January 21, 2010

Abstract: As part of the Federal Reserve Bank of Boston's commitment to supporting efforts to revitalize the economy of Springfield, Massachusetts, this paper explores the causes of and potential remedies for the city's low resident employment rates. When compared to the state as a whole and to other midsize New England cities, the share of employed city residents is low, particularly for residents of downtown Springfield and its nearby neighborhoods. By analyzing the availability of jobs across Springfield's various neighborhoods and in nearby towns and cities, this paper's goal is to learn why so few Springfield residents are employed, and thus to identify policy priorities to increase employment. This study finds that solving Springfield's low resident employment rates will require a combination of new job creation, improved informational and physical access to jobs, and strengthening the citizenry's job skills.

This paper is also published under the Federal Reserve Bank of Boston Research Department's Public Policy Discussion Papers series. For the latest version of this paper, please visit <http://www.bos.frb.org/economic/ppdp/index.htm>.

The views expressed in this paper are solely those of the authors and do not necessarily represent those of the Federal Reserve Bank of Boston or the Federal Reserve System.

Strategies to improve the well-being of Springfield residents must include a major focus on increasing employment. The share of city residents in the work force is low compared to Massachusetts as a whole and compared to other mid-sized New England cities. The lack of employment is particularly problematic for the residents of downtown Springfield and the nearby neighborhoods of the South End, Six Corners, Memorial Square, and Brightwood. At any given time in recent years, the majority of adults living in these areas of Springfield were neither employed nor actively looking for work. ¹

This discussion paper analyzes the availability of jobs across Springfield's neighborhoods and in nearby cities and towns. This examination seeks to unravel the mystery of why so few Springfield residents are employed, particularly those living in neighborhoods close to downtown. Are there few jobs in Springfield in relation to the number of its working-age residents? Are the available jobs located in areas that are difficult or impossible for inner-city residents to access? Are the answers to these questions different from what they were in the past? Do the answers vary by industry? And, in general, do the available data shed light on the extent to which Springfield's employment problems stem from issues related to job availability or accessibility—as opposed to the qualifications of jobseekers in the local labor pool?

The goal of this research is to help identify policy priorities. Increasing employment among Springfield residents will require some mix of job creation, improving physical and informational access to jobs, and strengthening its citizenry's job skills. The data from this study provide a basis for choosing specific initiatives.

This study's most important findings are:

- The jobs challenge is massive. Increasing the employment rate in Springfield to match the average in other comparable New England cities would require

¹ See Browne, Green, et al. (2009).

placing 6,000 more Springfield residents in jobs. Current total employment of Springfield residents is about 58,000; thus, the needed increase is over 10 percent.

- The number of available jobs in the Springfield area (about 76,000 within the city itself plus another 90,000 or so within a 10-mile radius of the city) is not abnormally low for a city with a working-age population of 113,000. The problem is that Springfield residents face significant barriers to being hired into and/or remaining employed in area jobs.
- Springfield residents who have not completed high school— as well as those who have not gone beyond high school—are less likely to be employed than similarly educated residents of other mid-sized New England cities. While policies to reduce dropout rates and expand access to postsecondary education are essential for Springfield’s future, local leaders need to focus on additional strategies to increase employment of city residents.
- The distance between residential neighborhoods and where jobs are located is one barrier to employment that deserves further attention. Springfield’s poor are concentrated near its downtown. Jobs within the city limits are scattered across various neighborhoods. Most of the retail jobs, for example, are located on the eastern edge of Springfield, requiring a lengthy bus ride from the city center for those without a car. Jobs in the suburbs are moving even farther away from the city. To have full access to employment opportunities in manufacturing and construction, in particular, workers must be able to commute outside of Springfield.
- Health care and social assistance is Springfield’s largest industry, and has been a source of growing employment opportunities for the city’s residents. Service-sector industries, particularly leisure and hospitality, also are significant employers in and near downtown Springfield. Hiring more people from inner-city neighborhoods in these industries should be a component of any jobs strategy.

- Expanded training, internship, mentorship, outreach, and other human capital-related programs are necessary in order to prepare more Springfield residents for employment. In addition, transportation enhancements or downtown job creation may be needed to improve their access to jobs in certain sectors.
- Given the demographic composition of Springfield’s poor neighborhoods, progress toward raising employment is likely to be limited unless minorities become better connected to local job networks.
- In order for Springfield’s resident employment to increase without decreasing the employment of current jobholders who live outside the city, Springfield and its surrounding region must engage in aggressive job creation efforts.

Overall Employment Patterns

As this section of the study will show, the evidence on overall job availability is clear: Low employment among Springfield residents is *not* due primarily to a lack of jobs in and near the city. Nonetheless, jobs have been moving farther away from the downtown neighborhoods in recent years, exacerbating any problems the residents of these areas face in finding work and remaining employed.

Springfield’s Low Employment Rate

Springfield’s residents have an exceptionally low rate of employment. Table 1 shows the total population, the working-age population, and the employed population in 2005–2007 for Springfield and six comparable New England cities. The selection of these other New England cities—Bridgeport, Hartford, New Haven, Providence, Waterbury, and Worcester—is based on size, manufacturing orientation, and regional significance, as described in an earlier Federal Reserve Bank of Boston discussion paper.² In 2005–2007, Springfield had a population of approximately 148,000, of whom 113,000 were 16 years of age and older. By these measures, Springfield was the third largest city in the comparison group, behind Providence and Worcester. Judged by the number of employed residents, however, Springfield was only the

² Kodrzycki, Muñoz, et al. (2009).

fourth largest city. It had an employed population of 58,000, smaller than in Worcester, Providence, and Bridgeport, and only slightly higher than New Haven.

Comparing the number actually employed with the size of the potential work force, only 51.4 percent of Springfield's working-age population was employed in 2005–2007. This is the lowest resident employment rate of all six cities. Except for Hartford, all of the other four New England cities had employment rates of between 57 and 60 percent. To raise Springfield's employment rate to match the average of the other four New England cities would require some 6,300 more of its adult residents to find jobs. This amounts to more than a 10 percent increase in the number of Springfield jobholders.

Job Availability in Springfield and Surrounding Areas

In contrast to the overall patterns in resident employment rates, the number of jobs located within the city limits varies widely across the six cities used in our comparison, and Springfield is neither extremely low nor extremely high in terms of jobs concentrated within the city. In 2005–2007, there were almost 76,000 jobs located in Springfield (table 1). The numbers in the other cities ranged from roughly 43,000 to 45,000 in Waterbury and Bridgeport, to between 113,000 and 115,000 in Providence and Hartford. As state capitals, Providence and Hartford have large numbers of government jobs. Counting only private industries, Providence, Worcester, and Hartford were the largest jobs centers—each with between 95,000 and 97,000 jobs in 2005–2007.

One useful measure of the availability of employment is job density: the number of jobs relative to the size of the working-age population. Springfield had 67.0 jobs per 100 residents 16 years of age and older, somewhat lower than the 76.9 average for the other six cities but higher than the average excluding the two state capitals, Providence and Hartford.³ In terms of the number of private-industry jobs per 100 residents 16 years of age and older, Springfield's job density rate was 64.4, very similar to the average of the other cities.

³ See the box at the end of this section that compares the various sources of employment and demographic data, including an explanation for the use of different dates for different sources.

In this particular sample of cities, job density appears to have little or no bearing on resident employment. Hartford had by far the highest job density, but its employment rate among residents was almost as low as Springfield's. Bridgeport had the lowest job density, but the highest resident employment rate.

City resident employment rates correlate poorly with city job density rates because labor markets extend beyond municipal boundaries. In the case of Springfield, 27,000 residents, or 46 percent of the employed population, worked outside of the city in 2000. Meanwhile, about 45,000 other Massachusetts residents commuted to Springfield for work, as shown in table 2. In other words, city residents "compete with" residents of the greater Springfield area for jobs located in Springfield.

Another way to measure job availability for city residents is by more direct measures of accessibility, such as commuting time or distance. A recent study on "job sprawl"⁴ in 98 metropolitan areas across the United States provided mixed results for Springfield. The positive finding is that compared to other similar cities in New England, a relatively high share of the jobs in the Springfield metropolitan area are located within a 10-mile distance from the downtown (table 3).⁵ The study estimated that in 2006 there were a total of about 245,000 jobs within 35 miles of downtown Springfield, of which about 166,000 or 68 percent were within 10 miles and the remaining 79,000 or 32 percent were beyond 10 miles. For the other New England cities, the average shares were 57 percent within a 10-mile radius and 43 percent between 10 and 35 miles.⁶

⁴ Kneebone (2009).

⁵ Locations 10 miles from downtown Springfield lie outside the boundaries of the city. The area of Springfield is 33.2 miles; it measures roughly 7 miles from east to west and roughly 5 miles from north to south. Downtown Springfield is located along the western border of the city.

⁶ The comparable statistics for Bridgeport were not available, and Waterbury was not included in the study. The numbers refer only to jobs within the same metropolitan area. Therefore, for example, the totals for the Springfield metropolitan area do not take into account the availability of jobs in the Hartford metropolitan area.

On the other hand, the study found that the past decade has witnessed a pronounced decentralization of jobs in the Springfield metropolitan area. Between 1998 and 2006, the area on the whole gained 4,200 jobs. However, this figure reflects a 12,100 job loss within 10 miles of downtown Springfield that was more than offset by a 16,300 job gain outside this 10-mile radius. From 1998 to 2006 the share of Springfield-area jobs within 10 miles of downtown Springfield fell by 6.2 percentage points, compared to an average of 2.6 percentage points across all 98 metro areas nationwide and only 0.4 to 1.6 percentage points in the other five New England metro areas covered in the study. The implication is that since the late 1990s physical access to jobs has worsened for residents of Springfield's downtown neighborhoods.⁷

Box: Overview of Data Sources and Time Periods

The availability of data on employment and demographic characteristics varies depending on the geographic unit (city versus zip code) and on the concept (jobs versus employed residents). The study presents the most recent data available. Where feasible, older data are extrapolated to the mid-2000s in order to facilitate comparisons.

The most recent data for employment at the city level refer to 2005-2007. Information on employed residents comes from the 2005-2007 American Community Survey (ACS) three-year estimates. Information on the number of jobs is derived from the Quarterly Census of Employment and Wages (commonly called the ES-202 program). We took the average of the ES-202 figures from 2005, 2006, and 2007 in order to compare the jobs data with the data on employed residents.

Data on the number of jobs at the zip code level are available from the ZIP Business Patterns (ZBP), which provides annual detailed geographic, industry, and other information for U.S. business establishments. The most recent figures at the time of this analysis were from the 2006 ZBP. To compare employed residents to employment in establishments located in Springfield, we estimated the number of employed residents by industry and area in 2005-2007. This was done by applying the growth rate of employed residents by industry in Springfield from 2000 (from the Decennial Census) to 2005-2007 (from the ACS) to the employed residents by area and industry.

For the demographic characteristics by area, we used the 2000 Decennial Census Information because the 2005-2007 ACS does not have data at the zip code level. For instance, when we calculated the employment rate by area we used employed residents and total population 16 years and over in 2000.

⁷ Since 1998 Springfield's share of Hampden County residents has remained approximately constant at around 32 percent. Thus, while the jobs have decentralized, the population has not.

Demographics and City Employment

Previous papers in this series have noted that Springfield has experienced profound demographic changes over the past several decades.⁸ The percentages of city residents who are non-white and non-Anglo have increased dramatically. In addition, the percentages of Springfield's population who have completed high school and college have not kept pace with the numbers in other cities. This section shows that other mid-sized southern New England cities have higher jobholding rates than Springfield across all the population segments examined, but especially for minorities and the less educated. Thus, Springfield's employment deficit is due mostly to the fact that its disadvantaged groups are less likely to be employed than in other cities—and hardly at all to their high shares in Springfield's population.

Table 4 shows employment rates in 2005-2007 for three major categories of race and ethnicity: white (non-Hispanic), black, and Hispanic. These three groups accounted for almost 97 percent of the age-16-and-over population in Springfield, and also for most of the population in each of the other mid-sized New England cities. A lower share of Springfield Hispanics (47 percent) was employed in 2005-2007 than was the case for the city's blacks and whites (each about 53 percent). More noteworthy, however, was the fact that each racial/ethnic group in Springfield had a lower jobholding rate than in the comparison cities. For white non-Hispanics, the gap between Springfield and the average of other New England locations was only 2 percentage points. For blacks and Hispanics, the gaps were substantially larger: 7 and 9 percentage points, respectively

Table 5 shows similar information by level of educational attainment, for the share of the population between the ages of 25 and 64. In 2005-2007, 63 percent of Springfield's population in this age range had a job. As was the case in other locations, employment rates in Springfield increased with the level of education completed. A smaller share of Springfield's adult population had a bachelor's or advanced degree than the average in the other cities (19 percent

⁸ Browne, Green, et al. (2009) and Kodrzycki and Muñoz, et al. (2009).

versus 23 percent), while larger shares in Springfield than elsewhere had not completed high school, had completed only high school, or had some college education.

The table indicates that educational attainment played a relatively minor role in explaining the 5-point difference in the employment rate between Springfield and the average of the other cities. Most of the gap arose because Springfield residents at *each* level of educational attainment had lower rates of employment than comparably educated residents in most cities. The difference was especially noteworthy for less educated segments of the population. In Springfield, only 39 percent of high school dropouts and only 64 percent of high-school-only completers were employed in 2005-07, compared to ranges of 45 percent to 53 percent and 65 to 75 percent, respectively, in the other cities. More detailed data (not presented in the tables) indicate that, for these education levels, the residents of Springfield were much less likely to be in the labor force (working or actively looking for work) than in the other New England urban locations.

On the whole, the analysis indicates that while lack of employment poses a problem across the full range of Springfield residents, minorities and high school dropouts are particularly disadvantaged relative to their situations in other southern New England cities. These findings serve to highlight the need for policies to put special focus on improving economic opportunities for the inhabitants of Springfield's downtown and nearby neighborhoods.

Jobs by Industry

Health care is by far Springfield's largest industry, providing more jobs in the city and employing more city residents than any other sector. However, as this section of the study shows, from 1990 to 2005–2007, the number of Springfield residents working in the health care industry increased by less than the number of health care jobs available in Springfield. These findings suggest that Springfield's non-employed population needs better skills, information, and job networks to take advantages of the growing opportunities in the health care industry. Manufacturing accounts for fewer jobs than in the past, but it remains the second largest source

of employment for Springfield's population. Many Springfield residents commute to manufacturing and construction jobs outside the city. In addition, a high share of wholesale trade employees work outside Springfield. Hence, even if Springfield residents have the qualifications to work in these industries, enhanced transportation options might be needed to enable more city dwellers to commute to the jobs located outside the city boundaries.

Current Employment Patterns

The left panel of figure 1 shows the private-industry breakdown for Springfield's employed population in 2005–2007. Of the 58,000 resident job holders in this period, close to 56,000 worked outside of public administration. By far the largest concentration of employment was in health care and social assistance, comprising 20 percent of the total. The next largest employment sectors for Springfield residents were manufacturing (13 percent), retail trade (11 percent), leisure and hospitality (9 percent), and educational services (9 percent).⁹

The right panel of figure 1 shows the comparable breakdown for the 73,000 employees of private-industry establishments located in Springfield in 2005–2007. As in the case of resident employment, the largest industry located in the city was health care and social assistance (26 percent of all private-industry jobs).¹⁰ The next largest concentrations were educational services (11 percent), financial activities (10 percent), professional and business services (9 percent), and retail trade (9 percent). Manufacturing (6 percent) accounted for a much smaller share of city jobs than of city resident employment.

Table 6 shows these same concepts—the jobs held by city residents and the jobs located in Springfield—as numbers rather than percentage shares. The difference between each pair of numbers is an indicator of commuting patterns. If the number of jobs exceeds (falls short of) the number of employed residents, there is net in-commuting (out-commuting). The industries

⁹ Table 3 of Kodrzycki, Muñoz, et al. (2009) showed similar data for Springfield and the comparison group cities. In that paper, the calculations included public-sector employment. Figure 1 excludes the public sector in order to facilitate comparison with a data source based on the location of private-sector jobs by zip code.

¹⁰ From 2005 to 2007, healthcare accounted, on average, for 89 percent of the jobs in this sector, with social assistance accounting for the remaining 11 percent.

with the largest numbers of net in-commuters were health care and social assistance (8,000), financial activities (3,500), educational services (2,800), miscellaneous services (2,600), and professional and business services (2,300). The only sectors with large numbers of net out-commuters were manufacturing (2,600) and construction (1,000). Wholesale trade had an estimated 440 net out-commuters, as the number of Springfield residents working in this industry exceeded the number of Springfield jobs in this industry by nearly 30 percent.

Retail trade and leisure and hospitality had roughly the same number of Springfield jobs and Springfield employees. This means that—for these industries—although some of the jobs in Springfield might have been filled by nonresidents, the number of commuters into the city was approximately the same as the number of workers commuting in the other direction.

Changes over Time

Examining trends over time is complicated by the fact that industry classification codes changed substantially around 2000. Figure 2 shows industries for which the definitional changes were relatively minor; the underlying data are presented in Appendix A table 1.

Springfield's current pattern of net out-commuting to jobs in manufactured goods industries contrasts with the situation present at the beginning of the 1980s.¹¹ At that time, there were more manufacturing and construction jobs located in Springfield than there were Springfield residents working in these industries. During the 1980s and in subsequent decades, manufacturers made dramatic cuts in jobs located within the city. The number of Springfield residents working in manufacturing has also fallen, but not as sharply. The number of city

¹¹ It is difficult to compare data from the Covered Employment and Wages program (commonly called the ES-202 program) with Decennial Census data prior to 1980 because ES-202 coverage changed substantially in the 1970s. ("ES-202" refers to the form once used by employers to report employment data to state agencies.) Before 1972, ES-202 records did not include employment at facilities owned by the federal government or nonprofit organizations. In 1972, coverage was extended to non-profit organizations, state institutions of higher education, and state hospitals. In 1978, coverage was extended to all state and local government entities, nonprofit pre-elementary, elementary and secondary schools, and certain types of domestic workers. In 2003, the Covered Employment and Wages program was renamed the Quarterly Census of Employment and Wages, but many researchers continue to refer to the new data by the moniker "ES-202."

residents working in the construction sector is greater now than in 1980, although employment at construction contractors located within the city has not increased.¹²

Services-sector firms have accounted for net commuting into the city of Springfield for many years. The pattern in the health care industry has been the exact opposite of that in manufacturing: the number of health care jobs in Springfield increased to a larger degree than did the employment of city residents in health care. The number of Springfield jobs in finance and related industries during the 2000s is not very different from what it was in 1980, but the number of financial sector employees who live in Springfield has fallen.

Jobs by Neighborhood

This section of the study compares the locations of jobs and workers across different parts of Springfield. In general, jobs are scattered throughout the city, and people appear to commute in response to job opportunities rather than concentrating on finding work in their own section of the city. Many residents of the poor neighborhoods located in and near downtown Springfield are constrained in their job possibilities by single-parenting responsibilities and reliance on shared transportation (carpooling and public transit). Therefore, strategies to increase their employment might need to focus on connecting job seekers with nearby job opportunities. As it turns out, job density rates are quite high in and near the neighborhoods of Springfield where residents have low incomes and low employment rates. The study finds that health care and social assistance and leisure and hospitality are two possible industries to target for expanded training, internship, mentorship, or job creation programs because of their already strong presence in the vicinity of downtown Springfield.

Springfield's Various Areas

The initial Federal Reserve Bank of Boston discussion paper on Springfield¹³ presented

¹² The statistics on construction industry jobs refer to the location of the firm, not the construction work they perform. However, the two measures are probably positively correlated.

¹³ Browne, Green, et al. (2009).

demographic and economic characteristics of the population in the 17 neighborhoods that comprise the city; see figure 3, top panel. Comprehensive information on the location of jobs within Springfield is not available at the neighborhood level. To map job locations, the most detailed source is the Census Bureau's ZIP Business Patterns (ZBP). As described in Appendix B, we divided Springfield into seven areas that conform closely to these neighborhood groupings; see figure 3, bottom panel. The poorest sections of the city are mostly in Area 2 (which includes Metro Center, Six Corners and South End) and area 3 (which includes Brightwood and most of Memorial Square). Areas 1 and 4 include both poor and more affluent neighborhoods.¹⁴

The ZBP files contain total employment in private establishments by zip code, as well as additional information on the size distribution of establishments for individual industries. These data, along with some additional assumptions described in Appendix C, formed the basis of our estimates of employment by industry and by area for 2006. We were able to classify approximately 61,000 Springfield jobs by industry and area. This is less than the 64,000 citywide jobs in privately-owned establishments for 2005–2007 because the ZBP files omit certain categories of jobs.¹⁵

Location of Jobs by Industry

Rather than being concentrated in the central business district, jobs are spread out across the city of Springfield; see figure 4, top panel. Of the 61,000 jobs in privately-owned establishments, 13,700 were located in Area 4 (mostly East Springfield and Liberty Heights). Area 2 (Metro Center, Six Corners, and South End) was the second largest employment center, with over 11,000 jobs. Area 1 (Bay, McKnight, Old Hill, Pine Point, and Upper Hill), Area 3 (Brightwood and Memorial Square), and Area 6 (Boston Road, East Forest Park, and Sixteen Acres) each had between 8,000 and 9,000 jobs. The remaining parts of the city contained relatively few jobs.¹⁶

¹⁴ Bay, McKnight, and Old Hill form part of Area 1, and parts of Metro Center and Memorial Square are in Area 4.

¹⁵ The ZBP excludes most government establishments. See Appendix C for details on the ZBP data.

¹⁶ For details on the distribution of jobs by area and industry, see Appendix A table 2.

Different sections of Springfield vary considerably in their industry mix. Health care and social assistance accounts for over 80 percent of the jobs in Area 3 and almost 40 percent in Area 4; the largest employer in these two areas is Baystate Medical Center, a major regional medical facility. Financial services (mostly MassMutual) comprise the dominant source of employment in Area 1, and manufacturing is the largest industry in Area 5. Close to 40 percent of the jobs in Area 6 are retail; this section of the city includes several shopping plazas on the eastern and southern borders.

Despite the variation of jobs across the city, Springfield workers' employment patterns by industry do not vary much by area of residence. For example, the workers residing in Areas 3 and 4 are only slightly more likely to work in health care and social assistance than workers residing in other parts of the city (figure 4, bottom panel). Similarly, residents living near financial services or retail jobs are not substantially more likely to work in these sectors than are residents living in other parts of Springfield. In general, therefore, it appears that commuting from one part of Springfield to another part of the city is common.¹⁷

Jobs Near the Areas of Concentrated Poverty

Bay, Brightwood, McKnight, Memorial Square, Metro Center, Old Hill, Six Corners, and South End are the Springfield neighborhoods where poverty is concentrated.¹⁸ As noted already, these neighborhoods are found mostly in Areas 2 and 3, as well as parts of Areas 1 and 4. Their residents' educational levels tend to be low, and sizable fractions of their residents do not speak English well.¹⁹ Not surprisingly, Areas 2 and 3 have the lowest labor force employment rates in Springfield: respectively, only 40 and 41 percent of the working age population of these two areas held jobs in 2000 (figure 5, top panel). Yet these same parts of Springfield have the highest job densities: the numbers of jobs located in Areas 2 and 3 exceed the numbers of working-age residents (figure 5, bottom panel and Appendix A table 5).

¹⁷ For details on employed residents as a percent of total employment by area and industry see Appendix A table 3.

¹⁸ Browne, Green, et al. (2009) provide relevant indicators by neighborhood.

¹⁹ See Appendix A table 4

The racial and ethnic compositions of the poor parts of Springfield are quite different from the rest of the city. About three-quarters of the population of Area 3 and one-half of the population of Area 2 are Hispanic (figure 6).²⁰ Roughly one-half of the residents of Area 1 classify themselves as black or African-American. In all of the remaining areas, non-Hispanic whites account for the majority of the population.

Other distinguishing characteristics of Springfield's poor neighborhoods are that relatively high fractions of families are headed by single females, and relatively few households own their own car. Of the residents who are employed, a relatively high fraction uses some form of shared transportation. The shares of workers who commute to work by carpool or public transportation are higher in Areas 1, 2, 3, and 7 than in other parts of the city; see figure 7. Reliance on shared transportation complicates commuting because of the extra time involved and because of limited availability, especially outside of "normal" workweek hours.

Given the multiple barriers to job-holding among Springfield's poorer residents, including parenting responsibilities and transportation constraints, it is useful to identify the types of employment opportunities that are located near the neighborhoods with concentrated poverty. There may be particular merit in expanding job training, internship, mentorship, and other human capital-related programs centered on these industries. In addition, it may be worth considering policies aimed at expanding the number of jobs located downtown, either in these industries or related industry clusters.

Table 7 shows the number of jobs by industry and by area of residence (top panel) and area of employment (bottom panel) for the entire city. One strategy to consider is preparing more residents from poor neighborhoods for jobs in health care, a stable and growing industry. As shown in figure 8, health care jobs are available in most areas of Springfield. Although most health care and social assistance jobs are in Areas 2, 3 and 4, very few residents of those areas are employed in this industry. Only about 1,500 residents of Areas 2 and 3 worked in health care and social assistance in 2005–07. There were close to 10,300 health care and social

²⁰ See Appendix A table 6 for additional social, economic and demographic information by area.

assistance jobs in these two sections of the city in 2006, including approximately 6,500 jobs at Baystate Medical Center. Another strategy might revolve around the leisure and hospitality industry, which had close to 1,500 jobs in Area 2, but employed only about 500 workers living in these neighborhoods.

Conclusions and Further Observations

Springfield has a massive jobs challenge. For the city to match the average employment rate in other southern New England cities, thousands more residents need to find work. The source of the problem is not so much that the Springfield area lacks job opportunities—on the contrary, Springfield’s job availability is comparable to many of its peer cities cited in this study—but that many city residents are unable to compete successfully for the jobs that are available.

Employment rates in Springfield are lower than in the other comparable New England cities across a range of population subgroups. However, the disparities are much greater for blacks and Hispanics, and for high school dropouts, than they are for (non-Hispanic) whites and for residents who have more than a high-school education.

Some of the existing jobs are located far from the neighborhoods in and near downtown Springfield where poverty is concentrated. Without more effective means of transporting inner-city residents to suburban job locations or to “off-hours” jobs in the more affluent east-lying city neighborhoods, the poorest neighborhoods and residents are likely to remain poor. However, many of Springfield’s inner-city residents also have problems accessing jobs in their own neighborhoods. Health care is the largest potential source of employment in and near the city areas of concentrated poverty. Other services sectors, including leisure and hospitality, also provide substantial job opportunities in the downtown area.

Other discussion papers in this series provide further perspectives from employers and from poor residents as to why such a large share of Springfield’s population is unable to find work.²¹ Both groups cite issues related to education and training. Employers say that many job

²¹ Plasse et al. (2009) and Green et al. (2010).

seekers lack the skills and other qualities to make good workers, while job-seekers cite the many neighborhood and institutional barriers to getting an adequate education that would lead to better employment opportunities.

In addition, Springfield's employers and job seekers mention aspects of the job-matching process that pose obstacles to increasing employment opportunities for the city's residents. For example, given the large numbers of applicants for entry-level positions, employers indicate that they rely heavily on referrals from existing employees in the screening process. Unfortunately, many residents of the poor neighborhoods of Springfield lack connections to current jobholders, putting them at a disadvantage relative to other job seekers who are able to secure references from employees. In a related vein, applicants from poor neighborhoods say that many employers are not open to hiring them, even if they have the necessary credentials. These observations from interviews and surveys in Springfield are consistent with national statistical studies that probe the causes of low employment rates among Hispanics and African-Americans.²² According to these studies, policies to bring jobs to low-income neighborhoods or low-income workers to job locations do little to increase Hispanic or African-American employment unless these jobs are made more available to Hispanics and African-Americans than is typically the case. This conclusion holds even when the jobs in question appear to require the skill and education levels that minority job-seekers have, often a high-school diploma or equivalent certification.

The implications of the interviews, surveys, and national research—together with the data on minority-group jobholders presented in this study—are that increasing the employment rate in Springfield will take even greater effort than the aggregate 6,000+ employment gap figure implies. Meeting the challenge will likely require not only an upgrade in residents' education and work preparedness, but also considerable attention to opening up job networks to more members of minority communities. Current hiring and job-search

²² See Hellerstein, McInerney, and Neumark (2008a, 2008b, 2009). These three studies deal exclusively with male employment.

practices may be rational given the realities of the Springfield labor market, but they add to the many factors that exacerbate the concentration of poverty in the city.

Of course, the focus of any workforce development strategies for Springfield should be to increase employment among the city's residents *without* decreasing the employment of the residents of nearby cities and towns who work in Springfield or the Springfield area. The city and region will have to develop a complementary, aggressive job creation program to accomplish this dual goal.

Appendix B

Springfield Areas

Employment in establishments located in the city of Springfield was estimated using the ZIP Business Patterns (ZBP) data. The ZBP provides information on the number of establishments by industry and size class by zip code.¹ Comparing data by zip code to data by neighborhood raises the following challenges:

- 1) Zip codes change from time to time and do not have specific boundaries. However, a good approximation of zip code area boundaries is provided by the Census ZIP Code Tabulation Areas (ZCTA)² that the U.S. Census Bureau uses for tabulating summary statistics from Census 2000.
- 2) ZBP data includes establishments with P.O. Box addresses and unique zip codes that, in most cases, cannot be assigned to a geographic location.
- 3) Zip code boundaries can be very different from census tract and neighborhood boundaries.

Since, in most cases, zip code areas in the city of Springfield are bigger than individual neighborhoods, we divided Springfield into seven areas to match as best as possible neighborhood group boundaries. Appendix Table 6 shows the seven areas and their corresponding zip codes.

Most areas are composed of neighborhoods that have similar economic and demographic characteristics. The exceptions are area 1 (Old Hill, McKnight, Bay, Pine Point and Upper Hill) where Pine Point and Upper Hill have better social and economic indicators and a different

¹ Most ZIP codes are derived from the physical location address reported in Census Bureau programs. The Internal Revenue Service provides supplemental address information. Those employers without a fixed location or with an unknown ZIP Code are included under an "Unclassified" category indicated by ZIP Code 99999. For more information go to <http://www.census.gov/econ/cbp/index.html>.

² Each ZCTA is built by aggregating the Census 2000 blocks, whose addresses use a given ZIP Code, into a ZCTA which gets that ZIP Code assigned as its ZCTA code. They represent the majority of USPS five-digit ZIP Codes found in a given area. For those areas where it is difficult to determine the prevailing five-digit ZIP Code, the higher-level three-digit ZIP Code is used for the ZCTA code. For more information on the ZCTAS go to <http://www.census.gov/geo/ZCTA/zctafaq.html>.

demographic composition than the other three neighborhoods, and area 4 (Liberty Heights and East Springfield) where East Springfield has better social and economic indicators than Liberty Heights.

Appendix C

Estimation of Employment in Springfield by Industry and Area

The estimation of employment for the areas of Springfield is based on the 2006 Zip Code Business Patterns (ZBP).³ The ZBP provides data on total employment for most zip codes; however, employment figures are not available at the industry level because of confidentiality issues. Using information on the number of establishments by size class and industry from the ZBP and data on total employment in Springfield from the ES-202 data,⁴ we estimated the number of jobs by industry and area as follows:

- 1) Calculate number of establishments by area.⁵
- 2) Estimate employment by industry by multiplying the number of establishment in each size class by the U.S. average number of employees per class⁶ (see estimates 1 in Appendix Table 7).⁷
- 3) Adjust number of employees in Baystate and MassMutual (see estimates 2 in Appendix C Table 1) using published estimates of these firms' workforces⁸. Using Baystate and MassMutual's unique zip codes (01199 and 01111, respectively) we adjusted employment in the largest size class so that total employment in the healthcare and finance industries

³ Data are excluded for self-employed persons, employees of private households, railroad employees, agricultural production workers, and for most government employees (except for those working in wholesale liquor establishments, retail liquor stores, federally-chartered savings institutions, federally-chartered credit unions, and hospitals). For more information on ZBP go to <http://www.census.gov/econ/cbp/faq.htm>.

⁴ The ES-202 data come from quarterly tax reports submitted by over eight million employers subject to State unemployment insurance (UI) laws and from federal agencies subject to the Unemployment Compensation for Federal Employees (UCFE) program. Nationwide, the ES-202 data encompass 99.7 percent of all wage and salary civilian employment.

⁵ ZBP classifies the number of establishments in the following employment-size classes: 1–4, 5–9, 10–19, 20–49, 50–99, 100–249, 250–499, 500–999, 1000 or more.

⁶ Available at http://factfinder.census.gov/servlet/IBQTable?_bm=y&-ds_name=CB0600A2.

⁷ Similar methodology has been applied by Kneebone (2009) to calculate total employment for zip codes with suppressed employment data. That study does not use data by industry. Massachusetts average of employees per establishments by size class and industry are almost identical to U.S. figures. We used the national average for our estimation since some figures by industry and size class are not reported at the state level.

⁸ Pioneer Valley Planning Commission (2009).

matched the number of workers in Baystate (6,565) and MassMutual (4,366), respectively. Although MassMutual and Baystate have unique zip codes, in our analysis we included them in the areas where they are located, MassMutual in area 1 and Baystate in area 3.

- 4) Adjust the estimates to better match total employment by industry in Springfield from the 2006 ES-202 data (see estimation 3 in Appendix C Table 1). We re-estimated employment figures when the difference between ZBP and ES-202 was larger than 15 percent and the industry employment share was higher than 1.5 percent. In seven industries (wholesale trade; information; finance and insurance; professional services; business services; educational services; arts, entertainment and recreation) our employment estimates were at least 15 percent larger than ES-202 data. For these industries, we used the minimum of the establishment size range instead of U.S. average to calculate the number of workers per industry and area.

Technical notes:

- a. ZBP employment in healthcare and social assistance includes government employees working in **hospitals**. Therefore for this industry, we used ES-202 data for all **establishments** for our comparison.
- b. Since the ZBP excludes most government employees⁹ we used ES-202 data for **private establishments** for our comparisons.
- c. ZBP data also excludes employment in private households. For our comparisons we excluded private households from the “other services” industry in the ES-202 employment data.

Final estimates by **industries** are very close to ES-202 data both in nominal terms and in industry shares (See Appendix Table 8). Final estimates of jobs by area are also very similar to total employment counts from ZBP¹⁰ (See Appendix C Table 2).

⁹ Except for those working in wholesale liquor establishments, retail liquor stores, federally-chartered savings institutions, federally-chartered credit unions, and hospitals.

¹⁰ ZBP provides data on total employment for most zip codes.

Appendix C Table 1 Comparison of ES-202 Employment to ZBP Estimates

	2006 ES-202 Employment			Estimation 1 ^a	Estimation 2 ^b		Estimation 3 ^c			
	All establishments	Private establishments	Percent private establishments in total private establishments except private households	Employment	Employment	Percent difference relative to ES-202	Employment	Percent of total employment estimates	Percent difference relative to ES-202	Difference relative to ES-202
