35 gallons) per capita per day and a one day retention period.		
Related Sites/Structures:	The septic tank received sanitary sewage effluent from the 105-B Reactor Building, the 190-B Pumphouse and the 100-B Area office buildings. The office buildings have been removed.		
Waste Type:	Sanitary Sewage		
Waste Description:	This unit received sanitary sewage from the 100 B/C Area office buildings, the 105-B Reactor Building, and the 190-B Pumphouse. All office buildings have been removed; however, the sewer lines to the respective buildings remained in place.		
Closure Info:	1607-B2 and 100-B-14:2 were addressed as a group. The information below documents information for the group of sites.		

The Remaining Sites Verification Package (RSVP) 2006-055 for 1607-B2 and 100-B-14:2 has documented that the current site conditions supported a reclassification to interim closed out. Evaluations and verification sampling results for the RSVP demonstrated that the sites have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site (Remaining Sites ROD).

Remediation of the 100-B-14:2 and 1607-B2 waste sites was performed in stages from January 2005 through June 2006 as part of the 100-B/C Area Remaining Pipes and Sewers remediation project. All excavation was restricted within the shallow zone (less than 4.6 meters [15 feet] bgs), with an average depth of approximately 2.5 meters [8 feet] bgs, and a maximum depth of approximately 4 meters [13 feet] bgs at the septic tank. Excavation at the northern portion of the site continued to greater depth due to concurrent remediation of the underlying 100-B-14:1 process sewer. Excavated and disposed material quantities could not be explicitly separated for

each site due to co-location and concurrent remediation of differing functional pipeline groups.

This Site has the Following SubSites:

Code: 1607-B2:1
Names: 1607-B2:1; 1607-B2 Septic Tank
Code: 1607-B2:2
Names: 1607-B2:2; 1607-B2 Septic Tank Drain Field

Code: 1607-B2:1	Classification: Accepted
Names: 1607-B2:1; 1607-B2 Septic Tank	Reclassification: Interim Closed Out (3/13/2007)
Type: Septic Tank	Start Date:
Status: Inactive	End Date:

Description: The septic tank had a capacity of 59,620.24 liters (15,750 gallons). The system could support 450 persons assuming input of 132.5 liters (35 gallons) per capita per day and a one day retention period. The septic tank was constructed of reinforced concrete. The walls and floor are 25 centimeters (10 inches) thick.

During the March 2000 field visit, it was observed that the top of the septic tank was at grade level except on the north side, where it was above grade. In many areas the edges of the concrete were obscured by soil and vegetation. There were three manholes in the top of the tank covered by metal covers with handles. The septic tank was surrounded by six black and yellow striped posts, each about 0.9 meter (3 feet) high, and a light-duty barricade chain. The site was identified with a blue and white "Septic Tank" sign.

Location: The septic tank was located 390 meters (1280 feet) north of the 105-B Building.

The SubSite is Part Of:

Code: 1607-B2
Names: 1607-B2; 1607-B2 Sanitary Sewer System; 1607-B2 Septic Tank System; 124-B-2

Code: 1607-B2:2	Classification: Accepted
Names: 1607-B2:2; 1607-B2 Septic Tank Drain Field	Reclassification: Interim Closed Out (3/13/2007)
Type: Septic Tank	Start Date:
Status: Inactive	End Date:

Description: A historical drawing states that the drain field was "to be located in field" near the septic tank, but does not show exact location. The drain field is constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a total of 1097.3 meters (3600 linear feet) of piping (2.4 meters [8 linear feet] per capita). The laterals are open-jointed and spaced 2.4 meter (8 feet) apart.

The drain field was a vegetation-covered area surrounded with light-duty steel posts and light-duty barricade chain. During the March 2000 field visit, it was noted that some of the barricade has fallen. The site was identified with "Drain Field" signs.

Location: The drain field is located 240 meters (787 feet) northwest of the septic tank.

The SubSite is Part Of:

Code: 1607-B2
Names: 1607-B2; 1607-B2 Sanitary Sewer System; 1607-B2 Septic Tank System; 124-B-2

Code: 1607-B5 **Classification:** Accepted

Names: 1607-B5; 1607-B5 Septic Tank System; 124-B-4; **Reclassification:** None
1607-B4; 1607-B4 Sanitary Sewer System; 1607-B4 Septic Tank System

Type: Septic Tank **Start Date:** 1/1/1944

Status: Inactive **End Date:**

Description: The septic tank can be identified by a 20 centimeter (8 inch) capped steel vent pipe. The cap is stamped with the words septic tank. It is surrounded by a vegetation-free graveled parking lot. The pipe extends above grade about 0.76 meters (2.5 feet). The drain field runs southeast of the tank. The residue in the tank was sampled in January 2001. Elevated levels of cesium resulted in the tank being posted with Underground Radioactive Material signs. The tank was not backfilled. In 2007, analysis of additional samples of tank contents found no radiological constituents above background in either the liquid or sludge waste in the tank. For this reason, the site was down posted from URMA status. HEIS numbers for the 2007 sampling effort are: liquid--J14XJ3, J14XJ4, J14XJ5, and J14XJ6; sludge--J14XH9, J14XJ0, J14XJ1, and J14XJ2.

Location: The site is located southeast of the 181-B/C Pump House.

Process Description: The unit received sanitary sewage from the 181 B/C Pumphouse.

Related Sites/Structures: The site is associated with the 181-B pump house building.

Waste Type: Sanitary Sewage

Waste Description: This unit received sanitary sewage from 181-B/C River Pumphouse. The flow rate to the unit was estimated at approximately 35 gal/day (130 L/day). In January 2001, the tank was sampled and analyzed for radionuclides. All radionuclides were undetected except for cesium-137, which was 38.3 picocuries per liter and gross beta, which was 1.8 picocuries per liter.

Code: 1607-B7 **Classification:** Accepted

Names: 1607-B7; 1607-B7 Sanitary Sewer System; 1607-B7 Septic Tank System; 124-C-1 **Reclassification:** Interim Closed Out (7/27/2003)

Type: Septic Tank **Start Date:** 1/1/1944

Status: Inactive **End Date:** 1/1/1969

Description: The site has been remediated and interim closed out. The site consisted of a septic tank and drain field. The tank was constructed of reinforced concrete with a brick manhole access. The drain field was located due east of the tank.

Location: The unit was located northeast of the 183-B Filter Plant.

Process Description: The tank walls were 20 centimeters (8 inches) thick, the floor was 15 centimeters (6 inches) thick, and 2.5 meters (8 feet 3 inches) deep. It had a 12-person capacity (130 liters [35 gallons] per capita) with an average detention period of 24 hours. The drain field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a minimum of 2.4 meter (8 linear feet) per capita. The laterals were open jointed and spaced about 2.4 meters (8 feet) apart.

Related Sites/Structures: The 183-B water treatment facility discharged effluent to the septic system via the 100-B-14 pipeline.

Waste Type: Sanitary Sewage

Waste Description: This unit received an unknown amount of sanitary sewage from 183-B Water Treatment Plant.

Description:

Closure Info: Remedial action objectives and goals for the 1607-B7 site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL- 96-17).

The selected remedial action for the 1607-B7 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

Waste site COPCs for the 1607-B7 site were identified through process knowledge and analogous site data and are included in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (BHI 2003). From BHI (2003), the COPCs for this site consist of metals, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds (SVOCs). Additional COPCs for this site included at the request of the regulatory agency are radionuclides (gross alpha, gross beta, and gamma emitters) and hexavalent chromium. Gross alpha and gross beta analyses were conducted for screening purposes.

The cleanup verification results indicate that the soils primarily affected by past waste disposal activities associated with the 1607-B7 site were removed, and that remaining soil (with the possible exceptions of lead and BHC) is below soil background concentrations. For the various reasons given above, lead, BHC, hexavalent chromium, and the individual radionuclides (cesium-137, cobalt-60, europium-152, europium-154, and europium-155) are carried throughout this CVP as COCs. The final 1607-B7 cleanup verification COC list is as follows: cesium-137, cobalt-60, europium-152, europium-154, europium-155, lead, hexavalent chromium, BHC.

At the completion of the remedial action, the total excavation was approximately 369 meters squared (3,709 square feet) in area with a depth of 3.5 meters (11.5 feet). Approximately 198 metric tons (218 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The septic system inlet pipe was partially removed, see map and co-ordinates in the Cleanup Verification Package (CVP) for a more precise location. The remainder of the pipeline (100-B-14) from the 183-B water treatment facility will be dispositioned with the other pipelines in that site.

Results of the sampling, laboratory analyses, and data evaluations for the 1607-B7 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Code: 116-C-1	Classification: Accepted
Names: 116-C-1; 107-C Liquid Waste Disposal Trench	Reclassification: Interim Closed Out (1/21/1999)
Type: Trench	Start Date: 1/1/1952
Status: Inactive	End Date: 1/1/1968
Description: This site has been interim closed out after remediation. It has been backfilled and revegetated. The revegetation included a test plot to determine the need for additional topsoil and irrigation	

on remediated waste sites. The 116-C-1 site was constructed in 1952 and is located northeast of the 116-C-5 Retention Basin facility, approximately 253 meters (830 feet) from the 100-year flood level of the Columbia River.

Location: 116-C-1 was an inactive liquid waste site located approximately 300 meters (1,000 feet) east of 116-B-11 (107-B Retention Basin).

Release Description: The 116-C-1 Trench received 700 million liters (184 million gallons) of contaminated cooling water from the 100-B/C Area Retention Basins. The site continued to receive contaminated cooling water until reactor operations ceased in 1968. An additional 40 billion liters (more than 10 billion gallons) of high-temperature reactor cooling water was discharged to the site during a 150-day infiltration test in 1967

Process Description: The 167-meters-long, 32-meters-wide, 5-meters-deep (548-ft-long, 105-ft-wide, 16.4-ft-deep) site was a former process effluent disposal trench (unlined) that received 700 million liters (184 million gallons) of contaminated cooling water from the 100-B/C Area Retention Basins after ruptured fuel elements were detected in the reactors (DOE-RL-93-06). The 116-C-1 site continued to receive contaminated cooling water until reactor operations ceased in 1968. An additional 40 billion liters (more than 10 billion gallons) of high-temperature reactor cooling water was discharged to the site during a 150-day infiltration test in 1967. This test likely influenced the distribution of contaminants beneath the site. Influent water was transferred to the trench via two 107-centimeters (42-inches) steel pipes leading from the 168-centimeters (66 inches) outfall pipelines that lead from the 116-C-5 Retention Basins to the river. Two additional 61-centimeters (24-inches) pipes discharged influent water to the site. The contaminated water discharged to the site soils continued from 1952 to 1968. After operations ceased in 1968, the site was decommissioned as part of the Radiation Area Remedial Action (RARA) Program. The RARA activities at the 116-C-1 site included the placement of at least 1.5 meters (4.9 feet) of fill material (shielding) over the entire base of the trench to stabilize the exposed contaminated surfaces of the engineered structure.

Related Sites/ Structures: The site was associated with 116-C-5 (107-C Retention Basin) and 116-B-11 (107-B Retention Basin).

Waste Type: Process Effluent

Waste Description: The site received effluent overflow from 116-C-5 (107-C Retention Basin) during reactor outages due to ruptured fuel elements. Beginning in 1955, this site also served 116-B-11 (107-B Retention Basin). The trench was used in 1967 for an infiltration test in which the total cooling water volume from B-Reactor was disposed in the trench. During the test, an estimated $4.4E+10$ liters ($1.17E+10$ gallons) of effluent water were released. From process knowledge, the waste site contaminants of concern (COCs) identified are: Americium-241, Cobalt-60, Cesium-137, Europium-152, -154, -155, Nickel-63, Plutonium-238, -239/240, Strontium-90, Uranium-238, Total Chromium, Hexavalent chromium, Mercury, and Lead.

Closure Info: The 116-C-1 site cleanup activities consisted of the 100-B/C Demonstration Project and the final remedial action. Both efforts are described below.

The purpose of the 100-B/C Demonstration Project was to initiate a limited remedial action in the 100 areas to address uncertainties in remedial design and planning.

The excavation area boundary was a 38- by 38-m (124.7- by 124.7-ft) square located in the southwest third of the trench. The material was removed in 1.5-m (5.0-ft) lifts to an approximate elevation of El. 126 m (413 ft). The side slopes were approximately 1.5 horizontal to 1.0 vertical. Figure 2 shows the location and topography of the demonstration project excavation.

The excavation and disposal of the engineered structure and RARA backfill began on July 15, 1996, and was completed on November 15, 1996. Eight contaminated soil plumes extending beyond the engineered structure were identified during the subsequent field screening and sampling efforts. The excavation and disposal of the plume areas began on April 23, 1997, and were completed on October 28, 1997.

After the soil plume excavation was completed, a test pit was excavated down to groundwater to further characterize the subsurface. The test pit was centered at an area of elevated activity (identified by radionuclide field surveys) near the 116-C-1 inlet pipes. The test pit effort began on December 15, 1997, and was completed on January 15, 1998. Soil samples were taken from each quadrant of the test pit and composited for each of the eight 1-m (3-ft) test pit lifts. When the final test pit samples were obtained, 1 m of clean native soil from identified borrow pits to the south was placed in the bottom of the pit. Backfill of the test pit occurred in approximately the same sequence as when the soils were removed using the stockpiled materials. The backfill was placed in 1-m (3-ft) compacted lifts.

During excavation, field screening and onsite gamma energy analysis (GEA) at the Radiological Counting Facility (RCF) were used to distinguish between potentially clean materials and contaminated materials for disposal at ERDF.

More than 230 samples were collected for GEA, and 35 grab samples were taken and analyzed at quick turn-around laboratories. Data from these samples were used to corroborate data obtained from field screening and to assist in waste characterization. A total of 37 final verification composite samples were taken and sent to an offsite laboratory for analysis.

Excavated overburden materials that were identified as potentially clean were placed in segregated piles near the site for potential use as clean backfill. Soils that did not meet direct exposure RAGs (based on field screening) were disposed of at ERDF.

Code:	116-C-5	Classification:	Accepted
Names:	116-C-5; 116-C-5 Retention Basins; 107-C Retention Basins	Reclassification:	Interim Closed Out (12/8/1999)
Type:	Retention Basin	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1969
Description:	The site has been remediated, backfilled, and revegetated.		
Location:	The 116-C-5 Retention Basins were located approximately 1,040 meters (3,400 feet) north of the 105-C Reactor and southeast of 116-B-11 (107-B Retention Basin).		
Process Description:	The 116-C-5 Retention Basins were constructed to hold cooling water effluent from the 105-C Reactor to allow for thermal cooling and radioactive decay prior to release to the Columbia River. When in operation, the retention basins were two circular, 3.8E+07 liter (1.0E+07 gallon), open-topped tanks. Each tank had a diameter of 100 meters (330 feet), a depth of 4.9 meters (16 feet), and had internal baffles to prevent water from channeling across the tanks into the discharge lines. The tanks were constructed of welded carbon steel and were set on a reinforced concrete foundation with a crushed rock subfloor.		
Related Sites/ Structures:	The 116-C-5 Retention Basins are associated with the 105-C Reactor, 105-B Reactor, 116-C-1 Liquid Waste Disposal Trench, 132-B-6 (1904-B2) Outfall, and the 132-C-2 (1904-C) Outfall.		
Waste Type:	Process Effluent		
Waste Description:	The basins received cooling water effluent from the 105-B and 105-C Reactors for radioactive decays and thermal cooling prior to release to the Columbia River. The total radionuclide		

inventories in the vicinity of the basins ranged from 5 to over 400 curies. Eighty percent of the total radionuclide inventory is contained within the soil adjacent to the basins. Approximately 10 curies leached into the basins' floors and walls.

Closure Info: The site has been excavated, remediated, and closed out. The material removed from the site was disposed of in the Environmental Restoration Disposal Facility (ERDF).

In accordance with the Interim Action Record of Decision and Remedial Design Report/Remedial Action Work Plan, a rural residential exposure scenario was assumed in calculating cleanup levels. Results of the sampling, testing, and analyses for the 116-C-5 site cleanup indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of surface waters (including the Columbia River) have been met.

At the completion of the remedial action, the excavation floor area was approximately 26,000 square meters (6.4 acres) at a depth of 4.6 meters (15 feet), and approximately 224,709 metric tons (246,695 tons) of material from the site, including pipelines within the excavation footprint, were disposed of at the ERDF. The excavation is to be backfilled to the reference grade of 133.5 meters (438 feet).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown that no IC restrictions were required but the sites were remediated with deep zone criteria so that ICs actually were required. The ICs for this site have been revised accordingly.

Code: 132-C-2	Classification: Accepted
Names: 132-C-2; 1904-C Outfall; 116-C-4	Reclassification: Interim Closed Out (7/25/2002)
Type: Outfall	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and closed out.	
Location: The site is located just north of the 116-B-11 (107-B Retention Basin) and downstream of 116-B-7 (1904-B1 Outfall) and 132-B-6 (1904-B2 Outfall).	
Related Sites/Structures: The site received effluent from the 100C process effluent lines (100-C-6) and discharged effluent via the 132-C-2 Outfall, 100B/C river effluent pipelines (100-B-15) and/or flumes (100-B-26) .	
Waste Type: Process Effluent	
Waste Description:	
Closure Info: 116-B-7, 132-B-6 and 132-C-2 were addressed as a group. The information below documents information for the group of sites.	

The cleanup verification package (CVP-2002-00003) for the sites, also referred to as B/C Outfall, has demonstrated that remedial action has met the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the approved interim action Interim Action Record of Decision (ROD) (EPA 1999) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17 Rev. 3).

Remedial action at the B/C Outfall site began on June 4, 2001. Excavation of the three outfall sites involved removing the overburden materials and debris, the contaminated structure, and underlying contaminated soil.

The COCs and COPCs for this site consist of the following: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239/240, and strontium-90. Sampling and analysis during remediation indicated that additional COPCs should be identified. The additional COPCs are as follows: total chromium, hexavalent chromium, lead, mercury. Total chromium, hexavalent chromium, lead, and mercury were detected in cleanup verification samples and were therefore evaluated as COCs for the B/C Outfall site.

Cleanup verification sampling for the deep and shallow zones was done on January 14 and 15, 2002. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the SAP.

The sampling results indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

Institutional control (IC) information has been revised for 116-B-7, 132-B-6, and 132-C-2 as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including these, WIDS had shown that no IC restrictions were required but the sites were remediated with deep zone criteria so that Ics actually were required. The Ics for this site have been revised accordingly.

Code: 600-230	Classification: Accepted
Names: 600-230; RCRA General Inspection 200WFY97 Item #4 Historic Disposal Site	Reclassification: No Action (5/25/2006)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:
Description:	The site has been evaluated and reclassified to "No Action". The site consisted of an area of household debris typical of items found at pre-Manhattan Project farm sites.
Location:	The site was located on the right bank of the Columbia River (facing downstream) between 100B Area and 100K Area, approximately 1/3 mile west of the old Hanford Irrigation Project Pumphouse and approximately 40 yards from the river.
Process Description:	The area appeared to have been used as a dumping area for domestic waste before the Manhattan Project.
Waste Type: Batteries	
Waste Description:	Miscellaneous household garbage including, one C cell battery was found.
Waste Type: Barrels/Drums/Buckets/Cans	
Waste Description:	Empty food cans, paint cans, buckets and glass.

existing historical information for the site. The COPC list identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) included polychlorinated biphenyls (PCBs), pesticides, semivolatile organic compounds (SVOCs), total petroleum hydrocarbons (TPH), volatile organic compounds (VOCs), asbestos, silver, barium, cadmium, chromium (total), hexavalent chromium, mercury, lead, and selenium. Field screening for VOCs was conducted during excavation and confirmatory sampling activities. No VOCs were identified, and therefore VOCs were excluded as COPCs. As a result of further evaluation of the site history, asbestos was also included as a COPC. Gross alpha, gross beta, and gamma energy analyses were also performed on samples to evaluate the potential presence of radionuclide contaminants.

Confirmatory sampling was performed April 2 through 14, 2003. All samples were collected as described in Waste Site Evaluation for the 100-B-1 Surface Chemical and Solid Waste Dumping Area and documented. Confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency (EPA) and the results were compared against the cleanup criteria specified in the RDR/RAWP. The results were stored in the Environmental Restoration (ENRE) project-specific database prior to archiving in the Hanford Environmental Information System (HEIS) and were included in Appendix A of the RSVP.

Because of the presence of TPH, pesticides, SVOCs, and PCBs at concentrations exceeding RAGs and visual observations of debris during confirmatory sampling, approximately 51,099 metric tons (56,327 US tons) of material was removed for disposal at ERDF. The site was excavated to a maximum depth of 3.7 to 4 meters (12 to 13 feet) below ground surface.

Verification sampling was performed on August 22, 2005, based on statistical evaluation of the resulting data, the residual contaminant concentrations meet the cleanup criteria specified in the RDR/RAWP and the ROD. The analytical results illustrated completeness of remediation and verify that cleanup objectives for direct exposure, groundwater and river protection have been met. Residual contaminant concentrations support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario. In accordance with this evaluation, the verification sampling results support a reclassification of the 100-B-1 site to interim closed out. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 100-B-23	Classification: Accepted
Names: 100-B-23; 100-B/C Surface Debris	Reclassification: Interim Closed Out (6/16/2008)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:
Description:	The site consisted of various sizes and forms of scattered surface debris in the 100-B/C Area which has been identified as potentially dangerous/CERCLA waste.
Location:	The surface debris included in this site was scattered over the 100 B/C Area. A GPS was used to record the location of field observations.
Process Description:	A field walk-down of the 100-B/C Area was conducted during July and August 2004 as a final closure screening activity. Scattered surface debris that was created during the construction, operating, decontamination and decommissioning (D&D), and remedial action (RA) activities at the 100-B/C Area was identified as potentially dangerous/CERCLA waste. The locations of the debris were recorded using Global Positioning System (GPS) technology and a description was entered into a field logbook. For some features, additional information was obtained using digital photography. Subsequent evaluation of the collected data yielded 4 generic groupings of wastes: asbestos-containing material, lead, oil and oil filters, and treated wood. The field walk-down of the 100-B/C Area did not include the 30-meter by 30-meter grids where cleanup activities were being conducted or within posted areas. The field walk-down was limited to observations; no sampling was conducted. Observations of potential physical hazards, cultural

artifacts, and nonhazardous, nondangerous solid waste were GPSd and noted in a logbook. A spreadsheet was also created listing the coordinates of the debris that had been observed. The spreadsheet is in the WIDS hardcopy file of this site.

Waste Type: Oil

Waste Description: Oil from automobile oil filters on soil surface; scattered oil filters.

Waste Type: Misc. Trash and Debris

Waste Description: The treated wood locations are isolated; that is, not within existing or abandoned railroad beds or utility laydown yards. These locations contain one or more horizontal railroad ties, posts, or poles imbedded or resting on the surface, more or less weathered. The locations do not include posts, poles, plywood, or other wood materials that does not appear to have been a treated wood.

Waste Type: Misc. Trash and Debris

Waste Description: Pieces of lead sheet.

Waste Type: Asbestos (non-friable)

Waste Description: Contaminants of potential concern (COPCs) include asbestos, lead, oil, and creosote. Debris is scattered across the 100-B/C area.

Closure Info: As documented in the Remaining Sites Verification Package 2008-027, the current site conditions have achieved the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-B/C-1, 100-B/C-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site.

Remediation of the 100-B-23 waste site was performed in accordance with the site-specific remediation approach as outlined in the work instruction and the site specific soil-sampling documents. The design consisted of the removal of suspect hazardous material identified at the surface of the site (friable ACM, lead sheeting and batteries, oil filters, and treated wood) along with any associated stained soils. Verification sampling of underlying stained soils was performed concurrently with the cleanup action to support waste site closure. The sampling approach was agreed to by EPA and DOE-RL.

Remediation and verification sampling of the site was performed between June 2007 and February 2008. Evaluation of the collected information for the surface debris features yielded four generic waste groupings: asbestos-containing material (ACM); lead debris; oil and oil filters; and treated wood. The various forms of scattered surface debris were thought to be created during the construction, operating, decontamination and decommissioning, at the 100-B/C Area.

The contaminants of potential concern (COPCs) for the 100-B-23 site were identified based on process knowledge and site visit observations. The identified COPCs for the oil-stained soils were total petroleum hydrocarbons (TPH), inductively coupled plasma (ICP) metals (antimony, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, lead, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc), mercury, polychlorinated biphenyls (PCBs), and semivolatile organic compounds (SVOCs). The oil-stained soil sites were screened first using TPH, a primary contaminant associated with the presence of automobile oil. The results of the TPH analysis were evaluated to determine if further laboratory analysis or remediation of the oil-stained soils was required. The full list of COPCs for the oil-stained soils was analyzed only if TPH was detected, but below the screening level of 200 mg/kg (Washington Administrative Code [WAC] 173-340). No geophysical survey was performed

because the position and character of debris was well established by visual reconnaissance.

Verification samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The analytical results were stored in the Environmental Restoration (ENRE) project-specific database prior to being provided to the Hanford Environmental Information System (HEIS) and were included in Appendix C of the RSVP.

A total of approximately 680 metric tons (750 US tons) of debris and stained soils were removed from the site and disposed at the Environmental Restoration Disposal Facility. All nonfriable ACM material and most of the inert wood material was left in-place at the site. The nonfriable ACM and inert wood material did not present a potential release to the environment; therefore, no cleanup action was required for these items.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The verification sampling results supported a reclassification to Interim Closed Out. The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. Site contamination did not extend into the deep-zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone were not required.

Code: 100-B-31	Classification: Accepted
Names: 100-B-31; Garnet Sand Located at 183-C Clearwell Pads	Reclassification: Interim Closed Out (1/13/2010)
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:
Description:	The site consisted of scattered garnet sands on the 183-C Clearwell concrete pads and the surrounding soils. The complete extent of the garnet sands has not been investigated.
Location:	The site was located south of Bells Street and east of Tank Avenue in south central 100-B/C Area. The center of the site was located at Washington State Plane coordinates E 565072.91, N 144009.16.
Process Description:	The exact process that caused the garnet sand to be located at this site is unknown. However, garnet sand (grit) was used in sandblasting operations throughout the Hanford site.
Waste Type: Chemicals	
Waste Description:	The waste is garnet sand mixed with the material that was sandblasted. Confirmatory sampling is needed to determine if there are any contaminants of potential concern.
Closure Info:	The remaining sites verification package, RSVP-2009-046, documents that the site has achieved remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units.(Remaining Sites ROD). A reclassification to Interim Closed Out is supported based on site history, process knowledge, field observations, and comparison of residual contaminant concentrations against RAGs.

The 100-B-31 waste site was an area of scattered garnet sand on the 183-C Clearwell concrete pads and surrounding soils. The garnet sand was suspected to be the result of sandblasting operations at the former clearwell tanks. The site has been remediated as a shallow scraping and

does not require backfill. The site measures 134 m (440 ft) in length by 122 m (400 ft) in width, for a total area of 16,400 m² (176,000 ft²).

Remedial action at the site was performed from May to July 2009. Remediation included scraping along the edge of the clearwell pads and removal of garnet sand, asphalt, and contaminated soil from the area. In total, approximately 2,330 bank cubic meters (3,050 bank cubic yards) of contaminated material was removed from the site. This material, composed of garnet sand, soil, and asphalt, was stockpiled on the northeastern and southeastern tank pads before being disposed at the Environmental Restoration Disposal Facility.

Verification sampling was conducted in August 2009. The results indicated that the waste removal action had achieved compliance with the RAOs and (RAGS) for the site. Verification samples were analyzed using U.S. Environmental Protection Agency (EPA)-approved analytical methods. The 95% upper confidence limits on the true population means for residual COPCs were calculated for the excavation footprint as specified by the RDR/RAWP with calculations provided in Appendix B of the RSVP. When a nonradionuclide COPC was detected in fewer than 50% of the verification samples collected for the area, the maximum detected value was used for comparison to RAGs. If no detections for a given COPC were reported in the data set, then no statistical evaluation or calculations were performed for that COPC.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to inclusion into the Hanford Environmental Information System and are presented as an attachment to the statistical calculations in Appendix B of the RSVP.

Residual concentrations at the site support future unrestricted remaining sites land uses that can be represented (or bounded) by a rural-residential scenario and are considered protective of human health, groundwater, and the Columbia River. The site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

Code:	118-B-1	Classification:	Accepted
Names:	118-B-1; Ext. to BG No. 1; Operations; Solid Waste Burial Ground; 105-B Burial Ground; 105-B Solid Waste Burial Ground; 108-B Burial Ground	Reclassification:	Interim Closed Out (1/9/2008)
Type:	Burial Ground	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1973
Description:	This unit currently appears as a vegetation-free mound of cobbles raised 0.6 to 0.9 meters (2 to 3 feet) above the surrounding terrain. A 12 by 60-meter (40 by 200-foot) vegetation-covered extension near the northwest corner of the main burial ground, is raised 0.9 to 1.2 meters (3 to 4 feet) above the surrounding terrain. Part of the site is also bounded by permanent yellow markers. The site is now posted as a Soil Contamination Area, signs are required as an institutional control to prevent irrigation.		
Location:	The site was located 914 meters (3,000 feet) due west of the 105-C Reactor Building		
Process Description:	This waste site operated from 1944 to 1973, receiving general radioactive and non-radioactive wastes from the 105-B and 105-N Reactors, construction wastes from modification of the 105-B Reactor Building, and process wastes from the P-10 Tritium Separation Project. The original burial ground contained six to eight trenches that ran in a east-west direction, receiving general reactor waste from the B Reactor which included: aluminum tubes, lead bricks, thermocouples, vertical and horizontal aluminum thimbles, stainless-steel gun barrels and expendables (e.g.,		

plastic, wood, and cardboard). Spline silos were also constructed at the burial ground, which were vertical metal culverts, 3 to 3.7 meters (10 to 12 feet) in diameter, built presumably to receive reactor poison splines and other metal wastes. One extension to the south side of the original burial ground was known as the 108-B Solid Waste Burial Ground, measuring 46 meters (150 feet) long by 73 meters (240 feet) wide by 6.1 meters (20 feet) deep. The burial ground contained three trenches oriented from east to west. This burial ground received contaminated tritium pots, irradiated process tubing (in 1952), contaminated fuel spacers (perfs), solid tritium wastes, and high-level liquid tritium wastes that were sealed in a 7.6-centimeter (3-inch)-diameter iron pipe. The second extension to the burial ground was added in 1956 and was referred to as the "extension to Burial Ground No. 1." It measured 61 meters (200 feet) long by 15 meters (50 feet) wide and ran in a north-south direction, adjacent to and at the midpoint of the original burial ground's west side. This extension contained two trenches that ran in a north-south direction and was used for the burial of contaminated yokes from B Reactor. The third extension was added to the north side of the original burial ground in the mid 1960s and measured 106 meters (350 feet) long by 91 meters (300 feet) wide, with trenches running in an east-west direction. Historical data on the contents of these trenches are not as detailed as with earlier extensions but are presumed to include "general" reactor and construction waste from modifications to B Reactor. Waste materials from the Tritium Separation (P-10) Project were also buried here, including lithium-aluminum alloy, lead, mercury, aluminum cladding, and palladium.

Waste Type: Equipment

Waste Description: The burial ground received general reactor waste from the 105B and 105N reactors, including the following: aluminum tubes, irradiated facilities, thermocouples, vertical and horizontal aluminum thimbles, stainless steel gun barrels, wastes from operation of the P-10 tritium separation project, and expendables such as plastic, wood, and cardboard. Waste materials were typically buried 6.1 meters (20 feet) below grade and were covered with a minimum of 1.2 meters (4 feet) of clean soil; actual soil cover ranged from 0.6 meters (2 feet) to greater than 4.3 meters (14 feet). Potential Contaminants include Ag-108m, C-14, Co-60, Cs-137, Eu-152, Eu-154, Eu-155, H-3, Ni-59, Ni-63, Sr-90, cadmium, Cr+6, lead, mercury, boron, graphite, PCBs, SVOAs, TPH, and VOAs.

Permanent concrete markers surrounded the site, and "Caution: Underground Radioactive Material" signs were posted. Blue and green ground penetrating radar survey stakes had been placed around the perimeter and in lines crossing the site. A 12 by 4.6-meter (40 by 15-foot), vegetation-free, cobble-covered portion about 46 meters (50 yards) north of the southeast corner is bounded by steel posts and light-duty barricade chain; warning signs are posted on that section.

Closure Info: The Cleanup Verification Package (CVP) for the 118-B-1 Burial Ground has documented that the site has met the remedial action objectives and goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP), the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (ROD), and the Explanation of Significant Difference for the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, (ESD).

Remedial action began on February 2, 2004, with overburden removal. Approximately 20,000 bank cubic meters (BCM) [26,200 bank cubic yards (BCY)] of overburden material was removed before beginning excavation and sorting of the burial ground on March 16, 2004. Suspect spent nuclear fuel (SNF) was discovered on September 15, 2004, and remedial activities suspended until the Authorization Basis could be assessed and revised to address spent nuclear fuel (SNF). Load-out operations resumed on April 11, 2005, for previously sorted and segregated material. All remedial activities (excavation, sorting, and load-out) resumed on

August 24, 2005, and were completed on June 7, 2007, with the exception of characterization and dispositioning of the SNF and approximately 100 remaining anomalous containers.

During remediation, it was discovered that 2 of the 23 trenches had not been used for waste disposal. The burial ground also consisted of several spline silos constructed from 3 to 3.7 meter (10 to 12 foot) diameter metal culvert piping and 3 spacer pits shored with railroad ties. The overall lateral footprint of the burial ground prior to remediation was approximately 225 meters by 90 meters (740 feet by 300 feet).

Over 120,000 metric tons (132,300 tons) of debris and contaminated soil from the Burial Ground was removed and disposed at ERDF. At the conclusion of remediation activities, the excavated area was approximately 10 meters (33 feet) at its deepest, with a lateral footprint of approximately 21,600 meters squared (5.3 acres). Approximately 136,000 meters squared (33.6 acres) in total at the site were disturbed, including stockpiles and waste sorting and staging areas.

The sampling and analysis plan (SAP) identified the contaminants of concerns (COCs) for burial grounds based on waste forms encountered. Additional waste site COCs/COPCs were identified for the 118-B-1 Burial Ground based on process knowledge and results of in-process sampling. Based on the observed waste forms found during remediation activities and the results of waste characterization sampling, COCs/COPCs were identified for each decision unit in the Site Specific Instruction for Close-Out Approach for 118-B-1. The SSI documents the agreements between the Department of Energy Richland Operations Office (DOE-RL) and the EPA regarding interim waste site closeout for the 118-B-1 Burial Ground. The COCs/COPCs identified in the 118-B-1 SSI include americium-241, carbon-14, cesium-137, cobalt-60, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, plutonium-241, silver-108m, strontium-90, tritium, uranium-233/234, uranium-235, uranium-238, the expanded list of inductively coupled plasma (ICP) metals (arsenic, antimony, barium, beryllium, boron, cadmium, total chromium, cobalt, copper, lead, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc), hexavalent chromium, mercury, polychlorinated biphenyls (PCBs), total petroleum hydrocarbons (TPH), semi-volatile organic compounds, volatile organic compounds, herbicides, pesticides, and asbestos.

Verification sampling was conducted in July 2006 and October through December 2006. Additional focused verification samples were collected from March to June 2007. Verification sampling is performed to collect data to determine if the remedial action goals (RAGs) have been met. RAGs are the specific numeric goals against which the verification data are evaluated to demonstrate attainment of the remedial action objectives as established in the Burial Ground ROD.

The results of verification sampling show that residual concentrations of contaminants other than tritium do not preclude any other future uses (as bounded by the rural-residential scenario) of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The remaining soils at this site have been sampled, analyzed, and modeled. The results of verification sampling indicated that vadose zone soils beneath the burial ground contained residual tritium concentrations in excess of remedial action objectives for the protection of groundwater. Therefore, the Tri-Parties on consideration of balancing factors have required institutional controls (postings) remain in place to prohibit future irrigation. The acceptability of direct exposure to residual tritium contamination in the deep vadose zone has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are also required.

In accordance with the CVP, the verification sampling and modeling results support a reclassification of the 118-B-1 Burial Ground to Interim Closed Out.

Code:	118-B-2	Classification:	Accepted
Names:	118-B-2; Construction Burial Ground No. 1; Minor Construction Burial Ground No. 1	Reclassification:	Interim Closed Out (4/5/2005)
Type:	Burial Ground	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1956
Description:	The site has been remediated and interim closed out. The unit was a burial ground containing a trench that ran east and west.		
Location:	Site characterization data collected in 2001 and 2002 indicated the trench may have actually been within the 118-B-3 Burial Ground. The site was originally thought to be located approximately 128 meters (420 feet) east of the 105-B Building and immediately west of the 118-B-3 Burial Ground.		
Process Description:	This burial ground received dry waste from the 107-B Basin repairs and from the 115-B Gas Recirculation Facility alterations. Operation of the unit began in 1952 and ended in the Summer of 1956.		
Related Sites/ Structures:	Received waste from the 107-B Basin repairs and from the 115-B Gas Recirculation Facility alterations.		
Waste Type:	Construction Debris		
Waste Description:	The unit was used for disposal of 100 cubic meters (131 cubic yards) of dry waste from the 107-B Basin repairs and waste from the 115-B Gas Recirculation Facility alterations. Potential Contaminants are: Co-60, Cs-137, Eu-152, Eu-154, Eu-155, Sr-90, chromium, Cr+6, lead, mercury, PCBs		
Closure Info:	118-B-3 and 118-B-2 were addressed as a group. The information below documents information for the group of sites.		

Results of geophysical investigations and test pit excavations conducted in 2001 and 2002 indicated that the 118-B-2 Burial Ground was located within the mapped boundaries of the 118-B-3 Burial Ground (CCN105241 and CCN115320). Therefore, the sites were combined in closure documentation, and collectively referred to as the 118-B-3 Burial Ground. The cleanup verification package (CVP), CVP-2005-00001, has documented completion of remedial action of the burial grounds and its adjacent staging piles. The remedial action achieved the RAOs and corresponding RAGs established in the approved Interim Remedial Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site, Benton County, Washington 100 Area Burial Grounds ROD (EPA 2000) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 5).

Final waste site contaminants of concern (COCs) were agreed upon by the operable unit managers (CCN115320). The COCs consisted of the following: cobalt-60, plutonium-239/240, cesium-137, strontium-90, europium-152, chromium, europium-154, hexavalent chromium, europium-155, lead, nickel-63 mercury and plutonium-238. Six focused sampling areas were identified within the 118-B-3 Burial Ground to support remediation activities. Sampling numbers included J01TK1 through J01TK9, J01TL3 through J01TL7 and J01TM0 through J01TM5. The focused sampling effort on 10/19/04 and laboratory analyses results have been loaded into HEIS. None of the contaminants of potential concern identified for focused sampling were encountered at concentrations above the RAGs. Therefore, they were not added to the list of COCs for the site. Excavation and waste disposal were completed and the exposed surfaces (including an area used for staging of excavated waste) have been sampled and analyzed to verify attainment of the RAGs.

At the completion of remedial action, the excavation was 4,803.8 meters squared (51,708 square feet) in area with an average depth of less than 4.6 meters (15 feet). Approximately 9,525 metric tons (10,500 tons) of material, including soil and burial ground debris, were removed from the burial ground and disposed of at the ERDF. Results of the sampling, laboratory analyses, and data evaluations for the site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

The results of this effort indicated that the materials from the 118-B-3 Burial Ground containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at ERDF. These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site are protective of groundwater and the Columbia River. Shallow zone soil cleanup criteria have been applied to the entire vadose zone underlying the 118-B-3 excavation; therefore, institutional controls against drilling or digging are not required for this site. The Burial Ground is verified to be remediated in accordance with the 100 Area Burial Grounds ROD (EPA 2000) and may be backfilled.

Code:	118-B-3	Classification:	Accepted
Names:	118-B-3; Construction Burial Ground No. 2	Reclassification:	Interim Closed Out (4/5/2005)
Type:	Burial Ground	Start Date:	1/1/1956
Status:	Inactive	End Date:	1/1/1960
Description:	The site has been remediated and interim closed out. The unit contained many trenches running east and west.		
Location:	This unit was located approximately 160 meters (525 feet) northeast of the 105-B Building and directly east of 118-B-2.		
Process Description:	The burial ground was in operation from the summer of 1956 until 1960 and was used for disposal of solid waste from effluent pipeline modifications and for disposal of reactor-generated solid waste during various modification programs.		
Waste Type:	Construction Debris		
Waste Description:	The unit was used for the disposal of solid waste from the effluent line modification and for disposal of reactor-generated solid waste during various modification programs. Potential contaminants include: Co-60, Cs-137, Eu-152, Eu-154, Eu-155, Ni-63, Pu-238, Pu-239/240, Sr-90, chromium, lead, mercury, PCBs		
Closure Info:	118-B-3 and 118-B-2 were addressed as a group. The information below documents information for the group of sites.		

Results of geophysical investigations and test pit excavations conducted in 2001 and 2002 indicated that the 118-B-2 Burial Ground was located within the mapped boundaries of the 118-B-3 Burial Ground (CCN105241 and CCN115320). Therefore, the sites were combined in closure documentation, and collectively referred to as the 118-B-3 Burial Ground. The cleanup verification package (CVP), CVP-2005-00001, has documented completion of remedial action of the burial grounds and its adjacent staging piles. The remedial action achieved the RAOs and corresponding RAGs established in the approved Interim Remedial Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site, Benton County, Washington 100 Area Burial Grounds ROD (EPA 2000) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 5).

Final waste site contaminants of concern (COCs) were agreed upon by the operable unit managers (CCN115320). The COCs consisted of the following: cobalt-60, plutonium-239/240, cesium-137, strontium-90, europium-152, chromium, europium-154, hexavalent chromium, europium-155, lead, nickel-63 mercury and plutonium-238. Six focused sampling areas were identified within the 118-B-3 Burial Ground to support remediation activities. Sampling numbers included J01TK1 through J01TK9, J01TL3 through J01TL7 and J01TM0 through J01TM5. The focused sampling effort on 10/19/04 and laboratory analyses results have been loaded into HEIS. None of the contaminants of potential concern identified for focused sampling were encountered at concentrations above the RAGs. Therefore, they were not added to the list of COCs for the site. Excavation and waste disposal were completed and the exposed surfaces (including an area used for staging of excavated waste) have been sampled and analyzed to verify attainment of the RAGs.

At the completion of remedial action, the excavation was 4,803.8 meters squared (51,708 square feet) in area with an average depth of less than 4.6 meters (15 feet). Approximately 9,525 metric tons (10,500 tons) of material, including soil and burial ground debris, were removed from the burial ground and disposed of at the ERDF. Results of the sampling, laboratory analyses, and data evaluations for the site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

The results of this effort indicated that the materials from the 118-B-3 Burial Ground containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at ERDF. These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site are protective of groundwater and the Columbia River. Shallow zone soil cleanup criteria have been applied to the entire vadose zone underlying the 118-B-3 excavation; therefore, institutional controls against drilling or digging are not required for this site. The Burial Ground is verified to be remediated in accordance with the 100 Area Burial Grounds ROD (EPA 2000) and may be backfilled.

Code:	118-B-4	Classification:	Accepted
Names:	118-B-4; 105-B Dummy Burial Ground; 105-B Spacer Burial Ground	Reclassification:	Interim Closed Out (5/24/2004)
Type:	Burial Ground	Start Date:	1/1/1956
Status:	Inactive	End Date:	1/1/1958
Description:	The site has been remediated and interim closed out.		
Location:	The unit was located 91 meters (300 feet) northeast of the 105-B Reactor Building within the 105-B exclusion area fence.		
Process Description:	This site received irradiated aluminum fuel spacers from the 105-B Reactor .		
Waste Type:	Equipment		
Waste Description:	The unit was used for disposal of fuel spacers dummies. Potential contaminants included: Co-60, Cr+6		
Closure Info:	The site has been remediated in accordance with remedial action goals (RAGs) established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. For the 118-B-4 Burial Ground site, these goals and objectives are documented in the Interim Remedial Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units (100 Area Burial Grounds ROD) (EPA 2000) and the		

Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE RL 2002). The 100 Area Burial Grounds ROD provides the U.S. Department of Energy, Richland Operations Office the authority, guidelines, and objectives to conduct this remedial action. The preferred remedy specified in the 100 Area Burial Grounds ROD and conducted for the 118-B-4 Burial Ground site was excavation, treatment as necessary, and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF).

Waste site COCs identified through process knowledge are listed in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (DOE RL 2001). The COCs identified in the sampling and analysis plan for this site consisted of cobalt-60 and hexavalent chromium.

During excavation of the burial ground, five wooden and three metal caissons containing metallic debris were found. The caissons contained aluminum fuel spacers, splines, and lead-cadmium "poison pieces" used during operation of the 105-B Reactor.

The pieces were found to be intact. Which substantially reduced the leachability potential of the slugs. This observation and conclusion was further supported by waste profiling, which provided Bechtel Hanford, Inc. Waste Management designation of the waste form as fully encapsulated by the aluminum jacket; therefore, not technically requiring macro encapsulation treatment for disposal at ERDF. At the completion of remedial action, the excavation was approximately 531.5 meters squared (5,721square feet) in area with an average depth of approximately 3.9 meters (13 feet). Approximately 3,171 metric tons (3,495 tons) of material, including soil and burial ground debris, were removed from the site and disposed of at ERDF.

Cleanup verification samples, including QA/QC samples, were collected and analyzed for the established contaminants of concern. Shallow zone samples (J01700 and J01701, and J016Y7 through J016Y9) were collected on January 15, 2004. The staging area cleanup verification data included samples (J016Y1 through J016Y5) collected January 15, 2004. Sample results are in the HEIS database.

CVP-2004-00002 demonstrated that remedial action at the 118-B-4 Burial Ground site achieved the RAOs and corresponding RAGs established in the approved 100 Area Burial Grounds ROD (EPA 2000) and the RDR/RAWP (DOE RL 2002). The remaining soils were, including the staging area, have been sampled, analyzed, and modeled. The results indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River.

Institutional controls against drilling or digging are not required for this site; however, shallow zone soil cleanup criteria have been applied to the entire vadose zone underlying the excavation.

Code:	118-B-6	Classification:	Accepted
Names:	118-B-6; 108-B Solid Waste Burial Ground; 108-B Solid Waste Burial Ground No. 2	Reclassification:	Interim Closed Out (6/8/2006)
Type:	Burial Ground	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1953
Description:	The site has been remediated and interim closed. The site has been backfilled and leveled to grade. The unit consisted of two concrete caissons (pipes) 5.5 meters (18 feet) long by 1.8 meters (6 feet) in diameter, that were buried vertically in the ground and capped with a concrete pad. The concrete pad had two pear-shaped steel lids that provided access to the caissons.		
Location:	This site was located approximately 107 meters (350 feet) northeast of the B Reactor.		
Process	This site was used for disposal of wastes from the "metal line" of the P-10 Tritium Separation		

Description: Project. One of the vertical caissons was filled with waste and capped, the other was partially filled with waste and capped by a concrete pad. The pad measured about 4.6 by 3.0 meters (15 by 10 feet) with two pear-shaped steel lids that provided access to the caissons' burial chambers.

Waste Type: Equipment

Waste Description: The unit received the following types and amounts of wastes: 26,500 kilograms (58,500 pounds) of spent lithium-aluminum alloy, 21,300 kilograms (47,000 pounds) of lead from pots, 45 kilograms (100 pounds) of mercury from manometers and Toepler pumps, 1,720 kilograms (3,800 pounds) of aluminum cladding, and 1,360 kilograms (3,000 pounds) of palladium. Additionally, it contains a total of 21,200 kilograms (23.4 tons) of wastes generated as a result of the P-10 tritium production project in the 108-B Facility. Potential contaminants include: H-3, lead, mercury

Closure Info: The cleanup verification package (CVP-2006-00002) documented that the site has achieved remedial action objectives and goals established in the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (100 Area Burial Grounds) (ROD) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Remedial action at the site began in November 2004. Excavation of the site involved removing the uncontaminated overburden, caissons, concrete pad, buried materials, and underlying contaminated soil.

Waste site contaminants of concern (COCs) identified in the RDR consisted of tritium, lead, and mercury. Although the majority of the excavation was completed by December 2004, leach tests done on soil samples taken from the bottom of the excavation showed levels of tritium that required an additional 1.5 meters (5 feet) of soil removal. This additional excavation was completed in June 2005.

At the conclusion of excavation activities, the elevation of the bottom of the excavation was at 136 meters (446 feet). The excavation was approximately 885 meters squared (9,523 square feet) in area with a depth of approximately 7 meters (23 feet). Nearly 577 metric tons (636 tons) of contaminated material was disposed at ERDF.

Final cleanup verification samples (J10VP0 through J10VP9 and J10VN8 and J10VN9) were collected on January 9, 2006. The samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan. The sample data were stored in the Environmental Restoration project-specific database for data evaluation prior to archiving in the Hanford Environmental Information System.

These remedial action results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. Institutional controls are required for the site to prevent drilling or excavation into deep zone soils. The site has been verified to be remediated in accordance with the ROD and the RDR and may be backfilled.

Code: 1607-B8	Classification: Accepted
Names: 1607-B8; 1607-B8 Sanitary Sewer System; 1607-B8 Septic Tank System; Septic Tank & Disposal Field for 190-C Pumphouse; 124-C-2	Reclassification: Interim Closed Out (7/29/2003)
Type: Septic Tank	Start Date: 1/1/1951

Status:	Inactive	End Date:	1/1/1969
Description:	The site has been remediated and interim closed out. The site consisted of a septic tank and tile field. The vertical tank was constructed of steel and had a 1,325-liter (350-gallon) capacity. The tile field was oriented north-south and was located to the south of the septic tank. The tile field was constructed of 20-centimeter (8-inch) vitrified clay pipe laid with open joints.		
Location:	The site was located east of the southeast corner of the 190-C Process Pumphouse.		
Related Sites/ Structures:	The 190-C Pumphouse discharged sanitary effluent via the 100-C-9 pipeline to the septic system.		
Waste Type:	Sanitary Sewage		
Waste Description:	This unit received an unknown quantity of sanitary sewage from the 190-C Pumphouse.		
Closure Info:	The Cleanup Verification Package (CVP-2003-05) has documented that the site meets the remedial action objectives (RAOs) and remedial action goals (RAGs) for the site as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).		

The contaminants of potential concern (COPCs) were identified through process knowledge and analogous site data and are included in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort. Based on the data quality objectives summary report, the COPCs for this site consisted of metals, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds (SVOCs). Additional COPCs for this site included at the request of the regulatory agency are radionuclides (gross alpha, gross beta, and gamma emitters) and hexavalent chromium. Gross alpha and gross beta analyses were conducted for screening purposes.

Of the metals analyzed (arsenic, barium, cadmium, total chromium, lead, mercury, selenium, and silver), only lead was detected in cleanup verification samples at levels greater than Hanford Site or Washington State background. Because concentrations of lead in soil were greater than background, lead was included as a cleanup verification contaminant of concern (COC) for the site. Because the other metals were not detected above soil background concentrations, they were not included as site COCs.

Of the 21 pesticides, 7 PCB Aroclors, and 64 SVOC constituents analyzed, only dichlorodiphenyltrichloroethane (DDT) and Aroclor-1254 were detected in cleanup verification samples at concentrations greater than the analytical method practical quantitation limits (PQLs). DDT and the PCB Aroclor-1254 are included as cleanup verification COCs because of the detections above the analytical method PQL. None of the other pesticides, PCBs, or SVOCs was detected at concentrations greater than the analytical method PQL and are therefore not included as site COCs. These analyses were performed using the EPA SW-846 Methods 8081 for pesticides, 8082 for PCBs, and 8270 for SVOCs. With the exception of the SVOCs and a limited number of PCBs, the analyses met the specified detection limits included in the 100 Area Remedial Action Sampling and Analysis Plan or the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort.

Cleanup verification sampling was conducted on March 31, 2003. The samples, including QA/QC samples, were collected and analyzed for the following COCs: cesium-137, cobalt-60, europium-152, europium-154, europium-155, lead, hexavalent chromium, DDT, aroclor-1254.

At the completion of remedial action, the total excavation was approximately 255 meters squared (2,740 square feet) in area with a depth of 2.5 meters (8.2 feet). Approximately 361

metric tons (397 tons) of site materials were disposed at the Environmental Restoration Disposal Facility. The septic system inlet pipe was removed to the extent of the site excavation. The approximately 12 meters of remaining pipeline between the 190-C Pump House and the 1607-B8 site has been included in the 100-C-9 pipeline site and will be dispositioned with the other pipelines in that site. At the conclusion of excavation activities, the bottom elevation of the excavation was at 143.7 meters (471.3 feet). The excavation was approximately 255 meters squared (2,740 square feet) in area with a depth of approximately 2.5 meters (8.2 feet).

The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicated that the materials from the site containing contaminants at concentrations exceeding RAGs have been excavated and disposed at the ERDF. These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The 1607-B8 site is verified to be remediated in accordance with the ROD and may be backfilled.

Code:	1607-B9	Classification:	Accepted
Names:	1607-B9; 1607-B9 Sanitary Sewer System; 1607-B9 Septic Tank System; 124-C-3	Reclassification:	Interim Closed Out (8/28/2003)
Type:	Septic Tank	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed out. The site was a septic tank and tile field.		
Location:	The unit was located south of the 118-C-1 Burial Ground, southeast of the 105-C Reactor building and north of the perimeter road.		
Process Description:	Effluent from the tank was routed a short distance (about 16 meters [52 feet]) through a pipeline to the tile field. The tile field located southeast of the tank was constructed of 20-centimeters (8-inches)-diameter vitrified clay pipe laid with open joints. The 20-centimeters (8-inches)-diameter pipeline between the reactor building and the septic tank was part of the 100-C-9 pipelines site. A small portion of the pipeline was removed with the 1607-B9 site. The remainder of the septic tank influent pipeline will be dispositioned with other pipelines included in the 100-C-9 pipelines site. The tank had a 9,085-liter (2,400-gallon) capacity.		
Related Sites/ Structures:	The site received sanitary sewer effluent from the 105 C reactor via an influent pipeline (100-C-9).		
Waste Type:	Sanitary Sewage		
Waste Description:	This unit received an unknown amount of sanitary sewage from the 105-C Reactor Building.		
Closure Info:	The Cleanup Verification Package (CVP-2003-06) has documented that the site meets the remedial action objectives (RAOs) and remedial action goals (RAGs) for the site as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).		

Waste site COPCs for the 1607-B9 site were identified through process knowledge and analogous site data and are included in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort. The COPCs for this site were identified in the document BHI 01249 and consisted of metals, pesticides, polychlorinated

biphenyls (PCBs), and semivolatile organic compounds (SVOCs). Additional COPCs were included at the request of the regulatory agency, they are: radionuclides (gross alpha, gross beta, and gamma emitters) and hexavalent chromium. Gross alpha and gross beta analyses were conducted for screening purposes.

Concentrations of lead greater than background, were detected in the cleanup verification soil samples. Therefore, lead was included as a cleanup verification contaminant of concern (COC). Cleanup verification sample results for cesium-137, cobalt-60, europium 152, europium 154, europium 155 and soil background concentrations for metals were included in Appendix A of the CVP. The final 1607-B9 cleanup verification COC list included: cesium-137, cobalt-60, europium-152, europium-154, europium-155, lead, hexavalent chromium, dieldrin.

At the completion of the remedial action, the total excavation was approximately 1,773 meters squared (19,084 square feet) in area with a depth of 3.5 meters (11.5 feet). Approximately 3,060 metric tons (3,370 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility.

The CVP demonstrated that remedial action has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils have been sampled, analyzed, and modeled. The results of this effort indicated that the materials, containing COCs at concentrations exceeding RAGs, have been excavated and disposed at the ERDF. These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site do not pose a threat to groundwater or the Columbia River. As stated in CVP-2003-00006, the site was verified to be remediated in accordance with the ROD and may be backfilled.

Code:	1607-B10	Classification:	Accepted
Names:	1607-B10; 1607-B10 Septic Tank System; Sewage Disposal Field	Reclassification:	Interim Closed Out (7/29/2003)
Type:	Septic Tank	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1969
Description:	The site has been remediated and interim closed out. The site consisted of a septic tank and tile field. A steel pipe riser 20 centimeters (8 inches) in diameter and 84 centimeters (33 inches) above grade marked the location of the tank.		
Location:	The unit was located south of the former site of the 183-C Head House and east of the road that passed the 183-C Water Plant in a north/south direction.		
Related Sites/ Structures:	The 183-C Head House discharged sanitary effluent to the septic system via the 100-C-9 pipeline.		
Waste Type:	Sanitary Sewage		
Waste Description:	The unit received only sanitary sewer wastes from the headhouse of the 183-C Water Treatment Plant. There were no known discharges of hazardous chemicals or radionuclides.		
Closure Info:	Remedial action objectives and goals for the 1607-B10 site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL-96-17).		

The selected remedial action for the 1607-B10 site included (1) excavating the site to the extent

required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to the average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of potential concern (COPCs).

Waste site COPCs for the 1607-B10 site were identified through process knowledge and analogous site data and are included in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (BHI 01249). From BHI 01249, the COPCs for this site consist of metals, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds (SVOCs). Additional COPCs for this site included at the request of the regulatory agency are radionuclides (gross alpha, gross beta, and gamma emitters) and hexavalent chromium. Gross alpha and gross beta analyses were conducted for screening purposes.

Of the metals analyzed for (arsenic, barium, cadmium, total chromium, lead, mercury, selenium, and silver), only total chromium, lead, and mercury were detected at levels greater than Hanford Site or Washington State background. Because concentrations of total chromium, lead, and mercury in soil are greater than background, these metals are included as cleanup verification contaminants of concern (COCs) for the 1607-B10 site. Because the other metals were not detected above soil background concentrations, they were not included as site COCs.

Of the 21 pesticides, 7 PCB Aroclors, and 64 SVOC constituents analyzed for, only dichlorodiphenyltrichloroethane (DDT) and the PCB Aroclor-1254 were detected in cleanup verification samples at concentrations greater than the analytical method practical quantitation limits (PQLs). DDT and the PCB Aroclor-1254 are included as cleanup verification COCs because of the detections above the analytical method PQL. None of the other pesticides, PCBs, or SVOCs were detected at concentrations greater than the analytical method PQL and are therefore not included as site COCs. These analyses were performed using the EPA SW-846 Methods 8081 for pesticides, 8082 for PCBs, and 8270 for SVOCs (EPA 1986). With the exception of one PCB Aroclor, the analyses met the specified detection limits included in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL-96-22) or the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (BHI 01249).

Of the radionuclides analyzed for, only cesium-137 was detected at a concentration greater than the analytical method minimum detectable activity or greater than Hanford Site background for naturally occurring radionuclides. The radionuclide analyses met the radionuclide detection limits specified in SAP or are well below cleanup criteria (additional discussion is included in the CVP Appendix B). Cleanup verification HEIS sample results for cesium-137, cobalt-60, europium 152, europium 154, and europium 155 are included in Appendix A of the CVP and are included as cleanup verification COCs for the 1607-B10 site. These radionuclides were included as COCs because they are common COCs for liquid waste sites throughout the 100 Area. Gross alpha and beta results are also included in Appendix A of the CVP. The gross alpha and gross beta analyses were conducted for screening purposes and are not site COCs.

Hexavalent chromium was not detected in the 1607-B10 cleanup verification samples at concentrations greater than the analytical method PQL, but was detected in the split sample used for quality assurance purposes at a concentration of 0.61 mg/kg, well below applicable cleanup criteria. Additional discussion is included in the CVP, Appendix B. Because hexavalent chromium is a common contaminant for 100 Area liquid waste sites, it is included as a cleanup verification COC for the 1607-B10 site. Hexavalent chromium was analyzed for using the EPA SW-846 Method 7196 (EPA,1986). Hexavalent chromium cleanup verification

results are included in Appendix A of the CVP.

For the various reasons given above lead, mercury, total chromium, DDT, the PCB aroclor-1254, hexavalent chromium, and the individual radionuclides (cesium-137, cobalt-60, europium 152, europium 154, and europium 155) are carried throughout this CVP as COCs for the 1607-B10 site. The final 1607-B10 cleanup verification COC list is as follows: cesium-137, cobalt-60, europium-152, europium-154, europium-155, lead, total chromium, hexavalent chromium, DDT.

At the completion of the remedial action, the total excavation was approximately 178 meters squared (1,915 square feet) in area with a depth of 2.5 meters (8.2 feet) and the bottom elevation of the excavation was 145.0 meters (475.6 feet). Approximately 328 metric tons (361 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The 1607-B10 septic system inlet pipe was removed to the extent of the site excavation. The remainder of the pipeline between the 183-C Head House and the 1607-B10 site is included in the 100-C-9 pipelines site and will be dispositioned with the other pipelines in that site.

The CVP demonstrates that remedial action at the 1607-B10 site has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the 1607-B10 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 1607-B10 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The 1607-B10 site is verified to be remediated in accordance with the ROD and may be backfilled

Code:	1607-B11	Classification:	Accepted
Names:	1607-B11; 1607-B11 Septic Tank System	Reclassification:	Interim Closed Out (7/29/2003)
Type:	Septic Tank	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1969
Description:	The site has been remediated and interim closed out. The site consisted of a septic tank and drain field.		
Location:	The unit was located north of the 183-C Filter Building site, west of the 183-C Filter Building site entrance road. The drain field was located northwest of the tank.		
Process Description:	A steel riser 20 centimeters (8 inches) in diameter and 46 centimeters (18 inches) above grade marked the location of the tank. The vertical tank was constructed of steel and had a capacity of 1,325 liters (350 gallons).		
Related Sites/ Structures:	The septic system was associated with the 183-C Filter Building, Pump Room and 100-C-9 pipeline site.		
Waste Type:	Sanitary Sewage		
Waste Description:	There were no known discharges of hazardous chemicals or radionuclides into the unit. The unit received only sanitary sewer wastes from the 183-C Filter Building & Pump Room (183-C Water Treatment Plant).		
Closure Info:	Remedial action objectives and goals for the 1607-B11 site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These		

goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL-96-17).

The selected remedial action for the 1607-B11 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to the average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of potential concern (COPCs).

Waste site COPCs for the 1607-B11 site were identified through process knowledge and analogous site data and are included in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (BHI 01249). The COPCs for this site consisted of metals, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds (SVOCs). Additional COPCs for this site included at the request of the regulatory agency are radionuclides (gross alpha, gross beta, and gamma emitters) and hexavalent chromium. Gross alpha and gross beta analyses were conducted for screening purposes.

Of the metals analyzed for (arsenic, barium, cadmium, total chromium, lead, mercury, selenium, and silver), only lead was detected at levels greater than Hanford Site or Washington State background. Because concentrations of lead in soil were greater than background, it is included as a cleanup verification contaminant of concern (COC) for the 1607-B11 site. Because the other metals were not detected above soil background concentrations, they were not included as site COCs.

None of the 21 pesticides, 7 PCB Aroclors, or 64 SVOCs (with the exception of bis[2-ethylhexyl]phthalate) analyzed for were detected in cleanup verification samples at concentrations greater than the analytical method practical quantitation limits (PQLs). Bis[2-ethylhexyl]phthalate is included as a cleanup verification COC because of the detections above the analytical method PQL. None of the other pesticides, PCBs, or SVOCs were detected at concentrations greater than the analytical method PQL and are therefore not included as site COCs. These analyses were performed using the EPA SW-846 Methods 8081 for pesticides, 8082 for PCBs, and 8270 for SVOCs (EPA, 1986). With the exception of the SVOC analysis for one verification sample, the analyses met the specified detection limits included in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL-96-22) or the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (BHI 01249) (Appendix B has additional discussion). The PCB, pesticide, and SVOC results are included in Appendix A of BHI 01249.

With the exception of cesium-137 in one sample, none of the radionuclides analyzed for were detected at concentrations greater than the analytical method minimum detectable activity or greater than Hanford Site background for naturally occurring radionuclides. The radionuclide analyses met the radionuclide detection limits specified in SAP or are well below cleanup criteria. Cleanup verification sample results for cesium-137, cobalt-60, europium 152, europium 154, and europium 155 are included in Appendix A of the CVP and are included as cleanup verification COCs for the 1607-B11 site. These radionuclides were included as COCs because they are common COCs for liquid waste sites throughout the 100 Area.

Hexavalent chromium was not detected in the 1607-B11 cleanup verification samples at concentrations greater than the analytical method PQL. Hexavalent chromium was detected in the split sample used for quality assurance purposes at a concentration of 0.38 mg/kg, well

below applicable cleanup criteria. Because hexavalent chromium is a common contaminant for 100 Area liquid waste sites, it is included as a cleanup verification COC for the 1607-B11 site. Hexavalent chromium was analyzed for using the EPA SW-846 Method 7196 (EPA,1986). Hexavalent chromium cleanup verification results are included in Appendix A of the CVP.

For the various reasons given above, lead, bis(2-ethylhexyl)phthalate, hexavalent chromium, and the individual radionuclides (cesium-137, cobalt-60, europium 152, europium 154, and europium 155) are carried throughout the CVP as COCs for the 1607-B11 site. The final 1607-B11 cleanup verification COCs include: cesium-137, cobalt-60, europium-152, europium-154, europium-155, lead, hexavalent chromium, bis(2-ethylhexyl)phthalate.

At the completion of the remedial action, the total excavation was approximately 136 meters squared (1,460 square feet) in area with approximate depth of 3.0 meters (9.8 feet). Approximately 131 metric tons (144 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF). The 1607-B11 septic system inlet pipeline was removed to the extent of the site excavation. The remainder of the pipeline is included in the 100-C-9 pipelines site and will be dispositioned with it.

The CVP demonstrates that remedial action at the 1607-B11 site has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the 1607-B11 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 1607-B11 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site do not pose a threat to groundwater or the Columbia River. The 1607-B11 site is verified to be remediated in accordance with the ROD and may be backfilled.

Code:	100-C-3	Classification:	Accepted
Names:	100-C-3; 119-C French Drain; 119-C Sample Building French Drain	Reclassification:	Interim Closed Out (7/28/2003)
Type:	French Drain	Start Date:	1/1/1960
Status:	Inactive	End Date:	
Description:	The 100-C-3 French Drain was a 0.61 m (2 ft)-diameter gravel-filled pit that received effluent from the 119 C Sample Building. The site has been remediated and interim closed out.		
Location:	The site was located east of the 105-C Building.		
Process Description:	The 100-C-3 French Drain was a 0.61 m (2 ft)-diameter gravel-filled pit that received effluent from the 119 C Sample Building. The 119-C Sample Building was built in 1960 and contained water-cooled air sample monitoring equipment. Effluent from the sampling equipment, the building's swamp cooler, and possibly janitorial waste would have been disposed to the 100-C-3 French Drain.		
Related Sites/ Structures:	The 119-C Sample Building discharged effluent to this site.		
Waste Type:	Water		
Waste Description:	The 119-C Sample Building was built in 1960 and contained "water cooled" air sample monitoring equipment. Effluent from the sampling equipment, the building's swamp cooler, and janitorial waste would have been disposed to this drain.		
Closure Info:	Remedial action objectives and goals for the 100-C-3 site were established by the U.S.		

Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).

The selected remedial action for the 100-C-3 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify contaminants of potential concern (COPCs). Because none of the metals were detected in the cleanup verification samples above soil background concentrations, they were not included as site contaminants of concern (COCs). Verification sample results and soil background concentrations for metals are included in appendix A of the CVP.

Although low levels of methylene chloride, acetone, and toluene were detected, their presence have been attributed to laboratory-introduced contamination and are not considered waste site contaminants or COCs for cleanup verification. Hexavalent chromium, a common contaminant for the 100 Area liquid waste sites, and the individual radionuclides (cesium-137, cobalt 60, europium 152, europium 154, and europium 155) are included as cleanup verification COCs.

At the completion of remedial action, the total excavation was approximately 94 meters squared (1,011 square feet) in area with a depth of approximately 3 meters (9.8 feet). Approximately 49 metric tons (54 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

The CVP demonstrates that remedial action at the site has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials containing contaminants at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site do not pose a threat to groundwater or the Columbia River. As stated in CVP 2003-00009 the site has been verified to be remediated in accordance with the ROD and may be backfilled.

Code:	100-C-6	Classification:	Accepted
Names:	100-C-6; 100-C Reactor Cooling Water Effluent Underground Pipelines	Reclassification:	Interim Closed Out (9/19/2011)
Type:	Radioactive Process Sewer	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1969
Description:	The site includes the underground 105-C Reactor cooling water effluent pipelines. These include those effluent pipelines that transported 105-C Reactor cooling water from the reactor to the 116-C-5 (107-C Retention Basin), and from the basin to the 132-B-6 and 132-C-2 Outfall Structures and/or to the 116-C-1 Liquid Waste Disposal Trench. This waste site includes all associated expansion and valve boxes and excludes the retention basin (separate site), outfall structures (separate sites), and those effluent pipelines that are within the confines of the 105-C Reactor Building or that run from the outfall structures to the bottom of the river.		

It also excludes all reactor influent pipelines that are upstream of the reactor building.

Location: The site is the location of all underground reactor effluent lines running from the 105-C Reactor Building to the Columbia River. This includes segments between the reactor building and the retention basin, and between the basin and the outfall structures. Also included are the underground lines that run from the retention basin to the 116-C-1 Trench. It excludes the reactor building (and a 1.5 meter [5 foot] buffer), retention basin, and outfall structures, each of which is treated as a unique waste site.

Process Description: Effluent water passed from the reactor rear face and gravity flowed through the underground effluent lines, junction boxes and diversion boxes to the retention basins where it was held up for a short period of time to allow thermal and radiological cooling before being released through the outfall structure to the Columbia River. During periods of reactor fuel cladding ruptures, some effluent was diverted to an open trench.

Related Sites/ Structures: Related structures include the 116-C-5 Retention Basin, the 132-B-6 and 132-C-2 Outfalls, the 116-C-1 Trench, the 105-C Reactor, the 100-B-8 Effluent Pipelines, and the 100-B-15 River Pipelines.

Waste Type: Process Effluent

Waste Description: The waste was contaminated steel piping, concrete, and soil. Reactor cooling water became radioactively contaminated as it passed through the reactor core. Activation products created in the water included calcium-41, chromium-51, and zinc-65. Activation products from the reactor core that were picked up and transported by the cooling water included tritium, carbon-14, cobalt-60, nickel-63, and europium-152/154/155. Fuel element fission products such as strontium-90, and cesium-137, as well as transuranics such as plutonium-239/240 were introduced into cooling water due to fuel cladding failures. Concentrations of radionuclides in cooling water during normal reactor operations were approximately (0.2 microcuries/liter). Concentrations of radionuclides have built up in rust flakes and scale on the inner surfaces of the pipelines and in sludge in the diversion and junction boxes. Average beta-gamma concentrations for the effluent line scale and junction/diversion boxes are 83,000 and 120,000 picocuries/liter, respectively. Average plutonium-239/240 concentrations are 66 picocuries/gram for the effluent line scale and 720 picocuries/gram for the sludge at the bottom of the diversion and junction boxes. Direct readings of the bottom of the effluent lines averaged approximately 40,000 counts/minute with a Geiger-Mueller probe. Additional chemicals were added to the effluent for purposes of water treatment. These included aluminum sulfate (alum), with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter. The waste is any remaining process effluent and the contaminated pipelines.

This Site has the Following SubSites:

Code: 100-C-6:1

Names: 100-C-6:1; 100-C Area South Effluent Pipelines

Code: 100-C-6:2

Names: 100-C-6:2; 100-C Area North Effluent Pipelines

Code: 100-C-6:3

Names: 100-C-6:3; 100-C Retention Basin to Outfalls Effluent Pipelines

Code: 100-C-6:4

Names: 100-C-6:4; B/C Pipelines Discovery Areas

Code: 100-C-6:5

Names: 100-C-6:5; Pipelines Sections Under Export Water Line (transferred to 100-B-34)

mercury, europium-155, total chromium, plutonium-238, hexavalent chromium.

Cleanup verification samples including QA/QC samples consisted of 50 shallow zone samples, 11 deep zone samples, 56 overburden samples. The final verification samples were collected between November 10, 2003, and concluded on November 19, 2004, and were analyzed for the established COCs. The numerous sample numbers were listed in appendix A of CVP-2003-00022 and also in the HEIS database.

100-B-8:1 and 100-C-6:1

At the completion of remedial action, the excavation was approximately 48,260 meters squared (519,466 square feet) in area. Approximately 244,656 metric tons (269,742 tons) of material, including soil, debris, and piping were removed from the 100-B/C south pipelines site and disposed of at the Environmental Restoration Disposal Facility.

The remaining soils at these sites have been sampled, analyzed, and modeled, while contaminated material has been excavated and disposed at ERDF. These results also indicated that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The site was verified to be remediated in accordance with the ROD and may be backfilled.

The SubSite is Part Of:

Code: 100-C-6

Names: 100-C-6; 100-C Reactor Cooling Water Effluent Underground Pipelines

Code: 100-C-6:2

Classification: Accepted

Names: 100-C-6:2; 100-C Area North Effluent Pipelines

Reclassification: Interim Closed Out (2/17/2004)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: Cleanup Verification Package 2003-00019 (CVP) documented completion of remedial action for the 100-B/C Effluent Pipeline subsites located north of B Avenue (100-B-8:2, 100-C-6:2, 100-C-6:3, and 100-C-6:4) (collectively referred to as the 100-B/C north pipelines site). The 100-C-6:2 subsite included the 105-C Reactor effluent pipelines from B Avenue north to the 116-C-5 Retention Basin, and included the diversion box just south of the 116-C-5 Retention Basin (labeled as pipes 22, 23, and 26 in Figures 2 and 3 of CVP 2003-00019).

Location: These pipelines were north of the 105-C Reactor, north of B Avenue, to the 116-C-5 Retention Basin, and the diversion box is located just south of the 116-C-5 Retention Basin.

Waste Type: Not Specified

Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Closure Info: 100-B-8:2, 100-C-6:2, 100-C-6:3 and 100-C-6:4 were addressed as a group. The information below documents information for the group of sites.

Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide

contaminants of concern (COCs).

Waste site COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE RL 2001). The COCs identified in the sampling and analysis plan for this site consisted of americium-241, cesium 137, cobalt-60, europium-152, europium-154, europium-155, plutonium-238, plutonium 239/240, strontium-90, and uranium-238.

Based on verification sampling results from the 100-B/C outfalls site, total chromium, hexavalent chromium, lead, and mercury were added to the original COC list as contaminants of potential concern (COPC). Since verification sample analyses returned detected results for all four analytes, they were retained and evaluated as COCs.

Cleanup verification samples including QA/QC samples consisted of 193 shallow zone samples, 104 deep zone samples, 260 overburden samples, and 72 discovery area samples. The final verification samples were collected between August 12, 2002, and concluded on July 24, 2003, and were analyzed for the established contaminants of concern. The sample numbers are too numerous to list and as of March 2004 have not been reported to HEIS, however they are available in appendix A of CVP-2003-00019 .

At the completion of remedial action, the excavation was approximately 135,000 meters squared (443,000 square feet) in area with an average depth of approximately 7.5 meters (25 feet). Approximately 244,656 metric tons (269,742 tons) of material including soil, debris, and piping were removed from the 100 B/C north pipelines site and disposed at the Environmental Restoration Disposal Facility.

The CVP demonstrated that remedial action at the 100-B/C north pipelines site had achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1995), and in the RDR/RAWP (DOE RL 2002). The remaining soils at these sites have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-B-8:2, 100-C-6:2, 100 C-6:3, and 100-C-6:4 sites that contained COCs at concentrations exceeding RAGs have been excavated and disposed of at ERDF.

These results also indicate that residual concentrations in the shallow zone and discovery areas will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

Reclassification: Interim Closed Out (2/17/2004)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: Cleanup Verification Package 2003-00019 (CVP) documented completion of remedial action for the 100-B/C Effluent Pipeline subsites located north of B Avenue (100-B-8:2, 100-C-6:2, 100-C-6:3, and 100-C-6:4) (collectively referred to as the 100-B/C north pipelines site). The

100-C-6:3 subsite included the 105-C underground effluent pipelines that ran between the 116-C-5 Retention Basin, 116-C-1 Trench, 132-B-6 Outfall, and 132 C 2 Outfall, and between the 116-B-11 Retention Basin and 116-B-1 Trench. Also included are the westernmost pipelines from the 116-C-5 Retention Basin to the junction box south of 116-C-5, and the pipeline on the north side of 116-C-5 that ran to the junction box immediately north of the eastern basin. The pipelines in this subsite are labeled as 12 through 21 and 42, in Figures 2 and 3 of CVP-2003-00019. One section of this subsite, labeled as pipeline 16 in the sample design figures, was removed and backfilled but not entirely sampled as part of the 116-C-5 remedial action (BHI 1997). Section 16 has been sampled for cleanup verification with this subsite.

For complete documentation from CVP-2003-00019 and cleanup verification sampling information refer to 100-C-6:2.

Location: 100-C-6:3 subsite included the 105-C underground effluent pipelines that ran between the 116-C-5 Retention Basin, 116-C-1 Trench, 132-B-6 Outfall, and 132 C 2 Outfall, and between the 116-B-11 Retention Basin and 116-B-1 Trench. Also included are the westernmost pipelines from the 116-C-5 Retention Basin to the junction box south of 116-C-5, and the pipeline on the north side of 116-C-5 that ran to the junction box immediately north of the eastern basin.

Waste Type: Not Specified

Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Closure Info: 100-B-8:2, 100-C-6:2, 100-C-6:3 and 100-C-6:4 were addressed as a group. The information below documents information for the group of sites.

Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide contaminants of concern (COCs).

Waste site COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE RL 2001). The COCs identified in the sampling and analysis plan for this site consisted of americium-241, cesium 137, cobalt-60, europium-152, europium-154, europium-155, plutonium-238, plutonium 239/240, strontium-90, and uranium-238.

Based on verification sampling results from the 100-B/C outfalls site, total chromium, hexavalent chromium, lead, and mercury were added to the original COC list as contaminants of potential concern (COPC). Since verification sample analyses returned detected results for all four analytes, they were retained and evaluated as COCs.

Cleanup verification samples including QA/QC samples consisted of 193 shallow zone samples, 104 deep zone samples, 260 overburden samples, and 72 discovery area samples. The final verification samples were collected between August 12, 2002, and concluded on July 24, 2003, and were analyzed for the established contaminants of concern. The sample numbers are too numerous to list and as of March 2004 have not been reported to HEIS, however they are available in appendix A of CVP-2003-00019 .

At the completion of remedial action, the excavation was approximately 135,000 meters squared (443,000 square feet) in area with an average depth of approximately 7.5 meters (25 feet). Approximately 244,656 metric tons (269,742 tons) of material including soil, debris, and piping were removed from the 100 B/C north pipelines site and disposed at the Environmental Restoration Disposal Facility.

The CVP demonstrated that remedial action at the 100-B/C north pipelines site had achieved the

RAOs and corresponding RAGs established in the approved ROD (EPA 1995), and in the RDR/RAWP (DOE RL 2002). The remaining soils at these sites have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-B-8:2, 100-C-6:2, 100-C-6:3, and 100-C-6:4 sites that contained COCs at concentrations exceeding RAGs have been excavated and disposed of at ERDF.

These results also indicate that residual concentrations in the shallow zone and discovery areas will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

The SubSite is Part Of:

Code: 100-C-6:4

Classification: Accepted

Names: 100-C-6:4; B/C Pipelines Discovery Areas

Reclassification: Interim Closed Out (2/17/2004)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: Cleanup Verification Package 2003-00019 (CVP) documented completion of remedial action for the 100-B/C Effluent Pipeline subsites located north of B Avenue (100-B-8:2, 100-C-6:2, 100-C-6:3, and 100-C-6:4) (collectively referred to as the 100-B/C north pipelines site). This CVP also included eleven areas discovered to have radiological contamination above background, called "discovery areas." They are collectively identified as subsite 100-C-6:4. Some areas were identified prior to commencement of the 100-B/C pipeline remediation activities, while others were found during the pipeline remediation process. The source of contamination for these areas has not been established, although the adjacent effluent piping and the 116-C-5 Retention Basins are suspected sources. The locations of the discovery areas in relation to the pipelines were shown in Figure 2 of CVP-2003-00019. For complete documentation from CVP-2003-00019 and cleanup verification sampling information refer to 100-C-6:2.

Location: These eleven pipeline segments are about 650 meters (2,145 feet) north-northeast of the 105-B Reactor, surrounding the 107-C and 107-B Retention basins.

Waste Type: Not Specified

Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

Description:

Closure Info: 100-B-8:2, 100-C-6:2, 100-C-6:3 and 100-C-6:4 were addressed as a group. The information below documents information for the group of sites.

Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide contaminants of concern (COCs).

Waste site COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE RL 2001). The results of this effort indicate that the materials from the 100-B-8:2, 100-C-6:2, 100 C-6:3, and 100-C-6:4 sites that contained COCs at concentrations exceeding RAGs have been excavated and disposed of at ERDF.

These results also indicate that residual concentrations in the shallow zone and discovery areas will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

The SubSite is Part Of:

Code: 100-C-6

Names: 100-C-6; 100-C Reactor Cooling Water Effluent Underground Pipelines

Code: 100-C-6:5

Classification: Not Accepted

Names: 100-C-6:5; Pipelines Sections Under Export Water Line (transferred to 100-B-34)

Reclassification: None

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This waste site is two sections of pipe, approximately 110 feet long, that crossed under the active Export Water line. The line segments were left in place so as not to undermine the active 42 inch export water line that passes above these effluent lines. For remediation purposes, these sections of piping were transferred to waste site 100-B-34.

Location: These sections are north of the 105-C reactor.

Process Description: Because these sections of pipe are being transferred to waste site 100-B-34 for remediation, this subsite is being Classified to Not Accepted - per E:Mail from WCH Leonard Habel.

Waste Type: Not Specified
Waste Description: The waste is radioactively contaminated steel piping, concrete, and soil.

The SubSite is Part Of:

Code: 100-C-6
Names: 100-C-6; 100-C Reactor Cooling Water Effluent Underground Pipelines

Code: 100-C-7 **Classification:** Accepted
Names: 100-C-7; 183-C Filter Building /Pumproom Facility Foundation and Demolition Waste **Reclassification:** None
Type: Dumping Area **Start Date:**
Status: Inactive **End Date:**

Description: The site has been backfilled and graded to match the surrounding terrain. No trace of the 183-C Filter Building/Pumproom was identified. Another area of yellow stained soil has been observed near the sedimentation basins. Information about this area has been added as a subsite. The area has a chain around it with a 'Danger Authorized Personnel Only' sign.

Location: The site is located in the southwestern portion of the 100B/C Area, 340 meters (1,115 feet) west of the 105-C Reactor Building, between the 183-C Sedimentation Basins and the four 183-C Clearwell Tank Pads. The area of yellow stained soil described as a subsite is located near the northwest corner of the sedimentation basins and north of the head house.

Process Description: One of the purposes of the 183-C Pump room was to treat the cooling water with sodium dichromate, a rust inhibitor, prior to storage in the four exterior 1.89E+07-liter (5E+06-gallon) tanks (183-C Clearwells). Water was drawn from the 183-C Filter Building clearwells and injected with sodium dichromate in the pump room prior to being pumped to the four, large tanks for storage. During past practices, the sodium dichromate was stored, mixed, and spilled in various locations throughout the building.

Related Sites/ Structures: The 183 Filter Building/Pump Room Facility received water from the 183-C Sedimentation Basins and sent treated water to the 183-C Clearwells where it was stored for the 190-C Process Pump House, 100-C-7, 183-C Filter Building /Pumproom Facility Foundation and Demolition Waste (See Subsites).

Waste Type: Chemicals
Waste Description: The concrete foundation located in the 183-C Pumproom is contaminated with sodium dichromate. Characterization data showed the contamination at the worst location to be 20 centimeters (8 inches) deep, half the thickness of the floor. Therefore, assuming the contamination averaged a depth of 15 centimeters (6 inches) throughout and covered a total area of 93 square meters (1000 square feet), a quantity of 14 cubic meters (500 cubic feet) was calculated.

Waste Type: Demolition and Inert Waste
Waste Description: The 183-C Filter Building foundation and clearwells were filled with demolition and inert waste materials and leveled to grade.

Waste Type: Asbestos (friable)
Waste Description: An underground asbestos wrapped steam line was encountered during the foundation demolition along the north clearwell. Due to the length and location of the steam line, the small area uncovered during the excavation work was not remediated. The pipe was wrapped in plastic, marked with "DANGER ASBESTOS HAZARD" tape, and covered again with soil.

This Site has the Following SubSites:

The flume contained two side-by-side 4 foot by 6 foot (1.2 meter by 1.8 meter) process sewers that eventually drained at the 132-C-2 Outfall Structure.

Process Description: These pipelines carried a variety of non-radioactive waste fluids, treated cooling water (pre-reactor), and septage. This site did not include the clean water pipelines, pipelines otherwise identified with septic systems, or the main reactor effluent pipelines (100-C-6).

Related Sites/ Structures: The buildings that discharged to the process and septic sewers are the 183-C Facilities and 190-C Pump House discharged to 1607-B8; the 105-C Reactor discharged to the 1607-B9 Septic system pipeline, and the 190-C Pump House connected to the 105-C Reactor through the treated cooling water pipelines.

Waste Type: Equipment

Waste Description: The subsite consisted of the non-radioactively contaminated process and septic sewer pipelines associated with the 105-C Reactor operations. The 1607-B9 septic system serviced the 105-C Reactor and thus may be radioactively contaminated. Any contamination associated with these pipelines was expected to be in residual amounts.

Chemical additives to the reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, the free chlorine residual was approximately 0.2 milligrams/liter, and sodium dichromate was added at a rate of about 2 milligrams/liter. (Note: Reference: WHC-SD-EN-TI-169 is for 100-F, and applies equally to 100-C).

This Site has the Following SubSites:

Code: 100-C-9:1

Names: 100-C-9:1; 100-C Main Process Sewer Collection Line

Code: 100-C-9:2

Names: 100-C-9:2; 100-C Sanitary Sewer Lines

Code: 100-C-9:3

Names: 100-C-9:3; 183-C Clearwell Pipelines

Code: 100-C-9:4

Names: 100-C-9:4; 100-C Cooling Water Transfer Pipelines and Tunnels

Code: 100-C-9:1

Classification: Accepted

Names: 100-C-9:1; 100-C Main Process Sewer Collection Line

Reclassification: Interim Closed Out (6/6/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: In accordance with the Remaining Sites Verification Package (RSVP-2004-012), the verification sampling results supported a reclassification of the subsite to Interim Closed Out. The current site conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The subsite included pipelines from the 183-C and 190-C facilities that fed into the main process sewer which consisted of a dual 1.2-meter by 1.8-meter (48-inch by 72-inch)-reinforced concrete box sewer that shared a central dividing wall. The dual reinforced concrete box sewers

were often referred to as the twin box culvert. The floor, top, and walls of the twin box culvert were approximately 0.3 meters (1 foot) thick. Given the construction sequence, leaks from the cold joints could have developed at any point along the length of the structure between the floor and walls.

Location: The main process sewer began down-gradient from the 183-C sedimentation basins and was oriented east-west, running to the north of the 100-C Area water treatment and pump house facilities. Multiple feeder pipes of various sizes from the 183-C and 190-C facilities discharged into the twin box culvert. The intended purpose of these pipelines was to handle diluted, nonhazardous process wastes and storm water. Sanitary wastes were handled separately via multiple septic systems. North of the 105-C Reactor Building, the twin box culvert changed orientation to approximately north-south and ran north to the former 132-C-2 outfall.

Waste Type: Not Specified

Waste Description: Potentially contaminated pipeline (and contents), concrete, and underlying/associated soils.

Closure Info: Remedial action was divided into a northern and a southern section due to the length of the required excavation of approximately 1875 meters (6150 feet). The entire northern section along with a minimum of 0.3 meters (1 foot) of underlying soil was excavated between November 22, 2004, and February 2005. Approximately 14,639 metric tons (16,137 U.S. tons) of contaminated soil and concrete were disposed at the Environmental Restoration Disposal Facility. Verification sampling of the northern excavation was performed on August 23, 2005.

The southern portion consisted of a deep zone [i.e., more than 4.6 meters (15 feet) deep section of the twin box culvert and a shallow zone which included a section of the twin box culvert and the feeder lines from the 100-C water treatment facilities. Remediation of the southern portion shallow zone began in December 2004, and was completed on April 19, 2006. Approximately 5,851 metric tons (6,450 U.S. tons) of contaminated soil and concrete were removed for disposal at ERDF. The deep zone portion of the southern twin box culvert was left in place. Verification sampling of the southern excavation was performed July 27 through July 29, 2006.

The results of confirmatory sampling, cold joint soil sampling, and agreements with the EPA were used to develop the contaminants of concern (COCs) for verification sampling. Confirmatory sampling found concentrations of antimony, cadmium, total chromium, hexavalent chromium, copper, lead, manganese, and mercury to be above the cleanup criteria. These analytes were carried forward as COCs for verification sampling. Gridded radiological surveys of the excavations and stockpiles did not indicate the presence of radiological contamination above background; therefore radionuclides were not included as COCs for verification sampling. All analytical data were stored in the ENRE project-specific database prior to being submitted for inclusion in the HEIS database and summarized in Appendix A of the RSVP.

The results of verification sampling for both areas showed that residual contaminant concentrations in the shallow zone did not preclude any future uses (as bounded by the rural-residential scenario) and allowed for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. The suitability of direct exposure to deep zone soils has not been demonstrated. Therefore, institutional controls will be needed to prevent uncontrolled drilling/excavation of the deep-zone section of the 100-C-9:1 Main Process Sewer Collection Line that was left in place.

Although not required by the Remaining Sites ROD, a comparison of ecological risk screening levels to the available analytical data has been made. Ecological screening levels for shallow zone soils were exceeded for antimony, boron, mercury, and vanadium. Exceedance of screening values does not necessarily indicate the existence of added risk to ecological

receptors. Specifically, the values for antimony and vanadium were below the Hanford Site background levels, the concentrations measured for mercury were within the range of Hanford Site background levels, and the concentrations measured for boron were consistent with values seen elsewhere at the Hanford Site. Exceedance of ecological risk screening levels at the waste site will be evaluated in the context of additional lines of evidence for ecological effects following a baseline risk assessment for the river corridor portion of the Hanford Site, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for the waste site.

The SubSite is Part Of:

Code: 100-C-9

Names: 100-C-9; 100-C Area Process and Sanitary Sewer Underground Pipelines

Code: 100-C-9:2

Classification: Accepted

Names: 100-C-9:2; 100-C Sanitary Sewer Lines

Reclassification: Interim Closed Out (7/11/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The Remaining Sites Verification Package (RSVP-2004-013) has documented that the 100-C-9:2 subsite has met the objectives for reclassification of the subsite to Interim Closed Out. The current subsite conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The subsite consisted of the feeder pipelines for the former 1607-B8, 1607-B9, 1607-B 10, and 1607-B 11 septic systems (septic tank and drain field). All four of the septic systems and underlying contaminated soils were removed between March and May 2003, leaving the feeder pipelines in place.

Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. Residual concentrations of antimony, cadmium, total chromium, copper, lead, mercury, vanadium, and zinc were within the range of Hanford Site background levels, and boron concentrations were consistent with those seen elsewhere at the Hanford Site (no established background value is available). Concentrations of chromium, copper, lead, mercury, and zinc were within the range of Hanford Site background levels. All exceedances of screening values at the subsite will be evaluated in the context of additional lines of evidence for ecological effects following a baseline risk assessment for the river corridor portion of the Hanford Site, which will include a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for the 100-C-9 site.

Location: These pipelines came from the 183-C, 190-C, and west side (pre-process side) of the 105-C Reactor buildings.

Waste Type: Not Specified

Waste Description: Potentially contaminated pipeline (and contents), concrete, and underlying/associated soils.

Closure Info: Remedial action associated with each of the four feeder pipelines began in early 2005 and concluded on September 29, 2006. A total of approximately 3,701 metric tons (4,080 U.S. tons) of contaminated material was disposed at ERDF. Statistical and focused sampling to verify the completeness of remediation was performed, and analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. A

summary of the remediation for each of the four septic system pipelines follows:

The pipeline from the 1607-B8 septic system was removed between March 23, 2005 and April 13, 2005. The site was excavated 2 meters (6.6 feet) below grade. A total of 266 metric tons (293 U.S. tons) of contaminated material was disposed at ERDF. The resulting trench was approximately 9 meters (29.5 feet) in length by 3.5 meters (11.5 feet) wide.

Remediation of the 1607-B9 pipeline began on May 23, 2005 through July 11, 2005. The site was excavated to 3.5 meters (11.5 feet) below grade, removing a total of 2,626 metric tons (2,895 U.S. tons) of contaminated material that was disposed at ERDF. An additional 310 metric tons (342 U.S. tons) was removed on September 29, 2006, following detection of strontium-90 above the cleanup criterion in one verification sample.

During excavation of the pipeline on May 25, 2005, an anomaly consisting of reddish-brown material was discovered after a concrete structure was removed. Radiological readings were all at background levels. A sample (J03701) of the material was collected and analyzed for total metals, leachable metals (toxicity characteristic leaching procedure [TCLP]), and semivolatile organic compounds (SVOCs) to support waste characterization and disposal. There were no significant metal or SVOC concentrations associated with this anomaly. The COPCs for the pipeline were identified through process knowledge and analogous site data and consisted of inductively coupled plasma (ICP) metals, hexavalent chromium, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds. Radiological screening was also performed using gross alpha, gross beta, and gamma energy analyses.

The 1607-B 10 pipeline was removed by March 2005. A total of approximately 9 meters (29.5 feet) of sanitary sewer pipeline and an estimated 45 metric tons (50 U.S. tons) of contaminated material was removed and sent to ERDF. The resulting trench was approximately 9 meters (29.5 feet) in length by 3.5 meters (11.5 feet) wide.

The 1607-B-11 pipeline was co-located and remediated with the subsite 100-C-9:1, (100-C main process sewer collection pipelines). The 100-C-9:1 process sewer pipeline was excavated to at least 4 meters (13 feet) below grade, which concurrently removed the 1607-B 11 sanitary sewer pipeline that was approximately 1.2 meters (4 feet) below grade. The remediation activities were completed by April 2006, removing approximately 40 meters (131 feet) of the sanitary sewer pipeline and an estimated 454 metric tons (500 U.S. tons) of contaminated material was removed and sent to ERDF.

Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels was made for the site contaminants of concern (COC), contaminants of potential concern (COPC), and other constituents. Ecological screening levels were exceeded for antimony, boron, cadmium, total chromium, copper, lead, mercury, vanadium, and zinc.

Verification sampling for the subsite was performed between April 25, 2006, and September 29, 2006, to support interim closeout. The samples were analyzed by offsite contract laboratories using U.S. Environmental Protection Agency (EPA) approved analytical methods, and the results were compared to the cleanup criteria specified in the RDR/RAWP. The laboratory results were stored in the Environmental Restoration (ENRE) project-specific database prior to being provided to the Hanford Environmental Information System (HEIS). The results were also presented in Appendix A of the RSVP.

The results of verification sampling have illustrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were sufficiently protective of

groundwater and the Columbia River to preclude further remedial action. Accordingly, an interim closure reclassification was supported for the pipelines subsite. The site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

The SubSite is Part Of:

Code: 100-C-9

Names: 100-C-9; 100-C Area Process and Sanitary Sewer Underground Pipelines

Code: 100-C-9:3

Classification: Accepted

Names: 100-C-9:3; 183-C Clearwell Pipelines

Reclassification: No Action (6/3/2004)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite included the process sewer pipelines surrounding the 183-C Clearwells (demolished) to the point of junction with the main process sewer collection line. The clearwells were used to store treated cooling water for the 105-C reactor. Chromium was added to the treated water at concentrations between 2-4 ppm (parts per million) as a corrosion inhibitor. The primary contaminant of concern was hexavalent chromium.

This subsite consisted of the process sewer pipelines that drained from the 183-C Clearwells. The clearwell drains ran from circular aboveground steel tanks and connected to cast-iron process sewers surrounding the tanks. The cast-iron process sewers eventually drained to the main twin box process sewers that connected to the 190-C Facility. The basis for separating this site from the other 100-C-9 sites is that these process sewer lines were isolated from facilities known to be potential sources of radioactive and chemical contaminants.

Location: This subsite consists of the process sewer pipelines that drained from the 183 C Clearwells. The clearwell drains ran from circular aboveground steel tanks and connected to cast-iron process sewers surrounding the tanks. The cast-iron process sewers eventually drained to the main twin box process sewers that connected to the 190-C Facility.

Waste Type: Not Specified

Waste Description: Potentially contaminated pipeline (and contents), concrete, and underlying/associated soils.

Closure Info: Sampling and evaluation of this site have been performed in accordance with remedial action objectives and goals established by the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD). The selected action involved (1) sampling of the site, (2) demonstration through a combination of field screening and confirmational sampling that cleanup goals have been met, and (3) proposal of no further action.

The 183-C Clearwells Site (100-C-9:3) meets the Remedial Action Objectives specified in the Remaining Sites ROD, U.S. Environmental Protection Agency, Region 10, Seattle, Washington. These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results demonstrate that residual concentrations in the deep zone are protective of groundwater and the Columbia River. Institutional controls will be required because the evaluation of compliance with direct exposure standards failed for some of the semivolatiles.

Confirmatory sampling was conducted in October 2003. The COPCs included inductively coupled plasma (ICP) metals, mercury, hexavalent chromium, semivolatile organic compounds, and polychlorinated biphenyls. The sampling approach consisted of collecting four samples,

two of soil and two of pipe scale material below 4.6 meters (15 feet) from the east junction box that was accessible where the cast-iron pipe connected to the main process sewer box (BHI 2003). The maximum detected results from the scale and soil samples were used to support waste site reclassification.

The 100-C-9:3 183-C Clearwells Process Sewer Pipelines (100-C-9:3) (BHI 2003) sample results demonstrate that the site has achieved the objectives of remedial action and remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE RL 2002) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (commonly called the Remaining Sites Record of Decision) (EPA 1999). These results show that scale and associated residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The results demonstrated that residual concentrations in the deep zone are protective of groundwater and the Columbia River. Institutional controls will be required because the evaluation of compliance with direct exposure standards failed for some of the semivolatiles.

The SubSite is Part Of:

Code: 100-C-9

Names: 100-C-9; 100-C Area Process and Sanitary Sewer Underground Pipelines

Code: 100-C-9:4

Classification: Accepted

Names: 100-C-9:4; 100-C Cooling Water Transfer Pipelines and Tunnels

Reclassification: No Action (6/3/2004)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite consisted of the Cooling Water transfer lines located in tunnels between the 190-C Pump House and the 105-C Reactor building. Six 0.6 meter (24 inch) steel pipes located in two tunnels transferred treated cooling water from the 190-C Pump House to the 105-C Reactor. The portions of the tunnels from the 190-C building to just west of the Ventilation house of each tunnel were removed with D of the 190-C Building. Radiological contamination may also have existed as contaminated biological waste products (i.e. bat guano)

Location: This sub-site includes the Cooling Water transfer lines located in tunnels between the 190-C Pump House and the 105-C Reactor building.

Waste Type: Not Specified

Waste Description: The waste is the feedwater pipelines and their contents.

Closure Info: In the RSVP attached to the Reclassification Form 2004-015 the scope of the confirmatory sampling effort consisted of the cooling water pipes and tunnels to the reactor. Sampling efforts were conducted only on the pipes. Previous sampling and survey data associated with decontamination and decommissioning (D) activities at the 105-C cooling water pipe tunnels was used to evaluate the tunnels and soil. This D data, as well as a focused sampling approach at the analogous 100-B-14:4 site, were used to confirm current site conditions. The analogous, focused sampling data, previous tunnel sampling and survey data, and previous soil sampling beneath the tunnels was used to make decisions for reclassifying the site in accordance with the TPA-MP-14 (RL-TPA-90-0001) process.

The contaminants of potential concern (COPCs) for the feedwater pipes were identified based on existing analytical data, historical process information, and historical uses and practices

associated with the 183-C Filter Building, the 190-C Process Pump House, and the associated feedwater pipelines. The COPCs included inductively coupled plasma (ICP) metals, mercury, hexavalent chromium, and polychlorinated biphenyls (PCBs).

In accordance with this evaluation, the confirmatory sampling results for pipe scale at an analogous site, previous sampling and surveying data associated with the concrete floor of the tunnels, and previous soil sampling from beneath the tunnels, support a no action reclassification of the 100-C-9:4 site. The current site conditions achieve the remedial action objectives and the corresponding RAGs established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD). These results show that the site and contaminant levels remaining in the soil will be protective of groundwater and the Columbia River. It should be noted, however, that with the maximum residual concentration of hexavalent chromium in the pipes, institutional controls are required to prevent an inhalation exposure pathway.

The SubSite is Part Of:

Code: 100-C-9

Names: 100-C-9; 100-C Area Process and Sanitary Sewer Underground Pipelines

Code: 116-C-2A	Classification: Accepted
Names: 116-C-2A; 105-C Crib; 105-C Pluto Crib; 116-C-2	Reclassification: Interim Closed Out (3/15/2000)
Type: Crib	Start Date: 1/1/1952
Status: Inactive	End Date: 1/1/1969

Description: This site has been remediated and closed out. The pluto crib was constructed of concrete ties that were notched and stacked in a log cabin formation. Walls of concrete ties were constructed to divide the crib into 12 sections. Spaces between the ties were filled with sand. The crib was covered over by concrete roof slabs. A 20-centimeter (8-inch) well casing extended through the crib and ended 36 meters (118 feet) below grade.

Location: The crib is located 275 feet east of the northeast corner of the 105-C Building

Waste Type: Process Effluent

Waste Description: This unit was initially used for the disposal of reactor cooling effluent after fuel cladding failures. Unknown additional quantities of contaminated wastes included wash water from the decontamination of dummy fuel elements on the 105-C wash pad, contaminated water received from the 105-C Metal Examination Facility, and liquid wastes received from the 105-C Reactor rear face. Potential contaminants of concern include americium-241, plutonium-238/239/240, cobalt-60, cesium-137 and strontium-90. Reports vary as to the amounts of different chemicals disposed of at the Pluto Crib site. Two reports state that the crib contained 500 kilograms (1,100 pounds) of sodium dichromate, 1,000 kilograms (2,200 pounds) of sodium oxalate, and 1,000 kilograms (2,200 pounds) of sodium sulfamate. Another report, states that the crib contained 990 kilograms (2,180 pounds) of sodium dichromate, 2,100 kilograms (4,630 pounds) of sodium oxalate, and 6,600 kilograms (14,550 pounds) of sodium sulfamate. Sodium hydroxide and nitric acid were also believed to be disposed at the site. The total waste volume is listed as 7.5E+06 liters (1.98E+06 gallons).

Closure Info: 116-C-2A, 116-C-2B and 116-C-2C were addressed as a group. The information below documents information for the group of sites.

The cleanup verification package for the 116-C-2A Pluto Crib, 116-C-2B Pump Station, & 116-C-2C Sand Filter were combined into a single remediation area and are hereinafter referred to as

the 116-C-2ABC site. The overburden was removed from the 116-C-2ABC, 116-B-2, 116-B-3, 116-B-4, 116-B-9 and 116-B-12 waste sites located in the 100-BC-1 and 100-BC-2 Operable units.

In accordance with the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995), the remedial actions were performed so as to allow future land uses at the site that can be represented (or bounded) by a rural-residential exposure scenario. The scenario assumes multiple exposure pathways for shallow zone soils (e.g., ingestion and inhalation) and no contact with or exposure to deep zone soils (e.g., below 4.6 meters [15 feet]); institutional controls will be required to prevent drilling or excavation into the deep zone.

At the completion of the remedial action, the area of the excavation was approximately 2,516 square meters (27,728 square feet) at a maximum depth of approximately 9.15 meters (30 feet). Approximately 15,939 metric tons (17,570 tons) of material were disposed of at ERDF. Approximately 2,000 cubic meters (70,629 cubic feet) of overburden was set aside from the 116-C-2ABC site as potentially clean. The excavation will be backfilled in the near future (written April 6, 2000) with clean fill materials to the reference grade of El. 150.5 meters (494 feet).

Results of the sampling, testing, and analyses for the 116-C-2ABC site and BC Overburden indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of surface waters (including the Columbia River) have been met.

Code:	116-C-2B	Classification:	Accepted
Names:	116-C-2B; 116-C-2B Pump Station; 105-C Pluto Crib Pump Station; 116-C-2-1	Reclassification:	Interim Closed Out (3/15/2000)
Type:	Pump Station	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1969
Description:	This site has been remediated and interim closed out. This unit was a rectangular shaped, concrete sump. A diamond-plate steel access hole cover was located in the northwest corner, and a vent was located at the east end. The site included all underground pipelines between the 105-C Reactor and the 116-C-2C Sand Filter.		
Location:	The site was located northwest of the 116-C-2C Sand Filter.		
Related Sites/ Structures:	The associated structures were the 116-C-2A Pluto Crib, 116-C-2C Sand Filter, and the 105-C Reactor.		
Waste Type:	Process Effluent		
Waste Description:	The unit received waste from the 105-C Reactor and pumped it into the 116-C-2C (105-C Pluto Crib Sand Filter).		
Closure Info:	116-C-2A, 116-C-2B and 116-C-2C were addressed as a group. The information below documents information for the group of sites.		

The cleanup verification package for the 116-C-2A Pluto Crib, 116-C-2B Pump Station, & 116-C-2C Sand Filter were combined into a single remediation area and are hereinafter referred to as the 116-C-2ABC site. The overburden was removed from the 116-C-2ABC, 116-B-2, 116-B-3, 116-B-4, 116-B-9 and 116-B-12 waste sites located in the 100-BC-1 and 100-BC-2 Operable units.

In accordance with the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995), the remedial actions were performed so as to

allow future land uses at the site that can be represented (or bounded) by a rural-residential exposure scenario. The scenario assumes multiple exposure pathways for shallow zone soils (e.g., ingestion and inhalation) and no contact with or exposure to deep zone soils (e.g., below 4.6 meters [15 feet]); institutional controls will be required to prevent drilling or excavation into the deep zone.

At the completion of the remedial action, the area of the excavation was approximately 2,516 square meters (27,728 square feet) at a maximum depth of approximately 9.15 meters (30 feet). Approximately 15,939 metric tons (17,570 tons) of material were disposed of at ERDF. Approximately 2,000 cubic meters (70,629 cubic feet) of overburden was set aside from the 116-C-2ABC site as potentially clean. The excavation will be backfilled in the near future (written April 6, 2000) with clean fill materials to the reference grade of El. 150.5 meters (494 feet).

Results of the sampling, testing, and analyses for the 116-C-2ABC site and BC Overburden indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of surface waters (including the Columbia River) have been met.

Code:	116-C-2C	Classification:	Accepted
Names:	116-C-2C; 116-C-8; 105-C Pluto Crib Sand Filter; 116-C-2-2	Reclassification:	Interim Closed Out (3/15/2000)
Type:	Sand Filter	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1969
Description:	This site has been remediated and closed out. The structure was an open-bottom concrete box placed in a sand and gravel pit. It was covered with concrete shielding slabs. Contaminated water was spread over the surface of the sand filter media by distribution trays. The site included the underground pipelines from the 105-C Pluto Crib Sand Filter to the 116-C-2A Pluto Crib.		
Location:	The site is located west of the 116-C-2A (105-C Pluto Crib).		
Process Description:	Effluent passed through this filter prior to being discharged to the soil column of the 116-C-2 Crib.		
Related Sites/Structures:	This unit was associated with 116-C-2A (105-C Pluto Crib) and 116-C-2B (105-C Pluto Crib Pump Station).		
Waste Type:	Process Effluent		
Waste Description:	The 105-C Pluto crib sand filter was sampled and surveyed between 2/6/76 and 4/5/76. Based on sample results, the sand filter contains an estimated radioactive inventory of 260 curies (Table 3.4-9, page 3-30) in 90,000 cubic feet of soil (about 6,100,000 Kg). Beta-gamma concentrations in the sand filter averaged 42,000 pCi/g with a maximum value reported of 7,300,000 pCi/g in a sample taken from an inlet distribution tray. Radioactivity in this sample was primarily due to cobalt-60 although high levels of strontium-90 (29,000 pCi/g) and cesium-137 (140,000 pCi/g) were present as well. This sample also contained 1,500 pCi/g plutonium-239/240. The average concentration of plutonium-239/40 in the sand filter was reported to be about 20 pCi/g for the entire mass of potentially contaminated soil column. Sample analyses for the sand filter are presented in Table 3.4-7 (page 3-28) by Dorian and Richards. The site may have received contaminated wastes from the decontamination of dummy fuel elements on the wash pad. Americium-241 is another potential contaminant of concern.		
Closure Info:	116-C-2A, 116-C-2B and 116-C-2C were addressed as a group. The information below documents information for the group of sites.		

The cleanup verification package for the 116-C-2A Pluto Crib, 116-C-2B Pump Station, & 116-C-2C Sand Filter were combined into a single remediation area and are hereinafter referred to as the 116-C-2ABC site. The overburden was removed from the 116-C-2ABC, 116-B-2, 116-B-3, 116-B-4, 116-B-9 and 116-B-12 waste sites located in the 100-BC-1 and 100-BC-2 Operable units.

In accordance with the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995), the remedial actions were performed so as to allow future land uses at the site that can be represented (or bounded) by a rural-residential exposure scenario. The scenario assumes multiple exposure pathways for shallow zone soils (e.g., ingestion and inhalation) and no contact with or exposure to deep zone soils (e.g., below 4.6 meters [15 feet]); institutional controls will be required to prevent drilling or excavation into the deep zone.

At the completion of the remedial action, the area of the excavation was approximately 2,516 square meters (27,728 square feet) at a maximum depth of approximately 9.15 meters (30 feet). Approximately 15,939 metric tons (17,570 tons) of material were disposed of at ERDF. Approximately 2,000 cubic meters (70,629 cubic feet) of overburden was set aside from the 116-C-2ABC site as potentially clean. The excavation will be backfilled in the near future (written April 6, 2000) with clean fill materials to the reference grade of El. 150.5 meters (494 feet).

Results of the sampling, testing, and analyses for the 116-C-2ABC site and BC Overburden indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of surface waters (including the Columbia River) have been met.

Code:	116-C-3	Classification:	Accepted
Names:	116-C-3; 105-C Chemical Waste Tanks	Reclassification:	Interim Closed Out (1/31/2008)
Type:	Storage Tank	Start Date:	1/1/1964
Status:	Inactive	End Date:	1/1/1969
Description:	The site has been remediated, backfilled, and revegetated. Before remediation the site consisted of two below-grade chemical waste storage tanks, designed to receive and store chemical waste from the 105-C Reactor Metals Examination Facility (MEF) dejacketing process.		
Location:	The site was located approximately 100 m (330 ft) northeast of the 105-C Reactor safe storage enclosure, just outside the exclusion area fence.		
Process Description:	The tanks were originally installed to receive liquid wastes from the 105-C Metal Examination Facility (MEF), which was part of the 105-C Reactor Building, and was used to examine and test irradiated fuel elements. Examination included chemical dejacketing of the fuel slugs, which consisted of two cycles of immersing the fuel slugs in a 50% sodium hydroxide solution, draining the resulting solution, and rinsing the dejacketed slugs with water. The slugs were then cleaned with a 10% nitric acid solution, followed with multiple water rinses. Each of the waste tanks was approximately 3.5 m (11.5 ft) in diameter, and approximately 10.9 m (36 ft) in length, with a nominal capacity of 102,200 L (27,000 gal). The long axis of each tank was oriented east-west on a horizontal plane, with one tank located north of the other. The crests of the tanks were located approximately 3.4 m (11 ft) below existing grade, with centerlines spaced approximately 6.2 m (20 ft) apart. Waste was discharged to the tanks from the 105-C MEF via a 5-cm (2-in.) stainless-steel pipeline connected to top-feed distribution piping at the tanks. This discharge line was included in the 100-C-6:1 subsite as Pipeline 31 and was removed up to a point immediately upstream of the discharge to the southern 116-C-3 tank (BHI 2004c). Multiple additional small-diameter pipelines were also connected to the tops of the tanks,		

including vent risers, overflow lines, and conduits for the cathodic protection system used for corrosion control.

**Related Sites/
Structures:** The site is associated with the 105-C Reactor Building.

Closure Info: The Remaining Sites Verification Package, (RSVP-2008-002) for the 116-C-3 waste site, has documented that the current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan (RDR/RAWP) for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The tanks were installed in 1955, conflicting reports existed as to their usage, for example, that the tanks were potentially unused. Remediation of the influent pipeline and confirmatory evaluation of the waste site in 2003 confirmed that the site had received radiological waste, and subsequent additional characterization in 2004 indicated that the southern tank was approximately one-third full of mixed waste consistent with the 105-C Reactor Metals Examination Facility (MEF) dejacketing process. The north tank was found to contain only a small volume of suspect condensate or residual water from pressure testing, as no significant radiological activity or metals concentrations were detected.

Remediation of the waste site was performed from February through December 2007. Initially, the overburden and surrounding soils were removed sufficiently to provide a sub-grade staging and operations area for waste treatment activities. During excavation, a small volume of radiologically-contaminated soil was encountered beneath the influent pipelines near the southern tank, and staged onsite in the waste staging pile area before disposal at the Environmental Restoration Disposal Facility (ERDF). A concrete pad unrelated to the 116-C-3 waste site was also partially demolished and removed from the northeastern corner of the operations area. Systematic global positioning system environmental radiological surveys (GPERS) were performed across each 1 m (3 ft) lift of stockpiled overburden soil; no significant radiological activity was detected.

The COCs and COPCs for verification sampling were determined in consideration of process knowledge and characterization sampling results. Metals (including hexavalent chromium and mercury), nitrate, americium-241, carbon-14, plutonium-238, plutonium-239/240, strontium-90, tritium, uranium-233/234, uranium-235, uranium-238, cesium-137, cobalt-60, europium-152, europium-154, and europium-155 were considered COCs/COPCs for verification sampling.

Site remediation consisted of the removal and stockpiling of overburden material, followed by a proof-of-principle demonstration at the empty northern tank following the general treatment and remediation process planned for the southern tank. Subsequently, the southern tank was treated in accordance with an approved treatment plan, using chemical treatment to address the corrosivity characteristic of the waste and reduce hexavalent chromium to trivalent chromium, followed by physical treatment using in situ grout stabilization. Treatment verification sampling indicated that requirements had been met, and the treated tank was demolished and removed, along with approximately 1.5 m (5 ft) of underlying soil.

Treated material, demolition rubble, and approximately 1 m (3 ft) of soil underlying the tank was removed for disposal at ERDF. Initial soil samples from the tank footprint indicated residual hexavalent chromium concentrations above soil remedial action goals (RAGs) and elevated residual radiological activity. This information is in appendix A, Table A-2 of the

RSVP. Therefore, an additional 0.7 m (2 ft) of soil was removed from the southern tank footprint and disposed at ERDF. Excavation at the site extended to a maximum depth of approximately 28 ft (8.5 m) below ground surface (bgs), and the footprints of the remediated waste tanks are entirely in the deep zone (greater than 4.6 m [15 ft] bgs). Approximately 3,767 metric tons (4,152 U.S. tons) of treated waste, debris, and soil was removed from the site and disposed at ERDF. Following verification of attainment of cleanup criteria, the site was backfilled and re-vegetated.

Remedial actions were performed so as to not preclude any future uses (as bounded by the rural-residential scenario), and to allow unrestricted use of shallow-zone soils (i.e., surface to 4.6 m [15 ft] deep). Following site remediation, verification sampling of overburden material and soil within the remediation and waste staging pile area footprints was conducted in October and December 2007. The results indicated that the waste removal action achieved compliance with the remedial action objectives. The results of the verification sampling were used to make reclassification decisions for the site in accordance with the Tri-Party Agreement Handbook Management Procedures, TPA-MP-14 procedure.

All characterization samples were analyzed at offsite commercial laboratories; results were stored in the Environmental Restoration (ENRE) project-specific database prior to being provided to the Hanford Environmental Information System (HEIS) and were provided in Appendix A of the RSVP-2008-022.

Verification samples were analyzed using U.S. Environmental Protection Agency-approved analytical methods. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. The verification sampling results support a reclassification to Interim Closed Out. The acceptability of direct exposure to residual deep-zone contamination has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are required.

Code:	116-C-6	Classification:	Accepted
Names:	116-C-6; 105-C Fuel Storage Basin Cleanout Percolation Pit; 105-C Pond	Reclassification:	Interim Closed Out (12/8/2003)
Type:	Process Pit	Start Date:	1/1/1984
Status:	Inactive	End Date:	1/1/1985
Description:	The site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification to interim closed out. The site was an unlined, L-shaped open excavated pit. Soil was excavated from the center and used as a berm around its perimeter.		
Location:	The site was located east of the 105-C Reactor Building, east of the reactor exclusion fence.		
Process Description:	The pit was constructed to receive liquid from the clean out of the 105-C Fuel Storage Basin. The radiologically contaminated shielding water in the basin was processed through an ion exchange column and filter system. After being sampled to determine if the radioactivity was below release criteria, the water was discharged to the pit. Chemical analysis for hazardous substances was not a standard practice and there was no evidence that it was performed. The water percolated into the soil as fast as it was discharged to the site.		
Related Sites/ Structures:	The site was related to the 105-C Fuel Storage Basin		

Waste Type: Water
Waste Description: This unit received water from the 105-C Fuel Storage Basin cleanout. Before being discharged to the pit, the radiologically contaminated shielding water in the basin was processed through ion exchange columns. Composite samples were taken to ensure that radionuclide concentrations were below release criteria in Table II of DOE Order 5480.1. No known hazardous substances were present in the water; however chemical analysis during that period was not a standard practice, and there is no evidence that any chemical analyses were performed.

Closure Info: In 2003 the waste site evaluation 0100B-CA-V0121, Rev. 4 demonstrated that information which included previous sample results, a 2003 field walkdown (site evaluation), and historical data supported reclassification to “interim closed out” of the 116-C-6 site. The site soil conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 2002) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (EPA 1999).

Cleanup verification samples collected in March 2003 were analyzed by offsite contract laboratories using U.S. Environmental Protection Agency approved analytical methods. Sample results from test pit #3 had elevated levels of cesium-137. Per agreement with the EPA, the area of the hot spot was excavated and contaminated soil removed and disposed of at the Environmental Restoration Disposal Facility. After remediation, a confirmatory sample was collected to verify cleanup levels had been met.

Residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario and pose no threat to groundwater or the Columbia River.

Code: 118-C-1	Classification: Accepted
Names: 118-C-1; 118-C-1 Burial Ground; 105-C Burial Ground; 105-C Solid Waste Burial Ground	Reclassification: Interim Closed Out (7/19/2007)
Type: Burial Ground	Start Date: 1/1/1953
Status: Inactive	End Date: 1/1/1969
Description: The site was a burial ground that contained six small engineered disposal structures (rectangular pits with reinforced side walls) and many trenches running north and south. The site boundaries were permanently marked with concrete posts numbered C-70-1 through C-70-20.	
Location: The site was located approximately 152 meters (500 feet) southeast of the 105-C Building.	
Process Description: This site was the primary burial ground for general wastes from the operation of the 105-C Reactor. It received process tubes, aluminum fuel spacers, control rods, reactor hardware, and soft wastes.	

Waste Type: Equipment
Waste Description: The unit was used for miscellaneous solid waste from 105-C Building that included process tubes, aluminum spacers, control rods, soft waste, and reactor hardware. The C Area Land Burial log (1962-1965) identified waste as trash, poison splines, dummies, hot laundry, fan filters, irradiated boron balls, ceramic samples, thimbles, gun barrels, and hoses.

The Burial Ground ROD reported that an estimate of the waste was 86 metric tons (94.8 tons) of boron, 1.1 metric tons (1.2 tons) of graphite, 0.51 metric tons (0.56 tons) of lead, 21.6 metric tons (23.8 tons) of lead/cadmium, and 96 metric tons (105.9 tons) of other materials. Potential contaminants include: Ag-108m, C-14, Co-60, Cs-137, Eu-152, Eu-154, Eu-155, H-3, Ni-59, Ni-63, Sr-90, Ba-133, Ca-41, cadmium, Cr+6, lead, boron, mercury, PCBs, SVOAs, TPH, and

VOAs.

Closure Info: The cleanup verification package (CVP) CVP-2006-00011 documents that remedial action of the site has met the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, (ROD), and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Remedial action began on February 2, 2004 and was completed on May 27, 2006. Excavation of the ten trenches, (eight oriented in a north-south direction and the other two oriented east to west) involved removing the uncontaminated overburden, the buried contaminated debris, and the underlying contaminated soil. Visual observations of the buried waste confirmed that the following items had been disposed in the Burial Ground during its operation: several thousand perforated and non-perforated spacers, piping and tubing, vertical control rods, sheet metal, boron balls, boron ball vacuums, bismuth, paint, high-dose piping, wax, casks, tar, tar paper, miscellaneous metal, mercury tubes, lead items, reactor parts and hardware, Spent Nuclear Fuel (SNF), hydraulic hoses and parts, degraded drums, glassware, concrete, electrical components, and other miscellaneous debris. Photographs of the waste site debris and remediation activities were provided in Appendix B of the CVP.

During remedial excavation and sorting, SNF was discovered on September 27, 2004. All remedial activities were suspended until the Authorization Basis could be properly assessed and revised to include the SNF. Load-out operations were re-established on April 11, 2005, for previously sorted and segregated material. All remedial activities (excavation, sorting, and load-out) resumed on October 25, 2005 and were completed on May 27, 2006. Over 75,300 metric tons (83,000 tons) of waste and contaminated soil from the Burial Ground was disposed at the Environmental Restoration Disposal Facility (ERDF). The SNF was transferred to the 100-K Basins for interim storage prior to final packaging and disposal. ERDF and approximately 9,300 bank cubic meters (BCM) of overburden soil was removed for subsequent backfill. At the conclusion of excavation activities, the elevation at the deepest part of the remedial excavation was 146 meters (480 feet) above sea level. The remediation excavation was approximately 20,500 meters squared (220,600 square feet) in area with a maximum depth of approximately 5 meters (17 feet).

Waste site contaminants of concern (COCs) and contaminants of potential concern (COPCs) were identified in the RDR/RAWP and included tritium, carbon-14, cesium-137, cobalt-60, nickel-63, strontium-90, silver-108m, europium-152, europium-154, cadmium, lead and mercury. Additional waste site COCs/COPCs were identified for this site based on the observed waste forms found during remediation activities and the results of waste characterization sampling as documented in the Site Specific Instruction (SSI) for Close-Out Approach for 118-C-1. The SSI identified additional COCs/COPCs which included: americium-241, plutonium-238, plutonium-239/240, uranium-233/234, uranium-235, uranium-238, the expanded list of inductively coupled plasma (ICP) metals (arsenic, antimony, barium, beryllium, boron, cadmium, chromium, lead, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc), hexavalent chromium, polychlorinated biphenyls (PCBs), total petroleum hydrocarbons (TPH), semi-volatile organic compounds, and volatile organic compounds.

Final cleanup verification samples were collected in August and September, 2006 and May 2007 to confirm acceptability of residual contaminant concentrations in the soil. The verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (SAP). All analytical data were found to be acceptable for decision-making purposes. The evaluation verified that the sample design was sufficient for the purpose of clean site verification. The analytical data results were stored in the Environmental Restoration (ENRE) project-specific database for data evaluation prior to submittal for archival in the

Hanford Environmental Information System (HEIS) and were summarized in Appendix A of the CVP.

Screening levels were not exceeded for the site constituents, with the exception of barium, boron, copper, lead, and molybdenum. It was believed that the presence of these constituents did not pose a risk to ecological receptors. Concentrations of barium, copper, and lead were within the range of Hanford Site background levels and boron and molybdenum concentrations were consistent with those seen elsewhere at the Hanford Site (no established background value was available for boron or molybdenum). A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

The remaining soils at the site were sampled, analyzed, and modeled. The results of this effort indicated that the materials from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed at the ERDF.

These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. Institutional controls are required for the site to prevent uncontrolled drilling or excavation into deep zone soils. The site was verified to be remediated in accordance with the ROD and may be backfilled.

Code:	118-C-2	Classification:	Accepted
Names:	118-C-2; Ball 3X Storage Tank; 105-C Ball Storage Tank	Reclassification:	Interim Closed Out (7/30/2004)
Type:	Storage Tank	Start Date:	1/1/1969
Status:	Inactive	End Date:	1/1/1969
Description:	The site has been remediated and interim closed out.		
Location:	The site was located approximately 6 meters (20 feet) directly north of the northeast corner of the 105-C Reactor Building (original footprint).		
Process Description:	Operation of this waste site began in 1969, coinciding with the Ball 3X Project work. The project operation ended that same year. During Ball 3X Project work with a prototype-contaminated ball sorter, the tank received highly radioactive, irradiated, nickel-plated boron-steel and carbon-steel balls. The tank served as temporary storage until the balls decayed radiologically before burial. The storage box had a slope with vents at each end. One vent was used to put the balls into the tank and the other was used to remove them (following a cool down period). Approximately 9,070 kilograms (20,000 pounds) of highly activated balls remained in the storage tank. Approximately 70% of the balls remaining are boron-steel and 30% are carbon-steel.		
Waste Type:	Equipment		
Waste Description:	During Ball 3X project work with a prototype contaminated ball sorter, the tank received highly radioactive, irradiated, nickel-plated boron steel and carbon steel balls for temporary storage so that they would decay radiologically before burial. Approximately 9,070 kilograms (20,000 pounds) of highly activated balls remain in the storage tank. Seventy percent of the balls remaining are boron steel, and thirty percent are carbon steel. A 1987 evaluation of the tank waste estimated that 80 curies of cobalt-60 and 1.6 curies of nickel-63 are present. Potential contaminants include: Co-60, Ni-63, Sr-90, Cs-137, Eu-152, Eu-154, U-238, Pu-238, Pu-239/240, chromium, lead, mercury		

Closure Info: Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives were documented in the Interim Remedial Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units (100 Area Burial Grounds ROD) (EPA 2000) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17, Rev. 4).

Waste site contaminants of concern (COCs) were identified through process knowledge and listed in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-2001-35). The COCs included cobalt-60 and nickel-63. Cleanup verification samples, including QA/QC samples, were collected and analyzed for the established contaminants of concern. HEIS samples (J016W0 through J016W9 and J016V6 through J016V9) were collected on January 14, 2004.

Remedial action began on November 10, 2003. Excavation of the site involved removing the overburden materials, debris, and underlying contaminated soil. Both the collection tank and loose boron balls exposed during the excavation were removed. The tank was a light gage stainless steel tank installed about two feet below grade, about 8 feet long x 8 feet deep and 4 feet wide (long rectangular box) with two ~4 inch diameter riser pipes in the top of the tank that were about 4 feet apart and protruded above ground about 2 feet. The box tank was installed at a slight slope, possibly to allow the 1-centimeter (0.39 inch) diameter nickel-plated 1 weight % borated stainless steel balls to roll to one end. The field staff reported that the light gage stainless steel box tank was about half full of the 3/8-inch diameter metal balls. The tank was flattened, crumpled up and hauled off with the soil waste to ERDF. There was no external piping to or from the tank. There was no exposed piping removed during the excavation. All contaminated materials were disposed of at the ERDF.

At the completion of remedial action, the site excavation was approximately 123.8 meters squared (1,333 square feet) in area, while the former staging pile area was approximately 166.1 meters squared (1,787 square feet). The excavation had an average depth of approximately 3.1 meters (10.3 feet). Approximately 420 metric tons (463 tons) of material, including soil and debris, were removed from the 118-C-2 Burial Ground site and transferred to ERDF for disposal. Both the collection tank and loose boron balls exposed during the excavation were removed and transferred to ERDF. There was no piping associated with this remediation.

The CVP demonstrated that remedial action at the site, including the staging pile area, has achieved the RAOs and corresponding RAGs established in the approved 100 Area Burial Grounds ROD (EPA 2000) and RDR/RAWP (DOE/RL-96-17, Rev. 4). The contaminated materials from the site and staging pile area have been excavated, removed, and disposed of at the ERDF. The remaining soil at the site has been sampled, analyzed, and modeled. The analytical and modeling results also indicate that residual concentrations at the 118-C-2 Burial Ground site and staging pile area will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The site is verified to be remediated in accordance with the 100 Area Burial Grounds ROD and may be backfilled. The CVP demonstrated the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]); therefore deep zone institutional controls are not required.

Code:	118-C-4	Classification:	Accepted
Names:	118-C-4; 105-C Horizontal Control Rod Storage Cave	Reclassification:	Interim Closed Out (9/11/2003)
Type:	Storage	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1969

-
- Description:** The site has been remediated and interim closed out. The site consisted of two steel-plate tunnels covered with 1.2-meters (4-foot) of soil, gravel and asphalt emulsion. The two tunnels were grouted onto a concrete floor that had three equally spaced 0.6-meter (2-foot) diameter by 0.6-meter (2-foot) deep french drains beneath the centerline of the long axis of the structure. The french drains removed water runoff that could collect between the tunnels in the earth shielding.
- Location:** The site was located south of the 105-C Reactor Building, within the 105-C exclusion area fence.
- Process Description:** The tunnels were used for temporary storage of control rods, and possibly miscellaneous equipment, to allow radioactive decay prior to disposal. Three french drains were located along the center of the structure floor for the removal of precipitation runoff that could potentially percolate and collect between the tunnels.
- Related Sites/ Structures:** The site was associated with the operation of the 105-C Reactor.
- Waste Type:** Equipment
- Waste Description:** The tunnel was used for temporary storage for radioactive decay pending subsequent disposal. Some miscellaneous components are currently in the rod cave. The radiation reading at the entrance to the tunnel with the door open was once documented to be 5 millirads/hour.
- Closure Info:** The rod cave was demolished as part of decontamination and decommissioning activities in March 2003. The cleanup verification package (CVP) documents completion of remedial action for the soil beneath the former 118-C-4 Horizontal Control Rod Cave. The 118-C-4 waste site consisted of the soils underlying the former 118-C-4, 105-C Horizontal Control Rod Cave (rod cave) building.

Field screening was used to guide the excavation to quickly assess the presence and level of contamination. Field screening for the 118-C-4 site included using a radiological data mapping system survey. The radiological mapping survey was performed over more than 50% of the site excavation surface area. Final cleanup verification samples were collected following variance sampling. Cleanup verification sampling was conducted on May 15, 2003. Each verification sample was a composite formed by combining soil collected at four randomly selected nodes within each sampling area. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the Sampling and Analysis Plan (SAP) (DOE/RL-96-22). The sample design methodology and sample location figure is presented in the calculation briefs for variance analysis and sample design.

Remedial action objectives and goals from the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA, 1995) are used for the 118-C-4 site. Although the 118-C-4 site is not identified in the ROD, the remedial action objectives and goals documented in the ROD, and in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17), are designated for the 118-C-4 site in the Approved Action Memorandum for the 100 B/C Area Ancillary Facilities and the 108-F Building Removal Action (EPA, 1997 CCN 042276). The remedial action goals and objectives were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology.

The selected remedial action for the 118-C-4 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility near the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and

protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of concern (COCs) and contaminants of potential concern (COPCs).

Waste site COCs for the 118-C-4 site were identified through process knowledge and are included in Table 1-4 of the SAP (DOE/RL-96-22) as specified in the Technical Memorandum Sampling and Analysis Planning Summary 118-C-4 Rod Cave (CCN 048578). The COCs consist of the following:

americium-241, barium, arsenic, cadmium, cesium-137, total chromium, cobalt-60, hexavalent chromium, europium-152, lead, europium-154, europium-155, uranium-234, plutonium-238, uranium-235, plutonium-239/240, uranium-238, strontium-90 and mercury.

COPCs identified through process knowledge included selenium, silver, polychlorinated biphenyls (PCBs), volatile organic compounds (VOCs), and semivolatile organic compounds (SVOCs). None of the 7 PCB Aroclors nor any of the 103 VOCs and SVOCs analyzed for were detected in cleanup verification samples at concentrations greater than the analytical method practical quantitation limits (PQLs). These analyses were performed using the EPA SW-846 Methods 8082 for PCBs, 8260 for VOCs, and 8270 for SVOCs (EPA 1986). The PCB, VOC, and SVOC results are included in Appendix A of the CVP document.

The COCs listed above and the COPCs selenium and silver were evaluated throughout the CVP as COCs to demonstrate cleanup verification of the 118-C-4 site. Selenium and silver were selected and included as COCs because they are identified as potential contaminants for the former rod cave structure, which the 118-C-4 site underlies (DOE/RL-97-33). None of the other COPCs were selected because they were not detected at concentrations above the analytical method practical quantitation limits (PQL).

Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 122 square meters (1,310 square feet) in area with an approximate depth of 0.85 meters (2.8 feet). Approximately 453 metric tons (500 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

Results of the sampling, laboratory analyses, and data evaluations for the 118-C-4 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

CVP-2003-00015 demonstrates that remedial action at the 118-C-4 site has achieved the RAOs and corresponding RAGs established in the ROD and RDR/RAWP. The remaining soils at the 118-C-4 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 118-C-4 site containing Contaminates of Concerns at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The 118-C-4 site is verified to be remediated in accordance with the RAOs and RAGs of the ROD and may be backfilled.

Code: 128-C-1	Classification: Accepted
Names: 128-C-1; 100-C Burning Pit	Reclassification: Interim Closed Out (8/10/2005)
Type: Burn Pit	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed out.	

- Location:** The site was located east of the 105-C Reactor Building and west of the eastern leg of the 100-B/C perimeter road. It was bounded on the north by an export water line and on the east by a soil berm.
- Process Description:** This unit was a vegetation and ash-covered field strewn with pieces of green, clear, and bright blue glass; small glass bottles; metallic wastes such as rusted cans, auto parts and assorted scrap metal; chunks of concrete; and pieces of asbestos transite.
- Waste Type:** Misc. Trash and Debris
- Waste Description:** The burning pit received combustible materials such as office wastes, paint wastes, vegetation, and chemical solvents. Large metal items such as hardware, machinery, and other noncontaminated equipment were also deposited at the site.
- Closure Info:** The REMAINING SITES VERIFICATION PACKAGE FOR THE 128-C-1 BURN PIT WASTE SITE (Attachment to Waste Site Reclassification Form 2005-019) report demonstrated that the waste site meets the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units.

Cleanup verification samples were collected and analyzed 2/2/05 for the established contaminants of concern (COCs). Waste site COCs identified through process knowledge were: lead and asbestos. The COPCs were: arsenic, barium, boron, cadmium, chromium, copper, mercury, molybdenum, silver, zinc, PCBs, SVOCs and TPH.

Based on the Work Instruction for Verification Sampling of the Waste Site 128-C-1, Burn Pit Waste Site, statistical sampling was required for this site because the spatial distribution of potential residual soil contamination over the study area (site) was uncertain. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

|---|--|
| Code: 132-C-1 | Classification: Accepted |
| Names: 132-C-1; 105-C Reactor Stack Site; 116-C Reactor Exhaust Stack Site | Reclassification: No Action (9/11/2003) |
| Type: Burial Ground | Start Date: 1/1/1952 |
| Status: Inactive | End Date: 1/1/1969 |
- Description:** The site has been reclassified to "No Action". This site was a burial area that contained rubble from the 105-C Reactor Stack, also known as the 116-C Reactor Exhaust Stack. The reactor stack was 5.1 meters (16.6 feet) in diameter and 61 meters (200 feet) high. It operated from 1952 through 1969, exhausting confinement air from the work areas in the reactor. The site currently appears as a vegetation-free, cobble-covered field adjacent to the 100-C Reactor. There are no markings or posts to identify it.
- Process Description:** Exhaust air flowed through concrete ducts from the 105-C Building directly out the exhaust stack. Following completion of the confinement project in the 1950's, the air was diverted via underground, reinforced concrete ducts to the 117-C Filter Building. After flowing through the filters, the air went through below-grade and above-grade concrete ducts into the exhaust stack.
-

Related Sites/ Structures: Air was exhausted from the 105-C Reactor Building and the 117-C Filter Building.

Waste Type: Demolition and Inert Waste

Waste Description: Sampling of the stack inlet was performed in 1976, using standard smear techniques. Low-level beta and gamma radiation was detected in the stack. It was estimated that the interior of the unit contained approximately 2.8 millicuries of radioactive materials. At the time of demolition (1983), the interior of the reactor stack contained approximately 2 millicuries of radioactive materials.

Closure Info: Based on this evaluation, the historical data supports no action interim closure of the 132-C-1 site. The site achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17) and the Interim Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (Remaining Sites ROD) (EPA, 1999). Residual soil concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River based on RESRAD modeling.

Code: 132-C-3

Classification: Accepted

Names: 132-C-3; 117-C Filter Building

Reclassification: No Action (9/11/2003)

Type: Process Unit/Plant

Start Date: 1/1/1961

Status: Inactive

End Date: 1/1/1969

Description: The site has been evaluated and reclassified to "No Action". The site now resembles a gravel parking lot.

Location: The site was located east of the southeast corner of the 105-C Reactor Building.

Process Description: The unit was a reinforced concrete structure that was 10.7 meters (35 feet) high, and was constructed such that approximately 8.2 meters (27 feet) was below-grade, and 2.4 meters (8 feet) was above grade. The maximum thickness of the walls and floors was 0.6 meters (2 feet), while the majority was 0.3 meters (1 foot) thick or less. The ducts were made of reinforced concrete with a maximum wall thickness of 30 centimeters (12 inches). The inlet tunnel was approximately 12 meters (40 feet) long, and the exhaust tunnel was approximately 18 meters (60 feet) long.

Related Sites/ Structures: The building received exhaust fan discharge through an inlet duct from the 105-C Reactor Building and discharged the filtered air through a discharge duct and out the 116-C Stack.

Waste Type: Demolition and Inert Waste

Waste Description: Total radionuclide inventory in this unit is estimated to be 0.84 millicuries. The radionuclides comprising this inventory are tritium, carbon-14, cobalt-60, cesium-137, strontium-90, europium-154, plutonium-152, and plutonium-239/240. Of these radionuclides, strontium-90 is the most restrictive in the Allowable Residual Contamination Level (ARCL) calculations calculations.

Closure Info: Using the greatest activities from the pre-demolition characterization data to represent residual contamination levels over 100% of the inner surface area of the former facility, RESidual RADioactivity (RESRAD) modeling was performed in 2003 to support the previous decision to demolish and bury the facility in place. The RESRAD modeling accounts for radioactive decay from 1988 (the year of building demolition) to 2003, and conservatively predicts that the site achieves the dose limits and risk objectives for rural residential land use, groundwater protection, and river protection.

Based on this evaluation, the historical data supports no action interim closure of 132-C-3. The site achieves the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL 96-17), implemented for the Interim Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (Remaining Sites ROD) (EPA,1999). Any residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that based on RESRAD modeling, residual concentrations at the site pose no threat to groundwater or the Columbia River.

Code: 600-232 **Classification:** Accepted

Names: 600-232; 100B Electrical Laydown Area **Reclassification:** Interim Closed Out (1/27/2005)

Type: Dumping Area **Start Date:**

Status: Inactive **End Date:**

Description: The site has been remediated and interim closed. The area has been returned to its natural appearance.

Location: The site was located approximately 200 meters south of 105-C Reactor Building and north of Route 6. The railroad tracks run east-west through the site.

Waste Type: Chemicals

Waste Description: Tar

Waste Type: Equipment

Waste Description: The treated wood ends of the utility poles are categorized as dangerous waste. The site also contained various electrical utility materials such as steel cable, aluminum high-voltage wire, aluminum beams, aluminum poles, and insulators.

Waste Type: Equipment

Waste Description: The aluminum wire beams and poles are potentially recyclable.

Closure Info: The Remaining Sites Verification Package (attachment to reclass form 2004-066) demonstrates that the site meets the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-22. Rev. 4) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (EPA, 1999). This report also shows that site soil contaminant concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario, and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

The primary contaminants of potential concern (COPCs) for the soil at the site are associated with the presence of the tar-like material and treated wood poles. The COPCs include total petroleum hydrocarbons (TPHs), aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, molybdenum, nickel, potassium, selenium, silicone, silver, sodium, vanadium, zinc, polychlorinated biphenyls (PCBs), and semivolatile organic constituents (SVOCs).

A cleanup action was initiated on February 19, 2004. Visual observation of the wooden poles indicated that the poles were treated throughout; therefore, the poles were size reduced and

removed for disposal to the Environmental Restoration Disposal Facility (ERDF). A layer of soil underlying the poles and in areas with visible tar was excavated and disposed due to the presence of TPH associated with the tar. Remedial action efforts included flagging the visible tar areas and removing the tar by excavating a layer of soil. In areas where the poles appeared to have been treated, a 30 centimeter (12 inch) layer of soil was removed. Where there were isolated, scattered small tar droppings, approximately 8 centimeters (3 inches) of soil was removed. The cleanup action also included a very small area to the east of the 50 x 50 meters (164 x 164 feet) area that contained similar surface contamination. From March 5 through April 16, 2004, a total of 9,005 metric tons (9,905 tons) of debris were sent to the ERDF for disposal. After the debris, tar, and soil were removed, verification samples were collected.

The verification sample numbers are too numerous to list, the results have been stored in the ENRE project-specific database prior to archiving in HEIS and are included in Appendix A of the RSVP attached to the reclass form 2004-066.

The verification sampling results support a reclassification of the 600-232 site to interim closed out. The analytical results from underlying soil samples were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

Code: 600-233	Classification: Accepted
Names: 600-233; Vertical Pipe Near 100B Electrical Laydown Area	Reclassification: Interim Closed Out (12/8/2005)
Type: Storage Tank	Start Date:
Status: Inactive	End Date:
Description:	The site has been remediated and interim closed out. Originally the site consisted of one vertical pipe extending 1.5 meters (4.9 feet) from the ground. During remedial activities two small pipes were discovered and added to the site, for a total of three. The area has been revegetated with grasses and native shrubs.
Location:	The site was located approximately 250 meters (820 feet) southeast of the 105-C Reactor Building and just north of the railroad tracks, inside the 600-232 waste site.
Waste Type:	Equipment
Waste Description:	Steel pipelines.
Closure Info:	The REMAINING SITES VERIFICATION PACKAGE FOR THE 600-233 WASTE SITE, VERTICAL PIPE NEAR 100-B ELECTRICAL LAYDOWN AREA (Attachment to Waste Site Reclassification Form 2005-041) report demonstrated that the waste site has met the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD) (EPA 1999).

During remedial activities and exploratory excavations, a 0.025-meter (1-inch) pipe segment and a 0.019-meter (0.75-inch) steel pipe were also discovered in the site vicinity, generally laying perpendicular to the 0.064-meter (2.5-inch) pipe. These discovered pipelines contained residual liquids that were drained and characterized for disposal and subsequently determined to have been used for diesel fuel supply unrelated to the vertical pipe. It was decided that the discovery pipelines posed no adverse risk to human health or the environment and could be abandoned in place

Remediation of the waste site consisted of the removal of the 0.064-meter (2.5-inch) steel pipeline via excavation of a 23-meter (75-foot)-long by 0.5-meter (1.6-foot)-deep trench. The eastern end of the pipeline was discovered to terminate with a pipe cap, and the pipeline was removed for disposal at the Environmental Restoration Disposal Facility. No radiation was detected above background levels during excavation, and no staining or anomalous materials were observed.

Cleanup verification samples (J03WJ1 through J03WJ4), including QA/QC samples, were collected on 8/9/05 and analyzed for the established contaminants of concern (arsenic, lead, TPH, cadmium, PCBs, SVOCs, nickel, chromium). The results illustrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep).

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River and support a reclassification of this site to interim closed out. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

through January 11, 2010 to remove the associated pipelines. Remediation removed all pipes that were associated with the junction box; however, the portion of pipe that was removed did not extend to the river. Process history indicates a portion of the pipe was previously removed; the portion of the pipe that was there appears to lead to the 100-D-65 site, a spillway that does lead to the river shoreline. The two sites were not connected and the potential association could not be confirmed.

A section of pipeline associated with 100-D-65 waste site was uncovered during remediation of the 100-D-1 waste site. The 100-D-65 pipeline was left in place and is located at the western end of the 100-D-1 waste site excavation. It has been assigned to the 100-D-105 waste site.

A total of approximately 495 bank cubic meters (647 bank cubic yards) of soil and debris were removed and directly loaded for disposal at Environmental Restoration Disposal Facility (ERDF).

The cumulative COPCs for the 100-D-1 waste site are americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, barium, cadmium, chromium (total), hexavalent chromium, lead, mercury, selenium, silver, PCBs, VOCs, SVOCs, and TPH. While not COPCs, arsenic, antimony, beryllium, boron, cobalt, copper, manganese, molybdenum, nickel, vanadium, and zinc concentrations were included in the expanded inductively coupled plasma (ICP) metals analytical list.

Code: 100-D-2	Classification: Accepted
Names: 100-D-2; Lead Sheeting; Solid Waste Site	Reclassification: Interim Closed Out (3/19/2008)
Type: Foundation	Start Date:
Status: Inactive	End Date:
Description:	The site appeared as a small lead sheet covering a concrete pad. It was not marked or posted.
Location:	The unit was located southwest of the 185-D Building about 16 meters (52 feet) north of an east/west roadway and 16 meters (52 feet) west of the access road to the west side of the 185 Building.
Waste Type:	Construction Debris
Waste Description:	
Closure Info:	The Remaining Sites Verification Package for the 100-D-2 Lead Sheeting, RSVP-2007-030, has documented that site verification sampling results support a reclassification to Interim Closed Out. The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 1004U-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

Remediation of the waste site was performed on April 12, 2007. The lead sheet, which was approximately 0.64 centimeters (0.25 inches) thick, was removed and placed in a drum for later treatment and disposal to the Environmental Restoration Disposal Facility (ERDF). The soil surrounding the concrete pad was moved aside to expose the concrete pad for inspection. The concrete was determined to be solid to at least a depth of 0.6 meters (2 feet).

The 100 Area Remedial Action Sampling and Analysis Plan (SAP) specified lead as the

contaminant of potential concern (COPC) for the site. Although not COPCs, the expanded list of inductively coupled plasma metals was analyzed and included arsenic, antimony, barium, beryllium, boron, cadmium, total chromium, cobalt, copper, manganese, molybdenum, nickel, phosphorous, selenium, silver, strontium, tin, uranium, vanadium, and zinc. Due to the potential of handling sulfuric acid, mercury and soil pH were also analyzed. Hexavalent chromium was included as a COPC for verification sampling because of its presence as a contaminant in groundwater and the proximity of the site to historical sodium dichromate handling facilities in the 100-D Area.

Verification soil sampling was performed on October 8, 2007, with one soil sample collected adjacent to each side of the concrete pad. Each sample consisted of 20 aliquots of soil distributed across the surface (0 to 0.15 meters [0 to 6 inches]) below the existing ground surface, combined into one sample representative of each of the four sides. The analytical results indicated the presence of lead up to 578 milligrams/kilogram, exceeding the direct exposure cleanup criteria. Additionally, a sample chipped from the surface of the concrete exhibited lead at a concentration of 32,900 milligrams/kilogram. Therefore, additional excavation to remove the concrete pad and surrounding soil was performed on October 15, 2007. Approximately a total of 216 metric tons (239 US tons) of soil and concrete were excavated and disposed of at ERDF.

Following the October 15th excavation, a second set of verification samples were collected on October 17, 2007, to determine if the remedial action was adequate to support site closure. The analytical results of this sampling indicated that the waste removal action achieved compliance with the RAOs and RAGs. The results of the verification sampling were used to make reclassification decisions in accordance with the TPA-MP-14 procedure in the Tri-Party Agreement Handbook Management Procedures.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. This site did not have a deep zone; therefore, no deep zone institutional controls were required.

Code:	100-D-3	Classification:	Accepted
Names:	100-D-3; Silica Gel; Solid Waste Burial Ground	Reclassification:	No Action (3/12/2009)
Type:	Burial Ground	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been reclassified to No Action. It was a suspected burial ground that would have received contaminated silica gel from the drying towers in the 115-D/DR building. The site has been surface stabilized and resembles a gravel parking lot.		
Location:	The site is located east/northeast of the south end of the 115-D/DR Building site.		
Process Description:	The site was used to contain contaminated silica gel removed from the drying towers in 115-D. Inert gas (helium and/or carbon dioxide) was circulated through the 105-D Reactor for the purpose of removing moisture. The gas circulation system was housed in the 115-D Building and consisted of blowers, silica gel drying towers, and filters. Silica gel is a granular material made from sodium silicate. It was used as a desiccant to reduce the humidity of the reactor gas and was regenerated by condensing the moisture. The moisture-absorbing efficiency of the silica gel was reduced as the material aged and eventually required removal from the gas circulation system.		

Waste Type: Abandoned Chemicals
Waste Description: The site contains contaminated silica gel removed from drying towers in the 115-D/DR Building.

Closure Info: Three locations characteristic of disturbed soil were identified in the vicinity of the reported silica gel burial ground. The suspected primary location for the silica gel burial ground was excavated during remediation of the 116-D-2/116-D-2A waste site (BHI 2000). The presence or absence of the silica gel at this location would have been difficult to discern given that the physical characteristics of the silica gel waste resemble soil (dark brown silicate material) and that the silica gel will have been expected to have decomposed after more than 40 years in contact with soil moisture.

Two alternative locations based on geophysical survey data were excavated. Neither location contained evidence of silica gel. Soil samples collected within the excavation did not detect carbon-14 or tritium above the minimum detectable activity (MDA).

One location was remediated in 1999 as the 116-D-2 waste site. The other two were excavated as part of the 100-D-3 site investigation, but no evidence of waste was found.

The radionuclide associated with spent silica gel from the 100 Area reactors was identified as carbon-14 (Miller and Wahlen 1987). This is supported by a 1963 status report that discusses carbon-14 as being a contaminant in the condensate from the silica gel dryers (Barton 1963).

Excavation of the two potential locations for the 100-D-3 waste site was completed on October 9, 2007. Both sites were excavated to approximately 4.5 m (15 ft) below ground surface. No evidence of waste was encountered at either location. The sites were backfilled a few days later to eliminate the safety hazard of an open excavation.

Two test pits were excavated on November 5, 2008 to collect verification samples based on consultation with the Washington Department of Ecology. No radiological contamination was detected during field excavation. Soil samples were collected at four different depths from the center of each of the two potential locations and analyzed for carbon-14 and tritium. Carbon-14 and tritium were not detected above the MDA in any of the soil samples. Therefore, this site has been reclassified to No Action.

Code: 100-D-4	Classification: Accepted
Names: 100-D-4; 107-D5; 107-D-5; 107-DR Sludge Trench #5; Sludge Trench #5	Reclassification: Interim Closed Out (3/25/1999)
Type: Trench	Start Date: 1/1/1955
Status: Inactive	End Date:

Description: The 100-D-4 site was constructed in 1953. This pit and two other identified sludge pits were associated with maintenance cleanout of the 116-DR-9 Liquid Effluent Retention Basin, which was constructed in the late 1940s. The 116-DR-9 Liquid Effluent Retention Basin was used to hold reactor effluent water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water was discharged to the Columbia River. The sludge pits were built for disposal of sludge removed from the bottom of the effluent retention basin to enable periodic maintenance and repairs to the basin during operation of the 100-D and 100-DR Reactors. There is no indication from available records that this sludge pit directly received any regular and/or high-volume liquid effluent wastes. The sludge pit consisted of an approximately 630-square meter (6,779-square feet) unlined excavation (bottom dimension) with moderately sloped side walls. This pit extended to a depth of about 3 m (10 ft) below grade, and was surrounded by native sandy gravel soils at the base and side walls of the excavation. After shutdown of the 100-D and 100-DR Reactors in the 1970s, subsequent

decommissioning of the effluent retention basin and associated sludge pits (as part of the Radiation Area Remedial Action Program) included placement of approximately 2 m (6 ft) of materials within the sludge pit. These materials consisted primarily of soil with some miscellaneous debris from the effluent basin and surrounding area. This sequence of material placement was followed by placement of approximately 1 m (3 ft) of clean soil cover for interim radiological, health, and safety protection purposes. The materials previously placed over the engineered pit structure (original pit excavation) are identified collectively as overburden materials.

Location: The site is located on the east side of the 107-DR Retention Basin, at the southeast corner.

Process Description: In the Spring of 1953 sludge was removed from the bottom of the 107-DR Retention Basin (116-DR-9) to facilitate repairs. The sludge was deposited in this and other nearby trenches.

Waste Type: Sludge

Waste Description: The site received radioactively contaminated sludge from the bottom of the 107-DR Retention Basin. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following (DOE-RL 1998a): Americium-241, Cobalt-60, Cesium-137, Europium-152, Europium-154, Europium-155, Plutonium-238, Plutonium-239/240, Strontium-90, Hexavalent chromium, and Polychlorinated biphenyls (PCBs).

Closure Info: Excavation of the 100-D-4 site began on March 18, 1997, by removing the overburden materials and underlying contaminated soil. Based on field screening, overburden materials that were identified as potentially clean were placed in stockpiles for potential use as backfill. Overburden materials that were found to be contaminated were disposed of at the ERDF. On March 27, 1997, the excavation had reached the design limits at the base of the engineered structure (El. 135.0 m [443 ft]) and closeout sampling was initiated.

During excavation, field screening and onsite gamma energy analysis (GEA) at the Radiological Counting Facility (RCF) were used to distinguish between potentially clean materials and contaminated materials for disposal at ERDF. Based on the size of the site, 24 random samples were collected for GEA and submitted to the RCF for analysis. Data from these samples were used to corroborate data obtained from field screening and to assist in waste characterization. Screening technologies, such as hand-held and cart-mounted sodium iodide (NaI) detectors, were used to guide day-to-day excavation activities and provided 100% coverage of the entire final excavation. The GEA indicated a low degree of variability and contaminant levels below the lookup values. These samples were used to determine the number of final cleanup verification samples required. Four final verification composite samples were taken and sent to an offsite laboratory for analysis.

Waste materials that were excavated, loaded into shipping containers, and disposed of at the ERDF consisted of soils not meeting direct exposure RAGs based on field screening results.

For the exposed surface of the excavation, initial confirmation sampling and testing using GEA began on March 28, 1997, to determine the number of final verification samples at the base of the engineered structure. Verification sampling and testing were finished on September 24, 1997 (El. 132.1 m [433 ft]).

At the completion of the remedial action, the excavation area was approximately 630 square meters (6,779 square feet) at a depth of 2.9 m (9.5 ft), and approximately 1,678 metric tons (1,850 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 135 m (443 ft). Clean backfill will be taken from overburden and Borrow Pit 21, which is located due south of the 100-D-4 site. The material in the borrow pit has been surveyed in accordance with the SAP (DOE-RL 1998a) and is appropriate for use as backfill. The overburden soil is also

appropriate for use as backfill.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code:	100-D-5	Classification:	Accepted
Names:	100-D-5; Undocumented Solid Waste Site; Undocumented Solid Waste Site Near 103-D; Waste Site Near 103-D	Reclassification:	Interim Closed Out (4/23/2001)
Type:	Burial Ground	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1950
Description:	The site was remediated and closed out with the 100-D, Group 3 waste sites.		
Location:	The site is located adjacent to the east side of the 103-D Building, north of the 105-D Building.		
Process Description:	The effluent water lines from 105-D and 105-DR join inside a concrete junction box located within the reactor exclusion area at a point north of 105-D and east of 103-D. At the completion of the underground line tie-in phase in 1950, contaminated soil and pipes were also placed in the excavation and buried. Later the steel effluent pipes were replaced with reinforced concrete piping and the junction box was no longer needed.		
Related Sites/ Structures:	The site is associated with 105-D and 105-DR.		
Waste Type:	Demolition and Inert Waste		
Waste Description:	The waste included reactor cooling water discharge, and debris generated in a 1950 modification. The contaminated soil and debris were removed and taken to ERDF along with 100-D, Group 3 waste site remediation (100-D-48:3, 100-D-49:3, and 100-D-6).		
Closure Info:	100-D-48:3, 100-D-49:3, 100-D-5 and 100-D-6 were addressed as a group. The information below documents information for the group of sites.		

The sites included in this remediation are 100-D-48:3, 100-D-49:3, 100-D-5, and 100-D-6. The entire remedial action for these sites is referred to as the 100-D-48:3/49:3 pipelines site. Remedial action at the 100-D-48:3/49:3 site began on October 28, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation was completed. The excavation design depth generally corresponded with the invert elevation of the pipelines.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 24,574 square meters (264,517 square feet) in area with a maximum depth of approximately 5.7 meters (18.7 feet). Approximately 55,561 metric tons (61,245 tons) of material from the 100-D-48:4 and 100-D-48:3/49:3 pipeline sites combined were disposed of at ERDF. Overall, approximately 107,266 metric tons (118,241 tons) from all D Area pipeline sites were disposed of at the ERDF through July 2000. Cleanup verification sampling began on June 7, 2000 (for the overburden piles), and was finished on October 4, 2000 (in the excavation). The excavation is being backfilled with appropriate materials to match the surrounding surface grade (average elevation of 143.7 meters [471 feet]).

The CVP demonstrates that the remedial action at the 100-D-48:3/49:3 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved Interim Action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 100-D-48:3/49:3 Pipelines site and overburden have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-D-48:3/49:3 site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the overburden and shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:3/49:3 Pipelines site is verified to be remediated in accordance with the ROD.

Code:	100-D-6	Classification:	Accepted
Names:	100-D-6; 118-D-4D; Burial Ground 4D; Buried VSR Thimble; Minor Construction Burial Ground #1	Reclassification:	Interim Closed Out (4/23/2001)
Type:	Burial Ground	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1953
Description:	The site was remediated and interim closed out with the 100-D, Group 3 waste sites.		
Location:	The solid waste burial ground site was located about 300 meters (1000 feet) east of the 105-D Reactor Building, outside the reactor security fence and south of the railroad spur that services the 100-D Area.		
Process Description:	The burial ground sat astride the two 152-centimeter (60-inch) reactor effluent lines. It received contaminated thimbles and other solid reactor materials related to the Ball 3X installation project in 1953.		
Waste Type:	Equipment		
Waste Description:	The burial ground contains contaminated thimbles, radioactive guides and miscellaneous waste removed from the 105-D Reactor during Ball 3X outage. The thimbles were made of aluminum, similar to that used for process tubes. Isotopic analysis of process tubes indicated the presence of manganese-54 and cobalt-60. The thimbles are expected to have similar composition. When buried, the thimbles' exterior surfaces would have been contaminated with activated graphite products and any remaining potassium borate solution from within the thimble tubes.		
Closure Info:	100-D-48:3, 100-D-49:3, 100-D-5 and 100-D-6 were addressed as a group. The information below documents information for the group of sites.		
	<p>The sites included in this remediation are 100-D-48:3, 100-D-49:3, 100-D-5, and 100-D-6. The entire remedial action for these sites is referred to as the 100-D-48:3/49:3 pipelines site. Remedial action at the 100-D-48:3/49:3 site began on October 28, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:3/49:3 Pipelines site is verified to be remediated in accordance with the ROD.

Code: 100-D-7	Classification: Accepted
Names: 100-D-7; Undocumented Solid Waste Site	Reclassification: Interim Closed Out (10/10/2011)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:
Description:	The site contains a variety of debris such as broken concrete, brick, vitrified clay pipe, wood, rebar, various types of metal, lathe turnings, empty oil, solvent, paint cans, tar, and a white substance in two localized areas. The site appears to have additional debris buried under the surface and there is evidence of disturbance from heavy equipment. Several areas of stressed vegetation and two areas of subsidence were also observed.
Location:	The site was located northeast of the 128-D-2 Burn Pit and approximately 700 meters (2,300 feet) northeast of the 105-D Reactor Building.
Process Description:	This site received solid wastes related to the construction and/or operation of the 100-D Area.
Waste Type:	Misc. Trash and Debris
Waste Description:	Wastes include vitrified clay pipe, concrete, empty metal containers, glass, metal and wooden debris.
Closure Info:	Remediation at the 100-D-7 waste site was performed between December 22, 2009 and March 6, 2010. Because the 100-D-7 site was a debris site, the excavation focused on the areas identified by geophysics; however, the excavation extent was conducted as necessary to remove waste and debris and remove contaminated soil. The drawings, visual observations radiological surveys, and collection of in process soil samples guided the extent of excavation during remediation. Approximately 24,120 bank cubic meters (31,548 bank cubic yards) of contaminated soil and debris were removed from the 100-D-7 waste site. The soil and debris

were staged in a staging pile to the southeast of the 100-D-7 waste site before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). The staging area includes a smaller area where topsoil from the waste sites was placed for use on top of the backfill to support successful revegetation as required by the ecological review for the 128-D-2 and 100-D-7 waste sites. All staged waste has been disposed to the ERDF. The staging area was then scraped to remove surface contaminated soil, which was disposed to the ERDF.

Only a portion of the 100-D-7 waste site within the WIDS boundary required remediation. An agreement with the Washington State Department of Ecology (Ecology) that the areas within the WIDS boundary where remediation was not performed would become a separate decision unit subject to additional sampling for closeout of the site (WCH 2009c).

Eight anomalies were initially identified during the remediation at the 100-D-7 waste site. These consisted of three 3.8-L (1-gal) bottles containing liquid (anomalies 100D-AN-10-001, 100D-AN-10-002, and 100D-AN-10-010); three areas of uncontained solid material: white powder (anomaly 100D-AN-09-082), a pink solid (anomaly 100D-AN-10-003), and a yellow/brown solid (anomaly 100D-AN-10-004). The remaining two anomalies are identified as grease and a metal cylinder (anomalies 100D-AN-10-006 and 100D-AN-10-008). The solid materials were sampled and characterized prior to removal and shipment to ERDF. Anomaly 100D-AN-09-082 was determined by the project engineer to be the same material as anomaly 100D-AN-09-065, so no sample was required for characterization. Anomalies 100D-AN-10-001, 100D-AN-10-002, 100D-AN-10-010, and 100D-AN-10-008 were overpacked and transferred to the 118-D-3:2 waste site anomaly characterization area.

Code:	100-D-8	Classification:	Accepted
Names:	100-D-8; 105-DR Process Sewer Outfall Site; 1907-DR; Undocumented Liquid Waste Site	Reclassification:	None
Type:	Outfall	Start Date:	1/1/1949
Status:	Inactive	End Date:	1/1/1968
Description:	In 1978, the outfall structure was demolished, leveled, and covered to blend with the riverbank appearance.		
Location:	The site is located upstream of the 181-D Pumphouse on the Columbia River bank.		
Process Description:	The outfall was constructed in 1949 as a spillway for an emergency discharge for the DR Reactor. It consisted of a 1.8-meter (72-inch) diameter, reinforced concrete pipe. The pipe discharged into a concrete box flume that spilled onto a grouted riprap surface and extended about 13.1 meters (43 feet) beyond the low-water level of the Columbia River. In 1950 it was modified to increase the discharge flow capacity. Historical records indicate the outfall ceased operation in 1968 and was idle until 1978, when it was demolished.		
Waste Type:	Water		
Waste Description:	The outfall was used to discharge waste water from the 183-DR and 190-DR Water Treatment Facilities. Effluents included filter backwash effluent, storm runoff, and chemical discharges resulting from spills or releases relating to water treatment facilities. There is a potential for radioactive contamination from the 100-D Area Cask Pad storm drains.		
Closure Info:	Remediation was performed from August 19, 2008 through February 8, 2009. Approximately 1,170 bank cubic meters (BCM) (1,530 bank cubic yards [BCY]) of concrete debris, asphalt emulsion, tan fibrous material, black plastic, grout, steel, and soil was removed from the waste site and disposed at the Environmental Restoration Disposal Facility (ERDF). An additional 0.53 BCM (0.69 BCY) of soil was removed from the area at the south degreasing pit and approximately 1.0 BCM (1.2 BCY) of soil was removed from the south radiological		

contamination area. This material was also disposed of at ERDF.

No further remediation can be conducted at the location with the cesium-137 direct exposure exceedance, without incurring significant adverse impacts to the bat colonies at the 100-D-50:2 pipeline subsite. A study conducted between June 2007 and September 2008 (WCH 2009a) showed that the bats at the 100-D-50:2, Reactor Cooling Water Pipelines from 190-DR Pumphouse subsite use the site as a maternity roost where they give birth and rear their young.

The preferred alternative to eliminate or mitigate impacts to the bat colony is to leave the structure intact and add perimeter fencing and signage to deter human entry. Therefore, institutional controls are required at the location of the cesium-137 contamination south of the 116-D-8 cask storage pad.

A summary of the cleanup evaluation for the soil results against the applicable criteria is presented in Table ES-1. The results of the verification sampling are used to make reclassification decisions for the 116-D-8 waste site in accordance with the Tri-Party Agreement Handbook Management Procedures (DOE-RL 2007).

Code:	100-D-9	Classification:	Accepted
Names:	100-D-9; 184DA; 184-DA Boiler Oil Tank	Reclassification:	Interim Closed Out (8/10/2006)
Type:	Storage Tank	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed. This site consisted of an underground fuel storage tank that was believed to have been removed during general demolition efforts of the 100-D/DR area during 1985 and 1986. It now appears as a cobble-covered field with vegetation on the surface. The elevation at the top of the tank was 141 meters (464.0 feet) and was covered by at least 0.6 meters (2 feet) of overburden.		
Location:	The tank was located in the 100-D Area, west of the northwest corner of the 184-DA Boiler House site, 55 meters (180 feet) south of Palouse Street and 165 meters (540 feet) east of Puget Avenue.		
Process Description:	The tank held fuel oil for the 184-DA Boiler House. It had a capacity of 94,600 liters (25,000 gallons). The fuel tank was installed in 1967 or 1968 to hold oil that fueled the boilers in the 184-DA Steam Generating Building (Boiler House).		
Waste Type:	Equipment		
Waste Description:			
Closure Info:	The current site conditions achieve the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD). Additionally, the site was evaluated in accordance with the requirements for underground storage tanks specified in Washington Administrative Code (WAC) 173-360, "Underground Storage Tank Regulations." These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario.		
	A geophysical survey was performed at the site in October 2005. Ground-penetrating radar, EM31 electromagnetic surveys, and magnetic gradiometer surveys were performed over an extended area surrounding the former tank location. Several linear anomalies were interpreted		

within the survey area, all trending roughly east-west. The former tank location appeared to be in the "disturbed" area that was near the center of the survey area. Small, relatively subtle geophysical anomalies were noted within this disturbed area, more typical of small debris or metal, but there was clearly no evidence of a tank of the documented size [94,600 Liters (25,000 gallons)].

Contaminants of potential concern (COPCs) for the site included semivolatile organic compounds (SVOCs), petroleum hydrocarbons, VOCs, arsenic, barium, cadmium, total chromium, lead, selenium, and polychlorinated biphenyls (PCBs). Suspect asbestos-containing material was observed during confirmatory sampling; however the sample results were used to eliminate asbestos as a COPC for the site.

Radionuclides were not COPCs for this site. However, the possible presence of radiological contaminants was evaluated using field radiological survey instrumentation (capable of detecting alpha, beta, and gamma radiation) during excavation. Although not specifically COPCs, antimony, beryllium, boron, cobalt, copper, manganese, molybdenum, nickel, silver, vanadium, zinc, and mercury levels were also evaluated for the site.

Confirmatory sample results have been stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System. A summary of the samples collected and laboratory analyses performed is provided in Table 1 of the RSVP-2006-030.

A test trench approximately 10 meters (23.8 feet) long and up to approximately 3.7 meters (12.1 feet) deep (to native soil) was excavated through the former fuel oil tank location. The excavation confirms that the tank was previously removed. No COC/COPCs were detected above the RAGs during confirmatory sampling.

The waste site has been evaluated and remediated in accordance with the Remaining Sites ROD, the RDR/RAWP, and the requirements for underground storage tanks specified in WAC 173-360, "Underground Storage Tank Regulations." Focused sampling was performed and the analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the confirmatory sampling results support a reclassification of the waste site to interim closed out.

The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-D-18	Classification:	Accepted
Names:	100-D-18; 107-D Sludge Trench #4; 107-D4; 107-D-4; Sludge Trench #4	Reclassification:	Interim Closed Out (9/26/2000)
Type:	Trench	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1953
Description:	This site has been remediated and was interim closed out on September 26, 2000. It is no longer posted.		
Location:	The site was located north of and adjacent to the western half of the 107-D Retention Basin (116-D-7), and was directly over the 100-DR Group 2 pipelines.		
Process Description:	In the Spring of 1953 sludge was removed from the bottom of the 107-D Retention Basin (116-D-7) to facilitate repairs. The sludge was deposited in this and other nearby trenches.		

Related Sites/ Structures: This site was associated with the 116-D-7 Retention Basin.

Waste Type: Sludge

Waste Description: The site received contaminated sludge from the bottom of the 107-D Retention Basin (116-D-7).

Closure Info: The site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The Remedial Action Objectives (RAOs) were established in the Interim Action ROD (EPA,1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP).

Contaminants of concern (COCs) and contaminants of potential concern (COPCs) for 100 Area waste sites identified through process knowledge are listed in the SAP. The COCs for the site consist of americium-241, cobalt-60, cesium-137, europium-152, europium-154, plutonium-238, plutonium-239/240, strontium-90, hexavalent chromium, and polychlorinated biphenyls.

Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at Environmental Restoration Disposal Facility (ERDF). On December 3, 1998, the excavation reached the design limit at El. 127.8 meters (420.3 feet). Cleanup verification sampling began on September 13, 1999, and was finished on September 13, 1999.

Remedial action at this site began on September 8, 1997 and ended on December 3, 1998. During that time, the shallow zone sidewalls were lost to other nearby remedial activities, leaving only the floor of the excavation for the site. At the completion of remedial action, the excavation area was approximately 344.3 square meters (3,706 square feet) with a maximum depth of approximately 6.6 meters (21.7 feet). Approximately 8,700 metric tons (9,592 tons) of material from the site were disposed of at ERDF. Clean backfill is to be taken from the clean stockpile and from other sources of clean material that have been surveyed in accordance with the SAP and that are appropriate for use as backfill.

The CVP demonstrated that remedial action at the site has achieved the RAOs and corresponding RAGs established in the approved Interim Action ROD and the RDR/RAWP. Materials from the site have been excavated and handled in accordance with the RDR/RAWP. As a result of remedial actions at adjacent sites, the sidewalls of the 100-D-18 site excavation have also been excavated. The consequence is that there are no residual shallow zone soils left at the site to sample and evaluate. Protection of potential future rural-residential receptors will be ensured by backfilling the site with clean soils.

For the deep zone, this CVP demonstrated that residual COC concentrations pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The site has been verified to be remediated in accordance with the ROD.

Code: 100-D-19

Classification: Accepted

Names: 100-D-19; 107-D Sludge Trench #6; Sludge

Reclassification: Interim Closed Out (3/26/2001)

Trench #6

Type:	Trench	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1953
Description:	This site has been remediated and closed out. It was a trench dug for disposal of sludge from the bottom of the 107-D Retention Basin. The waste was covered by about 1.8 meters (6 feet) of clean fill.		
Location:	The site is located north of the eastern half of the 107-D Retention Basin (116-D-7).		
Process Description:	HW-46715 documents that in the Spring of 1953 sludge was removed from the bottom of the 107-D Retention Basin (116-D-7) to facilitate repairs. The sludge was deposited in this and other nearby trenches.		
Waste Type:	Sludge		
Waste Description:	The site received radioactively contaminated sludge from the bottom of the 107-D Retention Basin.		
Closure Info:	100-D-48:1, 100-D-49:1, 100-D-19 and UPR-100-D-4 were addressed as a group. The information below documents information for the group of sites.		

Remedial action at the 100-D-48:1/49:1 Pipelines site began on December 28, 1998. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit.

Because remediation of the 100-D-48:1/49:1 Pipelines site required moving an active overhead power line, site remedial action and sampling were conducted in two phases. These separate phases are reflected by the long time period between the start and finish dates for excavation.

The excavation design depth generally corresponded with the invert elevation of the pipelines. At the completion of remedial action and removal of the engineered structure, the excavation was approximately 15,504 square meters (166,800 square feet) in area with a maximum depth of approximately 6.0 meters (20 feet) below ground surface. Approximately 107,266 metric tons (118,241 tons) of material from the D Area pipelines site have been disposed of at the ERDF through July 2000. Cleanup verification sampling began on April 3, 2000, and was finished on August 8, 2000. The ground surface in the vicinity of the site varies with an average elevation of approximately 134.4 meters (441 feet).

The CVP demonstrated that remedial action at the 100-D-48:1/49:1 Pipelines site achieved the RAOs and corresponding RAGs established in the approved interim action ROD and RDR/RAWP. The remaining soils at the 100-D-48:1/49:1 Pipelines site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-D-48:1/49:1 Pipelines site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. Residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:1/49:1 Pipelines site (includes the 100-D-19 and UPR-100-D-4 sites) is verified to be remediated in accordance with the interim

action ROD.

Code: 100-D-20	Classification: Accepted
Names: 100-D-20; 107-D Sludge Trench #3; 107-D3; 107-D-3; Sludge Trench #3	Reclassification: Interim Closed Out (3/25/1999)
Type: Trench	Start Date: 1/1/1953
Status: Inactive	End Date: 1/1/1953

Description: This site has been remediated and interim closed out. The 100-D-20 Sludge Pit was constructed in 1953. This pit and two other identified sludge pits were associated with maintenance clean out of the 116-D-7 Liquid Effluent Retention Basin, which was constructed in the late 1940s. The 116-D-7 Liquid Effluent Retention Basin was used to hold reactor effluent water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water discharged to the Columbia River. The sludge pits were built for disposal of sludge removed from the bottom of the effluent retention basin to enable periodic maintenance and repairs to the basin during operation of the 100-D and 100-DR Reactors. There is no indication from available records that this sludge pit directly received any regular and/or high-volume liquid effluent wastes. The sludge pit consisted of an approximate 575-square meter (6,189-square feet) unlined excavation (bottom dimension) with moderately sloped side walls, extended to a depth of about 2.1 meters (7 feet) below grade, and the pit was surrounded by native sandy gravel soils at the base and side walls of the excavation. After shutdown of the 100-D and 100-DR Reactors in the 1970s, subsequent decommissioning of the effluent retention basin and associated sludge pits (as part of the Radiation Area Remedial Action Program) included placement of approximately 2 meters (7 feet) of material within the sludge pit, which consisted primarily of soil with some miscellaneous debris material from the effluent basin and surrounding area. This sequence of material placement was followed by placement of approximately 1 meter (3 feet) of clean soil cover for interim radiological, health, and safety protection purposes. The materials previously placed over the engineered pit structure (original pit excavation) are identified collectively as overburden materials. A Geophysical Survey was done in 1996 that identified this trench as a disturbed zone that may also contain buried construction debris.

Location: The trench was outside of the south perimeter of 107-D. Refer to Hanford Drawing H-1-4046.

Process Description: In the Spring of 1953 sludge was removed from the bottom of the 107-D Retention Basin (116-D-7) to facilitate repairs. The sludge was deposited in this and other nearby trenches.

Waste Type: Sludge

Waste Description: The site received radioactively contaminated sludge from the bottom of the 107-D Retention Basin. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, hexavalent chromium, and polychlorinated biphenyls.

Closure Info: The cleanup verification package (CVP-1998-00003) has documented that the 100-D-20 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision (ROD) (EPA 1995) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17).

Excavation of the 107-D3 Sludge Pit began on July 30, 1997, by removing the overburden materials and underlying contaminated soil. Based on field screening, all overburden materials were found to be contaminated and were disposed of at the Environmental Restoration Disposal Facility (ERDF). On August 1, 1997, the excavation had reached the design limits at the base

of the engineered structure (El. 132.3 meters [434 feet]) and closeout sampling was initiated.

During excavation, field screening and onsite gamma energy analysis (GEA) at the Radiological Counting Facility (RCF) were used to distinguish between potentially clean materials and contaminated materials for disposal at ERDF. Based on the size of the site, 24 random samples were collected for GEA and submitted to the RCF for analysis. Data from these samples were used to corroborate data obtained from field screening and to assist in waste characterization. Screening technologies, such as hand-held and cart-mounted sodium iodide (NaI) detectors, were used to guide day-to-day excavation activities and provided 100% coverage of the entire final excavation site. The GEA indicated a low degree of variability and contaminant levels below the lookup values. These samples were used to determine the number of final cleanup verification samples required. Four final verification composite samples were taken and sent to an offsite laboratory for analysis.

Waste materials that were excavated, loaded into shipping containers, and disposed of at the ERDF consisted of soils not meeting direct exposure RAGs based on field screening results.

For the exposed surface of the excavation, initial confirmation sampling and testing using GEA began on January 1, 1998 (El. 132 meters [434 feet]).

At the completion of the remedial action, the excavation area was approximately 575 square meters (6,189 square feet) at a depth of 2.1 meters (7 feet), and approximately 9,710 metric tons (10,700 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 134.4 meters (441 feet). Clean backfill will be taken from Borrow Pit 21, which is located due south of the 100-D-20 site. The material in the borrow pit has been surveyed in accordance with the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL -96-22) and is appropriate for use as backfill.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code: 100-D-21	Classification: Accepted
Names: 100-D-21; 107-D-2; 107-D-2; 107-DR Sludge Trench #2; Sludge Trench #2	Reclassification: Interim Closed Out (3/25/1999)
Type: Trench	Start Date: 1/1/1953
Status: Inactive	End Date: 1/1/1953
Description: The 100-D-21 Sludge Pit was constructed in 1953. This pit and two other identified sludge pits were associated with maintenance cleanout of the 116-D-7 Liquid Effluent Retention Basin (LERF), which was constructed in the late 1940s. The 116-D-7 Liquid Effluent Retention Basin was used to hold reactor effluent water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water was discharged to the Columbia River. The sludge pits were built for disposal of sludge removed from the bottom of the effluent retention basin to enable periodic maintenance and repairs to the basin during operation of the 100-D and 100-DR Reactors. There is no indication from available records that this sludge pit directly received any regular and/or high-volume liquid effluent wastes. The sludge pit consisted of an approximate 891-square meter (9,591-square feet) unlined excavation (bottom dimension) with moderately sloped side walls, extending to a depth of about 3 meters (10 feet) below grade. The pit was surrounded by native sandy gravel soils at the base and side walls of	

the excavation. After shutdown of the 100-D and 100-DR Reactors in the 1970s, subsequent decommissioning of the effluent retention basin and associated sludge pits (as part of the Radiation Area Remedial Action Program) included placement of approximately 2 meters (7 feet) of material within the sludge pit. The materials consisted primarily of soil with some miscellaneous debris material from the effluent basin and surrounding area. This sequence of material placement was followed by placement of approximately 1 meters (3 feet) of clean soil cover for interim radiological, health, and safety protection purposes. The waste was covered with about 1.8 meters (6 feet) of clean fill and marked with an above-ground concrete marker. The materials previously placed over the engineered pit structure (original pit excavation) are identified collectively as overburden materials.

Location: The site is outside the west perimeter of 107-DR Basin.

Process Description: In the Spring of 1953 sludge was removed from the bottom of the 107-DR Retention Basin (116-DR-9) to facilitate repairs. The sludge was deposited in this and other nearby trenches.

Waste Type: Sludge

Waste Description: The site received radioactively contaminated sludge from the 107-DR Retention Basin. From process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following (DOE/RL-96-22): Americium-241, Cobalt-60, Cesium-137, Europium-152, Europium-154, Europium-155, Plutonium-238, Plutonium-239/240, Strontium-90, Hexavalent chromium, and Polychlorinated biphenyls (PCBs).

Closure Info: Excavation of the 100-D-21 Sludge Pit (135.0 meters [443 feet]) began on December 31, 1997, by removing the overburden materials and contaminated soil. Based on field screening, all overburden materials were found to be contaminated and were disposed of at the Environmental Restoration Disposal Facility (ERDF). On January 8, 1998, the excavation had reached the design limits at the base of the engineered structure (El. 131.9 meters [433 feet]) and closeout sampling was initiated. Elevated levels of PCBs were found at this elevation (El. 131.9 meters [433 feet]) and excavation was continued. On March 17, 1998, the final excavation was completed at El. 130.5 meters (428 feet) and analysis of verification samples found the site to be clean.

During excavation, field screening and onsite gamma energy analysis (GEA) at the Radiological Counting Facility (RCF) were used to distinguish between potentially clean materials and contaminated materials for disposal at ERDF. Based on the size of the site, 24 random samples were collected for GEA and submitted to the RCF for analysis. Data from these samples were used to corroborate data obtained from field screening and to assist in waste characterization. Screening technologies, such as hand-held and cart-mounted sodium iodide (NaI) detectors, were used to guide day-to-day excavation activities and provided 100% coverage of the entire final excavation site. The GEA indicated a low degree of variability and contaminant levels below the lookup values. These samples were used to determine the number of final cleanup verification samples required. Four final verification composite samples were taken and sent to an offsite laboratory for analysis.

Waste materials that were excavated, loaded into shipping containers, and disposed of at the ERDF consisted entirely of soils not meeting direct exposure RAGs based on field screening results.

For the exposed surface excavation, initial confirmation sampling and testing using GEA began on April 29, 1998, to determine the number of final verification samples at the base of the engineered structure. Verification sampling and testing were completed on May 21, 1998 (El. 130.5 meters [14.8 feet]).

At the completion of the remedial action, the excavation area was approximately 891 square

meters (9,591 square feet) at a depth of 4.5 meters (14.8 feet). Approximately 9,943 metric tons (10,957 tons) of contaminated soil were disposed at the ERDF. The excavation will be backfilled to the reference grade of El. 135 meters (443 feet). Clean backfill will be taken from Borrow Pit 21, which is located due south of the 100-D-21 site. The material in the borrow pit has been surveyed in accordance with the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22) and is appropriate for use as backfill.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code:	100-D-22	Classification:	Accepted
Names:	100-D-22; 107-D1; 107-D-1; 107-DR Sludge Trench #1; Sludge Trench #1	Reclassification:	Interim Closed Out (3/25/1999)
Type:	Trench	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1953
Description:	The site has been remediated and interim closed out.		
Location:	The site is outside the east perimeter of the 107-DR Basin.		
Process Description:	<p>The 100-D-22 Sludge Pit was constructed in 1953. This pit and two other identified sludge pits were associated with maintenance cleanout of the 116-DR-9 Liquid Effluent Retention Basin, which was constructed in the late 1940s. The 116-DR-9 Liquid Effluent Retention Basin was used to hold reactor effluent water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water was discharged to the Columbia River. The sludge pits were built for disposal of sludge removed from the bottom of the effluent retention basin to enable periodic maintenance and repairs to the basin during operation of the 100-D and 100-DR Reactors. There is no indication from available records that this sludge pit directly received any regular and/or high-volume liquid effluent wastes. The sludge pit consisted of an approximate 340-square meter (3,658-square feet) unlined excavation (bottom dimension) with moderately sloped side walls, extended to a depth of about 3 meters (10 feet) below grade, and the pit was surrounded by native sandy gravel soils at the base and side walls of the excavation. After shutdown of the 100-D and 100-DR Reactors in the 1970s, subsequent decommissioning of the effluent retention basin and associated sludge pits (as part of the Radiation Area Remedial Action Program) included placement of approximately 2 meters (7 feet) of material within the sludge pit, which consisted primarily of soil with some miscellaneous debris materials from the effluent basin and surrounding area. This sequence of material placement was followed by placement of approximately 1 meter (3 feet) of clean soil cover for interim radiological, health, and safety protection purposes. The materials previously placed over the engineered pit structure (original pit excavation) are identified collectively as overburden materials. The site is outside the east perimeter of the 107-DR Basin. Sludge was removed from the bottom of the 107-DR Basin in the spring of 1953 and buried in a nearby trench. The waste was covered with about 1.8 meters (6 feet) of clean fill and marked with an above-ground concrete marker. The Technical Baseline Report (Carpenter, 1993) says more than one sludge trench was placed in this area. Refer to Hanford Drawing H-1-4046. A Geophysical Survey was done in 1996 that identified the trench as a disturbed zone and contains what appears to be construction debris.</p>		
Related Sites/ Structures:	The site was associated with maintenance cleanup of the 116-DR-9 Liquid Effluent Retention Basin during operation of the 100-D and 100-DR Reactors.		
Waste Type:	Sludge		

Waste Description: process knowledge, the waste site contaminants of concern (COCs) identified in the SAP include the following: Americium-241, Cobalt-60, Cesium-137, Europium-152, Europium-154, Europium-155, Plutonium-238, Plutonium-239/240, Strontium-90, Hexavalent chromium, and Polychlorinated biphenyls (PCBs). A small volume of debris containing lead was encountered during remedial action, which was subsequently transported, treated, and disposed of at the ERDF. Because of the presence of lead-containing debris, lead was included as a COC per regulator request.

Closure Info: Excavation of the 100-D-22 Sludge Pit began on March 14, 1997, by removing the overburden materials and underlying contaminated soil. Based on field screening, all overburden materials were found to be contaminated and were disposed of at the Environmental Restoration Disposal Facility (ERDF). On March 25, 1997, the excavation had reached the design limits at the base of the engineered structure [elevation 132.4 meters (434 feet)], and closeout sampling was initiated. Because of the presence of polychlorinated biphenyls (PCBs) at that depth, the excavation was extended to 4.8 meters (16 feet) below grade [elevation 130.2 meters (427 feet)] on November 11, 1997, to remove residual PCB contamination. Closeout sampling for PCBs was initiated at this depth.

During excavation, field screening and onsite gamma energy analysis (GEA) at the Radiological Counting Facility (RCF) were used to distinguish between potentially clean materials and contaminated materials for disposal at ERDF. Based on the size of the site, 24 random samples were collected for GEA and submitted to the RCF for analysis. Data from these samples were used to corroborate data obtained from field screening and to assist in waste characterization. Screening technologies, such as hand-held and cart-mounted sodium iodide detectors, were used to guide day-to-day excavation activities and provided 100% coverage of the entire final excavation site. The GEA indicated a low degree of variability and contaminant levels below the lookup values. These samples were used to determine the number of final cleanup verification samples required. Four final verification composite samples were taken and sent to an offsite laboratory for analysis.

Waste materials that were excavated, loaded into shipping containers, and disposed of at the ERDF consisted of soils not meeting direct exposure Remedial Action Goals (RAGs) based on field screening results. This included overburden material removed from the southeast portion of the excavation (to construct an equipment access ramp). A nominal amount of material was found to contain PCBs above cleanup levels and was subsequently disposed of at the ERDF.

For the exposed surface of the excavation, initial confirmation sampling and testing using GEA began on June 25, 1997, to determine the number of final verification samples at the base of the engineered structure [elevation 132.4 meters (434 feet)]. Verification sampling and testing began on July 29, 1997, and identified the presence of PCBs above cleanup criteria levels. Field screening was used to monitor PCB levels as excavation at the 100-D-22 Sludge Pit continued to a final elevation of 130.2 meters (427 feet) on November 11, 1997. The PCB samples were taken again on December 16, 1997, for clean site verification.

At the completion of the remedial action, the bottom of the excavation was approximately 340 square meters (3,658 square feet) at a depth of 4.8 meters (16 feet), and approximately 9,710 metric tons (4,960 loose cubic meters) of material from the site were disposed of at the ERDF. Upon regulatory approval, the excavation will be backfilled with clean fill materials to the reference grade of elevation 135 meters (443 feet). Clean backfill will be taken from Borrow Pit 21 (Gravel Pit 21). The material in the pit has been surveyed in accordance with the Sampling and Analysis Plan (SAP) (DOE/RL-96-22) and is appropriate for use as backfill.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to

shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code:	100-D-24	Classification:	Accepted
Names:	100-D-24; 119-D Sample Building Drywell	Reclassification:	No Action (9/19/2006)
Type:	French Drain	Start Date:	1/1/1959
Status:	Inactive	End Date:	
Description:	The site consisted of a drywell that received drainage from a floor drain in the 119-D Sample Building. The sample building has been demolished and the surrounding area has been graded.		
Location:	The drywell was located south of the 119-D Sample Building, between the intake and exhaust ducts for the 117-D Filter Building.		
Process Description:	The 119-D Sample Building was situated over the intake and exhaust ducts to the 117-D Filter Building and was used to sample effluent gases and particulates. The drywell was connected to the 119-D Sample Building by a 5-centimeter (2-inch) drainage pipe buried at least 0.9 meters (3 feet) below grade. A 1.9-centimeter (3/4-inch) drain line from the building's evaporative cooler connected into the 5-centimeter (2-inch) drain line near the southern edge of the building.		
Related Sites/ Structures:	The drywell was associated with the 119-D Sample Building.		
Waste Type:	Process Effluent		
Waste Description:	The drywell received effluent from the building's evaporative cooler. It was likely that the floor drain also received sample waste and janitorial waste since the building had no other drains or connections to the process sewer system.		
Closure Info:	In accordance with evaluation for the Remaining Sites Verification Package it was determined that site reclassification to No Action was supported by confirmatory sampling results. The results also determined that the current site conditions meet the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, (Remaining Sites ROD).		
	The contaminants of potential concern (COPCs) for the site were identified based on existing information for the site. The COPC list identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) included carbon-14, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, strontium-90, uranium-234, uranium-235, uranium-238, hexavalent chromium, mercury, lead, semivolatile organic compounds (SVOCs), and volatile organic compounds.		
	Although not considered COPCs, antimony, arsenic, barium, beryllium, boron, cadmium, chromium (total), cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc concentrations were also measured by analyzing for the expanded inductively coupled plasma (ICP) metals analytical list. Confirmatory sampling was conducted on November 3, 2005. Because the drywell was not located during excavation, samples were taken of the soils presumed to underlie the former location of the drywell.		
	For reclassification purposes soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels were made for the site contaminants		

of potential concern and other constituents. Screening levels were not exceeded for the site constituents, with the exception of boron and vanadium. Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. It was believed that the presence of these constituents does not pose a risk to ecological receptors as residual vanadium concentrations were below site background levels, and boron concentrations were consistent with those seen elsewhere at the Hanford Site (no established background value was available).

A baseline risk assessment for the river corridor portion of Hanford began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for the 100-D-24 site.

Per discussion with the Washington Department of Ecology and review of historical drawings referenced by the WIDS summary report, the coordinates provided in WIDS for the drywell were determined to be incorrect. Accordingly, one test pit was excavated at the drywell location shown on historic drawings. The drywell was not identified within the test pit area and was, therefore, presumed to have been removed at the time of decommissioning and demolition activities. Therefore, in accordance with the work instruction, the excavation proceeded to 3 meters (10 feet) below ground surface (bgs), at the suspected location of the former base of the drywell. One soil grab sample was collected at 2.4 meters (8 feet) bgs, and another grab sample was collected at 3 meters (10 feet) bgs.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System and were presented in Appendix A of the RSVP.

The analytical results from soil samples were also shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-D-25	Classification:	Accepted
Names:	100-D-25; Unplanned Release: 107-DR Basin Leaks	Reclassification:	Interim Closed Out (1/6/2000)
Type:	Unplanned Release	Start Date:	1/1/1951
Status:	Inactive	End Date:	
Description:	Leakage from the 107-DR Basin was confined to the south end and beneath the basin. Today the area cannot be separately distinguished in the gravel retention basin area.		
Location:	The site was located beneath the 107-DR Retention Basin.		
Release Description:	The release involved leakage from the 107-DR Basin.		
Related Sites/Structures:	The leak was associated with the 107-DR Basin.		
Waste Type:	Water		
Waste Description:	Radioactively contaminated effluent was released to the site.		
Closure Info:	116-DR-9 and 100-D-25 were addressed as a group. The information below documents information for the group of sites.		

The Cleanup Verification Package, CVP-1999-00006, documents that the 116-DR-9 and 100-D-25 waste sites have met the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 0), and the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995). A rural residential exposure scenario was assumed in calculating cleanup levels.

The retention basin received cooling water effluent from the 105-DR Reactor from 1950 until 1965. After the 105-D Reactor was deactivated in 1965, the basin remained active until 1967 as part of the 105-D Reactor effluent system. Leakage occurred as unplanned releases in 1951 beneath the basin and outside the south end of the basin when seals in the concrete floor of the basin failed and the pipes pulled away from the basin walls at the retention basin inlet. Waste site 100-D-25, an unplanned release that occurred as floor leaks beneath the basin, could not be distinguished from other contaminated soil. It was remediated with the 116-DR-9 Retention Basin under the provisions for "proximity sites."

Excavation began on October 21, 1997, by removing the overburden materials and underlying contaminated soil. Overburden materials, which were contaminated, were disposed at the ERDF. On December 28, 1998, the excavation had reached the design limits below the base of the engineered structure (El. 130.25 m [427.35 ft]) and cleanup verification sampling was initiated. At the completion of the remedial action, the excavation area floor was approximately 16,352 m² (176,013 ft²) at a depth of 4.75 m (15.6 ft), and approximately 201,519 metric tons (222,122 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 135.0 m (443 ft).

Contaminated soil associated with the process effluent pipelines was not removed completely, but remained for final remediation with the pipelines. The 100-DR process effluent pipelines are scheduled to be removed during the next year. The 116-DR-9 sidewall areas that are adjacent to future pipeline excavation areas were not sampled as part of the cleanup verification effort. These areas will be sampled and verified clean as part of the effluent pipeline remediation efforts.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, WIDS had shown that no IC restrictions were required but the sites were remediated with deep zone criteria so that Ics actually were required. The Ics for this site have been revised accordingly.

Code: 100-D-29	Classification: Accepted
Names: 100-D-29; Effluent Line Leak #2	Reclassification: Interim Closed Out (3/25/2010)
Type: Unplanned Release	Start Date: 1/1/1951
Status: Inactive	End Date:
Description: The site is a release from the 107-DR Retention Basin. In the fall of 1952, there was extensive leakage of effluent water at the inlet end of the 107-DR retention basin that was caused by the pipes pulling loose from the basin wall from thermal expansion and contraction of the steel pipelines and the concrete basin wall. In order to repair the leak, a trench was dug to receive the leaked effluent so that repairs could be made. This trench formed a "dogleg" adjacent to the southwest corner of the basin towards the southeast end of the 107-D Retention Basin. (UNI-946)	

The trench was covered by about 1.2 meters (4 ft) of clean fill material upon completion of the basin repair. In the fall of 1952, a portion of the contaminated soils from this leak was used as fill around the pipeline anchor blocks south of the basin. All contaminated soil was then covered by 0.61 meters (2 ft) of soil. Contaminated soil associated with the pipeline anchor blocks would have been removed with the 100-D-49, 100-DR Effluent Cooling Water Pipelines.

Location: The site is located southwest of the 107-DR Basin and southeast of the 107-D Retention Basin. The site is centered at Washington State Plane coordinates, E 573832.364, N 152132.5.

Release Description: In 1951, extensive leakage of effluent water was detected above ground about 46 meters (105 feet) southeast of the 107-D Basin. A maximum dose rate of 50 millirads/hour was observed at the surface. Two excavations were made to investigate the leakage, but the effluent continued to seep to the surface.

Process Description: The site was a planned release to allow for the repair of the 107-DR Retention Basin.

Related Sites/ Structures: The site was related to the 107-DR Retention Basin.

Waste Type: Soil

Waste Description: Contaminants of potential concern (COPCs) include: Co-60, Cs-134, Cs-137, Eu-152, Eu-154, Eu-155, H-3, The waste is contaminated soil from a temporarily constructed drainage trench. In the fall of 1952, readings up to 100 mrad/hr were detected at the surface of the mud leaking from the retention basin. The source is radioactive process effluent from the 107-D Retention Basin.

Closure Info: In accordance with the Remaining Sites Verification Package, RSVP-2009-038, the verification sampling results support a reclassification of this site to Interim Closed Out. The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD).

Remedial activities at the 100-D-29 waste site began on March 7, 2008, and were completed on March 28, 2008. The excavation was approximately 4.6 m (15 ft) deep and 30 m (100 ft) long with variable width. Approximately 5,200 bank cubic meters (BCM) (6,800 bank cubic yards [BCY]) of soil was excavated and stockpiled adjacent to the site.

Historical information indicated that residual radiological contamination associated with the 100-D-29 waste site would be expected to be encountered at approximately 1.2 meters (4 feet) below ground surface (bgs) because the trench that formed the site had been backfilled with 1.2 meters (4 feet) of soil. However, no field detectable contamination was encountered during excavation to this depth. Therefore, the excavation was extended to a depth of 4.6 meters (15 feet), but still with no radiological contamination detected.

Based on field observations, in combination with hand-held radiological surveys that indicate the absence of detectable contamination associated with a retention basin leak, it is suspected that the contaminated soil associated with the 100-D-29 site was removed in the fall of 1952 and used as backfill for the anchor blocks at the 107-DR Retention Basin inlet.

An alternative suggestion is that the waste site location in Waste Information Data System (WIDS)/Stewardship Information System (SIS) is an approximation. A September 1954 photograph shows a release adjacent to the basin inlet, with a dogleg to the north, similar to the

shape of the 100-D-29 waste site depicted in WIDS and SIS. This release appears to have resulted from a trench that was used to control effluent drainage away from the basin as described in the historical documents (Rupert 1953, Heid 1956).

If this is the case, it is possible that the location of the 100-D-29 waste site in WIDS and SIS may not be the actual trench location since the location was developed using historical sketches and the actual location may have been the release observed in the 1954 photograph. Contamination associated with the release shown in this photograph may have had some portion removed during remediation of the 107-DR Retention Basin (CVP-99-00006). As a result of this new information, this release will be identified as discovery site 100-D-102 in WIDS for further evaluation using the TPA-MP-14 process.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-D-30	Classification:	Accepted
Names:	100-D-30; 185-D; 185-D Sodium Dichromate Trench & Sump; 189-D Decontamination & Demolition Project; 190-D Sodium Dichromate Soil Contamination	Reclassification:	None
Type:	Unplanned Release	Start Date:	1/1/1945
Status:	Inactive	End Date:	1/1/1967
Description:	The site is sodium dichromate contaminated soil. The site was discovered during the 185-D/189-D Subgrade Decontamination and Demolition Project. Sodium dichromate contamination was discovered in the soil along the entire length of the sodium dichromate trench of 185-D. The contamination was visually identified on concrete surfaces and on large cobbles in the soil by the yellow film on the surface. Photographs were taken during demolition of the subgrade structures and show the contaminated soil and structures.		
Location:	The site is located in 100-D Area, between the 105-D Building and the 183-D Building.		
Release Description:	Sodium dichromate solutions were released from cracks or expansion joints in the "chromate trench" which extended the length of the 185-D Building.		
Process Description:	The process water flowed from the 185-D Building into the refrigeration room of the 189-D Building where it was chilled and pumped into either or both of the two center storage tanks in the 190-D Building. Four large 6.62E+06-liter (1.75E+06-gallon) steel storage tanks were provided in the 190-D High Bay to supply water to the coolant pumps for the reactor. The water in the tanks was treated with sodium dichromate to inhibit corrosion in the reactor process tubes. The 185-D Building contained sodium dichromate mixing tanks and a pipe trench to convey sodium dichromate solutions to be added to the large 190-D Storage Tanks.		
Related Sites/ Structures:	The site was related to the 190-D, 185-D, 189-D and 105-D process piping.		
Waste Type:	Chemical Release		
Waste Description:	Sodium dichromate contamination is in the soil.		

Code:	100-D-31	Classification:	Accepted
Names:	100-D-31; 100-D Water Treatment Facilities Underground Pipelines	Reclassification:	None
Type:	Process Sewer	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1994
Description:	<p>The waste site encompasses the underground pipelines that transported pre-reactor, non radioactive cooling water and process sewer waste streams from water treatment, reactor, and laboratory facilities. All of these underground pipelines are pre-reactor (pre-irradiation) disposal and supply lines, except for the septic sewer lines that fed the 1607-D2 septic tank. All the underground process sewer and drainage piping from water treatment facilities to the 116-D-5 Outfall Structure are part of this site. The site also includes the feed pipelines from the 117-DR Filter Building and the 105-DR Reactor to the 100-D-13 septic System.</p> <p>Excluded from this site are the process sewer system that was constructed specifically for the 100-DR Reactor facilities, chemical supply, or underground effluent pipelines designed to dispose of radionuclide contaminated effluents and pipelines within buildings. These systems are addressed as separate WIDS sites. This site does not include the 120-D-1 Ponds, used for process sewer discharge from 1977 to 1994 or the 116-D-5 Outfall Structure and river pipelines. This site also does not include raw river water, potable water, or fire system water pipelines, or the sodium dichromate underground supply pipelines (100-D-56).</p>		
Location:	<p>The pipelines are located in the 100-D Area. The system is a network of underground piping that extends from water treatment facilities, the 184-D Powerhouse, 1700-Series Buildings, and 105-D Reactor to the 116-D-5 Outfall and septic tank 1607-D2. These pipelines run from the 182-D Reservoir, the 183-D Basins, Filters and Clearwells, the 185-D, 183-DR, and 189-D/190-D Complex, the 105-D Reactor and the 1700-D Series Buildings. The individual subsites contain the pipeline descriptions and associated structures.</p>		
Process Description:	<p>Water was taken from the Columbia River and treated extensively to purify it prior to use as reactor cooling water. The cooling water was used in a single pass operation and once through the reactor cores became irradiated reactor effluent. The non-radioactive overflows, process cooling waste streams, filter backwashes, and floor drains in non-radioactive areas became process sewer wastes. The 107-D Retention Basin discharged to the process sewer pipeline just prior to the 116-D-5 Outfall Structure.</p>		
Related Sites/ Structures:	<p>The process sewer received effluent from the following facilities: 182-D, 183-D, 183-DR, 184-D, 185-D 186-D, 189-D, 190-D, 105-D, and 107-D. All associated facilities except the 181-D, 182-D, 183-D, and 105-D have been demolished.</p>		
Waste Type:	Water		
Waste Description:	<p>The waste consists of steel piping, concrete, and soil (if contaminants are present). The water supply and process sewer drain pipelines at the 100-D Area provided for the supply and disposal of non-radioactive streams generated in water treatment and water treatment laboratories facilities and powerhouse operations. Known chemical additions to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained near 7.5, free chlorine residual at about 0.2 milligrams per liter, and sodium dichromate was added at a rate of about 2 milligrams per liter. The sodium dichromate product pipelines would have much greater concentrations. Sodium chloride was also used to regenerate water softeners in both water treatment and powerhouse operations.</p> <p>The process sewer system connected to the 116-D-5 (1904-D Outfall) at the Columbia River shoreline. (The outfall and the pipelines that carried the process sewer and reactor effluent to</p>		

vitrified clay pipe (VCP) and was located to the northwest of the 105-D Reactor. The pipelines fed into the 1607-D2:3 portion of the 1607-D2 sanitary sewer system, which was the main sanitary sewer servicing the 100-D Area. It transported sewage from manhole S-21D north to manhole S-25D. This system of sewers was active from 1944 to 1994 and received effluent from the 1700-D, 1704-D, 1707-D, 1707-DA, 1708-D, 1713-D, 1716-D, 1717-D, 1718-D, 1719-D, 1722-D, 182-D, 183-D, 184-D, 185-D, 186-D, 189-D, 190-D, and 108-D Buildings.

Several miscellaneous pipelines crossing over the subsites were encountered during excavation, however, none were connected. All of these pipelines will be addressed separately.

Location: The 100-D-31:1, 1607-D2 septic sewer pipeline subsite is located northwest of the 105-D Reactor in the 100 DR-1 Operable Unit. The 100-D-31:1 waste site addresses a portion of the 1607-D2 septic sewer pipeline that transported sewage from manhole S-21D north to manhole S-25D.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil.

Closure Info: 100-D-31:1 and 100-D-31:2 were addressed as a group. The information below documents information for the group of sites.

Remedial action was performed between June 18, 2007 and July 17, 2008. The final excavation depths for 100-D-31:1 and 100-D-31:2 were approximately 5 m (16 ft) and 3 m (9 ft), respectively. The excavation resulted in approximately 2,512 bank cubic meters (BCM) (3,287 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility, including 756 m (2,480 ft) of pipe.

The Contaminants of potential concern for the subsites included antimony, barium, copper, cadmium, chromium (total), lead, manganese, nickel, silver, zinc, mercury, hexavalent chromium, cesium-137, cobalt-60, europium-152, europium-154, europium-155, uranium-233/234, uranium-235, uranium-238, polycyclic aromatic hydrocarbons (PAH), total petroleum hydrocarbons (TPH), volatile organic compounds (VOCs), and polychlorinated biphenyls (PCBs).

Verification sampling was performed on August 11 and 12, 2009. The laboratory-reported verification data results for all constituents were stored in the WCH Environmental Restoration project-specific database prior to archival in the Hanford Environmental Information System and were also presented as Attachment 1 of the 95% upper confidence limit (UCL) calculation (Appendix B of the RSVP).

Analytical results show that residual contaminant concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

The SubSite is Part Of:

Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:2

Classification: Accepted

Names: 100-D-31:2; 1700-D Series Buildings Septic Sewer Pipelines

Reclassification: Interim Closed Out (10/7/2010)

Type: Process Sewer**Start Date:****Status:** Inactive**End Date:**

Description: The Remaining Sites Verification Package for subsites 100-D-31:1 and 100-D-31:2, RSVP-2010-006, has documented that the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) have been met as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17, Rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999).

Subsite two consisted of multiple segments of 8 in. diameter VCP, totaling approximately 365 m (1,200 ft) in length. This pipeline segment was located between manholes S-19D and S-21D, where it connected with the 100-D-31:1 pipeline. The pipelines from the following 1700-D Buildings were connected to the 100-D-31:2 pipelines: 1704-D, 1707-D, 1707-DA, 1713-DD, 1717-D, 1719-D, and 1722-D. Another portion of the pipeline was located east of manhole S-21D and serviced the 108-D Building.

For specific remedial information see subsite 1.

Waste Type: Not Specified**Waste Description:** The waste consists of steel piping, concrete, and soil .

Closure Info: 100-D-31:1 and 100-D-31:2 were addressed as a group. The information below documents information for the group of sites.

The SubSite is Part Of:**Code:** 100-D-31**Names:** 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

190-D High Bay - A 45.7 cm (18 in) process sewer line exited the north side to a 91.4 cm (36 in) line, which headed west to the 205.74 cm (6 ft 9 in) line to the 116-D-5 outfall, and a 76.2 cm (30 in) process sewer line exited the north side to a 91.4 cm (36 in) line, which headed west to the 205.74 cm (6 ft 9 in) line to the 116-D-5 Outfall. Three other lines exited the east side of the 190-D Building, a 10 cm (4 in) cast iron, a 15 cm (6 in) cast iron, and a 15 cm (6 in) VCP, which all joined into a 15 cm (6 in) VCP that headed north to the west side of the 1728D Building location (M-1904-D, Sheet 5, W-71477).

Location: The 190-D sewer pipelines are bound by manholes S-13D and P-9D to the east and manholes S-11D and P-13D to the west. The pipelines included in this subsection transported process sewer waste from the northeast corner of the 186-D Building and the north side of the 190-D Building toward the 116-D-5 outfall. The pipelines also transported the septic sewer waste from the 185-D, 186-D, and 190-D Buildings.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil .

Closure Info: Remedial action at the 100-D-31:4 pipeline subsite was performed between September 26, 2008 and December 10, 2009. Excavation continued until all debris and contamination associated with the pipeline structure had been removed. The site was excavated to depths ranging from approximately 3.8 to 4.8 m (13 to 16 ft), resulting in approximately 9,883 BCM (12,926 BCY) of soil and piping/debris being removed for disposal at ERDF. In addition, approximately 636 linear m (2,087 linear ft) of pipe were removed. This piping was sorted within the excavation and direct loaded for disposal at ERDF.

During the remediation of the 100-D-31:4 pipeline subsite, it was determined that construction of a land bridge spanning a portion of the open excavated waste site trench was needed to support both existing and future pump-and-treat lines prior to cleanup verification statistical sampling. Three focused samples were collected within 1 m (3.3 ft) of either side of the pipeline along the center line of the bottom of the 100-D-31:4 excavation. No results from focused sampling within the area of the then proposed land bridge were above shallow zone remedial action goals (RAGs). The Washington State Department of Ecology approved construction of the land bridge in a regulatory agreement titled ???Soil Bridges at 100-D-31:4 and 100-D-31:8?? (Ecology 2009). The 100-D-31:4 land bridge was constructed on November 16, 2009.

The SubSite is Part Of:

Code: 100-D-31

Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:5

Classification: Accepted

Names: 100-D-31:5; 188-D Ash Disposal Pipeline

Reclassification: Interim Closed Out (10/22/2009)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The Remaining Sites Verification Package for the 100-D-31:5 subsite, (RSVP-2008-058), documents that the subsite has achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and in the Remaining Sites ROD.

The site is a 133 meter (370 foot) long underground 20 centimeter (8 inch) diameter ashcolite pipeline. The pipeline was located in a north-south orientation between the former 184-D Powerhouse and the 188-D Ash Disposal Basin. From the powerhouse, the 100-D-31:5 pipeline

carried a slurry of coal ash and raw river water. The slurry was transported to the ash disposal basin (126-D-1 waste site).

Remedial action was performed between October 29, 2007, and January 9, 2008. There were no anomalies or stained soil discovered during remediation. Even though coal ash was present throughout the site, no ash or sediment was present in the pipeline. The 100-D-31:5 site was excavated to between 1.2 m (4 ft) and 1.7 m (5.5 ft) below grade. Approximately 852 bank cubic meters (BCM) (1,114 bank cubic yards [BCY]) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill. Approximately 94 BCM (123 BCY) of material was disposed at the Environmental Restoration Disposal Facility, including removal of the pipeline.

The COPCs for verification sampling were determined using historical process knowledge. Metals were identified as site COPCs; hexavalent chromium was also included as a COPC to support an evaluation of chromium in the vadose zone soil at the 100-D Area. Analytical data from coal ash samples collected in 1992 from the 188-D ash disposal basin indicated the presence of fluoride, nitrate, sulfate, and cyanide. Therefore, these constituents were added to the list of COPCs.

A preliminary examination of the analytical data from samples collected on August 26, 2008 found hexavalent chromium data with elevated practical quantization limits. In an effort to get better quality assurance/quality control (QA/QC) values, the project recollected the entire sample set on October 13 and December 30, 2008 and analyzed them for hexavalent chromium. The resulting data returned improved QA/QC values for hexavalent chromium. Rather than pick and choose individual sample data from the two sets of data the project chose to use the second data set, with the improved QA/QC values. However, it should be noted that the analytical results for hexavalent chromium were non-detected for all samples in both data sets.

Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the ROD, a comparison against ecological risk screening levels has been made for the site contaminants of potential concern and other constituents. Screening levels were exceeded for barium, boron, mercury, manganese, selenium, vanadium, and zinc at the 100-D-31:5 subsite. Exceeding screening values is intended to trigger additional evaluation and does not necessarily indicate the existence of additional risk to ecological receptors. Concentrations of manganese, mercury, and vanadium are below site background levels. Concentrations of barium, selenium, and zinc are above background levels. No established background value is available for boron, although one is expected to be established as part of the Risk Assessment/Feasibility Study (RI/FS). Concentrations of barium, boron, selenium, and zinc will be evaluated in the context of additional lines of evidence for risk to ecological receptors as part of the final closeout decision for this site.

A calculation of the Hazard Quotient and Carcinogenic Risk Calculation for Protection of Groundwater was provided in Appendix A of the RSVP. A comparison of ecological risk screening levels to the barium, boron, mercury, manganese, selenium, vanadium, and zinc data was provided in Appendix E of the RSVP.

Verification sampling results support an evaluation that residual contaminant concentrations at the subsite do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep).

Location: The pipeline was located in a north-south orientation between the former 184-D Powerhouse and the 188-D Ash Disposal Basin.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil .

The SubSite is Part Of:**Code:** 100-D-31**Names:** 100-D-31; 100-D Water Treatment Facilities Underground Pipelines**Code:** 100-D-31:6**Classification:** Accepted**Names:** 100-D-31:6; 184-D Powerhouse Sewer Pipelines**Reclassification:** Interim Closed Out (8/24/2009)**Type:** Process Sewer**Start Date:****Status:** Inactive**End Date:**

Description: The Remaining Sites Verification Package, (RSVP-2008-054) documents that the 100-D-31:6 (184-D Powerhouse Sewer Pipelines) subsite, has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) for interim closure. The objectives were established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. This subsite consists of four segments of sewer pipes, approximately 329 m (1,079 ft) of vitreous clay pipe encased in concrete and 30 m (98 ft) of steel pipe that serviced the 184-D Powerhouse: two 30.48 cm (12 in) process sewer lines exited the south side, each joining a 45.72 cm (18 in) line to the 205.74 cm (6 ft 9 in) line to the 116-D-5 outfall; & two 38.1 cm (15 in) process sewer lines exited the north side and headed east, connecting to the 205.74 cm (6 ft 9 in) line to the 116-D-5 outfall.

Location: The 100-D-31:6 subsite is located northwest of the 105-D Reactor and included a total of four pipeline segments, two on the north side and two on the south side of the 184-D Powerhouse.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil .

Closure Info: Remedial action at the subsite was performed between November 1, 2007 and March 5, 2008. The site was excavated between 1.5 m (5 ft) and 3.3 m (7.5 ft) below grade resulting in approximately 371 bank cubic meters (BCM) (485 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility, including approximately 329 m (1,079 ft) of vitreous clay pipe encased in concrete and 30 m (98 ft) of steel pipe. Approximately 2,440 BCM (3,192 BCY) of soil (overburden) was removed and stockpiled for evaluation as clean backfill.

The 100-D Area Technical Baseline Report indicated sodium sulfate, tri-sodium phosphate, and chromates were used to treat the 184-D powerhouse boiler water; therefore, analysis for anions by ion chromatography was added primarily to measure levels of sulfate. Verification sampling was performed on October 7, 2008, to collect data to determine if the remedial action goals had been met. The contaminants of potential concern for verification sampling included total chromium, lead, mercury, anions, pesticides, and polycyclic aromatic hydrocarbons. Although not COPCs, arsenic, antimony, barium, beryllium, boron, cadmium, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc were included in the analyses of inductively coupled plasma (ICP) metals.

Verification samples were analyzed using U.S. Environmental Protection Agency-approved analytical methods. The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to archival in the Hanford Environmental Information System and are presented in the RSVP in Attachment 1 of the 95%

UCL calculations.

Soil cleanup levels were established in the ROD based on a limited ecological risk assessment. Although not required by the ROD, a comparison against ecological risk screening levels has been made for the site contaminants of concern and other constituents and is presented in Appendix C. Screening levels were exceeded for antimony, barium, boron, manganese, mercury, vanadium, and zinc. Exceeding screening values is intended to trigger additional evaluation and does not necessarily indicate the existence of risk to ecological receptors. Because concentrations of antimony, manganese, and vanadium are below background levels, it is believed that the presence of these constituents does not pose a risk to ecological receptors. Background values for Washington State are used only when Hanford Site specific background values are not available. An established background value is not available for boron at this time. Mercury (95% upper confidence limit [UCL] value above background), barium (95% UCL value below background but individual statistical sample results above background), and boron (no established background), will be evaluated in the context of additional lines of evidence for risk to ecological receptors as part of the final closeout decision for this site.

The subsite has been remediated in accordance with the Remaining Sites ROD and the RDR/RAWP. Analytical results for the sampling decision units were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. Accordingly, an interim closure reclassification is supported for the 100-D-31:6 subsite. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

The SubSite is Part Of:

Code: 100-D-31

Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:7

Classification: Accepted

Names: 100-D-31:7; 116-D-5 and D-Pond Sewer Pipeline

Reclassification: Interim Closed Out (10/14/2010)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The Remaining Sites Verification Package for the 100-D-31:7, RSVP-2010-046, has documented that the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) have been met as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Remaining Sites Record of Decision (ROD).

Subsite 7 consisted of pipelines that transported process and septic sewer waste from 1944 to 1994. This subsite is a 2-meter (6-foot, 9-inch) square pipeline that collected sewer wastes from smaller pipelines and fed into the 116-D-5 Outfall. The pipeline was approximately 480 meters (1,574.9 feet) long. The 116-D-5 and D-Pond sewer pipeline transported process waste from junction box P 13D north to the 116-D-5 outfall. It also includes the vitrified clay pipe transporting septic sewer waste from manhole S-19D to manhole S-18D.

Location: The 100-D-31:7 is a north-south oriented pipeline located north-northwest of the 105-D Reactor.

Waste Type: Not Specified

Waste The waste consists of steel piping, concrete, and soil .

Description:

Closure Info: Remedial action at the subsite began on November 5, 2007, and continued through December 9,

2009. The site was excavated to depths between 12 m (40 ft) and 16 m (53 ft) below grade, resulting in approximately 17,684 bank cubic meters (BCM) (23,130 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility, including approximately 480 m (1,574.9 ft) of pipe.

An intact 946.3-L (250-gal) motor oil storage tank was found within the layback of the subsite approximately 12 m (36 ft) west of the demolished 1716-D Building. The tank was identified as being associated with the 130-D-1, 1716 Gasoline Storage Tank waste site.

While relocating the tank from the excavation layback, approximately 95 L (25 gal) of oily fluid spilled onto a polyethylene-lined containment area set up adjacent to the tank. No oily fluid was released to the soil. The oily fluid was sampled for waste designation, and the remaining fluid was absorbed using soil from the surrounding area. The soil underneath the tank was inspected and it was determined that no leaks had occurred from the pipe that was previously attached to the tank. All piping associated with the 130-D-1 waste site that was present within the 100-D-31:7 excavation was removed. The remaining soil will be assessed during remediation and closeout verification of the 130-D-1 waste site.

Contaminants of potential concern for the subsite were identified based on process knowledge and existing information about the 100-D-31 pipelines sites plus those identified in the 100 Area RDR/RAWP included: chromium (total) and mercury, antimony, barium, copper, cadmium, lead, manganese, nickel, silver, zinc, hexavalent chromium, cesium-137, cobalt-60, europium-152, europium-154, europium-155, strontium-90, uranium-233/234, uranium-235, uranium-238, pesticides, semivolatile organic compounds (SVOCs), polycyclic aromatic hydrocarbons (PAH), total petroleum hydrocarbons (TPH), and polychlorinated biphenyls.

On February 10, 2010, four verification soil samples were collected to support the construction of a land bridge at the northern end of the 100-D-31:7 pipeline subsite. The remaining statistical and focused verification soil samples were collected on April 27 and 29, 2010. All sampling was performed in accordance with the 100 Area Remedial Action Sampling and Analysis Plan. The laboratory-reported verification data results for all constituents were stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were also presented as part of the 95% UCL calculation in Appendix B of the RSVP.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

The SubSite is Part Of:

Code: 100-D-31

Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:8

Classification: Accepted

Names: 100-D-31:8; 183-D and 186-D Northern Sewer Pipelines

Reclassification: Interim Closed Out (10/18/2011)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-D-31:8 pipeline subsite is made up of piping from two different sewer systems (sanitary and process sewers).

The following are part of the process sewer:

A 121.94 cm (48 in) reinforced concrete process sewer line exited the north side of the 183-D filter Plant connecting to a 144.2 cm (4 ft 9 in) concrete box pipe, connecting to a 167.54 cm (5 ft 6 in) concrete box pipeline, to the 205.74 cm (6 ft 9 in) line (100-D-31:7) to the 116-D-5 outfall (W-72688).

The following are part of the sanitary sewer:

A 20 cm (8 in) vitrified clay pipeline north of the 183-D filter plant and extending to above the northwest side of the 186-D Building and connecting to the 100-D-31:4 pipeline (W-72688).

Location: The 183-D and 186-D northern sewer pipelines are vitrified clay pipelines and reinforced concrete pipelines exiting the north side of the 183-D Building, as well as an east-west trending reinforced concrete pipeline segment from junction box P-3D to junction box P-13D.

Process Description: The process sewer received raw water drained from the 182-D and 183-D Buildings (also see 100-D-31:11). It also received waste water (backwash) and overflow from the 183-D Filter Building. The sanitary sewer received septic waste from the lavatories in the 182-D Pump House and 183-D Headhouse. The 100-D-31:8 pipelines received waste water from the north side of the 182-D and 183-D Buildings via the 100-D-31:11 pipelines at junction box P-3D and at a second connection along the same pipeline approximately 23 meters (75 ft) to the south. The 100-D-31:8 pipelines also received waste water from the 186-D Building where it connected to the 100-D-31:9 pipelines at manhole S-10D and at a second connection approximately 18 meters (59 ft) to the east along the same pipeline. The waste water was then transferred to the 100-D-31:4 and 100-D-31:7 pipeline segments at junction box P-13D and manhole S11D.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil .

Closure Info: 100-D-31:8, 100-D-31:9 and 100-D-31:10 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-31:8 subsite was performed between August 27, 2009, and May 19, 2010. The final excavation depth for 100-D-31:8 was approximately 9 meters (30 ft). The excavation resulted in approximately 5,732 bank cubic meters (BCM) (7,509 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Additionally, approximately 535 meters (1,755 ft) of pipe were removed and disposed at the ERDF. Approximately 61,330 BCM (80,432 BCY) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill. It was determined that construction of a land bridge spanning a portion of the open excavated waste site trench was needed to support both existing and future pump-and-treat lines prior to conducting cleanup verification sampling. Demolition of the 1902-D water tank in January 2010 resulted in a rust stained area outside the north end of the 100-D-31:8 waste site footprint. This area was sampled (J19KJ9) for characterization and the impacted surface soils were disposed of at ERDF.

Remedial action at the 100-D-31:9 subsite was performed between July 15, 2009, and April 21, 2010. The final excavation depth for 100-D-31:9 was approximately 7 meters (23 ft). The excavation resulted in approximately 11,485 BCM (15,045 BCY) of material removed for disposal at the ERDF. Additionally, approximately 705 meters (2,313 ft) of pipe were removed and disposed of at the ERDF. Approximately 44,310 BCM (57,957 BCY) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill.

Remedial action at the 100-D-31:10 subsite was performed between December 29, 2009, and January 27, 2010. The final excavation depth for 100-D-31:10 was approximately 3 meters (10 ft). The excavation resulted in approximately 208 BCM (272 BCY) of material removed for disposal at the ERDF. Additionally, approximately 128 meters (420 ft) of pipe were removed and disposed of at the ERDF. Approximately 1,544 BCM (2,019 BCY) of soil (overburden) was removed and stockpiled for evaluation for use as clean backfill. A section of the 100-D-31:10 pipeline subsite is located adjacent to the active 199-D5-33 groundwater monitoring well. To maintain structural integrity of the well, a section of the 100-D-31:10 pipeline subsite was left in place, resulting in a small land bridge measuring 11 meters (36 ft) wide across the pipeline excavation.

On February 22, 2010, confirmatory sampling was being conducted at 100-D-63, test pit 16. While backfilling the test pit, a piece of concrete fell out of the backhoe bucket and struck one of the two pipes in the bottom of the excavation, causing it to leak water. Approximately 37,854 liters (10,000 gal) of raw water was released due to this pipeline not being properly valved off from the export water line. It was unclear whether the leaking water was contaminated. Therefore, Ecology agreed to allow the released raw water to be pumped to the 100-D-31:9 open excavation. In the course of isolating and draining the export water pipeline to repair the leak, and waiting for approval to pump the water into the 182-D Reservoir, approximately 7,571 liters (2,000 gal) of water was pumped from the export water line to the 100-D-31:8 subsite. On March 2, 2010, in-process samples were collected from inside the water release footprints within the 100-D-31:8 and 100-D-31:9 open excavations. On March 4, 2010, an in-process soil sample (J19L76) was collected from outside the water release footprint in 100-D-31:9. Based on results of these in-process samples, the soil from within the water release footprints was placed in the associated overburden stockpiles. These in-process sample results were not used for determining the interim closure.

The SubSite is Part Of:

Code: 100-D-31

Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:9

Classification: Accepted

Names: 100-D-31:9; 183-D and 186-D Process Sewer Pipelines

Reclassification: Interim Closed Out (10/18/2011)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-D-31:9 pipeline subsite is made up of piping from two different sewer systems (sanitary and process sewers).

The following are part of the process sewer:

A 106.7 cm (42 in) process sewer line exiting the east side of the 183-D Building to junction P-6D, connecting to a 114.3 cm (3 ft 9 in) pipe (100-D-31:8) that runs north to a 167.54 cm (5 ft 6 in) line, east to the 205.74 cm (6 ft 9 in) line (100-D-31:7) to the 116-D-5 outfall (W-72883, W-72688, W-72689). Two concrete process sewer pipes running north-south between the 183-D and 186-D buildings, joining together to a 114 cm (45 in) reinforced concrete box pipe between the buildings (M-1904-D, Sheet 5).

The following are part of the sanitary sewer:

A 20 cm (8 in) vitrified clay pipeline that exited the east side of the 183-D building and turned

north to connect to the 100-D-31:8 pipeline (W-72883). Two 15 cm (6 in) vitrified clay pipelines that exited the west side of the 186-D Building and connected to the 20 cm (8 in) main sanitary sewer trunkline (W-71788).

Location: The 183-D and 186-D process sewer pipelines extend from the intersection with the reinforced concrete pipe (RCP) exiting the east side of the 183-D Building to manhole S-10D, and comprise the vitrified clay pipe and RCP pipelines from the east side of the 183-D Building and the west side of the 186-D Building.

Process Description: The process sewer received waste water from floor drains and sumps in the 183-D Pump House and drainage from the 186-D Waste Acid Reservoir (120-D-2). A portion of the process sewer was the main trunkline that was downstream from the 100-D-50:7 pipeline. The sanitary sewer received septic waste from the lavatories in the 183-D Pump House and 186-D Demineralization Plant. The 100-D-31:9 pipelines consist of the 183-D and 186-D Buildings process sewer. These pipelines exit the buildings at various locations, including a 24 inch diameter vitrified clay pipe (VCP) and a 54 inch diameter concrete pipe, which are continuations of the 100-D-50:7, 183DR Head House Floor Drain and Catch Basins Pipelines, and connect to the 100-D-31:8 pipelines at manhole S-10D and a second connection approximately 18 meters (59 ft) to the east along the same pipeline.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil .

Closure Info: 100-D-31:8, 100-D-31:9 and 100-D-31:10 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-31:8 subsite was performed between August 27, 2009, and May 19, 2010. The final excavation depth for 100-D-31:8 was approximately 9 meters (30 ft). Code: 100-D-31

Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:10

Classification: Accepted

Names: 100-D-31:10; 182-D North Septic Sewer Pipeline

Reclassification: Interim Closed Out (10/18/2011)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite is a 20 cm (8 in) vitrified clay process sewer pipeline about 144 meters long.

Location: The pipeline exited the northwest corner of the 182-D Building, turns east and continues on the north side of the 182 Building, and ends at manhole P-20D.

Process Description: The process sewer receives drainage from the 182-D Inlet House No. 1. The structure contains the main level control cone valves for the inlet pipes to the reservoir. The second floor contains the chlorinating equipment for treating the incoming water (HAN-10970, Volume 3). The 100-D-31:10 pipelines consist of the 182-D Building septic sewer. These pipelines exit the building at various locations and connect to the 100-D-31:11 pipelines at manhole P-20D. The 100-D-31:11 pipelines transported the waste water to the 100-D-31:8 pipelines at the junction box P-3D and a second connection along the same pipeline approximately 23 meters (75 ft) to the south.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil.

Closure Info: 100-D-31:8, 100-D-31:9 and 100-D-31:10 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-31:8 subsite was performed between August 27, 2009, and May 19, 2010. The final excavation depth for 100-D-31:8 was approximately 9 meters (30 ft). The excavation resulted in approximately 5,732 bank cubic meters (BCM) (7,509 bank cubic yards [BCY]) of material removed for disposal at the Environmental Restoration Disposal Facility (ERDF). To maintain structural integrity of the well, a section of the 100-D-31:10 pipeline subsite was left in place, resulting in a small land bridge measuring 11 meters (36 ft) wide across the pipeline excavation.

On February 22, 2010, confirmatory sampling was being conducted at 100-D-63, test pit 16. While backfilling the test pit, a piece of concrete fell out of the backhoe bucket and struck one of the two pipes in the bottom of the excavation, causing it to leak water. Approximately 37,854 liters (10,000 gal) of raw water was released due to this pipeline not being properly valved off from the export water line. It was unclear whether the leaking water was contaminated. Therefore, Ecology agreed to allow the released raw water to be pumped to the 100-D-31:9 open excavation. In the course of isolating and draining the export water pipeline to repair the leak, and waiting for approval to pump the water into the 182-D Reservoir, approximately 7,571 liters (2,000 gal) of water was pumped from the export water line to the 100-D-31:8 subsite. On March 2, 2010, in-process samples were collected from inside the water release footprints within the 100-D-31:8 and 100-D-31:9 open excavations. On March 4, 2010, an in-process soil sample (J19L76) was collected from outside the water release footprint in 100-D-31:9. Based on results of these in-process samples, the soil from within the water release footprints was placed in the associated overburden stockpiles. These in-process sample results were not used for determining the interim closure.

The SubSite is Part Of:

Code: 100-D-31

Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:11

Classification: Accepted

Names: 100-D-31:11; 182-D and 183-D Sewer Pipelines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-D-31:11 pipeline subsite is made up of piping from two different sewer systems (sanitary and process sewers).

The following are part of the process sewer:

A 91.4 cm (36 in) line exits northeast side of the 182-D Reservoir, east to the 121.9 cm (48 in) process sewer line, ending up at the 116-D-5 outfall (W-71520).

A 106.7 cm (42 in) process sewer line exits the east corner of the building to the 121.9 cm (48 in) line heading to the 116-D-5 outfall (W-72845).

A 20 cm (8 in) vitrified clay sewer pipe exits the northeast corner of the 182-D building and connects to the 91.4 cm (36 in) line mentioned above (W-72835).

A 45.5 cm (18 in) vitrified clay pipe exited the west side of 183-D and connected to the 121.9 cm (48 in) north-south concrete pipe between the 182-D and 183-D Buildings.

Also, see the site comments for additional short segments subsequently added to this subsite (W-72688).

The following are part of the sanitary sewer:

A 15 cm (6 in) vitrified clay sewer pipe exits the east side of the 182-D building and joins with the 20 cm (8 in) vitrified clay pipe traveling north between the 182-D and 183-D buildings (H-1-26378).

Location: The 182-D and 183-D sewer pipelines transported process sewer and septic sewer waste from the east side of the 182-D building and the west side of the 183-D Building. The subsite is bounded to the south by the concrete manhole, and it is bounded at the north end by junction box P-3D. Additional short segments, transferred from other subsites, are connected to the 183-D and 182-D Buildings.

Process Description: The process sewer received raw water drained from the suction wells in the 182-D Pump House; raw water from the 182-D Reservoir overflow and drainage from the 182-D Inlet House No. 1 (100-D-31:10). The sanitary sewer received septic waste from the lavatories in the 182-D Pump House and 183-D Headhouse.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil .

The SubSite is Part Of:

Code: 100-D-31

Names: 100-D-31; 100-D Water Treatment Facilities Underground Pipelines

Code: 100-D-31:12

Classification: Accepted

Names: 100-D-31:12; 183-D West Process Sewer Pipelines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 183-D west process sewer pipelines transported treated cooling water from eight process sewer pipelines exiting the west side of the 183-D Building. The pipeline subsite is bounded on the north end by junction box P-2D.

Location: Between the west side of the 183-D Building and the junction box P-2D to the north.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil .

The SubSite is Part Of:**Code:** 100-D-31**Names:** 100-D-31; 100-D Water Treatment Facilities Underground Pipelines**Code:** 100-D-32**Classification:** Accepted**Names:** 100-D-32; Minor Construction Burial Ground #6**Reclassification:** Interim Closed Out (12/10/2009)**Type:** Burial Ground**Start Date:** 1/1/1956**Status:** Inactive**End Date:****Description:** The site has been evaluated and reclassified to interim closed out. It consisted of a small 3.0-meter (10-foot) by 3.0-meter (10-foot) burial ground. During the March 1999 visit, there was no evidence of the site.**Location:** The site is approximately 150 meters (500 feet) southeast of the 105-D Reactor Building and 25 meters (82 feet) north of the railroad tracks (north of 118-D-3 Burial Ground).**Process Description:** The trench was excavated in the Fall of 1956. HW-46715 states the site will be used for disposal of contaminated material and equipment. It has been assumed that the site was used as planned.**Waste Type:** Equipment**Waste Description:** The burial ground was excavated to receive contaminated reactor and effluent system equipment. Potential contaminants include: Co-60, Ni-63, No-59, Sm-151, Pd-107, Sr-90, Ag-108, Am-241, Ba-133, C-14, H-3, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113, Kr-85, U-238, Tc-99, Zr-93, chromium, lead and mercury.**Closure Info:** The Cleanup Verification Package for 100-D-32 Minor Construction Burial Ground #6, (CVP-2009-00003), has documented that site verification sampling results support a reclassification to Interim Closed Out. The waste site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (100 Area Burial Grounds), Benton County, Washington (Burial Grounds ROD).

Remedial action began on August 28, 2007, with the removal of 375 bank cubic meters (BCM) (490 bank cubic yards [BCY]) of overburden material. The overburden was stockpiled east of the burial ground. Excavation continued through September 5, 2007, to a remedial design depth of approximately 3 m (10 ft), resulting in approximately 600 BCM (785 BCY) of material removed for disposal at ERDF. Only a small amount of concrete debris was unearthed in the northwest corner of the site.

Given that only a small amount of concrete debris was encountered during excavation, the floor of the excavation had not reached beyond the limit of disturbed soil, and the uncertainty of the depth of the burial ground, further exploratory excavation was completed on July 31, 2008, at the base of the burial ground excavation to verify that no waste was present below the 3 m (10 ft) remedial design limit. An additional 525 BCM (687 BCY) of soil was removed from the side slopes and excavation floor and placed on the overburden stockpile. Exploratory excavation was performed to a depth of 6 m (20 ft), with native soil encountered at a depth of approximately 5 m (17 ft) below surface grade.

During remedial excavation only a minor amount of concrete debris was unearthed in the northwest corner of the 100-D-32 Burial Ground. No spent nuclear fuel, anomalous material

(containers, stained soils, or other waste forms), or other waste indicative of the disposal of contaminated material or equipment were discovered. It is likely that the 100-D-32 Burial Ground was never used and, as reported in Heid (1956), it had been excavated and discussed in the context of potential future use (i.e., "will be used").

The contaminants of potential concern (COPCs) for the 100-D-32 Burial Ground are cobalt-60, cesium-137, europium-152, europium-154, americium-241, nickel-63, strontium-90, plutonium-238, plutonium-239, plutonium-240, uranium-238, chromium (total), lead, and mercury as specified in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL 2001a). Due to a site-wide effort to identify the source of chromium contamination in the groundwater, hexavalent chromium was added as a COPC for closeout.

Results of the verification sampling, laboratory analyses, and data evaluations for the site (which includes the remediation footprint and the overburden stockpile) indicated that all RAOs and RAGs for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Verification sampling results show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River.

Code: 100-D-42	Classification: Accepted
Names: 100-D-42; Buried VSR Thimble Site	Reclassification: Interim Closed Out (5/13/2010)
Type: Burial Ground	Start Date: 1/1/1955
Status: Inactive	End Date: 1/1/1955
Description:	The site is a solid waste burial ground. The burial ground is east of the two 152-centimeter (60-inch) reactor effluent lines.
Location:	The site is located east of the 100-D Reactor Building, outside the reactor security fence and south of the railroad spur that services 100-D.
Waste Type:	Equipment
Waste Description:	The waste is a buried Vertical Safety Rod (VSR) thimble. The VSR thimbles were made of aluminum similar to that used in the process tubes and should contain similar isotopic composition. Sampling of process tubes was conducted in March 1967. The radionuclide levels, when decay corrected by Dorian and Richards to March 1977, were 5.9E+03 picocuries of manganese-54 per gram of aluminum and 2.5E+07 picocuries of cobalt-60 per gram of aluminum. When buried, the thimble's exterior surfaces would also have been contaminated with activated graphite products and potassium borate.
Closure Info:	100-D-42, 100-D-43 and 100-D-45 were addressed as a group. The information below documents information for the group of sites.

The Cleanup Verification Package (CVP-2009-00004) demonstrates that the 100-D-42, 100-D-43, and 100-D-45 waste sites have met the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17, Rev. 6) and the Records of Decision (EPA 1999 and 2000). The 100-D-42 Buried VSR Thimble Site was included in the Explanation of Significant Differences for the 100 Area Remaining Sites Interim Remedial Action Record of Decision (EPA, 2004). The 100-D-43 and 100-D-45 Buried VSR Thimble Sites were included in the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, 100-KR-2, Operable Units (EPA 2000).

Due to the close proximity to each other and the type of debris encountered during excavation, the three sites were included in one CVP and interim closed out as one decision unit.

Remedial action at the sites began on September 6, 2007, and was completed on April 22, 2008. Contaminated soil and debris were excavated and removed from the burial grounds for shipment to ERDF. Field observations during excavation indicated the presence of VSR thimbles in two of the three burial grounds. Only concrete debris and plastic sheeting were found to be present in the 100-D-42 Burial Ground. The 100-D-43 Burial Ground contained VSR thimbles and other reactor hardware. Mastic, aluminum pipe, VSR thimbles, reactor hardware, and a drum containing rags were found in the 100-D-45 Burial Ground.

One anomaly was encountered in the 100-D-43 Burial Ground. A 57-L (15-gal) metal container partially filled with liquid was found during excavation. The container was found to have been breached and the contained liquid is suspected to have been water used for dust suppression during excavation activities. No suspect spent nuclear fuel was present in the burial grounds.

The remaining soils at the 100-D-42, 100-D-43, and 100-D-45 waste sites have been sampled, analyzed, and modeled. The results of this effort indicate that the materials containing COCs/COPCs at concentrations exceeding RAGs have been excavated and disposed at ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The excavation area has a maximum depth of approximately 7 m (23 ft). However, the entire excavation area is considered one decision unit and meets the more restrictive shallow zone cleanup criteria. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code: 100-D-45	Classification: Accepted
Names: 100-D-45; 118-D-4B; Burial Ground 4B; Buried VSR Thimble Site	Reclassification: Interim Closed Out (5/13/2010)

Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	100-D-48	Classification:	Accepted
Names:	100-D-48; 100-D Reactor Cooling Water Effluent Underground Pipelines	Reclassification:	Interim Closed Out (4/23/2001)
Type:	Radioactive Process Sewer	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1967
Description:	All four subsites have been remediated and interim closed out. The 100-D-48 site includes those underground pipelines that transported radioactive treated and untreated waste water from the 105-D Reactor Building to the 116-D-7 (107-D) Retention Basin and the 116-D-5 Outfall. The included pipeline components are listed below. There are many small drain pipelines that leave from the east and south sides of the 105-D Reactor Building and terminate at the 132-D-3 (1608-D) Building site. The pipelines that run from the 105-D Reactor and the 132-D-3 (1608-D) Building to either the 116-D-1A Trench and 116-D-1B Trench or connect to the main cooling water effluent pipelines are part of this site. The main cooling water effluent pipeline is a large 1.5-meter (60-inch) diameter reinforced concrete pipeline that exits the 105-D Reactor		

Building on the north side and continues north to the 116-D-7 (107-D) Retention Basin. A map in the Dorian and Richards document, UNI-946, indicates that some sections of the pipeline were replaced at least once (as does M-1904-D Sheet 8). The second (replacement) pipeline begins at a junction box south of the 116-D-7 (107-D) Retention Basin and runs parallel to the original pipeline up to the 116-D-7 (107-D) Retention Basin. Currently, a portion of the steel replacement pipeline remains in place above grade at the retention basin, and a soil berm indicates the location of the pipeline. This pipeline system also includes a 1.5-meter (60-inch) diameter by 1.3-centimeter (0.5-inch) thick wall, carbon steel cross-tie pipeline to the 105-DR effluent pipelines that begins adjacent to the 103-D Building and connects at a junction box to the west 100-DR Reactor Cooling Water Effluent Pipeline (site 100-D-49). This site includes a single pipeline that runs from the west end of the 116-D-7 (107-D) Retention Basin to the 116-DR-1 Trench and 116-DR-2 Trench and two pipelines from the west end of the 116-D-7 (107-D) Retention Basin to the 116-D-5 Outfall. Because of their length, these pipelines have been broken into four subsites: 100-D-48:1, the pipelines from 116-D-7 to the outfalls; 100-D-48:2, the pipelines from D Avenue to 116-D-7; 100-D-48:3, the pipelines from D Avenue to the 105-D Reactor; and 100-D-48:4, the small cooling water effluent pipelines at the 105-D Reactor. The site does not include the facilities where the pipelines terminate, or the pipelines (100-D-60) from the 116-D-5 Outfall to the bottom center of the Columbia River. The pipelines associated with (100-D-49) 100-DR Reactor Cooling Water Effluent Underground Pipelines or (100-D-50) 100-DR Reactor Process Sewer Underground Pipelines [pipelines that transported nonradioactive treated and untreated waste water from the 183-DR, 183-DR Clearwell area and the 105-DR Reactor Buildings to the 100-D-8 (1907-DR) Outfall] are not included in this site.

Location: Generally, the underground pipelines run in a north-south direction north of the 105-D Reactor, go to the 116-D-7 Retention Basin, and from there end at the 116-D-5 Outfall. Pipeline descriptions and associated structures are as follows. 105-D Reactor: - a 20 centimeter (8 inch) vent pipe exits the north side and extends to a junction box in the cross-tie pipeline - a 15 centimeter (6 inch) line and a 20.32 centimeter (8 inch) line exit the northeast corner to a 76 centimeter (30 inch) pipe, to a diversion box for the 116-D-1A trench - a 30 centimeter (12 inch) effluent line exits the northeast corner and runs to the 152.4 centimeter (60 inch) DR effluent mainline to 116-DR-9 - a 41 centimeter (16 inch) effluent pipe exits the east side and runs to a junction box, then to 116-D-1A - a 66 centimeter (26 inch) effluent line exits the south side and runs to a 76.2 centimeter (30 inch) line - a 152 centimeter (60 inch) main line runs to the 116-D-7 Retention Basin from the north side. A new main line was made just east of the original, crossing the original line approximately 160 meters (530 feet) south of the basin - a 152 centimeter (60 inch) cross-tie line connects the D and DR effluent lines, approximately 75 meters (250 feet) north of the 105-D Reactor. 1608-D Waste Water Pump House: - a 15 centimeter (6 inch) waste pipe exits the south side and proceeds east to the 116-D-1A Trench - a 61 centimeter (24 inch) pipe exits the east side, then runs north to the new 168 centimeter (66 inch) effluent line to 116-D-7 - a 66 centimeter (26 inch) line exits the east side and continues to the southeast corner of the 105-D Reactor. 107-D Retention Basin: - a 107 centimeter (42 inch) bypass line flows from the north west corner east to the 116-DR-1&2 Trench - a 107 centimeter (42 inch) line flows out the west end to the 116-D-5 Outfall - a 152 centimeter (60 inch) bypasses the before- mentioned 107 centimeter (42 inch) line, and flows northwest intersecting the 152 centimeter (60 inch) line coming from the DR retention basin.

Process Description: The pipelines were used to dispose of radioactive cooling and waste water from the reactor facility. One large main effluent pipelines drained cooling water from the 105-D Reactor. The small effluent pipelines that drained process waste from the sides (east and south) of the 105-D were joined into a single pipeline that ran to the 1608-D Building (Waste Water Pumping Station or Process Lift Station). The 1608-D Building was a rectangular shaped, two-story, reinforced concrete structure that was half below grade elevation. The purpose of this facility was to pump process effluent to the main effluent pipeline.

Related Sites/ Structures: The associated structures are the 105-D Building, the 132-D-3 (1608-D), the 116-D-7 Retention

Structures: Basin and the 116-D-5 Outfall. Other related sites are the 116-D-1A, 116-D-1B Trenches, and 116-DR-1, 116-DR-2 Trench, 100-D-85 105D Reactor Effluent Pipelines, 100-D-49.

Waste Type: Process Effluent

Waste Description: The waste is contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radionuclides discovered at the retention basin during sampling by Dorian and Richards (1978) included the following: plutonium-238, cesium-134, plutonium 239/240, cesium-137, strontium-90, hydrogen-3, uranium, europium-152, europium-154, europium-155, nickel-63, cobalt-60, and carbon-14.

This Site has the Following SubSites:

Code: 100-D-48:1

Names: 100-D-48:1; North Pipelines from 116-D-7 to the Outfalls

Code: 100-D-48:2

Names: 100-D-48:2; West Pipelines from D Avenue to 116-D-7

Code: 100-D-48:3

Names: 100-D-48:3; Effluent Pipelines from D Avenue to 105-D Reactor

Code: 100-D-48:4

Names: 100-D-48:4; Small Cooling Water Effluent Pipelines at 105-D Reactor

Code: 100-D-48:1

Classification: Accepted

Names: 100-D-48:1; North Pipelines from 116-D-7 to the Outfalls

Reclassification: Interim Closed Out (3/19/2001)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-D-48:1 pipeline sections were located north of the 116-D-7 Retention Basin and went to the 116-D-7 (1904-D Outfall). Pipeline components consisted of a 106.7 cm (42 in) reinforced concrete pipeline (RCP) from the retention basin to the outfall structure, a 106.7 cm (42 in) bypass pipeline, a 152.4 cm (60 in) steel pipeline, and a cross-tie pipeline from the 106.7 cm (42 in) RCP to the 152.4 cm (60 in) steel pipeline. These pipelines have been removed.

Location: Generally, the underground pipelines run in a north-south direction north of the 105-D Reactor, go to the 116-D-7 Retention Basin, and from there end at the 116-D-5 Outfall. Pipeline descriptions and associated structures are as follows.

107-D Retention Basin:

- a 107 centimeter (42 inch) bypass line flows from the north west corner east to the 116-DR-1&2 Trench
- a 107 centimeter (42 inch) line flows out the west end to the 116-D-5 Outfall
- a 152 centimeter (60 inch) bypasses the before- mentioned 107 centimeter (42 inch) line, and flows northwest intersecting the 152 centimeter (60 inch) line coming from the DR retention basin.

Waste Type: Not Specified

Waste Description: The waste was contaminated steel piping, concrete, and soil.

Waste Description:

Closure Info: 100-D-48:1, 100-D-49:1, 100-D-19 and UPR-100-D-4 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-48:1/49:1 Pipelines site began on December 28, 1998. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit.

Because remediation of the 100-D-48:1/49:1 Pipelines site required moving an active overhead power line, site remedial action and sampling were conducted in two phases. These separate phases are reflected by the long time period between the start and finish dates for excavation.

The excavation design depth generally corresponded with the invert elevation of the pipelines. At the completion of remedial action and removal of the engineered structure, the excavation was approximately 15,504 square meters (166,800 square feet) in area with a maximum depth of approximately 6.0 meters (20 feet) below ground surface. Approximately 107,266 metric tons (118,241 tons) of material from the D Area pipelines site have been disposed of at the ERDF through July 2000. Cleanup verification sampling began on April 3, 2000, and was finished on August 8, 2000. The ground surface in the vicinity of the site varies with an average elevation of approximately 134.4 meters (441 feet).

The CVP demonstrated that remedial action at the 100-D-48:1/49:1 Pipelines site achieved the RAOs and corresponding RAGs established in the approved interim action ROD and RDR/RAWP. The remaining soils at the 100-D-48:1/49:1 Pipelines site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-D-48:1/49:1 Pipelines site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. Residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:1/49:1 Pipelines site (includes the 100-D-19 and UPR-100-D-4 sites) is verified to be remediated in accordance with the interim action ROD.

The SubSite is Part Of:

Code: 100-D-48

Names: 100-D-48; 100-D Reactor Cooling Water Effluent Underground Pipelines

Code: 100-D-48:2

Classification: Accepted

Names: 100-D-48:2; West Pipelines from D Avenue to 116-D-7

Reclassification: Interim Closed Out (9/26/2000)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This section contained two parallel pipelines that ran from D Avenue to the 116-D-7 Retention Basin. The most westerly of the pipelines was a 152.4 cm (60 in) reinforced concrete pipeline (RCP). The other was a 152.4 cm (60 in) steel pipeline. At approximately 237 m (777 ft) south of the entrance to the 116-D-7 Retention Basin the steel pipeline entered a junction box. In the junction box, a new 152.4 cm (60 in) pipeline was added. This pipeline continues north to the 116-D-7 Retention Basin.

Location: This segment ran from D Avenue north to the 116-D-7 Retention Basin.

Location:**Waste Type:** Not Specified**Waste Description:** The waste was contaminated steel piping, concrete, and soil.**Closure Info:** 100-D-48:2, 100-D-49:2, UPR-100-D-2 and UPR-100-D-3 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-48:2/49:2 Pipelines site began in July 1997. Excavation of the site involved removing the overburden materials, contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. In August 1999, the excavation reached the design limit. The excavation design depth generally corresponded with the invert elevation of the pipelines. The pipeline excavation profiles are in the sample design calculation briefs in Appendix D.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 20,475 square meters (220,280 square feet) in area with a maximum depth of approximately 6 meters (20 feet) below ground surface. During the time of excavation and waste disposal (December 1998 through September 1999) at the 100-D-48:2/49:2 Pipelines site, approximately 57,106 metric tons (62,960 tons) of material from 100-DR-1 Operable Unit pipelines were disposed of at the ERDF. Cleanup verification sampling began on August 23, 1999, and was finished on October 20, 1999. Because of the length of the pipeline site, the top-of-excavation elevation ranges from 138 meters (453 feet) near the retention basins to 143 meters (469 feet) near D Avenue.

The CVP demonstrated that remedial action at the 100-D-48:2/49:2 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17). Materials from the 100-D-48:2/49:2 Pipelines site that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils, including pipeline overburden stockpiles, have been sampled, analyzed, and modeled to show that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site and in overburden soils pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:2/49:2 Pipelines site is verified to be remediated in accordance with the ROD and may be backfilled. The pipeline overburden is verified as suitable for use as backfill in accordance with the ROD.

The SubSite is Part Of:**Code:** 100-D-48**Names:** 100-D-48; 100-D Reactor Cooling Water Effluent Underground Pipelines**Code:** 100-D-48:3**Classification:** Accepted**Names:** 100-D-48:3; Effluent Pipelines from D Avenue to 105-D Reactor**Reclassification:** Interim Closed Out (4/23/2001)**Type:** Radioactive Process Sewer**Start Date:****Status:** Inactive**End Date:****Description:** This subsite is the last section of the 105-D Reactor cooling water effluent pipelines, extending south from D Avenue to about 1.5 meters (5 feet) from the wall of the reactor foundation. The

subsite includes a 1.5 meter (60 inch) diameter reinforced concrete pipeline extending south from D Avenue to about 1.5 meters (5 feet) from the wall of the reactor foundation, a parallel 2 meter (66 inch) steel pipe that extends south from D Avenue to an east-west trending cross-tie line to 100-D-49:3, a 1.5 meter (60 inch) steel east-west trending cross-tie line connecting these subsite pipelines to 100-D-49:3 and two 20 centimeter (8 inch) steel lines ending south from the cross-tie to about 1.5 meters (5 feet) from the wall of the reactor foundation. The Decontamination and Decommissioning project is responsible for the remaining stub as part of the foundation removal.

Location: These pipelines extend south from D Avenue to about 1.5 meters (5 feet) from the wall of the reactor foundation. The site is located near the center of the 100-D/DR Area and is approximately 750 meters (2,461 feet) from the Columbia River at the nearest location.

Process Description: The pipelines were used to dispose of large quantities of radioactive cooling and waste water from the 105-D Reactor facility to the 116-D-7 (107-D) Retention Basin.

Waste Type: Not Specified

Waste Description: The waste was contaminated steel piping, concrete, and soil.

Closure Info: 100-D-48:3, 100-D-49:3, 100-D-5 and 100-D-6 were addressed as a group. The information below documents information for the group of sites.

The sites included in this remediation are 100-D-48:3, 100-D-49:3, 100-D-5, and 100-D-6. The entire remedial action for these sites is referred to as the 100-D-48:3/49:3 pipelines site. Remedial action at the 100-D-48:3/49:3 site began on October 28, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation was completed. The excavation design depth generally corresponded with the invert elevation of the pipelines.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 24,574 square meters (264,517 square feet) in area with a maximum depth of approximately 5.7 meters (18.7 feet). Approximately 55,561 metric tons (61,245 tons) of material from the 100-D-48:4 and 100-D-48:3/49:3 pipeline sites combined were disposed of at ERDF. Overall, approximately 107,266 metric tons (118,241 tons) from all D Area pipeline sites were disposed of at the ERDF through July 2000. Cleanup verification sampling began on June 7, 2000 (for the overburden piles), and was finished on October 4, 2000 (in the excavation). The excavation is being backfilled with appropriate materials to match the surrounding surface grade (average elevation of 143.7 meters [471 feet]).

The CVP demonstrates that the remedial action at the 100-D-48:3/49:3 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved Interim Action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 100-D-48:3/49:3 Pipelines site and overburden have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-D-48:3/49:3 site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the overburden and shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone

(i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:3/49:3 Pipelines site is verified to be remediated in accordance with the ROD.

The SubSite is Part Of:

Code: 100-D-48

Names: 100-D-48; 100-D Reactor Cooling Water Effluent Underground Pipelines

Code: 100-D-48:4

Classification: Accepted

Names: 100-D-48:4; Small Cooling Water Effluent Pipelines at 105-D Reactor

Reclassification: Interim Closed Out (4/23/2001)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite has been remediated and reclassified to interim closed out. It includes the many small drain pipelines that leave from the east and south sides of the 105-D Reactor Building and terminate at the 132-D-3 (1608-D) Building site. The pipelines that run from the 105-D Reactor and the 132-D-3 (1608-D) Building to either the 116-D-1A Trench and 116-D-1B Trench or connect to the main cooling water effluent pipelines are also part of this subsite.

Location: These pipelines are on the north, east, and south sides of the 105-D Reactor.

Waste Type: Not Specified

Waste Description: The waste was contaminated steel piping, concrete, and soil.

Closure Info: Remedial action at the 100-D-48:4 site began on October 28, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit at El. 136 meters (446 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 3,291 square meters (35,420 square feet) in area with a maximum depth of approximately 7 meters (23 feet). Approximately 27,738 metric tons (30,576 tons) of material from the site were disposed of at ERDF. Cleanup verification sampling began on September 11, 2000, and was completed on October 18, 2000. The excavation is to be backfilled with appropriate materials to the reference grade of El. 143 meters (469 feet).

The CVP demonstrates that remedial action at the 100-D-48:4 site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 100-D-48:4 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-D-48:4 site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF, that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

The SubSite is Part Of:

Code: 100-D-48
Names: 100-D-48; 100-D Reactor Cooling Water Effluent Underground Pipelines

Code: 100-D-49
Classification: Accepted
Names: 100-D-49; 100-DR Reactor Cooling Water Effluent Underground Pipelines
Reclassification: Interim Closed Out (1/15/2004)
Type: Radioactive Process Sewer
Start Date: 1/1/1950
Status: Inactive
End Date: 1/1/1967

Description: There are four subsites associated with this site. The entire site includes those underground pipelines that transported radioactive treated and untreated waste water from the 105-DR Reactor Building, and the 132-DR-1 (1608-DR) Building to the 116-DR-9 (107-DR) (107-DR) Retention Basin and both of the 116-D-5 and 116-DR-5 Outfalls. The included pipeline components are listed below. There are many small drain pipelines that originate on the east side of the 105-DR Reactor Building and terminate at the 132-DR-1 (1608-DR) Building site. The drain pipelines that run from the 132-DR-1 (1608-DR) to either the 116-DR-6 Trench or connect to the main cooling water effluent pipelines are part of this site. The main cooling water effluent pipelines are two large 1.5-meter (60-inch) diameter by 1.3-centimeter (0.5-inch) thick wall carbon steel pipelines. The east pipeline exits the 105-DR Reactor Building on the south side and runs due east to the corner of the building and then heads northeast to a point about 75 meters (210 feet) east of the existing exclusionary fence and then north to the 116-DR-9 (107-DR) Retention Basin. The west pipeline exits the 105-DR Reactor Building on the north side and heads northeast to a point 55 meters (154 feet) east of the existing exclusionary fence and then north to the 116-DR-9 (107-DR) Retention Basin. The pipelines run parallel to each other and are separated by about 25 meters (70 feet). This site also includes the discharge pipelines from the 116-DR-9 (107-DR) Retention Basin to the 116-DR-1 and 116-DR-2 Trench and both 116-D-5 and 116-DR-5 Outfalls. At the outlet of the 116-DR-9 (107-DR) Retention Basin, two 1.5-meter (60-inch) carbon steel pipelines are combined into a single 1.5-meter (60-inch) pipeline at a junction box. This pipeline then runs to the outfall structure. The outfall discharge pipeline is a 1.7-meter (66-inch) carbon steel pipeline that continues to the center of the Columbia River. Because of its length, this site has been broken into four subsites: 100-D-49:1, the pipelines from 116-DR-9 to the Outfalls; 100-D-49:2, the pipelines from D Avenue to 116-DR-9; 100-D-49:3, the pipelines from D Avenue to the 105-D Reactor; and 100-D-49:4 the effluent pipelines within 60 meters of the reactor. The facilities where these pipelines terminate are not included as part of this site. The following pipelines are not included as part of this site (included as part of 100-D-48): Opposite the 105-D Reactor Building, the west 105-DR Reactor effluent pipeline is cross-tied to the 105-D Reactor 1.5-meter (60-inch) effluent pipeline by a 1.5-meter (60-inch) diameter by 1.3-centimeter (0.5-inch) thick wall, carbon steel pipeline. The underground pipelines (100-D-50) that transported nonradioactive treated and untreated waste water from the 183-DR, 183-DR Clearwell area, and the 105-DR Reactor Buildings to the 100-D-8 (1907-DR) outfall are not included in this site.

Location: Generally, the pipelines run in a north-south direction east of the 100-D Reactors. Several expansion boxes are apparent at the ground surface along the length of the pipelines. Pipeline descriptions and associated structures are as follows. 105-DR Reactor: - a 20.32 centimeter (8 inch) effluent line exits the south side and runs to the east side of 1608-DR - a 45.72 centimeter (18 inch) effluent line exits the south side and also runs to the east side of 1608-DR - two 152.4 centimeter (60 inch) effluent pipe exit the northeast side and run to the 116-DR-9 Retention Basin 116-DR-9 Retention Basin: - two 152.4 centimeter (60 inch) lines exit the north end and flow, parallel, west to the 116-D-5 Outfall. - a 152.4 centimeter (60 inch) bypass line intersects the southern DR basin to the outfall effluent line, and flows north to the 116-DR-5 Outfall. - a 10.16 centimeter (4 inch) line exits the south end and flows into the 100-D-4 Trench. - two 30.48 centimeter (12 inch) lines flow east from the north end into the 116-DR-1&2 Trench.

Process The pipelines were used to dispose of radioactive cooling and waste water from the reactor

Process Description: facility. Two large main effluent pipelines drained cooling water from the 105-DR Reactor. The small effluent pipelines that drained process waste from the sides (east and south) of the 105-DR were joined into a single pipeline that ran to the 132-DR-1 [1608-DR Building] Waste Water Pumping Station or Process Lift Station). The 132-DR-1 (1608-DR) Building was a rectangular shaped, two-story, reinforced concrete structure that was half below grade elevation. The purpose of this facility was to pump process effluent to the main effluent pipeline.

Related Sites/ Structures: The associated structures are the 105-DR Building, the 132-DR-1 (1608-DR), the 116-DR-9 (107-DR) Retention Basin, the 116-D-5 Outfall and 116-DR-5 Outfall. Other related sites are the 116-DR-1 and 116-DR-2 Trench, and the 116-DR-6 Trench, 100-D-85 105D Reactor Effluent Pipelines.

Waste Type: Process Effluent

Waste Description: The waste is contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radionuclides discovered at the retention basin during sampling by Dorian and Richards (1978) for UNI-946, included: plutonium-238, cesium-134, plutonium 239/240, cesium-137, strontium-90, hydrogen-3, uranium, europium-152, europium-154, europium-155, nickel-63, cobalt-60, and carbon-14.

This Site has the Following SubSites:

Code: 100-D-49:1

Names: 100-D-49:1; North Pipelines from 116-DR-9 to the Outfalls

Code: 100-D-49:2

Names: 100-D-49:2; East Pipelines from D Avenue to 116-DR-9

Code: 100-D-49:3

Names: 100-D-49:3; Effluent Pipelines from D Avenue to About 60 Meters from the 105-DR Reactor

Code: 100-D-49:4

Names: 100-D-49:4; 100-DR Effluent Pipelines Within About 60 Meters of the Reactor

Code: 100-D-49:1

Classification: Accepted

Names: 100-D-49:1; North Pipelines from 116-DR-9 to the Outfalls

Reclassification: Interim Closed Out (3/26/2001)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-D-49:1 pipeline sections were located north of the 116-D-7 Retention Basin and went to the 116-D-5 (1904-D Outfall). Pipeline components consisted of a 1.5 meter (60 inch) steel pipeline, part of another 1.5 meter (60 inch) steel pipeline coming from the 116-DR-9 Retention Basin, up to its connection with the 1.5 meter (60 inch) steel pipeline associated with the 116-D-7 Retention Basin), and part of a 1.1 meter (42 inch) bypass pipeline (up to the northeast end of 116-D-7).

Location: These pipelines are north of the 107-D and 107-DR Retention Basins, extending to the 1904-D and 1904-DR Outfalls.

Process Description: These pipelines drained radioactive cooling water from the retention basins to the 1904-D and 1904-DR Outfalls structures.

Waste Type: Not Specified

Waste Description: The waste was contaminated steel piping, concrete, and soil.

Closure Info: 100-D-48:1, 100-D-49:1, 100-D-19 and UPR-100-D-4 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-48:1/49:1 Pipelines site began on December 28, 1998. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation reached the design limit.

Because remediation of the 100-D-48:1/49:1 Pipelines site required moving an active overhead power line, site remedial action and sampling were conducted in two phases. These separate phases are reflected by the long time period between the start and finish dates for excavation.

The excavation design depth generally corresponded with the invert elevation of the pipelines. At the completion of remedial action and removal of the engineered structure, the excavation was approximately 15,504 square meters (166,800 square feet) in area with a maximum depth of approximately 6.0 meters (20 feet) below ground surface. Approximately 107,266 metric tons (118,241 tons) of material from the D Area pipelines site have been disposed of at the ERDF through July 2000. Cleanup verification sampling began on April 3, 2000, and was finished on August 8, 2000. The ground surface in the vicinity of the site varies with an average elevation of approximately 134.4 meters (441 feet).

The CVP demonstrated that remedial action at the 100-D-48:1/49:1 Pipelines site achieved the RAOs and corresponding RAGs established in the approved interim action ROD and RDR/RAWP. The remaining soils at the 100-D-48:1/49:1 Pipelines site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-D-48:1/49:1 Pipelines site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. Residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:1/49:1 Pipelines site (includes the 100-D-19 and UPR-100-D-4 sites) is verified to be remediated in accordance with the interim action ROD.

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This section of two parallel pipelines runs from D Avenue to 116-DR-9. The two pipelines were

constructed of 1.5 m (5 ft)-diameter by 1.3 cm (0.5 in.)-thick carbon steel with welded joints. The two parallel pipelines were about 25 m (66 ft) apart.

Location: This section of two parallel pipelines runs from D Avenue to the 116-DR-9 Retention Basin.

Waste Type: Not Specified

Waste Description: The waste was contaminated steel piping, concrete, and soil.

Closure Info: 100-D-48:2, 100-D-49:2, UPR-100-D-2 and UPR-100-D-3 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-48:2/49:2 Pipelines site began in July 1997. Excavation of the site involved removing the overburden materials, contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. In August 1999, the excavation reached the design limit. The excavation design depth generally corresponded with the invert elevation of the pipelines. The pipeline excavation profiles are in the sample design calculation briefs in Appendix D.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 20,475 square meters (220,280 square feet) in area with a maximum depth of approximately 6 meters (20 feet) below ground surface. During the time of excavation and waste disposal (December 1998 through September 1999) at the 100-D-48:2/49:2 Pipelines site, approximately 57,106 metric tons (62,960 tons) of material from 100-DR-1 Operable Unit pipelines were disposed of at the ERDF. Cleanup verification sampling began on August 23, 1999, and was finished on October 20, 1999. Because of the length of the pipeline site, the top-of-excavation elevation ranges from 138 meters (453 feet) near the retention basins to 143 meters (469 feet) near D Avenue.

The CVP demonstrated that remedial action at the 100-D-48:2/49:2 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17). Materials from the 100-D-48:2/49:2 Pipelines site that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils, including pipeline overburden stockpiles, have been sampled, analyzed, and modeled to show that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site and in overburden soils pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:2/49:2 Pipelines site is verified to be remediated in accordance with the ROD and may be backfilled. The pipeline overburden is verified as suitable for use as backfill in accordance with the ROD.

Start Date:

Status: Inactive**End Date:**

Description: This subsite extends south from D Avenue to about 60 meters (200 feet) from the wall of the reactor foundation, longer for the east pipeline and shorter for the west pipeline. These two parallel pipelines were constructed of 1.5 m (5 ft) diameter carbon steel with welded joints. The Decontamination and Decommissioning project is responsible for the remaining pipelines as part of the foundation removal.

(Note: Figure 3 in the CVP is incorrect. It does not show the total length of the excavation at the south end. Refer to Attachment 3 of the CVP for a map of the entire excavation, including sampling locations.)

Location: These pipelines run from the 105-DR Reactor to D Avenue.

Waste Type: Not Specified

Waste Description: The waste was contaminated steel piping, concrete, and soil.

Closure Info: 100-D-48:3, 100-D-49:3, 100-D-5 and 100-D-6 were addressed as a group. The information below documents information for the group of sites.

The sites included in this remediation are 100-D-48:3, 100-D-49:3, 100-D-5, and 100-D-6. The entire remedial action for these sites is referred to as the 100-D-48:3/49:3 pipelines site. Remedial action at the 100-D-48:3/49:3 site began on October 28, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On July 24, 2000, the excavation was completed. The excavation design depth generally corresponded with the invert elevation of the pipelines.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 24,574 square meters (264,517 square feet) in area with a maximum depth of approximately 5.7 meters (18.7 feet). Approximately 55,561 metric tons (61,245 tons) of material from the 100-D-48:4 and 100-D-48:3/49:3 pipeline sites combined were disposed of at ERDF. Overall, approximately 107,266 metric tons (118,241 tons) from all D Area pipeline sites were disposed of at the ERDF through July 2000. Cleanup verification sampling began on June 7, 2000 (for the overburden piles), and was finished on October 4, 2000 (in the excavation). The excavation is being backfilled with appropriate materials to match the surrounding surface grade (average elevation of 143.7 meters [471 feet]).

The CVP demonstrates that the remedial action at the 100-D-48:3/49:3 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved Interim Action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 100-D-48:3/49:3 Pipelines site and overburden have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-D-48:3/49:3 site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the overburden and shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:3/49:3 Pipelines site is verified to be remediated in accordance with the ROD.

The SubSite is Part Of:

underwater collection, storage, and transfer facility for the irradiated fuel elements discharged from the reactor. This zone was located entirely within the deep zone.

Zone 2 consisted of the valve pit that received wastewater from the reactor building. During the cleanup verification sampling, high levels of hexavalent chromium and polychlorinated biphenyls (PCBs) were discovered on the valve pit concrete floor. Therefore, the floor was removed and disposed of at the ERDF, then the valve pit walls and soil underneath the concrete floor were sampled and analyzed for hexavalent chromium and PCBs for verification purposes. Zone 2 was entirely within the deep zone.

Zone 3 consisted of the solids feed area, the north water tunnel, and the trench under the accumulator room. The below-grade rooms, tunnel, and trench have been wetted by isolated spills and standing rainwater that may have acted as a hydraulic driver for potential contamination. Only concrete floors were sampled and analyzed for these areas, as the walls are expected to contain little or no contamination. Ceilings were removed and disposed of at the ERDF. Zone 3 was within the shallow zone

Zone 4 consisted of the gas tunnel, exhaust plenum, gas recirculation tunnel, and the instrument room. Similar to Zone 3, these rooms and tunnels would have been wetted by isolated spills and standing rainwater, which may have acted as a hydraulic driver for potential contamination. Therefore, only the concrete floors were sampled and analyzed. Zone 4 was entirely within the deep zone.

Zone 5 consisted of the side slope soils around the FSB, the south effluent pipeline, and the soil under the slab. The soils adjacent to the 105-DR FSB were sampled to verify that shallow zone soil cleanup levels would be met if the walls of the FSB were removed. The soils beneath the slab were sampled for mercury because of the potential for mercury contamination from a floor drain in the slab.

Also included in Zone 5 was a section of 105-DR process effluent pipeline located adjacent to the south side of the FSB that was removed and the soil was sampled as part of the adjacent soils beneath the FSB. The concrete was removed from this location and the soil was sampled for verification purposes. This area was included in Zone 5 because of its proximity to the side slopes of the FSB. Zone 5 was within the shallow zone.

The three decon areas were located around the reactor for the purpose of equipment decontamination. The northwest decon area was approximately 8.0 meters by 8.8 meters (26 feet by 29 feet). The northeast decon area was approximately 12 meters by 9.8 meters (39 feet by 32 feet), and the south decon area was approximately 16 meters by 17 meters (52 feet by 56 feet).

An individual calculation of contaminated material removed for cleanup of the pipeline area was not provided in the CVP. A total of approximately 7,220 cubic meters (25,500 cubic feet) of contaminated materials were disposed at the ERDF. The results of this effort indicated that the materials from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed at the ERDF.

These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The site is verified to be remediated in accordance with the Action Memorandum (EPA et al. 1998) and can be backfilled.

The SubSite is Part Of:

Code: 100-D-49
Names: 100-D-49; 100-DR Reactor Cooling Water Effluent Underground Pipelines

Code: 100-D-50
Classification: Accepted
Names: 100-D-50; 100-DR Water Treatment Facilities
Underground Pipelines
Reclassification: None
Type: Process Sewer
Start Date: 1/1/1950
Status: Inactive
End Date: 1/1/1965

Description: This site includes those underground pipelines that transported nonradioactive treated and untreated waste water from the 183-DR, 183-DR Clearwell area, and the 105-DR Reactor Buildings to the 100-D-8 (1907-DR) Outfall. It consists of 0.3-meter (12-inch) to 1.8-meter (72-inch) reinforced concrete piping located to the south of the facilities listed above.

Location: Generally, these pipelines run in an east-west direction with north-south lines connecting to the individual facilities. Several manhole access points are located along the length of the system. Pipeline descriptions and associated structures are as follows. 183-DR - three 30 centimeter (12 inch) process sewer lines exit from the south side and join the 183 centimeter (72 inch) reinforced concrete pipe at manhole MH T-3. The reinforced concrete pipe runs to the 100-D-8 outfall 183-DR Clearwells - 122 centimeter (48 inch) drain borders the south and southeast sides of the Clearwells - 91 centimeter (36 inch) drain borders the west side - 76 centimeter (30 inch) and 46 centimeter (18 inch) drains the north side of the Clearwells. - two pipelines, a 61 centimeter (24 inch) and a 46 centimeter (18 inch) pipe went between the Clearwells All of these lines are connected and flow south to the 183 centimeter (72 inch) line that flows west to 100-D-8 105-DR Reactor - a 107 centimeter (42 inch) line exits the west side, flows south of the 183-DR Clearwells in a 137 centimeter (54 inch) pipe, which then becomes the 183 centimeter (72 inch) pipe to the 100-D-8 outfall.

Process Description: This site was used to dispose of nonradioactive waste water from water treatment facilities associated with the 100-DR Reactor. These pipelines discharged to the 100-D-8 (1907-DR) Outfall just upstream of the 181-D Building. The 100-D-8 (1907-DR) Outfall and the facilities connected to this system are not addressed by this site, nor are the 100-D-56 sodium dichromate pipelines.

Related Sites/Structures: The site is associated with the 116-D-8 Cask Storage Pad, 183-DR, the 183-DR Clearwell Area, the 105-DR Reactor Buildings, and the 1907-DR Outfall (100-D-8).

Waste Type: Water

Waste Description: The waste is steel pipelines, concrete, and soil (if contaminants are present). Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, free chlorine residual was about 0.2 milligrams/liter, and sodium dichromate was added at a rate of about 2 milligrams per liter. Water and chemical storage tank overflows and other drains discharged to this disposal system. Drawings indicate that it also received storm drainage from the 183-DR Tank Clearwell Basin.

Sodium dichromate was used to treat reactor cooling water to assist in the control of process tube corrosion. Sodium dichromate storage tanks may have discharged to this system and potentially act as a source of elevated chromium found in the 100-D groundwater. However, unless there was a deliberate discharge of sodium dichromate to the system, only very dilute discharges would have occurred.

This Site has the Following SubSites:

Code: 100-D-50
Names: 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

Code: 100-D-50:2
Classification: Accepted
Names: 100-D-50:2; Reactor Cooling Water Pipelines from 190-DR Pumphouse
Reclassification: None
Type: Process Sewer
Start Date:
Status: Inactive
End Date:

Description: The 100-D-50:2 subsite consists of the residual process cooling water supply lines between the 183-DR clearwells and the 105 DR Reactor Building.

The administrative boundaries for the 100-D-50:2 pipelines encompass those process supply lines from the points of discharge at the former 183-DR clearwells to the boundaries of demolition of the 190-DR Pumphouse and from the points of discharge from the 190-DR valve houses to the boundaries of interim safe storage activities at the 105-DR Reactor Building. The pipelines formerly connecting these two groups have been removed as part of decommissioning and demolition of the 190-DR facility. Residual supply piping within the boundaries of the interim safe storage project has been encased in concrete.

The process lines upstream of the former 190-DR Pumphouse consist of four 0.61-m (24-in.) subsurface steel pipelines. Downstream of the 190-DR facility, these pipelines are housed in two separate tunnels that converge upstream of the 105-DR Reactor Building. Several small diameter water lines are also located in the pipe tunnels, including raw water, filtered water, fire protection water, and potential dichromate-treated process water piping. Raw water, fire protection water piping, and filtered water piping are expected to be part of the 100-D/DR clean water/service water pipelines (100-D-63 waste site). This functional pipeline group has been rejected from consideration as a WIDS site based on process knowledge at other production reactor areas (100-B-7, 100-C-5, 100-H-35, and 100-K-59), but potential process water lines (i.e., the lines labeled "SOUTH RISER," "NORTH RISER," "SOUTH PROCESS WATER," and "NORTH PROCESS WATER") will be considered as part of the 100-D-50:2 subsite.

Location: The 100-D-50:2 pipelines are located between the former 183-DR Clearwells and 190-DR Pumphouse and the former 190-DR Pumphouse and 105-DR Reactor Building. The pipelines downstream of the former 190-DR facility are located within subsurface pipe tunnels.

Waste Type: Not Specified
Waste: The waste is any potentially contaminated pipelines

Description: This subsite consists of steel piping designed to deliver treated cooling water from the 190-D High Bay to the 105-DR Reactor.

Location:

Waste Type: Not Specified

Waste The waste is any potentially contaminated pipelines

Description:

The SubSite is Part Of:

Code: 100-D-50

Names: 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

Code: 100-D-50:4

Classification: Accepted

Names: 100-D-50:4; Gas Recirculation Pipelines (Unused) **Reclassification:** None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite consists of the steel piping in the subsurface tunnel between the former 115-D Gas Recirculation Facility and the 105-DR Reactor. The 100-D-50:4 subsite is composed of two 0.41 m (16- n.) steel pipelines with a combined length of approximately 270 m (900 ft). These pipelines presently exist within the collapsed subsurface tunnel between the former 115-D/DR Gas Recirculation Facility and the 105-DR Reactor. Characterization of analogous pipelines in the gas recirculation wing of the 105-H Reactor revealed the accumulation of oil sludge containing multiple radionuclides at levels above remedial action goals (RAGS). These pipelines may never have been used.

In a 4/19/2005 Remove, Treat, and Dispose Report based on a review of historical site information and analogous analytical data, it was cited that this subsite contains hazardous constituents at levels in accordance of RAGs. Remedial action was recommended for this site in accordance with the ROD (EPA, 1999).

Location: The surface area of the 100-D-50:4 subsite is currently within the southern portion of the decommissioning equipment laydown yard between the 105-D and 105-DR Reactors, but no surface expressions of the site are present. Design drawings with as-built verification show the pipelines stacked vertically along the eastern wall of the tunnel (H-1-853ODR 1948). The exact present depth of the pipelines is unknown, but the invert elevation of the tunnel was up to 3 m (10 ft) below presently existing grade. The tunnel was a 1.5 m (5 ft) wide by 2.0 m (6.5 ft) deep structure, narrowing to 1.2 m (4 ft) wide approximately 9.1 m (30 ft) before entering the 115-D/DR facility.

Waste Type: Not Specified

Waste The waste is the pipelines and any contaminated soil associated with this site.

Description:

The SubSite is Part Of:

Code: 100-D-50

Names: 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

Code: 100-D-50:5

Classification: Accepted

Names: 100-D-50:5; 183-DR Sedimentation Basin Drain Pipelines **Reclassification:** No Action (11/6/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The subsite encompassed the southern process sewers for the 183-DR coagulation and

sedimentation basins, The subsite consisted of approximately 200 meters (650 feet) of pipeline: three 0.15-meters (6-inches) drain lines immediately south of the former 183-DR coagulation and sedimentation basins, which discharged to a 0.30-meter (12-inch) reinforced concrete collection line, trending generally north-south. A 0.30-meter (12-inch) feeder line also connected a runoff collection drain (catch basin U) to the collection line.

As part of the coolant water treatment facilities for the 105-DR Reactor, the 183-DR coagulation and sedimentation basins used physical and chemical treatment to condition raw river water for reactor use. The chemicals added at the 183-DR coagulation basins or at the upstream 183-DR Headhouse included: sulfuric acid, lime chlorine, and commercial coagulants containing primarily ferrous sulfate or alum. Sodium dichromate was also added to cooling water as a corrosion inhibitor, but was injected downstream of the sedimentation basins.

Located on the southern side of the 183-DR facility, these sewers were designed to provide underflow drainage for the 183-DR coagulation and sedimentation basins and possibly overflow drainage as well. Several surface runoff collection drains for the area south of the 183-DR facility also discharged to this sewer. The subsite process sewers discharged to the 100-D-50:1 process sewer collection line, which ultimately discharged to the Columbia River at the 100-D-8 outfall. Additional drainage for the 183-DR basins was also provided by higher capacity process sewers on the northern side of the 183-DR facility (100-D-50:7 subsite).

- Location:** The 100-D-50:5 process sewers are on the south side of the 183-DR facility.
- Waste Type:** Not Specified
- Waste Description:** The waste is the pipelines, pipeline sediments, and any contaminated soil associated with this site.
- Closure Info:** Results of the confirmatory sampling event conducted on November 7 and December 28, 2005 were used to make decisions for reclassification of the site. Evaluation of the confirmatory results has been documented in the Remaining Sites Verification Package (RSVP) 2006-025. The report indicated that the 100-D-50:5 subsite has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) for No Action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The COPC list identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) for subsite included cobalt-60, cesium-137, europium-152, europium-154, strontium-90, lead, hexavalent chromium, and metals. While process knowledge of the subsite does not suggest historic discharge of radionuclides, cobalt-60, cesium-137, europium-152, europium-154, and strontium-90 were identified as COPCs for the 100-D-50 site in its entirety and retained for the 100-D-50:5 subsite. Polychlorinated biphenyls (PCBs) were also identified as COPCs for the process sewers based on the potential presence of rubber gaskets and other PCB-containing materials in the water treatment facilities serviced by the pipelines. At the request of the Washington Department of Ecology, total uranium evaluation by kinetic phosphorescence analysis (KPA) was also included in confirmatory analysis.

The laboratory-reported results for all constituents have been stored in the Environmental Restoration (ENRE) project-specific database prior to archiving in the Hanford Environmental Information System (HEIS) and were included in Appendix A of the RSVP. The results of confirmatory sampling confirmed that residual contaminant concentrations did not preclude any future uses (as bounded by the rural-residential scenario) and allowed for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River.

The subsite has been evaluated in accordance with the Remaining Sites ROD, and a no action decision is supported based on the confirmatory investigation and sampling results. The analytical results from the subsite pipe sediment and underlying soil samples were shown to meet the remedial action objectives for direct exposure, groundwater protection, and river protection. The subsite has no deep zone; therefore, no deep zone institutional controls are required.

The SubSite is Part Of:

Code: 100-D-50

Names: 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

Code: 100-D-50:6

Classification: Accepted

Names: 100-D-50:6; 183-DR Clearwell Drain Pipelines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite includes three functional groups of piping at the 183-DR Clearwells: 1) process piping used to deliver water from the filter building to the clearwells, 2) process piping used to deliver water from the clearwells to 190-DR Pumphouse, and 3) drain piping servicing the clearwells and pumphouse floor drains and discharging to the 100-D-50:1 Emergency Discharge Pipeline. The subsite also includes the four concrete pads remaining from the 190-DR Clearwells, and surrounding soil.

Location: 1) piping running from filter building to the clearwells, 2) piping running from the clearwells to the 190-DR Pumphouse. 3) piping running from the clearwells and pumphouse to the Emergency Discharge Pipeline. This site is directly east of the 183-DR Water Treatment Facility (demolished) and west of 190-DR. It is southwest of the 105-DR Reactor Building.

Waste Type: Not Specified

Waste The waste includes piping, concrete pads and surrounding contaminated soils.

Description:

The SubSite is Part Of:

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite includes the pipelines that provided drainage for the 183-DR Coagulation Basins, floor drains and catch basins at the 183-DR Head House, and mixing tanks in the vicinity of the 186-D Waste Acid Reservoir. These pipelines ultimately discharged to the 100-D Area process sewer systems.

Process sewers for the 183-DR Head House floor drains, 183-DR Coagulation and Sedimentation Basins, and nearby catch basins are:

- 82 m (269 ft) of 0.20-m (8-in.) vitrified clay pipe (VCP)
- 40 m (131 ft) of 0.25-m (10-in.) VCP

- 36 m (118 ft) of 0.51-m (20-in.) cast iron pipe
- 158 m (518 ft) of 0.69-m (27-in.) reinforced concrete pipe (RCP)
- 332 m (1,089 ft) of 1.37-m (54-in.) RCP

The pipe for the 186-D Mixing Tank process sewer is:
- 90 m (295 ft) of 0.61-m (24-in.) VCP.

Location: These pipelines extend from the 183-DR Head House north to the 186-D Building..

Waste Type: Not Specified

The SubSite is Part Of:

Code: 100-D-50

Names: 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

Code: 100-D-50:8 **Classification:** Accepted

Names: 100-D-50:8; 117-DR Condensate Drain Pipelines **Reclassification:** None

Type: Process Sewer **Start Date:**

Status: Inactive **End Date:**

Description: The 100-D-50:8 subsite is a 10 cm (4 in) diameter nonfriable asbestos cement distribution pipe that connected the 117-DR Filter Building to the 116-DR-8 Seal Pit Crib. The distribution pipe had a total length of 83 m (272 ft) and operated independently from all other pipelines. The distribution pipe received radioactive process effluent from the 117-DR HEPA Filter Building.

Location: The 117-DR Filter Building was located south of the 105-DR Reactor Building. The pipeline and crib are located south of 117-DR Filter Building.

Waste Type: Not Specified

Waste The waste is potentially contaminated piping and soil.

Description:

The SubSite is Part Of:

Code: 100-D-50

Names: 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

Code: 100-D-50:9 **Classification:** Accepted

Names: 100-D-50:9; 1607-DR3 Sanitary Sewer Pipelines **Reclassification:** None

Type: Process Sewer **Start Date:**

Status: Inactive **End Date:**

Description: The 100-D-50:9 site encompasses two functional pipeline groups: (1) the overflow drain line and (2) the residual sanitary sewer lines. The overflow drain line begins north of the 105-DR Reactor Building, travels south along the western side of the building, and then turns west to join the sanitary sewage system. The sanitary sewer cuts across the southeast corner of the 116-D-8 cask storage pad and was accessible through a manhole set in the concrete pad.

The Hanford Site Waste Management Units Report (DOE/RL-88-30) stated the pad was designed with a drain to facilitate pad decontamination and rain runoff, and the drain discharged into the 105-DR sewer (100-D-50:9). The residual sanitary sewer lines are located south and southeast of the 105-DR Reactor Building. Both pipeline functional groups discharged into the

100-D-13 septic tank. Although sections of the former sewer system have been removed under past Group 3 remedial efforts for coexistent sites (the 116-DR-6 Liquid Disposal Trench and the 100-D-48 Reactor Cooling Water Effluent Underground Pipelines), excavations for confirmatory sampling established that portions of the 100-D-50:9 pipelines still remain.

During remediation of 118-D-5 Burial Ground (CVP-2009-00008) a concrete junction vault located in the southern portion of the burial ground was opened prior to the start of the burial ground excavation and found to contain a breached 15-cm (6-in.) vitrified clay pipe. The pipeline was part of the 100-D-50:9, 1607-DR-3 Sanitary Sewer. The concrete junction vault and pipe located within the excavation were removed for disposal to ERDF.

Location: The overflow drain line (1) begins north of the 105-DR Reactor Building, travels south along the western side of the building, and then turns west to join the sanitary sewage system. The residual sanitary sewer lines (2) are located south and southeast of the 105-DR Reactor Building.

Waste Type: Not Specified

Waste Description: The waste is the pipelines, pipeline sediments, and any contaminated soil associated with this site.

The SubSite is Part Of:

Code: 100-D-50

Names: 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines

Code: 100-D-50:10

Classification: Accepted

Names: 100-D-50:10; Construction Camp Potable Water Supply Pipelines

Reclassification: No Action (6/29/2005)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite consists of the residual cast iron pipelines used to supply potable water to the temporary construction camp southeast of the 105-DR Reactor. The exact operational period of the subsite is uncertain, but is believed to be limited to 1947 to 1949 when the construction camp was in use. The system was supplied with water via the fire protection loop piping, which in turn was supplied by the 100-D Area water treatment train at a point prior to any chemical treatment. The subsite is composed of approximately 680 m (2,220 ft) of 0.15-m (6-in.) cast iron pipe around the northern, eastern, and southeastern sides of the 105-DR Reactor. Portions of the former supply system were removed under past Group 3 remedial efforts for coexistent sites (the 116-DR-6 Liquid Disposal Trench and the 100-D-48 Reactor Cooling Water Effluent Underground Pipelines). No evidence has been located to suggest that operation of these sites impacted the 100-D-50:10 pipelines beyond the boundaries of previous remedial efforts.

Location: These pipelines are on the north, east, and south sides of the 105-DR Reactor.

Closure Info: The 100 Area Remedial Action Sampling and Analysis Plan identifies contaminants of potential concern (COCs) for the 100-D-50 pipelines, but they were not applicable to this subsite given process knowledge of the operational history of the pipelines. Further, the same process knowledge provides no basis for the introduction of any hazardous or dangerous wastes to these pipelines. Therefore, no further evaluation or confirmatory sampling is necessary for this subsite.

The Remaining Sites Verification Package (RSVP) report demonstrates that the subsite meets the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County,

Washington. The evaluation shows that there is no hazardous/dangerous materials present at the subsite and, accordingly, no residual contamination in the soil. Therefore, the current status of the subsite is protective of human health, groundwater, and the Columbia River, and no institutional controls are required.

The SubSite is Part Of:**Code:** 100-D-50**Names:** 100-D-50; 100-DR Water Treatment Facilities Underground Pipelines**Code:** 100-D-52**Classification:** Accepted**Names:** 100-D-52; 105-D Downcomer Insulation Space Dry Well**Reclassification:** Interim Closed Out (11/8/2000)**Type:** French Drain**Start Date:** 1/1/1955**Status:** Inactive**End Date:**

Description: This site has been remediated and interim closed out. The site consisted of a french drain (dry well). The 1-meter (3-foot) diameter dry well was filled with 2.2 meters (5 feet) of 2.5 to 5-centimeter (1 to 2-inch) gravel from the bottom at 6.9 meters (22 feet) below grade to the top at 5.2 meters (17 feet) below grade. The dry well was fed by a 10.2-centimeter (4-inch) steel drain pipe from Room 38A that entered the dry well at 5.8 meters (19 feet) below grade. The drain line discharged into the annulus between a vertical 25.4-centimeter (10-inch) diameter distributor pipe and vertical 10.2-centimeter (4-inch) diameter radiation monitor housing pipe in the center of the dry well. The monitor was used to ensure detection of radiation in the water (condensate or cooling water leakage) from Room 38A. (Room 38A of the 105-D Building is the concrete enclosure for the 105-D Downcomer.) The concentric distributor pipe and radiation monitoring housing pipe ended 30 centimeters (1 foot) above the bottom of the dry well. The radiation monitor pipe extended about 0.6 meters (2 feet) above grade with a valve on the upper end.

Location: The site was located next to the 105-D Reactor Building at Washington Coordinate System (WCS83S) Easting 573797.076, Northing 151625.344.

Process Description: This drywell was installed in 1955 to drain noncontaminated condensate water and contaminated cooling water from the space between the D Reactor process effluent downcomer and the reactor wall. The contaminated cooling water resulted from potential leakage from the downcomer (a metal baffled structure through which collected reactor cooling water cascaded prior to entry into the effluent discharge line). This site also contained a pipe providing access for radiation monitoring that extended from the bottom of the drywell to just above grade.

Related Sites/ Structures: The site was related to 105-D Reactor Building Room 38A.

Waste Type: Water

Waste Description: No record could be found that indicated any radiological or chemical contamination data.

Description: Based on available information it was assumed that contamination would be limited to those radionuclides found in reactor effluent water that potentially leaked from the metal downcomer and collected nonradioactive condensate water. The COPCs for the remedial action were developed in the Sampling and Analysis Plan.

Closure Info: The cleanup verification package (CVP-2000-00018) has documented that the 100-D-52 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Waste site contaminants of concern (COCs) and contaminants of potential concern (COPCs) identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP). The COPCs that were detected during field sampling (i.e., during remediation) were reclassified as COCs and are addressed in the CVP. These COCs are cesium-137, europium-152, uranium-233/234, uranium-238, total chromium, and lead.

Hexavalent chromium is not a COC or COPC at the 100-D-52 Downcomer Insulation Space Drain Dry Well because this was a small site that was known not to have received process effluent and was not associated with disposal of liquids containing hexavalent chromium.

Remedial action began on January 4, 2000, the excavation involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Contaminated materials were disposed at ERDF. On February 25, 2000, the excavation reached the design limit at elevation 134.9 meters (443 feet).

At the completion of remedial action the excavation was approximately 415 square meters (4,467 square feet) in area with a maximum depth of approximately 7.6 meters (25 feet). Approximately 199 metric tons (219 tons) of material from the site were disposed at ERDF. Cleanup verification sampling began on March 21, 2000, and was finished on the same day. The excavation will be backfilled with appropriate materials to the reference grade of elevation 142.5 meters (468 feet).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	100-D-56	Classification:	Accepted
Names:	100-D-56; 100-D Area Sodium Dichromate Underground Supply Lines	Reclassification:	None
Type:	Product Piping	Start Date:	
Status:	Inactive	End Date:	
Description:	The site consists of two abandoned 7.6-centimeter (3-inch) underground sodium dichromate supply lines that transported concentrated liquid sodium dichromate between the 108-D, 185-D, 189-D, 190-D, 183-DR, and the 100-D Sodium Dichromate Transfer Station.		
Location:	The underground lines run between the former 108-D, 185-D, 189-D, 190-D, 183-DR Buildings, and the 100-D Sodium Dichromate Transfer Station. The north pipeline exited the north side the 190-D Pump Room and flowed to the west side of 108-D. 183-D Filter Plant - 7.62centimeter (3inch) line exits west side and flows south to near the 100-D-12 pump station 183-DR - Two 7.62centimeter (3inch) lines exit the west side of 183-DR Head House and flow east to 185-D		
Process Description:	Sodium dichromate was used to treat reactor cooling water to assist in the control of process tube corrosion. Sodium dichromate was received in solid and liquid form. The solid form was dissolved in the 189-D Building.		
Related Sites/ Structures:	Co-located with the lines is 100-D-92 the encasement for the lines.		

Waste Type: Equipment
Waste Description: The waste is abandoned 7.6-centimeter (3-inch) pipe contaminated with sodium dichromate.

This Site has the Following SubSites:

Code: 100-D-56:1
Names: 100-D-56:1; Pipeline Exiting North Side of 185-D
Code: 100-D-56:2
Names: 100-D-56:2; Pipelines Exiting South Side of 185-D

Code: 100-D-56:1 **Classification:** Accepted
Names: 100-D-56:1; Pipeline Exiting North Side of 185-D **Reclassification:** None
Type: Product Piping **Start Date:**
Status: Inactive **End Date:**

Description: The 100-D-56 site consists of two abandoned 7.6 cm (3 in) underground pipelines that transported sodium silicate and sodium dichromate liquids between the 108-D, 190-D, 185-D, and 189-D facilities; the 100-D-12 Sodium Dichromate Pumping Station; and the 183-DR Building. Pipeline descriptions and associated structures are as follows:

183-DR - Two 7.62 cm (3 in) lines (one sodium dichromate and one sodium silicate) exit the west side of 183-DR Head House and flow east to 190-D.

190-D Pump Room - Two 7.62 cm (3 in) (one sodium dichromate and one sodium silicate) pipelines exit the north side and flow to the west side of 108-D. 100-D-56:1 site addresses the northern portion of the pipeline. The pipelines exiting the north side of the 185-D Building were used during the initial dry material handling operations. The pipeline ran from 190-D to 108-D. The total length was approximately 272 meters (892 feet).

Location: The northern portion of the 100-D-56 pipeline ran from the 108-D Building to the 185-D Building. The 108-D Building was located north of the 105-D Reactor and east of the 1709-D Building. The 185-D Building was located west of the 105-D Reactor.

Waste Type: Not Specified
Waste Description: The waste is potentially contaminated equipment (pipelines) and any contaminated soil associated with the pipeline.

The SubSite is Part Of:

Code: 100-D-56
Names: 100-D-56; 100-D Area Sodium Dichromate Underground Supply Lines

Code: 100-D-56:2 **Classification:** Accepted
Names: 100-D-56:2; Pipelines Exiting South Side of 185-D **Reclassification:** None
Type: Product Piping **Start Date:**
Status: Inactive **End Date:**

Description: The 100-D-56 site consists of two abandoned 7.6 cm (3 in) underground pipelines that transported sodium silicate and sodium dichromate liquids between the 108-D, 190-D, 185-D, and 189-D facilities; the 100-D-12 Sodium Dichromate Pumping Station; and the 183-DR Building. 100-D-56:2 subsite addresses the southern portion of the pipeline. The pipelines

exited the south side of the 185-D Building to 100-D-12 and continued to the 183-DR building. This pipeline continued to be used after the transition to concentrated liquid sodium dichromate. The pipeline measured a total of 788 meters (2,585 feet).

Location: The southern portion of the 100-D-56 pipeline ran from the 185-D Building to the 183-DR Head House. The 185-D Building was located west of the 105-D Reactor. The 183-DR Head House is located west of the 190-DR Building.

Waste Type: Not Specified

Waste: The waste is abandoned 7.6 cm (3 in) pipe contaminated with sodium dichromate.

Description:

The SubSite is Part Of:

Code: 100-D-56

Names: 100-D-56; 100-D Area Sodium Dichromate Underground Supply Lines

Code: 100-D-60

Classification: Accepted

Names: 100-D-60; 100D River Lines; 100D/DR River Effluent Pipelines

Reclassification: None

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This site includes the river effluent pipelines (river lines) that extend from the two outfalls in the 100D/DR area into the main channel of the Columbia River.

Location: The river effluent pipelines extend from the discharge (river side) face of their respective outfall structure. The river lines are located in the Columbia River, adjacent to the 100-D/DR area. The lines extend northwest from two outfall structures located near the river shore, through D Island, into the main channel of the river.

Process Description: Reactor cooling water and process sewer wastes were collected and temporarily stored in the 107-D and 107-DR Retention Basins before being pumped to the river via the 116-D-5 and 116-DR-5 outfall structures and associated river effluent pipelines. The river pipeline extends from the 116-D-5 (1904-D Outfall) via two buried 107-centimeter (42-inch) diameter reinforced concrete/steel pipes. The steel pipes have a 1.3-centimeter (1/2-inch) thick wall. The pipe extends approximately 400 meters (1300 feet) into the river, passing through D Island. The pipelines are buried along their entire run to a depth of 0.6 meters (2 feet) to 2.1 meters (7 feet). The outlets are not exposed on the river bed. The riverpipe line extends from the 116-DR-5 (1904-DR Outfall) via a buried 168-centimeter (66-inch) diameter carbon steel pipe with a 1.3-centimeter (1/2-inch) thick wall pipe. The line also extends approximately 400 meters (1300 feet) into the river, passing through D Island (100-D-67, D Island Contamination). The pipeline is buried along its entire run to a depth of 0.6 meters (2 feet) to 1.8 meters (6 feet). The DR outlet is exposed on the river bed.

Related Sites/Structures: The site is associated with the 116-D-5 (1904-D outfall), 100-D-65 Spillway, the 116-DR-5 (1904-DR outfall), 100-D-66 Spillway, 100-D-48 (the 100D process effluent lines), 100-D-49 (the 100DR process sewer lines), and the 100-D-31 (100D water treatment facilities underground pipelines).

Waste Type: Equipment

Waste: The waste includes the pipelines and the contaminated scale contained within them.

Description:

The contaminants of potential concern are based on those for the outfalls themselves. The contaminants of concern for all D/DR river effluent pipelines include C-14, Cs-137, Sr-90, U-

235, -238, and Pu-239/240.

Code: 100-D-61 **Classification:** Accepted
Names: 100-D-61; Utility Pole and Fixture Debris Piles **Reclassification:** Interim Closed Out (10/22/2009)
Type: Dumping Area **Start Date:**
Status: Inactive **End Date:**

Description: The site consisted of debris piles containing utility poles, lead-tipped bolts, railroad ties, light fixtures, scrap wire and cable, scrap construction wood, and other miscellaneous debris from tearing down electrical utility poles. The exact history of the site was unknown.

Location: The site was located northwest of the 105-D Reactor on the northern side of Palouse Street, occupying a surface area of approximately 500 m² (5,400 ft²). The coordinates as reported by Ron Del Mar are N152838, E573481, northeast of the 183-D Filter Plant.

Related Sites/ Structures: Underlying the debris pile was a segment of 100-D-31:6 pipeline.

Waste Type: Misc. Trash and Debris

Waste Description: The waste includes creosote-treated wood poles and cross beams, wood pallets, metal debris, lead-tipped bolts and other debris.

Closure Info: The Remaining Sites Verification Package for the 100-D-61, RSVP-2008-047, has documented that site verification sampling results support a reclassification to Interim Closed Out. The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 1004U-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

Initial remediation of the waste site was performed from November 12, 2007, through January 24, 2008. Approximately 270 metric tons (300 U.S. tons) of surface debris and soil was removed including utility poles, railroad ties, light fixtures, scrap wire and cable, scrap construction wood, and other miscellaneous debris. The soil within the waste site footprint was excavated to a depth of 0.3 m (1 ft) below ground surface (bgs); the resulting 100 bank cubic meters (BCM) (130 bank cubic yards [BCY]) of soil was disposed at the Environmental Restoration Disposal Facility (ERDF).

A global positioning survey was used to delineate the boundaries of the excavation footprint for the purpose of the verification sampling design. The site footprint was located above a section of vitrified clay sewer pipeline associated with the 100-D-31:6 waste site. Subsequent to the initial 100-D-61 excavation, the 100-D-31:6 pipeline was removed. The area associated with the 100-D-31:6 remediation trench was excavated to 1.5 m (5 ft) below grade.

Verification sampling at the site was conducted on June 18, 2008. A statistical sample design was selected for verification sampling because the distribution of potential residual soil contamination was uncertain. The contaminants of potential concern (COPCs) were identified based on types of material (e.g., railroad ties, light fixtures) located at the site and included: lead, barium, cadmium, chromium (total), mercury, selenium, silver, hexavalent chromium, creosote, arsenic, polychlorinated biphenyls (PCBs), total petroleum hydrocarbons (TPH), pesticides, and polycyclic aromatic hydrocarbons (PAHs).

The analytical results indicated residual contamination exceeding cleanup criteria in the

southern portion of the waste site. Further (Phase II) remediation was conducted at the location on October 13, 2008. The soil within the Phase II waste site footprint was excavated to a depth of 1 m (3 ft) bgs. The resulting 50 BCM (65 BCY) of soil was disposed at ERDF. A global positioning survey was used to delineate the boundaries of the Phase II excavation footprint for the purpose of the verification sampling design. A Phase II sample design was developed with regulator concurrence and included a statistical sample design with 10 samples to be analyzed for the COPCs that previously exceeded cleanup criteria. These COPCs included ICP metals, hexavalent chromium, and PAHs.

Phase II verification sampling at the site was conducted on January 21, 2009. The analytical results indicated that the residual concentrations of COPCs at the site have met the remedial action objectives for direct exposure, groundwater protection, and river protection.

All verification samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The complete laboratory results were stored in the WCH Environmental Restoration project-specific database prior to being submitted to the Hanford Environmental Information System for archiving, and were provided in Appendix C of the RSVP.

In accordance with the RSVP evaluation, the verification sampling results support an Interim Closed Out reclassification for the site. These results show that residual soil concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. Site contamination was limited to the shallow zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	100-D-63	Classification:	Accepted
Names:	100-D-63; 100-D/DR Clean Water Pipelines; 100-D/DR Service Water Pipelines	Reclassification:	None
Type:	Product Piping	Start Date:	
Status:	Active	End Date:	
Description:	The waste site is comprised of the 183-D acid addition facility. It includes a concrete trench that protected the service piping (air, steam, filtered water, lime slurry, sulfuric acid) and drained acid waste to the neutralization pit. The underground piping contained in the trench are part of the site with the exception of the filtered water line which is assigned to 100-D-63. The site also includes a dry well, two sumps (exterior to the trench), two storm drains, a storm sewer and an acid/silica supply line.		
Location:	These pipelines were located in the 100-D Area within 100-DR-1 and 100-DR-2 Operable Units.		
Process Description:	The pipelines were designed to supply raw river water from the 181-D River Pump House, treated and filtered at the 183-D Filter Plant to 100-D Area facilities, including the 184-D Boiler House, 182-D Pump House, 190-D and 190-D Annex Pump Houses, 190-DR and 190-DR Annex Pump Houses, 105-D and 105-DR Reactor Buildings, and the 187-D and 187-DR elevated water tanks adjacent to the 105-D and 105-DR Reactor Buildings. The 183-D and DR Filter Plants were used to remove suspended fine solids from river water using chemical flocculation and pH additives, sedimentation basins, and sand/coal bed filters for the physical and chemical treatment of river water to provide solids-free water suitable for reactor cooling, producing steam, and to supply the ancillary water uses within the 100-D and 100-DR Areas, e.g. water makeup, fire water, emergency cooling water (high towers), etc. Prior to 1956 - 1957, the 182-D reservoir was used as the principal water supply source for the 183-D filter		

plants. Following implementation of Project CG-558, the purpose of the reservoir was to provide reserve (emergency) water for reactor cooling, condenser water for the steam condensers, and raw water (export water) to the 200 Areas. The 182-D Reservoir consists of a rectangular, sloped, reinforced concrete basin. The reservoir was divided into two sections by a 25.4 centimeters (10 inches) reinforced concrete wall running parallel to the short dimension of the structure. The inlet section of the reservoir, known as the reserve section, held 56.8 million liters (15 million gallons) of water, while the other, or working section, holds 37.9 million liters (10 million gallons). The Columbia River water was filtered and chemically treated to prevent filming in the reactor process tubes. Alum, sulfuric acid and chlorine were proportioned in the 183-D Head House (component of the 183-D Filter Plant). Raw bauxite was stored in bunkers in the 183-D Filter Building Head House and flowed to a proportional dry chemical feeder which supplied bauxite at the required rate. From the conveyor belt of the proportional feeders, the bauxite fell into a lead-lined mixing chamber together with sulfuric acid and water. The sulfuric acid was used to control the pH of the water. The reaction of the bauxite and diluted sulfuric acid formed a solution of alum and excess diluted sulfuric acid. Chlorine was added at this point for algae control in the settling basins. There were two flocculators in series for each settling basin in the 183-D Filter Plant. The purpose of the settling basins was to allow heavier particulate matter to settle out of the water before entering the filters. The filter media consisted of 0.31 meters (12 inches) of graded gravel, 0.15 meters (6 inches) of sand, and 0.61 meters (24 inches) of crushed and graded anthracite coal. Water entered the gullet from the influent flume through an influent valve and flowed to both halves of the filter through port openings. An organic polyelectrolyte filter aid to improve filter efficiency was added to the water in the gullet to improve water quality. The filtered water collected in the false bottom below the filter and flowed through effluent piping to the effluent flumes. Valves controlled the amount of water passing through the effluent flumes and into the 183-D Clearwells (still within the 183-D Filter Building). The 183-D pump room was the primary supply point for filtered water for the entire production reactor plant. The eastern most clearwell provided the filtered water for power house water, fire and sanitary water (chlorinated before delivery), and for emergency filtered water. Separate pumps and clearwells provided water for the primary reactor cooling water. Filter backwashing was supplied from the clearwells by backwash pumps located in the 183-D Filter Building Pump Room. Backwash water entered the filter collection area, flowed upward through the filter media into the gullet and through a waste valve into a sewer. The backwash water for the 183-DR filters was supplied from the 183-D Pump Room via a 0.76 meters (30 inches) cross-tie pipeline to the 183-DR Pipe Gallery. There was no equivalent to the 183-D Filter Plant Clearwells at 183-DR Filter Plant. This same pipeline was also used to supplement the 183-DR water requirements. The 183-D and 183-DR Filter Plant Pump Rooms were the primary supply points for filtered water for each reactor area and the associated limited area (outside the reactor exclusion area). For the primary reactor cooling system, pumps were provided to transfer water to the 190-D and 190-DR Storage Tanks via 0.91 meter (36 inch) and 0.41 meter (16 inch) pipelines, backwash water for the filters and filtered water for the emergency high tanks. The pumps that supplied the four 1,135,624 Liter (300,000 gallon) high tanks (two at 105-D and two at 105-DR) also provided filtered water for cooling the primary coolant pumps and motors, filter controls and service, reactor thermal loop and control rod cooling. Pumps at 183-D Filter Plant were provided to supply the power house water, fire and sanitary water and for additional emergency filtered water. Four pumps at the 183-D Filter Plant were connected to the combined sanitary and fire protection system. For the 184-D Power House, boiler feed water was provided from four sources of supply, the first three from the 183-D Filter Plant Pump Room and a last ditch source of raw water from the 182-D Reservoir. At the 184-D Power House, three Zeolite water softeners were used to soften the filtered water. In the 184-D, boiler water treatment chemicals, sodium sulfite and tri-sodium phosphate, were used to reduce scale. In the event of total failure of the electric power to the Hanford Site, a secondary power source was available. It was independent of the electrical or primary source, and was capable of providing adequate cooling water to the reactor until the primary system could be re-established.

Related Sites/ Structures: The structures related to this site were the 184-D Boiler House, 182-D Pump House, 190-D and 190-D Annex Pump Houses, 190-DR and 190-DR Annex Pump Houses, 105-D and 105-DR Reactor Buildings, and the 187-D and 187-DR elevated water tanks adjacent to the Reactor Buildings. Related WIDS sites include: 100-D-63, 100-D/DR Service Water Pipelines, 100-D/DR Clean Water Pipelines, 100-D-31, 100-D Water Treatment Facilities Underground Pipelines (See Subsites), 100-D-77, DR Reactor Water Treatment Facility, Acid Facility, 183-DR Head House, 183-DR Filter Building, Sodium Dichromate Systems, 183-DR Flocculation Basins, 183-DR Sedimentation Basins.

Waste Type: Water

Waste Description: The pipelines were the waste, they were associated with the raw water, filtered water, sanitary water, and fire water systems in the 100-D Area. Chemical treatment included pH adjustment (with sulfuric acid or lime), chlorination for algae control, the addition of flocculants, (primarily alum prepared at the 183-D Filter Plant (Head House component) with bauxite and sulfuric acid), and a commercial organic polymer flocculation/filtration aid. This site also includes the potable and fire water that was delivered to the 1700 (site service buildings) series buildings.

Contaminants of potential concern include radiological contaminants.

Code: 100-D-65	Classification: Accepted
Names: 100-D-65; 116-D-5 Outfall Spillway; 1904D Spillway; 100-D-60:1 Flume	Reclassification: None
Type: Outfall	Start Date:
Status: Inactive	End Date:
Description: The site consists of a concrete spillway (a.k.a. flume) that served as an alternate discharge point for the 1904-D Outfall Structure.	
Location: The site is located northwest of 116-D-7 (the 107-D Retention Basin) and upstream of 116-DR-5 (the 1904 DR Outfall Structure). There is an engineered erosion barrier of heavy riprap beginning at the discharge end and extending for an additional 6 meters (20 feet).	
Process Description: The spillway was an alternate discharge point for the 1904-D Outfall Structure. It was planned to be used only if the 100-D-60 river effluent pipelines were blocked, damaged, or undergoing maintenance. There is no corroborated physical or historical evidence that the spillway was ever used.	

Related Sites/ Structures: The site is associated with 100-D-60 (the 100-D River Effluent Pipelines) and 116-D-5 (the 1904-D Outfall Structure).

Waste Type: Construction Debris

Waste Description: No evidence has been found that the spillway was ever put into service, the COPCs for the 100-D-65 spillway would be the same as those for the 116-D-5 outfall structure. The contaminants of concern include carbon-14, cesium-137, strontium-90, uranium-235/238, and plutonium-239/240.

Code: 100-D-66	Classification: Accepted
Names: 100-D-66; 116-DR-5 Outfall; 1904-DR Spillway; 100-D-60:1 Flume	Reclassification: None
Type: Outfall	Start Date:
Status: Inactive	End Date:
Description: The site consisted of a concrete spillway (also referred to as a flume).	

Location: The site is located northwest of 116-D-7 (the 107-D Retention Basin) and downstream of 116-D-5 (the 1904-D Outfall Structure).

Process Description: The spillway was an alternate discharge point for the 116-DR-5 Outfall Structure. It was planned to be used only if the 100-D-60 river effluent pipelines were blocked, damaged, or undergoing maintenance. There is no corroborated physical or historical evidence that the spillway was ever used. Originally the spillway exited the east side of the 116-DR-5 outfall structure, made a rounding 90-degree turn, and continued to the river shoreline. The majority of the spillway was covered over with soil, about 1978 when the outfall structure was demolished. During a site visit on February 7, 2005, a portion of one wall of the spillway was visible.

Related Sites/ Structures: The site is associated with the 100-D-60 River Effluent Pipelines and the 116-DR-5 Outfall Structure.

Waste Type: Construction Debris

Waste Description: No evidence has been found that the spillway was ever put into service, the COPCs for the 100-D-66 spillway would be the same as those for the 116-DR-5 outfall structure. The contaminants of concern include carbon-14, cesium-137, strontium-90, uranium-235/238, and plutonium-239/240.

Code: 100-D-67

Classification: Accepted

Names: 100-D-67; D Island; D Island Contamination

Reclassification: None

Type: Unplanned Release

Start Date:

Status: Inactive

End Date:

Description: The site consists of contamination spread from vent risers that extended from the buried river effluent pipelines (100-D-60).

Location: D Island is a tapered, 213 meter (700 foot) wide island, located approximately 183 meters (600 feet) from the shoreline, directly across from the D and DR outfalls.

Process Description: The island received contamination from the 116-D-5 and 116-DR-5 Outfall Structures via vented river effluent pipelines during operation of 100D/DR Area.

Related Sites/ Structures: 100D River Effluent Pipelines (100-D-60), 100-DR Outfall Structure, (116-DR-5), 1904-D Outfall Structure, (116-D-5)

Code: 100-D-69

Classification: Accepted

Names: 100-D-69; Sodium Dichromate Found Near Pacific Avenue and Paddock Street

Reclassification: None

Type: Unplanned Release

Start Date:

Status: Inactive

End Date:

Description: The site consists of a stained concrete foundation and potentially contaminated soil.

Location: The site is located in a parking lot southwest of the intersection of Pacific Avenue and Paddock Street (the "T" intersection southwest of 105-D Reactor and northeast of the 151-D Substation). The center of the site is estimated at E573695.26, N151358.74.

Process Description: Reportedly, during early D&D activities at 100D, involving the 100D water plants, concrete debris was crushed and spread in-lieu of gravel fill. Adjacent areas have been covered with

gravel as part of field remediation's parking lot construction activities. Likely, the material has been there for approximately 10 years. Gravel covered areas are not characterized.

Related Sites/ Structures: The site may have been related to the decommissioning of the 190-D Complex in 1996.

Waste Type: Chemical Release

Waste Description: The waste is sodium dichromate contaminated concrete. Sodium dichromate was the only contaminant of potential concern.

Code: 100-D-70

Classification: Accepted

Names: 100-D-70; 184-DA; 184DA Steam Generating Plant Dry Well

Reclassification: No Action (7/7/2011)

Type: French Drain

Start Date:

Status: Inactive

End Date:

Description: The waste site consists of a 122 centimeter (48 inches) diameter drywell located on the south side of the 184-DA Building. It received steam separator discharge from equipment within the former 184-DA (demolished) Building. The pipeline from the building to the dry well is part of site 100-D-88. Confirmatory sampling results supported a reclassification of the 100-D-70 waste site to No Action.

Location: The drywell is on the south west side of the former 184DA Building. The 184DA building was located just south of the 1719D First Aid Station, southeast of the 1716D Gas Station, and north of the 189D building.

Process Description: The 184DA Building was a metal building constructed in 1968 and was designed as a steam generating facility. The facility contained a steam generator, fuel oil storage tank, fuel oil pump, deaerator, water softener, chemical treatment, fuel tank, steam separator, heater, diesel generator, liquid level gauges, and steam flow meter. One fuel tank (100-D-9) was located near the northwest corner of the building and has been removed. The other fuel tank was located near the southeast corner of the building. GPR was conducted in the southeast corner of the building and could not confirm if the tank was present.

Related Sites/ Structures: The site was associated with 184-DA Building only.

Code: 100-D-71

Classification: Accepted

Names: 100-D-71; Vertical Safety Rod Tower Components

Reclassification: None

Type: Laboratory

Start Date:

Status: Inactive

End Date:

Description: The site currently consists of the following components: A 1.2 meter (4 foot) diameter by 2.2 meter (7 foot) deep concrete drywell, a below grade pit that is approximately 30.5 centimeters (12 inches) square, a 7.6 centimeter (3 inch) diameter underground cast iron process waste pipe, originating at the bottom of the tower's elevator shaft, and any potentially contaminated soil. It is unknown to whether the components are still at the site. The cast iron pipe extended underground from the pit, on the north side of 195-D Building, west about 12 meters (39 feet) to the drywell. Wastes generated in the tower collected in a floor pit located at the bottom of the tower's elevator, which then drained to a drywell.

Location:	french drain is centered at coordinates E573542.5, N151538.6. The pit is centered at coordinates E573558.9, N151541.4.
Process Description:	Constructed in 1957 (Project CA-548), the structure was a steel tower built to replace the original wooden VSR at White Bluffs. It was constructed of corrugated steel wall over steel framing and sat on a 1 meter (3 feet) thick underground octagonal shaped concrete base. Its construction coincided with major upgrades and expansions of the pumping and piping systems of the Hanford reactors to allow increased power levels. At the time these power level increases were proposed, an intensive review was performed of all of the safety and control equipment associated with the eight reactors.
	The Ball 3X systems were investigated in 1959 and in-pile ball removal equipment was designed and tested in the 195-D building. By the late 1960s, the N Reactor was experiencing multiple problems with the Ball 3X system. During N Reactor's next 15 years of operation, tests were conducted to evaluate various aspects of ball mechanics and operation and of the issues and difficulties raised by graphite distortion effects on the ball channels. The testing in this tower helped establish criteria for the ball system upgrade that actually occurred in 1984. Following these tests, very little work was done in the building.
Related Sites/ Structures:	This site relates to the 195-D VSR Tower. The tower was a stand-alone test facility.
Waste Type:	Oil
Waste Description:	Potential contaminants of concern (COPCs) would include oils and PCBs.
	No testing with radiological materials was known to have occurred in the tower. A transformer bearing PCB oil was located inside the tower on the ground floor. Industrial chemicals and lubricating oils were used in the building. It is not known what, if any, dangerous or hazardous chemical wastes may have been discharged to the dry well.

Code:	100-D-72	Classification:	Accepted
Names:	100-D-72; 183D Acid Facility	Reclassification:	None
Type:	Process Unit/Plant	Start Date:	
Status:	Inactive	End Date:	
Description:	The waste site is comprised of the 183-D acid addition facility. It includes a concrete trench that protected the service piping (air, steam, filtered water, lime slurry, sulfuric acid) and drained acid waste to the neutralization pit. The underground piping contained in the trench are part of this waste site, with the exception of the filtered water line which is assigned to 100-D-63. The site also includes a dry well, two sumps (exterior to the trench), two storm drains, a storm sewer and an acid/silica supply line.		
Location:	The site is south of the 183-D Head House, east of the railroad car spot and on the west side of the flocculation basins.		
Release Description:	All activities associated with this waste site are related to the unloading, storage and use of acid to support water treatment in the 183-D Head House.		
Process Description:	All components were associated with the storage and flow of sulfuric acid to the 183-D Head House where it was added for water treatment. The 183-D Head House was designed to treat raw river water before it entered the reactor. Chemicals were added to the river water in the head house. The head house was used for the storage, preparation, and addition of alum, sulfuric acid, and chlorine for water treatment. Alum was used as a flocculating agent and the excess sulfuric acid was used to control the acidity of the water. Bauxite was stored in bunkers		

on the third floor and used at a required rate. Chlorine was added to control algae. Concentrated sulfuric acid was received by railroad car and stored in the outside acid storage tanks. It was pumped from the storage tank to the head tank through black iron pipelines. The building also contained a laboratory, restrooms, janitor's room, electrical switchgear room, and locker room. As of August 2006, the 183-D Head House is inactive, but still intact.

Related Sites/ Structures: The site was associated with the 183-D Head House, flocculation basins and 100-D-31 water treatment facilities underground pipelines.

Waste Type: Soil

Waste Description: Contaminants of potential concern (COPCs) include lead and mercury. Sulfuric acid used at the head house may have contaminated impurities, such as lead and mercury.

The trench exits the south side of the 183-D Head House and continues toward the two sulfuric acid storage tanks. The trench is 0.76 m (2 ft 6 in) wide and depending on the location contains different piping. From the south side of the 183-D Building to the sulfuric acid pumps, the trench contains a 2.5 cm (1 in) steam line, a 5 cm (2 in) filtered water line, a 5 cm (2 in) lime slurry line and a 1.9 cm (0.75 in) air line. From the sulfuric acid pumps to the two sulfuric acid storage tanks, the trench contains 1 steam line, a 5 cm (2 in) lime slurry line, a 5 cm (2 in) sulfuric acid line that goes to the storage tank, a 5 cm (2 in) sulfuric acid line that goes to the head tank, and 2-5 cm (2 in) PVC storage tank drains in the bottom of the trench.

Code: 100-D-73

Classification: Accepted

Names: 100-D-73; 108-D Chemical Pump House

Reclassification: None

Type: Process Unit/Plant

Start Date:

Status: Inactive

End Date:

Description: The site is the soil and possibly the demolition debris under the former 108-D Building. It was identified as part of the Orphan research for sodium dichromate investigation conducted for the D/DR Reactor area.

Location: The 108-D Building was located north of the 105-D Reactor and east of the 1709-D Building.

Release Description: A mixing tank may have discharged high concentrations of sodium dichromate into the soil. It was reported that "several sodium dichromate storage tanks associated with the water treatment facilities overflowed or drained into the process sewer and outfall. Monitoring wells near the 108-D Building indicate that up gradient well 199-D5-15 contained chromium concentrations higher than the down gradient well 199-D5-14. Suggesting sodium dichromate may have originated from this area.

Process Description: From about 1944 until 1950, the receiving, mixing, and transfer of sodium dichromate were conducted in the 108-D Building. The 108-D facility received, stored, and prepared various chemicals for the preparation of solution concentrations. Chemicals were unloaded from railcars at the weather-proof unloading railroad car spot in either bags or barrels (Spec. HW-2036). The method utilized for the mixing of sodium dichromate chemicals in the 108-D Building was referred to as the "batch method" that consisted of dichromate in crystalline form. The crystalline material was dissolved in water and diluted to a 10% to 15% dichromate solution, mixed, and transferred to feed tanks in the 105-D and 185-D Buildings. Although the total quantity of material used in the facility is unknown, some indication is available; for example, from January 29 through February 25, 1945, 8,960 kilograms (19,736 pounds) were mixed into solution (HW-7-1388 Del). Required additives were prepared in batches and emptied into the conical mix tank (HAN-10970). Water was added and a 10% concentration of sodium dichromate solution was prepared and pumped by two transfer pumps to one of two

solution feed tanks located near the #1 deaerator on the mezzanine floor in the 185-D Building. Each tank in the 185-D Building had a 3,800 Liter (1,000 gallon) capacity and dimensions of 1.6 meters by 2.4 meters (5 feet 4 inches by 8 feet) (Spec. 2017). From the tanks, sodium dichromate was added to the process water at the exit side of the deaerators in the 190-D Building. The above grade structures of the 185-D and 190-D Buildings have been demolished. Mixed sodium dichromate was pumped from the 108-D Building through two different pipelines. One overhead pipeline connected to the 105-D Reactor and the other below grade to the 185-D Building (W-74552). Pumps in the 108-D Building transferred sodium dichromate to the 105-D Reactor through a 7.6 centimeter (3 inches) diameter overhead pipeline to the valve pit extension into a storage tank located in the acid mixing area (Spec. HW-2036 and W-73176). The second pipeline was a 7.6-centimeter (3 inches) diameter sodium dichromate pipeline (100-D-56) that extended from the west side of the 108-D Building to the north side of the 185-D Building. Mixed solutions were injected into the process water systems in the 105-D and 185-D Buildings (Spec. HW-2036). These pipelines were active until about 1950 when the mixing facility was relocated to the 185-D Building as part of Project C-396 (H-1-2901). Research suggests that the mixing of sodium dichromate into solution in the 108-D Building and associated pipelines was discontinued in 1950. Previous investigations stated that sodium dichromate storage tanks were located on the west side of the 108-D Building. Historical research indicates that no sodium dichromate storage tanks ever existed outside the west side of the 108-D Building. The only tanks located on the west sides of the facility were two sulfuric acid tanks and two sodium silicate tanks.

Related Sites/ Structures: A total of eight pipelines were associated with the 108-D Building. The 108-D Building was associated with the two sodium dichromate lines (100-D-56) that exited the west side of the facility and extended to the 185-D Building. It is also associated with a 7.6 centimeter (3 inches) diameter overhead sodium dichromate line that extended from the 108-D to the 105-D Reactor (removed). There are also two pipelines (100-D-63) that exit the northwest corner of the facility. Three pipelines are associated with 100-D-31. Structures associated with the sodium dichromate system included the 185-D, 190-D Pump Room and sodium dichromate tank and the 183-DR Head House.

Waste Type: Chemicals

Waste Description: The waste is potentially contaminated soil because of the releases from the 108-D Building. There is a potential for sodium dichromate, oxalic acid, sodium silicate, and radionuclides under the existing below grade footprint of the 108-D Building.

Soil samples collected in 1994 indicate the presence of radionuclide contamination that may include Carbon-14, Potassium K-40, radium Ra-226, Thorium-228, and Thorium-232 (DOE/RL-93-29). The possibility also exists for sodium dichromate. It is not known what would cause the presence of radionuclide contamination.

Code: 100-D-74	Classification: Accepted
Names: 100-D-74; Drywell Well	Reclassification: No Action (6/15/2011)
Type: French Drain	Start Date:
Status: Inactive	End Date:
Description: The site is a drywell.	
Location: The drywell is located north of the northwest side of original 105D Reactor footprint. The coordinates of the dry well are E 573744.2, N 151316.3.	
Process Description: Drawing H-1-8522-DR, indicates the purpose of the dry well was to receive steam condensate from the heaters inside the 105-DR Building. In conjunction with the dry well is a flash tank (flash steam to condensate) and a 5.1 cm (2 in) line to the dry well. Although the drawing is not	

clear, it also appears that some floor drains were connected also. Steam heating is a non-contact system isolated from radiological contaminated portions of the facility. The entire building was a negative draft system vented through the 117-D Filter Building eliminating the possibility of radiological contamination in this part of the building.

Related Sites/ The site is associated with the 105-DR Reactor.

Structures:

Waste Type: Steam Condensate

Waste The site received steam condensate from the heating units inside the 105-DR Reactor.

Description:

Code: 100-D-75 **Classification:** Accepted

Names: 100-D-75; 151-D Primary Electrical Substation; **Reclassification:** None
152-C1-D & 152-E1-D Secondary Electrical Substations

Type: Electrical Substation

Start Date:

Status: Inactive

End Date:

Description: The waste site contains of three components: the area within the fence at the 151-D Primary Substation, and two Secondary Electrical Substations (152-C1-D and 152-E1-D). Electrical substations are automatically categorized as New Discovery Sites because historically leaks and spills of PCBs from the electrical transformers, circuit breakers, and transfer systems during the early years of operation went unreported. An analogous site, the 151-H Primary Substation (100-H-24) was remediated in 2000, by removing and disposing of more than 21,000 tons of PCB-contaminated material. All three substations are inactive (not providing any electrical power to D Area), although live 230KV power lines will be routed across the 151-D switchyard for the foreseeable future. The site has been divided into three subsites as follows:

100-D-75:1, 151-D Primary Electrical Substation

100-D-75:2, 152-E1-D Secondary Electrical Substation, Substation C4-S1

100-D-75:3, 152-C1-D Secondary Electrical Substation

Location: The 151-D Building and associated switchyard are located approximately 350 m (107 ft) southwest of the 105-D Reactor building and 235 m (72 ft) northwest of the 105-DR Reactor building, with the center point of the yard at N 151328, E 573542.

The 152-C1-D Secondary Electrical Substation, centered at (N 151584, E 573369), is near the 183-D Filter Building.

The 152-E1-D Secondary Electrical Substation, centered at (N 151692.84, E 572833.69), is near the 181-D Pump House.

Release Description: The only significant reported release of transformer oil was in 1995 in the 151-D switchyard. The site was remediated, and reclassified to Closed Out. See WIDS General Summary Report 100-D-27 for details.

Process Description: The Midway Station fed 230KV power to the 31,250KVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D/DR Area. Circuit breakers were also in service to support the switchyard operations. PCB-containing oil was transferred, as needed, from a rail tanker on the railroad spur through over ground hoses and piping to transformers and oil circuit breakers in the yard. The smaller transformers at the

secondary and distribution substations were also filled via over ground hoses from oil trucks.

Related Sites/ Structures: The 151-D Primary Substation distributed 13.8KV power to transformers located at the 181-D River Pump House, 182 Head Houses, 183 Filter Houses, 184-D Power House, 186-D Water Treatment Plant, 190 Pump Houses, and 105-D/DR Reactors, which in turn distributed power to associated facilities. The 151-D Switch House is essentially a one-story building, having a sub-level cable pit equipped with a sump pump. All duct lines originate/terminate at the Switch House. The cable pit is a completely enclosed reinforced concrete pit with floor slab, varying from 0.3 to 0.4 meters (1 to 1.5 feet) in thickness, and with 0.3 meters (1 foot) thick walls. Switchgear is located on the main floor directly above the cable pit. The overall dimensions of the Switch House are 25 meters by 9.3 meters by 8.7 meters (83 feet by 30.5 feet by 28.5 feet.)

Waste Type: Soil

Waste Description: PCB contamination of the soil surrounding the transformer and circuit breaker pads is the

primary waste concern. PCB-contaminated soil could also exist along the railroad spur.

This Site has the Following SubSites:

Code: 100-D-75:1

Names: 100-D-75:1; 151-D Primary Electrical Substation

Code: 100-D-75:2

Names: 100-D-75:2; 152-E1-D Secondary Electrical Substation; Substation C4-S1

Code: 100-D-75:3

Names: 100-D-75:3; 152-C1-D Secondary Electrical Substation

Code: 100-D-75:1

Classification: Accepted

Names: 100-D-75:1; 151-D Primary Electrical Substation

Reclassification: None

Type: Electrical Substation

Start Date:

Status: Inactive

End Date:

Description: The substation consists of a fenced, gravel-bed yard measuring approximately 165 m (541 ft) on a side with the 151-D Switch House along the northern fence line. A railroad spur enters the yard from the east, and parallels the north fence line. Concrete pads of various sizes protruded from the crushed gravel bed throughout the yard, supporting a variety of electrical equipment, including transformers, circuit breakers, and power line towers and stands.

The 31,250 KVA transformers were originally located at N 151338, E 573515; and N 151338, E 573556. Sometime after 1956 a third very large ground transformer was added at N 151374, E 573516. The circuit breakers were located at N 151300, E 573494; N 151300, E 573536; and N 151300, E 573576.

Location: The 151-D Building and associated switchyard are located approximately 350 m (107 ft) southwest of the 105-D Reactor building and 235 m (72 ft) northwest of the 105-DR Reactor building, with the center point of the yard at N 151328, E 573542.

Process Description: The Midway Station fed 230KV power to the 31,250KVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D/DR Area. Circuit breakers were also in service to support the switchyard operations.

PCB-containing oil was transferred, as needed, from a rail tanker on the railroad spur through over ground hoses and piping to transformers and oil circuit breakers in the yard.

An oil spill from one of the 151-D switchyard transformers was remediated in 1995 (100-D-27). This may not have been the extent of transformer leaks and spills, because such events were not consistently recorded before about 1985. And there is anecdotal information from power operators that transformer spills and leaks were not uncommon. Therefore, any transformer or circuit breaker pad and surrounding soil may have PCB contamination.

According to the Electrical Utilities Craft Supervisor, the equipment in the 151D yard is inactive. The only thing energized is the overhead lines going through the yard. Because there is a section of energized 230kV buswork that runs through the substation yard, the yard is off-limits to all except qualified T system workers. Most of the equipment within the substation has already been drained of oil.

The circuit breakers stored in the northeast corner of the switchyard are disconnected and drained. These circuit breakers could not have been in use at this location. When in service the circuit breakers would have to be put on a concrete pad and bolted to the overhead bus.

Two smaller transformers that were added at the switchyard are old 181D transformers (100-D-75:2). Both PCB Contaminated Transformers were drained on 7/12/2005. This action stopped the 5-year TSCA time requirement. Based on the available aerial photography it is evident that the two smaller transformers were added to the switchyard sometime between April 2008 and August 2009.

The switch house was used as a regulatory component to the switchyard. Historically, there are no processes that indicate any type of contamination to be associated with this structure.

Related Sites/ Structures: The 151-D Primary Substation distributed 13.8KV power to transformers located at the 151-D Switch House, 181-D River Pump House, 182 Head Houses, 183 Filter Houses, 184-D Power House, 186-D Water Treatment Plant, 190 Pump Houses, and 105-D/DR Reactors, which in turn distributed power to associated facilities.

Waste Type: Soil

Waste Description: There may be PCB contaminated soil at these substation sites.

The SubSite is Part Of:

Code: 100-D-75

Names: 100-D-75; 151-D Primary Electrical Substation; 152-C1-D & 152-E1-D Secondary Electrical Substations

Code: 100-D-75:2

Classification: Accepted

Names: 100-D-75:2; 152-E1-D Secondary Electrical Substation; Substation C4-S1

Reclassification: None

Type: Electrical Substation

Start Date:

Status: Inactive

End Date:

Description: The secondary substation consists of a small fenced area with concrete pads for the former transformers and inactive electrical components.

Location: The 152-E1-D Secondary Electrical Substation, centered at (N 151692.84, E 572833.69), is near the 181-D Pump House.

The shape of the 152-E1-D Secondary Electrical Substation is rectangular and has a perimeter of 478.9 m (1571.2 ft). Its length is 137.6 m (451.44 ft), width 91.25 m (299.38 ft), Square Area

12959.5 m2 (139494.9 ft)

Process Description: The Midway Station fed 230KV power to the 31,250KVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D/DR Area. The smaller transformers at the secondary and distribution substations were filled with PCB-containing oil via over ground hoses from oil trucks.

Based on the historical photograph (P-4479) originally the two transformers existed behind the power poles. According to the D-Area, National Code Inspector, two concrete pads that are currently located at this secondary substation is suspected to have housed two smaller transformers after downsizing to provide power for 181D Pump House. The transformers have since been removed, but the concrete pads remain. The transformers were added to the 151-D switchyard (100-D-75:1). The transformers were drained of PCB-containing oil on 7/12/2005. This action stopped the 5-year TSCA time requirement. Based on the available aerial photography it is evident that the two smaller transformers were added to the switchyard sometime between April 2008 and August 2009.

Waste Type: Soil

Waste Description: There may be contaminated soil at these substation sites.

The SubSite is Part Of:

Classification: Accepted

Names: 100-D-75:3; 152-C1-D Secondary Electrical Substation

Reclassification: No Action (8/8/2011)

Type: Electrical Substation

Start Date:

Status: Inactive

End Date:

Description: Three transformers were located at this substation, but have since been removed; leaving the three concrete pads that supported the transformers.

Location: The 152-C1-D Secondary Electrical Substation, centered at (N 151584, E 573369), is near the 183-D Filter Building.

The 152-C1-D Secondary Electrical Substation has a rectangular perimeter of 42.3 m (138.8 ft). Length 8.60 m (28.22 ft), width 13.6 m (44.62 ft)

Process Description: The Midway Station fed 230KV power to the 31,250KVA transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary and distribution substations located throughout the 100-D/DR Area. The smaller transformers at the secondary and distribution substations were filled with PCB-containing oil via over ground hoses from oil trucks.

A portion of the 100-D-31:9 pipeline was located directly beneath the 152-C1-D Secondary Electrical Substation. During the remediation of the 100-D-31:9 waste site the three concrete pads at the 152-C1-D Secondary Electrical Substation and portions of the surrounding soil were removed and disposed of at the Environmental Restoration Disposal Facility (ERDF). Additional surrounding soil was collected as part of the overburden for the 100-D-31:9 waste site. The 152-C1-D secondary substation will be addressed using the sample results associated

with the 100-D-31:9 closeout sampling.

Waste Type: Soil

Waste Description: There may be PCB contaminated soil and concrete at these substation sites.

Description:

The SubSite is Part Of:

Code: 100-D-75

Names: 100-D-75; 151-D Primary Electrical Substation; 152-C1-D & 152-E1-D Secondary Electrical Substations

Code: 100-D-76

Classification: Accepted

Names: 100-D-76; Potential Crib Next to 108D; Potential Former 116-D-3 Crib

Reclassification: None

Type: Crib

Start Date: 1/1/1951

Status: Inactive

End Date: 1/1/1967

Description: The site is possible crib located near the former 108D building. It was identified during a geophysical investigation. The waste site is either a french drain or crib. It may be the crib formerly known as 116-D-3. Historical documentation, a construction drawing, and GPR results indicate that waste site 116-D-3 probably remains near the southeast corner of the 108-D Building.

Location: The site is located just off the edge of southeast corner of the former 108D building.

Related Sites/Structures: The crib is associated with the 108-D Building and a vitrified clay pipe known as 100-D-31:3 that crosses this waste site in a north/south direction. It is also associated with 116-D-3.

Waste Type: Process Effluent

Waste Description: Due to the confusion of the location of the crib, the same historical documentation may apply to waste sites 116-D-3 and 116-D-4. Historical information suggests the crib may have received low level fission product wastes from the contaminated maintenance shop and cask decontamination pad in the 108-D Building. The crib received 0.08180 curies of Cs-134 and 30,000 liters. (7,920 gallons) of liquids. The contaminants of potential concern are assumed to be the same for 116-D-4 that were uranium-238 and hexavalent chromium.

Code: 100-D-78

Classification: Accepted

Names: 100-D-78; 100D Yellow Stained Soils

Reclassification: None

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: The site consists of four locations of contaminated soil between the 183-D and 186-D Buildings. The staining for these locations is yellowish in color with some areas of white crusty material. Stain one and two are in the area where the acid trench was located and may parallel nearly the entire length of the west wall of the 186-D Building. Stain three is near the southwest corner of the Waste Acid Trench (120-D-2). Stain four is southwest of the Waste Acid Reservoir.

Location: The patches of yellow-stained soil are scattered throughout the 100D area.

Process Description: The potentially contaminated soil may have originated from activities associated with the 186-D Building, which was initially constructed as a demineralization plant to remove dissolved calcium, magnesium, and salts through sulfonated coal. However, the building was not used for

this purpose. Historical information is very limited for this facility. Although the exact historic use of the facility is unknown, it is believed that it was used for a period of time for storage. The overall dimensions of the building were 204 by 39 by 27 meters (670 feet by 128 feet by 87 feet). The demineralization plant was a two story structure with a reinforced concrete foundation, reinforced concrete slab floor, steel framework, concrete block superstructure and built-up roofing over precast concrete tile slabs. The ground floor contained two banks of twelve wood mixing tanks located on the east side of the facility. Between the mixing tanks were four wood acid reclaiming tanks and two steel soda reclaiming tanks. Two steel soda dissolving tanks were located at the southern end of the facility. The second floor contained 24 wood tanks along the east wall. The building contained acid tanks, pumps, clearwells and associated equipment. The clearwells were mostly below grade and were located along the east side of the facility with dimensions of 166 by 17 by 9 meters (545 feet by 55 feet by 30 feet). The clearwells and pump building adjoined the 185-D Building. Adjacent to and east of the center portion of the clearwells was a pump house that contained seven stainless steel water pumps. Along the west wall is an acid-proof brick trench approximately 1.2 meter by 1.8 meters (4 feet deep by 6 feet wide), that extends almost the entire length of the building. The trench empties into the 186-D Waste Acid Reservoir (120-D-2). Approximately 3 meters (10 feet) west of the plant at the south end of the building were six, outside, horizontal sulphuric acid steel tanks. West of the 186-D Building was the Waste Acid Reservoir (120-D-2) used for the disposal of waste acid from the facility. The Waste Acid Reservoir was constructed of acid proof brick with a 3 ply water proof membrane. Drain pipes were connected to the D-Area process sewer system. It was demolished in 1979 and buried in place.

Related Sites/ Structures: Related structures included: the 186-D Waste Acid Reservoir waste site 120-D-2 and the 186-D Building.

Waste Type: Soil

Waste Description: The 186-D Waste Acid Reservoir has been identified as a site requiring remediation as stated in the interim ROD for the 100-DR-1, 100-DR-2 Operable Units, so the waste is potentially contaminated soil.

Contaminants of Potential Concern indicated by sample data are asbestos, ICP metals, mercury, PCB, herbicide, pesticide, and hexavalent chromium were present.

Code: 100-D-80

Classification: Accepted

Names: 100-D-80; 100D Tar Stained Soils & Miscellaneous Debris

Reclassification: None

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: The site consists of four areas that were discovered during the 2006 Orphan Site's Evaluation (OSE) field investigation (EL-1583-6). The areas contain a broken light bulb, tar like material, oil staining and a valve box. The site has been divided into two subsites as follows: 100-D-80:1 Tar Stained Soil & Miscellaneous Debris (Areas 1, 2 and 3) and 100-D-80:2, Valve Box with Possible Asbestos Insulation (Area 4).

Location: The debris and patches of tar-stained soil are scattered throughout the 100D area. See subsites for precise locations.

This Site has the Following SubSites:

Code: 100-D-80:1

Names: 100-D-80:1; Tar Stained Soil & Miscellaneous Debris (Areas 1, 2 and 3)

Code: 100-D-80:2
Names: 100-D-80:2; Valve Box with Possible Asbestos Insulation (Area 4)

Code: 100-D-80:1
Classification: Accepted
Names: 100-D-80:1; Tar Stained Soil & Miscellaneous Debris (Areas 1, 2 and 3)
Reclassification: No Action (3/30/2011)
Type: Dumping Area
Start Date:
Status: Inactive
End Date:

Description: This subsite consists of three areas identified during the 2006 100-D Area Orphan Site Evaluation (OSR-2006-0001). These areas are not associated with any particular process other than by proximity. Area 1 was identified on April 10, 2006. Area 2 was identified on April 11, 2006. Area 3 was identified on May 8, 2006.

Area 1 was identified as a single broken light bulb (Orphan Site ID# D48), located approximately 100 m (328 ft) south of the 118-D-1 waste site. Area 1 is centered at coordinates E 573068.8, N 151491.248. The bulb had a metal base, a clear glass cover, and two internal fluorescent-type bulbs. The bulb was approximately 6.4 cm (2.5 in.) in diameter and 0.61 m (2 ft) in length. Fixtures were not associated with this bulb, and the bulb may have been an early intrinsically safe bulb with hand-blown glass. During a site visit on November 4, 2009, no evidence of a light bulb was found at this location.

Area 2 contained a tar-like material with a fiber matrix that appeared to have been dumped (Orphan Site ID# D49). The area lies within the 118-D-3 Burial Ground sorting cells and has been previously removed during 118-D-3 remediation activities. Area 2 was located approximately 260 m (853 ft) southeast of the 100-DR Reactor and 110 m (387 ft) northwest of the 100-D-17 waste site and centered at coordinates E 574022.38, N 151103.16. A 1948 photo indicates that the site was east of construction support buildings and apparent lay down areas.

Area 3 is classified as a tar-and oil-stained area (Orphan Site ID# D65), located approximately 50 m (164 ft) south of the southwest corner of the 182-D Reservoir. Area 3 is centered at coordinates E 573757.9, N 150857.4. The site is vegetated with native grasses. Area 3 appears to be a possible oil changing location. Confirmatory sampling was performed on this portion of the waste site in August 2010.

Location: Area 1 is located approximately 100 m (328 ft) south of the 118-D-1 waste site. Area 1 is centered at coordinates E 573068.8, N 151491.248.

Area 2 is located approximately 260 m (853 ft) southeast of the 100-DR Reactor and 110 m (387 ft) northwest of the 100-D-17 waste site. Area 2 is centered at coordinates E 574022.38, N 151103.16.

Area 3 is located approximately 50 m (164 ft) south of the southwest corner of the 182-D Reservoir. Area 3 is centered at coordinates E 573757.9, N 150857.4.

Waste Type: Soil
Waste Description: The waste is any potentially contaminated soil.

Closure Info: One shallow soil sample (0 to 0.15 m [0 to 6 in.] below ground surface) and one duplicate soil sample were collected from Area 3 at the location where evidence of tar and oil staining were observed during the orphan sites investigation in 2006. No radiological activity or volatile organic compounds (VOCs) were detected during confirmatory sampling. Analysis was performed to evaluate if contamination associated with tar or oil was present. Confirmatory

sampling at the 100-D-80:1 subsite indicated that environmental contamination was not present, and remedial action was not necessary. The confirmatory sampling data has been used for a No Action determination. Table 1 identifies the locations and analyses for each confirmatory sample.

The SubSite is Part Of:

Code: 100-D-80

Names: 100-D-80; 100D Tar Stained Soils & Miscellaneous Debris

Code: 100-D-80:2

Classification: Accepted

Names: 100-D-80:2; Valve Box with Possible Asbestos Insulation (Area 4)

Reclassification: None

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: Subsite two consists of Area 4, located south of the 182-D Reservoir and northwest of the 183-DR Head House. This area contained a small wooden structure, which contained piping (Orphan Site ID# D76). This structure is believed to be a valve box cover, possibly to prevent freezing pipes during the winter months. A raw water pipeline was known to have existed in the area. The proximity of the valve box to the 91 cm (36 in) raw water pipeline would suggest that it is associated with the 100-D-63 pipelines. Due to the presence of friable asbestos, this structure will be recommended for remediation without further confirmatory evaluation.

Location: This subsite is located south of the 182-D Reservoir and northwest of the 183-DR Head House. Area 4 is centered at coordinates E 573111.347, N 151295.8. The area dimensions are 1 m (3 ft) by 1 m (3 ft).

Waste Type: Not Specified

Waste Description: The waste is potential asbestos containing materials that have been abandoned.

The SubSite is Part Of:

Code: 100-D-80

Names: 100-D-80; 100D Tar Stained Soils & Miscellaneous Debris

Code: 100-D-81

Classification: Accepted

Names: 100-D-81; 100D Burn Areas and Other Stained Areas

Reclassification: None

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: During the 4/26/06 Orphans Sites field walk down a total of eight soil areas were identified as either stained soil or a burn area.

Location: The burned and stained areas are scattered throughout the 100D area.

Code: 100-D-82

Classification: Accepted

Names: 100-D-82; 100D Garnet Sand Sites

Reclassification: No Action (1/6/2011)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: This site has three areas. They were all discovered during the WCH Orphan Site's Evaluation

field investigation during 2007. Area 1 was located during the OSE field investigation on 4/11/06, area ID 77, photos 10 and 11. The site contains garnet sand. Area 2 is a garnet sand location discovered during the OSE field investigation. The garnet sand was recorded on 5/4/06, area ID 291, photos 9 and 10. Area 3 was discovered during the OSE field investigation on 5/2/06, point ID 265, photo 40. The garnet sand is located in an area with what appears to be a concrete sidewalk.

Location: Area 1 is located southeast of the 105-DR Reactor. The site is centered at coordinates E 573909.37, N 151021.07. Area 2 is located just west of the 1716-D Building. It is centered at coordinates E 573516.8, N 151794.9. Area 3 is located northwest of the 105-D Reactor and northeast of the 190-D Building. It is centered at E 573695.229, N 151676.929.

Process Description: Garnet sand was recorded as waste sites due to their potential to contain contaminants. Garnet grit was commonly used in sandblasting operations to remove rust, paint, and other contaminants from the surface of metal components. The garnet sand itself is not hazardous.

Related Sites/ Structures: Area 1 was associated with 105-DR (Reactor). Area 2 was associated with 1717-D (Maintenance Shop) and 184-D (Power House). Area 3 was associated with 105-D (Reactor) and 190-D (Main Pump House). Also with waste sites 100-D-31:1, 31:2, and 31:7.

Waste Type: Soil

Waste Description: Garnet grit was commonly used in grit-blasting operations to clean rust, paint, or contamination from the surface of metal components. The garnet material is not a hazardous substance, but there was a potential for contamination from the surface material that was removed by grit blasting. Contaminants of potential concern include lead, mercury and polychlorinated biphenyls (PCBs).

Closure Info: The Remaining Sites Verification Package (RSVP) for the 100-D-82 has documented that the site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGS) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD). The RSVP and sampling results support a reclassification of the site to No Action.

A site visit was performed in October 2009. Areas 2 and 3 were observed to have been removed as a part of the 100-D-31:1, 100-D-31:2 and 100-D-31:7 pipelines remediation. Area 1 of 100-D-82 was readily identifiable; it existed as flat terrain and could be readily accessed for confirmatory sampling.

Due to the extent of the 100-D-31 excavations, Areas 2 and 3 of the 100-D-82 waste site were fully removed and disposed at the Environmental Restoration Disposal Facility. Only Area 1 was addressed by the confirmatory work instruction for this waste site.

The COPCs included polychlorinated biphenyls (PCBs), mercury, chromium, lead, and the remaining inductively coupled plasma (ICP) metals. While it was not considered a COPC, analysis for hexavalent chromium was performed to support the effort to identify hexavalent chromium sources across the 100-D Area.

Confirmatory sampling was performed, and the analytical results indicate that the residual concentrations of COPCs at this site meet the RAOs for direct exposure, groundwater protection, and river protection. The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to provision to the Hanford Environmental Information System (HEIS) and were presented as an attachment to the Direct Contact Hazard Quotient and Relative Percent Different (RPD) calculation in Appendix C of the RSVP.

These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow-zone soil (i.e., surface to 4.6 m [15 ft]), and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The 100-D-82 waste site did not extend into the deep zone; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required.

Code:	100-D-83	Classification:	Accepted
Names:	100-D-83; 100D Treated Water Pipelines	Reclassification:	None
Type:	Product Piping	Start Date:	
Status:	Inactive	End Date:	
Description:	The site includes 56 additional treated water pipe segments that were not previously identified within an existing waste site. The pipelines supported the pre-reactor non-radioactive cooling water processing facilities. The pipelines were used to transfer chemical products to the water treatment building and treated cooling water to the reactor and laboratory facilities. The additional pipeline segments also include any associated manholes (with associated drains), catch basins, junction boxes, valve control systems or any other below surface related feature. The site has been divided into four subsites as follows: 100-D-83:1 183-DR Acid Addition Pipelines 100-D-83:2 183-DR Filter Backwash Connection 100-D-83:3 108-D Acid Addition Facility Pipelines 100-D-83:4 Additional Treated Water Pipelines 100-D-83:5 186-D Acid Neutralizing System Pipelines		
Location:	The treated water pipelines are located adjacent to related facilities 108D, 183D, 186D, 190D, 183DR, and 187-DR).		
Process Description:	The 2009 WCH 100-D Area Orphan Site Evaluation identified a number of treated water pipe segments that were not accounted for in other waste sites. Some of the pipe segments connect to (or are extensions of) other waste sites. In some cases the pipe segments have been previously removed by remediation of co-located waste sites. See individual subsites for detailed process descriptions.		
Related Sites/ Structures:	The 108D, 183D, 185D, 186D, 189D, 190D, 183DR, 190DR, annexes, pipe tunnels and associated rail/car unloading spots are associated with this pipeline classification. Associated waste sites include: 100-D-31, 100-D-56, 100-D-77 100-D-77, DR Reactor Water Treatment Facility, Acid Facility, 183-DR Head House, 183-DR Filter Building, Sodium Dichromate Systems, 183-DR Flocculation Basins, 183-DR Sedimentation Basins, 100-D-73.		

This Site has the Following SubSites:

Code:	100-D-83:1
Names:	100-D-83:1; 183-DR Acid Addition Pipelines
Code:	100-D-83:2
Names:	100-D-83:2; 183-DR Filter Backwash Connection
Code:	100-D-83:3
Names:	100-D-83:3; 100-D-83:3 108-D Acid Addition Facility Pipelines
Code:	100-D-83:4
Names:	100-D-83:4; Additional Treated Water Pipelines
Code:	100-D-83:5
Names:	100-D-83:5; 186-D Acid Neutralizing System Pipelines

Code: 100-D-83:1 **Classification:** Accepted
Names: 100-D-83:1; 183-DR Acid Addition Pipelines **Reclassification:** None
Type: Product Piping **Start Date:**
Status: Inactive **End Date:**
Description: This subsite consists of the pipeline segments associated with the 100-D-77 (183-DR Acid Facility) and includes low pressure steam, sulfuric acid, and lime slurry. The compressed air lines and the above ground piping at the acid storage tanks were excluded. A filtered water line is also present in the trench but was assigned to site 100-D-63.

Sulfuric acid was received by railroad car and stored in two outside aboveground acid storage tanks. The acid was fed by gravity to the 183-DR Head House by maintaining the supply in the Acid Head Tank. The piping between the head tank and the 183-DR Head House was all above grade. Sulfuric Acid was added to the raw water supply before coagulation and filtration to reduce the pH below 7.5 and to aid in the suspension of solids. After filtration, lime was added to the water to raise the pH to between 7.5 and 7.8 (BHI-01771). Lime slurry was returned to the acid trench for neutralization of the waste acid. The sulfuric acid was reportedly purchased from a mining company and contained mercury and lead.

Location: The facility was located on the north side of the 183-DR Head House. The majority of the pipeline segments were contained in the acid pipe trench.

Waste Type: Not Specified

Waste Description: The waste is the pipelines and any contaminated soil associated with leaks from the pipelines.

The SubSite is Part Of:

Code: 100-D-83
Names: 100-D-83; 100D Treated Water Pipelines

Code: 100-D-83:2 **Classification:** Accepted
Names: 100-D-83:2; 183-DR Filter Backwash Connection **Reclassification:** None
Type: Product Piping **Start Date:**
Status: Inactive **End Date:**
Description: This subsite consists of the 183-DR water reducing valve pit and three pipeline segments located 20 m (65.6 feet) northeast of the 183-DR Filter Building.

The backwash water for the 183-DR filters is supplied from the 183-D Pump Room via a 76.2 cm (30 in) carbon steel cross-tie line (100-D-63) to the 183-DR pipe gallery. This line is also used to supplement the 183-DR water requirements including make-up water for the DR Reactor cooling water system (HW-74094, Vol3). A redundant supply of filtered water is provided via a 40.6 cm (16 in) pipeline (100-D-63) from the 105-D filtered water supply. These two lines laid parallel to each other and were joined in the water reducing valve pit. The water reducing valve pit had two drain lines (H-1-9660-DR). One was connected to the cross-tie between the backwash and filtered water lines. It received intermittent discharges during pressure surges between the lines. The other drain line collected water in the bottom of the valve pit from leaking valves or pipe repairs. Both drain lines discharged to the process sewer (100-D-50:7).

Location: Subsite is located at 183-DR water reducing valve pit and three pipeline segments located 20 m (65.6 feet) northeast of the 183-DR Filter Building.

Waste Type: Not Specified
Waste Description: The waste is the pipeline segments, the valve pit, and any contaminated soil associated with leaks from the pipelines.

The SubSite is Part Of:

Code: 100-D-83
Names: 100-D-83; 100D Treated Water Pipelines

Code: 100-D-83:3
Classification: Accepted
Names: 100-D-83:3; 100-D-83:3 108-D Acid Addition Facility Pipelines
Reclassification: None
Type: Product Piping
Start Date:
Status: Inactive
End Date:
Description: This subsite consists of the pipeline segments associated with the 108-D Acid Addition Facility (100-D-101) and includes the sulfuric acid pipeline and a process sewer.

Sulfuric acid was added to the cooling water upstream of the reactor to lower the pH. The acid was received by railroad tank cars and stored in two above ground storage tanks just west of 108-D. The acid was fed to the 105-D building through a 5.08 cm (2 in) steel pipeline by gravity. The acid neutralization pit was used to balance the pH of the waste acid. The pit drained to the process sewer (100-D-31:3) through a 15.24 cm (6 in) vitrified clay pipe.

Location: The facility (100-D-101) was located approximately 10 m (32.8 ft) west of the 108-D Chemical Pump House.

Waste Type: Not Specified
Waste Description: The waste is the pipeline segments, the process sewer, and any contaminated soil associated with leaks from the pipelines.

The SubSite is Part Of:

Code: 100-D-83
Names: 100-D-83; 100D Treated Water Pipelines

Code: 100-D-83:4
Classification: Accepted
Names: 100-D-83:4; Additional Treated Water Pipelines
Reclassification: No Action (7/5/2011)
Type: Product Piping
Start Date:
Status: Inactive
End Date:

Description: This subsite consists of the remaining treated water pipeline segments that were not addressed by 100-D-83:1, 100-D-83:2, 100-D-83:3 and 100-D-83:5. They include piping associated with the sulfuric acid and sodium silicate supply lines, reused water return lines at the 190-D building and an elevated storage tank drain line south of the 105-DR Reactor Building.

Originally, 100-D-83:4 consisted of four areas of pipelines that were used for treated water and chemical transfer; however, Area 1 is now addressed by the 100 D 83:5, 186-D Acid Neutralizing System Pipelines. Area 1 consisted of the 18 pipeline segments located west of the 186-D building that are associated with the acid and lime slurry transfer from tanks to the 120 D-2, 186-D Waste Acid Reservoir. A portion of these pipelines entering the reservoir were removed during 120-D-2 remediation activities. During confirmatory sampling of the 100 D 83:4 subsite, the pipe tunnels were encountered, and it was determined that these segments would be sent to remove, treat, and dispose (RTD). Areas 2, 3, and 4 of the 100 D 83:4 subsite

were addressed by the "No Action" reclassification form and remaining sites verification package.

Area 2 consisted of 19 pipeline segments located southwest of the 190-D Building that were associated with acid and reused water transfer from the 185-D Deaerating Plant to the underwater test facility. It was known prior to confirmatory sampling that many of these pipelines were removed with previous 100-D-30 remediation activities. As confirmatory sampling was conducted, it became apparent that all of these pipelines had been previously removed. The above ground portion of the 100-D-83:4 pipeline that went south from this location had also been previously removed.

Area 3 consisted of the pipeline segment located at the 187-DR elevated water tank that was associated with transporting untreated emergency cooling water to the 105-DR Reactor in the event that normal flow of cooling water was disrupted.

An additional area of pipelines, which included segments in both the 100-D-83:3 and 100-D-83:4 subsites, was located west of the 108-D Building, and is associated with the sulfuric acid and sodium silicate tanks. Area 4 of the 100 D 83:4 subsite consisted of the pipeline sections that ran from the 108-D tanks towards the 105 D Reactor, but will not be recommended for RTD along with the north-trending 100-D-83:3 pipeline sections, because the pipeline was not located during confirmatory sampling, and is believed to have been removed with the 100-D-31:3 remedial activities.

Location: The sulfuric acid and sodium silicate supply tanks are located just outside the southwest corner of the 190-D Building. Another sulfuric acid line runs between the 108-D Acid Storage Tanks and the 105-D Reactor. The reused water return lines are on the southside of the 190-D Building. The 187-DR elevated storage tank is located on the southeast side of the 105-DR Reactor.

Process Description: 190-D Sulfuric Acid Supply

Sulfuric acid was added to lower the pH of reactor coolant and to prepare activated silica from sodium silicate (HW-34095). The original facility included two acid storage tanks outside the southwest corner of building 190-D that were supplied by piping from a rail car. The acid was later supplied by truck (HW-29542, HW-34095). An acid trench ran from under the two storage tanks to building 185-D where it continued the length of the building. The acid trench has also been referred to as the sodium dichromate trench and was assigned to the 100-D-30 waste site. The original two sulfuric acid storage tanks were relocated to building 183-D in January 1957 (HW-35606, HW-48046). The piping inside the trench was removed during remediation of 100-D-30. A new acid storage tank was installed outside the 185-D building in 1962 as part of the half-reactor test. A 7.6 cm (3 in) acid pipeline was installed between the storage tank and an acid unloading station off the railroad spur just north of the electrical substation 151-D. The test (IP-442-A) which began on January 30, 1963 fed sulfuric acid to lower the pH of the process water for one-half of D Reactor (HW-76398). Two pumps were added to the sulfuric acid storage tank a few months later to permit pH adjustment on the other half of the reactor.

190-D Sodium Silicate Supply

A sodium silicate storage tank was installed in November 1964 south of the 190-D Building not far from the acid storage tanks. The sodium silicate tank was used for another half-reactor test conducted between January 15, 1965 and March 11, 1966 (RL-REA-472 and DUN-1293). Sodium silicate was added to inhibit the formation of film on slug and tube surfaces in the reactor.

190-D Reused Water Return

Filtered water was deaerated before going to the 190-D process water storage tanks or to the refrigeration units (189-D) to remove dissolved oxygen and carbon dioxide (while 186-D was in operation). Steam ejectors exhausted the gases from the deaerators to barometric condensers. The barometric condensers discharged the gases to the atmosphere. Raw water was used to operate the barometric condensers. The raw water (condenser water) was heated in the barometric condensers and emptied into the hotwells below. The condenser water overflowed the condenser hot wells into the reuse water reservoir through a 61 cm (24 in) reused water return line (TNX-PG-4). Hot condenser water was also returned to the storage reservoir (182-D) during the winter through a 50.8 cm (20 in) cast iron pipeline (100-D-63).

108-D Acid Supply Line

Sulfuric acid was added to the cooling water upstream of the reactor to lower the pH. The acid was received by railroad tank cars and stored in two above ground storage tanks just west of 108-D. The acid was fed to the 105-D building through a 5.08 cm (2 in) steel pipeline by gravity. The northern portion of this pipeline is assigned to 100-D-83:3.

105-DR Elevated Storage Tank Drain Line

Two elevated storage tanks (187-DR) with a capacity of 1.14 ML (300,000 G) each were erected to serve 105-DR. Both tanks were located in the vicinity of, and on opposite sides of the 105-DR Building. With the exception of the tank supports, which were cylindrical columns, these installations were the same as the 187-D elevated tanks (HW-24800-34). Both tanks had 7.62 cm (3 in) drain lines that emptied a sump in the floor of the valve pit (W-72733). The tank on the northwest side of 105-DR drained to the process sewer (100-D-50:9). The tank on the southeast side drained to the process sewer (100-D-85:2) on the east side of the reactor. It is this second drain line that has been assigned to 100-D-83:4.

Waste Type: Not Specified

Waste The waste is the contaminated piping, concrete, and soil.

Description:

The SubSite is Part Of:

Code: 100-D-83

Names: 100-D-83; 100D Treated Water Pipelines

Code: 100-D-83:5

Classification: Accepted

Names: 100-D-83:5; 186-D Acid Neutralizing System Pipelines

Reclassification: None

Type: Product Piping

Start Date:

Status: Inactive

End Date:

Description: This subsite consists of the treated water pipeline segments that were associated with the 186-D Acid Neutralization System and the reactor cooling water piping between the 190-D building and the 105-D Reactor. The lime neutralization plant (186-D Acid Neutralizing System) is located on the southwest side of the 186-D Demineralization Plant. The reactor cooling water piping is housed in two separate tunnels that converge at the 190-D Building upstream of the 105-D Reactor. Several small diameter water lines are also located in the pipe tunnels, including raw water, filtered water, fire protection water, and potential dichromate-treated process water piping.

Location: The lime neutralization plant (186-D Acid Neutralizing System) is located on the southwest side of the 186-D Demineralization Plant. The reactor cooling water piping is located in two tunnels

that run between the 190-D Building and the 105-D Reactor.

Waste Type: Not Specified

Waste Description: The waste is the pipelines and any contaminated soil associated with leaks from the pipelines.

The SubSite is Part Of:

Code: 100-D-83

Names: 100-D-83; 100D Treated Water Pipelines

Code: 100-D-84

Classification: Accepted

Names: 100-D-84; 100D Sanitary Sewer Pipelines

Reclassification: None

Type: Sanitary Sewer

Start Date:

Status: Inactive

End Date:

Description: The site consist of numerous sanitary sewer pipe segments discovered during the Orphan Site Evaluation process that were not previously identified or addressed within WIDS site database. The entire site includes underground sanitary sewer connections including associated manholes (and associated drains), catch basins, junction boxes and valve control systems or any other below surface associated feature not previously identified. The sanitary sewer pipelines are service connections supporting ancillary and temporary construction facilities and discharge to associated septic systems. The site has been divided into two subsites as follows:

100-D-84:1, Sanitary Sewer Pipelines - Areas 1 and 2

100-D-84:2, Sanitary Sewer Pipelines - Areas 3 and 4

Location: The pipeline segments were observed in various locations throughout the 100-D Area.

Process Description: The pipelines carried non-radioactive liquid sanitary sewage waste.

Related Sites/ Structures: Ancillary support and temporary construction facilities

Waste Type: Sanitary Sewage

Waste Description: The waste consists of pipelines and any contaminated soil associated with leaks from the pipelines. The contaminants of potential concern (COPCs) are unknown.

This Site has the Following SubSites:

Code: 100-D-84:1

Names: 100-D-84:1; 2; Sanitary Sewer Pipelines - Areas 1

Code: 100-D-84:2

Names: 100-D-84:2; Sanitary Sewer Pipelines - Areas 3 and 4

Code: 100-D-84:1

Classification: Accepted

Names: 100-D-84:1; 2; Sanitary Sewer Pipelines - Areas 1

Reclassification: No Action (7/7/2011)

Type: Sanitary Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite consists of piping from two areas (Areas 1 and 2) as defined in the Confirmatory Work Instruction (0100D-WI-G0092). Area 1 includes 23 pipeline segments south of the 105-DR Reactor Building. Area 2 includes seven pipeline segments northwest of the 105-D Reactor

Building.

Location: Area 1 is located approximately 121 m (400 ft) southeast of the 105-DR Reactor. Area 2 is located approximately 150 m (500 ft) northwest of the 105-D Reactor.

Process Description: The pipelines in Area 1 were the result of temporary construction that was put into place to support 1947 modification of 100-D Area Buildings and facilities and provide a water supply for the existing 105-D Pile Building (water supply unrelated to 100-D-84:1) (per HW-24800-34). At the completion of the construction program, all temporary construction was removed with the exception of the Atkinson-Jones and G.E. Warehouses, a sewage disposal system, and the Atkinson-Jones (A.J.) Superintendent's Building. It is believed that all the Area 1 piping drained to the 100-D-50:9 piping system. Confirmatory sampling was conducted at this area in August 2010.

The pipelines in Area 2 were service lines that carried waste from various buildings north of the 105-D reactor to the sanitary sewer main. These buildings included 190-D, 1703-D, 1717-D, 1725-D, 1726-D, 1727-D, 1728-D, and 1729-D. A number of these pipelines were previously removed during remediation of 100-D-31:4 or have been recommended for remove, treat, and dispose (RTD) along with other portions of the 100-D-84:2 subsite. The service line for the 1725-D trailer ran parallel to the 100-D-63 pipelines, and underwent confirmatory sampling in August 2010.

Related Sites/ Structures: The site was related to ancillary support and temporary construction facilities

Waste Type: Not Specified

Waste Description: The waste is the pipelines, pipe contents, and any contaminated soil associated with leaks from the pipelines.

The SubSite is Part Of:

Code: 100-D-84

Names: 100-D-84; 100D Sanitary Sewer Pipelines

Code: 100-D-84:2

Classification: Accepted

Names: 100-D-84:2; Sanitary Sewer Pipelines - Areas 3 and 4

Reclassification: None

Type: Sanitary Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite consists of piping from two areas (Areas 3 and 4) as defined in the Confirmatory Work Instruction (0100D-WI-G0092). Area 3 includes one pipeline segment adjacent to the 107-DR retention basin. Area 4 includes one pipeline segment south of the 181-D River Pump House.

Location: Area 3 is located partially within the post-remediation footprint of the 116-DR-9 (107-DR) Retention Basin and protrudes approximately 40 m (132 ft) southwest from this waste site. Area 4 is east of the 181-D River Pump House.

Process Description: The pipeline in Area 3 was associated with the 1607-D2 Septic Tank. It carried waste from the septic tank to the drainfield. Most (if not all) of the pipeline was likely removed in 1950 when the 107-DR Retention Basin was built. The pipeline in Area 4 was the sanitary sewer line that carried waste from the 181-D River Pump House to the 1607-D5 Septic Tank.

Waste Type: Not Specified

Waste Description: the pipelines.

The SubSite is Part Of:

Code: 100-D-84

Names: 100-D-84; 100D Sanitary Sewer Pipelines

Code: 100-D-85

Classification: Accepted

Names: 100-D-85; 100D Reactor Effluent Pipelines

Reclassification: None

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The site consists of those underground pipelines that transported radioactive treated and untreated waste water from the 105-DR Reactor Building, and the 1608-DR (132-DR-1) Building to the 107-DR (116-DR-9) Retention Basin. The pipelines are divided into two subsites containing seventeen reactor effluent pipe segments that were not previously identified within an existing WIDS site. Subsite one consists of Additional 107-DR Effluent Pipeline and subsite two consists of Additional 105-DR Reactor Effluent Pipelines. Pipelines that were presumed to have been removed in their entirety because they were located within an existing cleanup verification package (CVP) footprint were excluded. Also included are below grade features associated with the pipeline segment (i.e. manholes, catch basins, junction boxes and valve boxes) not already assigned to another waste site.

Location: The 100-D-85:1 pipeline is located adjacent to the southwest corner of the 107-DR retention basin. The 100-D-85:2 pipelines are located on the east side of the 105-DR reactor.

Process Description: The pipelines were used to dispose of radioactive cooling and waste water from the reactor facility. Two large main effluent pipelines drained cooling water from the 105-DR Reactor. The small effluent pipelines that drained process waste from the sides (east and south) of the 105-DR were joined into a single pipeline that ran to the 132-DR-1 [1608-DR Building] Waste Water Pumping Station or Process Lift Station). The building was a rectangular shaped, two-story, reinforced concrete structure that was half below grade elevation. The purpose of this facility was to pump process effluent to the main effluent pipeline. All but one of the pipeline segments are associated with the 105-DR Reactor discharge to the 1608-DR Lift Pump Station (100-D-85:2). The remaining segment (100-D-85:1) connects the two effluent lines (100-D-48:2 and 100-D-49:2) that empty into the 107-D and 107-DR Retention Basins. The reactor effluent pipelines were used to carry reactor cooling water effluent away from the 105-DR Reactor to the 107-DR Retention Basin (116-DR-9), and to the associated outfalls for final discharge to the Columbia River. Contaminated water from building drains in the reactor and piping at elevations below the elevation of the 107-DR Retention Basin flowed by gravity to the 1608-DR Building (132-DR-1) where it was pumped to the 107-DR Retention Basin.

Related Sites/ Structures: The associated structures include the 105-DR Building, the 132-DR-1 (1608-DR), the 116-DR-9 (107-DR) Retention Basin, the 116-D-5 Outfall and 116-DR-5 Outfall. Other related sites include the 116-DR-1 and 116-DR-2 Trench, the 116-DR-6 Trench, 100-D-48, 100-D Reactor Cooling Water Effluent Underground Pipelines (See Subsites), and 100-D-49, 100-DR Reactor Cooling Water Effluent Underground Pipelines (See Subsites), and 100-D-60, 100D/DR River Effluent Pipelines, 100D River Lines.

Waste Type: Process Effluent

Waste Description: Waste site contaminants of concern (COCs) identified through process knowledge were identified in the Sampling and Analysis Plan for the 105-F and 105-DR Phase III Below Grade Structures and Underlying Soils (SAP), (DOE/RL-99-35). The 105-DR SAP classified the different areas and structures into affected media that were similar in characteristics and

contaminants. The COCs included: americium-241, barium-133, carbon-14, cobalt-60, cesium - 137, europium-152, europium-154, europium-155, nickel-63, plutonium 238, plutonium-239/240, strontium-90, technitium-99, uranium-234, uranium-235, uranium-238, hexavalent chromium, lead, mercury and polychlorinated biphenyls.

The waste consisted of contaminated steel piping, concrete, and soil. Chemical additives to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, diatomaceous earth (a scouring agent), and sodium dichromate. Water pH was maintained at about 7.5, and free chlorine residual was about 0.2 milligrams per liter. Radionuclides discovered at the retention basin during sampling by Dorian and Richards (UNI-946), included: plutonium-238, cesium-134, plutonium 239/240, cesium-137, strontium-90, 155, nickel-63, cobalt-60, and carbon-14.

Post Reactor cooling water effluent had anti corrosive chemical additives including pH adjustment and was radioactive.

This Site has the Following SubSites:

Code: 100-D-85:1

Names: 100-D-85:1; Additional 107-DR Effluent Pipeline

Code: 100-D-85:2

Names: 100-D-85:2; Additional 105-DR Reactor Effluent Pipelines

Code: 100-D-85:1

Classification: Accepted

Names: 100-D-85:1; Additional 107-DR Effluent Pipeline **Reclassification:** No Action (1/27/2010)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The Remaining Sites Verification Package (RSVP-20010-080) for subsite one has documented that the confirmatory sampling data, site evaluations, and supporting documentation demonstrate that this site meets the objectives as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL96-17, rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario.

The subsite consisted of a single pipeline segment identified on one historical drawing, H-1-8348, (HEW 1948); however, it was unknown whether it was ever constructed. The pipeline was believed to be approximately 92 m (300 ft) in length, buried at approximately 5 m (16 ft) below ground surface (bgs) and was composed of unknown construction material. If constructed, it was anticipated that the pipe would not have been removed by any previous effluent sewer remedial actions. During excavation of the 100-D-29 waste site, which extended to approximately 4.6 m (15 ft) bgs in this location, there was no indication of a pipeline.

Location: The pipeline is located adjacent to the southwest corner of the 107-DR retention basin.

Waste Type: Soil

Waste Description: The waste is potentially contaminated soil.

Closure Info: The Remaining Sites Verification Package (RSVP-20010-080) for subsite one has documented that the confirmatory sampling data, site evaluations, and supporting documentation demonstrate that this site meets the objectives as established in the Remedial Design

Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL96-17, rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario.

The contaminants of potential concern (COPCs) for the subsite were identified based on historical information and process knowledge of the 107-D and 107-DR retention basins. These COPCs included cesium-137, cobalt-60, europium-152, europium-154, alpha and beta emitting radionuclides, hexavalent chromium, total chromium, lead, and mercury.

During confirmatory sampling, initiated and performed in August 2010, undisturbed native soil was encountered at approximately 3 m (6 ft) bgs. Native black sand was encountered until the base of the test pit excavation ended at 4.9 m (16 ft) bgs. No pipe was found. Based on field observations and the confirmatory sampling results, remedial action was determined to be unnecessary.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to submittal to the Hanford Environmental Information System (HEIS) and were presented as an attachment to the Direct Contact Hazard Quotient and Relative Percent Different calculation in Appendix C of the RSVP.

The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow-zone soil (i.e., surface to 4.6 m [15 ft]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. Confirmatory sampling activities extended into the deep zone (i.e., greater than 4.6 m [15 ft]); however, no pipe was found and soil sample results indicated no contamination was present in the deep zone. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep-zone soil were not required.

The SubSite is Part Of:

Names: 100-D-85; 100D Reactor Effluent Pipelines

Code: 100-D-85:2

Classification: Accepted

Names: 100-D-85:2; Additional 105-DR Reactor Effluent Pipelines

Reclassification: None

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: Subsite two consists of sixteen additional reactor effluent pipe segments that were identified during the WCH D Area Orphan Site Evaluation (OSE). The segments are associated with the 105-DR Reactor that discharged to the 1608-DR Waste Water Pump House. These segments have not been associated as part of an existing WIDS site. There was insufficient information to account for their removal during nearby remedial actions (i.e. 118-DR-2:2 and 100-D-49:4; see CVP-2003-00016).

The pipelines consists of various sizes of cast iron pipe and black steel pipe.

Location: They are located on the east side of the 105-DR reactor.

Process Description: The pipelines carried process water and steam condensate collected from sumps, floor drains, sinks and steam traps on the eastern half of the 105-DR building. The processes water drained

by gravity to the 1608-DR Waste Water Pumping House (132-DR-1) where it was pumped to the main effluent pipeline (100-D-49:3). Many of the 100-D-85:2 pipelines were found to be leaking in 1958 (HW-56911 and HW-57840). Repairs were made and the steam condensate drains were disconnected from the sewers (100-D-85:2) on the north end of the building (HW-58360).

Waste Type: Not Specified

Waste Description: The waste is contaminated steel piping, concrete, and soil.

Description:

The SubSite is Part Of:

Code: 100-D-85

Names: 100-D-85; 100D Reactor Effluent Pipelines

Code: 100-D-86

Classification: Accepted

Names: 100-D-86; 100D Process Sewer Pipelines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The site encompasses 32 additional process sewer pipelines that were not previously identified within an existing WIDS site. Pipelines that were presumed to have been removed in their entirety because they were located within an existing cleanup verification package (CVP) footprint were excluded. The entire site includes those underground pipelines that transported non-radioactive waste streams from water treatment, reactor, and laboratory facilities. The site includes any other below grade feature associated with the pipeline segment (i.e. manholes, catch basins, junction boxes and valve boxes) not already assigned to another waste site. The site has been divided into three subsites as follows: - 100-D-86:1 105-D Gas Recirculation Pipelines - 100-D-86:2 Additional Process Sewer Pipelines - 100-D-86:3, 105-DR Fan Room Sewer Pipelines

Location: Refer to the subsites for locations of the pipeline segments.

Process Description: The 100-D Orphan Site Evaluation Report (OSR-2006-0001) identified a number of process sewer pipe segments that were not accounted for in another waste site. These pipe segments were upstream of the reactor effluent discharges and were presumed to carry non-radioactive waste streams from various 100-D/DR Area facilities including the 105-D, 105-DR, 190-D, and 190-DR buildings. The pipelines ultimately discharged to the Columbia River through one of the outfalls (1904-D, 1904-DR and 1907-DR).

Related Sites/Structures: The process sewer received effluent from the following facilities: 182-D, 183-D, 183-DR, 184-D, 185-D 186-D, 189-D, 190-D, 105-D, 107-D, 183-DR, the 183-DR Clearwell Area, the 105-DR Reactor Buildings, and the 1907-DR Outfall (100-D-8).

Waste Type: Equipment

Waste Description: Minor amounts of radionuclide, chemical, and mercury contamination may be present in process sewer lines from the 185-D and 189-D/190-D complex as a result of laboratories once located in these now demolished facilities.

The waste consists of steel piping, concrete, and soil (if contaminants are present). The water supply and process sewer drain pipelines at the 100-D and DR Areas provided for the supply and disposal of non-radioactive streams generated in water treatment and water treatment laboratories facilities and powerhouse operations. Known chemical additions to reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid,

chlorine, and sodium dichromate. Water pH was maintained near 7.5, free chlorine residual at about 0.2 milligrams per liter, and sodium dichromate was added at a rate of about 2 milligrams per liter. Sodium chloride was also used to regenerate water softeners in both water treatment and powerhouse operations.

This Site has the Following SubSites:

Code: 100-D-86:1

Names: 100-D-86:1; 105-D Gas Recirculation Pipelines

Code: 100-D-86:2

Names: 100-D-86:2; Additional Process Sewer Pipelines

Names: 100-D-86:3; 105-DR Fan Room Sewer Pipelines

Code: 100-D-86:1

Classification: Accepted

Names: 100-D-86:1; 105-D Gas Recirculation Pipelines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: Subsite one consists of the steel gas recirculation piping in the subsurface tunnel between the former 115-D Gas Recirculation Facility and the 105-D Reactor. Features of the subsite include a pipeline described as a 41 cm (16 in) steel pipe that carried reactor atmosphere to and from the 115-D/DR Gas Recirculation Facility. The second feature is a 320 square meter (3,444 sq ft) pipe tunnel between the 115-D/DR Gas Recirculation Facility and the 105-D Reactor. The tunnel was 2.0 m (6.5 ft) tall with the floor being 3.4 m (11 ft) below the 1st floor of the 115-D/DR Building. It includes the vacuum and pressure seal pit, located north of the 1608-D Lift Station.

Startup of the 105-D Reactor occurred on December 17, 1944. The 105-D Reactor was provided with an inert, non-radioactive gas environment (reactor atmosphere) to remove moisture and foreign gases. The reactor atmosphere was a mixture of helium and carbon dioxide (HW-74094). The initial and make-up reactor atmosphere was supplied from storage tanks (110-D) located west of 115-D/DR Gas Recirculation Facility. The reactor atmosphere was purified in the 115-D/DR Building and returned to the 105-D Reactor. Parallel 41 cm (16 in) steel pipes carried the reactor atmosphere to and from the 115-D/DR Building inside an underground reinforced concrete pipe tunnel (W-73950). Connected to and part of the 105-D tunnel was the vacuum and pressure seal pit, which contained two vacuum seal tanks filled with oil (UNI-4281, W-74375). The tunnel also formed part of the 1608-D Lift Station (132-D -3).

The 115-D/DR Recirculation Facility was also used to purify the reactor atmosphere for 105-DR between 1950 and 1964. The piping contained in the 105-DR pipe tunnel was assigned to the 100-D-50:4 waste site. The 115-D/DR Recirculation Facility and the underground pipe tunnels were no longer used after the 105-D Reactor was shut down on June 26, 1967.

The 115-D/DR Gas Recirculation Facility and adjoining tunnels were decommissioned by UNC Nuclear Industries in 1985 and 1986 using the Allowable Residual Contamination Levels (ARCL) methodology in conjunction with the in situ decommissioning alternative. The vacuum and pressure seal tanks were removed and disposed of as radioactive waste. The tunnel piping and valves were not removed. The tunnel roof was collapsed from the 115-D/DR Building up to but not including the 1608-D Building. The void was filled with rubble and clean fill. Based on survey data and pre-demolition dose assessment, the tunnel piping/valves met in situ decommissioning criteria (UNI-4281).

Characterization of analogous pipelines in the gas recirculation wing of the 105-H Reactor revealed the accumulation of soil sludge containing multiple radionuclides at levels above remedial action goals (CCN 120410). Consequently the two 41 cm (16 in) circulation lines between the 115-D and 105-D buildings were added to the 100-D-86 waste site on October 19, 2008.

Location: The piping is located in the subsurface tunnel between the former 115-D Gas Recirculation Facility and the 105-D Reactor.

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil (if contaminants are present).

The SubSite is Part Of:

Code: 100-D-86

Names: 100-D-86; 100D Process Sewer Pipelines

Code: 100-D-86:2

Classification: Accepted

Names: 100-D-86:2; Additional Process Sewer Pipelines

Reclassification: No Action (5/11/2011)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The subsite consists of an additional 13 process sewer pipelines identified on historical drawings during the 100-D Orphan Site Evaluation (OSE). They include piping associated with the 105-D and 190-DR buildings.

The 105-DR LSFF pipelines have been transferred from the 100-D-86:2 subsite to the 100-D-86:3 subsite, and are recommended for Remove, Treat, and Dispose (RTD).

Location: The pipelines are located adjacent to the related facilities (105-D, 105-DR and 190-DR).

Process Description: 105-D Drainage Piping

The 105-D Building housed a graphite-moderated, water-cooled reactor for the production of weapons grade plutonium. The reactor was located in the process area of the building. Other areas of the building included the control room, fan house, valve pit, work area, storage basin, various offices and equipment storage rooms. Drainage piping was provided throughout the building to carry water from floor drains, steam traps, sumps and trenches to the process sewer (W-71186, W-71617). The process sewer (100-D-31:3) on the west side of 105-D was rerouted when the 190-D Annex was constructed in 1956. A catch basin located outside the northeast corner of the 190-D Annex emptied into the process sewer (100-D-31:3).

190-DR Main Process Water Pump House

The 190-DR Building housed pumps that supplied primary cooling water to the 105-DR Reactor (HW-74094 Vol.3). At 190-DR there were two pump rooms with four pumps in each. The filtered water used for cooling was stored in four large steel storage tanks outside of the 190-DR building. The water was treated with sodium dichromate at the 183-DR Building following filtration prior to entering the storage tanks.

Waste Type: Not Specified

Waste Description: No waste was observed at the site.

Description:

Closure Info: Investigation at the 100-D-86:2 subsite was carried out on November 16 and 17 2010. Test pits

were excavated at six locations. The purpose of each test pit was to determine if process sewer segments associated with the 100-D-86:2 subsite were present in any location.

Test pit 1 (N 151287, E 573725) was excavated to a total depth of 6 m (19 ft) below ground surface (bgs) attempting to access a pipeline associated with the 105-DR Large Sodium Fire Facility (LSFF). Because no pipeline was found in this test pit, an additional test pit was excavated to 6 m (19 ft) bgs at an alternate location (WSP coordinates N 151275, E 573725). Because a pipeline was found at the alternate test pit location, the entire test pit 1 area was sent to RTD, including the 36 m (120 ft) of pipeline that extends from this location to the south. Approximately 17 m (55 ft) of pipeline in the area south of the test pit is in the shallow zone, at a depth of approximately 3 m (9 ft). The test pit 1 area was transferred to the 100-D-86:3 subsite for RTD.

Test pit 2 (N 151189, E 573551) was excavated to a total depth of 1.2 m (4 ft) bgs, attempting to access the center of a north-south-trending pipeline shown approximately 15 m (50 ft) to the east of the 190-DR pump house and west of the valve house test pits 1 and 2 on a temporary drawing. Because the pipeline segment was not found in this test pit, it is concluded that the segment was not present because the pipeline was identified on a temporary piping drawing as being located inside a shallow trench with only 45 cm (18 in.) of sediment covering.

Test pit 3 (N 151127, E 573543) was excavated to a total depth of 4.6 m (15 ft) bgs to access the corner of a 20- to 61-cm (8- to 24-in.) steel discharge pipeline. No pipeline was found. The pipeline is concluded to have been removed with demolition of the 190-DR pump house.

Test pit 4 (N 151622, E 573697) was believed to be the location of a manhole connecting to the 100-D-31:3 subsite and was to be excavated to a maximum depth of 4.6 m (15 ft) bgs. However, the test pit 4 location was determined to be within the excavation boundary of the 100-D-31:4 subsite, which was at a depth of 5.4 m (18 ft) bgs. Therefore, no excavation was necessary to determine that there was no manhole at this location.

Test pit 5 (N 151592, E 573698) was excavated to a maximum depth of 4.6 m (15 ft) bgs, attempting to access a 91-cm (36-in.)-diameter manhole associated with the 190-D building annex. However, only miscellaneous debris was found during the excavation. This miscellaneous debris included rebar, pieces of concrete, a piece of sheet metal, and a section of conduit. Due to the non-hazardous nature of this debris, the material was backfilled into the test pit when excavation was completed. It was concluded that the manhole and associated piping had been previously removed during demolition of the 190-D building annex.

Test pit 6 (N 151036, E 573549) was excavated to a maximum depth of 4.6 m (15 ft) bgs to access a 30-cm (12-in.)-diameter drain shown on historical drawings to run north-south and connect with the 100-D-50:1 sewer pipelines. However, no pipeline was found and it is concluded that it was never constructed.

The SubSite is Part Of:

Code: 100-D-86

Names: 100-D-86; 100D Process Sewer Pipelines

Code: 100-D-86:3

Classification: Accepted

Names: 100-D-86:3; 105-DR Fan Room Sewer Pipelines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The site consists of process sewer pipelines that received waste from the 105-DR Fan Room

floor drains and condensate. The 105-DR LSFF pipelines have been transferred from the 100-D-86:2 subsite to the 100-D-86:3 subsite, and are recommended for Remove, Treat, and Dispose (RTD).

Location: The pipelines are located on the west side of the 105-DR Fan Room.

Process Description: The 105-DR Building housed a graphite-moderated, water-cooled reactor for the production of weapons grade plutonium. The fan room housed the main blowers, heaters and air-filters (HAN-10970 Vol. 3). Air was supplied to the 105 Building by two separate supply systems. These supply systems conditioned the air and distributed it to a particular section of the building. The ventilation air supplied to the building spaces outside the confinement zone was exhausted to the atmosphere through roof ventilators. The ventilation air supplied to spaces in the confinement zone was collected by exhaust ducts which discharged into the exhaust tunnel (HW-74094 Vol. 3). The air in the exhaust tunnel flowed to the exhaust fans in the fan room. At the exhaust fans, the exhaust air became pressurized and was exhausted through an aboveground concrete duct which ran to the base of the 200-foot exhaust stack (116-DR). Originally the ventilation air was released directly to the 116-DR stack. In 1960, air filtering systems (117-DR) were added to minimize the release of radioactive matter (WHC-SD-EN-TI-181).

Waste Type: Not Specified

Waste Description: The waste consists of steel piping, concrete, and soil (if contaminants are present).

The SubSite is Part Of:

Code: 100-D-86

Names: 100-D-86; 100D Process Sewer Pipelines

Code: 100-D-87

Classification: Accepted

Names: 100-D-87; Spill Near Railroad Car Spot

Reclassification: No Action (1/6/2011)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: The waste site consists of a suspected unplanned release of liquid near the acid railroad tank car spot. The spill was photographed on January 1, 1945, liquid was present on the surface of the ground north of the railroad car spot on track "B". The only documentation identifying the spill were construction drawings H-1-281, W-74157 and W71800. The drawings indicate that a 45 centimeters (18 inches) tile is buried in the ground at the car spot. The car spot contained two transfer pumps and two 7.6 centimeters (3 inches) diameter pipelines. The pipelines transported acid to the acid tanks at the 186-D and 185-D Buildings. There were six acid tanks on the west side of the 186-D Building and two on the south side of the 185-D Building.

Location: The railroad car spot was located between the 186-D and 189-D Buildings.

Process Description: The car spot was used to unload acid that was transported through overhead lines to storage tanks at the 186-D and 190-D Buildings.

Related Sites/Structures: The 186-D and 190-D Buildings and waste sites 100-D-63 (clean water pipelines) is about 20 m (65 ft) northeast of 100-D-2 (lead sheet covering a concrete pad).

Waste Type: Chemical Release

Waste Description: The spill was probably acid associated with the car spot unloading facility. The contaminant of potential concern was acid.

Closure Info: that confirmatory sampling results support a reclassification of this site to No Action. The current site conditions have met the remedial action objectives (RA0s) and the corresponding remedial action goals (RAGS) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD).

The contaminants of potential concern (COPCs) for the 100-D-87 waste site were identified based on process knowledge of the 186-D and 195/190-D facilities, the 120-D-2 waste site COPCs, and the River Corridor Closure Stewardship Information System report. Sulfate was included as a COPC because of the use of sulfuric acid in testing the demineralization process at the 186-D building. Mercury was included because evidence of mercury-contaminated sulfuric acid has been found at other waste sites in the 100 Area. The 185-D building carried out processes involving the preparation of sodium dichromate; therefore, hexavalent chromium and total chromium were considered COPCs.

No staining, anomalies, or linear features were encountered during confirmatory sampling. Analysis was performed to evaluate if contamination associated with the potential spill was present. Field surveys for radiological contamination and volatile organic compounds were also conducted during sampling. Confirmatory sampling indicated that environmental contamination was not present at this waste site. Based on confirmatory sampling at the site, remedial action was determined to be unnecessary.

The laboratory-reported data results for all constituents are stored in the Environmental Restoration (ENRE) project-specific database prior to provision to the Hanford Environmental Information System (HEIS) and are presented as an attachment to the Direct Contact Hazard Quotient and Relative Percent Different (RPD) calculation in Appendix B.

These results show that residual contaminant concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow-zone soil (i.e., surface to 4.6 m [15 ft]), and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The waste site did not extend into the deep zone; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required.

Code: 100-D-88	Classification: Accepted
Names: 100-D-88; 100D Miscellaneous Pipelines	Reclassification: No Action (5/16/2011)
Type: Product Piping	Start Date:
Status: Inactive	End Date:
Description: The site consists of 27 underground pipeline segments observed during the WCH Orphan Site's Evaluation. The additional pipeline segments include associated manholes (with associated drains), catch basins, junction boxes, valve control systems or any other below surface related feature.	
Location: The pipeline segments are located throughout the 100-D Area.	
Process Description: Miscellaneous pipeline segments are associated within unique building processes; boiler fuel delivery systems, elevator shafts, air conditioning systems, railcar/truck delivery spots, equipment drains, storage tanks pressure relief systems, compressor blowdowns and potential contact steam system condensate returns drained to below ground features.	

Related Sites/ The 105DR, 185D, 184DA, 183D, 190D and elevated tank 187-DR1

Structures:

Closure Info: Focused samples from eight test pit locations were planned to be used to evaluate the 100-D-88 waste site. However, upon preparation for confirmatory sampling, it was determined that test pit 7 could not be excavated, due to the presence of an internet tower in this location. The tower, which includes a base in the location of the french drain, indicates that this drain no longer exists due to the presence of guy wires at approximately 2 to 2.5 m (6 to 8 ft) below ground surface. Therefore, sampling was not necessary to make a No Action decision for this portion of the 100-D-88 waste site. Test pits were excavated at the remaining seven locations of the Pipeline segments of the 100-D-88 waste site to collect samples or verify removal of the associated piping. These seven test pits are adequate to represent the 100-D-88 waste site, as the absence of a french drain at the test pit 7 location changes the condition of the waste site such that seven sampling locations, instead of eight, are adequate to evaluate the waste site. All radiological and volatile organic vapor readings in the field were less than detectable.

Code: 100-D-90	Classification: Accepted
Names: 100-D-90; 100-D/DR Out of Service Transformers	Reclassification: No Action (1/6/2011)
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:

Description: The site consists of the soil located below two transformers sitting on railroad ties.

Location: The transformers had been located 18 meters (60 feet) west of the 183-D Facility next to the paved two lane road. The transformers and railroad ties were removed and staged in the 200 Area laydown yard. Although the waste site had been originally described as an unplanned release, it became apparent through further research that a known release had not occurred.

Process Description: There is no process associated with this site. The site is only the staging area for two transformers which may have originated from the 190-DR facility.

Related Sites/Structures: These transformers are possibly associated with the 190-DR Building. The transformers were removed from service in 2003 and drained by the Fluor Electrical Utilities group in July 2005.

Waste Type: Soil

Waste Description: The transformers contained oil with <499 ppm of PCBs (per Fluor Electrical Utilities). The site has the potential to contain PCBs. However, there was no evidence of staining associated with this site, therefore, there are no contaminants of potential concern.

Closure Info: The Remaining Sites Verification Package for the 100-D-90, 100-D/DR Out-of-Service Transformers, RSVP-2009-050, has documented that confirmatory sampling data, site evaluations, and supporting documentation support a reclassification to No Action. The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 1004U-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario.

The soil exhibited no visible staining, and the transformers and railroad ties had since been removed and staged in the 200 Area laydown yard. Although the waste site had been originally described as an unplanned release, it became apparent through further research that a known release had not occurred.

Because analytical documentation on the drained fluid from the transformers was not available, confirmatory sampling was performed in August 2010.

The transformers were recorded using WIDS because this is the only process utilized for tracking purposes. Thus, PCBs were determined to be the only COPC for the site, based on professional judgment and other transformer COPCs. PCBs were analyzed for this waste site using EPA Method 8082.

The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow-zone soil (i.e., surface to 4.6 m [15 ft]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not extend into the deep zone; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required.

Code:	100-D-96	Classification:	Accepted
Names:	100-D-96; 100-D/DR Additional French Drains	Reclassification:	None
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site consists of eight components (seven 100-D and 100-DR area French Drains and one dry well) and their underlying soils. These French Drains received steam condensate from non-radioactive buildings.		
Process Description:	The 184-D Power House boiler facility supplied high pressure steam to all D area buildings for heating purposes through an above grade pipeline system. The boiler facility utilized clean filtered water from the 183-D filter building. The steam supply was used in a non-contact radial heating system and remained uncontaminated. The steam transport process utilized a high pressure supply line and a low pressure return or discharge line. It was necessary to bleed both the supply and return lines to prevent condensate build up. The condensate was typically blown off from the above grade piping system into a below grade covered French Drain as a safety precaution as illustrated on construction drawing H-1-9644-DR and H-1-15203. Construction drawings H-1-9640-DR thru H-1-9645-DR of the outside steam distribution system indicate steam trap locations (French Drains) and typical construction.		

Code:	100-D-97	Classification:	Accepted
Names:	100-D-97; 184DA; 184-DA 500-Gallon Fuel Tank	Reclassification:	None
Type:	Storage Tank	Start Date:	
Status:	Inactive	End Date:	
Description:	This site consisted of an underground storage tank (UST), associated fuel oil supply (FOS), fuel oil return (FOR) piping [1.27 centimeter (1.5 inch) diameter] and the underlying soil. It is believed that these items were removed in 1985/1986 as part of the 100-D/DR general demolition efforts. The area now appears as a cobble-covered field with vegetation.		
Location:	The tank was located in the 100-D Area, west of the southeast corner of the 184-DA Boiler House site, approximately 1 meter (3 feet) near the southeast corner of the 184-DA building, 184-DA Boiler Oil Tank., south of Palouse Street and 165 meters (540 feet) east of Puget Avenue.		
Process	The UST was a 500 gallon fuel oil tank which supplied fuel to the 184-DA Steam Generating		

Description: Facility. The 184-DA Building was a metal building constructed about 1968 and was designed as a steam generating facility. The facility contained a steam generator, fuel oil storage tank [94,600 Liters (25,000 gallons)], fuel oil pump, deaerator, water softener, chemical treatment, fuel tank, steam separator, heater, diesel generator, liquid level gauges, and steam flow meter. The 500 gallon fuel oil tank was located near the southeast corner of the 184-DA Building. The tank was installed about 1968 under Project No. Dap-515 and buried two feet below grade. The equipment number was K1-7-1 the tank had a 2 inch fill connection and a 2 inch sounding connection. Within the floor of the 184-DA Building were three trenches that contained pipelines used to transport fuel oil and vent lines associated with the fuel oil tanks. In 1973, the building was assigned to Atlantic Richfield Hanford Company (ARHCO), it contained a package boiler which was used to provide steam heat for the occupied facilities in 100-D Area. In case of electrical power outage, the boiler also provided steam for turbine driven pumps used to provide fire and service water to the 100-D facilities. The facility was required to remain in service as long as the area was occupied. It is assumed that the tank was removed during the demolition of the 184-DA Building.

Related Sites/ Structures: The UST (100-D-9) supplied fuel oil to the 184 DA Steam Generating Facility which provided steam to the 183-D and other 100-D facilities.

Code: 100-D-98	Classification: Accepted
Names: 100-D-98; 152D Substations	Reclassification: None
Type: Electrical Substation	Start Date:
Status: Inactive	End Date:

Description: This site consists of two active (C4S17 and 152-D1-D) and nine former electrical substations and underlying soil. During the Orphan Sites Evaluation (OSE) no staining or evidence of a substation was observed at the mapped locations of the nine former substations. They each had a primary voltage of 13.8 KV and a secondary voltage ranging from 110 V to 2300 KV. Each was an open, wooden pole structure surrounded by a picket fence and contained transformers at or near ground level, set on concrete pads. Excluded from the site were an additional six distribution substations known to have been associated with buildings 107-D, 108-D, 115-D, 183-D, 1717-D, and 1720-D. These six could not be located during the OSE field investigation. Each was constructed identical to secondary substations. All had a primary voltage of 2.4 KV, and a secondary voltage ranging from 110 V to 480 V. Information on the exact location of these substations is extremely limited. There was no physical evidence of transformer pads or staining on the ground near the suspect locations. It is assumed that the distribution substations were removed during demolition of the buildings.

Location: The secondary substation locations follow: Substation C4S17, Associated Facility 181-D, Center Coordinates N151718 E572797, Min. Pads 2 Substation 152-D1-D, Associated Facility 182-D, Center Coordinates, N151565 E573202, Min. Pads 2 Substation 152-F1-D, Associated Facility 184-D, Center Coordinates N151872 E573364, Min. Process Description: The Midway Station, located near the Vernitia Bridge, fed 230KV power to the 31,250KVA

transformers located in the 151-D switchyard. From these transformers, power was transmitted via overhead and underground cables to secondary distribution substations located throughout the 100-D Area. Circuit breakers were also in service to support the switchyard operations. The 151-D Switch House is essentially a one-story building, having a sub-level cable pit equipped with a sump pump. All duct lines originated/terminated at the Switch House. The cable pit is a completely enclosed reinforced concrete pit with floor slab, varying from 0.30 to 0.45 meters (1 to 1.5 feet) in thickness, and with 0.30 meters (1 foot) thick walls. Switchgear is located on the main floor directly above the cable pit. The overall dimensions of the Switch House are 25 meters by 9.3 meters by 8.7 meters (83 feet by 30.5 feet by 28.5 feet.) Beneath the switch yard, and throughout the D/DR area there is an extensive subsurface "highway" of electrical conduits, which may still contain lead and/or asbestos wrapped cable inside "Korduct" lining, all surrounded by reinforced concrete. Korduct is believed to be a transite-like material. These concrete monoliths are up to 1.8 meters by 1.8 meters (6 feet wide by 6 feet deep) and up to 152 meters (500 feet) long per segment, and are buried 0.9- 1.5 meters (3-5feet) below the surface. There are at least 20 major segments in the D/DR area. The segments are connected by mammoth concrete manholes, 2.4 meters by 2.4 meters by 2.4 meters (8 feet by 8 feet by 8 feet high). Each monolith contains up to 2 dozen conduits, each of which may contain 0.6- 12.7 centimeters (2-5 inches) electrical cables. PCB-containing oil was transferred, as needed, from a rail tanker on the railroad spur through over ground hoses and piping to transformers and oil circuit breakers in the yard. The smaller transformers at the secondary and distribution substations were also filled via over ground hoses from oil trucks.

Related Sites/ Structures: The 151-D Primary Substation distributed 13.8KV power to transformers located at the 181-D River Pump House, 182-D Head House, 183-D Filter House, 184-D Power House, 186-D Water Treatment Plant, 190-D Pump House, and 105-D Reactor, which in turn distributed power to associated facilities.

Waste Type: Transformer

Waste Description: The two active substations (C4S17 and 152-D1-D) will be evaluated upon termination of operations. There was no documented waste information found during the OSE historical evaluation. There were no contaminants of potential concern assigned to the sites discovered during historical evaluation.

Code: 100-D-99

Classification: Accepted

Names: 100-D-99; Two Suspect Features Identified by Ground Penetrating Radar

Reclassification: None

Type: Septic Tank

Start Date:

Status: Inactive

End Date:

Description: The site consists of a septic system and the underlying soils.

Location: This site is located between the 1716-D Maintenance Garage and the 1719-D First Aid Station.

Process Description: During construction of the Hanford Engineer Works, temporary sewer lines and septic tanks were installed for the disposal of non-radioactive liquid sanitary sewage waste.

Related Sites/ Structures: The septic system supported the 1716-D Maintenance Garage and the 1719-D First Aid Station.

Waste Type: Sanitary Sewage

Waste Description: Transfer of non-radioactive liquid sanitary sewage waste.

Code: 100-D-101 **Classification:** Accepted
Names: 100-D-101; 108-D Acid Pit and Sump; 108-D **Reclassification:** None
Car Spot; 108-D Sodium Silicate Sump; 108-D
Storage Tanks; Miscellaneous Structures
Type: Sump **Start Date:**
Status: Inactive **End Date:**

Description: The site consists of four chemical storage tanks, an acid neutralization pit/sump, a sodium silicate sump, two sets of pumps, and a car spot. All located to the west of the 108-D building. Two chemicals were stored near 108-D, sulfuric acid and sodium silicate, which each had its own set of two large storage tanks. Additionally, each chemical had a set of two pumps for unloading solution out of railroad tank cars. An acid neutralization pit/sump was located underneath the acid storage tanks, while another sump was placed near the sodium silicate tanks. A car spot and railroad line passed through the site for delivering the solutions.

Location: The site was located west of the 108-D building.

Process Description: Two elevated sulfuric acid storage tanks were located in the site footprint. Each measured 2.7 by 11.0 m (9 by 36 ft) and was oriented horizontally, at a height of approximately 5 m off the ground (HAN-10970, HW-75014). A set of wooden stairs allowed workers to reach the top of the tanks (HW-74549). To fill the tanks, two self-priming unloading pumps were situated nearby in a protective shed. The capacity of each pump was 50 gpm and they were run by 440 V electric motors. These storage tanks were removed sometime prior to 1952. The two sulfuric acid tanks were located west of the 108-D building at (E573738.62886, N151772.25873) and (E573738.70631, N151768.65750). The separation between the two tanks was .9 m (3 ft). The pumps for sulfuric acid were located at (E573744.09046, N151775.85017), off the northeast corner of the tanks. The sulfuric acid brought in by railroad tank cars, was delivered to the storage tanks, which were filled with 68-70% sulfuric acid. From the storage tanks, a gravity-flow line supplied the 105-D building with acid for controlling the pH of process water. In addition, equipment was set up in the 108-D building for diluting the sulfuric acid. Pumps with suction piping were used to transport acid from the tanks into the 108-D building. Historic photographs indicate that the sulfuric acid tanks were removed before 1952. The 108-D Acid Neutralization Pit and Sump was located underground beneath the sulfuric acid storage tanks on the west side of the 108-D building. The pit was covered with a removable 1.4 m (4 ft, 8 in) wooden plank. A 10.1 cm (4 in) overflow pipe was attached to the south end of the pit, which connected to the water treatment process sewer. The northern portion of the pit was separated from the rest by a brick barrier and was used as a sump. Two 5.1 cm (2 in) inlet pipes inside an underground wooden box structure brought acidic solution into the sump. In addition, there were two 10.1 cm (4 in) drain pipes extending from the west ends of the acid tanks, with another 10.1 cm (4 in) drain line originating from the pump shed. Another overflow drain line connected from the center of the tanks. All of these overflow lines connected to the sump portion of the pit. All piping was above ground, except the 5.1 cm (2 in) inlet lines in the wooden box and the sewer drain line. The 108-D Acid Pit was located to the west of the 108-D building, directly underneath the elevated sulfuric acid tanks, at coordinates (E573736.72, N151770.62). It is also in the sidewall of 100-D-31. The Acid Pit consisted of two layers of acid-proof brick. The bottom layer was laid in asphalt, while the top layer was laid in Tegal Vitrabond. Joints were sealed with Vitrabond. The acid pit (excluding the sump portion) had an additional third layer, which was coated with 10.1 cm (4 in) of asphalt (HW-74807). The acid pit was used to safely neutralize acidic solutions. In particular, piping was in place to transfer acid that overflowed or leaked out of the tanks and pumps during the unloading process. Also, by using valves located both near the pumps and near the acid pit, acid could be released directly into the pit. According to drawing HW-74807, only sulfuric acid was supposed to be used in the acid pit. Two elevated sodium silicate tanks were located just north of the sulfuric acid tanks. Each of these measured 6.1 m (20 ft) in diameter and 4.6 m (15 ft) in height, and had an internal steam heating coil system (HAN-10970, SPEC HW-2036). The tanks were removed prior to

1970 (photograph 53352-5CN) and most of the soil underneath them falls within the cleanup footprint for 100-D-56. According to HAN-10970, the pumps used for unloading sodium silicate from the car spot were identical to those used for the sulfuric acid (50 gpm flow rate). However, SPEC-HW-2036 states instead that there were two 100 gpm pumps. These pumps were also used to transfer sodium silicate into the 108-D building and were housed in a wooden shed with a radiator (SPEC-HW-2036, HW-74550). The tanks were located to the west of the 108-D building and north of the sulfuric acid tanks at (E573737.28065, N151780.51975) and (E573737.28309, N151787.92000). The two tanks were separated by 1.5 m (5 ft). The sodium silicate pumps were located at (E573744.18968, N151787.46223), east of the northernmost storage tank. Both tanks are partially located in the sidewall of 100-D-56. Sodium silicate was received in railroad tank cars and moved to the two storage tanks by using the nearby pumps. Those same pumps were then used to transfer the silicate into the 108-D building, where it was diluted with process water. This weaker solution was later transported to 185-D for process water treatment (SPEC-HW-2036). The 108-D Sodium Silicate Sump was constructed in 1954, as part of a series of modifications to the water treatment system (HW-29542). It was located just north of the sodium silicate pumps, and received liquid from the process sewer. The underground structure was fed by a single 15 cm (6 in) vitrified clay pipe that drained the sump (H-1-5239). The sump was covered by a steel grating. The 108-D Sodium Silicate Sump was built as part of the Alum-Activated Silica Water Treatment Facilities project in 1954. The purpose of the sump was to address the issue of potential spills during the unloading and transfer of sodium silicate solution. However, there is no indication of any drains extending to it from the sodium silicate tanks or pumps, so it is not clear how the sump addressed this issue. The sump drained to the process sewer (H-1-5239). The 108-D Sodium Silicate Sump was just north of the sodium silicate pumps, at (E573743.77016, N151790.73936) between the sulfuric acid tanks and the sodium silicate tanks, and was used for unloading liquids. It included a platform for unloading chemicals, stairs to reach the top of railroad tank cars, flexible hoses to unload liquids, and a safety shower (HW-75250). The 108-D Car Spot was used to unload liquid chemicals for the 108-D building and the nearby storage tanks. Using flexible connecting hoses, sodium silicate solution and sulfuric acid were pumped out of railcars and into the storage tanks. A second car spot, 100-D-73, was used to unload solids and move them into the 108-D building. Among the chemicals transported this way was sodium dichromate.

Waste Type: Soil

Waste Description: Site contaminants of potential concern include mercury, lead, sodium silicate, and sodium dichromate. It is possible that contaminants leaked into the soil during the lifetime of the sulfuric acid storage tanks and the associated components, particularly prior to 1954 when there was no sump. Resulting in potentially high concentrations of heavy metals such as mercury and lead. In addition, during the process of filling the tanks or pumping it into the 108-D building, acid may have spilled into the soil elsewhere in the site footprint.

Near the southern portion of the site boundary, sodium dichromate may have been released as it was being unloaded in the nearby car spot, which is included in the adjacent waste site 100-D-73.

Code: 100-D-102	Classification: Accepted
Names: 100-D-102; Suspect Effluent Leak Adjacent to 107-DR Basin	Reclassification: None
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:
Description: The site code 100-D-102 was assigned to this site in April 2009. It was created to address potential contamination observed in a historical photograph outside the boundaries of waste site	

100-D-29.

The site was an irregular shaped feature visible in a 1962 aerial photograph (10974-PHOTO). The surface of the site has been re-graded many times and is no longer discernible from the surrounding area.

Location: The site is located immediately to the southwest corner of 107-DR retention basin.

Release Description: The first known inventory of radioactive releases to the ground in the 100-D/DR area is contained in the January 29, 1953 report titled "Unconfined Underground Radioactive Waste and Contamination" (HW-27337) by H.G. Ruppert. The report identifies five locations near the retention basins. These sites are later assigned the following waste site codes: 100-D-29, 116-DR-1&2, UPR-100-D-2, UPR-100-D-3 and UPR-100-D-4. A memo was issued with corrections to this report on July 16, 1953 (HW-28737). The corrections to the report did not affect any of the releases near the 107-D/DR retention basins.

Another inventory was made in October 1954 (HW-33305). The report listed those facilities that used for disposal of radioactive liquid wastes. It did not contain unplanned radioactive releases (as was done previously in HW-27337). The report listed just two locations (100-D-29 and 116-DR-1&2) near the 107-D/DR retention basins.

The inventory was updated again in May 1956 (HW-43121). It contained six additional disposal facilities from that reported in HW-33305. The new facilities were later assigned the following waste site codes: 100-D-4, 100-D-18, 100-D-19, 100-D-20, 100-D-21 and 100-D-22.

A comprehensive listing of underground radioactive contamination including planned and unplanned releases was issued again in November 1956 (HW-46715). It contained all of the waste sites mentioned previously but did not add any new ones in the vicinity of the 107-D/DR retention basins.

Hanford drawing (H-1-4046) which shows the underground radioactive waste sites in the 100-D/DR Area was revised in June 1964. It shows many (but not all) of the waste sites previously discussed. The drawing depicts two effluent leaks south of 107-DR. One of these is consistent with the location of 100-D-29. The shape and location was used for the remediation design of the 100-D-29 waste site. The other leak identified on the drawing did not correspond to any of the previously reported releases. This location was subsequently assigned to the UPR-100-D-5 waste site.

A report was issued in November 1967, following the deactivation of the 105-D/DR reactors (DUN-3063). This report mentioned the two retention basins and the sludge buried from 107-DR (100-D-22). It did not reveal any new information related to releases near the 107-D/DR retention basins.

Process Description: The 107-DR retention basin (116-DR-9) received cooling water effluent from the 105-DR Reactor, and reactor floor wastes from the 1608-DR Waste Water Pump House. The cooling water was held in the basin for as long as operating time would permit, allowing the water to thermally cool and for short-lived radionuclides to decay. The water was then discharged to the center of the river via the outfall structures and associated pipelines. The basin experienced several unplanned liquid releases during its lifetime.

The irregular shaped feature visible in the 1962 aerial photograph (10974-PHOTO) is suspected to be an effluent leak. There are several planned and unplanned releases of cooling water effluent reported near the 107-D and 107-DR retention basins. A number of reports published during the operation of the 100-D/DR Area detail the releases. Previously identified releases have been documented as 100-D-4, Sludge Trench #5 , 100-D-18, Sludge Trench #4, 100-D-19,

Sludge Trench #6, 100-D-20, Sludge Trench #3, 100-D-21, Sludge Trench #2, 100-D-22, Sludge Trench #1, 100-D-29, Effluent Leak #2, 100-D-48, 100-D Reactor Cooling Water Effluent Underground Pipelines, 100-D-49, 100-DR Reactor Cooling Water Effluent Underground Pipelines, 116-D-7, 107-D Retention Basin, 116-DR-1&2, 107-DR Liquid Waste Disposal Trench #1, 116-DR-9, 107-DR Retention Basin, UPR-100-D-2, Effluent Line Leak #1, UPR-100-D-3, Effluent Line Leak #3, UPR-100-D-4, 107-D Basin Leaks, UPR-100-D-5, Effluent Line Leak #4 waste sites. The footprint of the waste site 100-D-102 falls outside the footprints of all the other waste sites previously identified. The original drawings which were used to define the boundary of the waste sites were imprecise. It is possible that the aerial photograph shows the actual footprint of a waste site that was previously identified and located using the less precise historical drawings.

Related Sites/ Structures: The waste sites located near and associated with the retention basins include the following WIDS site codes:
100-D-4, Sludge Trench #5 , 100-D-18, Sludge Trench #4, 100-D-19, Sludge Trench #6, 100-D-20, Sludge Trench #3, 100-D-21, Sludge Trench #2, 100-D-22, Sludge Trench #1, 100-D-29, Effluent Leak #2, 100-D-48, 100-D Reactor Cooling Water Effluent Underground Pipelines, 100-D-49, 100-DR Reactor Cooling Water Effluent Underground Pipelines, 116-D-7, 107-D Retention Basin, 116-DR-1&2, 107-DR Liquid Waste Disposal Trench #1, 116-DR-9, 107-DR Retention Basin, UPR-100-D-2, Effluent Line Leak #1, UPR-100-D-3, Effluent Line Leak #3, UPR-100-D-4, 107-D Basin Leaks, UPR-100-D-5, Effluent Line Leak #4.

Waste Type: Process Effluent

Waste Description: Contaminants of potential concern (COPCs) include: Co-60, Cs-134, Cs-137, Eu-152, Eu-154, Eu-155, H-3, Pu-238, Pu-239, Pu-241, Sr-90, U-238, Am-241, Sr-90, arsenic, chromium, lead, and zinc and should be the same as those for the 107-D/DR Retention Basins. The waste is contaminated soil from an unplanned release of process effluent.

Code: 100-D-103 **Classification:** Accepted

Names: 100-D-103; Suspected Trench and French Drain from 116-D-8 Cask Pad **Reclassification:** None

Type: French Drain **Start Date:**

Status: Inactive **End Date:**

Description: WCH investigation identified a surface feature resembling a trench, it is visible in a December 1949 aerial photograph running south from the 116-D-8 Cask Pad.

Location: The area is located at approximately (E) 573,698, (N) 151,250.

Code: 100-D-104 **Classification:** Accepted

Names: 100-D-104; Unplanned Release near 185-D Sodium Dichromate Storage Tank and Acid Neutralization French Drain **Reclassification:** None

Type: Unplanned Release **Start Date:**

Status: Inactive **End Date:**

Description: This site consists of stained soil near the former sodium dichromate storage tank and acid french drain outside of building 185-D. The stain encompasses an area of 910 square meters (9,792 square feet). The site geometry was established by drawing an arbitrary polygon around an existing excavation to a depth of 6.0 m (19.6 ft) that contained stained soil with an elevated concentration of hexavalent chromium.

Location: The centroid of the stain is located at approximately (E) 573.586.7 (N) 151.521.7.

Code: 116-D-1A	Classification: Accepted
Names: 116-D-1A; 105-D Storage Basin Trench #1	Reclassification: Interim Closed Out (3/5/2001)
Type: Trench	Start Date: 1/1/1947
Status: Inactive	End Date: 1/1/1952

Description: The site has been remediated and closed out.

Location: The 116-D-1A/116-D-1B site is located within the 100-DR-1 Operable Unit in the 100 Areas of the Hanford Site in southeastern Washington State. The 116-D-1A site is located approximately 30 meters (100 feet) east of the 105-D Reactor Building.

Process Description: This trench was 40 meters (130 feet) by 3 meters (10 feet) by 1.8 meters (6 feet) deep. It was used from 1947 to 1952 and received contaminated water and sludge from the 118-D-6 Fuel Storage Basin. The 116-D-1B Trench was constructed in 1953 to replace the 116-D-1A Trench. This trench was 30 meters (100 feet) by 3 meters (10 feet) by 5 meters (15 feet) deep and received contaminated water and sludge from the 118-D-6 Fuel Storage Basin from 1953 to 1967. The 100-D-46 site is a burial ground that received radioactive and nonradioactive solid wastes and construction debris generated from various reactor modifications from the 105-D Reactor building after 1967. The 100-D-46 site was co-located with the 116-D-1A and 116-D-1B sites and was remediated along with these sites and their associated plumes.

Waste Type: Process Effluent

Waste Description: The site received contaminated water and sludge from 118-D-6 Fuel Storage Basin. Records also show approximately 1,000 kilograms (1.1 tons) of sodium dichromate was disposed in this trench.

Closure Info: 116-D-1A, 116-D-1B and 100-D-46 were addressed as a group. The information below documents information for the group of sites.

The 116-D-1A/116-D-1B Storage Basin Trenches and the 100-D-46 Burial Ground were remediated together, with the documentation presented in the same Cleanup Verification Package (CVP) and all sites are referred to as the 116-D-1A/116-D-1B site.

Remedial action objectives (RAOs) and goals (RAGs) for the 116-D-1A/116-D-1B site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995) and the Remedial Design Report/Remedial Action Work Plan (RDR/RAWP) (DOE/RL-96-17).

The selected remedial action for the 116-D-1A/116-D-1B site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, RAGs were established to identify radionuclide and no radionuclide contaminants of concern (COCs) and contaminants of potential concern (COPCs). Waste site COCs and COPCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22).

The COCs for this site were cesium-137, cobalt-60, europium-152, europium-154, plutonium-

239/240, strontium-90, uranium-238, americium-241, and hexavalent chromium.

At the completion of the remedial action, the total excavation was approximately 2,648 square meters (28,470 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 10,987 metric tons (12,111 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

The CVP demonstrated that remedial action at the 116-D-1A/116-D-1B site achieved the RAOs and corresponding RAGs established in the approved interim action ROD and RDR/RAWP. The remaining soils at the 116-D-A/116-D-1B site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-D-1A/116-D-1B site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF, that residual COC concentrations in the shallow zone will support future land uses that can be represented (or bounded) by rural-residential scenario, and that residual COC concentrations throughout the site are protective of groundwater and the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

The 116-D-1A/116-D-1B site is verified to be remediated in accordance with the ROD.

Code: 116-D-1B	Classification: Accepted
Names: 116-D-1B; 105-D Storage Basin Trench #2	Reclassification: Interim Closed Out (3/5/2001)
Type: Trench	Start Date: 1/1/1953
Status: Inactive	End Date: 1/1/1967

Description: The site has been remediated and closed out.

Location: The trench is located approximately 30 meters (100 feet) northeast of the 105-D Reactor.

Process Description: The 116-D-1B Trench was constructed in 1953 to replace the 116-D-1A Trench. This trench was 30 meters (100 feet) by 3 meters (10 feet) by 5 meters (15 feet) deep and received contaminated water and sludge from the 118-D-6 Fuel Storage Basin from 1953 to 1967.

Waste Type: Process Effluent

Waste Description: The site received contaminated water and sludge from 105-D Fuel Storage Basin and liquid waste from the decontamination of fuel spacers and reactor hardware. Records show approximately 700 kilograms (0.8 tons) of sodium dichromate, 2000 kilograms (2.2 tons) of sodium oxybate and 2000 kilograms (2.2 tons) of sodium sulfate were also disposed in this trench.

Closure Info: 116-D-1A, 116-D-1B and 100-D-46 were addressed as a group. The information below documents information for the group of sites.

The 116-D-1A/116-D-1B Storage Basin Trenches and the 100-D-46 Burial Ground were remediated together, with the documentation presented in the same Cleanup Verification Package (CVP) and all sites are referred to as the 116-D-1A/116-D-1B site.

Remedial action objectives (RAOs) and goals (RAGs) for the 116-D-1A/116-D-1B site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995) and

the Remedial Design Report/Remedial Action Work Plan (RDR/RAWP) (DOE/RL-96-17).

The selected remedial action for the 116-D-1A/116-D-1B site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, RAGs were established to identify radionuclide and no radionuclide contaminants of concern (COCs) and contaminants of potential concern (COPCs). Waste site COCs and COPCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22).

The COCs for this site were cesium-137, cobalt-60, europium-152, europium-154, plutonium-239/240, strontium-90, uranium-238, americium-241, and hexavalent chromium.

At the completion of the remedial action, the total excavation was approximately 2,648 square meters (28,470 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 10,987 metric tons (12,111 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

The CVP demonstrated that remedial action at the 116-D-1A/116-D-1B site achieved the RAOs and corresponding RAGs established in the approved interim action ROD and RDR/RAWP. The remaining soils at the 116-D-A/116-D-1B site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-D-1A/116-D-1B site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF, that residual COC concentrations in the shallow zone will support future land uses that can be represented (or bounded) by rural-residential scenario, and that residual COC concentrations throughout the site are protective of groundwater and the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

The 116-D-1A/116-D-1B site is verified to be remediated in accordance with the ROD.

Code:	116-D-2	Classification:	Accepted
Names:	116-D-2; 116-D-2A; 105-D Pluto Crib	Reclassification:	Interim Closed Out (10/23/2000)
Type:	Crib	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1956
Description:	This site has been closed out. The crib was a 3 meter (10 feet) by 3 meter (10 feet) crib, 3 meters (10 feet) deep. The unit had been shored with railroad ties and filled with sand.		
Location:	The 116-D-2 site was located approximately 920 meters (3,018 feet) from the Columbia River and about 30.5 meters (100 feet) east of the 115-D/DR Gas Treatment Facility (132-D-1).		
Process Description:	The 116-D-2 site was used to isolate coolant flow from process tubes containing ruptured fuel elements until the ruptured fuel could be discharged. A pluto valve was installed on the downstream end of the process tube, connecting the tube to a rubber hose. The coolant then flowed through the rubber hose into the crib. An estimated 4,000 liters (1,000 gallons) of liquid wastes were disposed at the 116-D-2 site, and the known hazardous chemical inventory included an estimated 0.004 kilograms (0.009 pounds) of sodium dichromate.		

Waste Type: Process Effluent
Waste Description: The site received effluent water from isolated tubes containing ruptured fuel elements.
Closure Info: The cleanup verification package (CVP-2000-00013) has documented that the 116-D-2 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

The COCs for the site as listed in the Sampling and Analysis Plan consisted of americium-241, cobalt-60, cesium-137, europium-152, europium-154, plutonium-238, plutonium-239/240, strontium-90, uranium-233/234, uranium-238, and hexavalent chromium.

Remedial action at the 116-D-2 site began on November 1, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil which were disposed at ERDF. On November 2, 1999, the excavation reached the design limit at El. 137.9 meters (452.4 feet).

At the completion of remedial action, the excavation was approximately 217.9 square meters (2,331.5 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 623.2 metric tons (687 tons) of material from the site were disposed of at ERDF. Cleanup verification sampling was conducted on January 3, 2000. The excavation will be backfilled in the near future with appropriate materials to the reference grade of El. 142.5 meters (467.5 feet).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 116-D-3	Classification: Accepted
Names: 116-D-3; 108-D Crib #1	Reclassification: No Action (1/30/2003)
Type: Crib	Start Date: 1/1/1951
Status: Inactive	End Date: 1/1/1967

Description: Based on excavations, the review of site drawings, and ground penetrating radar, it has been determined that the 116-D-3 Crib is a duplicate number for site 116-D-4.

Location: This crib is actually a duplicate number for the 116-D-4 Crib.

Process Description: Crib 116-D-4/116-D-3 received low-level fission product wastes in contaminated wash water from the 108-D Shipping Cask Handling Facility.

Related Sites/Structures: See sitecode 100-D-76 for additional information.

Waste Type: Process Effluent
Waste Description: The site (a duplicate number for the 116-D-4 Crib) is a crib containing contaminated soil and rock. The site received low-level fission product wastes in contaminated wash water from the 108-D Shipping Cask Handling Facility.

Closure Info: The actual crib, 116-D-4, was remediated on October 20 and 21, 1999. The possibility of 116-D-3 being a separate site has been investigated through excavation at all historically reported locations. Initial excavation at the contract design coordinates (N151739, E573774) occurred on 10/20/99; however, the excavation showed no engineered structure or contamination (using field instruments). Excavation activities occurred on 11/4/99 at location coordinates N151757, E 573768, which is also referenced as a possible location for 116-D-3. No evidence of a structure or contamination (using field instruments) was found. Excavation also occurred on 12/30/99 at coordinates N151725, E573807 and N151731, E573832. No structures or contamination (using field instruments) were found.

Code: 116-D-4	Classification: Accepted
Names: 116-D-4; 108-D Crib #2	Reclassification: Interim Closed Out (10/23/2000)
Type: Crib	Start Date: 1/1/1951
Status: Inactive	End Date: 1/1/1967

Description: This unit has been remediated and closed out. The site was a 2.4 by 2.4-meter (8 by 8-foot) crib, 5 meters (16 feet) deep. Site 116-D-3 is an alias for this crib.

Location: The site is located 65.45 meters (281 feet) directly east of 108-D Shipping Cask Handling Facility, now demolished. This location is the southeast corner of the 108-D Building and east of the wash area of the 108-D.

Process Description: The site received low-level fission product wastes in contaminated wash water from the 108-D Shipping Cask Handling Facility maintenance shops and technical laboratory.

Related Sites/ Structures: The site is related to the 108-D Shipping Cask Handling Facility and to the maintenance shops and technical laboratory of that facility.

Waste Type: Process Effluent

Waste Description: The site was a crib containing contaminated soil and rock. The site received low-level fission product wastes from contaminated maintenance shops in the 108 buildings. Assuming that H-1-3091 represents the correct information, the crib received wash water from the 108-D Shipping Cask Handling Facility.

Closure Info: The cleanup verification package (CVP-2000-00008) has documented that the 116-D-4 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Remedial action began on October 20, 1999. Based on field screening, excavated materials identified as potentially clean were placed in stockpiles for potential use as backfill. On October, 21, 1999, the excavation reached the design limit at El. 140.7 meters (462 feet).

At the completion of remedial action, the excavation was approximately 137.8 square meters (1,482 square feet) in area with a maximum depth of approximately 2.8 meters (9 feet). Cleanup verification sampling began on January 3, 2000, and was finished on January 4, 2000. The backfill reference grade is El. 143.5 m (471 feet). Backfill will be taken from the clean stockpile and/or from other sources of clean material surveyed in accordance with the SAP and that are appropriate for use as backfill.

The contaminants of concern listed in the Sampling and Analysis Plan were uranium-238 and hexavalent chromium.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 116-D-5	Classification: Accepted
Names: 116-D-5; 1904-D Outfall Structure	Reclassification: Interim Closed Out (8/10/2011)
Type: Outfall	Start Date: 1/1/1944
Status: Inactive	End Date: 1/1/1975

Description: The outfall structure had been an open, reinforced, compartmentalized concrete outfall structure. The outfall structure was demolished, caved into itself and backfilled with soil in 1998. In the spring of 2009, the engineered structure, contaminated debris and soil was removed and disposed in the ERDF facility.

Location: The site is located at the top of river bank, northwest of 116-D-7 (107-D Retention Basin).

Process Description: Process sewer wastes, and reactor cooling water collected and temporarily stored in the 116-D-7 and 116-DR-9 retention basins, were pumped to the river via the 116-D-5 outfall structure and associated 100-D-60 river effluent pipelines. The reactor cooling water discharged into the upper chamber of the concrete outfall structure, flowed through a bar grillwork and fell about 6.10 meters (20 feet) to the lower chamber of the outfall structure. Then it overflowed from the lower chamber into the discharge pipe to the river. The discharge pipe to the river (100-D-60) was connected to the side wall of the lower chamber of the outfall structure. The inlet to the discharge pipe from the outfall structure was about 0.10 meters (4 inches) above the floor of the lower chamber. The Outfall Structure was open to the atmosphere which allowed rain and snow to collect in the bottom 4 inches of the lower chamber. Prior to the structure being demolished and caved into itself, the Outfall Structure was enclosed with a chain-link security fence and an aviary exclusion mesh cover.

Related Sites/ Structures: The site is associated with the 107-D Retention Basin (116-D-7), the 107-DR Retention Basin (116-DR-9), 100D Reactor Cooling Water Effluent Lines (100-D-48), the 100DR Reactor Cooling Water Effluent Lines (100-D-49), the 100D River Effluent Lines (100-D-60) and Flumes (100-D-66).

Waste Type: Construction Debris

Waste Description: This unit received reactor coolant water from the 107-D & 107-DR Retention Basins and waste water from the 100-D Water Support Facilities including 183-D and 190-D.

The contaminants of concern include C-14, Cs-137, Sr-90, U-235, -238, and Pu-239/240.

Closure Info: Remedial action at the 116-D-5 waste site was performed between February 6 and April 1, 2009. Additional remediation was conducted on March 15, 2011 to remove residual contamination identified after the initial round of verification sampling. The site was originally excavated to a depth of approximately 5 m (16 ft) on the northwestern side of the excavation and 10 m (33 ft) on the southeastern side of the excavation. The depth of the excavation following additional remediation is approximately 6 m (20 ft) on the northwestern side and 11 m (36 ft) on the southeastern side of the excavation. The engineered structure was completely removed. The entire excavation resulted in approximately 2,275 bank cubic meters (2,976 bank cubic yards) of contaminated soil and debris being removed for disposal to the Environmental Restoration Disposal Facility (ERDF). Some of the material removed from the excavation was

placed in a staging pile area prior to being loaded out for disposal at ERDF.

The COCs and COPCs for the 116-D-5, 1904-D Outfall Structure, specified in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL 2009a) are identified as carbon-14, cesium-137, strontium-90, uranium-235, uranium-238, and plutonium-239/240. Based on process knowledge, analyses of shallow and deep zone samples at the 116-D-7 retention basin (BHI 2000), and identification as COCs/COPCs for other outfall waste sites, cobalt-60, europium-152, europium-154, europium-155, nickel-63, plutonium-238, lead, mercury, chromium (total), and hexavalent chromium have also been identified as COPCs for the 116-D-5 waste site. Americium-241, uranium-234, pesticides, SVOCs, polycyclic aromatic hydrocarbons (PAH), and ion chromatography (IC) anions were also added, as they were identified as COCs/COPCs for the 100-D-31:7 pipeline that fed into the 116-D-5 outfall. Although not considered COCs/COPCs, antimony, arsenic, barium, beryllium, boron, cadmium, cobalt, copper, manganese, magnesium, molybdenum, nickel, silver, selenium, vanadium, and zinc will be evaluated by performing analyses for the constituents of the expanded inductively coupled plasma (ICP) metals lists.

Code:	116-D-6	Classification:	Accepted
Names:	116-D-6; 105-D Cushion Corridor French Drain	Reclassification:	Interim Closed Out (11/8/2000)
Type:	French Drain	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1967
Description:	This site has been remediated and closed out. The waste site was a 1-meter (3.3-foot) diameter french drain, 1 meter (3.3 feet) deep covered by approximately 1 meter (3.3 feet) of gravel and soil.		
Location:	The site was located adjacent to the northeast corner of the 105-D Reactor Building, bordered on two sides by the reactor wall and foundation, and on the other two sides by the 100-D-48 cooling water effluent pipelines.		
Process Description:	The drain received domestic wastewater from the change room and wastewater from the mask decontamination station located in the cushion corridor during reactor operation from 1953 to 1967. Additional decontamination effluents and solvents were also likely disposed into this french drain.		
Waste Type:	Water		
Waste Description:	The site received domestic water from the changing room and water from the mask decontamination station. The site may have received chemical decontamination wastes and solvents.		
Closure Info:	Site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the Interim Action ROD (EPA 1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL-22).		
	Waste site contaminants of concern (COCs) and contaminants of potential concern (COPCs) identified through process knowledge are listed in the SAP (DOE-RL 1998a). All of the 116-D-		

6 site contaminants in the SAP were listed as COPCs. No COCs were specifically identified at the 116-D-6 site. The COPCs that were detected during field sampling and then added to the final list of COCs included americium-241, cesium-137, europium-152, europium-154, plutonium-239/240, uranium-233/234, uranium-238, total chromium, lead, and mercury. The remaining COPCs identified in the SAP are not addressed in this document because they were not detected or were significantly below background levels.

Because the site was bordered on two sides by the reactor wall and foundation, and on the other two sides by the 100-D-48 cooling water effluent pipelines, shallow soils associated with the 116-D-6 site were excavated and disposed of at the ERDF during the remediation of the 100-D-48 cooling water effluent pipelines. Remedial action at the 116-D-6 site began on October 21, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and the underlying deep zone soils. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On January 3, 2000, the excavation reached the design limit at El. 137.9 meters (452 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 10.1 square meters (109 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 200 metric tons (221 tons) of material from the site were disposed of at ERDF. Cleanup verification sampling began on February 29, 2000, and was finished the same day. The excavation will be backfilled with appropriate materials to the reference grade of El. 142.5 meters (468 feet).

The CVP demonstrated that remedial action at the 116-D-6 site achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and RDR/RAWP (DOE-RL-96-17). Materials from the 116-D-6 site that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 116-D-6 site is verified to be remediated in accordance with the ROD.

Code:	116-D-7	Classification:	Accepted
Names:	116-D-7; 107-D; 107-D Retention Basin	Reclassification:	Interim Closed Out (8/15/2000)
Type:	Retention Basin	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1967
Description:	The unit was an open concrete basin with a vertical concrete baffle constructed lengthwise in the middle of the basin. The floor consisted of concrete slabs, with joints originally closed with neoprene water seals. The walls sloped from the floor to a point 3 meters (10 feet) above the floor level with the remaining wall (approximately 3.0 meters [10 feet]) being vertical. The sloping wall sections were 10 centimeters (4 inches), and the vertical walls were reinforced construction with a minimum thickness of 0.3 meters (1 foot) at the top and 1.75 meters (5.75 feet) at the bottom.		
Location:	The 116-D-7 site is located near the northern edge of the 100-D Area and is approximately 110 meters (360 feet) from the Columbia River.		
Process Description:	The 116-D-7 Retention Basin was constructed in 1944 to hold cooling water effluent from the 105-D Reactor for a brief period of time to allow for thermal cooling and decay of short-lived		

radionuclides prior to release to the Columbia River. The retention basin received reactor cooling water effluent until 1967.

Related Sites/ Structures: Four sludge trenches were excavated in the 107-D and 107-DR Retention Basin area to dispose of sludge that had accumulated at the bottom of the basins. The trenches were dug in the Spring of 1953 to facilitate repair of the basins by minor construction forces, and were covered after use with 1.8 meters (6 feet) of clean soil. The approximate coordinates for the trenches are: N94600, W95291; N94453, W52888; N94511, W52092; N94252, W52039, although the exact locations are not certain. An additional trench was excavated in 1955 to receive effluent from the 107-D and 107-DR systems following an undetermined number of fuel cladding failures. Approximate coordinates for this trench are N94698, W53149.

Waste Type: Process Effluent

Waste Description: This site retained cooling water effluent from the 105-D Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Total radionuclide inventories in the vicinity of the basin ranged from 5 curies to over 400 curies. Seventy percent of the total radionuclide inventory was contained within the soil adjacent to the unit. Approximately 10 curies had leached into the concrete floor and walls.

Closure Info: Site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the Interim Action ROD (EPA 1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL-96-22).

Waste site contaminants of concern (COCs) identified through process knowledge are listed in the SAP (DOE-RL-96-22). Additional COCs including total chromium, mercury, and lead were identified in the field during remedial action. The COCs for this site are americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, hexavalent chromium, total chromium, mercury, and lead.

Excavation of the 116-D-7 site began on May 1, 1997, and involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. The excavation design limit elevation was El. 129.85 meters (425.9 feet); however, after the original excavation and sampling, hexavalent chromium concentrations were above the soil RAG for river protection (2.2 milligrams/kilogram). To remediate areas that were above the hexavalent chromium soil RAG for river protection, approximately two-thirds of the floor (deep zone sampling areas A2, B5, C7, C8, and C9) was excavated an additional meter to an elevation of El. 128.85 meters (422.6 feet).

The lowest elevation that the excavation extended to was El. 127 meters (417 feet), about 7.4 meters (24.4 feet) below the ground surface (backfill reference El. 134.43 meters [440.9 feet]). The low areas (El. 127 meters [417 feet]) of the site excavation are two relatively small areas near the east and west ends of the site. The remainder of the site, with the exception of the sidewalls, was generally excavated to the design elevation of El. 129.85 meters (425.9 feet). Cleanup verification sampling was conducted during August, September, and November 1998 and during January and February 1999.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 12,940 square meters (139,200 square feet or 3.2 acres). Approximately 177,724 metric tons (195,941 tons) of material from the site were disposed of at ERDF.

The CVP demonstrates that remedial action at the 116-D-7 site achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and the RDR/RAWP (DOE-RL 1998). Materials that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils have been sampled, analyzed, and modeled to show that residual COC concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario. This scenario, described in Section 5.2, assumes multiple exposure pathways (e.g., ingestion, inhalation, and direct exposure) for shallow zone soils.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone [i.e., below 4.6 m (15 ft)] are required. The verification package demonstrates that residual COC concentrations pose no threat to groundwater or the Columbia River. Thus, those areas of the 116-D-7 site represented by the CVP are verified to be remediated in accordance with the ROD.

Code: 116-D-9	Classification: Accepted
Names: 116-D-9; 117-D Crib; 117-D Seal Pit Crib	Reclassification: Interim Closed Out (3/19/2001)
Type: Crib	Start Date: 1/1/1960
Status: Inactive	End Date: 1/1/1967
Description:	This site has been remediated and closed out. The waste site and associated piping was excavated. Site remediation began in 1999 and ended in 2000. The site was a crib and pipeline filled with gravel and covered to grade with clean soil. The surface was covered with cobbles, and a large steel vent cap was located in the center.
Location:	The crib was located 90.7 meters (200 feet) southeast of the 105-D Building.
Process Description:	The 116-D-9 Crib operated from 1960 to 1967. It received stack drainage through a 10-centimeter (4-inch)-diameter pipeline from the confinement system 117 Building seal pits. The 117 Building received exhaust fan discharges from the 105-D Reactor through an inlet duct and released the filtered air through the 132-D-4 exhaust stack. The crib was a 3 meter by 3 meter by 3 meter (10 by 10 by 10 foot) gravel-filled crib with a large steel vent cap extending above the ground surface. It received an estimated 420,000 liters of process effluent drainage from the confinement seal pits located at the 117-D Building. The seal pit effluent entered the 116-D-9 Crib through a 91.4 meter (300-foot) long, 10.2 centimeter (4 inch.) diameter asbestos cement pipe. Sampling in 1978 revealed contamination at the 116-D-9 site was at or below background.
Related Sites/Structures:	The crib is associated with the 117 Filter Building (site 132-D-2).
Waste Type:	Process Effluent
Waste Description:	The site received drainage from the confinement system 117 Building seal pits.
Closure Info:	The cleanup verification package (CVP-2000-00012) has documented that the 116-D-9 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work

Plan for the 100 Area (RDR/RAWP).

Waste site COCs and COPCs identified through process knowledge were listed in the 100 Area Remedial Action Sample Analysis Plan. The contaminants of concern for this site were strontium-90, uranium-238 and hexavalent chromium. No contaminants of potential concern were identified at this site.

Remedial action began on October 29, 1999. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed at ERDF. On August 11, 2000, the excavation reached the design limit at elevation 137.3 meters (447.2 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 598.4 square meters (6,441 square feet) in area with a maximum depth of approximately 5.5 meters (18 feet). An estimated 100 meters (328 feet) of pipeline was removed. Cleanup verification sampling was conducted on January 5, 2000, for the 116-D-9 Crib, and on September 12, 2000, for the pipeline excavation. The excavation was backfilled with appropriate materials to the reference grade elevation of 142.5 meters (467 feet). Approximately 7.3 metric tons (8.0 tons) of material was removed and disposed at the Environmental Restoration Disposal Facility (ERDF).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 116-D-10	Classification: Accepted
Names: 116-D-10; 105-D Fuel Storage Basin Cleanout Percolation Pit; 105-D Fuel Storage Discharge Ponds; 105-D Ponds	Reclassification: Interim Closed Out (12/2/2010)
Type: Pond	Start Date: 7/1/1984
Status: Inactive	End Date: 9/1/1984
Description:	The unit consists of two open excavated pits with a crossover channel connecting them. The west excavation was 10.7 meters (35 feet) long, 6.7 meters (22 feet) wide, and 0.9 meters (3 feet) deep. The east excavation was 15.2 meters (50 feet) long, 7.3 meters (24 feet) wide, and 1.2 meters (4 feet) deep. Both pits have been back filled and graded to resemble the natural terrain.
Location:	The site is located east of the 105-D Reactor Building and just outside of the AC-5-40 permanent markers.
Process Description:	The site was used during the 1984 cleanout of the 105-D Fuel Storage Basin (FSB) to dispose of water to the soil. During cleanout of the basin, radiologically contaminated shielding water was processed through ion-exchange columns and retained in holding tanks for analysis before being released to the soil. The water was released to two open excavated pits (ponds) with a connecting channel. The west pond was small and only allowed for the discharge of one holding tank per day, while the east pit was designed to handle an increase in needed capacity. During cleanout of the basin, radiologically contaminated shielding water was processed through ion-exchange columns and released to the ponds. It is reported that no hazardous substances were released with the water; however, chemical analysis was not a standard

practice during that period. Additionally, as discussed in Decommissioning of the 105-D Fuel Storage Discharge Ponds Final Radiological Release Report (Beckstrom 1985), "minute quantities of radionuclides in the processed water presented a potential for accumulation of radionuclides in the soil" at the bottom of the ponds. On August 27, 1984, a process equipment failure affected approximately 2,350,000 L (620,000 gal) of water that was processed from the 105-D FSB and introduced very fine particles of sludge into the processed water holdup tanks (Beckstrom 1985). When the previously clean water from the holdup tanks (verified by radiochemical and isotopic analysis) was discharged, the fine sludge particles were also released, allowing radioactive material to enter the soil. Water processing operations were immediately suspended and a detailed radiological survey was performed. Contamination levels ranged from 1 pCi/g to several hundred pCi/g. Equipment was repaired and operations resumed on September 6, 1984. The final tank of processed water was discharged on September 22, 1984. After discharge of the fuel storage basin water was complete, approximately 28 m³ (1,000 ft³) of contaminated soil was removed from the bottom of the ponds and taken to the 200 West Area for burial. Radiological surveys and sampling were then performed to support the completion of contamination removal. The mean alpha and beta-gamma activities were calculated to be less than 1 pCi/g and 17.7 pCi/g, respectively, which met the unrestricted release criteria of less than 1 pCi/g alpha activity and less than 20 pCi/g beta-gamma activity that was applicable at that time. The ponds were then filled to grade with 0.9 to 1.2 m (3 to 4 ft) of clean soil. A 2005 review of the maximum detected isotopic activity levels concluded that residual beta-gamma activity exceeded current remedial action goals (RAGs) in some areas.

Related Sites/ Structures: 105-D Fuel Storage Basin

Waste Type: Water

Waste Description: The unit received processed water from the 105-D Fuel Storage Basin. During the cleanout of this basin, the radiologically contaminated shielding water was processed through ion exchange columns. Before discharging the water to the unit, composite samples were taken to ensure that radionuclide concentrations were below release criteria in Table II of DOE Order 5480.1. No known hazardous substances were present in the water, however chemical analysis was not a standard practice during that period and there is no evidence that analyses were performed. It should be noted that water removed from the 1608-D is believed to be comparable to the storage basin water, and EP-TOX testing results for the 1608-D water were negative.

Closure Info: The Remaining Sites Verification Package (RSVP-2009-042) has documented that the 116-D-10, waste site meets the remedial action objectives (RAOs) and remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999).

Remedial action was performed from April 24 to May 13, 2008. Approximately 2,700 bank cubic meters (3,500 bank cubic yards) of soil was removed and stockpiled. The excavation is approximately 33 m (110 ft) long, 25 m (84 ft) wide, and 5 m (15 ft) deep. Contaminated soil was not found during this remediation, likely because the contamination would have been localized in a very thin layer, located about 1 m (3 ft) below grade, and would not be readily separated from the surrounding clean soil without using smaller tools than the large scale remediation equipment. Since the excavation reached a depth of 4.6 m (15 ft), the contaminated soil was certainly blended within the soil stockpile as a result of the excavation and stockpiling. Although no radiological contamination was identified, the staged material was removed to the Environmental Restoration Disposal Facility because of the potential for residual contamination existing within the stockpile. This removal occurred on January 7 through 26, 2009.

The contaminants of potential concern (COPCs) for the 116-D-10 waste site were determined based on the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL96-22, Rev. 5), historical sample results, in-process sample results, and professional judgment based on field remediation observations. The COPCs for verification sampling included americium-241, carbon-14, cesium-137, cobalt-60, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, tritium, uranium-233/234, uranium-235, uranium-238, hexavalent chromium, lead, lithium, mercury, and polychlorinated biphenyls (PCBs).

Verification sampling was performed on May 19 through 26, 2009. The laboratory-reported verification data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as Attachment 1 of the 95% upper confidence limit (UCL) calculation in Appendix C of the RSVP.

The verification sampling results support a reclassification of the site to Interim Closed Out. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	120-D-2	Classification:	Accepted
Names:	120-D-2; 186-D Waste Acid Reservoir	Reclassification:	Interim Closed Out (7/28/2009)
Type:	Surface Impoundment	Start Date:	
Status:	Inactive	End Date:	1/1/1979
Description:	The waste site consisted only of the 186-D waste acid reservoir and associated soils. The unit was constructed of acid-proof brick, 3-ply waterproof membrane, vitrified pipe, #8 lead flashing, and gunnite. The sides of the reservoir were sloped 2:1 from 1.5 meters (5 feet) below grade level to the bottom. As of June 21, 1991 the site area was covered with gravel and annual weeds. No evidence remained on the surface of the building structure.		
Location:	The site is located west and south of the center of the 186-D Building.		
Process Description:	The 120-D-2, 186-D Waste Acid Reservoir was part of the 186-D demineralization facilities (WHC 1994). The waste acid reservoir was located west and south of center of the 186-D Building. Unique to the 100-D Area, the 186-D Building originally contained demineralization facilities intended as a water treatment system for reactor cooling water. However, research indicates that the facilities were never used as intended. The building apparently was converted to a warehouse. An acid-proof brick-lined trench, running almost the entire length of the 186-D Building, was designed to gather waste acid from the demineralization process and deliver it to the 120-D-2 waste acid reservoir. Acid stored in the reservoir could be transferred to the 186-D acid mixing/neutralization tanks, and subsequently discharged to the 100-D-50:7 segment of the process sewer. Underflow and overflow drains in the waste acid reservoir could also discharge directly to the 100-D-31:9 segment of the process sewer.		
Related Sites/ Structures:	The reservoir drains were connected to the 100-D Area process sewer system. The 186-D Building was originally constructed to be used as a water treatment plant, and the acid waste reservoir was constructed to receive waste acid from processes in the 186-D Building. The 186-D Building was never used as a water treatment plant, however it was used as a warehouse.		
Waste Type:	Chemicals		
Waste Description:	This unit was never used for waste acid storage. No records have been found documenting the disposal of waste of any kind in this facility. No written documentation has been found concerning the disposal of the lead flashing that was used in the construction of the waste acid reservoir; however, it is assumed that the lead flashing was disposed in-situ during the		

demolition of the 186-D Facility.

Closure Info: The Remaining Sites Verification Package (RSVP-2003-053) has documented that the 120-D-2 site meets the remedial action objectives (RAOs) and remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units,(Remaining Sites ROD). The RSVP shows that the site has been successfully remediated and that there are no residual hazardous/dangerous materials present above the remedial action objectives (RAOs) in the soil.

Remediation of the waste site was performed in May through July 2007. Approximately 3,361 m³ (4,396 yd³) of stained soil, stained concrete, demolition debris, and lead sheet were excavated and disposed directly to the Environmental Restoration Disposal Facility. Observations during remediation confirmed that the visible yellow stains were present outside of the waste acid reservoir. All of the visibly impacted soils were removed (WCH Logbook, EL-1607-1). Soil pH was monitored during excavation to help direct the extent of the excavation and ensure all of the impacted soils were removed. Piping associated with an overflow and an underflow drain in the northwest corner of the waste acid reservoir was removed from within the footprint of the 120-D-2 remediation. Remaining portions of the drain sewer will be removed with remediation of the 100-D-31:9 pipelines planned to occur in fiscal years 2009 and 2010.

Process knowledge, historical information, field observations, and in-process sampling information (RSVP-2008-053, Appendix A) were used to finalize the list of COPCs for verification sampling. The COPCs included pH, sulfate, hexavalent chromium, mercury, and lead. Radionuclides were not COPCs because the waste acid reservoir was not a radioactive site and field radiological survey results did not identify radioactivity inconsistent with background levels. Contingencies for additional analyses discussed in the work instruction were not needed because no other suspect hazardous materials were found or detected during remediation or sampling.

Following site remediation, verification sampling was conducted on September 17, 2008 (WCH Logbook EL-1607-4, pp 12, 49-52), to support a determination that residual contaminant concentrations at this site have met the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD. The verification sample results were provided in Appendix B of the RSVP and indicated that the waste removal action achieved compliance with the RAOs for the site. The laboratory-reported verification data results for all constituents were stored in the Environmental Restoration project-specific database prior to archival in the Hanford Environmental Information System and were presented as Attachment 1 of the 95% UCL calculation (RSVP-2008-053, Appendix B).

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. The site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

Code: 126-D-2	Classification: Accepted
Names: 126-D-2; 184-D Coal Pit; Inert Landfill	Reclassification: Interim Closed Out (10/14/2010)
Type: Inert/Demolition Landfill	Start Date: 1/1/1943
Status: Inactive	End Date: 1/1/1986

Description: and later used as a demolition and inert waste landfill. This unit is full of debris. It has been covered with about 0.3 meters (1 foot) of pit run backfill material and graded to conform with the natural terrain. Numerous surface depressions are visible, indicating a potential cave-in hazard.

Location: The site is located just west of the site of the demolished 184-D Power House, north of the 183-D Water Treatment Facility, and northwest of the 105-D Reactor Building.

Process Description: The site was first used as a coal pit in 1943. Use as a demolition and inert waste landfill began in 1970.

Related Sites/ Structures: The site was originally associated with the 184-D Power House.

Waste Type: Asbestos (friable)
Waste Description: Asbestos containing waste has been disposed of at this site.

Waste Type: Demolition and Inert Waste
Waste Description: The unit contains demolition and inert waste from demolished facilities in and around 100-D. This includes debris from 184-D (including stacks), 108-D, released portions of the 115-D/DR, and 186-D. The site is suspected to contain some radioactively contaminated solid wastes. Potential contaminants include: Chromate, lead, mercury, undetermined organic and inorganic chemicals.

Waste Type: Chemicals
Waste Description: The site is known to contain paint cans and paint wastes, solvents, acids, dry chemicals, photo chemicals, and herbicide cans.

Closure Info: The cleanup verification package (CVP-2009-00007, Rev. 1) has demonstrated that remedial action at the 126-D-2 site has met the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, (Burial Grounds ROD) (EPA 2000).

Initial remedial action at the site began on May 29, 2007, and excavation continued through October 6, 2008. Supplemental remedial action began on October 19, 2009 and excavation continued through March 16, 2010. The debris removed included concrete, steel reinforcing rod, metal pipes, reactor components, drums, various containers, transite material, and a white powdery substance. Approximately 41,873 BCM (54,770 BCY) of soil and debris were removed for disposal to the ERDF.

The contaminants of potential concern (COPCs) for the site were developed in consideration of those specified in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (DOE-RL- 2001-35), field observations of the types of waste removed from the site, evaluation of constituents detected in waste characterization and in-process samples, and results of the Global Positioning Environmental Radiological Surveyor (GPERS) surveys. As a result, the COPCs included asbestos, barium, chromium (total), hexavalent chromium, copper, lead, mercury, nickel, zinc, polychlorinated biphenyls (PCBs), semivolatile organic compounds (SVOCs), polycyclic aromatic hydrocarbons (PAHs), pesticides, and gamma-emitting radionuclides. Although not considered COPCs, antimony, arsenic, beryllium, cobalt, manganese, molybdenum, selenium, silver, and vanadium were also evaluated for by requesting analysis of the expanded list of inductively coupled plasma (ICP) metals.

Initial verification sampling was performed on June 22 and 23, 2009. The laboratory-reported

data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as part of the 95% UCL calculation in Appendix D or in Appendix E, for the asbestos results, of the CVP.

Excavation continued to a depth below the base of the original coal pit, at which debris was no longer present. The final depth of the excavation ranged from approximately 5.5 m (18 ft) in a small portion of the southeast corner of the excavation to 3 m (10 ft) in a variety of locations in the excavation. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils.

The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. However, the entire excavation area was considered one decision unit, and will be closed out using the more restrictive shallow zone cleanup criteria; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required

Code: 128-D-2	Classification: Accepted
Names: 128-D-2; 128-D-2 Burn Pit	Reclassification: Interim Closed Out (9/8/2011)
Type: Burn Pit	Start Date:
Status: Inactive	End Date:

Description: The waste site has been remediated. The site was a large landfill area that showed evidence of surface burning and has no definite boundaries. The site was marked with signs of plant stress, depressions, and berms. Concrete and metallic debris exposed on the surface indicated the possibility that this site was also used as a solid waste landfill. The following items were also noted during the March 31, 1999, visit: rigging equipment, bricks, and unidentified white powder that may be ash, and a north-south running trench. The site has been used as a disposal site for compacted tumbleweeds collected from area fences. Knapweed was noted during the March 1999 walkdown.

Location: The site is located northeast of 105-D and southwest of 100-D-7.

Waste Type: Misc. Trash and Debris

Waste Description: Some pieces of non-contaminated reactor hardware and graphite blocks were found at the site.

Closure Info: Remediation at the 128-D-2 waste site was performed between July 22, 2009 and January 14, 2010. Approximately 39,570 bank cubic meters (BCM) (51,756 bank cubic yards [BCY]) of contaminated soil and debris were removed from the 128-D-2 waste site. The debris removed from the 128-D-2 waste site consisted of miscellaneous noncombustible debris including concrete, metal, bricks, vitrified clay pipe, and electrical wiring. Although radionuclides cesium-137, potassium-40, thorium-228, thorium-232, radium-226, radium-228, and strontium-90 were detected in confirmatory soil samples at the 128-D-2 waste site, no radiologically contaminated material was discovered during remediation at the 128-D-2 waste site. No indications of previous spills or releases were detected during remediation at the 128-D-2 waste site.

The soil and debris from the 128-D-2 Burn Pit and the 100-D-7 Undocumented Solid Waste Site were staged in a staging pile to the east of the 128-D-2 waste site and southeast of the 100-D-7 waste site before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). The staging area includes a smaller area where topsoil from the waste sites was placed for use on top of the backfill to support successful revegetation as required by the ecological review for the 128-D-2 and 100-D-7 waste sites. All staged waste has been disposed

to the ERDF. The staging area was then scraped to remove surface contaminated soil, which was disposed to the ERDF. The location of the staging pile was closed out with the 100-D-7 waste site.

Three anomalies were initially identified during the remediation at the 128-D-2 waste site. These consisted of white powder (anomaly 100D-AN-09-060), an area with clumps of yellow sand (anomaly 100D-AN-09-064), and a white solid material (anomaly 100D-AN-09-065). All these materials were sampled and characterized prior to removal and shipment to ERDF, and the sample results are reported in the Work Instruction for Verification Sampling of the 128-D-2 Burn Pit and the 100-D-7, Undocumented Solid Waste Site. The 100-D-7 waste site is located approximately 700 meters (2300 feet) northeast of the 105 Reactor Building, and immediately northeast of the 128-D-2 Burn Pit.

Code:	130-D-1	Classification:	Accepted
Names:	130-D-1; 1706-D Gasoline Storage Tank; 1716-D Gasoline and Oil Storage Tanks	Reclassification:	Interim Closed Out (8/15/2011)
Type:	Storage Tank	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1968
Description:	Originally the site consisted of two underground storage tanks. One of the tanks was filled with leaded gasoline and had a capacity of 3,800 L (1,000 gal). The other was an oil tank with a capacity of approximately 300 gallons (H-1-5017).		
Location:	The gasoline tank was located northeast of 190-D and on the east side of the demolished 1716-D Building. The oil tank was located on the west side of the 1716-D Building.		
Process Description:	From 1944 until 1968, the gasoline tank was used to support vehicle fueling operations at the 1716-D Garage. The oil tank was installed during construction of the lubrication pits in 1953 (HW-27932). The drawing shows two lines from the tank to the 1716-D Building. The text describing the tank in drawing (H-1-5017) is not legible. No other historical information is available about the oil tank. The oil tank was added to the 130-D-1 waste site after it was discovered while excavating the 100-D-31:7 pipeline subsite in 2010. The oil tank was subsequently removed and disposed of at ERDF.		

When the garage operations were centralized following deactivation of the 100-D/DR Area, the gasoline tank was emptied of product and filled with water. In 1989, the tank was removed as part of the Hanford Site Underground Storage Tank (UST) removal program and was noted to be devoid of any contents and heavily deteriorated. Underlying soils were visibly impacted, and characterization showed elevated levels of petroleum hydrocarbons. (WHC-N-270) No soil remediation or removal activities were performed, and the excavation was backfilled with clean material. Slightly elevated concentrations of lead were detected in subsequent site characterization activities (DOE/RL-93-29).

The coordinates for the gasoline tank, provided in the Technical Baseline Report, are incorrect per H-1-1520, revision 1. The coordinates would place the gasoline storage tank by the water tower (sanitary water tank 1902-D) approximately 122 m (400 ft) west of the garage and gas station. During the April 1999 site walkdown, no evidence of the site could be found except for some soil gas probes left from the soil gas investigation WHC-SD-EN-ES-031). The concrete marker mentioned in the Technical Baseline Report could not be found at either the coordinates mentioned in that document or at the site's mapped location. The top of the former gasoline UST is believed to have been located 1.3 to 1.5 m (4 to 5 ft) below ground surface, and soils impacted by past product releases may currently exist up to 3 m (10 ft) of clean overburden.

In June 2004, a geophysical survey was performed at the 130-D-1 site to verify the absence of

the underground storage tank (UST) and delineate any residual anomalous subsurface features (CCN 115042). The survey was conducted using ground penetrating radar, electromagnetic induction, and magnetometry. No subsurface anomalous features with the characteristics of a UST were observed. Several subsurface anomalous features were observed during the survey, including linear anomalies and magnetic anomalies indicative of basalt-rich gravels commonly used for parking areas and roadways.

The project team conducted a site visit in February 2005. The objectives of the visit were as follows: (1) Evaluate the site in consideration of geophysical survey information and historic documentation to assist in the development of an effective environmental strategy, (2) Confirm the waste site boundary, (3) Locate and evaluate surface debris and anomalies that would require removal to allow for reclassification of the waste site, (4) Evaluate access and staging considerations for heavy excavation equipment. The suspected location of the former gasoline tank was identified during the site visit based on the presence of soil gas sampling debris and grid markings from the geophysical survey.

Related Sites/ Structures: The two storage tanks were related to the former 1716-D Garage.

Waste Type: Oil

Waste Description: The two storage tanks were related to the former 1716-D Garage. Contaminants of potential concern (COPCs) include TPH, SVOAs, VOCs, arsenic, barium, chromium, lead, selenium, silver, and polychlorinated biphenyls (PCBs). Radionuclides are not a COPC for this site. Based on a review of historical process information and the results of past characterization, the 130-D-1 site is expected to contain hazardous constituents at levels in exceedance of remedial action goals.

Closure Info: Remedial action at the 130-D-1 waste site began on July 21, 2010, and continued through July 26, 2010. Additional remediation was conducted on March 17, 2011, and April 15, 2011, due to residual contamination identified following verification sampling activities. The entire excavation resulted in approximately 780 bank cubic meters (BCM) (1,020 bank cubic yards [BCY]) of soil and debris being removed for disposal at the ERDF. The site was excavated to an approximate depth of 3.5 m (11.5 ft) deep.

Prior to being loaded out for disposal at ERDF, the contaminated soil and debris was staged in a staging pile area on asphalt located east of the 130-D-1 excavation. Following loadout of the waste material, the staging pile area was excavated, removing the asphalt and underlying soil to a depth of approximately 0.5 m (1.5 ft) below the surface.

Code: 132-D-1	Classification: Accepted
Names: 132-D-1; 115-D/DR Gas Recirculating Facility	Reclassification: Interim Closed Out (12/5/2011)
Type: Process Unit/Plant	Start Date: 1/1/1944
Status: Inactive	End Date: 1/1/1967

Description: The waste site has been remediated. It consisted of the demolished 115-D/DR Gas Recirculation Facility footprint, debris and pipe tunnels. This remedial action did not include the some portions of the 115-D/DR facility (the seal pit, inlet and outlet ductwork, and tunnels connecting to the 105-D and 105-DR Reactors) that will be included in remedial activities of the 100-D-86:1 and 100-D-50:4. The 115-D/DR Gas Recirculation Facility was a single-story, reinforced concrete structure, 6.1 meters (20 ft) high, with a basement. At ground level, an operating gallery ran the length of the building and was flanked on either side by cells that contained the gas processing equipment. The cells, including walls, ceilings and floors, were constructed of reinforced concrete slabs with composition surfaces. At right angles to the operating gallery and

building was divided into two large filter cells with a smaller operating area between them. The filter cells each held six filter frames (two wide and three deep). The filter frames were designed to hold twenty-eight filters that were 0.6 meters (2 feet) square by 0.3 meters (1 foot) thick. There were spaces between the frames to allow access for filter maintenance. The operating area between the two cells was divided into two levels. The upper level, called the access gallery had ten doors that led from it. Four doors opened into each of the filter cells and the two other doors provided access to the intake and exhaust ducts. The operating gallery was located below the access gallery. A sump was located at each end of the operating gallery to collect incidental drainage from above. A large open area extended the full length of the structure above the access gallery and the filter cells. It ranged in height between 2.5 and 2.4 meters (8.1 and 7.8 feet) due to the structure's sloping roof. The space provided access to the cement cover blocks that were positioned over each of the filter frames.

Related Sites/ Structures: The site was associated with the 105-D Reactor (118-D-6), the 116-D Stack (132-D-4), the 119-D Sample Building, and the 117-D Seal Pit Crib (116-D-9).

Waste Type: Demolition and Inert Waste

Waste Description: The site contained radiological contamination from 105-D Reactor ventilation exhaust. Total radionuclide inventory in the 117-D building was estimated to be 3.9E-03 curies. The radionuclides comprising this figure were tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and plutonium-239.

Closure Info: The Remaining Site Verification Package (RSVP-2005-024) documents the current site condition as achieving the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (ROD) (EPA 1999).

Soil cleanup levels were established in the interim action ROD based on a limited ecological risk assessment. A baseline risk assessment for the river corridor portion of The Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final ROD for this site.

Using the maximum radiological activities from the pre-demolition characterization data to represent residual contamination levels over 100% of the paint and concrete of the former building, RESidual RADioactivity (RESRAD) modeling was performed in 2005 to support the previous decision to demolish and bury the building in place. The RESRAD modeling accounts for radioactive decay from 1985 (year of sampling) to 2005, and predicts that the site achieves the dose limits and risk objectives for rural residential land use with institutional controls, groundwater protection, and river protection. Further excavation of the site to collect more information (i.e., samples) was not likely to result in a change to the interim closed out decision because the residual contamination occurred within a thin surface layer of paint on the interior surfaces of the building and would be unlikely to be detected in the deep zone rubble resulting from demolition of the building.

The RSVP demonstrates that the site meets objectives for Interim Closed Out Status as established in the RDR and the ROD. The site and contaminant levels remaining in the soil will be protective of direct exposure, groundwater, and the Columbia River. However, the acceptability of unrestricted direct exposure to below-grade structure surfaces in the deep zone has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required.

Code: 132-D-3

Classification: Accepted

Names: 132-D-3; 1608-D Effluent Pumping Station; 1608-D Waste Water Pumping Station **Reclassification:** Interim Closed Out (5/9/2006)

Type: Pump Station **Start Date:** 1/1/1944

Status: Inactive **End Date:** 1/1/1965

Description: The site consisted of the effluent pumping station facility which was decommissioned and demolished in 1986. The area was backfilled to grade and gravel added, it now resembles a gravel parking lot. As documented in the Remaining Sites Verification package RSVP-2005-033, the site meets the objectives for interim closure. Prior to decommissioning, the structure extended 1.2 meters (4 feet) above grade and 9.8 meters (32 feet) below grade. The walls and floor were constructed of reinforced concrete and the roof was constructed of a wood frame with composition surface. The facility consisted of an accumulation sump, which supplied three separate sumps.

Location: The unit was located adjacent to the south side of the 105-D Reactor (118-D-6) within the 105-D/DR Exclusion Fence.

Process Description: This unit received water from the 105-D reactor building drains containing trace amounts of low-level radionuclides and decontamination chemicals. Water was pumped from the reactor collection pits into the reactor effluent lines near the reactor building and became part of the 107-D effluent (116-D-7) that was discharged to the Columbia River.

Waste Type: Process Effluent

Waste Description: This unit received water from reactor building drains containing trace amounts of low-level radionuclides and decontamination chemicals. Radionuclides were primarily miscellaneous fission and activation products. The decontamination chemicals consisted of sodium fluoride, oxalic acid, and citric acid.

Waste Type: Demolition and Inert Waste

Waste Description:

Closure Info: The current site condition has been documented in the Remaining Sites Verification Package (RSVP) 2005-033 as achieving the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (EPA 1999) (ROD).

Demolition and site grading were performed in 1986 using conventional heavy equipment. The structure was demolished to at least 1 meter (3.3 feet) below grade and the rubble buried in situ under at least 1 meter (3.3 feet) of clean fill. The site was released for unrestricted use based on the post-decontamination characterization results and the Dose Assessment of In Situ Burial of the 1608-D Lift Station.

Soil cleanup levels were established in the interim action ROD based on a limited ecological risk assessment. A baseline risk assessment for the river corridor portion of Hanford began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final ROD for this site.

In accordance with the RSVP, the 1986 sampling results support a reclassification of the site to interim closed out. The RSVP also illustrates that the site and contaminant levels remaining in the soil will be protective of direct exposure, groundwater, and the Columbia River. However, the acceptability of unrestricted direct exposure to below-grade structure surfaces in the deep zone has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling

or excavation into the deep zone are required.

Code: 1607-D2 **Classification:** Accepted

Names: 1607-D2; 1607-D2 Sanitary Sewer System; 1607-D2 Septic Tank; 1607-D2 Septic Tank and Associated Drain Fields; 124-D-2 **Reclassification:** None

Type: Septic Tank **Start Date:** 1/1/1944

Status: Inactive **End Date:** 1/1/1996

Description: The 1607-D2 Septic System has been divided into five sub-sites: The 1607-D2:1 Abandoned Tile Field; 1607-D2:2 Replacement Tile Field, 1607-D2:3 Septic Pipelines, 1607-D2:4 Septic Tank, and 1607-D2:5 Inlet Pipe to Replacement System Tile Field. This site was broken into sub-sites to allow for close out of each part as remediation progressed in the area.

Location: The septic tank was located approximately 30 meters (100 feet) southeast of the 116-D-7 Retention Basin. The original tile field (abandoned in 1950) was near the east side of the 116-DR-9 Liquid Effluent Retention Basin facility and approximately 91.5 meters (300 feet) northeast of the 1607-D2 Septic Tank. The replacement tile field is located approximately 244 meters (800 feet) north of the septic tank, north of the perimeter road.

Related Sites/Structures: The site serviced the 189-D (Storage Yard and Mechanical Development Laboratory), the 185-D (Thermal Hydraulics Laboratory), the 182-D (Reservoir and Pump House), the 183-D (Water Filter Plant), the 1700-D Administration and Services, and the 105-D Reactor Building.

Waste Type: Sanitary Sewage

Waste Description: This unit received sanitary waste from office, maintenance services, and process water pumping buildings (190-DA, 189-D, 185-D, 182-D, 183-D, 170-D, and 105-D). The flow rate to this unit was estimated at 4,640 liters/day (1,225 gallons/day). There were several clay brick access manholes associated with this septic system located throughout the 100-D Area. Potential contaminants include Eu-152, U-235, U-238, Cs-137, C0-60, chromium, mercury and lead.

This Site has the Following SubSites:

Code: 1607-D2:1
Names: 1607-D2:1; Eastern 1607-D2 Tile Field; Original 1607-D2 Tile Field

Code: 1607-D2:2
Names: 1607-D2:2; Northern Tile Field; Replacement 1607-D2 Tile Field

Code: 1607-D2:3
Names: 1607-D2:3; 1607-D2 Septic Pipelines

Code: 1607-D2:4
Names: 1607-D2:4; 1607-D2 Septic Tank

Code: 1607-D2:5
Names: 1607-D2:5; 1607-D2 Inlet Pipe to Replacement System Tile Field

Code: 1607-D2:1 **Classification:** Accepted

Names: 1607-D2:1; Eastern 1607-D2 Tile Field; Original 1607-D2 Tile Field **Reclassification:** Interim Closed Out (3/25/1999)

Type: Septic Tank **Start Date:**

Status: Inactive **End Date:**

Description: The 1607-D2:1 Abandoned Tile Field is a sub-site associated with the 100-D Area sanitary

sewage system. The tile field consisted of a clay pipe drain field positioned approximately 1 to 2 meters (3.3 to 6.6 feet) below surrounding grade. A thick layer of aggregate and native sandy gravel soils were placed around the clay pipes. The 1607-D2:1 site was created in 1944, and sewage liquid from the 553-person-capacity 1607-D2 septic tank discharged to the tile field from 1944 to 1950. The septic tank was designed to capture the solids, and decant liquid effluent which was transported to the tile field. Solids and sludge were retained in the 91,500-liter (24,160-gallon) septic tank (the septic tank is subsite 1607-D2:4).

Closure Info: In 1950 the tile field was partially demolished for the construction of the 116-DR-9 Liquid Effluent Retention Basin, and a replacement tile field (subsite 1607-D2:2) was constructed north of the retention basins. The name "abandoned tile field" was assigned to the infrastructure remaining and adjacent to the 116-DR-9 retention basin. The approximate area of the abandoned tile field sub-site is approximately 1,203 square meters (12,949 square feet). The septic pipelines for this system are subsite 1607-D2:3.

Part of the original tile field was removed during the construction of the retention basin. In December 1997 and January 1998, the remaining tiles of the eastern tile field (subsite 1607-D2:1) were removed and disposed of in the Environmental Restoration Disposal Facility along with the sludge trenches (100-D-4 and 100-D-22).

Excavation of the 1607-D2:1 site began on January 8, 1998, by removing the overburden materials, contaminated soil, and the engineered structure (i.e., clay tiles and aggregate). This first excavation effort removed approximately the top 2 meters (6.6 feet) of soil. All overburden material was found to be contaminated based on field screening results and was disposed at the ERDF with other contaminated material. Contamination was encountered at the base of the first excavation (i.e., below the engineered structure elevation) based on field screening results. A second excavation effort was initiated on January 9, 1998, and was completed on February 4, 1998. The site was judged to be clean based on field screening results. Cleanup verification sampling was initiated at the final excavation elevation of 131.6 meters (431.8 feet).

Based on the sample results from investigation of the 1607-D2 septic tank contents and the immediately adjacent 107-D1 Sludge Pit, the waste site contaminants of concern (COCs) included the following: europium-152, uranium-235, uranium-238, hexavalent chromium, lead, mercury, bis (2-ethylhexyl) phthalate, and polychlorinated biphenyls (PCBs).

During excavation of the overburden materials, field screening was used to distinguish between potentially clean materials and contaminated materials for disposal at the ERDF. The field screening results indicated that all removed overburden material did not meet direct exposure RAGs. The overburden material was disposed of at the ERDF.

At the completion of the remedial action, the area of the excavation was approximately 1,203 square meters (12,949 square feet) at a depth of 3.4 meters (11 feet), and approximately 10,040 metric tons (11,064 tons) of material from the site were disposed at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 135 meters (443 feet). Clean backfill will be taken from Borrow Pit 21, which is located due south of the 1607-D2:1 site. The material in the borrow pit has been surveyed in accordance with the SAP and is appropriate for use as backfill.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

The SubSite is Part Of:**Code:** 1607-D2**Names:** 1607-D2; 1607-D2 Sanitary Sewer System; 1607-D2 Septic Tank; 1607-D2 Septic Tank and Associated Drain Fields; 124-D-2

Code: 1607-D2:2**Classification:** Accepted**Names:** 1607-D2:2; Northern Tile Field; Replacement
1607-D2 Tile Field**Reclassification:** Interim Closed Out (9/16/2010)**Type:** Septic Tank**Start Date:****Status:** Inactive**End Date:**

Description: This drain field replaced the original drain field in 1950 when the 116-DR-9 Retention Basin was built partially over the top of the original drain field. The replacement drain field serviced buildings in the 100-D Area until 1996 when a new underground septic system was installed to support facilities associated with the 100-D waste sites remediation. Buildings serviced by the replacement drain field included the 189-0 Storage Yard and Mechanical Development Laboratory, 185-D Thermal-Hydraulics Laboratory, 182-D Reservoir and Pump House, 183-D Water Filter Plant, 1700-D Administration and Services Building, and the 105-D Reactor Building.

Closure Info: The cleanup verification package (CVP-2009-00006) has documented that the 1607-D2:2 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the (ROD) (EPA, 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 6). The subsite was also included in the Explanation of Significant Differences for the Remaining Sites ROD (EPA 2009).

Remedial action at the subsite began on April 7, 2008, and concluded on April 23, 2008 with approximately 3,471 bank cubic meters of material removed and disposed to ERDF. The excavation was approximately 100 m (330 ft) long, 60 m (200 ft) wide, and ranges from 1.8 m (6 ft) to 3.1 m (10ft) deep.

During remediation, the inlet pipeline to the drain field was located in the sidewall of the excavation at Washington State Plane Coordinates N 151445, E 573808. A review of the excavation footprint for the 1607-D2:3 subsite (CVP-2000-00004) indicated that a portion of the pipeline north of the perimeter road had not been removed. It was also observed that the active 100-D Area Pump-and-Treat Project pipelines run directly over the ground surface in this location. Therefore, due to the proximity of the pump-and-treat pipelines, this remaining pipeline has been administratively identified as the 1607 -D2:5 subsite and will be remediated at a future date.

A geophysical survey conducted in February 2008 to locate electrical utilities in the vicinity of the 1607-D2:2 Replacement Drain Field, identified surface electrical lines from a nearby pump-and-treat operation. Piping and electrical lines from the pump-and treat operation precluded the excavation of a section of the inlet piping to the replacement drain field. This small section was administratively placed in to the 1607-D2:5 subsite to ensure the section of pipe will be remediated at a later date. Other than the surface electrical lines, the geophysical investigation did not find anything in the data to indicate other structures or hazards at the 1607-D2:2 subsite.

Final cleanup verification samples were initially collected between October 7, 2008 and December 16, 2008. A laboratory error resulted in rejection of most of the mercury data. To mitigate this, the project recollected samples on May 4, 2009 for mercury only. The initial mercury data set is not used for closeout calculations or decisions. Both the initial data set and the replacement mercury data set are presented within the data tables found attached to the 95%

UCL calculation in Appendix A of the CVP. The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as part of the 95% UCL calculation in Appendix A of the CVP.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River.

The SubSite is Part Of:

Code: 1607-D2

Names: 1607-D2; 1607-D2 Sanitary Sewer System; 1607-D2 Septic Tank; 1607-D2 Septic Tank and Associated Drain Fields; 124-D-2

Code: 1607-D2:3

Classification: Accepted

Names: 1607-D2:3; 1607-D2 Septic Pipelines

Reclassification: Interim Closed Out (9/26/2000)

Type: Septic Tank

Start Date:

Status: Inactive

End Date:

Description: This section of the sanitary sewer pipelines runs from Manhole S-250, through the 1607-D2 Septic Tank, and from there to the D Area North Perimeter Road. It has been removed.

Closure Info: Remedial action at the 1607-D2:3 pipeline site began on August 20, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and the underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. On August 30, 1999, the excavation reached the design limit at El. 131 meters (430 feet).

The final COCs for the 1607-D2 septic pipelines are: cesium-137, cobalt-60, europium-152, total chromium, hexavalent chromium, mercury, and lead.

At the completion of remedial action and removal of the engineered structure, the shallow zone excavation was approximately 1,780 square meters (19,200 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). The overburden area was approximately 1,850 square meters (19,900 square feet). Cleanup verification sampling was conducted on December 9, 1999. The excavation has been backfilled to the reference grade of El. 136 meters (445 feet). Backfill was taken from the clean stockpile and/or from other sources of clean material surveyed in accordance with the SAP and that are appropriate for use as backfill.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

The SubSite is Part Of:

Code: 1607-D2

Names: 1607-D2; 1607-D2 Sanitary Sewer System; 1607-D2 Septic Tank; 1607-D2 Septic Tank and Associated Drain Fields; 124-D-2

Code: 1607-D4 **Classification:** Accepted
Names: 1607-D4; 1607-D4 Sanitary Sewer System; 1607-D4 Septic Tank; 1607-D4 Septic Tank and Associated Drain Field; 124-D-4 **Reclassification:** Interim Closed Out (2/23/2006)
Type: Septic Tank **Start Date:** 1/1/1944
Status: Inactive **End Date:** 1/1/1968

Description: The site has been remediated and interim closed out. The site consisted of a small septic tank and drain field. The unit was a septic tank and tile field. The tank was 2.5 meters (8 feet 4 inches) deep, constructed of reinforced concrete, and had a 6-person capacity [130 liters (35 gallons) per capita] with an average detention period of 24 hours. The walls were 20 centimeters (8 inches) thick, and the floor was 15 centimeters (6 inches) thick. The tile field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a minimum of 2.4 meters (8 feet) per capita. The laterals were open jointed and spaced 2.4 meters (8 feet) apart.

Location: The system was located between the 105-D and the 105-DR Reactors.

Process Description: The system received sanitary sewage from the 115-D/DR Gas Recirculation Facility. Historic drawings indicate that the 1607-D4 Septic System consisted of a rectangular prismatic septic tank and tile field. The tank dimensions were 0.6 by 1.2 meters (2 by 4 feet) in plan view and 2.5 meters (8.3 feet) deep. The design waste capacity of the tank was 795 Liters (210 gallons), leaving up to 1.4 meters (4.5 feet) of freeboard/headspace. The tank was constructed of reinforced concrete with 0.2 meters (8-inches)-thick walls and a 0.15-meter (6-inch)-thick floor. Historic piping layouts show the influent to the tank as a 0.15-meter (6 inch) vitrified clay pipe (VCP) running from the southeast corner of the 115-D/DR Building.

Related Sites/ Structures: The site serviced the 115-D and 115-DR (Gas Recirculation Buildings).

Waste Type: Sanitary Sewage

Waste Description: This unit received an unknown amount of sanitary waste from the 115-D Gas Recirculation Building.

Closure Info: The Remaining Sites Verification Package for the 1607-D4 Septic System (Attachment to Waste Site Reclassification Form 2005-036) (RSVP) has demonstrated that the site has met the objectives for interim closed out status as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD) (EPA 1999).

The 115-D/DR facility was decommissioned in 1985 and 1986, including demolition of above-grade features. The septic system may have been filled in as part of the decommissioning of the facility, or at some other time after its operational lifetime ended in 1968.

A geophysical survey conducted in 1992 and field observations made during a site visit in February 2005 were used to confirm the location of the site. Existing historical information was used to identify the contaminants of potential concern (COPCs) for the system. The COPC list identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) included lead, pesticides, and semivolatile organic compounds. Based on further site-specific evaluations of septic systems, polychlorinated biphenyls were also included as COPCs in the work instructions. Confirmatory samples were collected on 7/5/05, sample numbers J03717 through J03719 and J03730, and analyzed for the COPCs.

Examination of the data has led to the conclusion that the site passes the RAGs without further remedial action. In accordance with this evaluation, the confirmatory sampling results support a reclassification of the site to interim closed out. The analytical results from soil and drain field samples were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. The results support future land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 1607-D5 **Classification:** Accepted

Names: 1607-D5; 1607-D5 Sanitary Sewer System; 1607-D5 Septic Tank; 1607-D5 Septic Tank and Associated Drain Field; 124-D-5 **Reclassification:** Interim Closed Out (10/10/2011)

Type: Septic Tank **Start Date:** 1/1/1944

Status: Inactive **End Date:**

Description: The site resembles a gravel covered parking area. There are no signs designating the septic and tile field areas.

Location: The unit was located east of the northeast corner of the 181-D Pumphouse.

Process Description: The unit consists of a septic and a tile field. The septic was a concrete tank measuring approximately 3 by 5 ft (0.9 by 1.5 m) in plan and 7 ft 10 in (2.4 m) deep, with a metal cover. The septic tank had a 6-person capacity (35 gal [130 L] per capita) with an average detention period of 24 hours. The walls were 8 in (20 cm) thick, and the floor is 6 in (15 cm) thick. The tile field is constructed of 6-in (15 cm) or 8-in (20 cm) vitrified pipe, concrete pipe, or drain tile with a minimum of 8 linear feet (2.4 m) per capita. The laterals were open jointed and spaced 8 ft (2.4 m) apart.

Related Sites/Structures: The site received effluent from the 181-D (River Pump House). The influent pipe is assigned to waste site 100-D-84:2

Waste Type: Sanitary Sewage

Waste Description: This unit received sanitary waste from the 181-D Pumphouse. The flow rate to this unit was estimated at 35 gallons per day (130 Liters per day).

Closure Info: Remedial action at the 1607-D5 waste site was performed between October 22 and 26, 2010. Excavation continued to a maximum depth of 3.3 m (11 ft) until all contaminated soil and debris associated with the waste site had been removed. The post-excavation civil survey is shown in Figure 3. Approximately 500 bank cubic meters (BCM) (654 bank cubic yards [BCY]) of contaminated soil and debris were removed from the excavation and directly loaded out for disposal at the Environmental Restoration Disposal Facility. The originally planned above cleanup level (ACL) stockpile proved to be in an inaccessible location. A second location was planned for the ACL, but it proved to be easier to direct load the material. Therefore, neither of the potential stockpile locations was used. No overburden material was retained for use as clean backfill.

Code: 116-DR-1&2 **Classification:** Accepted

Names: 116-DR-1&2; 116-DR-2; Emergency Crib Trench; 107-DR Liquid Waste Disposal Trench #1; 107-DR Liquid Waste Disposal Trench #2; **Reclassification:** Interim Closed Out (9/26/2000)

116-DR-1

Type: Trench **Start Date:** 1/1/1950**Status:** Inactive **End Date:** 1/1/1967**Description:** The site has been remediated and closed out. It is no longer marked or posted. The site was constructed of two trenches that were later joined together to form a single trench.**Location:** The site is located east of the northeast corner of 107-DR Retention Basin.**Process Description:** Normally, the site received effluent from the 107-D and 107-DR Retention Basins when cooling water was contaminated due to ruptured fuel elements. The trench was used also for a 4-month test period during which the total volume of waste effluent from the 107-D and 107-DR Retention Basins was discharged to the soil column.**Waste Type:** Water**Waste Description:** The site received effluent from the 107-D and 107-DR Retention Basins when cooling water was contaminated due to ruptured fuel elements. In addition to the 4.0E+07 liters (1.06E+07 gallons) of effluent from ruptured fuel elements listed in PNL-6456 (Stenner et al), the site also received 3.87E+08 liters (1.02E+08 gallons) of cooling effluent daily during the four month test.

Waste site COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL 1998a). The COCs identified for this site are: americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, and hexavalent chromium.

Closure Info: The site remediation was performed in accordance with an Interim Action Record of Decision (ROD) (EPA 1995). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the ROD (EPA 1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).

Remedial action at the 116-DR-1&2 Trench began on November 25, 1996. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at ERDF. On October 21, 1999, the excavation reached the design limit at elevation 131.1 meters (430.1 feet). At the completion of the remedial action, the total excavation was approximately 9,730 square meters (104,734 square feet) in area with a maximum depth of approximately 5.0 meters (16.4 feet). Approximately 82,768 metric tons (91,236 tons) of material from the site were disposed of at the ERDF.

The contaminants of concern identified for the site include americium-241, cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90 and hexavalent chromium.

Cleanup verification sampling began on November 30, 1999, and was finished on December 17, 1999. Results of the sampling, laboratory analyses, and data evaluations for the 116-DR-1&2 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

The results indicate that the maximum dose rate above background is 3.6 millirem/year and would occur at present; this dose decreases to 3.8×10^{-2} millirem/year in 1,000 years. The estimated total dose rate in the year 2018 is 2.1 millirem/year. Total dose rate estimates never exceed the direct exposure RAG of 15 millirem/year above background. The only nonradionuclide contaminant of concern is hexavalent chromium; its concentrations are below detection and thus it also meets the remedial action goals.

The CVP does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]); therefore, institutional controls to prevent uncontrolled drilling or excavation into deep zone soils are required.

Code:	116-DR-5	Classification:	Accepted
Names:	116-DR-5; 1904-DR; 1904-DR Outfall Structure	Reclassification:	Interim Closed Out (1/6/2011)
Type:	Outfall	Start Date:	1/1/1956
Status:	Inactive	End Date:	1/1/1967
Description:	The site consists of an open, reinforced, compartmentalized concrete outfall structure that routinely discharged effluent to the Columbia River via the river effluent pipelines (100-D-60). When the river pipelines were blocked, damaged or undergoing maintenance, the flow was diverted to a concrete overflow spillway (flume) (100-D-66).		
Location:	The site is located at the top of the river bank, north of the northwest corner of 116-D-7 (107-D Retention Basin).		
Process Description:	Reactor cooling water collected and temporarily stored in the 116-D-7 and 116-DR-9 retention basins, could be pumped to the river via the 116-DR-5 outfall structure and associated river effluent pipeline (100-D-60).		
Related Sites/Structures:	The site is associated with the D Island Contamination (100-D-67), 107-D Retention Basin (116-D-7), the 107-DR Retention Basin (116-DR-9), 100D Reactor Cooling Water Effluent Lines (100-D-48), the 100DR Reactor Cooling Water Effluent Lines (100-D-49), the 100D River Effluent Lines (100-D-60) and Flumes (100-D-66).		
Waste Type:	Construction Debris		
Waste Description:	This unit received reactor coolant from the 107-D and 107-DR Retention Basins.		
	The contaminants of concern include C-14, Cs-137, Sr-90, U-235, -238, and Pu-239/240.		

Code:	116-DR-9	Classification:	Accepted
Names:	116-DR-9; 107-DR; 107-DR Retention Basin	Reclassification:	Interim Closed Out (1/6/2000)
Type:	Retention Basin	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1967
Description:	This site has been remediated and closed out.		
Location:	This site is located north of the 105-D Reactor Building.		
Related Sites/Structures:	Four sludge trenches were excavated in the 107-D and 107-DR Retention Basin area to dispose of sludge that had accumulated at the bottom of the basins. The trenches were excavated in the Spring of 1953 to facilitate repair of the basins by minor construction forces and were covered after use with about 1.8 meters (6 feet) of clean soil. In 1955 an additional trench was excavated near the southeast side of the 107-DR Retention Basin to receive effluent from the 107-D and 107-DR systems following an undetermined amount of fuel cladding failures.		

Waste Type: Process Effluent

Waste Description: This site received cooling water effluent from the 105-DR Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Total radionuclide inventories in the vicinity of the basin ranged from 5 curies to over 400 curies. Seventy percent of the total radionuclide inventory is contained within the soil adjacent to the unit. Approximately 10 curies have leached into the concrete floor and walls. The basin was known to have leaked on several occasions.

Closure Info: 116-DR-9 and 100-D-25 were addressed as a group. The information below documents information for the group of sites.

The Cleanup Verification Package, CVP-1999-00006, documents that the 116-DR-9 and 100-D-25 waste sites have met the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 0), and the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995). A rural residential exposure scenario was assumed in calculating cleanup levels.

The retention basin received cooling water effluent from the 105-DR Reactor from 1950 until 1965. After the 105-D Reactor was deactivated in 1965, the basin remained active until 1967 as part of the 105-D Reactor effluent system. Leakage occurred as unplanned releases in 1951 beneath the basin and outside the south end of the basin when seals in the concrete floor of the basin failed and the pipes pulled away from the basin walls at the retention basin inlet. Waste site 100-D-25, an unplanned release that occurred as floor leaks beneath the basin, could not be distinguished from other contaminated soil. It was remediated with the 116-DR-9 Retention Basin under the provisions for "proximity sites."

Excavation began on October 21, 1997, by removing the overburden materials and underlying contaminated soil. Overburden materials, which were contaminated, were disposed at the ERDF. On December 28, 1998, the excavation had reached the design limits below the base of the engineered structure (El. 130.25 m [427.35 ft]) and cleanup verification sampling was initiated. At the completion of the remedial action, the excavation area floor was approximately 16,352 m² (176,013 ft²) at a depth of 4.75 m (15.6 ft), and approximately 201,519 metric tons (222,122 tons) of material from the site were disposed of at the ERDF. The excavation will be backfilled in the near future with clean fill materials to the reference grade of El. 135.0 m (443 ft).

Contaminated soil associated with the process effluent pipelines was not removed completely, but remained for final remediation with the pipelines. The 100-DR process effluent pipelines are scheduled to be removed during the next year. The 116-DR-9 sidewall areas that are adjacent to future pipeline excavation areas were not sampled as part of the cleanup verification effort. These areas will be sampled and verified clean as part of the effluent pipeline remediation efforts.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, WIDS had shown that no IC restrictions were required but the sites were remediated with deep zone criteria so that Ics actually were required. The Ics for this site have been revised accordingly.

Code: 628-3	Classification: Accepted
Names: 628-3; 628-3 Burn Pit	Reclassification: Interim Closed Out (5/11/2011)
Type: Burn Pit	Start Date:

Status: Inactive

End Date:

Description: The site as roughly oval shaped area with a length of 76 m (250 ft), a width of 12 m (40 ft), and a depth of 1.2 m (4 ft). The center of the burn pit was distinguished by a 1.2-in (4-ft) depression. The waste site showed signs of severe plant stress and soil discoloration, and there was debris consisting of burnt wood, nails, metal pipes, rebar, and glass scattered across the area. The depression shows signs of severe plant stress and soil discoloration. The depression, as well as the area around it, is littered with debris. It appears that at one time cat tractors bulldozed some of the surrounding soil.

Location: The unit is located approximately 300 meters (1,000 feet) east of 128-D-2 and approximately 92 meters (300 feet) east of the D Area Perimeter Road.

Waste Type: Misc. Trash and Debris

Waste Description: Debris, consisting mostly of burnt wood, nails, metal pipes, rebar, and glass, is scattered over the area. In some spots, the site also contains what looks like friable and nonfriable asbestos. The site could not definitely be found in 1992 surveys of the area.

Closure Info: Remedial activities were carried out from March to June 2009. The excavation depth reached a maximum depth of 4.6 m (15 ft) near the center of the pit. All contaminated material consisting of: soil, concrete/debris, suspected asbestos-contaminated material, and metal pipe and concrete debris was disposed of at the Environmental Restoration Disposal Facility (ERDF).

After further review of the post-excavation civil survey and comparison to the geophysical survey the northern excavation boundary was extended. This excavation was completed in January 2010. The additional area of investigation was excavated to 1m (3ft). No debris or indication of previous subsurface disturbance was encountered; therefore, the sample design was not changed to reflect this extended boundary. The geophysical anomalies present in the survey were believed to have been interference from surface debris and/or the basalt layer in this area.

Code: UPR-100-D-1

Classification: Accepted

Names: UPR-100-D-1; Oil Soaked Soil

Reclassification: No Action (4/13/2005)

Type: Unplanned Release

Start Date:

Status: Inactive

End Date:

Description: The site was an unplanned release that appeared as a small depression surrounded by oil contaminated soil. During the March 1999 visit, a buried pipe was observed to the south of the stained soil.

Location: The site was located approximately 18.3 meters (60 feet) east of the 190-D Building Trampoline Test Facility and 4.6 meters (15 feet) south of the paved road leading to the Trampoline Test Facility.

Release Description: The site contains oil-soaked soil, the source of which could not be determined.

Waste Type: Oil

Waste Description: The source of the oil could not be determined. However, the volume appeared to be small.

Code: UPR-100-D-2

Classification: Accepted

Names: UPR-100-D-2; Effluent Line Leak #1

Reclassification: Interim Closed Out (9/26/2000)

Type: Unplanned Release

Start Date: 1/1/1951

Status: Inactive**End Date:****Description:** This release was remediated with the source pipelines (100-D-48 and 100-D-49) and closed out on September 26, 2000.**Location:** The site is located southeast of the 107-D Basin and west of the 107-DR Basin.**Release Description:** In 1951, extensive leakage of effluent water was detected above ground southeast of the 107-D Basin. A maximum dose rate of 50 millirads/hour was observed at the surface. Two excavations were made to investigate the leakage, but the effluent continued to seep to the surface. In 1951, the area was marked with a rope fence and marked as a "Radiation Area" (see Drawing H-1-4046).**Waste Type:** Water**Waste Description:** The site received radioactively contaminated water from the 107-D/DR Retention Basins.**Closure Info:** 100-D-48:2, 100-D-49:2, UPR-100-D-2 and UPR-100-D-3 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-48:2/49:2 Pipelines site began in July 1997. Excavation of the site involved removing the overburden materials, contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. In August 1999, the excavation reached the design limit. The excavation design depth generally corresponded with the invert elevation of the pipelines. The pipeline excavation profiles are in the sample design calculation briefs in Appendix D.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 20,475 square meters (220,280 square feet) in area with a maximum depth of approximately 6 meters (20 feet) below ground surface. During the time of excavation and waste disposal (December 1998 through September 1999) at the 100-D-48:2/49:2 Pipelines site, approximately 57,106 metric tons (62,960 tons) of material from 100-DR-1 Operable Unit pipelines were disposed of at the ERDF. Cleanup verification sampling began on August 23, 1999, and was finished on October 20, 1999. Because of the length of the pipeline site, the top-of-excavation elevation ranges from 138 meters (453 feet) near the retention basins to 143 meters (469 feet) near D Avenue.

The CVP demonstrated that remedial action at the 100-D-48:2/49:2 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved interim action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17). Materials from the 100-D-48:2/49:2 Pipelines site that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF. The remaining soils, including pipeline overburden stockpiles, have been sampled, analyzed, and modeled to show that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site and in overburden soils pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:2/49:2 Pipelines site is verified to be remediated in accordance with the ROD and may be backfilled. The pipeline overburden is verified as suitable for use as backfill in accordance with the ROD.

Code: UPR-100-D-3**Classification:** Accepted

Names: UPR-100-D-3; Effluent Line Leak #3 **Reclassification:** Interim Closed Out (9/26/2000)
Type: Unplanned Release **Start Date:** 1/1/1951
Status: Inactive **End Date:**
Description: This site was remediated with the source pipelines and closed out on September 26, 2000,
Location: The site is along the south perimeter of the 107-DR Basin.
Release Description: In 1951, extensive leakage of effluent water was caused by pipes pulling loose from the basin wall.
Waste Type: Water
Waste Description: The site was soaked with radioactively contaminated reactor cooling water from the 107-DR Basin.
Closure Info: 100-D-48:2, 100-D-49:2, UPR-100-D-2 and UPR-100-D-3 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-D-48:2/49:2 Pipelines site began in July 1997. Excavation of the site involved removing the overburden materials, contaminated structure, and underlying contaminated soil. The remaining soils, including pipeline overburden stockpiles, have been sampled, analyzed, and modeled to show that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site and in overburden soils pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-D-48:2/49:2 Pipelines site is verified to be remediated in accordance with the ROD and may be backfilled. The pipeline overburden is verified as suitable for use as backfill in accordance with the ROD.

Code: UPR-100-D-4 **Classification:** Accepted
Names: UPR-100-D-4; Unplanned Release: 107-D Basin **Reclassification:** Interim Closed Out (3/26/2001)

zone institutional controls are required.

100-DR-2

Code: 100-D-12 **Classification:** Accepted
Names: 100-D-12; Sodium Dichromate/Acid Railcar and Truck Unload Station and Associated French Drain; Undocumented Liquid Waste Site **Reclassification:** Interim Closed Out (10/23/2000)
Type: Pump Station **Start Date:**
Status: Inactive **End Date:**

Description: The site has been remediated and was interim closed out on October 23, 2000. It is no longer marked or posted. An underground line allowed solutions to be pumped to storage tanks. Before remediation, the site appeared as a small concrete pad with an adjacent 0.9 meters (3 feet) diameter concrete pipe french drain that supported the flushing and draining of lines that were connected to railroad tank cars.

Location: The 100-D-12 site is located in the 100-D Area and is approximately 710 meters (2,329 feet) from the Columbia River. It is located just south of the 183-D and 184-D Buildings next to the railroad tracks.

Release Description: Spills and hose drainage were routinely discharged to the french drain.

Process Description: Undiluted sodium dichromate and acid solutions were pumped through underground lines to storage tanks located outside the 185-D and 190-DR facilities. Prior to remediation, the site appeared as a small concrete pad enclosed by a curb. The containment area drained to an adjacent concrete pipe french drain that supported the flushing and draining of lines that were connected to railroad tank cars. The majority of the spills and hose drainage were routinely discharged to the french drain. Undiluted volumes of sodium dichromate and acid solutions were spilled directly to the soil column at this location.

Waste Type: Chemical Release
Waste Description: Wastes consisted of sodium dichromate and sulfuric acid.

Closure Info: The cleanup verification package (CVP-2000-00016) has documented that the 100-D-12 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Remaining Sites Record of Decision Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1; 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

The only Contaminant of Concern (COC) at the site was hexavalent chromium, a non-radionuclide. Remedial action at the site began on November 8, 1999 and was completed on April 19, 2000; when the excavation reached the design limit at El. 140.1 meters (460 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 202.5 square meters (2,180 square feet) in area with a maximum depth of approximately 2.4 meters (7.9 feet). Approximately 34.5 metric tons (38 tons) of contaminated material were disposed at ERDF. Cleanup verification sampling was performed on May 1, 2000.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that

IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	100-D-13	Classification:	Accepted
Names:	100-D-13; 100DR Area Sewage Disposal Unit; 124-DR-3; 1607-DR3; Septic Tank D-13; Unnumbered Septic System A	Reclassification:	None
Type:	Septic Tank	Start Date:	1/1/1947
Status:	Inactive	End Date:	1/1/1949
Description:	<p>The site is a septic system installed for use during the construction of the 105-DR Reactor. The system consisted of an IMHOFF tank, a chlorination house, a dosing tank, a filter bed, and associated piping. Most of the system remains in place, except for the chlorination house which has been removed. The septic tank is surrounded by a steel pipe fence. The filter bed is distinguishable as a rock-filled depression with distribution piping visible on the surface. The IMHOFF tank is a reinforced concrete structure with overall dimensions of 7.9 meters (25.9 feet) long, 3.8 meters (12.3 feet) wide, and 7.3 meters (24 feet) deep. The tank is divided lengthwise into three equally sized chambers. A single 15-centimeter (6-inch) pipe passes through the bottom of the partitions that separate the chambers. An influent flume connected to the first chamber controls and distributes flow from the incoming 30-centimeter (12-inch) line. An effluent flume connected to the third chamber controls flow into the 20-centimeter (8-inch) discharge line. A small line from a nearby chlorination house entered at the effluent flume and chlorinated the waste prior to discharge from the tank. The dosing tank is connected to the IMHOFF tank by the 20-centimeter (8-inch) discharge line. The dosing tank is constructed of reinforced concrete. It has surface dimensions of 3.1 meters (10.25 feet) long by 1.7 meters (5.67 feet) wide. It controlled the flow of waste into the adjacent filter bed. The filter bed is a 3.0-meter (10-foot) deep excavation measuring 21.3 meters (70 feet) by 21.3 meters (70 feet) at the surface and 12.2 meters (40 feet) by 12.2 meters (40 feet) at the base. The excavation was filled with 2.5 to 5-centimeter (1 to 2-inch) gravel. A main discharge line with six laterals (three on each side) lies on top of the gravel fill. Sprinkler heads that were tapped into the laterals distributed the treated sewage across the surface of the filter bed.</p>		
Location:	<p>The septic tank is approximately 240 meters (800 feet) east-southeast of the of 105-DR, south of the power line road. The filter bed is approximately 120 meters (400 feet) east of the tank on the north side of the road. The pipeline that flows to the tank has been mapped from the 117-DR Building, and surrounds the 105-DR Building, but no connection to the reactor has been found on drawings.</p>		
Waste Type:	Sanitary Sewage		
Waste Description:	<p>The tank received sanitary waste from temporary construction facilities at 105-DR. The 100-D Area Technical Baseline Report indicates that the tank also received overflow from the high tanks (water towers) at 105-DR, but no drawings could be found to verify this. The tank may have also received waste from the 105-DR Reactor (see Site Comment), so radioactive contamination may be present.</p>		

Code:	100-D-14	Classification:	Accepted
Names:	100-D-14; Unnumbered Septic System (b); Unnumbered Septic Tank #2	Reclassification:	None
Type:	Septic Tank	Start Date:	
Status:	Inactive	End Date:	

Description: The site appears as a vegetation-covered field. A small depression may indicate the presence of the tank. A 10-centimeter (4-inch) cement pipe is likely to be a vent pipe to the drain field. The site is adjacent to a small soil pile.

Location: The tank is located south of the 105-DR Building, outside the 100D perimeter fence and north of Route 2 North.

Waste Type: Sanitary Sewage

Waste Description: The unit received sanitary wastes.

Code: 100-D-15

Classification: Accepted

Names: 100-D-15; Debris North of 100-D Area Perimeter Road and Debris South of 100-D Perimeter Road Within 100-D-55; Gravel Pit #2; Pit 21

Reclassification: Interim Closed Out (9/16/2010)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: The site consists of two separate areas containing debris. The northern pit has been mostly backfilled with construction-type debris. The southern pit (inside Gravel Pit 21) has been partially backfilled and contoured.

Location: There are two solid waste disposal pits containing debris located south of 100-D Area near the perimeter road. One disposal area is located north of the perimeter road and west of the railroad track. The other disposal area is south of the perimeter road, inside Gravel Pit #21 (site code 100-D-55).

Process Description: The 100-Area Technical Baseline Report states that this location contains construction debris consisting of concrete rubble, metallic materials, asphalt material, and broken floor tiles (potentially asbestos-containing). The site was also reportedly used to dispose of empty cans formerly containing oil and cleaning solvents from Army sites located northeast of the 100-D Area.

Related Sites/ Structures: The site is associated with Gravel Pit #21 (100-D-55).

Waste Type: Construction Debris

Waste Description: The southern pit contains construction debris including concrete, metal, asphalt, and other debris. Asbestos may be present. The exact contents of the debris are unknown. In August 1994, Kaiser Engineers Hanford (KEH) removed sediments from the 182-D River Water Basins and deposited the material in the east end of the pit over part of the existing waste site. This disposal option was chosen rather than the demolition landfill option because the sediment did not meet the demolition landfill acceptance criteria. In a September 1997 memo, it was determined that the material classified as "clean soils or clean dredge soils" as defined in Washington Administrative Code (WAC) 173-304 definition that "Clean soils or clean dredge soils" means soils which are not dangerous waste or problem wastes. This classification excludes material from regulation and requires no specific management or disposal requirements. Therefore, there is no requirement to dispose of the material in any type of permitted landfill.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: The northern pit is assumed to be the older of the two pits. The pit has been reported to have been used as a disposal site for empty cans collected from army sites located northeast of the 100-D Area. Army wastes could include oil cans, solvent cans, and other miscellaneous solid wastes. Asbestos may be present. The exact contents of the debris is unknown.

Closure Info: The remaining sites verification package (RSVP-2009-066) has documented that the 100-D-15 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the (ROD) (EPA, 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 6).

The northern area of the site contained debris consisting of concrete rubble, metallic and asphalt debris, and other inert materials. Potential asbestos-containing materials were also found to be present. The southern area of the 100-D-15 waste site was used as a disposal location for sediment that was removed during the cleanout of the 182-D Basin. The sediment was observed to contain clamshells and clumps of asphalt-type sealant used in the 182-D Basin.

Remedial action at the site was performed between October 6 and December 1, 2008. The northern location was excavated between 2 m (6.6 ft) and 4 m (13ft) below grade, and the southern location was excavated 3.5 m (11.5 ft) below grade. Approximately 9,198 bank cubic meters (BCM) (10,059 bank cubic yards [BCY]) of soil and debris were removed from the north area, and 4,003 BCM (4,378 BCY) was removed from the south area. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility.

The contaminants of potential concern (COPCs) identified in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL-96-22) include barium, cadmium, chromium (total), lead, mercury, selenium, silver, polychlorinated biphenyls (PCBs), hexavalent chromium, semivolatile organic compounds, pesticides, total petroleum hydrocarbons, volatile organic compounds (VOCs), and asbestos.

The laboratory-reported verification sampling results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS). They were also presented as part of the 95% UCL calculation in Appendix B of the RSVP, Appendix C for the asbestos results. All asbestos results were non-detected with the exception of two results that were reported as "Trace", which is less than 1 % asbestos.

Following site remediation, verification sampling was conducted in September 2009. The results indicated that RAOs and RAGs for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Code:	100-D-23	Classification:	Accepted
Names:	100-D-23; 119-DR Sample Building Drywell	Reclassification:	Interim Closed Out (3/4/2004)
Type:	French Drain	Start Date:	1/1/1959
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed out. The site was a drywell that received drainage from a floor drain in the 119-DR Sample Building.		
Location:	The drywell was located south of the 119-DR Sample Building, between the intake and exhaust ducts for the 117-DR Filter Building.		
Process Description:	The 119-DR Sample Building was situated over the intake and exhaust ducts to the 117-DR Filter Building and was used to sample effluent gases and particulates. The 119-DR Sample Building Drywell was connected to the facility by a 5-centimeter (2-inch) drainage pipe buried at least 0.9 meters (3 feet) below grade. A 1.9-centimeter (3/4-inch) drain line from the building's evaporative cooler connected into the 5-centimeter (2-inch) drain line near the southern edge of the building.		

Related Sites/ Structures: The drywell was associated with the 119-DR Sample Building.

Waste Type: Process Effluent

Waste Description: The drain received effluent from the building's evaporative cooler. It is likely that the drain also received sample waste and janitorial waste since the building had no other drains or connections to the process sewer system.

Closure Info: 122-DR-1:2, 100-D-53, 122-DR-1:4, 132-DR-2, 122-DR-1:5, 100-D-64, 100-D-23 and 100-D-54 were addressed as a group. The information below documents information for the group of sites.

Remedial or removal objectives and goals for the components of the LSFF TSD unit pre-filter exhaust tunnel [122-DR-1:2], the 117-DR Exhaust Filter Building [100-D-53/122-DR-1:4], 116DR reactor exhaust stack(132 DR 2/122-DR-1:5), were obtained from the Action Memorandum, USDOE Hanford 100 Area National Priorities List (NPL) 105-F and 105 DR Reactor Buildings and Ancillary Facilities (Action Memorandum). The objectives and goals were also included in the Phase III SAP (DOE/RL-99-35) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17), which was referenced in the Action Memorandum.

Based on consideration of the requirements of CERCLA and detailed analysis of alternatives, the Tri-Parties have selected the remove/dispose alternative under a rural-residential land use scenario for the 117-DR facilities site.

The objective for the structures included the removal of the structure to a minimum of 0.9 meters (3 feet) below surface grade. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide contaminants of concern (COCs) and contaminants of potential concern.

Waste site COCs for the 117 DR facilities site were identified through process knowledge and are specified in the Phase III SAP (DOE/RL-99-35). The COC list was further refined and amended with the 117 DR Exhaust Filter Building Proposed Additional Soil Sampling and 1720-HA Arsenal Removal/ Disposal Summary (CNN 106839). The COCs consist of the following: americium-241, arsenic, carbon-14, barium, cesium-137, cadmium, cobalt-60, total chromium, europium-152, hexavalent chromium, europium-154, lead, europium-155, lithium, ninel-63, mercury, plutonium-238, selenium, plutonium-239/240, silver, strontium-90, sodium, uranium-234, uranium-235 and uranium-238.

At the completion of the remedial action, the total excavation was approximately 1,010 meters squared (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). Approximately 14,011 metric tons (15,412 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

The 117-DR facilities site is verified to be remediated in accordance with the RAOs and RAGs of the Action Memorandum and the Remaining Sites ROD and may be backfilled.

In addition, demonstration that remedial action at the 117-DR facilities site has achieved the RAOs and corresponding RAGs established in the Action Memorandum and the Remaining Sites ROD meets the RCRA closure requirements for the underlying soils. Final RCRA TSD certification of closure is pending.

Code: 100-D-27 **Classification:** Accepted

Names: 100-D-27; 151-D Substation UPR; A-2 Substation Transformer #A401C Leak **Reclassification:** Closed Out (8/4/2005)

Type: Unplanned Release **Start Date:**

Status: Inactive **End Date:**

Description: The site has been reclassified to Closed Out. The site consisted of an unplanned release within the 151-D Substation.

Location: The release occurred at the #A401C transformer, located in the 151-D Substation. The substation is west of the 105-DR Reactor and southwest of the 105-D Reactor.

Release Description: During a routine inspection of the 151-D substation, a non-PCB oil leak was discovered. Occurrence report RL--WHC-KHELEC-1995-0013 was issued.

Waste Type: Oil

Waste Description: The release was less than 100 gallons (380 L) of non-PCB mineral oil. According to a transformer inventory, oil in the #A401C transformer contains 42.0 parts per million PCBs.

Closure Info: The transformer was power washed, the contaminated material was shoveled into seven 208 liter (55 gallon) drums, and the site was backfilled. The drums were taken to a staging area.

The spill was less than 100 gallons of 42 ppm PCB oil. Therefore, no more than 0.016 kilogram PCB would have been released, significantly less than the CERCLA RQ of 0.45 kilogram (1 pound). The remedial action objectives and remedial action goals in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (EPA 1999) are therefore not applicable to the 100-D-27 waste site. The site will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario and no institutional controls are required.

Code: 100-D-28 **Classification:** Accepted

Names: 100-D-28; 190-DR Building Septic System **Reclassification:** None

Type: Septic Tank **Start Date:**

Status: Inactive **End Date:**

Description: The site consists of two septic systems, the original septic and the replacement. See the subsites for more detail.

Location: The unit is located southwest of the 190-DR Building.

Process Description: The system processed and disposed of septage from the 190-DR Main Pump House. The 190 DR Building housed the pumps and related equipment used to supply the 105-DR Reactor with cooling water from the 183 DR Clearwells. Until August 2004, part of this building was also used for the storage of radiological material. A confirmatory radiological survey of the area following removal of the material located no contamination (RSR-105DR-04-0077).

Related Sites/ Structures: 190-DR Building and Annex,

Waste Type: Sanitary Sewage

Waste Description: The system received sanitary wastes.

This Site has the Following SubSites:

Code: 100-D-28:1
Names: 100-D-28:1; Replacement Septic System
Code: 100-D-28:2
Names: 100-D-28:2; Original Septic System

Code: 100-D-28:1	Classification: Accepted
Names: 100-D-28:1; Replacement Septic System	Reclassification: Interim Closed Out (10/11/2011)
Type: Septic Tank	Start Date:
Status: Inactive	End Date:

Description: The 100-D-28:1 site consists of a septic tank and drain field located approximately 25-meters (82-feet) southwest of the 190-DR Building. The septic system includes a 2,730 liters (720-gallons) steel tank and a vitrified clay pipe drain field due west of the septic tank used in association with the 190-DR Building.

The 190-DR Annex constructed in 1955 added approximately 21.3 m (70 ft) to the east side of the 190-DR Building. The 190-DR Annex is approximately 3 m (10 ft) below grade. Photographs from 1955 (see attachment) show the depth and amount of disturbance for the excavation of the annex. It does not appear that this septic tank and tile field could have survived the construction of the 190-DR Annex. Likely a new septic system (100-D-28:1) was installed per drawing H-9923 southwest of the 190-DR as a replacement system.

Location: The system is located approximately 25 m (82 ft) southwest of the former 190-DR Building. The drain field is centered at E573491.6, N151105.6 and the septic tank at E573498.7, N151104.8.

Process Description: The system processed and disposed of sewage from the 190-DR Main Process Water Pumphouse.

Waste Type: Not Specified

Waste Description: The waste would be septage from the 190-DR Main Pump House.

Closure Info: Remedial action at the 100-D-28:1 subsite was performed between July 27 and August 17, 2010. Additional remediation was conducted on March 17, 2011 due to residual contamination identified following verification sampling activities. The excavation continued to a maximum depth of 5 m (16 ft) until all contaminated soil and debris associated with the waste site had been removed. Approximately 2,760 bank cubic meters (BCM) (3,610 bank cubic yards [BCY]) of contaminated soil and debris were removed from the excavation and staged in a staging pile area (SPA) to the north of the excavation before being loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 1,275 BCM (1,668 BCY) of overburden material was stockpiled for use as clean backfill. However, verification sampling found unacceptable contaminant concentrations and after additional remediation and resampling, contamination was still present above direct exposure remedial action goal (RAGs); therefore, the entire overburden soil stockpile was loaded out for disposal at the ERDF between April 20 and 21, 2011.

Three miscellaneous pipeline sections were encountered during remediation of the 100-D-28:1 subsite. Two of the sections located are part of the 100-D-50:6 pipeline subsite and one section is part of the 100-D-63 pipeline. The 100-D-50:6 and 100-D-63 pipelines will be addressed separately from the 100-D-28:1 subsite.

The debris removed from the 100-D-28:1 subsite consisted of contaminated soil, concrete, and piping associated with the septic tank and drain field. No anomalous material was encountered during excavation.

The SubSite is Part Of:

Code: 100-D-28

Names: 100-D-28; 190-DR Building Septic System

Code: 100-D-28:2

Classification: Accepted

Names: 100-D-28:2; Original Septic System

Reclassification: Rejected (8/1/2005)

Type: Septic Tank

Start Date:

Status: Inactive

End Date:

Description: The 100-D-28:2 site consisted of a septic tank and drain field located approximately 15.2-meters (50-feet) from the northeast side of the original 190-DR Pump House. The tank capacity was 2,839-liters (750-gallons). The 190-DR Annex constructed in 1955 added approximately 21.3-meters (70-feet) to the east side of the 190-DR Building. It does not appear that the 100-D-28:2 septic tank and tile field could have survived the construction of the 190-DR Annex. The 100-D-28:1 septic system was installed per drawing H-9933-DR on the southwest side of the 190-DR Building as a replacement system.

The 190-DR Annex constructed in 1955 added approximately 21.3 meters (70 feet) to the east side of the 190-DR Building. The 190-DR Annex is approximately 3 meters (10 feet) below grade. Photographs from 1955 (see attachment) show the depth and amount of disturbance for the excavation of the annex. It does not appear that this septic tank and tile field could have survived the construction of the 190-DR Annex. Likely a new septic system (100-D-28:1) was installed per drawing H-9923, southwest of the 190-DR as a replacement system.

Based on the historical documentation, the 100-D-28:2 septic system has not existed or been used in over 50 years. A reclassification status of rejected has been assigned for the 100-D-28:2 septic system. The site achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington. The site will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario and no institutional controls are required.

Location: This subsite is located approximately 15.2 m (50 ft) from the northeast side of the original 190-DR Pump House.

Waste Type: Not Specified

Waste: No cleanup was performed at this site.

Description:

The SubSite is Part Of:

Code: 100-D-28

Names: 100-D-28; 190-DR Building Septic System

Code: 100-D-43 **Classification:** Accepted

Names: 100-D-43; 118-D-4C; Burial Ground 4C; Buried VSR Thimble Site **Reclassification:** Interim Closed Out (5/13/2010)

Type: Burial Ground **Start Date:**

Status: Inactive **End Date:**

Description: The site is a solid waste burial ground. The burial ground is in very close proximity to the (exhumed) 152-centimeter (60-inch) effluent lines.

Location: The site is located east of the 105-D Reactor Building, outside the reactor security fence and south of the railroad spur that services 105-D.

Waste Type: Equipment

Waste Description: The waste is a buried Vertical Safety Rod (VSR) thimble. The VSR thimbles were made of aluminum similar to the that used in the process tubes and should contain similar isotopic composition. Sampling of process tubes was conducted in March 1967. The radionuclide levels, when decay corrected by Dorian and Richards to March 1977, were 5.9E+03 picocuries of manganese-54 per gram of aluminum and 2.5E+07 picocuries of cobalt-60 per gram of aluminum. When buried, the thimble's exterior surfaces would also have been contaminated with activated graphite products and potassium borate.

Closure Info: 100-D-42, 100-D-43 and 100-D-45 were addressed as a group. The information below documents information for the group of sites.

The Cleanup Verification Package (CVP-2009-00004) demonstrates that the 100-D-42, 100-D-43, and 100-D-45 waste sites have met the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17, Rev. 6) and the Records of Decision (EPA 1999 and 2000). The 100-D-42 Buried VSR Thimble Site was included in the Explanation of Significant Differences for the 100 Area Remaining Sites Interim Remedial Action Record of Decision (EPA, 2004). The 100-D-43 and 100-D-45 Buried VSR Thimble Sites were included in the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, 100-KR-2, Operable Units (EPA 2000).

Due to the close proximity to each other and the type of debris encountered during excavation, the three sites were included in one CVP and interim closed out as one decision unit.

Remedial action at the sites began on September 6, 2007, and was completed on April 22, 2008. Contaminated soil and debris were excavated and removed from the burial grounds for shipment to ERDF. Field observations during excavation indicated the presence of VSR thimbles in two of the three burial grounds. Only concrete debris and plastic sheeting were found to be present in the 100-D-42 Burial Ground. The 100-D-43 Burial Ground contained VSR thimbles and other reactor hardware. Mastic, aluminum pipe, VSR thimbles, reactor hardware, and a drum containing rags were found in the 100-D-45 Burial Ground.

One anomaly was encountered in the 100-D-43 Burial Ground. A 57-L (15-gal) metal container partially filled with liquid was found during excavation. The container was found to have been breached and the contained liquid is suspected to have been water used for dust suppression during excavation activities. No suspect spent nuclear fuel was present in the burial grounds.

The remaining soils at the 100-D-42, 100-D-43, and 100-D-45 waste sites have been sampled, analyzed, and modeled. The results of this effort indicate that the materials containing COCs/COPCs at concentrations exceeding RAGs have been excavated and disposed at ERDF. These results also indicate that residual concentrations will support future land uses that can be

represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The excavation area has a maximum depth of approximately 7 m (23 ft). However, the entire excavation area is considered one decision unit and meets the more restrictive shallow zone cleanup criteria. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code: 100-D-46 **Classification:** Accepted
Names: 100-D-46; 118-D-4A; Burial Ground 4A **Reclassification:** Interim Closed Out (3/1/2001)
Type: Burial Ground **Start Date:**
Status: Inactive **End Date:**

Description: This site has been remediated and interim closed out as part of the excavation for the 116-D-1A and 116-D-1B Trenches. The site was a 19 by 59-meter (62 by 195-foot) construction burial ground. Both of the referenced drawings refer to the site as Burial Ground No. 4A.

Location: The site was approximately 30 meters (100 feet) east of the 105-D Reactor Building.

Process Description: The 100-D-46 site received radioactive and nonradioactive solid wastes and construction debris generated from various reactor modifications from the 105-D Reactor.

Related Sites/ Structures: This burial ground received debris from the 105-D Reactor.

Waste Type: Construction Debris
Waste Description: Potential contaminants include: Co-60, Ni-63

Closure Info: 116-D-1A, 116-D-1B and 100-D-46 were addressed as a group. The information below documents information for the group of sites.

The 116-D-1A/116-D-1B Storage Basin Trenches and the 100-D-46 Burial Ground were remediated together, with the documentation presented in the same Cleanup Verification Package (CVP) and all sites are referred to as the 116-D-1A/116-D-1B site.

Remedial action objectives (RAOs) and goals (RAGs) for the 116-D-1A/116-D-1B site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995) and the Remedial Design Report/Remedial Action Work Plan (RDR/RAWP) (DOE/RL-96-17).

The selected remedial action for the 116-D-1A/116-D-1B site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, RAGs were established to identify radionuclide and no radionuclide contaminants of concern (COCs) and contaminants of potential concern (COPCs). Waste site COCs and COPCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22).

The COCs for this site were cesium-137, cobalt-60, europium-152, europium-154, plutonium-

239/240, strontium-90, uranium-238, americium-241, and hexavalent chromium.

At the completion of the remedial action, the total excavation was approximately 2,648 square meters (28,470 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 10,987 metric tons (12,111 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

The CVP demonstrated that remedial action at the 116-D-1A/116-D-1B site achieved the RAOs and corresponding RAGs established in the approved interim action ROD and RDR/RAWP. The remaining soils at the 116-D-A/116-D-1B site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-D-1A/116-D-1B site containing COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF, that residual COC concentrations in the shallow zone will support future land uses that can be represented (or bounded) by rural-residential scenario, and that residual COC concentrations throughout the site are protective of groundwater and the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

The 116-D-1A/116-D-1B site is verified to be remediated in accordance with the ROD.

Code: 100-D-47	Classification: Accepted
Names: 100-D-47; 118-D-4E; Burial Ground 4E; Construction C.G. 558-Rod Burial	Reclassification: Interim Closed Out (1/15/2010)
Type: Burial Ground	Start Date:
Status: Inactive	End Date:
Description: 100-D-47 is located within the 118-D-4 cobble field, but is not separately marked.	
Location: The site is located east of the 105-D Reactor Building, outside the reactor exclusion area fence and south of the railroad spur that services the reactor building. The burial ground is west of Burial Ground 4F (118-D-4) and south of Minor Construction Burial Ground #5 Pit (100-D-40) and Trench (100-D-41).	
Process Description: The site is a burial ground used to dispose of fuel rod waste during project CG-558.	
Waste Type: Equipment	
Waste Description: The site is described as a rod burial site. The type and quantity of rods disposed of at this site is not known. Potential contaminants include: C-14, Co-60, Ni-63, H-3, Nb-94, Ni-59, Pd-102, Sm-151, Tc-99, Am-241, Ag-108m, Ba-133, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113m, Kr-85, Zr-93, cadmium, lead.	
Closure Info: The Cleanup Verification Package, CVP-2009-00002 documents that the 100-D-47 Burial Ground 4E waste site has met the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (Burial Grounds ROD).	

Remedial action began on January 16, 2008, and continued through March 20, 2008. A total of approximately 2,800 bank cubic meters (BCM) (3,660 bank cubic yards [BCY]) of material was removed for disposal at ERDF. Approximately 247 BCM (323 BCY) of overburden and layback was stockpiled for use as clean fill. The material excavated was consistent with the

burial of scrap (piping, concrete, valves, etc.) from miscellaneous equipment modifications accomplished during Project CG-558. The horizontal control rods, if present, were not distinguishable from the other debris.

The 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (SAP) identified COCs for the site as cobalt-60 and nickel-63. In addition, the work instruction for verification sampling added cesium-137, europium-152, europium-154, strontium-90, plutonium-238, plutonium-239, plutonium-240, uranium-238, chromium (total), lead, and mercury to the COC list. Carbon-14 was identified as a contaminant of potential concern (COPC) based on the potential presence of activated graphite in wastes disposed to the site. Boron was added as a COPC as the chemical was applied to the horizontal control rods during manufacture. Due to a site-wide effort to identify the source of chromium contamination in the groundwater, hexavalent chromium was added as a COPC. Finally, asbestos was included as a COPC as asbestos-containing material was found in the burial ground.

The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicated that the materials containing COCs at concentrations exceeding RAGs have been excavated and disposed at ERDF. These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The excavation area has a maximum depth of approximately 5.5 m (18 ft), which included both shallow zone and deep zone soils. However, the entire excavation area was considered one decision unit, and will be closed out using the more restrictive shallow zone cleanup criteria; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. The site is verified to be remediated in accordance with the Burial Grounds ROD.

The laboratory-reported data results for all constituents were stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as part of the 95% UCL calculation in Appendix E or in Appendix F of the CVP for the asbestos results.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils. The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River.

Code: 100-D-54	Classification: Accepted
Names: 100-D-54; Drywell Near Fire Facility Gravel Scrubber	Reclassification: Interim Closed Out (3/4/2004)
Type: French Drain	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed out. The site was a 56-centimeter (28-inch) drywell. The unit was constructed of concrete pipe and had a steel cover. When opened during a field visit, the drywell was found to be approximately 1.5 meters (4.9 feet) deep with a 5-centimeter (2-inch) pipe entering it near the bottom on the east side.	
Location: The site was located approximately 5.5 meters (18 feet) southwest of the southwest corner of the 119-DR Sample Building.	
Closure Info: 122-DR-1:2, 100-D-53, 122-DR-1:4, 132-DR-2, 122-DR-1:5, 100-D-64, 100-D-23 and 100-D-54 were addressed as a group. The information below documents information for the group of sites.	

Remedial or removal objectives and goals for the components of the LSFF TSD unit pre-filter exhaust tunnel [122-DR-1:2], the 117-DR Exhaust Filter Building [100-D-53/122-DR-1:4], 116DR reactor exhaust stack(132 DR 2/122-DR-1:5), were obtained from the Action Memorandum, USDOE Hanford 100 Area National Priorities List (NPL) 105-F and 105 DR Reactor Buildings and Ancillary Facilities (Action Memorandum). The objectives and goals were also included in the Phase III SAP (DOE/RL-99-35) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17), which was referenced in the Action Memorandum.

Based on consideration of the requirements of CERCLA and detailed analysis of alternatives, the Tri-Parties have selected the remove/dispose alternative under a rural-residential land use scenario for the 117-DR facilities site.

The objective for the structures included the removal of the structure to a minimum of 0.9 meters (3 feet) below surface grade. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide contaminants of concern (COCs) and contaminants of potential concern.

Waste site COCs for the 117 DR facilities site were identified through process knowledge and are specified in the Phase III SAP (DOE/RL-99-35). The COC list was further refined and amended with the 117 DR Exhaust Filter Building Proposed Additional Soil Sampling and 1720-HA Arsenal Removal/ Disposal Summary (CNN 106839). The COCs consist of the following: americium-241, arsenic, carbon-14, barium, cesium-137, cadmium, cobalt-60, total chromium, europium-152, hexavalent chromium, europium-154, lead, europium-155, lithium, niel-63, mercury, plutonium-238, selenium, plutonium-239/240, silver, strontium-90, sodium, uranium-234, uranium-235 and uranium-238.

At the completion of the remedial action, the total excavation was approximately 1,010 meters squared (10,872 square feet) in area with an approximate depth of 5 meters (16.4 feet). Approximately 14,011 metric tons (15,412 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

The 117-DR facilities site is verified to be remediated in accordance with the RAOs and RAGs of the Action Memorandum and the Remaining Sites ROD and may be backfilled.

In addition, demonstration that remedial action at the 117-DR facilities site has achieved the RAOs and corresponding RAGs established in the Action Memorandum and the Remaining Sites ROD meets the RCRA closure requirements for the underlying soils. Final RCRA TSD certification of closure is pending.

Code: 100-D-62	Classification: Accepted
Names: 100-D-62; 183-DR Headhouse Septic Tank	Reclassification: None
Type: Septic Tank	Start Date:
Status: Inactive	End Date:
Description: The septic system received sanitary sewage from the 183-DR headhouse. The entire 183-DR water treatment facility is a nonradiological area; therefore, the 100-D-62 septic system waste site is not considered radiologically contaminated. This system was designed for the use of 6 people with a 2,271 L (600 gal) capacity.	
Location: The septic system is located about 15.2 m (50 ft) south of the 183-DR Head House and west of	

the 183-DR Flocculation Basin.

Process Description: The 100-D-62 septic system waste site received sanitary sewage from the 183-DR water treatment facility headhouse. The 183-DR water treatment facility was operational from 1952 to 1964, per documentation these facilities were demolished to grade in 1978. The operational period of the septic system is assumed to be the same as the 183-DR facility. The 183-DR water treatment facility filtered and chemically treated raw Columbia River water prior to use to cool components within the 105-DR Reactor. Sulfuric acid, potentially containing impurities such as lead and mercury, was added to raw river water prior to entry into the flocculation basins. Sodium dichromate was added to the water in the filter building to inhibit metal corrosion of reactor components. The 183-DR headhouse served as a receiving, storage, and transfer point for sodium dichromate. Sodium dichromate was received from the 185-D Building into one or more storage tanks located in the equipment room in the northeast corner of the headhouse on the ground floor. The sodium dichromate solution was pumped via an overhead line across the flocculation and sedimentation basins to the eastern end of the filter building. It was then injected into a mixing flume that was located along the eastern side of the building. The 183-DR headhouse was the western most building of the water treatment facility. The building was 34 m by 24 m (1.10 ft by 80 ft) and supplied an appropriate mixture of chemicals to provide the desired treated water to the reactor. River water entered the headhouse through two 9.1 cm (36 in) diameter steel pipes. The 183-DR headhouse contained inlet control valves, flash mixer chambers, chlorinators, and the ferric sulfate, lime, and silicate storage and feeding equipment used to chemically treat water. The 183-DR headhouse received 10% sodium dichromate solution from the 185-D Building through a 7.6 cm (3 in) diameter pipeline that connected with two tanks, each with a 15,142 L (4,000 gal) capacity. From the storage tanks, two, 1.9 cm (0.75 in) diameter sodium dichromate pipes crossed above the flocculation and sedimentation basins where they entered the sample room and mixing pumps in the filter building.

Related Sites/ Structures: The site was associated with the 183-DR Head House.

Waste Type: Sanitary Sewage

Waste Description: The waste is the remaining septic system (tank and piping) and any remaining septage.

The Contaminants of potential concern (COPCs) for the 100-D-62 waste site were identified based on existing historical information for the 183-DR water treatment facility and contaminants associated with previously sampled septic systems. The COPCs for the 100-D-62 septic system include constituents associated with the chemicals used in the 183-DR headhouse: chromium, hexavalent chromium, mercury, lead, and anions. Although not COPCs, arsenic, antimony, barium, beryllium, boron, cadmium, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc concentrations will be evaluated by performing the expanded inductively coupled plasma metals analytical list. Based on findings from other septic systems in the 100-D Area, semivolatile organic compounds, pesticides, and polychlorinated biphenyls are also considered COPCs. Additional COPCs may be identified as part of planning for remedial actions.

Radionuclides are not COPCs for this site. However, the presence of radiological contaminants should be evaluated using field radiological survey instrumentation (capable of detecting alpha, beta, and gamma radiation) during remediation of the septic system. If radiological activity is detected during remediation, the verification sampling work instruction will incorporate specific requirements for radionuclide analysis.

Code: 100-D-77

Classification: Accepted

Names: 100-D-77; 183-DR Filter Building; 183-DR Flocculation Basins; 183-DR Head House; 183-

Reclassification: None

DR Sedimentation Basins; Acid Facility; DR
Reactor Water Treatment Facility; Sodium
Dichromate Systems

Type: Process Unit/Plant

Start Date:

Status: Inactive

End Date:

Description: The entire water treatment system was demolished to grade. The flocculation and sedimentation basins remain below grade and were demolished in situ. The site includes the sodium dichromate systems that were located within the 183-DR Head House and 183-DR Filter Building, Acid Facility, the six 183-DR Flocculation Basins, and the six 183-DR Sedimentation Basins, all of which were components of the cooling water treatment system to support the 105-DR Reactor.

Location: The site is located west of 105-DR, west the remediated 183-DR Clearwells (126-DR-1).

Process Description: These components are of interest because they stored, mixed, or processed liquid contaminants of concern, especially sodium dichromate and sulfuric acid (potentially contaminated with lead and mercury). The sedimentation basins and possibly the flocculation basins received demolition debris from the 183 DR area facilities that may have been contaminated. Sodium dichromate was supplied to the 183-DR Head House through a 7.6 centimeter (3 inch) diameter pipeline (100-D-56) that entered the west side of the 183-DR Head House. The 183 DR Head House contained the inlet control valves, flash mixer chamber, chlorinators, ferric sulphate and lime storage, and feeding equipment, silicate and sodium dichromate solution storage and feeding equipment. The 183-DR Head House had its own sodium dichromate storage facility that consisted of two tanks with a 15,200 liter (4,000 gallon) capacity. Sodium dichromate solution was pumped and injected into the process water after the filters in the filter building by the proportioning pumps in the head house. The 183-DR Filter Building also received sodium dichromate from the 183-DR Head House. Two 1.9 centimeter (0.75 inch) diameter sodium dichromate pipelines extended from the mixer in the 183-DR Head House, over the flocculation and sedimentation basins, to the 183-DR Filter Building where it entered the sample room, mixing pumps, and flume. Acid Facility: The Acid Facility was located on the north side of the 183-DR Head House. Sulfuric acid was received by railroad car and stored in two outside above grade acid storage tanks. The acid facility contained two acid storage tanks (No. 1 & 2), two acid pumps, car spot, acid head tank, one drywell, two sumps, acid piping, pipe flume/trench and an acid pit (H-1-5662). The acid pumps were designed to transport sulfuric acid from the railroad cars to the storage tanks and from the storage tanks to the acid head tank (H-1-5663). The GPS coordinates for the acid pumps are E573251, N151223. The railroad car spot was located west of the pipe trench and south of acid storage tank No. 1. Sulfuric acid was unloaded at this location and pumped to either storage tank No. 1 or 2 (H-1-5663). Between the sulfuric acid tanks was a pipe flume/trench that contained seven pipes that included, two 5 centimeter (2 inch) sulfuric acid pipes (100-D-83), a 10 centimeter (4 inch) overflow pipe, a 2.5 centimeter (1 inch) low pressure steam pipe, 3.2 centimeter (1.25 inch) compressed air pipe, 5 centimeter (2 inch) lime slurry pipe, and a 5 centimeter (2 inch) filtered water pipe (H-1-5663). From the acid tanks, material was transported through the pipe trench to the acid head tank then to the 183-DR Head House. Each of the other pipes also connected to the northwest wall of the 183-DR Head House (H-1-5662). The acid head tank was located on the east side of the pipe trench and south of acid tank No. 2. A 5 centimeter (2 inch) sulfuric acid line and a 5 centimeter (2 inch) sulfuric acid drain line connected the tank to the pipe trench. Another 5 centimeter (2 inch) pipe connected to the flume/trench between the 183-DR Head House and the flocculation basin (H-1-5663). The GPS coordinates for the acid head tank are E573256, N151222. There is one drywell and two sumps associated with the acid facility. The 31 centimeter (12 inch) diameter drywell was located on the west side of the acid trench and south of acid tank No. 1 (E573251, N151220). There is a sump located on the west side of acid tank No. 1. The sump was a 61 centimeter (24 inch) diameter feature that was installed in 1957 (E573248, N151121). The second sump is west of the pipe trench and the

acid pumps. It is 61 centimeter (24 inch) in diameter (H-1-5663) (E573249, N151232). The acid pit was located north of the acid storage tanks. The pipes in the flume/trench drained into the pit (H-1-5663) (E573252, N151239). The former site of the tanks and the unloading and transfer systems have the potential for contaminated soils caused by leaks and spills (potential lead and mercury). Although the facility has been demolished, subsurface contamination may be present.

Head House The 183-DR Head House was the western most segment of the water treatment facility. The building contained three floors that included a basement. The basement contained a sump pit. The first floor contained the equipment room, electrical room, control room, chlorinator room, lab, and chlorine room. The top floor contained the chemical feeder (H-1-915). The dimensions were 34 m by 24 meters (110 feet by 80 feet). It was designed to supply the appropriate mixture of chemicals to provide the desired water treatment to the reactor. Chemicals were received by railcar at the train shed located on the west side of the Head House. River water entered the west side of the head house through two 91 centimeter (36 inch) diameter steel pipes. The 183-DR Head House contained the inlet control valves, flash mixer chamber, chlorinators, ferric sulphate and lime storage, and feeding equipment, silicate and sodium dichromate solution storage and feeding equipment used to chemically treat water (HDC-1418). Alum, sulfuric acid, chlorine and sodium dichromate were mixed in the facility. The 183-DR Head House never received sodium dichromate in pure form. It received a 10% sodium dichromate solution from the 185-D Building through a 7.6 centimeter (3 inch) diameter pipeline (100-D-56) that connected with two tanks, each with a 4,000 gallon capacity. From the storage tanks, two 1.9 centimeter (0.75 inch) diameter sodium dichromate pipes crossed above the flocculation and sedimentation basins where the pipes entered the sample room and mixing pumps in the filter building. From the filter building treated water entered the 190-DR Storage Tanks (H-1-9147, H-1-9601, HW-28360, and SK-1-8261). Water treated with sodium dichromate entered the 190-DR Clearwells followed by the 190-DR Pump House and through the pipe tunnels to the 105-DR Reactor. From the reactor, effluent was pumped to the retention basin (116-DR-9) and to the outfalls (100-D-65 and 116-DR-5). Sulfuric acid and sodium dichromate were mixed in the facility. Sulfuric acid was received from the Acid Facility into the head tank. Sodium dichromate was received through the 7.6 centimeter (3 inch) pipelines (100-D-56) from 185-D Building into two storage tanks, located on the ground floor of the Equipment Room in the northeast corner of the head house. Sulfuric acid was added immediately to the river water arriving from the 182-D Reservoir to adjust the pH. With the addition of the sulfuric acid early in the water treatment system, there is a potential for trace amounts of lead and mercury in the flocculation basins, sedimentation basins, and filter buildings.

183-DR Flocculation and Sedimentation Basins The flocculation and sedimentation basins received hundreds of millions of gallons of river water treated with sulfuric acid. The 183-DR flocculation and sedimentation basins were designed to allow heavier particulate matter to settle out of the water before it entered the filter building. The flocculation basins were located between the 183-DR Head House and the sedimentation basins. The flocculation basins contained six chambers, each containing a paddle wheel to mix chemical additives. The six chambers were 112.5 meters (369 feet) wide and 13 meters (43 feet) wide (H-1-9212). Also located in the basins were at least two drywells (H-1-9213 and H-1-9214 sh2). The sedimentation basins joined the east side of the flocculation basins and also contained six chambers. There were six sludge hoppers, one for each basin, near the west wall of the sedimentation basins (H-1-9211, H-1-9212, H-1-9216). Combined they were 112.5 meters (369 feet) wide, 58.5 meters (200 feet) long, and at least 5 meters (16 feet deep). The sedimentation basins later received demolition material from the D & D of the head house and the filter building in 1978 (both of which may have had sodium dichromate, mercury, and/or lead contamination). This component of the site is analogous to the 183-B flocculation and sedimentation basins contamination.

183-DR Filter Building The filter building received water treated with sodium dichromate and sulfuric acid. The 183-DR Filter Building was located on the east side of the sedimentation basin. The filter building contained a pipe galley and operating floor. The operating floor contained the ventilation equipment, switchgear room, pump room, and suction header and hot well bay. (H-1-9401). The facility was 171 meters by 15 meters (560 feet by 52 feet) and contained two halves with a gullet between them. The

original filters were modified and replaced with 30.48 centimeters (12 inch) of graded gravel, 15 centimeters (6 inch) of sand and 61 centimeters (24 inch) of crushed and graded anthracite coal. Water entered the gullet from the influent flume through an influent valve and flowed to both halves of the filter components through port openings. There were 10 filters in the facility. From the filter building, water entered the 190-DR Clearwells and pumphouse (H-1-9606). After demolition, the facility was disposed of in the 183-DR sedimentation basins.

Related Sites/ Structures: The 183-DR Head House is on the west side and immediately adjacent to the 183-DR Coagulation Basins. The 183-DR Filter Building is located between the 183-DR Sedimentation Basins and the 190-DR Storage Tanks.

Waste Type: Demolition and Inert Waste

Waste Description: The waste form would be contaminated soil from leaks and spills during operation, and contaminated fill material from the demolition of the two buildings. Sodium dichromate, lead, and mercury may be present under the site footprint and in the flocculation and sedimentation basins.

Code: 100-D-94

Classification: Accepted

Names: 100-D-94; Dichromate Contaminated Pit Associated with 187-DR

Reclassification: No Action (3/31/2011)

Type: Depression/Pit (nonspecific)

Start Date:

Status: Inactive

End Date:

Description: The site consists of an area of chromium observed in a pit under the DR water tower. This area was identified during the D Area orphan site evaluation.

Location: The site was directly under the 100-DR water tower south of the 105-DR Reactor.

Process Description: This site served as a valve pit for process water stored in the 187-DR water tower. The water tower provided emergency cooling water to the 105-DR reactor. The reinforced concrete valve pit with 1.06 m (3.5 ft) thick floor slab, 0.3 m (1 ft) thick side walls and 0.76 m (2.5 ft) thick roof, was located below ground directly beneath the tank. A central riser extended into this pit from the water tank.

While excavating Test Pit 3 on August 24, 2010 (during confirmatory sampling of 100-D-83:4), beta and gamma radiation up to 6,000 dpm was detected on broken pipe debris approximately 0.3 m (1 foot) to 2.4 m (8 feet) below ground surface (EL-1649, pgs 32-33).

Related Sites/ Structures: This site is associated with the 187-DR high tower.

Waste Type: Process Effluent

Waste Description: Potential Contaminant of Concern, Chromium.

Code: 100-D-100

Classification: Accepted

Names: 100-D-100; Sodium Dichromate Near Southern Portion of 100-D-56

Reclassification: None

Type: Unplanned Release

Start Date:

Status: Inactive

End Date:

Description: The site consists of chromate contaminated stained soil near the former sodium dichromate/

acid railcar and truck unloading station (100-D-12).

Location: The stained soil was located in an area north of the 183-DR Headhouse and approximately 50 meters (164 feet) south of Paddock Street, adjacent to the remediated 100-D-56 pipeline. The staining was between the 100-D-56 pipelines and the railroad tracks that previously serviced the 183-DR building. The lateral and horizontal extent of contamination has not been defined. The center of the site is located at Washington State Plane coordinates, E 573351, N 151359.

Process Description: To inhibit corrosion, sodium dichromate was added to the reactor cooling water. Initially the chemical was prepared in the 108-D Chemical Pump House. The concentrated solution was pumped to feed tanks in the 105-D and 185-D Buildings. The preparation of the sodium dichromate feedstock was relocated from the 108-D Chemical Pump House to the 185-D Deaeration Plant in 1950. Two 7.6 centimeter (3 inches) diameter dichromate lines (100-D-56) were installed between the 185-D building and 183-DR building during the 100-DR Water Plant construction. A new spur track was also installed leading to the 183-DR building from the existing railroad tracks south of the 186-D building.

Related Sites/ Structures: The nearest structures (including those previously demolished) include the railroad spur leading to the 183-DR building and the sodium dichromate/ acid railcar and truck unloading station (100-D-12). The stain was approximately 38 meters (125 feet) south of the 100-D-12 waste site.

Waste Type: Process Effluent

Waste Description: The waste consists of hexavalent contaminated soil. The potential contaminant of concern is hexavalent chromium.

Code: 116-D-8

Classification: Accepted

Names: 116-D-8; 100-D Cask Storage Pad

Reclassification: Interim Closed Out (8/10/2011)

Type: Storage

Start Date: 1/1/1946

Status: Inactive

End Date: 1/1/1975

Description: The site is a rectangular pad covered with gray grout (shotcrete). It is surrounded with Underground Radioactive Material signs. It had also been posted with Cave-in Potential signs, but the Cave-in potential signs were removed in November 1999.

Location: The site is located on the west side of the 100-DR Reactor, outside the fence.

Process Description: The concrete pad had two drains. The drain that handled pad decontamination and rain runoff, discharged into the 105-DR process sewer. The second drain discharged to a french drain, the location of which is unknown; however, an excavation that may be the drain was dug in 1949. There may also be a french drain beneath the loading dock, located on the west side, that provided drainage for storm runoff which is likely to be contaminated. The pad has been stabilized with a sprayed grout material and reinforced with a metal mesh material. There are two structures just south of the pad - one is a red aluminum storage tank and the other appears to be a furnace or shipping cask.

Related Sites/ Structures: The site was associated with the 1607-DR3 Sanitary Sewer Pipelines subsite and may discharge to the 100-D-50:9 pipeline.

Waste Type: Chemicals

Waste Description: This site contains trace amounts of radionuclides and decontamination chemicals.

Code: 118-D-1

Classification: Accepted

Names: 118-D-1; 100-D Burial Ground No. 1 **Reclassification:** None
Type: Burial Ground **Start Date:** 1/1/1944
Status: Inactive **End Date:** 1/1/1967

Description: This unit contains many trenches running north and south. Typically, the trenches are 90 meters (300 feet) long by 6 meter (20 feet) wide and 6 meters (20 feet) deep with a 6 meters (20 feet) of space between them. Several trenches are greater than 6 meters (20 feet) deep. A 106 centimeter (42 inch) diameter, reinforced concrete water pipe runs through the northwest corner of the burial ground boundary, but not through any of the waste trenches (see WIDS sitecode 100-D-50).

Location: The unit is located south of the 105-DR Building just outside of the 100-D Perimeter Fence.

Waste Type: Equipment

Waste Description: The unit was used for the disposal of irradiated dummies, thimbles, rods, gun barrels, and other contaminated solid waste. It may contain spent nuclear fuel elements. Potential contaminants include: H-3, C-14, Co-60, Ni-63, Sr-90, Ag-108m, Cs-137, Eu-152, Eu-154, am-241, Pu-238,239 and 241, Sm-151, Se-79, Tc-99, U-235 and 238, Kr-85, Zr-93, cadmium, lead, mercury. Historical research identified some specific buried items that include a one ton Aimer track cut into 12 pieces, mattress plate extensions, poison pieces, vertical safety rods, rod guides and tips, shield plugs and contaminated soil.

Code: 118-D-2 **Classification:** Accepted
Names: 118-D-2; 100-D Burial Ground No. 2 **Reclassification:** None
Type: Burial Ground **Start Date:** 1/1/1949
Status: Inactive **End Date:** 1/1/1970

Description: The 118-D-2 waste site includes the entire disturbed area visible in historical aerial photographs that was used as the 100-D Burial Ground No. 2. The two subsites are: 118-D-2:1, 100-D Burial Ground No. 2 Trenches and Disposal Pits 118-D-2:2, Anomaly Characterization Area

Location: This unit is located 400 meters (1,312 feet) west-southwest of the 183-DR Headhouse.

Process Description: Refer to the subsites for the process description.

Waste Type: Equipment

Waste Description: The unit was used for miscellaneous contaminated solid waste such as irradiated dummies, splines, vertical safety rods, thimbles, and gun barrels. Waste includes 16,329 kg of aluminum tubes, 36287 kg of aluminum spacers, 89,040 kg of lead poison slugs, 3719 kg of cadmium poison slugs, 5987 kg of aluminum poison slugs, 54 kg of lead and 16,329 kg of miscellaneous metallic waste. This burial ground has the potential to contain spent nuclear fuel rods. Beginning in April 1966, 100-N Area solid wastes were also buried here. A large fire in this burial ground in March 1958. The large volumes of water that were required to extinguish the fire could have potentially washed contaminants into the soil column beneath the burial ground. Potential contaminants include H-3, carbon-14, cobalt-60, Ni-63, Sr-90, Ag-108, Ba-133, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113, Kr-85 and Zr-93.

This Site has the Following SubSites:

Code: 118-D-2:1
Names: 118-D-2:1; 100-D Burial Ground No. 2 Trenches and Disposal Pits

Code: 118-D-2:2
Names: 118-D-2:2; Anomaly Characterization Area

Contaminated gravel from the road was removed. A can of water into which pieces downstream of ruptured slugs were removed from the storage basin were buried. Water samples showed $1.1E-3$ uc/cc. All material are assumed to be buried in 118-D-2.

In 1951, a VSR thimble section with a reading of 5r/hr was momentarily removed from the burial trench. A box containing swabs from a process tube from 105-D were buried. That same year, from the 105-D decontamination vat and two small chips were found during the removal of a tip-off contained dosage rates of 200 and 10r/hr respectively. All material was believed to be buried in 118-D-2.

Location: The site is located 417 meters (1,368 feet) southwest of the 183-DR Headhouse.

Process Description: The waste site was the primary burial ground for the disposal of 105-D Reactor operations waste, including irradiated dummies, splines, rods, thimbles, and gun barrels. Each pair of pits was constructed by stacking railroad ties, creating two spaces with interior dimensions of approximately 1.8 by 1.8 m (6 by 6 ft) that shared a common wall. The structures were built within an excavation 7.3 m (24 ft) wide by 7.3 m (24 ft) deep. All were covered with 1.8 m (6 ft) of soil. It was extended in April of 1966 to provide space for the burial of contaminated solid wastes from N-Area.

The SubSite is Part Of:

Code: 118-D-2

Names: 118-D-2; 100-D Burial Ground No. 2

Code: 118-D-2:2

Classification: Accepted

Names: 118-D-2:2; Anomaly Characterization Area

Reclassification: None

Type: Burial Ground

Start Date:

Status: Inactive

End Date:

Description: The subsite consists of the northern portion of the 118-D-2 burial ground where geophysical testing revealed that no waste was buried (BHI-00064). The area measures 5661 square meters (1.4 acres).

Location: The site is located 379 meters (1,243 feet) west-southwest of the 183-DR Headhouse.

Process Description: The anomaly characterization area was used to characterize anomalous materials found in the 118-D-2 Burial Ground during remediation.

The SubSite is Part Of:

Code: 118-D-2

Names: 118-D-2; 100-D Burial Ground No. 2

Code: 118-D-3

Classification: Accepted

Names: 118-D-3; 100-D Burial Ground No. 3

Reclassification: None

Type: Burial Ground

Start Date: 1/1/1956

Status: Inactive

End Date: 1/1/1973

Description: The site encompasses the 100-D Burial Ground Number 3 which consists of two subsites. Subsite one contains multiple (6 to 8) trenches running east and west. Subsite two contains the fuel characterization area and the anomaly characterization area.

Location: The unit is located 106.7 meters (350 feet) east of the 105-DR Building.

Process Description: The burial ground was the primary disposal site for 105-DR Reactor operations waste, including irradiated dummies, splines, rods, thimbles, and gun barrels. The burial ground has the potential to contain spent nuclear fuel elements. The site also contained a burning pit used to dispose of low-level radioactive combustible materials. The eastern boundary was used for the disposal of 100-N solid wastes.

Related Sites/ Structures: The site received waste from the 105-DR Reactor and 100-N area solid waste.

Waste Type: Equipment

Waste Description: The unit contains miscellaneous contaminated solid wastes and irradiated dummies, splines, rods, thimbles, and gun barrels. This burial ground has the potential to contain spent nuclear fuel rods. It was also used for disposal of 100-N solid wastes. Potential contaminants include: H-3, C-14, Co-60, Ni-63, Sr-90, Ag-108m, Cs-137, Eu-152, Eu-154, Kr-85, Zr-93, Cd-113, Se-79, Tc-99, Sm-151, Am-241, Pu-238, 239 and 241, U-235 and 238, Ba-133, cadmium, lead, and mercury.

Waste Type: Equipment

Waste Description: The waste site received 23.8 tons of lead, 97 tons of aluminum, 137.7 tons of Pb/Cd, 1 ton of boron, and 0.06 tons of graphite.

This Site has the Following SubSites:

Code: 118-D-3:1

Names: 118-D-3:1; 100-D Burial Ground No. 3 and Process Cells

Code: 118-D-3:2

Names: 118-D-3:2; Fuel and Anomaly Characterization Areas

Code: 118-D-3:1

Classification: Accepted

Names: 118-D-3:1; 100-D Burial Ground No. 3 and Process Cells

Reclassification: None

Type: Burial Ground

Start Date:

Status: Inactive

End Date:

Description: The subsite consists of multiple trenches in the burial ground, they were oriented east and west. Typically, trenches were 61 m (200 ft) long by 6.1 m (20 ft) wide at the bottom and 6.1 m (20 ft) deep. The spacing between trenches was not uniform. The subsite also includes the process (sorting) cells used to determine the presence of suspect spent nuclear fuel and the north anomaly storage area.

The burial ground was the primary disposal site for 105-DR Reactor operations waste, including irradiated dummies, splines, rods, thimbles, and gun barrels. The burial ground has the potential to contain spent nuclear fuel elements. The site also contained a burn pit used to dispose of low-level radioactive combustible materials. The eastern boundary was used for the disposal of 100-N solid wastes.

Location: The burial ground is located 106.7 m (350 ft) east of the 105-DR Building. The sorting cells are 137 meters (449 feet) south of the burial ground. The centroid of the two sorting cells is N 151139.7 m, E 573966.5 m and N151109.0 m, E 573967.1 m. The north anomaly storage area covers a portion of the burial ground along the north side. The centroid of the north anomaly storage area is N 151348.2 m, E 574047.3 m.

The SubSite is Part Of:

Code: 118-D-3
Names: 118-D-3; 100-D Burial Ground No. 3

Code: 118-D-3:2 **Classification:** Accepted

Names: 118-D-3:2; Fuel and Anomaly Characterization Areas **Reclassification:** None

Status: Inactive **End Date:**

Description: The subsite includes two areas (fuel characterization and anomaly characterization). The fuel characterization area was used to investigate suspect spent nuclear fuel and confirm presence of spent nuclear fuel pieces. The anomaly characterization area was used to characterize anomalous materials found at 100-D.

Location: The site is located 321 meters (1053 feet) southeast of the 105-DR building.

The SubSite is Part Of:

Code: 118-D-3

Names: 118-D-3; 100-D Burial Ground No. 3

Code: 118-D-4 **Classification:** Accepted

Names: 118-D-4; 118-D-4F; Burial Ground 4F; Construction Burial Ground **Reclassification:** Interim Closed Out (10/14/2010)

Type: Burial Ground **Start Date:** 1/1/1956

Status: Inactive **End Date:** 1/1/1967

Description: The site appears as a gravel and cobble field.

Location: The site is located 300 meters (1000 feet) southeast of 105-D Reactor Building and 30 meters (100 feet) south of the 100-D railroad tracks.

Process Description: This irregularly shaped burial ground received construction waste, primarily reactor components and hardware, associated with Project CG-558. Based on historical photograph 3738-Photo, this site (118-D-4F) likely began operations around 1956 instead of 1953. A geophysical survey detected three distinct trenches.

Waste Type: Equipment

Waste Description: This unit contains contaminated material generated during Project CG-558. The contaminated material consisted mainly of reactor components and hardware. Potential contaminants include: C-14, Co-60, Ni-63, H-3, Nb-94, Ni-59, Pd-102, Sm-151, Tc-99, Am-241, Ag-108m, Ba-133, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113m, Kr-85, Zr-93, cadmium, lead.

Closure Info: The Cleanup Verification Package (CVP-2009-00001) has documented that the 118-D-4 waste site has met the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17, Rev. 6) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, (Burial Grounds ROD) (EPA, 2000).

Remedial action began on October 10, 2007, with the removal of 5,500 bank cubic meters (BCM) (7,200 bank cubic yards [BCY]) of overburden material. The overburden was stockpiled southeast of the burial ground. Excavation continued through March 20, 2008, to a maximum depth of approximately 6.5 m (21 ft), resulting in approximately 7,067 BCM (9,243 BCY) of

waste material removed for disposal at ERDF. Although the excavation extended into the deep zone, the entire excavation area is treated as shallow zone for verification sampling.

Waste encountered consisted of primarily contaminated reactor components and hardware associated with Project CG-558. Field observations during excavation indicated the presence of piping, lead, concrete, steel, reactor hardware, valves, a metal solvent container, and leaded glass.

The contaminants of potential concern (COC/COPCs) were identified in the RDR/RAWP and the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-2001-35) and included carbon-14, cobalt-60, nickel-63, cadmium, and lead. The 100 Area Burial Grounds SAP further identified cesium-137, strontium-90, europium-152, europium-154, uranium-238, plutonium-238, plutonium-239/240, chromium, and mercury as COPCs for construction burial grounds. Boron was identified as a COPC based on its usage in reactor operations.

Verification sampling was performed between December 9, and December 11, 2008, to collect data to determine if the RAGs had been met. RAGs are the specific numeric goals against which the verification data are evaluated to demonstrate attainment of the RAOs for the site.

The laboratory-reported data results for all constituents were stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as part of the 95% UCL calculation in Appendix C of the CVP.

The 118-D-4 excavation area had a maximum depth of approximately 6.5 m (21 ft), which included both shallow zone and deep zone soils. However, the entire excavation area was considered one decision unit, and was closed out using the more restrictive shallow zone cleanup criteria; therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone were required.

Code:	118-D-5	Classification:	Accepted
Names:	118-D-5; Ball 3X Burial Ground; Burial Ground 4G; Minor Construction Burial Ground Number 3; Minor Construction Burial Ground Number 5; 118-D-4G	Reclassification:	Interim Closed Out (2/1/2010)
Type:	Burial Ground	Start Date:	1/1/1954
Status:	Inactive	End Date:	1/1/1954
Description:	The unit consists of two burial trenches located parallel to each other. Each trench is 12.2 meters (40 feet) long by 6.1 meters (20 feet) wide, however, the exact location is unknown.		
Location:	The unit is located 30.5 meters (100 feet) south of the 105-DR Building, just outside the exclusion area fence. Hanford drawings H-1-4046 and H-1-19823 show a discrepancy in the site location.		
Process Description:	This burial ground received thimbles from the 105-DR Reactor during the Ball 3X Project in 1954.		
Waste Type:	Equipment		
Waste Description:	This site received thimbles removed from the 105-DR Reactor during the Ball 3X work in 1954. Potential contaminants include: Co-60, Ni-63, Ag-108, Ba-133, Cs-137, Eu-152 and 154, Pu-238, 239 and 241, Ca-41, Cd-113, Kr-85, Zr-93, cadmium, lead.		

Closure Info: 118-D-5 Burial Ground 4G meets the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, 100-KR-2, Operable Units, Hanford Site (100 Area Burial Grounds).

Remedial action at the 118-D-5 Burial Ground began on June 2, 2008, and continued through August 12, 2008. Approximately 1,943 bank cubic meters (BCM) (2,541 bank cubic yards [BCY]) of overburden material was stockpiled for use as clean fill. Approximately 314 BCM (411 BCY) of soil and debris were removed for disposal to the Environmental Restoration Disposal Facility (ERDF).

The depth of the excavation ranged from 2 m (6.5 ft) in the easternmost portion of the excavation to 7 m (23 ft) in the westernmost portion of the excavation. Although defined trenches were not observed on the geophysical data, the debris removed indicates that the 118-D-5 Burial Ground was located and remediated. Concrete, piping, and split tubes (reactor process tubes that were split to allow removal from the reactor core) were among the type of debris removed from the burial ground excavation. No thimbles were identifiable in debris found during the remediation of the burial ground.

The COCs for the 118-D-5 Burial Ground, specified in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (Burial Grounds SAP) (DOE-RL 2001a), are identified as cobalt-60 and nickel-63. Europium-152, europium-154, boron, cadmium, lead, and mercury were added as COPCs based on the disposal of Ball 3X Project waste to the site. Although not considered COPCs, antimony, arsenic, barium, beryllium, chromium (total), cobalt, copper, manganese, molybdenum, nickel, silver, selenium, vanadium, and zinc were evaluated by performing analyses for the constituents of the expanded inductively coupled plasma (ICP) metals list. Due to a site-wide effort to identify the source of chromium contamination in the groundwater, hexavalent chromium was added as a COPC for closeout.

An in-process soil sample, consisting of scale from debris and co-mingled soil, was collected during remediation activities at a location where the post-excavation radiological survey showed elevated radiological activity. The sample detected carbon-14, cesium-137, strontium-90, and tritium; therefore, those radionuclides were added as COPCs to the focused sample location only. The laboratory-reported data results for all constituents were stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and are presented as part of the 95% UCL calculation in Appendix D of the CVP.

The remaining soils at the 118-D-5 waste site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the site containing COCs/COPCs at concentrations exceeding RAGs have been excavated and disposed at ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site posed no threat to groundwater or the Columbia River.

The excavation area had a maximum depth of approximately 7 m (23 ft), which included a shallow zone and a deep zone. However, the entire excavation area was considered one decision unit, and was interim closed out using the more restrictive shallow zone cleanup criteria; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. The site was verified to be remediated in accordance with the Burial Grounds ROD. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the

Columbia River.

Code: 128-D-1 **Classification:** Accepted
Names: 128-D-1; 100 D/DR Burning Pit **Reclassification:** No Action (4/12/2004)
Type: Burn Pit **Start Date:** 1/1/1944
Status: Inactive **End Date:** 1/1/1967

Description: Documentation in the Calculation Brief (0100D-CA-V0126) demonstrated that this site is a duplication (misidentified location) of 128-D-2 or 628-3.

Location: This site was located (in error) east of the intersection of the perimeter road and the railroad track that leads to the 184-D Powerhouse, just northeast of 100-D Area. The exact location of the site is unknown.

Process Description: The site was originally thought to have been used for the disposal of nonradioactive, combustible materials, such as paint waste, office waste, and chemical solvents.

Waste Type: Misc. Trash and Debris

Waste Description: The site was used for the disposal of nonradioactive, combustible materials, such as paint waste, office waste, and chemical solvents. The exact location of this waste site is unknown, although evidence of burning and waste materials were found at the site. On September 29, 1951, contaminated materials were found in the burning pit (Radiation incident: Class 1 #180). All contaminated materials were removed to the radioactive burial ground for proper disposal.

Code: 1607-D1 **Classification:** Accepted
Names: 1607-D1; 1607-D1 Sanitary Sewer System; 1607-D1 Septic Tank; 1607-D1 Septic Tank and Associated Drain Field; 124-D-1 **Reclassification:** None
Type: Septic Tank **Start Date:** 1/1/1944
Status: Inactive **End Date:** 1/1/1965

Description: The site is a septic tank and associated drain field. The tank is 3.4 meters (11 feet) deep, constructed of reinforced concrete, and has a 125-person capacity (130 liters [35 gallons] per capita) with an average detention period of 24 hours. The walls and floor are 25 centimeters (10 inches) thick. The tile field is constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a minimum of 2.4 meters (8 feet) per capita. The laterals are open jointed and spaced 2.4 meters (8 feet) apart.

Related Sites/Structures: The septic system is associated with the 1701-D Badgehouse and the 1709-D Patrol Change Room and Offices.

Waste Type: Sanitary Sewage

Waste Description: This unit received an unknown amount of sanitary waste from the 1701-D Badgehouse (security check point) and the 1709-D Patrol Change Room and Offices.

Code: 116-DR-3 **Classification:** Accepted
Names: 116-DR-3; 105-DR Storage Basin Trench **Reclassification:** None
Type: Trench **Start Date:** 1/1/1955
Status: Inactive **End Date:** 1/1/1955

Description: The site appears as a vegetation-free, cobble and soil-covered field within a larger area bounded

by permanent concrete markers posted with Underground Radioactive Material warning signs. The trench is approximately 15 meters (50 feet) long.

Location: The trench is located directly south of the 105-DR Building, outside the exclusion fence. The site is 45.7 meters (150 feet) east of the 117-DR Reactor Exhaust Filter Building.

Process Description: Water and sludge were pumped through an overground line from the fuel storage basin to the trench. The trench was backfilled as soon as practical to avoid contamination spreads.

Waste Type: Sludge

Waste Description: The site received contaminated sludge and water removed from 105-DR Fuel Storage Basin.

Code: 116-DR-4

Classification: Accepted

Names: 116-DR-4; 105-DR Pluto Crib

Reclassification: Interim Closed Out (10/23/2000)

Type: Crib

Start Date: 1/1/1950

Status: Inactive

End Date: 1/1/1956

Description: The crib has been remediated and closed out. It is no longer marked or posted.

Location: The crib was located approximately 61 meters (200 feet) southeast of the 105-DR Building and northeast of 116-DR-3.

Waste Type: Process Effluent

Waste Description: The site received liquid wastes from isolated tubes containing ruptured fuel elements in the 105-DR Fuel Storage Basin. The site may have also received excess "ink" (liquid boron solution) used in the 3X safety system.

Closure Info: The cleanup verification package (CVP-2000-00015) has documented that the 116-DR-4 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Amendment to the Interim Action Record of Decision (ROD) (EPA 1997). Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).

Remedial action at the 116-DR-4 site began on November 5, 1999. On November 8, 1999, the excavation reached the design limit at El. 138.2 meters (453.3 feet). A plume of contamination was detected and excavated, resulting in an excavation 0.7 meters (2.3 feet) deeper than originally planned. The final excavation elevation was El. 137.5 meters (451 feet); the final excavation was completed on January 3, 2000.

The contaminants of concern for the site are cesium-137, cobalt-60, europium-152, strontium-90, and hexavalent chromium.

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 237.9 square meters (2,560 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 523 metric tons (575 tons) of contaminated material were disposed at ERDF. Cleanup verification sampling was conducted on January 17, 2000. The excavation will be backfilled in the near future (as of October 2000) with appropriate materials to the reference grade of 142 meters (466 feet).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that

IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	116-DR-6	Classification:	Accepted
Names:	116-DR-6; 1608-DR Liquid Disposal Trench; Wash Pad Liquid Waste Site 3C	Reclassification:	Interim Closed Out (10/23/2000)
Type:	Trench	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been remediated and was closed out on October 23, 2000. It is no longer marked or posted.		
Location:	The 116-DR-6 Liquid Disposal Trench was located approximately 37 meters (120 feet) east of 100-DR Reactor and approximately 1,120 meters (3,670 feet) from the Columbia River.		
Process Description:	The 116-DR-6 Trench received DR Reactor cooling water effluent during upgrade of the reactor emergency shutdown system (Ball 3X upgrade). During reactor shutdown, the trench also received water during maintenance of the cooling water effluent system. In addition, decontamination effluents from the DR fuel storage decontamination pad were routed into the trench. The trench received an estimated 7 million liters (26.5 million gallons) of liquid during its use between 1953 and 1965. The 116-DR-6 Trench has also been described as a crib (subsurface trench) that would sometimes receive effluent volumes great enough to cause seepage to the surface with drainage across the ground surface to the east. Aerial photographs from the period of trench operation (1953-1965) do not indicate the presence of an open trench in the 116 DR-6 site area. Upon closure in 1965, the area of the 116-DR-6 Trench was covered with about 1.8 meters (6 feet) of soil.		
Waste Type:	Process Effluent		
Waste Description:	The site received diverted coolant during the Ball 3X upgrade. It also received diverted water when maintenance was necessary on the effluent system during a reactor shutdown. It is reported that the volume of liquids disposed of at this unit would cause it to overflow, and a solvent odor was present at the site on very hot days.		
Closure Info:	The site remediation was performed in accordance with the Amendment to the Interim Action Record of Decision (ROD) (EPA 1997). The ROD provides the U.S. Department of Energy, Richland Operations Office (RL) the authority and guidelines to conduct this remedial action at the site. The preferred remedy specified in the ROD is excavation and disposal of contaminated materials at the Environmental Restoration Disposal Facility (ERDF). The Remedial Action Objectives (RAOs) were established in the Interim Action ROD (EPA 1995) and are summarized in the Cleanup Verification Package (CVP) along with the corresponding Remedial Action Goals (RAGs). Methods to attain the RAOs are presented in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17) and are discussed in further detail in the 100 Area Remedial Action Sampling and Analysis Plan (SAP). Waste site contaminants of concern (COCs) identified through process knowledge are listed in the SAP. The COCs for this site consist of the following: uranium-238, strontium-90, cesium-137, cobalt-60, europium-152, europium-154, and hexavalent chromium.		

Remedial action at the 116-DR-6 site began in November 2, 1999. Excavation of the site involved removing the overburden materials, the contaminated structure, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Materials that were found to be contaminated were disposed of at the ERDF. The excavation design floor elevation was 138.5

meters (454 feet), but because field screening at that depth indicated the presence of radionuclides above the RAGs, an additional meter of soil was removed from the bottom of excavation. The final floor elevation was 137.5 meters (451 feet).

At the completion of remedial action and removal of the engineered structure, the excavation was approximately 485 square meters (5,218 square feet) in area with a maximum depth of approximately 4.8 meters (16 feet). Approximately 2,140 metric tons (2,354 tons) of material from the site were disposed of at the ERDF. Cleanup verification sampling was conducted on February 1, 2000.

The CVP demonstrated that remedial action at the 116-DR-6 site has achieved the RAOs and corresponding RAGs established in the approved amendment to the interim action ROD and the RDR/RAWP. Materials from the 116-DR-6 site have been excavated and handled in accordance with the RDR/RAWP. The remaining soils have been sampled and analyzed to show that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 116-DR-6 site has been verified to be remediated in accordance with the ROD.

Code:	116-DR-7	Classification:	Accepted
Names:	116-DR-7; 105-DR Inkwell Crib	Reclassification:	Interim Closed Out (9/26/2000)
Type:	Crib	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1953
Description:	The site was remediated in December 1999 by removing the structure and associated contaminated soil. As of September 2000, the excavation was still open, but is to be backfilled in the near future to a reference grade of elevation 142.0 meters (466 feet).		
Location:	The site is located south of the 105-DR Building and is approximately 1,100 m (3,609 ft) from the Columbia River. The site was marked by a single concrete marker and was adjacent to a concrete pad that once supported a storage building.		
Process Description:	The crib was used to receive the liquid potassium borate solution (called "ink" because it resembles printers ink in color and viscosity) that was drained from the 3X system prior to the Ball 3X system upgrade.		
Waste Type:	Process Effluent		
Waste Description:	Liquid potassium borate solution was drained from the 3X System prior to the Ball 3X System upgrade.		
Closure Info:	The cleanup verification package (CVP-2000-00019) has documented that the 116-DR-7 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-1, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17). 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).		

The contaminants of concern (COCs) identified through process knowledge and listed in the

100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22) were: cobalt-60, cesium-137, europium-152, europium-154, strontium-90, uranium-233/234, and uranium-238. Potassium borate, which was disposed of at the 116-DR-7 site, was discounted as a COC since potassium borate is not carcinogenic, hazardous, nor toxic.

Remedial action of this site began on December 7, 1999, and ended on December 8, 1999. Approximately 59 metric tons (65 tons) of material were disposed at the Environmental Restoration Disposal Facility (ERDF). The excavation reached a final depth of 4.6 meters (15 feet) [at an elevation of 137.2 meters (450 feet)], and had an area of approximately 250.6 square meters (2,697 square feet).

Cleanup verification sampling began and finished on January 21, 2000. Twenty-four variance samples were taken; plus four final verification samples (and an additional three QA/QC samples) were taken and analyzed. All variance data indicated that contaminant levels were below the direct exposure RAGs.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	116-DR-8	Classification:	Accepted
Names:	116-DR-8; 117-DR Crib; 117-DR Seal Pit Crib (CERCLA)	Reclassification:	Interim Closed Out (9/20/2010)
Type:	Crib	Start Date:	1/1/1960
Status:	Inactive	End Date:	1/1/1964
Description:	The 117-DR Seal Pit Crib is documented in WIDS as two separate sites. The first site, 122-DR-1:6, which is part of the Large Sodium Fire Facility, a RCRA TSD, and has been closed for hazardous/dangerous constituents. The second site, 116-DR-8, which represents the radioactive constituents remaining at the site will be addressed under CERCLA. Note: this information on the pipeline in the Current Site Description was entered on March 14, 2001. If the remedial design has already been completed for this site and it does not include the feed pipeline, the pipeline will be added to another pipeline site for remediation.		
Location:	The unit is located south of the exclusion area fence and directly east of the 118-DR-1 Burial Ground.		
Related Sites/Structures:	The site received effluent from the 117-DR HEPA Filter Building seal pits and wash water from the 105-DR Large Sodium Fire Facility.		
Waste Type:	Process Effluent		
Waste Description:	The site received drainage from the 117-DR Building seal pits.		
Closure Info:	The Remaining Sites Verification Package (RSVP-2009-037) for 116-DR-8 has documented that the site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGS) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17, Rev. 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999).		

The contaminants of potential concern (COPCs) for confirmatory sampling of the 116-DR-8 waste site were identified based on existing historical information, process knowledge of the 105-DR Reactor, and the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL-96-22, Rev. 4). These COPCs included carbon-14, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, strontium-90, uranium-234, uranium-235, uranium-238, hexavalent chromium, mercury, lead, lithium, polychlorinated biphenyls (PCBs), semivolatile organic compounds (SVOCs), and volatile organic compounds (VOCs).

Remedial action at the 116-DR-8 waste site was performed from June 18 through July 24, 2008. Approximately 3,056 bank cubic meters (BCM) (3,997 bank cubic yards [BCY]) of soil overlying the crib was removed and stockpiled as overburden for potential use as clean backfill. The depth of overburden was determined using confirmatory sampling information and construction history for the crib. The site was then further excavated to a depth of approximately 6.8 m (22 ft) below grade resulting in approximately 1,991 BCM (2,604 BCY) of material that was directly loaded out and disposed at the Environmental Restoration Disposal Facility (ERDF). Portions of the 100-D-50:8 and 100-D-50:10 pipelines among others were encountered during remediation.

Verification sampling was conducted May 19 through 26, 2009 to support a determination that residual contaminant concentrations at this site meet the cleanup criteria specified in the 100 Area RDR/RAWP and the Remaining Sites ROD. The verification sample results were provided in Appendix D of the RSVP. The laboratory-reported verification data results for all constituents are stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as Attachment 1 of the 95% UCL calculation in Appendix D of the RSVP.

Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	116-DR-10	Classification:	Accepted
Names:	116-DR-10; 105-DR Fuel Storage Basin Cleanout Percolation; 105-DR Fuel Storage Discharge Pond; 105-DR Pond	Reclassification:	Interim Closed Out (12/28/2010)
Type:	Pond	Start Date:	1/1/1984
Status:	Inactive	End Date:	1/1/1984
Description:	Prior to remediation the unit was an open excavated pit located in a natural depression. The excavation has been backfilled and graded to match the natural terrain. The original natural depression remains.		
Location:	The site is located east and slightly south of the 105-DR Reactor Building, just outside the HPS AC-5-40 permanent markers.		
Process Description:	It consisted of an open pit that was excavated in a natural depression and used for disposal of processed water from the 105-DR Fuel Storage Basin cleanout during October and November 1984. The water had been used in the bottom of the fuel storage basin for the process of storing irradiated reactor fuel elements. The processed water was filtered to remove particulate, run through ion-exchange columns to remove colloidal material, and then held in 76,000-L (20,000-gal) batch tanks until sampling verified that radiological release criteria had been met. However, minute quantities of radionuclides remained in the processed water and presented the potential for accumulation of radionuclides at the bottom of the pond. The pit was 24.4 m (80 ft) long and 15.2 m (50 ft) wide with an area of 371.6 m ² (4,000 ft ²). The bottom of the pit was irregular with an average depth of 1.8 to 2.4 m (6 to 8 ft) (Beckstrom 1987).		

Related Sites/ Structures: The site is associated with the 105-DR Fuel Storage Basin.

Waste Type: Water

Waste Description: The unit received processed water from the 105-DR Fuel Storage Basin. During the cleanout of this basin, the radiologically contaminated shielding water was processed through a system using ion exchange columns. Before discharging the water to the unit, composite samples were taken to ensure that radionuclide concentrations were below release criteria in Table II of DOE Order 5480.1. Although the water was cleaned to applicable release limits, minute quantities (below release limits) of radionuclides remaining in the water accumulated in the soil at some low points in the floor. No known hazardous substances were present in the water; however, chemical analysis was not a standard practice during that period, and there is no evidence that one was performed. It should be noted that water removed from the 1608-DR is believed to be comparable to the storage basin water, and EP-TOX testing results for the 1608-DR water were negative.

Closure Info: The Remaining Sites Verification Package for the 116-DR-10 (Attachment to Waste Site Reclassification Form 2010-015), has documented that the waste site verification sampling results support reclassification of the site to Interim Closed Out. The current site condition has met the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA, 1999.)

Remedial activities at the 116-DR-10 waste site began on November 11, 2008, and concluded on January 7, 2009. The depth ranged from 2.7 m (9 ft) to 4 m (13 ft), resulting in approximately 6,000 bank cubic meters (BCM) (7,847 bank cubic yards [BCY]) of soil being removed to the Environmental Restoration Disposal Facility. Approximately 2,462 BCM (3,220 BCY) of overburden material was stockpiled adjacent to the site.

The historical information provided in Beckstrom (1987) was used to develop a remediation strategy for the percolation pond. Since the bottom of the pond ranged from 1.8 to 2.4 m (6 to 8 ft) below surface grade and was then later backfilled to the local terrain, the remediation strategy consisted of removing the surface soil at the site to a depth of approximately 1.2 m (4 ft) and stockpiling it at the site as overburden soil. The soil from 1.2 m (4 ft) to a depth of approximately 2.7 m (9 ft) was to be excavated and direct loaded for disposal to the Environmental Restoration Disposal Facility (ERDF) since it delimited the original bottom of the pond that was reported as having residual radiological contamination.

The contaminants of potential concern (COPCs) for verification sampling of the 116-DR-10 waste site were identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL96-22, Rev. 5). These COPCs included americium-241, carbon-14, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, nickel-63, plutonium-238, plutonium-239/240, strontium-90, uranium-234, uranium-235, uranium-238, lead, mercury, and polychlorinated biphenyls (PCBs). Although not considered COPCs, antimony, arsenic, barium, beryllium, boron, cadmium, chromium (total), cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc were evaluated by performing analyses for the constituents of the expanded inductively coupled plasma (ICP) metals list. In addition, hexavalent chromium was included as a COPC.

Verification sampling was conducted on January 25 and February 3, 2010, to support a determination that residual contaminant concentrations in the soil met cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD. A statistical sampling design was used to collect verification soil samples from the excavation and the overburden soil stockpile to

support closeout of the waste site. The complete laboratory results were stored in the ENvironmental REstoration (ENRE) project-specific database prior to submitting to the Hanford Environmental Information System (HEIS) for archiving and were provided in Appendix B of the RSVP.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. This site did not extend into the deep zone; therefore, no deep zone institutional controls are required.

Code:	118-DR-1	Classification:	Accepted
Names:	118-DR-1; 105-DR Gas Loop Burial Ground	Reclassification:	Interim Closed Out (6/10/2010)
Type:	Burial Ground	Start Date:	1/1/1963
Status:	Inactive	End Date:	1/1/1964

Description: The site contains a gunite-lined trench running north and south that was water-filled and used for the sectioning and examinations performed on test assemblies removed from the 105-DR Reactor.

Location: The unit was located 183 m (600 ft) south of the 105-DR Building.

Process Description: This site was a test loop burial ground and received about 20 cubic meters (26 cubic yards) of irradiated stainless steel assemblies. It was originally a gunite-lined trench used to perform examination and sectioning of test assemblies, and later received irradiated metal assemblies from the 105-DR gas loop.

Waste Type: Equipment

Waste Description: This unit contains irradiated metal assemblies from the 105-DR Gas Loop.

Closure Info: The Cleanup Verification Package, CVP-2009-00010, has documented that remedial action at the 118-DR-1, 105-DR Gas Loop Burial Ground site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, (Burial Grounds ROD).

Remedial action at the 118-DR-1 Burial Ground began on June 3, 2008, and continued through July 23, 2008. Approximately 1,673 bank cubic meters (BCM) (2,188 bank cubic yards [BCY]) of soil and debris was removed for disposal at ERDF. Approximately 221 BCM (290 BCY) of clean soil was removed from outside of the burial ground excavation footprint and stockpiled west of the burial ground excavation. The soil was removed during construction of a ramp into the excavation, allowing the excavator equipment access to continue to remove soil and debris at a greater depth. The ramp soil stockpile is not considered overburden; therefore, it was not included in the closeout sample design. This material will be used as backfill material during general backfill of the site.

One anomalous waste item was encountered in the 118-DR-1 Burial Ground. A breached 208-L (55-gal) drum suspected of containing an undetermined amount of liquid was removed from the sidewall of the excavation. The drum, along with the soil directly below the drum, was placed on a plastic sheet within the burial ground footprint for waste characterization sampling. However, the drum was found to be empty so the soil that was removed with the drum was

sampled for waste characterization.

No spent nuclear fuel was discovered at the 118-DR-1 Burial Ground.

The 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (Burial Grounds SAP identified contaminants of concern (COCs) for the 118-DR-1 Burial Ground as cobalt-60 and nickel-63. Cesium-137, lead, and mercury were detected in the waste characterization soil sample and therefore were included as contaminants of potential concern (COPCs). Due to a site-wide effort to identify the source of chromium contamination in the groundwater, hexavalent chromium was added as a COPC.

In addition to the COCs/COPCs listed above, polychlorinated biphenyls, pesticides, and polyaromatic hydrocarbons were included as COPCs for the focused sample location where the breached drum was found within the excavation.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as part of the 95% UCL calculation in Appendix B of the CVP. The remaining soils have been sampled, analyzed, and modeled. The results of this effort indicated that the materials from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed at ERDF.

These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The excavation area had a maximum depth of approximately 6 m (20 ft), which included both shallow zone and deep zone soils. However, the entire excavation area was considered one decision unit and will be closed out using the more restrictive shallow zone cleanup criteria; therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required. The site is verified to be remediated in accordance with the Burial Grounds ROD.

Code: 126-DR-1	Classification: Accepted
Names: 126-DR-1; 190-DR Clearwell Tank Pit; 100-DR Clearwells	Reclassification: Interim Closed Out (4/23/2009)
Type: Dumping Area	Start Date: 1/1/1975
Status: Inactive	End Date:
Description:	The site has been remediated and interim closed out. The unit is an excavated area between the 183-DR and 190-DR that contained four 1.42E+07 liter (3.75E+06-gallon) steel water storage tanks. The four tanks were removed, but the concrete slab foundations remained. In the northwest section of the pit, approximately 25% of the concrete slab area contained a layer of waste 1.5 to 3 meter (5 to 10 feet) deep that is covered with pit run backfill. The southern section was posted as an asbestos area.
Location:	The unit is located directly east of the site of the demolished 183-DR Water Treatment Facility and west of the demolished 190-DR building. It is west-southwest of the 105-DR Reactor Building.
Process Description:	The tanks were constructed in 1950 and operated until 1964 when the 105-DR Reactor was deactivated. The tanks were most likely dismantled by a salvage operator between 1978 and 1979 when all salvageable material was removed from the 190-D Main Pump Room. After the tanks were removed, the area was used as a dump site for D&D rubble. This site was also suspected of containing hazardous materials, including low-level radioactive waste because of uncontrolled dumping. Other waste that has been observed include paint and solvent cans, oil

drums, sodium dichromate crystals, alum, creosote drums, herbicide cans, carbon tetrachloride containers, methanol containers, acetone containers, welding materials, laboratory glassware, furniture, and other solid wastes. The site may contain chromates in both the soil and underground piping because of the use of chromates in water treatment.

**Related Sites/
Structures:** The unit is associated with the 183-DR Water Treatment Facility and the 190-DR Main Pump House. Both of these facilities were involved in providing primary coolant water for the 105-DR Reactor.

Waste Type: Misc. Trash and Debris

**Waste
Description:** The unit contains demolition and inert waste from demolished facilities, including rubble from released portions of the 115-D/DR, and some rubble from 183-DR. In 1989, small amounts of friable asbestos were found scattered throughout the southern sector. The asbestos is believed to be the result of salvage operations during the 1970's. This site may contain chromates in both the soil and underground piping as a result of its association with water treatment. Because of this potential, it is closed to waste disposal. There is potential for chemical and radioactive contamination similar to that found in the 126-D-2 Burial Ground as uncontrolled dumping reportedly occurred at the site, but it is thought to be in much smaller volumes. Potential contaminants include: Chromate, lead, undetermined organic and inorganic chemicals

Closure Info: The Remaining Sites Verification Package for the 126-DR-1 (RSVP-2008-046) waste site evaluation and supporting documentation has demonstrated that the site meets the remedial action objectives (RAOs) specified in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, 100-KR-2, Operable Units,(100 Area Burial Grounds ROD). The site consisted of debris disposed in the 190-DR clearwell pit. All waste has been removed to the lower boundary of the waste site; and underlying concrete and soil will be removed as part of future remediation of the 100-D-50:6 waste site. The sidewalls of the waste site will be sampled, based on the sample results the soil will be remediated as necessary,

Field work to remediate the site commenced on April 5, 2007, by demarking the excavation boundary. The site was prepared by leveling the surface and constructing a soil berm around the open face of the waste pile. The soil berm was built to prevent the spread of contamination by rainwater and/or dust suppression water during excavation of the waste.

An excavator was the primary piece of equipment used for excavation, sorting, segregation, and load out of waste material. The excavated material was directly loaded into roll-off boxes. Remediation of the waste site concluded on July 24, 2008, after 23,790 metric tons (26,230 U.S. tons) were removed, transported, and disposed at Environmental Restoration Disposal Facility (ERDF). A radiation detector, on the arm of the backhoe, was used during excavation of this waste site and there was no evidence of radiation during the excavation.

The majority of waste was described as construction and demolition debris including concrete rubble, rebar, soil, and rocks. The debris also contained pipe insulation, suspected to contain asbestos; cans of dry paint; empty drums; welding material; laboratory glassware; steel beams; empty process tanks; electrical panels and fuses; actuators; empty cylinders; and structural steel, piping, valves, and duct work. There was no low-level radioactive waste; sodium dichromate crystals; alum; or containers of creosote, herbicide, carbon tetrachloride, or methanol discovered, as stated in the 100 Area Burial Ground ROD. A number of anomalous waste items were identified, characterized, and disposed during the project. The analytical data associated with these items are included in Appendix A of the RSVP. All but one of these items was determined to be inert debris and required no additional treatment prior to disposal at ERDF. The single exception was the discovery of three drums filled with white granular material on June 21, 2007. After treating, the material was spread out in small batches, neutralized with water, then mixed with soil and loaded into a roll-off box. The treated material was sampled

(J16VK2) and analyzed prior to disposal at ERDF.

No institutional controls are required for the 126-DR-1 waste site; potential institutional controls for underlying waste sites will be evaluated as part of reclassification of those sites.

Code:	132-DR-1	Classification:	Accepted
Names:	132-DR-1; 1608-DR Effluent Pumping Station; 1608-DR Waste Water Pumping Station	Reclassification:	Interim Closed Out (9/22/2005)
Type:	Pump Station	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1964

Description: The site has been remediated and interim closed out. The unit consisted of: 1) an above ground section constructed of concrete block walls, a reinforced concrete floor, and a reinforced concrete roof with a composition surface; 2) a below-grade section constructed of reinforced concrete. The facility contained an operating level, which consisted of pumping equipment, and an accumulation inlet chamber, in the northern section, which fed three discharge sump chambers.

Location: The unit was located adjacent to the northeast corner of the 105-DR Reactor Building within the 105-D/DR Exclusion Area Fence.

Process Description: The facility contained three sumps to collect radioactively contaminated liquid wastes from the 105-DR Reactor Building. The liquid wastes were collected in the sumps for final disposal by pumping to the 107-D/DR Retention Basin via a 41 centimeters (16 inches) diameter pipe. The facility extended 3.7 meters (12 feet) above grade and 9.8 meters (32 feet) below grade and was 11 meters (36 feet) in length and 10.4 meters (34 feet) in width.

Related Sites/ Structures: The site received effluent from the 105-DR Reactor Building (118-DR-2).

Waste Type: Water

Waste Description: This site received water from reactor building drains containing trace amounts of low-level radionuclides and decontamination chemicals. Radionuclides were primarily miscellaneous fission and activation products. The decontamination chemicals consisted of sodium fluoride, oxalic acid, and citric acid. Water was pumped from the reactor collection pits into the reactor effluent lines near the reactor building and became part of the 107-DR effluent that was discharged to the Columbia River.

Closure Info: The closure report "Remaining Sites Verification Package, (RSVP 2005-035), demonstrated that the 132-DR-1 site has met the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington.

Prior to demolition in 1987 samples of sludge from the sumps were taken and sent to the Pacific Northwest National Laboratory for analysis. The sludge was designated based on the equivalent concentration of various possible toxic compounds in the sludge. Equivalent concentrations were derived by making "worst-case" assumptions about the form of the various cations in the waste. The sludge did not designate as a hazardous waste. However, the concentrations of lead and phosphate were used to calculate a concentration of lead phosphate (7,300 ppm) that resulted in designating the sludge as a state-only toxic dangerous waste (i.e., extremely hazardous waste) according to Washington State regulations (WAC 173-303). The sludge was also radioactive, giving it the classification of radioactive mixed waste.

The concrete and rust/scale samples were analyzed at the Decommissioning Health Physics Laboratory in the 183-KE Building and by the Pacific Northwest National Laboratory in the Hanford 300 Area. Samples were analyzed for carbon 14, cesium-137, cobalt-60, europium-152, europium-154, tritium, strontium-90, and gross alpha activity. The gross alpha results were assumed to represent plutonium-239.

The sample results were used to support calculation of the residual dose contribution for the demolished 1608-DR Effluent Pumping Station in accordance with U.S. Department of Energy guidelines and Allowable Residual Contamination Levels for Decommissioning Facilities on the Hanford Site. The allowable residual contamination level (ARCL) calculation indicated that the demolished facility would contribute less than 1 millirem/year dose to a hypothetical, maximally exposed site resident if the site was released for unrestricted use after the demolition and burial in situ of the facility.

At the time of decommissioning of the 1608-DR facility, the ARCL calculation determined that the site would contribute less than 1 millirem/year to an overall hectare dose rate and, therefore, no further decontamination to reduce the source term was necessary and the facility could be buried in-situ.

The RSVP documentation results show that the site and contaminant levels remaining after the 1987 decommissioning will be protective of direct exposure, groundwater, and the Columbia River. However, the acceptability of unrestricted direct exposure to below-grade structure surfaces in the deep zone has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required.

Code: 600-30	Classification: Accepted
Names: 600-30; 100-DR Construction Lay-down Area	Reclassification: Interim Closed Out (8/10/2011)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:
Description:	The unit is a 4 hectare (10 acre) site covered with scattered construction related debris. Vegetation at the site includes grasses and rabbit brush. There are numerous areas that show signs of plant stress ranging from reduced to no vegetation. There is also evidence of burning throughout the unit.
Location:	The west edge of the site is located approximately 420 meters (1378 feet) east of the junction of Route 2 North and Route 4 North. The northern edge of the site is approximately 12 meters (39 feet) south of Route 2 North. The western edge of the site lies east of a north-south line with the cross country transmission line leading from the 151-D Substation.
Process Description:	Based on physical and photograph evidence, it appears to have been a lay-down yard during construction of 105-DR.
Waste Type:	Construction Debris
Waste Description:	Waste consists of broken sheet asbestos, buckets of tar, steel, galvanized pipe, rebar, angle iron, deteriorated keg of nails, burned and crushed drums, steel plate, chain, wire rope, bolts, metal hinges, shovels, gas and oil cans, welding rod cans, evidence of concrete blocks, metal tubing, and broken shipping boxes.
Closure Info:	Initial remediation was performed in October and November 2008 (WCH 2009a). Remediation consisted of scraping 0.5 to 1 m (1.6 to 3.3 ft) of soil and debris into piles that were then loaded into Environmental Restoration Disposal Facility (ERDF) containers. Scraping removed the surface debris at the site. At two locations the excavation extended to 1.5 m (4.9 ft) deep to

remove additional sub-surface material.

Additional materials discovered during remediation included lead acid batteries and a suspected fire extinguisher (WCH 2009a). The batteries stacked in two shallow pits were hand removed from the ground, drummed and then disposed at ERDF. There was no indication that the fire extinguisher had leaked hazardous material to the ground, therefore, it was disposed using anomalous media procedures. No other items were discovered during remediation that were considered anomalous. Approximately 7,400 bank cubic meters (BCM) (9,679 bank cubic yards [BCY]) of material were removed and disposed at ERDF.

Following initial remediation, verification sampling performed in August 2009 found a sample result that exceeded the direct exposure RAG for lead at 2,770 mg/kg. A walkdown of the area determined that lead acid debris was widespread. The recommended path forward was to remediate a 45.7- by 6.1- by 0.6-m (150- by 20- by 2-ft) area, combining the rectangular area and a circular area.

Additional remediation was performed in February and March 2011, which involved scraping 0.5 to 1 m (1.6 to 3.3 ft) of soil and debris across the northern boundary of the waste site (area 1) and the lead-contaminated area associated with sample locations F-5 and F-6 (area 2). Approximately 3,500 additional BCM (4,578 BCY) of soil was removed for disposal at ERDF.

100-FR-1

Code: 141-C **Classification:** Accepted
Names: 141-C; 141-C Animal Barn; Hog Barn; 100-F **Reclassification:** Interim Closed Out (5/24/2006)
Experimental Animal Farm Large Animal Barn &
Biology Laboratory
Type: Laboratory **Start Date:** 1/1/1945
Status: Inactive **End Date:** 1/1/1976

Description: After the site was remediated, the verification sampling results supported a reclassification to interim closed out.

The 141-C Building provided facilities for the long-term housing and care of research animals associated with the Experimental Animal Farm.

Location: The site was located in the 100-F Experimental Animal Farm area, west of 132-F-2 (144-F Inhalation Laboratory), west of the north end of 107-F Retention Basin, and approximately 500 meters (1640 feet) northeast of the 105-F Reactor Building.

Process Description: A portion of the radiobiological experiments carried out at 100-F Experimental Animal Farm Area involved the use of large animals. The 141-C Building provided facilities for the long-term housing and care of these research animals. The building was a single L-shaped structure with each wing measuring 35.4 meters (116 feet) by 6.1 meters (20 feet) wide by 2.4 meters (8 feet) high. It was a Butler-type building of all-steel construction and was set on a concrete pad. The animal stalls were of steel construction and each was equipped with feeding and watering facilities. A common drainage trench served all of the stalls. The 141-C Building included a dry well at its southwest corner that drained a loading dock at the facility's southwest end. It was likely that this dry well received only storm water runoff, but it may have been contaminated by wash water containing radioactive animal waste.

Waste Type: Water

Waste Description: Wash down water may have included the radionuclides used in the animal studies (iodine-131, strontium-90, cesium-137, and plutonium-239).

Closure Info: The Remaining Sites Verification Package 2006-017 has documented that the current site condition has achieved the remedial action objectives and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999).

Prior to remediation it was determined that the primary isotopes used during experimentation were iodine-131, strontium-90, cesium-137, ruthenium-106, and plutonium-239. Strontium-90 was detected above the direct exposure dose-equivalence lookup value in the confirmatory samples. Arsenic and multiple polycyclic aromatic hydrocarbons (PAHs) were detected above direct exposure remedial action goals (RAGs) and soil RAGs for groundwater and/or river protection. Additional metals and PAHs were also detected above soil RAGs for groundwater and/or river protection.

Based on the confirmatory sample results, remediation of the waste site consisted of the removal of soil and debris within the building footprint to a depth of approximately 1 meter (3 feet). Because arsenic, strontium-90, and multiple PAHs were detected above direct exposure RAGs in confirmatory sampling results, approximately 900 bank cubic meters (1,200 bank cubic yards) of soil and debris was excavated and staged onsite before disposal at the

Environmental Restoration Disposal Facility (ERDF).

Exploratory trenches were excavated during remedial action efforts to confirm that the sewer lines formerly servicing the Building were removed during previous decommissioning and demolition activities. No sewer lines were located by these excavations, and field instrumentation did not detect any beta-gamma or alpha activity above background levels.

Following site remediation, verification soil sampling within the remediation footprint and remediation waste staging pile footprint was conducted on January 30, 2006. Verification samples (J112WO through J112W9 and J112X0 through J112X2X) were analyzed using analytical methods approved by the U.S. Environmental Protection Agency, and the results were compared against the cleanup criteria specified in the RDR/RAWP. The sample results were stored in the Environmental Restoration (ENRE) project-specific database prior to archiving in the Hanford Environmental Information System (HEIS) and are provided in Appendix A of RSVP-2006-027.

The results indicated that the waste removal action achieved compliance with the remedial action objectives for the waste site. Residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). A summary of the cleanup evaluation for the soil results against the applicable criteria was presented in Table ES-1 of the RSVP-2006-027. Based on statistical evaluation of the resulting data, the residual contaminant concentrations meet the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD (EPA 1999). This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-F-4	Classification:	Accepted
Names:	100-F-4; 108-F Building 12-Inch French Drain	Reclassification:	Interim Closed Out (7/25/2002)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and closed out. The french drain was constructed of 30-centimeter (12-inch) vitrified clay pipe, or similar material and was filled with gravel. A 1.3-centimeter (0.5-inch) steel pipe entered the drain from the 108-F Building. The drain was visible on Hanford photograph 106669-90-CN. Documentation suggests that the drain was likely removed as part of the layback zone of the 108-F Building excavation.		
Location:	The site was located adjacent to the southwest wall of the 108-F Building, just west of the building's southwest corner.		
Related Sites/ Structures:	The site served as a french drain for the 108-F building (site 100-F-36).		
Waste Type:	Water		
Waste Description:	The types and quantities of waste the unit received are unknown.		
Closure Info:	100-F-4, 100-F-11, 100-F-15 and 100-F-16 were addressed as a group. The information below documents information for the group of sites.		
	The cleanup verification package (CVP-2002-00001) has documented that the site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17).		

The COCs for this site consisted of the following: total chromium, hexavalent chromium, plutonium-238 and plutonium-239/240 as listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).

A cleanup verification sampling strategy was developed for the site based on the SAP and was approved in a status meeting by the U.S. Environmental Protection Agency. Because the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains were removed during decommissioning and demolition activities and backfilled with clean material, variance sampling was eliminated and cleanup verification samples were collected. The 100-F-15 french drain was sampled as per the SAP. The 100-F-4, 100-F-11, and 100-F-16 french drains were considered analogous to the 100-F-15 french drain and were verified as clean by excavating and sampling a test pit at each location.

Site excavation was completed as reported in the 108-F Biological Laboratory D&D Project Closeout Report. The CVP report documents that the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 362.2 meters squared (3898.7 square feet) in area with a depth of 4.6 meters (15.0 feet). No material from the sites was disposed of at the Environmental Restoration Disposal Facility as a result of the Remedial Action Project activities described here. Verified clean materials were used as backfill at the completion of the remedial action.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	100-F-7	Classification:	Accepted
Names:	100-F-7; Underground Fuel Tank - 1705-F Building	Reclassification:	No Action (2/15/2005)
Type:	Storage Tank	Start Date:	1/1/1948
Status:	Inactive	End Date:	
Description:	The site is not distinguishable from the surrounding terrain of vegetation and scattered rocks and has been reclassified to No Action.		
Location:	The site was located north-northwest of the northwest corner of the 107-F Retention Basin fence and north-northeast of the northeast corner of 108-F Building.		
Process Description:	The site was an underground fuel tank that supplied the oil furnace in the 1705-F Building Heater Room. The building has been decommissioned and demolished. Debris and asphalt are strewn about the area. The tank's presence could not be confirmed with a metal detector due to multiple underground magnetic anomalies in the area. During an April 1999 visit, a survey grade GPS was used to locate the site based on its mapped coordinates. No evidence of the site could be found at this point.		
Related Sites/ Structures:	The tank supplied the oil furnace in the 1705-F Building heater room.		
Closure Info:	The site consisted of an underground fuel tank that supplied the oil furnace in the 1705-F		

Building heater room. The tank was installed in 1948 and had a capacity of 3,800 Liters (1,000 gallons). When the 1705-F Building and surrounding facilities were demolished in 1975, no mention was made to indicate the tank was also removed. The presence of the tank could not be confirmed during various site walkdowns or Geophysical surveys.

A site evaluation conducted as part of the Remaining Sites Verification Package attached to the Reclassification Form 2004-124 through field observations and focused sampling and analysis to assess the presence of contaminated media and to determine if the underground fuel tank was still present. One test pit was excavated at the center of the suspected underground fuel tank location, to a depth of 2.4 meters (8 feet), where native soil was encountered. The tank was not present. A soil sample was collected from the bottom of the test pit and submitted for laboratory analysis.

Contaminants of potential concern (COPCs) for the site, as identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL96-22, Rev. 4), include semivolatile organic constituents (SVOCs), total petroleum hydrocarbons, volatile organic constituents (VOCs), arsenic, barium, cadmium, total chromium, lead, selenium, silver, and polychlorinated biphenyls (PCBs). Based on experience with similar sites, mercury was included as a COPC. Detected values of all contaminants of potential concern were below the remedial action goals for direct exposure, groundwater, and river protection. Therefore, no remedial action was required, and the site was reclassified to no action. Confirmatory sample numbers were reported as J01XV3, J01XV4 and J01XV5. The results of the confirmation samples were used to make reclassification decisions for the site in accordance with the TPA-MP-14 (DOE-RL 1998) process.

The RSVP demonstrates that the site meets the objectives for no action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17, Rev. 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (EPA 1999). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-F-9	Classification:	Accepted
Names:	100-F-9; French Drain at East End of 105-F Storage Room (Northeast Corner)	Reclassification:	No Action (2/15/2005)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	No remnants of this french drain have been identified, indicating that it was likely removed during the 105-F Reactor decommissioning project. The site has been reclassified to No Action.		
Location:	The french drain was located adjacent to the northeast corner of the Miscellaneous Storage Room of the 105-F Reactor Building. The Storage Room was the eastern-most portion of the 105-F Reactor Building.		
Related Sites/ Structures:	105-F miscellaneous storage room and the 105-F Reactor.		
Waste Type:	Water		
Waste:			

Description:

Closure Info: Field observations and confirmatory sampling were used to evaluate the site for reclassification. It was believed that the 100-F-9 French Drain received steam condensation via lines from the 105-F miscellaneous storage room building's steam heaters. The storage room facilitated the lunchroom, shower, and locker room and was demolished in 1999 during the 105-F Reactor decommissioning project. Apparently the french drain was removed during that operation.

Focused sampling and analysis were used to determine if the french drain had been removed and if hazardous or radiological contaminants were still present. One test pit was excavated to native soil at the WIDS coordinates for the site. No remnants of the french drain were found, indicating that it was likely removed during the 105-F Reactor decommissioning project.

On September 21, 2004 a soil sample was collected from the bottom of the excavation at the native soil interface. Detected values of all contaminants of potential concern were below remedial action goals, with the exception of mercury. The maximum detected result for mercury of 0.41 milligrams/kilograms was above the groundwater and river protection remedial action goals of 0.33 milligrams/kilograms. However, RESidual RADioactivity model results for analogous sites indicated that mercury will not reach groundwater (and, therefore, the Columbia River) within 1,000 years. Therefore, residual contaminant concentrations achieve the remedial action objectives for groundwater and river protection.

No notable anomalies were detected that would suggest the presence of a french drain. However, french drains usually have a very subtle geophysical signature, and the abundance of disturbed soil and buried debris from the 105-F Reactor D&D activities could hide an intact drain.

The RSVP-2004-125 report demonstrated that the site has met the objectives for reclassification to no action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD). These results have documented that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 100-F-10	Classification: Accepted
Names: 100-F-10; French Drain at East End of 105-F Storage Room (Southeast Corner)	Reclassification: Interim Closed Out (5/6/2004)
Type: French Drain	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed out. The site consisted of a 91-centimeter (36-inch) concrete pipe buried to an unknown depth. The upper surface was a few inches above grade and was cobble-filled. The unit was fed by one or more 2.5-centimeter (1-inch) steel pipes coming from the 105-F Building. Only one pipe was visible. A 1.9-centimeter (0.75-inch) pipe also entered the top of the drain.	
Location: The french drain was outside and adjacent to the southeast corner of the Miscellaneous Storage Room of the 105-F Reactor Building. The Storage Room was the eastern-most portion of the 105-F Reactor Building.	

Waste Type: Water

Waste

Description:

Closure Info: 118-F-8:1, 118-F-8:3 and 100-F-10 were addressed as a group. The information below documents information for the group of sites.

Demolition of the facilities in subsites 1 and 3 began in fiscal year 1998. In 2004 the Cleanup Verification Package (CVP) 2003-00017 documented completion of the removal action and verified the protectiveness of subsites 118-F-8:1 (105-F Reactor Ancillary Support Areas, Below-Grade Structures and Underlying Soils) and 118-F-8:3 (105-F Fuel Storage Basin (FSB) and underlying soils).

Removal action "applicable or relevant and appropriate requirements" (ARARs) and cleanup standards for the 105-F site were established by the U.S. Environmental Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These ARARs and cleanup standards for the subsites were documented in the Action Memorandum.

Removal of below grade structures to a minimum of 0.9 meters (3 feet) below surrounding grade outside of the 105 F Reactor core shield walls, verification that structures and soil left in place achieved specified cleanup standards, and disposal of contaminated excavation materials at the Environmental Restoration Disposal Facility in the 200 Area of the Hanford Site. In some cases, the floors of the below-grade structure (i.e., the valve pit and the solids feed area) or the entire structure (i.e., the FSB) were removed.

The subsite was divided into areas or zones as specified in the 105-F SAP and the FSB SAP according to process history and structure depth. These zones were treated as separate units such that cleanup evaluations were conducted on each individual area or zone. The 118-F-8:3, the underlying soils of the former FSB, was zone 1. The 118-F-8:1 subsite was divided into three zones (zones 2, 3, and 4), and also included the equipment decontamination areas, which were used during 105-F D and ISS activities.

Cleanup verification samples, including QA/QC samples, were collected and analyzed for the established contaminants of concern (COC) from 1999 to December 2003. Components of each zone were summarized, including structure floor depths and contaminants of concern (COCs). Floor depths were below ground surface. COCs were identified through process knowledge and were listed in the 105-F SAP and the FSB SAP. For the following zones 118-F-8:3; Zone 1 - FSB and underlying soils, 118-F-8:1; Zone 2 - Valve pit, and the 118-F-8:1; Equipment Decontamination Areas the COCs were: americium-241, barium-133, carbon-14, cobalt-60, cesium-137, europium-152, europium -154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, technetium-99, uranium-234, uranium-235, uranium 238, hexavalent chromium, barium lead, mercury and PCBs.

For subsites 118-F-8:1; Zone 3 (Gas recirculation tunnel, solids feed area, flow laboratory basement, East water tunnel, trench under accumulator room) and 118-F-8:1; Zone 4, (West inlet water tunnel, east inlet water tunnel, 315 exhaust plenum, 316 exhaust plenum, pipe tunnel, southeast tunnel) the COCs were: americium-241, barium-133, carbon-14, cobalt-60, cesium-137, europium-152, europium -154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, hexavalent chromium and lead.

The CVP-2003-00017 demonstrated that the removal action at the 105-F Reactor subsites 1 and 3 have achieved the objectives established in the Action Memorandum and have achieved the corresponding cleanup standards established in the 105-F SAP, the FSB SAP, and the 100 Area RDR/RAWP.

The remaining soils and concrete at the 105 F Reactor site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 105 F Reactor site containing COCs at concentrations exceeding the cleanup standards have been excavated and disposed of at ERDF. These results also indicated that residual concentrations in the shallow zone will support future land uses. However, the acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 105-F Reactor subsites 1 and 3 are verified to meet protectiveness standards in accordance with the Action Memorandum.

Code: 100-F-11 **Classification:** Accepted
Names: 100-F-11; 108-F Building 18-Inch French Drain **Reclassification:** Interim Closed Out (7/25/2002)
Type: French Drain **Start Date:**
Status: Inactive **End Date:**

Description: The site has been remediated and closed out. The french drain was constructed of 46-centimeter (18-inch) concrete pipe of unknown length. The unit had no cover and was filled with gravel. A 2.5-centimeter (1-inch) steel pipeline entered the drain from the 108-F Building. The drain was visible on Hanford photograph 106669-90-CN. Documentation suggests that the french drain was likely removed with the layback zone of the 108-F Building.

Location: The unit was adjacent to the southwest corner of the 108-F Building.

**Related Sites/
Structures:** This site served as a french drain for the 108-F building (site 100-F-36).

Waste Type: Water
**Waste
Description:**

Closure Info: 100-F-4, 100-F-11, 100-F-15 and 100-F-16 were addressed as a group. The information below documents information for the group of sites.

The cleanup verification package (CVP-2002-00001) has documented that the site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17).

The COCs for this site consisted of the following: total chromium, hexavalent chromium, plutonium-238 and plutonium-239/240 as listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).

A cleanup verification sampling strategy was developed for the site based on the SAP and was approved in a status meeting by the U.S. Environmental Protection Agency. Because the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains were removed during decommissioning and demolition activities and backfilled with clean material, variance sampling was eliminated and cleanup verification samples were collected. The 100-F-15 french drain was sampled as per the SAP. The 100-F-4, 100-F-11, and 100-F-16 french drains were considered analogous to the 100-F-15 french drain and were verified as clean by excavating and sampling a test pit at each location.

Site excavation was completed as reported in the 108-F Biological Laboratory D&D Project Closeout Report. The CVP report documents that the 100-F-4, 100-F-11, 100-F-15, and 100-F-

16 french drains have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 362.2 meters squared (3898.7 square feet) in area with a depth of 4.6 meters (15.0 feet). No material from the sites was disposed of at the Environmental Restoration Disposal Facility as a result of the Remedial Action Project activities described here. Verified clean materials were used as backfill at the completion of the remedial action.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	100-F-12	Classification:	Accepted
Names:	100-F-12; 36-Inch French Drain at 105-F Building	Reclassification:	No Action (2/15/2005)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site is currently a flat, cobble-covered area.		
Location:	The site was located at the northeast corner of the 105-F Reactor Building, adjacent to a steel door marked "Electrical Equipment Room No. 1".		
Process Description:	The site was a French drain, 0.9 meters (3 feet) diameter concrete pipe, buried to an unknown depth. The upper surface of the drain was a few inches above grade and had a steel lid (manhole cover) marked "confined space." The drain was fed by four 19-millimeter (0.75 inch) and one 25-millimeter (1-inch) steel pipes coming from the northeast corner of the 105-F Building. Based on the pipe size it is believed that these pipes may have been steam condensate lines associated with the building's steam heaters.		
Related Sites/ Structures:	The site was associated with the 105-F Reactor Building.		
Waste Type:	Water		
Waste Description:			
Closure Info:	The Remaining Sites Verification Package (RSVP-2004-126) demonstrates that the site meets the objectives for no action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17, Rev . 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (EPA 1999). Based on the pipe sizes of the four 19-millimeter (0.75 inch) and one 25-millimeter (1-inch) steel pipes coming from the northeast corner of the 105-F Building to the drain, it was believed that these pipes may have been steam condensate lines associated with the buildings steam heaters. This portion of the building was removed during the decommissioning and demolition (D) portion of the 105-F Reactor Interim Safe Storage (ISS) Project.		

The contaminants of potential concern (COPCs) were identified based on existing historical information and the drains proximity to the 105-F Reactor Building. Potential contaminants included cobalt-60, cesium-137, europium-152, europium-154, europium 155, plutonium 238,

plutonium-239/240, strontium-90, hexavalent chromium, and lead (DOE/RL-96-22, Rev. 4). As a result of further evaluation of this site, a decision was made to add polychlorinated biphenyls, arsenic, barium, cadmium, total chromium, silver, selenium, and mercury as COPCs. A focused sampling approach (BHI 0100-F-WI-G0006) was designed and implemented for confirmatory sampling of this site on October 11, 2004. Two samples were taken, one from the soil contents and one field duplicate. The samples were taken at a depth of approximately 4.0 meters (13.1 feet) below ground surface. Sample numbers for this site were J01XR3, J01XR4 and J01XR5 and have been reported to HEIS.

The French drain was removed and the site backfilled with clean borrow material on February 23, 2011 (WCH EL-1651, pgs 58 and 59, Email 04262011). The removed material was disposed to ERDF. The results of the confirmatory sampling were used to make reclassification decisions for the site in accordance with the TPA-MP-14 (DOE-RL 1998) process.

The current site conditions have achieved the remedial action objectives and the corresponding remedial action goals. The sampling results also show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-F-16	Classification:	Accepted
Names:	100-F-16; 108-F Building 30-Inch French Drain	Reclassification:	Interim Closed Out (7/25/2002)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and closed out. The french drain was constructed of steel pipe, filled with gravel, and covered with a steel lid. The drain extended 18 centimeters (7 inches) above grade and was 76 centimeters (30 inches) in diameter. Documentation suggests that the drain was likely removed with the layback zone of the 108-F Building excavation.		
Location:	The drain was next to the south wall of the 108-F Building east loading dock, between the gas cylinder storage shed and the loading dock exit stairs.		
Related Sites/ Structures:	This site served as a french drain for the 108-F building (site 100-F-36).		
Waste Type:	Water		
Waste Description:	The dates of operation and type and quantity of waste are unknown.		
Closure Info:	100-F-4, 100-F-11, 100-F-15 and 100-F-16 were addressed as a group. The information below documents information for the group of sites.		

The cleanup verification package (CVP-2002-00001) has documented that the site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17).

The COCs for this site consisted of the following: total chromium, hexavalent chromium, plutonium-238 and plutonium-239/240 as listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).

A cleanup verification sampling strategy was developed for the site based on the SAP and was approved in a status meeting by the U.S. Environmental Protection Agency. Because the 100-F-

4, 100-F-11, 100-F-15, and 100-F-16 french drains were removed during decommissioning and demolition activities and backfilled with clean material, variance sampling was eliminated and cleanup verification samples were collected. The 100-F-15 french drain was sampled as per the SAP. The 100-F-4, 100-F-11, and 100-F-16 french drains were considered analogous to the 100-F-15 french drain and were verified as clean by excavating and sampling a test pit at each location.

Site excavation was completed as reported in the 108-F Biological Laboratory D&D Project Closeout Report. The CVP report documents that the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 362.2 meters squared (3898.7 square feet) in area with a depth of 4.6 meters (15.0 feet). No material from the sites was disposed of at the Environmental Restoration Disposal Facility as a result of the Remedial Action Project activities described here. Verified clean materials were used as backfill at the completion of the remedial action.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	100-F-18	Classification:	Accepted
Names:	100-F-18; 105-F Condensate Drain Field; Underground Tank at 105-F Building	Reclassification:	No Action (2/15/2005)
Type:	Drain/Tile Field	Start Date:	
Status:	Inactive	End Date:	
Description:	The site was demolished during the 105-F Reactor Interim Safe Storage Project.		
Location:	The site was located adjacent to the north wall of the 105-F Reactor supply fan room of the Building, which was the northwest corner of the 105-F Reactor Building.		
Process Description:	The site was not visible at the surface, but was identifiable by a 20-centimeter (8-inch) diameter, 91-centimeter (36-inch) long steel pipe welded to what appeared to be the top of a 91-centimeter (36-inch) diameter steel tank. The upper surface of the "tank" was above grade. Liquid was observed through the steel pipe when the site was investigated for the 100-F Technical Baseline Report.		
Related Sites/ Structures:	118-F-8, 105-F Reactor and Fan Room.		
Waste Type:	Water		
Waste Description:			
Closure Info:	During the reclassification investigations for the Remaining Sites Verification Package (RSVP) (2004-137) a focused sampling design was implemented on October 22, 2004, in accordance with Work Instruction for 100-F-18 Condensate Drain Field and Underground Tank. The site was investigated through field observations and focused sampling and analysis for the purpose of determining if hazardous or radiological contaminants were present.		

One test trench was excavated to explore the location specified in the 2/05/04 Geophysical Survey of a metallic geophysical anomaly. The survey was done to determine if the tank and drain field were present or if they were completely, or partially, removed during decommissioning and demolition activities. No remnants of the tank or drain field were found, indicating that the "tank" and drain field (if present) were likely removed during the 105-F Reactor Interim Safe Storage Project.

The contaminants of potential concern (COPCs) for the site are carbon-14, cobalt 60, cesium-137, europium 152, europium-154, europium-155, tritium, uranium-234, uranium-235, uranium-238, strontium-90, hexavalent chromium, lead, mercury, semivolatile organic compounds, volatile organic compounds, plutonium-238, plutonium-239/240, polychlorinated biphenyls, total petroleum hydrocarbons, arsenic, barium, cadmium, total chromium, silver, and selenium.

The RSVP demonstrated that the site meets the objectives for no action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17, Rev. 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (EPA 1999). This report also shows that site soil contaminant concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future land uses of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-F-19	Classification:	Accepted
Names:	100-F-19; 1904-F Process Sewer; Contaminated Underground Lines; Effluent Water System; 100-F Reactor Cooling Water Effluent Underground Pipelines	Reclassification:	Interim Closed Out (9/15/2003)
Type:	Radioactive Process Sewer	Start Date:	1/1/1945
Status:	Inactive	End Date:	1/1/1965
Description:	This site contained the 100-F Reactor cooling water effluent lines which have been divided into a small pipeline or trench and three subsites. The three subsites have been remediated and Interim Closed Out. Only the 116-F-2 trench section remains to be remediated. See cleanup activities field and each subsite for documentation of the remediation and closure. Subsite 19:1 contained a line that was constructed of steel (152 centimeters [60 inches] in diameter, 235 meters [770 feet] long) and concrete (182 centimeters [72 inches] in diameter, 280 meters [920 feet] long) from the basin to the 1904-F Outfall Structure. Subsite 19:2 consisted of effluent lines that transported 105-F Reactor cooling water from the reactor core to the 107-F Retention Basin (three lines - one measuring 106-centimeters [42-inches] in diameter and 635 meters [2,080 feet] long, a second measuring 152 centimeters [60 inches] in diameter and 283 meters [930 feet] long and the third measuring 105 centimeters [41 inches] in diameter and 238 meters [781 feet] long). The large effluent lines running between the 105-F Reactor Building and the 107-F Retention Basin were underground for the western section of the lines and above ground for the remainder. The above ground portions of each line have been removed, cut into sections, and placed in the retention basin where they are currently covered with a layer of soil. Subsite 19:3 consisted of the effluent line that ran from the 105-F Reactor and the 182-F and 183-F Buildings to the 116-F-1 Lewis Canal. It also included all associated expansion and valve boxes, but excluded the retention basin, outfall structure, and those effluent lines that were within the confines of the 105-F Reactor Building. Other excluded lines were all the clean water pipelines that were upstream of the reactor building, all underground lines that were		

unique to the Experimental Animal Farm, and the smaller reactor effluent lines on the southwest side of the reactor. The underground process sewers show little evidence of their location at the surface. Effluent pipe ends are exposed on the east side of the 100-F Area entrance road.

Location: Subsite 100-F-19:1 included the lines from the 107-F Retention Basin that extend to the north where they met the 116-F-8 (1904-F) Outfall Structure. These pipelines are in the northeast section of the 100-F Area, near the 146-F biology facilities, the 100-F Retention Basins, and the 100-F Outfalls.

Subsite 100-F-19:2 included the main effluent lines that exited the 105-F Reactor Building, extending to the east and then curving to the north where they discharged to the 107-F Retention Basin. This subsite also included the pipeline that exited the north side of the reactor and extended to the west emptying into the Lewis Canal.

Subsite 100-F-19:3 included pipelines from both the 182-F and 183-F Buildings to the Lewis Canal, and the process sewer line connecting 182-F and 183-F.

Process Description: Effluent water passed from the reactor rear face and flowed via gravity through the underground effluent lines, junction boxes and diversion boxes to the retention basins where it was held up for a short period of time to allow thermal and radiological cooling before being released through the outfall structure to the Columbia River. These pipelines carried radioactive effluent from the 100-F Area Retention Basins to the 1904-F and 116-F-16 outfalls and spillways.

During periods of reactor fuel cladding ruptures, some effluent was diverted to an open trench. Cooling of the 105-F Reactor during operation required that a large volume, approximately 380,000 liters/minute (100,000 gallons/minute) of high quality water be continuously supplied to the reactor on a single pass basis. This water was obtained from the Columbia River and, after chemical treatment and filtering in the water treatment plant, was directed through the reactor process tubes. As it passed through the reactor, the cooling water became radioactive to a degree due to irradiation of the remaining impurities and the pick-up of corrosion products from within the piping and process tubes. Upon exiting from the reactor, the coolant was conveyed to the 107-F Retention Basin by gravity flow via a large diameter pipe, the effluent water line. After being retained in the 107-F Retention Basin long enough to permit decay of the short half-life radioactive elements, the water flowed through another large diameter pipe to the 116-F-8 (1904-F) Outfall Structure.

Occasionally during reactor operation, failure of the protective cladding on one of the fuel elements would occur. The reactor coolant would then pick up debris from this failure and, for a limited time, be contaminated with long half-life radionuclides. On these occasions, the effluent would not be permitted to return directly to the river, but would be diverted from the 107-F Retention Basin to the 107-F Liquid Waste Disposal Trench which was located near the retention basin. The trench functioned as a large filter with the highly radioactive particulate matter being retained in the soil below the trench and the purified water eventually finding its way back to the river.

Related Sites/ Structures: Related sites include the 105-F Reactor Building, the 1608-F Lift Station, the 107-F Retention Basin (116-F-14), the 1904-F Outfall Structure (116-F-8), the 107-F Liquid Waste Disposal Trench (116-F-2), and the 116-F-1 Lewis Canal. The water treatment pipelines are site 100-F-26, the clean water pipelines are 100-F-41, and pipes associated with the animal farm are 100-F-29.

Waste Type: Process Effluent

Waste Description: The waste was radioactively contaminated steel piping, concrete and soil. Reactor cooling water became radioactively contaminated as it passed through the reactor core. Activation

products created in the water included calcium-41, chromium-51, and zinc-65. Activation products from the reactor core that were picked up and transported by the cooling water included tritium, carbon-14, cobalt-60, nickel-63, and europium-152/154/155. Fuel element fission products such as strontium-90, and cesium-137, as well as transuranics such as plutonium-239/240 were introduced into cooling water due to fuel cladding failures. Concentrations of radionuclides in cooling water during normal reactor operations were approximately 0.2 microcuries/liter. Concentrations of radionuclides have built up in rust flakes and scale on the inner surfaces of the pipelines and in sludge in the diversion and junction boxes. Average beta-gamma concentrations for the effluent line scale and junction/diversion boxes are 83,000 and 120,000 picocuries/liter, respectively. Average plutonium-239/240 concentrations are 66 picocuries/gram for the effluent line scale and 720 picocuries/gram for the sludge at the bottom of the diversion and junction boxes. Direct readings of the bottom of the effluent lines averaged approximately 40,000 counts/minute with a Geiger-Mueller probe. Additional chemicals were added to the effluent for purposes of water treatment. These included aluminum sulfate (alum), with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter.

This Site has the Following SubSites:

Code: 100-F-19:1

Names: 100-F-19:1; 100-F Reactor Cooling Water Effluent Underground Pipelines (North Group)

Code: 100-F-19:2

Names: 100-F-19:2; 100-F Reactor Cooling Water Effluent Underground Pipelines (South Group)

Code: 100-F-19:3

Names: 100-F-19:3; 100-F Reactor Cooling Water Effluent Underground Pipelines (West Group)

Code: 100-F-19:1

Classification: Accepted

Names: 100-F-19:1; 100-F Reactor Cooling Water Effluent Underground Pipelines (North Group)

Reclassification: Interim Closed Out (5/22/2002)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-F-19:1 North Pipelines subsite included piping that ran north-northwest from the north side of the 116-F-14 Retention Basin to the 116-F-8 Outfall Structure and also included a second underground effluent pipeline that extended northwest from the 116-F-14 Retention Basin to a junction box and to the 116-F-16 Outfall Structure.

The pipelines in this area have been removed including miscellaneous co-located pipelines that were within the excavation boundary.

Location: These pipelines are in the northeast section of the 100-F Area, near the 146-F biology facilities, the 100-F Retention Basins, and the 100-F Outfalls.

Process Description: These pipelines carried radioactive effluent from the 100-F Area Retention Basins to the 1904-F and 116-F-16 outfalls and spillways.

Waste Type: Not Specified

Waste Description: The waste was radioactively contaminated steel piping, concrete and soil.

Closure Info: 100-F-19:1, 100-F-19:3, 100-F-34 and 116-F-12 were addressed as a group. The information below documents information for the group of sites.

The 100-F-19:1 North Pipelines, 100-F-19:3 West Pipelines, 100-F-34 Biology Facility French Drain, and the 116-F-12 French Drain were remediated as a group in CVP-2001-00002. These sites meet the cleanup standards specified in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units, U.S. Environmental Protection Agency, Region 10, Seattle, Washington.

The site remedial action began on August 7, 2001. Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Cleanup verification sampling began on September 7, 2001, and was finished on September 25, 2001. The results showed that the materials from the 100-F-19:3 subsite containing COCs at concentrations exceeding RAGs have been excavated and disposed of.

Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. All cleanup verification samples for the 100-F-19:3, 100-F-34 and 116-F-12 sites are listed under 100-F-19:1.

The SubSite is Part Of:

Code: 100-F-19

Names: 100-F-19; 1904-F Process Sewer; Contaminated Underground Lines; Effluent Water System; 100-F Reactor Cooling Water Effluent Underground Pipelines

Code: 100-F-19:2

Classification: Accepted

Names: 100-F-19:2; 100-F Reactor Cooling Water Effluent Underground Pipelines (South Group)

Reclassification: Interim Closed Out (9/15/2003)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003.

See 126-F-1 for information on cleanup of leaks from the 100-F-19:2 above-ground pipelines.

Location: This group of effluent lines exited the reactor building, extending to the east, and to the north where they discharged to the 107-F Retention Basin. A portion of these pipelines were above ground before emptying into the retention basin. Another section of pipe in this subsite ran from the north side of the reactor and emptied into Lewis Canal.

Waste Type: Not Specified

Waste Description: The waste was radioactively contaminated steel piping, concrete and soil.

Closure Info: 100-F-19:2, 116-F-11, UPR-100-F-1 and 100-F-29 were addressed as a group. The information below documents information for the group of sites.

The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003.

Remedial Action ran from August 2001 until December 2002. Verification sampling was

conducted in January 2003. Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. Contaminants of concern (COCs) were C-14, Cs-137, Co-60, Eu-152, Eu-154, Eu-155, Ni-63, and Sr-90.

Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. The basis for reclassification was described in detail in the Cleanup Verification Package 2001-00003.

The cleanup verification package does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]); therefore, institutional controls to prevent uncontrolled drilling or excavation into deep zone soils are required.

The SubSite is Part Of:

Code: 100-F-19

Reclassification: Interim Closed Out (5/22/2002)

Type: Radioactive Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-F-19:3 West Pipelines subsite included sections of effluent pipelines located north of the reactor running west from the 182-F Reservoir and the 126-F-12 (183-F) Clearwell to the 116-F-1 Lewis Canal. This subsite also included piping running in a north-south direction between the 182-F Reservoir and the 126-F-12 (183-F) Clearwell. The site contaminants of concern included C-14, Co-60, Cs-137, Eu-152, Eu-154, Eu-155, Ni-63, Sr-90, hexavalent chromium.

Location: Subsite 100-F-19:3 included pipelines from both the 182-F and 183-F Buildings to the Lewis Canal, and the process sewer line connecting 182-F and 183-F. These pipelines are in the northern part of the 100-F Area, running from the 182-F Reservoir and 183-F Clearwell to the Lewis Canal.

Waste Type: Not Specified

Waste Description: The waste was radioactively contaminated steel piping, concrete and soil.

Closure Info: 100-F-19:1, 100-F-19:3, 100-F-34 and 116-F-12 were addressed as a group. The information below documents information for the group of sites.

The 100-F-19:1 North Pipelines, 100-F-19:3 West Pipelines, 100-F-34 Biology Facility French Drain, and the 116-F-12 French Drain were remediated as a group in CVP-2001-00002. These sites meet the cleanup standards specified in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units, U.S. Environmental Protection Agency, Region 10, Seattle, Washington.

The site remedial action began on August 7, 2001. Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Cleanup verification sampling began on September 7, 2001, and was finished on September 25, 2001. The results showed that the materials from the 100-F-19:3 subsite containing COCs at

concentrations exceeding RAGs have been excavated and disposed of.

Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. All cleanup verification samples for the 100-F-19:3, 100-F-34 and 116-F-12 sites are listed under 100-F-19:1.

The SubSite is Part Of:

Code: 100-F-19

Names: 100-F-19; 1904-F Process Sewer; Contaminated Underground Lines; Effluent Water System; 100-F Reactor Cooling Water Effluent Underground Pipelines

Code: 100-F-23

Classification: Accepted

Names: 100-F-23; 141-C Drywell; 100-F Experimental Animal Farm Drywell

Reclassification: Interim Closed Out (8/14/2003)

Type: French Drain

Start Date:

Status: Inactive

End Date:

Description: The site has been remediated and closed out.

The site was a drywell (french drain). The 141-C Building included a dry well at its southwest corner that drained a loading dock at the facility's southwest end.

Location: The waste site was located in the 100-F Experimental Animal Farm are. The 141-C Drywell was located approximately 90 meters (295 feet) east of the 107-F Retention Basin Perimeter Fence and approximately 45 meters (148 feet) northeast of Well #A4596.

Process Description: Animals were monitored for radioactivity in this facility. The french drain received wash down of animal wastes. The french drain may have received liquid waste from the 141-C Isotope Study Facility/Animal Barn, which housed plant and animal research on the effects of ionizing radiation. The site may have received liquid wastes from animal pens and 141-C Building research laboratories. It is also likely that the french drain received storm water runoff from the loading dock.

Related Sites/Structures: The 141-C Drywell received liquid wastes from animal pens and 141-C Building research laboratories.

Waste Type: Animal Waste

Waste

Description:

Closure Info: Remedial action at the 100-F-23 site began and was completed on April 12, 2003. Excavation of the site involved removing the overburden materials and underlying contaminated soil. The elevation of the bottom of the excavation was approximately 124.3 m (408 ft) upon completion. The excavation was approximately 170 m² (1,829 ft²) in area with a maximum depth of approximately 3.2 m (11 ft). Approximately 458 m³ (505 t) of material from the site was disposed at ERDF. No associated pipeline structure was discovered during excavation of the site. Contaminants of concern are C-14, Cs-137, Co-60, Eu-152, Sr-90, hexavalent chromium. Cleanup verification sampling began and was finished on April 16, 2003.

The CVP demonstrates that remedial action at the 100-F-23 site has achieved the RAOs and corresponding RAGs as established in the ROD (EPA 1999) and RDR/RAWP (DOE/RL-96-17). These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that

residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

Code: 100-F-24 **Classification:** Accepted
Names: 100-F-24; 145-F Drywell **Reclassification:** Interim Closed Out (8/12/2003)
Type: French Drain **Start Date:**
Status: Inactive **End Date:**
Description: The site has been remediated and closed out.
Location: The site was located approximately 93 meters (305 feet) west of the 107-F Retention Basin perimeter fence and approximately 46 meters (151 feet) northwest of Well #A4596.
Process Description: The french drain received liquid animal wastes from the 145-F Building laboratories, which conducted experiments on the effects of ionizing radiation.
Related Sites/ Structures: The site received liquid waste from the 145-F Building research laboratories.
Waste Type: Animal Waste
Waste Description:
Closure Info: The CVP-2003-00012 has documented that remedial action at the 100-F-24 site has achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1999) and RDR/RAWP (DOE/RL-96-17).

Remedial action began and ended on April 12, 2003. At the completion of remedial action, the total excavation was approximately 113 meters squared (1,216 square feet) in area with a depth greater than 2.7 meters (8.9 feet). Approximately 259 metric tons (286 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. The pipeline structure associated with the site was entirely within the footprint of the excavation and removed during remediation. Contaminants of concern are C-14, Cs-137, Co-60, Eu-152, Sr-90, hexavalent chromium. Verification samples were collected on April 16, 2003.

Since the Remaining Sites DQO (BHI-01249) COPC lists were originally established, remediation of contaminated soil associated with the Experimental Animal Farm facilities in the 100-F Area, such as the 116-F-9 Experimental Animal Farm Animal Waste Leaching Trench (CVP-2001-00008), has provided potential contaminant information based on sampling and analysis. Cleanup verification sampling at the 116-F-9 site indicated that the COCs identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/R-96-22) (carbon-14, cesium-137, cobalt 60, europium-152, strontium-90, and hexavalent chromium) are appropriate for waste sites associated with Animal Farm activities studying the effects of radiation.

The 100-F-24 French drain is believed to have received liquid wastes from 145-F Animal Monitoring Laboratory. Based on verification sampling results from remediation of the 116 -F-9 site, and with concurrence from the regulators, the COCs selected for the 100-F-24 site are the same as those identified in the SAP (DOE/RL-96-22) for the 116-F-9 site (CVP-2001-00008).

The remaining soils at the 100-F-24 site have been sampled, analyzed, and modeled. The results of this effort indicated that the materials from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The 100-F-24 site is

verified to be remediated in accordance with the ROD (EPA 1999) and may be backfilled.

Code: 100-F-25	Classification: Accepted
Names: 100-F-25; 146-FR Drywells	Reclassification: Interim Closed Out (8/14/2003)
Type: French Drain	Start Date: 1/1/1956
Status: Inactive	End Date: 1/1/1975

Description: The site has been remediated and closed out. The 100-F-25, 146-FR Drywells, were a pair of french drains associated with the 146-F and 146-FR Aquatic Biology and Fish Ponds Laboratories, which both housed research on the effects of ionizing radiation on fish.

Location: The site was located approximately 75 meters (246 feet) south-southwest of the 116-F-8 Outfall Site and 15 meters (49 feet) east of Well # 1-F5-6. The 100F Area coordinates for the drywells are N80511.5, W29327.9 (center) and N80521.5, W29327.9.

Process Description: The french drains are believed to have received liquid wastes from 146-F and 146-FR research laboratories and ponds.

Related Sites/ Structures: The site was related to the 146-FR and 146-F Buildings, both housed research on the effects of ionizing radiation on fish.

Waste Type: Steam Condensate

Waste Description:

Closure Info: 100-F-25 and UPR-100-F-3 were addressed as a group. The information below documents information for the group of sites.

The CVP-2003-00010 has documented that remedial action at the site has achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1999) and RDR/RAWP.

Waste site contaminants of potential concern (COPCs) for the 100-F-25 site were originally identified in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (Remaining Sites DQO) (BHI-01249). Process effluent from the 105-F Reactor was used in the 146-F and 146 FR aquatic laboratories, which fed the 100-F-25, 146-F Drywells. Since the Remaining Sites DQO was published, remediation of contaminated soil associated with process effluent has provided additional potential contaminant information. The contaminants of concern are: carbon-14, cesium-137, cobalt-60, europium-152, europium-154, nickel-63, strontium-90, mercury and hexavalent chromium.

Remedial actions were conducted on April 12, 2003. At the completion of remedial action, the total excavation was approximately 243 meters squared (2,615 square feet) in area with a depth of approximately 4.0 meters (13 feet). Approximately 809 metric tons (892 tons) of material (structures and soil) from the site were disposed at the Environmental Restoration Disposal Facility. Contaminants of Concern are c-14, Cs-137, Co-60, Eu-152, Eu-154, Ni-63, Sr-90, hexavalent chromium, mercury. Verification samples were collected on April 16, 2003.

The CVP demonstrates that remedial action at the site have achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1999) and RDR/RAWP (DOE/96-17). The remaining soils at the UPR-100-F-3 site have been sampled, analyzed, and modeled. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

Code:	100-F-26	Classification:	Accepted
Names:	100-F-26; 100-F Water Treatment Facility Underground Pipelines	Reclassification:	None
Type:	Process Sewer	Start Date:	1/1/1945
Status:	Inactive	End Date:	1/1/1965
Description:	<p>The site encompasses the upstream (pre-reactor) process sewers for the 100-F Area, including all underground water lines used to transport reactor cooling water between water treatment facilities and the 105-F Reactor Building. These include potentially contaminated underground lines running between buildings and those that run to drainage facilities. Excluded lines consist of those located within buildings, lines downstream of the reactor building, (100-F-19 i.e., those lines that carry cooling water from the reactor to the retention basin, trench, and/or the river outfall) some of the underground lines associated with the Experimental Animal Farm (100-F-29 and 100-F-33) and clean water pipelines (100-F-41). For evaluation purposes, the site has been divided into 16 subsites based on design purpose (e.g., sanitary sewer or process water), expected sources of contamination, and potential remedial actions. The 16 subsites are as follows: - 100-F-26:1 North process sewer collection pipelines - 100-F-26:2 Process water pipelines to the aquatic biology and strontium gardens - 100-F-26:3 184-F Powerhouse pipelines - 100-F-26:4 South process pipelines - 100-F-26:5 190-F bypass pipelines - 100-F-26:6 190-F Reservoir pipelines - 100-F-26:7 Sodium dichromate and sodium silicate pipelines - 100-F-26:8 1607-F1 sanitary sewer pipelines - 100-F-26:9 1607-F2 sanitary sewer pipelines - 100-F-26:10 1607-F3 sanitary sewer pipelines - 100-F-26:11 1607-F4 sanitary sewer pipelines - 100-F-26:12 1.8-m (72-in.) main process sewer pipeline - 100-F-26:13 108-F drain pipelines - 100-F-26:14 116-F-5 influent pipelines - 100-F-26:15 Miscellaneous pipelines associated with the 1608-F sump - 100-F-26:16 Reactor cooling water pipelines.</p>		
Location:	<p>The location is described as underground lines running from the 181-F River Pumphouse to the 182-F Reservoir, the 183-F Basins and Clearwells, the 184-F Powerhouse, the 190-F Buildings, 108-F Biology Laboratory, and to the 105-F Reactor Building. Also, the drainage lines running from the water treatment buildings to the junction with the 100-F-19 Effluent Pipeline at the Animal Farm are included in the site. Septic sewer system pipelines are included only where they are co-located with the other pipelines in this site.</p>		
Process Description:	<p>Reactor cooling water was pumped from the Columbia River, settled and treated to remove minerals, and pumped to the reactor core at a rate of 1.93E+05 liters (51,000 gallons) to 2.69E+05 liters (71,000 gallons) per minute.</p>		
Related Sites/ Structures:	<p>Related structures include the 181-F River Pumphouse, the 182-F Settling Basin, the 183-F Basins and Clearwells, the 184-F Powerhouse, the 190-F Water Treatment Building, the 105-F Reactor, 185-F, the 108-F Biology Laboratory, and the several 1700-series support buildings. Pipeline sites in the 100-F Area include the Process Effluent Pipelines in site 100-F-19, the Water Treatment Pipelines in site 100-F-26, the river effluent lines are site 100-F-39, the clean water pipelines were 100-F-41, the experimental animal farm pipelines in site 100-F-29 and miscellaneous pipelines in 100-F-44.</p>		
Waste Type:	Water		
Waste Description:	<p>The waste consists of contaminated pipelines made of various materials (i.e. steel piping, concrete and soil). Chemical additives to the reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter.</p>		

This Site has the Following SubSites:

100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100 KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, ROD).

The 100-F-26:1 subsite pipelines were stratified into five service areas based on the contributing discharges to pipeline segments from each of the two facilities. The subsite is a network of reinforced concrete and vitrified clay process sewer pipelines that received flow from the 182-F Reservoir and 183-F Clearwells.

Location: These pipelines are adjacent to the 182-F Reservoir and 183-F Clearwell.

Waste Type: Soil

Waste Description: The waste was pipeline sediment/scale and underlying soil.

Closure Info: The Remaining Sites Verification Package (RSVP). 2005-008, has documented that the subsite has achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100 KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, ROD).

Confirmatory sampling of the subsite was conducted between December 1, 2004, and January 10, 2005. A stratified sampling design with focused sampling of pipeline sediment/scale and underlying soil was implemented in each of the five service areas. In each service area, a test pit was excavated and a section of the pipeline was removed. The inverts of the pipelines were identified at depths of 4 to 4.9 m (13 to 16 ft) below ground surface (bgs) at the locations excavated, with the exception of the sewer line southwest of the 182-F Reservoir, for which a junction box was located at 1.5 m (5 ft) bgs. Soil samples beneath the pipe and samples of the scale/sediment inside the pipe were collected.

The contaminants of potential concern (COPCs) are cobalt 60, cesium-137, europium-152, europium-154, strontium-90, silver, barium, cadmium, chromium (total), mercury, lead, selenium, arsenic, hexavalent chromium and polychlorinated biphenyls (PCBs).

The confirmatory sampling results supported a reclassification of this site to no action. The results demonstrated that residual contaminant concentrations supported future unrestricted land use that can be represented (or bounded) by the rural-residential scenario. These results also indicated that contaminant levels remaining in the soil were protective of groundwater and the Columbia River. This subsite does not have a deep zone; therefore, no deep zone institutional controls are required.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:2

Classification: Accepted

Names: 100-F-26:2; Process Water Pipelines to the Aquatic Biology and Strontium Gardens

Reclassification: No Action (5/26/2005)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: According to the Work Instruction for 100-F-26:2 Process Water Pipelines to the Aquatic Biology Fish Ponds and Strontium Gardens, the subsite consisted of a 5.1-centimeter (2-inch) diameter carbon steel pipeline that exited the east side of the 190-F Pumphouse, then split and

conveyed flow to both the Aquatic Biology Fish Ponds and the Strontium Gardens. However, field excavation of test pits and exploratory trenches did not reveal the pipeline to the Strontium Gardens, nor did it reveal any indication that the Strontium Gardens pipeline split from the Aquatic Biology pipeline. The Aquatic Biology pipeline was opened and found to contain enough residual scale/sediment for the collection of one sample.

Location: These pipelines ran diagonally across the 100-F Area, from the 190-F Pumphouse northeast to the 146-F biology facilities, and southeast to the Strontium Gardens.

Waste Type: Not Specified

Waste Description: The waste is the pipeline and any contaminated soil that may have occurred because of leaks in the pipeline.

Closure Info: The Remaining Sites Verification Package for 100-F-26:2, RSVP-2005-005, has documented that the subsite has achieved the remedial action objectives (RAOs) and the remedial action goals (RAGs) for a no action reclassification. The RAOs/RAGs were established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Sit (Remaining Sites ROD).

Contaminants of potential concern (COPCs) for the 100-F-26 underground pipeline waste site included strontium-90, cesium-137, cobalt-60, europium-152, europium-154, hexavalent chromium, arsenic, barium, cadmium, total chromium, lead, mercury, selenium, and silver. Historical information and process knowledge for the 190-F Pumphouse was used to further develop the COPCs, resulting in the inclusion of polychlorinated biphenyls (PCBs). In addition, as a precautionary measure, gross-alpha samples were collected to determine if alpha emitters were present at levels above background.

Confirmatory sampling of the subsite was conducted from November 17 through 18, 2004, in accordance with the site work instruction. Since no manholes or junction boxes were indicated on site drawings, three test pits were excavated in search of the two 5.1 cm (2 in) process water pipelines conveying flow to the Aquatic Biology Fish Ponds and the Strontium Gardens. According to historical information discussed in the work instruction, the pipeline split at the location of test pit 1, and one 5.1 cm (2 in) pipe traveled southwest to the Strontium Gardens while the other 5.1 cm (2 in) carbon steel pipe traveled northeast to the Aquatic Biology Fish Ponds.

However, excavation of test pits and exploratory trenches at the locations of test pit 1 and test pit 3 did not reveal the pipeline to the Strontium Gardens, nor did they reveal any indication that there was ever a pipeline to the Strontium Gardens that split from the Aquatic Biology pipeline at the location of Test Pit 1. Further excavation of exploratory test trenches in the vicinity of test pits 1 and 3, between test pits 1 and 3, and between test pit 1 and the 190-F Pumphouse also did not reveal any indication that the Strontium Gardens pipeline split from the Aquatic Biology pipeline, nor that it exists in its presumed location. Consequently, as it could not be located, no confirmatory samples from the Strontium Garden pipeline were collected.

The purpose of excavating test pit 1 was to collect a sample of pipe scale from the pipe at the location where it split and formed two separate pipelines. As previously discussed, field excavation did not locate a split in the Aquatic Biology pipeline at or in the vicinity of test pit 1; therefore, it was determined by the field sampling task lead that test pit 1 was no longer a defensible focused sampling location. Since test pit 2 was located at a 90 degree bend in the pipeline, and no other pipelines contributed flow upstream or downstream of test pit 2, it was determined that residual contamination at test pit 2 was representative of the residual contamination throughout the pipeline. Therefore, test pit 2 was identified as a defensible worst case focused sampling location for the Aquatic Biology pipeline. Confirmatory samples of the

residual scale/sediment in the 5.1 cm (2 in) carbon steel pipe and soil beneath the pipe were collected at the 90 degree elbow in the pipe at test pit 2.

The no action decision for the 100-F-26:2 subsite is supported based on current reviews of the site history and confirmatory sampling results. The analytical results from soil samples collected were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. The sampling results were stored in the Environmental Restoration (ENRE) project-specific database prior to archiving in the Hanford Environmental Information System (HEIS). They were also included in Appendix A of the RSVP.

These results indicated that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future land uses of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The subsite does not have a deep zone; therefore, no deep zone institutional controls were required.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:3

Classification: Accepted

Names: 100-F-26:3; 184-F Powerhouse Pipelines

Reclassification: No Action (12/3/2004)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The selected action for this subsite involved evaluation of the 100-B-14:6 pipeline subsite RSVP and data, evaluation of process knowledge for the 100-F-26:3 pipeline subsite, and proposal of no further action. The 100-F-26:3 pipeline subsite consisted of a network of process sewer pipelines that serviced the 184-F power house and 188-F ash disposal basin. The 184-F power house was primarily a boiler house, containing four boilers and one small turbine generator for emergency power generation. The 188-F ash disposal basin was an open rectangular-shaped pit used for the disposal of ashes from the 184-F Power House. Ash from the power house was combined with raw river water and pumped directly from the sluice pit in the power house to the ash disposal basin. Contaminants of Concern were ICP metals, mercury, hexavalent chromium, PCBs.

This site is analogous to the 100-B-14:6 subsite (184-B Power House pipelines, Waste Site Reclassification Form Control Number 2004-010, dated 5/10/2004).

Analytical results obtained from confirmatory sampling at the analogous 100-B-14:6 subsite indicated that the 100-F-26:3 subsite had also met the Remedial Action Objectives specified in the Remaining Sites ROD. The 100-B-14:6 site evaluation showed that there were no hazardous/dangerous materials present at the site and, accordingly, no residual contamination in the soil. The basis for reclassification of the subsite was supported, based on reviews of the processes associated with steam boilers, site history, and confirmatory sampling at the analogous subsite which was determined to meet the cleanup criteria. The remaining contaminant levels were protective of human health, groundwater and the Columbia River.

Location: Subsite location is the network of pipelines running from the 184-F power house to the 188-F ash disposal basin.

Waste Type: Not Specified

Waste The waste was the remaining pipelines and any potentially contaminated soil.

Description:

DESCRIPTION.

Closure Info: The selected action for this subsite involved evaluation of the 100-B-14:6 pipeline subsite RSVP and data, evaluation of process knowledge for the 100-F-26:3 pipeline subsite, and proposal of no further action. The 100-F-26:3 pipeline subsite consisted of a network of process sewer pipelines that serviced the 184-F power house and 188-F ash disposal basin. The 184-F power house was primarily a boiler house, containing four boilers and one small turbine generator for emergency power generation. The 188-F ash disposal basin was an open rectangular-shaped pit used for the disposal of ashes from the 184-F Power House. Ash from the power house was combined with raw river water and pumped directly from the sluice pit in the power house to the ash disposal basin. Contaminants of Concern were ICP metals, mercury, hexavalent chromium, PCBs.

This site is analogous to the 100-B-14:6 subsite (184-B Power House pipelines, Waste Site Reclassification Form Control Number 2004-010, dated 5/10/2004).

Analytical results obtained from confirmatory sampling at the analogous 100-B-14:6 subsite indicated that the 100-F-26:3 subsite had also met the Remedial Action Objectives specified in the Remaining Sites ROD. The 100-B-14:6 site evaluation showed that there were no hazardous/dangerous materials present at the site and, accordingly, no residual contamination in the soil. The basis for reclassification of the subsite was supported, based on reviews of the processes associated with steam boilers, site history, and confirmatory sampling at the analogous subsite which was determined to meet the cleanup criteria. The remaining contaminant levels were protective of human health, groundwater and the Columbia River.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:4

Classification: Accepted

Names: 100-F-26:4; South Process Pipelines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite is a network of process sewer pipelines that received flow from the 105-F Reactor, the 190-F Pumphouse, the 1717-F Combined Shops Buildings and the 108-F Biology Laboratory in the 100-F Areas. This subsite is a network of process sewer pipelines that received flow from the 105-F Reactor, the 190-F Pumphouse, the 1717-F Combined Shops Buildings and the 108-F Biology Laboratory in the 100-F Areas. The pipelines in 100-F-26:4 were subdivided into "service areas" for purposes of planning the confirmatory sampling effort. These service areas are:

Service Area 1 (105-F Reactor Building process sewer)
 - 39.6 m (130 ft) of 0.2-m (8-in.) vitrified clay pipe (VCP)
 - 62 m (203 ft) of 0.3 m (12-in.) VCP

Service Area 2 (108-F Biology Laboratory process sewer)
 - 96 m (315 ft) of 0.15-m (6-in.) VCP
 - 32 m (105 ft) of 0.15-m (6-in.) cast iron pipe

Service Area 3 (190-F Pumphouse process sewer)
 - 21.3 m (70 ft) of 0.76-m (30-in.) reinforced concrete pipe (RCP)

Service Area 4 (189-F Refrigeration Building process sewer)

- 54.9 m (180 ft) of 1.4-m (54-in.) RCP

Service Area 5 (1717-F Combined Shops Building process sewer)

- 120.4 m (395 ft) of 0.15-m (6-in.) VCP

Service Area 6 (central process sewer collection line)

- 285 m (935 ft) of 1.5-m (60-in.) RCP

- 53.3 m (175 ft) of 0.91-m (36-in.) RCP

- 72 m (236 ft) of 0.3-m (12-in.) VCP.

The contaminated cast-iron pipe found during the February 2002 excavation of the 108-F building was not located during this remedial action. Therefore, an additional test pit was excavated on November 29, 2005, in an attempt to locate the contaminated 15-centimeter (6-inch)-diameter cast-iron pipe. The additional excavation was unsuccessful, and the excavated material was placed back in the pit. Additional efforts in July 2006 to locate the contaminated pipe using a metal detector were also unsuccessful. However, the contaminated 15-centimeter (6-inch)-diameter cast-iron pipe (100-F-26:4) was found during test pitting activities in December 2006. The contaminated pipe was associated with the 100-F-26:4 pipeline site and was not a part of the 116-F-15 sump as previously indicated. Remediation and sampling activities for the 100-F-26:4 pipeline site will be included in a future work instruction and verification package.

Location: The pipelines in this subsite are located in the center of the 100-F Area, east of the 105-F Reactor and the 190-F Pumphouse and west of the 108-F Biology Laboratory and the 1717-F Combined Shops Building.

Waste Type: Not Specified

Waste Description: The waste is potentially contaminated equipment (pipelines) and any contaminated soil associated with the pipeline.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:5

Classification: Accepted

Names: 100-F-26:5; 190-F Bypass Process Sewer Pipelines

Reclassification: No Action (7/21/2005)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The Remaining Sites Verification Package, RSVP-2005-007 demonstrates that the 100-F-26:5 subsite has met the objectives for no action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE RL 2005b) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD).

The subsite included the underground pipelines that serviced the 185-F Building and the 190-F Pumphouse Building, they were composed of 1.2-meter (48-inch) reinforced concrete pipe (RCP) and 0.46-meter (18-inch) vitrified clay pipe (VCP). The historic design flow direction consisted of discharges from the 185-F and 190-F Facilities traveling generally south before the pipeline turned west to discharge to one of the 100-F-19:3 [100-F Reactor Cooling Water Effluent Underground Pipelines (West Group)]. A discrepancy as to the termination point of the 100-F-26:5 pipeline was found, the CVP for the 100-F-19:3 waste site indicated that the 100-F-

26:5 pipeline was approximately 63 meters (207 feet) longer at the southwest end of the subsite than was shown on Drawing 0100F-DD-C0189.

Contaminants of potential concern (COPCs) for the subsite included strontium-90, cesium-137, cobalt-60, europium-152, europium-154, hexavalent chromium, arsenic, barium, cadmium, total chromium, lead, mercury, selenium, silver, and polychlorinated biphenyls (PCBs).

A total of 10 samples were collected between November 2004 and January 2005 from the service areas consisting of soil under the pipes, sediment inside of the pipes or manholes, one field duplicate, and an equipment blank. Samples (J022P0 through J022P6, J026X4, J02D79, J02D80 and J022M5) were collected and analyzed for the established COPCs. The samples and results have been reported to the HEIS database.

Mercury levels in test pit 2 (805 milligrams/kilograms) were significantly higher than the direct exposure remedial action goal (RAG) of 24 milligrams/kilograms. However, the sample that contained the high mercury concentration was taken at a depth of 5.5 meters (18 feet) below ground surface in the deep zone, and therefore direct exposure RAGs were not applicable.

The results demonstrated that residual contaminant concentrations support future land use that can be represented (or bounded) by the rural-residential scenario. These results also showed that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. However, because mercury concentrations in deep vadose zone soil exceed direct exposure, institutional controls are required for the 100-F-26:5 waste site to prevent excavation or drilling into the deep vadose zone soils.

Location: pipelines running from the 185-F and 190-F Facilities traveling generally south before the pipeline turned west to discharge to one of the 100-F-19:3 [100-F Reactor Cooling Water Effluent Underground Pipelines (West Group)].

Waste Type: Not Specified

Waste Description: The waste includes the pipelines, the contaminated scale and sediment which may be contained

within them, and the underlying soils.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:6

Classification: Accepted

Names: 100-F-26:6; 190-F Reservoir Pipelines

Reclassification: No Action (12/3/2004)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The subsite includes cast iron pipe servicing the 190-F Pumphouse Building.

Location: The location is described as underground lines running from the 190-F Building to the 105-F Reactor Building.

Process Description: The subsite received flow via a cast iron pipeline (CIP) with lead joints, from the re-use water reservoir portion of the 190-F Pumphouse. Waste water from the steam jet condensers was collected in the re-use water reservoir and pumped back to the main reservoir (182-F Building) during the winter months to maintain the temperature of the process water.

Closure Info: The 100-F-26:6 pipeline subsite has been determined to meet the Remedial Action Objectives (RAOs) and Remedial Action Goals (RAGs) as established by the Interim Action Record of

Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD). The selected action for this subsite involved (1) evaluation of the analogous 100-B-14:7 subsite's RSVP and data, (2) evaluation of process knowledge, and (3) proposal of no further action.

The lead contained in the pipeline did not present a direct exposure risk to human health, no exposure pathway to groundwater existed. There was no history of radiological contamination associated with the 190-F Reservoir Pipelines and no radiological contamination was detected during decommissioning of the 190-F complex. There were no known process incidents at 105-F Reactor that would have introduced radiological contamination from the reactor into the 190-F Reservoir Pipelines.

The 190-F re-use water reservoir and pipeline are analogous to the 190-B Sump and Pipelines (100-B-14:7), as they had a similar source of water and supported a similar process.

The 100-B-14:7 pipeline subsite was determined to meet the cleanup criteria, consequently the 100-F-26:6 subsite also has met the cleanup criteria and the remaining contaminant levels were protective of human health, groundwater and the Columbia River. The site has been reclassified to No Action.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:7

Classification: Accepted

Names: 100-F-26:7; Sodium Dichromate and Sodium Silicate Pipelines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: Note from the WIDS Administrator: After this reclassification form was approved, the pipeline was cut through as part of a different waste site remediation. Sodium dichromate was still present in the pipeline. Plans are being developed to remove/remediate the entire pipeline. The reclassification status listed on the reclassification form is no longer valid. The reclassification status for this subsite was cleared in WIDS on 6/10/2010.

The subsite consisted of two parallel, 0.07 meter (3 inch) steel pipelines that conveyed sodium dichromate and sodium silicate, respectively, from the 108-F Chemical Pumping Building to the 190-F Water Treatment Building.

The 100-F-26:7 waste site is a pair of 7.6-centimeter (3-inch) steel pipelines that conveyed sodium dichromate and sodium silicate, respectively, from the 108-F Chemical Pumping Building to the 190-F Water Treatment Building.

Based on historical information, the sodium silicate pipeline conveyed only chemicals with low inherent toxicity or that readily degrade to compounds of low inherent toxicity, and therefore is not considered hazardous/dangerous or to present a risk to human health or the environment.

Because the sodium silicate pipeline was within 0.8 m (2 ft) of the sodium dichromate pipeline along their entire lengths, the two were treated as twin pipelines for confirmatory sampling. Samples were taken of the soil beneath a 90-degree bend in the sodium dichromate pipeline and from a section of the pipe. The maximum detected results from the soil and pipe samples were

used to support site reclassification. The samples met the cleanup criteria so the pipes were left in place. A waste site reclassification to interim closed out was approved (120708).

During overburden removal of the 100-F-26:9 pipeline on February 14, 2007, WCH unearthed, broke open, spilled and cleaned up 1 to 2 gallons of liquid from the 100-F-26:7 interim closed out pipeline where it crossed diagonally over the top of the 100-F-26:9 pipeline. Conclusions from the soil sample results affected by the spill were that concentrations of total and hexavalent chromium were above cleanup standards. The waste site reclassification for 100-F-26:7 was withdrawn and the site was referred for remove, treat and disposal (135297).

Location: The pipelines ran from the 108-F Chemical Pumping Building to the 190-F Water Treatment Building.

Waste Type: Not Specified

Waste The waste is contaminated steel piping and underlying soils.

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite includes the 1607-F1 influent sanitary sewer pipelines. These pipelines were 200 m (660 ft) long and constructed of 8-inch vitrified clay. The pipelines serviced the 1701-F, 1709-F, and 1720-F Buildings.

Location: The 100-F-26:8 sanitary sewer pipelines and 1607-F1 sanitary sewer system waste sites are located within the 100-FR-1 Operable Unit of the Hanford Site, approximately 730 m (2395 ft) south of the 105-F Reactor Building.

Waste Type: Not Specified

Waste The waste is any potentially contaminated pipelines and associated soils.

Description:

Closure Info: 1607-F1 and 100-F-26:8 were addressed as a group. The information below documents information for the group of sites.

The Remaining Sites Verification Package (RSVP) for the 1607-F1 sanitary sewer system and 100-F-26:8 sanitary sewer pipelines waste sites has documented that they have met the Remedial Action Objectives (RAOs) and the corresponding Remedial Action Goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD) for interim closure.

Remediation of the 1607-F1 and 100-F-26:8 waste sites were performed from January 8 to April 3, 2007 and documented as one RSVP. Both sites were excavated to approximately 3.4 meters (11 feet) below grade resulting in a combined volume of approximately 464 cubic meters (607 cubic yards) of material stockpiled for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 266 meters (872 feet) of pipeline were removed during remediation. There were no anomalies or stained soil discovered during remediation.

During pipeline excavation, a french drain was discovered on the west side of the former 1709-F facility. Although this french drain was independent of the pipelines, it was removed.

The COCs/COPCs were established using the confirmatory sampling analytical results. Based on these results, the COC/COPCs for the 1607-F1 and 100-F-26:8 waste sites verification sampling design were the metals barium, lead, and zinc; pesticides (dichlorodiphenyl-dichloroethane [DDD], dichlorodiphenyl-dichloroethylene [DDE], dichlorodiphenyl-trichloroethane [DDT]); SVOCs (benzo(a)pyrene, benzo(k)fluoranthene, and chrysene); and PCBs (aroclor-1260). Petroleum hydrocarbons and mercury were added as COCs/COPCs based on the discovery of the 1709-F french drain during remediation of the 100-F-26:8 pipelines. These additions were based on the assumption that the probable sources of effluent in the french drain were from hose drying and truck washing activities. Therefore, potential contaminants in the effluent were from motor oil leaks and broken mercury switches.

Verification sampling for the remediated 1607-F1 and the 100 F 26:8 waste sites was performed in September and October 2007. Evaluation of the verification sampling results shows that all direct exposure cleanup levels were met for the four decision units of the 1607-F1 and 100-F-26:8 waste sites: the 1607-F1 septic tank and 100-F-26:8 pipelines excavation footprint, 1709-F french drain, road crossing areas, and overburden stockpiles.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. No institutional controls are required for this site to prevent uncontrolled drilling or excavation into deep zone [i.e., below 4.6 m (15 ft)].

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:9

Classification: Accepted

Names: 100-F-26:9; 1607-F2 Sanitary Sewer Pipelines

Reclassification: Interim Closed Out (10/29/2008)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100 F 26:9 subsite consisted of underground pipelines of the 1607-F2 sanitary sewers servicing the 105-F, 108-F, 184-F, 185-F, and 190-F buildings, and the 1700 F administration and service buildings (1704-F, 1707-F, 1707-FA, 1713-F, 1717-F, 1719 F, and 1722-F). According to documentation the 1607-F2 septic tank, which was Interim Closed Out in CVP-2002-00005, was posted as an underground radioactive material area. No evidence was found to substantiate the posting.

Location: The collection pipelines were located at 105-F, 108-F, 184-F, 185-F, 190-F, 1704-F, 1707-F, 1707-FA, 1713-F, 1717-F, 1719 F, and 1722-F Buildings, and ran to the south and east to the 1607-F2 septic tank.

Waste Type: Not Specified

Waste Description: The waste includes the pipelines and the contaminated scale and sediment which may be contained within them, and any contaminated soil associated with leaks from the pipelines.

Closure Info: In accordance with the Remaining Sites Verification Package, (RSVP-2008-029), the confirmatory and verification sampling results support a reclassification to Interim Closed Out.

The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD).

Twelve test pits were excavated and sampled in the 100-F-26:9 pipeline subsite. The contaminants at seven of the service areas (1, 3, 4, 5, 6, 7 and 8) were found to be at concentrations protective of human health, groundwater, and the Columbia River. A remedial action requirement was determined for service areas 2, 9, and 10. Service Area 11 was remediated because it was downstream of service areas 2 and 10.

Remediation of these service areas was performed from February 8 through October 30, 2007. The site was excavated to a depth of approximately 3.7 m (12 ft) below grade, resulting in approximately 1,360 bank cubic meters (BCM) (1,780 bank cubic yards [BCY]) of material disposed of at the Environmental Restoration Disposal Facility. Approximately 6,340 BCM (8,290 BCY) of overburden and layback soil was removed and stockpiled for use as clean backfill. Verification sampling for the 100-F-26:9 service areas 2, 9, 10, and 11 pipeline site was performed between February 2007 and February 2008.

The contaminants of concern for verification sampling were identified in the 100-F-26:9, 1607-F2 Sanitary Sewer Pipelines Verification Work Instruction (0100F-WI-G0024) as gamma-emitting radionuclides by gamma energy analysis, alpha emitting radionuclides by gross alpha proportional counting; beta-emitting radionuclides by gross beta proportional counting and for inductively coupled plasma metals, mercury, hexavalent chromium, TPH, semivolatle organic compounds, and PCBs.

The results of sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. The site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:10

Classification: Accepted

Names: 100-F-26:10; 1607-F3 Sanitary Sewer Pipelines

Reclassification: Interim Closed Out (12/3/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-F-26:10 underground pipeline subsite consisted of underground sanitary sewer pipelines that received effluent from the 182-F, 183-F, and 151-F Buildings and discharged to the 1607-F3 septic system. This subsite includes the 1607-F3 influent sanitary sewer pipelines. These pipelines were constructed of 6 and 8-inch vitrified clay. These pipelines serviced the 151-F, 182-F and 183-F Buildings. The Remaining Sites Verification Package (RSVP), 2007-028, has documented that the subsite achieved the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites

ROD).

Location: The pipelines and septic systems were about one-quarter mile northwest and north of the 105-F Reactor.

Waste Type: Not Specified

Waste Description: The waste was contaminated pipelines and associated soils.

Waste Type: Not Specified

Waste Description: The waste was contaminated pipelines and associated soils.

Closure Info: In preparation for the site remediation, two road crossings were excavated, sampled, and immediately backfilled in January 2007. Remedial action was performed from March 7 through March 12, 2007. The site was excavated between 2.4 meters (8 feet) and 4.3 meters (14 feet) below grade, resulting in approximately 1,900 bank cubic meters (BCM) (2,500 bank cubic yards [BCY]) of material disposed at the Environmental Restoration Disposal Facility, including removal of approximately 600 meters (1,970 feet) of pipeline. Approximately 4,200 BCM (5,500 BCY) of overburden soil was removed and stockpiled for use as clean backfill.

According to documentation, a portion of the north-south vitrified clay pipeline (VCP) line that serviced the 182-F Pump Station and a portion of the 183-F Water Treatment Plant VCP line were removed during decommissioning of the buildings, leaving two separate sections of pipeline. The 1607-F3 septic tank, drain field, and associated contaminated soil were removed in September 2005. Remedial action objectives for the 1607-F3 waste site were met after the additional excavation of contaminated soil in 2006 and were addressed in RSVP-2006-047.

The Contaminants of Concern/Contaminants of Potential Concern (COCs/COPCs) for verification sampling were determined based on the confirmatory sampling results from the 100-F-26:10 waste site. The COCs/COPCs were identified in the verification work instruction (0100F WI G0064) as cesium-137, europium-152, arsenic, barium, boron, cadmium, total chromium, cobalt, copper, lead, manganese, molybdenum, nickel, vanadium, zinc, hexavalent chromium, gamma-chlordane, SVOCs, and aroclor-1260.

The verification samples were analyzed by gamma energy analysis and for pesticides, SVOCs, PCBs, metals by inductively coupled plasma analysis, mercury and hexavalent chromium, which included all of the COCs/COPCs listed in the verification work instruction. The road crossing samples were additionally analyzed for nickel-63 and total strontium.

Verification sampling for the site was performed in January and August 2007. The site was divided into three decision units for verification sampling. The first decision unit consisted of the excavation footprint of the pipeline, the second decision unit consisted of the overburden stockpiles, and the third decision unit consisted of the pipeline excavations underlying the haul road (road-crossing area) and the overburden stockpiles used to backfill in the road crossings. Statistical and judgmental sampling to verify the completeness of remediation was performed, and analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection.

The samples were analyzed using U.S. Environmental Protection Agency-approved analytical methods. The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) System project-specific database prior to submission for archival in the Hanford Environmental Information System (HEIS) site-wide database. The results were also included in Appendix D of the RSVP.

The results of verification sampling indicated that residual contaminant concentrations did not

preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

The SubSite is Part Of:**Code:** 100-F-26**Names:** 100-F-26; 100-F Water Treatment Facility Underground Pipelines**Code:** 100-F-26:11**Classification:** Accepted**Names:** 100-F-26:11; 1607-F4 Sanitary Sewer Pipelines**Reclassification:** No Action (5/26/2005)**Type:** Process Sewer**Start Date:****Status:** Inactive**End Date:**

Description: The subsite was located approximately 139 meters (456 feet) west of the 105-F Reactor Building. The subsite consisted of a 0.15-meter (6-inch) diameter vitrified clay pipe (VCP) that received effluent from the 115-F Gas Recirculation Building. The VCP originated at the southwest corner of the 115-F Gas Recirculation Building and carried flow west approximately 53.6 meters (178 feet). The pipeline terminated at the inlet to the 1607-F4 septic tank.

Location: The 100-F-26:11 subsite is located approximately 139 meters (456 feet) west of the 105-F Reactor Building.

Waste Type: Soil

Waste Description: The waste was the pipeline interior scale and the soil underneath the pipe.

Closure Info: The Remaining Sites Verification Package for 100-F-26:11, RSVP-2005-003, has documented that the subsite has achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) for a no action reclassification. The RAOs and RAGs were established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-I, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD).

Contaminants of concern (COCs) for the underground pipeline waste site included americium-241, strontium-90; cesium-137, cobalt-60, europium-152, europium-154, europium-155, hexavalent chromium, arsenic, barium, cadmium, total chromium, lead, mercury, selenium, silver, pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds.

Confirmatory sampling of the subsite was conducted on November 22, 2004, in accordance with the WCH work instructions. A focused sampling approach was selected using the probable worst-case locations for sampling. Confirmatory samples of the 0.15-m (6-in.) influent VCP were collected via excavation of two test pits, one at either side of the pipeline. Samples were taken of the pipeline interior scale and the soil underneath the pipe. The samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The results were stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archiving in the Hanford Environmental Information System (HEIS) and were included in Appendix A of the RSVP.

Analytical results of pipe scale and underlying soil samples for the subsite were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection,

excluding the soil sample for lead and the pipe scale sample for aroclor-1260.

The results also demonstrated that residual contaminant concentrations support unrestricted future land uses of shallow zone soil (i.e., surface to 4.6 meter [15 feet]) and that contaminant levels remaining in the soil were protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls were required.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:12

Classification: Accepted

Names: 100-F-26:12; 72-inch Main Process Sewer Pipeline

Reclassification: Interim Closed Out (4/29/2008)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This waste site has been remediated. No anomalies or stained soil were discovered during remediation.

The 100-F-26: 12 underground pipeline subsite consisted of an approximately 308 meters (1,011 ft) long, 1.8 meters (72 in.) diameter, east west-trending reinforced concrete pipe that joined the North Process Sewer Pipelines (100-F-26: 1) and the South Process Pipelines (100-F-26:4) with the 1.8-m (72-in.) reactor cooling water effluent pipeline (100-F-19).

Location: The 100-F-26:12 pipeline ran for 308 meters (1,011 ft) from west to east about 50 meters north of the 184-F Powerhouse.

Waste Type: Not Specified

Waste Description: The waste was the sewer pipe and surrounding soils.

Closure Info: Radiological field measurements and staining discovered during excavation of the 100-F-19 pipeline in August 2001 indicated that contamination was present within the 100-F-26:12 sewer pipe and its surrounding soils. The site was referred for remedial action without requiring additional confirmatory sampling (per WCH-CCN-117910). Remediation of the pipeline subsite was performed from January 11 through October 4, 2007. The subsite was excavated between 4.0 meters (13 ft) and 6.0 meters (20 ft) below grade, resulting in approximately 2,900 bank cubic meters (BCM) (3,800 bank cubic yards [BCY]) of material disposed of at the Environmental Restoration Disposal Facility that including removing of approximately 308 meters (1,011 ft) of pipe. Approximately 23,340 BCM (30,530 BCY) of overburden was stockpiled for use as clean backfill.

The portion of the pipeline that ran beneath the railroad crossing (near the coal conveyor structure) was encased in concrete to support the additional load. The pipeline encased in concrete was removed. The coal conveyor structure was evaluated and found to be absent of hydraulic systems. The large concrete monolith associated with the coal conveyor was abandoned in place.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:13

Classification: Accepted

Names: 100-F-26:13; 108-F Drain Pipelines **Reclassification:** Interim Closed Out (3/3/2008)
Type: Process Sewer **Start Date:**
Status: Inactive **End Date:**

Description: The 100-F-26:13 subsite consisted of one 0.15 meter (6 inch), two 0.2 meter (8 inch), and one 0.31 meter (12 inch) diameter vitrified clay pipe (VCP) segments encased in concrete. The pipelines discharged effluent from the former 108-F Biological Laboratory, which was originally built in 1944 to support treatment of cooling water for use in the 105-F Reactor, to the 188-D Ash Disposal Area (126-F-1). In 1949, the 108-F Building was completely remodeled for use in life-science studies to test the effects of radiation and contamination on plant and animal life. In 1999, the 108-F Building was decontaminated, demolished, and removed; however, the 100-F-26:13 pipeline segments were left in place.

This subsite was a network of process sewer pipelines that received effluent from the 108-F Biological Laboratory and then discharged it to the 188-F Ash Disposal Area (126-F-1 waste site). This subsite included one 0.15 m (6 in), two 0.2 m (8 in), and one 0.31 m (12 in) diameter vitrified clay pipe (VCP) segments encased in concrete. Routing of the 100-F-26:13 pipelines is as follows. One 0.2 m (8 in) VCP starts at the sulfuric acid storage tanks previously located on the west side of the 108-F Building and flows south to the confluence with the 0.31 m (12 in) VCP. The second 0.2 m (8 in) VCP starts at the east side of the 108-F Building and flows south to the confluence with the 0.31-m (12-in.) VCP. There is a 0.15 m (6 in) VCP that connects and flows into the 0.2 m (8 in) VCP before it connects into the 0.31 m (12 in) VCP. The 0.31 m (12 in) VCP that received flow from both 0.2 m (8 in) VCPs flows southeast and discharges into the 188-F Ash Disposal Pit.

Location: These pipelines are in the south-central part of the 100-F Area, running from the 108-F Building to the 126-F-1 Ash Disposal Pit.

Waste Type: Not Specified

Waste Description: The waste was potentially contaminated pipelines.

Closure Info: The Remaining Sites Verification Package for 100-F-26:13, RSVP-2005-011 has documented that the subsite has achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD).

Remediation of this subsite was performed in two stages because a portion of the pipelines were located under the main access road to the 100-F Area. The first stage was performed between February 5 and March 27, 2007, and consisted of excavating and removing all pipeline segments except the portion underlying the main access road. The second stage included excavation and removal of the pipeline segment under the access road and was performed on August 24, 2007.

Approximately 580 bank cubic meters (BCM) [(760 bank cubic yards (BCY))] of pipeline material and suspect contaminated adjacent and underlying soils were removed and stockpiled in the staged waste area for later disposal to ERDF. The staged waste area footprint will be addressed with the 100-F-26:9 subsite. Excavation depths at the subsite ranged from 4.3 meters to 5.2 meters (14 feet to 17 feet) below ground surface.

The contaminants of potential concern (COPCs) were identified in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22, rev. 4). Contaminants of potential concern

(COPCs) are identified in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL -96-22, Revision 4). The COPCs include cobalt-60, cesium-137, europium-152, europium -154, strontium-90, silver, barium, cadmium, chromium (total), mercury, lead, selenium, arsenic, and hexavalent chromium.

Historical information and process knowledge for the 108-F Biology Laboratory was used to further develop the COPCs for the 100-F-26:13 underground pipeline subsite. As a result, uranium-234, uranium-235, uranium-238, americium-241, plutonium-238, plutonium 239/240, and polychlorinated biphenyls (PCBs) were included as COPCs. Sulfuric acid was used at the 108-F facilities; however, samples will not require anion analysis because the groundwater protection value for sulfate is large (25,000 mg/kg) compared to other potential contaminants.

Verification sampling was performed in July and August 2007, the analytical results indicated that the residual concentrations of COCs/COPCs at this site have met the cleanup objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the verification sampling results support a reclassification to Interim Closed Out. The laboratory-reported data results for all constituents were stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and are presented in Appendix B of the RSVP.

The results of verification sampling illustrate that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. Excavation depths include both shallow-zone and deep-zone components. However, the excavation area was considered as one decision unit and was interim closed out using the more restrictive shallow-zone criteria; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:14

Classification: Accepted

Names: 100-F-26:14; 116-F-5 Influent Pipelines

Reclassification: Interim Closed Out (2/29/2008)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The subsite consisted of underground pipelines located southwest of the 105-F Building (a 10.2-centimeter (4- inch) influent pipeline that ran from the 105-F Reactor Building to the 116-F-5 ball washer crib, two process pipelines (30.48- centimeter [12- inch] and 15.24- centimeter [6- inch]) that connected to a previously remediated process pipeline (100-F-19:2); and a short 15.24- centimeter [6- inch] cast-iron pipe). These pipelines were associated with the 116-F-5 Ball Washer Crib and remnants of process pipelines on the west side of the 105-F Building.

The 30.48-cm (12 in) process line ran from the 115-F seal pit to the 60.96 cm (24 in) process sewer south of the fuel storage basin (W-73174). The 15.24 cm (6 in) process line received effluent from the tunnel eductor discharge (H-1-70185) and joined with the process line from the 115-F seal pit prior to entering the process sewer. The process sewer was remediated between August 2001 and December 2002 (CVP-2001-00003). The remedial design drawings also show a short 15.24 cm (6 in) cast-iron pipeline off the end of the ball washer influent line near the 105-F Building (0100F-DD-C0032). A possible reference to this pipeline is made on drawing M-1904 F sheet 5. The pipe is referenced by the notation "6 [inch] V.P. BELOW 12

[inch] V.P." with an arrow pointing to the 30.48 cm (12 in.) process line from the 115-F seal pit. No additional historical information is available regarding this pipe.

Location: The 100 F 26:14 pipeline subsite consists of underground pipelines associated with the 116-F-5 Ball Washer Crib and remnants of process pipelines on the west side of the 105-F Buildings. The 100-F-26:14 subsite is an influent pipeline that runs from 118-F-8 (105-F) Reactor Building to 116-F-5 trench.

Waste Type: Not Specified

Waste Description: The waste was contaminated pipelines and associated soils.

Closure Info: The Remaining Sites Verification Package (RSVP) 2007-029 for 100-F-26:14 documents that the subsite has achieved the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units.(ROD).

Remediation of this subsite was performed from February 1 through April 24, 2007. The excavation cut through the middle of the 118-F-8:4 which had been remediated. The total depth of the 118-F-8:4 (8 meters [26 feet] below ground surface) was below the deepest (6 meters [20 feet]) segment of the 100-F-26:14 pipeline.

Approximately 700 BCM (916 BCY) of contaminated soil was disposed at the Environmental Restoration Disposal Facility and 900 BCM (1,177 BCY) of overburden and layback soil were stockpiled for use as clean backfill.

The COCs/COPCs for verification sampling were strontium-90, cesium-137, cobalt-60, europium-152, europium-154, nickel-63, hexavalent chromium, arsenic, barium, cadmium, total chromium, lead, mercury, selenium, and silver.

Verification sampling was performed on August 8, 9, and 21, 2007, to determine if the RAGs had been met. The laboratory-reported data results for all constituents are stored in the WCH Environmental Remediation System (ENRE) project-specific database prior to submission for archival in the Hanford Environmental Information System (HEIS) site-wide database and were summarized in Appendix C of the RSVP.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. Site contamination did not extend into the deep-zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:15

Classification: Accepted

Names: 100-F-26:15; Miscellaneous Pipelines Associated with 1608-F Sump

Reclassification: Interim Closed Out (3/18/2008)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite includes the miscellaneous radioactive pipelines draining into the 1608-F sump and pumphouse.

The Remaining Sites Verification Package (RSVP) 2007-031, has documented that the subsite conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD). The RSVP supports a reclassification of this site to interim closed out.

Location: The 100-F-26:15 pipelines in the vicinity of the southeast corner of the 105-F Reactor.

Waste Type: Not Specified

Waste Description: The waste was radioactively contaminated piping and associated soils.

Closure Info: The 100-F-26:15 subsite was remediated from January 29 through January 31, 2007. Two distinct areas were excavated resulting in disposal of approximately 82 cubic meters (107 cubic yards) of contaminated materials to the Environmental Restoration Disposal Facility. Only 3 of the 16 pipeline segments (numbers 2, 4, and 15 in Table 1 of the RSVP [CCN 138712]) were found during the excavation. Excavations for the remaining pipeline segments were performed to native soil to verify their previous removal. Eight of the pipeline segments (numbers 7, 8, 9, 10, 11, 12, 14 and 16) were associated with the remediation of the 100-F-19:2, reactor cooling water effluent pipelines, in 2002 (CVP-2001-00003, CCN 133565). The five remaining pipeline segments (numbers 1, 3, 5, 6, and 13) were not discovered during either of the pipeline removal activities in 2002 and 2007. These were most likely removed during previous D activities or historical pipeline replacement projects.

For the five pipeline segments that were not found during either remediation (numbers 1, 3, 5, 6, and 13), excavations at the locations shown on historical drawings were performed until native soil was encountered to verify their previous removal. Additional verification was available for pipeline segments 1 and 6 as these were associated with the 1608-F building. The below grade portion of the 1608-F building is present in the subsurface and was used as a guide to verify these pipeline segments were no longer present. Excavation was performed next to the 1608-F building for pipeline segments 1 and 6 and continued until the bottom of the structure was reached, thereby verifying the pipeline segments were no longer present.

The subsite contaminants of potential concern (COPCs) are described in the verification work instruction (0100F-WI-G0059). COPCs for verification sampling included ICP metals, hexavalent chromium, and mercury. Gross alpha, gross beta, and gamma energy analysis (GEA) were used to detect radioactivity with isotope specific analyses performed for those samples with results greater than background. Americium-241, cesium-137, cobalt-60, europium-152, europium-154, and europium 155 were analyzed by gamma energy analysis (GEA).

Two samples (J14D62 and J14D63) were collected on January 30, 2007, in the primary excavation adjacent to the 105-F Building foundation to allow for an early backfill. The early backfill was necessary to secure the foundation from damage due to undermining. Note that in Table 2 of the RSVP (CCN 138712) these two samples were inadvertently omitted from the summary list of the verification samples, but they (and their results) are listed in Appendix A Attachment 1 "100-F-26:15 Verification Sampling Results."

The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental

Information System (HEIS) and were presented in Appendix A of the RSVP.

The sampling results illustrated that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and contaminant levels remaining in the soil were protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

Code: 100-F-26:16

Classification: Accepted

Names: 100-F-26:16; Reactor Cooling Water Pipelines

Reclassification: No Action (1/11/2005)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-F-26:16 subsite consisted of pipelines inside the Cooling Water Pipe Tunnels that ran between the 190-F Pumphouse and the 105-F Reactor.

Location: The process water tunnels were located due west of the 105-F Reactor (between 190-F and 105-F).

Closure Info: Evaluation of this site indicated that the remedial action objectives and goals have been met as established by the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-1U-6, and 200-CW-3 Operable Units, Hanford Site, (Remaining Sites ROD). The selected action for the 100-F-26:16 site involved using historical information and analogous confirmatory sampling data to support proposal of no action.

Originally, the process water piping was contained inside concrete tunnels. As part of decommissioning activities during 1987, the process water tunnels were filled to grade with clean soil (WHC-EP-0478). This document indicates that the pipelines inside the tunnels were removed and salvaged at the time of decommissioning of the water tunnels.

There was no history of radiological contamination associated with the 100-F Cooling Water Tunnels and no known process incidents at 105-F Reactor that would have introduced contamination from the reactor into the tunnels. Historical sampling of concrete and soil underlying the 105-C Cooling Water Tunnels (BHI-01050) and pipe scale sampling inside the cooling water pipelines at the 100-B Reactor valve pit indicate that residual contamination associated with the 105-B and 105-C Cooling Water Tunnels meets the cleanup criteria.

Given that (1) the 105 F Reactor pipelines are believed to be removed, (2) the tunnels have been back-filled, and (3) the 105-B and 105-C Reactor Cooling Water Tunnels have been determined to meet the cleanup criteria and through evaluation the 100-F-26:16 Reactor Cooling Water Pipelines are analogous to the 105-B and 105-C Reactor Cooling Water Tunnels, the 100-F-26:16 Reactor Cooling Water Tunnels meet the cleanup criteria and the residual contaminant levels are protective of human health, groundwater and the Columbia River.

The SubSite is Part Of:

Code: 100-F-26

Names: 100-F-26; 100-F Water Treatment Facility Underground Pipelines

surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. The basis for reclassification was described in detail in the Cleanup Verification Package 2001-00003.

The cleanup verification package does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]); therefore, institutional controls to prevent uncontrolled drilling or excavation into deep zone soils are required.

Code: 100-F-31	Classification: Accepted
Names: 100-F-31; 144-F Sanitary Sewer System	Reclassification: Interim Closed Out (8/24/2006)
Type: Septic Tank	Start Date:
Status: Inactive	End Date: 1/1/1977

Description: The site has been remediated and interim closed. The site consisted of a septic tank and drain field. The area has been restored to match the surrounding terrain.

Location: The site was located in the 100-F Area within the former Pacific Northwest Laboratory's Experimental Animal Farm site. The 144-F Building was located between the 141-C Animal Barn, Large Animal Barn & Biology Laboratory, Hog Barn Building and the 116-F-14 (107-F Retention Basin) site. The septic system was located directly south of 132-F-2 (144-F Building) and approximately 20 meters (65 feet) west of the 107-F Retention Basin Fence.

Process Description: The septic system was believed to have received both animal and human septic waste from the 132-F-2 (144-F Particle Exposure Laboratory). The 100-F Area included laboratories that performed radiological studies on various species of animals. These laboratories housed animals (mainly dogs) exposed to particulate materials. The 144-F Building was a one-story concrete block building with an office and six laboratories, and included indoor and outdoor animal runs. The 100-F experimental farm was abandoned when Pacific Northwest Laboratory moved its biological studies to the 300 Area and it was believed that the 144-F facility was decommissioned and demolished in 1977, leaving the septic system in place.

Related Sites/Structures: The site received effluent from the 132-F-2 (144-F Particle Exposure Laboratory Building). Pipeline sites in the 100-F Area include the Process Effluent Pipelines in site 100-F-19, the Water Treatment Pipelines in site 100-F-26, the river effluent lines are site 100-F-39, the clean water pipelines were 100-F-41, the experimental animal farm pipelines in site 100-F-29 and miscellaneous pipelines in 100-F-44.

Waste Type: Sanitary Sewage

Waste Description: It is unclear from the drawings H-1-14122, Grading Plan Facilities for Radioactive Inhalation Studies and H-1-14123, Plumbing & Details-Facilities for Radioactive Inhalation Studies, whether the site received animal waste as well as human sanitary waste. Since the site serviced the 144-F Building, there is the potential to have received hazardous contaminants.

Closure Info: The Remaining Sites Verification Package, RSVP- 2006-033, has documented that the site conditions have achieved the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999).

The contaminants of potential concern (COPCs) for the septic system were identified based on historical data, process knowledge, geophysical survey results, and site visit information with focused sampling of residual septic system contents. The COPC list identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) included cobalt-60, cesium-137, europium

152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, uranium-234, uranium 235, hexavalent chromium, mercury, lead, and polycyclic aromatic hydrocarbons (PAHs). As a result of further evaluation of this site, a decision was made to add arsenic, barium, cadmium, total chromium, selenium, silver, and polychlorinated biphenyls (PCBs) as COPCs.

Remediation of the 100-F-31 waste site consisted of the removal of the septic tank, drain field, associated piping, and overburden material. Approximately 350 bank m³ (460 bank yds³) of material was excavated and disposed at the Environmental Restoration Disposal Facility (ERDF). The site was excavated to a maximum depth of 3.0 m (9.8 ft) below ground surface.

Following excavation of the 100-F-31 waste site, verification sampling was performed on February 6, 2006 in accordance with the Verification Work Instruction for the 100-F-31 Septic System, 144-F Sanitary Sewer System. Analytical results from the verification soil samples indicated that the northern side of the excavation contained residual contamination of aroclor-1248. This residual PCB was detected at a concentration of 7.3 mg/kg, which exceeds the direct exposure RAG (0.5 mg/kg). Additional remediation was performed in April 2006 and the PCB-contaminated soil was removed from the north sidewall of the 100-F-31 excavation footprint. A second set of verification samples were collected on May 17, 2006. These samples were analyzed for PCBs to verify that the subsequent remediation efforts had successfully removed the contamination.

The verification sample results were stored in the Environmental Restoration (ENRE) project-specific database prior to archiving in the Hanford Environmental Information System (HEIS) and are included in Appendix A of the RSVP.

Per the RSVP and contact with field representatives, remediation of the waste site consisted of the removal of the septic system, drain field, associated piping, and overburden material. The system was much smaller than historical drawings illustrated. A total of approximately 350 bank cubic meters (460 bank cubic yards) of material was excavated and disposed at the Environmental Restoration Disposal Facility.

The results of verification sampling showed that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils [i.e., surface to 4.6 meters (15 feet) deep]. The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 100-F-33	Classification: Accepted
Names: 100-F-33; 146-F Aquatic Biology Fish Ponds	Reclassification: Interim Closed Out (8/25/2006)
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed. The waste site, also referred to as the 146-F Aquatic Biology Fishponds and the fish laboratory, was designed to conduct tests on fish. The ponds were removed in 1975, no visual evidence remains of their original location. The fish ponds were constructed of unlined reinforced concrete. Originally, there were 6 divided small ponds, 1 circular pond and 1 rectangular pond. The site is an area where unplanned releases likely occurred from the fish ponds.	
Location: The site was located approximately 610 meters (2,000 feet) northwest of the 105-F Reactor Building. Well 199-F5-6 was located just west of the site. The fish ponds were located west of 146-F Aquatic Biology Laboratory, which has been demolished.	

Release Description:	There was no documented record of an unplanned release from this site. However, due to leakage from the ponds and associated piping and/or splashing from within the ponds, the release of contaminated water to the surrounding environment was likely.
Process Description:	The studies involved exposing fish to varying concentrations of reactor cooling water effluent to assess possible effects of effluent discharge on aquatic life in the Columbia River. In addition to hatchery troughs, there were six rearing ponds located next to the laboratory. Effluent water was continuously circulated through the troughs at a rate of about 0.2 to 0.3 liters per second (3 to 5 gallons per minute) and was discharged to the Pacific Northwest Laboratory Outfall (116-F-16) via the 147-F Pump House. Testing began in 1945 and was conducted using various mixtures of river and effluent water to determine effects on fish. The effluent water contained a variety of chemicals that included process cooling water, sludge from the water purification area, condenser water, refrigeration cooling water, floor drainage containing radioactive substances and substances that inhibited corrosion, such as materials used for purging the tubes in the pile. From 1947 through 1950, salmon eggs, rainbow trout, carp, and crayfish were tested under several conditions. Testing included unrefrigerated effluent water, effluent treated with five parts of river water from the 107-F Retention Basin, charcoal filtered and unfiltered river water with 2 parts per million (ppm) dichromate added, pre-pile process water, 5 ppm sodium silicate, and copper sulfate. The testing was designed to determine the accumulation of activity in bone, liver, skin, and the gastrointestinal tract. Some of the feed supplied to the fish was algae and snails. Document HW-20266-RD stated that some of the feed was grown in effluent from the 107-F Retention Basin. The fish ponds were constructed of unlined reinforced concrete. The configuration of the fish ponds were 6 small rectangular ponds, in a 2 by 3 matrix, one large circular pond located due south of the smaller ponds. Two larger rectangular ponds may have been located between the 6 smaller ponds and the circular pond. There is a note on Drawing H-1-2898 Sheet M-1, Mechanical Plot Plan, Aquatic Biology Laboratory that says that these larger rectangular ponds were not built during 1951-1952 construction. These ponds may never have been constructed. Later drawings show only the six smaller rectangular ponds and the one large circular pond. The six pairs of small rearing ponds were numbered 1 through 12. The structures had outer dimensions of 3.35 meters (11 feet) by 2.90 meters (9.5 feet). Each had a center dividing wall separating it into two halves. If the outer walls and dividing walls were 15 centimeters (6 inches) thick, the dimensions of each half would have been 1.2 meters (4 feet) by 3.0 meters (10 feet) by 0.9 meters (3 feet) which is the size of a liquid waste disposal facility documented in both HW-43121 and HW-33305. Pond 13 was the largest, measuring 16 meters by 2 meters (51 feet by 6 feet). It also contained a circular pond that measured 9 meters (30 feet) in diameter. Drawing H-1-2898, Architectural Plot Plan, Aquatic Biology Laboratory, showed the addition of 3 additional ponds. Hanford Drawing, H-1-2898, Sheet 17, Rectangular Ponds - Aquatic Biology Laboratory shows a pair of the pond structures that were 5.8 meters (19 feet) by 3.5 meters (11.5 feet). Each of the ponds were split lengthwise down the middle by a divider. The divider was removable and did not extend the full length of the pond. The ponds sloped towards the end of the structure containing the drains (2 drains per structure). The depth of the ponds was 0.91 meters (3 feet) sloping to 1 meter (3.3 feet). There was a note on Drawing H-1-2898 Sheet M-1, Mechanical Plot Plan, Aquatic Biology Laboratory that stated these larger rectangular ponds were not built during 1951-1952 construction. These ponds may never have been constructed. Later drawings show only the six smaller rectangular ponds and the one large circular pond. Hanford Drawing H-1-2898, Sheet 18, Circular Pond - Aquatic Biology Laboratory shows the large circular pond to be 9.1 meters (30 feet) in diameter and about 0.87 meters (34 inches) high. The pond slopes to the middle toward a center drain.
Related Sites/ Structures:	The site was related to the 146-F Aquatic Biology Fish Ponds laboratory.
Waste Type:	Water

Waste Description:	contaminants as the radioactive process effluent. A pipeline containing radioactive process effluent came from the reactor to this site. The waste was the pipelines and contaminated soil.
	Contaminants of potential concern were Co-60, Ce-137, Eur-152, Eu-154, Eu-155, Pu-238, Pu-239/240, Sr-90, U-234, U-235, Cr6, Hg, Pb, and polycyclic aromatic hydrocarbons (PAHs).
Closure Info:	The Remaining Sites Verification Package, (RSVP-2006-021), for the 100-F-33 site, documents that the waste site has met the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999).
	Contaminants of concern were Cs-137, Co-60, Eu-152, Eu-154, Eu-155, Pu-238, Pu-239/240, Sr-90, U-234, U-235, PAH, mercury, lead, hexavalent chromium,
	Based on field observations during confirmatory sampling and the results of laboratory analysis of samples collected from trench 1 and trench 2, it was decided that the northern portion of the site required remediation. However, the confirmatory sample results for the southern portion of the site, collected in the area of the circular fish pond (test pit 3), did not indicate that residual contaminants were present exceeding cleanup criteria, and, therefore, it was decided that this portion of the site did not require remedial action. Site personnel noted that 10 m (33 ft) of the process sewer leading to the circular pond in the south half of the site appeared to be outside of the excavation. The drain at the head end of this sewer was sampled (J01TF8) as part of 100-F-33 test pit 3 and did not require remedial action. It is assumed that this segment was closed in place using the same information.
	Remedial action of the northern portion of the site was initiated on August 5, 2005, and continued through August 8, 2005, with excavation of 2,024 m ³ (2,231 U.S. t) of material including concrete debris, piping, and soil. Excavated soil and debris were staged at the site until disposal of the materials to the Environmental Restoration Disposal Facility (ERDF) occurred from September 19 to September 21, 2005. Radiological surveys were performed over the excavation and staging pile areas using a mobile sodium iodide detector.
	Verification sampling was performed on January 24, 2006 to evaluate if the remedial action objectives had been reached. Based on statistical evaluation of the resulting data, the residual contaminant concentrations met the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD. The laboratory-reported data results for all constituents were stored in the WCH ENRE project-specific database prior to archiving in HEIS and were presented in Appendix A of the RSVP.
	The results of verification sampling demonstrate that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 100-F-34	Classification: Accepted
Names: 100-F-34; Biology Facility French Drain	Reclassification: Interim Closed Out (5/22/2002)
Type: French Drain	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and closed out. The french drain was removed during the 100-F	

Area cooling water effluent pipeline remediation activity in 2002 (100-F-19:1).

Location: The drain was located due south of the demolished 1705-F Experimental Gardens. The drain location is noted on Hanford Drawing H-1-13850. There is a label titled "Greenhouse and Slab (Removed) June 6, 1975" and behind and between the "o" and the "v" of "Removed" is a small circle.

Process Description: It was not known what purpose this site served. The pipeline that connected the french drain to a facility has not been located on any of the numerous drawings that have been researched for this area.

Related Sites/ Structures: The site is believed to be associated with one of the Biology Facilities that were part of the Experimental Animal Farm.

Closure Info: 100-F-19:1, 100-F-19:3, 100-F-34 and 116-F-12 were addressed as a group. The information below documents information for the group of sites.

The 100-F-19:1 North Pipelines, 100-F-19:3 West Pipelines, 100-F-34 Biology Facility French Drain, and the 116-F-12 French Drain were remediated as a group in CVP-2001-00002. These sites meet the cleanup standards specified in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units, U.S. Environmental Protection Agency, Region 10, Seattle, Washington.

The site remedial action began on August 7, 2001. Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Cleanup verification sampling began on September 7, 2001, and was finished on September 25, 2001. The results showed that the materials from the 100-F-19:3 subsite containing COCs at concentrations exceeding RAGs have been excavated and disposed of.

Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. All cleanup verification samples for the 100-F-19:3, 100-F-34 and 116-F-12 sites are listed under 100-F-19:1.

Code: 100-F-36	Classification: Accepted
Names: 100-F-36; 108-F Biological Laboratory; 108-F Chemical Pump House	Reclassification: No Action (5/24/2007)
Type: Laboratory	Start Date: 1/1/1944
Status: Inactive	End Date: 1/1/1973

Description: The site has been remediated and reclassified to No Action. The site consisted of a building that was demolished in August of 1999. Most of the building debris and foundations were removed. All exposed piping was cut at the edge of the excavation; the piping trench, sump, and french drain 100-F-15 were removed (the pipe remains at the site); all disturbed areas were graded smooth, and the facility footprint soils were fixed in place with soil cement.

Location: The site was located approximately 100 meters (330 feet) east of the 105-F Reactor Building.

Process Description: The 108-F building was constructed in 1944 as part of the original Hanford site construction. It was originally a chemical makeup facility that supported the 105-F reactor. In 1949, the 108-F building was completely remodeled for use in life-science studies for the effects of radiation and contamination on plant and animal life. The original 108-F building was a four-story steel frame, concrete block structure with reinforced concrete foundation, and a total floor space of about 1,858 square meters (20,000 square feet). The roof was constructed of concrete tile with a built-up tar and gravel surface. In 1949, and again in 1962, the 108-F building was

remodeled, and the floor space increased by the addition of a 1,022 square meter (11,000 square foot) annex. This addition was a three-story concrete block structure adjoining the older building. The interior of the building contained 39 offices, 47 laboratories, and a heavily shielded cobalt-60 source room, 18 rooms for handling small animals, a large conference room, an administrative section, a library, lunch and locker rooms. Since radioactive materials were used in the work performed within the building, the laboratories and storage rooms were maintained in a controlled status until 1973 when the laboratory activities were phased out and transferred to 300 Area facilities. From 1983 through 1984, the first floor of the 108-F Building was used for office space.

Related Sites/ Structures: The initial intended use of the 108-F Building was to provide chemical treatment of the 105-F Reactor cooling water. Site 116-F-15 was a sump with an associated trench in the middle of the building. During excavations and sampling in Winter 2002, the 6 inch (15 centimeter) cast iron pipe at this location had radiation readings of 3000 disintegrations per minute (dpm) alpha and 250,000 dpm beta-gamma. The excavation was closed up without removing any material. French drains on the perimeter of the building included 100-F-4, 100-F-11, 100-F-15, and 100-F-16.

Waste Type: Equipment

Waste Description: The main drain trench and sump were posted as a radiological contamination area. Potential contaminants of concern for this facility were plutonium-238, strontium-90, cobalt-60, and cesium-137.

Waste Type: Equipment

Waste Description: On the first floor there are exposed sheets of lead, approximately 0.64 centimeters (0.25 inches) thick under the wallboard. All paint within the facility is suspected to contain lead.

Waste Type: Oil

Waste Description: Oil in the elevator motor, compressor motors, water coolant system and hoist equipment was suspected to contain polychlorinated biphenyl (PCB) and Resource Conservation and Recovery Act of 1976 (RCRA) metals.

Waste Type: Soil

Waste Description: Friable asbestos insulation, asbestos cement, pipe wrapping and suspected asbestos-containing floor tiles were in the building before demolition.

The 108-F closeout report reported contaminants of concern as mercury, PCBs, lead, asbestos, sodium dichromate, and miscellaneous low radiological contamination.

Closure Info: 100-F-36 and 116-F-15 were addressed as a group. The information below documents information for the group of sites.

The Remaining Sites Verification Package for 100-F-36 and 116-F-15 (RSVP-2007-002) has documented the reclassification of the co-located sites. The 100-F-36, 108-F Biological Laboratory waste site has met the objectives for No Action and the 116-F-15, 108-F Radiation Crib waste site has met the objectives for Interim Closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site (Remaining Sites ROD).

Remediation of the 116-F-15 waste site was performed on September 26, 2005, and consisted of the removal of approximately 86 metric tons (95 US tons) of material, including concrete debris, piping, and soil. The material was disposed at the Environmental Restoration Disposal Facility. The soil was excavated and field surveyed to a depth of approximately 2.6 meters (8.5 feet).

Following excavation, verification sampling was performed. Contaminants of potential concern (COPCs) were combined because the sites were co-located within the boundary of the 100-F-36 waste site. Each confirmatory and verification sample was analyzed for all constituents. The combined list of COPCs identified in the RDR/RAWP included the following: cobalt-60, cesium-137, europium- 152, europium- 154, europium- 155, plutonium-238, plutonium-239/240, strontium-90, uranium-238, inductively coupled plasma metals, mercury, hexavalent chromium, polychlorinated biphenyls, and asbestos.

After the remediation, verification sampling of the waste site was performed on December 12, 2006. All sample data results were stored in the Environmental Restoration (ENRE) project-specific database prior to being archived in the Hanford Environmental Information System (HEIS) and summarized in appendix B of the RSVP.

Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels has been made for contaminants of potential concern and other constituents. Screening levels were not exceeded for either site constituents, with the exception of boron, mercury, and vanadium.

Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. It is believed that the presence of these constituents does not pose a risk to ecological receptors because concentrations of vanadium and mercury are below site background levels and boron concentrations are consistent with those seen elsewhere at the Hanford Site (no established background value is available for boron). A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

The results of sampling indicated that residual contaminant concentrations did not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep).

The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. Remedial actions were not required for deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. The results indicated compliance with the remedial action objectives and goals for the site. The results of the sampling data were used to make reclassification decisions for the site in accordance with the TPA-MP-14 procedure.

The results indicated compliance with the remedial action objectives and goals for these sites. The results of the sampling are used to make reclassification decisions for the 100-F-36 and 116-F-15 sites in accordance with the TPA-MP-14 (DOE-RL 2007) procedure.

Code: 100-F-37	Classification: Accepted
Names: 100-F-37; French Drain Discovered Near Hydrant F-2	Reclassification: No Action (8/11/2004)
Type: French Drain	Start Date:
Status: Inactive	End Date:
Description: The site consisted of an abandoned french drain.	
Location: The site was about 235 meters (760 feet) east-northeast of the 100-F Reactor. It was in the northeast corner of the intersection of the F Area perimeter Road and the north-south road that	

ran on the east side of the 1716-F, 1713-F, 1717-F, and 1707-F facilities.

Waste Type: Soil

Waste Description: The analytical results showed a high level of lead at 214 ppm.

Closure Info: Sampling of the discolored stained soil associated with the french drain was performed on November 3, 2000 to support disposal of the concrete pipe that was removed during excavation of the electrical conduit trench. The sample was submitted for inductively coupled plasma metals (ICP metals), mercury, and semi-volatile organic analysis (SVOA). Radiological surveys during excavation and sampling did not identify any field detectable radiological activity and since the site was not associated with historical radiological processes, the sample was not analyzed for radionuclides.

The sample results demonstrated that the site had achieved the remedial action objectives and remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE RL-96-17, Rev. 5, Draft B) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site (commonly called the Remaining Sites Record of Decision) (EPA, 1999).

These results demonstrated that the associated residual soil concentrations support future unrestricted land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrated that residual contaminant concentrations support unrestricted future use of vadose zone soil and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site is not a deep zone site (i.e., below 4.6 meters [15 feet]); therefore, deep zone institutional controls are not required.

Code: 100-F-38	Classification: Accepted
Names: 100-F-38; Yellow Stained Soil Near Hydrant F-2	Reclassification: Interim Closed Out (3/13/2006)
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed out. The waste site consisted of yellow soil discovered during the excavation of a trench for electrical conduit in November 2000. The trench ran diagonally through the parking lot from the subcontractor trailer to Hydrant F-2.	
Location: The site was located approximately 235 meters (760 feet) east-northeast of the 100-F Reactor. It was in the northeast corner of the intersection of the F Area perimeter road and the north-south road that ran on the east side of the 1716-F, 1713-F, 1717-F, and 1707-F facilities.	
Related Sites/ Structures: A small unidentified structure north of this site can be seen in aerial photos shown in the 100-F Area Technical Baseline Report. The yellow stained soil was found immediately north of Hydrant F-2, and south of the unearthed rust coated rocks and french drain (100-F-37), discovered in the same excavation. Their relationship, however, was not known.	
Waste Type: Soil	
Waste Description: The stained soil showed high levels of chromium and lead. No radioactivity was detected with field instruments.	
Closure Info: The site has been evaluated and remediated in accordance with the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (commonly called the Remaining Sites Record of Decision [ROD]) (EPA 1999) and the	

Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR).

Sampling of the yellow soil at the site was performed during November 2000. A focused sampling approach was used to collect a sample of the yellow soil when it was first encountered while trenching at that location for the placement of underground utilities. At the time of discovery, the yellow soils were assumed to be associated with the disposal or spilling of unused paint. Therefore, inductively coupled plasma (ICP) metals were identified as the potential contaminants associated with the yellow soil. Although the excavation of the utility trench was not performed within a radiologically controlled area, a radiological control technician was directed to perform a field survey to verify that radiological contamination was not present. Radiological contamination was not detected during this survey.

The contaminants of concern (COCs) included arsenic, barium, beryllium, boron, cadmium, total chromium, Chromium VI, cobalt, copper, lead, manganese, molybdenum, nickel, vanadium, zinc, and Aroclor-1260. The laboratory analytical results for the single soil sample indicated that concentrations of barium, lead, and chromium exceed remedial action goals (RAGs). Remedial action occurred in September 15, 2005. Verification sampling occurred in November 21, 2005.

Barium, lead, and aroclor-1260 were quantified at levels exceeding applicable RAGs for the protection of groundwater and/or the Columbia River. However, results of the 100 Area Analogous Sites RESRAD Calculations indicate that none of these contaminants will reach groundwater (and therefore the Columbia River) within 1,000 years. Residual concentrations of all other COCs/COPCs were below applicable RAGs. The laboratory-reported analytical results for all constituents have been stored in the WCH Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System. The depth of the excavation was approximately 0.9 meters (3 feet), and there were no stockpile areas associated with this site.

Code:	100-F-39	Classification:	Accepted
Names:	100-F-39; 100F River Effluent Pipelines; 100F River Lines	Reclassification:	None
Type:	Radioactive Process Sewer	Start Date:	
Status:	Inactive	End Date:	
Description:	This site consists of the river effluent pipelines (river lines) that extend from 1904-F outfall (116-F-8) in the 100F area into the main channel of the Columbia River.		
Location:	The river lines are located in the Columbia River, adjacent to the 100F area. The lines extend north into the main channel of the river from the 1904-F outfall (116-F-8). The river effluent pipelines extend from, and are perpendicular to, the discharge (river side) face of the 116-F-8 outfall structure for 91 meters (300 feet) into the main channel of the river.		
Release Description:	No recorded releases were found.		
Process Description:	Reactor cooling water was discharged from the 105-F Building through 152 centimeter (60 inch) diameter effluent lines to temporary storage in 116-F-14 (the 107-F Retention Basin), before being pumped to the river via 116-F-8 and two associated 107 centimeter (42 inch) pipelines (100-F-39). In the event the lines became plugged or had to be removed from service during operation, the effluent overflowed the outfall and entered the river via an attached spillway (100-F-42). The two river lines were constructed of 107-centimeter (42-inch) diameter reinforced concrete/steel pipes with 1.3-centimeter (0.5-inch) thick walls. The two parallel lines were originally 91 meters (300 feet) long). During a survey in 1994, the pipes were found to extend about 24 meters (80 feet) offshore, protruding 1.2 to 2.4 meters (4 to 8 feet) above the		

riverbed. No buried or exposed pipelines could be found further offshore using geophysical instruments. The pipelines may have been obscured by large pieces of debris or rip rap. In 1946, damaged sections of pipe were removed from the river and buried in the riverbank. The broken pipe sections were buried in the riverbank just upstream of the outfall and marked with stakes.

Related Sites/ Structures: The site is associated with the 116-F-8 outfall, the process effluent lines (100-F-19), the water treatment facility pipelines (100-F-26), the 107-F Retention Basin (116-F-14), the animal barn (141-C), the 100F Experimental Animal Farm Process Sewer Pipelines (100-F-29), the aquatic biology fish ponds (100-F-33), the PNL outfall (116-F-16), the PNL spillway (100-F-43), and the 100-F-42 spillway. Pipeline sites in the 100-F Area include the Process Effluent Pipelines in site 100-F-19, the Water Treatment Pipelines in site 100-F-26, the river effluent lines are site 100-F-39, the clean water pipelines were 100-F-41, the experimental animal farm pipelines in site 100-F-29 and miscellaneous pipelines in 100-F-44.

Waste Type: Process Effluent

Waste Description: The waste includes the pipelines and the contaminated scale and sediment which may be contained within them.

Contaminants of concern/potential concern are based on those for 116-F-8 Outfall Structure. Contaminants of concern include cobalt-60, europium-152, europium-154, europium-155, and hexavalent chromium.

Contaminants of potential concern include carbon-14, cesium-137, nickel-63, and strontium-90.

Code: 100-F-42	Classification: Accepted
Names: 100-F-42; 1904-F Spillway; 100-F-39:1 Flume	Reclassification: Interim Closed Out (9/26/2006)
Type: Outfall	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed. The site consisted of a reinforced concrete spillway (also referred to as a flume). The spillway extended from the 116-F-8 Outfall to the Columbia River shoreline and into the river.	
Location: The spillway was located approximately 214 meters (700 feet) north of the 116-F-14 Retention Basin. The upper end of the spillway began at the west face of the outfall and terminated in the river.	
Process Description: The spillway was an alternate discharge point for the 116-F-8 Outfall Structure. It was to be used only if the 100-F-39 river effluent pipelines were blocked, damaged, or undergoing maintenance. There was no corroborated physical or historical evidence that the spillway was ever used. The flume was constructed of reinforced concrete and was 4 by 0.6 meters (14 by 2 feet) deep and about 40 meters (130 feet) long. It was an open concrete structure with a flat bottom and two sidewalls. An engineered erosion barrier composed of heavy riprap was constructed at the discharge end of the concrete structure. The spillway was designed to prevent excessive backwater at the 107-F Retention Basin during high water or in the event of a blockage of the outfall lines.	

Related Sites/ Structures: The site was associated with the 100-F-39, 100-F River Effluent Pipelines, the 116-F-8 Outfall Structure, the 116-F-16 (PNL) Outfall, and 100-F-43 (PNL) Spillway.

Waste Type: Construction Debris

Waste Description: If ever put into service, the COPCs for the 100-F-42 spillway would be the same as those for

Description:

the 116-F-8 outfall structure. The contaminants of concern include Cobalt-60, Europium-152/154/155, and hexavalent chromium.

Closure Info: 116-F-8 and 100-F-42 were addressed as a group. The information below documents information for the group of sites.

The Remaining Sites Verification Package (RSVP-2006-038) documented that the 116-F-8 and 100-F-42 waste sites have met the objectives for interim closure. The remedial action objectives (RAOs) and remedial action goals (RAGs) for these sites were established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The 100-F-42 Spillway was administratively separated from the 116-F-8 Outfall for inclusion within the Remaining Sites ROD by agreement among the Tri-Parties. It was subsequently determined that sufficient evidence existed to warrant remedial action during remediation of the 116-F-8 waste site, therefore both waste sites were remediated and evaluated as a single unit.

The waste site Contaminates of Concern (COCs) were based on the list presented in the Remaining Sites ROD, as expanded in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) for the 116-F-8 waste site. The COCs included: cobalt-60, europium-152, europium-154, europium-155, and hexavalent chromium. Cesium 137 was also included as a COC due to analytical detections within verification samples.

Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels has been made for the site COCs; screening levels were not exceeded. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which included a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decisions for the 116-F-8 and 100-F-42 waste sites.

Remedial action activities at the waste sites were conducted from August 31, 2004, to September 22, 2005. Remediation involved excavation and staging of clean overburden material and removal of the demolished concrete outfall structure, the concrete spillway structure above the Columbia River ordinary high water mark, and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. The residual 100-F-39 effluent pipelines will be sealed with concrete prior to backfill of the remediation footprint. Contaminated materials were disposed at the ERDF.

Final cleanup verification sampling was conducted from February 9 to 26, 2006, following variance analyses. The final verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency analytical methods as required per the SAP. Each verification sample was composed of a composite sample formed by combining soil collected at the required number of randomly selected locations within each sampling area (excluding the quality assurance/quality control samples).

Due to their immediate proximity and historic functional relationship, the 116-F-8 and 100-F-42 waste sites were combined into one unit for the purposes of decision unit stratification.

The cleanup verification sample analytical data were stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System. The sampling information was also included in Appendix A of the RSVP.

Approximately 1,325 meters squared (14,260 square feet) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 feet] below ground surface) up to 8 meters (26 feet) below ground surface. Approximately 4,900 metric tons (5,400 U.S. tons) of material from the sites was removed and disposed at the ERDF.

The results of verification sampling demonstrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also showed that residual contaminant concentrations were protective of groundwater and the Columbia River. The results of deep zone verification sampling also showed that residual deep zone contaminant concentrations met the requirements for unrestricted direct exposure; accordingly, no institutional controls are required for deep zone soils.

Code:	100-F-43	Classification:	Accepted
Names:	100-F-43; 116-F-16 PNL Outfall; Spillway for PNL Outfall; 100-F-39:1	Reclassification:	Interim Closed Out (9/14/2006)
Type:	Outfall	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed. The 100-F-43 spillway (also referred to as a "flume") was constructed of reinforced concrete, and extended from the 116-F-16 PNL Outfall to the Columbia River shoreline and into the river. An engineered erosion barrier composed of heavy riprap was constructed at the discharge end of the concrete structure.		
Location:	The site was located approximately 670 meters (2,200 feet) northeast of the 105-F Reactor Building and about 15 meters (50 feet) upstream of the 116-F-8 Outfall. It was connected to the 116-F-16 PNL outfall face at E580952 N148128, and extends into the river to E580975 N148160.		
Process Description:	The 116-F-16 PNL Outfall emptied into the spillway via direct discharge. The spillway was a 4.6-meter (15-foot) wide concrete structure that extended approximately 6.1 meters (20 feet) out from the shoreline and approximately 3.7 meters (12 feet) into the Columbia River. The sides were 46 centimeters (18 inches) high and extended down the length of the structure. The vertical walls of the upper portion had been demolished and covered with soil.		
Related Sites/ Structures:	The site was associated with 100-F-29 (100-F EAF Process Sewer Pipelines), 100-F-19, 100-F Reactor Cooling Water Effluent Underground Pipelines, Contaminated Underground Lines, Effluent Water System, 1904-F Process Sewer (See Subsites), the 116-F-8 (1904-F) Outfall Structure, the 100-F-42 (1904-F) Spillway, and the 116-F-16 PNL Outfall.		
Waste Type:	Animal Waste		
Waste Description:	The unit received animal sewage, 107-F Retention Basin water from fish studies, and low-level contamination resulting from various 100-F EAF projects.		
	If ever put into service, the COPCs for the 100-F-42 spillway would be the same as those for the 116-F-16 outfall structure, and include Plutonium-239/240, Strontium-90, Cesium-137, Lead, and hexavalent chromium.		
Closure Info:	116-F-16 and 100-F-43 were addressed as a group. The information below documents information for the group of sites.		
	The 100-F-43 waste site was administratively separated from the 116-F-16 waste site for future inclusion within the Remaining Sites Record of Decision by agreement among the Tri-Parties. It was subsequently determined that sufficient evidence existed to warrant remedial action of		

both waste sites as a single unit. All samples collected during remediation are listed under 116-F-16

The Remaining Sites Verification Package (RSVP-2006-039) has documented that the 116-F-16 and 100-F-43 waste sites were remediated in accordance with the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD). Remedial action objectives (RAOs) and remedial action goals (RAGs) for this site were documented in the Remaining Sites ROD and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Remedial action activities at the sites were conducted from August 31, 2004, to September 8, 2005. Remediation involved excavation and staging of clean overburden material and removal of the outfall, the concrete spillway structure above the Columbia River ordinary high water mark, and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. Final cleanup verification sampling was conducted on February 13 and 15, 2006.

The Contaminants of Concern included: cesium-137, plutonium-239/240, strontium-90, hexavalent chromium, and lead.

Approximately 384 meters squared (4,130 square feet) of plan area was excavated, with all remedial activities restricted to the shallow zone (less than 4.6 meters [15 feet] below ground surface). Approximately 2,090 metric tons (2,300 U.S. tons) of contaminated material was removed from the site and disposed at the ERDF. The cleanup verification sample data have been summarized in Appendix A of the RSVP. The data were stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System.

No institutional controls are required for this site to prevent uncontrolled drilling or excavation into deep zone [i.e., below 4.6 m (15 ft)].

Code: 100-F-44	Classification: Accepted
Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)	Reclassification: None
Type: Process Sewer	Start Date:
Status: Inactive	End Date:
Description: The site consists of a compilation of pipelines and pipeline segments not previously addressed in any closure documents. The various pipelines may require remedial action. See the subsite summaries for specific information.	
Location: The underground pipeline segments are located in the F Area and co-located with those described in waste site 100-F-26 (100-F Water Treatment Facility Underground Pipelines, 16 subsites).	
Related Sites/ Structures: Segments of pipelines were identified within the areas of the following buildings: 105-F, 1717-F, 190-F, 1608-F, 141-C, 187-F1 elevated water tower and 189-F. Pipeline sites in the 100-F Area include the Process Effluent Pipelines in site 100-F-19, the Water Treatment Pipelines in site 100-F-26, the river effluent lines are site 100-F-39, the clean water pipelines were 100-F-41, the experimental animal farm pipelines in site 100-F-29 and miscellaneous pipelines in 100-F-44.

Type: Process Sewer	Start Date:
Status: Inactive	End Date:

Description: The 100-F-44:1 pipeline site was discovered during confirmatory sampling at test pit 5 of the 100-F-26: 1 pipelines site. The test pit contained a junction box with two 76 centimeters (30-inches) reinforced concrete pipes and a previously unidentified 20-centimeter (8-inch) carbon steel pipe. The smaller pipe was just west of the 182-F Reservoir and ran north from the junction box an undetermined distance at a depth of (7 feet) below the ground surface. The only building in the vicinity was the former 182-FA Pump Test Stand. Drawing H-1-11253 shows a 20-centimeter (8-inch) pipe between the 182-FA building and the junction box where two 76-centimeter (30-inch) reinforced concrete pipes met.

The Pump Test Stand was built in 1959 to test new designs for impellers and prototype pumps for future use at the 190 Pumphouse. It was located west of the 182-F reservoir. The pumps, instrument panels and suction piping were housed inside an army surplus prefabricated building. Apparently the project was of a short duration, therefore sanitary and steam utilities were not constructed. The only underground piping installed from the pump test stand was between the 182-F reservoir and the process sewer. Water from the 182-F reservoir was recirculated through a suppression tank with constant makeup and bleed to control temperature rise.

Location: The pipeline runs north-south and west of the 182-F reservoir. The junction box was sampled at coordinates N148179 E580343 where the pipeline starts, before continuing north for an

undetermined distance at a depth of 2.1m (7 ft) below ground surface.

Waste Type: Not Specified

Waste Description: The waste is piping, scale/sediment, concrete, and soil (if contaminants are present).

Closure Info: The maximum detected results for all COPCs in pipeline scale/sediment and underlying soil samples were less than background or applicable RAGs and therefore meet the RAOs. Based on these results, no remedial action is required for this segment of pipeline. As documented in the Remaining Site Verification Package for 100-F-26:1 North Process Sewer Collection Pipelines (Attachment to Waste Site Reclassification Form 2005-008), the process sewer that joined the 182-FA discharge pipe at the junction box was sampled as part of confirmatory sampling for the 100-F-26:1 pipelines site.

Evaluation of the confirmatory sample results for the 100-F-26:1 satisfied the remedial action objectives and the site was reclassified to "No Action". The water carried by the 100-F-44:1 pipeline was essentially the same water as that carried by the 100-F-26:1 pipeline, therefore no remedial action for the 100-F-44:1 subsite was needed and it may be reclassified.

The SubSite is Part Of:

Code: 100-F-44

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:2

Classification: Accepted

Names: 100-F-44:2; Discovery Pipeline Near 108-F Building

Reclassification: No Action (5/30/2008)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: A geophysical survey of the 100-F-44:2 subsite was conducted in January 2007 (Geophysical Site Investigation Summary form CCN 0574490) using ground-penetrating radar. Two east-westerly trending linears were identified that appear to originate or pass through the former junction box location. The linear that extends to the east is consistent with the location and depth of the 100-F-26:4 pipeline. The linear that extends to the west is consistent with the location and orientation of the pipeline of interest (100-F-44:2). The assumed 100-F-44:2 pipeline linear is interpreted to be between 1 and 1.5 m (3 and 5 ft) deep.

Location: This pipeline is on the east side of the 187-F1 water tower.

Waste Type: Not Specified

Waste Description: The waste includes the pipelines and any contaminated soil associated with these pipelines.

Closure Info: The current subsite conditions as documented in the Remaining Sites Verification Package 2007-006, have achieved the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

Confirmatory sampling at the 100-F-44:2 subsite was performed on January 16. A test pit was excavated to a depth of approximately 2 meters (7 feet) where the pipeline was located (Washington State Plane Coordinates N 147619, E 580539). The pipe was located and uncovered eastward toward the 100-F-26:4 excavation boundary. The pipe was cut open at coordinates N 14618, E 580542. No interior pipe sample could be taken because there was no

sediment or scale inside the pipe.

The results of confirmatory sampling illustrated that contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that contaminant concentrations were protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to submission for archival in the Hanford Environmental Information System site-wide database and are summarized in Appendix B of the RSVP.

The SubSite is Part Of:

Code: 100-F-44

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:3

Classification: Accepted

Names: 100-F-44:3; 1607-F3 Sewer System Pipeline

Reclassification: Rejected (6/14/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-F-44:3 subsite was identified as a 30.1 cm (12 in) diameter steel or cast iron pipeline. During confirmatory sampling of the 100-F-26:10 test pit #2, in 2004, a pipeline was observed at the bottom of the manhole, estimated at a depth of approximately 6.4 m (21 ft). Based on the observation of the pipeline as recorded in the sampling logbook EL 1578-4 page 43, the pipeline was listed as a discovery site, and added as the Site 100-F-44:3 subsite. The logbook is the only source of information for this site.

No other pipeline was encountered during the excavation. There was no evidence to support the existence of the 100-F-44:3, 0.3-meter (1-foot)-diameter steel or cast iron pipe within the manhole at the 100-F-26:10 test pit #2. Therefore, 100-F-44:3 was reclassified as Rejected from consideration as a waste site. The 100-F-44:3 subsite does not pose a risk to human health or the environment and will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario, and no institutional controls are required.

The subsite was originally identified, by visual observation during confirmatory sampling within the manhole at 100-F-26:10 test pit #2. However, it has been determined, through the excavation of the 100-F-26:10 pipelines in 2007, that the visual observation of the 100-F-44:3, 0.3-meter (1-foot)-diameter steel or cast iron pipe was erroneous. The entire manhole was removed during the 100-F-26:10 remediation, as was a volume of the soil beneath and surrounding the manhole. The 100-F-26:10 vitrified clay pipelines intersecting with the manhole location were removed, and the excavated site will be closed out following completion of the selected remedial action per the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units.

The purpose of the pipeline was unknown, although a 0.3 m (1 ft) process sewer pipeline entering a manhole containing septic pipelines is certainly not a standard procedure. The test pit was located at coordinates E580259, N148001 and east of the 183-D Filter Plant.

Therefore, 100-F-44:3 was reclassified as "rejected" from consideration as a waste site. The

subsite does not pose a risk to human health or the environment and will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario, and no institutional controls are required.

Location: pipeline was reported to be within a manhole. The manhole was located at the Washington State Plane coordinates of E580259, N148001.

The SubSite is Part Of:

Code: 100-F-44

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:4

Classification: Accepted

Names: 100-F-44:4; Discovery Pipeline in Silica Gel Pit

Reclassification: No Action (9/23/2008)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-F-44:4 subsite consisted of a steel pipe discovered October 17, 2004, during trenching to locate the 118-F-4 Silica Gel Pit. The 110-F Gas Storage Tanks consisted of two low-pressure (carbon dioxide) storage tanks, 33 high-pressure (helium) storage tanks, an unloading platform, and a rail tank-car spot. The area is believed to have remained essentially unchanged from the time of the reactor's construction in 1944 until the demolition of nearby structures [i.e., 132-F-3 (115-F Gas Recirculation Facility)] in 1984. There were no pipelines indicated on historical drawings for the area. Water, sewer, fire, and steam lines were all north of the 110-F structure and entered the northwest corner of 132-F-3.

The nearest waste site was the 118-F-4 Silica Gel Pit. According to historical records silica gel was deposited once in 1949. No installation of pipelines was involved.

Location: The pipeline was located 122 m (400 ft) west southwest of 105-F, at coordinates N147522 E580298.

Waste Type: Soil

Waste Description: The waste was pipeline sediment/scale and underlying soil.

Closure Info: The Remaining Sites Verification Package 2008-030, documented that the 100-F-44:4 subsite has met the remedial action objectives and goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site. (Remaining Sites ROD)

A phased approach was used to evaluate the pipeline and collect samples in support of the sampling objectives. Confirmatory sampling began on February 13, 2008 (EL-1601-2 pp. 38, 49, 50). An exploratory test trench approximately 5 to 6 m (15 to 20 ft) long was excavated. However, the pipe was not found at that location. On February 21, 2008, another trench was dug approximately 6 m (20 ft) due east of the first trench and of approximately the same length. This time the pipe was found and observed to be approximately 5 cm (2 in.) in diameter and 0.9 m (3 ft) below grade. The pipe length was determined to be 6 m (20 ft).

The visual evidence indicated this pipe was a piece of electrical conduit debris and not a process pipeline or sewer pipeline. Though the pipe was identified as non-hazardous conduit debris, part of the confirmatory samples planned for the waste site was collected. On February 25, 2008 the pipe was cut and a sample of about 250 ml of soil was taken from inside the pipe.

Evaluation of the results from confirmatory investigative sampling indicates that all contaminants of potential concern (COPCs) listed are less than the direct exposure cleanup level. In addition, the vadose zone underlying the pipe is approximately 7.8 m (25 ft) thick. Therefore, residual concentrations of these contaminants are predicted to be protective of groundwater and the Columbia River. The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to submission for archival in the Hanford Environmental Information System site-wide database and were summarized in Appendix A of the RSVP.

Residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. No residual contamination existed within the deep zone; therefore, no deep zone institutional controls are required.

The SubSite is Part Of:

Code: 100-F-44

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:5

Classification: Accepted

Names: 100-F-44:5; Process Sewer Pipelines

Reclassification: No Action (4/22/2009)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The 100-F-44:5 subsite is a network of reinforced concrete and steel pipelines that received process flow from the 190-F Building and discharged to a 1.07 m (42-in.) diameter pipeline associated with the 100-F-19:3 reactor cooling water effluent pipelines (CVP-2001-00003), which have been remediated. This pipeline subsite includes reinforced concrete pipe (RCP) and steel pipe consisting of the following:

- Two 0.9 m (36-in.) diameter RCP, 14 m (46-ft) long process sewers
- Two 0.15 m (6-in.) diameter steel, 14 m (46-ft) long process sewers
- 1.2 m (48 in.) diameter RCP, 38 m (125 ft) long process sewer
- 0.15 m (6-in.) diameter steel, 25 m (82 ft) long process sewer
- 1.2 m (48 in.) diameter RCP, unknown length (up to 54 m [177-ft] long) process sewer.

In 1956, an annex was added to the south side of the 190-F Pump House to increase the process water flow throughout the system. It is assumed, based on the 190-F Annex construction photographs and site drawings, that in the process of excavation for the 190-F Annex below-grade pump room, approximately 54 m (177 ft) of the original 1.2 m (48 in.) diameter RCP running east to west was removed and replaced with the 1.2 m (48 in.) diameter RCP that elbows to the south in a path around the 190-F Annex. However, an unknown length of the original pipeline could remain, and therefore has been included in the 100 F-44:5 subsite decision.

The Remaining Sites Verification Package for the 100-F-44:5 (RSVP-2008-016) documents that the subsite has met the objectives for reclassification to No Action. The remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units,(Remaining Sites ROD) have also been met.

Confirmatory sampling at the site was conducted on January 17, 2008. Samples of soil underlying the below-grade concrete floor of the pump room that previously contained the 100-F-44:5 pipelines were collected. The two 0.9 m (36-in.) diameter reinforced concrete pipe, 14 m (46-ft) long process sewer pipelines were not in the pump room; however, it was confirmed that the location was consistent with the design drawing (H-1-26685). Evidence to that effect included two portals in the south vertical wall and two portals in the north vertical wall. The sampling logbook (WCH EL-1601) documents that the excavator operator confirmed a low spot in the floor that may have indicated a sump between the walls. A section of the floor was rumbled and removed, and the excavator collected soil from beneath the floor location as soil sample material.

Historical process knowledge of the subsite and similar sites were used to develop the site-specific confirmatory sample design and include nickel-63, uranium-238, and polychlorinated biphenyls as COPCs. Because the subsite was an extension of the 190-F bypass process water pipelines that were associated with the 100-F-26 waste site, the COPCs for the 100-F-26 (strontium-90, cesium-137, cobalt-60, europium-152, europium-154, hexavalent chromium, arsenic, barium, cadmium, total chromium, lead, mercury, selenium, and silver) waste site were included.

The complete laboratory results are stored in the WCH Environmental Restoration project-specific database prior to submitting to the Hanford Environmental Information System for archiving and were provided in Appendix B of the RSVP.

Site contamination did not extend into the deep zone soils; therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone at the waste site are required.

Location: It is located directly north of the 105-F Reactor and south of the 190-F Building Annex.

Waste Type: Soil

Waste Description: The waste is potentially contaminated soil.

The SubSite is Part Of:

Code: 100-F-44

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:6

Classification: Accepted

Names: 100-F-44:6; 189-F Refrigeration Pipeline

Reclassification: Rejected (4/30/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: A 76-centimeter (30-inch) pipe entering the foundation of the 189-F Refrigeration Building was discovered during excavation of a test pit for confirmatory sampling at 100-F-26:4 (South Process Sewer Pipeline) on December 17, 2004. The subsite has been reclassified as Rejected based on the absence of potential chemical or radionuclide contamination associated with service water pipelines.

The origin of the pipeline was investigated as part of the 100-F Orphan Sites Evaluation task. Initially, the pipeline was thought to be an abandoned 107-centimeter (42-inch)-diameter raw water line for the 189-F Refrigeration Building. As such, the pipeline was assigned to waste site 100-F-41 (100-F Service Water Pipelines, 100-F Clean Water Pipelines) and designated as subsite 2. Because its former use was uncertain, the pipeline was reassigned to 100-F-44 (Miscellaneous Pipelines) and designated subsite 6.

The subsite has been reclassified as Rejected based on the absence of potential chemical or radionuclide contamination associated with service water pipelines.

Location: This pipeline ran from the 181-F River Pumphouse to the 189-F Refrigeration Facility in the north-central part of the 100-F Area.

Process Description: The pipe has been identified as a raw water pipeline that supplied water to the condenser units in the 189-F Refrigeration Building. The pipeline also supplied backup raw water to the 182-F and 183-F facilities. The information discovered during the review substantiated the initial finding that the pipeline was the abandoned 107-centimeter (42-inch) raw water line for the 189-F Refrigeration Building. It varied in diameter from 76 centimeters (30 inches) to 107 centimeters (42 inches) and is 908 meters (2,979 feet) in total length, including laterals.

Waste Type: Not Specified

Waste Description: The waste is the old buried pipes from the raw water pipeline system.

The SubSite is Part Of:

Code: 100-F-44

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:7

Classification: Accepted

Names: 100-F-44:7; 1717-F Blowdown Pipeline

Reclassification: Rejected (8/27/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The reclassification form number 2007-012 and documentation states that the subsite has been reclassified to Rejected. The reclassification was based on the absence of potential chemical or radionuclide contamination within the pipelines.

This subsite, originally thought to be one pipeline, actually comprises two 10 cm (4 in.) cast-iron pipelines each 27 m (88 ft) in length.

The DS-100F-008 pipeline segment was a 10 centimeter (4 inch) cast iron blowdown pipeline, 27 meters (88 feet) in length. The pipeline discharged into WIDS Site 100-F-5, 1717-F Building Drywell. Conflicting construction drawings indicated there may be a drain line of identical size and length running in parallel to this line. The two pipelines had been used to connect the 1717-F auxiliary boiler system to the 105-F, 1717-F Building Drywell for safety reasons. As a rule the blowdown valve on a boiler was plumbed into a dedicated pipeline or drain. The existence of the pipelines was confirmed by geophysical methods. During decommissioning and demolition of the 1717 F Maintenance Shop structure in 1983, short sections of both pipelines were removed.

Location: The segment consisted of one or two pipelines extending 23 meters (76 feet) from N147757 E580622 to N147757 E580645. The two 10 centimeter (4 inch) diameter pipelines were identified, in historical construction drawings, on the west side of the former 1717-F Maintenance Shop.

Process Description: Both pipelines connected from an auxiliary boiler system in the 1717-F Building to the 100-F-5, 1717-F Building Drywell. Water carried in the pipelines consisted of sanitary (potable) water. The Blowdown pipe served to prevent an explosion if the boiler pressure got too high, hot liquids and vapors would not be able to backflow, and possibly damage other locations or personnel in or around the boiler system. Having a dedicated pipeline also ensured that the carrying capacity of that pipeline would not become restricted over time due to incidental use.

Therefore, each of the boilers in the heating system required a separate dedicated blowdown pipeline.

Steam condensate, from the heating systems serviced by the 1717-F auxiliary boiler system, was not returned to the boiler system for reuse. Therefore, water would not have contained chemical or radiological contaminants from the laboratories or other facilities serviced by the 1717-F auxiliary boiler (heating) system. Only unregulated concentrations of water treatment chemicals, used to produce potable water, would be present in the boiler system and, therefore, in the water carried by the pipelines.

The SubSite is Part Of:

Code: 100-F-44

Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:8

Classification: Accepted

Names: 100-F-44:8; 1717-F Fuel Oil Supply and Return Pipelines

Reclassification: Interim Closed Out (12/15/2011)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This waste site has been remediated. Segment DS-100-F-009 was two 3.8 centimeter (1.5 inch) diameter black steel pipelines. They extended 36 meters (118 feet) from N147753 E580610 to N147753 E580637 to N147756 E580645. They were fuel oil supply and return pipelines that serviced the three underground fuel oil tanks (WIDS site 100-F-32) and the 1717-F building. Evidence was found that the tanks were offered for sale and photographs showed a disturbance where the tanks were previously located. It is possible these pipelines were removed as part of the tank removal.

Location: These pipelines were located about 240 meters (787 feet) northeast of the 105-F Reactor.

Process Description: The pipelines allowed fuel oil to be supplied to the 1717-F maintenance shop and office buildings.

Waste Type: Not Specified

Waste Description: The waste includes the pipelines and any contaminated soil associated with these pipelines.

Closure Info: In 2008, the pipelines were located. Confirmatory sampling determined that liquid with a strong diesel odor was still present in the lines. Remedial action at the 100-F-44:8 pipelines began on October 27, 2010, and continued through January 4, 2011, to a depth of approximately 0.7 meters (2.3 ft) across the entire excavation footprint. Due to the shallow nature of the excavation, no overburden was associated with this site. The excavation resulted in approximately 80 bank cubic meters (BCM) (104.6 bank cubic yards [BCY]) of contaminated soil and debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 72 meters (238 ft) of 3.81 centimeters (1.5 inch) diameter steel pipe, along with contaminated soil, piping, conduit, wires, concrete, and used personal protective equipment was excavated from this waste site and disposed at the ERDF. Following the verification sample analysis, it was determined that additional remediation was needed due to sample locations that exceeded cleanup criteria. A second remediation was conducted on June 9, 2011, with the removal of 126.4 BCM (165.3 BCY) of contaminated soil. With agreement from the U.S. Environmental Protection Agency (EPA), additional soil was removed from areas that exceeded direct exposure and/or groundwater and river protection RAGs in the excavation and staging pile area footprint.

The SubSite is Part Of:**Code:** 100-F-44**Names:** 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)**Code:** 100-F-44:9**Classification:** Accepted**Names:** 100-F-44:9; 105-F Process Sewer Pipeline**Reclassification:** Interim Closed Out (9/14/2011)**Type:** Process Sewer**Start Date:****Status:** Inactive**End Date:****Description:** The pipeline has been removed. The segment was a 46 centimeter (18 inch) steel process sewer pipeline approximately 42 meters (140 feet) in length.**Location:** The 100-F-44:9 waste site was located in the 100-FR-1 Operable Unit of the Hanford Site. It was east of the former 105-F Reactor Building, within the 105-F Exclusion Area fence line. The pipeline was 42.5 meters (140 feet) long, extending from N147620 E580460 to N147620 E580473 to N147618 E580475, and ending at N147591 E580475.**Process Description:** The pipeline conveyed effluent from the east side of the 105-F Reactor Building and appeared to discharge to a 1.07-m (42-in.)-diameter pipeline associated with the 100-F-19:2 Reactor cooling water effluent pipelines that have since been remediated.**Related Sites/ Structures:** 100-F-44:9 was associated with the 100-F-19:2 cooling water pipeline.**Waste Type:** Not Specified**Waste Description:** Possible chemical and/or radionuclide contaminated pipelines and underlying soils.**Closure Info:** A geophysical survey of the site was conducted in January 2007. The geophysical survey findings agreed with historical documentation for the pipeline that shows a north-south trending, 18-in.-diameter steel pipeline paralleling the 105-F Reactor footprint along the east side. The pipeline turns to the west near the northern side of the reactor. Remedial action at the 100-F-44:9 pipeline subsite began on November 3, 2010, and continued through January 5, 2011, to a depth of approximately 3 meters (10 ft). One staging area was developed during the excavation for storing soil prior to disposal at the ERDF. Contaminated soil, pipe, asphalt, clay pipe, concrete, and rebar were removed from the 100-F-44:9 excavation for shipment and disposal to the ERDF. The post-excavation surveys, conducted on January 10, 2011, identified no residual radioactivity above twice background within the site.

An anomaly was discovered within the excavation of the 100-F-44:9 subsite that appeared to be a large metal valve. A sample of the anomaly not collected after the object was found to be empty. Industrial Hygiene and radiological readings did not detect contamination present within the anomaly.

The SubSite is Part Of:**Code:** 100-F-44**Names:** 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-44:10 **Classification:** Accepted
Names: 100-F-44:10; 141-C Sewer Pipelines; 100-F Experimental Animal Farm Sewer Pipelines **Reclassification:** Rejected (10/11/2007)
Type: Process Sewer **Start Date:**
Status: Inactive **End Date:**
Description: The basis for reclassification to rejection of subsite 100-F-44:10 (DS-100F-017) is supported by historical review, associated site information, exploratory trenching, and geophysical data. The subsite consisted of two 20.3-centimeters (8-inch)-diameter sewer pipeline segments exiting the 141-C building. It has been determined through the excavation results that there is no evidence to support the existence of the site. It has been determined through the excavation results that there is no evidence to support the existence of the pipelines. The pipelines were likely removed during earlier demolition activities. The subsite does not pose a risk to human health or the environment and will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario, and no institutional controls are required.

Historical review determined that during Decontamination and Decommissioning activities of the 141-C Building (between August and December 1979), the building, concrete pad, foundation and contaminated soils were removed. The only remaining structure was a temporary steel post that marked the location of a 6-inch gate valve. The valve and 36.5 meters (120 feet) of potentially contaminated 20 centimeter (8-inch) steel pipe that extended from the valve to the decommissioned waste lift station (141-N) was capped and abandoned in place.

Documentation in the Cleanup Verification Package-2001-0003 for sites 100-F-19:2, 116-F-11, 100-F-29, and UPR-100-F-1 stated that pipelines were excavated on March 22, 2002 that extended from just east of the former 141-C Building to the former 141-N waste lift station. A geophysical survey was performed in April 2004 to locate and map any buried remains from the demolished 141-C Building. The geophysical survey narrative stated that the entire site appeared to have been disturbed from operational or deactivation activities. There were no obvious anomalous features detected that had the characteristics of remnants of the infrastructure from the original site (e.g., foundation footings, buried debris, pipelines, utilities).

In August 2005 during the 141-C Building remediation, exploratory trenches were dug to confirm that the sewer lines formerly servicing the 141-C Building had been removed during previous deactivation activities. No sewer lines were located by these excavations and field instrumentation did not detect any beta-gamma or alpha activity above background levels. There was no evidence to support the existence of the pipe segments in the vicinity of the 141-C Building.

Location: The waste site was located within the 100-F Experimental Animal Farm area. The subsite consisted of two 20.3-centimeters (8-inch)-diameter sewer pipeline segments exiting the 141-C building. It has been determined through the excavation results that there is no evidence to support the existence of the pipelines.

The SubSite is Part Of:

Code: 100-F-44
Names: 100-F-44; 100-F Miscellaneous Pipelines (See Subsites)

Code: 100-F-45 **Classification:** Accepted
Names: 100-F-45; Buried River Effluent Pipelines **Reclassification:** Interim Closed Out (12/15/2011)
Type: Radioactive Process Sewer **Start Date:**
Status: Inactive **End Date:**

Description: from the river effluent pipeline.

Location: The site is located on a steep river bank approximately 10 meters (33 feet) from the Columbia River, approximately 670 meters (2,200 feet) northeast of the 105-F Reactor Building and about 15 meters (50 feet) upstream from the 116-F-16 PNL Outfall.

Process Description: The 100-F Area process sewers discharged via the 1904-F (116-F-8) Outfall to the Columbia River through two 106 centimeter (42 inch) steel lines (BHI-01141). Soon after the 105-F Reactor started up in 1945, these pipelines began to experience a problem common to all of the early reactors, floating river effluent lines. More than 100 feet of each of these lines were bent and broken. Historical documentation suggested that these broken sections were removed from the river and buried somewhere along the shoreline, although the exact location was not recorded. In 1946, the original pipelines were replaced with much shorter ones, causing confusion over time.

Related Sites/ Structures: These suspected pipeline sections are believed to have resulted from the failure of the 100-F-39, 100-F River Effluent Pipelines which are also co-located with 116-F-8 Outfall Structure, and the 100-F-42, 1904-F Spillway/Flume.

Waste Type: Equipment

Waste Description: Contaminants of concern/potential concern are based on those for the 1904-F outfall (116-F-8). Contaminants of concern include Co-60, Eu-152, Eu-154, Eu-155, and Cr+6. Contaminants of potential concern include C-14, Cs-137, Ni-63, and Sr-90.

Closure Info: Remedial action at the 100-F-45 waste site began on March 14, 2011, and continued through March 21, 2011, to a depth of approximately 0.5 to 2.0 m (1.7 to 6.6 ft). The excavation resulted in approximately 160.0 bank cubic meters (BCM) (208.0 bank cubic yards [BCY]) of contaminated soil and debris being removed, including 15.3 m (50.0 ft) of 42-in.-diameter steel pipe, for disposal at the Environmental Restoration and Disposal Facility (ERDF). Approximately 217.0 BCM (283.8 BCY) of overburden material was stockpiled southwest of the excavation for use as clean backfill. A small staging pile area was used for contaminated soil and pipe material, which was later loaded out and disposed at the ERDF.

Upon completion of remedial activities, high river flow caused water seepage into the excavated area. This seepage caused some of the surrounding bank to fall into the finished excavation area. Prior to verification sampling, this soil material was removed at the specified sampling locations.

No elevated radiological readings were detected during the excavation of the 100-F-45 waste site; therefore, no Global Positioning Environmental Radiological Surveyor (GPERS) surveys were conducted.

Contaminated soil and 15.3 m (50.0 ft) of 42-in.-diameter steel pipe were removed from the 100-F-45 excavation for shipment and disposal to the ERDF. No anomalous materials or stained soil were encountered during the excavation.

Code: 100-F-46	Classification: Accepted
Names: 100-F-46; 119-F Stack Sampling French Drain	Reclassification: No Action (8/8/2008)
Type: French Drain	Start Date:
Status: Inactive	End Date:
Description: The site consisted of the 119-F french drain, a gravel-filled vertical pipe, and the pipeline from the 119-F Stack Sampling Building to the french drain.	
Location: The french drain was located about 7.5 meters (25 feet) northwest of the west wall of the 119-F	

Stack Sampling Building. The influent end of the pipeline was at E580382.2 N147614.2. The pipeline depth was above the top of the 117-F air tunnels such that it was likely removed during the decontamination and decommissioning (D&D) activities for the 117 F Building and air tunnels.

Process Description: The 116-F reactor stack exhaust gases were sampled by pulling moist stack offgases through a steam-heated pipe to the 119-F Stack Sampling Building where the gas stream was sampled. The condensate from the stack offgases drained via a 2 inch cast iron pipeline to the 119-F french drain. A 5 centimeter (2 inch) cast iron pipe drained condensate from the 119-F Stack Sampling Building into the french drain. The drain pipeline is included as part of this waste site.

Related Sites/ Structures: The site was associated with the 118-F-8 Reactor Building 116-F Stack, 119-F Stack Sampling Building, 117-F Filter Building and Air Tunnels.

Waste Type: Equipment

Waste Description: The site may contain contaminated soil from condensate entering the french drain. The waste includes the french drain and the pipelines. It is likely that these structures no longer exist. However, remediation of these structures is not documented in a cleanup verification package.

The condensate from the 116-F stack potentially contained the same contaminants of concern identified for the 116-F stack during the characterization sampling performed for the allowable residual contamination level (ARCL) evaluation completed in 1985. Low levels of tritium-3, carbon-14, strontium-90, cobalt-60, cesium-13, europium-152, and plutonium-239 were reported for the 116-F stack.

Potential Contaminants of Concern: Low levels of tritium-3, carbon-14, strontium-90, cobalt-60, cesium-13, europium-152, and plutonium-239 were reported for the 116-F stack.

Closure Info: The Remaining Sites Verification Package, RSVP-2008-021, documents that the site has achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site (Remaining Sites ROD).

Both the 100-F-46 French drain and the condensate pipeline were presumed to have been removed during decommissioning and demolition of the 117-F Filter Building (132-F-5) and associated air tunnels in 1983. These structures were decontaminated, removed to a depth of 1 meter (3 feet) below grade, and backfilled to grade.

Confirmatory sampling at the 100-F-46 french drain site was performed on November 29, 2007. A test pit was excavated to approximately 4.5 m (15 ft) depth, with no indication of either the french drain or the associated cast iron condensate pipeline. The site contaminants of potential concern (COPCs) that were developed from process knowledge included: tritium, carbon-14, strontium-90, cobalt-60, cesium-137, europium-152, and plutonium-239/240. Based on further evaluation of contaminants potentially discharged to the 100-F-46 French drain, europium-154, europium-155, the expanded list of inductively coupled plasma metals, mercury, hexavalent chromium, polychlorinated biphenyls, polycyclic aromatic hydrocarbons, (PAHs), and total petroleum hydrocarbons (TPH) were added as COPCs.

The laboratory-reported data results for all constituents were stored in the WCH Environmental Remediation System (ENRE) project-specific database prior to submission for archival in the Hanford Environmental Information System (HEIS) site-wide database and were summarized in Appendix B of the RSVP.

The confirmatory sampling results support a reclassification of the site to No Action. The results also indicate that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required.

Code: 100-F-47	Classification: Accepted
Names: 100-F-47; 151-F Substation	Reclassification: Interim Closed Out (12/15/2011)
Type: Electrical Substation	Start Date: 1/1/1945
Status: Inactive	End Date: 1/1/1965

Description: The substation consisted of a fenced, gravel-bed yard measuring 92.4 meters (303 feet) by 137.2 meters (450 feet), with the 151-F Switch House along the eastern fence line. A railroad spur entered the yard from the south and paralleled the east fence line.

The 151-F Substation distributed power to transformers located at the 181-F River Pump House, 182-F Head House, 183-F Filter House, 184-F Power House, 190-F Pump House, and the 105-F Reactor, each of which, in turn, distributed power to associated facilities.

Location: The 151-F Building and associated switch yard were located approximately 350 meters (1148 feet) northwest of the 105-F Reactor Building. The 151-F Building was centered along the east fence line of the switch yard.

Process Description: The 151-F Substation was fully energized in January 1945 and supplied 13.8 KV electrical power to the 100-F Area.

More than 100 concrete footings and pads of various sizes protruded from the crushed gravel bed throughout the yard, supporting a variety of electrical equipment, including two 31,250 KVA, 220/13.8 KV transformers, one 37.5 KVA transformer, three oil circuit breakers, and several power line towers and stands. Underground concrete-encased "Korduct" ducts connected the switch house with the transformers and oil circuit breakers.

The single-story concrete block switch house was 24.4 meters (80 feet) long by 9.1 meters (30 feet) wide and 3.4 meters (11 feet) high. A 3.4 meter (11 foot) wide by 3.4 meters (11 feet) high by 21.9 meters (72 feet) long reinforced concrete cable pit ran beneath the block house.

Related Sites/ Structures: The 151-F Building and associated switch yard were located approximately 350 meters (1148 feet) northwest of the 105-F Reactor Building. The 151-F Building was centered along the east fence line of the switch yard

Waste Type: Soil

Waste Description: There have been no reported unplanned discharges of oil containing PCBs. Since leak/spill reporting is inconsistent for the entire period of operation of the substation, it is prudent to assume unplanned discharges of oil may have occurred at locations where transformers or oil circuit breakers were positioned, or where the railroad tanker was located. Confirmatory sampling around these locations should be considered.

There may be more than 2,744 meters (9,000 feet) of underground electrical cable, generally housed in fiber or transite conduit, and encased in at least 7.6 centimeters (3 inches) of concrete. It is suspected that much of this copper cabling is encased in an asbestos wrap and an outer lead sheath. Also, depending on the extent of unplanned releases, these lines may be contaminated by PCB-containing oil. This same cabling may also still remain in the cable pit of

the 151-F Building.

Potential Contaminants of Concern: PCBs, lead, and asbestos.

Closure Info: Remediation of the 100-F-47 waste site was performed from October 20, 2010, through June 27, 2011, to a depth between 1 and 4.35 m (3 and 14.3 ft) across the entire excavation footprint. Due to the shallow nature of the contamination, no overburden was associated with this site. Approximately 14,500 m³ (19,000 yd³) of contaminated soil, concrete, rebar, wire, steel cable, asphalt, asbestos, wood, steel, porcelain, and glass were removed from the 100-F-47 excavation and were directly loaded for shipment and disposal at the Environmental Restoration Disposal Facility. No anomalous materials were encountered during the excavation. Two small transformers were found during the excavation, and will be characterized for disposal at a later date.

Code: 100-F-48	Classification: Accepted
Names: 100-F-48; 184-F Coal Pit Debris	Reclassification: Interim Closed Out (12/15/2011)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:

Description: The waste site consisted of an area of debris that was identified in an aerial photograph and a historical literature search. The debris has been removed and disposed into the Environmental Restoration Disposal Facility.

Location: The coal pit debris is located immediately north of the 184-F Power House site (removed), about 500 meters (1,650 feet) northeast of the 105-F Reactor Building.

Process Description: Inert demolition debris was commonly disposed on site in the large operations support storage facilities such as the coal storage bins and the water treatment and storage basins. The criteria for what was allowed to be disposed on site are not documented but generally are thought to include nonradioactive solid debris such as building materials (e.g., siding, roofing, structural, concrete/concrete block, fencing) removed during demolition of administrative and ancillary support facilities between 1967 and 1990. Some unacceptable solid waste forms such as asbestos-containing siding or roofing were allowed to be disposed.

Related Sites/ Structures: The associated structures included the 184-F Power House and 184-F Coal Handling Facilities.

Closure Info: Confirmatory Sampling Failed. Analytical results from the confirmatory samples indicate that the material in the drum found in the geophysical anomaly area exceeded shallow-zone direct exposure Remedial Action Goals (RAGs) for thorium-230, uranium-233/234, uranium-238, and arsenic. The material also exceeded groundwater and river protection RAGs for copper, lead, mercury, and zinc.

Based on the confirmatory sampling results, the 100-F-48 waste site was recommended for remediation.

Remediation of the 100-F-48 waste site was performed from September 21, 2010, to January 11, 2011. The coal scrape area was remediated to a depth of approximately 0.3 m (1 ft), while the main excavation area had a final depth that ranged from approximately 0.2 m (0.7 ft) to 3.5 m (11.4 ft). The 100-F-48 waste site excavation resulted in approximately 13,922 BCM (18,209 BCY) of material being removed for disposal at the Environmental Restoration Disposal Facility (ERDF).

Soil and debris from the main excavation area were direct-loaded to ERDF, while material

removed from the coal scrape area was staged at the east stockpile area before eventual removal to ERDF. Types of debris uncovered include: concrete, steel pipe, rebar, porcelain, clay pipe, bricks, wire, cable, suspect ACM, and asphalt. No overburden soil stockpiles were associated with the waste site.

The 100-F-48 waste site anomalies included two deteriorated, leaking drums, and a single intact, non-leaking drum. The single intact, non-leaking drum was found to be empty. The two deteriorated, leaking drums were sampled, and one drum was found to contain high concentrations of TPH and lead.

Code:	100-F-49	Classification:	Accepted
Names:	100-F-49; 1716-F Maintenance Garage Lubrication Pit	Reclassification:	Interim Closed Out (12/15/2011)
Type:	Foundation	Start Date:	
Status:	Inactive	End Date:	
Description:	The waste site consisted of components of the 1716-F Maintenance Garage, including the foundation, the lubrication pit, and the contaminated drain(s). The waste site has been remediated. The foundation of the former garage building was T-shaped with overall dimensions of approximately 15 by 17 m (50 by 55 ft).		
Location:	The building was located in the northwest corner of the Service Building group approximately 1,101 meters (3,612 feet) north of the 100-FR-2 east-west perimeter road. The building was on the west side of F Avenue, about 13 meters (43 feet) from the road.		
Process Description:	The 1716-F facility provided automotive repair, light vehicle maintenance, and lubrication service for the 100 F Area vehicles.		
Waste Type:	Soil		
Waste Description:	There may have been oil spills in the lubrication pit and battery acid spills in the high bay area.		
	The Geophysical team identified this area as a potential new waste site due to the probable oil spills (polychlorinated biphenyls [PCBs], total petroleum hydrocarbons [TPH]) in the lube pit, potential battery acid in the high bay area, potential unknown pipelines, and the potential asbestos siding debris.		
Closure Info:	Confirmatory Sampling Failed. Results of confirmatory sampling indicated that test trench 1 met all remedial action goals. Results from the remainder of the site indicated contamination with lead and polychlorinated biphenyls (PCBs) above direct exposure RAGs. In addition, the remainder of the site also exceeded groundwater and river protection RAGs for numerous metals, semivolatile organic analytes, pesticides, and total petroleum hydrocarbons (TPH). In all, 29 different contaminants exceeded groundwater and/or river protection RAGs. Asbestos was also confirmed at the site. Based on these results, the entire 100-F-49 waste site, except for suspect utility lines associated with test trench 1, was recommended for remediation.		
	The 100-F-49 waste site was remediated between January 11 and April 12, 2011. During the 100-F-49 remedial activities, a steel tank was discovered at Washington State Plane (WSP) coordinates N 147891, E 580666. The tank was not expected to be present at this location, and therefore, the excavator had slightly broken into the tank, causing some of the liquid from the tank to spill into the surrounding soils. The spilled liquid from the tank and soil was sampled (J1F1N1) and determined that the tank was used for oil storage purposes. The tank and its location were carefully observed and determined to be the same oil tank that 2008 confirmatory sampling expected to find. The liquid and sludge contents were pumped from the tank prior to its disposal. The steel tank structure, oil saturated soils, and additional underlying soil were		

removed from the 100-F-49 excavation and disposed at the Environmental Restoration Disposal Facility (ERDF).

Remediation included removal of the 1-in.-diameter steel pipe, 20 m³(21.3 yd³) of concrete, a 1,325-L (350-gal) steel storage tank and approximately 1,325 L (350 gal) of fuel, oil and sludge from the tank. Miscellaneous debris such as concrete and rebar were removed from the excavation and stockpiled adjacent to the site for disposal at the ERDF. The deepest part of the 100-F-49 excavation extended to approximately 2.7 m (8.9 ft). Approximately 2,727 bank cubic meters (3,567 bank cubic yards) of soil and debris was excavated from the 100-F-49 waste site. Roughly half of the materials were stockpiled adjacent to the excavation prior to disposal at the ERDF. The other half of the excavated materials was directly loaded for disposal at the ERDF.

Following the load out of stockpile materials, the staging pile area was scraped to 0.3 m (1 ft) below ground surface. A very small green/yellow stain was observed at 0.3-m (1-ft) depth at WSP coordinates N 147943.3, E 580631.1. It was determined that the stain was not caused by the stockpile; rather the stain was present at this location prior to any 100-F-49 stockpiling activities. The stained soil was sampled (J1FHT7). The sample data of the stained soil indicates that all individual contaminant of potential concern concentrations are below RAGs.

Code: 100-F-51	Classification: Accepted
Names: 100-F-51; 146-F Fish Laboratory Soil	Reclassification: Interim Closed Out (9/26/2011)
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:

Description: The site is the soil under and around the former 146-F Fish Laboratory.

Location: The 146-F Fish Laboratory was located approximately 489 meters (1600 feet) northeast of the 105-F Reactor Building, and about 91 meters (300 feet) southwest of the 1904-F Outfall.

Process Description: The laboratory sat on a curbed, concrete pad, the laboratory was 5 meters (16 feet) wide by 24 meters (80 feet) long. The floor sloped toward a central trough that was 15.8 meters (52 feet) long by 0.4 meters (1.5 feet) wide by 0.2 meters (0.5 feet) deep, which in turn drained out the north end of the building and directly east into the 147-F Pump House pit. The laboratory contained ten pairs of elevated, open-top, wooden fish troughs, each 3.7 meters (12 feet) long by 0.3 meters (1 feet) wide by 0.2 meters (0.75 feet) deep, as well as three head tanks and associated piping to the troughs.

River water was pumped to the Fish Laboratory through a 15 centimeter (6 inch) line from the 181-F River Pump House; process water was pumped to the building through a 5 centimeter (2 inch) line from the 190-F Main Process Pump House and Annex; and process effluent was pumped to the facility (where it was cooled before use), via the 148-F Pump House from the 107 F Retention Basin. Spills and overflows from the troughs and head tanks drained to the 147-F Pump House pit, which pumped to the 1904-F Outfall and discharged to the Columbia River.

There were removable wooden walkways between the troughs. In addition, the building contained a process water refrigeration system, fish food bins, refrigerator and freezer, electric heater and swamp cooler, an office, and a bathroom. Immediately to the east of the building were the outdoor rearing ponds and the 149-F Biology Warehouse, and immediately to the south was the 146-FR Radioecology and Aquatic Biology Laboratory that was built in 1952.

Related Sites/ Structures: Associated structures included: 116-F-8 (1904-F Outfall), 100-F-57 (190-F Process Water Pump House Debris), 100-F-52 (146-FR Radioecology/Aquatic Biology Laboratory Soil), 116-F14 (107-F Retention Basin)

Waste Type:	Soil
Waste Description:	No reports were found of unplanned discharges to the soil from this building. However, because of the open-trough operations within the building it is prudent to assume such discharges may have occurred. A partial geophysical survey of the area recorded mixed subsurface debris that could be a portion of the original foundation.
	Contaminants of concern/potential concern are based on those for the 1904-F Outfall (116-F-8). Contaminants of concern include cobalt 60, europium 152, europium 154, europium 155, and hexavalent chromium. Contaminants of potential concern include carbon 14, cesium 137, nickel 63, and strontium 90.
Closure Info:	100-F-51 and 100-F-63 were addressed as a group. The information below documents information for the group of sites.
	In November 2007 and February 2008, confirmatory sampling of the 100-F-51 waste site was carried out during the excavation of two test pits, at the north end and southeast corner of the laboratory (WCH 2007b). Confirmatory sampling results failed to meet remedial action goals (RAGs) and indicated the need for remedial action at the 100-F-51 waste site. Confirmatory sampling was not performed for the 100-F-63 waste site; the site was added to the 100-F Area scope for remove, treat, and dispose in 2010 (WCH 2010a).
	Remedial action at the 100-F-51 and 100-F-63 waste sites began on December 20, 2010, and continued through January 20, 2011. Excavation depth ranged from 0.5 to 1.5 m (1.6 to 4.9 ft) below ground surface bgs and resulted in approximately 253 bank cubic meters (BCM) (331 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. Approximately 330 BCM (432 BCY) of overburden soil was stockpiled to be used as backfill. The 100-F-51 and 100-F-63 waste sites debris included concrete, clay pipe, steel pipe, and asphalt. The verification sampling results support a reclassification of the 100-F-51 and 100-F-63 waste sites to interim closed out.

Code:	100-F-53	Classification:	Accepted
Names:	100-F-53; 108-F Septic System	Reclassification:	No Action (6/26/2009)
Type:	Septic Tank	Start Date:	
Status:	Inactive	End Date:	
Description:	The site potentially consisted of pipelines, a septic tank, the drain field and any contaminated soil around them. The site represented what was thought to be a septic system. It was unknown if an engineered liquid waste disposal facility existed at the site, either as a septic system or a crib system.		
Location:	The site was located approximately 190 meters (625 feet) east of the 105-F Reactor Building.		
Release Description:	Releases unknown.		
Process Description:	Gravity drain sewer system, either sanitary or chemical, discharged to the soil column via a drain field.		
Related Sites/Structures:	Any liquid waste discharges to this suspect site would have originated from the 100-F-36 (108-F Chemical Pump House, 108-F Biological Laboratory) site.		
Waste Type:	Soil		
Waste Description:	The waste potentially consists of the pipelines, the septic tank, the drain field and any contaminated soil around them. Geophysical measurements were inconclusive. No clear evidence was found of a septic tank, a septic line, or a drain field.		

Since the septic system (if it existed) would have been associated with 108-F Building and the activities within the building (before 1949 and the addition of the biology facilities to 108-F), the contaminants of potential concern may have been hexavalent chromium or mercury.

Closure Info: The Remaining Sites Verification Package, 2008-019, has documented that the 100-F-53 waste site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD).

An aerial photograph P-1888 taken during construction of the 100-F Area showed that the Crafts Office was one of the first buildings constructed in the 100-F Area. This building did not appear on photographs taken during operation of the 100-F Area, indicating it was removed early in the operations time period. Based on the historic aerial photographs, the 100-F Area Plot Plan drawing (Drawing C-3231), and the building description in DuPont (1945), it was concluded that the TC-32 Crafts Office was the Layout building and that this is the building seen in the historic photographs. It follows that the drain field shown on the drawing (and found in the 100-F-53 test trench) serviced this temporary construction building. Thus, the septic tank associated with the 100-F-53 septic system was a wood framed box buried 0.3 m (1 ft) below grade and located somewhere between the drain field and the "Layout" building.

A geophysical survey was performed at the site in August 2005 (Bergstrom and Mitchell 2005) to locate evidence of a septic tank, underground pipelines, and a drain field based on the historical drawing (HEW 1944). Ground-penetrating radar and an electromagnetic induction (EM-61) metal detector were the geophysical methods used for the investigation. The results showed no features that would have been characteristic of a typical septic tank. Several linears were detected that could be characteristic of underground pipelines and/or utilities, but the results were inconclusive. Also, scattered anomalies throughout the surveyed area were likely buried remnants from decommissioning of the 108-F Building. It should be noted the geophysical methods used have only a limited capability to detect wood septic tanks and vitrified clay pipes (characteristic of drain fields and sanitary sewer piping).

The Contaminants of Potential Concern (COPCs) for the Phase II effort were identified based on the results of Phase I confirmatory sampling. The list of COPCs included inductively coupled plasma (ICP) metals, mercury, pesticides, polychlorinated biphenyls, and semivolatile organic compounds (SVOCs). Radionuclides were not COPCs for Phase II sampling because the nature of the site as a construction office did not suggest potential for radiological contamination, and all detected radionuclide values from the Phase I confirmatory sampling were less than background activity.

All confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to submission for archival in the Hanford Environmental Information System site-wide database and were summarized in Appendix B of the RSVP.

Based on historical and photographic evidence, including field observations during Phase I and Phase II confirmatory sampling, the 100-F-53 septic system was determined not to have been associated with the 108-F Biological Laboratory, but instead serviced a temporary construction building. Confirmatory sampling activities determined that the septic tank had previously been removed and sampling results indicated that the residual concentrations of COPCs at this site meet the remedial action objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the confirmatory sampling results supported a

reclassification of the site to No Action.

The results also show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario), allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep), and demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	100-F-54	Classification:	Accepted
Names:	100-F-54; 100-F Animal Farm Pastures	Reclassification:	No Action (4/17/2008)
Type:	Unplanned Release	Start Date:	
Status:	Inactive	End Date:	
Description:	The site consists of the soil associated with the former pastures for holding contaminated domestic farm animals used in experimental toxicology studies. This site consisted of the remaining soil associated with the former pastures. A major portion of the animal farm activities were conducted in the segregated complex northeast of the reactor building and near the outfalls.		
Location:	The pastures were located east of the 105 F larger pasture, north of the 1 larger pasture, was approximately 580 meters squared (6250 square feet) and was centered at the 141-N Building footprint, was approximately 1,500 meters squared (16,100 square feet) and was centered at N147942 E580895 (H-1-13850). The smaller pasture, directly to the east of the N147957 E580927.		
Process Description:	There were three general pasture areas associated with the complex. The first was a large, contiguous pasture extending from the 141-G Building north to the perimeter road. The second consisted of two smaller pastures; one adjacent and to the west of the 141-H Building; and the other adjacent and to the north of the 141 T Building. The third consisted of two larger pastures (one for hogs, one for goats) directly south of the 141-C and 145-F Buildings. Radioactively dosed animals were confined to the buildings until their feces and urine met certain limits; then they were allowed into the pastures. There was concern that the pastures may contain low-level contamination.		
Related Sites/ Structures:	Dosed animals were housed in the 141-H and 141-F Buildings, which were adjacent to these pastures.		
Waste Type:	Soil		
Waste Description:	Animals were pastured in these areas, their waste would have discharged to the ground and may have contaminated the soil.		
	Historical documents indicated strontium-90, iodide-131, isotopes of plutonium, cesium-137, and other radioisotopes were used in the animal exposure studies.		
Closure Info:	The Remaining Sites Verification Package, 2008-015, documents that the current site conditions have achieved the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD).		
	Three general pasture areas were associated with the experimental animal farm complex. Later a few areas were used for stockpiling soil associated with the 100-F Area Remedial Action		

excavations. These areas were subsequently surveyed and/or sampled to demonstrate no residual radiological activity.

Field observations indicated that only two pasture areas remained that were relatively undisturbed, potentially exhibited soil representative of the pasture, and were available for sampling. One area was within a pasture south of the former 141-C and 145-F Buildings, and the second area was within a pasture north of the former 141-T Building.

Confirmatory sampling at the site was conducted on November 19, 2007. A statistical sample design was selected for confirmatory sampling because the distribution of potential residual soil contamination was uncertain. Historical documents indicated strontium-90, iodide-131, isotopes of plutonium, cesium-137, and other radioisotopes were used in the animal exposure studies. Therefore, the contaminants of potential concern for this soil investigation included radionuclides evaluated using laboratory analytical methods for gamma-, beta-, and alpha-emitting radionuclides. The analytical results indicated no residual radiological activity above background activity or exceeding cleanup criteria.

All confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The complete laboratory results are stored in the WCH Environmental Restoration project-specific database prior to submitting to the Hanford Environmental Information System for archiving and are provided in Appendix A of the RSVP.

The results of confirmatory sampling illustrate that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

The results of confirmatory sampling were used to make reclassification decisions in accordance with the TPA-MP-14 procedure. In accordance with this evaluation, the confirmatory sampling results support a reclassification of this site to No Action.

Code:	100-F-55	Classification:	Accepted
Names:	100-F-55; 1607-F7 Contaminated Ash Layer	Reclassification:	Interim Closed Out (12/22/2011)
Type:	Unplanned Release	Start Date:	
Status:	Inactive	End Date:	
Description:	The waste site has been remediated. The ash layer was discovered during 1607-F7 sampling activities. The site consisted of a black layer of ash approximately 0.3 meters (1 foot) below the ground surface north of the 1607-F7 septic system, near the former 141-M building.		
Location:	The ash layer was observed in a trench near the 1607-F7 Septic System, approximately 0.3 meters (1 foot) below grade.		
Related Sites/ Structures:	The ash layer is unrelated to the 1607-F7 Septic System.		
Waste Type:	Soil		
Waste Description:	The waste is a contaminated ash layer. The only known contaminant of potential concern is hexavalent chromium.		
Closure Info:	100-F-55 and 100-F-62 were addressed as a group. The information below documents information for the group of sites.		

Remedial action at the 100-F-55 waste site was performed from September 16 to October 7, 2010 to a depth of 0.7 meters (2.3 ft). Remedial action at the 100-F-62 waste site was performed from December 2010 to March 2011. The 100-F-62 north pipeline excavation included the removal of the pipelines to the former 1607-F7 septic tank and contained the 100-F-55 waste site excavation. From the north excavation, approximately 2 meters (7 ft) of the 4 inch diameter vitrified clay pipe were removed, and approximately 5 meters (16 ft) of 4 inch diameter steel pipe with lead bells were removed. Verification sample results indicated additional remediation was required. Additional remediation was performed from July 29 to August 9, 2011. The center section of the north excavation was further remediated, and the entire south excavation was further remediated and expanded to the south. The final north excavation depth is 2.3 meters (7.6 ft), and the final south excavation depth is 4.4 meters (14.5 ft). Additional remediation also occurred at the east staging pile area and the northeast quadrant of the south staging pile area.

Code: 100-F-56	Classification: Accepted
Names: 100-F-56; 100-F Surface Debris/Stains	Reclassification: Interim Closed Out (12/15/2011)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:

Description: The waste site was miscellaneous discarded/abandoned materials across the 100-F Area. The waste site was divided into two subsites, 100-F-56:1, 100-F Garnet Sand Areas and 100-F-56:2, Other 100-F Surface Debris Areas. Both subsites have been remediated, so the parent site is also Interim Closed Out.

Location: The subsite areas were located throughout the 100-F Area.

Process Description: Various sizes and forms of hazardous (CERCLA) and/or dangerous (MTCA) surface debris were left during the construction, operation, decontamination and decommissioning (D), and remedial action (RA) activities at the 100-F Area.

Related Sites/Structures: Temporary and permanent 100-F Area facilities removed by remedial action or decontamination/decommissioning activities are listed in the Buildings section of the OSE report for 100-F.

Waste Type: Misc. Trash and Debris

Waste Description: The solid waste types addressed here are typically transite, lead battery residues, and treated wood including isolated railroad ties, treated power pole, and wood posts. Railroad ties in railroad beds are not addressed here.

The contaminants of potential concern relate to waste characterization for disposal of the debris. There are no significant environmental contaminants of concern for this site since the debris is expected to leave no residue during removal.

This Site has the Following SubSites:

Code: 100-F-56:1

Names: 100-F-56:1; 100-F Garnet Sand Areas

Code: 100-F-56:2

Names: 100-F-56:2; Other 100-F Surface Debris Areas

Code: 100-F-56:1	Classification: Accepted
Names: 100-F-56:1; 100-F Garnet Sand Areas	Reclassification: Interim Closed Out (12/15/2011)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: This subsite has been remediated. The subsite consisted of two garnet sand areas. The first area was described as red garnet sand (sand blasting) with some scattered miscellaneous debris (wood, metal, glass, vitrified clay chunks). The second area was described as stained soil - garnet sandblasting. Soil and debris was removed and disposed into the Environmental Restoration Disposal Facility.

Location: One area was located 200 meters (656 ft) north of the 105-F Reactor Building and the other located was 300 meters (984 ft) south of the 105-F reactor.

Process Description: The exact process that caused the garnet sand to be located at these locations is unknown. However, garnet sand was used in sandblasting operations to clean rust, paint, and contamination from the surface of metal components. The garnet material is not a hazardous substance. However, there is contamination potential due to the paint and other materials removed by sandblasting.

Waste Type: Not Specified

Waste Description: The waste consists of potentially contaminated soil, wood, metal, glass, vitrified clay and garnet sand.

Closure Info: Remediation of the 100-F-56:1 waste subsite occurred from March 1 to April 4, 2011. Following remediation, verification sampling was conducted in July 2011. Results showed that a single sample taken from the northern excavation contained contaminant concentrations in excess of the cleanup criteria for hexavalent chromium. Further remediation was performed to excavate an additional meter in depth at that location. A new sample was collected from the original failed location in August 2011.

The soil within the 100-F-56:1 northern and southern waste subsite footprints was excavated to a depth of approximately 0.2 meters (9 in.) below ground surface (bgs). The garnet sand was mixed with soil, therefore, no clean soil in the immediate vicinity was available for backfill.

The SubSite is Part Of:

Code: 100-F-56

Names: 100-F-56; 100-F Surface Debris/Stains

Code: 100-F-56:2

Classification: Accepted

Names: 100-F-56:2; Other 100-F Surface Debris Areas

Reclassification: Interim Closed Out (6/2/2011)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: This subsite consists of twenty locations having stained soil and/or debris across the 100-F Area. Seventeen of the sites are the result of treated wood debris. Two of the sites have oil filters and one site has lead debris.

Location: The debris is located throughout the 100-F Area. The GPS coordinates are provided in the 100-F Orphan Sites Evaluation Report (OSR-2005-0001) and are associated with the 100-F-56:2 waste site in the WCH GIS database using the OSE-ID field.

Waste Type: Not Specified

Waste Description: The waste includes discarded oil filters, lead debris, treated wood debris, and potentially contaminated soils.

Closure Info: The WCH Field Remediation (FR) project performed remedial action and housekeeping

activities at the 100-F Area from July 2005 to March 2008. During these activities, FR found that many of the previously identified 100-F-56 waste site components appeared to have been at other sites that were remediated after the orphan sites evaluation. A total of seven locations containing wood debris (i.e., rail road ties and a wooden utility pole) at the 100-F-56:2 subsite were remediated on March 1 and 2, 2011. Remedial action activities included surface pick up only, generating less than 20 bank cubic meters (26.16 bank cubic yards) of wood debris. This debris was directly loaded for disposal at the Environmental Restoration Disposal Facility.

The SubSite is Part Of:

Code: 100-F-56

Names: 100-F-56; 100-F Surface Debris/Stains

Code: 100-F-57

Classification: Accepted

Names: 100-F-57; 190-F Process Water Pump House Debris

Reclassification: None

Type: Foundation

Start Date: 1/1/1945

Status: Inactive

End Date: 1/1/1965

Description: The site consists of the remaining foundation of the demolished 190-F Process Water Pump House.

Location: The pump house and annex were directly north of the 105-F Reactor,

Process Description: The 100-F Area water treatment facilities were operated from 1945 until 1965 to provide large volumes of high quality cooling water to the 105-B Reactor. The 190-F Process Water Pump House was the final in a series of facilities that treated the raw river water before it was pumped to the 105-F Reactor. The water was transferred to underground clearwells (four 6.6 million L (1.75 million gal) tanks) located in the 190-F Process Water Pump House, where sodium dichromate was added to inhibit corrosion of the 105-F Reactor process tubes. The treated water was temporarily stored in the 190-F Process Water Pump House and pumped to the 105-F Reactor as needed.

Water was pumped from the Columbia River at the 181-F River Pump House and stored temporarily in the 182-F Reservoir. From 182-F, the water was pumped to the 183-F Filter Plant where it was treated for use as process cooling water for the 105-F Reactor. Additives for treatment of the water included chlorine, sulfuric acid (often contaminated with lead and mercury), and coagulants. The treatment process included flocculation and sedimentation process, chemical treatment, and filtration. Following coagulation and settling, the water was filtered, lime was added, and the water stored temporarily in underground clearwells.

The 190-F Process Water Pump House was the last facility in a series of facilities that treated the raw river water. Water arrived at 190-F after a flocculation and sedimentation process, chemical treatment, and filtration. At 190-F, the treated water was temporarily stored in four 6.6 million L (1.75 million gal) tanks (Clearwells), and sodium dichromate was added prior to pumping it through the F Reactor for cooling of the core and fuel. A several thousand gallon sodium dichromate storage tank was located within the facility. The facility shared a common wall on the north with the 185-F Water Treatment Plant, which later became a shop and storage facility. In 1956, an annex was added to the south of the pump house to increase the process water throughout the system. Both the pump house and the annex contained below-grade pump rooms.

Related Sites/ Structures: The 190-F Process Water Pump House was associated with the 100-F-36, 108-F Biological Laboratory, the 183-F Filter Plant, the 185-F Water Treatment Plant, the 189-F Refrigeration Building, 126-F-2, 183-F Clearwells and the 105-F Reactor Building.

Process Description: Surface debris waste (hazardous and/or dangerous) was tabulated for the 100-F Orphan Sites Evaluation (OSE) report to document the field results and to guide cleanup. A WIDS submittal (100-F-58) is required pending implementation of a waste control plan for the cleanup of surface debris/stains. Various sizes and forms of hazardous (CERCLA) and/or dangerous (MTCA) surface debris waste materials were left during the construction, operation, decontamination and decommissioning (D&D), and remedial action (RA) activities at the 100-F Area. During fiscal year 2005, a field walkdown of the area was conducted as a site closure screening activity. Surface debris identified as potential dangerous/CERCLA waste was precisely located and recorded using Global Positioning Satellite technology and a field logbook. For some features, additional information was obtained using digital photography. Subsequent evaluation of the collected data yielded four generic groupings of wastes: potentially asbestos containing material, lead, oil filters/oil stains, garnet (sand blasting material), and treated wood.

Originally, there were five categories of waste that were part of 100-F-56. At the request of the Remaining Sites Project, the potential asbestos containing material was moved to its own site, 100-F-58. The type of surface debris identified as either hazardous or dangerous waste materials according to CERCLA or MTCA was potentially asbestos containing material (including transite). Whereas this waste was created as a result of either operations or a site cleanup (i.e., D&D) activity, it would seem appropriate to dispose of them at the Environmental Restoration Disposal Facility under a project waste control plan. The concept for handling scattered surface debris under the Investigation Derived Waste (IDW) Strategy was presented at the June 2005 Unit Managers Meeting (UMM) and accepted at the July 2005 UMM meeting for implementation by the RA Project.

Various sizes and forms of hazardous (CERCLA) and/or dangerous (MTCA) surface debris waste materials were left during the construction, operation, decontamination and decommissioning (D&D), and remedial action (RA) activities at the 100-F Area. During fiscal year 2005, a field walkdown of the area was conducted as a site closure screening activity.

Surface debris identified as potential dangerous/CERCLA waste was precisely located and recorded using Global Positioning Satellite technology and a field logbook. For some features, additional information was obtained using digital photography. Subsequent evaluation of the collected data yielded four generic groupings of wastes, including potentially asbestos containing material, lead, oil filters/oil stains, garnet (sand blasting material), and treated wood.

Originally, there were five categories of waste that were part of 100-F-56. At the request of the Remaining Sites Project, the potential asbestos containing material was became its own site, 100-F-58. The type of surface debris identified as either hazardous or dangerous waste materials according to CERCLA or MTCA was potentially asbestos containing material (including transite). Whereas this waste was created as a result of either operations or a site cleanup (i.e., D&D) activity, it would seem appropriate to dispose of them at the Environmental Restoration Disposal Facility under a project waste control plan. The concept for handling scattered surface debris under the Investigation Derived Waste (IDW) Strategy was presented at the June 2005 Unit Managers Meeting (UMM) and accepted at the July 2005 UMM meeting for implementation by the RA Project.

Related Sites/ Structures: Temporary and permanent 100-F Area facilities removed by remedial action or decontamination/decommissioning activities are listed in the Buildings section of the Orphan Sites Evaluation report for 100-F.

Waste Type: Misc. Trash and Debris

Waste Description: The solid waste consists of scattered debris mainly in the form of transite. The debris is thought to potentially contain asbestos.

Closure Info: A total of eight locations containing ACM for the 100-F-58 waste site were remediated on March 2, 2011. Remedial action activities included surface pick-up only, generating less than 1 bank cubic meter (1.3 bank cubic yards) of potential ACM that was directly loaded for disposal at the Environmental Restoration Disposal Facility. Table 2, in the documentation attached to the reclass form, presents all remediated locations and their respective post-remediation photograph numbers, shown in Figures 2 through 9.

Code: 100-F-59

Classification: Accepted

Names: 100-F-59; Riparian Area Contamination
Originating from 128-F-2

Reclassification: None

Type: Burn Pit

Start Date:

Status: Inactive

End Date:

Description: The site consists of two areas known to contain contaminants above soil remedial action goals (RAGs). The first area was originally part of the 128-F-2 Burning Pit waste site located adjacent to the Columbia River. This portion of the site was remediated to an elevation below the ordinary high water mark (OHWM) of the river but sampling showed that metal contamination in excess of soil RAGs was present. The second area was located in riparian areas east and southeast of the 128-F-2 waste site. In January 2008, sampling of riparian areas surrounding the 128-F-2 waste site was conducted to determine the nature and extent of contamination. This area was sampled in accordance with WCH-227.

Location: The site is located in the northeast corner of the 100-F Area; approximately 30.5 meters (100 feet) east of the northeast corner of the 100F Area perimeter road which runs along the riverbank and directly east of the 107-F Retention Basin; and along the Columbia Rive, in the nearby riparian area which is occasionally under wate.

Related Sites/ Structures: 128-F-2 Burning Pit

100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]), and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The 100-F-60 waste site did not extend into the deep zone. Institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required.

The 100-F-60 waste site has been evaluated in accordance with the 100 Area Remaining Sites ROD and the Remedial Design Report/Remedial Action Work Plan. Confirmatory sampling was performed, and the analytical results indicate that the residual concentrations of COPCs at this site meet the RAGs and associated RAOs for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the verification sampling results support a reclassification of the 100-F-60 waste site to No Action.

Code: 100-F-61	Classification: Accepted
Names: 100-F-61; Stained Soil near 100-F-12	Reclassification: Interim Closed Out (12/22/2011)
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:
Description: The waste site has been remediated. It consisted of an area of stained soil discovered while excavating the 100-F-12 french drain, near 105-F.	
Location: The site was located northeast of the 105-F Reactor, approximately 30 centimeters (12 in.) east of the Electrical Equipment Room Number 1 at (E) 580460, (N) 147631 Washington State Plane.	
Closure Info: Demolition activities at this location had removed the upper portion of the 100-F-12 french drain. The french drain was then investigated by digging a test pit on October 11, 2004, to determine what structure remained and if the site was contaminated. Wood debris was uncovered just beneath the gravel surface and was identified as pieces of a power pole. A dark stain was uncovered approximately 1 meter (3.3 ft) below ground surface (bgs), along with power pole debris and asphalt. The stained soil was observed outside the red gravel exterior of the french drain and, as a result, was determined to be a discovery site (sitecode 100-F-61) and not associated with the french drain.	

Remediation of the 100-F-61 waste site began February 7, 2011, to remove the stained soil contamination. The stained soil associated with the confirmatory sampling description was located and removed. A layer of coal ash beneath the surface was removed with the excavation. Debris removed from the excavation consisted of asphalt, steel cable, steel conduit, and parts of steel pipe. All waste material was directly loaded for disposal at the Environmental Restoration Disposal Facility (ERDF). No overburden was associated with the waste site. An underground injection chamber associated with the No Action 100-F-12 french drain was removed with the excavation. Through in-process sampling of the excavated area, the 100-F-61 soil contamination was determined to extend north of the original stained soil location toward an active utility pole with overhead power lines. Remediation continued north of the existing excavation during an electrical power outage on March 24, 2011, removing contaminated soil, ash, and associated debris. The excavation was expanded toward the power pole area to the extent possible without affecting the stability of the pole. Due to remaining contamination indicated by in-process samples around the power pole, the decision was made to remove the pole and expand the excavation. The power pole was removed June 22, 2011, and the surrounding contaminated soil was excavated. On August 11, 2011, soil removal targeted the

area around the electrical equipment room and extended the excavation on the north side. The final excavation is an estimated 3 meters (10 ft) in depth.

Code: 100-F-62 **Classification:** Accepted
Names: 100-F-62; Animal Farm Septic Lines **Reclassification:** Interim Closed Out (12/22/2011)
Type: Sanitary Sewer **Start Date:**
Status: Inactive **End Date:**

Description: The waste site has been remediated. The site included influent pipes from the 141-M and 144-F 100-F Experimental Animal Farm (EAF) buildings. The 141-M Building vitrified clay pipe connected to the 1607-F7 septic tank and drain field. The 144-F steel pipe influent piping connected to the 100-F-31 septic tank and drain field.

Location: The Animal Farm (EAF) complex was located approximately 500 meters (0.3 miles) northeast of the 105-F Reactor.

Process Description: The 1607-F7 septic tank and drain field received sanitary sewage from the 141-M Building. The building was constructed in 1949 to provide office space and to serve as a change room for Animal Farm personnel working in the 100F Area. The EAF operations were discontinued in 1976. The 141-M building was also demolished in 1976.

A sample of the 1607-F7 septic tank contents was collected on October 6, 2004. The results indicated that the site required remediation. The septic tank and drain field was excavated between August 8 and November 30, 2005. Remediation of the 1607-F7 site was successful and it was reclassified as interim closed out. The post excavation civil survey (0100F-DD-C0309) shows the area excavated to remove the septic tank and drain field. The influent piping was not removed during the 2005 remedial action activities.

The 100-F-31 septic tank and drain field received animal and human septic waste from the 144-F Building. The building was constructed about 1960 as an L-shaped addition to the south end of the 141-F Sheep Barn. It contained an office, several laboratories, and a series of indoor/outdoor kennels. It was used for Pu-239 and Ra-226 inhalation studies first with mice, and then with dogs (BHI-00031). The 144-F facility was decontaminated and removed in 1978.

Samples of the 100-F-31 septic tank contents and stained soil were collected on October 15, 2004. The results indicated that the site required remediation. The septic tank and drain field was excavated in October 2004. Additional excavation was performed on February 6, 2006. Remediation of the 100-F-31 site was successful and it was reclassified as interim closed out. The post excavation civil survey (0100F-DD-C0309) shows the area excavated to remove the septic tank and drain field. The influent piping does not appear to have been removed by the remedial action activities. A portion of the influent piping was removed previously during the Group 4 Remedial Action (100-F-29) as shown in 0100F-DD-C0140. Approximately 13 meters (43 ft) of the influent piping was in an undisturbed area between the two excavations.

Related Sites/Structures: This was site is associated with the 1607-F7 septic system and 100-F-31 septic system and the 141-M and 144-F buildings.

Closure Info: 100-F-55 and 100-F-62 were addressed as a group. The information below documents information for the group of sites.

Remedial action at the 100-F-55 waste site was performed from September 16 to October 7, 2010 to a depth of 0.7 meters (2.3 ft). Remedial action at the 100-F-62 waste site was performed from December 2010 to March 2011. The 100-F-62 north pipeline excavation included the removal of the pipelines to the former 1607-F7 septic tank and contained the 100-F-55 waste

site excavation. From the north excavation, approximately 2 meters (7 ft) of the 4 inch diameter vitrified clay pipe were removed, and approximately 5 meters (16 ft) of 4 inch diameter steel pipe with lead bells were removed. Verification sample results indicated additional remediation was required. Additional remediation was performed from July 29 to August 9, 2011. The center section of the north excavation was further remediated, and the entire south excavation was further remediated and expanded to the south. The final north excavation depth is 2.3 meters (7.6 ft), and the final south excavation depth is 4.4 meters (14.5 ft). Additional remediation also occurred at the east staging pile area and the northeast quadrant of the south staging pile area.

Code: 100-F-63 **Classification:** Accepted

Names: 100-F-63; Animal Farm Radioactive Effluent Lines **Reclassification:** Interim Closed Out (9/26/2011)

Type: Radioactive Process Sewer **Start Date:**

Status: Inactive **End Date:**

Description: The site includes radioactive effluent piping and process sewers at the north end of the Experimental Animal Farm (EAF).

Location: The EAF complex was located approximately 500 meters (0.3 miles) northeast of the 105-F Reactor.

Process Description: Radioactive effluent was supplied to the EAF beginning in 1945 from the 147-F pump house. The effluent was used to perform studies by exposing fish to varying concentrations of reactor cooling water effluent (BHI-00031). Radioecology experiments also took place at the EAF. Greenhouses located in the 1705-F Building were used for growing potted plants. Samples of piping and soil were collected at the 146-F Aquatic Biology Fish Ponds site (100-F-33) in September 2004 (118428). The results indicated that the northern portion of the site required remediation. Excavation of contaminated concrete, piping and soil was performed between August 5 and 8, 2005. Remediation of the 100-F-33 was successful and it was reclassified as interim closed out (129492). Portions of the effluent pipelines and process sewer that ran between the 146-F and 147-F buildings appear to be outside of the excavated area. In addition, portions of the process sewer from drains in the 1705-F building appear to be outside the excavated area. Lastly 10 m (33 ft) of the process sewer leading to the circular pond in the south half of the 100-F-33 site appears to be outside of the excavation. The drain at the head end of this sewer was sampled (J01TF8) as part of 100-F-33 test pit 3 and did not require remedial action. It is assumed that this segment was closed in place using the same information. Two other remedial action events took place in the vicinity of the piping. Portions of the piping were likely removed by these activities. Refer to CVP-2001-00002 and CVP-2001-00010 for a description of the cleanup activities.

Related Sites/ Structures: 146-F, 147-F, 1705-F

Closure Info: 100-F-51 and 100-F-63 were addressed as a group. The information below documents information for the group of sites.

In November 2007 and February 2008, confirmatory sampling of the 100-F-51 waste site was carried out during the excavation of two test pits, at the north end and southeast corner of the laboratory (WCH 2007b). Confirmatory sampling results failed to meet remedial action goals (RAGs) and indicated the need for remedial action at the 100-F-51 waste site. Confirmatory sampling was not performed for the 100-F-63 waste site; the site was added to the 100-F Area scope for remove, treat, and dispose in 2010 (WCH 2010a).

Remedial action at the 100-F-51 and 100-F-63 waste sites began on December 20, 2010, and continued through January 20, 2011. Excavation depth ranged from 0.5 to 1.5 m (1.6 to 4.9 ft) below ground surface bgs and resulted in approximately 253 bank cubic meters (BCM) (331 bank cubic yards [BCY]) of soil and debris being removed and disposed at the Environmental Restoration Disposal Facility. Approximately 330 BCM (432 BCY) of overburden soil was stockpiled to be used as backfill. The 100-F-51 and 100-F-63 waste sites debris included concrete, clay pipe, steel pipe, and asphalt. The verification sampling results support a reclassification of the 100-F-51 and 100-F-63 waste sites to interim closed out.

Code:	116-F-1	Classification:	Accepted
Names:	116-F-1; Lewis Canal	Reclassification:	Interim Closed Out (11/3/2003)
Type:	Trench	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been remediated and closed out.		
Location:	The site was located approximately 160 meters (525 feet) west-northwest of the 105-F Building then turned north to the Columbia River.		
Release Description:	Contaminated coolant from the reactor front and rear faces were known to have drained into the unit. This included reactor cooling water diverted to the Columbia River via this waste site during the Ball 3X Project in 1953. It also received reactor coolant that was diverted to the trench during reactor process tube chemical scaling activities (i.e., when chemicals were flushed through the process tubes to remove scale that had built up on their inner surfaces and during the H-558 Increased Cooling Water Flow Project and other reactor upgrade projects).		
Process Description:	The 116-F-1 Trench was commonly known as Lewis Canal. The 105-F Reactor cooling water was diverted to the Columbia River via this trench. The water flowed west from the headwall, turned northward where it intersected with the Columbia River. Two additional ditches entered the main trench laterally from the east. The north lateral ditch was 194.5 meters (638 feet) long. The south lateral ditch was 219 meters (718 feet) long. Water from the main trench entered the Columbia River without an outfall structure. The water ran across a cobble-covered beach and into the river.		
Related Sites/ Structures:	The site was related to 105-F, 182-F, 183-F, and 190-F and 189-F Buildings.		
Waste Type:	Water		
Waste Description:	The site received liquid wastes from the 105-F, 182-F, 183-F, and 190-F Buildings and decontamination wastes from the 189-F Building. Reference RHO-CD-827 lists a calculated contaminated soil volume of 2.066E+05 cubic meters (7.3E+06 cubic feet) for the 914-meter (3000-foot) length of Lewis Canal (the length described in most of the documentation for the site). Estimated radionuclide inventories are available in Stenner (1988). Soil sample results are available in Dorian and Richards (1978). The hazardous chemical inventory included sodium dichromate and sulfamic acid. Surface soil and vegetation samples were collected from the areas adjacent to 116-F-1, analyzed for radionuclide concentrations (cobalt-60, strontium-90, cesium-137, plutonium-238, plutonium-239/240), and compared with the results from 1981 through 1986 (Jacques 1986).		
Closure Info:	Remedial action objectives and goals for the site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design		

Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).

The selected remedial action included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of concern (COCs). Waste site COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22). The COCs for this site consist of the following: carbon-14, cesium-137, cobalt-60, europium-152, europium-154, arsenic, and hexavalent chromium.

Cleanup verification samples for the shallow zone and overburden were collected on 12/11/2002 and 1/7/2003.

At the completion of remedial action, the total excavation was approximately 24,820 meters squared (267,000 square feet) in area with a depth of approximately 4.5 meters (14.8 feet). Approximately 77,696 metric tons (70,634 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

The remedial action at the 116-F-1 site has achieved the RAOs and corresponding RAGs established in the ROD (EPA 1997) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at ERDF. These results also indicate that residual concentrations at the site, including overburden, will support future land uses that can be represented (or bounded) by a rural-residential scenario, and are protective of groundwater and the Columbia River. The 116-F-1 site is verified to be remediated in accordance with the ROD (EPA 1997) and may be backfilled.

Code:	116-F-2	Classification:	Accepted
Names:	116-F-2; 107-F Liquid Waste Disposal Trench	Reclassification:	Interim Closed Out (3/12/2003)
Type:	Trench	Start Date:	6/4/1948
Status:	Inactive	End Date:	1/1/1965
Description:	The site was an open liquid waste trench. A 15-centimeter (6-inch), 12-gauge steel distribution pipe ran from the north end of the 107-F Basin to the north end of the trench. The length of piping inside the trench was unknown since piping was added as the trench was used and later backfilled. This site was also fed by two emergency bypass ditches that connected the 116-F-2 trench to the effluent line connected to the south end of the 107-F Basin. The first emergency bypass ditch, about 90 meters (295 feet) long, ran from the west center side of the 116-F-2 Trench to the gate valve on the 1.7 meter (5.6 feet) pipeline that ran to the 107-F Basin Inlet Distribution Box at the south end of the 107-F Retention Basin. A second emergency ditch bypass trench connected the 116-F-2 trench to a valve on the 107-centimeter (42-inch) diameter 105-F effluent pipeline. These ditches are also considered to be part of 116-F -2. The trench is shown on Hanford drawings H-1-70185, H-1-1522 and H-1-1540. The liquid waste and bypass trenches are visible in Hanford aerial photo 91062128-8.		
Location:	The site was located approximately 670 meters (2200 feet) east of the 105-F Reactor Building and approximately 60 meters (197 feet) east-southeast of the southeastern corner of 107-F Retention Basin.		
Process	The original trench was excavated June 4-5 1948 and used to dispose of the contaminated		

PROCESS

Description: reactor effluent from the first Hanford site fuel failure (HW-10284).

Related Sites/ Structures: The site was related to the 116-F-14 (107-F) Retention Basin and the 1.7-meter (5.6-foot) diameter pipeline exiting the south end of the Retention Basin and the 100-F-19, 100-F Reactor Cooling Water Effluent Underground Pipelines, Contaminated Underground Lines, Effluent Water System.

Waste Type: Process Effluent

Waste Description: The site received cooling water effluent from the 107-F Retention Basin during reactor outages due to fuel ruptures. During deactivation of the 105-F Reactor, the unit received overflow water from the 105-F Storage Basin via the retention basin. RHO-CD-827 lists the calculated volume of contaminated soil to be 2.5E+05 cubic meters (9E+06 cubic feet). Radionuclide inventory for 116-F-2 from Stenner (1988) lists, 0.37 curies of tritium, 0.8 curies of cobalt-60, 0.07 curies of strontium-90, 0.76 of cesium-137, 0.007 curies of plutonium-239, and 6.05 curies of europium-152. The site also has a hazardous chemical inventory that includes 60,000 kilograms (1.3E+05 pounds) of sodium dichromate. The results of four soil sample sites in the trench and four samples taken in the connecting ditch can be found in Dorian and Richards (1978).

Closure Info: In August of 2000 the site was noted as being backfilled and covered with 1.2 to 3.1 meters (4 to 10 feet) of soil (1970) and treated with defoliant to prevent vegetation growth.

The cleanup verification package (CVP-2001-00005) has documented that the remedial action objectives (RAOs) and remedial action goals (RAGs) for the 116-F-2 site have been met as established in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).

Remedial action began on November 22, 2000, and was completed on April 17, 2002. Excavation involved removing the overburden materials and underlying soil. Waste site COCs were identified through process knowledge and listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22). The COCs for this site included: carbon-14, cesium-137, cobalt-60, europium-152, europium-154, hexavalent chromium. On May 21 through May 29, 2002 cleanup verification samples from the shallow zone, deep zone and overburden were collected and analyzed for the established contaminants of concern.

At the completion of the remedial action, the total excavation was approximately 15,352 meters squared (50,367 square feet) in area with a depth greater than 4.6 meters (15 feet). Approximately 113,007 metric tons (124,534 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility.

These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 116-F-3

Classification: Accepted

Names: 116-F-3; 105-F Storage Basin Trench **Reclassification:** Interim Closed Out (6/16/2003)
Type: Trench **Start Date:** 1/1/1947
Status: Inactive **End Date:** 1/1/1951

Description: The site has been remediated and closed out. The contaminated soils have been excavated, but the site has not yet been backfilled. When active, the site had been an east-west oriented open excavation. After deactivation in 1951, the basin was backfilled with soil and cobbles. It was left unmarked and was not visually discernible. No vent pipes or other appurtenances were visible.

Location: The site was located approximately 39.6 meters (130 feet) south of the 105-F Reactor Building.

Process Description: The trench received reactor cooling water during a 1947 fuel rupture occurrence. In 1951, the trench received sludge from the 105-F fuel storage basin.

Related Sites/ Structures: The site is associated with the 105-F reactor and the 105-F fuel storage basin.

Waste Type: Process Effluent

Waste Description: The site received reactor effluent from the 105-F Reactor Building during an early fuel failure outage. In 1951, the site received sludge from the 105-F Storage Basin. During test pit activities in 1993, a buried pipe measuring 150 millimeters (6 inches) in diameter was found buried in the trench at approximately 1.8 meters (6 feet) below surface grade. The pipe was radiologically contaminated reading 500 counts per minute (5000 disintegrations per minute). The contaminants of concern (COC) for this site consist of Europium-152, Europium-154 and Hexavalent chromium.

Closure Info: Remedial action at the 116-F-3 site began in October 2002. Excavation of the site involved removing the overburden materials and underlying contaminated soil. Contaminated materials were disposed of at the ERDF. At the conclusion of excavation activities in February 2003, the elevation of the bottom of the excavation was at 121.7 meters (399.3 feet).

Field screening was used to guide the excavation to quickly assess for the presence and level of contamination. Field screening for the 116-F-3 site included using a radiological data mapping system survey, hand-held sodium iodide (NaI) detectors, and gamma energy analyses. The radiological mapping survey is performed over more than 50% of the site excavation surface area. The hand-held NaI detector is used to screen excavated waste material and to screen for potential excavation wall and floor hot spots. Gamma energy analyses were used to support waste characterization and to corroborate the radiological mapping survey and hand-held sodium iodide (NaI) detector data.

Remedial action objectives and goals for the 116-F-3 site were established by the U.S. Environmental Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 2002). The RAGs were developed to support a rural-residential exposure scenario. This scenario involves exposures to soils less than 4.6 meters (15 feet) deep only.

The selected remedial action for the 116-F-3 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and

protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of concern (COCs). Waste site COCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE RL 2001). The COCs for this site consist of Europium-152, Europium-154 and Hexavalent chromium.

Cleanup verification sampling began on January 6, 2003. Initial analytical results indicated areas of contamination, and additional remediation was completed. Following additional remedial excavation, resampling occurred on February 26, 2003. The 116-F-3 site consisted of only one shallow zone decision unit, which was divided into four sampling areas. One composite cleanup verification sample was collected from each sample area.

Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the Remedial Action Goals (RAG). At the completion of the remedial action, the total area of the excavation was approximately 843 square meters (9,074 square feet) with a depth of 4.7 meters (15.4 feet). Approximately 5,205 metric tons (5,738 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

Results of the sampling, laboratory analyses, and data evaluations for the 116-F-3 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

The Cleanup Verification Package (CVP) document demonstrates that remedial action at the 116-F-3 site has achieved the Remedial Action Objectives and corresponding Remedial Action Goals established in the Record of Decision (EPA 1997) and Remedial Design Report/Remedial Action Work Plan (DOE RL 2002). The remaining soils at the 116-F-3 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-F-3 site containing contaminants of concern at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. The results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The 116-F-3 site is verified to be remediated in accordance with the ROD (EPA 1997) and may be backfilled.

Code:	116-F-4	Classification:	Accepted
Names:	116-F-4; 105-F Pluto Crib	Reclassification:	Interim Closed Out (11/8/2001)
Type:	Crib	Start Date:	1/1/1950
Status:	Inactive	End Date:	1/1/1952
Description:	The site has been remediated and closed out. The unit consisted of a french drain-type distribution system. A 0.61-meter (2-foot) riser was attached to a bottomless 208-liter (55-gallon) drum that drained into a cobble leach field.		
Location:	The unit was located approximately 40 meters (130 feet) southwest of the southwestern corner of the 105-F Reactor Building		
Process Description:	The 116-F-4 Pluto Crib was an inactive waste site that operated from 1950 to 1952 receiving contaminated reactor cooling water from the 105-F Reactor building. The purpose of the crib was to receive liquid wastes from the 105-F Reactor Building during outages due to fuel ruptures. Cooling water was diverted from the affected tube through a valve known as a "pluto valve" or "pluto cap" and through a rubber hose to the crib. The hose ran above ground from the rear face of the reactor to the crib.		

Waste Type: Process Effluent
Waste Description: The site received coolant water from pressure tubes containing ruptured fuel elements. It was estimated that 280 curies of fission products were discharged to the crib during its operation (Dorian and Richards 1978). It was also assumed that the contaminated soil occupied a volume of 6 by 6 by 7.6 meters (20 by 20 by 25 feet).

Closure Info: Remedial action objectives and goals for the 116-F-4 site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL 2000).

The 116-F-4 site was excavated from September to November 1993 during a soil treatability study. Before excavation activities commenced, the vertical extent of contamination was estimated using February 1993 borehole data taken from a location next to the crib riser. As a result of an onsite decision by RL, EPA, and Ecology, two 2.4 meter (8-foot) deep test pits were excavated at the bottom of the soil treatability excavation for verification sampling. Cleanup verification sampling was conducted on November 10, 1993.

The COCs for this site include the following: Americium-241, Cesium-137, Cobalt-60, Europium-152, Europium-154, Plutonium-239/240, Strontium-90, Uranium-233/234, Uranium-238, Hexavalent chromium. Hexavalent chromium was identified as a 116-F-4 site COC in the SAP, but was not analyzed for during the 1993 treatability study. The treatability test soil samples including waste samples, however, were analyzed for total chromium and sodium. Total chromium and sodium were not detected in cleanup verification samples or waste samples at concentrations greater than Hanford Site background concentrations (18.5 mg/kg for total chromium and 690 mg/kg for sodium). Based on the 116-F-4 treatability study total chromium and sodium cleanup verification sample results and based on analogous pluto crib site information, hexavalent chromium was not considered further for the site.

The results of the verification sampling effort indicated that the materials from the 116-F-4 site containing COCs at concentrations exceeding RAGS have been excavated and disposed at the ERDF. Approximately 3,440 cubic meters (4,500 cubic yards) of soil was removed during the excavation. Over 382 cubic meters (500 cubic yards) of this material was designated contaminated soil. At the completion of the test, the clean top soil along with additional soil from a borrow pit was used to refill the excavation hole and return the surface to grade.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 116-F-5	Classification: Accepted
Names: 116-F-5; Ball Washer Crib	Reclassification: Interim Closed Out (8/16/2001)
Type: Crib	Start Date: 1/1/1954
Status: Inactive	End Date: 1/1/1964

Description: The site has been remediated and closed out. The 116-F-5 Crib has been fully backfilled and appears today as an unmarked, gravel-covered field. No vent pipes or other appurtenances remain. The crib was fed by a 76-meter (250 foot) long vitrified clay pipeline that ran from the

105-F Reactor Building, at which point a 10.2-centimeter (4-inch) schedule 40 steel pipe was used. The pipeline was about 1.2 meters (4 feet) below grade. The vitrified clay pipe consisted of 1.2-meter (4-foot) sections. The bell ends were sealed with lead rings. The pipeline ended in a 3 by 3 by 2.7-meter (10 by 10 by 9-foot) excavation filled with cobble. Approximately 36.5 meters (120 feet) of the pipe, from 116-F-5 to the north end of the 116-F-4 excavation, was removed in 1993 during the 100 Area Excavation Treatability Test. The remaining 39.5 meters (130 feet) of pipe is part of site 100-F-26 for remedial action.

Location: The site was located approximately 50 meters (140 feet) southwest of the 105-F Reactor Building.

Process Description: The site was used to dispose of liquid decontamination wastes from the 105-F Reactor ball washer assembly. It served to clean and decontaminate small, steel-jacketed boron balls used in the Ball 3X safety system. The ball washer assembly was located in the transfer basin area of the 105-F Reactor Building.

Related Sites/ Structures: The site was associated with the 105-F Reactor Building ball washer assembly and the 100-F-26:14 Influent Pipeline.

Waste Type: Process Effluent

Waste Description: The site received liquid waste associated with the decontamination of boron steel balls. Contaminants included strontium-90, cesium-137, europium-154, and europium-155. The waste also included nitric acid that was used for decontamination. However, sampling done in 1997 found only cobalt-60 and europium-155 to be above background levels.

The Cleanup Verification Package lists the final contaminants of concern (COCs) based on the Sampling and Analysis Plan (DOE/RL-96-22) as cesium-137 and cobalt-60.

Closure Info: The cleanup verification package (CVP-2001-00007) has documented that the remedial action objectives (RAOs) and remedial action goals (RAGs) for the 116-F-5 site have been met as established the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

The COCs for this site consisted of cesium-137 and cobalt-60. As identified through process knowledge in the 100 Area Remedial Action Sampling and Analysis Plan.

A large test pit was excavated at the 116-F-5 site on July 30, 1997. Field screening and sampling of soil were conducted during excavation. The test pit excavation was an ellipse approximately 6.1 meters by 7.3 meters (20 feet by 24 feet) by 3.4 meters (12 feet) in depth. During test pit excavation, the entire 3-meter (10-foot) by 3-meter (10-foot) by 2.7-meter (9-foot)-deep crib structure (gravels) was excavated, field screened, and sampled. No contaminated materials or soil were encountered. Verification samples were collected from the test pit on July 30, 1997. The site investigation and the CVP demonstrate that the 116-F-5 site meets the established RAOs and corresponding RAGs.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 116-F-6

Classification: Accepted

Names: 116-F-6; 1608-F Liquid Waste Disposal Trench; 105-F Cooling Water Trench **Reclassification:** Interim Closed Out (11/3/2003)

Type: Trench **Start Date:** 1/1/1952

Status: Inactive **End Date:** 1/1/1965

Description: The site has been remediated and closed out. The site was an open excavation used to receive reactor cooling water.

Location: The site is located about 55 meters (180 feet) southeast of the southeastern corner of the 105-F Building.

Process Description: The site was used intermittently to dispose of cooling water while maintenance and repairs were being performed on the effluent system. Dorian and Richards (1978) refer to the 116-F-6 Trench as the "1608-F Liquid Waste Disposal Trench", suggesting that the 1608-F Pumping Station wastes were disposed at this site. Several other documents, including Gano and Hall (1987), Hanford Drawing H-1-15244, and Kiser (1988) also use this nomenclature for 116-F-6. Hanford drawing H-1-70185 shows a "crib" pipe emerging from the east side of 1608-F and angling south toward 116-F-6. A ground penetrating radar (GPR) survey done in 1993 identified a linear anomaly that may represent this pipe.

Related Sites/ Structures: The site intermittently received cooling water from the 105-F Reactor Building.

Waste Type: Process Effluent

Waste Description: The site received water diverted during reactor shutdowns when maintenance was necessary on the effluent system. This practice was used during several reactor upgrades. Contaminants would include, europium-152, cobalt-60, europium-154, cesium-137, and sulfamic acid (3,000 kilograms [6600 pounds]).

Closure Info: Remedial action objectives and goals for the 116-F-6 site were established by the U.S. Environmental Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).

The selected remedial action for the 116-F-6 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of concern (COCs). Waste site COCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22). The COCs for this site consist of the following: cesium-137, cobalt-60, europium-152, europium-154, strontium-90, hexavalent chromium.

Cleanup verification samples were collected from the shallow zone (HEIS sample numbers J008F0 to J008F9) and the deep zone (J008D1 to J008D7) on November 25, 2002 and January 6, 2003.

At the completion of the remedial action, the total excavation was approximately 5,272 meters squared (56,747 feet) in area with a depth of 4.6 meters (15 feet). Approximately 32,156 metric

tons (35,446 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

The CVP demonstrates that remedial action at the 116-F-6 site has achieved the RAOs and corresponding RAGs established in the ROD (EPA 1997) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 116-F-6 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-F-6 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 116-F-6 site is verified to be remediated in accordance with the ROD (EPA 1997) and may be backfilled.

Code:	116-F-7	Classification:	Accepted
Names:	116-F-7; 116-F-7 Seal Pit Water Crib and Pipeline; 117-F Crib and Pipeline	Reclassification:	No Action (11/14/2005)
Type:	Crib	Start Date:	1/1/1960
Status:	Inactive	End Date:	1/1/1965
Description:	The site consisted of subsite 1) crib and 2) pipeline that has been filled with gravel and covered with clean soil. The pipeline originated at the 132-F-5 (117-F Filter Building) and terminated at the crib site.		
Location:	The site was located 137 meters (450 feet) south of the southwestern corner of 105-F Building.		
Process Description:	The crib was used to dispose water collected in exhaust system filter seal pits in the 117-F Ventilation Exhaust Filter Building (132-F-5). The 117-F facility filtered ventilation air from the confinement zone of the 105-F Reactor Building prior to its discharge to the atmosphere through the 105-F Reactor Building Stack.		
Related Sites/ Structures:	The site was associated with 132-F-5 (117-F Filter Building) and 116-F-7 Seal Pit Water Crib.		
Waste Type:	Process Effluent		
Waste Description:	The site received drainage from confinement exhaust system filter seal pits in the 117-F Building.		
	UNI-946 states that boring 7-A appears to have been drilled very close to the center of the crib and a sample was collected at a depth of 3 meters (10 feet). Analysis of this material shows concentrations of 0.032 picocuries/gram for cesium-137, 0.057 picocuries/gram for strontium-90, 0.1 picocuries/gram for plutonium-239/240, and 0.26 picocuries/gram for europium-152.		

This Site has the Following SubSites:

Code:	116-F-7:1
Names:	116-F-7:1; 117-F Crib; 116-F-7 Crib; 116-F-7 Seal Pit Water Crib
Code:	116-F-7:2
Names:	116-F-7:2; 117-F Crib Pipeline; 116-F-7 Crib Pipeline; 116-F-7 Seal Pit Water Crib Pipeline

Code:	116-F-7:1	Classification:	Accepted
--------------	-----------	------------------------	----------

Names: 116-F-7:1; 117-F Crib; 116-F-7 Crib; 116-F-7 Seal Pit Water Crib **Reclassification:** No Action (2/15/2005)

Type: Crib **Start Date:**

Status: Inactive **End Date:**

Description: Subsite 1 consisted of the 116-F-7 Seal Pit Water Crib. The crib was marked by a 122 cm (48 in) diameter steel vent pipe. The bottom was about 5.2 m (17 ft) below grade and was 6.1 m (20 ft) square. The steel vent marking the site was located in one corner of the crib and was placed on a concrete slab 1.8 m (6 ft) square by 20 cm (8 in) thick. The vent itself was constructed of 91 centimeter (36 in) steel pipe. A distribution piping system of 15 cm (6 in) perforated asbestos cement pipe, forming a cross, lies just beneath a polyethylene vapor barrier about 0.6 m (2 ft) below grade. The feed pipe was 10.16 cm (4 in) cement asbestos pipe. The remainder of the crib was filled with washed river-run gravels (H-1-19825).

Location: The site was located 137 m (450 ft) south of the southwestern corner of 105-F Building.

Waste Type: Not Specified

Waste Description: The waste would be the crib structure and soil contaminated from the material entering the crib via the pipeline.

Closure Info: A site evaluation was conducted as part of the Remaining Sites Verification Package (RSVP) attached to the Reclassification Form 2004-128 through field observations and focused sampling and analysis for the purpose of determining if hazardous or radiological contaminants were present.

One test pit was excavated to the bottom of the seal pit water crib structure. Four samples were collected at the site on October 12, 2004: a sample from nonfriable asbestos-cement pipe, a main sample and duplicate sample in the native soil below the gravel, and an equipment blank sample.

Contaminants of potential concern (COPCs) for this site were identified from historical information. The contaminants were carbon-14, cobalt-60, cesium-137, europium-152, europium-154, europium-155, tritium, strontium-90, uranium-234, uranium 235, uranium-238, hexavalent chromium, mercury, lead, semivolatile organics, and volatile organics (DOE/RL-96-17, Rev. 5). Based on further site-specific evaluation, plutonium-238, plutonium-239/240, arsenic, barium, cadmium, total chromium, selenium, silver, and polychlorinated biphenyls were also included as COPCs. Composite samples were collected and analyzed for the established contaminants of concern on 10/12/04. The results from the sampling event were reported as HEIS sample numbers J01XR0 through J01XR2.

The RSVP report demonstrated that the site met the objectives for a "No Action reclassification as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17, Rev. 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD) (EPA 1999). The report also documented that the site soil contaminant concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

The SubSite is Part Of:

Code: 116-F-7

Names: 116-F-7; 116-F-7 Seal Pit Water Crib and Pipeline; 117-F Crib and Pipeline

Code: 116-F-7:2

Classification: Accepted

Names: 116-F-7:2; 117-F Crib Pipeline; 116-F-7 Crib Pipeline; 116-F-7 Seal Pit Water Crib Pipeline **Reclassification:** No Action (11/14/2005)

Type: Crib **Start Date:**

Status: Inactive **End Date:**

Description: Subsite two consisted of the waste transfer pipeline. The pipeline originated at the 132-F-5 (117-F Filter Building) and terminated at the 116-F-7 Seal Pit Water Crib.

This 10-centimeter (4 inch) diameter transite pipeline was used to transfer water from the 132-F-5 (117-F Filter Building) sump pump discharge to the 116-F-7 Seal Water Crib about 168 meters (550 feet) south of the building. The pipeline drained into a perforated distributor pipe in the 116-F-7 crib, a total distance of about 185 meters (607 feet). The vented pipeline was fed from a sump pump and sloped for gravity drain with an average depth of about 1.5 meters (5 feet) below grade.

Location: The pipeline ran south from the 132-F-5 filter building to the 116-F-7:1 seal pit crib.

Waste Type: Not Specified

Waste Description: The waste consists of the piping, and underlying soil.

Closure Info: The 132-F-5 (117-F Filter Building) was reclassified as "No Action" based on a ResRad evaluation of the Allowable Residual Contamination Level (ARCL) information. The 116-F-7 Seal Pit Water Crib was closed with a "No Action" WIDS reclassification based on biased (worst case) sampling data for the soil in the crib. No significant contamination was found in the verification samples. There was no significant scaling or radiation detected during the inspection of the crib influent piping.

The 132-F-5 Filter Building and the 116-F-7 Seal Pit Water Crib waste sites have been remediated and reclassified to "No Action".

The fine soil at the top of the crib soil column had greater sorption capabilities for the contaminants of potential concern than either the 4-inch to 6-inch cobble fill in the Crib or the transite piping. The 116-F-7 influent pipeline was made of asbestos-cement which had less surface area than surface soils and did not adsorb ionic contaminants nor filter as effectively as fine soil particles. The soil analyses showed the crib and its internal piping met the cleanup standards. Because the pipeline was composed of the same material as in the crib and was exposed to the same waste stream, by analogy, the pipeline is also a candidate for "No Action" WIDS reclassification.

The absence of either detectable radiation reading or pipeline scaling indicates a low risk of significant contamination within the pipeline. The influent pipe is deemed to be a lower risk for contamination than within the crib since it has a lower sorptive or filtering capability. As such, the influent pipeline is recommended for acceptance as a "No Action" waste subsite of the 116-F-7 crib.

The SubSite is Part Of:

Code: 116-F-7

Names: 116-F-7; 116-F-7 Seal Pit Water Crib and Pipeline; 117-F Crib and Pipeline

Code: 116-F-8 **Classification:** Accepted

Names: 116-F-8; 1904-F Outfall Structure **Reclassification:** Interim Closed Out (9/25/2006)

Type: Outfall **Start Date:** 1/1/1945

Status: Inactive

End Date: 1/1/1965

Description: The site has been remediated and interim closed. This site consisted of an open-topped, compartmentalized, reinforced concrete outfall structure. A 183 centimeter (72 inch) diameter steel retention basin pipeline entered the south face; and two 107 centimeter (42 inch) pipelines exited the north face to the river.

Location: The site was located approximately 214 meters (700 feet) northeast of the 107-F Retention Basin, near the shore of the Columbia River.

Process Description: The outfall was designed as an open concrete structure for discharging reactor effluent cooling water from the 116-F-14 (107-F Retention Basin) to the center of Columbia River via 100-F-39 river pipelines. The outfall was constructed of a reinforced, compartmentalized concrete weir box, with walls extending from 7.6 meters (25 feet) below grade and 0.3 meters (1 foot) above grade. This unit was also connected to the Pacific Northwest Laboratory (PNL) Outfall (116-F-16) by a distribution box. The north effluent discharge consisted of two 107 centimeter (42-inch) diameter pipes. The second was a spillway flume (100-F-42) that ran from the outfall chamber, down the riverbank, and emptied into the river. The flume was constructed of reinforced concrete and was 4 by 0.6 meters (14 by 2 feet) deep and about 40 meters (130 feet) long. The spillway was designed to prevent excessive backwater at the 107-F Retention Basin during high water or in the event of a blockage of the outfall lines. Piping for the 116-F-8 outfall included two 107 centimeter (42 inch)-diameter by 139 meter (455 feet) steel effluent pipelines that exited the northeast side of the outfall and extended into the Columbia River. Two pipelines entered the south side of the outfall from the 107-F Retention Basin. One was a 152 centimeter (60 inch) diameter pipe. The other was a 91 centimeter (36 inch)-diameter pipe.

Related Sites/Structures: The site was associated with the 116-F-14 (107-F Retention Basin) and the 116-F-16 Pacific Northwest Laboratory (PNL) Outfall Structure. The outfall discharged effluent to the 100-F-39 River Effluent Pipelines and/or 100-F-42 Flume.

Waste Type: Construction Debris

Waste Description: Reactor water from the 107-F Basin was piped to the outfall structure that discharged into the Columbia River. The outfall could have also received reactor water that had been diverted for fish studies and other process wastes from the Experimental Animal Farm.

Contaminants of concern include cobalt-60, europium-152, europium-154, europium-155, and hexavalent chromium. Other contaminants of potential concern include carbon-14, cesium-137, nickel-63, and strontium-90.

Closure Info: 116-F-8 and 100-F-42 were addressed as a group. The information below documents information for the group of sites.

The Remaining Sites Verification Package (RSVP-2006-038) documented that the 116-F-8 and 100-F-42 waste sites have met the objectives for interim closure. The remedial action objectives (RAOs) and remedial action goals (RAGs) for these sites were established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

The 100-F-42 Spillway was administratively separated from the 116-F-8 Outfall for inclusion within the Remaining Sites ROD by agreement among the Tri-Parties. It was subsequently determined that sufficient evidence existed to warrant remedial action during remediation of the 116-F-8 waste site, therefore both waste sites were remediated and evaluated as a single unit.

The waste site Contaminates of Concern (COCs) were based on the list presented in the

Remaining Sites ROD, as expanded in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) for the 116-F-8 waste site. The COCs included: cobalt-60, europium-152, europium-154, europium-155, and hexavalent chromium. Cesium 137 was also included as a COC due to analytical detections within verification samples.

Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels has been made for the site COCs; screening levels were not exceeded. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which included a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decisions for the 116-F-8 and 100-F-42 waste sites.

Remedial action activities at the waste sites were conducted from August 31, 2004, to September 22, 2005. Remediation involved excavation and staging of clean overburden material and removal of the demolished concrete outfall structure, the concrete spillway structure above the Columbia River ordinary high water mark, and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. The residual 100-F-39 effluent pipelines will be sealed with concrete prior to backfill of the remediation footprint. Contaminated materials were disposed at the ERDF.

Final cleanup verification sampling was conducted from February 9 to 26, 2006, following variance analyses. The final verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency analytical methods as required per the SAP. Each verification sample was composed of a composite sample formed by combining soil collected at the required number of randomly selected locations within each sampling area (excluding the quality assurance/quality control samples).

Due to their immediate proximity and historic functional relationship, the 116-F-8 and 100-F-42 waste sites were combined into one unit for the purposes of decision unit stratification.

The cleanup verification sample analytical data were stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System. The sampling information was also included in Appendix A of the RSVP.

Approximately 1,325 meters squared (14,260 square feet) of plan area was excavated, including excavation within the deep zone (greater than 4.6 meters [15 feet] below ground surface) up to 8 meters (26 feet) below ground surface. Approximately 4,900 metric tons (5,400 U.S. tons) of material from the sites was removed and disposed at the ERDF.

The results of verification sampling demonstrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also showed that residual contaminant concentrations were protective of groundwater and the Columbia River. The results of deep zone verification sampling also showed that residual deep zone contaminant concentrations met the requirements for unrestricted direct exposure; accordingly, no institutional controls are required for deep zone soils.

Code: 116-F-9	Classification: Accepted
Names: 116-F-9; Animal Waste Leaching Trench	Reclassification: Interim Closed Out (10/16/2002)
Type: Trench	Start Date: 1/1/1963
Status: Inactive	End Date: 1/1/1976
Description: The site has been remediated and closed out. The site was a leaching trench that received waste	

*	water from the cleaning of animal pens in the Experimental Animal Farm. The pipelines that originated at the 141-C Building and terminated at the trench are documented in 100-F-29.
Location:	The site was located approximately 46 meters (150 feet) northeast of the 107-F Retention Basin.
Release Description:	An unplanned release that occurred in 1955 created what was known as the "basin leak ditch". This release formed a ditch that crossed the animal waste trench site from west to east.
Process Description:	During the time that Experimental Animal Farm was active, animal pens housed the animals used for experimental purposes. When the pens were cleaned, waste water containing animal wastes was flushed to the 116-F-9 Animal Waste Leaching Trench.
Related Sites/ Structures:	The site received wash waste water from the 141-C Animal Barn and the 141-N Animal Waste Collection Facility. Pipelines to the trench are included in site 100-F-29 100 F Experimental Animal Farm Process Sewer Pipelines.
Waste Type:	Soil
Waste Description:	Contaminants found during sampling in 1979 included cesium-137, cobalt-60, europium-152, europium-154, europium-155, strontium-90, plutonium-238, plutonium-239/240. The total estimated radioactive inventory (1979) of the 116-F-9 Animal Leach Trench contaminated soil column was 4.1 curies (See Memorandum from V. R. Richards to J. J. Dorian).
Waste Type:	Animal Waste
Waste Description:	The site received wash waste water from the cleaning of animal pens.
Closure Info:	Remedial action objectives and goals for the 116-F-9 site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).
	Remedial action at the 116-F-9 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.
	Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of remedial action, the total excavation was approximately 5,484 square meters (59,029 square feet) in area with a maximum depth of about 5.7 meters (19 feet). Approximately 49,405 metric tons (54,460 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.
	For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of concern (COCs). Waste site COCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/ RL-96-22). The COCs for this site consist of the following: carbon-14, cesium-137, cobalt-60, europium-152, strontium-90 and hexavalent chromium.
	Results of the sampling, laboratory analyses, and data evaluations for the 116-F-9 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Cleanup verification sampling for the deep and shallow zones was done on April 1 and April 10, 2002, respectively. The final verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency analytical methods, as required per the SAP.

The remedial action at the 116-F-9 site has achieved the RAOs and corresponding RAGs established in the approved Amendment to the Interim Action ROD (EPA 1997) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 116-F-9 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-F-9 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 ft]) are required. The 116-F-9 site is verified to be remediated in accordance with the ROD (EPA 1997) and may be backfilled.

Code:	116-F-10	Classification:	Accepted
Names:	116-F-10; 116-F-8; Perf Decontamination Drain; 105 Dummy/Perf Decontamination Crib; 105-F Dummy Decontamination French Drain	Reclassification:	Interim Closed Out (6/14/2003)
Type:	French Drain	Start Date:	1/1/1948
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been remediated and closed out. The site consisted of a vitrified clay pipe placed in the ground vertically with approximately 3.0 meters (10 feet) of sand and gravel beneath the tile. The site also included a 10.16-centimeter (4-inch) steel feed pipeline located about 1.2 meters (4 feet) below grade. This pipeline terminated at the "Wash Pad" located in the southeast corner of the 105-F Building fuels storage basin.		
Location:	The site was located approximately 50 meters (140 feet) south of the 105-F Building.		
Process Description:	The 116-F-10, 105-F Dummy Decontamination French Drain was used to dispose of decontamination fluids derived from the decontamination of dummy fuel element spacers and other reactor hardware.		
Related Sites/ Structures:	The site was associated with the 105-F Building.		
Waste Type:	Process Effluent		
Waste Description:	The site received radioactive water rinses and spent nitric acid from the decontamination of fuel element spacers and other reactor hardware, primarily pressure tube caps. In addition, the site received liquid waste containing 2000 kilograms (4400 pounds) of sodium dichromate, 2000 kilograms (4400 pounds) of sodium oxylate, and 2000 kilograms (4400 pounds) of sodium sulfamate. The site may have received other chemicals as well. Known decontamination solutions at 100-F included chromic acid, citric acid, oxalic acid, sulfamic acid, sulfuric acid, and sodium fluoride. Other chemicals, including organic solvents, were also used for some decontamination processes.		
	Three soil borings were drilled in the vicinity of the drain in 1975 (Dorian and Richards 1978). Boring 10-A was drilled next to the tile pipe, and borings 10-B and 10-C were completed approximately 3 meters (10 feet) and 9 meters (30 feet) east of the tile pipe respectively. Samples were collected from these borings at depths ranging from 3.8 to 8.2 meters (12.5 to 27		

feet). Analytical results indicated elevated concentrations of cobalt-60 (610 picocuries/gram), europium-152 (250 picocuries/gram), europium-154 (31 picocuries/gram), europium-155 (100 picocuries/gram), and cesium-137 (7.4 picocuries/gram) in boring 10-B. Elevated concentrations were not detected in the samples from borings 10-A and 10-C.

Closure Info: Remedial action objectives and goals for the 116-F-10 site were established by the U.S. Environmental Protection Agency and the U.S. Department of Energy, Richland Operations Office, in concurrence with the Washington State Department of Ecology. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17).

The selected remedial action for the 116-F-10 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to the average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River.

For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of concern (COCs). Waste site COCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22). The COCs for this site consist of the following: cesium-137, cobalt-60, europium-152, uranium-238, total chromium, hexavalent chromium.

At the completion of remedial action, the total excavation was approximately 195 square meters (2,100 square feet) in area with a depth of approximately 4.4 meters (14.4 feet). Approximately 848 metric tons (935 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

Results of the sampling, laboratory analyses, and data evaluations for the 116-F-10 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Shallow zone cleanup verification samples were collected and reported in the CVP with the HEIS sample numbers of J00BY3 through J00BY7 and J00BY9 on December 5, 2002. However, these samples could not be located in the HEIS database.

The site also included a 10-centimeter (4-inch)-diameter steel pipeline that discharged into the french drain about 1.2 meters (4 feet) below grade. This pipeline originated at the wash pad located in the southeast corner of the 105-F Building Fuel Storage Basin. The pipe ran to the northwest 9 meters (30 feet) and then entered the 116-F-3 excavation. The 10 centimeter (4 inch) diameter steel pipeline was removed without excavation during remediation of the fuel storage basin and the 116-F-10 French Drain and 116-F-3 Storage Basin Trench waste sites. Field screening indicated there was no contamination in the pipeline, and the area was not included in the final cleanup verification sampling design. Because the two associated waste sites (116-F-3 and 116-F-10) were verified clean as shallow zone sites, and the ends of the pipes originally terminated within the boundaries of these excavations, it can be concluded that the short distance between was also clean. This strategy was approved by the regulators and used during cleanup verification of the 116-F-2 Liquid Waste Disposal Trench and its associated feed pipeline.

The CVP demonstrates that remedial action at the 116-F-10 site has achieved the RAOs and corresponding RAGs established in the approved Amendment to the Interim Action ROD (EPA 1997) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 116-F-10 site have been

sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-F-10 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 116-F-10 site is verified to be remediated in accordance with the ROD (EPA 1997) and may be backfilled.

Code: 116-F-11	Classification: Accepted
Names: 116-F-11; 105-F Cushion Corridor French Drain	Reclassification: Interim Closed Out (9/15/2003)
Type: French Drain	Start Date: 1/1/1953
Status: Inactive	End Date: 1/1/1965

Description: The site has been remediated and interim closed out. A 0.9-meter (3-foot) diameter tile pipe was buried vertically with 2.5 to 5 centimeters (1 to 2 inches) extending above grade. The pipe had a metal lid.

Location: The site was located at the southeast corner of the 105-F Reactor Building.

Process Description: The cushion corridor french drain received liquid decontamination waste from the cushion corridor area of the reactor. Contaminated liquids were generated when reactor hardware was decontaminated on the concrete floor in the cushion corridor and the decontamination solutions were flushed through a floor-level wall opening drain into the french drain.

Related Sites/ Structures: The french drain was associated with 105-F reactor.

Waste Type: Process Effluent

Waste Description: The site received liquid decontamination wastes from the cushion corridor area when reactor hardware was decontaminated.

Boring 105-F-A was completed in this area in 1975 (Dorian and Richards 1978). The boring was drilled to a depth of 2.4 meters (8 feet) before terminating due to a concrete obstruction. A soil sample was collected at a depth of 1.5 meters (5 feet) and radionuclide concentrations varied from 0.01 to 5.6 picocuries per gram. Since this boring is approximately 30 meters (100 feet) away from 116-F-11, these results are not likely to be representative of soils near this waste unit.

Closure Info: 100-F-19:2, 116-F-11, UPR-100-F-1 and 100-F-29 were addressed as a group. The information below documents information for the group of sites.

The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003.

Remedial Action ran from August 2001 until December 2002. Verification sampling was conducted in January 2003. Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. Contaminants of concern (COCs) were C-14, Cs-137, Co-60, Eu-152, Eu-154, Eu-155, Ni-63, and Sr-90.

Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. The basis for reclassification was described in detail in the Cleanup Verification Package 2001-00003.

The cleanup verification package does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]); therefore, institutional controls to prevent uncontrolled drilling or excavation into deep zone soils are required.

Code:	116-F-12	Classification:	Accepted
Names:	116-F-12; 148-F French Drain	Reclassification:	Interim Closed Out (5/22/2002)
Type:	French Drain	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1964
Description:	The site has been remediated and interim closed out. The drain was excavated during the removal of the 100-F-19:1 effluent pipelines.		
Location:	The site was located approximately 300 feet (90 meters) north of the northwest corner of the 107-F Retention Basin (116-F-14).		
Process Description:	The 116-F-12 French Drain was used to dispose of effluent pump prime recovered from the 148-F Pumphouse.		
Related Sites/ Structures:	The site received pump prime from the 148-F Pump House and Lift Station. The 148-F French Drain was located about 2.4 meters (8 feet) east of the 148-F Pump House.		
Waste Type:	Water		
Waste Description:	This drain would have received minimal amounts of leakage or spillage from two pumps located in the facility that were used to supply reactor cooling water to the fish studies facilities. Although Stenner, et al (PNL-6456) states that the site received recovered effluent pump prime, drawings (H-1-459-VOID and H-1-1518) indicate that the site could not have received any effluent except leakage or spillage from maintenance activities on the pumps.		
Closure Info:	100-F-19:1, 100-F-19:3, 100-F-34 and 116-F-12 were addressed as a group. The information below documents information for the group of sites.		

The 100-F-19:1 North Pipelines, 100-F-19:3 West Pipelines, 100-F-34 Biology Facility French Drain, and the 116-F-12 French Drain were remediated as a group in CVP-2001-00002. These sites meet the cleanup standards specified in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units, U.S. Environmental Protection Agency, Region 10, Seattle, Washington.

The site remedial action began on August 7, 2001. Excavation of the site involved removing overburden materials, pipelines, french drain structures, and contaminated soil. Cleanup verification sampling began on September 7, 2001, and was finished on September 25, 2001. The results showed that the materials from the 100-F-19:3 subsite containing COCs at concentrations exceeding RAGs have been excavated and disposed of.

Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. All cleanup verification samples for the 100-F-19:3, 100-F-34 and 116-F-12 sites are listed under 100-F-19:1.

Code: 116-F-14	Classification: Accepted
Names: 116-F-14; 107-F; 107-F Retention Basin	Reclassification: Interim Closed Out (7/12/2002)
Type: Retention Basin	Start Date: 1/1/1945
Status: Inactive	End Date: 1/1/1965

Description: The site has been remediated and closed-out. The retention basin was a rectangular, concrete-lined, open-top reservoir designed to retain reactor cooling water prior to being discharged to the Columbia River. The basin had an estimated capacity of 5.67E+08 liters (1.5E+08 gallons). It was divided into two equal sections by weir walls running lengthwise from inlet to outlet end. Each section was subdivided by a series of wooden baffles. The site was surrounded by sprinklers (Hanford Drawing H-1-14321) installed on the top of the wall to keep the sludge from drying out during those times when effluent was not being discharged to the basin.

Location: The site was located approximately 530 meters (1488 feet) east-northeast of the 105-F Reactor Building.

Release Description: Numerous instances of retention basin and pipeline leakage occurred during the operation of the basin resulting in areas of soil contamination. The basin leaked at many locations along its walls and bottom. Hanford Drawing H-1-70247 (Retention Basin Leak Repair) shows some of the many types of repairs performed on the basin, including repairs of vertical cracks in the basin walls, removal of spilled concrete, rebuilding of expansion joint and repairs of cracks in the floor of the basin. The largest recorded leak extended roughly 7.6 meters (25 feet) from the foot of the unit wall. The leak, discovered in the summer of 1952, occurred in the effluent lines leading from the basin to the 148-F Pumphouse. Another release of contamination occurred at a large manhole located north of the 107-F basin (identified as P-22F on Hanford Drawing H-1-13850). Effluent overflowed intermittently for an extended period during the early 1950's before it was stopped. In 1955, water overflowed from the basin and contaminated the soils adjacent to the basin and a narrow path between the basin and the Columbia River. This release was identified as UPR-100-F-2. Contamination levels were 20,000 to 60,000 counts per minute with a maximum of 350 millirads/hour. HW-54636 contains information regarding the ground contamination size and shape. At least once during reactor operations, an unknown quantity of sludge was removed from the bottom of the basin and buried approximately 30.5 meters (100 feet) southeast of the southeastern corner of the basin. An estimated 1.8E+06 kilograms (2,000 tons) of sludge remained in the retention basin (Dorian and Richards 1978). In 1952, a hole was dug adjacent to the basin inlet pipe to drain the pipe. The hole and associated soil contamination were stabilized by covering it with clean soil, gravel, and cobbles. In 1964, high winds spread contamination when the basin was emptied and dry for maintenance. Known leakage from the 116-F-14 basin appears to have occurred primarily along the south and west sides. Estimates of leakage rates are not well documented, but the presence of a groundwater mound beneath the basin extended as high as 3 meters (10 feet) above the pre-existing water table elevation, suggests that significant leakage had occurred (Dorian and Richards 1978). The extent of these releases were contained within the AC-5-40 permanent Underground Radioactive Material posting.

Process Description: The site was used as a retention basin to hold the discharged reactor water for a brief period of time, allowing radioactive decay and thermal cooling to occur before the water was discharged to the Columbia River. Effluent was discharged to the basin by way of pipelines that were partially underground and partially above ground. The site received essentially all reactor cooling water passing from the reactor to the Columbia River. The total volume has not been estimated, but the flow rate ranged between 1.55E+05 and 2.95E+05 liters (41,000 and 78,000 gallons) per minute. Water flowed from the north end of the basin through a concrete pipeline to the 116-F-8 Outfall. The site is shown on Hanford drawings H-1-1522, M-1600-F, W-73199, W-69714 and Photo 9005316-1cn.

Related Sites/ Structures: The site was associated with the 105-F Reactor Building, the 100-F-19 pipeline and the 116-F-2 overflow trench.

Waste Type: Water

Waste Description: This site received cooling water effluent from the 105-F Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Seventy percent of the total radionuclide inventory was contained within the soil adjacent to the basin.

Waste Type: Demolition and Inert Waste

Waste Description: This site received cooling water effluent from the 105-F Reactor and held it to allow radioactive decay and thermal cooling prior to releasing the effluent to the Columbia River. Approximately 10 curies of radioactivity had leached into the concrete floor and walls.

Closure Info: Remedial action objectives and goals for the 116-F-14 site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE RL 2001b).

The selected remedial action at the 116-F-14 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and nonradionuclide contaminants of concern (COCs). Waste site COCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE RL 2001a). The COCs for this site consist of carbon-14, cesium-137, cobalt-60, europium-152, europium-154, europium-155, nickel-63, strontium-90, chromium (total), hexavalent chromium and cobalt.

Site excavation and waste disposal were completed on January 16, 2002, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 20,039 m² (215,698 ft²) in area with a depth greater than 4.6 m (15 ft). Approximately 212,015 metric tons (233,707 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility. Results of the sampling, laboratory analyses, and data evaluations for the 116-F-14 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Cleanup verification sampling began in the shallow zone on October 29, 2001, and deep zone sampling occurred on September 17, 2001. Initial results indicated areas of contamination, and additional remediation was performed. Following additional remedial excavation, resampling events occurred on December 17, 2001, and January 16, 2002, in the shallow zone. Verification sample results for some COCs were replaced with resampling data and used in calculations for this site.

The remedial action at the 116-F-14 site has achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1997) and RDR/RAWP (DOE-RL 2001b). The remaining soils at the 116-F-14 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-F-14 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations

throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 ft]) are required. The 116-F-14 site is verified to be remediated in accordance with the ROD (EPA 1997) and may be backfilled.

Code: 116-F-15	Classification: Accepted
Names: 116-F-15; 108-F Radiation Crib	Reclassification: Interim Closed Out (5/24/2007)
Type: Sump	Start Date:
Status: Inactive	End Date:

Description: The site has been remediated and interim closed. The site consisted of a floor drain that emptied into a 0.91 by 0.91 by 0.91-meter (3-by 3-by 3-foot) concrete sump that then emptied into a trench, near the center and under the 108-F Radiobiology Laboratory Building first floor.

Location: The site was located under the excavation of the 108-F Building (site 100-F-36).

Process Description: The trench drained from both ends into a sump located in approximately the center of the trench. Many laboratory floor and hood drains were connected to the trench and sump. The trench and sump were covered with plywood and posted as radioactive. A 15-centimeter (6-inch) earthenware (vitrified clay) pipeline exited the sump and the building to the south. A continuation drawing (W-2934, sheet 5) that would show the route and destination of the pipeline was no longer available. Hanford Drawing H-1-2037 showed a 20-centimeter (8-inch) vitrified clay tile pipe that ran south, then east, from the western side of 108-F to the ash pit. Although there was no clear connection between the sump and the pipelines known to run to the ash pit, there was a strong possibility they were interconnected. Several documents that would have likely discussed this site, if it was a crib, do not make such a reference. These documents included Herman, Stenner et al, (1988), Kiser (1988), and Clukey (1954, 1956). The noted omission from acknowledged texts casts doubt on the existence of this waste site as a crib.

Related Sites/Structures: The sump received effluent from the 100-F-36 site glove boxes and floor and hood drains. The sump then emptied into a trench that had the same WIDS site code.

Waste Type: Process Effluent

Waste Description: Prior to 1996, the unit had not been sampled for radiological or chemical contamination. It was known that alpha contamination experiments were conducted in the 108-F Building. The sump was reported to have received liquid wastes from the 108-F Building sinks, glovebox drains, and ventilation hoods. Alpha contamination experiments were conducted at the 108-F Building, therefore the potential for alpha contamination of this waste site exists.

Closure Info: 100-F-36 and 116-F-15 were addressed as a group. The information below documents information for the group of sites.

The Remaining Sites Verification Package for 100-F-36 and 116-F-15 (RSVP-2007-002) has documented the reclassification of the co-located sites. The 100-F-36, 108-F Biological Laboratory waste site has met the objectives for No Action and the 116-F-15, 108-F Radiation Crib waste site has met the objectives for Interim Closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site (Remaining Sites ROD).

Remediation of the 116-F-15 waste site was performed on September 26, 2005, and consisted

of the removal of approximately 86 metric tons (95 US tons) of material, including concrete debris, piping, and soil. The material was disposed at the Environmental Restoration Disposal Facility. The soil was excavated and field surveyed to a depth of approximately 2.6 meters (8.5 feet).

Following excavation, verification sampling was performed. Contaminants of potential concern (COPCs) were combined because the sites were co-located within the boundary of the 100-F-36 waste site. Each confirmatory and verification sample was analyzed for all constituents. The combined list of COPCs identified in the RDR/RAWP included the following: cobalt-60, cesium-137, europium- 152, europium- 154, europium- 155, plutonium-238, plutonium-239/240, strontium-90, uranium-238, inductively coupled plasma metals, mercury, hexavalent chromium, polychlorinated biphenyls, and asbestos.

After the remediation, verification sampling of the waste site was performed on December 12, 2006. All sample data results were stored in the Environmental Restoration (ENRE) project-specific database prior to being archived in the Hanford Environmental Information System (HEIS) and summarized in appendix B of the RSVP.

Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels has been made for contaminants of potential concern and other constituents. Screening levels were not exceeded for either site constituents, with the exception of boron, mercury, and vanadium.

Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. It is believed that the presence of these constituents does not pose a risk to ecological receptors because concentrations of vanadium and mercury are below site background levels and boron concentrations are consistent with those seen elsewhere at the Hanford Site (no established background value is available for boron). A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

The results of sampling indicated that residual contaminant concentrations did not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep).

The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. Remedial actions were not required for deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. The results indicated compliance with the remedial action objectives and goals for the site. The results of the sampling data were used to make reclassification decisions for the site in accordance with the TPA-MP-14 procedure.

The results indicated compliance with the remedial action objectives and goals for these sites. The results of the sampling are used to make reclassification decisions for the 100-F-36 and 116-F-15 sites in accordance with the TPA-MP-14 (DOE-RL 2007) procedure.

Code: 116-F-16	Classification: Accepted
Names: 116-F-16; PNL Outfall	Reclassification: Interim Closed Out (9/14/2006)
Type: Outfall	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed. This site consisted of an open-topped,	

	compartmentalized, reinforced concrete outfall structure.
Location:	The site was located approximately 670 meters (2200 feet) northeast of the 105-F Reactor Building and about 15 meters (50 feet) upstream of 116-F-8 outfall.
Process Description:	Animal Sewage and low-level contamination resulting from various Experimental Animal Farm projects, were pumped to the river via the 116-F-16 outfall structure and associated 100-F-43 spillway (flume). The site was a concrete outfall structure that received effluent from the experimental animal farm and aquatic biology laboratory. The Outfall emptied into the 100-F-43 Spillway via direct discharge then into the Columbia River. This unit was connected to the 116-F-8 Outfall Structure by a distribution box. A 183 centimeter (72 inch) diameter pipe extended from the north side of the 107-F Retention Basin, through a diversion box and connected to the south side of the outfall.
Related Sites/ Structures:	The site was associated with 100-F-29 (100-F Experimental Animal Farm Process Sewer Pipelines), 100-F-19, 100-F Reactor Cooling Water Effluent Underground Pipelines, Contaminated Underground Lines, Effluent Water System, 1904-F Process Sewer (See Subsites), the 116-F-8 Outfall Structure, 100-F-43 Flume and 100-F-39 River Lines.
Waste Type:	Construction Debris
Waste Description:	The unit received animal sewage from various Experimental Animal Farm projects, 107-F Retention Basin water from fish studies, and low-level contamination. The COPCs include Plutonium-239/240, Strontium-90, Cesium-137, Lead, and hexavalent chromium.
Closure Info:	116-F-16 and 100-F-43 were addressed as a group. The information below documents information for the group of sites. The 100-F-43 waste site was administratively separated from the 116-F-16 waste site for future inclusion within the Remaining Sites Record of Decision by agreement among the Tri-Parties. It was subsequently determined that sufficient evidence existed to warrant remedial action of both waste sites as a single unit. All samples collected during remediation are listed under 116-F-16 The Remaining Sites Verification Package (RSVP-2006-039) has documented that the 116-F-16 and 100-F-43 waste sites were remediated in accordance with the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD). Remedial action objectives (RAOs) and remedial action goals (RAGs) for this site were documented in the Remaining Sites ROD and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP). Remedial action activities at the sites were conducted from August 31, 2004, to September 8, 2005. Remediation involved excavation and staging of clean overburden material and removal of the outfall, the concrete spillway structure above the Columbia River ordinary high water mark, and contaminated soil to the extent required to satisfy the RAOs and corresponding RAGs. Final cleanup verification sampling was conducted on February 13 and 15, 2006. The Contaminants of Concern included: cesium-137, plutonium-239/240, strontium-90, hexavalent chromium, and lead. Approximately 384 meters squared (4,130 square feet) of plan area was excavated, with all remedial activities restricted to the shallow zone (less than 4.6 meters [15 feet] below ground surface). Approximately 2,090 metric tons (2,300 U.S. tons) of contaminated material was removed from the site and disposed at the ERDF. The cleanup verification sample data have

been summarized in Appendix A of the RSVP. The data were stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System.

No institutional controls are required for this site to prevent uncontrolled drilling or excavation into deep zone [i.e., below 4.6 m (15 ft)].

Code: 126-F-2	Classification: Accepted
Names: 126-F-2; 183-F Clearwells	Reclassification: Interim Closed Out (5/4/2006)
Type: Dumping Area	Start Date: 1/1/1945
Status: Inactive	End Date: 1/1/1965

Description: The unit consisted of covered, reinforced concrete basins (east and west), in the late 1970s, the eastern clearwell was used for the disposal of inert debris generated in the demolition of various 100-F Area buildings. The basins had a capacity of about 3.7E+07 liters (1E+07 gallons), they were separated in the center by a pump room. Part of the concrete cover on both clearwells has been demolished to permit dumping into the clearwell cavity. The pump room was reinforced concrete and largely below grade. The above-ground portion of the pump room has been demolished, and the below-ground portion has been filled with pump room rubble and backfilled. Approximately 25% of the eastern clearwell basin contained waste. The west clearwell remains intact.

Location: The site was located north of the 105-F Reactor Building, at the site of the 183-F Water Treatment Facility (demolished).

Process Description: Originally, the basins were used as part of the cooling water treatment train for the 105-F Reactor from 1944 to 1965. Chemical addition to this point in the treatment train was limited to coagulants (alum and hydrated calcium oxide), pH adjustment (sulfuric acid), and chlorination. Beginning in the 1970's, this site received demolition rubble and inert waste from building demolitions. It received rubble from the 183-F, 190-F, 189-F, 185-F and 171-F buildings.

Related Sites/ Structures: The clearwells were associated with the 183-F Water Treatment Facility.

Waste Type: Demolition and Inert Waste

Waste Description: The unit now contains demolition waste from demolished facilities. This waste includes rubble from the uncontaminated portion of 115-F as well as rubble from such noncontaminated facilities as 183-F, 190-F, 189-F, 185-F, 171-F. The rubble is believed to include asbestos siding tiles from several buildings.

The site has been included in the Remaining Sites Record of Decision, and is listed as having "possible low-level radioactive waste."

Closure Info: As documented in the Remaining Sites Verification Package 2006-017 evaluation, the verification sampling results, radiological surveys, and visual inspection support a reclassification of this site to interim closed out. The current site conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

Site remediation was performed from July to September 2005 and consisted of the removal of debris within the eastern clearwell structure down to the concrete floor. Radiological surveys

and visual inspection of the remediated clearwell structure revealed no residual contamination on the concrete floor or sidewalls and no indication of possible contaminant migration beyond the boundaries of the clearwells. No remediation or investigation was performed at the western clearwell, as no waste materials were disposed there, and the roof of the facility remains intact.

Verification sampling was performed at the remediation waste staging area on December 14, 2005, to confirm that no residual contamination associated with excavated materials existed in surficial soils. Evaluation of the results indicated that the waste removal action achieved compliance with the remedial action objectives for the site.

The results of verification sampling show that residual contaminant concentrations in soil do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. Approximately 28,986 metric tons (31,952 U.S. tons) of material was removed and staged at an area adjacent to the clearwells before disposal at the Environmental Restoration Disposal Facility.

The deep zone portion of the eastern clearwell structure has been shown to meet direct exposure criteria; therefore, no deep zone institutional controls are required.

Code:	128-F-2	Classification:	Accepted
Names:	128-F-2; 100-F Burning Pit	Reclassification:	Interim Closed Out (12/1/2008)
Type:	Burn Pit	Start Date:	1/1/1945
Status:	Inactive	End Date:	1/1/1965
Description:	Originally, the pit was an irregularly shaped depression that was used for burning wastes. The site has been covered and appears as a flat surface with no sign of the burn pit or its contents. The pit appears to have been filled and leveled in preparation for the installation of soil sampling test well 199-F5-42.		
Location:	The site is located approximately 30.5 meters (100 feet) east of the northeast corner of the 100F Area perimeter road which runs along the riverbank. The site is located directly east of the 107-F Retention Basin.		
Process Description:	The 128-F-2, 100-F Burning Pit waste site was an irregularly shaped depression that was used for incinerating nonradioactive, combustible materials (e.g., vegetation, office waste, paint waste, and chemical solvents) from 1945 to 1965. During Hanford Site cleanup operations in the late 1970s, unknown quantities of debris were removed from the burn pit and the site was backfilled. Historical documentation suggested that multiple burn pits were present at the site, with each pit having the dimensions of 31 by 31 by 3 m (100 by 100 by 10 ft) deep. According to documentation the waste site was 46 m (151 ft) by 18 m (60 ft) and was situated on a steep grade near the shoreline of the Columbia River. During remediation activities of the burn pit the waste site footprint was expanded because additional areas requiring remediation were discovered. Excavation of the soil containing debris and ash along the bank of the river eventually extended below the OHWM.		
Related Sites/ Structures:	An area of contamination from this site was designated as a new site, 100-F-59 Riparian Area Contamination, for later remediation.		
Waste Type:	Misc. Trash and Debris		
Waste Description:	The results of confirmatory sampling were used to determine the COCs and contaminants of potential concern (COPCs) for verification sampling. Metals (including hexavalent chromium and mercury), SVOCs (inclusive of the PAHs detected in confirmatory samples), chlorinated		

pesticides, TPH, PCBs, and asbestos were considered COCs/COPCs for verification sampling. Additionally, because radiological activity was detected above background levels during confirmatory sampling, laboratory radiological analysis was performed on verification samples to verify the absence of radiological contamination.

Closure Info: The Remaining Sites Verification Package (RSVP-2008-031) has documented remediation of the area within the final boundary of the 128-F-2 waste site, the 100-F Burning Pit, which does not include area C below the ordinary high water mark (OHWM). The site meets the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD).

Remediation of the site was initially performed August through October 2005, with 21,900 metric tons (24,100 US tons) of material excavated and disposed at the Environmental Restoration Disposal Facility (ERDF). Scrap metal, concrete debris, bottles, laboratory glassware, ash, potentially contaminated soil, asbestos debris, and other miscellaneous materials were removed from the waste site. Excavated materials were sorted and segregated based on visual inspection and location of origin and then staged onsite before disposal at ERDF. Samples of soil and debris were collected as needed to support waste characterization.

Soon after the onset of remediation, an area of cultural significance was discovered in the northwestern end of the riverside excavation. An investigation of the area revealed artifacts which resulted in the area being excluded from disturbance during remediation activities and was backfilled between February 20 and February 28, 2008.

During the initial 2005 remediation activities, it was observed that debris and ash material extended beyond the excavation design boundaries of the site toward the river shoreline and appeared to be present below the OHWM. Further excavation was delayed until October 2006 to take advantage of lower flows of the Columbia River and avoid impacts to endangered Upper Columbia River (UCR) spring Chinook salmon and steelhead. Remediation continued as Phase II with the excavation of the soil containing debris and ash within the slope extending to the OHWM in October 2006. The remediation proceeded to the shoreline, leaving a low berm to protect against site flooding in the event of higher river stages. Soil samples were collected from the berm to evaluate if it could be left in place or required removal. The data showed individual samples contained levels of hexavalent chromium and lead that exceeded direct exposure RAGs and levels of barium, cadmium, chromium, copper, manganese, mercury, nickel, silver, zinc, PAHs, and PCBs that exceeded the criteria for protection of groundwater and the Columbia River.

A comparison against ecological risk screening levels was made for the site contaminants of concern and other constituents. Using a conservative approach, the highest values were summed together. Using the combined values, screening levels were exceeded for antimony, arsenic, barium, boron, chromium, cobalt, copper, lead, manganese, mercury, nickel, selenium, vanadium, zinc, high molecular weight polycyclic aromatic hydrocarbons (HMW-PAHs), and DDT combined with its degradation products. Exceedance of screening values did not necessarily indicate the existence of risk to ecological receptors. It is believed that the presence of arsenic, antimony, manganese, mercury, and vanadium does not pose a risk to ecological receptors because their concentrations below site background levels. Boron concentrations were consistent with those seen elsewhere at the Hanford Site (no established background value is available for boron). If the highest value from each of the three areas was evaluated independently, then only lead, selenium, zinc, HMW PAHs, and DDT plus its degradation products would exceed the screening levels. These constituents will be evaluated in the context of additional lines of evidence for ecological effects as part of the final closeout decision for this site. For the purpose of verification sampling, the excavation boundary survey,

incorporating Phase I and Phase II excavation, was used to divide the site into five sampling areas: A. (Phase I excavated area between Columbia River and the upland excavation), B. (upland excavation), C. (phase II excavation), D. (waste staging area), and E. (asbestos-containing material [ACM] staging area).

The final verification sampling was performed in February 2007, March 2007, and March 2008 for area A; March and August 2007 for area B; and December 2007 for areas D and E to collect data to determine if the RAGs had been met. Verification data from the excavation areas A and B were evaluated independently by calculating the 95% UCL on the true population mean for residual concentrations of COPCs as specified by the RDR/RAWP. Excavation area C was combined with adjoining riparian areas to the east and southeast and assigned to a site code, 100-F-59. Evaluation of the verification data from area D was performed by direct comparison of the sample results against cleanup criteria. Evaluation of the sample results from area E was performed by direct evaluation of the amount of asbestos fibers present in the sample. Waste staged onsite during remedial activities consisted of soil and debris. The waste was completely removed and disposed at the ERDF, along with a layer of underlying soil. There was very little potential for contaminant migration into soils underlying the waste staging piles; therefore, statistical sampling designs were not warranted for the staging pile footprints and professional judgment was used to develop the sampling design.

Statistical sampling to verify the completeness of remediation was performed and analytical results for the decision units (areas A, B, D, and E) were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. Accordingly, an interim closure reclassification is supported for the site. These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 132-F-1	Classification: Accepted
Names: 132-F-1; 132-F-1 Chronic Feeding Barn; 141-F; 141-F 100-F Experimental Animal Farm Sheep Barn	Reclassification: Interim Closed Out (8/23/2006)
Type: Laboratory	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed. The barn has been demolished. When in use, it was an L-shaped concrete block building with a concrete floor and concrete animal pens located both inside and outside of the building.	
Location: The 141-F (132-F-1) barn site was located in the northeast corner of the 100-F Experimental Animal Farm area. The building site was northwest of the 107-F Retention Basin (116-F-14) and south of the 1904-F Outfall Structure (116-F-8) and the Pacific Northwest Laboratory (PNL) Outfall Structure (116-F-16).	
Process Description: Studies involving sheep began in the late 1940's. Up to 1,000 head of sheep were kept in 132-F-1 Barn (141-F) for use in dose studies using iodine-131, strontium-90, plutonium-239, and cesium-137. Most of the work performed involved 20-year lifetime exposure studies. The 141-F Building was one of the main facilities used to house the animals. Animal pens in the building had concrete floors and were connected to the special sewer (100-F-29) for contaminated animal wastes. Contaminated manure and sawdust that could not be shoveled out of the animal pens were washed into the sewer which went to the 141-N Sump. When the sump became full, the wastewater was pumped through a screen to the Columbia River via the PNL	

Outfall (116-F-16). The solids trapped by the screen were dried and sent to the 118-F-5 Sawdust Pit. The Remedial Investigation/Feasibility Study Work Plan for the 100-FR-1 Operable Unit, Hanford Site, Richland, Washington states that wash water from this facility went to the 1607-F6 septic system. A review of Hanford Site historical drawings H-1-13850 (sheets 2 and 3) and M-1904-F (sheet 5) and conditions encountered during remediation of the 132-F-1 site do not indicate piping between the 132-F-1 site and the 1607-F6 septic system. The drawings show that the only outgoing line [a 15 centimeter (6 inch) vitrified clay pipe] from the building discharged into the process sewer system (100-F-29) until 1963, when wastewater was diverted to the 116-F-9 Animal Leach Trench.

Related Sites/ Structures: Drawings indicate that the effluent discharged into the process sewer system (100-F-29) until 1963 then wastewater was diverted to the 116-F-9 Animal Leach Trench.

Waste Type: Demolition and Inert Waste

Waste Description: Residual strontium-90, cesium-137, and plutonium-239 contamination may remain in any buried debris.

Closure Info: In accordance with the REMAINING SITES VERIFICATION PACKAGE FOR THE 132-F-1, 141-F CHRONIC FEEDING SHEEP BARN (Attachment to Waste Site Reclassification Form 2006-029) (RSVP) evaluation, the current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999).

The contaminants of potential concern (COPCs) for the 132-F-1 site were cobalt-60, cesium-137, europium 152, europium-154, europium-155, plutonium-238, plutonium-239/240, uranium-234, uranium-235, strontium 90, lead, mercury, polycyclic aromatic hydrocarbons (PAHs), and hexavalent chromium. Based on further site specific evaluation, gamma-chlordane (found during test pitting during the remedial investigation/feasibility study phase), arsenic, barium, cadmium, total chromium, selenium, silver, and polychlorinated biphenyls were included as COPCs.

Remedial excavation and confirmatory sampling was performed in accordance with the 100 Area Remedial Action Sampling and Analysis Plan (SAP) and with WCH EE-01, Environmental Investigations Procedures, from September 27 through 30, 2004, per the approved work instruction. Excavation southeast of the former building footprint was extended up to 2.4 meters (8 feet) below ground surface (bgs) before native material was encountered, and no debris.

Strontium-90, the only constituent detected above remedial action goals (RAGs) by confirmatory sampling, was the only contaminant of concern (COC) identified for verification sampling. Because pesticide analysis was excluded for confirmatory sampling and gamma-chlordane was previously detected at a concentration above RAGs for the protection of groundwater and the Columbia River, pesticides were also considered contaminants of potential concern (COPCs) for verification sampling. Polycyclic aromatic hydrocarbons were detected at low levels in samples collected from native soil along the length of the test trench used for confirmatory sampling. Therefore, semivolatile organic compounds were also considered COPCs for verification sampling.

Confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The results were stored in the Environmental Restoration project-specific database prior to archiving in the Hanford Environmental Information System. A summary of the samples collected and laboratory analyses performed is provided in Table 1

of the RSVP.

No COPCs were detected above RAGs in the soil samples collected at the site. However, strontium-90 activity in the pipe scale sample was quantified at 1,030 pCi/g, exceeding the direct exposure lookup value correlating to a 15 mrem/yr dose rate. Cesium-137 was also detected in the scale sample (2.66 pCi/g), but at an activity below dose-equivalence lookup values. The maximum results for other COPCs were below applicable RAGs, but pesticide analysis was inadvertently excluded for the soil samples collected.

Final excavation began August 9, 2005 and extended through August 12, 2005. A total of approximately 3,400 bank cubic meters (4,400 bank cubic yards) of soil and debris was excavated and staged onsite before disposal at the Environmental Restoration Disposal Facility. After remediation, the site exists as a shallow (approximately 1 meter [3 feet] deep) excavation.

The RSVP has demonstrated that the site meets the objectives for interim closure as established in the RDR/RAWP and the Remaining Sites ROD, (EPA 1999). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 132-F-3	Classification: Accepted
Names: 132-F-3; 115-F Gas Recirculating Facility	Reclassification: No Action (12/9/2003)
Type: Burial Ground	Start Date: 1/1/1943
Status: Inactive	End Date: 1/1/1965
Description:	The site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification. This site was the below grade remaining material from the decommissioning of the 115-F Gas Recirculation Facility. The building was demolished in-situ using Allowable Residual Contamination Level (ARCL) methodology. At present, the site looks like a gravel parking lot that is free of any debris.
Location:	The site was located approximately 61 meters (200 feet) due west of 105-F Building.
Process Description:	The gas recirculation facility was a single-story concrete building that housed the reactor inert gas processing and recirculation system. The gas system continuously recirculated a large volume of gas at very low pressure. The recirculation cycle included cooling, drying, and filtering of the gas prior to reentry into the reactor. The purpose of the reactor inert gas system was to provide a closed-loop nonreactive gas environment in the graphite core that would remove moisture and gases from the core and serve as a heat transfer medium between the graphite core and the process tubes. The system also served to detect water leaks within the reactor core. When a leak was detected, the gas was routed to the ventilation exhaust system. Filters, gas coolers, blowers, condensers, and silica gel drying towers were located within the 115-F Building. The system was designed to maintain gas pressure in the reactor at a slightly positive value with respect to the ventilation air so that the air could not make contact with the graphite core. Contamination of the 115-F Building occurred on the inside surfaces of ducts, concrete surfaces, machinery, and filters, as indicated by analysis of smear samples taken from these surfaces. The tunnels that connected the 115-F Building to the 105-F Reactor Building were also radioactively contaminated. When in operation, the site was a single-story, reinforced concrete structure, 6.1 meters (20 feet) high. The unit's dimensions were 51.2 meters (168 feet) long, 29.9 meters (98 feet) wide, with 4.0 meters (13 feet) below grade. An operating gallery extended down the center and was flanked on either side by cells that contained the gas processing equipment. The equipment cell walls and floors were 0.9 meters (3 feet) thick. At

right angles to the operating gallery and extending across the full width of the west end was the service section, which contained the ventilation fan, air compressor, office, locker room, etc. A pipe tunnel 11.0 meters (36 feet) wide by 2.4 meters (8 feet) high ran beneath the full length of the building. The main gas lines to and from the 105-F Building entered through this tunnel.

Waste Type: Demolition and Inert Waste

Waste Description: The resident radionuclides are tritium, carbon-14, cobalt-60, strontium-90, cesium-137. Surface smears taken in the facility over a 100-square centimeter (15.5-square inch) area revealed alpha contamination of less than 200 disintegrations per minute (dpm) on all surfaces tested. The maximum direct reading of 15,000 counts per minute (cpm) was recorded in the east end of the piping tunnel that connected the gas recirculation facility to the reactor (Chattin and Powers 1985).

Closure Info: The 115-F Gas Recirculation Facility decommissioning activities began in July 1984 and were completed in October 1984. The decommissioning included radiological characterization, removal of tunnel piping, equipment/waste disposal, and demolition/site grading. The below-grade perimeter walls were demolished to at least 1 meter (3 feet) below grade. Remaining walls were left intact to provide containment for the rubble. The entire area was covered with clean backfill at least 1.2 meter (4 feet) deep. Final grading to approximate the surrounding terrain added another 1 meter (3 feet) of clean backfill material over the demolition site.

In 2003 the waste site evaluation 0100F-CA-V0182, Rev 2, demonstrated that reviews of information which included modeling results, facility information and historical data, supported reclassification to "no action" for the site. The site had achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 2002) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (EPA 1999).

Residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River based on RESRAD modeling.

Code:	132-F-4	Classification:	Accepted
Names:	132-F-4; 132-F-4 Reactor Stack Demolition Site; 116-F Reactor Exhaust Stack; 116-F Reactor Stack	Reclassification:	No Action (11/14/2005)
Type:	Burial Ground	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1965
Description:	The site consists of two subsites: one is the 116-F Reactor Stack and Subsite 2 is the stack's octagon-shaped base. The site is a cobble covered field next to the 105-F Reactor Building.		
Location:	The site was located just west of the 105-F Reactor Building. The stack was demolished into a trench extending west from the stack's original location.		
Process Description:	The stack was used to dispose of confinement air that originated from the work areas in the 105-F Reactor Building. The clean air entered the noncontaminated portions of the reactor building, then through zones with increasing levels of contamination, and finally entered the filter building where air passed through "absolute" (particulate) and "halogen" (activated charcoal) filters. The filtered air then vented through the 61-meter (200-foot) stack and discharged into the atmosphere.		

Related Sites/ Structures: Following completion of the confinement project in 1960, the air was diverted via underground, reinforced concrete ducts to the 117-F Filter Building. After flowing through the filters, the air went through below-grade and above-grade concrete ducts and into the exhaust stack.

Waste Type: Demolition and Inert Waste

Waste Description: The estimated radionuclide inventory for the 116-F Stack prior to demolition was 5.0 picocuries/gram. This amount was calculated from the concentration of nuclides over the interior of the stack to a depth of 1 centimeter (0.39 inches). The radionuclides found were tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and plutonium-239.

Testing performed on several of the reactor stacks in the 100 Area prior to decommissioning showed that the stacks contained residual quantities of radionuclide materials on their interior surfaces. Standard smear testing performed over a 100-square centimeter (15.5-square inch) area on these surfaces showed the presence of tritium at concentrations of 400 to 13,000 picocuries per square centimeter and carbon-14 at concentrations of 200 to 2.1E+07 picocuries per square centimeter (Dorian and Richards 1978). Beta-gamma activity from other radionuclides was also identified.

This Site has the Following SubSites:

Code: 132-F-4:1

Names: 132-F-4:1; 116-F Reactor Stack Demolition Site

Code: 132-F-4:2

Names: 132-F-4:2; 116-F Reactor Stack Base Burial

Code: 132-F-4:1

Classification: Accepted

Names: 132-F-4:1; 116-F Reactor Stack Demolition Site

Reclassification: No Action (12/8/2003)

Type: Burial Ground

Start Date:

Status: Inactive

End Date:

Description: The 116-F Stack was a reinforced concrete structure 61 meters (200 feet) high with a base diameter of 5.05 meters (16.58 feet) and a maximum thickness of 0.46 meters (18 inches) at the base. The stack rested on a double octagon-shaped base which extended 5.3 meters (17.5 feet) below grade. The interior of the unit contained 4.2 microcuries of radioactive materials. The stack was demolished by explosive demolition into a trench and then was broken into pieces smaller than 1 meter (3 feet) in diameter. Afterwards, all of the loose rubble was pushed into the trench and backfilled. The site was then graded to match the surrounding terrain.

Closure Info: RESRAD modeling was performed in 2003 to provide another data point. The RESRAD modeling accounted for radioactive decay from 1980 (the year of sample collection) to 2003, and predicted that none of the contaminants detected in the concrete from the interior of the stack would reach groundwater within 1,000 years.

This unit was demolished in September 1983 and buried in a trench between the 117-F Building Site and the 115-F Building Site. The trench was backfilled and covered with a 1-meter (3-foot) layer of soil. The site has been documented as achieving the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the 100 Area RDR/RAWP (DOE-RL 2002) and the Remaining Sites ROD (EPA 1999). Any residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that based on RESRAD modeling, pose no threat to groundwater or the Columbia River. The basis for reclassification is described in detail in the Waste Site Evaluation for 132-F-4, 116-F Reactor Exhaust Stack (0100F-CA-V0183), Bechtel Hanford Company, Richland, Washington.

The SubSite is Part Of:

Code: 132-F-4
Names: 132-F-4; 132-F-4 Reactor Stack Demolition Site; 116-F Reactor Exhaust Stack; 116-F Reactor Stack

Code: 132-F-4:2
Classification: Accepted
Names: 132-F-4:2; 116-F Reactor Stack Base Burial
Reclassification: No Action (11/14/2005)
Type: Burial Ground
Start Date:
Status: Inactive
End Date:

Description: Subsite 2 consists of the (116-F) Reactor Stack Base. The monolithic concrete stack base and foundation included an imbedded stack condensate drain line. The 116-F stack base burial site has a separate waste site boundary about 0.5 meters (1.5 feet) east of 116-F stack burial site.

Closure Info: The 5.6 meters (18.5 feet) diameter octagonal stack base was removed to about 1 meter (3 feet) below grade and extended to 7.2 meters (23.5 feet) below grade. The vertical 15-centimeters (6-inches) cast iron condensate drain pipe in the center of the stack base exited the side of the concrete monolith about 1.6 meters (5.2 feet) below grade. The condensate drain line from the stack base to the 105-F Building process sewer was removed during the demolition activities for the 105-F Reactor below-grade structures.

The stack base included a 15 centimeter (6 inch) diameter cast iron drain pipe in the center of the base that exited the east side of the base at a depth of 1.5 meters (5 feet) below grade. The 15 centimeter (6 inch) cast iron drain pipe ran east from the stack base to the 105-F Building wall a distance of 1.9 meters (6.2 feet) and entered the 105-F Building at a depth of 1.9 meters (6.2 feet) below grade. The external piping and the upper 1 meter (3 feet) of internal piping was removed during the demolition of the 116-F stack and the adjacent 105-F Building walls. About 3.4 meters (11 feet) of cast iron drain pipe remains imbedded in the stack base.

The potential contamination within the imbedded pipeline is deemed negligible since the pipe was a free draining condensate line to the process sewer. The 116-F stack, which was closed with a no action reclassification, represents the worst-case contamination potential for the drain line. The corresponding 105-D concrete base and foundation, including the imbedded cast iron drain line, was closed with no further action.

The SubSite is Part Of:

Code: 132-F-4
Names: 132-F-4; 132-F-4 Reactor Stack Demolition Site; 116-F Reactor Exhaust Stack; 116-F Reactor Stack

Code: 132-F-5
Classification: Accepted
Names: 132-F-5; 117-F Filter Building
Reclassification: No Action (12/8/2003)
Type: Burial Ground
Start Date: 1/1/1960
Status: Inactive
End Date: 1/1/1965

Description: The site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification.

Location: The site was located west of 105-F.

Related Sites/ Structures: The building received exhaust fan discharge through an inlet duct from the 105-F Reactor and discharged the filtered air through a discharge duct and out the 116-F Stack.

Waste Type: Process Effluent

Waste Description: The radionuclides found in the 117-F Building are tritium, carbon-14, cobalt-60, cesium-137, strontium-90, europium-154, and europium-152. During the decommissioning of the facility,

surface smears over 100-square centimeter (15.5-square inch) areas in the building revealed beta-gamma contamination of less than 200 counts/minute and alpha contamination less than 500 counts/minute.

Closure Info: The 117-F Filter Building was released for unrestricted use based on the post-decontamination characterization results cited in a letter from J. J. Dorian with the subject Radiological Criteria for Decontamination and Decommissioning of the Retired 100 Area 117-F Filter Buildings dated May 18, 1983. Consequently, demolition and site grading were performed in November 1983 using conventional heavy equipment. The rubble was buried under at least 1 meter (3 feet) of clean fill and the site was graded to blend with the natural terrain.

RESRAD modeling was performed in 2003 to provide another data point. The RESRAD modeling accounts for radioactive decay from 1983 (the year of building demolition) to 2003, and predicts that none of the contaminants detected in the paint will reach groundwater within 1,000 years.

Reclassification to "No Action" is supported by the 2003 waste site evaluation, 0100F-CA-10184, Rev 1, RESRAD modeling and historical data. The site has achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-96-17) and the Interim Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (EPA 1999).

Residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River based on RESRAD modeling.

Code:	132-F-6	Classification:	Accepted
Names:	132-F-6; 132-F-6 Lift Station; 1608-F Effluent Pumping Station; 1608-F Waste Water Pumping Station	Reclassification:	No Action (12/8/2003)
Type:	Pump Station	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification. The area where the demolished facility once stood is currently a cobble covered field.		
Location:	The site was located near the southeast corner of the 105-F Reactor Building.		
Related Sites/Structures:	This site was associated with 116-F-6 (1608-F Liquid Waste Disposal Trench) and the 105-F Reactor Building.		
Waste Type:	Demolition and Inert Waste		
Waste Description:	Before demolition, this site received water from reactor building drains containing trace amounts of low-level radionuclides and decontamination chemicals (primarily Turco). Radionuclides were primarily miscellaneous activation products, including tritium, carbon-14, cobalt-60, strontium-90, cesium-137, europium-152, and europium-154. The decontamination chemicals consisted of sodium fluoride, oxalic acid, and citric acid. Water was pumped from the reactor collection pits into the reactor effluent lines near the 105-F Reactor Building and became part of the 107-F effluent that was discharged to the Columbia River. During decommissioning of the facility in 1987, a survey of the walls, ceilings, and floor areas of the main floor, pump room, switch gear room, and valve room revealed direct beta-gamma contamination to less than 200 counts/minute (cpm). The maximum contamination levels		

recorded were for the floor areas of the sumps at 5,000 to 25,000 counts/minute (cpm) direct beta-gamma.

During the Dorian and Richards (1978) study in 1975-1976, samples were collected from a soil boring identified as location 132-F-6. Analytical results of material collected in this boring at depths of 7.6 meters (25 feet) and 9 meters (30 feet) revealed elevated concentrations, with a maximum of 92 picocuries/gram for europium-152.

Closure Info: The site was decommissioned and demolished in 1987. Prior to being demolished, the walls, ceiling and floors of the facility were radiologically surveyed. A total of sixty six concrete core samples and seven rust samples were collected and analyzed.

The facility demolition included removal, characterization and disposal of equipment and sump water. A total of 1.6 cubic meters (56 cubic feet) of asbestos material was removed and taken to the Hanford Central Landfill. Low level radiologically contaminated equipment was taken to the 200 Area burial grounds. Approximately 104,166 liters (27,000 gallons) of residual sump water was transported to the 1325-N Liquid Waste Disposal Facility. Sump sediments were placed into 55 gallon drums and disposed of at the 200 Area burial grounds.

Reclassification to "No Action" is supported by the 2003 waste site evaluation, 0100F-CA-V0191, Ref. 1, RESRAD modeling and historical data. The site has achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE RL-96-17, Rev. 4) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (EPA 1999). Residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and pose no threat to groundwater or the Columbia River based on RESRAD modeling.

Code: 182-F	Classification: Accepted
Names: 182-F; 182-F Reservoir	Reclassification: Interim Closed Out (9/12/2005)
Type: Dumping Area	Start Date:
Status: Inactive	End Date: 1/1/1977
Description:	The site has been remediated and interim closed out.
Location:	Reservoir was located approximately 400 meters (1,312 feet) due north of the 105-F Reactor Building.
Process Description:	The 182-F Reservoir received raw water from the Columbia River for reactor cooling water and raw water for the 100 Area supply system. The reservoir had a storage capacity of 94.6 million liters (25 million gallons). The reservoir was later used as a landfill for disposal of decontaminated rubble from buildings that were decommissioned in the 100 F Area. In 1997, the site was covered with clean fill.
Related Sites/ Structures:	The site was related to the 183-F Water Treatment Plant, the 126-F-2 (183-F) Clearwells and the 105-F Reactor Building.
Waste Type:	Demolition and Inert Waste
Waste Description:	This unit received demolition rubble from the 182-F Pumping Station and the 183-F Water Treatment Building and Sedimentation Basins, and debris from other building demolitions. Some of the debris was from 144-F, 144-R, 141-N, 141-P, 141-F, 141-H and 141-L. The unit was covered with fill from adjacent land.
Closure Info:	Based on a review of the site historical process information and the results of the geophysical

survey, the site appeared to be a disposal area for material that contained hazardous constituents at levels in exceedance of remedial action goals. Based on these determinations, and the implications of sampling a site of this magnitude, remedial action was recommended in accordance with the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (EPA, 1999)

The Remaining Sites Verification Package for the 182-F Reservoir (RSVP) demonstrated that the waste site met the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (EPA 1999)(ROD).

Excavation of the Reservoir began on March 29, 2005, with removal and stockpiling of debris and soil. Visual observations of soil and debris removed from the southern and eastern portions of the reservoir indicated the presence of inert demolition debris (e.g., concrete, wood, rebar) with a limited amount of lead, asbestos, and some batteries. Excavation of the western portion of the reservoir revealed essentially soil with no debris. Based on the results of the excavation and discussion with the U.S. Department of Energy and U.S. Environmental Protection Agency, it was decided that excavation would stop and sampling would be performed to support a decision if additional excavation was necessary.

Samples of stockpiled material removed from the reservoir and residual soil remaining in the reservoir were collected on April 29, 2005, and analyzed for asbestos, radionuclides, metals, and polychlorinated biphenyls. Additional sampling of soil within the reservoir for polychlorinated biphenyl analysis was performed on May 26, 2005. The cleanup verification sample numbers cited in the RSVP include: J030N6 and J030N7, J03342 through J03344 and J03702 through J03704. The sampling results indicated that the remedial action objectives have been met, however they do not appear in HEIS.

The results of the sampling indicated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: 1607-F2	Classification: Accepted
Names: 1607-F2; 1607-F2 Sanitary Sewer System; 1607-F2 Septic Tank; 124-F-2	Reclassification: Interim Closed Out (3/11/2003)
Type: Septic Tank	Start Date: 1/1/1944
Status: Inactive	End Date: 1/1/1988
Description: The site has been remediated and closed out. The unit included a septic tank, tile field and associated pipeline. The unit was 4.6 meters (14.9 feet) deep, constructed of reinforced concrete, and had a 522-person capacity (130 liters [35 gallons] per capita) with an average detention period of 24 hours. The walls and floor were 25 centimeters (10 inches) thick. The tile field was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a minimum of 2.4 meters (8 linear feet) per capita. The laterals were open jointed, spaced 2.4 meters (8 feet) apart. The tile field was irregularly shaped, measuring approximately 90.3 meters (296 feet) by 54.0 meters (177 feet).	
Location: The septic tank was located approximately 67 meters (220 feet) west and 15 meters (50 feet) south of the 116-F-14 (107-F Retention Basin). The tile field was located approximately 61	

meters (200 feet) south of the septic tank, within the 126-F-1 Ash Pit.

**Related Sites/
Structures:** This site received effluent from 184-F, 185-F, 190-F, 105-F, 108-F, and the 1700 Administration and Service Buildings.

Waste Type: Sanitary Sewage

**Waste
Description:** This unit received unknown amounts of sanitary sewage from the 184-F Powerhouse, the 185-F Chemical Treatment Building, the 190-F Pumphouse, the 105-F Reactor Building, the 108-F Building, and the 1700 Administration and Service Buildings. The unit now services the 105-F and 108-F Buildings only. The other buildings have been demolished. Since the site serviced both the 105-F and 108-F Buildings, there is the potential to have received hazardous contaminants. The sludge in the septic tank was measured and sampled as part of the Group 4 Remedial Design Field Investigations. The sludge volume was estimated to be 49,970 liters (13,200 gallons). Sample numbers B0LC76, B0LC77, B0LC78 and B0LC82 were analyzed for metals, volatile organics and semi-volatile organics. Radionuclides were determined by Gamma Spectroscopy. Polyaromatic hydrocarbons were identified as well as elevated levels (above background) of cobalt-60, cesium-137, strontium-90, europium-154/155, radium-226, plutonium-238,239/240 and uranium-234, 235/238. The estimated dose rate from the tank sludge is 157.2 millirem per year.

Closure Info: Remedial action objectives and goals for the 1607-F2 site were established by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Energy, Richland Operations Office (DOE-RL), in concurrence with the Washington State Department of Ecology. These goals and objectives were documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE RL 2002).

The selected remedial action for the 1607-F2 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to the average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify contaminants of potential concern (COPCs). Waste site COPCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE RL 2001). Process knowledge only identified COPCs and did not identify the final contaminants of concern (COCs) for the 1607-F2 site. The COPCs for this site listed in the SAP (DOE-RL 2001) consist of the following: cobalt-60, cesium 137, europium-154, europium-155, strontium-90, uranium-234, uranium-235, uranium 238, and arsenic. Based on characterization sample results for the 1607-F2 Septic Tank sludge, mercury was added to the list of COPCs for the 1607-F2 Septic System for evaluation during remediation (BHI 1997).

During remediation of the 1607-F2 site, in-process sampling and analysis of the sludge in the septic tank, septic system, and tile field (sampling conducted to guide remediation and for waste characterization) indicated that strontium 90, the uranium isotopes, mercury, and arsenic were not COCs for the 1607-F2 site. Therefore, these contaminants are not addressed further in this CVP. In process sampling indicated that strontium-90, the uranium isotopes, and mercury were at levels less than the Hanford Site background (DOE-RL 1996) of 0.18 pCi/g for strontium-90, 1.1 pCi/g for uranium 234, 0.11 pCi/g for uranium-235, 1.1 pCi/g for uranium-238, and 0.33 mg/kg for mercury.

Because a large portion of the 1607-F2 drain field is within the footprint of the 126-F-1 Ash Pit and based on agreement between the Tri-Parties, europium-152 was included in the final list

CVP COC list for the 1607-F2 site. The COC list for the 126-F-1 Ash Pit is included in the Sampling and Analysis Instruction for Confirmatory Sampling of the Southern Portion of the 126-F-1 Ash Pit (BHI 2001).

Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 6,679 m² (7,988 ft²) in area with a depth of 4.6 m (15 ft). Waste site cleanup was conservatively evaluated to meet shallow zone criteria. Approximately 35,099 metric tons (38,690 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

Results of the sampling, laboratory analyses, and data evaluations for the 1607-F2 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Ten cleanup verification samples including two QA/QC samples were collected from the shallow zone on August 13, 2002.

The CVP demonstrates that remedial action at the 1607-F2 site has achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1999) and RDR/RAWP (DOE-RL 2002). The remaining soils at the 1607-F2 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 1607-F2 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 ft]) are required. The 1607-F2 site is verified to be remediated in accordance with the ROD (EPA 1999) and may be backfilled.

Code:	1607-F3	Classification:	Accepted
Names:	1607-F3; 1607-F3 Sanitary Sewer System; 1607-F3 Septic Tank; 124-F-3	Reclassification:	Interim Closed Out (4/26/2007)
Type:	Septic Tank	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been remediated and interim closed. The site consisted of a septic tank, drainfield and associated pipeline. It was constructed of reinforced concrete; the walls and floor were 25 centimeters (10 inches) thick.		
Location:	The septic tank was located approximately 183 meters (600 feet) west of the 183-F Water Treatment Plant. The drainfield was approximately 23 meters (75 feet) west of the septic tank.		
Process Description:	The septic tank had a capacity of 5432.07 liters (1435 gallons). The system could support 41 persons assuming input of 132.49 liters (35 gallons) per capita per day and a one day retention period. The drainfield was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a total of 100 linear meters (328 linear feet) of piping (2.4 linear meters [8 linear feet] per capita). The 20 centimeter (8 inch) laterals were open jointed and spaced 2.4 meters (8 feet) apart.		
Related Sites/Structures:	The site was related to the 182-F Pump Station, the 183-F Water Treatment Plant, and the 151-F Substation.		

Waste Type: Sanitary Sewage

Waste Description: This unit received an unknown amount of sanitary sewage from the 182-F Pump Station, the 183-F Water Treatment Plant, and the 151-F Substation.

Closure Info: The Remaining Sites Verification Package (RSVP) 2006-047 has documented the evaluation and remediation of the site. The site evaluation and supporting documentation has demonstrated that the site has met the remedial action objectives and goals specified in the Remaining Sites Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, (Remaining Sites ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and has met the objectives for interim closure .

Remediation of the waste site began in September 2005 and consisted of the removal of the septic system, drain field, associated piping, and overburden material. During remediation approximately 2,798 metric tons (US 3,085 tons) of material was excavated, staged onsite, and subsequently disposed of at the Environmental Restoration Disposal Facility, (ERDF). Verification sampling of the excavation and staging area footprint was conducted in March 2006 to verify the completeness of remediation.

Contaminants of potential concern (COPCs) were identified based on existing analytical data and historical process information associated with the site. The COPCs were pesticides, polychlorinated biphenyls (PCBs), arsenic, barium, cadmium, total chromium, lead, selenium, silver, mercury, and semivolatle organic compounds (SVOCs). Additionally, 100-F Reactor Area Underground Pipeline Historical Information Summary stated that undetermined radionuclides could be present at this site. Therefore, gamma energy analysis and gross alpha and gross beta analyses were added to verify the presence or absence of radionuclides.

The analytical results indicated that the excavation contained residual arsenic and lead concentrations exceeding cleanup criteria. Additional remediation of the excavation was performed in December 2006 and consisted of removing an additional 3,791 metric tons (4,179 US tons) of material. A second set of verification samples was collected from the excavation and analyzed for arsenic and lead.

The results of both sampling events were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. The results were stored in the Environmental Restoration (ENRE) project-specific database prior to being provided to the Hanford Environmental Information System (HEIS) and were included in Appendix A of RSVP-2006-047.

In accordance with this evaluation, the verification sampling results support a reclassification of this site to Interim Closed Out. The current site conditions achieve the remedial action objectives and the corresponding remedial action goals established in the RDR, and the Remaining Sites ROD. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required

Code: 1607-F4	Classification: Accepted
Names: 1607-F4; 1607-F4 Sanitary Sewer System; 1607-F4 Septic Tank; 124-F-4	Reclassification: Interim Closed Out (12/3/2007)
Type: Septic Tank	Start Date: 1/1/1944

Status:	Inactive	End Date:	1/1/1965
Description:	The site consisted of a septic tank, drainfield, and associated pipeline. The tank was constructed of reinforced concrete.		
Location:	The site was located 61 meters (200 feet) west of the 115-F Gas Recirculation Building.		
Process Description:	The walls of the reinforced concrete septic tank were 20 centimeters (8 inches) thick, and the floor was 15 centimeters (6 inches) thick. It had a capacity of 794.94 liters (210 gallons). The system could support 6 persons assuming input of 132.49 liters (35 gallons) per capita per day and a one day retention period. The drainfield was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a total of 14.6 linear meters (48 linear feet) of piping (2.4 linear meters [8 linear feet] per capita). The laterals were open jointed and spaced 2.4 meters (8 feet) apart. The system supported the 115-F building.		
Related Sites/ Structures:	This unit received effluent from the 115-F Gas Recirculation Building.		
Waste Type:	Sanitary Sewage		
Waste Description:	This unit received an unknown amount of sanitary sewage from the 115-F Gas Recirculation Building. There is the potential for the site to have received hazardous contaminants from the 115-F Building.		
Closure Info:	The REMAINING SITES VERIFICATION PACKAGE FOR THE 1607-F4 SANITARY SEWER SYSTEM (RSVP 2004-131) has documented that the site meets the objectives for Interim Closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD).		

Remediation of the waste site was performed from April 3 through 5, 2007, and included removal of the septic tank, the drain field, and the associated piping. Overburden material and other soils presumed to contain no residual contamination above cleanup levels were stockpiled south of the excavation for post remediation verification sampling. Approximately 707 cubic meters (925 yards) of piping, concrete material, and suspect contaminated adjacent soils were removed and disposed at the Environmental Restoration Disposal Facility.

Excavation and confirmatory sampling was conducted on October 6, 2004. During excavation in sample area 1, the septic tank was discovered but was found to have been previously decommissioned and backfilled. The backhoe bucket used in the excavation was too large to enter the opening in the top of the tank. In addition, the septic tank was constructed of reinforced concrete and could not be penetrated with the excavation equipment. As a result, confirmatory samples of material inside the tank were not collected. Instead, a soil sample was collected underneath the septic tank at 2.9 meters (9.5 feet) below ground surface.

The verification sampling data to determine if the RAGs had been met, was collected in April and August 2007. The constituents that contributed to the exceedances of the cumulative hazard quotient were carried forward as contaminants of concern (COCs) for verification sampling. These included inductively coupled plasma (ICP) metals, hexavalent chromium, mercury, semivolatle organic compounds, polychlorinated biphenyls, and pesticides. Radionuclides were either not detected in any of the confirmatory samples, or were detected below RAGs and were, therefore, eliminated as COCs for verification sampling in the excavated area and below cleanup level (BCL) stockpile. At the road crossing portion of the waste site had not been previously characterized, gamma energy analysis, gross alpha, and gross beta analyses, in addition to the site COCs, were requested for samples collected in this area of the waste site. The results are stored in the Environmental Restoration (ENRE) project-specific database prior

to archival in the Hanford Environmental Information System (HEIS) and are included in Appendix A of the RSVP.

The RSVP and the verification sampling results support a reclassification of this site to Interim Closed Out. The current site conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the RDR/RAWP and ROD. The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also have demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	1607-F5	Classification:	Accepted
Names:	1607-F5; 1607-F5 Sanitary Sewer System; 1607-F5 Septic Tank; 124-F-5	Reclassification:	Interim Closed Out (9/14/2006)
Type:	Septic Tank	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been remediated and interim closed out. The system consisted of a septic tank, drainfield, and associated pipeline.		
Location:	The site was located approximately 122 meters (400 feet) east of the northeast corner of the old 182-F Reservoir. The drainfield was located just southeast of the septic tank.		
Process Description:	The septic tank was constructed of reinforced concrete; the walls are 20 centimeters (8 inches) thick, and the floor was 15 centimeters (6 inches) thick. The septic tank had a capacity of 794.94 liters (210 gallons). The system could support 6 persons assuming input of 132.49 liters (35 gallons) per capita per day and a one day retention period. The drainfield was constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a total of 14.6 linear meters (48 linear feet) of piping (2.4 linear meters [8 linear feet] per capita). The laterals were open jointed and spaced 2.4 meters (8 feet) apart. Piping for the system included a 15 centimeter (6 inch) diameter by 69 meters (225 feet) long vitrified clay pipe that exited the 181-F facility and connected to the northwest side of the septic tank		
Related Sites/ Structures:	The site received effluent from the 181-F Pumphouse.		
Waste Type:	Sanitary Sewage		
Waste Description:	This unit received an unknown amount of sanitary sewage from the 181-F Pumphouse.		
Closure Info:	The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD).		

Based on the results of confirmatory sampling performed in November 2004, and field observations, it was determined that the waste site required remedial action. However, the influent pipeline connecting the 181-F Pumphouse to the septic tank did not require remedial action. The remedial action was conducted on August 30 and 31, 2005, with excavation of 2,250 metric tons (2,480 US tons) of material that was disposed at the Environmental

Restoration Disposal Facility.

Following remediation, verification sampling of the excavation and the footprint of the waste staging pile was initiated on March 13, 2006, and concluded on March 20, 2006. The verification sample results indicated that the waste removal action achieved compliance with the remedial action objectives for the site. In accordance with the evaluation, the verification sampling results support a reclassification of the site to interim closed out.

Soil cleanup levels were established based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels has been made for the site contaminants of concern, contaminants of potential concern, and other constituents. The contaminants of potential concern for confirmatory sampling were identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) and by the evaluation of analogous sites. The COPCs for this site were identified as pesticides, polychlorinated biphenyls (PCBs), arsenic, barium, cadmium, total chromium, lead, selenium, silver, mercury, and semivolatile organic compounds (SVOCs). Screening levels were not exceeded for the site constituents, with the exception of boron, cobalt, and vanadium.

Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. It is believed that the presence of these constituents does not pose a risk to ecological receptors, as concentrations of cobalt and vanadium are below Hanford Site background levels and boron concentrations are consistent with those seen elsewhere at the Hanford Site (no established background value is available for boron).

All analytical data were found to be acceptable for decision-making purposes. The confirmatory sample analytical data are stored in the WCH ENRE project-specific database prior to archiving in HEIS and were summarized in Appendix B of the RSVP.

A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for this site.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	1607-F6	Classification:	Accepted
Names:	1607-F6; 1607-F6 Sanitary Sewer System; 1607-F6 Septic Tank; 124-F-6	Reclassification:	Interim Closed Out (11/8/2001)
Type:	Drain/Tile Field	Start Date:	1/1/1945
Status:	Inactive	End Date:	1/1/1975
Description:	The site has been remediated and closed out. The 1607-F6 Sanitary Sewer System was below grade. It included two old tanks, a new tank, a tile field, and pipelines. The old "tanks" were constructed of two 0.91-meter (3-foot) lengths of 91-centimeter (36-inch) concrete pipe connected in series. The pipes were sealed to a wood planking base with asphalt and had wood plank covers. The new tank was constructed of a 1.91-meter (6-foot 3-inch) section of 183-centimeter (72-inch) diameter steel pipe installed vertically with an attached bottom and two layers of tongue and groove planking for the top. The tank is shown on drawing H-1-1518 to have a 61-centimeter (24-inch) by 61-centimeter (24-inch) square access hole at the surface.		

Location: drawings show the old tanks being located under what was the east side of the 1705-F Building. The new tank is shown to be located 3 meters (6.8 feet) east of 1705-F Building. The tile field is located 40 meters (112 feet) east of the septic tank.

Process Description: This septic system operated from 1945 to 1975, receiving sanitary sewage from area buildings. The site is in close proximity to the 100-F-19 Reactor cooling water effluent pipelines, with a portion of the septic system drainfield located directly over one of the large cooling water effluent pipelines

Related Sites/ Structures: Currently no associated structures remain. The site received sanitary sewage from the former 1705-F, 146-F and 146-FR Buildings.

Waste Type: Sanitary Sewage

Waste Description: This unit received sanitary sewage from the 146-F and 146-FR Buildings. The amount of waste received is unknown. Since the site serviced both the 146-F and 146-FR Buildings, there is the potential to have received hazardous contaminants.

Waste Type: Sanitary Sewage

Waste Description: Waste site contaminants of concern (COCs) and contaminants of potential concern (COPCs) identified through process knowledge are listed in the SAP. Because a portion of the septic system drainfield piping was located over the 100-F-19 Reactor cooling water effluent pipelines, the COC/COPC lists for both sites were combined for the CVP. The COCs listed below are attributed to the 100-F-19 Reactor cooling water effluent pipelines, while the COPCs are attributed to the 1607-F6 site. Waste site COCs include: Carbon-14, Cesium-137, Cobalt-60, Europium-152, Europium-154, Europium-155, Nickel-63, Strontium-90. COPCs include: Lead, Polychlorinated biphenyls (PCBs), Semivolatile organic compounds.

Closure Info: The Cleanup Verification Package for the 1607-F6 Septic System and Pipelines, (CVP-2001-00010) documents that the waste site has met remedial action objectives (RAOs) and goals (RAGs) for interim closure as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area, (RDR/RAWP).

Remedial action at the 1607-F6 site began on July 28, 2000. Excavation of the site involved removing the overburden materials, septic system structure (tank and associated influent and drainfield piping), and underlying contaminated soil.

On April 25, 2001, the excavation was completed. There is a large gap between the excavation beginning date and completion date because the north-south septic pipeline was excavated at a later date, following the excavation of the septic tank and drain/tile field.

The final excavation and removal of the 1607-F6 site included the removal of one septic tank (the other two tanks were not found and were presumably removed during construction of the 1705-F Building), the north-south-oriented septic pipeline that served the 146-FR Building, the east-west-oriented septic pipeline that served the 146-F Building, the septic system drain/tile field, and underlying contaminated soil.

The contaminants of concern were C-14, Cs-137, Co-60, Eu-152, Eu-154, Eu-155, Ni-63, Sr-90, lead, PCB, SVOCs and arsenic. Cleanup verification sampling began on January 16, 2001, and was finished on May 14, 2001. Sample results demonstrated that remedial action at the 1607-F6 site achieved the RAOs and RAGs.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-

AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 1607-F7	Classification: Accepted
Names: 1607-F7; 124-F-7; 141-M Building Septic Tank	Reclassification: Interim Closed Out (10/19/2006)
Type: Septic Tank	Start Date: 1/1/1945
Status: Inactive	End Date: 1/1/1975

Description: The site has been remediated and interim closed. The site consisted of a septic tank, tile field, and interconnecting pipeline located under an area that was historically used for animal grazing (i.e., pasture). The septic tank received sanitary sewage from the former 141-M Building and had a volume of 3,800 Liters (1,000 gallons).

Location: The site was located within the 100-F Experimental Animal Farm area just off the northwest corner of the former 141-M Building and east of the 132-F-1 (The Chronic Feeding Barn) site. A walkway to the former 141-M Building was visible near three living juniper trees located south of the septic tank.

Related Sites/ Structures: There were no associated structures remaining at the site. Before remediation, the site received sanitary sewage from the former 141-M Building and runoff from the pasture use. The barns in the area were used for animals being tested with radioactive substances.

Waste Type: Sanitary Sewage

Waste Description: The site received sanitary sewage from the 141-M Building.

Closure Info: The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, (Remaining Sites ROD).

The contaminants of potential concern (COPCs) for the septic system were identified based on existing historical information for the 1607-F7 site. The COPCs identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) included americium-241, cobalt 60, cesium-137, europium 152, europium 154, europium 155, plutonium-239/240, strontium-90, cadmium, total chromium, hexavalent chromium, mercury, lead, pesticides, and semivolatile organic compounds (SVOCs). Based on further site-specific evaluation, volatile organic compounds (VOCs), arsenic, barium, selenium, silver, and polychlorinated biphenyls (PCBs) were included as COPCs.

No stained soil or suspected asbestos-containing material was encountered during confirmatory sampling activities.

Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels has been made for the site contaminants of concern, contaminants of potential concern, and other constituents. Screening levels were not exceeded for the site constituents, with the exception of antimony, barium, boron, lead, vanadium, zinc, total DDT/DDE/DDD, and total dibenzofurans. Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. It is believed that the presence of these constituents

does not pose a risk to ecological receptors because concentrations of antimony, barium, lead, vanadium, and zinc are within the range of Hanford Site background levels.

A Hanford Site background level for boron has not been established. The presence of total DDT/DDE/DDD and total dibenzofurans was believed to be due to historic application of pesticides and herbicides. The exceedance of soil screening values by boron, total DDT/DDE/DDD, and total dibenzofuran concentrations at the site will be evaluated in the context of additional lines of evidence for ecological effects. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for this site.

The site excavation began on August 8, 2005, and was completed November 30, 2005. Remediation of the waste site involved layback of overburden and removal of the septic tank, drain field, the interconnecting pipeline, and associated soils around and below those structures. Some of these materials were staged just south of the site before disposal; however, most of the waste was excavated using direct loadout and shipment to the Environmental Restoration Disposal Facility (ERDF). The overall depth of the excavation for the septic tank was approximately 3 meters (10 feet) below ground surface and approximately 1.5 meters (5 feet) below ground surface for the drain field. The excavation depths also included removal of 0.6 meters (2 feet) of soil below these structures. A total of approximately 1,088 metric tons (1,200 US tons) of contaminated material was disposed at ERDF.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils [i.e., surface to 4.6 meters (15 feet) deep]. The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code: UPR-100-F-1	Classification: Accepted
Names: UPR-100-F-1; 141 Building Sewer Line Spill; 141-C to 141-M Sewer Line Leak; UN-100-F-1	Reclassification: Interim Closed Out (9/15/2003)
Type: Unplanned Release	Start Date: 1/1/1971
Status: Inactive	End Date:
Description: The site has been remediated and interim closed out. The site was an unplanned release that occurred on March 13, 1971.	
Location: The site was located between the 141-C and 141-M Buildings northeast of the 105-F Reactor and west of 116-F-14 (107-F Retention Basin).	
Release Description: The release was a spill of wash water containing contaminated animal waste.	
Related Sites/ Structures: The site was related to the sewer line from the 141-C to the 141-M Buildings which have since been demolished.	
Waste Type: Animal Waste	
Waste Description: The spill consisted of wash water used to clean out animal pens. The water contained 4.0E-5 curies of strontium-90 and 1.06E-6 curies plutonium-239.	
Closure Info: 100-F-19:2, 116-F-11, UPR-100-F-1 and 100-F-29 were addressed as a group. The information below documents information for the group of sites.	

The 100-F-19:2 Reactor Cooling Water Effluent Pipeline and co-located sites, (116-F-11 Cushion Corridor French Drain, UPR-100-F-1 Sewer Line Leak, and the 100-F-29 Experimental Animal Farm Pipelines), were remediated as a group and documented in CVP-2001-00003.

Remedial Action ran from August 2001 until December 2002. Verification sampling was conducted in January 2003. Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. Contaminants of concern (COCs) were C-14, Cs-137, Co-60, Eu-152, Eu-154, Eu-155, Ni-63, and Sr-90.

Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. The basis for reclassification was described in detail in the Cleanup Verification Package 2001-00003.

The cleanup verification package does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]); therefore, institutional controls to prevent uncontrolled drilling or excavation into deep zone soils are required.

Code:	UPR-100-F-2	Classification:	Accepted
Names:	UPR-100-F-2; 100-F-3; 107-F Basin Leak Ditch; Basin Leak Ditch	Reclassification:	Interim Closed Out (4/23/2002)
Type:	Unplanned Release	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and closed out.		
Location:	The site ran northeast from the corner of the 107-F Retention Basin to the bank of the Columbia River.		
Process Description:	The Basin Leak Ditch was formed in 1955 following an overflow of the 107-F Retention Basin. The ditch was enlarged by repeated overflows from an effluent manhole located near the north end of the 107-F Retention Basin.		
Related Sites/Structures:	The site was associated with the 107-F Retention Basin and the 116-F-9, Animal Waste Leaching Trench.		
Waste Type:	Process Effluent		
Waste Description:	The waste was radioactive process liquid effluent from the 107-F Retention Basin.		
Closure Info:	The cleanup verification package (CVP-2001-00011) has documented that remedial action has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the approved Amendment to the Interim Action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17).		

The COCs for this site consisted of cobalt-60, cesium-137, europium-152, and europium-154, as listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22).

Site excavation and waste disposal began on February 6, 2001 and were completed on July 28, 2001. The exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. Cleanup verification sampling began on August 16, 2001, and was finished on August 16, 2001.

At the completion of the remedial action, the total excavation was approximately 2,388 meters squared (7,834 square feet) in area with a depth greater than 11 meters (36 feet). Approximately 670 metric tons (739 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility (ERDF).

Results of the sampling, laboratory analyses, and data evaluations for the UPR-100-F-2 site indicated that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	UPR-100-F-3	Classification:	Accepted
Names:	UPR-100-F-3; Mercury Spill	Reclassification:	Interim Closed Out (8/14/2003)
Type:	Unplanned Release	Start Date:	1/1/1977
Status:	Inactive	End Date:	

Description: The site has been remediated and closed out. The site was an unplanned release that occurred at the northeast corner of the 146-FR Fish Laboratory (demolished).

Location: The site was located at the northeast corner of the 146-FR Fish Laboratory.

Release Description: In 1977, an unknown quantity of mercury was spilled on the floor in the 146-FR Fish Laboratory and was "squeegeed" across the floor and out the door onto the ground at the northeast corner of the building. The mercury contaminated an area approximately 3.05 meters by 3.05 meters (10 feet by 10 feet). Personnel who remember the incident are unable to specify the volume of mercury, its chemical composition, or the exact area of soil which was contaminated (employee interview).

Related Sites/ Structures: The spill was originally in the 146-FR Fish Laboratory then "squeegeed" out the door near the 146-FR Drywells (100-F-25).

Waste Type: Chemical Release

Waste Description: The waste was an unplanned release of mercury. The quantity is unknown.

Closure Info: 100-F-25 and UPR-100-F-3 were addressed as a group. The information below documents information for the group of sites.

The CVP-2003-00010 has documented that remedial action at the site has achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1999) and RDR/RAWP.

Waste site contaminants of potential concern (COPCs) for the 100-F-25 site were originally identified in the Data Quality Objectives Summary Report for 100/300 Area Remaining Sites Analytical Sampling Effort (Remaining Sites DQO) (BHI-01249). Process effluent from the 105-F Reactor was used in the 146-F and 146 FR aquatic laboratories, which fed the 100-F-25, 146-F Drywells. Since the Remaining Sites DQO was published, remediation of contaminated soil associated with process effluent has provided additional potential contaminant information. The contaminants of concern are: carbon-14, cesium-137, cobalt-60, europium-152, europium-

154, nickel-63, strontium-90, mercury and hexavalent chromium.

Remedial actions were conducted on April 12, 2003. At the completion of remedial action, the total excavation was approximately 243 meters squared (2,615 square feet) in area with a depth of approximately 4.0 meters (13 feet). Approximately 809 metric tons (892 tons) of material (structures and soil) from the site were disposed at the Environmental Restoration Disposal Facility. Contaminants of Concern are c-14, Cs-137, Co-60, Eu-152, Eu-154, Ni-63, Sr-90, hexavalent chromium, mercury. Verification samples were collected on April 16, 2003.

The CVP demonstrates that remedial action at the site have achieved the RAOs and corresponding RAGs established in the approved ROD (EPA 1999) and RDR/RAWP (DOE/96-17). The remaining soils at the UPR-100-F-3 site have been sampled, analyzed, and modeled. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

100-FR-2

Code: 100-F-2	Classification: Accepted
Names: 100-F-2; PNL Ecological Study Strontium Garden; Strontium Garden	Reclassification: Interim Closed Out (7/25/2002)
Type: Laboratory	Start Date: 1/1/1952
Status: Inactive	End Date: 1/1/1970

Description: The site has been remediated and closed out. The site was a garden plot consisting of twelve 1.2 by 3 meter (4 by 10 feet) plots arranged in two rows of six plots each. The area was surrounded on all sides and overhead by a wooden frame with 0.63-centimeter (0.25-inch) screen material attached. Hanford Drawing SK-1-2847, Sheet 2 shows it measured 24 by 9 meters (80 by 30 feet). In 1997, a site visit confirmed that the dimensions of the site were 24 meters (80 feet) by 9.4 meters (31 feet).

Location: The site was located near the southwest corner of 100F Area, south of well 199-F7-1, and east of the 100-F Perimeter Road (F Avenue).

Process Description: The site was established to study the behavior of plants grown in soil containing cesium-137 and strontium-90, under controlled conditions of soil tillage, irrigation, cropping and abandonment. Uptake of the radionuclides was measured in alfalfa, barley, radishes, beans, cheatgrass, and tansy mustard. The screened enclosure was designed to exclude mammals and birds, but not insects. Each plot was edged with wooden planks to reduce the transfer of contaminants among the soil plots. An article, written in 1971 by J.F. Cline and W.H. Rickard (published in 1972 in the Health Physics Pergamon Press), describes how the experiments were conducted and indicates the active experiment dates were 1954 -1964. It lists the sample results from the active experiment, collected from 1954 through 1963. Although the plot may have been established in 1952, a total of 180 inches of strontium contaminated irrigation water was used on these plots over the 1954 -1964 time period. This article also states that, in 1970, dry litter and soil samples were collected and analyzed. This seems to be the conclusion of the experiment.

Related Sites/ Structures: The site was related to the Experimental Animal Farm and radiological experiments conducted by Pacific Northwest Labs (PNL).

Waste Type: Soil

Waste Description: The waste was contaminated soil. Approximately 39 microcuries of strontium-90 and 120 microcuries of cesium-137 were added to the soil for botany experiments.

Closure Info: Remedial actions conducted from December 2001 to January 2002 have been documented in CVP-2001-00001. Verification sampling was conducted on February 13, 2002. At the completion of the remedial action, the total excavation was approximately 373 m² (4,014 ft²) in area with a depth greater than 1.6 m (5.2 ft). Approximately 1,269 metric tons (1,399 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility.

The COCs for this site consisted of cesium-137 and strontium-90. Cleanup verification sampling for the shallow zone was done on February 13, 2002.

The CVP demonstrates that remedial action at the 100-F-2 site has achieved the RAOs and corresponding RAGs established in the approved Remaining Sites ROD (EPA 1999) and RDR/RAWP (DOE/RL-96-17). These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code:	100-F-14	Classification:	Accepted
Names:	100-F-14; 100-FR-2 Vent Pipe; 100-F Carpenter Shop Waste Site Vent	Reclassification:	No Action (3/2/2005)
Type:	Storage Tank	Start Date:	
Status:	Inactive	End Date:	
Description:	The site is a steel vent pipe extending above grade. The above grade pipe was 10 centimeters (4 inches) in diameter with a 180 degree bend at its top. The top points downward at its tip which is fitted with a vent assembly. Steel fence posts surrounded the vent pipe. During a April 1999 visit, several soil gas probes were observed. The area was fairly level with sandy soil and had a moderate cover of grasses. A concrete foundation pad (6 m x 9 m [20 ft x 30 ft]) is 13.7 m (45 ft) east of the site.		
Location:	The vent was located north of the northeast corner of 118-F-1 Burial Ground and approximately 244 meters (800 feet) southwest of the southwest corner of the 105-F Reactor Building. The unit was 13.7 meters (45 feet) west of a concrete floor pad that remains from a demolished carpenter shop.		
Related Sites/ Structures:	The site was probably related to the 100-F Carpenter Shop.		
Waste Type:	Water		
Waste Description:			
Closure Info:	A site evaluation was conducted as part of the Remaining Sites Verification Package attached to the Reclassification Form 2004-127. Historical data, process knowledge, geophysical survey results, site walkdown observations, and aerial photographs were used to develop a site-specific sample design.		
	A focused sampling approach was selected for the site, biased towards potential worst-case contaminant locations. Because the site walkdown observations and aerial photographs indicated that the site may have been a decontamination facility, the crib beneath the vent pipe was chosen as the suspected location for the terminus of the drain pipe that discharged liquid effluent from the floor drain.		
	The evaluation included a focused sampling approach consisting of excavating a test pit into the 3 by 3 meter (10 by 10 feet) subsurface anomaly located beneath the vent pipe (BHI 0100-F-WI-G0010). At 0.9 meters (3 feet) below ground surface a plastic vapor barrier was discovered, followed by the 0.15-meter (6-inch) lateral drain pipe that conveyed flow from the concrete pad floor drain at 1.2 meters (3.9 feet) below ground surface. The drain pipe appeared to consist of nonfriable asbestos-cement material, and a sample of the pipe material was taken.		
	Contaminants of potential concern (COPCs) for the site included semivolatile organic compounds (SVOCs), petroleum hydrocarbons, VOCs, arsenic, barium, cadmium, total chromium, lead, selenium, silver, polychlorinated biphenyls (PCBs) hexavalent chromium,		

mercury, pesticides, herbicides, radionuclides (gross alpha, gross beta, and gamma energy analysis) and asbestos.

The rock crib structure that drained the lateral pipe was revealed beneath the drain pipe, and a sample of the crib material was taken at 1.7 meters (5.6 feet) below ground surface. Native soil was discovered at 2.2 meter (7.2 feet), and a representative sample consisting of 15 aliquots distributed across the bottom of the test pit was taken. Results of the confirmatory sampling were used to make reclassification decisions for the site in accordance with the TPA-MP-14 (DOE-RL 1998) process.

The RSVP report demonstrates that the site meets the objectives for no action as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (commonly referred to as the Remaining Sites Record of Decision [ROD]) (EPA 1999). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future land uses of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-F-15	Classification:	Accepted
Names:	100-F-15; 108-F Building Ventilation French Drain	Reclassification:	Interim Closed Out (7/25/2002)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and closed out. The french drain was constructed of concrete buried to a depth that placed the upper drain surface at grade level. A highly degraded wooden cover was in place over the drain. The bottom of the drain consisted of soil and large gravel, which supported a five-gallon carboy container. A copper tube connected the exhaust duct from the third floor, room # 302, to the carboy.		
Location:	The unit was located next to the east wall of the 108-F Building.		
Related Sites/Structures:	This site was associated with the 108-F Building (site 100-F-36).		
Waste Type:	Water		
Waste Description:	The drain received condensate that formed inside several large hood ventilation ducts mounted externally on the east wall of the building. Condensate formed during cold weather and ran through 2.5-centimeter (1-inch) stainless steel lines to the drain. The quantity of waste received is not known.		

A bottle containing 3 gallons of liquid from the 100-F-15 french drain was characterized between 05/07/96 and 08/08/96. A radiological survey of the bottle was conducted using field detection equipment and the resulting readings showed less than detectable. A sample from the liquid was collected and sent to the laboratory for chemical and radiochemistry analysis. The resulting analysis was received on 08/28/96 and indicated the liquid contained above threshold amounts of radiological and hazardous material (i.e., plutonium and chromium). Specifically, the chemical constituents analyzed for were TCLP Metals, Inorganic Ions, and Total Cyanide, and the radiological constituents were GEA, Gross Alpha, Gross Beta, Strontium-90, Isotopic Plutonium, and Total Uranium.

Closure Info: documents information for the group of sites.

The cleanup verification package (CVP-2002-00001) has documented that the site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17).

The COCs for this site consisted of the following: total chromium, hexavalent chromium, plutonium-238 and plutonium-239/240 as listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22).

A cleanup verification sampling strategy was developed for the site based on the SAP and was approved in a status meeting by the U.S. Environmental Protection Agency. Because the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains were removed during decommissioning and demolition activities and backfilled with clean material, variance sampling was eliminated and cleanup verification samples were collected. The 100-F-15 french drain was sampled as per the SAP. The 100-F-4, 100-F-11, and 100-F-16 french drains were considered analogous to the 100-F-15 french drain and were verified as clean by excavating and sampling a test pit at each location.

Site excavation was completed as reported in the 108-F Biological Laboratory D&D Project Closeout Report. The CVP report documents that the 100-F-4, 100-F-11, 100-F-15, and 100-F-16 french drains have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 362.2 meters squared (3898.7 square feet) in area with a depth of 4.6 meters (15.0 feet). No material from the sites was disposed of at the Environmental Restoration Disposal Facility as a result of the Remedial Action Project activities described here. Verified clean materials were used as backfill at the completion of the remedial action.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 100-F-20	Classification: Accepted
Names: 100-F-20; PNL Parallel Pits	Reclassification: Interim Closed Out (1/17/2007)
Type: Trench	Start Date: 1/1/1962
Status: Inactive	End Date:
Description: The has been remediated and interim closed. The site consisted of two earthen pits or trenches, both oriented northeast to southwest. The pits were observed on aerial photographs (#7620 and #6451-5) from 1962, which show the site to be actively in use, with refuse material visible in the pit bottoms. The access roads appear well used, suggesting frequent motor vehicle access to the pit locations. Prior to remediation, the area was covered with cheat grass and rabbit brush vegetation. Evidence of surface disturbance was visible. Bricks and subsidence were observed at the site, but the exact location of the trenches is not visually discernible from the surface. Blue wooden stakes remain at the site from geophysical surveys. Between March 31, 1995 and April 4, 1995, a radiological survey was conducted over the general area of the Pacific Northwest Laboratory (PNL) parallel pits. Counts as high as 12,000 counts per minute (cpm)	

were collected over the surface of the site.

Location: The site was located about 30.5 meters (100 feet) west of the eastern 100-F Perimeter Road and immediately north of a dirt road that connects the 100-F Perimeter Road with the main reactor site access road, running along the southern boundary of the ash pit.

Process Description: The site was believed to have been used to dispose of both radioactive and nonradioactive material from the experimental animal farm. The Burial Ground ROD reported that the northern trench may have contained non-radioactive animal farm wastes, including hardware, lumber, and soft materials. The southern pit may have received radioactively contaminated animal feces and pen sweepings.

Related Sites/ Structures: The site was thought to have been related to the Experimental Animal Farm.

Waste Type: Misc. Trash and Debris

Waste Description: A retired Hanford employee was interviewed in 1995. He clearly remembered delivering waste to the pits. The southern pit may have received radioactively contaminated animal feces (mostly sheep) and pen sweepings, small quantities of animal tissue, and miscellaneous Experimental Animal Farm wastes. The northern pit may have received non-radioactive Experimental Animal Farm wastes including hardware, lumber, and soft materials. Neither of these pits was used as a burn pit. Potential contaminants included: Co-60, Sr-90, Pu-239/240

Closure Info: The waste site remedial action objectives (RAOs) and goals (RAGs) for interim closure as established in the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (100 Area Burial Grounds), (ROD) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) have been met. Documentation of the remedial action may be found in the Cleanup Verification Package (CVP), 2006-00009.

Remedial action began on December 5, 2005, with load out of waste material completed on August 8, 2006. Excavation of the site involved removing demolition debris that contained concrete, metal piping, steel sheeting, and wood. Approximately, 14 small laboratory-type containers were encountered throughout the burial ground. No asbestos-containing material was identified during waste excavation and no areas of the burial ground were identified for focused sampling.

After removal of all debris, radiological field screening was used to determine that excavation activities were complete. At the conclusion of the excavation activities, the remediation footprint was approximately 4.3 m (14 ft) below the ground surface and at the deepest point the elevation at the bottom of the excavation was 117 m (384 ft) above sea level. An estimated 11,953 metric tons (13,176 U.S. tons) of material was excavated from the 100-F-20 burial ground and disposed at ERDF. Final cleanup verification samples were collected in August of 2006. The contaminants of concern (COCs) were cobalt-60, strontium 90, and plutonium 239/240, nickel-63, cesium-137 and lead.

The cleanup verification sample analytical data were summarized in Appendix A of the CVP-2006-00009 and stored in the Washington Closure Hanford Environmental Restoration project-specific database for data evaluation prior to being submitted for inclusion in the Hanford Environmental Information System database.

The remaining soils at the site have been sampled, analyzed, and evaluated. The results of this effort indicate that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The site had no deep zone; therefore, no institutional controls were required. The site was verified to be remediated in accordance with

the ROD and may be backfilled.

Code: 100-F-35 **Classification:** Accepted
Names: 100-F-35; Soil Contamination Area Inside the 105-F Exclusion Area **Reclassification:** Interim Closed Out (6/16/2003)
Type: Unplanned Release **Start Date:**
Status: Inactive **End Date:**

Description: The site has been remediated and closed out. The site was a posted Soil Contamination Area with no distinguishing features.

Location: The site was located southwest of the 105-F Reactor Building, inside the Exclusion Area.

Release Description: An area of contamination was found inside the 105-F Exclusion Area on April 29, 1997. The area was initially found with the Mobile Surface Contamination Monitor (MSCM-II) Tractor (report #MSCMR243). A more detailed survey with an Electra reported 60,000 disintegrations/minute over an area approximately 3 by 3 meters (10 by 10 feet). A conversation with Steve Demers indicates that the source of contamination was a large container (commercial name "Terra-Store") that had been sitting on this area during the excavation of the 116-F-4 Pluto Crib. The Terra-Store container was filled with contaminated soil from the excavation and then transported to the Environmental Restoration Disposal Facility (ERDF). The 3 by 3-meter (10 by 10-foot) contaminated area is residual contamination from the container of contaminated soil (Terra-Store).

Related Sites/ Structures: The site was associated with 116-F-4 Crib.

Waste Type: Soil

Waste Description: An area of radiologically contaminated soil, reading 60,000 disintegrations/minute was identified within the 105-F Exclusion Area. The ground contamination was the result of a large container placed in this area to hold contaminated soil removed from 116-F-4 Crib. Soil samples from 116-F-4 Crib identified strontium-90 and cesium-137 as the major contaminants.

Closure Info: The Cleanup Verification Package (CVP) CVP-2002-00007) demonstrates that remedial action at the 100-F-35 site has achieved the remediation action objectives (RAOs) and corresponding remediation action goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17).

For the respective points of compliance, remedial action goals (RAGs) were established for the following radionuclide and nonradionuclide contaminants of concern (COCs) identified through process knowledge and listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22). The COCs for this site consist of the following: americium-241, cesium-137, cobalt-60, europium-152, europium-154, plutonium-239/240, strontium-90, uranium-233/234, uranium-238, chromium (hexavalent).

At the completion of remedial action, the total excavation was approximately 51.2 square meters (551 square feet) in area with a depth of 0.9 meters (3 feet). Approximately 75.4 metric tons (83 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility (ERDF). Evaluation of sample results indicated that all RAOs and RAGs for direct exposure, protection of groundwater, and protection of the Columbia River had been met.

Cleanup verification samples collected on November 20, 2002 and January 7, 2003 were reported in the CVP. The sample numbers reported for the first event were J008C4 through J008C8 and the sample numbers for the second event were J00FF2 through J00FF6.

The results indicate the site supports future land uses that can be represented (or bounded) by a rural-residential scenario and show that no threat to groundwater or the Columbia River is posed from residual soil concentrations.

Code:	100-F-50	Classification:	Accepted
Names:	100-F-50; Storm Water Run Off Culvert; 100-F Railroad French Drain	Reclassification:	No Action (4/15/2008)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	This site consisted of a circular concrete basin and a steel culvert (pipe). The basin, approximately 1 meter (3 feet) in diameter, collected surface water runoff that drained via a 36-centimeter (14-inch) diameter steel diversion culvert under one of the railroad grades and flowed down an embankment to the flat terrain below.		
Location:	The concrete retaining wall at the top of the french drain was located about midway between the two sets of track that were about 10 meters (30 feet) apart.		
Release Description:	Evidence of water erosion on the hillside below the culvert and vegetation in aerial photographs suggested water runoff.		
Process Description:	The purpose of the French drain and drain pipe was unknown. It appeared to have been installed as a water collector and drain for the land between the two tracks. Aerial photographs during Hanford operations show the presence of an unusually large amount of vegetation below the drain culvert, suggesting that water solutions were discharged. No water piping sources were found on drawings in this area, so it does not appear that rinsing processes were performed at the site. The French drain appeared to be located at a low point in the area between the two railroad tracks. A drain pipe ran east under one set of railroad tracks to discharge from a soil bank above a low area in the adjoining land. There was a line of vegetation below the drain pipe in older photographs, but there was only dead vegetation found during the field walkdown in 2005. Since radioactive solutions were not typically discharged to soil surfaces (to avoid airborne contamination and spreading), it does not appear that any dumping of radioactive solutions was involved at the site. Cask car drainage and flushing was typically done at the shipping or receiving areas that had process sewers. Chemical dumping was not suspected for this site. There was soil washout on the bank below the culvert east of the railroad tracks. There was evidence of dead vegetation and/or some darkening of the soil in the low area. There was no sign of soil stains that might indicate chemical solution dumping.		
Related Sites/Structures:	The site was associated with railroad tracks and rail cars.		
Waste Type:	Soil		
Waste Description:	There is evidence of soil erosion below the culvert from the french drain. The concrete ring (french drain) is filled with soil.		
Closure Info:	The Remaining Sites Verification Package, RSVP-2007-001, for 100-F-50 has documented site conditions have been verified to meet the remedial action objectives and the corresponding remedial action goals as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-		

KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, (ROD).

The site evaluation included investigation by confirmatory sampling conducted on November 19, 2007. The contaminants of concern included: hexavalent chromium, gamma-emitting radionuclides (cesium-137, cobalt-60, europium-152, europium-154), and strontium-90. Additionally, based on drainage, the following COPCs were: the expanded list of inductively coupled plasma metals, mercury, semivolatile organic compounds, pesticides, polychlorinated biphenyls, herbicides, total petroleum hydrocarbons, and alpha- and beta-emitting radionuclides.

All confirmatory samples were analyzed in accordance with the 100 Area Remedial Action Sampling and Analysis Plan (SAP). The confirmatory sample analytical data results were stored in the WCH Environmental Restoration project-specific database for data evaluation prior to their archival in the Hanford Environmental Information System (HEIS) and were summarized in Appendix B of the RSVP.

In accordance with this evaluation, the confirmatory sampling results support a reclassification of the site to no action. The residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	118-F-1	Classification:	Accepted
Names:	118-F-1; Burial Ground No. 1; Minor Construction Burial Ground No. 2; Solid Waste Burial Ground No. 2	Reclassification:	Interim Closed Out (12/20/2007)
Type:	Burial Ground	Start Date:	1/1/1954
Status:	Inactive	End Date:	1/1/1965
Description:	The site consisted of a combination of two locations formerly called Minor Construction Burial Ground No. 2 and Solid Waste Burial Ground No. 2. The burial ground received radioactive equipment and other miscellaneous wastes from the 100-F Reactor operations. There were three unlined trenches and a pit present at the site. The trenches were oriented north-south and were typically 91 meters (300 feet) long by 6.1 meters (20 feet) wide. The site appeared as a cobble-covered, open field after remediation.		
Location:	The site was located approximately 300 meters (1000 feet) southwest of the 105-F Reactor Building.		
Process Description:	The 118-F-1 Burial Ground combined two locations formerly called Minor Construction Burial Ground No. 2 and Solid Waste Burial Ground No. 2. Solid waste from 105-F Reactor Building construction work was put into two holes in 1954 and covered with soil to grade in late 1955 or early 1956. Adjacent to this site, on the south side, a solid waste burial ground was opened in 1955 and extended on two subsequent occasions. Miscellaneous solid waste was buried in the 2 trenches, oriented north and south, and covered to grade with a minimum of 0.6 meters (2 feet) of soil. West of these trenches a number of pits containing irradiated process tubing and dummy elements were similarly covered. A third trench on the east side of the burial ground was used during July and August 1965, for burial of gun barrel tips, steel sleeves, and metal chips removed from the reactor. Filter boxes containing reactor graphite chips were also buried in the trench which was then backfilled to grade with 1.2 meters (4 feet) of soil cover. A pit near the west side of the site was used during the same period for burial of miscellaneous surface contaminated waste and was subsequently backfilled with approximately 1.8 meters (6		

feet) of soil cover. The boundary of the burial ground is permanently marked by posts numbered F-65-1 through F-65-21

- Waste Type:** Equipment
- Waste Description:** This site received radioactive reactor components and hardware (dummy elements, process tubing, etc) and other miscellaneous radioactive solid wastes. Potential contaminants include: Co-60, Sr-90, Pu-239/240
- Closure Info:** The Cleanup Verification Package for the 118-F-1 Solid Waste Burial Grounds documents that the waste site has met the remedial action objectives (RAOs) and remedial action goals (RAGS) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, (ROD).

Remedial action began on December 27, 2005. All remedial activities (excavation, sorting, and load-out) were completed by June 22, 2007.

Wastes encountered in the 118-F-1 Burial Ground included reactor related waste including aluminum fuel spacers, splines, reactor hardware, equipment, piping, graphite dust, sheet metal, concrete, cardboard, wood timbers, other miscellaneous debris, and eight pieces of SSNF.

Approximately 88,800 metric tons (97,900 U.S. tons) of waste and contaminated soil from the site was disposed at ERDF and approximately 13,400 bank cubic meters (BCMs) of soil (overburden/below contaminant level [BCL] stockpile material) was segregated for use as clean backfill material. At the conclusion of excavation activities, the elevation at the deepest part of the remedial excavation was 117 meters (384 feet) above sea level. The remediation excavation was approximately 11,600 meters squared (125,000 square feet) in area with a maximum depth of approximately 5.5 meters (18 feet).

Final cleanup verification samples were collected in May 2007 and June 2007 to confirm acceptability of residual contaminant concentrations. The site contaminants of concern (COCs) for verification sampling as established in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (SAP) included: tritium (H-3), carbon-14, cobalt-60, nickel-63, strontium-90, silver-108m, cesium-137, europium-152, europium-154, cadmium, lead, and mercury. In addition, because SSNF was encountered in the 118-F-1 Burial Ground, americium-241, plutonium-238, plutonium-239, plutonium-240, and uranium-238 were added to the list of COCs for the site.

The laboratory-reported sampling data results for all constituents were presented in Appendix B of the CVP and stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in Hanford Environmental Information System (HEIS).

The remaining soils at the site have been sampled, analyzed, and modeled. The results of this effort indicated that the materials from the site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at ERDF. These results also indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The excavation area had a maximum depth of approximately 5.5 meters (18 feet), which included a shallow zone and a deep zone. However, the entire excavation area is considered one decision unit, and will be closed out using the more restrictive shallow zone cleanup criteria; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

The 118-F-1 site is verified to be remediated in accordance with the ROD and may be backfilled.

Code:	118-F-2	Classification:	Accepted
Names:	118-F-2; Burial Ground No. 2; Solid Waste Burial Ground No. 1	Reclassification:	Interim Closed Out (2/8/2008)
Type:	Burial Ground	Start Date:	1/1/1945
Status:	Inactive	End Date:	1/1/1965
Description:	The site consisted of a solid waste burial ground that served as the original solid waste disposal site for the 100F Area. It was formerly called Solid Waste Burial Ground No. 1.		
Location:	The site was located approximately 450 meters (1,475 feet) west-southwest of the 105-F Reactor Building. Prior to remediation the burial ground boundary was permanently marked by posts numbered F-65-22 through F-65-37.		
Process Description:	Eight trenches contained miscellaneous solid waste from 105-F and one trench contained solid waste from the biology facilities. According to historical documentation, these trenches were covered to grade prior to 1956. The individual trenches were oriented north and south and were typically 76 meters (250 feet) long by 6.1 meters (20 feet) wide. Several cylindrical sleeves, measuring 5.5 meters (18 feet) long and 1.8 meters (6 feet) in diameter, were used for disposal of animal carcasses and liquid waste from 108-F, and were covered with approximately 1.8 meters (6 feet) of soil in 1955. GPR data from the northern portion of the site indicate considerable disturbed areas which precludes easy and accurate delineation of possible trenches. A 2002 Geophysical Investigation identified nine smaller caissons, measuring one meter (3 feet) in diameter, roughly at grade, on the northwest side of the burial ground. These caissons were located in a mound of soil, approximately 1.5 meters (5 feet) high, running north-south. Uncertainty existed whether these caissons could be the same as the cylindrical sleeves mentioned above because the sleeves measure 1.8 meters (6 feet) in diameter. Additionally, the co-ordinates for the sleeves from HW-33305 (Clukey 1954) places them 90 meters to the west of the caissons.		
Waste Type:	Equipment		
Waste Description:	The site contains miscellaneous radioactive solid wastes, reactor components and hardware. Potential contaminants include: Co-60, Ni-63, Sr-90, Cs-137, Eu-152, Eu-154, U-238, Pu-238, Pu-239/240, chromium, lead, mercury		
Waste Type:	Animal Waste		
Waste Description:	The burial ground contains several long metal pipes with wooden lids used to dispose of contaminated animal carcasses.		
Closure Info:	The Cleanup Verification Package for the 118-F-2 waste site (CVP-2007-00002) documents that the site has been remediated in accordance with the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (100 Area Burial Grounds), Benton County, Washington (Burial Ground ROD), and meets the objectives and goals for interim closure as established in the Burial Ground ROD and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).		

Remedial action began on January 17, 2006, and was completed on August 8, 2007. Excavation of the site involved removing the uncontaminated overburden, the buried contaminated debris, and the underlying contaminated soil over an area approximately 14,197 meters squared (152,815 square feet. Approximately 4,020 bank cubic meters (BCM) (5,260 bank cubic yards [BCY]) of uncontaminated overburden soil was removed and stockpiled near the excavation for subsequent use as backfill. Approximately 16,100 BCM (21,100 BCY) of waste, including

contaminated soil and debris, was disposed at the Environmental Restoration Disposal Facility. At the conclusion of remediation activities, the elevation at the deepest part of the excavation was approximately 117.4 meters (385 feet) above mean sea level with a maximum depth of approximately 4.6 meters (15 feet) below original surrounding ground surface.

The 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (Burial Ground SAP) identified the contaminants of concern (COCs) for the site as cobalt-60, nickel-63, strontium-90, cesium-137, europium-152, europium-154, uranium-238, plutonium-238, plutonium-239/240, chromium, lead, and mercury. In-process characterization samples were analyzed for these COCs and for a wide range of metals, semivolatile organic compounds, polychlorinated biphenyls, pesticides, gamma-energy-emitting isotopes, gross alpha, and gross beta. Based on in-process characterization results, no additional COCs were identified for the burial ground. The analytical results of in-process and waste characterization sampling are located in the Administrative Record under sample delivery groups (SDGs) K0390, K0433, K0436, K0455, and K0592.

A total of 15 discrete soil verification samples (i.e., focused samples) were collected on July 30, 2007, in addition to the statistical cleanup verification samples. Verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency analytical methods, as required per the SAP. The laboratory-reported data for the focused samples were provided in Appendix D of the CVP.

The results of verification sampling illustrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

In accordance with the CVP evaluation, the verification sampling and modeling results support a reclassification of the 118-F-2 Burial Ground to Interim Closed Out.

Code:	118-F-3	Classification:	Accepted
Names:	118-F-3; Burial Ground No. 3; Minor Construction Burial Ground No. 1	Reclassification:	Interim Closed Out (12/21/2006)
Type:	Burial Ground	Start Date:	1/1/1952
Status:	Inactive	End Date:	1/1/1952
Description:	The site has been remediated and interim closed. The site was backfilled after use. The solid waste burial ground received irradiated reactor parts that were removed during the Ball 3X project to convert the 100-F Reactor from the liquid 3X to the ball 3X safety systems. The southern half of the burial ground ran in a north-south direction and the northern half angled toward the west forming a dogleg.		
Location:	The site was located approximately 85 meters (280 feet) southwest of the 105-F Reactor Building, adjacent to the reactor facility fence. The burial ground boundary was permanently marked by posts numbered F-65-38 through F-65-43.		
Process Description:	This site received irradiated parts from the Ball 3X Project at the 105-F Reactor during 1952. The waste was primarily vertical safety rod (VSR) thimbles and also step plugs. During the project 39 thimbles were removed and buried. Thimbles were described as being 11 meters (35 feet) long, with a diameter of 8.89 centimeters (3.5 inches), and a wall thickness of 0.38 centimeters (0.15 inches). Each weighed about 90 pounds and was made of aluminum. An		

additional 23 thimbles were replaced for maintenance purposes at an earlier date, it was unclear where these were buried.

- Waste Type:** Equipment
- Waste Description:** The site received irradiated reactor parts that were removed during the project to convert the 105-F Reactor from the Liquid 3X to the Ball 3X safety systems. The parts primarily included vertical safety rod thimbles and step plugs. Thirty-eight thimbles were known to have been buried there and possibly as many as 61. The principal radionuclide was short-lived cobalt-60.
- Closure Info:** The cleanup verification package (CVP), CVP-2006-00008, provided documentation that the waste site has been remediated in accordance with the Record of Decision (ROD) for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (100 Area Burial Grounds). Remedial action objectives and goals have been met for interim closure of the site as established in the 100 Area Burial Grounds ROD and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Remedial action began on January 31, 2006 with load out of waste material completed on May 23, 2006. Excavation of the site involved removing metal and concrete debris, including piping, sheet metal, an empty tank structure, a large heat-transfer tower, thimbles, and step plugs. No asbestos-containing material was identified during waste excavation. At the conclusion of excavation activities, the remediation footprint was approximately 3.5 meters (12 feet) below ground surface and the elevation at the bottom of the excavation was 121.5 meters (400 feet) above sea level.

An estimated 4,060 metric tons (4,476 U.S. tons) of contaminated material from the site was disposed at ERDF. In addition, approximately 1,400 cubic meters (49,441 cubic feet) of clean overburden material was excavated from the waste site and stockpiled for potential reuse as backfill.

Waste site contaminants of concern (COCs) were identified in the RDR/RAWP, verification samples, and in the remaining black surface ash located at the northern end of the burial ground. The COCs for the waste site included barium, boron, cobalt-60, cesium-137, nickel-63, and strontium-90.

The interim action ROD, based on a limited ecological risk assessment, established the soil cleanup levels. Although not required by the ROD, a screening comparison against ecological risk screening levels was made for the site COCs, as identified in the RDR/RAWP. The highest exceedance values were observed in the focused sample collected of the black surface ash located north of the site.

Barium, boron, and selenium exceeded screening level values. However, exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. Barium, boron, and selenium were below the range for generic background soil values. Exceedance of soil values by these constituents at the site will be evaluated in the context of additional lines of evidence for ecological effects. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

Final cleanup verification samples were collected in August of 2006 to confirm acceptability of residual contaminant concentrations in the soil. The verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required by the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (SAP). The remediation excavation footprint was classified as one shallow-zone decision unit based on its size and

depth. The overburden (stockpiled soil) and the above-cleanup-level staging pile footprint were separate decision units. As specified in the SAP, four composite samples and a duplicate were collected from each of the waste site decision units.

The cleanup verification sample analytical data results were summarized in Appendix A of the CVP. The sample data were then stored in the Washington Closure Hanford Environmental Restoration project-specific database for evaluation prior to being submitted for inclusion in the Hanford Environmental Information System database.

The remaining soils have been sampled, analyzed, and evaluated. The results of this effort indicated that residual concentrations will support future land uses that can be represented (or bounded) by a rural/residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. This site has no deep zone; therefore, no institutional controls are required. The site was verified to be remediated in accordance with the ROD and may be backfilled.

Code:	118-F-4	Classification:	Accepted
Names:	118-F-4; 115-F Crib; 115-F Pit	Reclassification:	No Action (2/14/2005)
Type:	Crib	Start Date:	1/1/1949
Status:	Inactive	End Date:	1/1/1949
Description:	The area appears today as an open field covered with cobbles. No vegetation grows on the surface. The unit was a small unlined disposal pit/crib.		
Location:	The site was located approximately 122 meters (400 feet) west-southwest of the 105-F Building, just inside the southwest corner of the 100-F Exclusion Area fence.		
Process Description:	The site was a small, unlined pit constructed to receive silica gel from the 115-F drying towers.		
Waste Type:	Chemicals		
Waste Description:	The site contains 270 kilograms (0.3 tons) of silica gel removed from a gel tower in one of the 115-F dryer rooms.		
Closure Info:	A site evaluation was conducted in the preparation of the Remaining Sites Verification Package (RSVP), reclass form number 2004-129. The evaluation consisted of field observations including ground-penetrating radar (GPR) and focused sampling and analysis for the purpose of determining if hazardous or radiological contaminants were present.		

Contaminants of potential concern (COPCs) were identified in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22, Rev. 4) included carbon 14, cobalt-60, cesium-137, europium-154, tritium, and strontium-90. Based on further site-specific evaluation, arsenic, barium, cadmium, total chromium, mercury, selenium, and silver were included as COPCs for potential suspect pipeline contents (no suspect pipeline contents were observed during the confirmation sampling field investigation) (BHI-0100F-WI-G00005).

A stratified sampling design with focused sampling was implemented on October 16, 2004, in accordance with the Work Instruction for 118-F-4, 115 Pit (BHI 0100F-WI-G0005). For the sampling event, one test pit and one test trench were excavated. At the southern end of the test trench three composite samples were collected from the bottom of the excavations, and one sample was collected from an area of ashy oil-stained surface soil. The test pit was excavated to explore the area of the waste site described by WIDS and a linear anomaly identified through GPR believed to be a pipe. A test trench was excavated to explore three other areas identified through GPR as containing a high concentration of subsurface anomalous features near the waste site. Three composite samples with HEIS numbers J01XP4 through J01XP9 were

collected on 10/07/04. The results of the confirmation sampling were used to make reclassification decisions for the site in accordance with the TPA-MP-14 (DOE/RL 1998) process.

Detected values of all contaminants of potential concern were below the remedial action goals (RAGs), with the exception of barium, lead, and zinc, which exceeded their respective groundwater or river protection RAGs in the surface soil sample collected in the area of ashy oil stained soil. Barium was detected at 394 milligrams/kilograms; its groundwater protection action level is 132 milligrams/kilograms. Lead was detected at 14.4 milligrams/kilograms; its groundwater and river protection action level is 10.2 milligrams/kilograms. Zinc was detected at 78.2 milligrams/kilograms; its river protection action level is 67.8 milligrams/kilograms. However, RESidual RADioactivity model results (outlined in DO/RL-96-17, Rev. 5) for analogous sites indicate that barium, lead, and zinc will not reach groundwater (and therefore the Columbia River) within 1,000 years. Therefore, residual concentrations achieve the remedial action objectives for groundwater and river protection for all contaminants of potential concern.

This RSVP report demonstrated that the site has met the objectives for no action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL96-17, Rev. 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (commonly referred to as the remaining sites ROD) (EPA 1999). This report also shows that site soil contaminant concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code:	118-F-5	Classification:	Accepted
Names:	118-F-5; Battelle Sawdust Pit; PNL Sawdust Pit; PNL Sawdust Respository	Reclassification:	Interim Closed Out (5/6/2008)
Type:	Burial Ground	Start Date:	1/1/1954
Status:	Inactive	End Date:	1/1/1975
Description:	The site consisted of a single, unlined trench that received radioactive sawdust from the floors of animal pens in the 100F Experimental Animal Farm. The site now appears as a large raised mound. Prior to backfilling, the site consisted of several trenches oriented north and south.		
Location:	The site was located approximately 305 meters (1000 feet) southeast of the 107-F Retention Basin outside the old perimeter road, and east of the 188-F Ash Disposal Area.		
Process Description:	According to the Technical Baseline Document, WHC-SD-EN-TI-169, past employees remember that sawdust from the Experimental Animal Farm was placed in boxes or 208-liter (55-gallon) metal drums before burial at this site. The material was transported to the sawdust pit in light trucks and the packaged waste was thrown into the pit by hand.		
Related Sites/ Structures:	The site was associated with the 100F Experimental Animal Farm.		
Waste Type:	Animal Waste		
Waste Description:	The site contains low-level activity sawdust and other solids from floors of dog kennels and swine pens. A facsimile sent from W. D. Richmond to M. R. Schneller on March 31, 1971 contains an estimate that the site had received 15 curies of strontium-90 and 0.3 curies of plutonium-239. The site was active and still receiving waste when the facsimile was sent. The facsimile is included in Appendix D of WHC-EP-0087.		

Closure Info: The Cleanup Verification Package 2007-00003 documents that the 118-F-5 PNL (Pacific Northwest Laboratory) Sawdust Pit was remediated in accordance with the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (Burial Ground ROD), and meets the remedial action objectives and goals for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP).

Remedial action of the 118-F-5 Burial Ground began on November 28, 2005, and was completed on August 29, 2007. Excavation of the site involved removing the uncontaminated overburden and the underlying contaminated soil. Sawdust was evident throughout the area excavated. There was no evidence of containers (i.e., boxes or metal drums) that reportedly been used for disposal of sawdust.

A small area (given a field designation of 118-F-5A), northwest of the main 118-F-5 excavation, was also remediated. The area had been identified by the geophysics investigation as a disturbed zone distinct from the larger area. During remediation of this area, no evidence of sawdust or other buried waste was discovered. The analytical results of samples taken on August 2, 2007 for the 118-F-5A area were slightly elevated for carbon-14. Additional material was removed from the 118-F-5A excavation and verification samples were collected.

The Burial Ground Sampling and Analysis Plan (SAP) identified the COCs for the site as cobalt-60, plutonium-239/240, strontium-90, carbon-14, and cesium-137.

Collectively, the sites had approximately 7,100 bank cubic meters (BCM) (9,287 bank cubic yards [BCY]) of uncontaminated overburden soil that would be reused as backfill. A total of approximately 25,500 BCM (33,354 BCY) of contaminated soil was excavated and disposed at the Environmental Restoration Disposal Facility.

At the conclusion of remediation activities, the elevation at the deepest part of the excavation was approximately 119.5 meters (392 feet) above mean sea level with a maximum depth of approximately 5.5 meters (18 feet) below ground surface. The remediation excavation covered an area of approximately 7,392 meters squared (79,535 square feet).

Following remediation and field screening of the 118-F-5 Burial Ground, verification sampling was conducted between August 1 and September 12, 2007. The sample results were summarized in Appendix C of the CVP.

The remaining soils at this site have been sampled, analyzed, and modeled. The results indicated that the residual concentrations of COCs at this site do not preclude any future uses (as bounded by a rural-residential scenario) and allow for unrestricted use of the shallow-zone soils (i.e., surface to 4.6 meters [15 feet]) deep. The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code: 118-F-6	Classification: Accepted
Names: 118-F-6; PNL Solid Waste Burial Ground	Reclassification: Interim Closed Out (9/23/2008)
Type: Burial Ground	Start Date: 1/1/1965
Status: Inactive	End Date: 1/1/1973
Description: The site was an unlined burial ground that received animal and laboratory wastes related to the 100F Experimental Animal Farm. A 2002 Geophysical investigation of this burial ground identified six north south trending trenches. Prior to remediation the burial ground was	

designated by HPS-AC-5-40 concrete markers.

- Location:** The site was located southwest of the 105-F Reactor Building and adjoined the southern border of 118-F-1, Minor Construction Burial Ground No. 2, Burial Ground No. 1, Solid Waste Burial Ground No. 2.
- Process Description:** The large tank cars were used for incineration of animal tissue and carcasses. The carcasses were dropped through a manhole and lime was placed on them to facilitate decomposition. When a tank was full, 1,500 to 1,900 liters (400 to 500 gallons) of fuel oil were added to the tank and ignited. The residual ash was left in a tank after each incineration.
- Related Sites/ Structures:** The site was associated with the 118-F-1, Minor Construction Burial Ground No. 2, Burial Ground No. 1, Solid Waste Burial Ground No. 2 and the 100F Experimental Animal Farm.
- Waste Type:** Animal Waste
- Waste Description:** This unit contains animal and laboratory wastes including plutonium-238 contaminated animal ash. The site did not receive reactor related waste.
- Closure Info:** The Cleanup Verification Package 2008-00001 documents that the 118-F-6 Burial Ground (also referred to as the Pacific Northwest Laboratory [PNL] Solid Waste Burial Ground) waste site has met the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (100 Area Burial Grounds).

Remedial action at the site began on December 12, 2005, and was completed on December 13, 2007. Remedial action activities involved removing the uncontaminated overburden, the buried contaminated debris, and the underlying contaminated soil. All liquid mixed waste was sent for off-site treatment and disposal.

Approximately 13,100 bank cubic meters (BCM) of material and contaminated soil was disposed at ERDF. Approximately 12,000 BCM of soil (overburden/layback stockpile material) was segregated for use as clean backfill material. At the conclusion of excavation activities the remediated area was approximately 7,075 meters squared (76,155 square feet) with a maximum depth of approximately 6.5 meters (21 feet). The deepest part of the remedial excavation (trench 4) was at an elevation of 115.5 meters (379 feet) above sea level.

All areas identified by geophysical survey as potentially containing debris or waste were excavated. An area north of trench one showed subsurface disturbance in the geophysical survey, however, this portion of the burial ground did not contain waste or contamination. It is likely that it was excavated for the purpose of waste disposal but was never used.

Wastes encountered in the 118-F-6 Burial Ground included a railroad tank car, laboratory equipment and bottles, cylinders and crushed drums, biological and animal wastes and carcasses, and limited reactor hardware. Some of these items contained small amounts of liquids.

The Burial Ground Sampling and Analysis Plan identified contaminants of concern (COCs) as cobalt-60, strontium-90, and plutonium-239/240. Plutonium-238 was identified as a COC based on a 1994 BHI report. During excavation, in-process samples were collected as necessary and analyzed for the identified COCs and for a wide range of metals, semi-volatile organic compounds, polychlorinated biphenyls, pesticides, gamma energy emitting isotopes, gross alpha activity, and gross beta activity. Based on the results of this sampling, europium-152 and cesium-137 were added as COCs.

The laboratory-reported data results for all constituents were stored in the Environmental

Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as part of the 95% UCL calculation in Appendix C of the CVP. Results of the verification sampling, laboratory analyses, and data evaluations indicated that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River were met.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The excavation area had a maximum depth of approximately 6.5 meters (21 feet), which included a shallow zone and a deep zone. However, the entire excavation area was considered one decision unit, and will be closed out using the more restrictive shallow zone cleanup criteria; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. The results also demonstrated that residual contaminant concentrations are protective of groundwater and the Columbia River.

Code:	118-F-7	Classification:	Accepted
Names:	118-F-7; Concrete Box; 100-F Miscellaneous Hardware Storage Vault	Reclassification:	Interim Closed Out (10/30/2006)
Type:	Storage	Start Date:	1/1/1945
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been remediated and interim closed out. The site consisted of an inactive solid waste storage vault used for temporary storage of slightly contaminated reactor parts. The majority of the vault was underground.		
Location:	The site was located just south of the 105-F Reactor Building south security fence, west of 116-F-10 and east of the rail line that connected to the 105-F Reactor Building.		
Process Description:	This site was an inactive solid waste storage vault used from 1945 to 1965 for temporary storage of slightly contaminated reactor parts that could be recovered and reused for the 100-F Area reactor operations. The storage vault was a partially buried, light-colored concrete box that extended approximately 46 centimeters (18 inches) above grade. The vault was approximately 23 meters squared (247.5 square feet) and 2.4 meters (8 feet) deep. It was covered with a wooden lid.		
Waste Type:	Equipment		
Waste Description:	This site served as temporary storage for miscellaneous reactor hardware. In 1965, contamination levels within the box were 200 to 300 counts-per-minute. There was some confusion in existing documentation as to whether equipment still remained in the vault. Table 11 of Miller and Wahlen (WHC-EP-0087) reported that 134,700 kilograms (148.3 tons) of lead of 5,600 kilograms (6.2 tons) of cadmium remains in the vault. Appendix A of the same report states that the vault contains only a small amount of radioactive material. DeFord (1993) reports that site personnel believe that the vault was empty.		
Closure Info:	The Cleanup Verification Package, CVP-2006-00007, documented that the waste site has met the remedial action goals (RAGs) and the remedial action objectives (RAOs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (100 Area Burial Grounds), (ROD).		

The vault was a partially buried concrete box that extended 46 centimeters (18 inches) above grade and was covered with a wooden lid. Underground Radioactive Material signs were

posted on the wooden lid.

Remedial action at the site began on January 31, 2006, with load out completed in April 2006. Excavation of the site involved removing the concrete vault structure, the wooden roof structure, and underlying contaminated soil. A single lead/cadmium reactor poison piece, measuring 15 centimeters (6 inches) in length and 3.8 centimeters (1.5 inches) in diameter, was discovered in the vault during excavation.

Waste site contaminants of concern (COCs) identified in the RDR included cobalt-60, cesium-137, silver-108M, strontium-90, cadmium, copper and lead. At the request of EPA cesium-137 and strontium-90 were added to the site verification COC list. Additionally, copper was added as a COC as a result of a single detection above the RAGs within the above cleanup level (ACL) staging pile footprint.

Soil cleanup levels were established in the interim action ROD based on a limited ecological risk assessment. Although not required by the ROD, a comparison against ecological risk screening levels were made for the site COCs. Copper and lead exceeded screening level values; however, exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. The exceedance of soil screening values by lead and copper concentrations at the site will be evaluated in the context of additional lines of evidence for ecological effects. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used as part of the final closeout decision for this site.

To confirm acceptability of residual contaminant concentrations in the soil, final cleanup verification samples were collected and analyzed on June 5, 2006 for the established COCs. The verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (SAP). The cleanup verification sample analytical data results were stored in the Environmental Restoration project-specific database for data evaluation prior to being submitted for inclusion in the Hanford Environmental Information System database. The verification data were also summarized in Appendix A of the CVP.

At the conclusion of excavation activities, the elevation at the bottom of the excavation was 123 meters (403.5 feet). The excavation area was 138 meters squared (1,487 square feet) with an approximate depth of 3.0 meters (9.8 feet). The total of an estimated 104 metric tons (115 U.S. tons) of material was disposed at ERDF.

The remaining soils have been sampled, analyzed, and evaluated. The results of this effort indicated that residual concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. This site has no deep zone; therefore, no institutional controls are required. The site was verified to be remediated in accordance with the ROD.

Code: 120-F-1	Classification: Accepted
Names: 120-F-1; Glass Dump	Reclassification: Interim Closed Out (6/27/2008)
Type: Trench	Start Date:
Status: Inactive	End Date:
Description: The site consisted of two distinct disposal areas, one a trench that ran east to west.	
Location: The site was located 275 meters (772 feet) south of 128-F-1, 100-F Burning Pit and south-southeast of the 105-F Reactor.	

Process Description: The site was originally described as a single, open trench filled with fluorescent tubes, incandescent light bulbs, instrument vacuum tubes, small alkaline batteries, chemical bottles and laboratory apparatus with a second area of disturbed soil with surficial plastic debris approximately 46 meters (150 feet) to the southeast. Due to its proximity, the probable source of the debris found at the 120-F-1 waste site is believed to be the 108-F Building, but the site may have contained debris from other locations within the 100-F Area.

Waste Type: Misc. Trash and Debris

Waste Description: The site is covered with approximately 0.61 meters (2 feet) of fluorescent tubes, incandescent light bulbs, instrument vacuum tubes, and small AAA, C, and D batteries. The site also contains an assortment of chemical bottles, both large and small.

Closure Info: In accordance with the Remaining Sites Verification Package 2008-028, the verification sampling results support a reclassification of this site to Interim Closed Out. The current site conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (EPA 1999).

On January 21, 2006, prior to remedial activities, an industrial hygiene investigation of the site was conducted to determine whether beryllium was present in the phosphor material used in the fluorescent tubes dumped at the 120-F-1 waste site.

Research indicated that prior to 1949 beryllium was used in the manufacture of fluorescent light bulbs, therefore, the samples were analyzed for metals, including mercury and beryllium. It was determined that the fluorescent tubes were not manufactured with beryllium and that beryllium would not be a health concern during remove, treat, and dispose (RTD). However, mercury and, to a much lesser extent, metals such as manganese, nickel, and cadmium were detected and determined to be possible airborne inhalation hazards. The previously interim-stabilized waste site was opened using a front-end loader. It was discovered that the plywood barrier had failed and the fluorescent tubes were crushed. Pieces of the fluorescent tubes and accompanying soils were sampled.

Remedial action at the 120-F-1 waste site began in September 2007 and was completed in March 2008. Two distinct areas were excavated resulting in disposal of approximately 1,505 bank cubic meters of contaminated materials to the Environmental Restoration Disposal Facility.

In preparation for remedial action at the site, a standard geophysical investigation was conducted in the vicinity of the glass dump. The second area of debris to the southeast proved to be larger than the glass dump. It contained concrete, wire debris, small drums with heavy oil-type petroleum hydrocarbons, and some stained soil with pesticides (dichlorodiphenyldichloroethylene [DDE] and dichlorodiphenyltrichloroethane [DDT]). The second area was remediated as part of the 120-F-1 Glass Dump Waste Site.

Verification sampling for both the northwest and the southeast excavations was performed in December 2007 to determine if the remedial action goals had been met. The contaminants of potential concern (COPCs) for verification sampling included inductively coupled plasma metals, hexavalent chromium, mercury, semivolatile organic compounds, and polychlorinated biphenyls (PCBs). In the southeast excavation, total petroleum hydrocarbons were also COPCs.

Verification samples were analyzed using U.S. Environmental Protection Agency-approved analytical methods. The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to archival in the Hanford

Environmental Information System and were summarized in Appendix C of the RSVP.

These results show that residual soil concentrations supported future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrated that residual contaminant concentrations supported unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]). Contaminant levels remaining in the soil were protective of groundwater and the Columbia River. Although a portion of the excavation extended into the deep zone, the site was closed out using shallow zone criteria; therefore, no deep zone institutional controls were required.

Code:	126-F-1	Classification:	Accepted
Names:	126-F-1; 184-F Powerhouse Ash Pit; 188-F Ash Disposal Area	Reclassification:	Interim Closed Out (9/20/2007)
Type:	Coal Ash Pit	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1965

Description: This waste site consisted of an area that had received coal ash from the 100-F Area coal-fired steam plant that operated from 1944 to 1965. Coarse textured bottom ash and boiler slag were evident at the site. The northern portion of the ash pit was delineated with AC-540 concrete markers (approximately 2.4 hectares [6 acres]).

Location: The site was located southeast of the 116-F-14, 107-F Retention Basin.

Process Description: The 126-F-1 site was created as a result of disposal of ash from the 184-F coal-fired steam plant that operated between 1944 and 1965. The ash pipeline originally terminated at a point between the aboveground reactor cooling water effluent lines that discharged to the 107-F Retention Basins. Large amounts of coal ash was sluiced to the ash pit with raw river water through a 20 centimeter (8 inch) ashcolite pipe. Leakage of reactor cooling water from the 116-F-14, 107-F Retention Basins flowed into the northern portion of the ash pit causing it to become radiologically contaminated., and was contained with an earthen dike. The coal ash sluice pipe was extended through the dike in the late 1940s to a point farther south, establishing coal ash discharge to the southern portion of the coal ash pit area.

Related Sites/ Structures: The site was related to the 184-F Powerhouse.

Waste Type: Ash

Waste Description: Unknown amounts of coal ash from the 184-F Powerhouse were sluiced to this unit with raw river water. The ash has been analyzed using the EP Toxicity Test in accordance with Washington Administrative Code (WAC 173-303), and no hazardous materials were found. This site also received low-level radionuclides from effluent system leakage. Radioactive contamination in excess of 50,000 counts/minute existed in the northwest corner of the pit.

Closure Info: The cleanup verification package (CVP), CVP-2002-00004 documented that the remedial action objectives (RAOs) and remedial action goals (RAGs) for the 126-F-1, 184-F Powerhouse Ash Pit have been attained. The RAOs/RAGs were established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD).

Portions of the Ash Pit were contaminated by unplanned releases of 105-F Reactor cooling water effluent. The northern portion of the site has been remediated and backfilled with clean soil to adjacent grade elevations. No remedial action was necessary in the southern portion of the 126-F-1 site, but this portion of the site could not be closed out until radioactive decay

occurred from the original sampling date in 2001 to 2007 to meet the radiological dose limit of 15 milirem/year above natural background.

The contaminants of concern (COCs) for the Ash Pit evolved from the time the site first appeared in the RDR/RAWP until the approval of the Sampling and Analysis Instruction for Confirmatory Sampling of the Southern Portion of the 126-F-1 Ash Pit. The COCs for the Ash Pit waste site consisted of the following: cesium-137, cobalt-60, europium-152, europium-154, europium-155, strontium-90, uranium-234, uranium-235, uranium 238, and arsenic.

Cleanup verification sampling in the northern portion of the site began on July 16, 2002, and concluded on July 17, 2002. The samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the SAP. The cleanup verification sample analytical data were stored in the Hanford Environmental Information System and were summarized in Appendix A of the CVP.

Remedial action at the site began on October 5, 2001. Excavation of the site involved removing the overburden materials and underlying contaminated soil in the northern portion of the site only. Based on field screening, overburden materials identified as potentially clean were placed in a stockpile for potential use as backfill.

The excavation of the northern portion of the site was completed on June 17, 2002, it measured approximately 10,689 meters squared (115,052 square feet) in area with a maximum depth of approximately 4 meters (13 feet). The average bottom elevation of the excavation was 119.8 meters (393.0 feet). A total of approximately 100,964 metric tons (111,313 tons) of contaminated material was disposed at ERDF.

These results also indicated that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

Remedial actions were not required for the northern and southern portions of the site deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	128-F-1	Classification:	Accepted
Names:	128-F-1; 100-F Burning Pit; 100-F Burning Pit No. 1	Reclassification:	No Action (12/8/2003)
Type:	Burn Pit	Start Date:	1/1/1945
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification. The site was used to dispose of nonradioactive, combustible materials from the 100F Area. The site has been backfilled.		
Location:	The site was located directly east of the 126-F-1 Coal Ash Disposal Pile and west of the 118-F-5 Burial Ground.		
Waste Type:	Misc. Trash and Debris		
Waste Description:	The site was used for the disposal of nonradioactive, combustible materials, such as paint waste, office waste, and chemical solvents.		
Closure Info:	In 2003 the waste site evaluation 0100F-CA-0165, Rev. 2 for this site demonstrated that information which included sample results, a field walkdown (site evaluation), and historical data supported reclassification to "No Action". The no action reclassification is documented by		

the signed reclassification form, Control Number 2003-35. However, the attached documentation mistakenly states that the evaluation supports interim closure.

Sampling and evaluation of this site have been performed in accordance with remedial action objectives and goals established by the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington, July 1999 (Remaining Sites ROD). The selected action involved (1) sampling of the site, (2) demonstration through a combination of field screening and confirmational sampling that cleanup goals have been met, and (3) proposal of no further action.

Residual material at the site achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE RL 2002) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999).

Residual soil concentrations support unrestricted future use of shallow zone soil (surface to 15 feet) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code: 128-F-3	Classification: Accepted
Names: 128-F-3; PNL Burn Pit	Reclassification: Interim Closed Out (10/20/2006)
Type: Burn Pit	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed.	
Location: The site was located 25 meters (82 feet) south of the dirt access road that passed south of the 126-F-1 Ash Pit and approximately 70 meters (230 feet) west of the southeast corner of the ash pit.	
Waste Type: Misc. Trash and Debris	
Waste Description: It was not known what was burned at the site. However, Pacific Northwest Laboratory (PNL) and Westinghouse Hanford Company (WHC) employees verified that the site was used for burning. It was assumed the burned material came from the Experimental Animal Farm.	
Closure Info: The Remaining Sites Verification Package, RSVP-2006-042, documents that the waste site has met the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).	

The contaminants of potential concern (COPCs) were identified based on existing historical information for the site and consideration of potentially disposed materials. They included asbestos, arsenic, barium, cadmium, chromium (total and hexavalent), lead, selenium, silver, mercury, pesticides, polychlorinated biphenyls (PCBs), semivolatile organic compounds (SVOCs), volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), gamma energy analysis (GEA), gross alpha, and gross beta.

Soil cleanup levels were established in the Remaining Sites ROD based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against

ecological risk screening levels was made for the site contaminants of concern, contaminants of potential concern, and other constituents. Screening levels were not exceeded for the site constituents, with the exception of barium, boron, and vanadium.

Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. It is believed that the presence of vanadium does not pose a risk to ecological receptors as residual concentrations are below site background levels. The exceedances of soil screening values by residual barium and boron concentrations at the site will be evaluated in the context of additional lines of evidence for ecological effects. A baseline risk assessment for the river corridor portion of the Hanford Site began in 2004, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for the waste site.

Remediation was performed on September 20, 2005, and consisted of the removal of coal ash and surrounding soil associated with excavation of the geophysical anomaly. The excavation was also performed to assure no residual debris or ash associated with historical burning was present at the site. During remediation, a limited amount of wood debris and ash associated with burning was found and removed. The excavation proceeded to a depth of approximately 1.1 meters (3.5 feet) within the site boundary. Approximately 690 metric tons (760 US tons) of coal ash, burn ash, debris, and soil was removed to Environmental Restoration Disposal Facility.

Verification sampling was performed on April 10 and 11, 2006, to collect data to make a decision as to whether the remedial action objectives had been reached. All analytical data were found acceptable for decision-making purposes. The verification sample analytical data were stored in the ENRE project-specific database prior to being submitted for inclusion in the HEIS database. The verification sample analytical data were also summarized in Appendix B of the RSVP.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

The site has been evaluated and remediated in accordance with the Remaining Sites ROD and the RDR/RAWP. Statistical and judgmental sampling to verify the completeness of remediation was performed, and analytical results were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the verification sampling results support a reclassification to interim closed out.

Code:	1607-F1	Classification:	Accepted
Names:	1607-F1; 1607-F1 Sanitary Sewer System; 1607-F1 Septic Tank; 1607-F1 Septic Tank and Associated Drain Field; 100-F Experimental Animal Farm Septic Tank; 124-F-1	Reclassification:	Interim Closed Out (3/14/2008)
Type:	Septic Tank	Start Date:	1/1/1944
Status:	Inactive	End Date:	1/1/1965
Description:	The unit includes a septic tank, drain field and associated pipeline. The septic tank is constructed of reinforced concrete; the walls and floor are 25 centimeters (10 inches) thick. The septic tank has a capacity of 16561.18 liters (4375 gallons). The system could support 125		

persons assuming input of 130 liters (35 gallons) per capita per day and a one day retention period. The drain field is constructed of 10-centimeter (4-inch) vitrified pipe, concrete pipe, or drain tile with a total of 304.8 meters (1000 linear feet) of piping (2.4 linear meters [8 linear feet] per capita). The four laterals are open jointed, 38 meters (125 feet) long, and spaced 2.4 meters (8 feet) apart.

Location: The 1607-F1 Septic Tank is located south of the 105-F Reactor Building. The septic tank and drain field are approximately 91.4 meters (300 feet) west of the 1720-F Building.

Related Sites/ Structures: The site was related to 100-F-26:8 Influent pipelines, 1701-F Badge House (security checkpoint), the 1709-F Fire Station, and the 1720-F Administrative Office and change room for security patrol personnel.

Waste Type: Sanitary Sewage

Waste Description: This unit received an unknown amount of sanitary sewage from the 1701-F Badge House (security checkpoint), the 1709-F Fire Station, and the 1720-F Administrative Office and change room for security patrol personnel. Since the site was connected to administrative and support facilities (security and fire protection), the site should not have received hazardous contaminants.

Closure Info: 1607-F1 and 100-F-26:8 were addressed as a group. The information below documents information for the group of sites.

The Remaining Sites Verification Package (RSVP) for the 1607-F1 sanitary sewer system and 100-F-26:8 sanitary sewer pipelines waste sites has documented that they have met the Remedial Action Objectives (RAOs) and the corresponding Remedial Action Goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD) for interim closure.

Remediation of the 1607-F1 and 100-F-26:8 waste sites were performed from January 8 to April 3, 2007 and documented as one RSVP. Both sites were excavated to approximately 3.4 meters (11 feet) below grade resulting in a combined volume of approximately 464 cubic meters (607 cubic yards) of material stockpiled for disposal at the Environmental Restoration Disposal Facility (ERDF). Approximately 266 meters (872 feet) of pipeline were removed during remediation. There were no anomalies or stained soil discovered during remediation.

During pipeline excavation, a french drain was discovered on the west side of the former 1709-F facility. Although this french drain was independent of the pipelines, it was removed.

The COCs/COPCs were established using the confirmatory sampling analytical results. Based on these results, the COC/COPCs for the 1607-F1 and 100-F-26:8 waste sites verification sampling design were the metals barium, lead, and zinc; pesticides (dichlorodiphenyl-dichloroethane [DDD], dichlorodiphenyl-dichloroethylene [DDE], dichlorodiphenyl-trichloroethane [DDT]); SVOCs (benzo(a)pyrene, benzo(k)fluoranthene, and chrysene); and PCBs (aroclor-1260). Petroleum hydrocarbons and mercury were added as COCs/COPCs based on the discovery of the 1709-F french drain during remediation of the 100-F-26:8 pipelines. These additions were based on the assumption that the probable sources of effluent in the french drain were from hose drying and truck washing activities. Therefore, potential contaminants in the effluent were from motor oil leaks and broken mercury switches.

Verification sampling for the remediated 1607-F1 and the 100 F 26:8 waste sites was performed in September and October 2007. Evaluation of the verification sampling results shows that all direct exposure cleanup levels were met for the four decision units of the 1607-F1 and 100-F-26:8 waste sites: the 1607-F1 septic tank and 100-F-26:8 pipelines excavation footprint, 1709-F

french drain, road crossing areas, and overburden stockpiles.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 meters [15 feet] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. No institutional controls are required for this site to prevent uncontrolled drilling or excavation into deep zone [i.e., below 4.6 m (15 ft)].

State background value of 20 mg/kg (Washington Administrative Code [WAC] 173-340), arsenic was added to the final list of COCs for the site.

On July 21, 2000, the majority of the excavation was completed. Because of elevated lead levels in an area of the site excavation, additional soil was excavated in December 2000. Pre- and post-remediation topographic maps including overburden pile locations are shown in the site Closeout Verification Package (CVP). The general average depth of the bottom of the excavation in the deep zone sampling areas was 5.6 meters (18.4 feet) below ground surface. The majority of the site excavation depth was 4.6 meters (15 feet) or less below ground surface, generally corresponding with the former pipeline invert depth. The excavation was approximately 17,629 square meters (189,660 square feet) in area. Approximately 32,725 metric tons (35,998 tons) of material from the site were disposed of at ERDF.

Cleanup verification sampling began on July 17, 2000, and was finished on December 12, 2000. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the Sample Analysis Plan (SAP) (DOE/RL-96-22).

The CVP demonstrated that remedial action at the 100-H-21 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved Interim Action Record of Decision (ROD, EPA 1995) and Remedial Design Report/Remedial Action Work Plan (RDR/RAWP, DOE/RL-96-17). The remaining soils at the 100-H-21 Pipelines site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-H-21 Pipelines site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in overburden and the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-H-21 Pipelines site is verified to be remediated in accordance with the ROD. The overburden has been verified as suitable for use as backfill in accordance with the ROD.

Code:	100-H-3	Classification:	Accepted
Names:	100-H-3; 1716-H Garage Fuel Tank Site	Reclassification:	Interim Closed Out (6/1/2011)
Type:	Storage Tank	Start Date:	1/1/1949
Status:	Inactive	End Date:	
Description:	The site may contain one or more underground storage tanks (USTs) from the 1716-H Garage. The garage has been demolished. Some disturbance of the concrete pavement is visible at the site.		
Location:	The 1716-H Garage was located west of the 107-H Retention Basin (116-H-7) and north of the 1717-H Combined Shops.		
Related Sites/ Structures:	The tanks supported the 1716-H Garage.		
Closure Info:	The 100-H-3 waste site was remediated between December 21 and 30, 2009. Approximately 894 bank cubic meters (1,170 bank cubic yards) of soil and debris were removed from the site and disposed at the Environmental Restoration Disposal Facility. Remediation included removal of the pump island as well as the fuel supply lines.		

At the expected location of the tanks, the excavation continued until the approximate depth of

3.5 m (11.5 ft) was reached. The adjacent french drain and debris at the former tank location were also removed. No soil staining or anomalous hazardous debris was noted during excavation and loadout of material associated with the waste site.

Code: 100-H-4 **Classification:** Accepted
Names: 100-H-4; 1717-H Hot Shop; Contaminated Storage Unit; French Drain **Reclassification:** Rejected (6/1/2011)
Type: Maintenance Shop **Start Date:**
Status: Inactive **End Date:**

Description: The french drain cannot be visually located.

Location: The 1717-H Maintenance Shop was located west of the 107-H Basins and south of the 1716-H Service Station. The building has been demolished. An employee interview indicates a portion of the shop was used for working on very low-level radioactive materials. Drawing SK-1-7325 identifies two "hot shops." Drawing SK-1-7328 proposed a building addition, also designated as a "hot shop." Drawing P-9343 indicates an existing drywell.

Waste Type: Water

Waste

Description:

Closure Info: Remedial action at the 100-H-4, 1717-H Hot Shop, French Drain, and Contaminated Storage Unit waste site was performed between January 4 and 18, 2010. The excavation resulted in approximately 3,148 bank cubic meters (4,117 bank cubic yards [BCY]) of contaminated soil. All material was direct loaded for disposal at the Environmental Restoration Disposal Facility (ERDF).

The footprint of the 1717-H Building, including the 1717-H Hot Shop and the foundation wall, was excavated to a depth of approximately 1 m (3 ft) below ground surface. The excavation activities included remediation of former locations of decontamination tanks and exterior exhaust, as per approved excavation design. The french drain located northeast of the building footprint was excavated to a depth of approximately 4 m (12 ft). A concrete floor trap with metal lid and insulation piece was uncovered and removed. All pieces including the drainpipe were excavated and loaded out in a void-space waste disposal can for grout filling at ERDF. The process sewer line and the sanitary sewer line were completely removed within the 1717-H Building footprint and excavation boundary. Other materials and debris such as concrete and asphalt were excavated and removed from the waste site.

Due to remediation exceeding the excavation design dimensions, two additional features were uncovered: a 6-in.-diameter cast iron (CI) pipeline running in the east-west direction to the northern side of the 1717-H footprint excavation and a Y-shaped concrete thrust block structure. These two features were left in place. Although not confirmed by historical drawings or historical aerial photographs, it is suspected that the 6-in.-diameter CI pipeline is part of the 100-H-35, 100-H Clean Water Pipelines, 100-H Service Water Pipelines. However, due to the lack of available historical information, this pipeline will be included with 100-H-56, H-Area Miscellaneous Pipelines. The Y-shaped thrust blocks do not encase any pipelines. These concrete thrust blocks do not appear on any historical drawings or historical aerial photographs

Code: 100-H-5 **Classification:** Accepted
Names: 100-H-5; 107-H Buried Sludge Site; 107-H Grave; 107-H Retention Basin Sludge Burial Site; Sludge Disposal Trench **Reclassification:** Interim Closed Out (12/18/2000)

Type:	Burial Ground	Start Date:	1/1/1953
Status:	Inactive	End Date:	
Description:	This site has been remediated and closed out. The trench was about 100 meters (328 feet) long, 16 meters (52 feet) wide, and 4.6 meters (15 feet) deep.		
Location:	The site is located east of the southeast corner of the 107-H Retention Basin. In 1997, a Ground Penetrating Radar (GPR) scan was done to establish the location of the trench. The GPR scan placed the trench approximately 52 meters (170 feet) east of the southeast corner of the 116-H-7 Basin, in an area formerly used for orchards. According to the Technical Baseline Report, people interviewed for information on this site placed it in several locations, including farther north, immediately adjacent to the 107-H Retention Basin or further south and east of the southeast corner of 107-H. (Note the references in the technical baseline report are inverted.)		
Process Description:	The site is a trench that received an unknown quantity of sludge removed from the 107-H Retention Basin during repair work in the Spring of 1953.		
Related Sites/ Structures:	The 107-H Retention Basin (116-H-7) is related to this site.		
Waste Type:	Sludge		
Waste Description:	In 1975, samples of sludge from the basin floor had a maximum Geiger-Mueller (GM) probe reading of 20,000 counts/minute. Samples had an average concentration of 3.1E+04 picocuries/gram beta/gamma and 57 picocuries/gram of plutonium-239/240. The sludge buried in the trench would have similar characteristics.		
Closure Info:	The site was remediated to meet the cleanup standards and closed out on December 12, 2000.		
	<p>Remedial action objectives and goals for the 100-H-5 site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Amendment to the Interim Action Record of Decision (ROD) for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1997) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 1998). Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established. Waste site contaminants of concern (COCs) identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE-RL 1998).</p> <p>The COCs identified for this site are cobalt-60, cesium-137, europium-152, europium-154, plutonium-238, plutonium-239/240, strontium-90, and lead.</p> <p>Remedial action at the 100-H-5 site began on September 27, 1999. Excavation of the site involved removing the overburden materials, buried sludge and debris, and underlying contaminated soil. Based on field screening (discussed in Section 4.2 of the CVP), overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at the Environmental Restoration Disposal Facility (ERDF). During site excavation, the area where buried sludge and debris were encountered at the south end of the site was not as wide as the estimated footprint of the sludge trench. To avoid unnecessarily excavating and disposing of uncontaminated soil, the excavation at the south end of the site narrowed from the original estimated design site footprint. On April 28, 2000, the excavation was completed.</p> <p>The elevation of the bottom of the excavation was at 121.4 meters (398.2 feet) upon completion. The surface reference elevation and design backfill elevation are 126.5 meters</p>		

(415 feet). The excavation was approximately 3,308 square meters (35,589 square feet) in area with a maximum depth of approximately 5.1 meters (16.7 feet). Approximately 23,525 metric tons (25,877 tons) of material from the site were disposed of at ERDF.

The Cleanup Verification Package (CVP) demonstrated that remedial action at the 100-H-5 site achieved the Remedial Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) established in the approved interim action ROD amendment (EPA 1997) and Remedial Design Report/ Remedial Action Work Plan (RDR/RAWP) (DOE-RL 1998). The remaining soils at the 100-H-5 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-H-5 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF, that residual COC concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-H-5 site has been verified to be remediated in accordance with the ROD amendment.

Code:	100-H-7	Classification:	Accepted
Names:	100-H-7; French Drain A	Reclassification:	No Action (7/28/2009)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site consists of a french drain and an adjoining pipeline. It is a vertical, 76-centimeter (30-inch) diameter vitrified clay pipe with a metal lid. Its upper surface is at grade. A 6.3 centimeter (2.5 inch) steel pipe exits the reactor building at a point in line with the drain, suggesting the possibility of drainage from the 105-H Building to the drain. The drain had no markings.		
Location:	The site was located south-southeast of the northeast corner of the 105-H reactor building.		
Related Sites/ Structures:	The drain was associated with the 105-H Reactor Building.		
Waste Type:	Process Effluent		
Waste Description:			
Closure Info:	The Remaining Sites Verification Package (RSVP-2008-056) for the 100-H-7 waste site has documented that the remedial action objectives (RAOs) and remedial action goals (RAGs) have been met as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL -2006-96-17, Rev. 5) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) and is recommended for reclassification to No Action.		

Confirmatory sampling for the site was performed in November 2008 to collect data to determine if the site met remedial action goals (RAGs). The contaminants of potential concern (COPCs) for confirmatory sampling as listed in the sampling and analysis plan included: cobalt-60, cesium-137, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, hexavalent chromium, lead, mercury, semivolatile organic compounds, and polychlorinated biphenyls (PCBs).

Results of the confirmatory sample analysis showed groundwater and/or Columbia River protection RAGS were exceeded by copper, lead, zinc, indeno(1,2,3-cd) pyrene, and aroclor-1260. However, RESidual RADioactivity (RESRAD) modeling illustrated that these contaminants were not predicted to reach groundwater from this site within the next 1,000 years. All confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The laboratory-reported data results for all constituents were stored in the WCH Environmental Restoration project-specific database prior to submission for archival in the Hanford Environmental Information System site-wide database. The data were also summarized in Appendix A of the RSVP.

A geophysical survey was performed for the purpose of obtaining an excavation permit (Bergstrom and Mitchell 2008). The results did not detect the french drain, they did show the site to be an area of scattered buried debris and possible buried utilities. Confirmatory sampling activities, however, found the french drain intact (minus the metal lid). The drain pipe from the 105-H building was also found in place connected to the 100-H-7 french drain.

Prior to confirmatory sampling activities, it was unknown whether demolition and decommissioning of the 105-H Reactor Building also removed the 100-H-7 waste site. Confirmatory sampling activities, found the french drain intact (minus the metal lid). The drain pipe from the 105-H building was also found in place connected to the 100-H-7 french drain. Sampling results show that residual contaminant concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	100-H-8	Classification:	Accepted
Names:	100-H-8; French Drain B	Reclassification:	No Action (12/3/2009)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site consisted of as a 91-centimeter (36-inch) diameter concrete pipe with a steel lid. The drain was buried vertically with its upper surface at grade and was filled with gravel to within 20 centimeters (8 inches) of its top. Prior to site evaluation the drain was surrounded by a rope and posts and signs that read "Danger - Keep Out".		
Location:	The unit is located east-southeast of the northeast corner of the 105-H Reactor Building.		
Process Description:	During site evaluation it was determined that this drain was designed and used to collect steam condensate from a former overhead steam line that serviced the emergency cooling water tower located on the northeast side of the 105-H Reactor Building. Sanitary river water was supplied to the 184-H power house, where it was converted to steam by the boiler and carried through aboveground steam lines to the 100-H Area facilities. Boiler water may have been treated with sodium sulfate, trisodium phosphate, and/or chromates.		
Related Sites/ Structures:	This site was associated with the 105-H reactor building.		
Waste Type:	Process Effluent		
Waste Description:			
Closure Info:	In accordance with evaluation for the Remaining Sites Verification Package, RSVP-2006-031,		

it has been determined that site reclassification to No Action was supported by confirmatory sampling results. The results determined that the current site conditions meet the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units.

Confirmatory sampling was performed in November 2008. The waste site was sampled for inductively coupled plasma metals, mercury, hexavalent chromium, and polychlorinated biphenyls (PCBs) at the request of the Washington State Department of Ecology and in agreement with the U.S. Department of Energy, Richland Operations Office. These were the only COPCs retained for confirmatory sampling of this site. Soil pH was performed to support site evaluation. Analytical results from confirmatory sampling show only copper and lead present at concentrations exceeding groundwater and river protection remedial action goals. However, RESidual RADioactivity modeling shows these contaminants are not expected to reach groundwater within the next 1,000 years.

Excavation of the site revealed the french drain was in place and largely intact. The metal lid described in WIDS was not in place. Inside the french drain were leach rocks that were stained red. There was no fine sediment inside the drain to sample. No elevated VOCs or radiological readings were detected on the french drain contents. Several pipes of various sizes were found during the excavation. None were intact or in service. Based on the location and size of the pipes they were determined to be either water or steam lines. No material was evident in the pipes to sample and no elevated VOCs or radiological readings were detected on the pipes. The discovered pipes were left in the excavation when it was backfilled.

The vertical concrete pipe comprising the french drain was found to extend to a depth of approximately 3.7 m (12-ft). Directly below the drain, red stained soil was visible extending to the bottom of the excavation. The red stain also extended horizontally in a thin layer around the sides of the excavation. The color of the stained soil beneath the french drain matched the stain on the rocks within the drain. A primary and duplicate sample was collected of the stained soil directly below the drain. The material present inside the drain consisted of only rock with no fine grained material and therefore was not amenable for sample collection.

All confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to submission for archival in the Hanford Environmental Information System site-wide database and were summarized in Appendix C of the RSVP.

Evaluation of the analytical results indicated the site meets RAGs for direct exposure, groundwater, and river protection. The site will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario, and no institutional controls are required. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code: 100-H-9	Classification: Accepted
Names: 100-H-9; French Drain C	Reclassification: Interim Closed Out (6/22/2006)
Type: French Drain	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed out. The waste site consisted of a vertical 61-	

centimeter (24-inch) diameter concrete pipe with a rusted metal lid. The drain had no markings.

Location: The unit was located east of the northeast corner of the 105-H Reactor Building, adjacent to the north wall.

**Related Sites/
Structures:** This unit was associated with the 105-H Reactor Building.

Waste Type: Process Effluent
**Waste
Description:**

Closure Info: 118-H-6:2, 118-H-6:3, 118-H-6:6, 100-H-9, 100-H-10, 100-H-13, 100-H-11, 100-H-12, 100-H-14 and 100-H-31 were addressed as a group. The information below documents information for the group of sites.

The CVP-2006-00003 documents that removal action at the 105-H Reactor subsites (118-H-6:2, 118 H-6:3, and 118-H-6:6) has achieved the removal action objectives and remedial action goals (RAO/RAGs) established in The Action Memorandum for the 105-D and 105-H Reactor Buildings and Ancillary Facilities and the Removal Action Work Plan for 105-D and 105-H Building Interim Safe Storage Projects and Ancillary Buildings. The RAGs were further detailed in the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 100 Area Remedial Action Sampling and Analysis Plan, and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.

Per the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF).

During D activities additional evaluation was required in order to determine if the soils underlying the former FSB floor (118-H-6:3) had achieved the RAGs. Therefore, the evaluation of the FSB soils and deep zone side-slope soils also refer to the soils underlying waste sites 100-H-11, 100-H-12, and 100 H 14.) To determine compliance with the RAGs, and in accordance with the 105-H Reactor SAP, radiological surveys and verification sampling analysis were performed on the FSB underlying soils and deep zone side-slope soils.

These data were used in the RESRAD computer model to verify that cleanup criteria were satisfied. The local contamination was removed in preparation for clean demolition, and a fixative was applied as required. With one exception, there are no below-grade structures remaining. A portion of the FSB floor, at its northern end between the two access labyrinths to the D elevator, remains.

Verification soil samples were collected from soils underlying the former FSB floor in conformance with the 105-H Reactor SAP. Samples numbers All demolition debris from excavations associated with the area was sent to ERDF. Final cleanup verification samples for the FSB underlying soils and deep zone side-slope soils were collected following evaluation of field screening for radiological contaminants using global positioning environmental radiological surveyor (GPERS) and laser-assisted ranging and data system (LARADS) surveys. This field screening was performed in order to obtain an initial assessment of attainment of radiological cleanup levels

The sample design for the FSB underlying soils was developed specifically to address potential contamination from the known leakage of the FSB. Samples were collected from 10 random

sample locations and 3 judgmental sample locations. At each location, soil grab samples were collected from two intervals: the first native soils below the FSB over a 0.3 meter (1 foot) interval and also at 2.4 meters (8 feet) to 3.1 meters (10 feet) below the surface. Soil samples were collected on March 24 and 25, 2004, and on April 6, 2004. The results of the focused sampling (i.e., 3 judgmental samples) are consistent with the statistical sampling results (i.e., the 10 random sample locations) and are provided in Appendix A of the CVP-2006-00003. As yet the results from the HEIS sample numbers have not been loaded into the database.

The verification sample design for the deep zone side-slope soils in 118-H-6:6 consisted of dividing the area into three equal sections, with a composite of four soil grab samples being collected within each area. Soil samples were collected on March 29, 2004. The verification sample design for the deep zone side-slope soils was in accordance with the 100 Area SAP and was detailed in the SAP.

Waste site contaminants of concern (COCs) identified in the SAP through process knowledge classified the different areas and structures into affected media, a summary list of the COCs included: Americium-241, Carbon-14, Cesium-137, Cobalt-60, Europium-152, Europium-154, Europium-155, Neptunium-237, Nickel-63, Plutonium-238, Plutonium-239/240, Strontium-90, Thorium-228, Thorium-232, Tritium (H-3), Uranium-234, Uranium-235, Uranium-238, Hexavalent chromium, Lead, Mercury, and PCBs.

The remaining soils at the 105 H Reactor site have either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The subsite has been verified to be remediated in accordance with the Removal Action Work Plan for 105-D and 105 H Building Interim Safe Storage Projects and Ancillary Buildings and the Remedial Design Report/Remedial Action Work Plan for the 100 Area and can be interim closed. The CVP does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]) therefore, institutional controls to prevent uncontrolled drilling or excavation into these deep zone soils are required.

Code:	100-H-10	Classification:	Accepted
Names:	100-H-10; French Drain D	Reclassification:	Interim Closed Out (6/22/2006)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed. The unit consisted of a vertically buried 122-centimeter (48-inch) diameter vitrified clay pipe with a steel lid. It was suspected to be a french drain. The unit had no markings.		
Location:	The unit was located north of the center point of the 105-H Reactor Building, adjacent to the north wall.		
Waste Type:	Process Effluent		
Waste Description:			
Closure Info:	118-H-6:2, 118-H-6:3, 118-H-6:6, 100-H-9, 100-H-10, 100-H-13, 100-H-11, 100-H-12, 100-H-14 and 100-H-31 were addressed as a group. The information below documents information for		

the group of sites.

The CVP-2006-00003 documents that removal action at the 105-H Reactor subsites (118-H-6:2, 118 H-6:3, and 118-H-6:6) has achieved the removal action objectives and remedial action goals (RAO/RAGs) established in The Action Memorandum for the 105-D and 105-H Reactor Buildings and Ancillary Facilities and the Removal Action Work Plan for 105-D and 105-H Building Interim Safe Storage Projects and Ancillary Buildings. The RAGs were further detailed in the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 100 Area Remedial Action Sampling and Analysis Plan, and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.

Per the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF).

The remaining soils at the 105 H Reactor site have either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The subsite has been verified to be remediated in accordance with the Removal Action Work Plan for 105-D and 105 H Building Interim Safe Storage Projects and Ancillary Buildings and the Remedial Design Report/Remedial Action Work Plan for the 100 Area and can be interim closed. The CVP does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]) therefore, institutional controls to prevent uncontrolled drilling or excavation into these deep zone soils are required.

Code: 100-H-11	Classification: Accepted
Names: 100-H-11; Expansion Box French Drain E	Reclassification: Interim Closed Out (6/22/2006)
Type: French Drain	Start Date:
Status: Inactive	End Date:
Description:	The site has been remediated and interim closed. It appeared that the drain was installed to provide drainage for an expansion box. The drain had no markings.
Location:	The unit was located next to the west wall of the south wing of the 105-H Reactor Building.
Process Description:	This unit was a vertical 0.76 meters (30-inch) diameter steel manhole set in concrete that provided access to it. It appeared to be a french drain (drain) located at the bottom of a concrete expansion box in which a 1.52 meters (60-inch) steel effluent line made a 40-degree turn to the southwest. The 100 H-11 french drain provided drainage for any leakage that might have occurred from the effluent line within the expansion box.
Closure Info:	118-H-6:2, 118-H-6:3, 118-H-6:6, 100-H-9, 100-H-10, 100-H-13, 100-H-11, 100-H-12, 100-H-14 and 100-H-31 were addressed as a group. The information below documents information for the group of sites.

The CVP-2006-00003 documents that removal action at the 105-H Reactor subsites (118-H-6:2, 118 H-6:3, and 118-H-6:6) has achieved the removal action objectives and remedial action goals (RAO/RAGs) established in The Action Memorandum for the 105-D and 105-H Reactor Buildings and Ancillary Facilities and the Removal Action Work Plan for 105-D and 105-H Building Interim Safe Storage Projects and Ancillary Buildings. The RAGs were further detailed in the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 100 Area Remedial Action Sampling and Analysis Plan, and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.

Per the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF).

During D activities additional evaluation was required in order to determine if the soils underlying the former FSB floor (118-H-6:3) had achieved the RAGs. Therefore, the evaluation of the FSB soils and deep zone side-slope soils also refer to the soils underlying waste sites 100-H-11, 100-H-12, and 100 H 14.) To determine compliance with the RAGs, and in accordance with the 105-H Reactor SAP, radiological surveys and verification sampling analysis were performed on the FSB underlying soils and deep zone side-slope soils.

These data were used in the RESRAD computer model to verify that cleanup criteria were satisfied. A portion of the FSB floor, at its northern end between the two access labyrinths to the D elevator, remains.

Verification soil samples were collected from soils underlying the former FSB floor in conformance with the 105-H Reactor SAP. Samples numbers All demolition debris from excavations associated with the area was sent to ERDF. Final cleanup verification samples for the FSB underlying soils and deep zone side-slope soils were collected following evaluation of field screening for radiological contaminants using global positioning environmental radiological surveyor (GPERS) and laser-assisted ranging and data system (LARADS) surveys. This field screening was performed in order to obtain an initial assessment of attainment of radiological cleanup levels

The sample design for the FSB underlying soils was developed specifically to address potential contamination from the known leakage of the FSB. Samples were collected from 10 random sample locations and 3 judgmental sample locations. At each location, soil grab samples were collected from two intervals: the first native soils below the FSB over a 0.3 meter (1 foot) interval and also at 2.4 meters (8 feet) to 3.1 meters (10 feet) below the surface. Soil samples were collected on March 24 and 25, 2004, and on April 6, 2004. The results of the focused sampling (i.e., 3 judgmental samples) are consistent with the statistical sampling results (i.e., the 10 random sample locations) and are provided in Appendix A of the CVP-2006-00003. As yet the results from the HEIS sample numbers have not been loaded into the database.

The verification sample design for the deep zone side-slope soils in 118-H-6:6 consisted of dividing the area into three equal sections, with a composite of four soil grab samples being collected within each area. Soil samples were collected on March 29, 2004. The verification sample design for the deep zone side-slope soils was in accordance with the 100 Area SAP and was detailed in the SAP.

Waste site contaminants of concern (COCs) identified in the SAP through process knowledge classified the different areas and structures into affected media, a summary list of the COCs included: Americium-241, Carbon-14, Cesium-137, Cobalt-60, Europium-152, Europium-154, Europium-155, Neptunium-237, Nickel-63, Plutonium-238, Plutonium-239/240, Strontium-90, Thorium-228, Thorium-232, Tritium (H-3), Uranium-234, Uranium-235, Uranium-238, Hexavalent chromium, Lead, Mercury, and PCBs.

The remaining soils at the 105 H Reactor site have either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean

backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The subsite has been verified to be remediated in accordance with the Removal Action Work Plan for 105-D and 105 H Building Interim Safe Storage Projects and Ancillary Buildings and the Remedial Design Report/Remedial Action Work Plan for the 100 Area and can be interim closed. The CVP does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]) therefore, institutional controls to prevent uncontrolled drilling or excavation into these deep zone soils are required.

Code:	100-H-12	Classification:	Accepted
Names:	100-H-12; Expansion Box French Drain F and Shielding Lead	Reclassification:	Interim Closed Out (6/22/2006)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed. The site consisted of a french drain, accessed through a 0.76-meter (30-inch) vertical steel manhole set in a concrete pad.		
Location:	The site was located in the corner formed by the east wall of the south wing and the south wall of the east wing of the 105-H Reactor Building. The drain was at the bottom of a concrete expansion box.		
Process Description:	The site consisted of a french drain, accessed through a 0.76-meter (30-inch) vertical steel manhole set in a concrete pad. The french drain was located at the bottom of a concrete expansion box, in which a 1.5-meter (60-inch) steel reactor effluent pipeline made a 90-degree turn from south to east. The french drain appeared to have been installed to provide drainage for any leakage that might have occurred in the expansion box. The drain had no markings.		
Related Sites/Structures:	The site was associated with the 105-H Reactor Building and radioactive process effluent pipelines. 100-H-11, Expansion Box French Drain F, was of a similar structure and over the same radioactive process effluent pipeline.		
Waste Type:	Process Effluent		
Waste Description:	The french drain may have received radioactive process effluent.		
Closure Info:	118-H-6:2, 118-H-6:3, 118-H-6:6, 100-H-9, 100-H-10, 100-H-13, 100-H-11, 100-H-12, 100-H-14 and 100-H-31 were addressed as a group. The information below documents information for the group of sites.		

The CVP-2006-00003 documents that removal action at the 105-H Reactor subsites (118-H-6:2, 118 H-6:3, and 118-H-6:6) has achieved the removal action objectives and remedial action goals (RAO/RAGs) established in The Action Memorandum for the 105-D and 105-H Reactor Buildings and Ancillary Facilities and the Removal Action Work Plan for 105-D and 105-H Building Interim Safe Storage Projects and Ancillary Buildings. The RAGs were further detailed in the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 100 Area Remedial Action Sampling and Analysis Plan, and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.

Per the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 105 H Reactor ancillary support areas and

below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF).

During D activities additional evaluation was required in order to determine if the soils underlying the former FSB floor (118-H-6:3) had achieved the RAGs. Therefore, the evaluation of the FSB soils and deep zone side-slope soils also refer to the soils underlying waste sites 100-H-11, 100-H-12, and 100 H 14.) To determine compliance with the RAGs, and in accordance with the 105-H Reactor SAP, radiological surveys and verification sampling analysis were performed on the FSB underlying soils and deep zone side-slope soils.

These data were used in the RESRAD computer model to verify that cleanup criteria were satisfied. The local contamination was removed in preparation for clean demolition, and a fixative was applied as required. With one exception, there are no below-grade structures remaining. A portion of the FSB floor, at its northern end between the two access labyrinths to the D elevator, remains.

Verification soil samples were collected from soils underlying the former FSB floor in conformance with the 105-H Reactor SAP. Samples numbers All demolition debris from excavations associated with the area was sent to ERDF. Final cleanup verification samples for the FSB underlying soils and deep zone side-slope soils were collected following evaluation of field screening for radiological contaminants using global positioning environmental radiological surveyor (GPERS) and laser-assisted ranging and data system (LARADS) surveys. This field screening was performed in order to obtain an initial assessment of attainment of radiological cleanup levels

The sample design for the FSB underlying soils was developed specifically to address potential contamination from the known leakage of the FSB. Samples were collected from 10 random sample locations and 3 judgmental sample locations. At each location, soil grab samples were collected from two intervals: the first native soils below the FSB over a 0.3 meter (1 foot) interval and also at 2.4 meters (8 feet) to 3.1 meters (10 feet) below the surface. Soil samples were collected on March 24 and 25, 2004, and on April 6, 2004. The results of the focused sampling (i.e., 3 judgmental samples) are consistent with the statistical sampling results (i.e., the 10 random sample locations) and are provided in Appendix A of the CVP-2006-00003. As yet the results from the HEIS sample numbers have not been loaded into the database.

The verification sample design for the deep zone side-slope soils in 118-H-6:6 consisted of dividing the area into three equal sections, with a composite of four soil grab samples being collected within each area. Soil samples were collected on March 29, 2004. The verification sample design for the deep zone side-slope soils was in accordance with the 100 Area SAP and was detailed in the SAP.

Waste site contaminants of concern (COCs) identified in the SAP through process knowledge classified the different areas and structures into affected media, a summary list of the COCs included: Americium-241, Carbon-14, Cesium-137, Cobalt-60, Europium-152, Europium-154, Europium-155, Neptunium-237, Nickel-63, Plutonium-238, Plutonium-239/240, Strontium-90, Thorium-228, Thorium-232, Tritium (H-3), Uranium-234, Uranium-235, Uranium-238, Hexavalent chromium, Lead, Mercury, and PCBs.

The remaining soils at the 105 H Reactor site have either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that

residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The subsite has been verified to be remediated in accordance with the Removal Action Work Plan for 105-D and 105 H Building Interim Safe Storage Projects and Ancillary Buildings and the Remedial Design Report/Remedial Action Work Plan for the 100 Area and can be interim closed. The CVP does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]) therefore, institutional controls to prevent uncontrolled drilling or excavation into these deep zone soils are required.

Code:	100-H-13	Classification:	Accepted
Names:	100-H-13; French Drain G	Reclassification:	Interim Closed Out (6/22/2006)
Type:	French Drain	Start Date:	
Status:	Inactive	End Date:	
Description:	The site has been remediated and interim closed. The site consisted of a french drain that was constructed of vitrified clay pipe and covered by two metal lids (the second metal lid positioned 15.2 centimeters [6 inches] below the first).		
Location:	The site was located on the east side of the 105-H Reactor Building, 5.5 meters (18 feet) south of the ramp, and 6.1 meters (20 feet) east of the east wall of the 105-H Reactor Building.		
Process Description:	The site had a metal lid with a second metal lid located 15.2 centimeters (6 inches) below the first. A 6.3-centimeter (2.5-inch) stainless steel pipe emerged from the 105-H Reactor Building wall, ran downward to the surface, and disappeared at a point in approximate alignment with the site. An asphalt surface repair mark ran through the asphalt from the point where the pipeline entered the ground to the french drain. This suggests the possibility of drainage from the Reactor Building.		
Related Sites/ Structures:	This unit was associated with the 105-H Reactor Building.		
Waste Type:	Process Effluent		
Waste Description:	The site is suspected of having received drainage from the 105-H Reactor Building.		
Closure Info:	118-H-6:2, 118-H-6:3, 118-H-6:6, 100-H-9, 100-H-10, 100-H-13, 100-H-11, 100-H-12, 100-H-14 and 100-H-31 were addressed as a group. The information below documents information for the group of sites.		

The CVP-2006-00003 documents that removal action at the 105-H Reactor subsites (118-H-6:2, 118 H-6:3, and 118-H-6:6) has achieved the removal action objectives and remedial action goals (RAO/RAGs) established in The Action Memorandum for the 105-D and 105-H Reactor Buildings and Ancillary Facilities and the Removal Action Work Plan for 105-D and 105-H Building Interim Safe Storage Projects and Ancillary Buildings. The RAGs were further detailed in the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 100 Area Remedial Action Sampling and Analysis Plan, and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.

Per the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF).

During D activities additional evaluation was required in order to determine if the soils underlying the former FSB floor (118-H-6:3) had achieved the RAGs. Therefore, the evaluation of the FSB soils and deep zone side-slope soils also refer to the soils underlying waste sites 100-H-11, 100-H-12, and 100 H 14.) These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The subsite has been verified to be remediated in accordance with the Removal Action Work

Plan for 105-D and 105 H Building Interim Safe Storage Projects and Ancillary Buildings and the Remedial Design Report/Remedial Action Work Plan for the 100 Area and can be interim closed. The CVP does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]) therefore, institutional controls to prevent uncontrolled drilling or excavation into these deep zone soils are required.

Code: 100-H-14 **Classification:** Accepted

Names: 100-H-14; Surface Contamination Zone H **Reclassification:** Interim Closed Out (6/22/2006)

Type: Unplanned Release **Start Date:**

Status: Inactive **End Date:**

Description: The site has been remediated and interim closed. The site consisted of an area of surface contamination located next to the south wall of the 105-H Reactor Building fuel storage basin (FSB). The area had been surface stabilized with 46 to 61 centimeters (18 to 24 inches) of gravel and cobbles.

Location: The site was located inside the exclusion area, on the southeast side of 105-H.

Related Sites/ Structures: The site was associated with the 105-H Reactor Building.

Waste Type: Chemical Release

Waste Description: No documentation has been found to identify the source of the contamination or describe the stabilization activity.

Closure Info: 118-H-6:2, 118-H-6:3, 118-H-6:6, 100-H-9, 100-H-10, 100-H-13, 100-H-11, 100-H-12, 100-H-14 and 100-H-31 were addressed as a group. The information below documents information for the group of sites.

The CVP-2006-00003 documents that removal action at the 105-H Reactor subsites (118-H-6:2, 118 H-6:3, and 118-H-6:6) has achieved the removal action objectives and remedial action goals (RAO/RAGs) established in The Action Memorandum for the 105-D and 105-H Reactor Buildings and Ancillary Facilities and the Removal Action Work Plan for 105-D and 105-H Building Interim Safe Storage Projects and Ancillary Buildings. The RAGs were further detailed in the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 100 Area Remedial Action Sampling and Analysis Plan, and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.

Per the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF).

The subsite has been verified to be remediated in accordance with the Removal Action Work Plan for 105-D and 105 H Building Interim Safe Storage Projects and Ancillary Buildings and the Remedial Design Report/Remedial Action Work Plan for the 100 Area and can be interim closed. The CVP does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]) therefore, institutional controls to prevent uncontrolled drilling or excavation into these deep zone soils are required.

Code: 100-H-17

Classification: Accepted

Names: 100-H-17; 116-H-2 Trench Overflow

Reclassification: Interim Closed Out (3/1/2001)

 Underground Pipelines

Type: Radioactive Process Sewer **Start Date:** 1/1/1949

Status: Inactive **End Date:** 1/1/1965

Description: This site has been remediated and was closed out in March 2001. The site is the underground 100-H Reactor cooling water effluent lines. These include those effluent lines that transported 105-H Reactor cooling water from the reactor to the 116-H-7 (107-H) Retention Basin, and from the basin to the 116-H-5 (1904-H) Outfall Structure and/or to the 116-H-1 Trench. This waste site includes all associated expansion and valve boxes and excludes the retention basin, outfall structure, and those effluent lines that are within the confines of the 105-H Reactor Building. It also excludes all reactor influent lines that are upstream of the reactor building. The site also includes the pipeline(s) from the 1608-H Waste Water Pumphouse to 116-H-2 (1608-H Liquid Waste Disposal Trench).

Location: The site is the location of all underground reactor effluent lines running from the 105-H Reactor Building to the 1904-H Outfall Structure. This includes segments between the reactor building and the retention basin, and between the basin and the outfall structure. It excludes the reactor building, retention basin, and outfall structure, each of which is treated as a unique waste site. Also included are the underground lines that run from the retention basin to the 116-H-1 Trench (running on the west side of 116-H-7) and from the 1608-H Waste Water Pumphouse to the 116-H-2 Trench.

Process Description: Effluent water passed from the reactor rear face and flowed via gravity through the underground effluent lines, junction boxes and diversion boxes to the retention basins where it was held up for a short period of time to allow thermal and radiological cooling before being released through the outfall structure to the Columbia River. During periods of reactor fuel cladding ruptures, some effluent was diverted to an open trench.

Related Sites/ Structures: Related structures are the 105-H Reactor, the 1608-H Waste Water Pumphouse, the 116-H-7 (107-H) Retention Basin, the 116-H-1 and 116-H-2 Trenches, and the 116-H-5 (1904-H) Outfall.

Waste Type: Process Effluent

Waste Description: The waste was contaminated steel piping, concrete, and soil. Reactor cooling water became radioactively contaminated as it passed through the reactor core. Activation products created in the water included calcium-41, chromium-51, and zinc-65. Activation products from the reactor core that were picked up and transported by the cooling water included tritium, carbon-14, cobalt-60, nickel-63, and europium-152/154/155. Fuel element fission products such as strontium-90, and cesium-137, as well as transuranics such as plutonium-239/240 were introduced into cooling water due to fuel cladding failures. Concentrations of radionuclides in cooling water during normal reactor operations were approximately 0.2 microcuries/liter. Concentrations of radionuclides built up in rust flakes and scale on the inner surfaces of the pipelines and in sludge in the diversion and junction boxes. Average beta-gamma concentrations for the effluent line scale and junction/diversion boxes were 83,000 and 120,000 picocuries/liter, respectively. Average plutonium-239/240 concentrations were 66 picocuries/gram for the effluent line scale and 720 picocuries/gram for the sludge at the bottom of the diversion and junction boxes. Direct readings of the bottom of the effluent lines averaged approximately 40,000 counts/minute with a Geiger-Mueller probe. Chemicals during water treatment included aluminum sulfate (alum), hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter. The waste was any remaining process effluent and the contaminated pipelines.

Closure Info: 100-H-21, 100-H-22 and 100-H-1 were addressed as a group. The information below documents information for the group of sites.

Remedial action at this site has been performed in accordance with Remedial Action Objectives (RAOs) and Goals (RAGs) established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. The selected remedial action involved (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Area of the Hanford Site, and (3) backfilling the site with clean soil to adjacent grade elevations.

Remedial action at the 100-H-21 Pipelines site began on October 19, 1999. Excavation of the site involved removing the overburden materials, pipelines (including miscellaneous small pipelines near the reactor building), the 100-H-1 Rod Cave structure, 100-H-22 Pipeline leakage, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at the ERDF.

Waste site contaminants of concern (COCs) identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22). The COCs for this site are cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, uranium-238, hexavalent chromium, and lead.

Arsenic was identified as a contaminant of potential concern (COPC) during remediation. Arsenic was included as a site COPC because of the likely use of lead-arsenate pesticide on the former orchard areas and based on agreement with the regulatory agencies. Because arsenic was detected in two cleanup verification samples at concentrations greater than the Washington State background value of 20 mg/kg (Washington Administrative Code [WAC] 173-340), arsenic was added to the final list of COCs for the site.

On July 21, 2000, the majority of the excavation was completed. Because of elevated lead levels in an area of the site excavation, additional soil was excavated in December 2000. Pre- and post-remediation topographic maps including overburden pile locations are shown in the site Closeout Verification Package (CVP). The general average depth of the bottom of the excavation in the deep zone sampling areas was 5.6 meters (18.4 feet) below ground surface. The majority of the site excavation depth was 4.6 meters (15 feet) or less below ground surface, generally corresponding with the former pipeline invert depth. The excavation was approximately 17,629 square meters (189,660 square feet) in area. Approximately 32,725 metric tons (35,998 tons) of material from the site were disposed of at ERDF.

Cleanup verification sampling began on July 17, 2000, and was finished on December 12, 2000. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the Sample Analysis Plan (SAP) (DOE/RL-96-22).

The CVP demonstrated that remedial action at the 100-H-21 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved Interim Action Record of Decision (ROD, EPA 1995) and Remedial Design Report/Remedial Action Work Plan (RDR/RAWP, DOE/RL-96-17). The remaining soils at the 100-H-21 Pipelines site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-H-21 Pipelines site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in overburden and the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The acceptability of unrestricted direct exposure to deep

zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-H-21 Pipelines site is verified to be remediated in accordance with the ROD. The overburden has been verified as suitable for use as backfill in accordance with the ROD.

Code:	100-H-22	Classification:	Accepted
Names:	100-H-22; Soil Contaminated by Effluent Line Leakage	Reclassification:	Interim Closed Out (3/19/2001)
Type:	Unplanned Release	Start Date:	
Status:	Inactive	End Date:	
Description:	The release occurred from the reactor cooling effluent lines. Both the lines and the unplanned release have been remediated and cleaned up.		
Location:	The 100-H-22 Effluent Pipeline Leakage site is associated with general underground leaks from the cooling water effluent pipelines.		
Release Description:	Several sources indicate evidence of leaks in the underground 152-centimeter (60-inch) steel reactor cooling effluent lines. Dorian and Richards (UNI-946) indicates backhoe sampling was done in 1971. Excavated soil was less than detection levels with a Geiger-Mueller (GM) probe. UNI-946 documents 1975 characterization studies of the pipeline contents and borehole soil sample results for two holes drilled adjacent to the effluent lines.		
Related Sites/ Structures:	The 107-H Retention Basin, 105-H Reactor, and 100-H-21 Effluent Pipelines are related to this unplanned release.		
Waste Type:	Process Effluent		
Waste Description:	Contaminants at the 100-H Area included plutonium, strontium, europium, cobalt, cesium, uranium, nickel, hexavalent chromium, lead, and arsenic.		
Closure Info:	100-H-21, 100-H-22 and 100-H-1 were addressed as a group. The information below documents information for the group of sites.		

Remedial action at this site has been performed in accordance with Remedial Action Objectives (RAOs) and Goals (RAGs) established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. The selected remedial action involved (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Area of the Hanford Site, and (3) backfilling the site with clean soil to adjacent grade elevations.

Remedial action at the 100-H-21 Pipelines site began on October 19, 1999. Excavation of the site involved removing the overburden materials, pipelines (including miscellaneous small pipelines near the reactor building), the 100-H-1 Rod Cave structure, 100-H-22 Pipeline leakage, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at the ERDF.

Waste site contaminants of concern (COCs) identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22). The COCs for this site are cobalt-60, cesium-137, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, uranium-238, hexavalent chromium, and lead.

Arsenic was identified as a contaminant of potential concern (COPC) during remediation. Arsenic was included as a site COPC because of the likely use of lead-arsenate pesticide on the former orchard areas and based on agreement with the regulatory agencies. Because arsenic was detected in two cleanup verification samples at concentrations greater than the Washington State background value of 20 mg/kg (Washington Administrative Code [WAC] 173-340), arsenic was added to the final list of COCs for the site.

On July 21, 2000, the majority of the excavation was completed. Because of elevated lead levels in an area of the site excavation, additional soil was excavated in December 2000. Pre- and post-remediation topographic maps including overburden pile locations are shown in the site Closeout Verification Package (CVP). The general average depth of the bottom of the excavation in the deep zone sampling areas was 5.6 meters (18.4 feet) below ground surface. The majority of the site excavation depth was 4.6 meters (15 feet) or less below ground surface, generally corresponding with the former pipeline invert depth. The excavation was approximately 17,629 square meters (189,660 square feet) in area. Approximately 32,725 metric tons (35,998 tons) of material from the site were disposed of at ERDF.

Cleanup verification sampling began on July 17, 2000, and was finished on December 12, 2000. The final verification samples were submitted to offsite laboratories for analysis using approved EPA analytical methods, as required per the Sample Analysis Plan (SAP) (DOE/RL-96-22).

The CVP demonstrated that remedial action at the 100-H-21 Pipelines site has achieved the RAOs and corresponding RAGs established in the approved Interim Action Record of Decision (ROD, EPA 1995) and Remedial Design Report/Remedial Action Work Plan (RDR/RAWP, DOE/RL-96-17). The remaining soils at the 100-H-21 Pipelines site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 100-H-21 Pipelines site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in overburden and the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 100-H-21 Pipelines site is verified to be remediated in accordance with the ROD. The overburden has been verified as suitable for use as backfill in accordance with the ROD.

Code:	100-H-24	Classification:	Accepted
Names:	100-H-24; 100-H-24 Substation; 151-H Electrical Facilities; 151-H Substation	Reclassification:	Interim Closed Out (5/9/2001)
Type:	Electrical Substation	Start Date:	1/1/1948
Status:	Inactive	End Date:	1/1/1978
Description:	The site has been remediated and closed out. It is the area of the demolished 151-H Substation, which includes the 151-H Building and adjacent Switchyard. The former switchyard area had a layer of crushed gravel with several remaining concrete structures that were used to support electrical equipment. Electrical conduit was observed protruding up from underground areas near the concrete structures. Two manholes that appeared to provide access to the main electrical feeder cables that ran from the switchyard to the 151-H Building were observed near the center of the site. These features were removed during the remedial action excavation of the site. In the area of the former 151-H Building, the southwest corner of the building appears to be protruding through the ground surface and several pieces of rebar were		

visible to the north. An area of subsidence was also visible near the former northeast corner of the building. An inactive power pole structure exists off the northeast corner of the site. The railroad spur that serviced the switchyard area has been removed. A former chain link fence, that has been cut off and removed just above ground level, surrounds the site. Demolition debris, such as rebar and broken concrete, was observed in the area of the former 151-H Building. Note: The soil samples taken in 1991 were located at oil stained sites adjacent to existing concrete transformer foundations. A site visit on 3/20/96 observed that no oil spills or stains were visible at the site. The 151-H Substation was constructed west of the 105-H Reactor to provide electrical service to the 100-H Area. The 151-H Substation was comprised of a fenced area and a switch house. The fenced area contained two power transformers, overhead static wires, large ground mat, lightning arrestors, and underground 13.8 kV feeders. Outgoing feeder cables were run in underground ducts approximately 60 meters (200 feet) from the substation building to overhead pole lines. The 151-H building contained the 13.8 kV switchgear. The 151-H building was a one story building with a basement. The basement portion contained a sump and conduit openings for underground feeder wires. The main floor housed the switchgear room, battery room, shop, mechanical equipment room, locker room and toilet. The switchgear from this facility was reused at 151-B.

Location: The 151-H Substation site was located approximately 200 meters (656 feet) west northwest of the 105-H Reactor Building.

Process Description: Two power transformers at the 151-H Substation provided 13.8 kV (rated at 31,250 kVA) power to two distribution systems that serviced the 100-H Area from 1948 to about 1965.

Related Sites/ Structures: The site was related to 100-H Area electrical utilities.

Waste Type: Demolition and Inert Waste

Waste Description: The 151-H Building was demolished in 1978. The demolition debris was placed in the basement cavity and covered with earth.

Waste Type: Oil

Waste Description: The site contains polychlorinated biphenyls (PCBs) contaminated soil. Seven samples were taken from stained area around the transformer foundations. The sample results indicated the presence of PCBs, however, the PCB levels were below Toxic Substance Control Act cleanup levels.

Closure Info: The cleanup verification package (CVP-2000-00030) has documented that the 100-H-24 site has achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Remaining Sites ROD (EPA 1999) and Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-13).

Waste site COCs listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22) and identified through process knowledge was polychlorinated biphenyls (PCBs).

Because of the likely use of lead-arsenate pesticide on the former orchard areas and based on an agreement with the U.S. Environmental Protection Agency and the Washington State Department of Ecology (EPA et al. 2000), arsenic was included as a site contaminant of potential concern. Arsenic was not detected in cleanup verification samples at concentrations above Washington State background of 20 milligrams per kilogram (Washington Administrative Code 173-340) and therefore is not included in further analysis for this site.

Remedial actions began in November 1999 and were completed in December 2000. Excavation of the site involved removing contaminated concrete, debris, and contaminated soil. Based on process knowledge and visual observation, the remaining portions (all below ground surface) of the 151-H Building concrete basement walls, foundation, and demolition debris did not require

removal and were therefore left in place. The debris is from the demolition of the 151-H Building in 1978. Based on the history of operations at the H Area, the 151-H Building contained mechanical switchgear for control of electrical operations. Operational history, building demolition observations, and remedial action observations indicate that no hazardous materials were stored or used in the building and that there was no contamination associated with the building.

At completion the lowest elevation of the bottom of the excavation was at 121.9 meters (400 feet). The excavation was approximately 12,289.8 square meters (132,286.4 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 19,924 metric tons (21,268 tons) of material from the site were disposed at the Environmental Restoration Disposal Facility (ERDF).

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, WIDS had shown IC restrictions but the sites were remediated to shallow zone criteria so that no ICs were required. The ICs for this site have been revised accordingly.

Code:	100-H-28	Classification:	Accepted
Names:	100-H-28; 100-H Water Treatment Facilities Underground Pipelines	Reclassification:	None
Type:	Process Sewer	Start Date:	1/1/1949
Status:	Inactive	End Date:	1/1/1965
Description:	The site encompasses the upstream (pre-reactor) process sewers for the 100-H Reactor, including all underground water lines used to transport reactor cooling water between water treatment facilities and the 105-H Reactor Building. These include all underground lines running between buildings and those that run to drainage facilities and to the emergency cooling high tanks (water towers). Lines excluded from this site are those within buildings and all lines that are downstream from the reactor building, i.e., those lines that carry cooling water from the reactor to the retention basin, trench, and/or the river.		
Location:	The underground lines connect the 181-H River Pumphouse to the 182-H Reservoir, the 183-H Basins and Clearwells, the 190-H Buildings, and to the 105-H Reactor Building. Also, any underground drainage lines running from the water treatment buildings to the 116-H-5 Outfall Structure (1904-H Outfall) are included in this site.		
Process Description:	Reactor cooling water was pumped from the Columbia River, settled and treated to remove minerals, and pumped to the reactor core at a rate of 1.78E+05 liters (47,000 gallons) to 2.69E+05 liters (71,000 gallons) per minute.		
Related Sites/ Structures:	The other pipeline sites at the 100-H Area are 100-H-21 (Reactor Cooling Water Effluent Underground Pipelines); 100-H-34, (River Effluent Pipeline); and 100-H-35, (Clean Water Underground Pipelines). Related structures are the 181-H River Pumphouse, the 182-H Settling Basin, the 190-H Water Treatment and Storage Tank Facility, and the 105-H Reactor.		
Waste Type:	Water		
Waste Description:	The waste is steel piping, concrete, and soil (if contaminants are present). Chemical additives to the reactor cooling water included aluminum sulfate (alum) with excess hydrated calcium oxide, sulfuric acid, chlorine, and sodium dichromate. Water pH was maintained at about 7.5, and the free chlorine residual was approximately 0.2 milligrams/liter.		

This Site has the Following SubSites:

remedial action objectives for direct exposure, groundwater protection, and river protection. A summary of the evaluation of the sampling results against the applicable criteria was presented in Table ES-1 of the RSVP.

Analytical results for Hanford Site coal ash samples from the 126-D-1 ash pit by total metals analytical methods were provided in DOE/RL-92-71, Rev. 2. Other data for these samples, including for organics and radionuclides were contained in the Hanford Environmental Information System. Subsite COPCs included polycyclic aromatic hydrocarbons (PAHs), arsenic, barium, cadmium, chromium, lead, selenium, silver, and mercury. Additionally, antimony, beryllium, boron, cobalt, copper, manganese, molybdenum, nickel, uranium, vanadium, and zinc were reported as part of the expanded inductively coupled plasma (ICP) metals analysis in the analytical results package. In agreement with the Washington State Department of Ecology, hexavalent chromium analysis was not required due to matrix interference concerns associated with coal ash.

Confirmatory sampling was performed on August 28, 2008, and September 24, 2008. A focused sampling design was selected for confirmatory sampling based on historical drawings, process knowledge, and other available information.

Due to the expected uniform distribution of residual material, no sampling location was preferred for collecting a focused sample within the pipeline. Therefore, a sample representative of pipeline contents was collected from a location selected based on access considerations at the outfall of the pipeline. The most appropriate focus location for characterization of potential impact to underlying soils was also selected at the outfall of the pipeline, as the pipeline terminus was a free discharge to soil.

During excavation, a 0.20 m (8-in.-) steel pipeline was encountered, it was broken at the end and filled with soil and gravel, see photo. Field observations of the end of the pipeline and the broken concrete slab were that the pipeline outfall had been demolished in place and backfilled. The excavator was then used to break into the pipeline near the exposed end. No scale or sediment was found inside the pipeline. To collect a soil sample it was decided to excavate below the concrete slab underlying the pipeline. On September 24, 2008, at test pit 2 the excavator broke into the pipeline, no material was observed inside the pipeline. Therefore, no additional sampling was performed and the excavation was backfilled.

All confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency (DOE-RL -96-22). The laboratory-reported data results for all constituents were stored in the Environmental Restoration project-specific database prior to submission for archival in the Hanford Environmental Information System site-wide database and were summarized in Appendix B of the RSVP.

The results of confirmatory sampling show that residual contaminant concentrations do not preclude any future uses, as bounded by the rural residential scenario, and allow for unrestricted use of shallow-zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrated that residual contaminant concentrations were protective of groundwater and the Columbia River. This subsite does not have a deep zone component; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required. In accordance with the RSVP, the confirmatory sampling results support a reclassification of the subsite to No Action.

The SubSite is Part Of:

Code: 100-H-28

Names: 100-H-28; 100-H Water Treatment Facilities Underground Pipelines

Code: 100-H-28:2

Classification: Accepted

pipeline north of the 182-H Reservoir. The pipeline was approximately 4.6 m (15 ft) below ground surface.

Location: The 100-H-28:6 subsite runs from the north side of the 182 H Reservoir northeast to the upper river bank, approximately 1.8 meters (6 feet) down slope of the present embankment crest. The exact location of the pipeline was documented in drawings P-1215 and P-1216 (GE 1949a, 1953).

Process Description: The pipeline was installed during construction of the 182-H Reservoir. The water that traveled through the pipeline originated directly from the Columbia River via the 181-H Pumphouse, with the exception of steam condensate.

Waste Type: Soil

Waste Description: The waste was pipeline sediment/scale and underlying soil.

Closure Info: The Remaining Sites Verification Package, (RSVP-2006-026), documents that the 100-H-28:6 subsite has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) for No Action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD).

Confirmatory sampling activities at the site were conducted on September 2, 3, and 24, 2008. A focused sampling design was selected for confirmatory sampling based on historical drawings and process information. The contaminants of potential concern (COPCs) for the 100-H-28:6 subsite were selected based on the entire COPC list identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) for the site. They included: cobalt-60, cesium-137, europium-152, europium-154, strontium-90, lead, hexavalent chromium, and metals. Polychlorinated biphenyls (PCBs) were also added at the request of the Washington State Department of Ecology. Confirmatory sampling results indicated that the residual concentrations of COPCs at this site met the remedial action objectives for direct contact, groundwater protection, and river protection.

Soil cleanup levels were established in the ROD based on a limited ecological risk assessment. Although not required by the ROD, a comparison against ecological risk screening levels has been made for the site contaminants of concern and other constituents and is presented in Appendix A of the RSVP.

Screening levels were exceeded for antimony, arsenic, barium, boron, cadmium, chromium, copper, lead, manganese, vanadium, and zinc. Exceeding screening values is intended to trigger additional evaluation and does not necessarily indicate the existence of risk to ecological receptors. Because concentrations of antimony, manganese, and vanadium are below background levels (DOE/RL -92-24, Rev. 4), it is believed that the presence of these constituents does not pose a risk to ecological receptors. Since no site background exists for antimony, a state-wide background reference is provided. An established background value is not available for boron at this time. Arsenic, barium, cadmium, chromium, copper, lead and zinc present at concentrations exceeding background, as well as the boron concentration, will be evaluated in the context of additional lines of evidence for risk to ecological receptors as part of the final closeout decision for this site.

During excavation and sampling, radiological field screening was performed as specified in the confirmatory sampling work instruction. No radiological contamination was detected above background levels. Field screening for the presence of volatile organic compounds (VOCs) was also negative. No anomalous media indicated by staining, evidence of burning, and/or debris

were observed during test pit excavations.

All confirmatory samples were analyzed using analytical methods approved by the U.S. Environmental Protection Agency. The laboratory-reported data results for all constituents were stored in the WCH Environmental Restoration project-specific database prior to submission for archival in the Hanford Environmental Information System site-wide database. The results were also summarized in Appendix B of the RSVP.

The results of confirmatory sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

The SubSite is Part Of:

Code: 100-H-28

Names: 100-H-28; 100-H Water Treatment Facilities Underground Pipelines

Code: 100-H-28:7

Classification: Accepted

Names: 100-H-28:7; 183-H Process Water Lines

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: This subsite encompasses the filtered/treated water supply lines originating at the 183-H Filter Plant, including two 0.91-meters (36-inches) steel lines terminating at the 190-H building, a 0.76-meters (30-inches) line terminating at the 182-H Reservoir pumphouse, two 0.25-meters (10-inches) steel lines terminating at the 184-H Power House, and the former supply lines to the emergency cooling water high tanks at the 105-H Reactor Building.

Location: The 100-H-28:7 process water lines are part of the 100-HR-1 Operable Unit. These pipelines are located between the former 183-H Filter Plant Pump House, 184-H Boiler House, 190-H Pump House, the 187 Elevated Water Towers, and the 105-H Reactor. These pipelines are approximately 1.8 to 3 m (6 to 10 ft) below existing grade.

Waste Type: Not Specified

Waste Description: The waste would be any potentially contaminated soil and remaining pipeline components.

The SubSite is Part Of:

Code: 100-H-28

Names: 100-H-28; 100-H Water Treatment Facilities Underground Pipelines

Code: 100-H-28:8

Classification: Accepted

Names: 100-H-28:8; 190-H Process Water Lines

Reclassification: No Action (4/19/2007)

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The subsite consisted of four 0.61 -meter (24-inch)-diameter seamless welded steel pipelines located in two subsurface, reinforced concrete tunnels between the 190-H and 105-H facilities, as well as possible ancillary piping within the tunnels. The 100-H-28:8 pipelines were

Structures:**Waste Type:** Process Effluent**Waste Description:** The trench is likely to have received radionuclide and chemical contamination from the overflows of the 116-H-2 (1608-H) Crib. The crib received cooling water from the 105-H Reactor Building during the Ball 3X system upgrade program. The site was used during other upgrade programs and on the effluent system when maintenance was necessary.**Waste Type:** Sanitary Sewage**Waste Description:** The unit received unknown amounts of sanitary sewage from the 110-H Building.**Closure Info:** 100-H-17, 116-H-2, 100-H-2 and 100-H-30 were addressed as a group. The information below documents information for the group of sites.

The cleanup verification package (CVP-2000-00031) has demonstrated that remedial action at for the 100-H-17 Overflow, 116-H-2 Liquid Waste Disposal Trench, 100-H-2 Buried Thimble Site, and the 100-H-30 Sanitary Sewer Trench sites have achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995), and the amendment to the ROD (EPA 1997), and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17). This site is located in an area that, prior to World War II and formation of the Hanford Site, was occupied by fruit tree orchards. These sites were grouped together due to their proximity and similarity in the type of waste they received.

The COCs identified in the 100 Area Remedial Action Sampling and Analysis Plan for this site consisted of plutonium-239/240, uranium-238, strontium-90, cesium-137, cobalt-60, europium-152, europium-154, and hexavalent chromium.

At the completion of the remedial action, the total excavation was approximately 6,240 square meters (67,170 square feet) in area with a maximum depth of approximately 2.6 meters (8.5 feet). Approximately 19,920 metric tons (21,960 tons) of material from the site were disposed of at the ERDF.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Code: 100-H-31	Classification: Accepted
Names: 100-H-31; Polychlorinated Biphenyl in Soil on North Side of 105-H Reactor Building	Reclassification: Interim Closed Out (6/22/2006)
Type: Unplanned Release	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and interim closed. The site consisted of a gravel area near a former electrical substation with no visible oil stains or vegetation. The adjacent concrete pad had electrical conduit and wiring extending up to the surface where the electrical equipment was removed. The site was not marked or posted. The reactor exclusion fence was posted as Underground Radioactive Material. The reactor exclusion fence was posted as Danger,	

Restricted Area, Multiple Hazards, No Entry Without Written Authorization and Underground Radioactive Material.

Location: The site was located on the north side of the 105-H Reactor Building (inside the exclusion area fence) and off the southeast corner of a former electrical transformer pad. The site is 4 meters (11.2 feet) south of 100-H-10 French Drain site.

Release Description: Polychlorinated Biphenyls were detected in the soil.

Related Sites/ Structures: The site is related to electrical transformers that were formerly located on the concrete pad near the site.

Waste Type: Soil

Waste Description: The waste is polychlorinated biphenyl (PCB) contaminated soil.

Closure Info: 118-H-6:2, 118-H-6:3, 118-H-6:6, 100-H-9, 100-H-10, 100-H-13, 100-H-11, 100-H-12, 100-H-14 and 100-H-31 were addressed as a group. The information below documents information for the group of sites.

The CVP-2006-00003 documents that removal action at the 105-H Reactor subsites (118-H-6:2, 118 H-6:3, and 118-H-6:6) has achieved the removal action objectives and remedial action goals (RAO/RAGs) established in The Action Memorandum for the 105-D and 105-H Reactor Buildings and Ancillary Facilities and the Removal Action Work Plan for 105-D and 105-H Building Interim Safe Storage Projects and Ancillary Buildings. The RAGs were further detailed in the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 100 Area Remedial Action Sampling and Analysis Plan, and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.

Per the Sampling and Analysis Plan for Interim Closure of 105-D and 105-H Reactor Below-Grade Structures and Underlying Soils (SAP), the 105 H Reactor ancillary support areas and below-grade structures (118-H-6:2) did not require sampling and analysis because the structures were removed in their entirety and then disposed at the Environmental Restoration Disposal Facility (ERDF).

During D activities additional evaluation was required in order to determine if the soils underlying the former FSB floor (118-H-6:3) had achieved the RAGs. Therefore, the evaluation of the FSB soils and deep zone side-slope soils also refer to the soils underlying waste sites 100-H-11, 100-H-12, and 100 H 14.) To determine compliance with the RAGs, and in accordance with the 105-H Reactor SAP, radiological surveys and verification sampling analysis were performed on the FSB underlying soils and deep zone side-slope soils.

These data were used in the RESRAD computer model to verify that cleanup criteria were satisfied. The local contamination was removed in preparation for clean demolition, and a fixative was applied as required. With one exception, there are no below-grade structures remaining. A portion of the FSB floor, at its northern end between the two access labyrinths to the D elevator, remains.

Verification soil samples were collected from soils underlying the former FSB floor in conformance with the 105-H Reactor SAP. Samples numbers All demolition debris from excavations associated with the area was sent to ERDF. Final cleanup verification samples for the FSB underlying soils and deep zone side-slope soils were collected following evaluation of field screening for radiological contaminants using global positioning environmental radiological surveyor (GPERS) and laser-assisted ranging and data system (LARADS) surveys. This field screening was performed in order to obtain an initial assessment of attainment of

 radiological cleanup levels

The sample design for the FSB underlying soils was developed specifically to address potential contamination from the known leakage of the FSB. Samples were collected from 10 random sample locations and 3 judgmental sample locations. At each location, soil grab samples were collected from two intervals: the first native soils below the FSB over a 0.3 meter (1 foot) interval and also at 2.4 meters (8 feet) to 3.1 meters (10 feet) below the surface. Soil samples were collected on March 24 and 25, 2004, and on April 6, 2004. The results of the focused sampling (i.e., 3 judgmental samples) are consistent with the statistical sampling results (i.e., the 10 random sample locations) and are provided in Appendix A of the CVP-2006-00003. As yet the results from the HEIS sample numbers have not been loaded into the database.

The verification sample design for the deep zone side-slope soils in 118-H-6:6 consisted of dividing the area into three equal sections, with a composite of four soil grab samples being collected within each area. Soil samples were collected on March 29, 2004. The verification sample design for the deep zone side-slope soils was in accordance with the 100 Area SAP and was detailed in the SAP.

Waste site contaminants of concern (COCs) identified in the SAP through process knowledge classified the different areas and structures into affected media, a summary list of the COCs included: Americium-241, Carbon-14, Cesium-137, Cobalt-60, Europium-152, Europium-154, Europium-155, Neptunium-237, Nickel-63, Plutonium-238, Plutonium-239/240, Strontium-90, Thorium-228, Thorium-232, Tritium (H-3), Uranium-234, Uranium-235, Uranium-238, Hexavalent chromium, Lead, Mercury, and PCBs.

The remaining soils at the 105 H Reactor site have either been deferred to the Field Remediation Closure Project or have been shown to meet the applicable RAGs through verification sampling, analysis, and RESRAD modeling. All excavated materials generated during the D activities were disposed at ERDF, and the area was backfilled to grade with clean backfill. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River.

The subsite has been verified to be remediated in accordance with the Removal Action Work Plan for 105-D and 105 H Building Interim Safe Storage Projects and Ancillary Buildings and the Remedial Design Report/Remedial Action Work Plan for the 100 Area and can be interim closed. The CVP does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]) therefore, institutional controls to prevent uncontrolled drilling or excavation into these deep zone soils are required.

Code:	100-H-33	Classification:	Accepted
Names:	100-H-33; 183-H Solar Evaporation Basins Radionuclide Components	Reclassification:	None
Type:	Retention Basin	Start Date:	1/1/1949
Status:	Inactive	End Date:	1/1/1985
Description:	The site was created to address the radionuclides of the former 183-H Solar Evaporation Basins (116-H-6 TSD) that was used for solar evaporation of liquid wastes from the 300 area. The basins were remediated in 1985 and 1995 and closed out on May 13, 1997, under a Modified Closure signed by Washington State Department of Ecology. This RCRA closure did not address any radionuclide COCs that were associated with the site (gross alpha, gross beta, uranium-234, uranium-235, technetium-99, total uranium, and gamma energy analysis). This RCRA closure did not address any radionuclides that were associated with the site.		

20.3 meters (66.5 feet), then take a 19-degree downstream bend and continue on for another 209.2 meters (686.5 feet).

Process Description: The River Effluent pipelines discharged reactor coolant water to the river. Effluent was received from the 107-H Retention Basin and the area process sewer system to the outfall structure. In the event that the outfall line plugged, effluent would back up into the outfall structure and overflow into an underground concrete sluiceway (flume) that led to the river. Reactor (105-H) effluent cooling water was collected and temporarily stored in the 107 H Retention Basin. This cooling water, as well as process sewer wastes, were discharged to the river via the river effluent pipelines after passing through the 1904-H outfall structure. In the event the pipelines became plugged or were out of service for any reason, the discharge streams would overflow to an underground, emergency spillway (100-H-36), which was also routed to the river. The total drop from the face of the outfall structure to the discharge end of the pipeline is 8.5 meters (28 feet). The pipelines are separated by approximately 90 centimeters (35 inches) and are covered by a minimum of 1 meter (3 feet) of soil over their entire length, as well as large pieces of basalt riprap extending from the face of the outfall to the shoreline. The top portion of the outfall structure has been partially demolished, and backfilled with clean soil. It is not known what condition the outfall ends of the river effluent pipelines were left in following outfall demolition. During February and March 2005 visits to the site, it was noted that the bottom portion of the underground spillway (flume) (100-H-36) associated with the outfall structure is partially intact and visible. The total drop from the face of the outfall structure to the discharge end of the pipeline is 8.5 meters (28 feet). The pipelines are separated by approximately 90 centimeters (35 inches) and are covered by a minimum of 1 meter (3 feet) of soil over their entire length, as well as large pieces of basalt riprap extending from the face of the outfall to the shoreline. The top portion of the outfall structure has been partially demolished, and backfilled with clean soil. It is not known what condition the outfall ends of the river effluent pipelines were left in following outfall demolition. During February and March 2005 visits to the site, it was noted that the bottom portion of the underground spillway (flume) (100-H-36) associated with the outfall structure is partially intact and visible.

Related Sites/ Structures: The site is associated with the 116-H-5 Outfall Structure, 100-H-36 Spillway (Flume), 116-H-7 Retention Basin and 184-H Power House. The site is associated with the 116-H-5 outfall structure, 116-H-7 (the 107-H Retention Basin), the lines (116-H-21) from the retention basin to the outfall structure, and 100-H-36 (the 1904 H spillway).

Waste Type: Process Effluent

Waste Description: The waste includes the pipelines and the contaminated scale contained within them.

Contaminants of concern/potential concern are based on those for the outfall itself.

Contaminants of potential concern include Co-60, Cs-137, Eu-152, -154, -155, Ni-63, Pu-238, -239/240, Am-241, C-14, H-3, Tc-99, Sr-90, U-234, -235, -238, Cr+6, Cr (total), Pb, and Hg.

Code: 100-H-35 **Classification:** Accepted

Names: 100-H-35; 100-H Clean Water Pipelines; 100-H Service Water Pipelines **Reclassification:** None

Type: Product Piping **Start Date:**

Status: Unknown **End Date:**

Description: The site encompasses the clean water pipelines for the 100-H Area, including underground pipelines used to transport raw water from the river pumphouse to the water treatment facilities and to 100-H Area facilities and fire hydrants. Pipelines excluded from this site include those within buildings, process and sewer pipes, pipes that carried water treated with sodium

dichromate, and all lines that were downstream from the reactor building, i.e., those lines that carried cooling water from the reactor to the retention basin, trench, and/or the river.

Location: The clean water (non-contaminated) underground pipelines were located across the 100-H Area, from the 181-H intake structure to the water treatment facilities, reactor (fire and potable water, not reactor cooling water), south to the fire and patrol headquarters near the 1607-H-3 Patrol Headquarters area, west to miscellaneous shops and warehouses, and the 184-H Coal Fired Powerhouse. The export water line entered the H Area from the 100 D/DR Area north of the coal storage area, it turned south along the road then east to the 182-H Reservoir. This line also continued further south and turned east where it entered the 105 H reactor on the north side.

Process Description: The site encompasses the clean water pipelines for the 100-H Area, including underground pipelines used to transport raw water from the river pumphouse to the water treatment facilities and to 100-H Area facilities and fire hydrants.

Related Sites/ Structures: The clean water and fire protection water pipelines ran to or near virtually all the facilities at the 100-H Area. The other pipeline sites at the 100-H Area are 100-H-21 (Reactor Cooling Water Effluent Underground Pipelines); 100-H-28 (Water Treatment Facilities Underground Pipelines); and 100-H-34, (River Effluent Pipeline)

Waste Type: Equipment

Waste Description: The waste is the old buried pipes from the clean water pipeline system.

Code: 100-H-36

Classification: Accepted

Names: 100-H-36; 116-H-5 Spillway; 1904-H Spillway; 100-H-34:1 Flume (Spillway) for the 116-H-5 Outfall Structure

Reclassification: None

Type: Outfall

Start Date:

Status: Inactive

End Date:

Description: The 100-H-36 Spillway (also referred to as a flume) is an underground concrete sluiceway that led from the 116-H-5 Outfall Structure to the river shoreline.

Location: The site is located on the Columbia River shoreline north of the 116-H-7 Retention Basin. Assuming midline Washington State Plane coordinates, the underground spillway exits the south face of the 116-H-5 outfall. takes an immediate 45 degree turn in the upstream direction, and terminates.

Process Description: The spillway carried effluent overflow from the outfall (116-H-5) structure to the shoreline of the river for release. It was planned to be used only if the river effluent pipelines (100-H-34) were blocked, damaged, or undergoing maintenance. There is no corroborated physical or historical evidence that the spillway was ever used. The slope between the outfall and the river is covered with large basalt riprap boulders that have been mortared in place, extending about 73 meters (80 yards) north and south of 116-H-5. The exit end of the underground sluiceway has been covered with concrete rubble and is no longer visible. A shallow, dish-shaped concrete runoff pad extends across the beach from the spillway exit to the low water line.

Related Sites/ Structures: The site is associated with the 100-H-34 River Effluent Pipelines and the 116-H-5 Outfall Structure.

Waste Type: Construction Debris

Waste Description: Possible chemical and/or radionuclide contamination (see Contaminants of Potential Concern).

The contaminants of potential concern are based on those for the 116-H-5 outfall, and include C-14, Cs-137, Sr-90, U-235, -238, and Pu-239/240.

Code: 100-H-41 **Classification:** Accepted

Names: 100-H-41; Contaminated Area; Contaminated Vertical Pipe **Reclassification:** Interim Closed Out (3/15/2011)

Type: Unplanned Release **Start Date:**

Status: Inactive **End Date:**

Description: This site consisted of soil in a posted radiologically Contaminated Area (CA). Also within the CA area is a 35.6 centimeter (14 inch) diameter, vertical concrete structure. The posted area appears as a flat, graded, gravel covered area with rabbit brush.

Location: The site was located 16.29 meters (53.44 feet) east of the 190-H building.

Process Description: The concrete structure inside the CA appeared to be associated with a filtered water line from the 183-H facility. The filter water line serviced the 190-H Building operations via a 60.96 centimeter (24 inch) cast iron pipe. The 35.6 centimeter (14 inch) diameter concrete structure may be related to the 100-H-28 Water Treatment Facilities Underground Pipelines. The basis for the radiological posting of the site as a CA was unknown. There was no process knowledge indicating radiological contamination would be present at the location. It was also believed that the radiological CA posting may have been associated with mud dauber contamination that was prevalent in the surrounding area. Because process knowledge was inconclusive, WIDS information identified the site as an Unplanned Release.

Related Sites/Structures: 100-H-41 is associated with other contaminated mud dauber nests found in 100-H-37 and 100-H-58. Associated structures include the 183-H and 190-H buildings. Associated WIDS sites include: 100-H-28, Water Treatment Facilities Underground Pipelines and 100-H-35, 100-H Service Water Pipelines, 100-H Clean Water Pipelines.

Closure Info: Because the contamination was determined to be due to the presence of mud dauber nests, it was determined that the contamination was more appropriately identified as part of the 100-H-37 Mud Dauber Contamination Area waste site. Therefore, on November 12, 2009, the Field Remediation project excavated and removed the contaminated materials, including the pipe and soil, for disposal at the Environmental Restoration Disposal Facility as part of the ongoing 100-H-37 remediation effort.

Code: 100-H-42 **Classification:** Accepted

Names: 100-H-42; 1906-H Drainage Lift Station **Reclassification:** None

Type: Pump Station **Start Date:**

Status: Inactive **End Date:**

Description: The site consists of the following components: -An underground reinforced concrete flume/reservoir filled with building rubble and clean soil. The concrete structure is in contact with underlying soil which may be contaminated from past leaks from the structure. There are no documented unplanned releases from this facility. -A 183 cm (72 in) diameter, 37 m (121 ft) long, reinforced concrete pipeline exiting the east side of the underground structure and connecting to the 1904-H diversion box (outfall structure). The pipeline is in contact with

underlying soil which may be contaminated from past leaks. There are no documented unplanned releases from this pipeline. -A 15.2 cm (6 in) diameter, 67 m (220 ft) long, steel effluent sample line between the 1904-H outfall and the 1908-H effluent monitoring station. A 9.18 m (30.13 ft) section of this pipeline is drawn on drawing P-4407 with a different orientation than what is shown on drawing P-1220. Both versions of the pipe orientation are shown on the waste site drawing to ensure that it is not missed. -A 20.3 cm (8 in) diameter, 94 m (308 ft) long, steel sample drain line from the 1908-H effluent monitoring station that empties into the 1904-H outfall. A 10.84 m (35.55 ft) section of this pipeline is drawn on drawing P-4407 with a different orientation than what is shown on drawing P-1220. Both versions of the pipe orientation were shown on the waste site drawing to ensure that it was not missed.

Location:	The site is located in the 100-HR-1 Operable Unit and is approximately 75 m (246 ft) north of the 107-H retention basin. The approximate center of the remaining underground structure in Washington State Plane coordinates is E578058, N152819 (Washington State Plane coordinates).
Process Description:	The 1906-H Drainage Lift Station was designed to receive process sewer discharges (primarily floor drains) from all of the non-radioactive buildings in H Area. The structure consisted of a rectangular-shaped reinforced concrete reservoir and by-pass flume, surmounted by a one-story concrete-block building over a portion of the reservoir section. The facility originally contained three 66,245 LPM (17,500 GPM) electric pumps, one 56,781 LPM (15,000 GPM) electric pump, and one 7,571 LPM (2,000 GPM) electric pump. A concrete dividing wall running the length of the structure separates the flume and reservoir sections. Two electrically operated gates controlled the flow into the structure, and flow between the bypass flume and the reservoir sections. A 15 cm (6 in) concrete slab cover supported the above grade building. This building contained the pump room, switch gear, and controls. A 183 cm (72 in) pipeline entered the facility on the west end of the flume, and exited the east end of the flume directly to the 1904-H Diversion Box (P-2091). Construction materials included 1,489 m ³ (1,950 cubic yards) of concrete, 126 tonnes (139 tons) of reinforcing steel, 1.36 tonnes (1.5 tons) of structural steel, and 4,370 concrete blocks. In 1974 this above grade building was demolished into the reservoir and the site backfilled with clean soil (letter UNI-7231974). The entire below grade reservoir is made of 0.9 m (3 ft) thick reinforced concrete. The 1908-H Effluent Monitoring Station was used to sample and monitor cooling water process effluent which was being discharged to the river via the 1904-H Diversion Box. The 1904-H Diversion Box received process waste from the 107-H Retention Basin and the 1906-H Drainage Lift Station.
Related Sites/ Structures:	Primary structures discharging to this site include 182-H, 183-H, 184-H, 190-H, 1908-H, 1715-H, 1716-H, and 1717-H buildings. Other associated structures include: 100-H-36 Spillway, 116-H-5, 1904-H Outfall Structure, 116-H-7 Retention Basis, and 100-H-34 River Effluent Pipelines.
Waste Type:	Soil
Waste Description:	The waste associated with the 1906-H lift station includes piping and remaining equipment (pipeline and concrete reservoir), rubble and underlying soils associated. Potential contaminants of concern include sodium dichromate, total petroleum hydrocarbons (TPH), polychlorinated biphenyls (PCBs), sulfuric acid, lead, mercury, and paint solvents. The waste associated with the 1908-H Effluent Monitoring Station includes the piping and underlying soils associated. Potential contaminants of concern include Cs-137, Co-60, Eu-152, Eu-154, Eu-155, Ni-63, Pu-238, Pu-239/240, Sr-90, U-238, hexavalent chromium, total chromium, lead, mercury, paint solvents, sulfuric acid, TPH and PCBs.

Code: 100-H-43	Classification: Accepted
Names: 100-H-43; Maintenance Garage; Repair Shop	Reclassification: None

Type: Foundation**Start Date:****Status:** Inactive**End Date:**

Description: This site consists of the below-grade components of the 1716-H Maintenance Garage. The facility was used to service the area vehicles. The site includes the following components: -An 8.4 m (27.6 ft) long concrete lubrication pit. -A 2,082 L (550 gal) underground waste oil tank located on the north side of the facility and the 10.2 cm (4 in) diameter underground cast iron pipeline running to it from the lubrication pit. -A 10.2 cm (4 in) diameter, underground cast iron pipeline that carried waste from floor drains in the battery room, compressor and oil storage room, lubrication pit, and the repair shop to the process sewer (100-H-28:2). -A 61 cm (24 in) french drain on the north side of 1716-H that received steam condensate through a 5.1 cm (2 in) cast iron pipeline (See orphan site photo # 03122008-962). The french drain may also have been available to receive other wastes through a 10.2 cm (4 in) cleanout near the wall opening in the battery room (P-1435). -A 61 cm (24 in) french drain on the north side of 1716-H (just west of the french drain described above) that received effluent from a floor drain and sink in the battery room (See orphan site photo # 03122008-963). The two underground pipelines that carried the waste to the french drain were a 7.6 cm (3 in) cast iron pipe and a 3.8 cm (1.5 in) lead pipe. -A 122 cm (48 in) diameter french drain, built in 1963, received steam condensate through two 3.8 cm (1.5 in) underground pipelines (See orphan site photo # 03122008-964). -A pump island and underground piping associated with two 18,927 L (5,000 gal) underground storage tanks. The tanks, one for diesel fuel and the other for gasoline, are part of the 100-H-3 waste site. The piping included two 3.8 cm (1.5 in) cast iron suction lines and two 5.1 cm (2 in) vent risers (partially above grade).

Location: The site is located 200 m (650 ft) northeast of the former 105-H Reactor, and 40 m (131 ft) east of the former 105-H Retention Basin. The center of the original facility in Washington State Plane coordinates is at E577990, N152691. The center of the used oil storage tank in Washington State Plane coordinates is E577995, N152709. The center of the lubrication pit is E577995, N152697. The center of the fuel island is E577972, N152683. The center of the two northern french drains are (east and west respectively) E577989, N152709 and E577987, N152709. The center of the southern french drain is E577997, N152673.

Process Description: The 657 sq m (7068 sq ft) maintenance garage was constructed between March and August 1949. The building was a one-story wood-frame structure with wood columns which supported the roof frame and trusses; the exterior concrete foundation walls extended four feet above the finished concrete floors of the building; and concrete footing pads carried the laminated columns which supported the high roof wood trusses (HW-24800-2). The building contained a repair shop, tire shop, battery room, compressor and oil storage room, mechanical equipment room, office, parts, toilet, locker, and lunch room. The 1716-H Maintenance Garage was equipped as a service station, and for light maintenance and repair. At one point about half of the building was converted to shops for maintenance, calibration, and repair of electrical and electronic instruments (GEH-26434-100). Operations were discontinued at the 1716-H building when 105-H was deactivated in 1965 (BHI-00127). The building was dismantled prior to 1974. The footings and foundation were demolished, backfilled and the site was leveled in 1974 (letter UNI-7231974). A past employee reported that he believes waste oil was commonly dumped on ground surface near auto shop as dust inhibitor (DC-0227).

Related Sites/Structures: The 100-H-3, 1716-H Garage Fuel Tanks were approximately 6.7 meters (22 feet) directly south of the building. Other associated structures include: 100-H-28, 100-H Water Treatment Facilities Underground Pipelines (See Subsites), and the 116-H-6, 183-H Solar Evaporation Basins.

Waste Type: Process Effluent

Waste Description: Automobile wastes may include gasoline, diesel, motor oil, antifreeze, automatic transmission fluid, battery acid, engine and radiator flushes, brake fluid, engine and metal degreasers.

Contaminants of potential concern include volatile organic compounds, semi-volatile organic compounds, sulfate, pH, lead, cadmium, mercury, chromium, hexavalent chromium, polychlorinated biphenyls, TPH-Gasoline Range, TPH -Diesel Range, and TPH-Oil Range.

Code: 100-H-44 **Classification:** Accepted

Names: 100-H-44; 183-H Neutralization Pit; H-016 **Reclassification:** None

Type: Process Unit/Plant **Start Date:**

Status: Inactive **End Date:**

Description: The site consists of the 183-H Neutralization Pit and its potentially contaminated soils, possibly a concrete structure (pit), acid brick and associated piping. There are no visible surface features that identifies the pit. The neutralization pit lies within the footprint of the 100-H-28 Process Sewer.

Location: The site is located in the 100-HR-1 Operable Unit. The Neutralization Pit was located 59 m (194 ft) west of the 183-H Head House (west of the railroad car spot) and 9 m (30 ft) north of the 183-H Flocculent Basin flume wall. The center coordinates are E577712.58, N152881.48.

Process Description: The 183-H Filter Plant was designed to treat raw river water before it entered the 190-H building. Chemicals were added to the river water in the head house. The head house was used for the storage, preparation, and addition of alum, chlorine, and sulfuric acid for water treatment. Alum was used as a flocculating agent and sulfuric acid was used to control the acidity of the water. Chlorine was added to control algae. Concentrated sulfuric acid was received by railroad car and stored outside in horizontal storage tanks. Chemicals were delivered as bulk materials and unloaded from railroad cars by either bottom dumping or side unloading to conveyors. Concentrated sulfuric acid, received by railroad car, was stored outside in horizontal storage tanks. It was pumped from the storage tanks to the head tank through black iron pipelines. Pipelines used to transport lime slurry and acid solutions were encased in an underground concrete trench with a concrete cover. The interior surface of the trench was coated with AMERCO at #55 chemical resistance coating (H-1-5671). Along the length of the trench various pipelines made connection outside of the trench to above grade ancillary equipment including the acid pumps and the acid tanks. The concrete trench was sloped to allow drainage of liquids to the neutralization pit. The neutralization pit served as a structure to treat excess concentrated sulfuric acid (from acid tank cleanouts) prior to disposal through the north process sewer. In addition to receiving sulfuric acid the neutralization pit received lime slurry from the 183-H Head House. The building also contained rooms for chlorine storage, lavatories, janitor's room, electrical switchgear room, and a locker room (HW-74094). The neutralization pit served as a structure to treat excess concentrated sulfuric acid (from acid tank cleanouts) prior to disposal through the north process sewer. The Neutralization Pit received sulfuric acid from two storage tanks and one acid head tank, and lime slurry from the 183-H Head House. The surface elevation was 126.97 m (416.56 ft). In the center of the pit is a vertical orientated vitrified clay pipe (VCP) with a Vitrabond seal at approximately 0.9 m (3 ft) below grade surface (bgs). Vitrabond consists of a conventional glass ionomer, in conjunction with a light-curing resin and hydroxy-ethylmethacrylate. The pit was constructed on top of a concrete monolith and vertically drained with a 10.2 cm. (4 in) VCP into a 76.2 cm (30 in) reinforced concrete pipe (RCP) extra strength process sewer line (100-H-28:3 North Process Sewer). The process sewer pipe was at inverse elevation 123.52 m (405.26 ft). The pit drain line was perforated with the pit itself and within the drain line was a 2.54 cm (1 in) diameter (Hastelloy) rod which seated into a 7.62 cm. (3 in) diameter lead hemisphere. The lead hemisphere was seated in the floor of the pit in the acid proof brick layer. Hastelloy is a trademark for a series of high-strength, nickel based, corrosion resistant alloys produced by Haynes International (H-1-5671). Portions of the above described neutralization pit may remain. The piping included a sulfuric acid supply and drain lines, a lime slurry pipeline, sludge trap drains, filtered water and steam condensate drain lines. The pipelines were

contained in a concrete trench extending from the Acid Head tank to the Neutralization Pit and then to the west wall of the 183-H Head House. Also included were short sections of pipelines connecting to ancillary equipment outside of the trench. Also included in the site are two french drains, a steam trap, and acid pump foundation. One 30.48 cm (12 in) french drain (E577728.89, N152882.85) was located adjacent to the covered car spot and was connected to a compressed air line. The second french drain (E577735.51, N152880.58) received steam condensate adjacent to the 183-H Head House Acid Facility Silica Tank. A steam trap was located between the silica tank and the 183-H Head House (E577732.5, N152876.2). The steam trap was the termination point for a silica tank condensate pipeline. Although the french drain and steam trap both supported the silica tank, the relationship of the two to each other is not known. The acid pump foundation (E 577721.0, N152883.2) held two pumps located to the north side of the trench. Portions of the foundation were below grade. Historical documentation does not indicate if the pumps were located above grade and were removed or are still within the below grade portion of the foundation. The foundation had a "Lead Fill" type cover measuring 1/16 of an inch thick (GEA, 1956b).

Related Sites/ Structures: The 183-H Neutralization Pit was associated with the 183-H Filter Plant, acid pipelines, railroad car spot and the North Process Sewer, which is located below and adjacent to the pit.

Waste Type: Equipment

Waste Description: The site received concentrated sulfuric acid which may have included lead and mercury. There may be contaminated equipment components, piping and soil that remain in place.

Code: 100-H-45

Classification: Accepted

Names: 100-H-45; 1717-H UST; H-015; Underground Propane Tank

Reclassification: No Action (7/8/2010)

Type: Unplanned Release

Start Date:

Status: Inactive

End Date:

Description: The site was a suspect propane underground storage tank (UST) and included any associated below grade piping or features. It is unknown if the propane tank shown in the historical construction drawing (SK-1-7325) was ever installed.

Location: The suspect propane UST is located near the northeast corner of the 1717-H building. The tank's location is shown on SK-1-7325 at coordinates E578018, N152621.

Process Description: The 1717-H Building housed a machine shop, sheet metal shop, fabrication, shop, and carpenter shop that provided services for all of the 100-Areas operations. The fabrication shop was outfitted for fabrication and repair of reactor system components, particularly those associated with water treatment and pumping systems. A portion of the 1717-H Building was also used as a hot shop, for work on very low-level radioactive materials.

Related Sites/ Structures: The propane tank is associated with the 1717-H building and the 1717-H Hot Shop (sitecode 100-H-4).

Waste Type: Chemical Release

Waste Description: Potential contaminants include propane hydrocarbons in the soil.

Description:

Closure Info: The Remaining Sites Verification Package (RSVP-2009-064) has documented that the 100-H-45 Underground Propane Tank waste site meets the remedial action objectives (RAOs) and remedial action goals (RAGs) for No Action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action

Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD) (EPA 1999).

Confirmatory sampling was performed on November 10, 2009. The contaminants of potential concern for confirmatory sampling included the expanded list of inductively coupled plasma metals, mercury, polycyclic aromatic hydrocarbons (PAH), and total petroleum hydrocarbons.

The complete laboratory sampling results were stored in the WCH Environmental Restoration project-specific database prior to submission to the Hanford Environmental Information System for archiving and were provided in Appendix A of the RSVP.

The results of confirmatory sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. The site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

Code:	100-H-46	Classification:	Accepted
Names:	100-H-46; 190-H Potential Contaminated Soil	Reclassification:	None
Type:	Process Unit/Plant	Start Date:	
Status:	Inactive	End Date:	
Description:	<p>This site consists of contaminated soils, concrete structures and drain pipes that were beneath the sodium dichromate process equipment, piping, unloading dock and railroad spur. This site is within the footprint of the 190-H Pump house which was demolished and removed to 1 m (3 ft) below grade in 1977. The site is approximately the northern twenty percent of the facility with original elevation of 421.0 ft. The site consists of several locations that existed along the northern and west sections of the 190-H building where sodium dichromate was handled, mixed and injected into the reactor process water system. There were 4 equipment pads which measured 3.04 m (10 ft) by 1.34 m (4.4 ft) by 0.61 m (2 ft) high. There were 3 concrete trenches that formed a "U" shape which measured 7.66 m (25.16 ft) by 10.56 m (34.66 ft) by 1.52 m (5 ft) depth. Each of the four process water storage tanks had concrete drain pits which measured overall 3.04 m (10 ft) by 4.87 m (16 ft) by 1.52 m (5 ft) depth. A 15.24 cm (6 in) drain line which received fifteen percent sodium dichromate, in the form of overflow, exited the building towards the south process sewer at an elevation of 417.5 ft. There was a loading dock, which received the dry sodium dichromate, it was located adjacent to the railroad spur. And there was an elevator which was used to transport dry sodium dichromate to the upper floors.</p>		
Location:	<p>This waste site is within the footprint of the 190-H Pump house, that was demolished and removed in 1977. The 190-H building was located 77 m (252 ft) north of the 105-H Reactor.</p>		
Process Description:	<p>The 190-H complex was a process water treatment plant which supplied the 105-H Reactor with nonradioactive cooling water. Sodium dichromate, in dry crystalline form, was added to filtered water as an anticorrosive agent. The fifteen percent sodium dichromate was injected into piping which fed to four 6,624 kL (1,750,000 gal) Process Water Storage Tanks within the 190-H facility. The sodium dichromate process consisted of a mixing tank, two feed tanks, two centrifugal pumps, eighteen proportioning pumps, piping, valves, and associated electrical and instrument equipment. Bagged sodium dichromate was delivered to the 190-H building via railcar. An unloading dock, with adjacent elevator inside, was used to convey the material from the railcar to an upper level of the 190-H building (P-1315). The mixing and feed tanks each had a 3,236 L (855 gallon) capacity and were located on the second through fourth floors of the 190-H building (P-1315). There was one mixing tank located directly above the two feed tanks.</p>		

At the top of the mixing tank were an agitator and a wooden cover with a bag hopper where the sodium dichromate was added. Water was added to the sodium dichromate and mixed to a fifteen percent concentration (HW-27270). A 7.62 cm (3 in) diameter process pipe, with a three way valve for draining purposes, exited the base of the mixing tank to the feed tanks. Also, a 7.62 cm (3 in) diameter overflow pipe exited near the top of the mixing tank and connected to the tank drain pipe. The 7.62 cm (3 in) mixing tank pipe entered through the top of two sodium dichromate feed tanks located below the mixing tank. The feed tanks were 1.5 m (5 ft) in diameter with a conical bottom. A 7.62 cm (3 in) diameter overflow pipe exited near the top of each tank. At the base of the feed tanks was a 3.8 cm (1 ½ in) diameter pipe that fed the liquid concentrate to four injection pump pads (P-1315). The sodium dichromate concentrate piping was located next to the north wall, elevated above the floor, and ran approximately the full length of the building servicing the four injection pump locations. The sodium dichromate liquid was added to the filtered water by injection pumps through chemical feed injection rings. The injection rings were located inline with 76 cm (30 in) and 107 cm (42 in) diameter pipes that entered the Process Water Storage Tanks through automatic control valves (P-1260, P-1874). The drain pipes from the mixing tank and the feed tanks entered a 15 cm (6 in) drain pipe that fed to the process sewer system which exited north out of the building (P-1221).

Related Sites/ Structures: 183-H Filter Building clearwells and pump room; the 187-H1 and 187-H2 emergency high tanks; the 151-H Primary Electrical Substation; 184-H Power House steam supply; 105-H Reactor and the 100-H-28-2 South Process Sewers.

Waste Type: Demolition and Inert Waste

Waste Description: The primary contaminate of concern is sodium dichromate. There may be buried debris, i.e., concrete, rebar, and piping below grade.

Code: 100-H-48 **Classification:** Accepted

Names: 100-H-48; 184-HA Underground Fuel Oil Tanks Associated Piping **Reclassification:** None

Type: Product Piping **Start Date:** 1/1/1965

Status: Inactive **End Date:**

Description: The site consists of potentially remaining fuel oil piping that was associated with two fuel oil underground storage tanks (UST's) that supported the 184-HA Boiler House Building. The two 45,651 liter (12,036 gallon) fuel oil tanks have already been removed from the site.

Location: The approximate location for the two fuel tanks was E577833, N152585.

Process Description: The 184-HA Boiler House Building and associated equipment was constructed in approximately 1965 to replace the 184-H boiler house that was being shutdown in conjunction with deactivation of the 100-H reactor (HW-82720). The reactor was shut down permanently in April of 1965. The boiler provided steam to the administration and Central Shops buildings, which consisted of 1703, 1704, 1716, 1717, 1719, 1722, 1760, and 1761. Buildings 1703, 1760, and 1761 were on one supply line and the remaining buildings on another (HW-82720). These steam supply lines were all above grade features (H-1-14575). The 184-H building water/chemical equipment consisted of the following above grade features: (1) fuel oil fired package boiler, (1) brine tank, (2) water softener tanks, (1) chemical treatment tank w/pump, (1) de-aerator w/boiler feed pump. Each tank had a 5.1 centimeter (2 inch) fuel oil supply (FOS) and fuel oil return (FOR) pipe line connected to it that comes from a pump pit on the south side of the building. The fuel oil piping, as it leaves the south end of the pump pit going to the tanks, is at 0.6 meters (2 feet) elevation (H-1-14579). The fuel oil piping consists of ASTM A-53 schedule 40 black steel covered with taping. This buried piping was required to have an exterior coat of coal tar enamel with bonded asbestos felt wrap, with the joints wrapped in coal tar tape (tapecoat). A U-shaped concrete trench in the floor of the 184-HA building contained fuel oil

supply and return lines, a propane (PR) line (boiler pilot light connection- H-1-14579), the 5.1 centimeter (2 inch) influent sanitary water (SW), and (2) trench floor drains that connected to the 5.1 centimeter (2 inch) sanitary drain (SD) connected at the east end of the building drain field's (west of the building) 20.3 centimeter (8 inch) perforated concrete main line (H-1-14576 and H-1-14577). Steam line vent valves and a 1.9 centimeter (0.75 inch) soot blower drain valve also emptied effluent into the trench (H-1-14583).

Related Sites/ Structures: The piping is associated with the 184-HA boiler and the 190-HA Main Process Pump House Annex.

Waste Type: Soil

Waste Description: Fuel oil potentially remains in the piping and the underlying soil.

Code: 100-H-49	Classification: Accepted
Names: 100-H-49; Potentially Contaminated French Drains	Reclassification: None
Type: French Drain	Start Date:
Status: Inactive	End Date:

Description: This site consists of sixteen french drains, the underlying soil of the potentially contaminated french drains, and their associated below grade piping components. The site has been divided into three subsites as follows: - 100-H-49:1, 184-H Boiler House and 1717-H Hot Shop French Drains - 100-H-49:2, 119-H, 181-H, 184-H, and 183-H French Drains - 100-H-49:3, 183-H and 1717-H French Drains

Location: Refer to the subsites for the detailed locations of each french drain.

Process Description: The french drains were discovered during the Orphan Site Evaluation (OSE) historical review. Each of the facilities that the french drains are associated with, were identified and the process or function of the buildings summarized. This information is incorporated into the list of french drains included in the site description for each of the subsites. Details of the inlet pipes sizes, depths of the french drains, and construction drawings are provided when available. Generally, french drains are a minimum of 4.6m (15 ft) from the edge of buildings. When exact locations were not available from construction drawings and these locations have been estimated by placing the location 4.6 m (15 ft) away from building. In other cases, the piping to the french drains is a well defined location. Orphan sites field investigations were conducted on March 12th and 17th of 2008. Photographs of the present site conditions were obtained.

Related Sites/ Structures: The french drains (and drywells) are related to 119-H, 181-H, 183-H, 184-H, 1717-H, and 1719-H.

Waste Type: Equipment

Waste Description: The waste consists of the french drains, piping to the french drains, and potentially contaminated soil. The contaminants of potential concern will be evaluated during work planning and confirmatory sampling.

This Site has the Following SubSites:

Code: 100-H-49:1

Names: 100-H-49:1; 184-H Boiler House and 1717-H Hot Shop French Drains

Code: 100-H-49:2

Code: 100-H-49:3
Names: 100-H-49:3; 183-H and 1717-H French Drains

Code: 100-H-49:1 **Classification:** Accepted
Names: 100-H-49:1; 184-H Boiler House and 1717-H Hot Shop French Drains **Reclassification:** None
Type: French Drain **Start Date:**
Status: Inactive **End Date:**

Description: This site consists of four french drains, the underlying soil of the potentially contaminated french drains, and their associated below grade piping components. The drains include:

FD4 is a 1 m (36 in) french drain with a 11 m (36.1 ft) long, 0.1 m (4 in) condensate (CNDS) drain line from the 184-H Boiler House Reclaiming Hopper (P-1418) to the french drain. The pipeline enters the french drain -1.07 m (-3.5 ft) below grade. The 184-H building utilized steam from the boilers to heat the coal conveyor system and coal shack. It's unknown whether a non-contact form of steam heating was used. The resulting condensate was drained to 0.1 m (4 in) VCT piping 1.07 m (3.5 ft.) below grade and was the inlet piping to the french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-939)

FD5 is a 0.6 m (24 in) french drain with a 7.2 m (24 ft) long, 0.1 m (4 in) vitrified clay type (VCT condensate (CNDS) drain line from the 184-H Boiler House Transfer House to the french drain. The pipeline enters the 1.9 m (76 in) deep french drain at 1.07 m (42 in) below grade (P-1417, P-1418). The 184-H building utilized steam from the boilers to heat the coal conveyor system and coal shack. It's unknown whether a non-contact form of steam heating was used. The resulting condensate was drained to 0.1 m (4 in) VCT piping 1.07 m (3.5 ft) below grade and was the inlet piping to the french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-940).

FD16 is a 0.9 m (36 in) french drain with a 5.2 m (17.1 ft) long, and a 11.0 m (36.1 ft) long pipeline; each is a 0.08 m (3 in) diameter heating/steam return line from 1717-H Hot Shop (west side) to the french drain. (P-1436) No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-969).

WCH requested that the 100-H-28:7 french drain be added as a subsite to 100-H-49:1. The french drain was discovered along the edge of a test pit that was excavated in support of confirmatory sampling for process water lines that were designed to supply water treated at the 183-H Filter Plant to the 105-H Reactor (TP3) at coordinates E577853, N152563, The french drain is a 0.9-m (36-in.) vitrified clay french drain at coordinates 577848 E, 152567 N, on the northeast side of the 105-H Reactor.

ICP metals, Mercury, Hexavalent Chromium, Polyaromatic Hydrocarbons, Pesticides and Total Petroleum Hydrocarbons.

Location: The locations for each of the French Drains are listed below. Washington State Plane coordinates are provided for each french drain. The associated drawings were rectified to Washington State Plane coordinates to obtain the coordinates listed below.

FD4 - E577504.29, N153006.45
 FD5 - E577553.28, N152996.60
 FD16 - E577970.71, N152553.58

100-H-28:7 TP3 FD - E577848, N152567

Process Description: The process description was inferred from the construction drawings and the function of the building that they were associated with. This information is provided for each of the french drains in the Site Description above.

Waste Type: Not Specified

Waste Description: The waste is the french drain, piping to the french drain, and potentially contaminated soil.

The SubSite is Part Of:

Code: 100-H-49

Names: 100-H-49; Potentially Contaminated French Drains

Code: 100-H-49:2

Classification: Accepted

Names: 100-H-49:2; 119-H, 181-H, 184-H and 183-H
French Drains

Reclassification: No Action (10/26/2011)

Type: French Drain

Start Date:

Status: Inactive

End Date:

Description: The subsite consists of nine french drains, the underlying soil of the potentially contaminated french drains, and their associated below grade piping components. The drains include:

FD1 was a dry well that was associated with the 119-H Sample Building. A 5.1 cm (2 in) cast iron pipeline ran from the 119-H Sample Building to the dry well. (H-1-19812, H-19805). During the Orphan Site's Walkdown the dry well could not be proven to exist or not exist from the view point outside the fence of the contamination area for the 105-H Reactor. No documents or records were obtained during historical research to indicate the end state of the dry well or underlying soil. Analogous sites include 100-D-24 and 100-F-46. (See orphan site photo # 031708-976).

FD2 was a 0.6 m (24 in) french drain with a 4.5 m (14.8 ft) long, 0.1 m (4 in) cast iron soil line from the 181-H Battery Room to the french drain (P-1337, P-1334). During the Orphan Site's Walkdown, there was no evidence of a recent disturbance or french drain existing within a 5 m (16.4ft) diameter area. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo #03172008-973).

FD3 was a 1 m (36 in) french drain with a 4.7 m (15.4 in) long, 0.1 m (4 in) vitrified clay type (VCT) condensate (CNDS) drain line (P-1417, P-1418). The french drain is 1.9 m (76 in) deep with the inlet pipeline at -1.1 m (-42 in) below grade. The pipeline comes from the 184-H Boiler House Coal Shack Track Hopper. The 184-H building utilized steam from the boilers to heat the coal conveyor system and coal shack. It is unknown whether a non-contact form of steam heating was used. The resulting condensate was drained via 0.1 m (4 in) VCT piping 1.07 m (3.5 ft.) below grade and was the inlet piping to the french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03172008-974).

FD6 was a 1 m (36 in) french drain with a 8.7 m (28.5 ft) long, 0.1 m (4 in) diameter vitrified clay type (VCT) condensate (CNDS) drain line from the 184-H Coal Crusher House to the french drain (P-1417, P-1418). The pipeline enters the 1.9 m (76 in) deep french drain at -1.04 m (42 in) below grade (P-1417, P-1418). The 184-H building utilized steam from the boilers to heat the coal conveyor system and coal shack. It's unknown whether a non-contact form of

steam heating was used. The resulting condensate was drained to a 0.1m (4 in) VCT pipe 1.07 m (3.5 ft.) below grade and was the inlet piping to french drain. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-941).

FD7 was a 0.6 m (24 in) french drain with two pipe segments that are 0.1 m (4 in) diameter vitrified clay type (VCT) condensate (CNDS) drain lines from the 184-H Coal Transfer Tower to the french drain (P-1418). The pipeline enters the 1.9 m (76 in) deep french drain at -1.07 m (42 in) below grade (P-1418). The french drain had a total below grade depth of 1.92 m (76 in) with two 10.2 cm (4 in) diameter VCT inlet pipes 1.07 m (42 in) below grade and located 4.5 m (15 ft) east from the transfer house and conveyor system. The piping appears to be condensate from a 15.25 cm (6 in) above grade steam main. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-942).

FD8 was a 1 m (36 in) french drain with a 5.9 m (19.4 ft) long, 0.1 m (4 in) vitrified clay type (VCT) line. The inverse elevation at the french drain is 125.9 m (413 ft). The pipeline runs from the 184-H Boiler House Battery Room floor drain to the french drain. There is a second inlet from an unknown source. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. The location is estimated. (P-1413, P-1417) (See orphan site photo # 03122008-944).

FD9 is a 1 m (36 in) french drain with a 5.6 m (18.4 ft) long segment, a 6.6 m (21.7 ft) long segment, and a 2.4 m (7.9 ft) long segment of pipe; all are 10.16 cm (4 in) vitrified clay type (VCT) line. The french drain is 1.9 m (76 in) deep with the line inlet at --1.04 m (42 in) below grade (P-1417). The line runs from the 184-H Boiler House laboratory and radiator heating system to the french drain. There is a second inlet pipe at the french drain from an unknown source. No documents or records were attained/obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-946).

FD12 is a 1 m (36 in) french drain with a 9.7 m (37.8 ft) long, 0.1 m (4 in) diameter vitrified clay pipeline from the 1719-H First Aid Building (Laboratory Waste) to the french drain. (P-1235) No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo #03122008-961).

FD14 is a 0.9 m (36 in) french drain with a 5.3 m (17.4 ft) long, 0.08 m (3 in) diameter cast iron (CI) pipeline from 1717-H (northwest side) pipe shop radiator heater to the french drain (P-1436). The pipeline is 1.07 m (3.5 ft) below grade. (P-1436) No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-966).

Location: The locations for each of the French Drains are listed below. Washington State Plane coordinates are provided for each french drain. The associated drawings were rectified to Washington State Plane coordinates to obtain the coordinates listed below. Order is maintained with the listing in the site description.

Process Description: building that they were associated with. This information is provided for each of the french drains in the Site Description above.

Related Sites/ Structures: The french drains (and drywells) are related to 119-H, 181-H, 184-H, 1717-H, 1719-H.

Waste Type: Not Specified

Waste Description: The waste consists of the french drain, piping to the french drain, and potentially contaminated soil. COPCs ICP metals, mercury, hexavalent chromium, polyaromatic hydrocarbons, polychlorinated biphenyls and total petroleum hydrocarbons.

Closure Info: This site is a confirmatory sampling site that did not need remediation.

The SubSite is Part Of:

Code: 100-H-49

Names: 100-H-49; Potentially Contaminated French Drains

Code: 100-H-49:3

Classification: Accepted

Names: 100-H-49:3; 183-H and 1717-H French Drains

Reclassification: None

Type: French Drain

Start Date:

Status: Inactive

End Date:

Description: This site consists of four french drains, the underlying soil of the potentially contaminated french drains, and their associated below grade piping components. One of the french drains is already part of the 100-H-4 waste site. The piping for the 100-H-4 french drain was not previously identified as a component of that waste site. Therefore the piping associated with the 100-H-4 french drain has been included within 100-H-49. The drains include:

FD10 is a 0.46 m (18 in) Drywell with a 45.5 m (149.3 in) long, 0.1 (4 in) diameter cast iron (CI) pipe to the french drain. The line runs from the 183-H Post Filter Building to the french drain. The site receives drainage from the battery, electrical, pump house and chlorine room. The inverse elevation at the french drain is 124.4 m (408.11 ft). The location is estimated. No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (P-1221, P-4302, P-4305) (See orphan site photo # 03122008-957).

FD11 is a 0.9 m (36 in) french drain with a 17.9 m (58.7 ft) long, 0.1 m (4 in) diameter pipeline from 183-H (post filter) to the french drain. The site receives drainage from the battery, electrical, pump house and chlorine room. The inverse elevation at the french drain is 124.4 m (408.11 ft). The location is estimated. (P-1221, P-4302, P-4305) No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-958).

FD13 is a 8.0 m (26.2 ft) long cast iron 0.08 m (3 in) diameter pipeline from the 1717-H machine/welding shop typical heaters to a 0.76 m (30 in) french drain (100-H-4). No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil (P-1436) (See orphan site photo # 03122008-967).

FD15 is a 0.76 m (30 in) french drain with a 7.8 m (25.6 ft) long, 0.08 (3 in) diameter cast iron (CI) pipeline from 1717-H (east side) Electrical Shop and Mechanical Equipment room heaters to the french drain (P-1436). No documents or records were obtained during historical research to indicate the end state of the french drain or underlying soil. (See orphan site photo # 03122008-968).

Location: coordinates are provided for each french drain. The associated drawings were rectified to Washington State Plane coordinates to obtain the coordinates listed below. Order is maintained with the listing in the site description.

FD10 - E577782.08, N152761.73 (No french drain exists)
 FD11 - E577778.37, N152752.41 (The location is estimated.)
 FD13 - E578009.56, N152598.17 (100-H-4; The location is estimated.)
 FD15 - E578009.69, N152570.62 (The location is estimated)

Process Description: The process description was inferred from the construction drawings and the function of the building that they were associated with. This information is provided for each of the french drains in the Site Description above.

Related Sites/ Structures: The french drains (and drywells) are related to 183-H and 1717-H.

Waste Type: Not Specified

Waste Description: The waste is the french drain, piping to the french drain, and potentially contaminated soil.

The SubSite is Part Of:

Code: 100-H-49

Names: 100-H-49; Potentially Contaminated French Drains

Code: 100-H-50

Classification: Accepted

Names: 100-H-50; 100-H Steam Condensate French Drains

Reclassification: No Action (6/16/2011)

Type: French Drain

Start Date:

Status: Inactive

End Date:

Description: The site consists of fourteen discrete locations, underlying soil and their associated below grade piping components for steam condensate French drains. The French drains were discovered during the Orphan Site Evaluation (OSE) historical review. Each of the facilities that the French drains are associated with, were identified and processes or functions of the buildings summarized in the list below. Details of inlet pipe sizes, depths and French drain size and construction details and depths are provided when available in the descriptions below. When exact locations were not available from construction drawings the location was estimated by placing the location 4.6 meters (15 feet) away from building. In these cases the inlet piping is in a well defined location. See detailed spatial analysis map for French Drain locations.

Orphan sites field investigations were conducted on March 12th and 17th of 2008. Photographs of the present site conditions were obtained.

FD1. The site is a 1.22 m (48 in) reinforced concrete pipe French drain with a 0.1 m (4 in) clay tile 6.1 m (20 ft) long at a 1% slope (1 in of slope per linear foot of pipe) from 1.1 m (42 in) raw water line. The site is associated with the 182-H Reservoir (north end) (P-4737 Sheet 1, P-4737 Sheet 2). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD2. The site is a 0.9 m (36 in) French drain with a 0.1 m (4 in) diameter cast iron (CI) pipeline from the 182-H Reservoir (south side) heater systems to the French drain (P-1368, P-1370). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD3. The site is a 0.46 m (18 in) dry well with a 2.54 cm (1 in) steam condensate pipeline from the 190-H Building (north side) (H-1-14575, H-1-14580, H-1-14581). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD4. The site is a 0.46 (18 in) dry well with a 0.05 m (2 in) steam condensate pipeline from the 190-H Building (east side) (H-1-14575, H-1-14580, H-1-14581). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD5. The site is a 0.61 m (24 in) dry well, 1.4 m (4.6 ft) deep with a 2.54 cm (1 in) steam condensate pipeline from 190-H Building to the dry well (H-1-14575, H-1-14580, H-1-14581). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD6. The site is a 0.61 m (24 in) dry well with a steam condensate pipeline from the 1703-H Office Building (west side) to the dry well (P-9340). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD7. The site is a 0.61 m (24 in) French drain with a ventilation drainage pipeline from the 1703-H Office Building (east side) to the French drain (P-9340). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD8. The site is a 0.9 m (36 in) French drain from the 184-H building (north side) that utilized steam radiator unit heaters with 1.9 cm (0.75 in) condensate blow off traps and drip legs which discharged to French drains with 0.1 m (4 in) diameter vitrified clay type (VCT) inlet piping to the French drain (P-1417).

FD9. The site is a 0.9 m (36 in) French drain with a 0.1 m (4 in) diameter VCT pipeline from a return riser and steam supply riser from the 184-H Boiler House (east side) to the French drain (P-1417). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD10. The site is a 0.9 m (36 in) French drain with a 0.1 m (4 in) diameter VCT condensate pipeline from the 184-H Boiler House (west side) to the French drain. (P-1417) No documents or records were obtained during historical research to indicate a final disposition for the site.

FD11. The site is a 0.61 m (24 in) French drain with a 0.1 m (4 in) diameter VCT pipeline from a return riser and steam supply riser from 184-H Boiler House (south side) to the French drain. (P-1417) No documents or records were obtained during historical research to indicate a final disposition for the site.

FD12. The site is a 1 m (36 in) French drain with a 9.4 m (31 ft) long, 2.54 cm (1 in) line connecting from the 1901-H Water Tower trap discharge to the French drain (P-1426). There is an additional pipeline to the French drain that is a 8.8 m (29 ft) long, 3.81 cm (1.5 in) line connecting from the 1901-H Water Tower ejector discharge to the French drain (P-1426). The pipelines are soft water trap discharge lines (P-1416 and P-1426).

FD13. The site is a 0.9 m (36 in) French drain with a 0.1 m (4 in) vitrified clay (VC) pipeline to the French drain (P-1237). No documents or records were obtained during historical research to indicate a final disposition for the site.

FD14. The site is a 0.61 m (24 in) French drain filled with soil/gravel. The drain was discovered in the field during the orphan site evaluation. The french drain does not appear on any construction drawings. The proximity of french drain FD5 to FD14 suggests that they might one in the same. The french drain is believed to receive steam condensate from the 190-H

Annex. This drain was later discovered to be the same as (duplicate) FD5.

Location: Selected as built construction drawings were rectified into the Geographic Information System (GIS) for each of the french drains and associated piping locations. The coordinates are provided in Washington State Plane coordinates. The coordinates are listed in the same sequence as the elements in the site description. Easting Northing 1. E577818.69, N153047.52 2. E577757.55, N152923.92 3. E577860.28, N152695.06 4. E577869.99, N152659.28 5. E577799.90, N152581.30 6. E577911.73, N152556.89 7. E577946.23, N152551.07 8. E577801.04, N152586.00

Process Description: The process descriptions were ascertained from construction drawings and are provided with construction drawing numbers. A spatial analysis was conducted for each of the french drains and dry well and all have been identified as receiving steam condensate. Steam was typically used at all facilities for heating purposes. The 184-H Power House boiler facility supplied high pressure steam to all buildings through an above grade pipeline system. The boiler facility utilized clean filtered water from the 183-H filter building. The steam supply was used in a non-contact radial heating system. As a non-contact system the steam remained uncontaminated. The steam transport process utilized a high pressure supply line and a low pressure return or discharge line. It was necessary to bleed both the supply and return lines to prevent condensate build up. The condensate was typical blow off from the above grade piping system into a below grade covered French Drain as illustrated on construction drawings as a safety precaution. French drains' diameters and construction material varied depending on steam piping size, service capacity or pounds per hour, and expected flow rate received.

Waste Type: Equipment
Waste Description: The waste is the French drain and associated piping.

Code: 100-H-51	Classification: Accepted
Names: 100-H-51; Potentially Contaminated Pipeline Segments	Reclassification: None
Type: Process Sewer	Start Date:
Status: Inactive	End Date:

Description: This site consists of five subsites. 1. Is a 15.2 cm (6 in) vitrified clay pipe sanitary sewer pipeline. 2. Is a 5.08 cm (2 in) steel brine discharge line. 3. Consists of two parallel pipelines, a 5.1 cm (2 in) steel brine discharge line and a 7.6 cm (3 in) steel filtered water line. 4. Is a 15.24 cm (6 in) vitrified clay storm drain (and smaller laterals) that run between the 1701-H, 1709-H and 1720-H buildings and a ditch (100-H-27). 5. Consists of a 25.4 cm (10 in) carbon steel pipe located between the Columbia River shoreline and the 184-H Power House.

Location: These pipeline segments were part of the 100-HR-1 Operable Unit. As built construction drawings were rectified into Washington State Plane coordinates. Pipelines were then incorporated into the Geographic Information System (GIS) for each of the four piping segments referred to in this site.

Process Description: The process descriptions were ascertained from construction drawings and are provided with construction drawing numbers. Miscellaneous pipeline segments are associated within unique building processes. Examples of the miscellaneous pipes include: boiler fuel delivery systems, elevator shafts, air conditioning systems, railcar/truck delivery spots, equipment drains, storage tanks pressure relief systems, compressor blow downs, and chemical transfer pipelines.

Related Sites/ Structures: Associated buildings and waste sites include: 1701-H, 1703-H, 1709-H, 1720-H, 184-H, 100-H-28, 116-H-9, 100-H-53, and 100-H-27.

Waste Type: Equipment

Waste Description: The waste will include the pipelines and any potential contaminated soil. Contaminants of potential concern have not been fully evaluated for each individual pipeline segment.

This Site has the Following SubSites:

Code: 100-H-51:1

Names: 100-H-51:1; 1703-H Sanitary Sewer Segment

Code: 100-H-51:2

Names: 100-H-51:2; 117-H Seal Pit Crib Feedline

Code: 100-H-51:3

Names: 100-H-51:3; 184-H Brine Discharge Line

Code: 100-H-51:4

Names: 100-H-51:4; 100-H Main Gate Storm Drain

Code: 100-H-51:5

Names: 100-H-51:5; Discovery Pipeline at 128-H-1

Code: 100-H-51:6

Names: 100-H-51:6; Carbon Steel Pipe

Code: 100-H-51:1

Classification: Accepted

Names: 100-H-51:1; 1703-H Sanitary Sewer Segment

Reclassification: None

Type: Process Sewer

Start Date:

Status: Inactive

End Date:

Description: The subsite consists of a 15.2 cm (6 in) diameter vitrified clay pipe (VCP) sanitary sewer segment. The line connects the 1703-H building with the 100-H-28, 100-H Water Treatment Facilities Underground Pipelines. The subsite also includes a short section of a 10.16 cm (4 in) soil pipe where the 15.2 cm (6 in) VCP connects to the 1703-H building.

The 1703-H building was constructed in 1949 and contained offices for area administrative and technical personnel. The building was demolished in 1974 leaving the footings and foundations after demolition of the building were buried and leveled (UNI-7231974). The 100-H-28:5 waste site has been identified by WCH for remediation, see WCH CCN #141052.

Location: The pipeline segment is located on the west side of 1703-H building and runs north, terminating at a manhole where it joins the 100-H-28:5 Sanitary Sewer pipeline.

Waste Type: Soil

Waste Description: The waste has been described as contaminated soil. The COPCs include: arsenic, barium, cadmium, chromium, hexavalent chromium, lead, selenium, silver, mercury, semivolatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), and chlorinated pesticides.

The SubSite is Part Of:

Code: 100-H-51

Names: 100-H-51; Potentially Contaminated Pipeline Segments

Code: 100-H-51:2

Classification: Accepted

Names: 100-H-51:2; 117-H Seal Pit Crib Feedline **Reclassification:** None
Type: Process Sewer **Start Date:**
Status: Inactive **End Date:**

Description: The subsite consists of a 10 cm (4 in) diameter cement asbestos feed line that ran from the 117-H Air Filter Building to waste site 116-H-9, 117-H Crib, 117-H Seal Pit Crib.

The 117-H Air Filter Building and crib were constructed in 1960. The building was closed under a determination of residual contamination levels (ARCL) (UNI-3001). The 117-H building was demolished in 1984. A distribution header lies approximately 1.5 m (5 feet) below grade and is covered by a polyethylene barrier.

The pipeline was identified as part of the 116-H-9 waste site initially and later reassigned to the 100-H-51 waste site on 2/19/2009. This was done to facilitate closure of 116-H-9 while postponing remediation of the pipeline. Per WCH documentation remediation of 116-H-9 began in October 2008.

Location: The pipeline segment is located between the 117-H Air Filter Building and the 117-H Seal Pit Crib.

Waste Type: Not Specified

Waste Description: The waste is remaining pipelines and any potentially contaminated soil. COPCs include: carbon-14, cesium-137, cobalt-60, europium-152, europium-154, europium-155, plutonium-238, plutonium-239/240, strontium-90, tritium, radium-226, thorium-228, thorium-232, uranium-238, cadmium, chromium (total), hexavalent chromium, mercury, lead, selenium, silver, and PCBs.

The SubSite is Part Of:

Code: 100-H-51
Names: 100-H-51; Potentially Contaminated Pipeline Segments

Code: 100-H-51:3 **Classification:** Accepted
Names: 100-H-51:3; 184-H Brine Discharge Line **Reclassification:** None
Type: Process Sewer **Start Date:**
Status: Inactive **End Date:**

Description: The subsite consists of two parallel pipelines, a 5.1 cm (2 in) steel brine discharge line and a 7.6 cm (3 in) steel filtered water line that ran from the 184-H Power House Building to the 184-H Salt Dissolving Pit and Brine Pump House.

Documentation established that the Power House was demolished in 1997. The 184-H Salt Dissolving Pit and Brine Pump House (100-H-16) were probably demolished in place as were similar brine pits at 184-B and 184-D.

Location: The pipelines were located between the 184-H Power House Building and the 184-H Salt Dissolving Pit and Brine Pump House.

Process Description: Filtered water was piped from the 184-H Power House to the 184-H Salt Dissolving Pit and Brine Pump House where sodium chloride was added and the brine was pumped back to the 184-H Power House for further use.

Waste Type: Not Specified

Waste Description: The waste is the remaining pipelines and any potentially contaminated soil.

The SubSite is Part Of:**Code:** 100-H-51**Names:** 100-H-51; Potentially Contaminated Pipeline Segments**Code:** 100-H-51:4**Classification:** Accepted**Names:** 100-H-51:4; 100-H Main Gate Storm Drain**Reclassification:** No Action (5/26/2011)**Type:** Process Sewer**Start Date:****Status:** Inactive**End Date:**

Description: The subsite consists of a 15.2 cm (6 in) diameter vitrified clay pipeline (VCP) storm drain that ran north from the 1701-H, 1702-H and 1709-H Buildings to 100-H-27, 100-H Area Patrol Headquarters Storm Runoff Ditch. The pipeline includes two 10.2 cm (4 in) lateral sections of VCP feed pipe from 1702-H and 1709-H buildings to the 15.2 cm (6 in) pipeline.

Location: The subsite was located between the 1701-H Building and the 100-H-27 storm runoff ditch. Additionally, the pipeline ran parallel and approximately 11 m (36 ft) north of the former location of the 1607-H3 septic system.

Waste Type: Not Specified**Waste Description:** The waste will include the pipelines and any potential contaminated soil.

Closure Info: Confirmatory sampling was performed on October 7, 2010 to determine if remedial action would be required. The results indicated that the waste site achieved compliance with the remedial action objectives (RAOs) and remedial action goals (RAGs) for the 100-H-5 1:4 subsite; therefore, remediation was not necessary. The results of the confirmatory sampling are used to make reclassification decisions for the 100-H-51:4 subsite in accordance with the TPA-MP-14 procedure in the Tri-Party Agreement Handbook Management Procedures (DOE-RL 2007).

A reclassification to No Action for the 100-H-51:4 subsite is supported based on site history, process knowledge, field observations, and comparison of residual contaminant concentrations against RAGs. The current site conditions achieve the Ras and the corresponding RAGs established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 2009) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR -2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD) (EPA 1999). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow-zone soil (i.e., surface to 4.6 m [15 ft]), and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The 100-H-51:4 subsite did not extend into the deep zone. No Institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are required.

The SubSite is Part Of:**Code:** 100-H-51**Names:** 100-H-51; Potentially Contaminated Pipeline Segments**Code:** 100-H-51:5**Classification:** Accepted**Names:** 100-H-51:5; Discovery Pipeline at 128-H-1**Reclassification:** None**Type:** Product Piping**Start Date:**

Status: Inactive

End Date:

Description: The pipeline is a steel pipe that ran from the Columbia River to the sanitary water system just south of the 1713-H building.

Location: The pipeline is located at the Columbia River shoreline and continues south ending 50 m (164 ft) beyond the 128-H-1 Burn Pit.

Process Description: There is no process history associated with this subsite.

Waste Type: Not Specified

Waste Description: The waste will include the pipelines and any potential contaminated soil.

The SubSite is Part Of:

Code: 100-H-51

Names: 100-H-51; Potentially Contaminated Pipeline Segments

Code: 100-H-51:6

Classification: Accepted

Names: 100-H-51:6; Carbon Steel Pipe

Reclassification: None

Type: Product Piping

Start Date:

Status: Inactive

End Date:

Description: The 100-H-51:6 waste site is a section of 25-cm (10-in) pipe that starts approximately 70-m (231-ft) south of the 100-H-51:5 waste site and ends near the 1713-H Building. This particular section of carbon steel pipe is thought to have connected to the southern side of a temporary wooden water tank and ended near the 1713-H Building. This pipeline and water tank is suspected to be part of an extensive temporary water system for construction of the 100-H Area in 1948 (HW-24800-2). This section of pipe (that is currently named 100-H-51:6) used to be part of 100-H-51:5 and 100 -H-53 waste site until confirmatory sample results exceeded direct exposure cleanup levels and was forced to be removed, treated, and disposed (RTD).

Location: The pipeline is located west of the 1713-H building.

Process Description: There is no process history associated with this subsite.

Waste Type: Not Specified

Waste Description: The waste will include the pipelines and any potential contaminated soil.

The SubSite is Part Of:

Code: 100-H-51

Names: 100-H-51; Potentially Contaminated Pipeline Segments

Code: 100-H-52

Classification: Accepted

Names: 100-H-52; 184-HA Septic Drain Field and Associated Piping

Reclassification: None

Type: Septic Tank

Start Date: 1/1/1965

Status: Inactive

End Date: 1/1/1974

Description: The site consists of a septic drain field and associated piping that supported the 184-HA boiler annex. In the center of the drain field (oriented east/west) are four, 20 centimeter (8 inch)

diameter perforated concrete pipe laterals.

Location: The drain field is located on the west side of the 184-HA Building. It is approx. 20.8 meters (68.6 feet) east of the 190-HA building. Global Positioning System (GPS) coordinates for the drain field are E577820/N152595. These are the coordinates of where the 5.1 centimeter (2 inch) sanitary drain (SD) effluent pipe line connects into the east side of the drain field.

Process Description: The 184-HA Boiler House Building and associated equipment was constructed in approximately 1965 to replace the 184-H boiler house. The 184-HA building was removed and its associated footings and foundations were demolished and backfilled in 1974. The site was leveled. The boiler provided steam to the administration and Central Shops buildings, which consisted of 1703, 1704, 1716, 1717, 1719, 1722, 1760, and 1761. Blow-down effluent from the boiler, drained via the 10.2 centimeter (4 inch) condensate line, that connected to the east end of the drain field, to the 20 centimeter (8 inch) perforated concrete main line.

Related Sites/ Structures: The septic system is associated with the 184-HA building.

Code: 100-H-53 **Classification:** Accepted

Names: 100-H-53; Carbon Steel Pipe in River Bank **Reclassification:** None

Type: Process Sewer **Start Date:**

Status: Inactive **End Date:**

Description: This site is a 25 cm (10 in) diameter and 1.8 m (6 ft) long (exposed portion) carbon steel pipe that runs northeast toward the river shore. A WCH Orphan Sites Field Evaluation was conducted in this area in August of 2007. Geophysics (GI # 0590309) was conducted in October 2007, and results indicate that the visible segment of the 25 cm (10 in) diameter pipe is not part of an intact system and does not extend below grade beyond the 1.8 m (6 ft) currently visible.

Location: This site is located approximately 28 m north-northeast of the southeast end of rejected WIDS site 600-258 (Pre-Hanford debris) and it is located near the shoreline.

Process Description: The process associated with this pipe is unknown. The pipeline may have been related to pre-Hanford activities, since there is this type of debris associated with 600-258. Site 600-258 is located on top of the bank and the pipe is located towards the south end of 600-258. See site 600-258.

Related Sites/ Structures: Pipe is NE of 600-151, (Dumping Areas 50 yards and 200 yards Downstream of River Mile 14. Co-located near 600-258.

Waste Type: Equipment

Waste Description: The waste is the pipeline and any potentially contaminated soil underlying the pipe. Since the pipeline can not be related to any particular human activity, the contaminants of potential concern are unknown.

Code: 100-H-57 **Classification:** Accepted

Names: 100-H-57; Water Tower Foundations at 100H **Reclassification:** None

Type: Foundation **Start Date:**

Status: Inactive **End Date:**

Description: The site consists of the underground piping, valves, sumps and other structures at the base of

the two elevated water towers adjacent to the 105-H Reactor.

Location: The towers are located on either side of the 105-H Reactor.

Process Description: Water was provided as a means to remove heat from the pile. A network of interconnecting pipelines, by-pass lines, and standby pumping facilities were provided to insure that water service to the pile was maintained even when a part of the system was inoperable (TNX-PG-4). The principal purpose of the two elevated storage tanks at the 105-H Reactor was to provide standby storage of cooling water in the event that the service to the pile was interrupted. The 105-H Reactor had two 300,000 gallon capacity, ellipsoidal-steel-plate tanks (187-H1 and 187-H2), elevated 120-feet above the ground level (HW-24800-2). Sodium silicate was supplied to the tanks for corrosion prevention (H-1-13254). The construction drawings (P-1257 and P-2031) for the 187-H1 and 187-H2 tanks show a french drain receiving condensate through a 3.8 cm (1.5 in) pipeline. The drawings also suggest that the sump in the bottom of the valve pit was emptied into this french drain. The drawings show that the french drains were installed a minimum of 4.6 m (15 ft) on the north side of the tanks. However this would put them very close to a labyrinth of pipes that run east/west on the north side of the reactor. It is possible that they were actually installed in another location. One possible location for the french drain from tank 187-H2 might be waste site 100-H-8. It is not known where the influent line for 100-H-8 is piped from. There are no french drains already identified in the area near tank 187-H1. Although process knowledge about the water system at the 100-H Area would suggest that sodium dichromate was not added to the water towers, the lead regulatory agency has requested that the bases of these water towers be identified as a waste site. Their premise is that a similar waste site (100-D-94) in the D Area was created to assess the potential impact from sodium dichromate. An email from Mark Morton to Earl Prichard and Stephen Hamblin on March 17, 2003 was the first to raise the issue of sodium dichromate in the H and DR water towers (147123). The valve pits at both of the 105-H water towers was completely removed by demolition and decontamination activities.

Code: 116-H-1	Classification: Accepted
Names: 116-H-1; 107-H Liquid Waste Disposal Trench	Reclassification: Interim Closed Out (4/3/2001)
Type: Trench	Start Date: 1/1/1952
Status: Inactive	End Date: 1/1/1965

Description: The site has been remediated and closed out. The disposal trench was oriented in a north-south direction and was divided into three separate lobes. The trench was fed by a single 51-centimeter (20-inch) pipe that originated in the pumphouse located at the northwest corner of the 107-H Retention Basin (this pipeline is part of 100-H-21).

Location: The site was located south of the 107-H Retention Basin (site code 116-H-7).

Process Description: The trench operated from 1952 until 1958, receiving mixed waste effluent from the 116-H-7 Retention Basin during reactor shutdowns caused by fuel element ruptures. The process effluent coolant received by this trench reportedly contained debris from fuel element ruptures. Additionally, the trench received water and sludge removed from the 116-H-7 Retention Basin in April and May 1965, during basin deactivation. The primary lobe was supplied by a DN500 50 centimeter (20-inch) steel pipe that entered near its bottom. The pipe originated at the 1607-H Pump House, near the northwest corner of the 116-H-7 Retention Basin.

Related Sites/Structures: The disposal trench is associated with the 105-H Reactor, 116-H-7 Retention Basin and the 100-H-21 pipeline site.

Waste Type: Water

Waste: The site received diversion effluent from the 107-H Retention Basin during reactor outages due

Description: to fuel element ruptures and water and sludge from 107-H during deactivation of the unit.

Closure Info: Remedial action objectives (RAO's) and goals (RAG's) for the 116-H-1 site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area. The selected remedial action involves excavating the site to the extent required to meet specified soil cleanup levels, disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Area of the Hanford Site, and backfilling the site with clean soil to adjacent grade elevations.

Remedial action at the 116-H-1 site began on June 29, 1999. Excavation of the site involved removing the overburden materials and underlying contaminated soil. Based on field screening (discussed in Section 4.2), overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF.

On June 8, 2000, the excavation was completed. The elevation of the bottom of the excavation was at 123.4 meters (405 feet) upon completion. The excavation was approximately 12,735 square meters (137,077 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 82,706 metric tons (91,168 tons) of material from the site were disposed of at ERDF.

Waste site contaminants of concern (COCs) identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22). The COCs and contaminants of potential concern (COPCs) for this site consist of cesium-137, cobalt-60, europium-152, europium-154, europium-155, plutonium-239/240, strontium-90, and hexavalent chromium.

Additional COPCs identified during remediation, based on past orchard land-use knowledge and excavated waste sampling analyses, included arsenic and lead. Arsenic was not detected in cleanup verification samples at concentrations above the Washington State background of 20 milligrams per kilogram (Washington Administrative Code 173-340). Lead was identified as a COPC based on excavated waste sample analyses. Because lead was detected above the Hanford Site background of 10.2 milligrams per kilogram, lead was added to the final list of COCs for the site.

Cleanup verification sampling for the deep and shallow zones was done on June 15, 2000, and July 25, 2000, respectively. The final verification samples were submitted to offsite laboratories for analysis using approved U.S. Environmental Protection Agency analytical methods, as required per the SAP (DOE/RL-96-22).

The remedial action at the 116-H-1 site has achieved the RAOs and corresponding RAGs established in the approved Interim Action ROD (EPA 1995) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 116-H-1 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-H-1 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site pose no threat to groundwater or the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 116-H-1 site is verified to be remediated in accordance with the ROD (EPA 1995).

Code: 116-H-2	Classification: Accepted
Names: 116-H-2; 1608-H Crib & Trench; 1608-H Liquid Waste Disposal Trench	Reclassification: Interim Closed Out (3/1/2001)
Type: Trench	Start Date: 1/1/1953
Status: Inactive	End Date: 1/1/1965

Description: This site, including its feed pipe, has been remediated and closed out. It was an open trench that was fed by a 15-centimeter (6-inch) vitrified clay pipe that originated from the 1608-H Pump House. The feed pipe is shown on Hanford drawings H-1-19824 and M-1904-H.

Location: The site was located 76 meters (250 feet) south of the 105-H Reactor Building.

Process Description: From 1953 to 1965, the site received effluent from the 105-H Ball 3X project. Water was pumped from the 105-H Reactor Building to the trench via the 1608 Pump House.

Related Sites/Structures: The trench is associated with the 105-H Reactor Building and 1608-H Pump House. In 1953, the 116-H-2 trench overflowed and flooded a triangular area bounded by railroad tracks, known as the 100-H-17 Overflow. The 100-H-30 Sanitary Sewer trench was also contaminated with effluent that overflowed from 116-H-2.

Waste Type: Water

Waste Description: The site received coolant water from the 105-H Reactor Building during the Ball 3X system upgrade program. The site was used during other upgrade programs and when maintenance was necessary on the effluent system.

Closure Info: 100-H-17, 116-H-2, 100-H-2 and 100-H-30 were addressed as a group. The information below documents information for the group of sites.

The cleanup verification package (CVP-2000-00031) has demonstrated that remedial action at for the 100-H-17 Overflow, 116-H-2 Liquid Waste Disposal Trench, 100-H-2 Buried Thimble Site, and the 100-H-30 Sanitary Sewer Trench sites have achieved the remedial action objectives (RAOs) and corresponding remedial action goals (RAGs) as established in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (ROD) (EPA 1995), and the amendment to the ROD (EPA 1997), and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17). This site is located in an area that, prior to World War II and formation of the Hanford Site, was occupied by fruit tree orchards. These sites were grouped together due to their proximity and similarity in the type of waste they received.

The COCs identified in the 100 Area Remedial Action Sampling and Analysis Plan for this site consisted of plutonium-239/240, uranium-238, strontium-90, cesium-137, cobalt-60, europium-152, europium-154, and hexavalent chromium.

At the completion of the remedial action, the total excavation was approximately 6,240 square meters (67,170 square feet) in area with a maximum depth of approximately 2.6 meters (8.5 feet). Approximately 19,920 metric tons (21,960 tons) of material from the site were disposed of at the ERDF.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (Ics) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15

feet]) are required.

Code: 116-H-3	Classification: Accepted
Names: 116-H-3; Perf Decontamination Drain; 105-H Dummy Decontamination French Drain	Reclassification: Interim Closed Out (4/3/2001)
Type: French Drain	Start Date: 1/1/1950
Status: Inactive	End Date: 1/1/1965

Description: This site has been remediated and closed out. The site was a french drain made of vitreous tile conduit. The upper surface of the french drain extended a few inches above the ground and had a metal cover. The waste site includes an underground feed pipeline which is 65 meters (215 feet) in length.

Location: The site was located southeast of the 105-H Building.

Process Description: The 116-H-3 French Drain received spent nitric acid and rinse water from the decontamination of fuel element spacers, reactor process tube caps, and other reactor hardware between 1950 and 1965.

Related Sites/ Structures: The site was related to the 105-H Reactor Building.

Waste Type: Process Effluent

Waste Description: The site received spent acid and rinse water from the 105-H Dummy Decontamination Facility, which decontaminated fuel element spacers and other reactor hardware.

Closure Info: The 116-H-3 French Drain has been remediated to meet the cleanup standards specified in the Amendment to the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units U.S. Environmental Protection Agency, Region 10, Seattle, Washington. Remedial actions were performed so as to allow rural-residential use of shallow zone soils (i.e., surface to 4.6 meters [15 feet] deep) and to protect groundwater and the Columbia River. The basis for reclassification is described in detail in the Cleanup Verification Package for the 116-H-3 French Drain, CVP-2000-00032, Bechtel Hanford, Inc., Richland, Washington. The cleanup verification package does not demonstrate the acceptability of unrestricted access to deep zone soils (i.e., below 4.6 meters [15 feet]). Therefore, institutional controls to prevent uncontrolled drilling or excavation into deep zone soils are required.

Remedial action at the 116-H-3 site began on February 17, 2000. Excavation of the site involved removing the overburden materials, the french drain, the pipeline leading from the reactor building to the french drain, and underlying contaminated soil. Based on field screening, overburden materials identified as potentially clean were placed in stockpiles for potential use as backfill. Contaminated materials were disposed of at ERDF.

Waste site contaminants of concern (COCs) identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE/RL-96-22). The COCs for this site consisted of cobalt-60, cesium-137, europium-152, europium-154, and hexavalent chromium.

Because of the likely use of lead-arsenate pesticide on the former orchard areas and based on agreement with the regulatory agencies, arsenic was included as a site contaminant of potential concern (COPC). The COPC arsenic was not detected in cleanup verification samples at concentrations above Washington State background of 20 mg/kg (Washington Administrative Code [WAC] 173-340), and is therefore not addressed further in this document. Arsenic cleanup verification sample results (maximum detection of 11.5 mg/kg) are listed in Appendix

A. Analysis of excavated waste samples did not indicate that lead should be identified as a COPC or COC for the 116-H-3 site.

On June 26, 2000, the excavation was completed. The elevation of the bottom of the excavation was at 123.5 meters (405 feet) upon completion. The excavation was approximately 855 square meters (9,203 square feet) in area with a maximum depth of approximately 4.6 meters (15 feet). Approximately 2,707 metric tons (2,985 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility (ERDF).

Cleanup verification sampling began on August 1, 2000. The final verification samples were submitted to offsite laboratories (Severn Trent, Thermo Analytical, and RECRA) for analysis using approved U.S. Environmental Protection Agency analytical methods, as required per the SAP (DOE/RL-96-22).

The cleanup verification package (CVP) sampling demonstrates that remedial action at the 116-H-3 site has achieved the Remedial Action Goals and Objectives (RAO's and RAG's) established in the approved Interim Action Record of Decision (ROD) Amendment (EPA 1997) and RDR/RAWP (DOE/RL-96-17). The remaining soils at the 116-H-3 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-H-3 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River. The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 116-H-3 site is verified to be remediated in accordance with the ROD and may be backfilled.

Code: 116-H-4	Classification: Accepted
Names: 116-H-4; 105-H Pluto Crib	Reclassification: None
Type: Crib	Start Date: 1/1/1950
Status: Inactive	End Date: 1/1/1952
Description: The site is currently a flat, cobble covered field located inside the 105-H security fence. The crib location is not marked.	
Location: The crib was located near the southwest corner of the 105-H Building and adjacent to the 132-H-3 Effluent Pumping Station.	
Related Sites/ Structures: The site was related to the 105-H Reactor.	
Waste Type: Process Effluent	
Waste Description: The site received effluent from tubes containing ruptured fuel elements. A 1953 document reports that approximately 270 curies of fission products were released to the crib as a result of the rupturing of ten slugs and the presence of 1,000 kilograms (2,200 pounds) of sodium dichromate.	

Code: 116-H-5	Classification: Accepted
Names: 116-H-5; 116-H-5 Outfall Structure; 1904-H Outfall Structure	Reclassification: None
Type: Outfall	Start Date: 1/1/1949

Status: Inactive **End Date:** 1/1/1965

Description: This site includes the open-topped, compartmentalized, reinforced concrete outfall structure. A 183 centimeter (72 inch) concrete process sewer line from the 1906-H Pump House, and two 152 centimeter (60 inch) diameter steel retention basin pipelines entered the eastern face; and two 152 centimeter (60 inch) concrete pipelines exited the western face to the river.

Location: The site is located on the Columbia River shoreline north of 107-H Retention Basin.

Process Description: The outfall was a reinforced concrete weir box that directed the water through either the river discharge pipelines (100-H-34) or through the spillway (flume) (100-H-36). The spillway was a concrete flume used when the river pipelines were blocked, damaged or undergoing maintenance. Process sewer wastes, and reactor cooling water collected and temporarily stored in the 107-H retention basin, were pumped to the river via the 116-H-5 outfall structure and associated 100-H-34 river effluent pipelines.

Related Sites/Structures: The outfall is associated with 116-H-7 Retention Basin, 184-H Power House, 100-H-34 (River Effluent Pipelines), the 100-H-36 spillway, the 100-H-21 process effluent lines, the 100-H-34 river effluent pipelines, and the 1906-H Pump House and associated pipelines.

Waste Type: Construction Debris

Waste Description: The site received effluent water through two lines from the 107-H Retention Basin. A third line from the 100 H Area process sewer also discharged to it.

Contaminants of potential concern include Co-60, Cs-137, Eu-152, -154, -155, Ni-63, Pu-238, -239/240, Am-241, C-14, H-3, Tc-99, Sr-90, U-234, -235, -238, Cr+6, Cr (total), Pb, and Hg.

Code: 116-H-7 **Classification:** Accepted

Names: 116-H-7; 107-H; 107-H Retention Basin **Reclassification:** Interim Closed Out (7/24/2001)

Type: Retention Basin **Start Date:** 1/1/1949

Status: Inactive **End Date:** 1/1/1965

Description: This site has been remediated and closed out. The basin was a concrete-lined rectangular structure. The unit had been partially demolished and backfilled to a depth of approximately 1.2 meters (4 feet) above the floor, and sloped to the top of the walls.

Location: The site is located northeast of 105-H.

Release Description: The unit and its effluent line developed leaks during the years of operation. The rate of leakage has been estimated to be as high as 19,000 to 38,000 liters-per-minute (5,000 to 10,000 gallons-per-minute) . The extent of contamination from these releases was within the area encompassed by the unit.

Related Sites/Structures: Sludge and waste removed from this unit during repair work in the spring of 1953 were buried in a trench east of the unit (WIDS Site Code 100-H-5). The trench was originally covered to grade with 1.5 meters (5 feet) of soil. In May 1965, the location was excavated to a depth of approximately 1.8 meters (6 feet) to obtain fill material for this unit. There was no indication of remaining radioactivity, and consequently the trench was released from radiological controls.

Waste Type: Process Effluent

Waste Description: This site received cooling water effluent from the 105-H Reactor for radioactive decay and thermal cooling prior to release to the Columbia River. Seventy percent of the total radionuclide inventory is contained within the soil adjacent to the unit. Approximately 10 curies have leached into the concrete floor and walls.

Closure Info: In 2000 the site was remediated, and closed out in 2001. Remedial action objectives and goals

for the 116-H-7 site were established by the U.S. Environmental Protection Agency and the Washington State Department of Ecology, in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-DR-1, and 100-HR-1 Operable Units (EPA 1995) and the Remedial Design Report/Remedial Action Work Plan (RDR/RAWP) for the 100 Area (DOE/RL-96-17).

The selected remedial action for the 116-H-7 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility (ERDF) at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives for direct exposure, protection of groundwater, and protection of the Columbia River. For the respective points of compliance, remedial action goals (RAGs) were established to identify radionuclide and no radionuclide contaminants of concern (COCs) and contaminants of potential concern (COPCs). Waste site COCs identified through process knowledge were listed in the 100 Area Remedial Action Sampling and Analysis Plan (DOE/RL-96-22). The COCs for this site consist of: cesium-137, cobalt-60, europium-152, europium-154, europium-155, nickel-63, plutonium-238, plutonium-239/240, strontium-90, uranium-238, hexavalent chromium, and lead.

Because of the likely use of lead-arsenate pesticide on the former orchard areas and based on regulatory agency agreement, arsenic was included as a site COPC. However, arsenic was not detected in cleanup verification samples at concentrations above Washington State background of 20 milligrams per kilogram (mg/kg) (Washington Administrative Code 173-340) (the maximum detected value was 6.5 mg/kg), and was not included in further analysis for this site.

Additional contaminants that were identified from analyses of material excavated during remediation were also evaluated as COPCs. The following COPCs identified during remediation were also detected in cleanup verification samples and were evaluated as COCs for closeout of the 116-H-7 site: total chromium, aroclor-1242, and aroclor-1260.

Based on agreement with the regulatory agencies, technetium-99 was identified as a site COPC, because of its presence in groundwater beneath the site. Technetium-99 was not detected in cleanup verification samples and therefore was not included as a COC in evaluation of the site for close out.

Site excavation and waste disposal are complete, and the exposed surfaces have been sampled and analyzed to verify attainment of the RAGs. At the completion of the remedial action, the total excavation was approximately 23,660 square meters (254,700 square feet) in area with a depth of approximately 4.8 meters (15.7 feet). Approximately 218,130 metric tons (240,440 tons) of material from the site were disposed of at the ERDF.

The Cleanup Verification Package (CVP) demonstrated that remedial action at the 116-H-7 site achieved the RAOs and corresponding RAGs established in the approved Interim Action ROD and RDR/RAWP. The remaining soils at the 116-H-7 site have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 116-H-7 site containing COCs at concentrations exceeding RAGs have been excavated and disposed of at the ERDF. These results also indicate that residual concentrations in the shallow zone will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations throughout the site are protective of groundwater and the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required. The 116-H-7 site is verified to be remediated in accordance with the Interim Action ROD (EPA 1995).

Code: 116-H-9	Classification: Accepted
Names: 116-H-9; 117-H Crib; 117-H Seal Pit Crib	Reclassification: Interim Closed Out (12/22/2010)
Type: Crib	Start Date: 1/1/1960
Status: Inactive	End Date: 1/1/1965

Description: The unit is a gravel filled crib. A distribution header lies approximately 1.5 meters (5 feet) below grade and is covered by a polyethylene barrier. The polyethylene barrier is covered by 1.2 meters (4 feet) of clean fill material. A large vent pipe marks the site and is placed off center of the crib structure. The site includes a 10-centimeter (4-inch) cement asbestos feed pipeline that runs from the demolished 117-H Air Filter Building to the crib. The pipeline is approximately 80 meters (263 feet) long.

Location: The site is located approximately 150 m (492 ft) southwest of the 105-H Building (118-H-6).

Related Sites/ Structures: The site was associated with the demolished 117-H Air Filter Building.

Waste Type: Water

Waste Description: The site received drainage from confinement system 117-H Building Seal Pits.

Closure Info: The Remaining Sites Verification Package (RSVP-2009-047) has documented that the 116-H-9, 117-H Seal Pit Crib waste site meets the remedial action objectives (RAOs) and remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999).

Remedial action began on October 28, 2008, and continued through February 3, 2009, to a depth of approximately 4.6 m (15 ft). Verification sampling was performed in July 2009, to collect data to determine if the site met remedial action goals. The contaminants of potential concern for verification sampling included carbon-14, cesium-137, cobalt-60, europium-152, europium-154, europium-155, radium-226, thorium-228, thorium-232, tritium, plutonium-238, plutonium-239/240, strontium-90, uranium-238, silver, cadmium, chromium (total), hexavalent chromium, mercury, lead, selenium, and polychlorinated biphenyls (PCBs).

The lateral extent of the excavation was determined based on the September 2008 geophysical survey that clearly defined a distinct boundary. Approximately 2,430 bank cubic meters (3,180 bank cubic yards) of soil and debris was removed for disposal at the Environmental Restoration Disposal Facility (ERDF). The material was direct loaded, and no staging pile was created for this site. In addition, during remediation, no stained soil or radiological or chemical contamination was identified.

Verification sampling was performed on July 16, 2009 (DOE/RL-96-22, Rev. 5), to support a determination that residual contaminant concentrations at this site met the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD. The verification sample results were provided within the 95% upper confidence limit (UCL) calculation in Appendix A of the RSVP and indicated that the remedial action achieved compliance with the RAOs for the site. Also, the laboratory-reported verification data results for all constituents were stored in the WCH Environmental Restoration project-specific database prior to archival in the Hanford Environmental Information System.

The results of the verification sampling showed that residual contaminant concentrations do not

preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6-m [15-ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. The site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

Code:	126-H-2	Classification:	Accepted
Names:	126-H-2; 183-H Clearwells/Disposal Pit	Reclassification:	None
Type:	Dumping Area	Start Date:	1/1/1975
Status:	Inactive	End Date:	
Description:	The clearwells were used as a disposal facility for demolition waste from the 183-H Basins. A portion of the backfilled clearwells is posted with Soil Contamination signs.		
Location:	The site is located approximately 220 meters (721.8 feet) north of the 105-H Reactor Building and just south of the demolished 183-H Solar Evaporation Basins.		
Process Description:	Presently, the site is being used as a landfill for the disposal of nonhazardous and nonradioactive demolition and inert waste. Allowable rubble was/is concrete, composition roof materials, wood, metal ducts, piping, floor tile (as long as it does not contain asbestos), and other non-salvage material normally found in buildings. Unallowable materials were/are radioactive waste, hazardous waste, garbage, organic waste, explosives, chemical waste, sludge, liquid waste, dispersible waste easily windblown, asbestos (friable or non-friable), and creosoted poles or railroad ties. Part of the clearwell is posted as a soil contamination area. The rubble material remaining from the demolition of the 183-H Solar Evaporation Basins (116-H-6) was added to the clearwell (in the belief that all requirements for radiological release had been met). The concrete was scabbled to remove the outer layer of surface contamination (approximately 6 millimeters [0.25 inches]). This material was disposed of as radioactive material. The remainder of the concrete and debris was sent to the clearwell on October 23, 1995. The site consisted of two below grade, reinforced concrete basins, having a capacity of approximately 3.8E+07 liters (1E+07 gallons). Each clearwell had a reinforced concrete roof, supported by 132 concrete columns. The roof was located at grade level and still remains over the west clearwell. The clearwells were separated in the center by a pump room. The pump room was reinforced concrete and largely below grade. The above ground portion of the pump room has been demolished, and the below ground portion has been filled with pump room rubble and backfill material. The east clearwell basin contains demolition debris and other nonradioactive nonhazardous solid waste. The west clearwell remains intact. Originally, the clearwells held clean, uncontaminated water. The site was part of the 183-H Water Treatment Facility.		
Related Sites/Structures:	The clearwells were associated with the 183-H Water Treatment Facility. A number of the drawings that are referenced are related to the 183-H Water Treatment Facility and have been included to provide context information.		
Waste Type:	Demolition and Inert Waste		
Waste Description:	The suspected contaminated waste is concrete and debris from the demolition of the 183-H Solar Evaporation Basins (116-H-6). The area is posted as a soil contamination area. After removal of the surface of the concrete, prior to demolition, all surfaces were surveyed with field instrumentation. The survey results for all surfaces were less than 1,000 disintegrations per minute per 100 square centimeters (15.5 square inches) smearable (loose) contamination and less than 5,000 disintegrations per minute per 100 square centimeters (15.5 square inches) total contamination.		

On October 23, 1995, 2,666.5 cubic meters (3,487.6 cubic yards) of concrete (90%), iron

(10%), including superstructure, walls, catwalks, pillars, rebar from 100-H/183-H Solar Basins were disposed of in the 183-H Clearwell.

Waste Type: Demolition and Inert Waste

Waste Description: The unit now contains nonhazardous and nonradioactive demolition and inert waste from demolished facilities. This waste includes rubble from such facilities as 190-H, 151-H, 1701-D and the 183-H Solar Evaporation Basins. The following materials were taken to the 183-H Clearwell:

- On (date unknown), 0.78 cubic meters (27.7 cubic feet) of transite from the 1717;
- On 11/10/1986, 125.4 cubic meters (164 cubic yards) of insulators from the Hanford power line cleanup;
- On (date unknown), 0.89 cubic meters (31.5 cubic feet) of transite from the 190 Annex;
- On 9/25/1987, 44.3 cubic meters (58 cubic yards) of non-excessible building equipment from the 1713-H Storage Facility;
- On 3/3/1987, (volume unknown) of galvanized posts and concrete from the perimeter fence;
- On 11/17/1987, 45.9 cubic meters (60 cubic yards) of decommissioned utility fixtures and cross arms;
- On 1/14/1988, 72.6 cubic meters (95 cubic yards) of decommissioned utility guy wires, rebar, and gravel;
- On 1/15/1988, 22.9 cubic meters (30 cubic yards) of decommissioned utility guy wires and concrete;
- On 10/10/1988, 880 used wooden pallets (1.07 by 1.07 meters [3.5 by 3.5 feet]) from the 183-H Basin;
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #1 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #2 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #3 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #4 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #5 for 8/30/1990); (radiological release record included);
- On 8/30/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #6 for 8/30/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #1 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #2 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (60%), wood (30%), insulation (5%), pipe (5%) from 1701-D; (record #3 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #4 for 8/31/1990); (radiological release record included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #5 for 8/31/1990); (radiological release record included);

- included);
- On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #6 for 8/31/1990); (radiological release record included);
 - On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #7 for 8/31/1990); (radiological release record included);
 - On 8/31/1990, 11.5 cubic meters (15 cubic yards) of cement block (90%), rebar (5%), pipe/conduit (5%) from 1701-D; (record #8 for 8/31/1990); (radiological release record included);
 - On 9/7/1990, 9.6 cubic meters (12.5 cubic yards) of roofing asphalt (80%), pipe metal (5%), toilet wood (5%), windows (10%) from 2719-W;
 - On 4/26/1991, 245 pallets, 2 cable spools, 53.6 meters (176 feet) of 2 by 6 (9.23 cubic meters [326 cubic feet]) of wood from 100-H;
 - On 9/11/1993, 332.6 cubic meters (435 cubic yards) of wood (85%), metal (5%), concrete (10%) from 1722-D and 1713-D; (radiological release record included);
 - On 9/12/1993, 137.6 cubic meters (180 cubic yards) of wood (60%), metal (10%), concrete (30%) from 1722-D; (radiological release record included);
 - On 11/30/1993, 11.5 cubic meters (15 cubic yards) of material not identified on form from 100-H;
 - On 2/22/1994, 1.36 cubic meters (48 cubic feet) of metal (70%), wood (20%), cardboard (10%) from 105-D;
 - On 8/10/1994, 0.28 cubic meters (10 cubic feet) of crushed vent ducting (100%) from 105-H; (radiological release survey included);
 - On 2/16/1995, 45.9 cubic meters (60 cubic yards) of wood (40%), concrete (40%), steel (40%) from laydown yard, east of the carpenter shop, outside 100-N double fence;
 - On 2/16/1995, 45.9 cubic meters (60 cubic yards) of wood (40%), concrete (40%), steel (40%) from laydown yard, east of the carpenter shop, outside 100-N double fence; (record #2 for 2/16/1995);
 - On 4/10/1995, 30.6 cubic meters (40 cubic yards) of roofing material, including tar and gravel (asphalt), fiberboard, metal flashing and wood debris from 105-D roof replacement; (radiological release statement included);
 - On 4/11/1995, 30.6 cubic meters (40 cubic yards) of roofing material, including tar and gravel (asphalt), fiberboard, metal flashing and wood debris from 105-D roof replacement; (radiological release statement included);
 - On 10/23/1995, 2,666.5 cubic meters (3,487.6 cubic yards) of concrete (90%), iron (10%), including superstructure, walls, catwalks, pillars, rebar from 100-H/183-H Solar Basins; (See second waste record);
 - On 12/14/1995, 11.5 cubic meters (15 cubic yards) of wood (50%), plastic (40%), metal (10%) from 100-N, N Reactor Deactivation;
 - On 10/11/1995, 38.2 cubic meters (50 cubic yards) of wood (99%), soil/metal (1%) from 100-D/190-D demolition;
 - On 10/11/1995, 7.6 cubic meters (10 cubic yards) of asphalt/concrete from 100-N waterline upgrade;
 - On 10/23/1995, 0.8 cubic meters (1.0 cubic yard) of scrap electrical wire from 100-N potable waterline upgrade;
 - On 11/10/1995, 122.3 cubic meters (160 cubic yards) of metal (75%), concrete (10%), wood (10%), conduit (5%) from 100-N, Buildings 1100 and 1101;
 - On 2/20/1996, 22.9 cubic meters (30 cubic yards) of asphalt (80%), dirt (20%) from 100-N/Field Deactivation;
 - On 3/4/1996, 0.4 cubic meters (0.5 cubic yards) of plastic (100%) from 100-HR-3 Pump and Treat;
 - On 5/9/1996, 12.2 cubic meters (16 cubic yards) of iron (5%), tar-rock (95%) from 100-H;
 - On 5/11/1996, 12.2 cubic meters (16 cubic yards) of tar (40%), iron (30%), wood (20%), tin (10%) from 100-H;

- On 5/12/1996, 12.2 cubic meters (16 cubic yards) of galvanized metal (60%), wood (40%) from 100-H; (truck #1);
- On 5/12/1996, 12.2 cubic meters (16 cubic yards) of galvanized metal (40%), wood (60%) from 100-H; (truck #2);
- On 5/17/1996, 12.2 cubic meters (16 cubic yards) of tar (95%), iron (5%) from 100-H;
- On 5/18/1996, 12.2 cubic meters (16 cubic yards) of tar (100%) from 100-H; (truck #1)
- On 5/18/1996, 12.2 cubic meters (16 cubic yards) of tar (85%), steel (15%) from 100-H; (truck #2);
- On 5/18/1996, 12.2 cubic meters (16 cubic yards) of tar (100%) from 100-H; (truck #2);
- On 5/19/1996, 12.2 cubic meters (16 cubic yards) of tar-rock (95%), iron (5%) from 100-H;
- On 8/18/1996, 24.5 cubic meters (32 cubic yards) of concrete (80%), iron (20%) from 100-DR;
- On 8/19/1996, 24.5 cubic meters (32 cubic yards) of concrete (80%), iron (20%) from 100-DR;
- On 2/12/1997, 84.1 cubic meters (110 cubic yards) of asphalt (95%), rock (4%), metal (1%) from 100-H/183-H;
- On 4/11/1997, 34.4 cubic meters (45 cubic yards) of old asphalt from 200 West Area, 200-ZP-1 Phase III;
- On 7/16/1997, 15.3 cubic meters (20 cubic yards) of fiberglass insulation from the exterior of the 1715-N Diesel Tanks;
- On 7/15/1997, 22.9 cubic meters (30 cubic yards) of fiberglass insulation from demolition from 163-N roofing;
- On 7/18/1997, 11.5 cubic meters (15 cubic yards) of fiberglass insulation from the exterior of the 1715-N Diesel Tanks;
- On 7/18/1997, 1.5 cubic meters (2 cubic yards) of hatch lid, metal on wood construction from 163-N Roof;
- On 8/7/1997, 7.6 cubic meters (10 cubic yards) of broken asphalt pieces from pipeline road crossings from 100-HR-3 Project;
- On 8/26/1997, 160.6 cubic meters (210 cubic yards) of concrete (80%), rebar (20%) from 100-N/105-NC;
- On 9/25/1997, 107.0 cubic meters (140 cubic yards) of concrete, rebar, metal roofing and miscellaneous steel from 100-N/1734-N;
- On 10/11/1997, 11.5 cubic meters (15 cubic yards) of concrete (90%), wood (10%) from 2614 E2, W2, W4, W5.

Code: 132-H-1	Classification: Accepted
Names: 132-H-1; 116-H Reactor Exhaust Stack Burial Site	Reclassification: Interim Closed Out (6/26/2007)
Type: Burial Ground	Start Date: 1/1/1945
Status: Inactive	End Date: 1/1/1965
Description:	The site consisted of an excavated trench that contained demolition rubble of the Reactor Exhaust stack and foundation. The stack was originally part of the 105-H Reactor Gas and Exhaust Air system.
Location:	The stack was located on the south side (southwest corner) of the 118-H-6 (105-H Reactor Building). The stack burial trench was excavated in a south-by-southwesterly direction from the base of the stack, between the 132-H-2 (117-H Filter Building) and the 132-H-3 (1608-H Lift Station Building.)
Process Description:	Before demolition the 116-H exhaust stack was part of the reactor building ventilation system, which was designed to provide clean air to the various work sites within the 105-H reactor building. The clean air entered the noncontaminated portions of the reactor building and then moved through zones with increasing levels of contamination before its discharge into the atmosphere. After the 1960 installation of the 117-H Filter Building, the air passed through

HEPA (high-efficiency particulate air) filters and halogen (activated charcoal) filters prior to its atmospheric release. Following completion of the confinement project in 1960, the air was diverted from the 118-H-6 (105-H Reactor) site via underground reinforced concrete ducts to the 132-H-2 (117-H Filter Building). After flowing through the filters, the air went through below-grade and above-grade concrete ducts and into the exhaust stack. Prior to demolition the stack was 61 meters (200 feet) tall and had a diameter of 5.1 meters (16.58 feet) at its base. The stack was toppled into a 60.96 meter (200 feet) long by 9.14 meter (30 feet) wide by 5.49 meters (18 feet) deep trench.

Related Sites/ Structures: The stack was part of the 118-H-6 (105-H Reactor Gas and Exhaust Air system) and the 132-H-2 (117-H Filter Building).

Waste Type: Demolition and Inert Waste

Waste Description: Air moving from the least contaminated zones through increasingly contaminated zones was discharged to the stack unfiltered. At the time of demolition low-level smearable alpha contamination was present measuring up to 30 disintegrations/minute per 100 square centimeters (190 disintegrations/minute per 100 square inches). Smearable beta contamination ranged from 100 to 5,000 disintegrations/minute per 100 square centimeters (650 to 32,000 disintegrations/minute per 100 square inches).

Closure Info: The Remaining Sites Verification Package (RSVP) 2006-053 has documented that current site conditions have met the remedial action goals (RAGs) and remedial action objectives (RAOs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU--2, 100-IU-6, and 200-CW-3 Operable Units.

As part of decommissioning activities in 1983, extensive radiological surveying and sampling activities were performed to characterize residual radiological contamination of the exhaust stack. Characterization results indicated that the contamination was confined to a 0.01-meter (0.4-inches) surface layer of concrete on the interior wall of the stack. The 1983 sampling results were also used to support the reclassification. Using the maximum radiological activities from the pre-demolition characterization data to represent residual contamination levels over the entire mass of concrete of the former stack, RESidual RADioactivity (RESRAD) modeling was performed in 2006 to support the previous decision to demolish and bury the stack in place.

The RESRAD modeling was performed only for the contaminated rubble which was buried in the shallow zone. An evaluation of the concrete foundation that extended greater than 4.5 meters (15 feet) was not required because the foundation was not contaminated. The condensate drain embedded in the stack foundation was located in the shallow zone. The RESRAD modeling accounted for radioactive decay from 1983 (year of sampling) to 2006 and predicted that the site achieved the dose limits and risk objectives for rural-residential land use, groundwater protection, and river protection.

A portion of the vertical 15-centimeter (6-inch) condensate drain pipe remained embedded in the center of the buried stack base. No deep zone evaluation was necessary because the embedded condensate drain did not extend into the deep zone. The pipe was a free draining condensate line that fed into the 1608-H effluent pumping station. The potential contamination remaining within the drain was considered to pose little risk to human health and the environment, such that further sampling activities were not required. Residual contamination that could remain in the floor drain pipe would be analogous to residual contamination in the buried 132-D-4 (105-D Reactor Exhaust Stack) and 132-F-4:2 (105-D Reactor Exhaust Stack) embedded stack condensate drain lines. Although the condensate drain lines were not sampled, these sites were reclassified as "interim closed out" and "no action," respectively.

The horizontal condensate drain line running from the stack base to the 1608-H effluent pumping station was removed during previous remedial actions associated with the 100-H-21 Reactor Effluent Pipelines. Based on excavation boundaries of the demolition activities required to place the 105-H Reactor into interim safe storage, the remaining portion of the horizontal condensate drain line external to the 105-H Reactor Safe Storage Enclosure has been removed. The drain line and underlying soils were not sampled; however, it was believed that contamination related to the drain line, as well as to the embedded drain remaining in the stack, was bounded by the waste profile for the 100-H-21 Reactor Effluent Pipelines.

The site residual contaminant levels which were based on reviews of the historical data and RESRAD modeling results were protective of direct exposure, groundwater, and the Columbia River. Using conservative inputs (e.g., highest activity sample results and assuming uniform contamination levels on the entire mass of residual concrete), the RESRAD outputs indicated that residual contamination levels do not present an unacceptable risk to the maximally exposed individual. The RESRAD evaluation and historical data supported a reclassification of the site to interim closed out. This site does not have a deep zone; therefore, no deep zone institutional controls are required.

Code:	132-H-3	Classification:	Accepted
Names:	132-H-3; 1608-H Effluent Pumping Station Site; 1608-H Waste Water Pumping Station Site; 116-H-8	Reclassification:	None
Type:	Pump Station	Start Date:	1/1/1949
Status:	Inactive	End Date:	1/1/1965
Description:	The unit was constructed of concrete block walls above ground and reinforced concrete for the remainder. It was 3.7 meters (12 feet) above grade and 9.8 meters (32 feet) below grade. The unit included a wastewater collection pit. The building has been demolished in-situ.		
Location:	The unit is located on the east side of the 105-H Reactor Building.		
Waste Type:	Process Effluent		
Waste Description:	This site received water from reactor building drains and irradiated fuel storage drains containing trace amounts of low-level radionuclides and decontamination chemicals, primarily Turco (a commercial chemical compound with a proprietary composition). Radionuclides were primarily activation and fission products. Other decontamination chemicals consisted of sodium fluoride, oxalic acid, and citric acid.		

Code:	1607-H2	Classification:	Accepted
Names:	1607-H2; 1607-H2 Sanitary Sewer System; 1607-H2 Septic Tank; 1607-H2 Septic Tank and Associated Drain Field; Septic System; 124-H-2	Reclassification:	Interim Closed Out (2/5/2001)
Type:	Septic Tank	Start Date:	1/1/1949
Status:	Inactive	End Date:	1/1/1965
Description:	The unit includes a septic tank, tile field, and associated piping (about 140 meters (460 feet) from the tank to the intersection with the Water Treatment Plant pipelines). The site has been remediated, and a Closeout Verification Package (CVP) has been approved. It is no longer marked or posted in the field.		
Location:	The septic system was located north of the 105-H Reactor Building, north of the 182-H Reservoir and northeast of the 183-H (116-H-6) Solar Basins.		
Related Sites/	The site received sanitary waste from the 182-H, 183-H, 190-H, and other 100 H Area office		

- Structures:** and maintenance buildings.
- Waste Type:** Sanitary Sewage
- Waste Description:** This unit received unknown amounts of sanitary sewage from 182-H, 183-H, 190-H, and all office and maintenance service buildings with "1700" designations. Based on measured sludge levels, the volume was estimated to be 28,500 liters (7,500 gallons).
- Closure Info:** The site has been remediated and was closed out on February 5, 2001.

Remedial action objectives and goals for the 1607-H2 site were established by the U.S. Environmental Protection Agency (EPA) and the Washington State Department of Ecology (Ecology), in concurrence with the U.S. Department of Energy, Richland Operations Office. These goals and objectives are documented in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999) and the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17). The selected remedial action for the 1607-H2 site included (1) excavating the site to the extent required to meet specified soil cleanup levels, (2) disposing of contaminated excavation materials at the Environmental Restoration Disposal Facility at the 200 Areas of the Hanford Site, and (3) backfilling the site with clean soil to average adjacent grade elevation. Excavation was driven by remedial action objectives (RAOs) for direct exposure, protection of groundwater, and protection of the Columbia River.

Waste site Contaminants of Concern (COCs) and Contaminants of Potential Concern (COPCs) for the 1607-H2 site were identified during site remediation through process knowledge, analogous site information, field investigation, past orchard land-use knowledge, and excavated waste sample analyses and consist of the following: cobalt-60, strontium-90, uranium-233/234, uranium-235, uranium-238, semi-volatile organic compounds, arsenic, lead, mercury, chromium (total), polychlorinated biphenyls (PCBs), cesium-137, and hexavalent chromium.

The radionuclide COPCs cobalt-60, strontium-90, and uranium-235 were not detected in cleanup verification samples and were not addressed further in the CVP. Of the approximately 64 semi-volatile organic analytes that the analytical method (EPA SW-836 Method 8270) analyzed for, none were detected in cleanup verification samples at concentrations greater than the analytical method practical quantitation limit and were therefore not addressed further. The COPC arsenic was not detected in cleanup verification samples at concentrations above Washington State background of 20 mg/kg (Washington Administrative Code 173-340), and was therefore not addressed further. Arsenic sample results (maximum detected value of 7.0 mg/kg) are listed in Appendix A of the CVP. Several of the COPCs (lead, total chromium, and mercury) were detected in cleanup verification samples at concentrations above Hanford Site background and were therefore added to the final list of COCs for the site. Of the PCBs, only Aroclor-1254 was detected in cleanup verification samples and was therefore added to the final COC list.

At the completion of the remedial action, the total excavation was approximately 5,054 square meters (54,405 square feet) in area with a maximum depth of approximately 5.6 meters (18.4 feet) for the septic tank/piping excavation and 1.5 meters (4.9 feet) for the drainfield excavation. Approximately 12,207 metric tons (13,456 tons) of material from the site were disposed of at the Environmental Restoration Disposal Facility.

Results of the sampling, laboratory analyses, and data evaluations for the 1607-H2 site indicate that all remedial action objectives and goals for direct exposure, protection of groundwater, and protection of the Columbia River have been met.

The CVP demonstrated that remedial action at the 1607-H2 site has achieved the Remedial

Action Objectives (RAOs) and corresponding Remedial Action Goals (RAGs) established in the interim action Record of Decision (ROD) and Remedial Design Report/Remedial Action Work Plan (RDR/RAWP). The remaining soils, including overburden, have been sampled, analyzed, and modeled. The results of this effort indicate that the materials from the 1607-H2 site that contain COCs at concentrations exceeding the RAGs have been excavated and disposed of at the ERDF, and that residual COC concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual COC concentrations throughout the site and overburden do not pose an unacceptable threat to groundwater or the Columbia River.

The acceptability of unrestricted direct exposure to deep zone soils has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 meters [15 feet]) are required.

The 1607-H2 site is verified to be remediated in accordance with the interim action ROD and may be backfilled. The overburden is verified as suitable for use as backfill in accordance with the ROD.

Code:	1607-H3	Classification:	Accepted
Names:	1607-H3; 1607-H3 Sanitary Sewer System; 1607-H3 Septic Tank; 1607-H3 Septic Tank and Associated Drain Field; 124-H-3	Reclassification:	Interim Closed Out (2/1/2011)
Type:	Septic Tank	Start Date:	1/1/1948
Status:	Inactive	End Date:	1/1/1968
Description:	The site was a septic tank and drain field. The tank is constructed of concrete and measures 5.6 by 2.1 by 4.0 meters (18.5 by 7 by 13 feet) deep. The tank had a 100-person capacity with an average detention period of 24 hours. The drain field was constructed of 10-centimeter (4-inch) vitrified pipe. It measured 15 by 30 meters (50 by 100 feet). It was oriented in-line with, and approximately 24 meters (80 feet) from the septic tank. A row of eight vent pipes were visible, running perpendicular to the entrance road.		
Location:	The 1607-H3 septic tank and drain field were located along H Avenue northeast of the 1701-H Badge House.		
Process Description:	The 1607-H3 septic system received sanitary sewage from the 1701-H Badge House, the 1709-H Fire Station, and the 1720-H Security Patrol Change Room. In addition to the sanitary sewage, liquids from the 1701-H Badge House darkroom (used for film badge processing) were disposed to the 1607-H3 septic system.		
Waste Type:	Sanitary Sewage		
Waste Description:	This unit received unknown amounts of sanitary sewage from the 1701-H Badge House (security checkpoint), the 1720-H Security Patrol Change Room, offices, and the 1709-H Fire Station. The sewage per capita is 130 liters (35 gallons) plus 20% for sludge.		
Closure Info:	All of the facilities associated with the septic system have been removed to grade. Remedial action at the 1607-H3 waste site was performed between October 13 and November 10, 2009, and encompassed the removal of the below-grade septic tank and the drainage field pipelines. The site was excavated to depths ranging from approximately 1.6 meters (5.3 feet) at the drain field to 4 meters (13 feet) at the septic tank location, resulting in approximately 3,763 bank cubic meters (BCM) (4,922 bank cubic yards [BCY]) of soil and piping/debris being removed for disposal at the Environmental Restoration Disposal Facility (ERDF). In addition, approximately 235 meters (771 feet) of vitrified clay pipe were removed. The soil was sorted within the excavation and direct loaded for disposal at ERDF. Approximately 1,729 BCM		

(2,261 BCY) of overburden soil was removed from above the drain field piping and stockpiled for evaluation for use as clean backfill.

The debris removed from the 1607-H3 waste site was consistent with that of a sewage system and in agreement with the pre-excavation geophysical survey findings. Some six and eight inch diameter piping was excavated that had soldered joints. These pipe segments were segregated for macro-encapsulation as a lead contaminate prior to disposal at ERDF. Small portions of lateral pipelines associated with the 100-H-51:4, 100-H Main Gate Storm Drain waste site were removed during the 1607-H3 waste site remediation.

Code:	1607-H4	Classification:	Accepted
Names:	1607-H4; 1607-H4 Sanitary Sewer System; 1607-H4 Septic Tank; 1607-H4 Septic Tank and Associated Drain Field; 124-H-4	Reclassification:	Interim Closed Out (2/26/2001)
Type:	Septic Tank	Start Date:	1/1/1948
Status:	Inactive	End Date:	1/1/1965
Description:	This site has been remediated and closed out. The unit included a septic tank, tile field, and associated piping. The system had a six-person capacity and an average detention period of 24 hours. The tile field was constructed of 10-centimeter (4-inch) pipe, 2.4 meters (8 feet) in length.		
Location:	The site was located on a bluff above the Columbia River, southeast of the 181-H Building and south of the 181-H access road.		
Related Sites/ Structures:	The septic system was associated with the 181-H River Pumphouse.		
Waste Type:	Sanitary Sewage		
Waste Description:	This unit received an unknown amount of sanitary sewage from the 181-H River Pumphouse. The sewage per capita is 130 liters (35 gallons) plus 20% for sludge.		
Closure Info:	The cleanup verification package (CVP-2000-00025) for 1607-H4 has documented that the remedial action goals and objectives have been met as established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, and the Remedial Design Report/Remedial Action Work Plan for the 100 Area.		

Remedial excavation at the 1607-H4 site began on November 5, 1999 and completed July 24, 2000. The elevation of the bottom of the excavation was at 120.4 meters (394.9 feet) upon completion. The excavation was approximately 161 square meters (1,732 square feet) in area with a maximum depth of approximately 3.6 meters (11.8 feet). Approximately 2,078 metric tons (2,286 tons) of material from the site were disposed at the ERDF.

The contaminants of potential concern (COPCs) included: cobalt-60, strontium-90, uranium-233/234, uranium-235, uranium-238, cesium-137, arsenic, lead, mercury, chromium (total), hexavalent chromium, polychlorinated biphenyls (PCBs), fluoranthene, pyrene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene.

Institutional control (IC) information has been revised as directed by the U. S. DOE letter, 05-AMRC-0078, 1/4/05, following a review of the Institutional Controls (ICs) in the WIDS. For some sites, including this one, both the CVP/reclassification forms and WIDS had indicated that IC restrictions were needed. However, these sites were remediated only with the more restrictive shallow zone criteria; deep zone criteria were not used. Therefore, no institutional

controls to prevent uncontrolled drilling or excavation into the deep zone (i.e., below 4.6 m [15 feet]) are required.

Names: 100-H-37; 100-H Mud Dauber Contamination Area	Reclassification: Interim Closed Out (8/5/2010)
Type: Contamination Migration	Start Date: 1/1/2002
Status: Inactive	End Date: 1/1/2003
Description:	The site consist of a set of radiologically dispersed contamination areas caused by mud dauber wasp nesting activity. During cleanup of the 105-H Fuel Storage Basin (FSB) while removing and processing dirt and sediment from the lower 38 cm (15 in) of the FSB, elevated airborne radioactivity levels that exceeded posting criteria were created. One of the corrective actions was to maintain at least 5.1 cm (2 in) of water on the basin floor. The mud daubers utilized the large source of mud on the 105-H Fuel Storage Basin (FSB) for construction of their tube nests. The mud daubers transported the contaminated mud from the FSB into the areas surrounding the reactor. The site contained 43 areas where contaminated nests were located. The majority of the areas contained more than one nest, some were greater than ten nests.
Location:	The nests are estimated to cover approximately 10.1 hectares (25 acres) throughout 100-H Area.
Release Description:	On December 11, 2002, while removing and processing dirt and sediment from the floor of the 105-H Fuel Storage Basin (FSB), elevated airborne radioactivity levels were generated and later observed on the air sample filter removed for the air sampler located on excavation equipment. A preliminary analysis of the filter indicated radioactivity greater than the threshold for posting an Airborne Radioactivity Area (ARA). The FSB was posted as a Radiation Area/Contaminated Area (RA/CA) at the time of the work. It was posted ARA and no one else entered the area. Work in the 105-H FSB was to proceed using a manned track-hoe excavator to remove basin fill from the lower 38 cm (15 in) between the basin floor stem walls. A contamination survey of the excavator bucket showed removable contamination levels that were higher than expected for both alpha and beta-gamma contamination. Based on the elevated bucket contamination levels, the entire FSB was re-posted as a High Contamination Area (HCA). Analysis at the Radiological Counting Facility (RCF) indicated the presence of americium and plutonium. Based on the analysis, the FSB was posted and controlled as an Airborne Radioactivity Area (ARA). The probable source of the airborne radioactivity was the contamination entrained in the cement dust released from the basin floor and stem walls during the excavation process. The 105-H FSB was approximately 6.1 m (20 ft) deep. The fill consisted of approximately 5.2 m (17 ft) of clean fill over a 76.2 cm (30 in) layer of sludge, debris and potential fuel fragments.
Related Sites/ Structures:	Some contaminated nests were deferred to 100-H-41 and 100-H-58. Other mud dauber sites in 100-H Area were remediated with these sites, 126-H-2, 116-H-5, 118-H-6:4, 118-H-3, 118-H-5, and 118-H-1.
Waste Type:	Soil
Waste Description:	The waste is contaminated mud dauber nests and other materials depending on the where the nest(s) were placed, including electrical utility poles, manholes, and other structures. The mud dauber contamination limits: removable - beta-gamma 1000 dpm/100cm ² ; alpha 20 dpm/100cm ² . Total - beta-gamma 5000 dpm/100cm ² ; alpha 100 dpm/100cm ² .
	The contaminants of potential concern include beta-gamma emitting isotopes C-14, Ni-63, H-3, Co-60, Sr-90, Cs-137, Eu-152, Eu-154. The alpha emitting isotopes would be Pu-239/240, and Am-241. RCF samples 11261, 11262, 11263, 11259, 11260 were used to determine the radioactive isotopes for the site.
Closure Info:	The site was included in the Explanation of Significant Differences for the 100 Area Remaining Sites Interim Remedial Action Record of Decision, for remediation, treatment, and disposal. The excavation took place between July 14 and August 21, 2008. Two additional mud dauber areas were excavated in December 2009. This second event only took one day to complete. A total of 19,153 BCM were removed and disposed at ERDF

The analyte list included gross alpha/beta, GEA, tritium, hex chromium, ICP metals and mercury for the mud dauber sites. Additional COPC's may be evaluated during preparation of the final RSVP/CVP. The contaminated areas were remediated by removing radiologically contaminated materials to ensure remedial action goals (RAGs) were achieved.

On July 7, 2009, Ecology concurred that the data collected for this study indicated that radiological field instruments are reliable to ensure RAGs are achieved. Remedial action began with the excavation of individual nests with a backhoe, due to the difficulty in hand digging and the sloughing of excavation material. Areas containing numerous and individual nests were removed. The number of nests in an area and the vegetative cover were considered in decisions to excavate individual nests or scrape an entire area. In addition to 40 small, dispersed excavations, 3 large areas of the waste site were excavated. These large scrapes ensured remediation of locations with many nests and protection of field radiological instrumentation that could be damaged by taking readings in areas with dense rabbit brush and other vegetation. After excavation, Global Positioning Environmental Radiological Surveyor (GPERS) surveys were performed on these 3 large areas and handheld radiological surveys verified that the 40 smaller excavations were no longer contaminated. Several of the areas which appeared on the original overall site location map were remediated with other waste sites at the 100-H Area, including 126-H-2, 116-H-5, 118-H-6:4, 118-H-3, 118-H-5, and 118-H-1.

Several of the mud dauber areas were located on active power lines that serve facilities in the 100-H Area. The power poles are located along H Avenue, Herron Avenue, and from the west of the 105-H Reactor Building to the warehouse. These locations have been deferred to the 100-H-58 waste site.

Additionally, during confirmatory sampling activities at waste site 100-H-41, it was found that the radiological contamination was the result of contaminated mud dauber nests located on the pipe of concern. The pipe and mud dauber contamination were removed to the Environmental Restoration Disposal Facility as part of 100-H-37 remediation activities. Additional information and sample results for 100-H-41 can be found in the RSVP for 100-H-41.

Code: 100-H-38	Classification: Accepted
Names: 100-H-38; Trenches and Pit Southwest of 105-H	Reclassification: None
Type: Burial Ground	Start Date:
Status: Inactive	End Date:
Description: The site consists of an area approximately 3 acres in size and is marked by ground scars resembling trenches and pits. The site is situated along a natural depression on the western boundary of the H Area perimeter fence.	

Code: 100-H-40	Classification: Accepted
Names: 100-H-40; Disposal Pit	Reclassification: No Action (5/20/2010)
Type: Trench	Start Date:
Status: Inactive	End Date:
Description: The site consists of a pit used for the disposal of maintenance shop waste.	
Location: The location was described by a former employee as being "west of central access road" (DC-0227). The interviewee sketched the approximate location on a map. The sketch showed the location south-southeast of the 118-H-1 burial ground and northwest of building 1709-H. The boundary of the waste site presented in photo 1 is intended to incorporate this area while allowing for the inherent inaccuracy of the sketch.	

Process Description: The 100-H area was constructed between March 1948 and October 1949. The disposal of solid wastes during construction was documented in the Design and Construction History, Project C-165-A, Pile Area "H" (HW24800-2). The report indicated that a burning pit (128-H-1) was "established at the northwest corner of the area for disposing of the trash and rubbish plus the usual odds and ends of waste construction material". The construction of 100-H area also included the creation of a solid waste burial ground (118-H-1). The burial ground was used for the disposal of solid dry wastes (HW-27337). Other burial grounds were created during the facility operations for the purpose of disposing reactor hardware. Documentation of solid waste disposal during the reactor operations (1949 through 1965) was limited to the facility's radioactive wastes. The disposition of nonradioactive solid waste is not otherwise documented but presumed to have disposed of at the 118-H-1 and 128-H-1 waste sites, with one notable exception.

Related Sites/ Structures: The site was associated with 1700-H buildings, including 1709-H, 1716-H, 1717-H and 1720-H (DC-0227).

Waste Type: Soil

Waste Description: Contaminants of potential concern may include lead, ICP metals, TPH, PAH, PCBs.

This site may contain maintenance shop waste, e.g. paint cans and auto repair waste (Denton, L interview 1990).

Closure Info: The Remaining Sites Verification Package, (RSVP-2009-065), demonstrates that the 100-H-40, 100-H Disposal Pit waste site meets the objectives for No Action as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (EPA 1999).

The COPCs for the site were identified based on the assumption that the site contained maintenance shop waste, including paint cans and auto repair waste. They included the expanded list of inductively coupled plasma metals, mercury, polycyclic aromatic hydrocarbons (PAH), polychlorinated biphenyls (PCBs), and total petroleum hydrocarbons. Radiological surveys were performed during sampling activities by a radiological control technician using instruments capable of detecting alpha, beta, and gamma radiation to identify potential radiologically contaminated materials, and no radiation was detected above background levels; therefore, radionuclides were not added to the list of COPCs.

Confirmatory sampling activities at the site were performed from October 27 to 29, 2009, in accordance with the Work Instruction for Confirmatory Sampling of the 100-H-40, 100-H Disposal Pit (WCH 0100H-WI-G0028). The eight locations with indications of geophysical anomalies were excavated to investigate for potential buried maintenance shop debris. Excavations unearthed small pieces of metallic surface debris and transite siding, then native soil, or small volumes of debris at shallow depths, with the exception of test pit 7. At test pit 7, materials observed within the excavation were consistent with the burial of a demolished building.

The complete laboratory results were stored in the Environmental Restoration (ENRE) project-specific database prior to submitting to the Hanford Environmental Information System (HEIS) for archiving and were provided in Appendix B of the RSVP.

The results of confirmatory sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the

Columbia River. Site contamination did not extend into the deep zone soils; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	100-H-58	Classification:	Accepted
Names:	100-H-58; Mud Dauber Nests On Active Powerlines In 100H Area	Reclassification:	None
Type:	Contamination Migration	Start Date:	
Status:	Active	End Date:	
Description:	The site consists of contaminated mud dauber (wasps) nests in the 100-H Area.		
Location:	The nests were identified along H Avenue, Herron Avenue, and from the west of the 105-H Reactor Building to the warehouse.		
Process Description:	During cleanup of the 105-H Fuel Storage Basin (FSB), dirt and sediment were removed from the lower 38 cm (15 in.) of the basin, which was 6.1 m (20 ft) below ground surface. Some dust became airborne during the scraping of the basin floor and stem walls, and airborne radiological posting criteria were exceeded. Consequently, one of the corrective actions was to maintain at least 5.1 cm (2 in.) of water on the basin floor to reduce airborne dirt and sediment, which created mud. The mud dauber wasps transported mud from the FSB floor to other sediment and debris areas surrounding the 105-H Reactor Building using the mud for construction of their tube nests. These mud dauber areas became the 100-H-37 waste site. However, during remediation of 100-H-37, multiple mud dauber nests were discovered on power lines that could not be remediated because the lines were in use. These lines are along H Avenue, Herron Avenue, and from the west of the 105-H Reactor Building to the warehouse. The nests are primarily within crevices in the wooden poles, and 35 nests have been counted. It is possible that more nests could be present, as characterization did not occur at heights above 7 ft. A mud dauber characterization strategy was developed and approved by the U.S. Department of Energy and Washington State Department of Ecology (Ecology) to guide remediation activities and provide closure documentation for the 100-H-37 waste site. The strategy included an initial characterization approach to verify the accuracy of radiological field instruments to be used in the place of soil sampling for verification and closeout purposes. On July 7, 2009, Ecology concurred that the data collected for this study indicated that radiological field instruments are reliable to ensure RAGs are achieved for the mud dauber waste site.		
Related Sites/ Structures:	Other mud dauber contamination sites were 100-H-37 and 100-H-41.		

Code:	118-H-1	Classification:	Accepted
Names:	118-H-1; 100-H Burial Ground No. 1; 100-H-1	Reclassification:	Interim Closed Out (10/12/2011)
Type:	Burial Ground	Start Date:	1/1/1949
Status:	Inactive	End Date:	1/1/1965
Description:	The waste site was a mixed solid waste burial ground. The overall site runs east and west. There are numerous trenches of various dimensions, generally running north and south. The boundaries are permanently marked with concrete posts numbered H-65-1 through H-65-23. The site has been divided into two subsites; 118-H-1:1 100-H-Burial Ground Trenches and Sorting Cells and 118-H-1:2 Anomaly Staging Area and Fuel Bunker.		
Location:	The site is located about 396 m (1,300 ft) southwest of the 105-H Building.		
Release	On October 4, 1960, a controlled fire was set at the north end of the burial site to reduce the		

Description: volume of contaminated material. Control over the fire was lost when two large explosions and several small explosions occurred from underlying drums containing residual combustible materials.

Process Description: This is the primary solid waste burial ground for the 100-H Area. The wastes disposed of in it include process tubing, contaminated lead bricks, dummy fuel elements, and miscellaneous hardware.

Waste Type: Misc. Trash and Debris

Waste Description: The site received activated components and miscellaneous solid wastes (surface contaminated).

Typical examples of activated components are aluminum dummies and process tubing, steel gun barrels and step plugs, thermocouple wires and balls from the 3X safety system. Portions of several horizontal control rods were buried in slit trenches near the southwest corner of the site. Typical examples of surface contaminated materials are hand tools, rags and sweeping compound, light bulbs, sheets of plastic and paper. This type of material was usually sealed in cardboard boxes and placed in separate trenches from the activated components.

This Site has the Following SubSites:

Code: 118-H-1:1

Names: 118-H-1:1; 100-H-1 Burial Ground trenches

Code: 118-H-1:2

Names: 118-H-1:2; Anomaly Staging Areas and Fuel Storage Bunker

Code: 118-H-1:1

Classification: Accepted

Names: 118-H-1:1; 100-H-1 Burial Ground trenches

Reclassification: Interim Closed Out (7/29/2011)

Type: Burial Ground

Start Date:

Status: Inactive

End Date:

Description: The 118-H-1:1 subsite consists of the original burial ground (trenches A-F) and sorting cells (1-3). In general, all trenches and sorting cells are angled from north to south.

The trenches (A-F) were the primary solid waste burial ground for the 100-H Area. Mixed solid waste such as lead bricks, process tubing, oil drums, and miscellaneous reactor hardware were disposed in the trenches between 1949 and 1965. The trenches were backfilled to grade with 6 feet of soil cover. The sorting cells were created during remediation of the burial ground in 2008 and were used to determine the presence of suspect spent nuclear fuel and anomalies.

The burial ground trenches received activated components and miscellaneous solid wastes (surface contaminated). Typical examples of activated components are aluminum dummies and process tubing, steel gun barrels and step plugs, thermocouple wires and balls from the 3X safety system. Portions of several horizontal control rods were buried in slit trenches near the southwest corner of the site. Typical examples of surface contaminated materials are hand tools, rags and sweeping compound, light bulbs, sheets of plastic and paper. This type of material was usually sealed in cardboard boxes and placed in separate trenches from the activated components.

Location: The site is located about 396 m (1,300 ft) southwest of the 105-H Building.

Closure Info: Remedial action began on July 22, 2008, and continued through June 29, 2009. Six trenches (A, B, C, D, E, and F) were excavated with approximately 8,160 bank cubic meters (BCM) (10,673 bank cubic yards [BCY]) of overburden soil stockpiled for use as clean fill. Approximately 34,496 BCM (45,119 BCY) of soil and debris were removed for disposal at ERDF. No spent

nuclear fuel or thimbles were discovered at the site. Field observations during excavation indicated the presence of concrete, piping, lead bricks, perforated tubes, and control rods among the types of debris removed from the burial ground excavation. There were not any patterns of waste found from one trench to another; there was a random assortment of waste throughout the burial ground. Burial Ground anomalies included a breached pipe with a white solid inside, a forklift battery, suspect hydraulic oil, a damaged drum containing liquid, gray waxy material, oil stained soil, and a deteriorated drum.

The SubSite is Part Of:

Code: 118-H-1

Names: 118-H-1; 100-H Burial Ground No. 1; 100-H-1

Code: 118-H-1:2

Classification: Accepted

Names: 118-H-1:2; Anomaly Staging Areas and Fuel Storage Bunker

Reclassification: Interim Closed Out (10/12/2011)

Type: Burial Ground

Start Date:

Status: Inactive

End Date:

Description: The 118-H-1:2 subsite consisted of the two anomaly staging areas and a fuel bunker. The areas were delineated using yellow and magenta rope with radiological postings.

All anomalous items found in the 118-H-1:1 Burial Ground were staged in the 118-H-1:2 anomaly staging area. The anomalies stored there included concrete, piping, lead bricks, process tubing, oil drums, and miscellaneous reactor hardware. The fuel bunker was constructed to store pieces of reactor fuel prior to characterization and dismantling. The staging area has been remediated.

118-H-1:1 anomalies include a breached pipe with a white solid inside, a forklift battery, suspect hydraulic oil, a damaged drum containing liquid, grey waxy material, oil stained soil, and a deteriorated drum. No spent nuclear fuel was discovered at the 118-H-1:1 Burial Ground.

Location: The fuel bunker was located approximately 400 m southwest of the 105-H Building and north of the 118-H-1:1 Trench E. The two anomaly staging areas were just west of 118-H-1:1 (one was north of Trench F and one was south).

Closure Info: On February 18, 2011, the SSNF was transferred from the 118-H-1:2 bunker area to the 100-D, 118-D-3:2 south bunker area. The fuel was shipped from 100-D Area to the 100-K Basins on April 27 and May 3, 2011.

Following the removal of the fuel and the concrete bunkers, and the characterization and processing of staged anomalies, a 0.3-m (1-ft) scrape of the staging area, characterization area, and SSNF bunker area was conducted. The soil was scraped from these areas to ensure that any potential contamination that may exist as a result of the anomaly characterization and processing has been removed. Approximately 272 bank cubic meters (BCM) (356 bank cubic yards [BCY]) of soil was direct loaded for disposal at the ERDF. An additional 80 BCM (105 BCY) was removed on June 8, 2011 to remove residual contamination identified after verification sampling was conducted.

The SubSite is Part Of:

Code: 118-H-1

Names: 118-H-1; 100-H Burial Ground No. 1; 100-H-1

Code: 118-H-2

Classification: Accepted

Names:	118-H-2; H-1 Loop Burial Ground; P-13 Test Loop; 100-H Burial Ground No. 2	Reclassification:	Interim Closed Out (11/15/2010)
Type:	Burial Ground	Start Date:	1/1/1955
Status:	Inactive	End Date:	1/1/1965
Description:	The site runs east and west and contains two in-line concrete vaults. Both vaults were covered to grade with approximately 3.7 meters (12 feet) of soil. The site boundaries are permanently marked with concrete posts numbered H-65-24 through H-65-29.		
Location:	The site is located approximately 457 meters (1,500 feet) west of the 105-H Reactor Building.		
Waste Type:	Equipment		
Waste Description:	The east vault received one stainless steel double tube removed from the reactor in 1955 after several years of irradiation. Within the same area there are also solutions which were used to clean the tube, and miscellaneous capsule components. The west vault was constructed in 1958 and used during deactivation of the 105-H Reactor Building for disposal of a small amount of contaminated pipe.		
Closure Info:	The cleanup verification package (CVP-2010-00002) documents that the 118-H-2 site has met the remedial action objectives (RAOs) and the remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17, rev. 6) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, (100 Area Burial Grounds ROD) (EPA, 2000).		

Remedial action began on April 20, 2009, and continued through June 3, 2009, with the removal of 4,366 bank cubic meters (BCM) (5,711 bank cubic yards [BCY]) of soil and debris. An initial Global Positioning Environmental Radiological Survey (GPERS) identified elevated residual radioactivity in the eastern end of the excavated area within the waste site. Additional soil was excavated from that area on June 16, 2009, and a second radiological survey was conducted to verify that the contamination was removed.

Waste encountered during excavation consisted of concrete rubble produced from demolition of the two concrete vaults and some metal piping of varying sizes. One pipe had a 20 R/hr radiological contact dose rate, which distinguished it from the other metal debris. All metal and piping was size-reduced as necessary and disposed at ERDF along with contaminated soil. No spent nuclear fuel or other anomalous material (e.g., containers or stained soils) or indications of previous spills or releases were discovered at the waste site.

The COCs/COPCs were based on site history, process knowledge, available characterization data, and visual observations during excavation. The initial list of COC/COPCs was identified in 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (100 Area Burial Grounds SAP) (DOE-RL 2001a) and included cobalt-60 and nickel-63. Carbon-14, plutonium-239/240, strontium-90, tritium, uranium-234, uranium-235, and uranium-238 were also included as COPCs based on the type of waste encountered at the site. Although not COPCs, inductively coupled plasma (ICP) metals analytical list was requested. Hexavalent chromium analysis was performed due to a site-wide effort to identify sources of hexavalent chromium contamination in the groundwater.

Verification sampling was performed January 26 and 27, 2010, to collect data to determine if the RAGs/RAOs had been met. The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and were presented as part of the 95% UCL calculation in Appendix B of the CVP.

The results of verification sampling show that residual contaminant concentrations did not

preclude any future uses (as bounded by the rural-residential scenario) and allows for unrestricted use of shallow zone soil (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River.

Code: 118-H-3	Classification: Accepted
Names: 118-H-3; Construction Burial Ground	Reclassification: Interim Closed Out (6/27/2011)
Type: Burial Ground	Start Date: 1/1/1953
Status: Inactive	End Date: 1/1/1957

Description: The site's shape is an uneven polygon with sides measuring approximately 30 by 114 by 95 by 122 meters (100 by 375 by 313 by 400 feet). It runs in a northeast to southwest direction and is permanently marked with concrete posts numbered H-81-1 through H-81-13. The trenches have been covered to grade with 1.8 meters (6 feet) of soil.

Location: The site is located southeast of the 105-H Building.

Process Description: The burial ground received components and hardware from reactor modification programs.

The site operated from 1953 to 1957 to receive approximately 3,000 cubic meters (3,924 cubic yards) of reactor components and hardware, including contaminated 41-cm (16-inch) diameter pipes that were used as chutes for the removal of reactor vertical safety rod thimbles and other components from reactor modification programs. Originally, two northern trenches were used mostly for the disposal of the chute pipes. A third trench, south of the original two trenches, was developed later as a disposal site for large reactor components and hardware.

Waste Type: Equipment

Waste Description: The site contains sections of contaminated 41-centimeter (16-inch) diameter pipe used as chutes for removal of thimbles from the 105-H Building during outages, reactor hardware, and components from reactor modification programs.

The COCs identified through process knowledge are listed in the 100 Area Remedial Action Sampling and Analysis Plan and are: cobalt-60, cesium-137, europium-152, europium-154, strontium-90, uranium-233/234, and uranium-238.

Closure Info: Remedial action at the 118-H-3, Construction Burial Ground waste site began on March 4, 2009. The excavation of the waste site continued through April 22, 2009, to a depth of approximately 4.6 to 5.5 m (15 to 18 ft), resulting in a total 6,384 bank cubic meters (BCM) (8,350 bank cubic yards [BCY]) of debris and soil removed for disposal at the ERDF. All material removed from within the trenches was taken to sorting cells for surveying and unloading. Large metal and reactor hardware components excavated from trench A were stockpiled in a waste staging area on the east side of the trench. These metal sections were staged for size reduction prior to shipment for disposal. After size reduction was completed on May 18, 2009; the metal debris and an additional 0.3-m (1-ft) layer of underlying soil (approximately 60 BCM [75 BCY]) within the waste staging area footprint was removed.

The debris from the 118-H-3, Construction Burial Ground consisted mostly of metal components and very large pieces of reactor hardware (pipes, elbows, etc.). Trench C also contained aluminum tubing. No areas of stained soil or anomalous soil material were identified during the excavation. The waste removed from the trenches was consistent with the types of material expected to be present in this burial ground site.

On March 17, 2009, a suspected flammable gas cylinder, believed to be propane, was discovered. This cylinder, approximately 1.2 m (4 ft) tall and 51 cm (20 in.) in diameter, was

located in the southeastern part of trench A (Washington State Plane coordinates N 152204.8, E 577837.2) and had no observable leakage nor was the surrounding soil discolored. This cylinder appeared rusted with blue/gray oxidation on the outlet female valve and the circular valve handle. On May 19, 2009, the cylinder was inspected and found to be empty. Following inspection, the cylinder was reduced in size and shipped to ERDF. No other anomalous material was discovered during the excavation.

Code:	118-H-4	Classification:	Accepted
Names:	118-H-4; Ball 3X Burial Ground	Reclassification:	Interim Closed Out (12/29/2010)
Type:	Burial Ground	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1953
Description:	The site consists of one trench running north-south. Concrete markers mark the north and south ends. The trench was covered to grade with approximately 1.5 meters (5 feet) of soil.		
Location:	The site is located directly west of the 105-H Building, within the 105-H exclusion area fence.		
Process Description:	This site received solid waste from the Ball 3X Project in 1953. The 118-H-4 Burial Ground was a solid waste site that operated in 1953 to receive thimbles, guides, and radioactive materials removed from the 105-H Reactor during installation of the 105-H Ball 3X System. The Ball 3X project replaced the original liquid boron system for emergency reactor shutdown with a system using solid, nickel-plated, boron-steel, and carbon-steel balls.		
Waste Type:	Equipment		
Waste Description:	The site contains thimbles, guides, and radioactive materials removed from the 100-H Reactor in 1953.		
Closure Info:	The Cleanup Verification Package (CVP-2010-00003) documents that the 118-H-4, Ball 3X Burial Ground waste site has met the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 5) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, (Burial Grounds ROD) (EPA 2000). The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils.		

Remedial action began on November 4, 2008, and continued through April 14, 2009 to an approximate depth of 4.5 m (14.8 ft), resulting in approximately 1,600 bank cubic meters (BCM) (2,100 bank cubic yards [BCY]) of soil and debris that were removed for disposal at ERDF.

Additional material was removed on May 4, 2010, because verification sample results indicated residual contamination exceeding direct exposure RAGs was present at two statistical sample locations. A total of approximately 48 BCM (63 BCY) were removed from the SZ-9 and SZ-10 sample locations and disposed at ERDF. Figure 3 shows the approximate locations where the additional soil was removed. Following the additional remediation, replacement samples were collected.

The contaminants of concern (COCs) for the site specified in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (Burial Grounds SAP) (DOE/RL-2001-35), were identified as cobalt-60 and nickel-63. Europium-152, europium-154, carbon-14, tritium, plutonium-238, plutonium-239/240, boron, cadmium, and lead are considered contaminants of potential concern (COPCs) based on process knowledge associated with the disposal of Ball 3X project wastes to the site. Gross alpha and gross beta analyses were performed to evaluate if

other radionuclides associated with miscellaneous reactor waste were present at detectable levels. Gross beta was detected at greater than 23 pCi/g; therefore strontium-90 was requested.

Although not considered COPCs, antimony, arsenic, barium, beryllium, chromium (total), cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc were evaluated by performing the expanded inductively coupled plasma (ICP) metals list. Mercury was not considered a COPC; however was analyzed for and subsequently included in the analytical results package. Hexavalent chromium was included as a COPC in support of the site-wide evaluation of chromium contamination in the 100-H Area groundwater.

For verification sampling the site was divided into two decision units: the burial ground excavation and the waste staging area footprints. Two methods for selecting the sampling locations were utilized: statistical sampling design and focused sampling. The laboratory-reported data results for all constituents are stored in the Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and are presented as part of the 95% UCL calculation in Appendix B of the CVP.

Contamination did not extend into the deep zone above direct exposure limits; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are not required.

Code:	118-H-5	Classification:	Accepted
Names:	118-H-5; 105-H Thimble Pit	Reclassification:	Interim Closed Out (1/5/2010)
Type:	Burial Ground	Start Date:	1/1/1953
Status:	Inactive	End Date:	1/1/1960
Description:	The 118-H-5, 105-H Thimble Pit, was a mixed solid waste burial ground that operated in 1953 to receive a single experimental thimble assembly and was reopened in 1960 to receive contaminated soil from the original 105-H Pluto Crib Site (116-H-4 waste site). The 105-H Pluto Crib received contaminated cooling water from reactor process tubes containing ruptured fuel elements.		
Location:	The site is located south of the 105-H Building, within the 105-H exclusion area fence.		
Process Description:	This site received a single experimental thimble assembly in 1953 and contaminated soil from the 105-H pluto crib in 1960.		
Waste Type:	Equipment		
Waste Description:	The site contains a thimble assembly from the B Experimental Hole, 105-H X-level, buried in 1953. In 1960, the 105 Pluto Crib (116-H-4) was excavated due to the construction of the 105-H Confinement System and placed in this site.		
Closure Info:	The Cleanup Verification Package, CVP-2009-00009, documents that the 118-H-5 waste site has met the remedial action objectives (RAOs) and remedial action goals (RAGs) for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-2, 100-HR-2, and 100-KR-2 Operable Units, Hanford Site (100 Area Burial Grounds),(Burial Grounds ROD).		

Remedial action at the 118-H-5, 105-H Thimble Pit waste site began on September 11, 2008, to excavate and expose the single thimble and any other waste buried at the site. Remedial action at the site involved removing contaminated soil and a single thimble for disposal to ERDF. The excavated material was maintained within the waste site footprint; therefore, no staging piles were generated outside of the remediation footprint. After the thimble was located, all material

was returned to the excavation until load out began on November 10, 2008. The excavation of the waste site continued through November 12, 2008, to a depth of approximately 3.5 m (11.5 ft), resulting in approximately 400 bank cubic meters (BCM) (523 bank cubic yards [BCY]) of contaminated soil and debris removed for disposal to the ERDF.

The COCs for the 118-H-5, 105-H Thimble Pit, specified in the 100 Area Burial Grounds Remedial Action Sampling and Analysis Plan (Burial Grounds SAP), were identified as cobalt-60, nickel-63, strontium-90, cesium-137, europium-152, europium-154, uranium-238, plutonium-238, plutonium-239/240, chromium (total), lead, and mercury. The Burial Grounds SAP also includes carbon-14 as a COPC for metallic waste such as thimbles; therefore, carbon-14 was added. In addition to the SAP COCs, americium-241, uranium-233/234, and hexavalent chromium were added, as they were included as COCs for pluto crib waste sites. Although not considered COCs/COPCs, antimony, arsenic, barium, beryllium, boron, cadmium, cobalt, copper, manganese, magnesium, molybdenum, nickel, silver, selenium, vanadium, and zinc were evaluated by performing analyses for the constituents of the expanded inductively coupled plasma metals lists.

The laboratory-reported data results from the verification sampling were used in the statistical calculations. The primary statistical calculation to evaluate compliance with cleanup standards is the 95% UCL on the arithmetic mean of the data. The 95% UCL values for each COC/COPC are computed for the 118-H-5 excavation decision unit as specified by the 100 Area RDR/RAWP. The laboratory-reported data results for all constituents are stored in the WCH Environmental Restoration (ENRE) project-specific database prior to archival in the Hanford Environmental Information System (HEIS) and are presented as part of the 95% UCL calculation in Appendix B of the CVP.

The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soil (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River. The site does not have a deep zone or other conditions that would warrant institutional controls.

Code:	128-H-1	Classification:	Accepted
Names:	128-H-1; 100-H Burning Pit; 100-H Burning Pit No. 1	Reclassification:	None
Type:	Burn Pit	Start Date:	1/1/1949
Status:	Inactive	End Date:	1/1/1965
Description:	The site is in a large depression or pit that appears to have been a borrow area. The western half of the site is posted with signs reading "Warning, Do Not Deposit Salvable (sic) Material." A berm runs north-south near the east end of the site. In the area surrounded by the signs, there is some scattered surface debris including: wood, glass, metal, wire, cable, and clay pipe. There are also fragments of charred material throughout this area. In the space between the area delineated by signs and the berm, visible surface debris includes scattered concrete and metal. Fragments of charred material are also found throughout this area. The majority of the surface debris is found between the berm and the eastern edge of the site. In this area, the debris includes: wood, metal, chunks of concrete, what appear to be solvent and spray paint cans, transite and large pieces of metal on wooden pallets. There are also fragments of charred material in this part of the site as well as soil gas tubes. At the eastern end of the site, debris is found on the hillside south of the depression. Also on the hillside is what appears to be an earthen ramp and a pit filled with tumbleweeds. Debris is visible through the tumbleweeds and includes cans, concrete and pails or small drums.		

The Contaminates of Potential Concern (COPCs), identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP), include: polychlorinated biphenyls (PCBs), pesticides, semivolatile organic compounds, volatile organic compounds, total petroleum hydrocarbons, asbestos, silver, cadmium, barium, chromium (total), hexavalent chromium, mercury, lead, and selenium. Although not COPCs, antimony, arsenic, beryllium, boron, cobalt, copper, manganese, molybdenum, nickel, vanadium, and zinc were evaluated by performing the expanded inductively coupled plasma metals analytical list. Ecological risk screening levels were exceeded for arsenic, boron, cobalt, lead, manganese, vanadium, zinc, and TPH at the waste site.

Confirmatory sampling was conducted on October 27, 2008. Five test pits were excavated to evaluate the subsurface soil for evidence of burning activities. Lead was detected at a concentration (94.1 mg/kg) above both the groundwater (10.2 mg/kg) and river protection (10.1 mg/kg) lookup values.

The use of pesticides on the orchard was a likely explanation for the elevated lead concentrations found. An evaluation of the distribution coefficient (Kd) for lead (30 mL/g), using RESidual RADioactivity (RESRAD) modeling (BHI 2005), predicts that lead will not migrate to groundwater or the river within the next 1,000 years. Therefore, it is concluded the contaminant concentrations at the 128-H-3 waste site meet the RAOs established in the RDR/RAWP. Beyond a few pieces of surface trash consisting of a piece of heavy wire and the lid from a metal can, no debris was found, and no evidence of use as a burning ground was found at either site.

No physical evidence of burning or debris consistent with burning grounds was found at the waste site. An evaluation of historical photographs, field observations of surface area features, geophysical data, historical research, and the confirmatory sampling data concluded that the site was a borrow area and not a burning ground.

The results of confirmatory sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River.

Code: 128-H-3	Classification: Accepted
Names: 128-H-3; 100-H Burning Ground #3	Reclassification: No Action (1/25/2010)
Type: Burn Pit	Start Date:
Status: Inactive	End Date:
Description: This site is a pit that resembles a trench. There is little evidence of burning with the exception that some of the rocks are charred and show signs of exposure to fire. The pit was almost completely filled with tumbleweeds.	
Location: The site is located west of 118-H-1 and north of 128-H-2. The pit is located on a rise above a cobble field.	
Waste Type: Ash	
Waste Description:	
Closure Info: 128-H-2 and 128-H-3 were addressed as a group. The information below documents information for the group of sites.	

In accordance with the Remaining Sites Verification Package, RSVP-2009-008 and 2009-009, the confirmatory sampling results support a reclassification of the 128-H-2 and 128-H-3 sites to No Action. The current site conditions have achieved the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD).

Historical photographs show that this site was in the southeast corner of what appears to be an orchard. A cultural resource inspection, performed in 2007, concluded that the trench associated with the 128-H-3 waste site was part of a pre-Hanford Site farm irrigation system and not a burn pit as identified in WIDS. As such, confirmatory sampling performed within the original WIDS boundaries surrounding the cobble field and not within the trench per agreement with the Washington State Department of Ecology (Ecology) and the U.S. Department of Energy, Richland Operations Office (RL). The Technical Baseline Report (BHI-00127) stated that it was a suspect waste site, while also stating, "Past (Hanford) employees were unable to verify that this site (128-H-3) was used as a burn pit". The site has limited access, deterring its selection as a burn pit site. No debris or waste consistent with burning pits has been found at the site.

The Contaminates of Potential Concern (COPCs), identified in the 100 Area Remedial Action Sampling and Analysis Plan (SAP), include: polychlorinated biphenyls (PCBs), pesticides, semivolatile organic compounds, volatile organic compounds, total petroleum hydrocarbons, asbestos, silver, cadmium, barium, chromium (total), hexavalent chromium, mercury, lead, and selenium. Although not COPCs, antimony, arsenic, beryllium, boron, cobalt, copper, manganese, molybdenum, nickel, vanadium, and zinc were evaluated by performing the expanded inductively coupled plasma metals analytical list. Ecological risk screening levels were exceeded for arsenic, boron, cobalt, lead, manganese, vanadium, zinc, and TPH at the waste site.

Confirmatory sampling was conducted on October 27, 2008. Five test pits were excavated to evaluate the subsurface soil for evidence of burning activities. Lead was detected at a concentration (94.1 mg/kg) above both the groundwater (10.2 mg/kg) and river protection (10.1 mg/kg) lookup values.

The use of pesticides on the orchard was a likely explanation for the elevated lead concentrations found. An evaluation of the distribution coefficient (Kd) for lead (30 mL/g), using RESidual RADioactivity (RESRAD) modeling (BHI 2005), predicts that lead will not migrate to groundwater or the river within the next 1,000 years. Therefore, it is concluded the contaminant concentrations at the 128-H-3 waste site meet the RAOs established in the RDR/RAWP. Beyond a few pieces of surface trash consisting of a piece of heavy wire and the lid from a metal can, no debris was found, and no evidence of use as a burning ground was found at either site.

No physical evidence of burning or debris consistent with burning grounds was found at the waste site. An evaluation of historical photographs, field observations of surface area features, geophysical data, historical research, and the confirmatory sampling data concluded that the site was a borrow area and not a burning ground.

The results of confirmatory sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are protective of groundwater and the Columbia River.

Code:	132-H-2	Classification:	Accepted
Names:	132-H-2; 117-H Filter Building Site	Reclassification:	Interim Closed Out (8/1/2006)
Type:	Burial Ground	Start Date:	1/1/1961
Status:	Inactive	End Date:	1/1/1965
Description:	The site has been remediated and interim closed. The structure had been demolished in-situ in 1984. The site now resembles a gravel parking lot.		
Location:	The site was located southwest of the 118-H-6 (105-H Reactor Building).		
Process Description:	The site consisted of a building that housed the filters for the 118-H-6 (105-H Reactor). The building received exhaust fan discharge through an inlet duct from 118-H-6 and discharged the filtered air through a discharge duct and out the 132-H-1 (116-H Stack). The building was a reinforced concrete structure, 10.7 meters (35 feet) high and 90% below grade. The maximum thickness of the walls and floors was 0.6 meter (2 feet), with the majority being 38 centimeters (15 inches) thick. The ducts were made of reinforced concrete with a maximum wall thickness of 46 centimeters (18 inches). The inlet duct was 23.2 meters (76 feet) long and the exhaust duct was 30.8 meters (101 feet) long.		
Related Sites/ Structures:	The building filtered exhaust air from 118-H-6 (105-H Reactor Building) to the 132-H-1 (116-H Reactor Exhaust Stack).		
Waste Type:	Demolition and Inert Waste		
Waste Description:	Total radionuclide inventory in the 117-H Building was estimated to be 0.41 millicuries. The radionuclides comprising this figure are tritium, carbon-14, cobalt-60, cesium-137, strontium-90, europium-154, europium-152, and plutonium-239/240. Of these radionuclides, strontium-90 is the most restrictive in the Allowable Residual Contamination Level (ARCL) calculations.		
Closure Info:	As part of decommissioning activities, extensive radiological surveying and sampling activities were performed to characterize residual radiological contamination on the accessible internal surface areas of the 117-H Filter Building. Characterization results indicated that residual contamination was confined to the 1 millimeter (0.04 inch) vinyl paint layer. An evaluation of the concrete beneath the paint showed that the contamination did not penetrate the paint or absorb into the concrete.		

The site was released for unrestricted use based on the ARCL Calculations for Decommissioning the 117-H Filter Building. The allowable residual contamination level (ARCL) calculation indicated that the demolished facility would contribute less than 1 millirem/year dose to a hypothetical, maximally-exposed site resident if the site was released for unrestricted use after the demolition and burial in situ of the facility. Consequently, demolition and site grading were performed in 1984 using conventional heavy equipment. The rubble was buried under at least 1 meter (3.3 feet) of clean fill, and the site was graded to blend with the natural terrain.

Using the maximum radiological activities from the pre-demolition characterization data to represent residual contamination levels over 100% of the paint and concrete surface of the former building, RESidual RADioactivity (RESRAD) modeling was performed in 2006 to support the previous decision to demolish and bury the building in place. The RESRAD modeling accounts for radioactive decay from 1984 (year of sampling) to 2006 and predicts that the site achieves the dose limits and risk objectives for rural residential land use with institutional controls, groundwater protection, and river protection.

In accordance with this evaluation documented in the Remaining Sites Verification Package for 132-H-2, 117-H Filter Building (RSVP-2006-049), the 1984 sampling results support a

reclassification of the site to interim closed out. The current site conditions have achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD) (EPA 1999).

These results show that the site and contaminant levels remaining in the soil will be protective of direct exposure, groundwater, and the Columbia River. However, the acceptability of unrestricted direct exposure to below-grade structure surfaces in the deep zone has not been demonstrated; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone are required.

Code: 1607-H1	Classification: Accepted
Names: 1607-H1; 1607-H1 Sanitary Sewer System; 1607-H1 Septic Tank; 1607-H1 Septic Tank and Associated Drain Field; 124-H-1	Reclassification: Interim Closed Out (9/1/2011)
Type: Septic Tank	Start Date: 1/1/1948
Status: Active	End Date:

Description: The 1607-H1 septic tank system was a nonhazardous, nonradioactive liquid waste site that began operation in 1948, and received sanitary sewage from the 105-H Reactor Building and the 151-H Primary Substation. The sanitary wastes from these buildings were conveyed to the 1607-H1 septic tank system via buried vitrified clay pipes (VCPs). These pipes are planned for remediation as the 100-H-28:4, 1607-H1 Sanitary Sewers waste site. The 1607-H1 drain field measured 17.1 by 15.2 m (56 by 50 ft) and was oriented on a northeast-southwest line from the tank. The at-grade portion of the septic tank was a concrete pad with two manhole covers and a third manhole cover located adjacent to the tank, which was clearly visible at the site in a photograph taken on September 30, 2009

In 1985, the 1607-H1 septic system was reactivated to be used by service trailers supporting deactivation and decommissioning (D&D) project personnel. At that time, the tank was discovered to have been backfilled with fly ash. The ash was vacuumed out of the septic tank and disposed to the ground surface prior to the successful reactivation of the septic system. No other records were located documenting the backfilling of the septic tank.

During an interview with a former employee it was stated that it was common practice for showers and sinks in the 100-H Area change rooms to be used for personnel decontamination, and these drains lead to the sanitary sewers not the process sewers.

In January 2007, the 1607-H1 waste site was assigned to remove, treat, and dispose in the interoffice memorandum "1607-H1 Remaining Site for Remedial Action".

This waste site has been remediated. The septic tank has a 50-person capacity, is constructed of concrete and measures 4.6 by 1.7 by 4.4 meter (15 by 5.5 by 14.5 feet).

Location: The 1607-H1 waste site is located southwest of the 105-H Reactor Building and the 151-H Primary Substation, near the 118-H-2 Burial Ground, in the 100-HR-2 Operable Unit.

Related Sites/ Structures: The septic system is associated with the 105-H Reactor and the 151-H substation.

Waste Type: Sanitary Sewage

Waste Description: This unit received sanitary sewage from 151-H and 105-H Buildings. The flow rate to this unit

was estimated to be 503 liters/day (140 gallons/day).

Waste Type: Not Specified

Waste Description: The waste included carbon steel pipes and drainage tiles/pipe from the area of the septic tank inlet, from the drain field, and concrete/brick from the septic tank and adjacent manhole structure, including all soils excavated from below the drain field piping.

Closure Info: Remedial action at the 1607-H1 waste site was performed between September 24 and November 2, 2009, and included the removal of the below-grade septic tank and the manhole cover surface features. Excavation continued until all debris and contamination associated with the septic tank, drain field pipes, and connecting pipeline structure had been removed. The site was excavated to a depth of approximately 3.2 m (10.5 ft), removing the drain and tile field pipes at approximately 2.5 m (8.2 ft) below surface grade, and to a depth of approximately 4 m (13 ft) at the septic tank and adjacent manhole structure. A total of approximately 1,166 bank cubic meters (BCM) (1,525 bank cubic yards [BCY]) of soil and debris were removed and directly loaded for disposal at the Environmental Restoration Disposal Facility, including all soils excavated from below the drain field piping. This debris included carbon steel pipes and drainage tiles/pipe from the area of the septic tank inlet and the drain field, and concrete/brick from the septic tank and adjacent manhole structure.

An additional 528 BCM (691 BCY) of soil was removed from outside of the septic tank and overlying the drain field to form the overburden pile for the 1607-H1 waste site. The 1607-H1 remediation design identified the separation of overburden soil from the 1607-H1 drain field into two separate soil stockpiles. This overburden soil was intended to be used as backfill after it had been sampled, analyzed, and determined to meet cleanup criteria.

Code: 600-151

Classification: Accepted

Names: 600-151; Dumping Areas 50 Yards and 200 Yards Downstream of River Mile 14; Military Installation NW of 100H Area

Reclassification: Interim Closed Out (10/27/2011)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: The site has been remediated. It was the debris remaining from a military installation that was located northwest of the 100H Area. A paved road entered the site from the southwest.

The 600-151 waste site consisted of scattered debris from U.S. Army Base Camp 130 (BC-130), a military camp covering approximately 162,000 square meters (40 acres) near the Columbia River, which was occupied from approximately 1950 to 1954. Debris found throughout the area in 1996 included a partially buried washtub, tin cans, a stove pipe, empty fuel and solvent cans painted "army green", broken concrete and transite, an old stove, wire fencing material, and a large pile of steel fence posts (screw in type for barbed wire fencing). There was evidence of ground disturbance at the site including three pits. A vertical culvert was observed at grade level extending into the ground. The culvert interior was obscured due to the presence of tumbleweeds. Several areas of stressed vegetation were also observed in the area. The 600-151 waste site is located within this historic-archaeological site and contains the remnants of a farmstead intentionally demolished by Hanford-related activities. In 2009, prior to field remediation, were some domestic military debris, several pits (some with wood lining), and shallow trenches (where communication lines were thought to be located) were documented.

Location: The site was located northwest of 105-H Reactor and begins 0.3 kilometers (0.2 miles) downstream of river mile post 14. The site has dirt and paved roads which form its boundary. A paved road enters the site from the southwest.

Waste Type: Equipment

Waste Description:

Waste Type: Soil

Waste Description: Several areas of stressed vegetation were found at the site.

Waste Type: Demolition and Inert Waste

Waste Description: A large pile of broken concrete, electrical wiring, piping and pieces of wood was observed at the site.

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: One 208 liter (55 gallon) drum, several 19 liter (5 gallon) cans, and several 0.95 liter (1 quart) cans were noted at the site. The 19 liter (5 gallon) containers appeared to be the type that would hold fuel such as gasoline or kerosene. Empty paint cans that contained "army green" paint are also present.

Closure Info: Prior to use by the Hanford Site Manhattan Project, the 600-151 waste site location was part of an historic agricultural site occupying some 202,000 square meters (50 acres) consisting of five tracts of land used circa 1938 to 1943. During the growing season, orchards were sprayed with lead arsenate from the time the trees bloomed until they were harvested. During remediation, a pattern of circular shaped, stained soil areas was noted beyond the areas identified for remediation in the remedial design. Field personnel suspected that these areas might be associated with historic agricultural pesticide applications and were not from Hanford waste disposal activities. In-process soil samples, collected to support waste characterization, identified high concentrations of arsenic (up to 229 mg/kg) and lead (up to 1,750 mg/kg) suspected to be associated with historic agriculture lead arsenate pesticide use.

Remediation of the 600-151 waste site consisted of mechanical excavation of concentrated debris and manually removing scattered debris from the ground surface as identified in the remediation design drawings. Areas of stained soil and stressed vegetation were scraped and removed to a minimum depth of 0.31 meters (1 ft). In addition, two water valves and a water box associated with the former septic system (the 600-152 waste site) were also removed.

Code: 600-152

Classification: Accepted

Names: 600-152; Military Septic Tanks

Reclassification: Interim Closed Out (4/1/2010)

Type: Septic Tank

Start Date:

Status: Inactive

End Date:

Description: The waste site consisted of an underground septic tank and several surface features, including three in-line concrete covers and two manholes, which allowed access to the septic tank. Underground piping connected the surface features and the septic tank.

Location: The site is located northwest of 105-H Reactor and begins 0.2 miles downstream of river mile post 14. The site has dirt and paved roads which form a boundary surrounding the site. A paved road enters the site from the southwest.

Process Description: The site was constructed to support a military base camp that was created as part of Camp Hanford, which supported the established air defense systems at the camp. Base Camp 130 was located in the vicinity of the 600-151 dumping areas waste site and was abandoned by 1954. In October 2001, liquid in the septic tank was sampled. Results from the sample, described as rainwater, showed elevated gross beta results. No other radionuclides were detected in the analyses. Based on this result, the site was posted with Underground Radioactive Material signs.

Waste Type: Sanitary Sewage

Waste Description: radioactive here because sampling showed gross beta at 72 pCi/liter (see field work discussion for comparisons with Hanford Site background). The site was posted with Underground Radioactive Material signs.

Closure Info: The Remaining Sites Verification Package (RSVP-2009-019) for 600-152 has documented that the site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGS) established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (ROD). These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario.

Remedial action at the 600-152 waste site was performed between October 13 and November 10, 2008, and encompassed the removal of the below-grade septic tank, the surface features (three concrete covers and two manholes), and associated soils. The concrete piping that linked the septic tank to these surface features was also removed. A section of cast iron pipe containing seals made of lead was removed from the waste site. The lead-containing material was containerized after removal from the excavation. The site was excavated up to 5 m (16 ft) below grade, resulting in the removal of approximately 287 BCM (375 BCY) of material for disposal at the Environmental Restoration Disposal Facility, including approximately 140 m (460 ft) of pipe. Approximately 1,584 BCM (2,070 BCY) of soil (overburden) was removed and stockpiled for evaluation as clean backfill.

The waste site contaminants of potential concern (COPCs) were described in the verification work instruction as lead, pesticides, and polycyclic aromatic hydrocarbons. Although not COPCs, arsenic, antimony, barium, beryllium, boron, cadmium, cobalt, copper, manganese, molybdenum, nickel, selenium, silver, vanadium, and zinc were evaluated by performing analyses for the constituents of the expanded inductively coupled plasma (ICP) metals list. Although not a COPC, mercury analysis was performed for the verification samples, and the results were compared against the RAGs for completeness. Analytical results were discussed in the Data Evaluation portion of the RSVP.

There is no process history to suggest that radiological contamination was present in the 600-152 septic tank. The in-process sample results from the tank contents (J17R76) did not detect radiological contamination; however, an elevated gross beta result from a water sample collected within the tank was reported in 2001. The beta emitter that is of most concern associated with this detection is strontium-90; therefore, strontium-90 was added as a COPC.

To determine if the remedial action goals had been met, verification sampling was performed on May 13, 2009. One focused sample was taken for strontium-90 analysis in accordance with an elevated radiological reading indicated by the GPERs survey. A summary of the cleanup evaluation for the soil results against the applicable criteria was presented in Table ES-1 of the RSVP. The results of the verification sampling were used to make reclassification decisions for the site in accordance with the Tri-Party Agreement Handbook Management Procedure, TPA-MP-14 procedure.

Verification samples were analyzed using U.S. Environmental Protection Agency-approved analytical methods. The laboratory-reported data results for all constituents were stored in the WCH Environmental Restoration project-specific database prior to archival in the Hanford Environmental Information System, and were presented in Attachment 1 of the 95% UCL calculations (Appendix D of the RSVP).

The results also demonstrated that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and contaminant levels remaining

in the soil were protective of groundwater and the Columbia River. Site contamination extended slightly into the deep zone soils, however, the remediation footprint was evaluated against the more restrictive shallow zone criteria. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep-zone are not required.

100-IU-1

Code: 600-44 **Classification:** Accepted

Names: 600-44; 600-68; Enyert Well Empty Pesticide Container Dump; Herbicide/Pesticide Empty Container Pile **Reclassification:** Deleted From NPL (7/8/1998)

Type: Dumping Area **Start Date:**

Status: Inactive **End Date:**

Description: During the Riverland Expedited Response Action, a visual inspection of the area found several empty aldrin and dieldrin herbicide/pesticide containers lying on the surface. The containers were rusty five gallon and one gallon cans covering an area of approximately 20.90 meters squared (225 square feet). The condition of the containers suggested that they were placed there after Hanford operations began. However, the site is located on an old abandoned homestead about 150 meters (500 feet) east of the commercial vineyard on the west side of the cold Creek Road.

Location: The site was located approximately 150 meters (500 feet) east of the commercial vineyard on the west side of Cold Creek Road. The site is on relatively flat ground located within an abandoned homestead site. There is a perimeter access road located approximately 50 feet west of the site. (at NW 1/4 of NW 1/4 of NW 1/4 of Section 26, T13N R24E)

Waste Type: Barrels/Drums/Buckets/Cans

Waste Description: The site waste includes empty pesticide and herbicide containers, and debris piles from the homestead.

Closure Info: The containers were removed from the area and properly disposed of as part of the Riverland Expedited Response Action. One surface soil sample (BO1939) and two splits of that sample (BO1940 and H92078) were analyzed for aldrin/ dieldrin and 4,4-DDE. Maximum values of 27,000 parts per billion of aldrin, 38,000 parts per billion of dieldrin and 57 parts per billion of DDE were identified before cleanup, and 0.45 ppb aldrin, and 3.6 ppb dieldrin, and 6.7 ppb 4, 4-DDE in the soil after cleanup. In addition, six old batteries north and east of the excavation were removed, the underlying soil showed only zinc was detected (Heiden 1992).

Code: 600-101 **Classification:** Accepted

Names: 600-101; Riverland Railroad Car Wash Pit; RRCWP **Reclassification:** Deleted From NPL (7/8/1998)

Type: Depression/Pit (nonspecific) **Start Date:** 1/1/1945

Status: Inactive **End Date:** 1/1/1963

Description: During the Expedited Response Action cleanup activities, the site resembled a concrete trench. Excavations were made to uncover the pits for sampling. The rail road car cleaning pits were about 1 meter (3 feet) deep and 2 meters (6 feet) wide. Following remediation activities, the pits were backfilled to grade.

Location: The site is approximately 0.8 kilometers (0.5 miles) west of State Highway 240 and 0.5 kilometers (0.3 miles) southwest of the Vernita Bridge .

Process Description: The Riverland Rail Yard Maintenance Facility (Building 6718) steam cleaned and decontaminated railroad cars of grease and radioactive contamination in two pits prior to service and maintenance activities. The decontamination removed grease and oil from the undercarriage, wheels, axles and brakes. Diesel locomotives had their engine compartment, radiators and fans cleaned. Low levels of radioactive contamination was removed. Radioactively contaminated pads, gloves and other wastes were sent to the 200 Area for

disposal. Periodically, the pit floor and walls were cleaned with a broom soaked in diesel fuel, then rinsed with water. Decontamination solutions drained into floor drains which then drained to an open ditch on the north side. The facility operated from 1943 until 1956. The facility was decontaminated in 1963 and the facility structures were sold to the public.

Waste Type: Water

Waste Description: The site was used as a steam cleaning and low-level decontamination station for locomotive engines and cars used at Hanford.

Closure Info: In 1992 and 1993, the Riverland Expedited Response Action characterized and cleaned up the site (DOE/RL-1995; Heiden 1992, 1993, 1994). About 260 cubic meters (340 cubic yards) of concrete and fill material was removed from the wash pits and recycled through a concrete recycling plant. In the 100-B/C Area, and 330 cubic meters (430 cubic yards) of diesel contaminated soil were sent off site for bioremediation DOE/RL-1995.

Radiological surveys did not identify any levels above background. Small quantities of man-made radionuclides were observed in pre-remediation sampling. (A maximum of 19.6 pico curie per gram of cesium-137.) However, based on the levels observed the operable unit was considered nonradioactive. The cleanup level for diesel fuel residue was 200 parts per million (ppm); the confirmatory sample results showed less than 2 ppm remaining. The confirmatory samples also showed all man-made radionuclides were below 1 pico Curie per gram.

About 330 cubic meters (430 cubic yards) of vitrified clay drain pipe fragments and contaminated soil were removed and bioremediated by "land farming" in the 100-C Area, and declared completed in 1996. The pits were backfilled with clean material from onsite. No further action was required for this site following the ERA (DOE/RL 1995) and subsequent ROD (EPA, 1996). On July 8, 1998 the site was deleted from the NPL (DOE/RL-2002).

Code: 600-102	Classification: Accepted
Names: 600-102; 600 AMBS; 600 Area Army Munitions Burial Site	Reclassification: Deleted From NPL (7/8/1998)
Type: Burial Ground	Start Date: 1/1/1971
Status: Inactive	End Date: 1/1/1976
Description: The site consisted of a shallow excavation area that contained a wooden crate used to bury emergency supplies of explosives and munitions used during the 1970's for military exercises (Smith & Stanley, 1993). The excavated area was approximately 0.61 meters (2 feet) wide by 0.91 meters (3 feet) long. The explosives were removed in 1986. The excavation was backfilled in 1993.	
Location: The site is located northwest of 200 West area, approximately 100 meters west of Gate 12, near the McGee Ranch.	
Waste Type: Ordnance	
Waste Description: The unit received military explosives as follows: 6 gun blast simulators, Model 110, dated October 1953; 78 boxes (packed 5 to a box) of fuse ignitors; Model M60, Lot KYC-1, dated May 1960; one trip flare, Model M49; one can containing 50 nonelectrical blasting caps, marked "ARMY"; 43 electrical blasting caps; ~500 ft of time fuse; ~200 ft of detonating cord; and remnants of one grenade or artillery simulator.	
Closure Info: One non intrusive soil sample was collected (sample B01937, with split sample B01938) (Heiden, 1992). The results showed 32.9 ppm nitrate/nitrite (DOE/RL 1993, 1995; Weston 1992) No other contamination was identified. The excavation was backfilled.	

Code: 600-274	Classification: Accepted
Names: 600-274; Riverland; 2,4-D Can Site at McGee Ranch	Reclassification: Deleted From NPL (7/8/1998)
Type: Dumping Area	Start Date:
Status: Inactive	End Date: 1/1/1994
Description:	The 2,4-D can site is surrounded by old-growth sagebrush with a cheatgrass understory. As it is near the far western border of the Hanford Site, there are no Hanford facilities nearby. Eleven 5-gallon cans were found here, nine of which were buried upright and adjacent to each other, with only their tops showing. Two other cans were on top of the ground nearby. The cans were removed and the soil sampled in 1994 as part of the closeout of the 100-IU-1 Operable Unit. In addition, while the original site was being located with the GPS coordinates in 2001, three other 5-gallon cans were found due north of the site about 100 meters (100 yards), also in sagebrush. This site was also GPS'd and flagged with white tape. All cans have been removed.
Location:	The site is about 300 meters (300 yards) north of Highway 24, and 3.2 kilometers (2 miles) west of the Yakima Barricade.
Process Description:	The material in the eleven cans removed in 1994 was 2,4-D, an herbicide. The three cans discovered in 2001 were empty and unmarked.
Related Sites/ Structures:	It is not apparent who placed the cans at this site, or if they were associated with Hanford operations or a nearby farm.
Waste Type:	Barrels/Drums/Buckets/Cans
Waste Description:	The site was 11 old herbicide cans (2,4-D) that had some soil and liquid (in one can) remaining.
Closure Info:	The original eleven cans were removed in 1994. Two composite samples were taken from the soil within the cans and one liquid (with one duplicate) sample. The liquid samples used up all the remaining liquid in the drum. After the cans were dug out of the hole, samples of the remaining soil immediately below the cans, and at 1, 2 and 3 foot depths were taken in three locations (see Field Work section for details and results). Jon Lucas, one of the samplers on the site in 1994, was interviewed in 2001. He said that based on standard operating procedure, any soil from within the cans would have been placed in the 55-gallon drums, especially if there was an odor of herbicide (as the logbook reports). He also said that the excavation would not have been filled back in, but kept open pending receipt of the sampling results. If the results had indicated a problem, they could have gone back to excavate further and re-sample. Since the reports concluded there was no problem with the levels remaining at the site (even if phrased very poorly), they would not have gone back to the site. Thus, he thinks the site may still be visible as a depression. The three remaining drums located about 100 meters north of the original eleven were removed and disposed of in December 2002. Site personnel determined that these drums were empty and not of RCRA concern. Due to the remote location of the site it is considered a "Category 1" radioactive area which allows for landfill disposal.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to provision to the Hanford Environmental Information System (HEIS) and were presented as an attachment to the direct contact hazard quotient and relative percent difference calculation in Appendix C of the RSVP.

This site does not extend into the deep zone. No institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are required.

Code: 600-52 **Classification:** Accepted

Names: 600-52; White Bluffs Surface Basin **Reclassification:** No Action (11/20/2003)

Type: Drain/Tile Field **Start Date:**

Status: Inactive **End Date:**

Description: The site has been evaluated and determined to meet remedial action objectives. The evaluation supports reclassification. The site was a depression.

Location: The site was located south of Federal Avenue and west of Route 2 North. It was southeast of the White Bluffs Pickling Acid Cribs (600-106), on the opposite side of a powerline road.

Process Description: A 1948 aerial photograph showed a ditch leading from the ice house waste water drain field to the 600-52 basin. It appeared that the southeast corner of the Pickling Acid Crib (600-106) washed out onto this basin. Three soil samples from this unit were collected during the White Bluffs Pickling Acid Cribs Environmental Risk Assessment (ERA) characterization conducted November and December 1992. Sample data may be found in the source document DOE/RL-93-48.

Related Sites/ Structures: 600-106 Pickling Acid Crib

Waste Type: Process Effluent

Waste Description: Nitric and hydrofluoric acids were discharged to the nearby Pickling Acid cribs. Sampling indicated slightly elevated levels of chrome and chloride when compared to background samples. Generally, the acid was neutralized prior to disposal, but may not have been completely neutralized prior to disposal.

Closure Info: This site was assumed to be associated with the Pickling Acid Cribs (sitecode 600-106). The Pickling Acid Cribs were characterized in 1992. Samples were also collected at three locations in the surface basin in 1992. A field walkdown done in April 2003 revealed no debris or anomalies. It was determined that no additional samples would be required.

Reclassification to "No Action" is supported by a preponderance of information (e.g., site history, previous sample results, field walkdown). The 600-52 White Bluffs Surface Basin site has achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL 2002) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (EPA 1999). Residual soil concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.5 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code: 600-98 **Classification:** Accepted

Names: 600-98; East White Bluffs City Landfills; East White Bluffs Dump and East White Bluffs Dump **Reclassification:** No Action (8/17/2004)

#2; East White Bluffs Landfill; EWBCL

Type: Sanitary Landfill **Start Date:**
Status: Inactive **End Date:** 1/1/1943

Description: This site consisted of two unlined, pre-Hanford landfills. A small amount of scattered surface debris (cans, glass and wood) was visible at dump #1. Dump area #2 was an area of gravel ridges and surface scars. The Technical Baseline Report stated that this area was a dumping area that had been bulldozed.

Location: The East White Bluffs Dump was located approximately 150 meters (492 feet) north of the White Bluffs Ferry Landing. The East White Bluffs Dump #2 was located approximately 275 meters (902 feet) west of the White Bluffs Ferry Landing and north of Federal Avenue.

Process Description: The East White Bluffs Dump reportedly operated from 1850 to 1943. The East White Bluffs Dump #2 operated from 1900 to 1943.

Related Sites/ Structures: upr--100-d-4

Waste Type: Misc. Trash and Debris

Waste Description: Both sites were used to dispose of industrial and domestic wastes common to the time that it was being used. Surface debris found around the East White Bluffs Dump included cans, glass and wood. Surface debris found the East White Bluffs Dump #2 included wood, metallic, domestic (pots, bowls, and glassware), and industrial debris (cables and plywood sheets). The sites contain no known radioactive constituents.

Closure Info: The evaluation of site history reviews, field observations, and geophysical surveys, provided the basis for reclassification of the site to no action. The site has achieved the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL-96-17, Rev. 5, Draft B) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (EPA 1999). The results of the evaluation have demonstrated that the site was a pre-Hanford dumping area and borrow pit. The site will support future unrestricted land uses that can be represented (or bounded) by a rural-residential scenario, and no institutional controls are required.

The 100 Area Remedial Action Sampling and Analysis Plan (SAP) (DOE-RL-96-22, Rev. 4, Draft B) identified contaminants of potential concern (COPCs) for dumping areas. The SAP categorically assumed COPCs associated with disposal of hazardous debris. However, further evaluation of the debris observed at the site during the confirmatory sampling walkdown, indicated the debris to be non-hazardous and disposed of prior to Hanford Operations. Therefore, no further evaluation or confirmatory sampling was necessary for this site.

The waste site evaluation and supporting documentation has demonstrated that the site meets the objectives established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE-RL-96-17, Rev. 5, Draft B) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (EPA 1999). The evaluation showed that there are no hazardous/dangerous materials present at the site and, accordingly, no residual contamination in the soil. Therefore, the site is protective of human health, groundwater, and the Columbia River.

Code: 600-99 **Classification:** Accepted

Names: 600-99; J. A. Jones #2; JA Jones 2; JA JONES2 **Reclassification:** No Action (9/12/2003)
Type: Burial Ground **Start Date:** 1/1/1948
Status: Inactive **End Date:** 1/1/1955
Description: The site has been reclassified and does not require remediation.
Location: The site was located northwest of the White Bluffs Townsite, north of H Avenue and east of Route 2.
Waste Type: Construction Debris
Waste Description: This site contained minor construction equipment used by the J. A. Jones Construction Company, including wood scraps, concrete, and some metallic waste. However, the excavation records indicate that the site contents were removed to the 200 Areas Burial Grounds in 1971 because of radioactive contamination in the landfill.
Closure Info: The site has been reclassified to "No Action" following evaluation with ground penetrating radar (GPR) and test pits to confirm that it does not require remediation and meets the remedial action objectives (RAOs) and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17) , implemented from the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999). Results of the test pit evaluations and residual soil concentrations for the 600-99 site support unrestricted future use of shallow zone soil (i.e., surface to 15 feet) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

A geophysics survey was done to verify locations of buried material and to dig a test pit to verify that no hazardous material were present in the debris. During the survey, no areas of debris/anomalies requiring removal and/or sampling were located.

Based on the site history, walkdown, and GPR evaluation, test pits were dug at the locations of three identified subsurface anomalies on May 20, 2003. These three anomalies were just outside the previously identified boundaries of 600-99, but close enough to be of concern as possible debris left behind from the previous excavation and removal project. Any debris encountered was to be evaluated by the sampler and certified waste shipper and samples taken to support waste designation. The results of the field activities demonstrate that there are no materials remaining at the 600-99 site that would exceed the RAGS.

Code: 600-100 **Classification:** Accepted
Names: 600-100; 600-119; WBL; White Bluffs City Dump; White Bluffs City Landfill; White Bluffs Landfill **Reclassification:** Interim Closed Out (1/18/2011)
Type: Sanitary Landfill **Start Date:**
Status: Inactive **End Date:** 1/1/1943
Description: The site is an unlined excavation that received industrial, commercial, domestic and farm wastes.
Location: The site is located west of Route 2 North and south of Federal Avenue. It is east of the White Bluffs Pickling Acid Cribs (600-106), approximately 540 meters (1,772 feet) south of the intersection of Route 2 North and Federal Avenue.
Waste Type: Misc. Trash and Debris
Waste Description: The site was used for normal commercial and domestic wastes at the time. It contains no known radioactive constituents. Per BHI-00049, the site was used for disposal of industrial,

commercial, and domestic wastes, cans, bottles, and farm debris.

Closure Info: Attached to the reclassification form for the site were supporting documentation, site evaluations and verification sampling results. They document that this site meets the remedial action objectives (RAOs) and remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE-RL-96-17) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD) (EPA 1999).

For consideration of potentially sensitive archaeological materials at the site, the trench material was brought up in 0.3-m (1-ft) lifts and sifted through by field personnel. No archaeologically sensitive materials were discovered during remediation. Due to a lack of anomalous material or evidence of subsurface waste disposal, no material from the trenches was disposed to the Environmental Restoration Disposal Facility (ERDF), no samples were collected from the trenches, and all six trenches were backfilled with the material removed from the trenches.

Remediation occurred from January 4 to 18, 2010. The results of an archaeological investigation in December 2009 indicated there was no underlying debris or anomalous material. The site was excavated only to a depth of 15 cm (6 in.) to remove debris and anomalous material.

One anomaly was found while blading the road during remediation. On January 4, 2010, a 208-L (55-gal) stainless steel container was found unbreached, but partially crushed. A waste management representative evaluated the drum and it was found empty and disposed at ERDF.

Following remediation, verification sampling was conducted in July 2010. The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to provision to the Hanford Environmental Information System (HEIS) and were presented as an attachment to the 95% UCL calculation in Appendix C of the attachment. The results of the verification sampling were used to make reclassification decisions for the site in accordance with the TPA-MP-14 procedure.

The exact duration of use was not confirmed. Study of the artifacts (e.g., ceramic fragments, tin cans) on the ground surface at the waste site suggests that the site dates back to at least the early 1900s. It has since been determined that the waste site was more likely used for opportunistic dumping rather than as a large scale landfill, and that this debris was buried during Hanford-era operations.

The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow-zone soil (i.e., surface to 4.6 m [15 ft]), and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The 600-100 waste site did not extend into the deep zone; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required.

Code: 600-120	Classification: Accepted
Names: 600-120; Spare Parts Burn Pit; White Bluffs Spare Parts Burn Pit	Reclassification: Interim Closed Out (3/16/2011)
Type: Burn Pit	Start Date: 1/1/1943
Status: Inactive	End Date: 1/1/1948
Description: The site was a burn pit that was used for industrial and commercial wastes. The site appears to have been backfilled with coal ash.	

Location:	The site was located west of Route 2 North and south of Federal Avenue, under a set of BPA lines. It is north of the exhumed White Bluffs Pickling Acid Cribs (sitecode 600-106).
Process Description:	White Bluffs Spare Parts Burn Pit waste site appears to have been a burn pit that was used for disposal of industrial and commercial wastes, including flammable wastes, solvents, and waste soils.
Related Sites/ Structures:	600-120 is associated with 600-297 because they were co-located and remediated at the same time.
Waste Type:	Chemicals
Waste Description:	The waste was solvents, waste oils, and flammable wastes. The site may have been used to dispose of other solid wastes. The site appears to have been backfilled with coal ash.
Closure Info:	Based on historical information, results of the geophysical survey and site walkdown observations, the 600-120 waste site was divided into three areas for confirmatory sampling. Confirmatory sampling was conducted in March 2004. It was determined that remedial action was necessary in Areas 1 and 3. Area 2 was determined not to need remediation.

Area 1 was a large depression that appeared to be an abandoned burn pit, backfilled with coal ash. Two test trenches were excavated for confirmatory sampling in Area 1. Evidence of vitrified clay pipe, rubber, burned wood, and coal were found. Confirmatory samples collected from the coal ash and native soil locations in Area 1 found that direct exposure remedial action goals (RAGs) were exceeded for benzo(a)pyrene, benzo(b)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene, indicating that site remediation was required. Barium, copper, and selenium were also present in concentrations exceeding soil cleanup criteria for groundwater or river protection.

Area 3 was identified during the geophysical survey as a depression northeast of Area 1 where buried debris was suspected to be present. One test trench was excavated in Area 3 for confirmatory sampling. Concrete walls, debris, coal ash, apparent rust, and oil stained soil were all observed in this test trench. Confirmatory samples of stained soils showed lead and silver concentrations in excess of direct exposure cleanup RAGs. Herbicides, pesticides, and polychlorinated biphenyls (PCBs) were also present in concentrations exceeding soil cleanup criteria for groundwater or river protection.

The COPCs for the 600-120 were preliminarily identified in the 100 Area RDR/RAWP as PCBs, pesticides, SVOCs, total petroleum hydrocarbons (TPH), volatile organic compounds (VOCs), asbestos, silver, cadmium, barium, chromium (total), hexavalent chromium, mercury, lead, selenium, and sulfate. Asbestos-containing material was not encountered during remedial activities and was therefore eliminated as a COPC.

Remediation occurred from January 7 to March 15, 2010. Materials that were excavated as a part of this remediation included coal ash. A concrete structure determined to be from the co-located 600-297 White Bluffs Imhoff Tank waste site. The concrete was fully removed and the bottom of the structure was at approximately 8 meters (28 feet) below ground surface. Groundwater was encountered at this location after the 600-297 waste site tank was removed. Cleanup verification sampling of the 600-120 waste site also included samples from the 600-297 waste site.

Following remediation, verification sampling was conducted in September 2010. The results indicated that the waste removal action achieved compliance with the remedial action objectives (RAOs) and RAGs for the 600-120 and 600-297 waste sites. The results of the verification sampling are used to make reclassification decisions for the 600-120 and 600-297 waste sites in accordance with the TPA-MP-14 procedure. The verification sampling results support a

reclassification of this site to Interim Closed Out.

The 600-120, White Bluffs Spare Parts Burn Pit waste site verification sampling data, site evaluations, and supporting documentation demonstrate that this site and the 600-297 waste site meet the objectives established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington Remaining Sites ROD. These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow-zone soil (i.e., surface to 4.6 m [15 feet]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. These sites do not have a deep zone. Therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the sites are not required.

Code: 600-124	Classification: Accepted
Names: 600-124; Burn Site and Paint Disposal Area; White Bluffs Burn Site and Paint Disposal Area	Reclassification: Interim Closed Out (1/27/2011)
Type: Burn Pit	Start Date:
Status: Inactive	End Date:

Description: The site is a burn area where there is evidence of surface burning and paint disposal. The entire area is littered with burned wood, partly burned roofing materials, glass, nails, metallic debris, transite and isolated paint cans. There is evidence of surface disposal of paint materials in dried paint chips and deposits. There is also a large area with decaying timbers laying in many parallel rows. It appears to be some type of floor structure.

Location: The site is located south of Federal Avenue and just west of the railroad tracks on the west side of Route 2 North. It is approximately 640 meters (2100 feet) southeast of the intersection of Route 2 North and Federal Avenue.

Waste Type: Chemicals

Waste Description: The waste is the remains from paint disposal.

Closure Info: The remaining sites verification package for 600-124, RSVP-2010-094, has documented that the site verification sampling data, site evaluations, and supporting documentation support a reclassification to Interim Closed Out. The site has met the objectives established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units,(Remaining Sites ROD) (EPA 1999).

Remediation occurred from January 11 to 18, 2010. The excavation extended to a depth of approximately 1 m (3 ft) bgs, while the vadose zone beneath the excavation was approximately 8.3 m (27.2 ft) thick. Approximately 1 m (3 ft) of material was scraped from the surface and disposed at the Environmental Restoration Disposal Facility. Several paint cans containing various colors of paint were encountered during remedial activities.

Verification sampling was conducted in September 2010 to support a determination that residual contaminant concentrations at this site meet the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD. Twenty-four statistical verification soil samples were collected on a grid that included the excavated area and the staging pile area footprint.

Verification samples were analyzed using U.S. Environmental Protection Agency-approved analytical methods. The 95% upper confidence limits (UCLs) on the true population means for residual concentrations of COPCs were calculated for the excavation and staging pile area decision units as specified by the RDR/RAWP.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to provision to the Hanford Environmental Information System (HEIS) and were presented as an attachment to the 95% UCL calculation in Appendix B of the RSVP.

These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not extend into the deep zone. Institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required.

Code: 600-125	Classification: Accepted
Names: 600-125; Waste Disposal Trenches; White Bluffs Waste Disposal Trench 1	Reclassification: Interim Closed Out (2/1/2011)
Type: Trench	Start Date:
Status: Inactive	End Date:
Description:	The site currently looks like a sandy depression with wood, ceramic and metal debris on the surface.
Location:	The site is located west of Route 2 North and south of Federal Avenue. It is approximately 1020 meters (3347 feet) south of the intersection of Route 2 North and Federal Avenue. The site is on the west side of a powerline road.
Waste Type:	Misc. Trash and Debris
Waste Description:	The waste includes metal shavings, steel piping, plumbing fixtures, paint cans and automotive parts; as well as other metallic and wooden debris. In the same area there are several piles of used railroad ties, broken vitrified clay pipe, concrete pipe, 30.5-centimeter (12-inch) diameter, 6.1-meter (20-foot) long spiral welded pipe, plumbing fixtures, and degraded asbestos insulation.
Closure Info:	The remaining sites verification package for 600-125, RSVP-2010-088, has documented that the site verification sampling data, site evaluations, and supporting documentation support a reclassification to Interim Closed Out. The site has met the objectives established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units,(Remaining Sites ROD) (EPA 1999).

Remediation occurred from February 11 to 17, 2010. The excavated area measured approximately 35 m (115 ft) across in an irregular shape, and was 0.8 m (2 ft) deep. The vadose beneath the excavation is approximately 10.6 m (34.8 ft) thick. The waste material, which included several 12 m (40 ft) of 12 in. diameter pipes, was staged in an area located southeast of the excavated area prior to being sent to the Environmental Restoration Disposal Facility. On March 1, 2010, two in-process samples were collected from the excavated area. These samples, J19L23 and J19L24, were comprised of random aliquots of soil collected from across the

surface of the waste site. The in-process sample data was provided in Appendix B of the RSVP.

Verification sampling was conducted in August 2010 to support a determination that residual contaminant concentrations at this site meet the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD. The laboratory-reported data results for all constituents are stored in the Environmental Restoration (ENRE) project-specific database prior to provision to the Hanford Environmental Information System (HEIS) and are presented as an attachment to the direct contact hazard quotient and relative percent difference calculation in Appendix C of the RSVP.

These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]), and contaminant levels remaining in the soil are protective of groundwater and the Columbia River. The site does not extend into the deep zone; therefore, institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not required.

Code:	600-127	Classification:	Accepted
Names:	600-127; Fuel Storage Area; White Bluffs Loading Docks and Fuel Storage Area	Reclassification:	Interim Closed Out (4/26/2011)
Type:	Storage	Start Date:	
Status:	Inactive	End Date:	
Description:	The site is two loading docks and a rectangular area surrounded by a low soil berm 0.5 meters (1.6 feet) high. The ground within the berm is covered by a layer of coal ash. Inside the bermed area are several wooden beams, the tops of which are flush with the ground surface. On the top of these beams are wooden shims placed so as to suggest that they once supported large round horizontal tanks associated with fuel storage. It appears that there were four or five of these large tanks located at the site. Other small debris piles are located nearby that consist of broken vitrified clay piping, plumbing fixtures, and concrete piping. On the north side just outside the berm, there appears to have been a smaller fuel tank site. The two loading docks located adjacent to the fuel storage area are described as the north loading dock and a south loading dock. Each loading dock was approximately 20 meters (66 feet) long by 12 meters (39 feet) wide. These two loading docks appear to have been a convenient location to offload heavy equipment.		
Location:	The site is located west of Route 2 North and south of Federal Avenue. It is approximately 1,100 meters (3609 feet) southeast of the intersection of Route 2 north and Federal Avenue. The north loading dock is visible from Route 2 North.		
Release Description:	Removal of small areas of the ash ground cover reveals soil discoloration and evidence of petroleum product contamination. The soil around the fuel tank site on the north side of the berm is also discolored and appears to be contaminated with a petroleum product, probably gasoline. Adjacent to and on the south side of the berm there appears to have bulk dumping of heavy oils or other petroleum products. The soil contamination in this area extends to the south from the berm for about 4 meters (13 feet). Just west of the north loading dock is a 1.5-meter (4.9-foot) chemical spill spot that appears to consist of a petroleum product.		
Waste Type:	Oil		
Waste Description:	The waste is petroleum product contaminated soil.		
Description:	During remedial activities as documented in RSVP-2004-064, it was observed that the inside of the berm contained coal ash and several wooden beams and shims thought to have once		

supported large tanks associated with fuel storage. To the west of the north loading dock was a chemical spill spot approximately 1.5 m (5 ft) in diameter, which appeared to consist of a petroleum product (BHI 1995). In addition to these areas, several small debris piles were located in the vicinity, and contained broken vitrified clay piping, plumbing fixtures, and concrete piping. Bulk dumping of petroleum products appeared to have occurred at the waste site.

Closure Info: The 600-127 waste site was identified in the Remaining Sites ROD (EPA 1999) as a candidate site for confirmatory sampling. Eight test pits and trenches were excavated based on a locations identified during a geophysical survey and site walkdown. Five of the test pits showed no signs of hazardous debris or discolored soil, so no samples were collected. Confirmatory sampling at the other three locations had elevated levels of barium, cadmium, copper, lead, zinc, polycyclic aromatic hydrocarbons (PAH), total petroleum hydrocarbons (TPH), and 4,4-DDE and required remediation.

Remedial action at the 600-127 waste site began on January 19, 2010, and was completed on June 7, 2010. The main excavation which encompassed two of the test pit areas was excavated to groundwater (approximately 8.5 m [28 ft] below ground surface [bgs]) while chasing a diesel or petroleum-product odor. The north loading dock and adjacent chemical spill spot was excavated to approximately 1 m (3 ft) bgs with an adjacent area scraped to 15 cm (6 in.) bgs. Soil and debris were staged in two stages piles prior to disposal at the Environmental Restoration Disposal Facility (ERDF).

Code: 600-128	Classification: Accepted
Names: 600-128; Oil and Oil Filter Dump Site; White Bluffs Oil and Oil Filter Dump Site	Reclassification: Interim Closed Out (9/16/2003)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:
Description:	The site has been remediated and interim closed out. The site had been an oil dump area that included several canister-type oil filters. Surface debris was removed in the spring of 2003.
Location:	The site was located west of Route 2 North and south of Federal Avenue. It was approximately 730 meters (2395 feet) south of the intersection of Route 2 North and Federal Avenue.
Process Description:	Several Hanford site construction shops and warehouse facilities were located in this area.
Related Sites/ Structures:	The site was associated with the White Bluffs Automotive Repair Shop, site code 600-139.
Waste Type: Oil	
Waste Description:	The waste is oil contaminated soil, oil cans and filters. There are also several small areas with broken glass, cans, and other metal debris.
Closure Info:	A remedial action activity was implemented to remove contaminated soil and associated debris identified during the April 2003 site walkdown. The material was removed to a depth of 25 centimeters (10 inches), sampled to support waste designation, collected and packaged in accordance with waste management plans, and removed from the site for subsequent disposal at the Environmental Restoration Disposal Facility or other approved facilities.

The cleanup verification samples were analyzed by offsite contract laboratories using approved U.S. Environmental Protection Agency analytical methods. The cleanup verification sample results are stored in the Hanford Environmental Information System.

The Waste Site Evaluation for 600-128 (BHI 2003) demonstrated that the site meets the remedial action objectives established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units, Hanford Site, Benton County, Washington (EPA, 1999). The remaining soils at these sites have been sampled and analyzed. The results of the evaluation demonstrated that the materials remaining at the 600-128 site do not exceed the remedial action goals (RAGs). These results also show that residual soil concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.5 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code: 600-129 **Classification:** Accepted

Names: 600-129; Pre-MED White Bluffs Community Dump Site (Oil Can Site); White Bluffs Pre-MED Community Dump Site 1 **Reclassification:** Interim Closed Out (3/2/2005)

Type: Dumping Area **Start Date:**

Status: Inactive **End Date:**

Description: The site has been remediated and interim closed out.

Location: The site was located west of Route 2 North, south of Federal Avenue, on the east side of a north/south dirt road. It was approximately 1.7 kilometers (1.1 miles) south-southeast of the intersection of Route 2 North and Federal Avenue.

Related Sites/ Structures: The site was co-located with 600-191.

Waste Type: Misc. Trash and Debris

Waste Description: The main part of the site is littered with cans, bottles, oil cans, glass, wire, rope, toys, and automotive bodies and parts. On the southern edge industrial wastes include insulators, fuse boxes, conduit, and six 208-liter (55-gallon) drums, one of which is labeled "Carbon Tet". Because of the large number of oil cans, it is believed that the site was used by both Manhattan Engineering District (MED) and White Bluffs residents for the disposal of domestic type waste (Carpenter, 1994). Three glass vials containing an unknown white powder were found on a site walkdown in 1999. Dry cell batteries were also observed on April 22, 1999.

Closure Info: 600-129 and 600-191 were addressed as a group. The information below documents information for the group of sites.

The Remaining Sites Verification Package (RSVP-2004-136) for the 600-129 and 600-191 White Bluffs Pre-Manhattan Engineering District (MED) Community Dump Sites 1 and 2, has demonstrated that the remedial action objectives established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (ROD) for interim closure of the site have been met.

The site was 305 meters (1,001 feet) long by 80 meters (262 feet) wide with an irregular shape. The total area was 23,768 meters squared (77,979 square feet).

The site was an area littered with miscellaneous trash and debris. It appeared that it was used by both MED and White Bluffs residents for the disposal of domestic waste materials. The debris was concentrated in a swath along the west side of a dirt road. Areas devoid of vegetation were also observed; most were natural (e.g., clay, insects) and occurred due to a physical disturbance that does not recover for lack of moisture. This site was not originally identified as a remaining site, but was included in the removal action due to similarity in debris

items and its location in the vicinity of the 600-129 site.

In May and June 2004, a site walkdown was conducted of the two sites and revealed debris and no evidence of burning. The site walkdown conducted in June 2004 included an EPA representative, who identified hazardous material to be removed. During the walkdown, it was also confirmed that a site-specific sampling plan would not be required. Then on July 28, 2004, a walkdown was conducted to identify, locate, and flag areas of hazardous material (mainly dry cell batteries) requiring removal.

The flagged items were removed in October 2004 by an Environmental Restoration Contractor (ERC) subcontractor. The waste included dry and wet cell batteries, battery cases, asbestos-containing material, and paint materials. The waste was collected, characterized, and packaged in accordance with the waste management plan, and removed from the site for subsequent disposal at the Environmental Restoration Disposal Facility (ERDF) or other approved facility.

The field investigation results indicated that there was no remaining hazardous material at the site and, accordingly, no residual contamination of the soil. The residual surface material at the site was inert debris and was protective of the groundwater and the Columbia River; therefore, no deep zone institutional controls are required.

Code: 600-131	Classification: Accepted
Names: 600-131; Special Fabrication Shop and Warehouse; White Bluffs Water Station and Special Fabrication Shops and Warehouse	Reclassification: Interim Closed Out (9/12/2003)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:
Description: The site has been remediated and closed out. The site included the remnants of the Special Fabrication Shop and Warehouse, boiler house, warehouse, loading dock/well and a water station.	
Location: The site was located approximately 1.3 kilometers (0.8 mile) northwest of the intersection of Route 2 North and Federal Avenue.	
Waste Type: Misc. Trash and Debris	
Waste Description: The waste was miscellaneous trash and debris, including concrete, transite, asphalt shingles, glass, and metallic debris. Transite contains asbestos, which was a hazardous substance. Asbestos was a CERCLA hazardous substance that may require action to mitigate a potential environmental impact. Asbestos wastes are excluded from the Dangerous Waste Regulations (WAC 173-303-071).	
Closure Info: A remedial action activity was implemented, after an April 2003 field walkdown, to remove identified waste material and debris from the site for subsequent disposal at the Environmental Restoration Disposal Facility. The maximum detected results and a composite sample of underlying soil at the location suspected of having the greatest potential for residual contamination, were used to support site reclassification.	

The cleanup verification samples were analyzed by offsite contract laboratories using approved U.S. Environmental Protection Agency analytical methods. A data quality assessment was performed to compare the sampling approach and resulting analytical data with the sampling and data quality requirements specified by the project objectives and performance specifications. The data quality assessment determined that the data are of the right type, quality, and quantity to support site verification decisions within specified error tolerances. The cleanup verification sample results are stored in the Hanford Environmental Information System.

The Waste Site Evaluation for 600-131 Fabrication Shops (BHI 2003) demonstrated that the site meets the remedial action objectives established in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units (EPA,1999). The remaining soils at this site has been sampled and analyzed. The result of this evaluation demonstrated that the materials remaining at the 600-131 site do not exceed the remedial action goals (RAGs). These results also show that residual concentrations will support future land uses that can be represented (or bounded) by a rural-residential scenario, and that residual concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.5 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code: 600-132	Classification: Accepted
Names: 600-132; Construction Contractor Shop Landfill; White Bluffs Construction Contractor Shop Landfill	Reclassification: Interim Closed Out (9/12/2003)
Type: Depression/Pit (nonspecific)	Start Date:
Status: Inactive	End Date:
Description:	The site has been remediated and interim closed out. The site was a large open borrow pit. The floor was mostly gravel and cobble with rabbitbrush and grasses. It contained scattered debris, such as broken concrete and pieces of metal, similar to the surrounding area. Surface debris was removed in 2003.
Location:	The site was located east of Route 2 North and north of Federal Avenue, approximately 1000 meters (3,281 feet) northwest of the intersection of Route 2 North and Federal Avenue.
Related Sites/ Structures:	The nearby fabrication shops are site 600-131.
Waste Type:	Misc. Trash and Debris
Waste Description:	If this site was actually the Construction Contractor Shop Landfill and not a borrow pit, the wastes that may have been disposed there could include oils, solvents, and cleaning agents (for example, carbon tetrachloride), typical of shop wastes. There may also be radioactive wastes, if this was not a mis-identified site (also see site 600-99). Carpenter (1995) identified two locations along the northwest boundary of the site with spots of oil (1.5-meter [4.9-foot] diameter for both spots).
	The waste that was visible in 1999 was surface debris, common to the entire 100-IU-2 Operable Unit, such as rusted metal cans, concrete rubble, a few pieces of transite, and wire. Two small piles of aluminum shavings are at the site, one on the floor of the pit and one at ground level, near the first pile. A small mound of dirt on the southwest corner, at the surrounding surface elevation, has partially buried pieces of yellow bricks and thick metal. A field walkdown done in April 2003 determined the site was a gravel borrow area and not a landfill.
Closure Info:	After an April 2003 field walkdown a remedial action activity was implemented to remove identified waste material and debris from the site for subsequent disposal at the Environmental Restoration Disposal Facility (ERDF). The maximum detected results from one grab sample and two composite samples of the underlying soil at locations suspected of having the greatest potential for residual contamination were used to support site reclassification.
	The cleanup verification samples were analyzed by offsite contract laboratories using approved U.S. Environmental Protection Agency analytical methods. A data quality assessment was performed to compare the sampling approach and resulting analytical data with the sampling

and data quality requirements specified by the project objectives and performance specifications. The data quality assessment determined that the data are of the right type, quality, and quantity to support site verification decisions within specified error tolerances. All analytical data were found to be acceptable for decision-making purposes. The cleanup verification sample results are stored in the Hanford Environmental Information System.

The Waste Site Evaluation for the 600-132 White Bluffs Construction Contractor Shop Landfill (BHI 2003) demonstrates that the site meets the objectives for interim closure as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE RL 2002), implemented for the Interim Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999). Residual soil concentrations support unrestricted future use of shallow zone soil (surface to 15 feet) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code: 600-139	Classification: Accepted
Names: 600-139; Automotive Repair Shop; White Bluffs Automotive Repair Shop and Associated Waste Sites	Reclassification: Interim Closed Out (9/12/2003)
Type: Dumping Area	Start Date:
Status: Inactive	End Date:
Description:	The site has been remediated and interim closed out. The site was an area thought to be associated with an automotive repair shop. Surface debris included numerous battery caps, engine gaskets, dumped waste oils, and fragments of tail light lenses. The surface debris was removed in May 2003.
Location:	The site was located west of Route 2 North and north of Federal Avenue. It was approximately 700 meters (2297 feet) southwest of the intersection of Route 2 North and Federal Avenue.
Waste Type:	Oil
Waste Description:	The waste included battery caps, engine gaskets, fragments of tail light lenses, and dumped waste oils.
Closure Info:	In April 2003, a field walkdown was conducted to finalize contaminants of potential concern, identify sample locations, and identify sample types for development of a sampling design. Subsequently, remedial action activity was implemented to remove identified waste material and debris from the site for disposal at the Environmental Restoration Disposal Facility. The maximum detected results and a composite sample of underlying soil at the location, suspected of having the greatest potential for residual contamination, were used to support site reclassification.

The cleanup verification samples were analyzed by offsite contract laboratories using approved U.S. Environmental Protection Agency analytical methods. A data quality assessment was performed to compare the sampling approach and resulting analytical data with the sampling and data quality requirements specified by the project objectives and performance specifications. The data quality assessment determined that the data are of the right type, quality, and quantity to support site verification decisions within specified error tolerances. The cleanup verification sample results are stored in the Hanford Environmental Information System and are summarized in the data summary tables

In accordance with this evaluation, the cleanup verification results from samples of underlying soil support the interim closure of the 600-139 site. Residual material at the site achieves the remedial action objectives and the corresponding remedial action goals established in the

Remedial Design Report/Remedial Action Work Plan for the 100 Area (DOE/RL-96-17), implemented for the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (EPA 1999). Residual soil concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters [15 feet]) and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code: 600-176 **Classification:** Accepted

Names: 600-176; White Bluffs Paint Disposal Area **Reclassification:** Interim Closed Out (5/2/2011)

Type: Dumping Area **Start Date:**

Status: Inactive **End Date:**

Description: The site is a dumping area where it appears that excess paint materials were disposed of by pouring them on the ground. The ground has dried paint chips on the surface. The paint spills and chips are scattered over a large area.

Location: The site is located approximately 570 meters (1870 feet) west of the intersection of Commercial Avenue and Federal Avenue within the warehouse storage area.

Related Sites/ Structures: Co-located with the 600-295 White Bluffs Paint Shop.

Waste Type: Construction Debris

Waste Description: Paint chips are on the surface of the ground.

Closure Info: Remedial activities took place from December 7, 2009 to February 10, 2010. During remediation, visible surface paint was placed in 208-L (55-gal) drums prior to excavation. Due to the presence of paint in the subsurface soil, the excavation continued to a depth of approximately 1.5 m (5 ft). Additionally, the remedial design for the 600-176 waste site overlapped the 600-295 waste site; therefore, remediation of the 600-176 waste site resulted in the concurrent remediation of the 600-295 Paint Shop waste site.

On December 17, 2009, an empty 10-in.-diameter vitrified clay pipe (VCP) was encountered during excavation and followed to the northeastern corner of the excavation, where it ended in a possible concrete septic tank that was approximately 1.5 m (5 ft) long with unknown depth and width. This VCP was believed to be part of the sewer lines associated with the 600-295 paint shop as shown in drawing H-11-3909 (Atkinson-Jones 1948). The VCP was removed with the material excavated during the 600-176 remediation. This septic system and tank have been identified as part of the 600-301 waste site.

During remediation, green soil was encountered and removed to an additional 1 m (3 ft) below the base of the excavation, until the associated solvent odor was no longer present. Although the material had a strong solvent-type odor, nothing was detected with the photo ionization detector (0.0 ppm readings) and soil samples did not reveal the chemical responsible for the odor. Additionally, coal ash was encountered on the southern side of the excavation that was as much as 46 cm (18 in.) thick in some areas and thinned out across the extent of the excavation. This material was removed and included in the stockpile to the southeast of the excavation. Wood debris was also encountered and stockpiled. The final excavation depth was 1.5 m (5 ft) bgs.

Code: 600-181 **Classification:** Accepted

Names: 600-181; White Bluffs Oil Dump **Reclassification:** Interim Closed Out (9/12/2003)

Type: Dumping Area **Start Date:**

Status: Inactive

End Date:

Description: The site has been remediated and interim closed out. The site was an oil dumping area. The surface was near asphalt-like in appearance as a result of the large quantities of oil that had been dumped.

Location: The site was located west of Route 2 North and south of Federal Avenue. It was approximately 740 meters (2,428 feet) southeast of the intersection of Route 2 North and Federal Avenue. The site was on the west side of an old powerline access road.

Waste Type: Oil

Waste Description: The waste was oil contaminated soil. The top of the soil had formed into an asphalt-like surface.

Closure Info: In April 2003, a field walkdown was conducted to finalize contaminants of potential concern, identify sample locations, and identify sample types for development of a sampling design. Subsequently, a remedial action activity was implemented to remove identified waste material and debris from the site for disposal at the Environmental Restoration Disposal Facility (ERDF). The maximum detected results for a composite sample of underlying soil at the location suspected of having the greatest potential for residual contamination were used to support site reclassification.

The cleanup verification samples were analyzed by offsite contract laboratories using approved U.S. Environmental Protection Agency analytical methods. A data quality assessment was performed to compare the sampling approach and resulting analytical data with the sampling and data quality requirements specified by the project objectives and performance specifications. The data quality assessment determined that the data are of the right type, quality, and quantity to support site verification decisions within specified error tolerances. The cleanup verification sample results are stored in the Hanford Environmental Information System.

In accordance with the evaluation, the cleanup verification results from samples of underlying soil support the interim closure of the site. Residual material at the site achieves the remedial action objectives and the corresponding remedial action goals established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) DOE/RL-96-17), implemented for the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 100-CW-3 Operable Units (Remaining Sites ROD) (EPA 1999). Residual soil concentrations support unrestricted future use of shallow zone soil [surface to 4.6 meter(15 feet)] and contaminant levels remaining in the soil are protective of groundwater and the Columbia River.

Code: 600-182

Classification: Accepted

Names: 600-182; White Bluffs Asbestos Pipe Lagging and Excess Piping

Reclassification: Interim Closed Out (1/4/2011)

Type: Dumping Area

Start Date:

Status: Inactive

End Date:

Description: The site is excess piping materials and an area of highly degraded piping insulation that appears to be made of asbestos or a similar material. Several 6.1-meter (20-foot) sections of 30.5-centimeter (12-inch) spiral welded steel pipe are nearby. Other small debris piles are located very nearby that consist of broken vitrified clay piping, plumbing fixtures, and concrete piping.

Location: The site is located west of Route 2 North and south of Federal Avenue. It is approximately 1050 meters (3445 feet) south of the intersection of Route 2 North and Federal Avenue and west of a power line road.

Waste Type: Asbestos (friable)
Waste Description: The waste is piping insulation material that appears to be made of asbestos or a similar material.

Closure Info: The Remaining Sites Verification Package (RSVP-2010-089) for 600-182 waste site has documented that verification sampling data, site evaluations, and supporting documentation have demonstrated that this site has met the remedial action objectives (RAOs) and the corresponding remedial action goals (RAGs) as established in the Remedial Design Report/Remedial Action Work Plan for the 100 Area (RDR/RAWP) (DOE/RL-96-17, Rev. 6) and the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, (Remaining Sites ROD) (EPA 1999).

Remedial action was performed on February 10, 2010. All excess piping material and debris, as well as potential ACM was removed. An overburden pile was created from the topsoil at the main excavation area. In addition to this excavation, two small areas were scraped where asbestos pipe lagging and vitrified clay pipe were found. A waste staging pile area was created to the side of these scraped areas. All scraped areas were excavated to approximately 8 cm (3 in.) below ground surface. The vadose zone beneath the excavation is approximately 5.1 m (16.7 ft) thick. No in-process samples were collected after remediation. The largest excavation has an area of approximately 1,000 m² (10,700 ft²). The scraped area with asbestos lagging is less than 100 m² (1,000 ft²). The scraped area with VCP is approximately 11 m² (118 ft²). The waste staging pile area is approximately 4 m² (43 ft²). The overburden pile is approximately 90 m² (970 ft²). Photographs of these areas were provided in Appendix A of the RSVP.

The contaminants of potential concern (COPCs) were identified based on professional knowledge and waste characterization sampling results. Lead and zinc were included as COPCs due to detection above remedial action goals (RAGs) during waste characterization sampling; therefore, they were included as site COPCs for all decision units. Total petroleum hydrocarbons (TPH) were included as COPCs because of burned material and ash observed at the site. Asbestos was included as a COPC only at the location where asbestos lagging was found. Although not considered COPCs, analyses for the constituents of the inductively coupled plasma (ICP) metals list also included antimony, arsenic, barium, beryllium, boron, cadmium, chromium (total), cobalt, copper, manganese, molybdenum, nickel, selenium, silver, and vanadium. Pesticides, volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), and polychlorinated biphenyls (PCBs) were not detected during waste characterization sampling, and were not included in the analyses for verification sampling at the 600-182 waste site. Mercury was not detected above background levels and was also excluded as a COPC for verification sampling.

Verification sampling was conducted in August 2010 to support a determination that residual contaminant concentrations met the cleanup criteria specified in the RDR/RAWP and the Remaining Sites ROD. The verification sample results were provided in Appendix C of RSVP-2010-089.

The laboratory-reported data results for all constituents were stored in the Environmental Restoration (ENRE) project-specific database prior to provision to the Hanford Environmental Information System (HEIS).

These results show that residual soil concentrations support future land uses that can be represented (or bounded) by a rural-residential scenario. The results also demonstrate that residual contaminant concentrations support unrestricted future use of shallow zone soil (i.e., surface to 4.6 m [15 ft]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. This site does not extend into the deep zone. Institutional controls to prevent uncontrolled drilling or excavation into the deep zone of the site are not

required.

Code: 600-188 **Classification:** Accepted
Names: 600-188; White Bluffs Waste Disposal Trench 2 **Reclassification:** Interim Closed Out (3/16/2011)
Type: Trench **Start Date:**
Status: Inactive **End Date:**

Description: The site is an open trench with industrial wastes filling about one-third of the site. There is evidence of chemical or oil dumping and burning along the east side of the trench. The White Bluffs Technical Baseline Report (BHI-00448) states the evidence includes discolored soils and empty 208-liter (55-gallon) drums that are bulging, as if its contents had been burned within the drums. During the April 1999 visit, three empty 208-liter (55-gallon) drums were observed. Only one of them appeared to be bulging. The drums are concentrated near the eastern edge of the site. The chemical or oil dumping and burning appears to have been confined to the area around these drums.

Location: The site is located west of Route 2 North and south of Federal Avenue. It is approximately 1000 meters (3,281 feet) southeast of the intersection of Route 2 North and Federal Avenue. The site is on the east side, and adjacent to, a powerline road.

Waste Type: Misc. Trash and Debris

Waste Description: The waste consists of industrial wastes of wooden and metallic debris. There has been chemical or oil dumping and burning. There are also empty 208-liter (55-gallon) drums.

Closure Info: The 600-188 waste site was remediated on February 10 and 11, 2010. Debris and soil to a depth no more than 1 m (3 ft) below the existing borrow pit surface were removed from the waste site. The excavation surface was 2.5 m (8 ft) below grade at the deepest area. Material removed from the perimeter around the excavation was placed into an overburden pile to be used as backfill material. Waste material was placed in a staging pile area, which was then loaded out to the Environmental Restoration Disposal Facility.

On March 3, 20 10, three in-process soil samples (J119L34, J119L35, and J119L36), one duplicate sample (J19L37), and one equipment blank (J19L3 8) were collected to evaluate the adequacy of remediation. The footprint of the excavation was divided into three sample areas, and a sample was collected from multiple aliquots of soil across the top of each area (Appendix A). No contaminant concentrations of in-process soil samples exceeded direct exposure RAGs. Concentrations of several metals exceeded soil cleanup levels for protection of groundwater and/or the Columbia River but no organic chemicals exceeded soil RAGs.

Code: 600-190 **Classification:** Accepted
Names: 600-190; White Bluffs Warehouse Tar and/or Paint Disposal Area **Reclassification:** Interim Closed Out (9/16/2003)
Type: Dumping Area **Start Date:**
Status: Inactive **End Date:**

Description: The site has been remediated and interim closed out. The site was an area where tar and/or paints appeared to have been dumped.

Location: The site was located east of Route 2 North and north of Federal Avenue. It was approximately 1000 meters (3,281 feet) northwest of the intersection of Route 2 North and Federal Avenue, by the southwest corner of 600-132, White Bluffs Construction Contractor Shop Landfill.
