Preface

The benefits of assessing U.S. mortality patterns in comparison with those of other nations have become increasingly evident. This chartbook is designed to facilitate such evaluations by presenting information ordinarily unavailable or difficult to obtain in standardized formats useful to the general and specialized user. Data from the National Vital Statistics System were combined with those provided by the World Health Organization (WHO) to produce a series of figures in which the level, trend, and cause pattern of U.S. mortality may be compared with those of other industrialized countries. For those interested in additional details, age-adjusted rates for selected causes for the years 1955-89 are provided for 40 countries.

Interpretations and conclusions drawn from these data are the responsibility of the National Center for Health Statistics and not the World Health Organization (WHO), which is responsible only for providing basic information.

--- Data not available

Introduction

For many years, the National Center for Health Statistics (NCHS) has included several important tabulations of U.S. and international data in its major statistical reports. Beginning with *Health, United States, 1975*, comparative tables dealing with infant mortality were included (1). These tables have been expanded to include feto-infant and postneonatal mortality rates as well as rates indicating life expectancy at birth and at age 65 (2).

This report enlarges upon previous efforts by bringing together mortality data from NCHS and the World Health Organization (WHO). Together with information already available (3-5), this chartbook can provide a foundation for a more comprehensive understanding of U.S. mortality as well as foster additional discussions and encourage further research.

Overview

This chartbook consists of five sections. The first three sections present levels, trends, and configurations of U.S. mortality compared with those of other developed countries or groups of developed countries. The final two sections consist of tables showing 5-year mortality rates for selected causes of death for individual countries. Also, for the user's convenience, a

quick reference table appears in the back of the chartbook; it lists several mortality indicators with estimated population for each of the countries included.

"Rankings," the first section, shows the relative standing of 36 countries according to level of age-adjusted mortality rates for selected causes. While the United States occupies an intermediate position for most causes, there are notable exceptions:

- All-causes mortality for U.S. white males and females ranks in the upper third among industrialized countries while that for U.S. black males and females ranks near the bottom among industrialized countries.
- Mortality for **cerebrovascular diseases** in the United States is the lowest of any developed country for males and nearly so for females.
- Mortality for **malignant neoplasms—all sites** among U.S. black men and women is particularly high.
- Mortality for **prostate cancer** among U.S. black males is much higher than that for any other industrialized country.
- Mortality for **respiratory cancer** is particularly high among white and black women in the United States.
- Mortality for **breast cancer** and **diabetes mellitus** among U.S. black women surpasses that among females of any other industrialized nation.

In "Trends," the second section, U.S. cause-specific mortality trends for a 35-year period are charted and compared with trends in the grouped mean mortality of a combination of 20 developed countries. The United States experienced sharp reductions in mortality for some causes (**diseases of heart, cerebrovascular diseases, unintentional injuries, and Intestinal/rectal cancer**) while it

experienced noticeable increases for others (**respiratory cancer** and **homicide**).

The aggregated 20-country trends have not always paralleled those in the United States, and this had resulted in some notable changes in the differences observed in the mid-1950s:

- A narrowing of gaps in mortality for **diseases of heart, Intestinal/rectal cancer, diabetes mellitus, pneumonia and influenza**, and, among males, **unintentional injuries—motor vehicle crashes**.
- A narrowing of the gap in mortality for **breast cancer (females)**; death rates from this disease remained stable in the United States but increased gradually in other countries.
- An increasingly low level of mortality for **cerebrovascular diseases** in the United States relative to the levels of other developed countries.
- A sharp widening of the difference in mortality for **respiratory cancer** among women, and a dramatic increase in male **homicide** mortality relative to that for the other 20 developed countries.

In "Cause profiles," the third section, the reader may compare U.S. mortality patterns of the major causes of death with the configuration or "profile" of these same causes in other countries. These figures reveal that the mortality pattern characterized by highest mortality from **diseases of heart** followed by **malignant neoplasms—all sites, cerebrovascular diseases, unintentional injuries, and chronic obstructive pulmonary diseases and allied conditions (COPD)** is widespread among English-speaking and Scandinavian countries. This pattern is not universal; among some Western and Southern European countries and Asian countries, mortality for **malignant neoplasms—all sites**

This chartbook was prepared in the Office of the Center Director. The author gratefully acknowledges the assistance of the numerous staff members of the Publications Branch, Division of Data Services. Publication management and editorial review were provided by Patricia Keaton-Williams. Typesetting support was provided by Zung T. N. Le. Printing was managed by Joan Burton, and publication design was supervised by Patricia A. Vaughan.

rivals or at times clearly surpasses that for **diseases of heart**. In Eastern European countries, mortality for **cerebrovascular diseases** is of much greater importance than elsewhere and contends with or exceeds mortality for **malignant neoplasms—all sites** in several instances. Although these observations are generally true regardless of sex, there are important differences between males and females regarding level and mortality configuration.

For readers interested in the data upon which these charts are based, "Selected causes," the fourth section, provides age-adjusted mortality rates for selected causes of death for 40 countries for each 5-year period from 1955 to 1989. "Selected neoplasm sites," the fifth section, contains 5-year mortality rates for each country for as many specific neoplasm sites as the database would permit.

Data

The figures and tables presented in this chartbook are based upon a mortality database containing information for 39 countries, covering the period from 1955 to 1991 (appendix, table 1). In addition, data were also tabulated for the United Kingdom (combined data for England and Wales, Scotland, and Northern Ireland) and the Federal Republic of Germany (combined data for the former Federal Republic of Germany and the German Democratic Republic), bringing the total to 41 countries for which data were tabulated. Data were not available for the nations that replaced the former Union of Soviet Socialist Republics, Yugoslavia, and Czechoslovakia. Data for the countries that compose the United Kingdom and the Federal Republic of Germany are provided in "Selected causes" and "Selected neoplasm sites."

The mortality indicators included in this chartbook consist of total (unadjusted and age-adjusted) mortality rates, expectation of life at birth, and infant mortality. The WHO "Old" European standard population was used to calculate age-adjusted rates. This population has been presented regularly in WHO's *World Health Statistics Annual* (4). A detailed description of the content, coverage, and quality of information contained in WHO's databank may also be found in that publication.

Cause-of-death data in the WHO data files are limited to those causes contained in the basic tabulation list of the *Ninth Revision, International Classification of Diseases* (ICD-9) and the "A" lists for the sixth, seventh, and eighth revisions. Because of this, tabulations based on these files are restricted to conditions coded to three digits; see appendix, table 2.

Data limitations

Although the countries for which data are presented were selected because their statistical agencies produce high quality statistics, the information presented in this chartbook is nonetheless subject to a number of important limitations. These include international differences in diagnostic practices and physician training (from country to country and year to year), the interpretation of internationally recommended rules for coding a cause of death and the organization of that function within countries, the availability of diagnostic aids, and the use of autopsies. These and a number of other difficulties attendant to the use of cause-of-death statistics based upon underlying cause classifications have been extensively treated elsewhere (6-10).

Although adequate for most purposes, the amount of detail available in the WHO

cause-of-death tabulation lists had several noticeable consequences for this report:

- Except for the United States, it was not possible to identify the category chronic obstructive pulmonary diseases and allied conditions as defined in ICD-9 before the implementation of ICD-9. Because a significant proportion of mortality from this cause of death is not included in the three-digit tabulations of previous ICD revisions, no tabulations for COPD are presented for the period before the late 1970s.
- Although it was possible to tabulate deaths attributed to colorectal cancer (ICD-9 category numbers 153-154) for the rates presented in "Rankings," deaths from this cause could not be separately identified before the ICD-9. The more inclusive grouping (ICD-9 category numbers 152-154), which includes malignant neoplasms of the small intestine as well as of the colon and rectum, has a mortality rate only slightly larger owing to the relatively small number of deaths from malignant neoplasms of the small intestine. For this reason, mortality from the broader category was tabulated for the entire 1955-89 period.
- Deaths due to injuries from motor vehicle traffic-related crashes could not be distinguished from those from motor vehicle non-traffic accidents before the implementation of the Ninth Revision. On the other hand, non-traffic accidents were not separately identifiable in the ICD three-digit codes for the Ninth Revision. The use of the Ninth Revision three-digit code had the result of excluding the relatively small number of deaths from motor vehicle non-traffic related crashes from tabulations involving countries and years.

where deaths were coded under that revision.

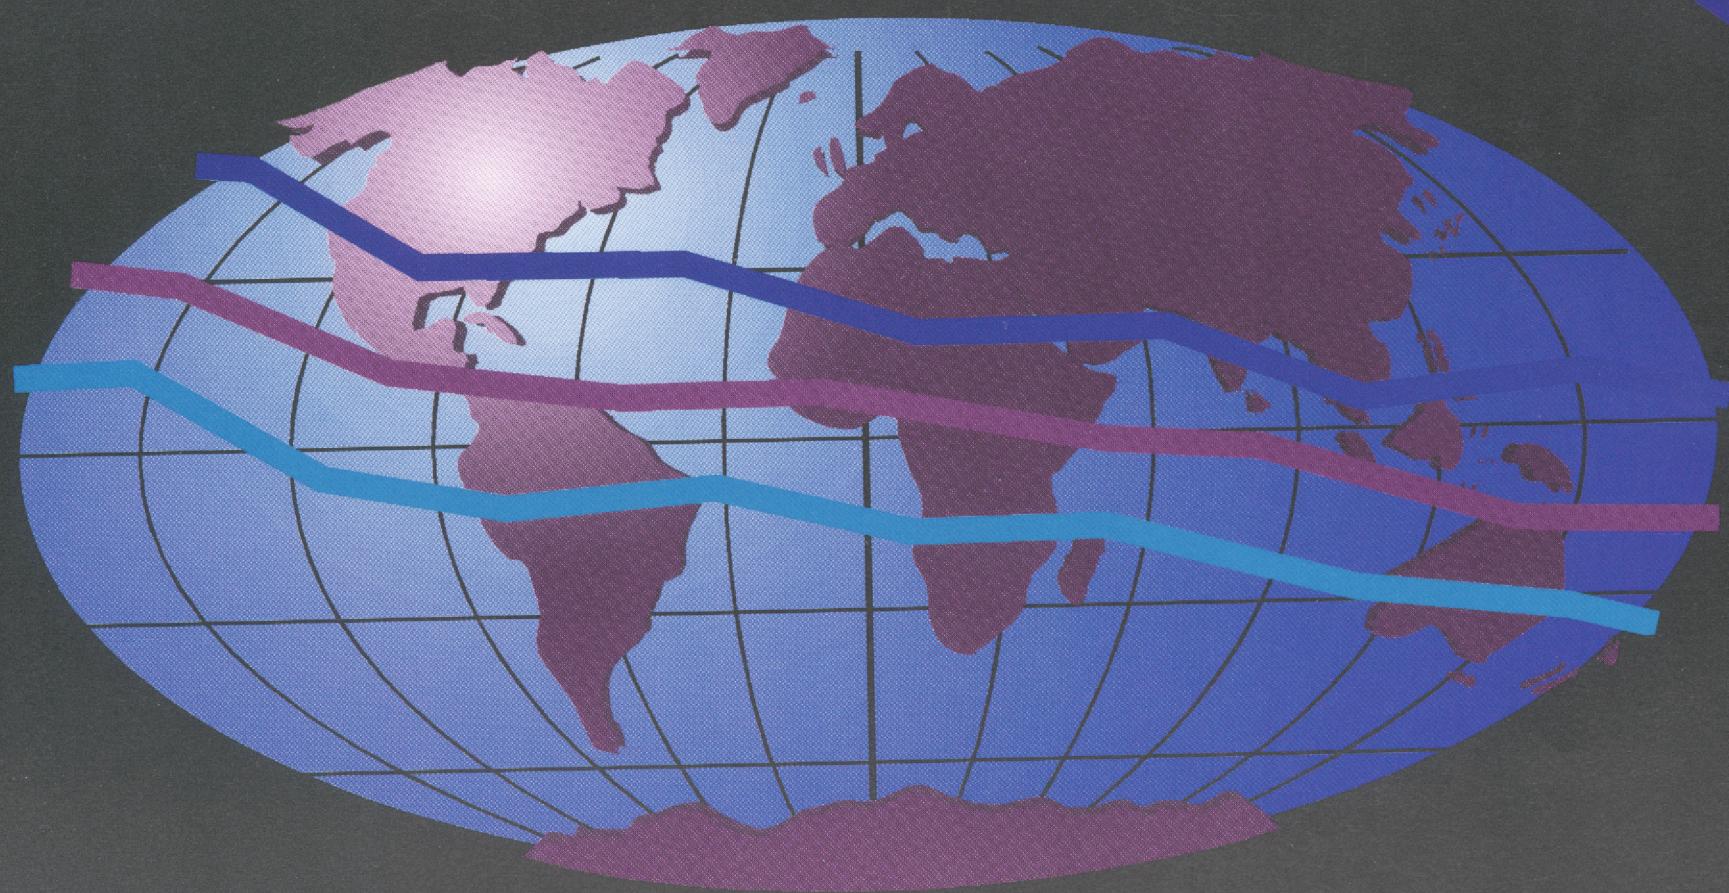

- Deaths from respiratory and intrathoracic cancer (ICD-9 category numbers 160–165) are presented in "Rankings." However, for comparability with earlier ICD revisions, a more limited grouping involving cancer of the trachea, bronchus, and lung and cancer of the trachea (ICD-9 category numbers 161–162) was necessary. The effect of this restriction is also relatively minor.

Additional notes and data qualifications are provided in specific sections as appropriate.

Rankings

In the following tables, adjusted and unadjusted mortality rates are given for 36 countries for the latest year for which such data are available. In all tables, countries are ranked according to the level of their age-adjusted mortality rate. For the majority of the countries, data are presented for 1990 or 1991. For the others, except Belgium, 1989 is the latest year for which data are available in the World Health Organization database.

For the United States, rates are provided for the total population as well as for the white and black populations.

Trends

The following figures compare trends in age-adjusted mortality in the United States with those based on pooled data from the following industrialized countries:

Austria	Italy
Canada	Japan
Denmark	Netherlands
England and Wales	New Zealand
Finland	Norway
France	Northern Ireland
Germany, Federal Republic of	Portugal
Hungary	Scotland
Ireland	Spain
	Sweden
	Switzerland

These countries were selected because a continuous series of annual cause-specific mortality data is available for each of them, making possible the calculation of a stable yearly rate.

It may be noted that with the possible exception of the countries comprising the Eastern European region, countries for each major world region considered as "developed" are well represented and that the mortality level of these countries combined is slightly lower than that of the United States.

The mortality trends in these figures reflect deaths assigned a cause under four different revisions of the *International Classification of Diseases* (ICD). As previously mentioned, a major difficulty with cause-of-death statistics referring to different years is the discontinuity introduced by changing definitions and practices from revision to revision. This, together with changes in coding practices within ICD revisions, often produces serious distortion in mortality trends. The rubrics used to identify the causes of death addressed in this chartbook appear in the appendix, table 2.

In the United States during the years 1955-89 causes of death were assigned codes under successive ICD revisions as follows:

Years	ICD Revision
1955-57	ICD-6
1958-67	ICD-7
1968-78	ICD-8
1979-89	ICD-9

In other countries, implementation of the sixth, seventh, and eighth revisions generally occurred within 1 to 3 years after the United States began assigning causes of death under the revisions. In a small number of countries, however, *Eighth Revision International Classification of Diseases* was replaced with *Ninth Revision, International Classification of Diseases* much later (Finland, Norway, and Sweden) or not at all during 1979-89 (Denmark and Switzerland). Because of national differences in year of implementation of ICD-9 and the fact that mortality rates for the disease category Chronic obstructive pulmonary diseases and allied conditions could only be calculated after its implementation, these countries were excluded from the calculation of trends for mortality from this disease.

A number of studies of the effect of these changes have been conducted, and the reader can refer to the comparability studies conducted in the United States (1-3) and other countries (4-6). Such studies and the questions they raise have been critical to international comparisons of mortality trends (7-9), and the large volume of research on such issues attests to their importance in interpreting trends such as those presented here.

Cause profiles

This section presents figures depicting mortality from the five leading causes of death in the United States. Data for males and females from 36 countries are grouped according to geographic proximity and/or cultural similarity.

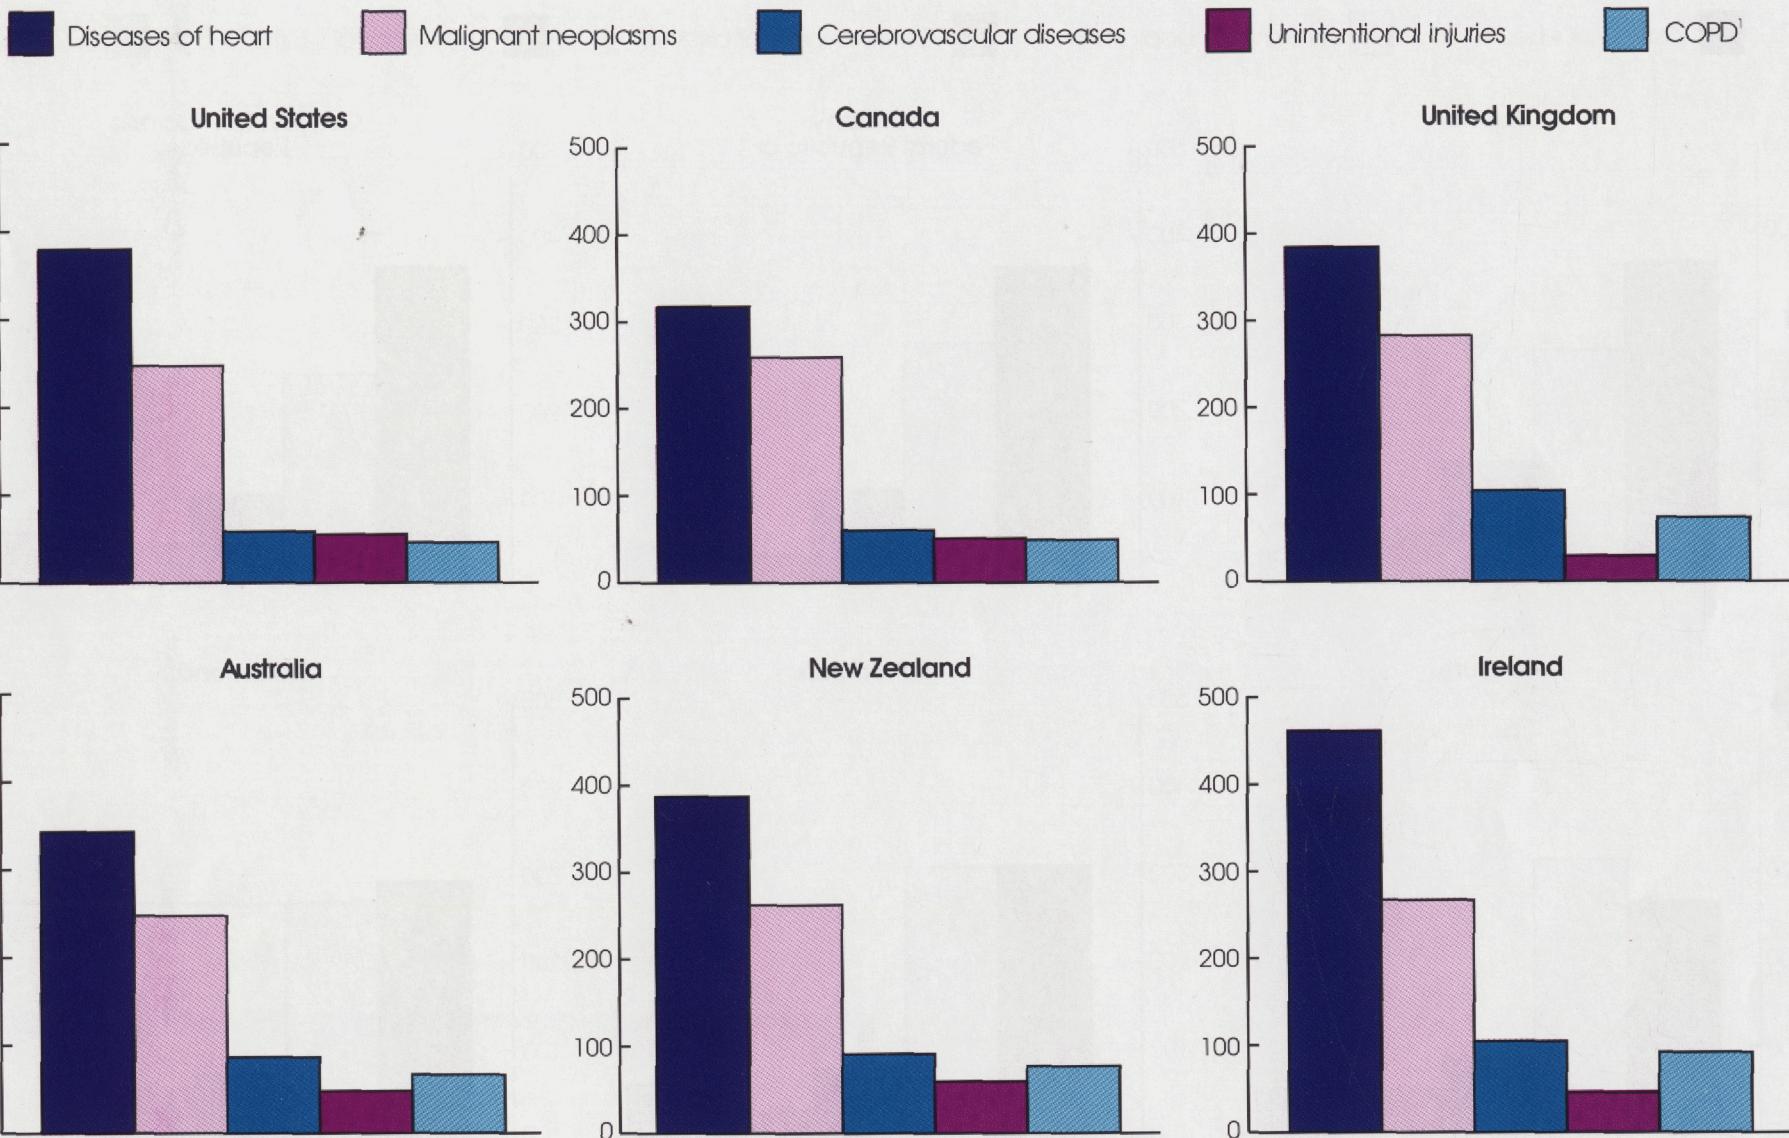

Each of the subfigures has been drawn to the same scale so that all figures may be compared. However, it should be noted that because female mortality is generally lower than male mortality, a different scale was used.

The deaths used to calculate mortality rates presented in this and the following sections have been age-adjusted and then averaged for the years 1985–89. Where data for only 1 year were available, however, rates were not calculated. This practice led to calculation of rates for all countries except the Federal Republic of Germany after reunification. In two other countries, Australia and Belgium, rates are based on data for 3 and 2 years, respectively. The rates for all other countries are based on data for all 5 years of the 1985–89 quinquennium.

Males

Selected causes

In this section, 5-year mortality rates are presented for the same causes as those presented in "Rankings."

As in "Trends," rates were calculated only when data for 2 or more years were available.

Males

**Selected
neoplasm
sites**

This section presents data for those neoplasm sites that were possible to identify with the restrictions imposed by the three-digit, special tabulation list in the World Health Organization database. Rates were calculated only when data for 2 years or more were available.

Males

Table 5-1. Age-adjusted 5-year mortality rates among males for selected neoplasm sites: English-speaking countries, 1955-89

[Numbers after causes of death are category numbers of the Ninth Revision, International Classification of Diseases, 1975]
