

Age and Sex Composition: 2010

Issued May 2011

2010 Census Briefs

C2010BR-03

INTRODUCTION

Focusing on a population's age and sex composition is one of the most basic ways to understand population change over time. Since Census 2000, the population has continued to grow older, with many states reaching a median age over 40 years. At the same time, increases in the number of men at older ages are apparent. Understanding a population's age and sex composition yields insights into changing phenomena and highlights future social and economic challenges.

This report describes the age and sex composition of the United States in 2010. It is part of a series that provides an overview of the population and housing data collected from the 2010 Census. It highlights analysis of age and sex at the national level, as well as for regions, states, and counties and for places with populations of 100,000 or more. A comparison with Census 2000 data is also provided, showing the changes in age and sex composition that have taken place over the last 10 years.

This report also provides information about how age and sex data were collected in the 2010 Census. The data for this report are based on the *2010 Census Summary File 1*, which is among the

first 2010 Census data products to be released.¹

SEX AND AGE QUESTIONS

Data on the sex and age composition of the United States and your community are derived from the 2010 Census questions on sex, age, and date of birth (Figure 1).

The sex question remains unchanged from the previous census. Information on the sex of individuals is one of the few items obtained in the original 1790 Census and in every census since.

As with sex, information on age has been collected since 1790. The 2010 Census age data were derived from a two-part question. The first part asked for the age of the person, and the second part asked for the date of birth. The question is

¹ The *2010 Census Summary File 1* (SF1) contains data on age, sex, race, Hispanic origin, group quarters, relationship, tenure, and households at a variety of geographic levels down to the block level. For a detailed schedule of 2010 Census products and release dates, visit www.census.gov/population/www/cen2010/glance/index.html.

designed in two parts in order to maximize both the accuracy and the number of people responding to this item. The age question itself is unchanged since Census 2000, however, an instruction was added to guide respondents to report the ages of babies as 0 years old if they were less than 1 year old. In previous censuses, researchers found that respondents often reported their babies' ages in terms of days, weeks, or months, rather than in terms of years. This instruction was added to reduce reporting problems for babies.

AGE AND SEX COMPOSITION

According to the 2010 Census, the population of the United States on April 1, 2010, was 308.7 million people, representing a 9.7 percent increase in population since 2000, when the population was 281.4 million (Table 1). Growth was slower than the 13.2 percent increase experienced during the previous decade, but similar to the growth between 1980 and 1990 (9.8 percent). Of the 2010 Census population, 157.0 million were

female (50.8 percent) while 151.8 million were male (49.2 percent). Between 2000 and 2010, the male population grew at a slightly faster rate (9.9 percent) than the female population (9.5 percent).

The population grew at a faster rate in the older ages than in the younger ages.

The data presented in Table 1 also include the distribution of the population for selected age categories. In the 2010 Census, the number of people under age 18 was 74.2 million (24.0 percent of the total population). The younger working-age population, ages 18 to 44, represented 112.8 million persons (36.5 percent). The older working-age population, ages 45 to 64, made up 81.5 million persons (26.4 percent). Finally, the 65 and over population was 40.3 million persons (13.0 percent).

Between 2000 and 2010, the population under the age of 18 grew at a rate of 2.6 percent. The growth rate was even slower for those aged 18 to 44 (0.6 percent). This contrasts with the substantially

faster growth rates seen at older ages. The population aged 45 to 64 grew at a rate of 31.5 percent. The large growth in this age group is primarily due to the aging of the Baby Boom population.² Finally, the population aged 65 and over also grew at a faster rate (15.1 percent) than the population under age 45.

Another important tool for analyzing the age and sex composition of the population is the age-sex pyramid (Figure 2). The age-sex pyramid shows the number of males (on the left) and number of females (on the right) by single years of age. The 2000 and 2010 pyramids are superimposed to make it easy to study the population at each point in time and to assess change. The shape of the pyramid can give important information about the population's

² The Baby Boom includes people born from mid-1946 to 1964. The Baby Boom is distinguished by a dramatic increase in birth rates following World War II and comprises one of the largest generations in U.S. history. For more information, see Howard Hogan, Deborah Perez, and William Bell, *Who (Really) Are the First Baby Boomers?* Joint Statistical Meetings Proceedings, Social Statistics Section, Alexandria, VA: American Statistical Association, 2008, pp. 1009-16.

composition. The 2010 Census age-sex pyramid is typical of developed countries, showing a broad base with a middle section of nearly the same dimension and then gradually tapering off at the oldest ages to a point at the top. Between 2000 and 2010, the population pyramid has become more rectangular in shape.

The Baby Boom population in 2010 is evident in the pyramid as a bulge at ages 46 to 64. Consistent with this trend, the age group 60 to 64 was the five-year age group with the largest percent increase (55.6 percent) followed by the 55 to 59 age group (46.0 percent) (Table 2). The five-year age group with the largest percent decrease

was the population aged 35 to 39 (11.1 percent decrease). The lopsided point at the top of the pyramid indicates differences in the number of males and females at older ages. This is a result of differences in mortality for men and women, where women tend to live longer than men. These mortality differences between men

and women also impact another important indicator of population composition, the sex ratio.

Faster growth in the male population led to increased sex ratios.

The sex ratio is a common measure used to describe the balance between males and females in the population. It is defined as the number of males per 100 females. A sex ratio of exactly 100 would indicate an equal number of males and females, with a sex ratio under 100 indicating a greater number of females. The sex ratio at birth in the United States has been around 105 males for every 100 females, however, since mortality at every age is generally higher for males, the sex ratio naturally declines with age. This tendency progresses

through ages 85 and above where there are considerably more surviving women. These trends result in more males at younger ages and more females at older ages. Sex ratios can vary from these patterns for many reasons such as the impact of international or domestic migration on a population or features of the geographic location (for example, the existence of college student housing or military facilities).

In 2010, there were 96.7 males per 100 females, an increase from 2000 when the sex ratio was 96.3 males per 100 females, resulting from a greater increase of males than females over the decade. Looking at five-year age groups reveals a noteworthy increase in the sex ratios for the population

aged 60 and older between 2000 and 2010 (Figure 3). This change results from a greater increase in the male population relative to the female population for these age groups. Males aged 60 to 74 increased by 35.2 percent while their female counterparts increased by 29.2 percent (Table 2). A narrowing of the mortality gap between men and women at older ages in part accounts for this difference.

Population aging led to an increased median age.

Changes in the structure of the population also impact another measure of population composition, median age. The median age is the age at the midpoint of the population. Half of the population is older than the median age and

Figure 3.
Sex Ratio by Age: 2000 and 2010

(For information on confidentiality protection, nonsampling error, and definitions, see www.census.gov/prod/cen2010/doc/sf1.pdf)

Note: Sex ratio is calculated as the number of males per 100 females.

Sources: U.S. Census Bureau, *Census 2000 Summary File 1* and *2010 Census Summary File 1*.

half of the population is younger. The median age is often used to describe the “age” of a population. In 2010, the median age increased to a new high of 37.2 years, from 35.3 years in 2000, with the proportion of the population at the older ages increasing similarly (Figure 4). This indicates that the U.S. population is aging. Globally, the median age of the United States is higher than countries that are less developed, but younger than most more-developed countries.³ The 1.9 year increase

³ More-developed regions include all regions of Europe, plus Northern America, Australia/New Zealand, and Japan. Less-developed regions include all regions of Africa, Asia (excluding Japan), Latin America, and the Caribbean, plus Melanesia, Micronesia, and Polynesia. For more information, see Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat, *World Population Prospects: The 2008 Revision*, <<http://esa.un.org/unpp>>.

between 2000 and 2010 was more modest than the 2.4 year increase in median age between 1990 and 2000. The aging of the Baby Boom population into older age groups is contributing to the increase in median age. In the United States, other contributors include stable birth rates and improving mortality.

DIFFERENCES IN AGE AND SEX BY GEOGRAPHY

A major strength of census data is its detail available at low levels of geography that can highlight variation in age and sex across the United States. This section compares basic age and sex distributions and selected measures among the geographies within regions, states, and counties as well as places with 100,000 or more population.

The Northeast had a higher percentage at the older ages, while the West had a higher percentage at the younger ages.

In the four census regions, the region with the oldest median age was the Northeast (39.2), followed by the Midwest (37.7), the South (37.0), and the West (35.6).⁴ Table 3 shows the variation in the distribution of population across

⁴ The Northeast region includes Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont. The Midwest includes Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin. The South includes Alabama, Arkansas, Delaware, the District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia. The West includes Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

Figure 4.
Age Distribution and Median Age: 1960 to 2010

(In percent. For information on confidentiality protection, nonsampling error, and definitions, see www.census.gov/prod/cen2010/doc/sf1.pdf)

Sources: U.S. Census Bureau, 2010 Census Summary File 1, Census 2000 Summary File 1, 1990 Census Summary File 2C, 1980 Census Summary File 2C, 1970 Census of Population, Vol. 1, Characteristics of the Population, Chapter B, Table 50, and 1960 Census of Population, Vol. 1, Characteristics of the Population, Chapter C, Table 156.

four age groups (under 18, 18 to 44, 45 to 64, and 65 and over). Comparing the percentages by age group shows that the West contains the largest percentages in the age groups under 18 and 18 to 44 (24.9 percent and 37.8 percent, respectively), while the Northeast contains the largest percentages in the age groups 45 to 64 and 65 and over (27.7 percent and 14.1 percent, respectively). The differences in distribution of the population across age groups accounts for the differences in median age across the regions.

All four regions had a sex ratio of less than 100, indicating more females than males.

The sex ratio also varies across regions. The Northeast has the lowest sex ratio (94.5 males per 100 females), followed by the South (96.1), the Midwest (96.8), and the West (99.3). All four regions had more females than males in their populations.

Maine and Vermont surpassed West Virginia and Florida as the states with the highest median age.

More variation in these distributions and measures can be seen when looking at state-level comparisons. As expected from the regional data, the states with the highest median ages are located largely in the Northeast, with the exception of West Virginia and Florida (Table 3 and Figure 5). In both 1990 and 2000, West Virginia and Florida had the highest median age of all states. This trend shifted in 2010 due to increases in median age between 2000 and 2010 for the states of Maine, Vermont, and New Hampshire. These three states had the largest increases in median age between 2000 and 2010, with an increase of 3.8 years in Vermont, 4.0 years in New Hampshire, and 4.1 years in Maine. Maine and Vermont surpassed West Virginia and Florida as the states with the highest median age.

There were seven states with a median age over 40 years.

The five states with the highest median age in 2010 were Maine (42.7), Vermont (41.5), West Virginia (41.3), New Hampshire (41.1), and Florida (40.7). In all, there were seven states, the previous five plus Connecticut and Pennsylvania, with a median age of 40 or higher. This was a shift from earlier decades, when all states had a median age below 40. Despite these shifts in median age, however, Florida and West Virginia remained the states with the highest percentage of the population age 65 and over, 17.3 percent and 16.0 percent, respectively.

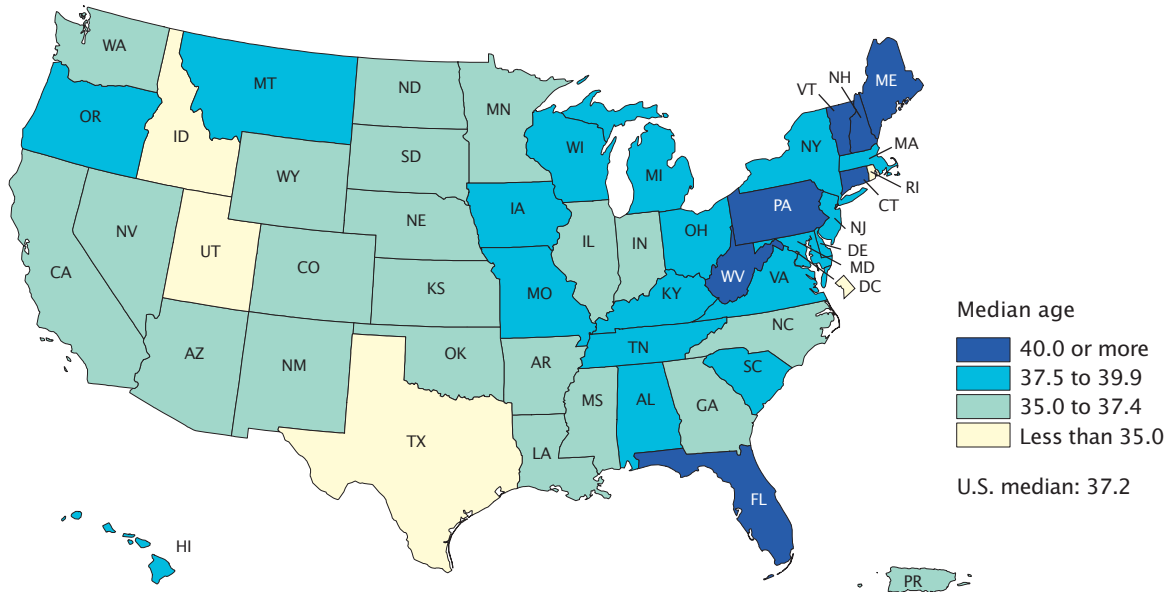

Utah remained the state with the lowest median age.

In contrast, the states with the lowest median age (excluding the District of Columbia) remained the same as they were in 2000: Utah (29.2), Texas (33.6), Alaska (33.8),

Figure 5.
Median Age by State: 2010

(For information on confidentiality protection, nonsampling error, and definitions, see www.census.gov/prod/cen2010/doc/sf1.pdf)

Source: U.S. Census Bureau, 2010 Census Summary File 1.

and Idaho (34.6). Among the states, Utah had the highest percentage of its population under age 18 (31.5 percent), which contributed to its low median age. Utah remained the only state with a median age under 30. All states experienced an increase in median age when compared with 2000—a further indication of population aging. The District of Columbia experienced a decrease in median age, going from 34.6 years to 33.8 years. In the District of Columbia, almost half (48.6 percent) of the 2010 Census population was ages 18 to 44.

Sex ratios were higher in Western states and lower in Northeastern states.

Table 3 contains the sex ratio for each state. There were ten states with more males than females in the population, indicated by a sex ratio greater than 100. These states were concentrated in the West and Midwest: Alaska (108.5 males per 100 females), Wyoming (104.1), North Dakota (102.1), Nevada (102.0), Utah (100.9), Montana (100.8), Colorado (100.5), Idaho (100.4), Hawaii (100.3), and South Dakota (100.1). In contrast, the five states with the lowest sex ratios (excluding the District of

Columbia from the ranking) were concentrated in the Northeast and South: Rhode Island (93.4 males per 100 females), Maryland (93.6), Massachusetts (93.7), New York (93.8), and Delaware (93.9). The District of Columbia had the lowest sex ratio, at 89.5 males per 100 females.

Counties with lower sex ratios were found in Northeastern states, while counties with higher sex ratios were found in Western states.

Data for age and sex were also evaluated for every county in the

United States.⁵ These sex ratios are illustrated in Figure 6, which provides a map of sex ratios by county. From this map, it is evident that counties in Northeastern and Southern states tend to have lower sex ratios, while counties in Western and Midwestern states tend to have higher sex ratios. In 2010, Alaska was the only state where males outnumbered females in every county. In 2000, Alaska, Hawaii, and Nevada had a greater number of males than females in every county. In 2010, three states had a sex ratio below 100 in every county: Delaware, Maine, and Rhode Island. Both Delaware and Rhode Island had sex ratios that were below the national level (96.7) in every county.

Compared to 2000, there were fewer counties in 2010 where the female population outnumbered the male population.

Of the 3,143 total counties in the United States, 1,096 of these (34.9 percent) had a sex ratio that was less than the national sex ratio of 96.7. In all, there were a total of 2,089 counties (66.5 percent) with a sex ratio below 100, indicating that the female population in the county outnumbered the male population. This is a decrease from what was seen in 2000, when

⁵ The primary legal divisions of most states are termed “counties.” In Louisiana, these divisions are known as parishes. In Alaska, which has no counties, the statistically equivalent entities are census areas, city and boroughs (as in Juneau City and Borough), a municipality (Anchorage), and organized boroughs. Census areas are delineated cooperatively for data presentation purposes by the state of Alaska and the U.S. Census Bureau. In four states (Maryland, Missouri, Nevada, and Virginia), there are one or more incorporated places that are independent of any county organization and thus constitute primary divisions of their states; these incorporated places are known as “independent cities” and are treated as equivalent to counties for data presentation purposes. The District of Columbia has no primary divisions, and the entire area is considered equivalent to a county and a state for data presentation purposes.

73 percent of counties had a sex ratio less than 100.

The county with the highest sex ratio was Crowley County, Colorado, with a sex ratio of 258.6, indicating that there were more than twice as many men as women in the county. This high sex ratio results from the presence of a state prison in Crowley County. The lowest sex ratio was found in Pulaski County, Georgia, with a sex ratio of 76.1. This low sex ratio is partly due to the presence of a state prison for women in Pulaski County. The total population of each of these counties, however, was less than 12,500 people.

Among counties with at least 100,000 people, there were three counties with a sex ratio greater than 110: Kings County, California (129.6), Onslow County, North Carolina (115.7), and Pinal County, Arizona (110.4). In both Kings County and Pinal County, the high sex ratios are due to the presence of multiple correctional facilities with majority male populations, while Onslow County owes its high sex ratio to the presence of a large Marine Corps base that houses a mostly male population. The lowest sex ratios among counties with at least 100,000 people were found in Hampshire County, Massachusetts (88.0), Bronx County, New York (88.3), and New York County, New York (88.3). In Hampshire County, the low sex ratio is influenced by the presence of several colleges, two of which are women’s colleges.

County-level median ages followed patterns seen at the state level.

There was also variation at the county level in the median age. Figure 7 provides a map of median age by county for all counties in the United States. While median age varied significantly among counties,

patterns emerge that are consistent with findings reported earlier. For example, counties in Florida, New England, and the Appalachian Mountain area tend to have higher median ages, along with a band of counties in the Great Plains and Pacific Northwest. Counties with lower median ages are found clustered along the United States–Mexico border and within the states of Utah and Alaska.

The number of counties with a median age over 40 grew, while those with a median age less than 30 declined between 2000 and 2010.

Of the country’s 3,143 counties, there were 1,683 counties with a median age over 40. This is an increase of more than double from Census 2000, where 734 counties were found to have a median age over 40. In contrast, there were only 93 counties with a median age below 30, compared with 131 counties in 2000. The county with the highest median age was Sumter County, Florida (62.7), a county with a population of just under 93,500, which is home to a large, age-restricted retirement community. The lowest median age was found in the Wade Hampton Census Area, Alaska (21.9), a county with a population of less than 7,500.

Among counties with a population of at least 100,000, the counties with the highest median ages were found in Florida.

Examining counties with a population of at least 100,000 shows that three counties, all in Florida, had a median age over 50: Charlotte (55.9), Citrus (54.0), and Sarasota (52.5). These were also the counties with the highest median ages in 2000. Counties with a low median age were consistent between 2000 and 2010 as well. The lowest median ages were

found in Brazos County, Texas (24.5), Utah County, Utah (24.6), Cache County, Utah (25.5), Onslow County, North Carolina (25.7), and Clarke County, Georgia (25.9). Three of these counties contain large universities, which drive the low median age in each county. Brazos County, Texas, is home to Texas A&M University; Utah County, Utah, contains Brigham Young University; and the University of Georgia is located in Clarke County, Georgia. As mentioned previously, Onslow County, North Carolina, is home to a large Marine Corps base with a primarily young, male population. The presence of this base contributes to the low median age and high sex ratio in the county. With the exception of Cache County, Utah, which was below 100,000 in population in 2000, all of these counties were also in the lowest five for median age in 2000 as well.

Among places of 100,000 or more population, the places with the highest and the lowest sex ratio were both in Florida.

Table 4 provides a list of the ten places (among places with a population of 100,000 or more) with the highest and lowest sex ratio in 2010.⁶ The highest sex ratio was found in Fort Lauderdale, Florida (111.8), followed by Tempe, Arizona (108.6), and Wichita Falls, Texas (107.5). Of the top ten places with the highest sex ratio, six are in the West, with the remaining four in Southern states. As mentioned previously, both Utah and Washington were among the states with the highest sex ratios, and both states contained a place with a sex ratio among the top ten places: Salt Lake City, Utah, with a sex ratio of 105.3

⁶ The 2010 Census showed 282 places in the United States with 100,000 or more population. They included 273 incorporated places (including 5 consolidated cities) and 9 census designated places (CDPs) that were not legally incorporated.

Table 4.
Ten Places With the Highest and Lowest Sex Ratio: 2010
(For information on confidentiality protection, nonsampling error, and definitions, see www.census.gov/prod/cen2010/doc/sf1.pdf)

Place ¹	Both sexes	Male	Female	Sex ratio
HIGHEST SEX RATIO				
Fort Lauderdale, FL	165,521	87,387	78,134	111.8
Tempe, AZ	161,719	84,200	77,519	108.6
Wichita Falls, TX	104,553	54,172	50,381	107.5

and Everett, Washington, with a sex ratio of 103.5.

Interestingly, the place with the highest sex ratio and the place with the lowest sex ratio were found in Florida. The highest sex ratio was found in Fort Lauderdale, Florida (111.8), while the lowest sex ratio was found in Pembroke Pines, Florida (85.9). All ten of the places with the lowest sex ratios were found in Southern states. The list of the lowest sex ratios included several places from the same states, with three places each from Alabama and North Carolina, and two from Florida.

Among places with a population of 100,000 or more, five of the ten places with the highest median ages were located in Florida.

The ten places with a population of 100,000 or more with the highest median ages were located in

the South and West regions (Table 5). Scottsdale, Arizona, had the highest median age at 45.4 years—a value 8 years higher than the national median age. Of the remaining places with the highest median age, five were found in Florida and two were in California.

Florida also had two places that were included on the list of places with the lowest median age: Gainesville, Florida (24.9), and Tallahassee, Florida (26.1). The place with the lowest median age was found in Provo, Utah (23.3), which is located in the state with the lowest median age overall. All three of these places were home to prominent universities, which directly contributed to their low median age. Provo, Utah, located in Utah County, as mentioned earlier, is the home of Brigham Young University. Gainesville, Florida, is the home of the University of Florida, while Tallahassee, Florida, is home

to both Florida State University and Florida A&M University. In all, nine of the ten places on the list of the places with the lowest median age contain large universities, with the remaining place, Killeen, Texas, home to a large military base. Three places in Texas are on the list of the ten lowest median ages.

ADDITIONAL FINDINGS ON AGE AND SEX

At what age were there almost twice as many women as men?

In the 2010 Census, there were approximately twice as many women as men at age 89 (361,309 compared with 176,689, respectively). This point occurs about 4 years older than it did in 2000, and 6 years older than it did in 1990. This increase is further evidence of the narrowing gap in mortality between men and women occurring at the older ages.

What are age heaping and digit preference?

The tendency for respondents to report certain ages at the expense of other ages is called age heaping. This is also referred to as digit preference, which is the preference for certain ages, such as those ending in "0" or "5." Age preference can also include preference for a particular age, like 29, 65, 85 or 100. This phenomenon varies across cultures and is impacted by data collection methods. The Census Bureau strives to reduce age heaping by collecting both age and date of birth information. Overall, age heaping did not appear to be a concern at the national level in Census 2000.⁷ Early evaluations of the 2010 Census data show similar results.

⁷ For more information, see Kirsten West, "Did Proxy Respondents Cause Age Heaping in Census 2000." Paper presented at the Annual Meeting of the American Statistical Association, August 7-11, 2005.

What drove the overall decline in the age dependency ratio?

The age dependency ratio provides a very rough approximation of economic dependency in a population by dividing the dependent-age population (children and older adults) by the working-age population. It is often derived as the number of people in the "dependent" age categories (under age 18 and 65 and over) per 100 working-age people (18 to 64). This ratio can be separated into two parts, the old-age dependency ratio (65 and over divided by the working-age population) and the child dependency ratio (under-18 population divided by the working-age population).

At the national level, the total age dependency ratio declined from 61.6 in 2000 to 58.9 in 2010, indicating that there were 2.7 fewer "dependent-age" people for every 100 working-age people. However, this overall decline masks the differing trends occurring in the younger and older population. When evaluating the two dependency ratios separately, the child dependency ratio declined by 3.3 (from 41.5 in 2000 to 38.2 in 2010) while the old-age dependency ratio increased slightly by 0.6 (20.1 in 2000 to 20.7 in 2010).

How does the dependency ratio differ by state?

Dependency ratios also varied from state to state, mirroring trends in median age by state that were discussed earlier. Figure 8 presents dependency ratios for every state, decomposing the total dependency ratio into its two parts (the old-age dependency ratio and the child dependency ratio). States are ranked according to their total dependency ratios. As is evident in Figure 8, Utah was the state with the highest total dependency ratio, and it also had the highest child dependency ratio. This is not surprising, given

Figure 8.

Age Dependency Ratios by State: 2010

(For information on confidentiality protection, nonsampling error, and definitions, see www.census.gov/prod/cen2010/doc/sf1.pdf)

Note: Total bar length represents the total dependency ratio, which is the number of children (ages 0-17) and older adults (ages 65 and over) per 100 people of working age (ages 18-64) in the state.

Source: U.S. Census Bureau, 2010 Census Summary File 1.

that Utah was the state with the lowest median age, as mentioned previously. The lowest child dependency ratio was found in Vermont, a state that also had a high median age. Excluding the District of Columbia, the state with the lowest total dependency ratio was Alaska. Alaska was also the state with the lowest old-age dependency ratio, while the state with the highest old-age dependency ratio was Florida, again matching trends in median age mentioned previously for these states. The District of Columbia had the lowest dependency ratio overall.

ABOUT THE 2010 CENSUS

Why was the 2010 Census conducted?

The U.S. Constitution mandates that a census be taken in the United States every 10 years. This is required in order to determine the number of seats each state is to receive in the U.S. House of Representatives. Age data are used to determine the voting age population (age 18 and older) for use in the legislative redistricting process.

Why did the 2010 Census ask the questions on age and sex?

The Census Bureau collects data on age and sex to support a variety of legislative and program requirements. These data are also used to aid in allocating funds from federal programs, in particular to programs targeting specific age groups. For example, age data are used to calculate the proportion of school-aged children in each district in order to properly allocate funds for education.

How are age and sex data beneficial?

All levels of government need information on age and sex to implement and evaluate programs, such as the Equal Employment Opportunity Act, the Civil Rights Act, the Women's Educational Equity Act, the Older Americans Act, the Juvenile Justice and Delinquency Prevention Act, and the Job Training Partnership Act. Age and sex data are used by the Department of Veterans Affairs, the Department of Education, the Department of Health and Human Services, and the Equal Employment Opportunity Commission, among others, to aid in planning and development of services.

Other equally important uses for census age and sex data are in planning adequate schools for the school age population and to determine funding distributions for schools and planning for numerous social services such as highways, hospitals, health services, and services for the older population. Census age data are also an important source of information on population aging, such as measurement of people eligible for Social Security and Medicare benefits. In addition to these public uses of census data, census data can also be used by private organizations. For example, census data can help researchers studying trends related to mortality and population aging or help small business owners in planning where to best locate their businesses to fit the needs of the community.

FOR MORE INFORMATION

For more information on age and sex in the United States, visit the U.S. Census Bureau's Internet sites at <www.census.gov/population/www/socdemo/age/> and <www.census.gov/population/www/socdemo/women.html>.

Data on age and sex from the *2010 Census Summary File 1* provide information at the state level and below and are available on the Internet at <factfinder2.census.gov/main.html> and on DVD. Information on confidentiality protection, nonsampling error, and definitions is available on the Census Bureau's Internet site at <www.census.gov/prod/cen2010/doc/sf1.pdf>.

Information on other population and housing topics is presented in the 2010 Census Briefs series, located on the U.S. Census Bureau's Web site at <www.census.gov/prod/cen2010/>. This series presents information about race, Hispanic origin, age, sex, household type, housing tenure, and people who reside in group quarters.
