MEMORANDUM FOR CHIEF, ENGINEERING DIVISION, ATTN: CECW-EP-W

SUBJECT: Lake Pontchartrain Storm Water Discharge, Jefferson Parish, Louisiana, August 1995 Technical Report

1. The subject report was provided to this office for Washington level review by CECW-P. During subsequent discussions it was determined that approval for the report was your responsibility and any comments on the document should be forwarded directly to you.
2. By memorandum dated 24 June 1994, CECW-EP-W provided comments on an earlier report which requested that additional information be provided in a technical document sufficient enough to support preparation of a Project Cooperation Agreement. The current report did not respond specifically to the comments in the 24 June memorandum, so it was difficult to determine how adequately the district responded to those comments. Our current review focused on the adequacy of the current report, considering the comments previously provided to the district.
3. The review assessment is attached. We note several areas that need to be modified or corrected prior to report approval.
4. Any questions may be directed to the review manager, Dave Reece, at 703-355-2379.

WASHINGTON LEVEL  
REVIEW TEAM ASSESSMENTLAKE PONTCHARTRAIN STORM WATER DISCHARGE  
JEFFERSON PARISH, LOUISIANA, DEMONSTRATION PROJECT  
AUGUST 1995

1. **BACKGROUND.** A reconnaissance study of urban flood and water quality management for Jefferson and Orleans Parishes was completed and approved in December 1993. One purpose of the study was to investigate ways to improve the water quality of storm water runoff into Lake Pontchartrain. The study concluded that more data are needed and recommended the use of demonstration projects. In a "consensus agreement" between the district and Jefferson Parish in July 1995, a plan developed by the Parish to capture and treat storm runoff using excess capacity of the Parish East Bank sewage treatment plant was adopted for a demonstration project.
2. **AUTHORITY.** The Water Resource Development Act of 1992, Public Law 102-580, Section 307, authorizes the Secretary of the Army to design and construct projects that address water quality problems associated with storm water discharges into Lake Pontchartrain and the Mississippi River. The fiscal year 1994 Energy and Water Appropriations Bill provided \$2 million to prepare a Project Cooperation Agreement (PCA) and technical documentation for a storm water management demonstration project proposed by Jefferson Parish officials. Senate Report 103-291, dated September 1994, allows cost reimbursement to the Parish for their design and construction of the facility, relegating the Corps to a technical management oversight role.
3. **PURPOSE OF REPORT.** The purpose of the submitted document (referred to by the district as a technical document) is to satisfy the intent of the authorizing legislation, and to establish a basis for execution of the PCA. Furthermore, the technical document was required by CECW-EP-W because the demonstration project was authorized without a feasibility report and is needed to support the PCA. The August 1995 subject report was to furnish additional information as required by a CECW-EP-W memo dated 24 June 1994.
4. **RECOMMENDED PROJECT.** The recommended plan is to modify the existing storm water runoff collection system and pump storm water from the drainage canals to the East Bank Waste Water Treatment Plant (EBWWTP) for treatment, and subsequent discharge into the Mississippi River. The report gives the total project cost as \$20 million. The cost sharing is 75 percent Federal and 25 percent non-Federal.

CECW-AR-E

SUBJECT: Lake Pontchartrain Storm Water Discharge, Jefferson Parish, Louisiana, August 1995 Technical Report

## 5. COMMENTS

a. The technical document under review does not strictly follow the guidance in ER 1105-2-100 regarding economic analysis. However, CECW-EP-W memorandum dated 24 June 1994 exempts the district from economic analysis requirements of the ER. The memo directs the district to provide average annual costs, but only generalized benefits. Furthermore, it explicitly states that detailed economic and NED analysis are not required.

b. There is no description of the Quality Assurance/Quality Control process that will be in place when the water quality data collection effort will be performed. A QA/QC process is necessary to assure that the samples are accurate, adequate, and meet the needs of the study, the model, or any other determined needs (reference ER 1110-2-8154). The sampling program must be carefully designed to assure the number of sampling sites, frequency of sample collection, and analysis performed are at a level that is adequate but not excessive. There are existing protocols for designing a sampling program available from WES. These efforts will greatly reduce costs and assure adequacy of the sampling program. Further, the collected data should be stored in a data system, such as STORET, that allows full access and distribution of the data to all potential users. The district should ensure that a quality control process is established prior to data collection.

c. The real estate arrangements contemplated for the project are unacceptable because they offer the local sponsor an opportunity to manipulate the fulfillment of its 25 percent cost sharing obligation. There is a lack of checks and balances in the determination of the amount of LERRD credits. The nature of the project's LERRD requirement would be determined by the local sponsor who would then acquire the LERRD and, further, submit this amount for LERRD credit. The lack of checks on such activities for the Government is disturbing, especially in the light of the findings regarding granting of LERRD credits from the 1991 Army Audit Agency Civil Works Cost Sharing Audit (Report WE 91-203).

(1) Accordingly, we must have input into establishing the LERRD requirements and in the 9th line of paragraph 12 (Real Estate) on page 27 of the technical report, "guidance" must be replaced with "approval".

(2) Additionally, an abbreviated gross appraisal should be prepared and approved by CELMV-ET-R. This abbreviated gross appraisal should, at a minimum, describe the project area, total acreage, land classification broken down on an acreage (rounded) basis, the estates to be utilized for construction of the project, HTRW assessment, cultural resources, a map or plate of the project area, relocations pursuant to PL 91-646, relocations of facilities and/or utilities, and an estimate of lands and damages. The gross appraisal should be of sufficient detail to support the final real estate cost estimate.

CECW-AR-E

SUBJECT: Lake Pontchartrain Storm Water Discharge, Jefferson Parish, Louisiana, August 1995 Technical Report

(3) Finally, the Attorneys' Opinions of Compensability of relocations discussed in the Technical Report must be prepared and approved by CELMV-ET-R prior to execution of the PCA.

d. A statement should be added to the top paragraph on page 28 that LERR will be credited as specified in Section 307 of Public Law 102-580.

e. The report is not clear about who is responsible for acquiring the necessary permits. This should be negotiated with the local sponsor and the draft PCA to be submitted to headquarters for review should specify who is responsible for assuring various permit actions.

MEMORANDUM FOR Commander, Lower Mississippi Valley Division

SUBJECT: Lake Pontchartrain Stormwater Discharge Project

1. References:

a. CECW-PE memorandum, dated 4 Mar 94, subject: Section 307 of the Water Resources Development Act of 1992 (WRDA 92), Water Quality Projects.

b. CECW-EP-W Second Endorsement, dated 24 Jun 94, subject: Lake Pontchartrain Stormwater Discharge, Louisiana, Technical Report, Jefferson Parish.

c. CECW-PE memorandum, dated 13 Dec 94, subject: Section 307 of the Water Resources Development Act of 1992 (WRDA 92), Water Quality Projects.

d. Senate Report Number 103-291, Second Session, 34-35, 1994.

e. ASA(CW) memorandum, dated 7 Jun 95, subject: Lake Pontchartrain Stormwater Discharge Project.

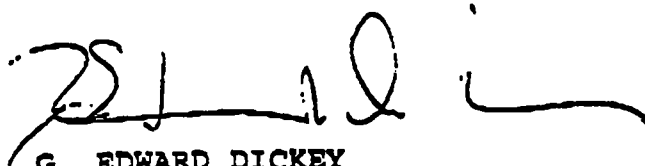

2. The purpose of this memorandum is to provide additional guidance on the implementation of the subject project.

3. The ASA(CW) requested the Army General Counsel's opinion on the authority of the Corps under Section 307 of WRDA 92, Public Law 102-580, to enter into an agreement in which the stormwater discharge facility owners would design and construct Federally authorized modifications at such facilities at Federal expense. The Army General Counsel concluded, in brief, that Section 307 provides such authority. Stating that it was the Army's policy "to comply with the intent of Congress on this matter as reflected in Senate Report Number 103-291," the ASA(CW) requested the Director of Civil Works to provide direction and guidance to

the Lower Mississippi Valley Division to prepare a draft cooperative agreement with the local sponsor of the Lake Pontchartrain Stormwater Discharge Project.

4. Accordingly, you are requested to draft a single Project Cooperation Agreement (PCA) which defines the roles of the Corps and non-Federal participants in this project. This agreement should reflect that modifications may be designed and constructed by the facility owners under the technical management oversight of the Corps. To that end, the Corps must ensure that the scope of the project is not above and beyond that which is necessary for the project to function properly to contribute toward compliance with the Federal Water Pollution Control Act. Any improvements not considered necessary for compliance with this Act will be done at 100 percent non-Federal cost.
5. The PCA should be based on the existing model PCA for the Section 307 Program which was included in the CECW-PE guidance dated 13 December 1994. Since this PCA will represent a departure from our standard PCA's you must submit the draft PCA to this office for approval prior to negotiating it with the non-Federal interests.
6. This project is not included in the President's FY 96 budget request and we cannot commit to include this project in future budgets. The PCA must be drafted to reflect this situation and execution strategies must reflect this uncertainty. We will proceed with the project within the limits of appropriations provided to date and should be fully prepared to continue with such funds as may be provided in the future.
7. The decision to allow non-Federal interests to participate in the project design and construction of the subject stormwater discharge modifications is limited to the Section 307 program authority only and is not extended to any other Corps program or project authority.

# **Jefferson Parish, Louisiana Stormwater Demonstration Project**

## **TECHNICAL REPORT EXECUTIVE SUMMARY**

This Technical Report has been prepared to describe a project designed to demonstrate a process that will reduce the impacts of stormwater discharges from Jefferson Parish to Lake Pontchartrain on water quality. This addresses the comments received from HQUSACE and EPA on a previous submission and reflects the extensive negotiations with the Sponsor regarding the scope of the project features essential to satisfy the intent of the authorizing legislation. In principle, it has been agreed that the project will be comprised of the features listed below. Project features are:

1. A 20,000 gpm stormwater pump station at the intersection of the Suburban Canal and Canal No. 4 and a 36-inch diameter force main to connect the station to the existing regional force main that currently transports sewage to the East Bank Wastewater Treatment Plant (EBWWTP).

2. Approximately 12,300 feet of new force main from the existing 48" diameter regional sewer force main adjacent to West Napoleon Avenue to the EBWWTP. A 48-inch force main is the apparent size required for the design flows projected. Jefferson Parish, the non-Federal sponsor, may request a larger diameter, and has agreed to pay the cost difference (100% non-Federal).

3. Modifications to the EBWWTP deemed necessary to accommodate the hydraulic and organic loadings imposed by the introduction of stormwater. Extent of the modifications will be based on the specific effluent limits requirements of a new permit that addresses the increased average daily flows to the EBWWTP. Upgrades will be based on increased loadings and flows to the EBWWTP and the current capability of the existing facilities.

4. A monitoring and modeling program to characterize the water quality of stormwater runoff accumulated in the Jefferson Parish East Bank Canal System, determine the water quality of Lake Pontchartrain, quantify pollutant loadings from the discharged stormwater to the Lake, assess the impacts of proposed actions on the Lake and the EBWWTP, demonstrate the effectiveness of the project, and evaluate the applicability of processes to other areas.

The latest guidance for the implementation of this project indicates that the Sponsor will be allowed to design and construct the required facilities and be reimbursed for costs in excess of 25% of the total project costs. The guidance is also specific that technical oversight is the responsibility of the Corps of Engineers and costs for items considered to be betterments will be 100% non-Federal, not subject to cost sharing.

The Project Cooperation Agreement (PCA) will be prepared and negotiated based on the information contained in this Technical Document. It is recommended that all the costs incurred by the Sponsor, consistent with project requirements, for the development of this project and for work associated with design, surveys, geotechnical investigations, and initiation of plans and specifications for the construction of project features that were incurred prior to the execution of the PCA be considered as project costs and be creditable as work-in-kind. All work-in-kind credits for this project will be subject to review and approval by the Corps of Engineers and shall be verified by audit.

LAKE PONTCHARTRAIN  
STORM WATER DISCHARGE, LOUISIANA

**JEFFERSON PARISH DEMONSTRATION PROJECT**

1. Authority. The Water Resource Development Act of 1992 (Oct 92), PL 102-580, Section 307, authorizes the Secretary of the Army to design and construct projects that address water quality problems associated with storm water discharges into Lake Pontchartrain and the Mississippi River. Project designs shall ensure the development of effective Federal and non-Federal actions which contribute toward compliance with the Federal Water Pollution Control Act (FWPCA). The Fiscal Year 1994 Energy and Water Appropriations Bill provided \$2 million to prepare a Project Cooperation Agreement and technical documentation for a storm water management demonstration project proposed by Jefferson Parish officials.

2. Purpose of Report. The purpose of this technical document is to describe the actions proposed to satisfy the intent of the authorizing legislation and to establish a basis for execution of the Project Cooperation Agreement (PCA) between the Corps of Engineers and Jefferson Parish, Louisiana (non-Federal sponsor). The report will also provide pertinent information relating to the location of the project, the characteristics of the area, details of the proposed actions, other alternatives considered, results of NEPA, HTRW and Cultural Resources coordination, and activities planned for evaluation of the processes implemented.

3. Requirements for Local Cooperation. Section 307 (c) of the Water Resources Development Act of 1992 requires that "the total project cost be shared at 75 percent Federal and 25 percent non-Federal. The non-Federal sponsor shall receive credit for lands, easements, rights-of-way, and relocations (LERR) toward its share of project costs, but not to exceed 25 percent of total project costs. Operation and maintenance cost shall be 100 percent non-Federal." The Parish of Jefferson, Louisiana has stated their intention to be the Local Sponsor for this project. See President Michael J. Yenni's January 25, 1994 letter in Appendix A, and follow-up letter dated April 12, 1995 outlining the scope of engineering features and agreement summary for the project. The June 9, 1995, Corps agreement summary response letter is also included. Resolution of issues relating to credits for work-in-kind has resulted in guidance that allows the Corps of Engineers to reimburse the non-Federal Sponsor for actual costs incurred in excess of 25% of the total project cost.

4. Purpose and Scope of Project. The purpose of this project is to demonstrate the capability to mitigate stormwater impacts on Lake Pontchartrain water quality by collecting, storing, and removing runoff from the drainage system prior to its discharge to the Lake and to determine if this runoff can be effectively treated by treatment facilities that have handled high infiltration/inflows. Further, the new force main will be used to augment the capacity of existing sewage lift stations during wet weather to reduce the potential for sewage overflows from a taxed system. A monitoring and modeling program will be used to determine existing conditions and to validate the extent of anticipated improvements.

5. Background. A reconnaissance study of urban flood control and water quality management for Jefferson and Orleans Parishes was completed and approved in December 1993. One purpose of the study was to investigate ways to improve the water quality of storm water runoff into Lake Pontchartrain. The technical work done for the reconnaissance study is the basis for this Technical Report. In the reconnaissance study, the nature and extent of the water quality problems were estimated using existing data and computer modeling. Some improvements were identified to relieve water quality problems and were evaluated for economic justification and environmental acceptability. The study concluded that more data are needed and demonstration projects are advisable.

The reconnaissance report recommended further study to more accurately determine the existing water quality, predict the effectiveness of various plans, and determine which management practices are best suited for a totally pumped drainage system.

Subsequent to the reconnaissance study Jefferson Parish developed a scheme to capture and treat storm water runoff using the excess capacity of the Parish East Bank sewage treatment plant. The Parish summarized their project Evaluation Phase in November 1994. A consensus agreement between the Corps and Jefferson Parish was reached in July 1995. This report will present and evaluate the consensus plan for the demonstration project.

6. Description of Project Area. The project area is located in southeastern Louisiana in the vicinity of the city of New Orleans and includes the highly urbanized portion of Jefferson Parish on the east bank of the Mississippi River. See Plate 1. The area is within the Pontchartrain Basin, situated near the center of the Gulf Coastal plain in the lower reaches of the Mississippi embayment. The basin is a shallow depression

lying between the alluvial ridge of the Mississippi River to the south, and sloping uplands to the north and west. The basin consists of Lakes Maurepas, Pontchartrain, and Borgne all of which are connected in a series by relatively narrow, but considerably deeper tidal passes. This system ultimately drains into the Mississippi Sound, Chandeleur Sound, and Breton Sound to the Gulf. Lake Pontchartrain is a shallow, land-locked tidal basin approximately 640 square miles in area with an average depth of 12 feet.

Generally, the ground near the Mississippi River is above sea level and elevations decrease with distance from the river. Most of the developed areas are protected from river and hurricane flooding by levee systems and drained by pumps which discharge into estuarine water bodies. The leveed areas are divided into many subbasins, by natural and man-made barriers, and are webbed with drainage canals that terminate at pumping stations.

Approximate minimum elevations on the east bank of the Mississippi River can be as low as -8 feet National Geodetic Vertical Datum (NGVD) in the artificially drained, former marsh and swamps that are presently commercially or residentially developed. A 4-foot ridge is located about 2 to 3 miles from Lake Pontchartrain, and runs generally parallel to the lakeshore in eastern Jefferson Parish and into Orleans Parish. This ridge, known as the Metairie-Gentilly Ridge, is the remains of the natural levee of an ancient distributary of the Mississippi River, and forms a natural drainage divide between the river and the south shore of Lake Pontchartrain.

The Jefferson Parish drainage system is an intertwined network of subsurface culverts, ditches, canals and pumping stations. See Plate 2. In contrast to conventional systems, which generally rely on gravity flow and free fall discharge, the Jefferson and Orleans Parishes drainage systems, unique to others in the United States, depend on the collection and pumping of all storm water falling on the area. The pumping stations on Jefferson Parish east bank discharge into Lake Pontchartrain. The treated effluent from the sewage treatment plant is discharged into the Mississippi River.

In most areas of the Jefferson Parish east bank, land elevations are lower than the surrounding water surface elevations. Levees protect the area from hurricane and Mississippi River flooding. However, the levees assume an opposite role, that of retaining water, where rainfall is concerned.

Jefferson Parish operates their drainage pumping stations to maintain a specific water surface elevation in the major outfall canals. Once those elevations are exceeded the pumps are engaged to discharge the excess. Previous subsidence problems in the parish dictate this operation, so that ground water is not drawn out of areas adjacent to the canals. However, subsidence has to a large extent stabilized.

The east bank storage areas are laterally connected by a "grid" of canals. The lateral canals equalize flow between the major outfall canals. This allows rain water to flow in different or opposite directions depending on available capacities at the pumping stations.

7. Description of Problem. The water quality of Lake Pontchartrain and the east Jefferson Parish drainage system is described in Appendix B. Based on historical data, Lake Pontchartrain along the Jefferson Parish lakeshore is contaminated by pathogenic organisms as indicated by fecal coliform levels of a magnitude of about 6 times the level considered safe for human contact. The primary source of this contamination is storm water discharge. Even though the east bank areas now pump their treated sewage into the Mississippi River instead of Lake Pontchartrain, high fecal coliform levels persist. Raw or partially treated sewage is often combined with storm water runoff as the result of overflows at sewage lift stations and subsequent runoff into the storm water drain lines. Also the initial storm water runoff washes urban pollution into the storm water drainage system. The major part of the problem, therefore, is the sewage overflows, infiltration and initial runoff.

8. Project History. In March of 1993, New Orleans District, in coordination with Jefferson Parish and the Lake Pontchartrain Basin Foundation proposed the subject project under Section 307 of WRDA '92. Since the project involved additions and modifications to the existing Parish sewer and drainage infrastructure, Jefferson Parish presented a conceptual plan to pump stormwater from the drainage canals to the East Bank Waste Water Treatment Plant (EBWWTP) for treatment. This would be a demonstration project at an estimated cost of \$20,400,000. The excess dry weather EBWWTP capacity could be used to treat stormwater runoff which remained in the canal system from the last storm event. The conceptual plan included a 32,750 gallon per minute lift station at the intersection of the Suburban Canal and Canal No. 4 at West Napoleon Avenue (see Plate 3), a 48-inch diameter sewer force main, and modifications to the EBWWTP.

With FY 94 funding, New Orleans District was directed to prepare a Technical Report as a basis for preparation of the Project Cooperation Agreement. The report was prepared, drawing heavily from Jefferson Parish input, and completed on 8 Mar 94. The report proposed that the technical design and bid documents, construction and construction management would be accomplished by the Parish. The Corps would maintain project management and technical oversight, be responsible for the monitoring plan, and reimburse the Parish to maintain the 75%-25% Federal - non-Federal cost sharing arrangement. The report was endorsed to HQUSACE and comments were forwarded to LMVD by 2nd End dated 24 Jun 94.

Upon HQUSACE review, a cost reimbursement issue arose as to the legality of transferring funds to the Parish for design and construction. Advantages existed to allowing local design and construction, including: 1) the Parish's institutional knowledge of their system; 2) their preliminary design work and familiarity with the project; and, 3) the likelihood of their completing the design expeditiously.

By separate Congressional action, Senate Report 103-291, dated September 1994, addressed the cost reimbursement issue with language that would allow cost reimbursement to the Parish. The report stated:

"The Committee is aware that development of this project as authorized in Public Law 102-580 will involve modifications or additions to existing locally-owned and operated public utilities. Although the Committee believes that the technical and management expertise of the Corps in developing and implementing the project is essential to ensure effective Federal and non-Federal actions, it also understands that design and construction of modification or additions to such facilities may be accomplished most

efficiently when conducted by the facility owners. Toward that end, the Committee directs the Secretary of the Army to develop the necessary agreements with the facility owners to allow them to design and construct such modifications under the technical management oversight of the Corps. The Committee has included \$800,000 to continue development of this project."

On 7 Jun 95, Dr. John H. Zirschky, Acting Assistant Secretary of the Army (Civil Works), advised that the Army General Counsel issued an opinion dated May 1, 1995, that the Corps is not legally precluded from entering into such agreements with the Parish. Dr. Zirschky requested that the Director of Civil Works provide direction and guidance, in accordance with Senate Report 103-291 and the intent of the Congress, to execute a cooperative agreement with the local project sponsor (Jefferson Parish) and proceed with negotiations.

HQUSACE implementation guidance memorandum dated 29 Jun 95 to LMVD requested preparation of a draft cooperative agreement with the local sponsor Jefferson Parish. The guidance was referred to New Orleans District by LMVD on 13 Jul 95 and requested that:

". . . a single [PCA be prepared] which defines the roles of the Corps and non-Federal participants in this project. This agreement should reflect that modifications may be designed and constructed by the facility owners under the technical management oversight of the Corps. To that end, the Corps must ensure that the scope of the project is not above and beyond that which is necessary for the project to function properly to contribute toward compliance with the Federal Water Pollution Control Act. Any improvements not

considered necessary for compliance with this Act will be done at 100% non-Federal cost."

The guidance further advised:

"This project is not included in the President's FY96 budget request and we cannot commit to include this project in future budgets. The PCA must be drafted to reflect this situation and execution strategies must reflect this uncertainty."

Also, the guidance provided:

"The decision to allow non-Federal interests to participate in the project design and construction of the subject stormwater discharge modifications is limited to the Section 307 program authority only and is not extended to any other Corps program or project authority."

This report is being prepared in accordance with the above guidelines.

9. Alternatives Considered. The approved Reconnaissance Study presents alternate plans to improve water quality. This Technical Report will not repeat all that was considered in the reconnaissance report but only that required to describe the viable alternatives for a demonstration project.

The alternatives can be divided into five general categories as follows:

1. In-line Detention
  - a. Concrete-Lined Canal with Bottom Collector Compartment
  - b. Pump Storm Water Runoff to Wastewater Treatment Plant
2. Disinfection
  - Chlorination or other disinfectants

3. Flush the System with Water
  - a. Mississippi River
  - b. Lake Pontchartrain
4. Diversion
  - a. Diversion into St. Charles Parish wetlands
  - b. Discharge storm water further into the lake (i.e. further away from existing south shore discharge points)
  - c. Divert a portion of the storm water discharge from the Lake to the River.
5. Sedimentation

### Alternative 1 - In-Line Detention

There are two basic alternatives to in-line detention:

- a. Construct the drainage canals so that the worst of the storm water runoff or the pollutants is segregated in the canals. The scheme offered in the Reconnaissance Report was a concrete lined canal with a bottom compartment that would fill first and would collect sediments. Then the material in the bottom compartment could then be pumped to some treatment facility.

Concrete lining of all major canals associated with in-line storage would have an extremely high cost if incorporated on an East Bank Parish-wide basis. Cost estimates are of the order of magnitude of \$375 million, and are deemed unfeasible since this amount is unacceptably high and engineering uncertainties would tend to drive the true cost higher.

- b. Another alternative is to time the pumping of the existing canals so that the worst of the runoff is sent to an existing treatment facility and the remaining less polluted runoff is pumped out without treatment. This is the selected plan and is detailed later.

The capture and storage of the first runoff, which contains an estimated 90% of total pollutants, requires significant storage capacities (See Appendix C). The existing lateral canals have significant storage capacity since they may be pumped down prior to a rain event. The canals are pumped down only prior to anticipated major events. Thus, first runoff, mixed with existing canal water, can be pumped away from the lake, to existing East Bank Waste Water Treatment Facilities. This can likely be done cost-effectively. A detailed water quality monitoring and modeling plan can be incorporated to determine whether and to what extent pumping canal water is an efficient and economical alternative for improving the quality of storm water discharges into Lake Pontchartrain. Virtually all of the pollutants to be pumped to the plant are within the existing plant treatment capability during wet weather conditions,. Thus, modifications, if any, are deemed to be needed to the existing treatment plant to accommodate pumped storm water during dry weather conditions. Modifications may be required to satisfy EPA and LA DEQ revised discharge permit requirements.

Further, installing a new 48-inch sewer force main at the approximate midpoint of the existing sewer main (See Plate 3) will reduce the likelihood of rainfall-induced sewerage overflows. This will have positive impacts on reducing the levels of pathogenic organisms pumped into Lake Pontchartrain. The improved water quality effects of the storm water discharge should be measurable.

## Alternative 2 - Disinfection

In these alternatives the storm water discharge is mixed with a disinfectant before entering Lake Pontchartrain. This is very effective against bacteria present in the water when treated but does nothing to remove inorganic compounds, poisons, metals and other pollutants present in urban run-off. And this does nothing to prevent regrowth of these organisms when the disinfectant is diluted in the Lake.

Other considerations for disinfection are that dangerous gases such as chlorine, chlorine dioxide and ozone are used, and thus highly trained personnel are required to operate the stations. Additional storage space for disinfection facilities is required, but insufficient space is available at existing stations. Also, dosage rates must be very high and uniform mixing is difficult, although modern technology has improved dosing and mixing. Chemicals formed can possibly affect other aquatic life. Further, disinfection must be accomplished on the discharge end as chlorine is corrosive to pump and equipment components.

Disinfection alternatives provide only a partial and impractical solution to improving storm water discharge quality. Therefore, the disinfection alternatives will not be considered further.

## Alternative 3 - Flush the System with Water

This is a dilution method and is divided into two alternatives depending on the source of water:

- a. the Mississippi River, or;
- b. Lake Pontchartrain.

Either alternative involves pumping water into the system to dilute the pollutants. The regenerative effects and assimilative capacities of the

water bodies, especially the Mississippi River, can dissipate the pollutants. This alternative can be combined with other alternatives that divert the storm water into adjacent wetlands. Odor problems can be diminished by flushing stagnant canals.

a. Mississippi River Water. Flushing the canal system with Mississippi River water is possible, to dilute pollutant concentrations entering Lake Pontchartrain. However, pumping the water back to the river is extremely expensive. A variable seasonal head requirement for pumps is necessary to pump water back into the river. Also, ground elevations decrease with increasing distance from the river, thus pumping must be uphill for canal reaches farther from the river. Further, using river water in the canals will likely result in canal sedimentation.

b. Lake Pontchartrain Water. Flush water from Lake Pontchartrain could be pumped into the drainage canals from the Bonnabel Pumping station (see Plate 3) and pumped out by another station. Introducing large amounts of lake water into the drainage system would cause a massive influx of marine life into the canal system which it cannot support, causing fish kills and odor problems. Further, introducing lake water into the drainage system could increase salinities of water handled by the stations, increasing maintenance and reducing equipment life.

Therefore, the flushing alternatives will not be adopted.

#### Alternative 4 - Diversion

This category is broken down into 3 alternatives.

a. Divert the Jefferson Parish storm water into the adjacent St. Charles Parish wetlands and allow the natural filtering action of the

wetlands to cleanse the storm water before it enters the Lake. The adjacent marsh areas are probably adequate in size to treat the runoff. However, discharging all or any large portion of Jefferson runoff at one end of the Parish is prohibitively expensive. Further, local opposition of St. Charles Parish officials to receiving Jefferson Parish storm water is likely.

b. Discharge storm water further into the Lake. This would divert the concentration of pollutants away from the populated south shore. This project consists of a large diameter metal outfall pipe extending from each smaller pump discharge pipe into the lake about 1500 feet. The increased areal extent and the somewhat deeper lake mixing zone would enhance pollutant dispersion and dilution and result in smaller short-term concentration increases.

However, overall pollutant loading in the lake would remain the same. The pipes would need to be buried under the lake floor, and poor soil stability of the lake bottom might cause excessive settlements. Pile support would likely be needed. Measures to preclude lake sediments from backing up into the discharge pipe would be required. Also, an increased head on the existing lake outfall pumping stations would reduce the pumping capacity. Maintenance costs for the discharges would be substantial. Further, the lake is not significantly deeper further out than near shore.

c. Divert a portion of the storm water discharge from the Lake to the River. This would be applicable to a community like Harahan, Louisiana; and would reduce the total load going into the Lake by diverting a portion to the River. Diversion of storm water would secondarily reduce flood potential of areas south of Jefferson Highway. However, drainage pumping stations at the river would be extremely

expensive and cost prohibitive on a Parish wide basis. Also, this would only address a small part of the overall volume of pollutants discharged to the lake. Significant modifications to the existing drainage system would be required by this plan. Further, this assumes that the dilution capability and natural process of the river will adequately handle the pollutant load.

### Alternative 5 - Sedimentation

Sedimentation can be divided into two alternatives:

- a) alum treatment, and;
- b) sediment traps.

a) Alum Treatment. Alum treatment would occur at the drainage pumps and the flocculent contained in the pumping station discharge and outfall canals. The suspended sediments would be precipitated before reaching Lake Pontchartrain. The outfall canals may offer a suitable mixing and sedimentation zone for treated storm water. The alum treatment method provides high removal rates of all pollutants. No detention basins or wetlands need to be constructed, thus large real estate acquisition is not needed. Further, the alum precipitate (floc) tends to remain inert and stable under chemical conditions likely to exist in the receiving water.

However, accumulated floc would probably need to be trapped in an outfall canal settling basin (or sediment trap) rather than be discharged to the lake because of its tendency to form visible deposits on the bottom. Suspended sediments will precipitate in the pumping station stilling basin on the lake side. This may require frequent cleanout or dredging of the pumping station stilling basin. Although alum dosages can be adjusted by using variable speed injection pumps, proper alum treatment requires precise pH and temperature controls, neither of which are practical for a

given subbasin, or for Parish wide implementation. Further, no locations exist for settling basins near the pumping stations without significant bank or structural modifications.

b) Sediment Traps. Sediment traps in the canals near the intakes of pumping stations would be somewhat effective in solids reduction for storm water, but would need to be located beyond the immediate vicinity of the intakes to avoid significant resuspension of solids. A sill on the outfall side would serve the same purpose, but would need to be able to withstand high dynamic loading during periods of large pumping rates.

However, frequent dredging would probably be needed in order to maintain proper storage capacity of solid material. A sill would probably require frequent repair unless armored with heavy riprap and containing geotextile lining material to retain fine sediment particles. Also, sediment traps would not greatly reduce concentrations of pathogenic organisms.

Further, the required velocities to induce settlement of suspended materials are extremely slow, which would impede pumping operations. Thus, there is no practical way to reduce the flow velocities to make this a viable alternative. Therefore, sediment traps will not be considered further.

#### Additional Qualitative Analyses

The alternatives were then evaluated based on three criteria;

- a. cost effectiveness
- b. acceptability to the citizens of Jefferson Parish and those adjacent to or using the Lake, and
- c. the ability to expand the demonstration project to the entire east bank of Jefferson Parish.

The alternatives were scored by a panel of experts including representatives of Jefferson Parish and the Lake Pontchartrain Basin Foundation. The panel was chaired by the District Engineer. The panel used a 5 point scoring system. In each criterion the best score was 5; and the lowest score was 1. The scoring is relative, in that it reflects how each alternative stands against the others. The results are tabulated in the following:

ALTERNATES	COST EFFECTIVENESS	ACCEPTABILITY	EXPANDABILITY	SCORE (RANK)
1A. In-Line Detention Concrete Lined Canals	3	5	4	12 (2)
1B. Pump Worst of Runoff To Existing Treatment Plant	4	5	4	13 (1)
3A. Flush With Mississippi River Water	1	1	1	3 (7)
3B. Flush with Lake Pontchartrain Water	2	3	1	6 (6)
4A. Divert Into St. Charles Parish Wetlands	3	2	1	6 (6)
4B. Discharge Further out into Lake Pontchartrain	3	2	4	9 (4)
4C. Divert Harahan runoff to the Mississippi River	4	3	1	8 (5)
5. Alum Treatment	5	2	4	11 (3)

Alternative 1B, pumping the worst of the runoff to the existing sewage treatment plant, was selected.

10. Description and Rationale of Selected Plan.

a. General. An overview of the existing Jefferson Parish Suburban Basin Canal system layout with the stormwater discharge demonstration project selected plan features added is shown on Plate 4. The selected plan consists of a 20,000 gallon per minute (GPM) storm water lift station located on the Suburban Canal near Canal No. 4; a new 48-inch diameter sewer force main from the intersection of West Napoleon and Woodlawn to the EBWWTP; and modifications to the East Bank Waste Water Treatment plant that are necessary to produce effluent conditions that satisfy the conditions and requirements of the National Pollution Discharge Elimination System (NPDES) permit issued for the increased loadings imposed by the addition of stormwater to the system.

The Jefferson Parish East Bank Waste Water Treatment Plant has a demonstrated wet weather capacity well in excess of the required dry weather capacity. For the demonstration project, this excess capacity will be used to treat the first runoff, mixed with the contents of the drainage canals and the dry weather flow from the sewage system. The lift station and force main will be used to transport the storm water from the drainage system to the treatment facility.

b. Process. This project is intended to demonstrate that improvements in the quality of storm water discharges into Lake Pontchartrain that contribute toward compliance with the Federal Water Pollution control Act (FWPCA) can be effected by the proposed actions. The existing Jefferson Parish major drainage and sewerage networks will be operated to use the capability of each in combination with the proposed new facilities to produce improvements in the operations of both systems. Runoff from storm events is normally stored in drainage canals and is ultimately pumped along with its constituent loading to Lake

Pontchartrain. The demonstration project will direct the contents of the Suburban basin drainage canals to the EBWWTP during dry weather periods when flows to the plant are low and system capability is available. Present drainage system operations in the Suburban Canal Basin maintain a near constant elevation (approximately 9 feet Cairo Datum (C.D.) in the canals to avoid subsidence and canal bank sloughing. When a rainfall event approaches, canal levels can be lowered up to two feet (approximately elevation 7 feet C.D.) using the Lake Pontchartrain outfall pumps to create additional storage capacity. The runoff from a rainfall event fills the canals. Once an elevation 10(+/-) C.D. is reached, the outfall pumps discharge the excess into Lake Pontchartrain (See Plate 5). The post-rainfall canal levels are restored to about elevation 9 feet C.D. The canal levels are generally static until lowering in anticipation of the next rain event. Stormwater contaminant materials are not removed or reduced prior to discharge into Lake Pontchartrain.

The Stormwater Demonstration project will direct canal water to the EBWWTP during low sewage flow periods. In lieu of using outfall pumps to lower the canals in anticipation of a rainfall event, this project will, after the effects of the rainfall event have subsided, begin pumping the canal contents to the EBWWTP. The stormwater is mixed with the sewage flows from the eastern portion of the sewer system as it enters the existing regional force main near the lift station and is transported to the EBWWTP via the new 48-inch force main. The amount of stormwater and its associated pollutant concentrations removed from the drainage canals is treated at the EBWWTP and discharged to the Mississippi River. This action will improve the water quality of Lake Pontchartrain by reducing the quantity of stormwater and pollutants discharged. The Stormwater Demonstration project facilities and operations are expected to be capable of storing, removing, and treating runoff from

rainfall events with magnitudes of up to 1/2 inch and recurrent frequencies of three to four days. Smaller, more frequent events will be handled by the systems; but larger events must be handled by the existing drainage system outfall pumps. A large percentage of storm events in this area have been historically within the range of capability of the proposed actions for this demonstration project. The project will not be capable of handling the larger more extraordinary rainfall events sometimes experienced in the area. These events will preclude the use of the demonstration project operations and must be handled by the existing drainage system facilities and operations procedures. The Stormwater Discharge project will not be used when there is a potential for rainfall events to produce urban flooding or when the sewerage system is surcharged by infiltration/inflows experienced during and immediately following storm events. It is anticipated that there will be a sufficient number of rainfall events of 1/2 inch or less that reliable data validating the viability of the demonstration can be accumulated.

To ensure that stormwater contaminant materials routed to the EBWWTP are properly treated prior to discharge to the Mississippi River, up to five treatment plant modifications proposed by the non-Federal Sponsor will be evaluated and incorporated, if needed, to maintain the level of treatment required to meet NPDES permit requirements. A study by Jefferson Parish, anticipated to be completed by October 1995, will determine specifically which modifications are needed, subject to review and approval of the Corps of Engineers, the Environmental Protection Agency, and the Louisiana Department of Environmental Quality. This report describes an upper limit, or "worst case scenario" of modifications needed. Required NPDES permit sampling and testing will remain in place and additional water quality monitoring and/or modeling as detailed herein will be done as part of the Stormwater Discharge project.

The Stormwater Discharge Demonstration project has four main features:

1) Force Main. A 48-inch diameter force main, tying into the existing regional force main, is required in the Suburban Canal subbasin to convey stormwater to the EBWWTP (See Plate 6). This force main is designed to convey about 13,000 gpm from the east side sewerage system (during dry weather conditions), plus up to 20,000 gpm of stormwater from the drainage canals to the EBWWTP for treatment. The force main routing is generally along an existing street alignment and through a railroad corridor adjacent to the plant. The force main will be utilized for sanitary flows during dry weather conditions in conjunction with this demonstration project and during wet weather to augment the existing sewerage system capability to handle high infiltration/inflow surcharges that traditionally have been experienced. The demonstration project will be instrumented to monitor pressures within the regional force main and control when and how much stormwater can be added to the EBWWTP. Jefferson Parish may opt to construct a 60-inch diameter force main, in lieu of 48-inch diameter, to better serve future Parish needs. They have agreed to fund the incremental cost as 100% Non-Federal. An M-CACES cost estimate for the 48-inch and the 60-inch force mains is included in Appendix E. A summary of project costs is given in paragraph 18.

The stormwater project operating plan is to consider two scenarios for stormwater pumping operations: 1) discontinue pumping stormwater based on a predetermined pressure level in the force main, and, 2) continuous pumping, but only if sufficient canal water is available to maintain canal elevation 7 C.D. as a minimum. It is not anticipated that continuous pumping will occur. Canal level monitoring will be needed to ensure the "pump off" condition when canal stages warrant. Jefferson Parish has an existing system that can be set up for such controls.

Generally, during wet weather peak flows, when infiltration and inflow cause an increase in treatment plant inflow, stormwater pumping will be discontinued until dry weather conditions resume. Thus, operation of the stormwater pumps will be closely interfaced with the existing Jefferson Parish control and monitoring systems of the sewerage and drainage departments. It may be advantageous to permit stormwater pumping to continue through the early part of the rainfall event to capture as much as possible of the probably higher contaminant concentrations of first runoff, but pumping will discontinue as needed to reserve treatment plant and force main capacity for wet weather. The optimum "pump on/pump off" point will be developed.

2) Pumping Station. A 20,000 gpm lift station will be installed on the Suburban subbasin canal bank near the intersection with the West Napoleon Canal, to pump stormwater runoff (mixed with canal water), from the drainage canal into the new force main (See Plate 8). The preliminary design for the lift station proposes a concrete sump approximately 25 feet by 30 feet inside dimensions with a base slab at elevation (-)0.0 feet C.D. (See Plates 9 and 10). The structure is supported on 60 foot timber piles about three to four feet on centers. A concrete block with masonry veneer enclosure will house the mechanical and electrical features of the lift station, with a floor elevation about 17.5 feet C.D. (See Plate 10).

The mechanical features include four 5000-gpm VTSH (vertical turbine solids handling) pumps with approximately 125-horsepower motors each. Approximately 16-inch diameter suction pipes with the pump bellmouth at approximate elevation 1.0 feet C.D. in the sump are anticipated for each pump. Each pump discharge will have a gate valve and a check valve for backflow prevention and maintenance. The intake structure from the Suburban Canal has been preliminarily designed as an 18-foot wide intake

channel with invert elevation 3.0 C.D. (See Plate 11). A 30-foot wide V-bottom flume channel lining will be included in the canal intake area. A Waskey type bridge is included for access to a trash rack for intake debris removal and maintenance. The discharge will be approximately a 36-inch diameter manifold routed to the existing regional force main. Electrical features include new electrical service, power distribution, a motor control center, control panels (consoles for the pumps), grounding facilities, a lightning protection system, a SCADA system and network interface, and other accessories for lighting, ventilation, communications, and maintenance.

An underground vault design concept for the lift station was studied by the Corps and presented to Jefferson Parish for consideration as a more economical alternate. The Parish opted for the masonry building presented herein, since this demonstration project, if sufficient results are not achieved, could leave non-functional storm water facilities in the Parish. Some allowance will be given to the Parish to design the lift station to avoid economic waste and to permit reusability of facilities.

The detailed cost estimate for the lift station presented is \$1,300,000 plus contingencies. A detailed breakdown of the cost estimate is given in Appendix E and a cost summary is given in paragraph 18.

3) Treatment Plant Modifications. A brief review of existing treatment plant facilities and unit operations is presented prior to the potential modifications. The treatment plant is a conventional activated sludge process supported by appropriate support peripheral facilities. The existing plant process is shown in the schematic on plate 12. The unit operations include preliminary treatment which includes screening and grit removal, followed by primary clarifiers. Secondary treatment consists of activated sludge aeration basins followed by secondary

clarifiers. Disinfection is accomplished by chlorinating at the secondary clarifier effluent channel. Odor control facilities are also provided at several locations throughout the plant. Solids are treated by a liquid treatment train with dissolved air flotation sludge thickeners, sludge holding tanks, sludge dewatering (belt filter press) units, and disposal to a landfill. Sludge recirculation to the aeration basins is also available to maintain appropriate mixed liquor suspended solids (MLSS) concentrations.

A list of five proposed upgrades to the EBWWTP is as follows:

- a) Site Work and Headworks Tie-In
- b) Conversion of Primary Clarifiers to Aeration Basins
- c) Add Sludge Handling Facilities - Belt Filter Presses (or alternately, Centrifuges) and Sludge Holding Tanks
- d) Dechlorination Facilities
- e) Electrical and Instrumentation Facilities.

All 5 features have been conditionally included in this report pending a study (August-October 1995) by Jefferson Parish consultants and subject to review. The potential need for each of these items will be explained briefly.

a) Site Work and Headworks Tie-In. Site work includes incidental building revisions for facility upgrades. The headworks tie-in includes valving of the new 48-inch (or 60-inch) force main into the treatment plant. Headworks facilities are preliminary treatment, which include mechanical bar screens and grit removal chambers. The character of inflow materials is different for stormwater and sewage (wastewater). Stormwater solid material is primarily non-biodegradable, and is composed of different-sized solids. Conversion to a smaller opening on the inlet bar screens may be required. Sieve analysis is recommended by the Parish to identify the particle sizes of total suspended solids (TSS)

anticipated from stormwater. Plant process and performance may be affected if certain-sized solids are not removed.

b) Conversion of Primary Clarifiers to Aeration Basins.

Preliminary estimates by the Sponsor's consultant indicate the average daily hydraulic capacity of the existing aeration basis to be 51 MGD and suggest the average daily flow to be plant with the addition of stormwater will be 71 MGD. The current measured and reported average daily flow to the plant is 35.5 MGD. The plant capacity estimate appears to be conservative and the 71 MGD applied load assumes continuous pumping of stormwater into the system. The extent of aeration basin modifications required will be governed by further and more detailed analyses and the necessity to provide expanded facilities to produce effluents that meet the new NPDES permit. Additional hydraulic, solids, and organic loads are anticipated and their impact on WWTP performance must be addressed to assure performance within the parameters outlined by the NPDES permit.

c) Add Sludge Handling Facilities - Belt Filter Presses (or alternately, Centrifuges) and Sludge Holding Tanks. Additional sludge facilities are proposed including belt filter presses, dissolved air flotation (DAF) units, and sludge holding tanks, due to the anticipated increase in sludge from pumping stormwater. This will also be reviewed in the Jefferson Parish study pending. Centrifuges involve a state-of-the-art change to the plant and may constitute a betterment.

d) Dechlorination Facilities. The addition of stormwater may result in the need to provide dechlorination of the plant effluent to the Mississippi River. Chlorination is used in the plant to control pathogenic organism levels in the treated wastewater, but must be removed prior to effluent discharge to the Mississippi River.

e) Electrical and Instrumentation Facilities. Selected electrical control systems and monitoring instrumentation are proposed to support the upgrades and modifications outlined herein.

Results of the pending study will be used to determine, after review, the actual treatment plant modifications needed. Proposed modifications will also be reviewed in the light of requirements for a new NPDES permit to accommodate the increased flows to the plant and of criteria established jointly by the Corps of Engineers and Jefferson Parish.

#### **11. WATER QUALITY MONITORING/MODELING PROGRAM.**

The preconstruction monitoring plan (See Appendix C) will provide existing conditions with respect to the storm water runoff quality in the drainage canal system and Lake Pontchartrain receiving area water quality. The sampling plan will be developed and implemented to define the characteristics (i.e. volume, duration and pollutant concentrations) of storm water runoff for the east bank of Jefferson Parish. The program will also define the duration and extent of negative impacts (i.e. depressed DO levels, elevated pathogenic organism levels, etc.) of stormwater runoff in Lake Pontchartrain.

Automatic water samplers with rain gauges and liquid level actuators will be located at the pumping stations and at the basin's interior non-pumping station locations. Flow measurements will also be taken at these locations. The samples will be analyzed for solids, oxygen demanding substances, nutrients, bacteria and metals. Sampling stations will also be established in Lake Pontchartrain to ascertain the impacts of storm water runoff in the receiving water body.

The post-construction monitoring program will provide with-project data with respect to storm water runoff and Lake Pontchartrain receiving area

quality. Ideally, the same sampling locations will be used for pre- and post-construction monitoring.

Baseline data in the drainage canals will be collected during non-storm events. Further sampling will provide both quantity and quality data for all overflows, along with rainfall data from the numerous gauges located throughout the basin.

The data collected during the pre- and post-construction monitoring programs will be used in developing a receiving area water quality model and to evaluate the impacts of the demonstration project on receiving area water quality. This will allow for the evaluation of a wide range of rainfall and treatment scenarios.

## **12. Real Estate.**

### **General Note: Real Estate and Relocations for Section 307 Projects.**

The obligations of the Government and the Non-Federal Sponsor for Real Estate and Relocations for the Stormwater project are to be developed in the Project Cooperation Agreement (PCA). Normally, in Section 307 Water Quality projects, the Government is the designer and thus develops the details of the required rights-of-way and relocations. In the Stormwater project, Senate language and ASA(CW) guidance authorize Jefferson Parish to perform detailed design and construction under Corps technical oversight. Thus, we intend to structure the PCA, such that Jefferson Parish will develop, with Corps guidance, the general written descriptions, including maps as appropriate, of the lands, easements, rights-of-way and relocations required for this project. Any items that the Parish seeks credit for must be presented in accordance with Federal laws, regulations and policies. Relocations and rights-of-way costs are subject to audit to determine whether the costs are reasonable, allocable, and allowable.

The real estate requirements for this project with the preliminary alignment include, at a minimum, one occupied residence in the vicinity of the pumping lift station, street right-of-way for the sewer force main, and the necessary rights-of-way to install force main beneath railroad tracks and a Louisiana state highway. Acquisition of all lands, easements, rights-of-way, and relocations will be performed by Jefferson Parish as local sponsor, and in accordance with Public Law 91-646, and Chapter 12 of Engineering Regulation 405-1-2. The cost of providing same may be credited toward Jefferson Parish's 25% share of the project's first cost.

Rights-of-way furnished by Jefferson Parish must be certified prior to construction and crediting in accordance with the requirements of Chapter 12. The Parish may also desire to seek "quicktake" authority, to insure acquisition of required rights-of-way in a timely manner.

Based on information from the local sponsor, Jefferson Parish, the selected route would be entirely constructed within existing Jefferson Parish rights-of-way with two exceptions. A permit will be required from Louisiana DOTD for crossing Airline Highway. Rights-of-way will need to be purchased from three railroad companies for the east/west portion of the force main south of Airline Highway.

The lift station will be constructed within the confines of the property which is presently owned by the Jefferson Parish Department of Sewerage; however, additional rights-of-way for access of construction equipment and operations, and excavation and storage purposes is required. Also, this will allow a "buffer" between the station and adjacent residential properties to allow for maintenance access, exterior storage and to minimize negative impacts on the neighborhood.

Therefore, the property adjacent to the proposed site will be purchased and the existing residential structure demolished.

13. Relocations. The proposed 48-inch force main will be installed on a residential street (North Woodlawn Avenue) in Jefferson Parish. Several drainage, water supply and other utilities will be affected. These items may be compensable under LERR provisions. A compensable interest determination must be made for each item based on the type of utility, whether it is privately or publicly owned, and who performs the coordination and design of the relocation.

14. Environmental Considerations. Anticipated direct construction impacts would result from the placement of the new sewer lift station, and 12,300 linear feet of 48-inch diameter sewer force main. Additional modification to the existing waste water plant would be conducted within the confines of the existing waste water treatment site and would not impact any significant resources. It is expected that residential thoroughfares and grassed areas along these traffic routes would receive the greatest impact. Additional anticipated negative impacts would occur to residences and commercial establishments located along the construction corridor from increased noise, rerouting of traffic, air pollution from heavy equipment, and dust from road disturbances. The overall environmental impacts of these construction features would be expected to be minimal and short term in duration.

Potential secondary impacts of the proposed demonstration project are possible increases of certain pollutants in the effluent discharged from the Waste Water Treatment Plant to the Mississippi River and possible increases of certain pollutants in sewage sludge deposited in the parish landfill. At this time we do not expect these increases, if any, to be significant. Impacts to recreational activities are expected to be minor.

There are no anticipated direct construction impacts to buried cultural resources resulting from the construction of 12,300 linear feet of 48-inch diameter sewer force main. The construction corridor passes through an area that appears to be disturbed by utility construction. A cultural resources investigation is presented in Appendix D. The results of this study have been coordinated with the State Historic Preservation Office.

An Environmental Assessment has been prepared to address the impacts of this demonstration project. We have received and prepared responses to EPA comments for the subject work. A Finding of No Significant Impact is anticipated, based on the project contribution toward compliance with the FWPCA. Coordination with the Louisiana Department of Wildlife and Fisheries, the U. S. EPA, the U. S. Fish and Wildlife Service, and other environmental agencies has occurred. Continued discussion with these organizations and agencies, primarily U.S. EPA, is on-going at this time in an effort to resolve concerned issues. It is not anticipated that a section 404 (b)(1) evaluation and state water quality certification will be required as the proposed construction activities are confined to developed urban areas and should not impact wetlands.

15. Cultural Resources Evaluation. A 24 March 1994 letter outlining the cultural resources evaluation for the proposed work has been sent to the State Historic Preservation Officer (see Appendix D). No adverse impacts to cultural resources are anticipated.

16. HTRW Initial Assessment. An initial HTRW assessment has been made for the subject work. The results are as follows:

The project reach was examined for the presence of hazardous, toxic, and radioactive waste (HTRW). This assessment relies on site inspections, aerial photography analysis, land-use studies, historical

records, and regulatory agency contacts. Based on this assessment, it is reasonable to conclude that no hazardous, toxic or radioactive waste would be encountered during construction activities for this project. No additional HTRW work is recommended, unless new information is developed or HTRW discovered.

17. NPDES Discharge Permit. The Jefferson Parish EBWWTP has an existing NPDES permit No. LA 0066630 authorizing the discharge of plant effluent to the receiving waters of the Mississippi River. The permit allows final discharge effluent limits as follows:

Item	30 Day Average (Lbs./Day)	30 Day Average Concentration mg/l	Maximum Daily Concentration mg/l
Biochemical Oxygen Demand (BOD-5)	8372	30	45
Total Suspended Solids (TSS)	8372	30	45
Fecal Coliform Bacteria (Colonies/100 ml)	n/a	200	400
Total Residual Chlorine (TRC)	Maximum at anytime 0.426 mg/l (Monitored Party)		

The WWTP must also, in accordance with Part III, Standard Conditions for NPDES permits, effect a percent removal of applied BOD-5 and TSS not less than 85%. The specific impacts of the stormwater pumping to the treatment plant will be developed further in the pending Parish

treatment plant modifications study to determine specifically the predicted impact of the stormwater project on the existing permit volume and loading limitations. A permit modification will be required to address the increase in average daily flows to the treatment plant and must be secured by Jefferson Parish from EPA and LA DEQ.

18. Cost Estimates. The estimated total incremental cost for the selected demonstration plan is \$20,000,000. This cost estimate is sufficient to proceed with a Project Cooperation Agreement between the Department of the Army and Jefferson Parish, Louisiana. This Technical Document presents the baseline cost estimate for the project. The breakdown of the estimate follows:

<u>Account Code</u>	<u>Item</u>	<u>Cost Estimate</u>
	20,000 GPM Lift Station	\$1,300,000
	48" Sewer Force Main	6,900,000
	Treatment Plant Modifications (Pending)	<u>3,500,000</u>
	Subtotal	\$11,700,000
	Contingencies 25% +/-	<u>2,800,000</u>
13	Pumping Plants	\$14,500,000
30	Planning, Engineering and Design	\$1,800,000
30	Water Quality Monitoring and Modeling Plan	\$1,300,000
31	Supervision and Administration	\$1,400,000
01	Lands and Damages	\$800,000
02	Relocations	<u>\$200,000</u>
	<b>TOTAL PROJECT COST</b>	<b>\$20,000,000</b>

Note: The 30 account for PED includes sunk costs (Federal and non-Federal) for project development, E&D for design and preparation of contract documents (non-Federal) and technical oversight and project management (Federal).

Jefferson Parish may desire to construct a 60-inch force main in lieu of a 48-inch to better suit future Parish needs. This results in a cost increment of \$800,000 (\$1,000,000 with 25% contingencies), which is 100% non-Federal cost.

An M-CACES cost estimate is included in Appendix E of this report for the force main. The lift station cost estimate is detailed, but based on assumptions made on a preliminary design. The cost estimate included herein for the pending treatment plant modifications is based on preliminary criteria that must be finalized from study results. An M-CACES cost estimate will be made for these items upon final determination of the treatment plant modifications.

19. Distribution of Cost. The authorizing act specifies that the total project cost be shared as 75% Federal cost and 25% non-Federal cost. The distribution of cost therefore is as follows:

Total Cost	\$ 20,000,000
Federal Cost	15,000,000
Non-Federal Cost	5,000,000

The Act further specifies that the non-Federal sponsor is responsible for lands, easements, rights-of-way, and relocations as part of the 25% share. The cost of these items is estimated at \$ 1,000,000, leaving a required non-Federal contribution of \$4,000,000, plus an additional \$1,000,000 (non-Federal) for the incremental cost difference between the 48-inch diameter and the 60-inch diameter force mains.

Jefferson Parish has spent an estimated \$160,000 in developing the concept of in-line treatment in their storm water collection system. The Reconnaissance Report presented a Parish developed scheme for in-line treatment using the surplus capacity of the East Bank Sewage Treatment

Plant. Subsequent to the Report, the Parish refined the plan to the selected plan presented in this report. Corps sunk costs through FY 95 are about \$500,000.

Given the nature of the work, basically additions and modifications to existing Parish sewer and drainage infrastructure, it is prudent to allow the Parish to complete the project design, primarily the plans and specifications for the new pumping station, sewer force main, modifications to the waste water treatment facilities, and the required connections and interfacing with the existing system and to award and manage the contracts for construction of the proposed facilities. The Corps will exercise technical management oversight including review and approval of Parish detailed design and contract documents for compliance with local and industry practice and applicable CE standards. The local sponsor will be credited with the cost of this work as part of their required cash contribution and will be reimbursed for expenditures over 25%. The current estimate of the non-Federal contribution is \$5,000,000. The amount finally credited to the local sponsor will be based on actual cost determined to be fair and reasonable and verified by audit.

20. Funds Control and Disbursements. A detailed financing plan must be developed between the Corps and Jefferson Parish for the 25% local cost share. Guidance for this plan has been forwarded to Jefferson Parish to begin preparation of the plan.

21. Operations, Maintenance, and Replacement. The Local Sponsor is responsible for operating and maintaining the project and furnishing any replacements as required through the life of the project. The local sponsor will do this using available operating personnel and maintenance

facilities and operate and maintain the project along with the Parish drainage and sewer system. The monitoring program as described in this report is a cost of construction. Any other water quality monitoring required for the proper operation of the project will be addressed in the operation and maintenance manual and will be part of the ordinary operation of the project.

**22. Schedule of Design and Construction.** A detailed schedule cannot be developed due to the current budget constraints on this project. However, the project is envisioned as follows:

Complete Environmental Assessment and FONSI	30 September 1995
Draft PCA Submission to Higher Authority	29 September 1995
Final PCA Submission to Higher Authority	31 December 1995
Financing Plan Submitted to Higher Authority	31 January 1996
Financing Plan Approval by Higher Authority	28 February 1996
Sign PCA	31 March 1996
Complete Plans and Specs	31 January 1996
Start Construction	15 May 1996
Complete Construction	15 May 1997
Evaluate and Report	30 September 1998

The Operation and Maintenance manual will be finished by the completion of construction and available for use at the start of project operation.

**23. Recommendation.** Approval of this report is recommended as a basis for preparing a Project Cooperation Agreement, subject to the completion of an environmental assessment and execution of a FONSI, between the Department of the Army and Jefferson Parish, Louisiana, for the design and construction of a demonstration project, as described herein, as the "Lake Pontchartrain Storm Water Discharge, Louisiana" project.

Subject: Water Resources Development Act  
Section 307 - Water Quality Projects  
Jefferson Parish Stormwater Quality Demonstration Project

Dear Colonel Diffley:

In accordance with agreements made on January 4, 1994 between members of our respective staffs, Jefferson Parish, by this letter, acknowledges intent to participate in this project to the fullest extent contained in the authorizing legislation.

In this regard, my staff has already begun preparation of the required request for Council authorization to solicit Statements of Qualification for selection of an engineer consultant to perform the project tasks attributable to the Parish.

As previously discussed with your staff, Jefferson Parish, via the selected consultant, will provide the preliminary and final designs for the Demonstration Project and will prepare the necessary construction documents. In addition, the Parish will prepare, in coordination with the Corps, the technical documents and design memoranda as defined in the cost sharing agreement.

At our meeting, we requested the New Orleans District to pursue with your higher authority the credits for preliminary design efforts accomplished to date and the efforts described herein. I believe that this work should be creditable toward the Non-Federal share for the project. I understand the District intends to make a formal request on behalf of the Parish in the near future. I hope that our willingness to expedite the project will be considered when the request is evaluated. Please provide acknowledgement of this letter of intent and our credit request.

Colonel Michael Diffley  
U.S. Army Corps of Engineers  
January 25, 1994

As always, we appreciate the efforts of the District in providing the residents of Jefferson Parish with flood protection and now, the potential for improvements in the water quality of Lake Pontchartrain. We look forward to an early start and completion of this project.

Sincerely,

  
MICHAEL J. YENNI  
PARISH PRESIDENT

Re: Jefferson Parish Stormwater Demonstration Project

Dear Colonel Clow:

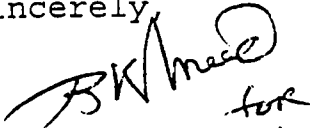

Jefferson Parish has completed the Evaluation Phase for the Stormwater Quality Demonstration Project. The project features proposed in your Draft Technical Report of March 94 have been further evaluated. Our evaluation has been provided to your staff for review.

The Parish intends to participate in the water quality monitoring program, and proceed with preliminary design on the three main features of the project. Specifically: a new lift station; a new force main; and necessary modifications to the East Bank Wastewater Treatment Facility.

As discussed in the report, the lift station will be sized at 20,000 GPM with construction to be as economical as possible. The force main will be analyzed for both 48" and 60" capacities. The larger diameter may be better suited for future Parish requirements with the Parish funding any incremental increase in cost due to the larger diameter. The modifications to the treatment facility will include those necessary to accept flows from the additional force main; however, some additional modifications to other treatment facility components might be required if the proposed demonstration project results in any adverse impacts to our NPDES permit. This determination will be made by the Environmental Protection Agency and/or the Louisiana Department of Environmental Quality.

Upon finalization of our design contract, Mr. B. K. Sneed, Director of Public Works for the Parish, will contact your staff to initiate the Project Cooperation Agreement.

Sincerely,

  
Michael J. Yenni  
Parish President

Project Management Division

Mr. Michael J. Yenni  
Parish President  
Jefferson Parish Louisiana  
P. O. Box 10242  
Jefferson, Louisiana 70181-0242

Dear Mr. Yenni:

In response to your letter of April 12, 1995, regarding the Lake Pontchartrain Storm Water Discharge Demonstration Project, I would like to inform you that we agree, in principle, with the scope of the proposals presented. We must focus on what is necessary to accomplish the project purpose and to satisfy the intent of the authorizing legislation. Recent meetings with your consultant have helped to shape the final design criteria for the project. Agreements on the features of the project design are being formulated.

We will proceed with revision of the Technical Report and incorporate the latest proposals for facilities design. Revisions will also include responses to issues raised by our Corps Headquarters during their earlier review of this project, data and rationale to support selection of the proposed plan, cost estimates, schedule, and allocation of resources. We also intend to initiate work on producing a draft Project Cooperation Agreement (PCA) and have your representative participate in developing the provisions of the agreement.

I am pleased that you have chosen to participate in this project and am looking forward to working with you to bring this unique project to fruition.

Sincerely,

  
Kenneth H. Clow  
Colonel, U. S. Army  
District Engineer

- 6.0 WATER QUALITY MONITORING/MODELING PROGRAM

## 1.0 INTRODUCTION

1.0.1. General. This section summarizes the U.S. Environmental Protection Agency's (EPA) National Pollutant Discharge Elimination System (NPDES) permit application requirements for municipal separate storm water discharges to waters of the United States; how these requirements will affect Orleans and Jefferson Parishes; and the existing storm drainage systems in Orleans and Jefferson Parishes.

### 1.1. EPA's NPDES PERMIT REQUIREMENTS FOR STORM WATER DISCHARGES

1.1.1. General. The Clean Water Act (CWA) requires that NPDES permits for discharges from municipal separate storm sewers systems to waters of the United States include: requirements to effectively prohibit non-storm water discharges into the storm sewers; and controls to reduce the discharge of pollutants to the maximum extent practicable (including management practices, control techniques and systems, design and engineering methods, and other provisions appropriate for the control of such pollutants). EPA or authorized NPDES states may issue system-wide or jurisdiction-wide permits covering all discharges from a municipal separate storm sewer system to waters of the United States. EPA defines storm water as storm water runoff, surface runoff and drainage related to storm events or snow melt.

The new storm water regulations published November 16, 1990 (revised March 21, 1991 and November 5, 1991) by the EPA require large and medium-sized municipalities with separate storm sewer systems and many industrial facilities to obtain NPDES permits for their storm water discharges. Large municipal separate storm sewer systems are those systems serving a population of 250,000 or more. Orleans Parish is a large municipality with a separate storm sewer system. Medium municipal separate storm sewer systems are those systems serving a population of 100,000 or more, but less than 250,000. Jefferson Parish is a medium municipality with a separate storm sewer system.

Operators of large and medium-sized municipal separate storm sewer systems must submit two part permit applications. For large municipal separate storm sewer systems, Part 1 should have been submitted by November 18, 1991. Part 2 must be submitted by November 16, 1992. Medium municipal separate storm sewer systems must submit Part 1 by May 18, 1992. Part 2 must be submitted by May 17, 1993.

Part one of the application requires information regarding existing programs and the means available to the municipality to control pollutants in storm water discharges. In addition, part one requires field screening of major outfalls to detect illicit connections. Part two of the permit application requires a limited amount of representative quantitative data and a description of proposed storm water management plans.

Operators of storm water discharges associated with industrial activity, including those discharging to municipal separated storm sewers, must also apply for NPDES permits which contain controls based on best available technology (BAT) and/or best conventional technology (BCT) considerations or water quality-based controls, if necessary. Three options are available for operators of storm water discharges associated with industrial activity: (1) individual permit applications; (2) group applications; and (3) filing a notice of intent requirements to be covered by an established general permit. A general permit is a permit that covers discharges from more than one facility within a state. General permits are either issued by EPA or, in states with authorized NPDES programs, by the State. Notices of intent requirements are established in general permits, and generally only require information such as the type of industry, location and name of receiving waters. EPA is the NPDES permitting authority in Louisiana. EPA expects to issue a final general permit in Louisiana in February or March 1991. For storm water discharges associated with industrial activity which require an individual permit, applicants must submit an individual application by October 1, 1992 or participate in a group application. Part one of the group application should have been submitted by September 30, 1991, and part two of the accepted group application must be submitted by May 18, 1992. However, EPA has proposed to extend this date to October 1, 1992. If Part 1 of the group application was rejected by EPA, then the applicants have until October 1, 1992 to submit an individual permit or file a notice of intent for a general permit.

1.1.2. Discharges from large and medium municipal separate storm sewers. This section will cover permit application requirements and the effective prohibition on non-storm water discharges to the municipal separate storm sewer systems.

1.1.2.1. Permit application requirements. A two-part application process for discharges from large and medium municipal separate storm sewer systems has been established.

1. Part 1 of the application includes:
  - o General information (name, address, etc.);
  - o Description of the existing legal authority to control pollutants in storm water discharges and a plan to augment legal authority where necessary;
  - o Source identification information including:
    - Topographic map or aerial photograph equivalent to a USGS 7.5 scale map;
    - Description of the historic use of ordinances or other controls which limited the discharge of non-storm water discharges to the municipal separate storm sewer;
    - Location of known major municipal separate storm sewer outfalls;
    - Description of procedures and a proposed program to identify additional major outfalls;

- Identification of the drainage area associated with known major outfalls;
- Description of major land use classifications in each drainage area;
- Description of soils;
- Ten year projections of population growth and development activities; and
- Location of industrial facilities, open dumps, sanitary landfills, municipal incinerators or RCRA hazardous waste treatment, storage or disposal facilities which discharge storm water to the municipal separate storm sewer system;

o Discharge characterization including:

- Existing quantitative data;
- Results of a field screening analysis to detect illicit discharges (non-storm water discharges without a NPDES permit) and illegal dumping to the municipal system;
- Identification of receiving waters with known water quality impacts associated with storm water discharges; and
- Plan to obtain representative data;

o Description of existing structural and non-structural prevention and control measures to reduce the discharge of pollutants from the municipal separate storm sewer;

o Description of financial budget and resources currently available to implement the proposed management plans required in part 2 of the application.

2. Part 2 of the application includes:

- o Demonstration of adequate legal authority to control discharges, prohibit illicit discharges, require compliance, and carry out inspections, surveillance, and monitoring;
- o Supplementation of the source identification submitted in part 1 of the application indicating the location of all major outfalls and inventorying the principal products or services provided by each facility discharging storm water associated with industrial activity to the municipal separate storm sewer;
- o Discharge characterization data including:

- Quantitative data from 5-10 representative locations in approved sampling plans;

- For selected conventional pollutants and heavy metals, estimates of the annual pollutant load and event mean concentration of system discharges;

- Proposed schedule to provide estimates of: seasonal pollutant loads; and the mean concentration for certain detected constituents in a representative storm event; and

- Proposed monitoring program for representative data collection;

o Proposed management program including descriptions of:

- Additional structural and source control measures that are to be implemented to reduce pollutants in runoff from commercial and residential areas including:
  - Maintenance activities;
  - Planning procedures to develop, implement, and enforce controls for areas of new development and significant redevelopment;
  - Practices for operating and maintaining public streets and highways;
  - Procedures to assure flood management projects assess impacts on water quality;
  - Program to monitor pollutants in runoff from operating or closed municipal landfills (or other facilities for municipal waste); and
  - Program to reduce pollutants in discharges associated with the application of pesticides, herbicides, and fertilizer;
  
- Program to detect and remove illicit discharges including:
  - Program to implement and enforce an ordinance or order;
  - Procedures to conduct on-going field screening activities;
  - Procedures to be followed to investigate potential illicit discharges;
  - Procedures to prevent, contain, and respond to spills;
  - Program to promote, publicize, and facilitate public reporting;
  - Educational activities for management of used oil and toxic material; and
  - Controls to limit infiltration of seepage from sanitary sewers;
  
- Program to monitor and control pollutants from municipal landfills; hazardous waste treatment, disposal, and recovery facilities; SARA Section 313, Title III facilities; and other priority industrial facilities including:
  - Priorities and procedures for inspection and enforcement;
  - Monitoring program; and
  - Program to implement and maintain structural and non-structural BMPs;
  
- Program to control pollutants in construction site runoff including:
  - Site planning requirements;
  - Enforceable requirements for non-structural and structural best management practices;

- Procedures for identifying priorities for inspecting sites and enforcement actions;
  - Educational and training measures for construction site operators;
- o Estimated reduction in loadings of pollutants as a result of the management program; and
  - o Financial analysis estimating the cost of implementing the proposed management programs along with identifying sources of revenue.

1.1.2.2. Effective prohibition of non-storm water discharges. For many municipalities, a first priority for reducing pollutants from municipal separate storm sewer systems is to effectively prohibit non-storm water discharges to their municipal separate storm sewer system. The permit application process implements this effective prohibition by establishing requirements for a field analysis to detect illicit connections and illegal dumping. In addition, applicants are required to submit a proposed program to control illicit connections and illegal dumping as part of their proposed management programs. The EPA does not interpret the effective prohibition on non-storm water discharges to municipal separate storm sewers to apply to discharges that are not composed entirely of storm water, as long as such discharge has been issued a separate NPDES permit. Rather, an effective prohibition would require separate NPDES permits for non-storm water discharges to municipal storm sewers.

## 1.2 DESCRIPTION OF STUDY AREA

1.2.1 EAST BANK JEFFERSON PARISH. East Bank Jefferson Parish encompasses approximately 30,710 acres. However, Hoey's Basin, approximately 2,425 acres, drains into the 17th St. Canal which is pumped by Orleans Parish's Pumping Station #6. Most of the land area is below sea level with a natural slope away from the Mississippi River, towards the lake. Through the use of a levee system the Parish has been able to prevent both the lake and river waters from entering East Jefferson. However, the levee system also retains all of the storm water falling on East Bank Jefferson Parish. Thus, East Bank Jefferson Parish's drainage system depends on the collection and pumping of all storm water falling on the area.

The drainage system is a complex, man-made interconnected network of sub-surface culverts, ditches, canals and pumping stations. Basically, there are five major north-south outfall canals (including the St. Charles parish line canal) and several east-west feeder canals. The east-west canal system serves as a collector system for the individual subdivisions. These canals then channel the water to the five main outfall canals. Another major function of the east-west canal system is to balance the drainage between the five main outfall canals so that more than one pumping station can provide relief for a heavy, localized rain storm. Since the water elevations in Lake Pontchartrain are lower than those of the Mississippi River, it is more efficient and

economical for East Bank Jefferson Parish to pump its excess rain water into Lake Pontchartrain. Major pumping stations are located on each of the main outfall canals. There are also several interior pumping stations which serve to provide localized relief from runoff. Table 1-1 list the five main East Bank Jefferson Parish pumping stations along with their pumping capacities.

Table 1-1  
East Bank Jefferson Parish Drainage Pumping Stations

<u>Station Number</u>	<u>Station Location</u>	<u>Nominal Pumping Capacity (cfs)<sup>1</sup></u>	<u>Receiving Waterbody</u>
1	Bonnabel	4306	Lake Pontchartrain
2	Suburban	3310	Lake Pontchartrain
3	Elmwood	3400	Lake Pontchartrain
4	Duncan	5526	Lake Pontchartrain
-	Parish Line	969	Lake Pontchartrain

---

1 Capacities noted are based on "installed" capacities.

## 2.0 WATER QUALITY CRITERIA AND STANDARDS

2.0.1 Introduction. Both the Louisiana Department of Environmental Quality (LDEQ) and the US Environmental Protection Agency have established ambient water quality criteria applicable to surface waters in the State of Louisiana. These criteria are discussed in the following paragraphs.

2.1 Applicable Louisiana state standards. The LDEQ has established general written water quality criteria which are applicable to all waters of the State of Louisiana. The general written standards relate to the condition of the water as affected by waste discharges or human activity as opposed to purely natural phenomena, and are as follows. The criteria were last revised in 1989.

### 2.1.1 Descriptive water quality standards.

(a) Aesthetics. The waters of the state shall be maintained in an aesthetically attractive condition and shall meet the generally accepted aesthetic qualifications.

All waters shall be free from such concentrations of substances attributable to wastewater or other discharges sufficient to:

1. settle to form objectionable deposits;
2. float as debris, scum, oil, or other matter to form nuisances or to negatively impact the aesthetics;
3. result in objectionable color, odor, taste, or turbidity;
4. injure, be toxic or produce demonstrated adverse physiological or behavioral responses in humans, animals, fish, shellfish, wildlife, or plants; or
5. produce undesirable or nuisance aquatic life.

(b) Color. Water color shall not be increased to the extent that it will interfere with present usage and projected future use of the state's waterbodies.

1. Waters shall be free from significant increases over natural background color levels;
2. The source of drinking water supply should not exceed 75 color units on the platinum-cobalt scale; and

3. No increases in true or apparent color shall reduce the level of light penetration below that required by desirable indigenous species of aquatic life.

(c) Floating, suspended, and settleable solids. There shall be no substances present in concentrations sufficient to produce distinctly visible solids or scum, nor shall there be any formation of long-term bottom deposits of slimes or sludge banks attributable to waste discharges from municipal, industrial, or other sources including agricultural practices, mining, dredging and the exploration for and production of oil and natural gas. Certain short-term activities, such as maintenance dredging of navigable waterways may be exempted by the administrative authority.

(d) Taste and odor. Taste- and odor- producing substances shall be limited to concentrations in the waters of the state that will not interfere with the production of potable water by conventional water treatment methods or impart unpalatable flavor to food fish, shellfish, and wildlife, or result in offensive odors arising from the waters, or otherwise interfere with the designated use of the waters.

(e) Toxic substances. Toxic substances shall not be present in the waters of the state or the sediments underlying said waters in quantities that alone or in combination will be toxic to human, plant, or animal life or significantly increase health risks due to exposure to the substances or consumption of contaminated fish or other aquatic life.

(f) Oil and grease. There shall be no free or floating oil or grease present in quantities large enough to interfere with the designated uses, nor shall emulsified oils be present in quantities large enough to interfere with the designated uses.

(g) Foaming or frothing materials. None of a persistent nature are permitted.

(h) Nutrients. The naturally occurring range of nitrogen-phosphorous ratio shall be maintained. To establish the appropriate range of ratios and compensate for natural seasonal fluctuations, the state will use site-specific studies to establish limits for nutrients. Nutrient concentrations that produce aquatic growth to the extent that it creates a public nuisance or interferes with designated water uses shall not be added to any surface waters. This shall not apply to designated intermittent streams.

(i) Turbidity. Turbidity other than that of natural origin shall not cause substantial visual contrast with the natural appearance of the waters of the state or impair any designated water use. Turbidity shall not significantly exceed the natural condition of the water.

As a guideline, maximum turbidity levels, expressed as nephelometric turbidity units (NTU), are established and shall apply for the following named waterbodies and major aquatic habitat types of the state:

1. Red, Mermentau, Atchafalaya, Mississippi, and Vermilion Rivers and Bayou Teche -- 150 NTU;
2. estuarine lakes, bays, bayous, and canals -- 50 NTU;
3. Amite, Pearl, Ouachita, Sabine, Calcasieu, Tangipahoa, Tickfaw, and Tchefuncte Rivers -- 50 NTU;
4. freshwater lakes, reservoirs, and oxbows -- 25 NTU;
5. designated scenic streams and outstanding natural resource waters not specifically listed above -- 25 NTU; and
6. for other state waters not included above and in waterbody segments where natural background turbidity exceeds the values specified above, the turbidity in NTU caused by any discharges shall be restricted to the appropriate background value plus 10 percent. This shall not apply to designated intermittent streams.

Certain short-term activities, such as maintenance dredging of navigable waterways may be exempted by the administrative authority.

(j) Flow. The natural flow of state waters shall not be altered to such an extent that the basic character and water quality of the ecosystem are adversely affected except in situations where alterations are necessary to protect human life or property. If alterations to the natural flow are deemed necessary, all reasonable steps shall be taken to minimize the adverse impacts of such alterations. Additionally, all reasonable steps shall be taken to mitigate the adverse impacts of unavoidable alterations.

(k) Radioactive materials. Radioactive materials in the surface waters of the state designated for drinking water supply use shall not exceed levels established pursuant to the Federal Safe Drinking Water Act (P.L. 93-523 et Seq.).

(l) Other materials. Limits on other substances not specified in these revised water quality standards shall be in accordance with recommendations set by the LDEQ and/or the Louisiana Department of

Health and Human Resources Administration for municipal raw water sources.

2.1.2 Numerical water quality standards. Additionally, LDEQ has established numerical criteria which apply to specified waterbodies, and to their tributaries, distributaries, and interconnected streams and waterbodies if they are not specifically named therein, unless it can be shown through a use attainability analysis that unique chemical, physical, and/or biological conditions preclude the attainment of the criteria. In those cases, natural background levels of these conditions may be used to establish site-specific water quality criteria. Those waterbodies officially approved and designated by the state and EPA as intermittent streams, man-made watercourses, or naturally dystrophic waters may be excluded from some or all numerical criteria during specified seasonal periods. The numerical criteria apply specifically with respect to substances or conditions attributed to waste discharges or activities of man as opposed to purely natural phenomena. A list of surface waters in the study area for which numerical criteria are included in the published tables is shown in Table 2-1. Table 2-1 also includes designated use categories for the surface waters listed. Designated water uses for each stream are represented as follows:

- A = Primary Contact Recreation
- B = Secondary Contact Recreation
- C = Propagation of Fish and Wildlife
- D = Drinking Water Supply
- E = Oyster Propagation
- F = Agriculture
- G = Outstanding Natural Resource Waters

The following is a description of the numerical water quality criteria presented in Table 2-1.

(a) pH. The pH represents minimum and maximum conditions throughout the segment with reasonable gradients applying toward segment boundaries.

In all cases, the pH shall fall within the range of 6.0 to 9.0 standard units (su) unless otherwise specified in the tables. No discharge of wastes shall cause the pH of the water body to vary by more than one pH unit within the specified pH range for that segment where the discharge occurs.

(b) Chlorides, sulfates, and dissolved solids. Values for these parameters apply to the approximate midpoint of the stream segment with reasonable gradients applying toward segment boundaries. Values listed in the standards, in general, represent the arithmetic mean of existing data plus one standard deviation.

(c) Dissolved oxygen. The following dissolved oxygen (DO) values represent minimum values for the type of water specified. These values shall apply at all times except in naturally dystrophic waters or where natural conditions cause the DO to be depressed. For short periods of time, diurnal variations below the standard specified might occur. However, no waste discharge or activity of man shall lower the DO concentration to the point where the diurnal variation falls below the specified minimum.

1. Freshwater. For a diversified population of warmwater biota including sport fish, the DO concentration shall be at or above 5 mg/L.

2. Estuarine water. DO concentrations in estuaries and tidal tributaries shall not be less than 4 mg/L at any time.

3. Coastal marine water. DO concentration in surface coastal waters shall not be less than 5 mg/L except when the upwellings and other natural phenomena might cause this value to be depressed.

(d) Temperature. The temperature standards enumerated in Table 2-1, in most cases, represent maximum values obtained from existing data. However, in a few cases, a limited number of unusually high temperatures in the range of 35 degrees to 36 degrees have been deleted as it is felt that these values were recorded during conditions of unseasonably high air temperatures and/or unusually low flows or water levels, and, therefore, do not represent normal maximum temperatures.

In order to protect a diversified warm water biota including game fish, the following temperature criteria shall apply (except when natural conditions cause the temperature to be raised above these limits).

The standard shall consist of two parts, a temperature differential and a maximum temperature. The temperature differential represents the maximum permissible rise above ambient conditions. There shall be no addition of artificial heat once the ambient temperature reaches the maximum temperature specified in the standards.

1. Freshwater (Temperature Differential).

- a. Maximum of 5°F [2.8° Centigrade (C)] rise above ambient for streams and rivers.
- b. Maximum of 3°F (1.7°C) rise above ambient for lakes and reservoirs.

2. Freshwater (Maximum Temperature). Ninety °F (32.2°C) except where otherwise listed in Table 2-1 or due to natural conditions such as unusually hot and/or dry weather.

3. Estuarine and Coastal (Temperature Differential).

- a. Maximum of 4°F (2.2°C) rise above ambient during the period October through May.
- b. Maximum of °F (1.1°C) during the period June through September.

4. Estuarine and Coastal (Maximum Temperature). Ninety-five °F (35°C) except when natural conditions elevate temperature above this level.

These temperature criteria shall not apply to privately-owned reservoirs, or reservoirs constructed solely for industrial cooling purposes.

(e) Bacterial standards. The bacterial standard applicable to a particular stream segment depends upon the use classification of that individual stream segment. Limitations are placed on either fecal coliform content, most probable number (MPN) total coliform content, or a combination of both in order to achieve the stream sanitary quality required for the most restrictive stream water usage.

Table 2-1, which contains applicable criteria for each water body, designates one of the following four standards as applicable according to present and anticipated usage of the waters.

Standard #1. PRIMARY CONTACT RECREATION - Based on a minimum of not less than five samples taken over not more than a 30-day period, the fecal coliform content shall not exceed a log mean of 200/100 mL nor shall more than 10 percent of the total samples during any 30-day period or 25 percent of the total samples collected annually exceed 400/100 mL.

Standard #2. SECONDARY CONTACT RECREATION - Based on a minimum of not less than 5 samples taken over not more than a 30-day period, the fecal coliform content shall not exceed a log mean of 1,000/100 mL nor shall more than 10 percent of the total samples during any 30-day period or 25 percent of the total samples collected exceed 2,000/100 mL.

Standard #3. DRINKING WATER SUPPLY - The monthly arithmetic mean of total coliform MPN shall not exceed 10,000/100 mL, nor shall the monthly arithmetic mean of fecal coliforms exceed 2,000/100 mL.

Standard #4. OYSTER PROPAGATION - The fecal coliform median MPN shall not exceed 14 fecal coliforms per 100 mL, and not more than 10 percent of the samples shall exceed an MPN of 43/100 mL for a 5-tube decimal dilution test in those portions of the area most probably exposed to fecal contamination during the most unfavorable hydrographic and pollution conditions.

(f) Toxic substances. The LDEQ has also established numerical criteria for several toxic substances that are of particular concern for the State of Louisiana. These substances were selected for human health considerations, taste and odor problems, persistence and bioaccumulative capabilities, and potential negative effects on aquatic biota. Table 2-2 is a listing of these substances and their criteria.

Table 2-1

1 Applies to surface waterbodies designated as a Drinking Water Supply and also protects for primary and secondary contact recreation and fish consumption.

2 Applies to surface waterbodies not designated as a Drinking Water Supply and protects for primary and secondary contact recreation and fish consumption.

3 ng/L = nanograms per liter, parts per trillion

4 mg/L = milligrams per liter, parts per million

5 total phenol as measured by the 4 - aminoantipyrine (4AAP) method

6 Includes Hexachloro-1,3-butadiene

7 Hardness-dependent criteria for fresh water based on the following natural logarithm formulas for acute and chronic protection respectively: acute =  $e(0.8190[\ln(\text{hardness})]+3.688)$ , chronic =  $e(0.8190[\ln(\text{hardness})]+1.561)$ , numbers in parenthesis represent criteria in ug/L at hardness values of 50, 100, 200 mg/L CaCo<sub>3</sub> rounded off a whole numbers

8 Hardness-dependent criteria for fresh water based on the following natural logarithm formulas for acute and chronic protection respectively: acute =  $e(0.8473[\ln(\text{hardness})]+0.8604)$ , chronic =  $e(0.8473[\ln(\text{hardness})]+0.7614)$ , numbers in parenthesis represent criteria in ug/L at hardness values of 50, 100, 200 mg/L CaCo<sub>3</sub> rounded off to whole numbers

**2.2 EPA water quality criteria.** The EPA has established ambient water quality criteria applicable to surface waters in the study area. These criteria are shown in Tables 2-3 and 2-4. The numerical criteria listed in Tables 2-3 and 2-4 have been developed for various physical

parameters, nutrients, metals, PCB's, and organic pesticides for uses of freshwater aquatic life and marine/estuarine aquatic life, respectively.

2.2.1 EPA water quality tables. EPA water quality tables follow.

2.2.2 Descriptive water quality criteria.

(a) Aesthetic qualities. All waters free from substances attributable to wastewater or other discharges that:

1. settle to form objectionable deposits;
2. float as debris, scum, oil, or other matter to form nuisances;
3. produce objectionable color, odor, taste, or turbidity;
4. injure or are toxic or produce adverse physiological responses in humans, animals or plants; and

5. produce undesirable or nuisance aquatic life.

(b) Color. Waters shall be virtually free from substances producing objectionable color for aesthetic purposes; the source of supply should not exceed 75 color units on the platinum-cobalt scale for domestic water supplies, and increased color (in combination with turbidity) should not reduce the depth of the compensation point for photosynthetic activity by more than 10 percent from the seasonally established norm for aquatic life.

(c) Dissolved oxygen. Water should contain sufficient DO to maintain aerobic conditions in the water column and, except as affected by natural phenomena, at the sediment-water interface. Numerical criteria are available for varying aquatic life stages for coldwater and warmwater species.

(d) Fecal coliform bacteria.

1. Bathing waters. Based on a minimum of five samples equally spaced over a 30-day period, the geometric mean of the E. coli density should not exceed 126 per 100 mL for freshwater bathing. For the above sampling period, the geometric means of the enterococci density should not exceed 33 and 35 per 100 mL for freshwater and marine bathing, respectively.

2. Shellfish harvesting waters. The median fecal coliform bacterial concentration should not exceed 14 MPN/100 mL for the taking of shellfish, with not more than 10 percent of samples exceeding 43 MPN/100 mL.

(e) Oil and grease. For domestic water supply: virtually free from oil and grease, particularly from the tastes and odors that emanate from petroleum products. For aquatic life: (1) levels of individual petrochemicals in the water column should not exceed 0.01 times the lowest continuous flow 96-hour LC<sub>50</sub> to several important freshwater or marine species, each having a demonstrated high susceptibility to oils and petrochemicals; (2) levels of oils or petrochemicals in the sediment which cause deleterious effects to the biota should not be allowed; and (3) surface waters shall be virtually free from floating nonpetroleum oils of vegetable or animal origin, as well as petroleum derived oils.

(f) Settleable and suspended solids. Freshwater fish and aquatic life: settleable and suspended solids should not reduce the depth of the compensation point for photosynthetic activity by more than 10 percent from the seasonally established norm for aquatic life.

(g) Tainting substances. Materials should not be present in concentrations that individually or in combination produce undesirable flavors which are detectable by organoleptic tests performed on the edible portions of aquatic organisms.

The LDEQ general criteria state that "all waters of the state shall be capable of supporting desirable diversified species of fish, shellfish and wildlife." Therefore, EPA criteria for freshwater or marine aquatic life, Tables 2-3 and 2-4, respectively, are held to apply to all surface waters. Also, EPA criteria for the protection of human health apply to all surface waters.

### 2.3 GENERAL DESCRIPTION OF WATER QUALITY PARAMETERS

Suspended solids in urban runoff consist mainly of particulate material which has accumulated along curbs and gutters of streets and roadways, although much of it had originated in other parts of the drainage area. Some of the more important sources of solids are eroded soil particles, particularly from construction sites or other unvegetated soil surfaces but also to an important extent from grassed areas, dirt and dust, fuel residue and other material including rubber, metal and synthetic substances associated with vehicular traffic, fallout from combustion of fossil fuels and other materials, solid waste and debris from poorly managed or exposed material storage sites, dumps and landfills, animal wastes, and leaves and other plant residue. Many pollutants become attached to the accumulating solid particles, and metals and organic compounds become physically or chemically adsorbed to clay particles. Excessive suspended solids levels in water generate unsightly turbidity plumes, and may interfere with the ability of sight - dependent fish and other organisms to obtain food, or may clog their gills or feeding apparatus.

Turbidity in water is caused by materials that inhibit light penetration and reduce the clarity of the water. It may be caused by microorganisms or various minerals, including plant detritus, silica and sediment particles. The turbidity of a water sample is a measure of the reduction in intensity of visible light passing through the sample. Turbidity affects the aquatic system by limiting light transmission and the process of photosynthesis which is vital to biological productivity. It is sometimes used as a broad indicator of suspended solids levels.

The pH level of a water body is a chemical measure of its tendency toward acidity or alkalinity. A pH value of 7.0 indicates neutrality. Most natural waters are slightly basic, with pH values between 7.0 and 8.0. Technically, pH is the  $\log_{10}$  of the reciprocal of the hydrogen ion concentration in water. Wide deviations of pH from the neutral or slightly basic range may signal the presence of important contaminants, particularly toxic substances. Industrial wastewater, for example, is often highly acidic.

Biochemical oxygen demand (BOD) is a useful indicator of biodegradable organic material, including natural materials such as simple sugars, fats and proteins, and more complex organic chemicals synthesized by man. For the most part, biodegradable materials are not toxic to aquatic organisms. Their primary importance from a water quality perspective is that their decaying process requires either dissolved or combined oxygen, and the oxygen supply of the receiving water body may

become dangerously depleted. Since certain levels of dissolved oxygen are needed to sustain life and permit normal functioning of aquatic species and to prevent the existence of undesirable anaerobic conditions, excessive BOD levels in runoff may produce oxygen deficits, depending on the assimilative capacity of the receiving water and its rate of natural reaeration. The most common BOD measurement is an oxygen consumption test over a five-day period. The ultimate BOD level may be estimated by extrapolation from test results over different time periods.

Chemical oxygen demand (COD) is a general indicator of the amount of potentially biodegradable material in water. Various industrial chemicals and other organic chemicals that degrade slowly or only under highly oxidized conditions are better represented by COD than by BOD. The COD test does not distinguish between stable and unstable organic matter and is therefore not directly related to BOD values in samples of industrial wastewater, urban runoff or receiving water.

Nutrients occur in nature in many forms. Nitrogen is an essential component of all proteins, chlorophyll and other important biological compounds. In organic matter, nitrogen decomposes from complex proteins through amino acids to ammonia, nitrites and nitrates, and is also synthesized from nitrates into plant and animal biomass (nitrogen fixation). The natural nitrogen cycle depends on microbiological activity for these processes. Nitrogen is present in urban runoff in many forms, including ammonia, organic nitrogen, nitrites and nitrates. Kjeldahl nitrogen refers to a laboratory process that is used to measure the ammonia content of a nitrogen sample.

Nitrates are the end product of the aerobic stabilization of organic nitrogen, but they may also result from excessive fertilizer applications or from untreated domestic wastewater. Chemical fertilizer plants produce high nitrate levels in their wastewater. Despite their many sources, nitrates do not normally persist at high levels in natural water bodies, but become converted to biomass by natural processes. When nitrate levels in runoff greatly exceed the biological requirements of a receiving water body, eutrophication (over - enrichment) may occur, resulting in algal blooms or other undesirable conditions. Nitrites are seldom present in natural surface waters at significant levels except under polluted conditions and in the presence of ammonia.

Phosphorus occurs most commonly in nature as phosphates and orthophosphates and is a constituent of fertile soils, plants and animal tissue. It is an essential nutrient along with nitrogen for biological productivity and also undergoes cycles of decomposition and photosynthesis. It is ordinarily more abundant in urban runoff than in natural waters, and originates in domestic and industrial wastes, detergents and fertilizers. Phosphorus is often the critical parameter in the eutrophication of lakes and other water bodies that act as nutrient sinks.

Pathogenic bacteria in water may be harmful to humans, particularly if ingested while swimming. Organisms that are discharged from the intestinal tracts of humans or animals in fecal material may be pathogenic to humans or may alternatively serve as useful indicators of fecal pollution and the probable presence of pathogens. The most commonly employed pathogenic indicators are in the coliform group of bacteria, which consist predominantly of harmless organisms.

Fecal coliforms are measured by federal and state regulatory agencies to monitor for the presence of human and/or animal fecal pollution in water. Total coliforms are also measured as a more general indicator of fecal pollution, but these organisms may also originate in natural soils. None of the coliform group are ideal indicators of fecal pollution since they do not always exist in the same proportions to the pathogens. In order to be a reliable indicator of fecal pollution, an indicator should have a somewhat longer survival time in water than intestinal pathogens, but should nevertheless die off soon after the pathogens, so that their absence would assure the bacteriological safety of the water. The *E. coli* bacterial strain has been promoted as a superior indicator of fecal pollution, and has been adopted by EPA as the regulatory parameter for human health in bathing waters. *E. coli* is expected to eventually replace fecal coliform as the official State of Louisiana indicator organism for primary contact recreation.

Many metals are known to be chronically or acutely toxic to various aquatic species above certain concentration levels in saltwater and in freshwater, usually as a function of hardness, or the levels of ionized calcium and magnesium in the water expressed as the equivalent concentration of calcium carbonate. Six metals, cadmium, chromium, copper, mercury, lead and arsenic, have been regularly monitored by Jefferson Parish in the study area and also by other agencies in the receiving waters. These metals and a seventh, zinc, will be briefly discussed as they relate to this study in the following paragraphs.

Cadmium usually occurs at low levels in the natural freshwater environment, often below 0.01 ug/L, but waters affected by municipal and/or industrial development probably have much higher concentrations. Industrial sources include effluents from petrochemical plants, metallurgical processes and electroplating. Since it is extremely toxic to fish, its EPA chronic and acute criteria are set at 1.6 and 6.2 ug/L, respectively for a carbonate hardness level of 150 mg/L.

Chromium is more common than cadmium in natural freshwater, typically at about 0.5 ug/L. Chromium salts are used for electroplating and in cleaning agents, and are also present in paints, fungicides and wood preservatives. The EPA and Louisiana criteria for chronic and acute toxicity to freshwater aquatic life are 11 and 16 ug/L, respectively at a hardness of 150 mg/L.

Copper is relatively plentiful in the natural freshwater environment, ranging from about 1 to 10 ug/L. Pertinent industrial sources of copper

include petroleum refineries. The EPA chronic and toxic criteria for freshwater aquatic life are 17 and 26 ug/L at a hardness of 150 mg/L.

Lead occurs in most natural freshwater at 1 ug/L or less. It is much more plentiful, however, in waters in and near inhabited areas. It is used in storage batteries and other metal products, but is no longer permitted in paint pigments and gasoline additives. The EPA chronic and acute freshwater aquatic life criteria for lead are 5.3 and 137 ug/L at a hardness of 150 mg/L.

Mercury background levels in natural freshwater may range from 0.01 to 0.1 ug/L. It is used in the electrolytic preparation of chlorine and caustic soda, in mercury battery cells and thermometers, and in various other laboratory and industrial applications. The EPA freshwater aquatic life criteria for mercury are 0.012 ug/L (chronic) and 2.4 ug/L (acute). The chronic criterion was derived on the basis that all mercury discharged to the environment is methylmercury, the form that evolves in sediment and in fish and the aquatic food chain. It is known, however, that almost all mercury discharged is mercury (II), a much less toxic form. The FDA action level for the concentration of methylmercury in the edible portions of fish is considered to be a more relevant criterion for consumable species than the referenced chronic criterion.

Arsenic concentrations in freshwater areas vary widely but are usually 5 ug/L or more. Arsenic is emitted to the environment by coal - fuel power plants. The EPA and Louisiana criteria for chronic and acute toxicity to freshwater aquatic life are 190 and 360 ug/L, respectively.

The chemistry of zinc is similar to that of cadmium, but it is much more abundant in the environment, with a median surface water concentration in the United States of about 20 ug/L. It is used as an oxide pigment in rubber and paint, in agricultural fertilizers and sprays and battery production. It is also used in galvanizing of metal and in the production of metal alloys. Its EPA chronic and acute criteria for freshwater aquatic life are 149 and 165 ug/L at a hardness of 150 mg/L.

### 3.0 EXISTING WATER QUALITY IN THE RECEIVING AREA

#### 3.1 LAKE PONTCHARTRAIN RECEIVING AREA.

The following paragraphs briefly address water quality by parameter groups in Lake Pontchartrain. Currently, there are three active water quality stations maintained by LDEQ. These three stations were initiated in January 1986 and are sampled monthly. All three stations are located along the Causeway Bridge. The parameters sampled are general physical parameters, such as temperature and solids, along with oxygen demanding substances, nutrients and metals. No pesticides are sampled. For parameter completeness, numerous historical stations which are now discontinued were also examined. Statistical summaries of these data can be found in Tables 3-1 through 3-12. Data presented in these tables was retrieved from EPA's water quality database, STORET. The Louisiana Department of Health and Hospitals' (LDHH) oyster monitoring data along the south shore of Lake Pontchartrain was also reviewed. Except for the LDHH data, the stations presented are, for the most part, indicative of the water quality on a lake-wide basis.

Turbidity levels are usually well below the LDEQ's guideline of 50 NTU for estuarine lakes with a mean level of 20 NTU. Suspended solids average about 27 mg/L. Mean BOD and COD values are approximately 2 and 75 mg/L, respectively.

As can be seen from Tables 3-3 and 3-4, there are rarely contraventions of the LDEQ standards for DO, pH and temperature. DO values are typically around 8 mg/L, well above the state standard of 4 mg/L.

On a lake-wide basis, in regard to eutrophication, nutrient levels do not seem excessive. However, Table 3-10 shows that phosphorus levels exceeded the chronic marine aquatic life criteria 23 percent of the time. Though the marsh areas surrounding Lake Pontchartrain are considered hypereutrophic (excessively nutrient rich), Lake Pontchartrain is considered to be oligotrophic to mesotrophic overall (nutrient deficient to moderately nutrient rich). One theory to explain Lake Pontchartrain's resistance to nutrient enrichment is that the nutrients are continuously removed from the water column by settling sediment particles.

Due to the wide range of salinities found in Lake Pontchartrain, both metals and pesticides were compared to both freshwater and marine aquatic life criteria. However, the saltwater criteria are more applicable as the mean salinity is approximately 4 parts per thousand. For metals, EPA recommends comparing only the dissolved fraction to the freshwater criteria. However, comparisons were also made for the total metal parameters at the Causeway water quality stations.

Tables 3-5 through 3-8 show exceedances for metals for both freshwater and marine aquatic life criteria. Generally, only copper significantly (greater than one percent) exceeded the acute marine water criteria.

Copper exceeded this criteria 78 percent of the time at the inactive water quality stations and 34 percent of the time at the Causeway stations. Both cadmium and copper significantly exceeded the acute freshwater criteria at the inactive stations. Their exceedances were 13 and 1.5, respectively. At the Causeway stations, the detection limit used in the analysis of mercury, 0.2 ug/L, was greater than both the freshwater and marine water chronic criteria. At the inactive stations cadmium, mercury and lead exceeded the chronic freshwater criteria 19, 22 and 6 percent of the time, respectively. Their respective chronic marine criteria exceedances were 1, 52 and 45. Many of the metal concentrations were remarked as "known to be less than the value shown". Therefore, these exceedances should be regarded as possible exceedances only.

As can be seen from Tables 3-9 and 3-10, aldrin and dieldrin are the pesticides most frequently detected in the water column in Lake Pontchartrain. Their percent frequency of detection levels are 35 and 31 percent, respectively. However, none of the pesticides sampled exceeded either the freshwater or marine acute aquatic life criteria by more than one percent.

Table 3-11 gives statistical information of fecal coliform densities along the south shore of Lake Pontchartrain and on a lake-wide basis. As mentioned in Section 2 of this report, the primary contact recreation criteria states that the log mean of the fecal coliform content shall not exceed 200 colonies per 100 mL and that 25 percent of the samples collected shall not exceed 400 colonies per 100 mL. Lake-wide the log mean of the fecal coliforms is 18 and the 75th percentile is approximately 90. Thus, lake-wide bacterial contamination is minimal. Along the south shore of Lake Pontchartrain the log mean is 430 and the 75th percentile is approximately 1900 colonies per 100 mL. Although the data presented is not the most recent data collected by the LDHH, it is still typical of the conditions that exist in Lake Pontchartrain today.

OVERALL PERIOD OF RECORD: Feb 1976 - Jun 1977

2 Some values are known to be less than the value reported.  
value reported

#### 4.0 URBAN RUNOFF WATER QUALITY

##### 4.1 MEASURED WATER QUALITY IN THE STORMWATER DRAINAGE CANALS .

###### Measured Water Quality in the Stormwater Drainage Canals (East Bank)

Thirteen stations were sampled monthly. The station locations are listed in Table 4-1. Analysis on the east bank of Jefferson Parish was also limited to samples collected after the operation of the east bank regional sewage treatment plan in 1988. Table 4-2 compares the canal data (aggregated) to the chronic freshwater and marine aquatic life criteria. However, since all but one of the stations are located on the protected side of the Lake Pontchartrain levee, the freshwater criteria are more applicable. Chronic criteria were chosen for comparison purposes since the canal data are more representative of the long term quality of water in the canal as opposed to stormwater runoff concentrations.

The TSS solids mean concentration is 46 mg/L although the maximum concentration recorded is 767 mg/L. This high concentration is likely the result of a high intensity runoff event and/or the resuspension or erosion of sediment in the drainage canals. The average BOD and COD levels are 6 and 56 mg/L, respectively. Their respective maximum concentrations are 29 and 360 mg/L. Seven percent of the pH values are greater than the LDEQ standard of 8.5 su; the mean pH level is 7.8 su.

Jefferson Parish stopped sampling for total coliforms in early 1989 since total coliforms are a poor indicator of fecal pollution and associated health risks. At the same time, they began sampling for E. coli, the indicator that EPA now uses as an indicator of fecal pollution in bathing waters. The LDEQ currently uses fecal coliform as its indicator as discussed in Section 2. Even with the recently improved sewage treatment plant, violations remain frequent. The log mean of the fecal coliform counts is 3,533 per 100 mL, well above the state standard of 200. However, the state standard is based on a minimum of not less than 5 samples taken over not less than a 30 day period. Fully 85 percent of the fecal coliform counts were greater than the state standard of not more than 25 percent of the total samples collected annually being greater than 400 colonies per 100 mL.

Since the minimum detection limits available for the analysis of water quality samples for mercury were 0.14 or 0.20 ug/L, the actual number of occurrences of chronic criterion violations in the canals is unknown. Concentrations above the minimum detection limit, and therefore violations of the criteria, were reported in approximately 35 percent of the 200 samples. No arsenic values are above the chronic aquatic life criteria for either freshwater or marine water. The percent exceedances for the freshwater chronic criteria for cadmium, chromium, copper and lead were 13, 6, 12 and 44, respectively.

Table 4-1  
JEFFERSON PARISH EAST BANK CANALS WATER QUALITY STATIONS

Station	Canal and Location
1.	Bonnabel Canal at the intake of Pumping Station No. 1
2.	Suburban Canal at the intake of Pumping Station No. 2
3.	Elmwood Canal at the intake of Pumping Station No. 4

Notes:

- \* No more than 25 percent of the samples collected annually shall exceed 400 colonies per 100 mL. Based on a minimum of not less than 5 samples taken over not more than a 30 day period, count should not exceed 200.
- \*\* Geometric mean should not exceed a one-sided confidence limit, based on a site-specific log standard deviation.
- \*\*\* Corresponds to hardness of 150 mg/L as CaCO<sub>3</sub>.
- \*\*\*\* Criteria are below analytical detection limits.
- \*\*\*\*\* Acute criterion, since there is no chronic criterion.

## 5.0 WATER QUALITY IMPACTS OF URBAN RUNOFF

### 5.1 LAKE PONTCHARTRAIN RECEIVING AREA.

To assess the impacts of urban stormwater runoff upon the receiving waters, it was essential to determine the quantity and quality of the urban stormwater runoff from the study area. For this type of receiving water quality analysis use of measured data would be preferable. However, useful water quality data were very limited. In Jefferson Parish, samples were collected approximately monthly since 1983, throughout the drainage systems on both the East Bank and the West Bank. These data were of little use in assessing runoff quality because of the timing of sample collection. To be useful, samples must be collected during storms in order to effectively characterize the quality of the runoff water. The available monthly data are, for the most part, not associated with storm events. They were, however, used as a general guide in assessing runoff quality.

Because insufficient stormwater quality data were available to assess runoff quality characteristics, mathematical simulation models were utilized to estimate runoff quality in the study area. An "Event Load Runoff" model was applied to the study area. This basic model was obtained from the following publication of the U.S. Environmental Protection Agency:

"Water Quality Assessment: A Screening Procedure for Toxic and Conventional Pollutants in Surface and Ground Water - Part I (Revised 1985)."

This model was designed for "desktop" analysis to provide a highly simplified first estimate of urban stormwater pollution quantities. The results from this model are rough estimates of urban runoff quality. A wide margin of error can be expected when default model parameter values are used. Local estimates of these parameters are preferable. We used default values, values from several other stormwater quality studies, and local estimated values. Due to the limited available data, we relied primarily on model parameter values obtained from other stormwater quality studies. The unique local character of the study area was considered when evaluating the appropriateness of these values.

Table 5-1 shows freshwater and marine acute aquatic life criteria comparisons for those modeled pollutants for which acute criteria exist, and chronic criteria comparisons where they exist in the absence of acute criteria. The marine criteria are more applicable to Lake Pontchartrain. The values listed in the tables represent the average pollutant concentrations in stormwater runoff at the pump station locations for the previously defined "worse case" storm event.

Of the metals modeled, only copper, lead and zinc exceed the marine acute aquatic life criteria. On a lake-wide basis only copper consistently exceeds this criteria with a percent exceedance value of 78

percent. Both lead and zinc exceed this criteria less than one percent of the time. As discussed earlier, the predicted lead concentration seems excessive. However, lead values reported in the NURP study, 160 to 500 ug/L, would still exceed the acute marine aquatic life criterion of 140 ug/L. The NURP study identified copper as the key toxic metal pollutant in urban runoff. The study further said that lead and zinc only pose a problem where copper poses a problem. Perhaps as important is that metals have a high affinity for sediments where they could adversely impact the benthic aquatic life. Data indicate that the metal concentrations in the near shore sediments greatly exceed those in the mid-lake area. At approximately 4 miles from the south shore of Lake Pontchartrain, the metal concentrations in the sediments approach those found in the mid-lake sediments, although no sediment levels in Lake Pontchartrain exceeded or approached the USGS proposed alert levels for copper, lead or zinc (Schurtz, 1984). Thus, even though criteria are violated during runoff events, we are not aware of any aquatic life use impairment directly attributable to high metal concentrations in stormwater runoff pumped into Lake Pontchartrain. However, there is potential for long-term, subtle adverse impacts such as a decrease in the benthic microinvertebrate ecosystem, the foundation of the aquatic food chain (Whipple, 1977) or a reduction in aquatic species reproduction levels (Hart, 1986).

The most visible impact of stormwater runoff into Lake Pontchartrain is the impairment of the primary contact recreation use classification along the south shore of Lake Pontchartrain. Swimming is currently inadvisable within 1/4 mile of the south shore of Lake Pontchartrain in both Jefferson and Orleans Parishes due to high fecal coliform levels. The model predicted fecal coliform counts of about 15,000 colonies per 100 mL in the stormwater runoff. Predicted total coliform counts were about an order of magnitude larger. Numerous reports have demonstrated that the highest coliform levels were found near pumping station outfalls and occurred during wet weather. Even though the east bank areas now pump their treated sewage into the Mississippi River instead of Lake Pontchartrain, high fecal levels persist. Aggravating the problem is that the stormwater runoff is often combined with raw or partially treated sewage as the result of bypasses and overflows.

The south shore of Lake Pontchartrain is known to experience severe oxygen depletion in the near shore areas. The model predicted BOD and COD levels around 22 and 130 mg/L, respectively. The average lake BOD and COD levels are 2 and 43 mg/L. Sewage bypasses and overflows also add to the oxygen demand of the stormwater runoff.

The modeled suspended solids concentrations were about 1,000 mg/L. While there is no criterion for this parameter, excessive sediment loads decrease light transmission in surface waters, leading to reduced photosynthesis and associated primary productivity. Suspended sediment can impact digestion and respiration of fish species. Aquatic species diversity can diminish (Hart, 1986). Also, when the solids settle out, they represent potential water use threats if physical or chemical

conditions would occur to cause the pollutants adsorbed to the sediments to be released into the water column and become bioavailable.

The predicted nutrient levels in the storm event were approximately an order of magnitude larger than the background levels found in Lake Pontchartrain. Earlier studies have shown that even though the runoff from the New Orleans metropolitan area constitutes only approximately 5% of Lake Pontchartrain's water supply, the runoff contributes around 20% of the total phosphorus loading to Lake Pontchartrain. It has been reported that phosphorus in Lake Pontchartrain had almost doubled between 1900 and 1980 (Houck, 1989). As mentioned earlier, Lake Pontchartrain has been classified as oligotrophic to mesotrophic. Organic enrichment of bottom sediments has been reported in the near shore areas of the pump station outfalls (USACE, 1989). Excessive levels of nutrients have the potential to cause eutrophication which can lead to the premature aging of the lake.

None of the predicted pesticide concentrations exceeded the acute marine aquatic life criteria. However, like metals they also tend to accumulate in the sediments where they could potentially adversely impact the benthic ecosystems.

Table 5-1  
EAST BANK JEFFERSON PARISH STORM EVENT MODEL RESULTS CRITERIA COMPARISON

Parameter	Units	Concentration	ACUTE MARINE CRITERIA		ACUTE FRESH CRITERIA	
			Criteria	Exceeded?	Criteria	Exceeded?
Total Solids	mg/L	1052.1

Notes:

\* Chronic criterion

\*\* Exceeds no more than 10% of samples during 30 days, or no more than 25% of samples in one year

\*\*\* Corresponds to hardness of 150 mg/L as CaCO3

## **6.0 WATER QUALITY MONITORING/MODELING PROGRAM**

The preconstruction monitoring plan will provide existing conditions with respect to the storm water runoff quality. The sampling plan will be developed and implemented to define the first flush characteristics (i.e. volume or duration and pollutant concentrations) of storm water runoff for the Eastbank of Jefferson Parish.

Automatic water samplers will be used at the pumping station locations and automatic water samplers with rain gauges and liquid level actuators will be utilized at the basin's interior non-pumping station locations. Velocity meters will also be installed in the interior station locations. The samples will be analyzed for solids, oxygen demanding substances, nutrients, bacteria and metals. Sampling stations will also be established in Lake Pontchartrain to ascertain the impacts of storm water runoff in the receiving area.

The postconstruction monitoring program will provide with-project data with respect to storm water runoff quality. Ideally, the same sampling locations will be used for pre- and postconstruction monitoring.

The data collected during the pre- and postconstruction monitoring programs will then be entered into a database so that it can be manipulated or interfaced with other statistical software.

Jefferson Parish will continue to collect baseline data in the drainage canals as in their current program with 13 sampling stations on the Eastbank. However, in conjunction with the Corps of Engineers, the sampling frequency would be increased to once monthly. Also, it would be preferable that this sampling not be conducted during or within three days of a rainfall event. Further sampling will provide both quantity and quality data for all bypasses and overflows along with rainfall data from the numerous gauges located throughout the basin.

The Stormwater Water Management Model, SWMM, will be developed for the Eastbank of Jefferson Parish. The model will be run in both the event mode and the continuous simulation mode using data collected during the pre- and post construction monitoring period for input and verification. A receiving water quality model will also be developed in ordered to predict the impacts of storm water runoff on the south shore of Lake Pontchartrain. These models, used together, will allow for the evaluation of a wide range of rainfall and treatment scenarios.

## SECTION 1

### INTRODUCTION

The Jefferson Parish Demonstration Project water quality monitoring/modeling program consists of two major components: the monitoring program and the modeling program. The monitoring program will collect and compile water quality, meteorologic, hydrologic, and hydraulic data which will be used in evaluating the demonstration project and for input to a receiving water quality simulation model. The modeling program will consist of a receiving water quality simulation model which will aid in evaluating the Demonstration Project's impacts to Lake Pontchartrain for a wide range of conditions and in assessing potential alternatives and applications throughout Jefferson Parish.

Any aspect of the monitoring - modeling program may be changed or adjusted during implementation of the program in response to new information, unanticipated field conditions, changing data requirements, or other reasons.

#### **Monitoring Program**

The monitoring program will consist of a pre-construction phase and a post-construction phase. The pre-construction phase of the program will take place prior to completion of construction of the Demonstration Project. The post-construction phase will take place after the Demonstration Project begins operating, upon completion of construction.

Pre-construction Monitoring Program - The pre-construction monitoring program will determine existing storm water runoff quality in the Jefferson Parish east bank drainage canal system. Existing water quality in Lake Pontchartrain and the impact of storm water runoff on the Lake Pontchartrain receiving area will also be determined.

The program will define the characteristics (i.e. volume or duration and pollutant concentrations) of storm water runoff from a major portion of the east bank of Jefferson Parish. It will also quantify the pollutant loading from that portion of the Jefferson Parish east bank drainage system to Lake Pontchartrain for various rainfall events. The program will define the duration and extent of negative impacts (e.g. depressed dissolved oxygen levels and elevated fecal coliform levels) of storm water runoff from Jefferson Parish on the Lake.

The pre-construction monitoring program will be active for approximately a twelve month period. Within this time frame, data from ten to twelve rainfall events of varied intensity and duration will be collected and analyzed. The program will determine if a first flush phenomenon occurs in Jefferson Parish's drainage system. This information will be valuable for designing and operating the Demonstration Project and in designing, operating, and evaluating the feasibility of any other proposed storm water treatment alternatives.

Post-construction Monitoring Program - The post-construction monitoring program will be similar to the pre-construction monitoring program. It will determine storm water runoff quality in the Jefferson Parish east bank drainage canal system for with project conditions. Water quality in Lake Pontchartrain and the impacts of storm water runoff on the Lake Pontchartrain receiving area will also be determined for post-construction conditions.

The post-construction monitoring program will define the characteristics of storm water runoff under post-construction conditions from the same portion of the Jefferson Parish east bank drainage system that the pre-construction monitoring program defined. It will also quantify the pollutant loading from that same portion of the Jefferson Parish east bank drainage system to Lake Pontchartrain for various rainfall events under post-construction conditions.

The post-construction monitoring program will also be active for approximately a twelve month period. Within this time frame, data from ten to twelve rainfall events of varied intensity and duration will be collected and analyzed.

Monitoring data from each program will be compared to evaluate the impacts of the Demonstration Project on drainage canal effluents and Lake Pontchartrain receiving area water quality.

#### **Modeling Program**

A receiving area water quality model will be developed to evaluate the impacts of the Demonstration Project on Lake Pontchartrain water quality. This will allow for a wide range of rainfall events, in addition to the ones for which data were collected, to be evaluated. The modeling program will also provide information to evaluate the feasibility and effectiveness of expanding Demonstration Project concepts to a larger scale that would cover a wider area. In addition, the model will be useful in evaluating the effectiveness of other potential alternative storm water pollution control projects.

## SECTION 2

### SAMPLING LOCATIONS

Sampling site locations have been selected to support the goals of the monitoring and modeling programs. Automatic samplers will be positioned to obtain samples in the drainage canals on the intake side of three East Bank drainage pump stations that discharge directly to receiving waters. These sampling sites will provide information to characterize the composition and pollutant loading of storm water entering Lake Pontchartrain for pre and post-construction conditions. An automatic sampler located at the intake of the proposed lift station will provide data about the composition of storm water that will be pumped to the wastewater treatment plant via the proposed force main. Two other automatic samplers will be located at strategic sites within the Jefferson Parish East Bank drainage system. These sites have been chosen for their proximity to sewage lift stations that are chronically bypassed during rainfall events. Data from these sites will show the effects of the Demonstration Project on water quality problems in the drainage canals caused by sewage lift station bypasses. These two sites may be moved from time to time during the sampling period depending upon evaluation of ongoing data. Near shore and far shore sampling sites located offshore of three drainage pump stations on Lake Pontchartrain will generate data to assess the impacts of storm water discharge on the Lake for pre and post-construction conditions. These data will be used in formulating a receiving water quality model and will aid in assessing the effectiveness of the Demonstration Project. Five sample sites throughout the drainage canal system will be used to establish baseline water quality conditions in the system.

Figure 1 shows the locations of all the sampling sites.

Sampling site descriptions follow:

#### **Automatic Water Samplers**

Automatic water samplers will be utilized to collect water samples during rainfall events. These samplers provide continuous unattended collection of samples under a wide variety of sampling configurations and options. Automatic water samplers will be deployed to collect samples at the following six sites:

**SITE JPPS001**

Bonnabel Canal near the inflow to Pumping Station No. 1 (Bonnabel Pumping Station). The Bonnabel Pumping Station is located in Metairie at the north end of Hesper Ave., which is two blocks west of Bonnabel Blvd., at Lake Pontchartrain.

**SITE JPPS002**

Suburban Canal near the inflow to Pumping Station No. 2 (Suburban Pumping Station). The Suburban Pumping Station is located in Metairie at the north end of Lake Villa Dr., which is two blocks east of Houma Blvd., at Lake Pontchartrain.

**SITE JPPS003**

Elmwood Canal near the inflow to Pumping Station No. 3 (Elmwood Pumping Station). The Elmwood Pumping Station is located in Metairie at the north end of Caryota Dr. at Lake Pontchartrain.

**SITE JPLS004**

Suburban Canal just south of its intersection with the West Napoleon Canal in Metairie. This is one block east of the intersection of Houma Blvd. and West Napoleon Ave. The intake for the proposed lift station will be at this location.

**SITE JPIN005**

West Napoleon Canal at Athania Parkway in Metairie.

**SITE JPIN006**

West Esplanade Canal at West William David Parkway in Metairie.

**Receiving Water Grab Samples**

Near shore and far shore grab samples will be collected in the receiving waters of Lake Pontchartrain offshore of three lakeside pumping stations. Personnel will access these sites by watercraft. These grab samples will be collected at the following six sites:

**SITE JPG1N07**

Lake Pontchartrain approximately 200 ft. north of the shoreline at Pumping Station No. 1 (Bonnabel Pumping Station).

**SITE JPG1F08**

Lake Pontchartrain approximately 1000 ft. north of the shoreline at Pumping Station No. 1 (Bonnabel Pumping Station).

**SITE JPG2N09**

Lake Pontchartrain approximately 200 ft. north of the shoreline at Pumping Station No. 2 (Suburban Pumping Station).

**SITE JPG2F10**

Lake Pontchartrain approximately 1000 ft. north of the shoreline at Pumping Station No. 2 (Suburban Pumping Station).

**SITE JPG3N11**

Lake Pontchartrain approximately 200 ft. north of the shoreline at Pumping Station No. 3 (Elmwood Pumping Station).

**SITE JPG3F12**

Lake Pontchartrain approximately 1000 ft. north of the shoreline at Pumping Station No. 3 (Elmwood Pumping Station).

**Wastewater Treatment Plant Effluent Samples**

Data collection currently in progress at the East Bank Waste Water Treatment Plant will be relied upon for these data.

**Drainage Canal Grab Samples**

Grab samples will be collected from drainage canals throughout the East Bank of Jefferson Parish. These grab samples will be collected at the following five sites:

**SITE JPG0113**

The location of this site is the same as the location of SITE JPLS004 - Suburban Canal just south of its intersection with the West Napoleon Canal in Metairie. This is one block east of the intersection of Houma Blvd. and West Napoleon Ave. This is the location of the intake for the proposed lift station.

**SITE JPG0214**

The location of this site is the same as the location of SITE JPIN006 - W.Esplanade Canal @ W.William David Parkway in Metairie.

**SITE JPG0315**

The location of this site is the same as the location of SITE JPIN005 - West Napoleon Canal at Athania Parkway in Metairie.

**SITE JPG0416**

Suburban Canal at the west end of Jasper St. in Metairie.

**SITE JPG0517**

West Metairie Canal at Waltham St. in Metairie.

## SECTION 3

### SAMPLING PERIOD AND FREQUENCY

#### Sampling Period

##### Pre-construction Sampling -

In order to assess the impacts of urban storm water runoff on water quality in the drainage canals and the receiving waters of Lake Pontchartrain for a wide range of existing conditions, water samples from rainfall events of many different intensities and durations will be collected and analyzed. Samples from rainfall events ranging from a light rain to major storms of three inches of rainfall or more, and a range of events in between, will be collected and analyzed. Collection of samples from ten to twelve events will cover the range of events needed. At least a three day dry period between sampled events will be necessary to allow time for the buildup of pollutants on land surfaces. Otherwise, the sampled runoff will be relatively free of pollutants and the analyses will not be indicative of the kind of runoff that could be improved by the Demonstration Project. It is anticipated that the necessary ten to twelve rainfall events will occur within a period of twelve months or less. Therefore, the pre-construction monitoring program will be ongoing for a period of approximately twelve months. It will be completed before operation of the Demonstration Project begins in order to accurately assess existing conditions.

##### Post-construction Sampling -

In order to evaluate the performance of the Demonstration Project for a wide range of conditions, water samples will be collected during rainfall events of many different intensities and durations.

During the post-construction sampling period, as in the pre-construction sampling period, water samples from ten to twelve rainfall events of many different intensities and durations will be collected and analyzed. These data will be used to compare with project conditions to existing conditions. It is expected that the ten to twelve rainfall events needed for the post-construction monitoring program would also occur within a period of twelve months or less. Therefore, the post-construction monitoring program will be ongoing for a period of approximately twelve months, starting some time after construction of the Demonstration Project is complete.

## Sampling Frequency

The sample collection frequency will vary for the different types of sampling methods and/or locations (i.e. automatic sampler samples, receiving water grab samples, drainage canal grab samples, etc.). The sample collection frequencies for the different types of samples are shown below.

### Automatic Water Samplers -

The collection frequency for each of the sites with automatic samplers will depend upon the occurrence of rainfall events which meet the needs of the sampling program. The automatic samplers will be programmed to collect samples based on rainfall and flow in the canals in which they are sampling. While the samplers may collect samples for many rainfall events, the samples will not necessarily be analyzed unless the event meets the needs of the monitoring program. If the event will not be used for the program then the samples will be discarded. In either case, after the samples are retrieved the automatic samplers will be re-programmed in preparation for the next event.

In the beginning of the program most rainfall events that produce runoff will be analyzed, provided the three day inter-event dry period is satisfied. As the program proceeds, more critical selection criteria will be necessary for analysis to proceed so that samples for the entire program will be derived from many different and varied rainfall events.

The automatic samplers will be programmed to collect composited flow-weighted samples for each rainfall event. The analyses of these composited samples will provide mean event pollutant concentrations which will be used to quantify total event pollutant loadings.

The automatic samplers will also be programmed to collect separate samples during the early stages of rainfall events to determine first flush characteristics, if they exist. Analyses of these samples will determine if pollutant concentrations are greater in the early stages of storm water runoff events than at other times during the event. This is known as the first flush phenomenon.

The installation and programming of the automatic samplers will be adjusted as the monitoring program progresses. Based on experience and data derived during the program, the locations,

sampling frequencies, and timing of sample collection may be changed in order to obtain the data needed to properly evaluate the Demonstration Project.

The automatic sampler sites are described in Section 2. They include sites at inflows to pumping stations, inflows to the proposed lift station, and some drainage system interior canal sites.

#### Receiving Water Grab Samples -

The timing of grab samples in Lake Pontchartrain in the vicinity of the pumping stations will also depend upon the occurrence of rainfall events which meet the needs of the sampling program.

Near Shore Samples - The near shore grab sample sites, which are described in Section 2, are located approximately 200 ft. into the Lake from three lakeside pumping stations. Samples from these sites will be collected at the beginning of rainfall events, prior to operation of the pumps. Data from these samples will provide information about background conditions in the Lake prior to the pumping of storm water during rainfall events. At the beginning of a rainfall event, it will not be known if the event will meet the needs of the monitoring program. This would not be known until the conclusion of the event, at which time it will be decided to either analyze or discard the samples.

Samples from these sites will also be collected approximately 12, 24, and 48 hours after pumping ceases for rainfall events which will be used for the monitoring program. Data from these samples will be compared to the pre-event data to provide information about the effects of a rainfall event on Lake Pontchartrain water quality. These samples will be collected and analyzed only after it has been concluded that an event meets the needs of the monitoring program. Therefore, none of these samples will be discarded.

Far Shore Samples - The far shore grab sample sites, which are described in Section 2, are located approximately 1000 ft. into the Lake from three lakeside pumping stations. Samples from these sites will be collected approximately 12, 24, and 48 hours after pumping ceases for rainfall events which will be used for the monitoring program. Data from these samples will be compared to the pre-event data to provide information about the effects of a rainfall event on Lake Pontchartrain water quality. These samples will be collected and analyzed only after it has been concluded that an event meets the needs of the monitoring program. Therefore, none of these samples will be discarded.

Wastewater Treatment Plant Effluent Samples -

Data collection currently in progress at the East Bank Waste Water Treatment Plant will be relied upon for these data.

Drainage Canal Grab Samples -

The drainage canal grab sample sites, which are described in Section 2, are located throughout the East Bank drainage canal system. Samples from these sites will be collected once a month throughout the duration of the pre-construction and post-construction monitoring programs. These samples will be collected at least three days after any rainfall event to insure that they are representative of ambient dry weather canal water conditions.

## SECTION 4

### SAMPLE COLLECTION

The sampling effort will require close coordination among Jefferson Parish departments, field personnel, the analytical laboratories, and the managing organizations (i.e. Jefferson Parish, the Corps of Engineers, consultants, etc.). Each type of sampling site will have different deployment, collection, and maintenance requirements. For example, the automatic sampler sites will require almost constant effort to assure that samples are collected and preserved properly, while the samples offshore of the pumping stations in the Lake will require a crew to operate watercraft for access to the sampling sites.

All sample collection will be conducted in accordance with applicable and accepted quality control/quality assurance procedures.

It is intended that sampling will be conducted during normal working hours (i.e. 7:00 AM to 5:30 PM Monday through Friday). Over the course of a year, at least ten to twelve rainfall events that meet the needs of the monitoring program should occur during these hours. If it becomes apparent that not enough events will be captured during normal working hours then arrangements will be made to conduct sampling during extended hours.

#### **Automatic Water Samplers**

Six sites will be equipped with automatic water samplers. All of them will be located at drainage canals within the drainage system. In order to obtain flow proportioned composite samples, which are needed to quantify pollutant loadings, the flow rates in the drainage canals at which the automatic samplers are located must be known. Rainfall data at these sites will also be needed to correlate canal flow and rainfall with pollutant concentrations in the samples to derive pollutographs and to determine if a first flush occurs in this drainage system.

In order to obtain all the required data, each of the six sites will be furnished with the following equipment:

- \* Automatic Sampler - ISCO 6700 Sampler (Or equivalent)
- \* Area-Velocity Flow Meter - ISCO 4250 Area-Velocity Flow Meter (Or equivalent)
- \* Automatic Rain Gauge - ISCO 674 Rain Gauge (Or equivalent)
- \* Remote Power Source
- \* Protective enclosure for the equipment
- \* Sample containers
- \* Miscellaneous hoses, cables, containers, etc.

Several manufacturers market this kind of equipment. For illustrative purposes, ISCO, Inc. product names and model numbers for this equipment are shown. Citation of ISCO trade names does not constitute an official endorsement or approval of the use of such commercial products.

Extensive preparations will be made to set up each automatic sampler site. Proper installation of the equipment will insure that suitable samples are collected and that accurate data are acquired. Discharge measurements at the sampling sites in the drainage canals will be taken to calibrate the area-velocity flow meters. The rain gages will be installed on poles, away from obstructions. Intakes for the water samples, velocity probes, and water level probes will be securely mounted in the water column. The automatic samplers, area-velocity flow meters, power supplies, and other electronic equipment will be housed in weatherproof enclosures. This will provide shelter from the elements and minimize vandalism.

When the sampler sites are set up and ready to be activated, collection of water samples will proceed. For each automatic sampler site a repeating sequence of site visits will take place during the monitoring program. A typical series of sampling site visits is shown below.

- \* Site Visit 1 - The following tasks will be performed:
  - Program sampler
  - Load sample containers into sampler
  - Check power supply (Replace battery if necessary)
  - Conduct total sampling site system check

\* Site Visit 2 - If there has been at least a three day period without rain, and rain is predicted, the samplers will be prepared for sample collection. The following tasks will be performed:

- Check sampler program
- Fill sampler with ice
- Check sample containers
- Check power supply (Replace battery if necessary)
- Conduct total sampling site system check

\* Site Visit 3 - If conditions indicate that enough rain has fallen for a first flush to have occurred, the following tasks will be performed:

- Remove first flush samples for fecal coliform, BOD, and E. Coli analyses; label; preserve with ice; fill out chain of custody tags; and deliver to lab within six hours from when the first sample was collected
- Remove first flush samples for all other analyses, label, preserve with ice, fill out chain of custody tags, and deliver to lab within a day after sample collection
- Check sampler program
- Check sample containers
- Check & add ice if needed

\* Site Visit 4 - When the rainfall event is over (When pumping related to the event is completed) a decision will be made to use, or not use, the event as one of the ten to twelve events that will be analyzed for the monitoring program. If it is decided that the event will be used, the following tasks will be performed:

- Remove the flow-weighted composite samples and pollutograph samples (if there are any), label, preserve with ice, fill out chain of custody tags, and deliver to lab within a day after sample collection
- Download flow and rainfall data
- Within the next two days perform site visit 1 tasks, in preparation for the next rainfall event that will be sampled, and continue from there

If it is decided that the event will not be used, the following tasks will be performed:

- Remove any samples and discard them
- Download flow and rainfall data
- Perform the site visit 1 tasks in preparation for the next rainfall event and continue from there

Upon completion of the pre-construction monitoring program, the automatic sampler site equipment will be dismantled and stored until completion of Demonstration Project construction. The equipment will be redeployed for the post-construction monitoring program.

### **Receiving Water Grab Samples**

The collection of receiving water grab samples will be associated with rainfall events that will be analyzed for the monitoring program. Any event for which the automatic samplers collect samples that are analyzed will be an event for which receiving water grab samples will also be collected and analyzed.

Because the receiving water grab sample sites are in Lake Pontchartrain, they will be accessed by watercraft. A crew of at least two persons will collect samples at these sites. The water samples will be collected at mid-depth with a free flushing, messenger-triggered type sampler. Samples for fecal coliform, BOD, and E. Coli analyses will be labeled, preserved with ice, chain of custody tags filled out, and delivered to the lab within the six hour holding time. All other samples will be labeled, preserved with ice, chain of custody tags filled out, and delivered to the lab within a day after sample collection.

Sampling sites will be located using a geographical positioning system (GPS). The GPS will be used to locate the sampling sites for each sampling event. This will assure that samples will be collected from the same locations for each sampling event.

Near Shore Samples - The near shore samples will be collected at the beginning of rainfall events before pumping begins. A crew will be ready to collect samples at almost all times. Since it will not be known in advance whether a rainfall event will be used for the monitoring program, samples will be collected for almost all rainfall events for which storm water pumping is expected to occur (provided that the three day inter event dry period is met). If it turns out that the rainfall event does not meet the needs of the monitoring program the samples will be discarded.

Near shore samples will also be collected after rainfall events which will be used for the monitoring program. Since these samples will be collected approximately 12 and 24 hours after the conclusion of pumping for rainfall events, it will be known if an event will be used before it would be time to collect the samples. A crew would have time to plan to collect the samples and none of them would be discarded.

Far Shore Samples - The far shore samples will be collected only for rainfall events which will be used for the monitoring program. Since the samples will be collected approximately 12, 24, and 48 hours after the conclusion of pumping for rainfall events, it will be known if an event will be used before it would be time to collect the samples. A crew would have time to plan to collect the samples and none of them would be discarded. The far shore samples that will be collected 12 and 24 hours after the conclusion of pumping will be collected at the same time as the after event near shore samples.

#### **Wastewater Treatment Plant Effluent Samples**

Sample collection currently in progress at the East Bank Waste Water Treatment Plant will be relied upon for collection of these samples.

#### **Drainage Canal Grab Samples**

The grab samples at the five drainage canal sites will be collected once a month throughout the duration of the pre-construction and post-construction monitoring programs. The sampling schedule will allow for at least the required three days of dry weather before any sample collection. Each month's sampling at these five sites will be conducted on the same day. These sites will be land based and easily accessible. Samples will be obtained from approximately two feet below the water surface except where the canal depth is less than two feet. If that is the case, samples will be obtained from directly below the water surface. Samples for fecal coliform, BOD, and E. Coli analyses will be labeled, preserved with ice, chain of custody tags filled out, and delivered to the lab within the six hour holding time after collection of that day's initial sample. All other samples will be labeled, preserved with ice, chain of custody tags filled out, and delivered to the lab within a day after sample collection.

## SECTION 5

### SAMPLE PARAMETERS

Because of the great number of samples associated with this program a selective number of water quality parameters will be analyzed. Emphasis will be placed on pollutants that are common in storm water and on pollutants that affect the designated uses of Lake Pontchartrain.

The following parameters will be analyzed for all samples:

- Total Suspended Solids (TSS)
- Total Dissolved Solids (TDS)
- Total Volatile Solids (TVS)
- Biochemical Oxygen Demand (BOD)
- Chemical Oxygen Demand (COD)
- Total Phosphorus
- Dissolved Phosphorus
- Total Ammonia
- Nitrate + Nitrite
- Total Kjeldahl Nitrogen (TKN)
- Total Organic Carbon (TOC)
- Dissolved Copper
- Dissolved Lead
- Dissolved Zinc
- Hardness
- Diazinon
- Malathion
- Glyphosate
- pH
- Oil & Grease

The holding time for samples to be analyzed for Fecal Coliform, E. Coli, and BOD is six hours. Because of this short holding time, not all of the automatic sampler samples will be analyzed for these parameters. The first flush samples collected by the automatic samplers will be retrieved in time for these analyses to be conducted. However, the rest of the samples, including the flow-weighted composites, may not be retrieved in time for the proper analysis of these parameters. If conditions allow, they will be analyzed for these parameters. All grab samples will include Fecal Coliform, E. Coli, and BOD analyses.

The laboratories selected to perform the analyses for the monitoring program will utilize applicable and accepted quality control/quality assurance procedures. They will be inspected and approved by the Corps of Engineers Waterways Experiment Station.

## SECTION 6

### RECEIVING AREA WATER QUALITY MODEL

A receiving area water quality model will be developed to evaluate the impacts of the Demonstration Project on Lake Pontchartrain water quality. This will allow for a wide range of rainfall events, in addition to the ones for which data were collected, to be evaluated. The modeling program will also provide information to evaluate the feasibility and effectiveness of expanding Demonstration Project concepts to a larger scale that would cover a wider area. In addition, the model will be useful in evaluating the effectiveness of other potential alternative storm water pollution control projects.

Selection of an appropriate receiving water quality simulation model will take place during the execution of the monitoring program. The model that is chosen will have the capability to simulate the transport and transformation of conventional pollutants; such as dissolved oxygen, biochemical oxygen demand, and bacteria; and toxic pollutants; such as heavy metals; in the water column of large open water bodies such as Lake Pontchartrain.

The model will be adapted to the Lake Pontchartrain receiving water area. Data collected during the monitoring program, as well as other geophysical data, will be used for model input and for model verification. The model will be an effective tool in evaluating the Demonstration Project for a wide range of conditions and potential alternatives.

## SECTION 7

### COST ESTIMATE

This cost estimate includes the costs for execution of the Jefferson Parish Demonstration Project Water Quality Monitoring - Modeling program as described in this report. In generating the cost estimate, it was assumed that all work would be performed by the Corps of Engineers. The assumption was also made that all laboratory work would be performed by the water quality laboratory at the Corps of Engineers Waterways Experiment Station (WES) and at the New Orleans District's water quality laboratory. The estimate is based on current labor, overhead, material, equipment, and laboratory costs. Any major changes to the program will affect the costs associated with its execution.

**SUMMARY OF COSTS FOR LAKE PONTCHARTRAIN DEMONSTRATION PROJECT  
WATER QUALITY MONITORING - MODELING PROGRAM**

		<b>Cost</b>
<b>Pre-Construction</b>		
1. Lake Pontchartrain Water Sample Collection		\$40,000
2. Monthly Grab Samples		\$3,150

Lake Pontchartrain Water Sample Collection

LS

shifts per day: 1.00

hours per shift: 8.00

PLAN OF OPERATION

This item is for all equipment, labor, and materials required for the collection of Lake Pontchartrain water quality samples in the vicinity of 3 pumping stations for 12 rainfall events. The water samples will be collected 200' from the stations before the rainfall event. In order to capture 12 events, it is assumed that the crew will collect samples 24 times for the before rainfall event.

After the rainfall event, the water samples will be collected as follows:

Hours after event	# of samples/event	distance from pumping station (ft)	total # of sample
12	3	200.00	36
12	3	1000.00	36
24	3	200.00	36
24	3	1000.00	36
48	3	200.00	36
48	3	1000.00	36

Crew:

1 GS-09 Technician & 1 GS-05 Technician

1 skiff

1 truck

Production: The crew can collect samples from the 3 sites in one day. When collecting the samples for 12 hours at 200' and 1,000'; 24 hours at 200' and 1,000'; and 48 hours at 200' and 1,000'; the crew can collect from all 6 sites in one day.

Before event Quantity: 24.00 Sample Days

Days: 24

After event Quantity: 36.00 Sample Days

Days: 36

Total Sample Days 60.00

Monitoring & Collection

shifts per day:

1.00

hours per shift:

8.00

PLAN OF OPERATION

This item is for all equipment, labor, and materials required for the monitoring & collection of water samples from 6 automatic samplers.

The monitoring & collection operation will consist of several sub-features as follows: **ESTIMATED HR**

Ice-application to samplers - 1 GS-9 with a truck will apply ice to samplers approximately 50 times. It will take a total of 4 hrs to apply ice to all samplers @ time. **200.00 (GS-9)**

Monitoring & Collection - 1 GS-12 will manage the study and monitor the samplers on a daily basis. It is assumed that the GS-12 will work six hours/day for a year to complete the monitoring process. The GS-12 will go out to the samplers approximately 50 times throughout the year to collect samples, reprogram samplers, and set new containers. 400 hours will be included for a truck for collecting samples 50 times. The time for the GS-12 is based on 260 days X 6hrs. **1560.00 (GS-12)**

In order to satisfy an additional requirement of collecting first flush samples, a GS-11 will collect samples and analyze data approximately 50 times. The time required to collect all samples will be approximately 8 hours/ event. A total of 400 hours will be required for a GS-11 and a truck for collecting first flush samples. **400.00 (GS-11)**

The samples for the 12 chosen events will be packed and shipped to WES.

Also included in this item is the washing of sample bottles. While the cost for cleaning bottles is included in the testing cost for the 12 chosen events, the remaining 38 events will require the cleaning of sample bottles. 9 bottles per site will be cleaned by a GS-9 technician. The time required to clean bottles is approximately 1.5 hrs / 9 bottles. The estimated time is based on 6 sites (9bottles/site) X 38 events X 1.5 hours. **342.00 (GS-9)**

Re: Proposed Demonstration Project  
Urban Storm Water Runoff  
Metairie, Jefferson Parish, LA

Dear Mr. Schroeder:

Reference is made to your letter dated March 24, 1994 concerning the above. We have completed our review of the proposed project plans and have the following comments to offer.

Based on the information contained in your letter describing the nature of the proposed construction and its location, it is our opinion that significant historic properties should not be affected. The protocol you have established for reporting unanticipated archaeological discoveries will insure that any finds of this nature will be properly assessed.

We concur with your assessment that additional cultural resources work is not warranted for this project. Should you have any questions concerning our comments, please contact Mr. Duke Rivet in the Division of Archaeology at (504) 342-8170.

Sincerely,

Gerri Hobdy  
State Historic Preservation Officer

Dear Ms. Hobdy:

The New Orleans District is planning a demonstration project to select a practical method of improving the water quality of Lake Pontchartrain and the Mississippi River by improving the quality of storm water discharges into these bodies of water. This demonstration project for urban storm water runoff is authorized under Section 307 of the Water Resources Development Act of 1992 (Public Law 102-580).

The proposed demonstration project will consist of constructing a 33,000-gallon-per-minute (gpm) sewer lift pumping station adjacent to the Suburban Canal near the intersection of Canal No. 4 and West Napoleon Avenue in Metairie. In addition, approximately 13,500 linear feet of 48-inch diameter sewer force main will be placed along the existing utility corridor on West Napoleon and North Woodlawn Avenues, and along the right-of-way of the Louisiana and Arkansas Railroad until the sewer force main enters the Eastbank Wastewater Treatment Plant.

The work completed for the report titled Preserving the Past for the Future: A Comprehensive Archeological and Historic Sites Inventory of Jefferson Parish, Louisiana, by R. Christopher Goodwin in 1985, did not identify any prehistoric or historic sites in the project area.

In the prehistoric and historic periods, the area between the natural levee of the Mississippi River and Lake Pontchartrain was marsh and swamp. Early French settlers established plantations along the Mississippi River with ownership of land from the Mississippi River to Lake Pontchartrain, but the land in the swamp was uninhabited until drained.

The sewer lift pumping station will be constructed adjacent to the Suburban Canal. This area is located adjacent to Canal No. 4 and the Suburban Canal and is presently occupied by a house built in recent years. Construction of these canals severely disturbed this area of the project.

The sewer main will be constructed under a 50-foot right-of-way along urban streets and a railroad corridor. Research in drainage, sewerage, and utilities maps has shown that the ground under and around Woodlawn Street and other streets in the project corridor has been severely disturbed by construction activities. Sewer lines are the deepest of all utility lines in the area and range from 4 feet to 12 feet deep with most sewers approximately 8 feet under present ground level. Construction of the sewers required disturbing the area below this level to place the utilities in the trench. Engineers estimate that an area two feet below the bottom of the trench was disturbed during construction. Other utilities, including drainage, are located along the project corridor either under the road or immediately on either side of the road within the 50-foot right-of-way.

Parts of the project area have been filled during construction of houses, particularly in the area of recent construction closest to Lake Pontchartrain. Streets were dug into the ground and the dirt was used for fill for the front yards of houses.

The entire project area was inspected by a New Orleans District archeologist. Houses are all of post-World War II construction and many were built in the 1960s. There are no standing structures eligible for the National Register of Historic Places.

In the unlikely event that construction disturbs a site potentially eligible for the National Register of Historic Places, construction inspectors and other construction personnel will be instructed to avoid adverse impacts to the buried site. If any archeological or historical remains are discovered in the course of construction, the contractor will leave the archeological material undisturbed and will immediately report the discovery to the Contracting Officer. At that time, procedures will be implemented to avoid adverse impacts to any sites potentially eligible for the National Register of Historic Places.

We are confident that no significant cultural resources exist in the project area and we do not plan to undertake additional

cultural resources work for this project. Please contact  
Dr. Edwin Lyon at (504) 862-2038 if you have any questions.

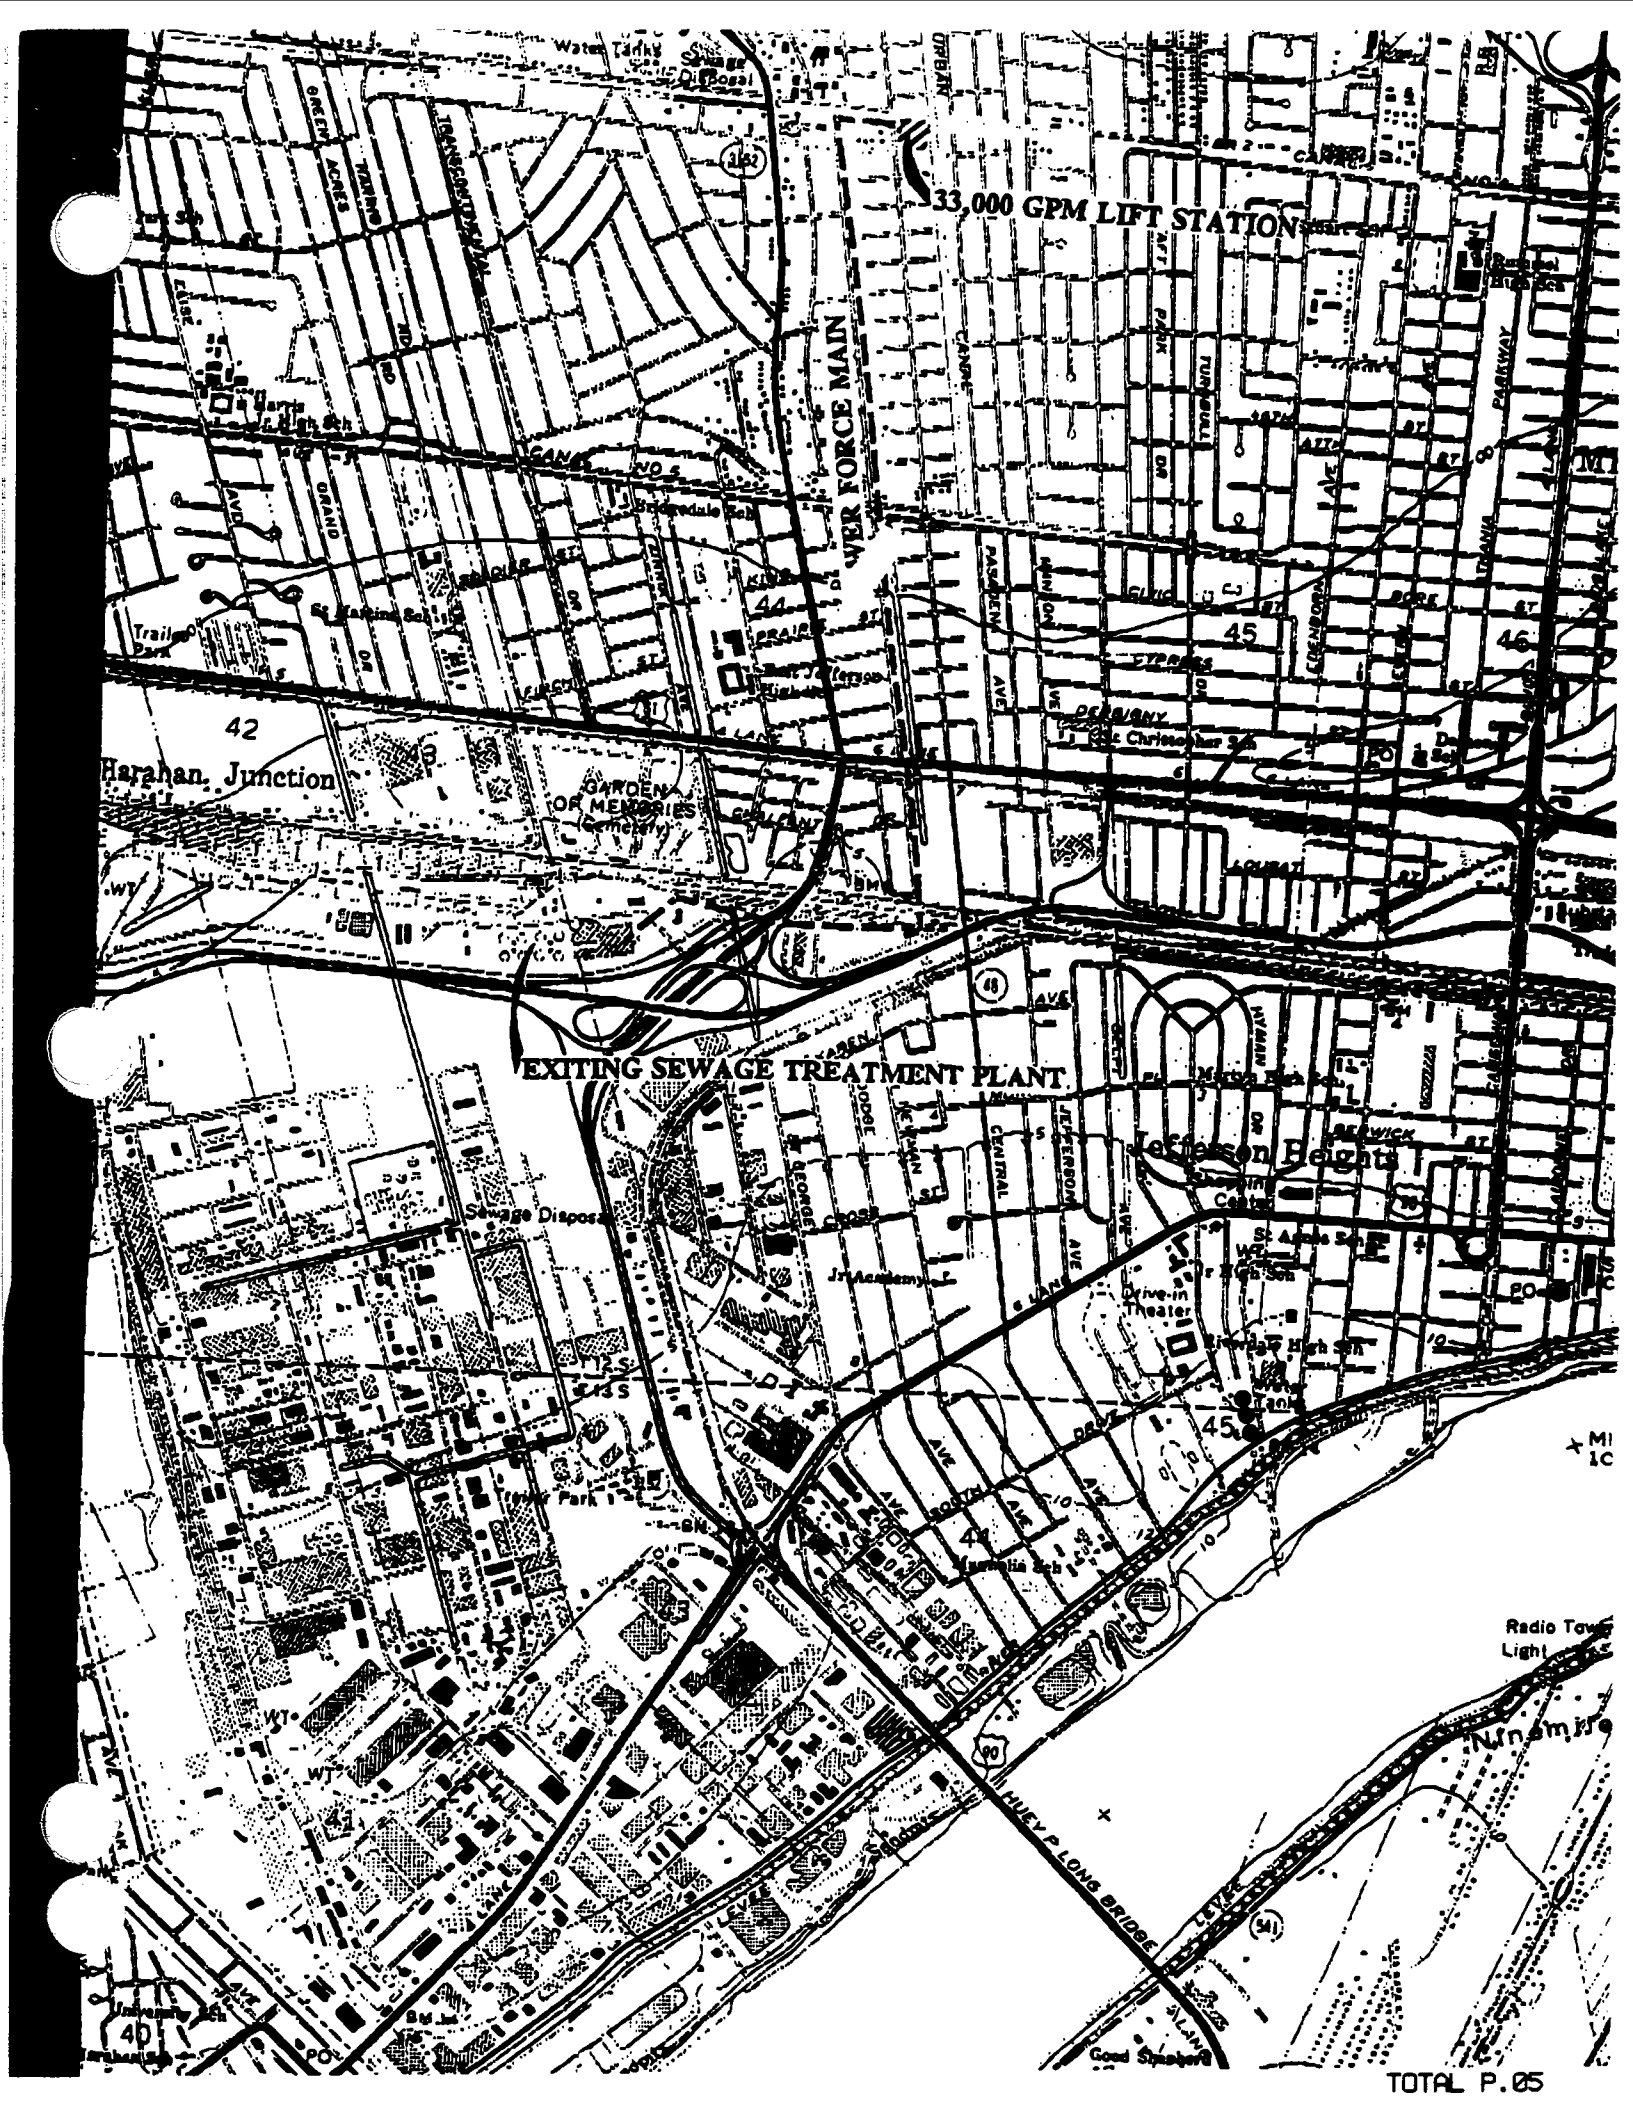

Sincerely,

A handwritten signature in cursive script, appearing to read "R. H. Schroeder, Jr.", written in dark ink.

A 19001800 02. Removal of Structures and Obstrc

This item is for all labor, equipment, and materials required for the removal of miscellaneous concrete obstructions. This item allows for the removal of 20 seperate concrete obstructions using a ldr/bkh with a air ram chisel and dump trucks to dispose of the debris. A second ldr/bkh will be used to load the debris into the trucks. Allow 16 cy debris/obstruction = 32 tons/obstruction with a disposal fee of \$3/ton. Removal will be done at a rate of 1 obstruction per day.

A 19001800 03. Traffic Control

This item is for all labor, equipment, and materials required to provide traffic control for the project. Three methods are used: a temporary by-pass road, concrete lane barricades, and traffic signs.

A) Temporary By-pass road

Use 2 temporary by-pass roads, 150' long each x 15' wide. Use 8" crushed stone = 120 cy. The material will be truck delivered, placed and spread by a small dozer assisted by a laborer/spotter, and compacted by a roller. Allow 2 wd.

B) Jersey Barricades

Use 450 lf of concrete lane barriers. The barriers will be delivered by a supplier and placed by a truck crane. Allow 1 wd to set out initially, 1 wd to move to the other side, and 1 wd to pick up and remove.

C) Signs

Allow for the following traffic signs:

- 12 rectangular "caution" type signs (5 sf/ea) = 40 sf
- 4 rectangular gen. construction signs (12 sf/ea) = 48 sf
- 16 diamond "warning" type signs (16 sf/ea) = 256 sf
- 8 diamond "caution" type signs (9 sf/ea) = 72 sf
- 44 sign posts
- 88 bolt & nut assemblies

Allow for misc reflectors and barrels also

Allow 3 wd to install the signs/traffic controls and 1 wd for removal.

A 19001800 02. Removal of Structures and Obstrc

This item is for all labor, equipment, and materials required for the removal of miscellaneous concrete obstructions. This item allows for the removal of 20 separate concrete obstructions using a ldr/bkh with a air ram chisel and dump trucks to dispose of the debris. A second ldr/bkh will be used to load the debris into the trucks. Allow 16 cy debris/obstruction = 32 tons/obstruction with a disposal fee of \$3/ton. Removal will be done at a rate of 1 obstruction per day.

DESCRIPTION	QUANTY	UOM	CREW ID	OUTPUT	LABOR	EQUIPMNT	MATERIAL	SUPPLIES	TOTAL COST	UNIT COST

A 19001800 03. Traffic Control

This item is for all labor, equipment, and materials required to provide traffic control for the project. Three methods are used: a temporary by-pass road, concrete lane barricades, and traffic signs.

A) Temporary By-pass road

Use 2 temporary by-pass roads, 150' long each x 15' wide. Use 8" crushed stone = 120 cy. The material will be truck delivered, placed and spread by a small dozer assisted by a laborer/spotter, and compacted by a roller. Allow 2 wd.

B) Jersey Barricades

Use 450 lf of concrete lane barriers. The barriers will be delivered by a supplier and placed by a truck crane. Allow 1 wd to set out initially, 1 wd to move to the other side, and 1 wd to pick up and remove.

C) Signs

Allow for the following traffic signs:

- 12 rectangular "caution" type signs (5 sf/ea) = 40 sf
- 4 rectangular gen. construction signs (12 sf/ea) = 48 sf
- 16 diamond "warning" type signs (16 sf/ea) = 256 sf
- 8 diamond "caution" type signs (9 sf/ea) = 72 sf
- 44 sign posts
- 88 bolt & nut assemblies

Allow for misc reflectors and barrels also

Allow 3 wd to install the signs/traffic controls and 1 wd for removal.

A 19001800 24. aerial crossing @ W. Metairie

This item is all labor, equipment, and materials required for construction of concrete pile bents to cross the W. Metairie canal. 4 pile bents will be used consisting of 2 -12" x 70' prestressed concrete piles and a 2' sq.x 6' cast in place cap for bracing, pipe support, and pile cap.

Allow 2 wd to do all formwork, including stripping the forms. Allow 1 wd for resteel installation, and allow 1 wd to pour the concrete caps.

NOTE: This item does NOT include the pipe for the crossing.

A 19001800 25. Connection to Existing F.M.

This item is for all labor, equipment, and materials required to tie the new 48" pipeline into the existing 48" forced main. The installation requires a 36" bypass line in order to have un-interrupted service in the main line. The 36" by-pass line will be hot-tapped into the existing 48" line, then the 48" line will be plugged, and the TEE installed to connect the new 48" concrete pipeline.

Prices for 36" bypass line work are referenced from items #7 - 11.  
Price quote on hot-tap from TDW Services.  
Price quote on pipe from N.O. Cement Products.

PLAN OF OPERATION

This item is for mob. and demob. of all labor and equip. necessary to accomplish the work in this job. Mob. is assumed to be from within 100 miles, as there are ample local contractors capable of performing this work.

Two days will be used for mob. and two days for demob. for most equipment. Trucks will use 1 day each way, and the Crane will use three days each way.

PLAN OF OPERATION

This item is for incidental Clearing & Grubbing prior to commencement of construction of the lift station.

For this item, only minor clearing is required. A Backhoe, a D-4 dozer, and a dump truck for hauling away debris will be utilized for one work day.

description of equipment	size	no.	hours	rate	amount
Backhoe	CAT 225	1	8	\$37.21	\$298

PLAN OF OPERATION

This item is for Dewatering the area for the pumping station construction.

For this item, the dewatered area is assumed to be a rectangular area, approximately 42' x 38'. The sheet pile wall will be driven first. 8 Deep wells will then be drilled to -50' and header pipes layed out and hooked-up. When the pumps begin running, the hole excavation will begin. As the hole excavation progresses, walers for the sheet pile cofferdam will be installed.

Drive Sheet Pile - 3 days with American 5299A

Drill wells - 2 days with drill truck and crew

Excavate - 1,200 CY's @ 50 CY/Hr = 24 hrs or 3 WD  
Am Crane with 3 Dump trucks to haul away material

Set-up pump and fuel tank - run avg. 50% of time for 3 months.

Weld in walers - 2 work days Am Crane with welders

Removal of sheet pile and walers at the completion of construction  
Am Crane with welder crew - 2 Work days

Backfilling operation - Cat Backhoe (225) and compactors.  
1,000 CY's @ 35 CY/hr = 29 hrs. - USE 4 WD

PLAN OF OPERATION

This subitem is for all equipment, labor, and materials required to place steel reinforcing in the concrete structure and facility. A cherry picker assisted by a laborer will shake out the steel along the jobsite ( 10 % of time).

Two ironworkers, 1 Helper, and 1 welder ( 10 %) will comprise a rebar placing crew.

Quantity

98,000 Lbs. ( Incls. 10 % for laps & splices )\*

Production

2500 lbs. / crew / WD

98,000 Lbs / 2500 Lbs / WD = 40 WD

\* NOTE: Includes the # 6 bar welded at the top of each sheetpile for cathodic protection.

### PLAN OF OPERATION

This subitem is for furnishing and installing all formwork, waterstops, expansion joint material, and chamfer strips required to build the structure. Forms will be steel wall forms with plyform facing.

All forming in this job is unique, so many of the forms will be used once.

A cherry picker will be used 50% of the time to assist in handling forms. Carpenters, helpers, and laborers will erect the formwork.

#### QUANTITY

Steel Wall Forms:	5,400 SF
Plyform Facing:	5,400 SF
1/2 in. Exp. Jt. Material:	210 SF
3-Bulb Waterstop:	200 LF
Chamfer Strip:	4,400 LF

d) Finishing

8:

PLAN OF OPERATION

This subitem is for all equipment, labor, and material required to finish the floodwall as shown on the drawings and specs. Included are patching the concrete and a sack rubbed finish.

One cement mason and one laborer will patch the concrete and two laborers will sack rub the wall.

QUANTITIES

Patching: Assume 30 % Of form area  
 $.3 \times 5,400 = 1,620$  SF

Sack Rub Finish: 5,400 SF

PRODUCTION

Patching:  $1,620$  SF /  $120$  SF/Hr =  $13.5$  Hrs. USE  $16$  Hrs.  
( 1 Cem. Mas. & 1 Lab )

Sack Rub Finish :  $5,400$  SF /  $200$  SF/Hr =  $27$  Hrs.
