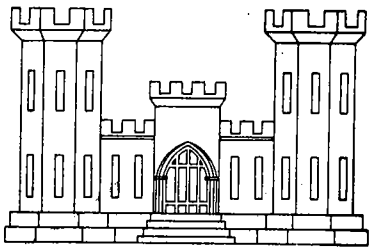
LAKE PONTCHARTRAIN, LOUISIANA AND VICINITY
LAKE PONTCHARTRAIN BARRIER PLAN
DESIGN MEMORANDUM NO. 2 - GENERAL
SUPPLEMENT NO. 4

NEW ORLEANS EAST BACK LEVEE

BL-1E, 1B, etc



DEPARTMENT OF THE ARMY
NEW ORLEANS DISTRICT, CORPS OF ENGINEERS
NEW ORLEANS, LOUISIANA

March 1971

LMVED-TD (NOD 18 Mar 71) 1st Ind
SUBJECT: Lake Pontchartrain, Louisiana and Vicinity, Lake Pontchartrain Barrier Plan, General Design Memorandum No. 2, Supplement No. 4, New Orleans East Back Levee

DA, Lower Mississippi Valley Division, Corps of Engineers, Vicksburg, Miss. 39180 7 May 71

TO: Chief of Engineers, ATTN: ENGCW-V/ENGCW-E

1. The subject design memorandum is forwarded for review and approval pursuant to para 20a, ER 1110-2-1150. Approval is recommended subject to the following comments.

2. Table of Contents, page vi. Title for Plate 29 should read "I-wall and levee configuration (Sta 664+73.3 to Sta 772+00)."

3. Para 33 b(1), page 13. Plate 61 referred to in this sentence is the stability analysis of an I-wall levee, not an earthen levee. This reference should be corrected.

4. Para 36b, page 17. This paragraph should be expanded to include the design load of the piles in both tension and compression.

5. Para 38, page 18. The third sentence states: "In order to utilize the maximum amount of Pleistocene soils and the minimum amount of Recent deposits, borrowing will be in the deepest portion of the borrow areas and to the maximum depth practicable (approximately el. -80.0)." This should be required in the specifications.

6. Paras 38, 39a, and plates 30, 31, and 32. These paragraphs and plates should cover the method, compaction, and the source of material for raising the levee to compensate for additional settlement (1.5' to 2.0') subsequent to third lift. Proposed compaction of third lift shaping should also be indicated.

7. Paras 55, 56, 57, and 58, page 25. The allowable design loads for the piles, pile load computation results, and the assumptions made in the analysis should be included. For instance, assuming a uniform distribution of loads on the pile arrangements shown for gate monoliths on plates 79 and 80 would not be appropriate since the gate piers and pile arrangements are not symmetrical.

LMVED-TD (NOD 18 Mar 71) 1st Ind 7 May 71
SUBJECT: Lake Pontchartrain, Louisiana and Vicinity, Lake Pontchartrain Barrier Plan, General Design Memorandum No. 2, Supplement No. 4, New Orleans East Back Levee

8. Table 3, page 32. a. The unit price of Z-27 sheet pile ($4.00/s.f.) is considered low and should be checked.

b. The basis for determining the relocations costs should be furnished.

9. Para 67, page 29. The spoil-disposal areas mentioned in the third sentence should be shown on the plates referenced, if not shown elsewhere.

10. Para 70, pages 29 and 30. a. The stated elevation of the Southern Natrual Gas Company high pressure gas lines does not agree with the profile of plate 3.

b. The baseline stations of 711+77.5, 718+34.2, and 765+75.0 for the pipeline crossings on page 30 do not agree with those on plan and profile plate 2. These discrepancies should be reconciled.

11. Para 71c, page 30. The stationing of Louisiana Cement Company conveyor system is given as 716+56.2 in this paragraph as 716+53.25 on plate 2 and as 716+55.25 on plate 74. These stations should be corrected during preparation of plans and specifications.

12. Para 74, page 34. The reported decrease of $4,957,000 should NOT be reflected in the PB-3 but should be retained in the project estimate as additional contingencies.

13. Plate 2. The electrical cables shown on the profile at approximate station 738+64 should be shown on the plan.

14. Plate 3. a. The 24" Southern Natural Gas pipeline at station 823+50 should be shown on the profile.

b. The stationing of the Southern Natural Gas pipelines should be made consistent on the plan and profile.

15. Plate 14. a. The compression indices (C_c) shown on plate 14 do not agree with those on plate 7. These differences should be reconciled.

b. The values of the coefficient of consolidation (C_v) used in establishing the U - t curves should be given.

16. Plate 15. The e-log p curve for the clay strata from el -10 to el -18 should be added to plate 8.

17. Plate 30. The meaning of the term "Recommended" shown on the third lift-shaping section should be explained.

18. Plates 30, 31, and 32. The quantity of fill available for third lift construction should be checked. If sufficient material is not available within the section, other provisions should be indicated.

19. Plates 33, 34, 36, 37, 38, 45, 59, 61. The shallowest failure surfaces intersect the tips of the sheet pile I-walls. This implies that either this is the location of a critical failure surface and that there are no critical failure surfaces at higher elevations, or that some value of shear strength has been assigned the sheet piling. I-wall sections should be analyzed as if the sheet piling was nonexistent. Any sections where this change in concept could cause an appreciable change in the factor of safety should be reanalyzed.

20. Plates 34 and 35. The stability analyses on these two plates should be checked. Our review revealed lower resisting forces on the central block for assumed failure surfaces B1 and B2, than that shown on plate 34 and an apparent error in the direction and location of the crossover at el -70 on plate 35.

21. Plate 56. The differential settlement between the levee and the pile supported T-wall will be significant and could be detrimental to the connecting I-wall. These portions of the I-wall should be constructed in the usual sequence, but the placing of the concrete cap should be delayed until most of the settlement of the levee has taken place. Interim protection can be provided by driving longer sections of sheet piling and allowing them to protrude to approximately el 17.5.

22. Plate 76. The possibility of interference between the piles beneath the inverted T-wall and those beneath the discharge basin should be investigated.

23. Appendix B, Fig. B-5. The actual modulus of subgrade reaction for a clay with shear strength equal to 300 lb/sq ft could be less than 140 lb/sq in instead of 400 lb/sq in as assumed. Axial pile loads should be determined using a conservatively low value for the modulus.

ENGCW-EZ (LMNED-PP, 18 Mar 71) 2nd Ind
SUBJECT: Lake Pontchartrain, Louisiana and Vicinity, Lake Pontchartrain Barrier Plan, General Design Memorandum No. 2, Supplement No. 4, New Orleans East Back Levee

DA, Office of the Chief of Engineers, Washington, D.C. 20314 18 August 1971

TO: Division Engineer, Lower Mississippi Valley, ATTN: LMVED-TD

1. Approved, subject to the comments of the Division Engineer in the 1st Indorsement and to the following comments.

2. Paragraph 3. The assurances of local cooperation should include additional assurances required by Sections 210 and 305 of Public Law 91-646, approved 2 January 1971. In accepting the additional assurances, it should be ascertained that the local sponsor is vested with adequate legal authority and economic capability to comply therewith.

3. Paragraph 33 and Plate 41. A stability analysis should be made with the vertical face of the active wedge located 130 feet floodside of the levee baseline and the base of the central block at Elevation -50.

4. Paragraph 38, and Plates 16 and 17. From Station 600+00 to Station 770+00 there are large quantities of pervious soils in the lower parts of the Michoud Canal borrow, from about Elevation -60 to Elevation -80. Specifications should state that these materials be placed on the landside zone of the levee.

5. Paragraphs 67 and 74b(4). Paragraph 74b(4) cites several reasons for the increase of $2,508,000 in the estimated cost for land and damages over the cost contained in the project document. One of the reasons is stated as being credit allowance for the area beneath the existing levee. This is not in accord with the statement in paragraph 67 indicating that the acreage under the levee was deducted from the total project requirements for rights-of-way. Table 3 reflects a reduction of $519,000 for 79 acres on which the existing levees are located. This apparent discrepancy should be explained.

6. Plate 34. A stability analysis should be made with the vertical face of the active wedge located 170 feet floodside of the levee base line and the base of the central block at Elevation -25.

7. Plate 42. Consideration should be given to leaving a 40-foot wide berm at Elevation 0.0 on the floodside of the levee.

8. Plate 51. The 1 on 2 dredged slopes should be flattened so that the factor of safety against local failure is at least 1.5. Local failures could lead to overall instability.

TO: District Engineer, New Orleans, ATTN: LMNED-PP

Referred to note approval subject to comments in previous indorsements.

FOR THE DIVISION ENGINEER:

GEORGE B. DAVIS
Acting Chief, Engineering Division

LMNED-PP (18 Mar 71) 4th Ind
SUBJECT: Lake Pontchartrain, Louisiana and Vicinity, Lake Pontchartrain Barrier Plan, General Design Memorandum No. 2, Supplement No. 4, New Orleans East Back Levee

DA, New Orleans District, Corps of Engineers, PO Box 60267, New Orleans, La. 70160 12 Nov 71

TO: Division Engineer, Lower Mississippi Valley, ATTN: LMVED-TD

1. The proposed disposition of comments presented in the 1st, 2d, and 3d Indorsements of this chain of correspondence follows (paragraph numbers refer to like-numbered paragraphs in the respective indorsements). All elevations contained herein are in feet and refer to mean sea level datum.

a. 1st Ind, para 2. Concur.

b. Para 3. Concur. Plate 61 should be referenced in para 33a(2), page 12.

c. Para 4. Concur. Para 36b should be modified to include the sentence: "The maximum design loads in tension and compression are 16.5 tons and 36 tons, respectively." The pile test loads will be approximately twice the design loads.

d. Para 5. Concur.

e. Para 6. After construction of the third lift, the levee will be maintained to the design grade by local interests and therefore the method, compaction, and source of material are not presented in the subject design memorandum. The amounts of additional settlement subsequent to the third lift were utilized in determining the maintenance costs shown in table 5, page 38. The plans and specifications for the third lift will specify that the levee be compacted in accordance with the standard guide specifications for semicompacted fill.

f. Para 7. Inclosed herewith is a table showing the allowable and computed pile loads for all T-wall and gate monoliths. The assumptions made in the analysis are as shown on figures B-5 and B-6 except that the modulus of subgrade reaction (AK) has been revised to 140 lbs/sq.in. (see incl 2).

g. Para 8a & 8b. Concur. Due to wage and material increases, the unit price for Z-27 and MA-22 sheet pile was increased to $4.50/s.f. This has resulted in a revision to pages 31 thru 38 as shown in incl 3. The pipe relocation costs were determined from the latest tabulation of bids for pipes of similar sizes. The costs for relocating the Southern Natural Gas Co. lines were estimated by owners and verified by NOD.

h. Para 9. All references to spoil-disposal areas in this paragraph should be deleted. No spoil-disposal areas are required.

i. Para 10a & 10b. The elevation of the Southern Natural Gas Co. high pressure gas line as shown on page 29 and plate 3 is in error and should read elevation -6.0. The baseline stations for the pipeline crossings as shown on plate 2 are the correct stations.

j. Para 11. The correct station for the Louisiana Cement Co. conveyor system should be station 716+55 as shown in plan on plate 2. The plans and specifications will indicate the correct station.

k. Para 12. Concur. The reported decrease will be retained in the PB-3 project estimate as additional contingencies.

l. Para 13. Concur.

m. Para 14a & 14b. Concur. The correct station should read 824+06 as shown in plan on plate 2.

n. Para 15a. Concur. The values of the compression indices shown on plate 14 are correct and accordingly the values on plate 7 should agree with those on plate 14.

o. Para 15b. The values of the coefficients of consolidation (C_v) used to develop the U-t curves shown on plate 14 are 7, 4, and $1.0X10^{-4}$ cm^2/sec for strata I, II, III, respectively.

p. Para 16. Sufficient undisturbed samples were not available between elevation -10.0 and -18.0 from boring 3-EU to perform consolidation tests.

q. Para 17. The third lift shaping section shown on plate 30 is the configuration which meets the design criteria and was forwarded to higher authority for approval. The word "Recommended" means the section is recommended for approval.

r. Para 18. The levees were designed such that sufficient material will be available to construct the third lift.

s. Para 19. The levee embankments containing the I-wall sections referred to in this paragraph were analyzed for the change in concept, i.e., considering the sheet piling as nonexistent, and there were no appreciable changes in the factors of safety. We can readily understand and appreciate the value of this type of concept for establishing a conservative design for cursory review. However, we feel that general use of this procedure for final design will result in ultra conservative designs and would prevent the use of I-type walls.

For purposes of maintaining currently approved designs inviolate and establishing mutually acceptable guidelines for future design, we propose a modified approach as follows:

(1) Using the construction (Q) shear strengths and the conventional cantilever I-type wall analysis, determine the minimum sheet pile penetration needed to retain the differential waterhead (F.O.S.=1.0) and the maximum penetration required for design.

(2) Disregard the sheet pile below the minimum penetration and conduct conventional levee stability analyses, deducting the lateral load of the differential head caused by the wedge of water supported by the I-wall, adding, however, the effects of the weight of all other water overlying the active wedges.

(3) The stability of the levee containing the I-type wall will be considered acceptable if the factors of safety for assumed failure surfaces between the minimum tip penetration and the required penetration are above 1.0 and the F.O.S. below the required tip penetration are 1.3 or higher. Further, for subsurface conditions having a soft stratum (low shear strength) overlying a firm stratum (high shear strength), the pile penetration into the firm stratum will be to a sufficient depth to prevent the pile tip from kicking up into the soft stratum.

t. Para 20. Concur. The factors of safety for analyses B1 and B2 on plate 34 should be 2.62 and 1.84, respectively. The cross-over referred to in this comment is in the correct direction and location. However, it should be shown at elevation -60.0 instead of elevation -70.0.

u. Para 21. Concur. The plans and specifications will indicate that placement of the concrete cap should be delayed to allow for levee settlement and the sheet pile will be driven to elevation 17.5 for interim protection.

v. Para 22. Concur. The batter should be changed from 1 on 2 to a batter of 1 on 2.5. The P&S will reflect this change.

w. Para 23. Concur. The pile foundations were reanalyzed using a modulus of subgrade reaction of 140 lbs/sq.in. The new pile loads are shown on the table in incl 2. This resulted in exceeding the allowable pile stress on the protected side vertical pile of Gate No. 2 by 6 percent, which would be tolerable. However, the addition of another vertical pile in the gate bay would provide a better designed monolith since most of the time the loading will be vertical resulting from vehicular traffic. This is tabulated in the table of incl 2. The gate monolith will therefore be revised in the plans and specifications to show this additional pile.

x. Para 24. We concur with the minor comments shown in red.

y. 2d Ind, para 2. The Attorney General of the State of Louisiana in his opinion of 7 April 1971 stated that the local assurers for the project are not now vested with adequate legal authority to comply with the provisions of Section 210 and 305 of P.L. 91-646. Only after passage of a proposed constitutional amendment early next year will the agencies be in a position to provide the additional assurances required by the act.

z. Para 3. A stability analysis was made with the vertical face of the active wedge located 130 feet flood side of the levee baseline and with the base of the central block at elevation -50.0 and the resulting minimum factor of safety is 1.80.

aa. Para 4. Hydraulic fill for construction of the levee from station 772+00 to station 1006+59 will be obtained from the GIWW. If the project "Michoud Canal Enlargement" is constructed coincident with one of the hydraulic fill lifts for the levee, an effort will be made to place the material removed from the Michoud Canal in the levee proper. Inasmuch as the Michoud Canal will be deepened only to elevation -40.0, the pervious soils between elevation -60.0 and elevation -80.0 will not be part of the fill placed in the levee.

bb. Para 5. That part of the statement in para 74b(4) stating that credit was allowed for the area beneath the existing levee is in error. The value of lands under the levee was correctly subtracted in table 3 from the total project requirements.

cc. Para 6. A stability analysis was made with the vertical face of the active wedge located 170 feet flood side of the levee baseline and with the base of the central block at elevation -25.0 and the resulting minimum factor of safety is 3.01.

dd. Para 7. As stated in para laa above, borrow material will not be obtained from the Michoud Canal for construction of the New Orleans East back levee. If the Michoud Canal is used as a borrow area for other projects in the future, the 40-foot wide berm at elevation 0.0 referred to in this paragraph will be complied with.

ee. Para 8. The requirement that slopes of borrow pits be designed to provide a factor of safety of 1.5 is considered too conservative. Slopes designed for a minimum factor of safety of 1.3 against local failure are considered satisfactory. We have not experienced any problems relative to local failure of the 1 on 2 dredged slopes in borrow pits located in

the MR-GO for levees previously constructed and/or under construction, i.e., Chalmette levee and Chalmette levee extension. Inasmuch as the soil conditions in the GIWW are similar to those in the MR-GO and the minimum factor of safety of the 1 on 2 slopes is 1.37 (see GDM, plate 64), it is strongly requested that the borrow pits with 1 on 2 side slopes presented in the GDM be approved. Further, it is requested that side slopes of borrow pits continue to be designed for a minimum factor of safety of 1.3, rather than a factor of safety of 1.5.

ff. Para 9.

(1) The riprap toe protection design, method A on plate 37 of EM 1110-2-1601, does not apply to this project because the water elevation which is tidal normally varies between +2.0 and -1.0 and the toe of riprap protection at -3.0. is therefore below the water level.

(2) The riprap toe protection design for the subject GDM has been changed to agree with the typical section, south bank, plate 2, Mississippi River-Gulf Outlet, General Design Memorandum No. 2, Supplement No. 4.

gg. 3d Ind. No replies required.

2. It is recommended that the proposed disposition of comments presented above be approved.

FOR THE DISTRICT ENGINEER:

JEROME C. BAEHR
Chief, Engineering Division

2. Tabulation of pile loads
3. Revised pages

d. New Orleans Sewerage and Water Board pumping station. At station 867+87, a new floodwall will be constructed south of an existing New Orleans Sewerage and Water Board pumping station. The existing floodwall with the top elevation at +16.0 will be replaced with a new T-wall with the top elevation at +23.0. Location and details of this floodwall are shown on plates 3 and 76 through 78.

ENVIRONMENTAL QUALITY

72. Environmental quality.

a. General. The engineering treatment required for preserving and maintaining the environmental quality of the project has been considered during preparation of this memorandum. Specifically, levee erosion protection, corrosion mitigation, and the disposition of dredge waste water are discussed in paragraphs 39a, 40, and 62, respectively. Further, as indicated in paragraphs 65 and 66 and in appendix A, extensive coordination has been accomplished with the appropriate agencies relative to effects of the project on fish and wildlife resources and water quality control during and subsequent to construction.

b. Enhancement. Construction of the protective works covered herein alters the existing terrain only to the extent of raising and strengthening existing work along the same alignment. Essentially all borrow material needed to enlarge the existing levee will come from within adjacent waterways or from a remote location in Lake Pontchartrain. Additional beautification measures beyond those normally associated with levee construction, i.e., grading and sodding, are not warranted. The logic behind this statement is that the adjacent developed area is occupied by industry which precludes the use of public funds for beautification of private vistas and that adjacent area which is not developed as industrially zoned.

ESTIMATE OF COST

73. General. Based on January 1971 price levels, the estimated first cost for the New Orleans East back levee is $15,000,000 This estimate consists of $2,773,000 for lands and damages, $496,000 for relocations, $9,657,000 for levees and floodwalls, which includes work done by local interests, $1,226,000 for engineering and design, and $848,000 for supervision and administration. The detailed estimate of first cost is shown on table 3.

[2]Includes work done by local interests.

74. Comparison of estimates.

a. GDM versus PB-3. The current estimate of $15,000,000 for the New Orleans East back levee represents a decrease of $4,807,000 over the latest PB-3 effective 1 July 1970. The estimate presented in the PB-3 is based on the estimate included in Lake Pontchartrain, Louisiana and Vicinity, Lake Pontchartrain Barrier Plan, General Design Memorandum No. 2, Citrus Back Levee, approved 29 December 1967, and escalated to July 1970 price levels. Table 4 shows a comparison of the project document, PB-3, and general design memorandum estimates. Reasons for the difference between the design memorandum and PB-3 estimates are as follows:

(1) Levees and floodwalls. The net decrease of $2,278,000 is comprised of a decrease of $1,382,000 attributable to the selection of floodwall construction instead of levee along the Michoud Canal and an additional $896,000 decrease reflecting the deletion in this GDM of the U. S. Highway 90 to GIWW reach from the project.

(2) Engineering and design. The increase of $295,000 resulted from recomputing the E&D cost based on an analysis of actual work required rather than applying a percentage to the construction cost.

(3) Supervision and administration. The net increase of $218,000 reflects the added S&A costs as a result of recomputing S&A costs based on an analysis of actual work required rather than applying a percentage to the construction cost.

(4) Lands and damages. The net decrease of $3,329,000 is the result of a decrease in land requirements for T-wall in place of levee, a more detailed estimate of levee requirements, the elimination in this GDM of the levee from the GIWW to U. S. Highway 90, and the assignment of credit for area beneath the existing levee.

(5) Relocations. The increase of $287,000 reflects general refinements in the cost estimate based on the more detailed information available during preparation of this memorandum.

TABLE 4

COMPARISON OF ESTIMATES

	Feature	Project document	PB-3 eff. 1 Jul 70	GDM No. 2 Supp.No. 4	Difference Supp.No.4 - PB-3	Difference Supp. No. 4 - Proj.document
		$	$	$	$	$
11	Levees and floodwalls	4,993,000	11,935,000	9,657,000	-2,278,000	+4,664,000
30	Engineering and design	195,000	931,000	1,226,000	+295,000	+1,031,000
31	Supervision and administration	300,000	630,000	848,000	+218,000	+548,000
	Subtotal	5,488,000	13,496,000	11,731,000	-1,765,000	+6,243,000
01	Lands and damages	265,000	6,102,000	2,773,000	-3,329,000	+2,508,000
02	Relocations	238,000	209,000	496,000	+287,000	+258,000
	Subtotal	503,000	6,311,000	3,269,000	-3,042,000	+2,766,000
	Total	5,991,000	19,807,000	15,000,000	-4,807,000	+9,009,000

b. GDM versus project document. The estimate of $15,000,000 for the New Orleans East back levee also represents an increase of $9,009,000 over the project document estimate. Reasons for the difference between the design memorandum and project document estimates are as follows:

(1) Levees and floodwalls. The increase of $4,664,000 is the result of increasing the height of all levee protection from elevation 16.0 to elevation 17.5, construction of approximately 2 miles of concrete I-wall, eight gate structures, and 130 feet of I-wall in lieu of earth levee, and increasing the contingencies by 5 percent over that presented in the project document.

(2) Engineering and design. The increase of $1,031,000 resulted from recomputing the E&D costs based on an analysis of actual work required rather than applying a percentage to the construction cost.

(3) Supervision and administration. The increase of $548,000 resulted from recomputing the S&A costs based on an analysis of actual work required rather than applying a percentage to the construction cost.

(4) Lands and damages. The increase of $2,508,000 is the result of an increase in acreage requirements, a 10 percent increase in contingencies, the escalation of land costs due to development in the area subsequent to the preparation of the project document, and credit allowance for the area beneath the existing levee.

(5) Relocations. The increase of $258,000 is due primarily to modifying the floodwall to accommodate the pipe crossings and roads which were constructed since presentation of the project document.

SCHEDULES FOR DESIGN AND CONSTRUCTION

75. Schedules for design and construction. The sequence of contracts and the schedules for design and construction are shown below:

Contracts	Design: Start	Design: Complete	Construction: Advertise	Construction: Award	Construction: Complete	Estimated Construction Cost Includes Contingencies and S&I
Levee raising[1] (interim protection sta. 664+73 to sta. 1006+59)			May 66	Jun 66	Apr 67	$ 75,000
Levee, 1st lift 1971 (Sta. 772+00 to Sta. 876+87)		Dec 71	Dec 71	Jan 72	Jan 73	1,381,000
Concrete floodwall (Sta. 664+73 to Sta. 772+00 and Sta. 874+42 to Sta. 879+32)		Feb 72	Feb 72	Mar 72	Mar 73	3,537,000
Levee, 1st lift (Sta. 876+87 to Sta. 1006+59)		Mar 72	Mar 72	Apr 72	Nov 73	2,088,000
Levee, 2d lift (Sta. 772+00 to Sta. 876+87)		Dec 74	Dec 74	Jan 75	Nov 75	1,097,000
Levee, 2d lift (Sta. 876+87 to Sta. 1006+59)		Oct 75	Oct 75	Nov 75	Oct 76	1,269,000
Levee shapeup & seeding, foreshore protection (Sta. 772+00 to Sta. 876+87)		Oct 77	Oct 77	Nov 77	Sept 78	397,000
Levee shapeup & seeding, foreshore protection (Sta. 876+87 to Sta. 1006+59)		Sept 78	Sept 78	Oct 78	Jun 79	482,000
Total						$10,326,000

[1]Raising 1965 levee by local interests to the existing interim protection levee. See plates 29 through 32.

76. Funds required by fiscal year. To maintain the schedules for design and construction, as shown above, of the New Orleans East back levee, funds[1] will be required by fiscal year as follows:

Funds required by FY	1971	$ 115,350[2]
	1972	4,749,000
	1973	2,019,670
	1974	633,930
	1975	695,880
	1976	1,412,210
Balance to complete		2,213,960
Total		$11,840,000

OPERATION AND MAINTENANCE

77. General. The New Orleans East back levee will be maintained and operated at the expense of local interests as a feature of local cooperation in the hurricane project. A detailed estimate of the annual operation and maintenance costs is shown in table 5. In addition, it is estimated that replacement of the overhead roller gates will be necessary at 30-year intervals. The annual charge for these replacements is $1,140.

TABLE 5

ESTIMATE OF ANNUAL OPERATION AND MAINTENANCE COSTS

Maintenance:	$4,650
I-wall	270
Foreshore protection	700
Overhead roller gates	960
Operation:	
Overhead roller gates	80
Total	$6,660

[1]Includes cost for construction (including contingencies 20%), supervision and administration, engineering and design.

[2]Includes costs for preparation of plans and specifications and credit for work accomplished by local interests.

LMVED-TD (NOD 18 Mar 71) 5th Ind
SUBJECT: Lake Pontchartrain, Louisiana and Vicinity, Lake Pontchartrain Barrier Plan, General Design Memorandum No. 2, Supplement No. 4, New Orleans East Back Levee

DA, Lower Mississippi Valley Division, Corps of Engineers, Vicksburg, Miss. 39180 9 Dec 71

TO: District Engineer, New Orleans, ATTN: LMNED-PP

1. The actions proposed and information furnished in response to comments in previous indorsements are satisfactory subject to the following comments.

2. Para 1e. It is considered that requiring local interests to provide the 1.5 feet of final levee fill is beyond the scope of normal maintenance. This procedure should be reexamined and the cost estimate revised, if applicable.

3. Para 1s. The proposed modified approach for designing cantilever I-type walls is not concurred in. The sheet pile should be considered nonexistent in analyses of the overall stability of the levee containing the I-wall. Because of the complexity and the many variations of this problem, a meeting will be held in the near future between NOD and LMVD to arrive at mutually acceptable design guidelines.

FOR THE DIVISION ENGINEER:

wd all incl

A. J. DAVIS
Chief, Engineering Division

LMNED-PP (18 Mar 71) 6th Ind
SUBJECT: Lake Pontchartrain, Louisiana and Vicinity, Lake Pontchartrain Barrier Plan, General Design Memorandum No. 2, Supplement No. 4, New Orleans East Back Levee

DA, New Orleans District, Corps of Engineers, PO Box 60267, New Orleans, La. 70160 7 Jan 72

TO: Division Engineer, Lower Mississippi Valley, ATTN: LMVED-TD

1. The proposed disposition of comments presented in the 5th Ind of this chain of correspondence follows (paragraph numbers refer to like-numbered paragraphs in the 5th Ind).

a. Para 2. The design of the ultimate levee section presented in the subject GDM was based on existing (Q) shear strengths. As stated in paragraph 42 of the GDM, additional soils borings, tests, and stability analyses will be made prior to each lift subsequent to the first. It is believed that these analyses will indicate that sufficient gains in shear strength have developed so that the 3d lift can be overbuilt 1.5 - 2.0 feet above net grade to compensate for long-term settlement. The information presented in para 1e of the 4th Ind concerning additional levee fill and its cost being included in maintenance costs, table 5, page 38 of the GDM, is incorrect. The additional material needed for the 1.5 feet of final levee fill was previously provided in the estimated quantities and costs reflected in table 3, page 32 of the GDM.

b. Para 3. A meeting between personnel from LMVD and NOD was held in the New Orleans District on 14 December 1971 to discuss the design of cantilever I-type floodwalls. The I-type floodwalls for the New Orleans East back levee were evaluated considering the design guidelines established at the aforementioned meeting and it was found that the passive resistance along inclined planes on the protected side (I-wall penetration analysis presented in GDM) was less than the resistance developed by assuming shear failure along horizontal planes similar to the conventional "Method of Planes" analysis. Therefore, the tip penetrations presented in the GDM meet the design requirements for stability.

2. It is recommended that the proposed disposition of comments presented above be approved.

FOR THE DISTRICT ENGINEER:

Annual precipitation:	Maximum	85.73 inches
	Minimum	31.07 inches
	Average	60.58 inches
Hydraulic design criteria--tidal		
Design hurricane--Standard Project Hurricane (SPH)		
Frequency		1 in 200 years
Central Pressure Index (CPI)		27.5 inches of mercury
Maximum 5-min. average wind		100 m.p.h.
Levee		
Method of construction		Hydraulic lifts & shapeups
Levee length		4.4 miles
Elevation--varies		17.5[1,2]
Crown width		10 feet
Floodwall		
Type		I-wall & inverted T-wall
Length		2 miles
Elevation--varies		19.0-23.0[1]
Rights-of-way		
Permanent rights-of-way		385 acres
Construction easements		59 acres
Estimated first cost		
Levees and floodwalls		$ 9,517,000
Engineering and design		1,226,000
Supervision and administration		848,000
Relocations		496,000
Lands and damages		2,773,000
Total		$14,860,000

[1]See table 1, Location and type of protective works, for specific reach construction grades.

[2]Elevations herein are in feet referred to mean sea level unless otherwise noted.

LAKE PONTCHARTRAIN, LOUISIANA AND VICINITY
LAKE PONTCHARTRAIN BARRIER PLAN
DESIGN MEMORANDUM NO. 2 - GENERAL
SUPPLEMENT NO. 4
NEW ORLEANS EAST BACK LEVEE

PROJECT AUTHORIZATION

1. Authority.

a. Public Law. Public Law 298, 89th Congress, 1st Session, approved 27 October 1965, authorized the "Lake Pontchartrain, Louisiana and Vicinity," hurricane protection project, substantially in accordance with the recommendations of the Chief of Engineers in House Document No. 231, 89th Congress, 1st Session, except that the recommendations of the Secretary of the Army in that document shall apply with respect to the Seabrook Lock feature of the project.

b. House Document. The report of the Chief of Engineers dated 4 March 1964 printed in House Document No. 231, 89th Congress, 1st Session, submitted for transmission to Congress the report of the Board of Engineers for Rivers and Harbors, accompanied by the reports of the District and Division Engineers and the concurring report of the Mississippi River Commission for those areas under its jurisdiction. The report of the Board of Engineers for Rivers and Harbors stated: "For protection from hurricane flood levels, the reporting officers find that the most suitable plan would consist of a barrier extending generally along U. S. Highway 90 from the eastern-most levee to high ground east of the Rigolets, together with floodgates and a navigation lock in the Rigolets, and flood and navigation gates in Chef Menteur Pass; construction of a new lakeside levee in St. Charles Parish extending from the Bonnet Carre Spillway guide levee to and along the Jefferson Parish line; extension upward of the existing riprap slope protection along the Jefferson Parish levee; enlargement of the levee landward of the seawall along the 4.1 mile lakefront, and construction of a concrete-capped sheet-pile wall along the levee west of the Inner Harbor Canal in New Orleans; raising the rock dikes and landward gate bay of the planned Seabrook Lock; construction of a new levee lakeward of the Southern Railway extending from the floodwall at New Orleans Airport to South Point; enlargement of the existing levee extending from U. S. Highway 90 to the Gulf Intracoastal Waterway, thence westward along the waterway to the Inner Harbor Canal, together with riprap slopes along the canal; construction of a concrete capped sheet-pile wall along the east levee of the Inner Harbor Canal between the Gulf Intracoastal Waterway and the New Orleans Airport...."

c. BERH recommendation. The report of the Chief of Engineers stated: "...The Board [of Engineers for Rivers and Harbors] recommends authorization for construction essentially as planned by the reporting officers...I concur in the recommendation of the Board of Engineers for Rivers and Harbors."

2. Purpose and scope. This supplement presents the essential data, assumptions, criteria, and computations for developing the plan, design, and cost for the New Orleans East back levee in sufficient detail to provide an adequate basis for preparing plans and specifications for the floodwall and first lift levee construction without additional design analysis.

3. Local cooperation. The conditions of local cooperation pertinent to this supplement and as specified in the report of the Board of Engineers for Rivers and Harbors and concurred in by the report of the Chief of Engineers are as follows: "...That the barrier plan for protection from hurricane floods of the shores of Lake Pontchartrain...be authorized for construction,...Provided that prior to construction of each separable independent feature local interests furnish assurances satisfactory to the Secretary of the Army that they will, without cost to the United States:

"(1) Provide all lands, easements, and rights-of-way, including borrow and spoil disposal areas, necessary for construction of the project;

"(2) Accomplish all necessary alterations and relocations to roads, railroads, pipelines, cables, wharves, drainage structures, and other facilities made necessary by the construction works;

"(3) Hold and save the United States free from damages due to the construction works;

"(4) Bear 30 percent of the first cost, to consist of the fair market value of the items listed in subparagraphs (1) and (2) above and a cash contribution presently estimated at $14,384,000 for the barrier plan...to be paid either in a lump sum prior to initiation of construction or in installments at least annually in proportion to the Federal appropriation prior to start of pertinent work items, in accordance with construction schedules as required by the Chief of Engineers, or, as a substitute for any part of the cash contribution, accomplish in accordance with approved construction schedules items of work of equivalent value as determined by the Chief of Engineers, the final apportionment of costs to be made after actual costs and values have been determined;

"(5) For the barrier plan, provide an additional cash contribution equivalent to the estimated capitalized value of operation and maintenance of the Rigolets navigation lock and

channel to be undertaken by the United States, presently estimated at $4,092,000, said amount to be paid either in a lump sum prior to initiation of construction of the barrier or in installments at least annually in proportion to the Federal appropriation for construction of the barrier;

"(6) Provide all interior drainage and pumping plants required for reclamation and development of the protected areas;

"(7) Maintain and operate all features of the works in accordance with regulations prescribed by the Secretary of the Army, including levees, floodgates and approach channels, drainage structures, drainage ditches or canals, floodwalls, seawalls, and stoplog structures, but excluding the Rigolets navigation lock and channel and the modified dual purpose Seabrook Lock; and

"(8) Acquire adequate easements or other interest in land to prevent encroachment on existing ponding areas unless substitute storage capacity or equivalent pumping capacity is provided promptly;

"Provided that construction of any of the separable independent features of the plan may be undertaken independently of the others, whenever funds for that purpose are available and the prescribed local cooperation has been provided...."

INVESTIGATIONS

4. Project document investigations. Studies and investigations made in connection with the report on which authorization is based (H.D. No. 231, 89th Congress, 1st Session) consisted of: research of information which was available from previous reports and existing projects in the area; extensive research in the history and records of hurricanes; damage and characteristics of hurricanes; extensive tidal hydraulics investigations involving both office and model studies relating to the ecological impact of the project on Lakes Pontchartrain and Borgne; an economic survey; and preliminary design and cost studies. A public hearing was held in New Orleans on 13 March 1956 to determine the views of local interests.

5. Investigations made subsequent to project authorization. Surveys and studies made subsequent to project authorization for the New Orleans East back levee include:

a. aerial and topographic surveys of the New Orleans East back levee;

b. soils investigations including general and undisturbed type borings and associated laboratory evaluations;

c. detailed design studies for levee and gap closure construction including levee section stability determinations;

d. tidal hydraulic studies required for establishing design grades for protective works based on revised hurricane parameters furnished subsequent to project authorization by the U. S. Weather Bureau;

e. real estate requirements and appraisals;

f. cost estimates for levees, road ramps, and relocations.

6. Planned future investigations. Additional soils borings and tests will be made prior to each levee lift subsequent to the first. Design analyses, utilizing information obtained from the additional borings, will be made and preparation of plans and specifications for each lift will be based on these analyses. Also, bearing pile tests will be conducted to determine the pile lengths for construction.

LOCAL COOPERATION

7. Local cooperation requirements. The conditions of local cooperation as specified by the authorizing laws are quoted in paragraph 3.

8. Status of local cooperation. On 2 November 1965, the Governor of the State of Louisiana designated the State of Louisiana, Department of Public Works, as "...the agency to coordinate the efforts of local interests and to see that the local commitments are carried out promptly...." By State of Louisiana Executive Order dated 17 January 1966, the Board of Levee Commissioners of the Orleans Levee District was designated as the local agency to provide the required local cooperation for all portions of the Lake Pontchartrain, La. and Vicinity project in Orleans, Jefferson, St. Charles, and St. Tammany Parishes. Assurances covering all of the local cooperation required for the Lake Pontchartrain Barrier Plan were requested through the Department of Public Works from the Board of Levee Commissioners of the Orleans Levee District on 21 January 1966, and a satisfactory act of assurances, supported by a resolution of the Board of Levee Commissioners of the Orleans Levee District dated 28 July 1966, were approved and accepted on behalf of the United States on 10 October 1966. The principal officers currently responsible for the fulfillment of the conditions of local cooperation are as follows:

Mr. C. H. Downs, Director
State of Louisiana
Department of Public Works
Baton Rouge, Louisiana 70804

Mr. Edward Lennox, President
Board of Levee Commissioners of the
Orleans Levee District
Room 200, Wild Life and Fisheries Building
418 Royal Street
New Orleans, Louisiana 70130

9. Views of local interests. The Board of Levee Commissioners of the Orleans Levee District represents local interests. The plan presented herein was coordinated in detail with the Board's engineering staff and bears the approval of the Board. The intention and capability of the local sponsor to provide the required non-Federal contribution for the entire Lake Pontchartrain Barrier Plan, presently estimated at $67,162,000, have been amply demonstrated; in fact, considerable work which ultimately will be incorporated into the overall project has already been accomplished by the sponsor.

LOCATION OF PROJECT AND TRIBUTARY AREA

10. Project location. The New Orleans East back levee segment of the Lake Pontchartrain, Louisiana and Vicinity hurricane protection project, as shown on plate 1, is located in southeastern Louisiana along the north bank of the GIWW (Gulf Intracoastal Waterway). The project area covered in this memorandum is located in Orleans Parish.

11. Tributary area. The tributary area of Lake Pontchartrain varies in character from flat tidal marsh at or near sea level to upland areas of significant relief with natural ground elevations as high as 250 feet above mean sea level. Runoff from within the project area is disposed of into either Lake Borgne or Lake Pontchartrain, generally by pumping, although some developed areas located on alluvial ridges in St. Charles, St. Bernard, and St. Tammany Parishes are drained by gravity. In addition to runoff from the project area, Lake Pontchartrain receives the runoff of 4,700 square miles located to the north and west of the lake. During major floods on the Mississippi River and its tributaries, floodflows may be diverted from the Mississippi River to Lake Pontchartrain through the Bonnet Carre' Spillway, a controlled overbank floodway constructed under the Flood Control, Mississippi River and Tributaries project.

PROJECT PLAN

12. General. The project, as shown on the flyleaf map, consists of two separate and distinct major features--the Chalmette Area Plan and the Lake Pontchartrain Barrier Plan. This memorandum is concerned only with a segment of the latter, the New Orleans East back levee. The overall Lake Pontchartrain Barrier Plan is described in GDM, Citrus Back Levee, approved 29 December 1967.

13. New Orleans East back levee. This levee is located on the north bank of the GIWW and extends from a junction with the Citrus Back Levee to the west end of the Chef Menteur Pass barrier levee. Under the project plan covered herein, the first 2 miles will consist of floodwall (I-type and inverted T-type) constructed to an elevation of 20.0 feet in an enlarged levee. The remaining 4.4 miles will consist of enlarging and raising the existing earth levee from its elevation of approximately 12 feet to a new net elevation of 17.5 feet and providing foreshore wave-wash protection on the flood side of the levee. The plan also provides for constructing four T-walls and eight gate closures; modifying eight road ramps, eight pipeline and four electric cable crossings, and the floodwall at an existing pumping station. The plan of improvement as described above is shown in general on plates 1 through 4 and is detailed on subsequent plates.

DEPARTURES FROM PROJECT DOCUMENT PLAN

14. Departures from project document plan. The net grades of the protective works presented herein were revised upward in accordance with the results of tidal hydraulic studies utilizing more severe hurricane parameters developed by the U. S. Weather Bureau subsequent to project authorization. Results of these studies relative to the protective works described herein are contained in "Design Memorandum No. 1, Hydrology and Hydraulic Analysis, Part I Chalmette," approved 27 October 1966. The revised net grades of the New Orleans East Back Levee are elevation 17.5 for levees and elevation 19.0 for most of the floodwalls except at the existing drainage pumping station where wave runup dictates a net grade of 23.0. The results of similar studies contained in "Design Memorandum No. 1, Hydrology and Hydraulic Analysis, Part III - Lakeshore," approved 25 February 1969, indicate that the entire South Point to GIWW reach will now have to be raised. Therefore, the U. S. Highway 90 to GIWW segment will be deleted from the New Orleans East back levee design and included in the South Point to GIWW design. This means that the structure for the Louisville and Nashville Railroad will also be covered in the South Point to GIWW design memorandum.

HYDROLOGY AND HYDRAULICS

15. General. The Hydrology and Hydraulic Analysis design memorandum for the Lake Pontchartrain Barrier Plan was presented in a series of three separate reports entitled Design Memorandum No. 1 and subtitled Part I - Chalmette, Part II - Barrier, and Part III - Lakeshore, respectively. Part I - Chalmette was approved on 27 October 1966; Part II - Barrier was approved on 18 October 1967; and Part III - Lakeshore was approved on 6 March 1969. These documents present detailed descriptions and analyses of the tidal hydraulic methods and procedures used in tidal hydraulic design of the features for the plan, and include the essential data, assumptions and criteria used, and results of studies which provide the bases for determining surges, routing, wind tides, runup, overtopping, and frequencies. All basic hydraulic information required for design of the New Orleans East back levee is included in Part I - Chalmette.

16. Design elevations. The design hurricane for the New Orleans East back levee is the SPH (Standard Project Hurricane) having a return frequency of once in about 200 years; a central pressure of 27.5 inches of mercury; a maximum 5-minute average wind velocity of 100 m.p.h. 30 feet above the surface at a radius of 30 nautical miles from the center; a forward speed of 11 knots; and progress along a track critical to the area of interest. Detailed information on the design hurricane is presented in "Design Memorandum No. 1, Hydrology and Hydraulic Analysis, Part I - Chalmette." The design hurricane would produce a maximum wind tide level of 13.0 feet along the New Orleans East back levee. Design elevations for protective structures and pertinent information relative thereto are as follows:

Type structure	Avg. depth	Significant Wave (H_s)	Wave period (T)	Runup	Ultimate or design elev. of protective structures
	ft.	ft.	sec.	ft.	ft.
Levee	12.7	4.9	5.5	4.5	17.5
Floodwall	12.7	4.9	5.5	6.0	19.0
Floodwall at pump station	12.7	4.9	5.5	10.0	23.0

17. Drainage. Inasmuch as an existing system of levees completely encompasses the New Orleans East area, as shown on the flyleaf map, interior drainage is required to prevent flooding of the developed areas as a result of direct rainfall. Local interests have provided the required drainage. Existing pump discharge pipes will be modified to pass through a new floodwall.

The plan presented herein consists of the raising or enlargement of the existing New Orleans East back levee and will not interfere with the existing interior drainage facilities.

GEOLOGY

18. Physiography. The project area is located within the Central Gulf Coastal Plain on the eastern flank of the Mississippi River Deltaic Plain. Physiographic features of the study area include: marshes, natural levees, abandoned distributaries, and many small, shallow ponds. Relief in the area is very slight with a maximum variation of 8 feet between remnant alluvial ridge (Gentilly-Bayou Sauvage Ridge) and the adjacent marshlands. Maximum elevations of 2 are found along the crest of the remnant alluvial ridge which trends east-northeastward through the project area. Minimum elevations of -4 to -6 are found in areas of artificially-drained marshland in the north and west sections of the project area.

19. General geology. For this project, only the geologic history at the close of and since the Pleistocene Epoch is relevant. Near the end of that time, sea level was about 450 feet below its present level and the project area was a flat, highland plain bordering on the northeast of the entrenched Mississippi River. During that period, the exposed Pleistocene surface was subjected to dessication and weathering. Sea level then began to rise and an extensive sand beach was formed which extended in a northeast direction generally parallel to, and to the northwest of the Bayou Sauvage Ridge. When sea level reached its present stand about 5,000 years ago, the Mississippi River began to migrate laterally, back and forth, across the alluvial valley. Sedimentation began in the project area 4,000 to 4,500 years ago when the Mississippi River occupied the Cocodrie Course, and the sand beach was buried beneath finer alluvial sediments. About 3,500 years ago, the river shifted its course to the western part of the delta and occupied the Teche Course until approximately 2,800 years ago. During this period, the project area was subjected to erosion and subsidence. About 2,800 years ago, the Mississippi shifted eastward to the La Loutre or St. Bernard Course and sedimentation again took place in the project area. At this time, Bayou Metairie-Bayou Sauvage, a major distributary of the Mississippi River, coursed through the area and left the remnant alluvial ridge that extends east-northeastward through the project area. The Mississippi abandoned the La Loutre Course about 1,500 years ago and occupied the Lafourche Course to the west. Sedimentation did not occur again in the project area until the river occupied its present course approximately 1,200 years ago. However, no large distributaries flowed into the area and the center of deposition shifted south of the project area. Levees constructed along the Mississippi

River have eliminated seasonal flooding of the lands adjacent to the river and at present no sediments are being introduced into the project area.

20. Subsidence. The project area lies in a region of active subsidence and downwarping which has been occurring since the close of the Pleistocene Epoch. The Pleistocene surface has been downwarped toward the south and west from elevation zero at the Pleistocene outcropping north of Lake Pontchartrain to about elevation -500 near the edge of the continental shelf, about 80 miles south of New Orleans. The overall rate of regional subsidence has been about 0.39 foot per century. In addition, large settlements of the ground surface have occurred in the drained marsh and swampland areas, a result of the shrinking of highly organic soils as the land was reclaimed and the water table lowered.

21. Investigations performed. Sufficient general type and undisturbed borings were made in conjunction with this segment of the project. In addition, borings and geologic information from other sources were available for interpretation of the physiography, subsurface, and foundation conditions of the area.

22. Foundation conditions. The subsurface, as indicated by the boring logs shown on plates 5 and 6, consists of Recent deposits averaging 43-47 feet in thickness except in the vicinity of station 750+00 where the Recent deposits increase in thickness to about 60 feet. Underlying the Recent materials are deposits of Pleistocene age. The Recent consists predominantly of very soft to soft interdistributary clays with lenses and layers of silt, with the exception of the area between stations 664+77.3 and 740+00. The subsurface from stations 664+77.3 to 693+00 consists of fill material of soft to medium clays with large layers and areas of silt, silty sand, and sand underlain by soft alternating intradelta clays and silts with layers and areas of silt, silty sands, and sands. The subsurface between stations 693+00 and 740+00 consists of fill material of soft to medium clays mixed with large layers of silts, silty sands, and sands underlain by abandoned distributary silts, silty sands, and sands. Underlying the interdistributary, intradelta, and abandoned distributary sediment are medium to stiff prodelta clays to the general vicinity of station 960+00. The prodelta clays rest unconformably on the stiff Pleistocene clays between stations 664+77.3 and 850+00 and vary in thickness from 6 feet at station 575+00 to 20 feet at station 850+00. From stations 850+00 to 960+00 the prodelta clays are underlain by a thin stratum of nearshore sands with shells and shell fragments. In the vicinity of station 960+00, the prodelta pinch-out and the interdistributary deposits directly overlie nearshore material. Stiff Pleistocene clays underlie the nearshore deposits for their entire length.

23. Mineral resources. Oil and gas production occur in the general area but not in the immediate vicinity of the project. However, this project will not adversely affect future exploration and production of these natural resources, nor will future exploration and production affect the project.

24. Sources of construction materials. A design memorandum, "Lake Pontchartrain, Louisiana and Vicinity, DM No. 12, Sources of Construction Materials," approved 30 August 1966, has been prepared listing sources of sand, gravel, shell, and rocks.

25. Conclusions. Because of the low shear strengths and compressibility of some of the Recent sediments, stability and settlement will be major problems. Also, the proximity of sand and silt layers to the surface between stations 693+00 and 740+00 may cause seepage and uplift problems.

SOILS AND FOUNDATIONS INVESTIGATION AND DESIGN

26. General. This report covers the soils and foundations investigations and design for the New Orleans East back levee and floodwalls extending from the eastern end of the Citrus back levee along the east bank of the Michoud Canal and along the north bank of the GIWW to the western extremity of the Chef Menteur Pass barrier levee. Soils and foundations coverage for other features of the Lake Pontchartrain Barrier Plan are included or will be included in the various supplements to the design memorandum.

27. Field investigations. Undisturbed borings 5 inches in diameter extending to approximate elevation -95.0 were made at seven locations along the existing levee alignment (stations 697+20 at levee toe, 715+50 at C/L levee, 815+00 at C/L levee, 875+55 at C/L levee and levee toe, 939+44 at C/L levee and levee toe). Logs of the undisturbed borings are shown on plates 7 through 13. Settlement analyses utilizing data from the undisturbed borings are shown on plates 14 and 15. General type core borings, 1 7/8-inch I.D., extending to approximate elevation -60.0 were made at 20 locations along the levee alignment. Logs of the general type borings and related data are shown on plates 5 and 6. Seventeen general type core borings, 1 7/8-inch I.D., extending to elevation -50.0 in the Michoud Canal and to elevation -70.0 in the GIWW were made in the recommended borrow areas adjacent to the levee and floodwall alignment. The logs of the borrow borings and related data are shown on plates 16 and 17. The locations of the borings are shown in plan on plates 2, 3, and 4.

28. Laboratory tests. Visual classifications were made on all samples obtained from the borings. Water content determinations were made on all cohesive soil samples. Unconfined compression

(UC), unconsolidated-undrained (Q), consolidated-undrained (R), and consolidated-drained (S) shear tests, and consolidation (C) tests were performed on representative soil samples from the undisturbed borings. Liquid and plastic limits were determined for tested samples. Results of laboratory tests are shown on plates 18 through 24.

29. Soil conditions. The subsurface along this project consists generally of 10 to 15 feet of artificial levee fill overlying 40 to 60 feet of Recent deposits of clays, silts, and sands which are underlain by a Pleistocene deposit encountered at approximate elevations -40.0 to -60.0. A generalized soil and geologic profile is shown on plates 25 and 26. The subsurface soils above the Pleistocene deposit which directly affect the design of this project consist generally of the following:

a. Station 664+77.3 to station 740+00. This reach is composed of soft clay down to elevation 1.0 underlain by a layer of silty sand to elevation -6.0, which overlies a layer of silt extending down to elevation -10.0, underlain by a soft clay layer with organic matter down to elevation -18.0, which overlies a layer of silt extending down to elevation -26.0, underlain by a fine sand layer down to elevation -36.0, which overlies a layer of medium clay extending down to elevation -50.0 at the top of the Pleistocene formation.

b. Station 740+00 to station 840+00. This reach is composed of soft to medium clay down to elevation -46.0, underlain by a silty sand layer down to elevation -51.0 at the top of the Pleistocene formation.

c. Station 840+00 to station 892+00. This reach is composed of medium clay with areas of soft to stiff clay and silt lenses down to elevation -50.0 at the top of the Pleistocene formation.

d. Station 892+00 to station 1006+59.2. This reach is composed of soft clay with organic matter and silt lenses down to elevation -45.0 at the top of the Pleistocene formation.

30. Water contents of soils. The ranges of water contents for organic clays, clays, silts, and Pleistocene clays are as follows: organic clays, 100 to 600 percent; clays, 30 to 80 percent; silts, 20 to 40 percent; and Pleistocene clays generally less than 45 percent.

31. Design and construction problems. The low shear strength and highly compressible Recent foundation clays, the utilities which cross the existing levee, and the dynamic and static wave forces on the floodwalls produce major design and construction problems outlined as follows:

a. types of protective works

b. stability

c. floodwalls

d. settlement

e. sources of fill material

f. method of construction

g. erosion protection

32. Types of protective works. Floodwalls will be used between station 664+73.3 and station 772+00 where the proximity of the existing plant facilities to the alignment and comparisons of costs to I-type floodwalls preclude the use of a conventional levee. Inverted T-type floodwalls, supported on bearing piles, will be utilized across the discharge pipes at the pumping station located in the vicinity of station 876+87 (see plate 56). I-type floodwalls will tie this T-type floodwall to the levee. A conventional earthen levee will be used along the remainder of the project. The existing earthen levee will be enlarged with hydraulic fill placed in lifts.

33. Stability analyses.

a. First lift hydraulic fill, retaining dikes, and I-wall levees. The slopes and locations of the retaining dikes, the slopes and heights of the hydraulic fill lifts, and the slopes and berm distances of levees with I-type floodwalls were designed (using cross sections representative of existing conditions) for the following conditions:

(1) hurricane floodwater to the elevation of the existing levee on the flood side and natural ground water to elevation zero on the protected side and anticipated failure towards the protected side (see plates 48 and 50)

(2) water at elevation zero on both sides of the levee and anticipated failure toward the adjacent canals, i.e., the GIWW and the Michoud Canal (see plates 33, 34, 35, 41, 42, 43, 44, 47, 49, 51, 52, and 57)

(3) For the stability analyses of levees with I-type floodwalls, the water elevation was considered to be equal to the top of the design hurricane wave on the flood side and equal to elevation zero on the protected side with anticipated

failure toward the protected side (see plates 36, 37, 38, and 59). In the reach between station 664+73.3 and station 755+00, uplift forces could develop in the sand and silt strata which extend and are opened to the Michoud Canal. Because of the close proximity of the levee to the Michoud Canal, the loss in pressure head between the canal and the protected side toe of the levee was considered to be zero. Accordingly, the uplift forces used for design were based on the total head differential between WTL (el. 13.0) on the flood side and ground water (el. 0.0) on the protected side and anticipated failure towards the protected side (see plate 36).

b. Ultimate earthen levee. The slopes and berm distances for the recommended ultimate levee were designed for the following conditions:

(1) water at elevation zero on both sides of the levee and anticipated failure toward the adjacent GIWW (see plates 53, 55, 61, 64, and 65)

(2) water to the WTL (el. 13.0) on the flood side and natural ground water to elevation zero on the protected side and anticipated failure toward the protected side (see plates 54, 58, and 60)

c. Method and criteria used. The stabilities were determined by the method of planes using the design (Q) shear strengths shown on plates 7 through 13 and applying a minimum factor of safety with respect to strength of approximately 1.3.

d. Borrow pit. The minimum distance a borrow pit with 1 on 2 slopes to elevation -100.0 could be located from the levee C/L was determined by applying a minimum factor of safety with respect to strength of approximately 1.5. The stability of the 1 on 2 slopes of the borrow pit was determined by applying a minimum factor of safety with respect to strength of approximately 1.3.

34. I-type floodwall stability.

a. Steel sheet piles. The stability and the required penetrations of the steel sheet piles below the earth surface were determined by the method of planes using the consolidated-drained (S) shear test result, i.e., $c=0$, $\phi_a=23°$. A factor of safety of 1.25 was applied to the friction angle as follows: $\phi_d = \tan^{-1} \frac{\tan \phi \text{ available}}{\text{factor of safety}}$. The developed friction angle was used to determine K_A and K_P values as follows: $K_A = \tan^2 (45° - \frac{\phi d}{2})$; $K_P = \tan^2 (45° + \frac{\phi d}{2})$. Using K_A and K_P values and the effective

unit weights, net horizontal water and earth pressure diagrams were determined for movement toward each side of the sheet pile. The sum of the horizontal forces on the protected side was equated to the sum of the horizontal forces on the flood side for various tip penetrations. At these penetrations, summations of overturning moments were determined. The required depths of penetration were established as those where the summation of moments were equal to zero. These analyses are shown on plates 39, 46, and 62.

b. Application of wave forces. The results of tidal hydraulic analyses indicate that the floodwalls will be subjected to the pressures and forces imparted by broken and breaking waves. In the design of the floodwalls, the wave effect was applied as a line force acting through the centroid of the dynamic wave pressure distribution diagram (see plate 39).

c. Governing design case. Sufficient (Q) stability analyses were performed to confirm that the (S) case governed for design.

35. Inverted T-type floodwall. Inverted T-type floodwalls on bearing piles will be utilized in lieu of I-type floodwalls at overhead utility crossings, gate monoliths, and at the pumping station. The height of the wall above the ground and the magnitude of the dynamic wave force at the pumping station render the use of I-wall unsatisfactory. A steel sheet pile cutoff will be used beneath the T-walls to provide protection against seepage. A diagrammatic presentation of the net pressure on the sheet pile cutoff is shown on plates 40, 46, and 62. The net pressure diagram along the sheet pile cutoff was determined as follows:

a. Method and criteria used. Conventional stability analyses by the method of planes, utilizing a factor of safety of 1.3 incorporated in the soil strength parameters, were performed to determine the stability against rotational failure. The use of a factor of safety of 1.3 is also recommended by Mr. Gregory P. Tschebotarioff in chapter 5 of "Foundation Engineering," edited by G. A. Leonards and dated 1962. The analyses were performed at 1-foot intervals with the active wedge located at the flood side edge of the structure and the passive wedge located at the protected side edge of the structure.

b. Assumption of value for resistance at base of structure. The assumption was made that the value of (R_B) at the bottom of the base of the structure was zero.

c. Driving force-magnitude. For each analysis the net driving force, i.e., $(D_A-D_P)-(R_A+R_B+R_P)$ was determined. The value of D_A included the weight of water between the tail water elevation and the WTL elevation located above the active wedge.

d. Driving force-assumption. The assumption was made that the net driving force above the bottom of the base of the structure was carried by the structure.

e. Pressure diagram derivation. Considering driving (D_A) positive and all resistance (D_P, R_P, R_B, and R_A) negative in the expression $\Sigma D = D_A - (D_P+R_P+R_B+R_A)$ and using the method of planes stability analyses, the ΣD was determined by assuming failure at the bottom of the base of the structure and at each foot in depth thereafter. The value of the algebraic difference in ΣD, between 1-foot intervals, was used to develop the pressure diagram. If the incremental difference were negative, the pressure diagram indicates an available horizontal resistance in excess of that required; and if the incremental difference were positive, the pressure diagram indicates an unbalanced horizontal pressure in excess of the available soil resistance.

f. Results of sheet pile cutoff analysis. The net pressure diagrams presented on plates 40, 46, and 62 indicate that the total available horizontal resistance is in excess of the total horizontal waterload on the sheet pile cutoff. Therefore, no lateral load acting on the sheet pile cutoff is transmitted to or is required to be carried by the bearing piles.

36. Foundations for T-type floodwalls.

a. Design considerations and criteria. Design compression and tension capacities versus tip elevations were developed for 12-inch square concrete piles. The piling is to be used to support the T-type walls. Design data were determined for the (Q) and (S) shear strengths. In compression, a factor of safety of 1.75 was applied to the shear strengths, and a conjugate stress ratio $(K_o) = 1.0$ was used in the (S) case for determining the normal pressure on the pile surface. In tension, a factor of safety of 2.0 was applied to the shear strengths and a conjugate stress ratio $(K_o) = 0.70$ was used in the (S) case. Further, pile design loads versus tip elevations are presented for 14-inch and 16-inch square concrete piles for the (Q) case only, inasmuch as the (Q) case governed for design. The results of pile design loads versus tip elevations analysis and bearing pile subgrade moduli are shown on plate 63. Pertinent data relative to floodwalls (and levees) are shown in table 1. The stabilities of the floodwalls, relative to failure of the soils foundation, were determined using the design (Q) shear strengths. The results of the stability analyses are shown on plates 33, 34, 36, 37, 38, and 45.

TABLE 1

LOCATION AND TYPE OF PROTECTIVE WORKS

Station location	Construction Grades feet m.s.l. Wall	Levee	Sheet Pile Tip Elev. ft.m.s.l. I-wall	T-wall	Base Elev. ft.m.s.l. T-wall
664+73.3 to 697+97.95	20.0	13.0	-5.0	-	-
697+97.95 to 698+27.95	20.0	-	-	-5.0	8.5

877+72.0 to 878+12.0	23.0	-	-	-6.0	2.0
878+12.0 to 879+09.0	20.0	13.0	-6.0	-	-
879+09.0 to 879+27.0	20.0	13.0 to 17.5	-6.0	-	-
879+27.0 to 879+32.0	20.0	17.5	-6.0	-	-
879+32.0 to 1006+59.2	-	17.5	-	-	-

b. Test piles. During construction, bearing pile tests will be conducted at two sites (in the vicinity of boring 3-EU and in the vicinity of boring 12-EU) for selecting the pile lengths to be used for construction. Three 12-inch square concrete piles of different lengths will be driven at each site. The elevations of the tips of the test piles will be -55, -60, and -65. The intermediate length pile will be tested in compression. If test results show that the pile can safely carry twice the design load, the pile will be tested in tension. If the intermediate length pile fails before the required capacity is attained in compression, the long pile will be tested in compression and in tension. If the intermediate pile safely carries compression loads significantly in excess of that required, the short pile will be tested in compression and in tension. Pile maximum test loads will be 25 tons in tension and 70 tons in compression. The test piles meeting the above criteria will be left in place.

37. Settlement.

a. General. Estimates of settlement beneath the levee were made based on consolidation test data from the undisturbed borings. Settlement analyses consisted of developing curves of: (1) void ratio (e) and compression index C_c versus depth; (2) load ($\overline{P}$) versus void ratio (e); (3) load ($\overline{P}$) versus settlement (ρ); and (4) percent consolidation ($U_Z\%$) versus time (t) for the strata in which consolidation will occur. A presentation of settlement analyses, applicable to undisturbed borings 2-EUT and 3-EU is shown on plates 14 and 15.

b. Adjustments. The computed settlement was increased by 25 percent to include the effect of possible lateral plastic displacement of the foundation. The determination of 25 percent was based on information contained on plate 70. The quantity of hydraulic fill was increased 20 percent and the quantity of hauled fill was increased 15 percent to compensate for consolidation and shrinkage of the fill. The settlements estimated for levees containing I-type floodwalls indicate that the proposed wall construction grade (el. 20.0) is sufficient to provide protection to ultimate grade (el. 19.0). To reduce differential settlement of the concrete portion of the floodwalls tying into the levees, the concrete capping will be performed subsequent to construction of the levee. Estimated ultimate settlements of the earth levees are shown in table 2.

TABLE 2

SETTLEMENT OF LEVEE

Lift No.	Type	Elevation (ft.m.s.l.) Crown	Base	Settlement (ft) Base
		Stations 664+77.3 to 740+00		
I-wall in Levee		13.0	11.0	Negligible
		Stations 7400 to 840+00		
1	Hyd fill	10.0	10.0	0
2	Hyd fill	9.8	9.8	0.2
3	Shape	17.5	9.5	0.5
	Ultimate	17.5	8.0	2.0
		Stations 840+00 to 892+00		
1	Hyd fill	10.0	10.0	0
2	Hyd fill	9.8	9.8	0.2
3	Shape	17.5	9.5	0.5
	Ultimate	17.5	8.0	2.0
		Stations 892+00 to 1006+59.2		
1	Hyd fill	11.0	11.0	0
2	Hyd fill	10.8	10.8	0.2
3	Shape	17.5	10.5	0.5
	Ultimate	17.5	8.5	2.5

38. Sources of fill materials. The levee will be constructed of hydraulic fill obtained from adjacent borrow areas located in the GIWW and the Michoud Canal. The borrow areas are composed of Recent deposits above elevation -60.0 and Pleistocene deposits below elevation -60.0. In order to utilize the maximum amount of Pleistocene soils and the minimum amount of Recent deposits, borrowing will be in the deepest portion of the borrow areas and to the maximum practicable depth (approximately el. -80.0). Logs of borings taken in these borrow areas are shown on plates 16 and 17. A generalized soil and geologic profile of these areas is shown on plates 27 and 28. The material for construction of the levee to elevation 13.0 in the floodwall areas will be obtained from a borrow area in the bottom of Lake Pontchartrain along the north shore. The borrow material from the lake, consisting of stiff Pleistocene clays, will be transported to the project on

barges. See plates 66 and 67 for the locations and soil boring sections of the borrow area in the lake. See plate 68 for compaction curves of material from the Lake Pontchartrain borrow area.

39. Method of construction.

a. Earthen levee. Construction of the levee will be by conventional successive hydraulic lifts on each side of the existing levee, utilizing adjacent borrow from the GIWW and Michoud Canal, and by shaping of the in-place hydraulic fill (see plates 30, 31, and 32). The waste water from the flood side will be returned through spill boxes directly into the GIWW. The land side waste water will be returned by the contractor, at intermediate points, over the levee and into the GIWW.

b. Earthen levee with I-type floodwall. The levee will be constructed by cast and haul methods utilizing borrow from Lake Pontchartrain. (See plates 29 and 46.) Subsequent to construction of the levee, steel sheet piling will be driven in the existing levee followed by placement of the concrete for the wall.

40. Erosion protection. Due to the short duration of hurricane flood stages and the resistant nature of the clayey soils, no erosion protection is considered necessary on the levee slopes. However, foreshore protection will be provided along the top of the canal bank along the GIWW to provide protection against erosion from boat traffic generated waves. The foreshore protection will consist of a 2-foot layer of riprap on a three-fourths-foot thick shell blanket and extending from elevation 3.0 to -3.0 (see plate 70).

41. Settlement observations. Settlement observations will be made along the floodwalls promptly after construction and yearly thereafter until settlement is essentially complete. Profiles and sections will be taken along the entire alignment during construction of each stage of the levees and berms, and annually after completion of the last stage until settlement is essentially complete. Reference markers will be installed along the structure walls to obtain data relative to vertical and lateral movement.

42. Additional soils borings and tests. Additional soils borings and tests will be made prior to each lift subsequent to the first. Design analyses, utilizing the information obtained from the additional borings, will be made and preparation of plans and specifications for each lift will be based on these analyses. The analyses will be submitted for review either prior to or concurrent with submission of the plans and specifications, as appropriate.

OTHER PLANS CONSIDERED

43. Recommended construction plan. In general, the recommended construction plan consists of two main segments. One segment, next to existing facilities, is to be a floodwall built on a levee enlarged by haul fill. The other segment is an existing levee which will be enlarged by hydraulic lifts and subsequent shapeups.

44. Alternate construction plans adjacent to existing facilities. Existing development along the Michoud Canal is such that the construction of a levee section enlarged to ultimate grade would require relocation of major portions of the $12-$25 million dollar facilities. This analogy results from the fact that the existing levee cannot be extended toward the water due to the absence of available land. Further, a landside extension to satisfy width requirements is restricted by the proximity of the plant facilities mentioned above. These circumstances dictated that some type of floodwall be erected in the vicinity of Michoud Canal. A comparison of ultimate section levee to I-wall differential costs for this reach follows:

Alternate	Total Cost
Levee	$59,468,000
I-wall	$ 2,329,000

Since the cost of T-type floodwall is approximately $350 per linear foot and I-type floodwall costs approximately $150 per linear foot, the I-type wall was used for the entire length in question except in special instances, at gates, existing overhead installations, etc., where only a T-type wall was practical. Of course, the only rational solution at the existing pumping station was to construct an adequate wall system. The alternative of relocating and reconstructing the entire station to accommodate a new levee section was out of the question due to the excessive costs involved.

45. Alternate construction plans for raising levee. For that portion of the project along the GIWW where there is no existing development, the existing levee is to be raised to ultimate grade and section. The alternate of constructing a floodwall in lieu of increasing the levee section was considered. However, as the following preliminary costs show, the levee option is more economical:

Alternate	Total Cost
Levee	$ 6,060,000
I-wall	$ 6,566,000

The method of hydraulically positioning the material needed for raising the levee was more practical than hauling the material for various reasons: (1) access in this reach is limited; and (2) the haul fill would be more costly by virtue of the fact that it would have to be excavated from the lake and then barge transported to the site.

ACCESS ROADS

46. Access roads. Main access to the project area is provided by U. S. Highway 90 and Intracoastal Drive (see plate 1). The floodwall along Michoud Canal can be reached by the use of existing local roads through the industrial plants adjacent to Intracoastal Drive. Access to that portion of the levee between the pumping station and Michoud Canal is by means of an existing shell road extending to the station from the end of Intracoastal Drive. Beyond the pumping station to the end of the project (station 1006+59.2) the top of the existing levee can serve for project vehicular travel. Access for floating plant as required by construction will be by the MR-GO, the GIWW, and the Michoud Canal.

STRUCTURAL DESIGN

47. Criteria for structural design. The structural design presented herein complies with standard engineering practice and criteria set forth in Engineering Manuals for Civil Works construction published by the Office, Chief of Engineers, subject to modifications indicated by engineering judgment and experience to meet local conditions. The floodwall and levee composite design is similar to the design presented in the Citrus Back Levee GDM. (See Lake Pontchartrain, La. & Vicinity, Lake Pontchartrain Barrier Plan, DM No. 2 - General, Citrus Back Levee, dated 21 August 1967 and approved 29 December 1967.)

48. Basic data. Basic data relevant to the design of the protective works are shown in the following table:

		Elevations ft. m.s.l.
a.	Water elevations	
	Wind tide level	13.0
	Landside of floodwall	0.0
b.	Floodwall gross grades	
	I-wall, T-wall, and gates (Sta. 664+77.3 to Sta. 772+00)	20.0
	Levee for I-wall	13.0
	I-wall (Sta. 874+42 to Sta. 875+42 and Sta. 878+32 to Sta. 879+32)	20.0
	T-wall (Sta. 875+42 to Sta. 878+32)	23.0

c. Unit Weights

	Lb. per cu.ft.
Water	62.5
Concrete	150
Steel	490
Earth	See plates 44 through 46

d. Design loads

(1) Earth pressures (lateral)
See figures B-1 through B-3

(2) Windloads 50 p.s.f.

(3) Water loads. See figures B-4 and B-39

(4) Wave characteristics

	Michoud Canal	Existing pumping sta.
(a) Wind speed, U	75 m.p.h.	75 m.p.h.
(b) Fetch length, F	5 miles	5 miles
(c) Significant wave height, H_s	4.94 feet	4.94 feet
(d) Wave period, T	5.45 seconds	5.45 seconds
(e) Depth at toe of levee, d_t	13 feet	12.73 feet
(f) Structural design wave height, H	8.25 feet	6.28 feet
(g) Structural design wave height, H_{10}	6.28 feet	5.2 feet
(h) Wind tide level elevation	13.0	13.0

49. Allowable working stresses. The allowable working stresses for concrete and structural steel are in accordance with those recommended in "Working Stresses for Structural Design," EM 1110-1-2101 dated 1 November 1963 and amendment 1 dated 14 April 1965. The basic minimum 28-day compressive strength for concrete will be 3,000 p.s.i., except for prestressed concrete piling where the minimum will be 5,000 p.s.i. Steel for steel sheet piling will meet the requirements of ASTM A328-69, "Standard Specification for Steel Sheet Piling." For convenient reference, pertinent allowable stresses are tabulated below:

Reinforced concrete

f'c	3,000 p.s.i.
fc	1,050 p.s.i.
v_c (without web reinforcement)	60 p.s.i.
v_c (with web reinforcement)	274 p.s.i.
fs	20,000 p.s.i.
Minimum area steel	0.0025 bd sq.in.
Shrinkage and temperature steel area	0.0020 bt sq.in.

Structural steel (ASTM A-36)

Basic working stress	18,000 p.s.i.

50. Location and alignment. The new floodwall will tie into an existing floodwall (see Citrus Back Levee GDM) at station 664+73.3 and follow an existing levee along the Michoud Canal to station 753+00 then along the GIWW to station 772+00. See plate 2. From station 772+00 to station 1006+59.2 the flood protection will consist of an earth levee except for a short length of I-wall and T-wall in the vicinity of an existing pumping station at station 876+87. See plate 3.

51. Foundation. The results of subsurface exploration, soils tests, and foundation studies are presented in previous paragraphs. Locations of general type borings are shown on plates 2 through 4. The general type boring logs are shown on plates 7 through 10. Undisturbed boring data are shown on plates 11 through 17.

52. I-type floodwall. All of the floodwall between stations 664+73.3 and 772+00 will be concrete I-wall except for four T-wall monoliths and eight gate monoliths. I-wall will also be constructed in the vicinity of an existing pumping station between stations 874+42 and 875+42 and between stations 878+32 and 879+32. The I-wall will consist of sheet piling driven into an enlarged levee section. The upper portion of the sheet piling will be capped with concrete. The sheet piling will be driven to the required depth with 1 foot of the sheet pile extending above the levee crown. The concrete portion of the floodwall will extend from 2 feet below the levee crown to elevation 20.0, the top of the floodwall. See plate 71.

53. I-wall loading cases. In the design of the I-wall, two loading cases were considered:

Case I - Static water to the WTL, elevation 13.0, 1.5 factor of safety in the soil, no dynamic wave force.

Case II - Static water to top of broken wave, 1.25 factor of safety in the soil, dynamic wave load from broken wave.

Since Case II proved to be the most critical, only the computations for this case are shown (see figures B-1 through B-3).

54. Joints. Expansion joints in the I-wall will be spaced 30 feet apart at sheet pile interlocks. Where the I-wall joins the T-wall, the deflection of the I-wall will produce a lateral displacement. To take care of this displacement, a special seal located in a notch in the I-wall has been designed to prevent water from flowing through this joint. See plates 71 and 72 for details.

55. T-type floodwall--vicinity of Michoud Canal. T-walls will be constructed below three aerial crossings and adjacent to a stiff-leg derrick. See plates 73 through 75 for the location and length of each T-wall. These walls were designed assuming the sheet pile cutoff to be impervious and under the following load conditions:

Case I - Water at WTL el. 13.0, no wave, no wind.

Case II - Water at WTL el. 13.0, no wave, wind from flood side. 33 1/3 percent increase in allowable stresses.

Case III - Broken waves to elevation 18.8, wave force, wind from flood side. 33 1/3 percent increase in allowable stresses.

Case IV - No water or wave force, wind from protected side. 33 1/3 percent increase in allowable stresses.

56. T-type floodwall--vicinity of pumping station. The existing floodwall will be removed and a T-type floodwall will be constructed in the vicinity of the pumping station between stations 875+42 and 878+32. See plates 76 through 78. Design computations for the T-wall are shown on figures B-37 through B-56. The new floodwall was designed assuming the sheet pile cutoff to be impervious and for the following load conditions:

Case I - Water at WTL el. 13.0, no wave, no wind, discharge pipes filled with water.

Case II - Water at WTL el. 13.0, no wave, no wind, discharge pipes empty.

Case III - Water at WTL el. 13.0, no wave, wind from flood side, discharge pipes filled with water. 33 1/3 percent increase in allowable stresses.

Case IV - Water at WTL el. 13.0, no wave, wind from flood side, discharge pipes empty. 33 1/3 increase in allowable stresses.

Case V - Broken waves to el. 17.4, wave force, wind from flood side, discharge pipes filled with water. 33 1/3 percent increase in allowable stresses.

Case VI - Broken waves to el. 17.4, wave force, wind from flood side, discharge pipes empty. 33 1/3 percent increase in allowable stresses.

Case VII - No water or wave force, wind from protected side, discharge pipes empty. 33 1/3 percent increase in allowable stresses.

57. T-wall piling. Factors considered in the selection of the type of piling include availability, economy, resistance to decay, resistance to corrosive soil and water conditions, and fitness for driving. In general, the above considerations indicate that 12-inch by 12-inch square, precast, prestressed concrete piles are the most suitable. The prestressed concrete piles will meet the requirements of the Joint AASHO and PCI Committee Standard Specifications for "Square Concrete Prestressed Piles."

58. Gates. Eight gate monoliths will be constructed for access roads in lieu of I-wall between station 664+73.3 and station 772+00. These gates are necessary to provide plant personnel and vehicles with access to the Michoud Canal and the GIWW. Each gate monolith will consist of a steel gate which will be closed by local interests when a hurricane approaches. See figures B-4 through B-36 for design of gate monoliths. The locations and details of these gates are shown on plates 79 through 85. The gate monoliths were designed for the following load conditions:

Case I - Water at WTL el. 13.0, no wave, no wind.

Case II - No water, no wave, no wind, truck loading on edge of slab at protected side.

Case III - No water, no wave, no wind, truck loading on edge of slab at flood side.

Case IV - Water at WTL el. 13.0, no wave, wind from flood side. 33 1/3 percent increase in allowable stresses.

Case V - Broken waves to el. 18.8, wave force, wind from flood side. 33 1/3 percent increase in allowable stresses.

Case VI - No water, no wave, wind from flood side, truck loading on edge of slab at protected side. 33 1/3 percent increase in allowable stresses.

Case VII - No water, no wave, wind from protected side, truck loading on edge of slab at flood side. 33 1/3 percent increase in allowable stresses.

59. Overhead roller gates. Seven overhead roller gates will be constructed. Each such structure will consist of a single leaf steel overhead roller gate, riding on an I-beam suspended from a reinforced concrete beam. The concrete beam will be supported by three concrete columns. Each opening will have a vertical clearance of 16 feet and a horizontal clearance of 20 feet. The concrete beam over the opening will be removable to permit the passage of over-height loads. A gate guide will be provided to restrain the gate against wind forces when the gate is being closed.

Each sill across the gate opening will be sloped 1 inch to prevent the bottom seal of the gate from sliding along the full length of the opening while the gate is being closed. The bottom of the gate will be sloped 1 inch to match the sill slope. The sloping of the sill and gate is designed to eliminate previous gate closing difficulties associated with resistance to sliding the seal over the sill. Design computations for a typical overhead gate are shown on figures B-12 through B-21. Typical plans, elevations, and details of the overhead gates are shown on plates 79 through 82.

60. Swing gate. One swing gate will be constructed at station 708+86. To assure a proper seal, the gate is constructed so that it can be adjusted in either the horizontal or the vertical direction. The side and bottom seals can also be adjusted as alternate or supplemental means to assure that a proper seal is obtained. Plan, elevation, and details are shown on plates 83 through 85.

61. Utility crossings. Details of pipeline crossings through the I-wall are shown on plate 86. Each utility crossing will be so constructed that any anticipated settlement or deflection of the I-wall or any small movements of the pipe will not seriously affect either the wall or pipeline.

62. Corrosion control.

a. General. The major cause of corrosion of iron and steel structures in soil can be attributed to moisture and the nonuniform distribution of oxygen on the surface of these structures. The National Bureau of Standards Monograph No. 58, April 1962, "Corrosion of Steel Pilings in Soils," states that when driven into natural undisturbed soil, steel piling does not corrode at a rate sufficient to significantly affect strength or useful life. The absence of significant corrosion on the piling inspected by the Bureau at 11 different locations is attributable to the probability that there is not enough oxygen available either originally or by replenishment to support corrosion on the underground sections. The conditions at the test sites varied widely and even though the soil properties and characteristics did indicate a corrosive environment at many of the sites, the data obtained indicate that sufficient oxygen is not available a short distance below the ground line, and especially below the water table, to promote corrosion by differential aeration or other causes.

b. Site condition. All of the steel sheet piling being driven for the New Orleans East back levee is located in existing levees 5 or more years old. While soil samples obtained from this area do indicate an environment which may be suspect,

from a corrosion standpoint, it is anticipated that sufficient oxygen will not be available to promote corrosion both below the ground line and below the water table.

c. Stray current considerations. Utility companies in this area have not encountered any corrosion problems on their gas, water, and sewer mains which can be attributed to stray currents. Therefore, stray current corrosion is not anticipated to present a problem at this time. However, since the project area is essentially an industrial area, stray current corrosion must be considered as a possible future problem.

d. Electrical continuity. Except for bonding, no corrosion protection measures are proposed, since all of the piling is to be driven in levees existing more than 5 years. All steel sheet piling shall be bonded together to obtain electrical continuity and provide for installation of cathodic protection if the need arises in the future. The piles shall be bonded together with No. 6 reinforcing bars welded to each of the piles near the top. Flexible jumpers insulated with cross-linked polyethelene shall be welded or brazed to adjacent sheet piles at the monolith joints 3 inches below the bottom of the concrete. See plate 71.

e. Coating. The overhead roller gates, swing gate, trolleys, "I" beams, corner plates, and all ferrous metal components which are not galvanized or stainless steel will be coated with a five-coat vinyl paint system.

SOURCES OF CONSTRUCTION MATERIALS

63. Sources of construction materials. In addition to the information presented in this memorandum relative to borrow area locations and materials, information relative to materials sources is also contained in Design Memorandum No. 12, "Sources of Construction Materials," dated 27 June 1966, approved 30 August 1966.

COORDINATION WITH OTHER AGENCIES

64. General. As previously mentioned, the State of Louisiana, Department of Public Works was appointed project coordinator for the State by the Governor of Louisiana. This agency has functioned to coordinate the needs, desires, and interests of state agencies and the Corps of Engineers. The Orleans Levee District will provide the local cooperation for all features of the project except those features located in St. Bernard Parish. The project plan presented herein is acceptable to both of the above agencies.

65. U. S. Department of the Interior, Fish and Wildlife Service. Extensive coordination with the U. S. Fish and Wildlife Service was accomplished during preauthorization studies and subsequent to authorization of the project. By letter dated 2 April 1968, the Regional Director, U. S. Fish and Wildlife Service, Atlanta, Georgia, was informed of the current layout for the Lake Pontchartrain Barrier Plan feature of the Lake Pontchartrain, Louisiana and Vicinity hurricane protection project and requested to furnish views and comments on the entire Lake Pontchartrain Barrier Plan. By letter dated 15 May 1968, the Acting Regional Director states "...We are of the opinion that hurricane control structures in the Rigolets and Chef Menteur tidal passes have little appreciable effect on salinities in Lakes Maurepas, Pontchartrain, and Borgne. Therefore, no adverse effects on fish and wildlife resources in these areas are expected." Any significant modification to the current plan will be forwarded to the Regional Director for further review and comment. Copies of the above letter and the response of the Acting Regional Director are included in appendix A.

66. U. S. Department of the Interior, Federal Water Pollution Control Administration (now Environmental Protection Agency, Federal Water Quality Administration).

a. Review and recommendations. By letter dated 8 April 1968, the Regional Director, Federal Water Pollution Control Administration, was informed of the current layout for the Lake Pontchartrain Barrier Plan feature of the Lake Pontchartrain, Louisiana and Vicinity hurricane protection project and requested to furnish views and comments on the entire Lake Pontchartrain Barrier Plan. The Regional Director requested in his letter of response dated 15 May 1968 that consideration be given to the following:

(1) Minimizing water quality degradation during construction.

(2) Minimizing the accidental spillage of petroleum products or other harmful materials and maintenance of sanitary facilities to adequately treat domestic wastes.

(3) Constructing and operating water quality control structures so as to insure that ecological conditions remain unchanged.

b. Project incorporation of recommendations. Provisions relative to water quality degradation during construction, control of accidental spillages, and maintenance of adequate sanitary facilities by construction contractors will be incorporated into the construction plans and specifications. The Seabrook Lock will be operated to provide a desirable salinity regimen in Lake

Pontchartrain to the end that deleterious alterations in the lake ecology will be avoided. The Regional Director has been advised of the action to be taken in connection with his comments. Copies of correspondence with the Regional Director are included in appendix A.

REAL ESTATE REQUIREMENTS

67. General. All rights-of-way required for construction of the New Orleans East back levee will be acquired by the Orleans Levee District and furnished without cost to the United States. There will be no acquisition by the United States. Rights-of-way limits and spoil-disposal areas are shown on plates 2, 3, 4, 29, and 45. The present levee extends an average of 50 feet on either side of the centerline over the entire project length. The acreage under the existing levee was deducted from the total project requirements for rights-of-way. See table 3.

RELOCATIONS

68. General. Under the authorizing law, local interests are responsible for the accomplishment of "...all necessary alterations and relocations to roads, railroads, pipelines, cables, wharves, drainage structures, and other facilities made necessary by the construction work;..." Included in the required modifications are road ramps, utilities, and drainage rectification work.

69. Road ramps. Shell roads over the existing levee provide each plant with individual access to the Michoud Canal. Since the levee section will be enlarged, these crossings will need to be replaced with new ramps constructed to grades approximating the existing declivities. The locations of the ramp modifications are shown on plate 2. See plate 87 for typical sections through the ramps.

70. Utility modifications. At station 823+50, 1-20" and 1-24" Southern Natural Gas Company high pressure gas lines pass through the existing levee at approximate elevation 7.0. These two lines will be removed from within the levee and will be raised above the top of the new levee. For the remaining modifications, utility services will be interrupted for a minimum period to permit the driving of sheet piling and other project construction activities. As soon as is possible thereafter, the utilities are to be put back in service. The crossings as indicated in the following tabulation will be modified to pass through the floodwall as shown on plate 86. The locations of the listed crossings are shown in plan and profile on plates 2 and 3.

Baseline station	Description	El. at top of pipe ft. m.s.l.
711+77.5	Two 8" pipelines	14.1
718+34.2	One 12" pipeline	14.2
738+64.0	Two 12" pipelines	17.5
	Four 1 1/2" elec. cables	
765+75.0	One 12" H.P. gas line	13.9
876+87	Three 72" pipes	15.0

71. Modifications at existing facilities.

a. General. In the vicinity of Air Products and Chemicals, Inc., plant and Louisiana Cement Company plant, the floodwall will pass below overhead pipelines and an overhead conveyor. These aerial crossings are supported by piling located within the levee section. See plates 2, 73 through 75 for location and detail. It is usually the policy of the New Orleans District to require that utilities or structures which support utilities be removed from the levee proper. However, relocating the existing piling outside the levee system would cause both plants to be shut down while expensive and extensive modifications to the aerial crossings were made. In view of the above and because the type of protection is a floodwall rather than a levee, the existing piling will not be relocated. T-type floodwalls supported on piling, in lieu of I-type floodwalls, will be constructed beneath the aerial pipeline crossings. The aerial pipelines are high enough to allow the sheet pile cutoff to be driven beneath the crossings without interrupting plant operation. The concrete bearing piles will be driven as close as possible to each of the pipeline crossings. The T-walls will be constructed in the locations cited below.

b. Air Products and Chemicals, Inc. At stations 698+12.95 and 708+40 the T-type floodwall will pass below overhead pipelines. Also adjacent to station 704+86, there is a stiffleg derrick foundation supported by piling. This foundation cannot be relocated since the derrick is used to service equipment in this area of the plant. A T-wall will also be constructed in this area for reasons stated in paragraph 4a. Location and details are shown on plates 2 and 73 through 75.

c. Louisiana Cement Company. At station 716+56.2 this floodwall will pass below an overhead conveyor system. Location and details of this floodwall are also shown on plates 2 and 73 through 75.

d. New Orleans Sewerage and Water Board pumping station. At station 867+87, a new floodwall will be constructed south of an existing New Orleans Sewerage and Water Board pumping station. The existing floodwall with the top elevation at +16.0 will be replaced with a new T-wall with the top elevation at +23.0. Location and details of this floodwall are shown on plates 3 and 76 through 78.

ENVIRONMENTAL QUALITY

72. Environmental quality.

a. General. The engineering treatment required for preserving and maintaining the environmental quality of the project has been considered during preparation of this memorandum. Specifically, levee erosion protection, corrosion mitigation, and the disposition of dredge waste water are discussed in paragraphs 39a, 40, and 62, respectively. Further, as indicated in paragraphs 65 and 66 and in appendix A, extensive coordination has been accomplished with the appropriate agencies relative to effects of the project on fish and wildlife resources and water quality control during and subsequent to construction.

b. Enhancement. Construction of the protective works covered herein alters the existing terrain only to the extent of raising and strengthening existing work along the same alignment. Essentially all borrow material needed to enlarge the existing levee will come from within adjacent waterways or from a remote location in Lake Pontchartrain. Additional beautification measures beyond those normally associated with levee construction, i.e., grading and sodding, are not warranted. The logic behind this statement is that the adjacent developed area is occupied by industry which precludes the use of public funds for beautification of private vistas and that adjacent area which is not developed as industrially zoned.

ESTIMATE OF COST

73. General. Based on January 1971 price levels, the estimated first cost for the New Orleans East back levee is $14,860,000. This estimate consists of $2,773,000 for lands and damages, $496,000 for relocations, $9,517,000 for levees and floodwalls, which includes work done by local interests, $1,226,000 for engineering and design, and $848,000 for supervision and administration. The detailed estimate of first cost is shown on table 3.

TABLE 3

ESTIMATE OF FIRST COST
(January 1971 price levels)

Cost acct. no.	Item	Estimated quantity	Unit	Unit price	Estimated amount
			$	$	$
	CONSTRUCTION				
11	Levees and floodwalls				
	Levees				
	Levee raising[1]	348	sta.	215.52	75,000
	Levee embankment(barge)	100,500	c.y.	3.50	351,800
	1st lift	2,530,000	c.y.	1.09	2,758,000
	2d lift	1,714,000	c.y.	1.13	1,937,000
	Shapeup	467,500	c.y.	.40	187,000
	Retaining dike (cast)	700,000	c.y.	.30	210,000

	TOTAL PROJECT COST				14,860,000

[2]Includes work done by local interests.

74. Comparison of estimates.

a. GDM versus PB-3. The current estimate of $14,860,000 for the New Orleans East back levee represents a decrease of $4,947,000 over the latest PB-3 effective 1 July 1970. The estimate presented in the PB-3 is based on the estimate included in Lake Pontchartrain, Louisiana and Vicinity, Lake Pontchartrain Barrier Plan, General Design Memorandum No. 2, Citrus Back Levee, approved 29 December 1967, and escalated to July 1970 price levels. Table 4 shows a comparison of the project document, PB-3, and general design memorandum estimates. Reasons for the difference between the design memorandum and PB-3 estimates are as follows:

(1) Levees and floodwalls. The net decrease of $2,418,000 is comprised of a decrease of $1,522,000 attributable to the selection of floodwall construction instead of levee along the Michoud Canal and an additional $896,000 decrease reflecting the deletion in this GDM of the U. S. Highway 90 to GIWW reach from the project.

(2) Engineering and design. The increase of $295,000 resulted from recomputing the E&D cost based on an analysis of actual work required rather than applying a percentage to the construction cost.

(3) Supervision and administration. The net increase of $218,000 reflects the added S&A costs as a result of recomputing S&A costs based on an analysis of actual work required rather than applying a percentage to the construction cost.

(4) Lands and damages. The net decrease of $3,329,000 is the result of a decrease in land requirements for T-wall in place of levee, a more detailed estimate of levee requirements, the elimination in this GDM of the levee from the GIWW to U. S. Highway 90, and the assignment of credit for area beneath the existing levee.

(5) Relocations. The increase of $287,000 reflects general refinements in the cost estimate based on the more detailed information available during preparation of this memorandum.

TABLE 4

COMPARISON OF ESTIMATES

	Feature	Project document	PB-3 eff. 1 Jul 70	GDM No. 2 Supp.No. 4	Difference Supp.No.4 - PB-3	Difference Supp. No. 4 - Proj.document
		$	$	$	$	$
11	Levees and floodwalls	4,993,000	11,935,000	9,517,000	-2,418,000	+4,524,000
30	Engineering and design	195,000	931,000	1,226,000	+295,000	+1,031,000
31	Supervision and administration	300,000	630,000	848,000	+218,000	+548,000
	Subtotal	5,488,000	13,496,000	11,591,000	-1,905,000	+6,103,000
01	Lands and damages	265,000	6,102,000	2,773,000	-3,329,000	+2,508,000
02	Relocations	238,000	209,000	496,000	+287,000	+258,000
	Subtotal	503,000	6,311,000	3,269,000	-3,042,000	+2,766,000
	Total	5,991,000	19,807,000	14,860,000	-4,947,000	+8,869,000

b. GDM versus project document. The estimate of $14,860,000 for the New Orleans East back levee also represents an increase of $8,869,000 over the project document estimate. Reasons for the difference between the design memorandum and project document estimates are as follows:

(1) Levees and floodwalls. The increase of $4,524,000 is the result of increasing the height of all levee protection from elevation 16.0 to elevation 17.5, construction of approximately 2 miles of concrete I-wall, eight gate structures, and 130 feet of I-wall in lieu of earth levee, and increasing the contingencies by 5 percent over that presented in the project document.

(2) Engineering and design. The increase of $1,031,000 resulted from recomputing the E&D costs based on an analysis of actual work required rather than applying a percentage to the construction cost.

(3) Supervision and administration. The increase of $548,000 resulted from recomputing the S&A costs based on an analysis of actual work required rather than applying a percentage to the construction cost.

(4) Lands and damages. The increase of $2,508,000 is the result of an increase in acreage requirements, a 10 percent increase in contingencies, the escalation of land costs due to development in the area subsequent to the preparation of the project document, and credit allowance for the area beneath the existing levee.

(5) Relocations. The increase of $258,000 is due primarily to modifying the floodwall to accommodate the pipe crossings and roads which were constructed since presentation of the project document.

SCHEDULES FOR DESIGN AND CONSTRUCTION

75. Schedules for design and construction. The sequence of contracts and the schedules for design and construction are shown below:

Contracts	Design: Start	Design: Complete	Construction: Advertise	Construction: Award	Construction: Complete	Estimated Construction Cost Includes Contingencies and S&I
Levee raising[1] (interim protection sta. 664+73 to sta. 1006+59)			May 66	Jun 66	Apr 67	$ 75,000
Levee, 1st lift 1971 (Sta. 772+00 to Sta. 876+87)	Dec 71	Dec 71	Jan 72	Jan 73		1,381,000
Concrete floodwall (Sta. 664+73 to Sta. 772+00 and Sta. 874+42 to Sta. 879+32)	Feb 72	Feb 72	Mar 72	Mar 73		3,434,000
Levee, 1st lift (Sta. 876+87 to Sta. 1006+59)	Mar 72	Mar 72	Apr 72	Nov 73		2,088,000
Levee, 2d lift (Sta. 772+00 to Sta. 876+87)	Dec 74	Dec 74	Jan 75	Nov 75		1,097,000
Levee, 2d lift (Sta. 876+87 to Sta. 1006+59)	Oct 75	Oct 75	Nov 75	Oct 76		1,269,000
Levee shapeup & seeding, foreshore protection (Sta. 772+00 to Sta. 876+87)	Oct 77	Oct 77	Nov 77	Sept 78		397,000
Levee shapeup & seeding, foreshore protection (Sta. 876+87 to Sta. 1006+59)	Sept 78	Sept 78	Oct 78	Jun 79		482,000
Total						$10,223,000

[1]Raising 1965 levee by local interests to the existing interim protection levee. See plates 29 through 32.

76. Funds required by fiscal year. To maintain the schedules for design and construction, as shown above, of the New Orleans East back levee, funds[1] will be required by fiscal year as follows:

Funds required by FY	1971	$ 115,350[2]
	1972	4,646,000
	1973	2,019,670
	1974	633,930
	1975	695,880
	1976	1,412,210
Balance to complete		2,213,960
Total		$ 11,737,000

OPERATION AND MAINTENANCE

77. General. The New Orleans East back levee will be maintained and operated at the expense of local interests as a feature of local cooperation in the hurricane project. A detailed estimate of the annual operation and maintenance costs is shown in table 5. In addition, it is estimated that replacement of the overhead roller gates will be necessary at 30-year intervals. The annual charge for these replacements is $1,140.

TABLE 5

ESTIMATE OF ANNUAL OPERATION AND MAINTENANCE COSTS

Maintenance:	$4,650
I-wall	270
Foreshore protection	700
Overhead roller gates	960
Operation:	
Overhead roller gates	80
Total	$6,660

[1]Includes cost for construction (including contingencies 20%), supervision and administration, engineering and design.

[2]Includes costs for preparation of plans and specifications and credit for work accomplished by local interests.

PROJECT FORMULATION AND EVALUATION

78. Project formulation and evaluation. The New Orleans East back levee is not a separable unit of the Lake Pontchartrain Barrier Plan; therefore, an incremental justification and independent economic analysis is not practicable.

ECONOMICS

79. Economic justification. The current economic analysis for the entire Lake Pontchartrain, Louisiana and Vicinity, hurricane protection project, based on the July 1970 PB-3 costs, indicates a benefit-to-cost ratio of 11.6 to 1. As stated in paragraph 78 above, an independent economic analysis for the project feature presented herein is not practicable. The reduced costs of the New Orleans East back levee protective works presented in this memorandum below that shown in the current PB-3 will not significantly change the approved benefit-to-cost ratio for the entire project.

RECOMMENDATIONS

80. Recommendations. The plan of improvement presented herein for the New Orleans East back levee consists of the construction of a floodwall in an enlarged levee joining the Citrus back levee floodwall and extending for 2 miles along the Michoud Canal to a point near the canal on the north bank of the GIWW and, from this point, the project work is the enlargement and raising of an existing levee for a distance of 4.4 miles to its intersection with the Chef Menteur barrier levee. Eight gates are to be provided in the floodwall to maintain access by existing industries to the adjacent waterways. Additionally, existing utilities and a floodwall at a pumping station will be modified to provide protective continuity in the system. This plan is considered to be the best means of accomplishing the project objectives and is recommended for approval.

CONSOLIDATION DATA

GENERAL NOTES

- UC– Unconfined compression shear test
- ● Ⓠ – Unconsolidated undrained triaxial shear test
- ▲ Ⓡ – Consolidated undrained triaxial shear test
- ⊡ Ⓢ – Consolidated drained direct shear test
- Ⓒ – Consolidation test
- W – Natural water content
- L.L.– Liquid limit
- P.L.– Plastic limit
- c – Unit cohesion
- φ – Angle of friction
- γ – Unit weight of soil-water system
- σ̄ – Normal stress
- ◉ $\bar{P}_c$ – Preconsolidation pressure
- e – Void ratio
- C_c – Compression index
- O.B.– Overburden

Borings were taken with a 5 inch diameter steel tube piston type sample.

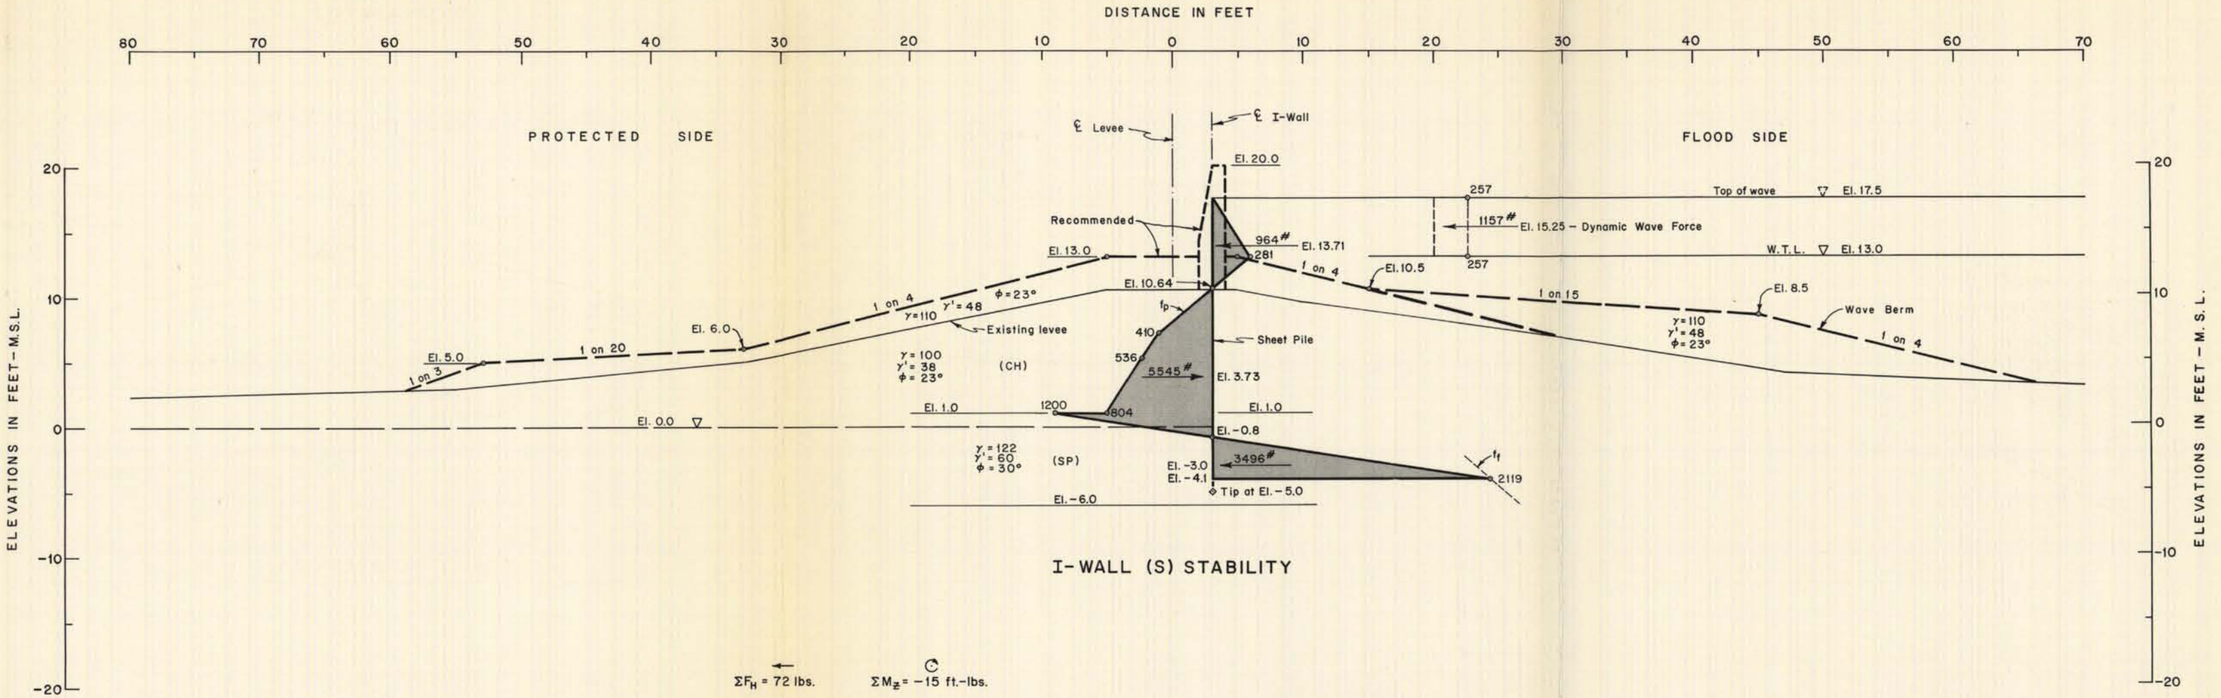
PLATE 38



I-WALL (S) STABILITY

$\overleftarrow{\Sigma F_H} = 72$ lbs. $\quad \overset{\circlearrowleft}{\Sigma M_{\bar{z}}} = -15$ ft.-lbs.

GENERAL NOTES

Cantilever sheet pile stability by method of planes analysis
(S) – Consolidated–drained shear strength, c = o
(f_ω) – Lateral water pressure
(f'_F) – Net lateral pressure on flood side, soil and water
(f'_P) – Net lateral pressure on protected side, soil and water
γ_ω – Unit weight of water in p.c.f.
γ – Unit weight of soil–water system in p.c.f.
γ' – Submerged unit weight of soil in p.c.f.
c – Unit cohesion in p.s.f.
ΣF_H – Summation of horizontal forces in lbs.
$\Sigma M_{\bar{z}}$ – Summation of moments about tip, in ft. lbs.
$\bar{z}$ – Penetration of sheet pile below levee crown in feet
F.S. – Factor of safety with respect to (S) shear strength, $\phi_d = \tan^{-1}\left(\frac{\tan\phi}{F.S.}\right)$
ϕ – Angle of internal friction in degrees

NOTES:

For location in plan see plate 2.
For soil boring data see plates 7 & 8.

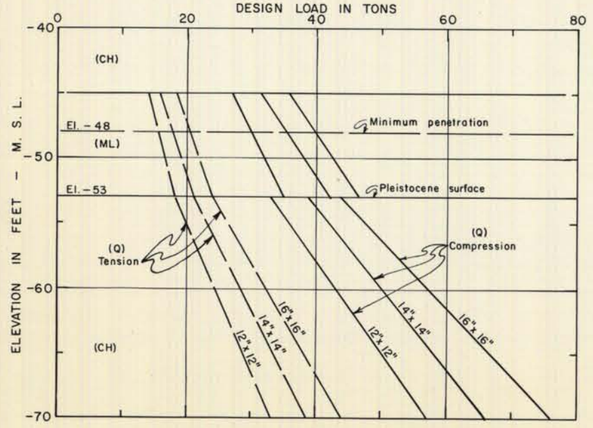
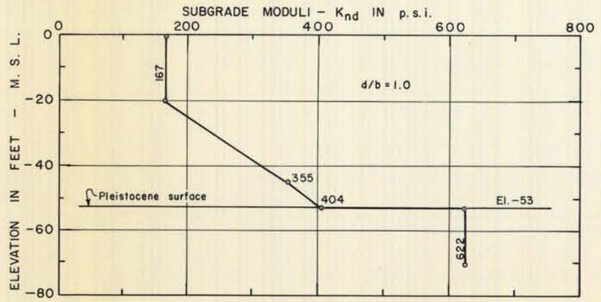
PILE CAPACITY ANALYSES IN VICINITY OF STATION 876+87

APPLICABLE BETWEEN STATION 740+00 AND STATION 880+00



DESIGN LOAD VS TIP ELEVATION



SUBGRADE MODULI VS ELEVATION

GENERAL NOTES

(Q) Case governs for design capacities.

See plate 10 for soil boring data.

Q_U = Unconfined compressive strength.

C_A = Unit cohesion available in p.s.f.

C_d = Unit cohesion developed = C ÷ F.O.S.

S_A = Shear strength = C + $\bar{P}_N$ tan Φ

S_d = Strength developed = S ÷ F.O.S.

$\bar{P}_N$ = Effective normal stress in t.s.f.

γ = Unit weight of soil - water system in p.c.f.

γ' = Submerged unit weight of soil in p.c.f.

Applied factors of safety: 1.75 in compression and 2.0 in tension.

Applied conjucate stress ratios: K = 1.0 in compression and 0.7 in tension.

Subgrade Modulus for cohesive soils: $K_o = 80 \cdot Q_u (p.s.f.) = 0.5555 \cdot Q_u (p.s.i.)$

$K_{nd} = 0.4\ K_o \cdot d/b = 0.2222 \cdot Q_u \cdot d/b$ (p.s.i.) (Design)

(Includes reduction factor for cyclic loading.)

K_o values are those proposed by Karl Terzaghi in "Evaluation of Coefficients of Subgrade Reactions," Geotechnique, London, England, Vol. V, 1955, p.p. 297-326.

d = Projected diameter of pile (inches)

b = Unit conversion factor = 12 inches

Design load is the structure load carried by the pile. The pile capacity curves include the factors of safeties used for design.

T-wall from stations 875+62 to 878+12.

NOTES:

FIGURES TO LEFT OF BORING UNDER COLUMN "W OR D_{10}"

- Are natural water contents in percent dry weight
- When underlined denotes D_{10} size in mm *

FIGURES TO LEFT OF BORING UNDER COLUMNS "LL" AND "PL"

- Are liquid and plastic limits, respectively

SYMBOLS TO LEFT OF BORING

- ▽ Ground-water surface and date observed
- (C) Denotes location of consolidation test **
- (S) Denotes location of consolidated-drained direct shear test **
- (R) Denotes location of consolidated-undrained triaxial compression test **
- (Q) Denotes location of unconsolidated-undrained triaxial compression test **
- (T) Denotes location of sample subjected to consolidation test and each of the above three types of shear tests **
- FW Denotes free water encountered in boring or sample

FIGURES TO RIGHT OF BORING

- Are values of cohesion in lbs./sq.ft. from unconfined compression tests
- In parenthesis are driving resistances in blows per foot determined with a standard split spoon sampler (1 3/8" I.D., 2" O.D.) and a 140 lb. driving hammer with a 30" drop
- Where underlined with a solid line denotes laboratory permeability in centimeters per second of undisturbed sample
- Where underlined with a dashed line denotes laboratory permeability in centimeters per second of sample remoulded to the estimated natural void ratio

* The D_{10} size of a soil is the grain diameter in millimeters of which 10% of the soil is finer, and 90% coarser than size D_{10}.

**Results of these tests are available for inspection in the U.S. Army Engineer District Office, if these symbols appear beside the boring logs on the drawings.

GENERAL NOTES:

While the borings are representative of subsurface conditions at their respective locations and for their respective vertical reaches, local variations characteristic of the subsurface materials of the region are anticipated and, if encountered, such variations will not be considered as differing materially within the purview of clause 4 of the contract.

Ground-water elevations shown on the boring logs represent ground-water surfaces encountered on the dates shown. Absence of water surface data on certain borings implies that no ground-water data is available, but does not necessarily mean that ground water will not be encountered at the locations or within the vertical reaches of these borings.

Consistency of cohesive soils shown on the boring logs is based on driller's log and visual examination and is approximate, except within those vertical reaches of the borings where shear strengths from unconfined compression tests are shown.

LMNED-PP

2 April 1968

Mr. C. Edward Carlson, Regional Director
U. S. Department of the Interior
Fish and Wildlife Service
Peachtree-Seventh Building
Atlanta, Georgia 30323

Dear Mr. Carlson:

Please refer to our letter dated 21 April 1967 requesting your views and comments on the general design memorandum for the Lake Pontchartrain Barrier Plan feature of the "Lake Pontchartrain, La. and Vicinity" project.

Our letter dated 21 April 1967 indicated that your views and comments would be requested for each supplement to the general design memorandum. However, we now feel that your views on the entire Lake Pontchartrain Barrier Plan would be preferable. The layout of the Lake Pontchartrain Barrier Plan, as described in House Document No. 231, 89th Congress, 1st Session, is shown in inclosure 1. The plan, layout of which is shown on inclosure 2, now under consideration is essentially the same as that presented in the House Document, with the following exceptions:

a. Barrier. The Chief of Engineers has approved a change in the alignment of the barrier in the Chef Menteur Pass area to that shown on inclosure 3. The barrier elevation will be 9 feet mean sea level or the elevation of existing U. S. Highway 90, whichever is higher. The remaining structures sites will remain as specified in the House Document, except that consideration is being given to widening the Rigolets Lock from 84 feet to 110 feet. The modification of the width of the Rigolets Lock is not for public release.

b. Seabrook Lock. The Chief of Engineers has approved a change in the controlling elevation of the Seabrook Lock from 13.2 feet to 7.2 feet mean sea level. This change will be effected by lowering the crown of the rock dike which will tie the lock to the levee system. In addition, auxiliary control structures, located on each side of the lock, will be added to provide for passage of flows or salinity control and riparian use when the lock is passing traffic.

c. Levees. Based on revised parameters for the standard project hurricane, as developed by the U. S. Weather Bureau, the levee grades recommended in House Document No. 231 were increased by as much as 1 to 2 feet.

d. St. Charles Parish Levees. The St. Charles Parish Lakefront levee will extend across the Parish Line Canal and tie into the Jefferson Parish Lakefront levee, rather than having a levee extending south approximately 3.5 miles along the west side of the Parish Line Canal to the Illinois Central Railroad. Drainage structures will be provided in the Lakefront levee to allow gravity drainage of the area.

We have received your comments on Seabrook Lock and the Citrus Back Levee, i.e., the levee along the north bank of the Gulf Intracoastal Waterway from the Inner Harbor Navigation Canal to the Michoud Canal, by letters dated 7 June 1967 and 22 June 1967, respectively. Your views, recommendations, and comments on the remainder of the Lake Pontchartrain Barrier Plan are requested.

Because of the urgency of providing protection to the areas vulnerable to hurricane flooding, we are operating on a much compressed planning schedule. Accordingly, it would be very much appreciated if your comments are provided not later than 1 June 1968.

Sincerely yours,

UNITED STATES
DEPARTMENT OF THE INTERIOR
FISH AND WILDLIFE SERVICE
BUREAU OF SPORT FISHERIES AND WILDLIFE
PEACHTREE-SEVENTH BUILDING
ATLANTA, GEORGIA 30323

May 15, 1968

District Engineer
U. S. Army, Corps of Engineers
P. O. Box 60267
New Orleans, Louisiana 70160

Dear Sir:

Reference is made to your letter of April 2, 1968, (LMNED-PP), requesting our views on the Lake Pontchartrain Barrier Plan feature of the Lake Pontchartrain, Louisiana, and Vicinity project.

The overall barrier plan and its influence on fish and wildlife resources have been discussed in prior Bureau reports, most recently our letter report of June 21, 1967.

As indicated in past reports, we are of the opinion that hurricane control structures in the Rigolets and Chef Menteur tidal passes will have little appreciable effect on salinities in Lakes Maurepas, Pontchartrain, and Borgne. Therefore, no adverse effects on fish and wildlife resources in these areas are expected.

Previous model tests have indicated that acceptable salinity levels for the preservation of fish and wildlife resources in Lake Pontchartrain can be obtained by utilization of the Seabrook Lock facility, which includes an auxiliary control structure on each side of the lock. Use of these auxiliary structures should insure that adequate diversion flows for salinity control and riparian use can be provided. The capability for adjusting salinities as may be required for fish and wildlife would tend to prevent the occurrence of detrimental effects.

New levee construction and levee enlargement works as planned, including the modified St. Charles Parish levee, are not expected to directly affect fish and wildlife resources to any great degree. Indirectly, the levee system will hasten urban and industrial development of additional marshland that now provides moderate quality habitat for wildlife. Your staff has indicated that the Parish Line Canal is no longer classed as a navigable waterway. Blockage of the channel, however, will inconvenience boat owners who now use the canal.

We are pleased with your previous recognition of the need for a salinity surveillance system at the Seabrook Lock upon its completion. This Bureau and the Louisiana Wild Life and Fisheries Commission will be glad to participate in the development and monitoring of such a system.

We appreciate the opportunity to provide these comments at this time. If current plans are modified, we request the opportunity for further review and comment.

A copy of this letter has been sent to the Louisiana Wild Life and Fisheries Commission. Any comments that agency wishes to make will be forwarded to you.

Sincerely yours,

W. L. Towns
Acting Regional Director

8 April 1968

Mr. William C. Galegar, Regional Director
Federal Water Pollution Control Administration
Third Floor--1402 Elm Street
Dallas, Texas 75202

Dear Mr. Galegar:

Please refer to our letter dated 21 April 1967 requesting your views and comments on the general design memorandum for the Lake Pontchartrain Barrier Plan feature of the "Lake Pontchartrain, La. and Vicinity" project.

Our letter dated 21 April 1967 indicated that your views and comments would be requested for each supplement to the general design memorandum. However, we now feel that your views on the entire Lake Pontchartrain Barrier Plan would be preferable. The layout of the Lake Pontchartrain Barrier Plan, as described in House Document No. 231, 89th Congress, 1st Session, is shown in inclosure 1. The plan, layout of which is shown on inclosure 2, now under consideration is essentially the same as that presented in the House Document, with the following exceptions:

a. Barrier. The Chief of Engineers has approved a change in the alignment of the barrier in the Chef Menteur Pass area to that shown on inclosure 3. The barrier elevation will be 9 feet mean sea level or the elevation of existing U. S. Highway 90, whichever is higher. The remaining structures sites will remain as specified in the House Document, except that consideration is being given to widening the Rigolets Lock from 84 feet to 110 feet. The modification of the width of the Rigolets Lock is not for public release.

b. Seabrook Lock. The Chief of Engineers has approved a change in the controlling elevation of the Seabrook Lock from 13.2 feet to 7.2 feet mean sea level. This change will be effected by lowering the crown of the rock dike which will tie the lock to the levee system. In addition, auxiliary control structures, located on each side of the lock, will be added to provide for passage of flows or salinity control and riparian use when the lock is passing traffic.

c. Levees. Based on revised parameters for the standard project hurricane, as developed by the U. S. Weather Bureau, the levee grades recommended in House Document No. 231 were increased by as much as 1 to 2 feet.

d. St. Charles Parish Levees.. The St. Charles Parish Lakefront levee will extend across the Parish Line Canal and tie into the Jefferson Parish Lakefront levee, rather than having a levee extending south approximately 3.5 miles along the west side of the Parish Line Canal to the Illinois Central Railroad. Drainage structures will be provided in the Lakefront levee to allow gravity drainage of the area.

We have received your comments on Seabrook Lock and the Citrus Back Levee, i.e., the levee along the north bank of the Gulf Intracoastal Waterway from the Inner Harbor Navigation Canal to the Michoud Canal, by letter dated 23 June 1967. Your views, recommendations, and comments on the remainder of the Lake Pontchartrain Barrier Plan are requested.

Because of the urgency of providing protection to the areas vulnerable to hurricane flooding, we are operating on a much compressed planning schedule. Accordingly, it would be very much appreciated if your comments are provided not later than 1 June 1968.

Your Ref: LMNED-PP

Colonel Thomas J. Bowen, District Engineer
Department of the Army
New Orleans District, Corps of Engineers
P. O. Box 60267
New Orleans, Louisiana 70160

Dear Sir:

Reference is made to your letter of April 8, 1968 requesting review and comment on the remainder of the Lake Pontchartrain Barrier Plan.

We have reviewed the information submitted in accordance with Executive Order 11288, Sections 1(3) and 1(7) in regard to water pollution control measures and find as follows:

a. All contractors should perform construction operations in a manner that will reduce turbidity and siltation to the lowest practicable level.

b. All contractors should take precautions to prevent water pollution by accidental spillage of hazardous materials which would result in substantial harm to fish or shellfish. Also, all contractors should provide and maintain sanitation facilities that will adequately treat domestic wastes to conform with Federal and local health regulations.

c. It is desirable that the water quality control structures be constructed and operated so as to prevent changes in the present water quality and to ensure that ecological conditions remain unchanged.

The comments of the Louisiana Stream Control Commission have been incorporated in our review.

Colonel Thomas J. Bowen
C/E, New Orleans, Louisiana

5/15/68

Your cooperation in carrying out the requirements of the Order is appreciated.

Sincerely yours,

for WILLIAM C. GALEGAR
Regional Director

15 July 1969

Mr. William C. Galegar, Regional Director
Federal Water Pollution Control Administration
Third Floor - 1402 Elm Street
Dallas, Texas 75202

Dear Mr. Galegar:

Please refer to our letter dated 8 April 1968 requesting your views on the entire Lake Pontchartrain Barrier Plan and your reply dated 15 May 1968. We are now considering a modification to that portion of the current plan located in the vicinity of the Rigolets Pass.

The layout of the Lake Pontchartrain Barrier Plan, provided with our letter of 8 April 1968, and the plan now under consideration are essentially the same; however, two additional schemes for the Rigolets Control Structure and Closure are presently being evaluated. The new schemes are as follows:

a. A control structure with sixteen 50-foot bays and a sill elevation of -30 feet m.s.l. (mean sea level). The structure would be located in the main channel of the Rigolets and constructed inside a cellular sheet pile cofferdam. A closure dam would extend from the east end of the structure thence across the Rigolets. This scheme required no approach channels. (Refer to inclosed layout.)

b. A control structure with twenty-three 50-foot bays and a sill elevation of -20 feet m.s.l. The layout is the same as for the above scheme.

It is requested that you furnish your views and comments on the above schemes at your earliest conveniience.

Sincerely yours,

Incl

Colonel Herbert R. Haar, Jr.
District Engineer
U. S. Army Engineer District, New Orleans
P. O. Box 60267
New Orleans, Louisiana 70160

Attention: LMNED-PP

Dear Sir:

Reference is made to your letter of July 15, 1969 requesting our comments on the modifications to your Lake Pontchartrain Barrier Plan in the vicinity of the Rigolets Pass.

We have reviewed this modification in regard to water pollution control measures and recommend that the final plans and specifications for the project require the contractors to:

1. Provide and maintain sanitation facilities that will adequately treat domestic wastes to conform with Federal and State health regulations.

2. Perform construction operations in a manner that will reduce turbidity and siltation to the lowest practicable level.

3. Take precautions to prevent water pollution by accidental spillage of hazardous materials which would result in substantial harm to fish or shellfish.

The comments of the Louisiana Stream Control Commission and Louisiana State Department of Health have been incorporated in our review.

Your cooperation in carrying out the requirements of the Order is appreciated.

Sincerely yours,

JERRY T. THORNHILL, Assistant Chief
Federal Activities Coordination

PEACHTREE-SEVENTH BUILDING
ATLANTA, GEORGIA 30323

August 21, 1969

District Engineer
U.S. Army, Corps of Engineers
P.O. Box 60267
New Orleans, Louisiana 70160

Dear Sir:

This is in reply to your letter of July 3, 1969, (LMNED-PP), requesting our comments on the two additional schemes you are considering in modifying plans for the Rigolets Control Structure and Closure, a part of the Lake Pontchartrain Barrier Plan. The new schemes described in your letter are as follows:

a. A control structure with sixteen 50-foot bays and a sill elevation of -30 feet mean sea level. The structure would be located in the main channel of the Rigolets and constructed inside a cellular sheet pile cofferdam. A closure dam would extend from the east end of the structure across the Rigolets. This scheme requires no approach channels.

b. A control structure with twenty-three 50-foot bays and a sill elevation of -20 feet m.s.l. The layout is the same as for the above scheme.

The control structure described under "b" above is identical in dimensions to the structure originally planned. The influence of the original structure on fish and wildlife was discussed in prior Bureau reports and most recently in our letter of May 15, 1968. Apparently, the structure described under "a" above is designed to pass approximately the same volume of water as structure "b". Therefore, we are of the opinion that the proposed modifications to the planned structure will have little effect on salinities in adjacent waters and no significant adverse effects on fish and wildlife resources. The proposed location of the structures in the main channel of the Rigolets does not alter our views.

We appreciate the opportunity to provide these comments at this time. If current plans are further modified, we request the opportunity for further review and comment.

A copy of this letter has been sent to the Louisiana Wild Life and Fisheries Commission. Any comments that agency wishes to make will be forwarded to you.

Sincerely yours,

W. L. Towns
Acting Regional Director

DETERMINATION OF WAVE FORCE

Wall seaward of shoreline

$H_1 = 8.25'$ W.T.L. = El. 13.0

Breaking depth $d_b = 0.67 \frac{8.25}{(5.45)^{\frac{1}{3}}} = 8.47'$

Bottom El. = 13.0 - 8.47 = 4.53'

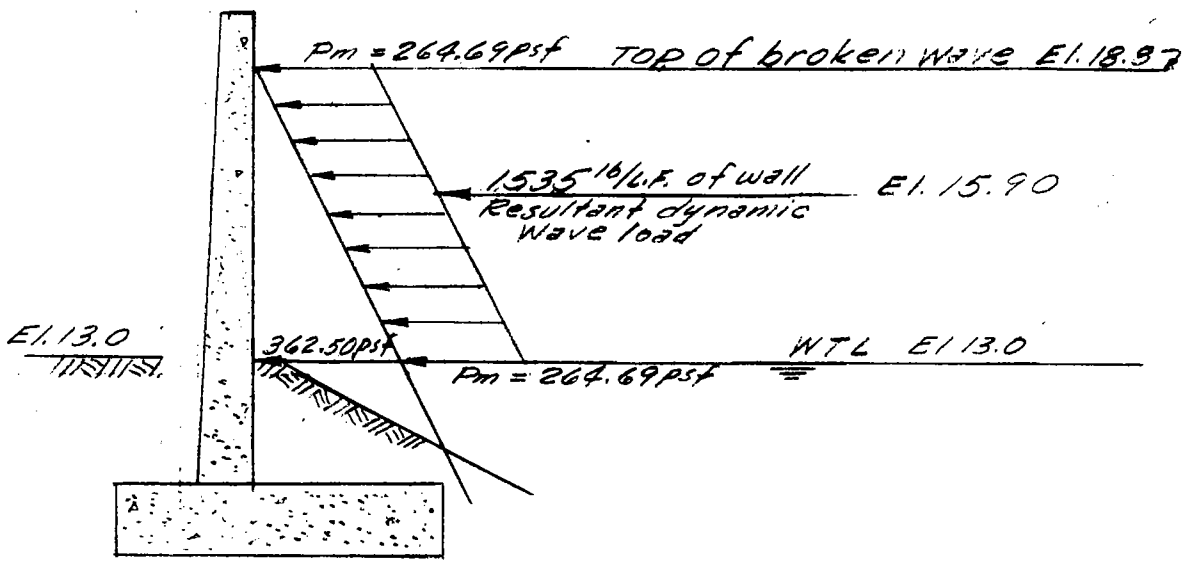
Wave breaks on berm, approx 60' from wall

USE BROKEN WAVE

Reference — U.S. Army Coastal Engineering Research Center, "Shore Protection, Planning and Design," Technical Report No. 4, 3rd ed. 1966.

Height of broken wave = $0.7(H_1) = 0.7(8.25) = 5.775'$

Top of broken wave = 13.0 + 5.8 = El. 18.8



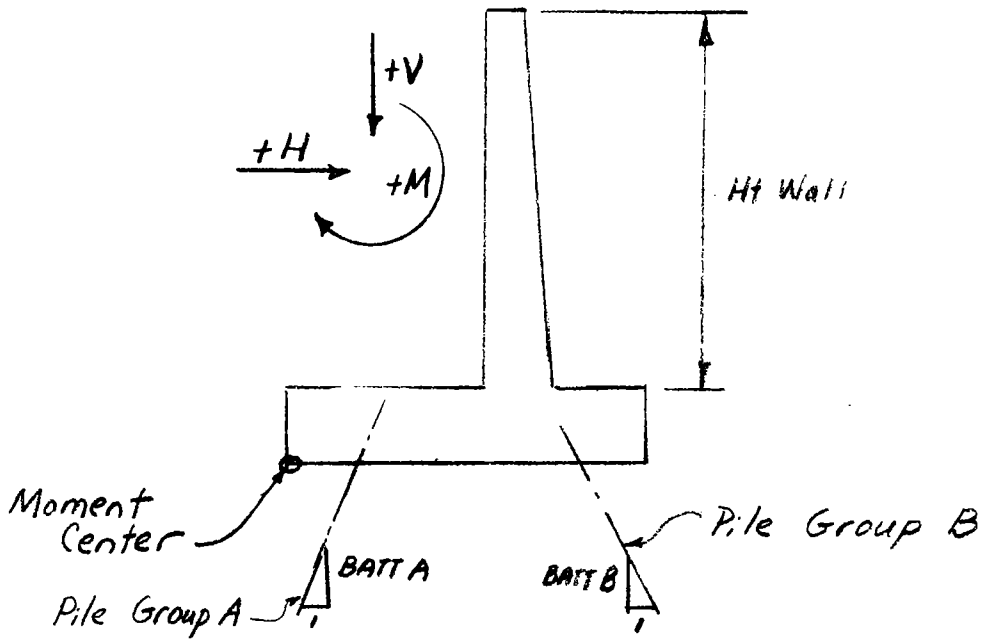
$P_m = \frac{w d_b}{2} = \frac{62.5 \times 8.47}{2} = 264.69 psf$

Resultant dynamic wave load = $P_m \times h_c = 264.69 \times 5.8 = 1535.2$ #/L.F.

FIG. B-4

Batter Pile Foundation

Determine Pile Group by Hrennikoff's Method with Computer Program K29HREN. This program obtains the pile loading when the resultant moment, vertical force, and horizontal force are known.



The following values are known or assumed.

(1.) All piles are 12"×12" prestressed concrete
- (a.) Area = 144 sq. in.
- (b.) Moment of Inertia $AI = 1728\ in^4$; $S = 288$
- (c.) Modulus of Elasticity $E = 4.29 \times 10^6\ lb/in^2$
- (d.) $f_c' = 5000$ psi; $f_c = 1750$ psi
- (e.) Effective prestress after losses = 840 psi (Ref. - Std Prestressed Concrete Piles (10" to 24" square) Design Sheet by Joint Committee of AASHO & PCI)
- (f.) Minimum prestress after losses = 700 psi
- (g.) Tension in precompressed tensile zone = 0

(2.) Modulus of subgrade reaction (AK) = 400 psi

(3.) Allowable pile compression load (PC) = 80 k

(4.) Allowable pile tension load (PT) = 40 k

Batter Pile Foundation

The following conditions are known or assumed:
(1.) Pile resistance is skin friction, no end bearing
(2.) Pile head is hinged at the base slab

Maximum moment in pile due to transverse load on pile head = $0.5 R Q_A$

Ref. - Journal # 3509 May, 1963 of Soil Mechanics and Foundations Division "Laterally Loaded Piles in a Layered Soil System" by M.T. Davisson and H.L. Gill pg. 72 Fig 5b

where 0.5 = Max. moment coefficient ($\ell_{max} = 5$)

$$R = \sqrt[4]{\frac{EI}{k}} = \sqrt[4]{\frac{4.29\times10^6 \times 1728}{400}} = \sqrt[4]{18.5\times10^6}$$

$R = 65.6''$

Q_A = Max. transverse load on pile head

$M = 0.5 (65.6) Q_A = 32.8 Q_A$

Allowable pile head deflection = y_A

$$y_A = \frac{1.375 R^3 Q_A}{EI}$$

Ref - Journal # 3509 pg 72 Fig 5b

1.375 = Deflection coefficient ($\ell_{max} = 5$)

$$y_A = \frac{1.375 (65.6)^3 Q_A}{4.29\times10^6 (1728)} = 52.4\times10^{-6} Q_A \quad (Q_A \text{ in lb})$$

Program K29HRN obtains the actual axial and transverse loads on the piles by Hrennikoff's method and compares them to the allowables. Allowable transverse loads are computed from the axial loads thusly:

Tension Pile

$$\frac{f_a}{F_a} + \frac{f_b}{F_b} = 1 \qquad f_a = \frac{P}{A} = \frac{P}{144} = 0.00694 P$$

$F_a = F_b = 700 psi$

FIG. B-6

Batter Pile Foundation

Tension Pile cont'd

$$f_b = \frac{M}{S} = \frac{32.8\,Q}{288} = 0.114\,Q \qquad F_b = 700 \text{ psi}$$

$$\frac{f_a}{F_a} + \frac{f_b}{F_b} = 1$$

$$\frac{0.00694P}{700} + \frac{0.114Q}{700} = 1$$

$$0.114Q = 700 - 0.00694P$$

$$Q = 6140 - 0.0609P$$

$$y = 52.4\times10^{-6}\,Q - 52.4\times10^{-6}(6140 - 0.0609P)$$

$$y = 0.3217 - 3.19\times10^{-6}P$$

Compression Pile

$$f_a = \frac{P}{A} = \frac{P}{144} = 0.00694P$$

$F_a = F_b =$ f_c — eff. prestress after losses

$= 1750 - 840 = 910$ psi

$$f_b = \frac{M}{S} = \frac{32.8\,Q}{288} = 0.114Q$$

$$\frac{f_a}{F_a} + \frac{f_b}{F_b} = 1$$

$$\frac{0.00694P}{910} + \frac{0.114Q}{910} = 1$$

$$0.114Q = 910 - 0.00694P$$

$$Q = 7982 - 0.0609P$$

$$y = 52.4\times10^{-6}Q = 52.4\times10^{-6}(7982 - 0.0609P)$$

$$y = 0.4183 - 3.19\times10^{-6}P$$
