Retro-plume

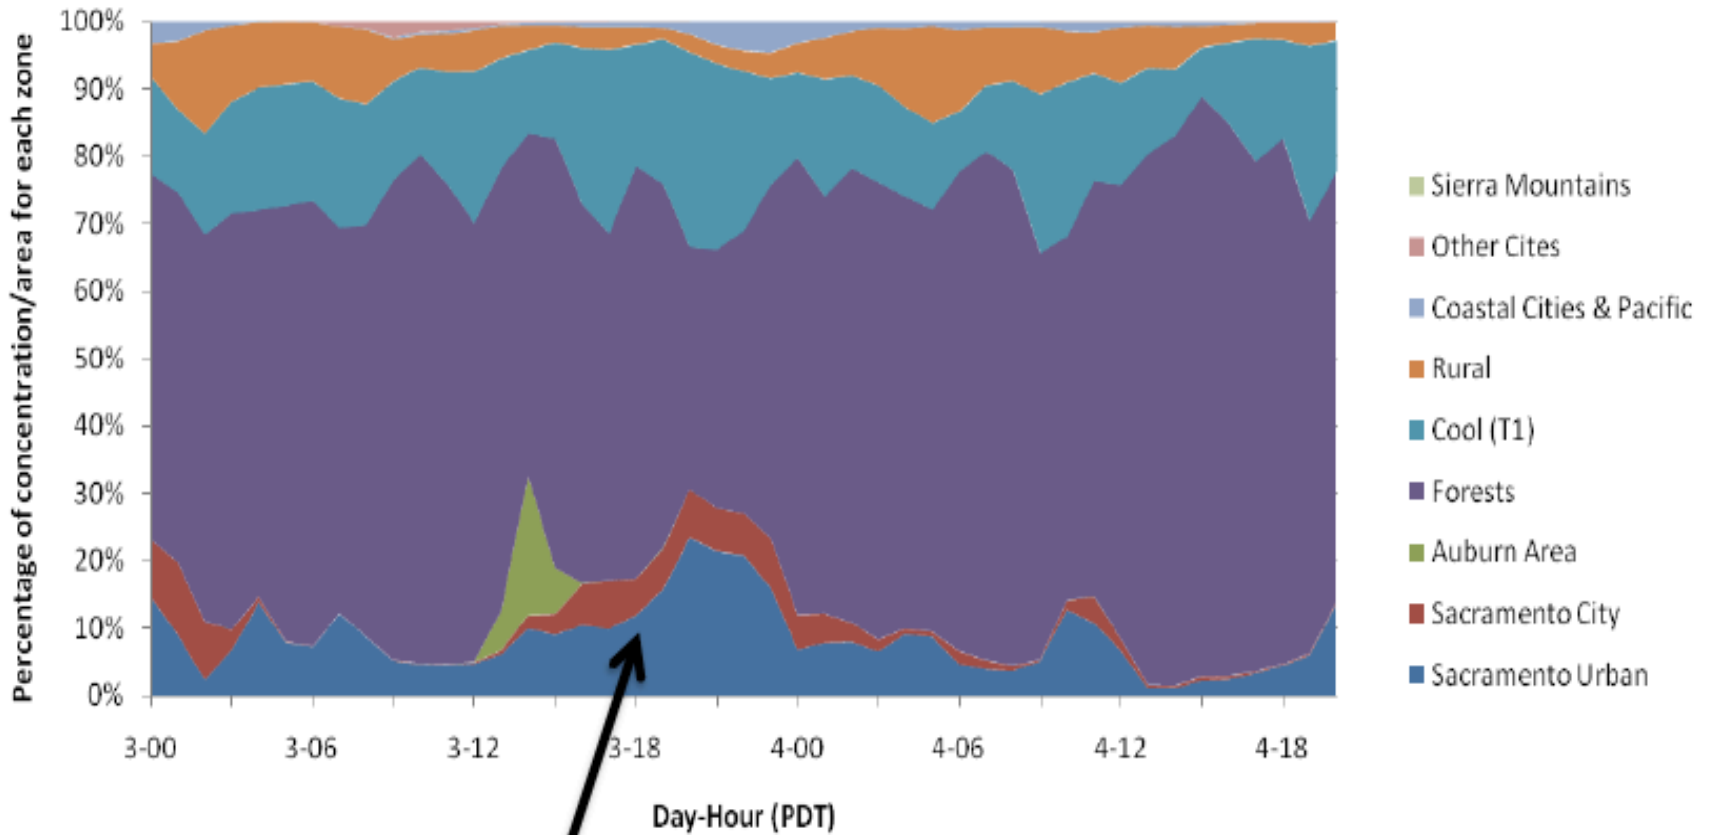

- The goal was to make an easy way to compare back trajectories to the data series. So first off I needed to convert the pollution maps into a usable time series.
- To accomplish this I used hysplit dispersion model, which released 6000 particles from the site (T1 or T0) and ran the meteorological data backwards. This creates a retro-plume of the pollution.
- I then divided California into different zones representing cities, rural area, mountains ext.
- Then I combined the retroplume and the zones to calculate what the concentration over each zone was.
- I then normalized by the exposure area in each zone to get a concentration/area for each zone which is what is shown in the graphs.

Retroplume overlaid on the zones

whole campaign.

All the data presented is for T1

Rise in Sacramento contribution, meaning stronger transport.

This graph shows where the airmass is coming from, but even though the Forests zone percentage is 50% doesn't mean 50% of the signal is from that zone.

mixed transport/local

■ Sacramento Urban ■ Sacramento City ■ Auburn Area ■ Forests ■ Coal(TL) ■ Rural ■ Coastal Cities & Pacific ■ Other Cities ■ Sierra Mountains

Probable Auburn/local transport

Probable Sacramento transport

Retro-plume

Legend: Sacramento Urban (blue), Sacramento City (red), Auburn Area (green), Forests (purple), Cool (T1) (teal), Rural (orange), Coastal Cities & Pacific (light blue), Other Cities (pink), Sierra Mountains (light green), Babs_B_405nm(1/Mm) (black line)

Useful for other data interpretation
