

Synoptic Classification

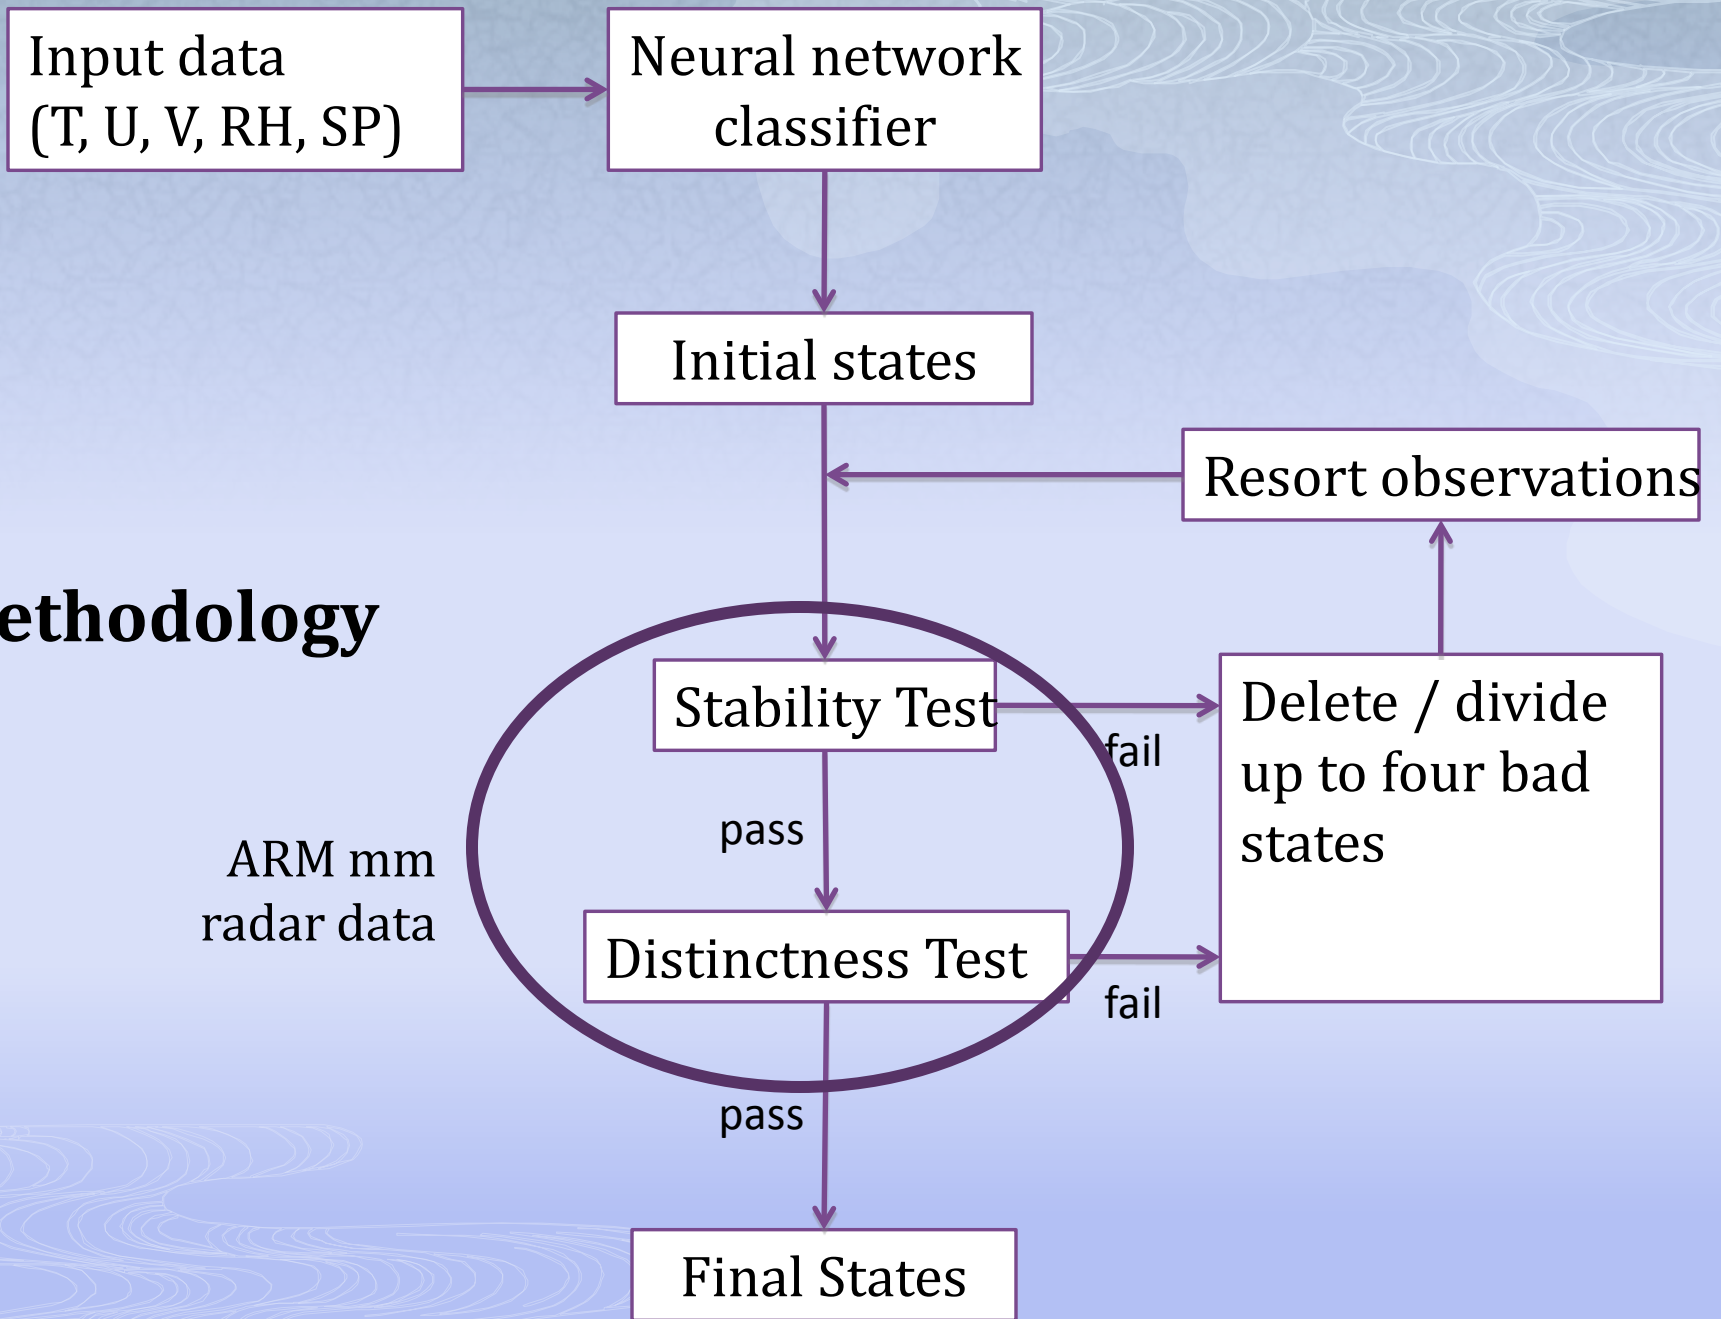

Applications to Brazil AMF Deployment

Tom Ackerman, Stuart Evans, Roger Marchand
University of Washington

The question

- Can we establish a statistical relationship between dynamical forcing at the large mesoscale and cloud occurrence and properties?
- More specifically: can we do this in the convective tropics where variations in large-scale forcing fields may be more subtle?

Methodology

Example: Darwin classification

ECMWF reanalysis

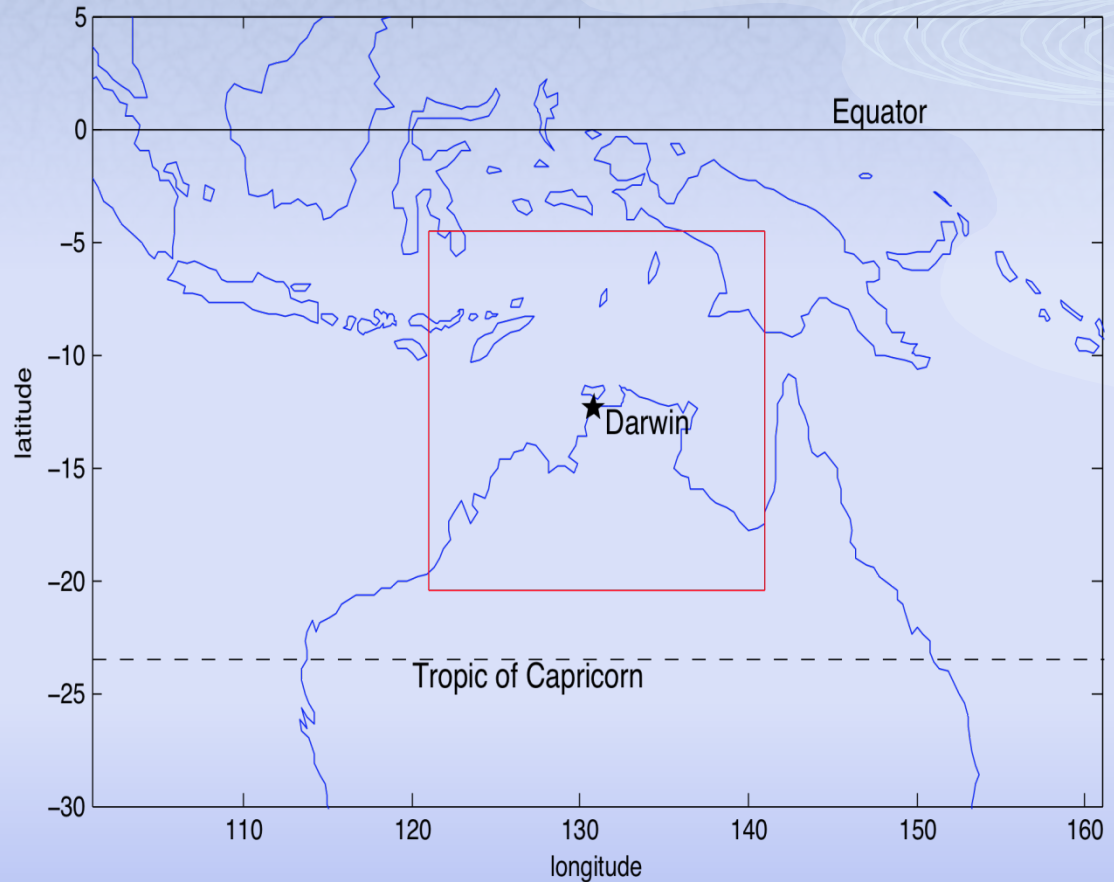

- June 06 – Sept 10
- 8x daily

At each timestep

- 9 x 9 horizontal grid
- centered on Darwin
- 2° x 2.5° spacing
- 7 vertical levels

Variables at each point

- T, U, V, RH, SP

2349 variables = 1 event or observation

Outcome

- ❑ 9 distinct states
- ❑ Meteorology associated with each state
- ❑ Cloud occurrence profiles associated with each state
- ❑ Statistical distribution of associated physical properties

State 2 – heart of monsoon season

1000 mb Dew Point ($^{\circ}\text{C}$) & Winds

1000 mb Temp ($^{\circ}\text{C}$) & Winds

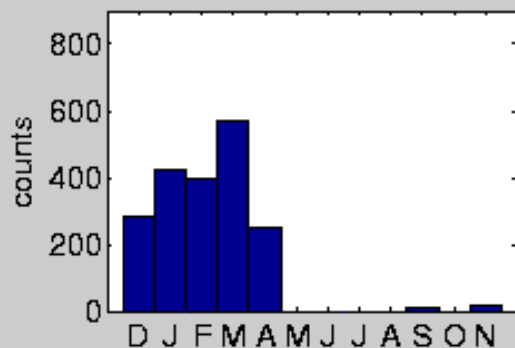

Srf Pres An & 500 mb Winds

500 mb RH & Winds

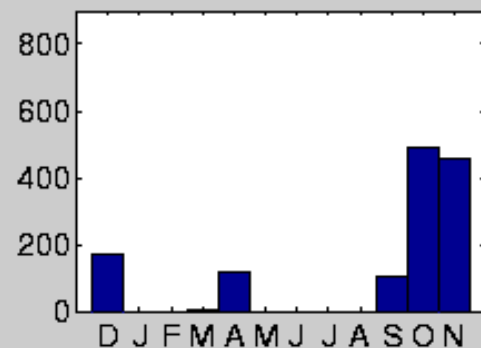

State 1: 1965

State 2: 1783

State 3: 1350

State 4: 1198

State 5: 1388

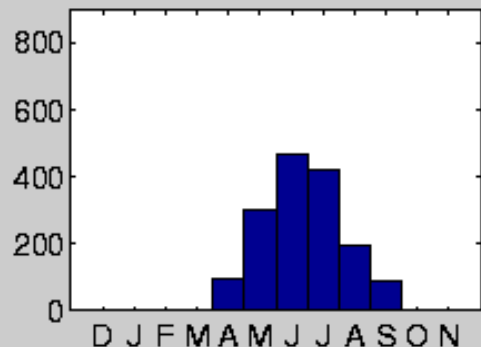

State 6: 947

State 7: 378

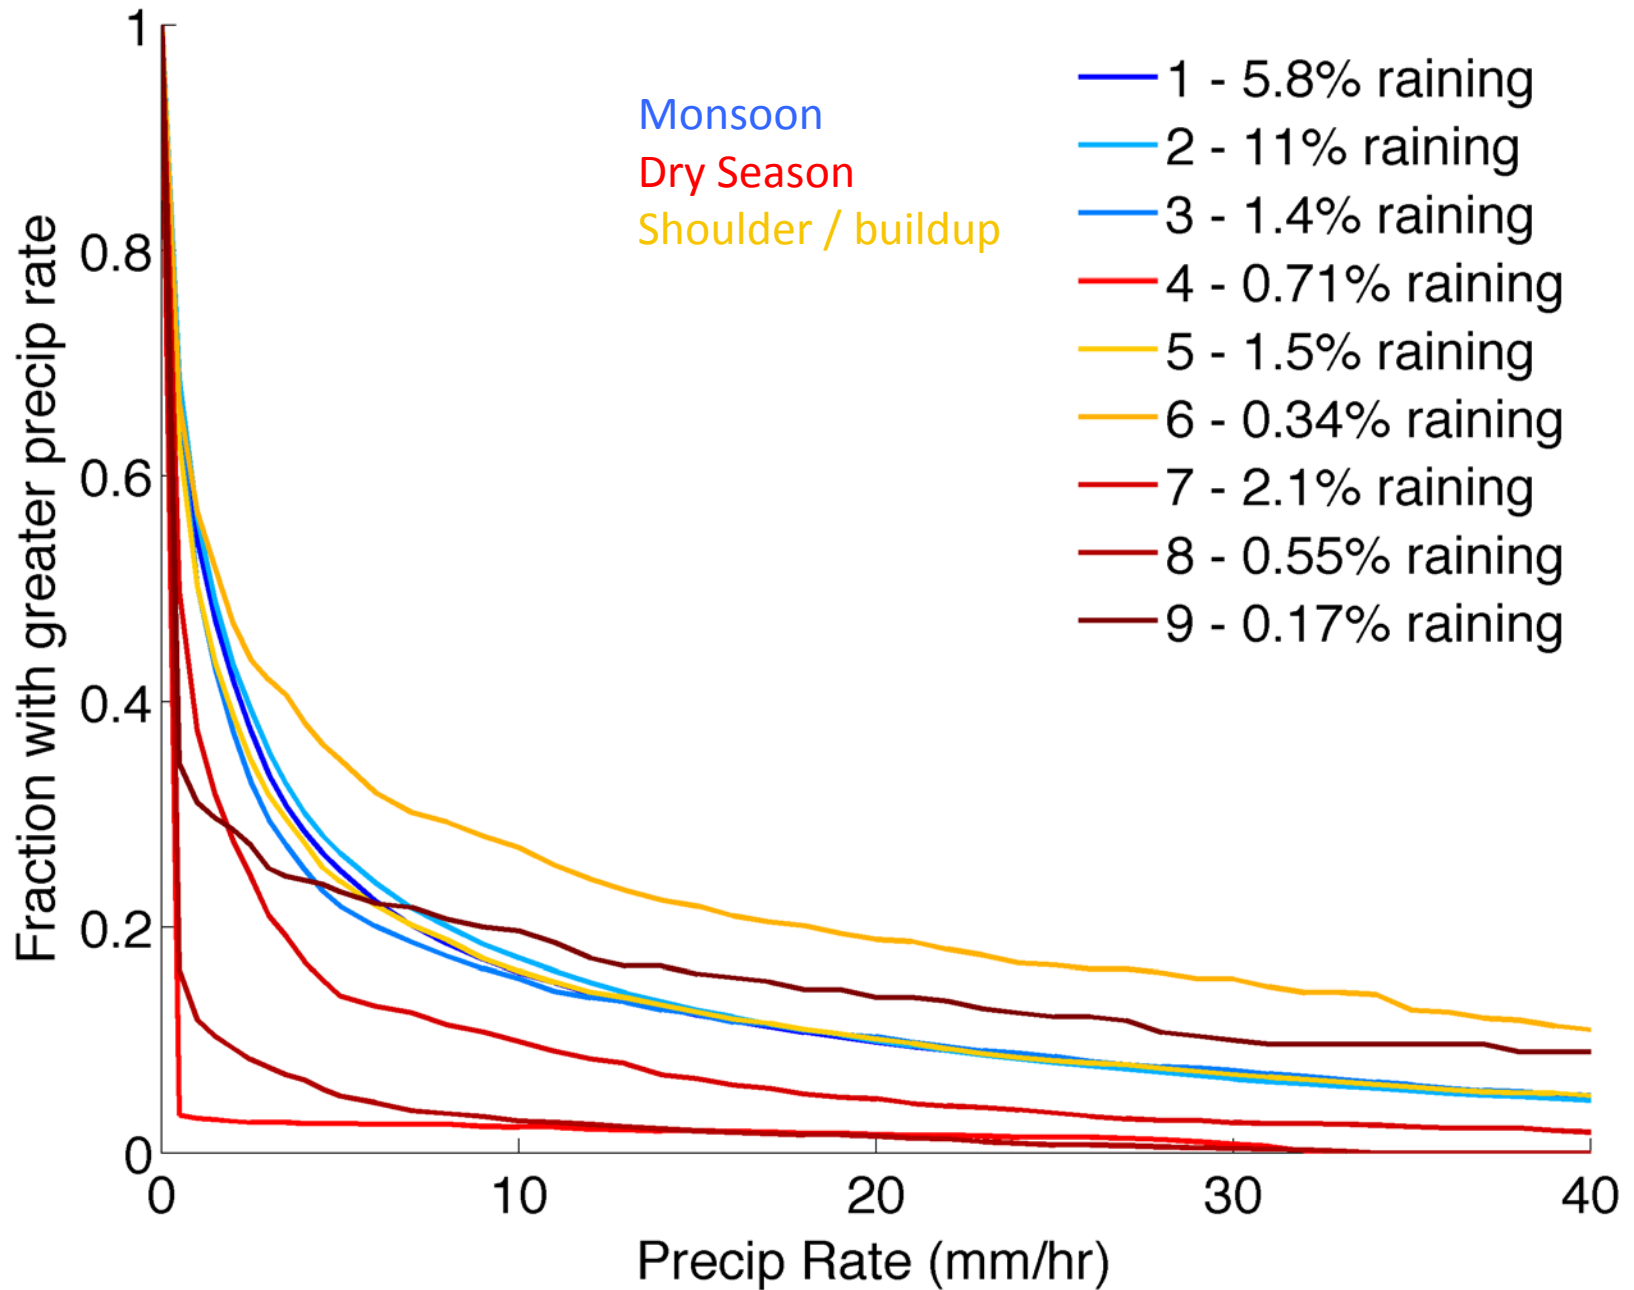

State 8: 1571

State 9: 935

Plans for Brazil

- Before deployment: Develop
 - Technique to substitute CloudSat profiles for ground-based radar profiles
 - Classification for Amazon
- During/after deployment
 - Map observed conditions into existing classification
 - Use ARM data to compare with and expand on existing distributions of cloud properties
 - Compare observed class properties with distributions from regional models

State 6 – build up to the monsoon featuring isolated convection

1000 mb Dew Point ($^{\circ}\text{C}$) & Winds

1000 mb Temp ($^{\circ}\text{C}$) & Winds

Srf Pres An & 500 mb Winds

500 mb RH & Winds

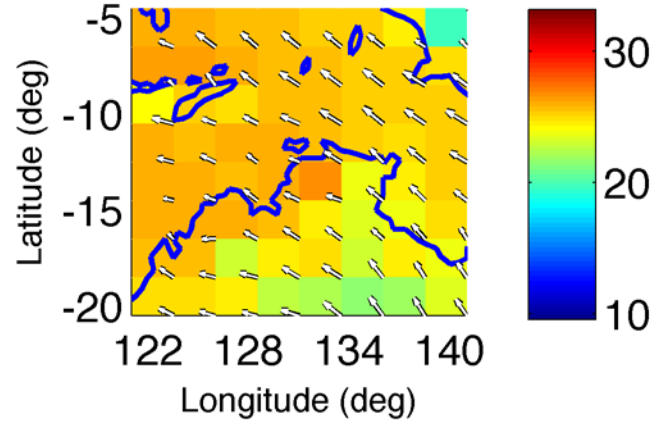

State 9 – dry season with isolated convection

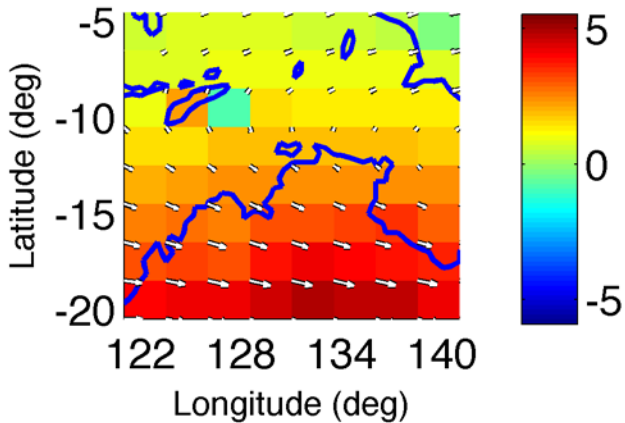

1000 mb Dew Point ($^{\circ}\text{C}$) & Winds

1000 mb Temp ($^{\circ}\text{C}$) & Winds

Srf Pres An & 500 mb Winds

500 mb RH & Winds
