The Office of Biological and Environmental Research within the U.S. Department of Energy's Office Science issued in January 2012 the Genomic Science: Biosystems Design to Enable Next-Generation Biofuels funding call (science.doe.gov/grants/pdf/SC_FOA_0000640.pdf).

Executive Summary

Given the sequent of the sequence of the seque

Technological advances enabling the design of new biological systems are already moving biofuels closer to becoming a viable, alternative renewable energy resource. Further advances are necessary for developing useful bioenergy crops that not only allow facile conversion of biomass into biofuels, but also do not compete with food crops for arable land. In other words, crops must be rationally redesigned to produce high biomass yields on marginal agricultural lands and under changing weather conditions.

To explore the current state-of-the-art in the field of biosystems design, discuss new biodesign technologies and approaches, and identify key scientific challenges and knowledge gaps, the Department of Energy's Office of Biological and Environmental Research organized the Biosystems Design Workshop in July 2011 in Bethesda, Maryland. The workshop's goal was to bring together scientific leaders in microbiology, plant biology, metabolic engineering, systems biology, bioinformatics, computational modeling, and other relevant disciplines to examine fundamental aspects of biosystems design from molecules to organisms to communities. The focus was on the fundamental biological principles that must be harnessed to make biological design possible as well as the tools and computer-aided testbeds needed to design, prototype, and functionally validate multiscale natural and hybrid biological systems.

Building on the outcomes of the genomic revolution that altered the course of biological research in the last decades, biosystems design research will identify modular components that can be modified, enhanced, and exchanged among different organisms, enabling the manipulation of biological systems. With the help of computational modeling, de novo design of new organisms with novel capabilities for defined purposes will be possible. These new biological systems and modules will not only generate new, useful functions but also provide powerful tools to further our understanding of the fundamental principles that rule biology.

The time is ripe for bold new research approaches that harness biology's potential. These approaches include designing new biosystems to address critical needs, such as sustainable production of advanced liquid bio-fuels, while contributing to carbon sequestration and reduction of greenhouse gas emissions and improving nutrient and water-use efficiency of bioenergy crops. The field of biosystems design will enable living organisms to be manipulated and tailored in unprecedented ways, paving the way for a bioeconomy that can meet our energy needs while minimizing impacts on the environment.
