Initial Global Ocean Observing System for Climate

Status against the GCOS Implementation Plan and JCOMM targets

Total *in situ* networks **57%**

January 2007

57% Surface measurements from volunteer ships (VOSclim)

200 ships in pilot project

100% Global drifting surface buoy array

5° resolution array: 1250 floats

42% Tide gauge network (GCOS subset of GLOSS core network)

170 real-time reporting gauges

81% XBT sub-surface temperature section network

51 lines occupied

91% Argo profiling float network

3° resolution array: 3000 floats

43% Repeat hydrography and carbon inventory

Full ocean survey in 10 years

Reference time series 21%

58 sites

48% Global reference mooring network

29 moorings planned

66% Global tropical moored buoy network

119 moorings planned

- A total of 5635 platforms are maintained globally.
- Of these, 2541 are sponsored by NOAA.

Annual State of the Climate report (SOTC)

3. GLOBAL OCEANS—J. M. LEVY, ED.

a. Overview—J. M. Levy

As the global ocean observing system matures, climatologies of essential climate variables are growing more robust, as are observations of anomalous departures that shed light on the evolving behavior of the coupled ocean-atmosphere system. Year 2006 exhibited numerous anomalies of interest:

- Global sea surface temperature anomalies were primarily positive, notably so in boreal summer in the N. Atlantic and in the latter part of the year in the central and eastern equatorial Pacific associated with the 2006 El Niño.
- Mean of latent plus sensible heat flux was similar to that in 2005; total flux in both years were at the high end of a long-term upward trend that started in 1977-1978. Significant heat flux anomalies were observed in the regions of the 2006 El Niño and Indian Ocean dipole mode event.
- Global sea surface salinity anomalies accentuated climatological patterns: fresh water regions were fresher, salty regions were saltier. The subpolar N. Atlantic and Nordic seas were anomalously salty in 2006.
- Dramatic westward surface current anomalies associated with the development of El Niño were observed late in the year in the tropical Pacific Ocean, while seasonal reversal of currents were particularly pronounced on the equator in the Atlantic Ocean. Exchange of water between the South and North Atlantic Oceans was weaker than normal.
- The meridional overturning circulation (MOC)

FIG. 3.1. Mean and standard deviation of monthly SST anomalies for 2006 on a 1° spatial grid. The anomalies are computed relative to a 1971-2000 base period. The contour interval is 0.3°C; the 0 contour is not shown. AVHRR satellite data are used.

- pogenic CO₂ uptake continues to exceed Pacific Ocean uptake.
- Global annual average ocean color anomalies were not markedly different from those observed in the satellite record over the past decade. However, anomalies in the Niño 3.4 region were indicative of a 2006 El Niño that was stronger (considerably weaker) than that of 2002-2003 (1997-1998).

b. Temperature

1) SEA SURFACE TEMPERATURE—R. W. REYNOLDS

The SSTs for 2006 are shown as monthly fields interpolated from the weekly 1° optimum interpolation (OI) analyses of Reynolds et al. (2002). All results presented here are shown as anomalies defined as differences from a 1971-2002 climatological base period described by Xue et al. (2003).

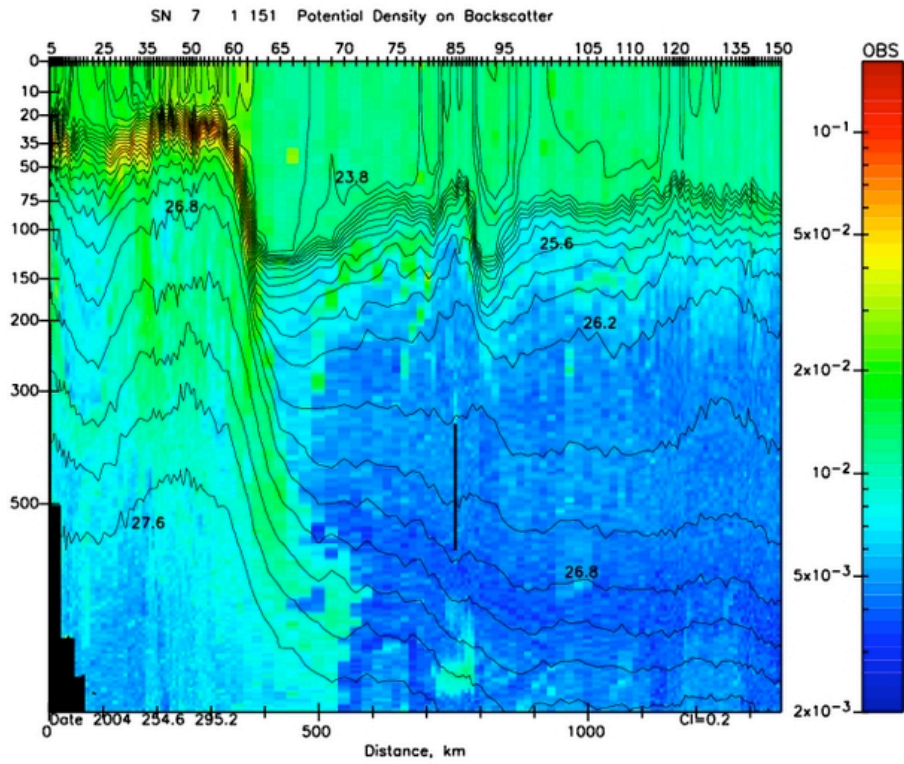

The yearly average and standard deviation of the

Forcing functions for the Observing System

- Transition from research to operations
- Technological advances
- Multi-purpose globalization of ocean observations
- Effectiveness
- Value

Observing system will evolve as it performs

Potenital density (contours) on optical backscatter (color)

Spray glider

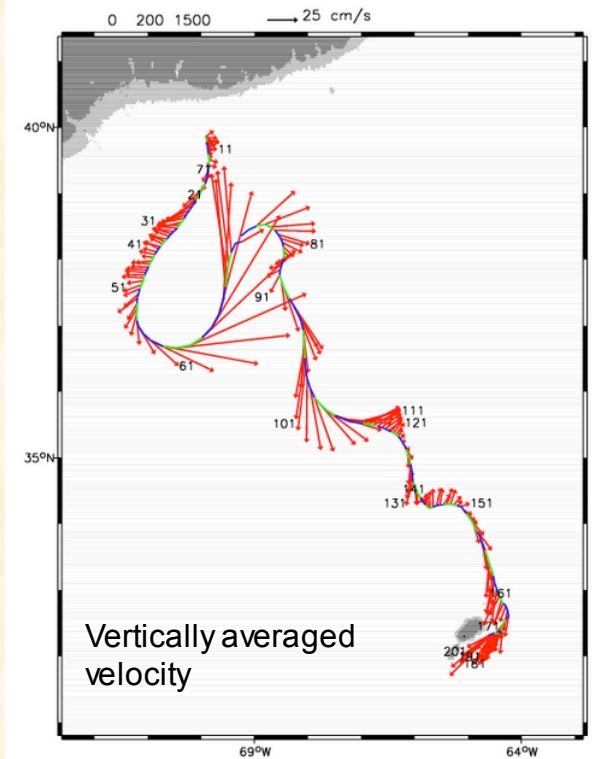

Evolution of observing technologies

Cross Gulf Stream transect

Gulf Stream 2004

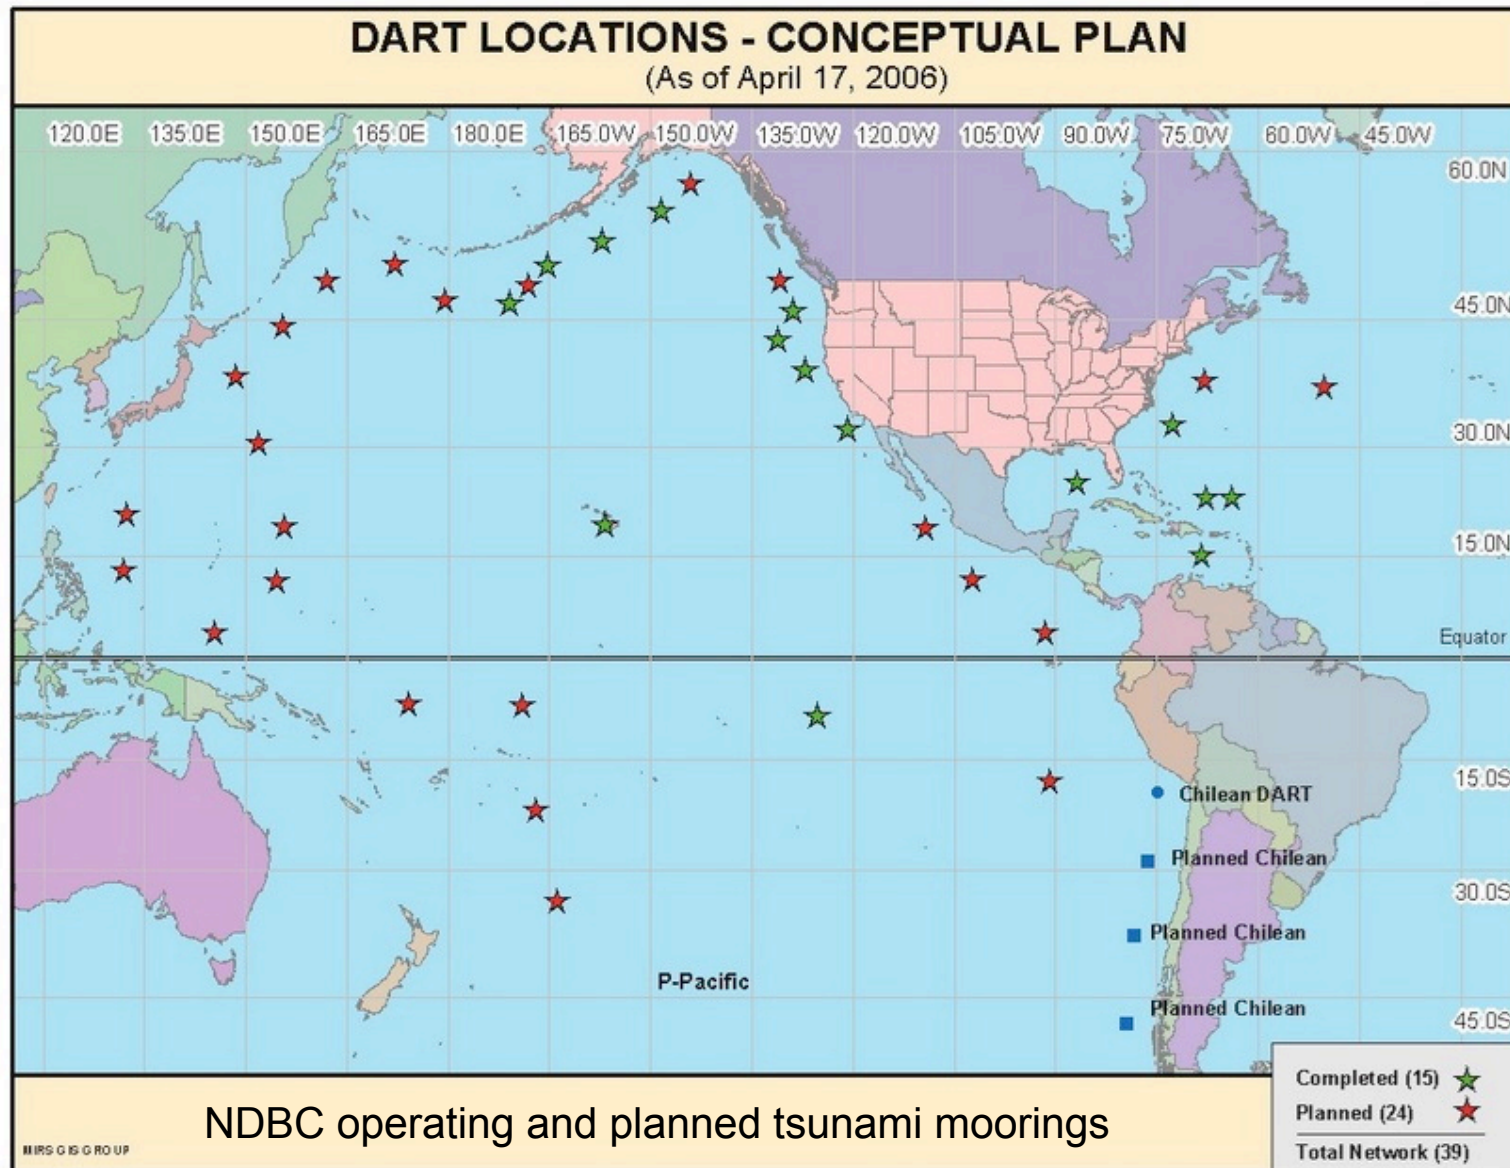

(from Breck Owens, WHOI)

Technological advances enabling progress towards *global, real-time*

- More data in real time (e.g., more subsurface data from moorings, NDBC data insertion on GTS)
- Communication between subsurface moorings and mobile, subsurface platforms and surface platforms
- Multidisciplinary sensors
- Platforms capable of operating in challenging regimes (e.g. KEO surface mooring; under ice)

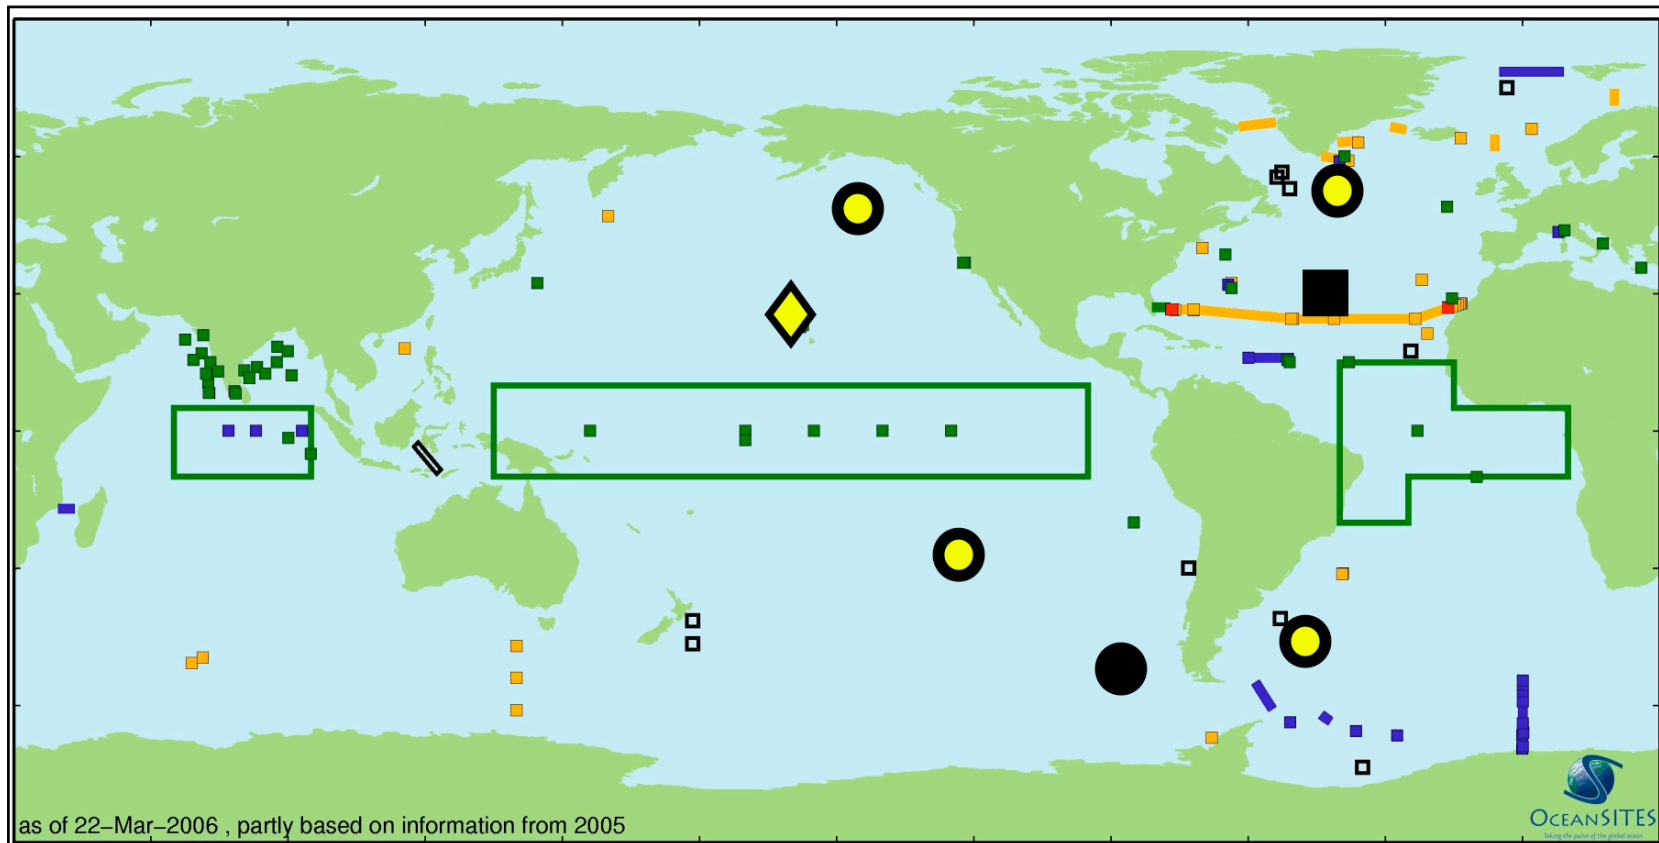

More platforms.....

Global observing - different drivers

National Science Foundation - ORION

Global Sites identified in Request for Proposals for
5-year build, 5-year operate

Circles - surface/subsurface mooring pair - real time
Square - stable platform, high bandwidth
Diamond - surface mooring for acoustic tomography

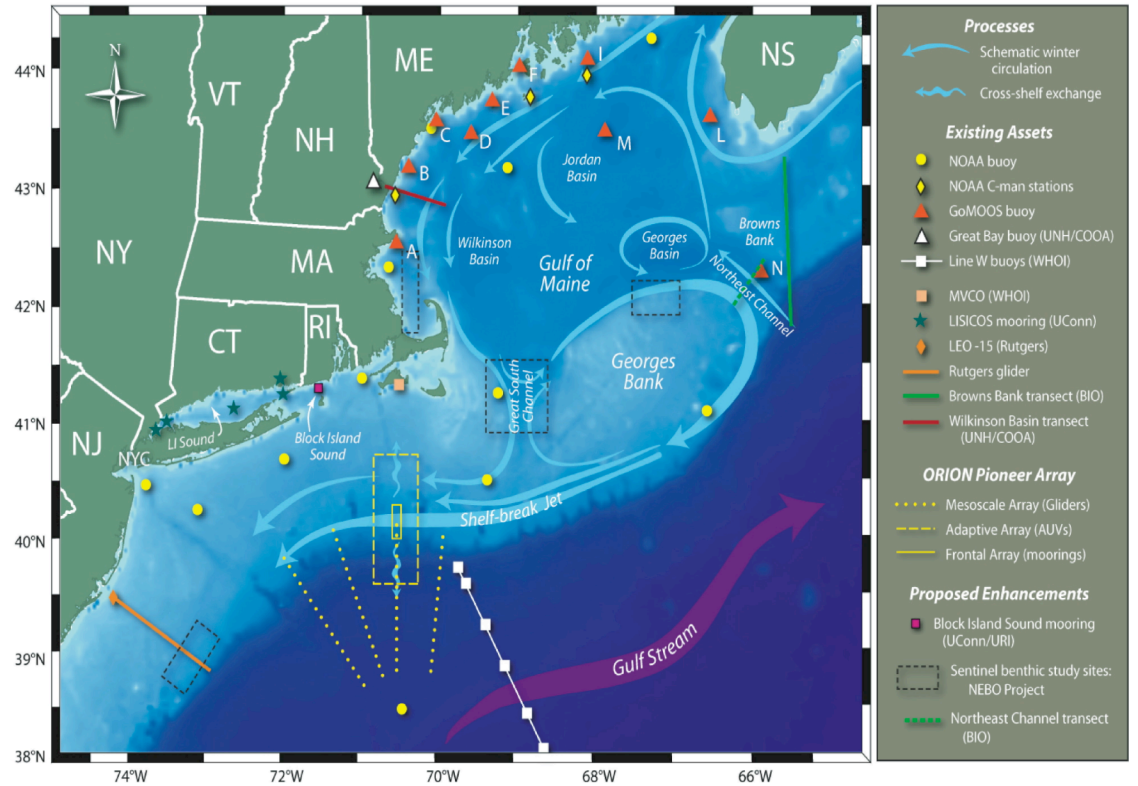

One design to be proposed for Orion stable platform for mid-Atlantic Ridge site

Power, bandwidth

Platform for comprehensive atmospheric observations; soundings, radar, aerosols, ...

 AO | **NAO** | PNA | PDO | SAM | SOI | AMO
 shorter series | longer series

NAO Index

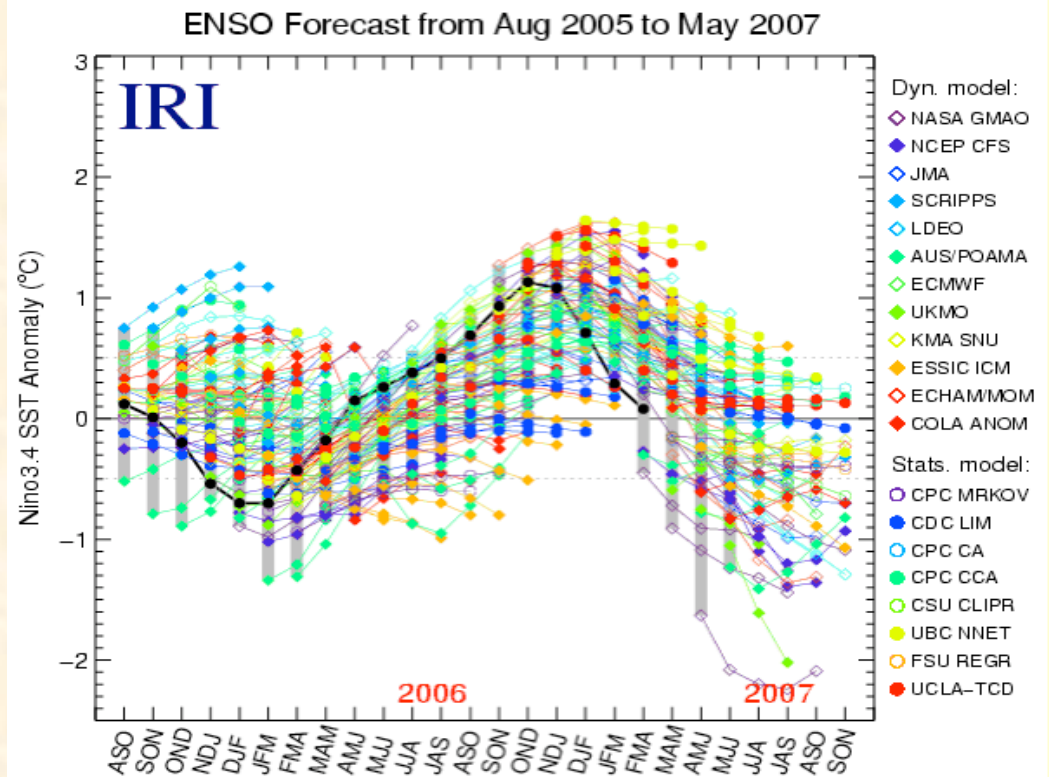

Indices

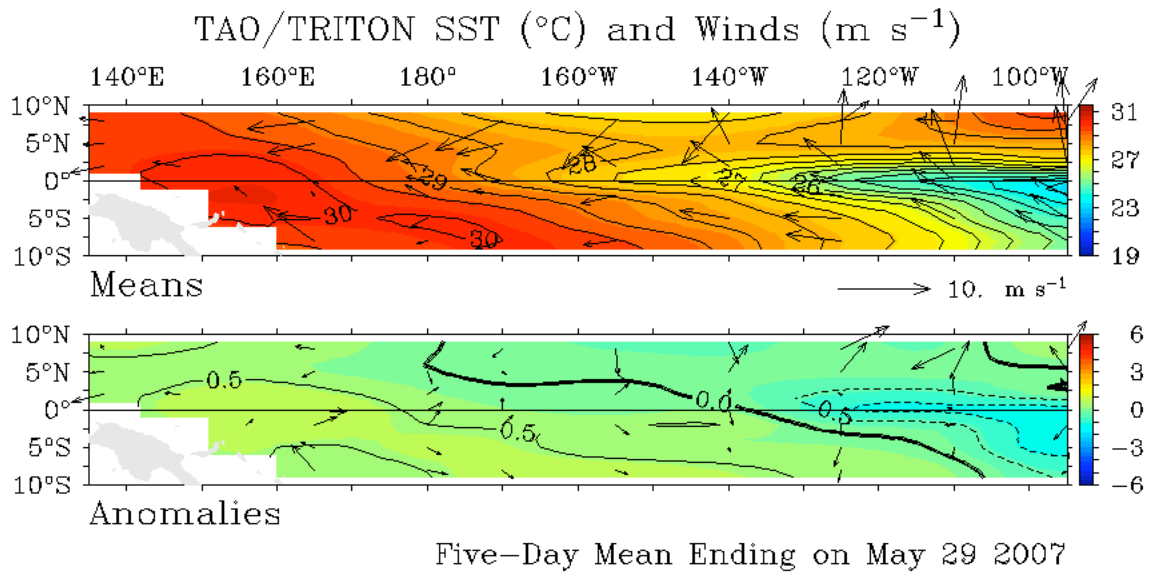

Eastern Tropical Pacific

What is used for monitoring, understanding, prediction?

What does the observing system need to deliver?

Do we now synthesize three-dimensional temperature, salinity fields using all data?

How robust is this when some data is missing?

Eastern Tropical Pacific

T300: Equatorial regions

Magdalena A. Balmaseda and Anthony Weaver CLIVAR GSOP Workshop

- **Eq Pac: Uncertainty decreases with time.**
- **Relatively robust interannual variability.**
- **Increased uncertainty after 2000. Why?**

- **Eq Indian: Uncertainty remains large throughout the record.**
- **Signal to noise <1. Outliers**
- **This is also the case for the Eq Atlantic**

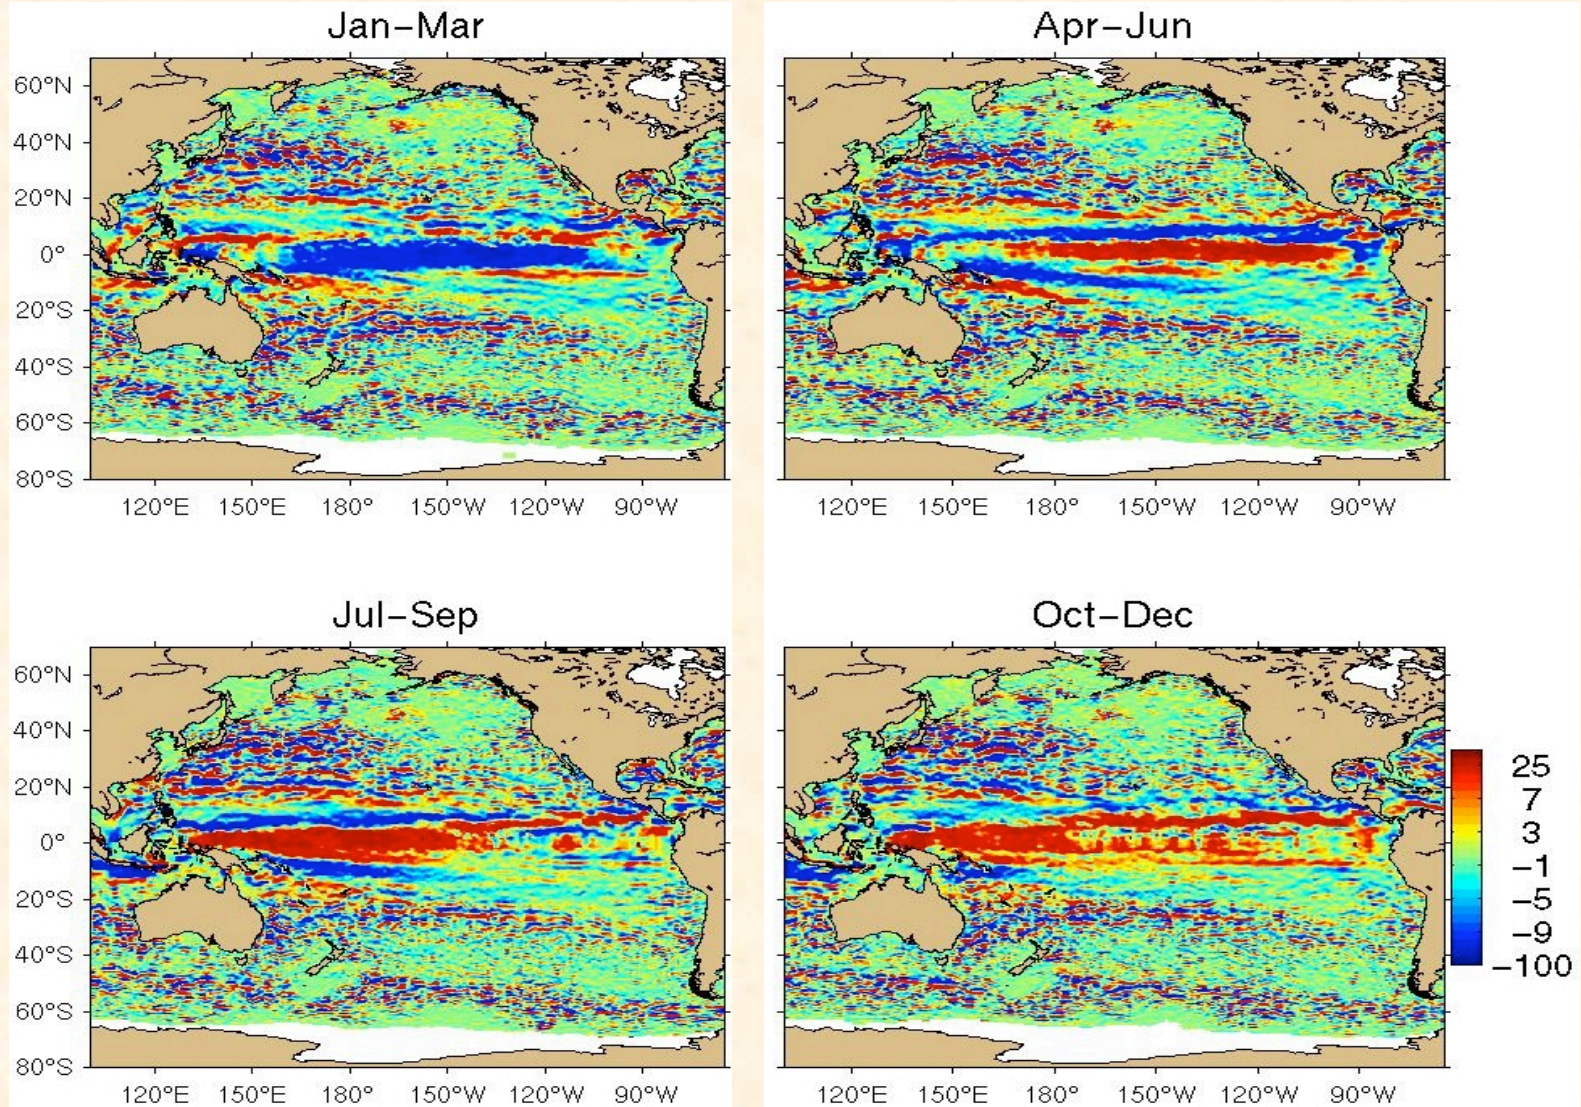

Eastern Tropical Pacific

How does the observing system deliver what is needed if in the next decade as fish stocks are depleted surface moorings will not be practical in the eastern tropical Pacific.

Argo? Gliders from the Galapagos? Surface drifters with acoustic wind? Satellite wind, altimetry?

Move and re-equip the TAO moorings and use the moorings to observe zonal velocities and drive model improvements?

(Lumpkin and Goni, SOTC, BAMS)

Some Summary and Conclusions from

Magdalena A. Balmaseda and Anthony Weaver CLIVAR GSOP Workshop

- There is large uncertainty in climate signals
 - Signal to noise ratio > 1 in the Eastern Pacific for Temperature
 - Signal to noise ratio < 1 for salinity in most regions
 - Warming trend in the 90's is consistently reproduced
 - What is happening now? There is not consistent picture
- Forcing fluxes and analysis methods are largest source of uncertainty
 - Data Assimilation does not always collapse the spread: We need to pay more attention to the assimilation methods.

Global averaged heat flux

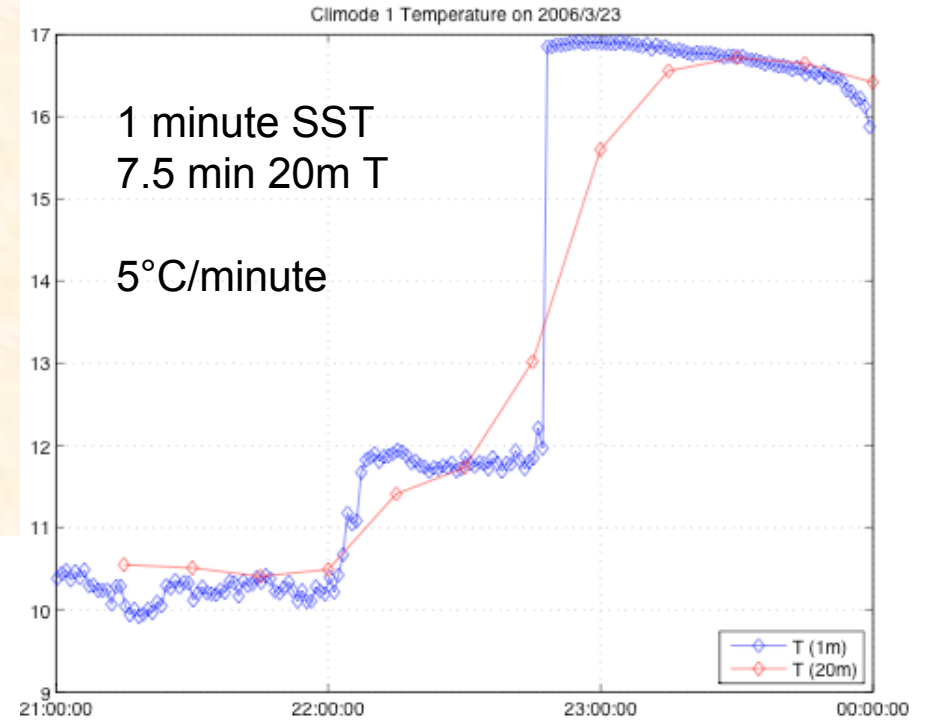

Lisan Yu, WHOI, CLIVAR GSOP Workshop 2006

<u>Model</u>		<u>Product</u>	
Q_{net} (Wm^{-2})		Q_{net} (Wm^{-2})

INGV	2.91		
NASA	6.29		

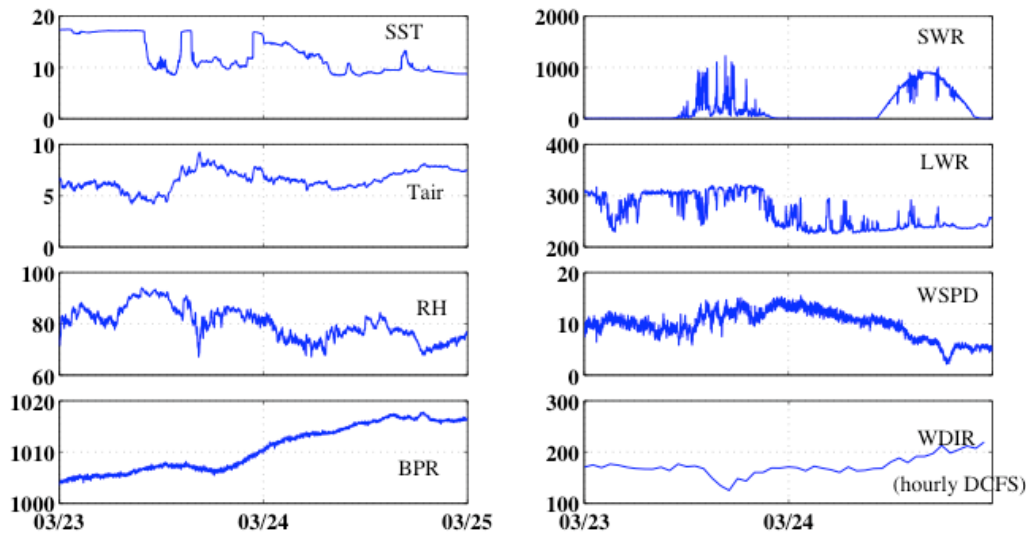

- Where do model fluxes differ most?
Ocean fronts: western boundary currents, the equatorial cold tongue, and Antarctic circumpolar currents.
- What are the implications? The surface flux estimation depends on the model's ability to resolve the frontal dynamics.

Can a global IOOS and or models used for syntheses address the frontal regions well enough to fix this mismatch in global fluxes?

Covariability of surface fluxes with SST?

Climode 1 ASIMET data. March 23,24 2006.

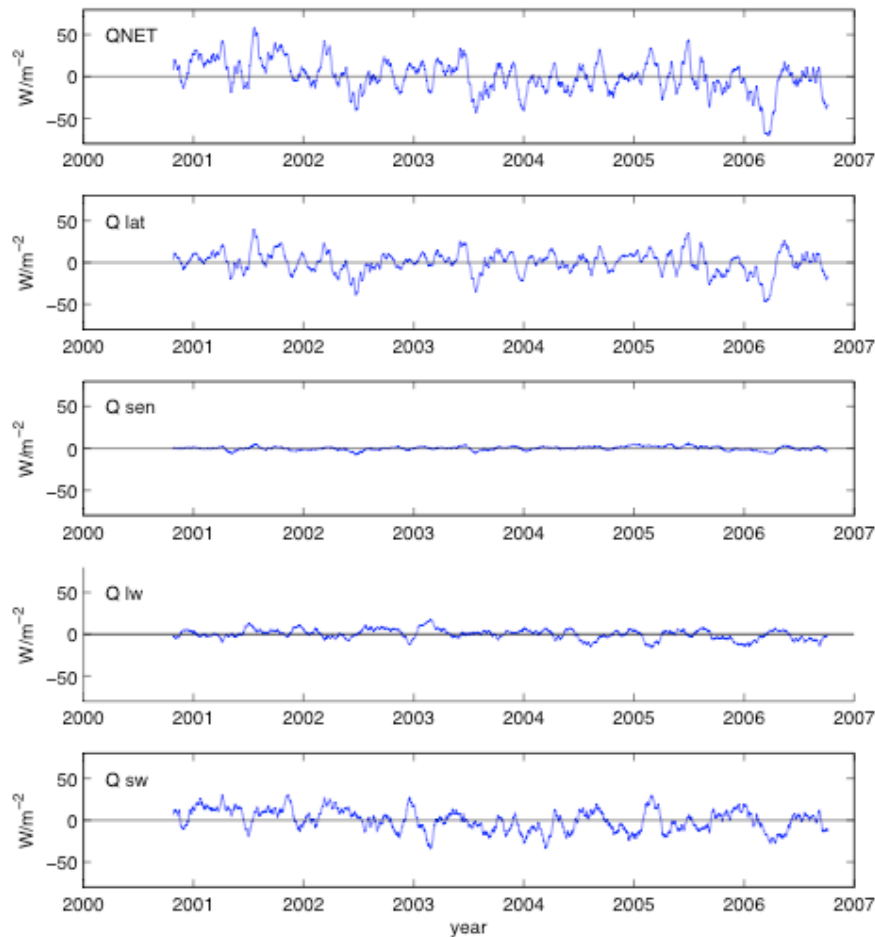

Surface mooring in the Gulf Stream

Regional syntheses - Ocean Reference Stations with nearby VOS tracks

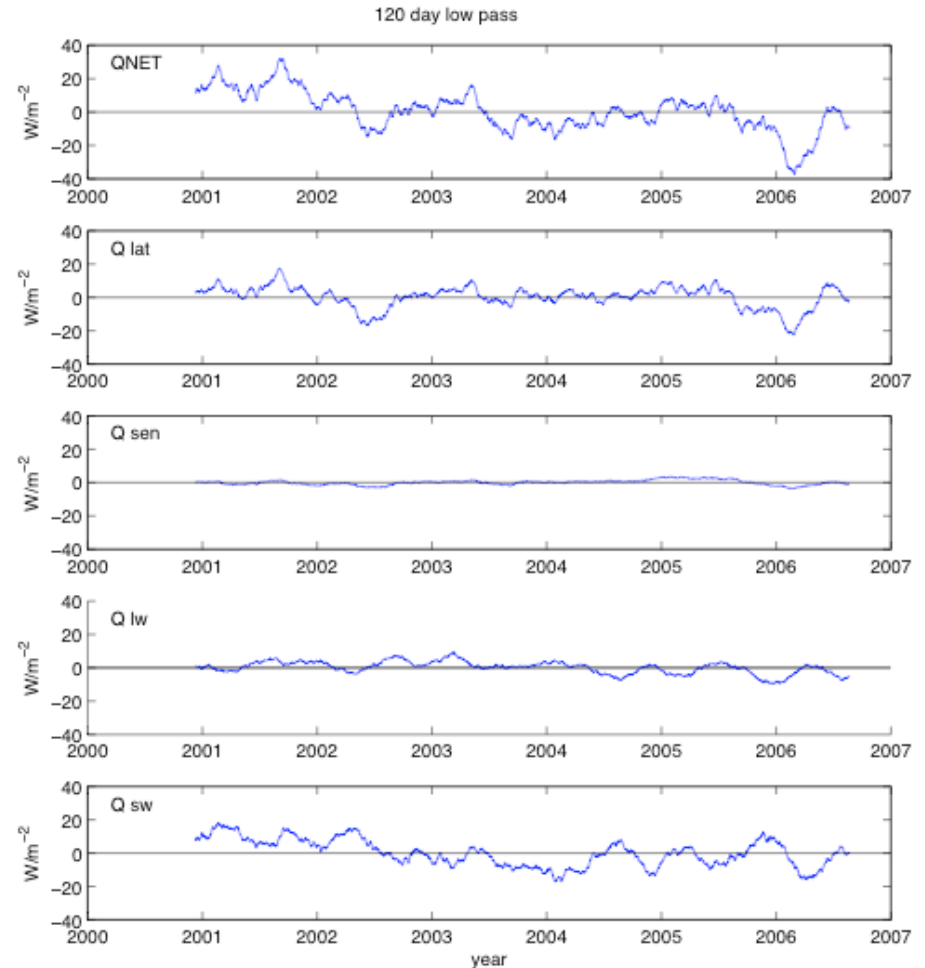

- Surface meteorology and fluxes
 - Known accuracy
 - Validation for flux products
 - Point info, fluxes, ocean structure
- Temperature (z), Salinity (z), U(z)
- Some with 6+ years of data
- Document air-exchange, ocean change/variability, air-sea covariability at the point
- Test local closure

TAO was completed and has been effective; other elements of the OOS have built their histories (ARGO, ORS, drifters, HR XBT lines,...)

Stratus ORS - 6 years of heat flux anomalies

30-day rm low pass

120-day rm low pass

Regional syntheses

- Extend radially the sea surface-meteorology and fluxes
 - Nearby VOS tracks, satellite, NWP, drifters, flux products
- Extend radially the ocean volume
 - ARGO, XBT, satellite, gliders
 - Space/time scales of the ocean/representativeness of the point
 - Increase regional sampling (XBTS, floats, gliders, drifters)
- Identify the space/time scales of the atmosphere, and ocean, the representativeness of the point
 - Decorrelation scales

Regional synthesis: Ocean Reference Stations

- Contrast this point/volume with model and model-based fields
- Capitalize on process studies to elucidate processes (e.g., VOCALS - in the Chilean stratus deck region)
- Perform regional OSSE's; withdraw some elements of the sampling
- Programs like TOGA COARE did balance the surface energy budgets, identify the important processes on both sides of the interface
- Challenge ocean reanalyses, analyses, and models to match the observations and understandings in the regions around the ORS

Regional syntheses

- Guide evolution of the observing system
 - Respond to pressures, evolve - eastern tropical Pacific
 - Make more robust, integrative products
 - Address uncertainties in models
 - Move away from vulnerable or overly redundant observations
 - Complete synthetic analyses at well-observed regions
 - The Ocean Reference Stations now
 - The NSF ORION global sites later
 - Verify air-sea fluxes, examine covariability across air-sea interface
 - Establish 'representativeness', space/time scales
 - Leverage process studies
 - Complement with additional elements to make long-term regional observing commitments
 - Determine what can be removed to accomplish Climate Obs Program goals and leave robust capability and products

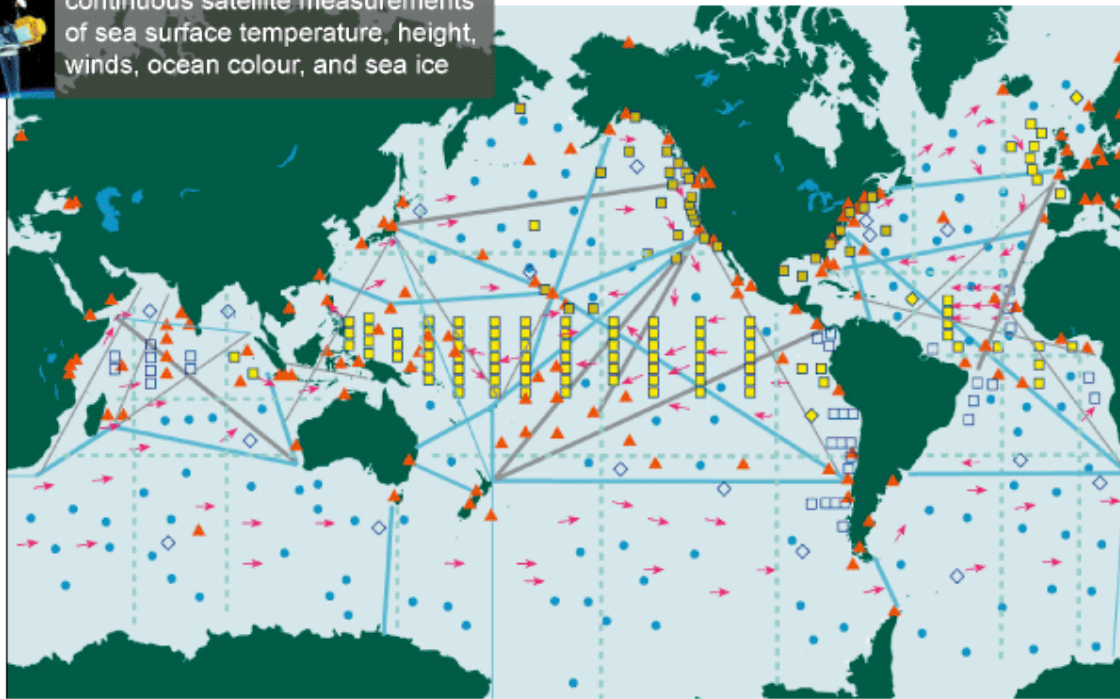

Regional syntheses

- Integration of the observing system
 - Bring on board other elements (e.g., DART)
- Construct the patchwork quilt of regional syntheses
 - Build toward the regional syntheses converging with global syntheses and analyses
 - This may lead to more effort to address ‘problem’ or challenging regions
 - Build toward understanding the differences between different integrative, global measures: transports, global averaged surface fluxes
- Take on ‘regions’ bordering coastal IOOS domains and work toward integration of the global and coastal observations and analyses
