

FORAGE KOCHIA

Bassia prostrata (L.) A.J. Scott

Plant Symbol = BAPR5

Contributed by: USDA NRCS Plant Materials Center,
Aberdeen, Idaho

Forage kochia. Photo by Derek Tilley.

Alternate Names

prostrate summer cypress, perennial summer cypress
Kochia prostrata

Uses

Range/livestock:

Forage kochia is highly nutritious to cattle and is most commonly used for standing fall and winter forage as an alternative to harvested hay. Crude protein levels range from 7 to 14% during fall and winter months (August to March) with higher protein levels than perennial cool season grasses, forbs and legumes during that period. Forage kochia plants do not develop nitrate accumulation or oxalate toxicity (Koch and Asay, 2001). For the best nutritional benefits, a combination of forage kochia and

dormant grass during fall and winter months is recommended (ZoBell et al 2004).

Range Rehabilitation:

Forage kochia was originally introduced into the U.S. to compete with halogeton (*Halogeton glomeratus*). It has since been shown to compete well against other aggressive, exotic annual weeds such as cheatgrass (*Bromus tectorum*), Russian thistle (*Salsola kali*) and medusahead (*Taeniatherum caput-medusae*). (Koch and Asay, 2001; Young and Clements, 2004). Studies have shown that forage kochia begins growth at very cool temperatures and thus photosynthesizes at the same time of year as cheatgrass providing direct competition for limited water resources (Monaco, 2004). Plantings of forage kochia can decrease densities of annual weeds, thus decreasing fire intervals of degraded rangelands while providing valuable forage to livestock and forage and cover for wildlife and upland game birds.

Antelope grazing on forage kochia in fall-winter. Photo by Burke Davenport.

Greenstrip Plantings:

Forage kochia has been successfully used for greenstrip or firebreak plantings in the Intermountain West for several reasons. Forage kochia is well adapted to the very dry areas of the region and establishes easily. Plants are competitive against annual weeds, thus decreasing the fine fuel load and fire interval. Forage kochia forms open stands, with individual plants having an open canopy. Forage kochia is fire tolerant and remains green through the fire season (Pellant, 1994). The evaluated fuel moisture content of species commonly used in greenstrip plantings following a wildfire including forage kochia was estimated at 40 percent as compared to crested wheatgrass (10 percent) and cheatgrass (1 percent). Forage kochia plants will burn with sufficient fuel but the plants quickly recover (Monsen and Kitchen, 1999).

Studies show that forage kochia reduces flame intensity and can suppress or even stop wildfires (Harrison et al., 2002).

Status

Please consult the PLANTS Web site and your State Department of Natural Resources for this plant's current status (e.g., threatened or endangered species, state noxious status, and wetland indicator values).

Description

General: Goosefoot Family (Chenopodiaceae). Forage kochia is an introduced, semi-evergreen, half-shrub. Plants are 0.3 to 1 m (1 to 3 ft) tall with a deep tap root and an extensive fibrous root system, and it may live up to 10 to 15 years. Although it is commonly only medium-lived, it readily re-establishes from seed. Leaves are linear, 3 to 12 mm long (0.1 to 0.5 inches) and hairy. Flowers are clustered on a spicate to paniculate inflorescence in the upper stems. Seed stalks and upper stems turn red in late summer and fall, while the lower branches retain a green appearance year round. (Harrison et al., 2000). Flowers bloom from July to September (McArthur and Monsen, 2004).

Two subspecies have been used in the United States. Subspecies *virescens* ([Fenzl] Prat.) is a diploid ($2n=18$) subspecies represented by the release 'Immigrant'. Subspecies *grisea* (Prat.) is represented by the tetraploid ($2n=36$) release 'Snowstorm'. Subspecies *grisea* is taller in stature, typically reaching approximately 76 cm (30 in) compared to the low-growing *virescens* which normally reaches heights of 30 to 38 cm (12 to 15 in). Subspecies *grisea* also exhibits more pubescence than subspecies *virescens*.

Forage kochia should not be confused with its weedy relative, *Kochia scoparia*. Forage kochia differs in that it is a perennial shrub and not an annual herb.

Distribution: This species has been successfully seeded in Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Texas, Utah, Washington and Wyoming at elevations ranging from 490 to 2,200 m (1,600 to 7,300

ft). For current distribution, consult the Plant Profile page for this species on the PLANTS Web site.

Habitat: Forage kochia is well adapted to a broad range of growing conditions found in the Intermountain West. Plants are commonly found in shadscale-saltbush, (saline desert and desert shrub), sagebrush steppe and piñon-juniper communities where it has been planted as a greenstrip species or for rangeland rehabilitation.

Adaptation

Forage kochia is well suited to rangelands receiving 15 to 40 cm annual precipitation (6 to 16 in), and is adapted to a wide range of soil textures including sands, gravels, clays, silts and loams. Plants do best in medium-textured soils. Forage kochia is highly saline and sodic tolerant. Plants perform well and will spread in high saline sites including slick spots (Harrison et al., 2000). Stevens et al (1984) reported that forage yields were not reduced when forage kochia plants were grown in soil salinity of 17.0 mmho/cm².

Establishment

Best establishment comes from dormant fall or winter seedlings which allow the seed to germinate and begin growth very early in the spring. Seed should be broadcast, aerially seeded, or drilled onto the soil surface which has been lightly disturbed by harrowing or spread directly onto snow. Seed drilled and pressed into soil to depths more than 1/16 inches (1.5 mm) will rarely germinate or establish. Burning prior to seeding has positively affected establishment (Monaco et al., 2003). Aerial seeding should be performed at altitudes from 50 to 70 meters (165 to 230 ft) with wind velocities less than 13 feet per second (Harrison et al., 2000).

For wildlife plantings, forage kochia should be used as part of a seed mixture. Seeding rates range from 0.025 to 0.25 lb PLS per acre depending on conditions and objectives. Planting 0.025 lb PLS per acre as a seed mixture component provides approximately 400 plants per acre (Ogle et al., 2006).

For greenstrip plantings, where forage kochia is planted as a monoculture with a drill and seed is pressed into soil, higher seeding rates (2.0 – 3.0 lb/acre or 18 to 27 seeds/ft²) are recommended to create a thick stand of kochia with smaller, lower-growing plants, which provide little fuel for wildfires and reduces annual weed production. Under greenstrip conditions, when seed is broadcast planted, seeding rates should be increased to 3.0- 4.0 lb/acre or 27 to 36 seeds/ft².

Forage kochia seed loses viability quickly, even when processed and stored under proper conditions. Always use current year's seed that has received a recent germination test to ensure the best chances for establishment success.

Management

Forage kochia can be used as year round forage under proper management. Spring grazing can be more detrimental to forage production than fall or winter grazing; however, it is rarely grazed during the spring when green grass is available. The earliest grazing occurs in late June to mid July when the grasses have gone dormant. Its “preference” increases throughout the summer and early fall. Plants grazed to less than two inches will show reduced growth the following year. In one study in Box Elder County, Utah, forage yields ranged from 500 to 700 lbs per acre (ZoBell et al., 2004).

Pests and Potential Problems

Although forage kochia does not appear to be affected by insect pests, it may serve as a host for lygus bugs (Harrison et al., 2000).

Environmental Concerns

There is concern that forage kochia could become invasive similar to the herbaceous kochia, *K. scoparia*, but this is mostly unwarranted. Studies indicate that plants will spread under favorable conditions into bare or disturbed sites where competition is limited. Forage kochia competes with and establishes readily into sites dominated by annual weeds, but it does not seem to reduce the density of stands of established perennials. Spread of forage kochia has been found to be related to the following: soil disturbance, predominant wind direction, lack of vegetative competition and open space near established plants (Harrison, 2000).

One source of concern is the ability of forage kochia to invade slick spot communities in southern Idaho. These sites are habitat for the federally-listed threatened species, slickspot peppergrass (*Lepidium papilliferum*) (Pellant, 2004).

It has been shown that forage kochia is only distantly related to annual kochia and Grey Molly (*Kochia americana*), and will not hybridize with either species (Lee et al., 2005).

Control

Forage kochia can be effectively controlled with 2,4-D (Harrison et al 2000). Contact your local agricultural extension specialist or county weed specialist to determine the best control methods in your area and how to use it safely. Always read and follow label and safety instructions for each chemical control method. Trade names and control measures appear in this document only to provide specific information. USDA NRCS does not guarantee or warranty the products and control methods named, and other products may be equally effective.

Seed and Plant Production

Seed production fields should be planted at a rate of 1.5 lb PLS per acre or planted with transplants with 12 inch in-row plant spacing and three feet between-row spacing

(Harrison et al 2000; Cornforth et al 2001). Seed production fields produce between 400 and 600 pounds per acre of clean seed (Cornforth et al., 2001). Stevens et al (1984) reported production as high as 1,500 pounds per acre during one production year, however seed production rates this high should not be expected under normal circumstances.

Seed requires a hard fall frost before it will mature. Seed fields in areas with a tendency to early to mid fall snowfall have resulted in complete seed production failure because the snow caused seed to drop before seed harvest could occur. Seed production begins to decline after plants are approximately 5 to 6 years old.

There are an estimated 395,000 PLS per pound. (Koch & Asay 2001; Harrison et al 2000). Seed needs to be dried to less than 7 percent moisture and stored in cool, dry conditions, 36 to 50° F (2.2 to 10° C).

Cultivars, Improved, and Selected Materials (and area of origin)

‘Immigrant’ forage kochia was released in 1984 by the USDA Forest Service, USDA Natural Resources Conservation Service, Utah Division of Wildlife Resources and the Idaho, Nevada, Oregon and Utah Agriculture Experiment Stations. The original collection was from the Stravopol Botanical Gardens, USSR, in May 1966. Immigrant was released for use as forage and soil erosion control on rangelands in the Intermountain West (Stevens et al 1984). Immigrant is a diploid (2n=18) release of subspecies *virescens*. Breeder and Foundation seed is maintained by Utah Crop Improvement Association.

‘Snowstorm’ forage kochia (left) and ‘Immigrant’ forage kochia right.

Use of Immigrant forage kochia for winter grazing has been limited due to the plant’s fairly low stature. ‘Snowstorm’ forage kochia was released in 2012 by the USDA Agricultural Research Service in Logan, Utah

based on improved stature, productivity and nutritional content compared to Immigrant. Snowstorm, a tetraploid ($2n=36$) release of subspecies *grisea*, was developed as a synthetic cultivar using germplasm collected in Uzbekistan. It was shown to be 64% taller, produce 68% more forage, have 22% higher protein content, and be 4% more digestible than Immigrant forage kochia. Breeder, Foundation, and Certified seed classes will be recognized. Breeder and Foundation seed will be maintained by the USDA-ARS Forage and Range Research Laboratory at Logan, UT. Foundation seed will be made available through the Utah Crop Improvement Association.
