**Integrally geared pipeline compressor for high pressure application;
Delivery of high pressure CO₂ gas in a supply pipeline for enhanced
oil recovery without any booster station**

**First integrally geared
compressor for high
pressure application**

In 1995 MAN GHH BORSIG received an order for a 200 bar discharge CO₂ compressor for Russia. This compressor was successfully tested and delivered as the first integrally geared compressor with 10 stages for high pressure application. (please refer to our brochure: World premiere; First 10-stage integrally-geared compressor).

**Integrally geared
pipeline compressor**

With above experience, MAN GHH BORSIG quoted in the end of 1997 the integrally geared design for a pipeline application, also for carbon dioxide, as the gas to be transported. This quote was in competition to beam type compressors with 2 or 3 casings and about 14 - 17 impellers, traditionally used as pipeline compressors.

Compressor Duty

Requested was a compressor to feed CO₂ in the front end station of a coal gasification plant in North Dakota/ USA. The pipeline routes

from North Dakota over the Canadian border to Saskatchewan oil fields, where the CO₂ is injected into oil wells for enhanced oil recovery. The total length of this 14 inch pipeline is

205 miles. There are no booster stations foreseen in between or at destination. The CO₂ gas is injected into the oil well directly out of the pipeline, what requires a quite high pressure at start.

Technical Data (per compressor unit):

Suction Pressure	1,1	bar
Discharge Pressure	187	bar
Power at Coupling	13,200	kW
Mass flow	123,000	kg/h
Pinion Speeds, No.1 pinion shaft	7,000	min ⁻¹

No. 4 pinion shaft 26,000 min⁻¹

Compressor Unit during test run in MAN GHH BORSIG test bed

Enhanced Oil Recovery (EOR)

EOR is, simplified spoken, the mixing of crude oil and CO₂ down in the wellbore. Under certain pressure and time the crude oil swells and reduces viscosity, allowing a greater percentage of the hydrocarbons trapped in the well pore volume to be recovered. In reality, EOR is much more complex, but pays back and extends the economic life of an oil reservoir.

Order in April 1998; Codeword: DACOPIPE

MAN GHH BORSIG received the order on two identical compressor units, type RG 080/08-L4, in April 1998 from Dakota Gasification Company, North Dakota/USA. The compression with below parameters is effected with 8 radial impellers and 6 air cooled intercoolers up to a pressure of approx. 190 bar absolute. The order consisted of the compressor units including the multi shaft gear, the special developed multi chamber carbon ring shaft sealing, the synchron drive motors, the lube oil systems and the complete monitoring of both units with anti surge control, load sharing and intercooler control via MAN GHH BORSIG control system Turbogol. The air cooled intercoolers and aftercoolers together with the interconnecting piping was in the scope of the client.

All compressor material in contact with process gas is in compliance to NACE criteria due to the H₂S content in the process gas. The compressor volutes as well as the intercoolers and the interconnecting piping are of black material because of dry carbon dioxide with no measureable content of water.

The units are shipped in July

Discharge pressure P_D in bara

Power at coupling P_X in kW

New gear concept with two horizontal shafts ensures excellent maintainability

1999 and are to be commissioned in early year 2000. The compressors are successfully performance tested in the MAN GHH BORSIG workshop in Berlin with original carbon dioxide gas. The final performance and acceptance test is agreed to take place with original air cooled interstage and aftercoolers at site in North Dakota. As visible in the performance maps, the turndown flexibility of this compressor is much better than that of beam type compressors for comparable applications.

Main merits over previous compressor concepts

The gear type compressor offers major advantages in comparison to conventional centrifugal beam type compressors. These are:

- Peak efficiencies through optimized speed adjustment, axial intake of each stage, and intercooling after each stage
- Tip speeds, which owing to the machine design, permit the number of stages to be reduced
- Higher operation flexibility, by inlet guide vane control
- Reduced construction volumes, so that machine house can become smaller
- Much lower investment cost

Outview

MAN GHH BORSIG is able to offer a sound solution with the new developed integrally geared compressor design. This design is not only limited to carbon dioxide application, much higher compression ratios than with standard beam type compressors can be achieved for nearly all other gases too, by improving the efficiency and reducing investment cost at the same time. MAN GHH BORSIG is leading the trend to deliver more and more process gas compressors as integrally geared units. Due to experiences with all kind of direct drivers, like gasturbines, steamturbines, expansion turbines and electric motors, MAN GHH BORSIG is able to serve all processes with this advanced design.
