8 Final Study Results and Recommended Planning Direction

TVA's IRP was developed in two major phases – the draft and final. The Draft IRP recommended retaining three of the five original planning strategies. This provided the starting point for the development of the final IRP in fall 2010. Considering updated forecast information and public comments, additional analyses were conducted with the goal of developing a "no-regrets" strategy. This was accomplished by fine-tuning and improving the strategies selected in the Draft IRP. The analyses included rescoring the ranking and strategic metrics in order to evaluate new component combinations identified in the analyses. This chapter describes the final analysis results and the Recommended Planning Direction that was produced by evaluating the analysis results, stakeholder input and other considerations.

8.1 Results Analysis

8.1.1 Firm Requirements and Capacity Gap

The final IRP used the same firm requirements and capacity gaps as discussed in Chapter 7 – Draft Study Results. In addition to the scenarios used in the Draft IRP, an additional reference case was created to reflect the lingering economic recession as shown in Figure 8-1.

Figure 8-1 – Firm Requirements by Scenario

8.1.2 Previously Identified Sensitivities

Additional sensitivity cases were identified from work done for the Draft IRP and feedback received from stakeholders. The type of sensitivity, the purpose for analysis and the method that was incorporated into the final IRP analysis are listed in Figure 8-2.

| Sensitivity Description | Basis for Selection | Method for Addressing |
|--|--|---|
| Evaluate increment/decrement of renewable additions for Strategy C | To identify the optimum level of renewable additions given the other assumptions already set in this strategy | • The range of renewable additions retained in the Draft IRP (along with additional increments) will be a selectable resource in the blended optimization |
| Evaluate alternate idled capacity values for Strategy C | To test the impact of varying idled capacity values | • The range of idled capacity retained in the Draft IRP will be evaluated with all other resources in the blended optimization |
| Evaluate increment/decrement of EEDR impacts for Strategy C | To identify the optimum level of EEDR given the other assumptions already set in this strategy | • The range of EEDR portfolios retained in the Draft IRP will be a selectable resource in the blended optimization |
| Test "gas-only" expansion in Strategy C | To evaluate the impact of gas capacity expansion on the short-term rate metric score | "Gas-only" expansion will not allow nuclear additions To be tested with 3,200 MW of idled capacity All other factors will be optimized |
| Evaluate an aggressive EEDR portfolio that targets 50% of the capacity gap beginning in 2015 | To evaluate the impact on plan cost and risk for a more aggressive portfolio of EEDR programs | The 50% target will be based upon the capacity gap in the latest reference case (Scenario 8) with 3,200 MW of idled capacity All other factors will be optimized |
| Test deferral of nuclear expansion in Strategy C until 2020 | To identify the capacity additions that would be required if nuclear was not available | • Schedule of nuclear additions will be optimally selected based on the options and constraints described previously |

8.1.3 Final Study Results

The study approach in the final IRP produced 12 portfolios that resulted from a blended optimization. The boundaries (resource constraints) were defined by the planning strategies (Strategies B, C and E) retained in the Draft IRP. The 12 cases were produced by testing four possible levels of idled coal-fired capacity in each of the three representative scenarios (Scenarios 1, 3 and 8) which represent the high, medium and low load forecasts described in Section 6.1 – Development of Scenarios and Strategies. Multiple iterations were used to test all levels of idled coal-fired capacity. Optimum renewable and EEDR portfolios were selected for each assumed level of idled coal-fired capacity. Figure 8-3 summarizes the results of those cases.

| PSH | Pumped-storage Hydro |
| WBN 2 | Watts Bar Nuclear Unit 2 |

Figure 8-3 – The 12 Portfolios

Referring to the blended optimization results, the following general observations were made:

- Nuclear expansion is present in the majority of portfolios with the first unit on line between 2018 and 2020
- Expanded energy efficiency and demand response (EEDR) portfolios performed well in the optimization cases. The mid level portfolio (3,600 MW and 11,400 annual GWh reductions by 2020) was chosen in half of the cases
- Renewable generation above existing wind contracts plays a key role in future resource portfolios
- Expansion of natural gas capacity is needed, but typically occurs after 2024. Gas may serve as the most advantageous way to address any emerging supply shortage
- Preliminary financial results show that component ranges considered produced relatively robust plans with little variation in total plan costs (PVRR) within scenarios

The cost and risk metrics for the portfolios produced in the blended optimization were relatively constant across the coal-fired capacity levels, especially in Scenarios 3 and 8. This is illustrated in Figure 8-4 which compares the short-term rates ranking metrics for the portfolios organized by idled coal-fired capacity level (2,400/3,200/4,000/4,700 MW).

Figure 8-4 – Short-Term Rate Impacts by Scenario

This outcome was primarily driven by two characteristics. First, new unit additions are very similar in these two scenarios for all four coal-fired idling levels. Second, as the amount of idled coal-fired capacity increased from 3,200 to 4,700 MW, a larger EEDR portfolio was selected in Scenario 8. This larger portfolio had similar costs in comparison to the smaller EEDR portfolio chosen at the 2,400 MW and 3,200 MW levels. In addition, no expansion resources were selected in Scenario 3. As a result, overall PVRR for the plans was essentially unchanged.

The two metrics that measure financial risk for these resource plans were also essentially unchanged across the levels of idled coal-fired capacity except for Scenario 3. The variation seen in Scenario 3 was the result of increasing idling levels, which had an impact on the dispatch of resources in the existing system since there were no expansion resources added in that scenario.

In general, the ranking metrics show that the 12 cases produced in the blended optimization represented robust expansion solutions. The overall results were clustered closely together despite the changes in idled coal-fired capacity assumed and the variation of the key assumptions tested in the stochastic analysis. This set of portfolios represents a more focused set of possible expansion alternatives and was used to define the characteristics of the Recommended Planning Direction.

8.2 Component Identification

The Recommended Planning Direction was designed by utilizing the findings from the blended optimization to select the components that became part of the strategy. The strategy design considered the following major factors:

| | Continuous dialogue with the Stakeholder Review Group |
|-------------------------------------|---|
| Stakeholder input | • Input received from the fall 2010 Draft IRP public comment period |
| | • Quarterly public briefings conducted by TVA staff and responses to surveys |
| Analysis results | • Output from the resource optimization cases and associated financial modeling translated into ranking and strategic metrics |
| | "No-regrets" approach |
| Recognition of non-quantified risks | • Broader considerations not fully captured in the quantitative analysis, but have some impact on the selection process |

8.2.1 Idled Coal-Fired Capacity

Selection of the preferred level of idled coal-fired capacity was the next step in producing the case results in the final IRP. Cost and risk ranking metrics used in the Draft IRP were applied to select a level of idled coal-fired capacity from the options considered. Each idled capacity level was given an ordinal rank for each metric within a scenario.

The ordinal rankings for each scenario were weighted using the same formula as applied in the Draft IRP. Scores were summed for each idled coal-fired capacity level to create total ranking scores. Results are shown in Figure 8-5.

| | Idled | | Totol | | |
|----------|----------|------|-------|------|-------|
| | Capacity | Sc 1 | Sc 3 | Sc 8 | Iotai |
| | 2,400 | 1.7 | 3.0 | 2.4 | 7.1 |
| Weighted | 3,200 | 2.7 | 2.2 | 2.7 | 7.7 |
| Ranking | 4,000 | 2.5 | 1.7 | 1.7 | 5.9 |
| | 4,700 | 3.1 | 3.1 | 3.2 | 9.4 |

Figure 8-5 – Weighted Ranking Scores

Based on the ranking results, the 4,000 MW level performed the best across the three scenarios and was used as the scorecard value. This level of idled coal-fired capacity was used as a fixed assumption for further refinement of the remaining components of the Recommended Planning Direction. Model results were then reviewed to identify optimal values for the renewable resources portfolio and the level of EEDR.

8.2.2 Renewable Portfolio

In the least-cost optimized plans, results tended to favor the 1,500 MW portfolio, which represented the current wind contracts as the preferred level. However, based on stakeholder comments and feedback on the Draft IRP desiring an increased emphasis on renewable development, the Recommended Planning Direction was increased to incorporate the 2,500 MW portfolio which was used as the scorecard value. This reflects projected growth of 1,000 MW of additional renewables above existing and contracted amounts. Figure 8-6 shows a potential mix of components in this renewable portfolio.

Figure 8-6 – Potential 2,500 MW Renewable Portfolio

Prior to making this decision, the cost premium to increase to the 2,500 MW portfolio was calculated. It was determined to be relatively small (typically less than 1 percent of total plan cost). Not all of this cost change was directly attributable to the renewable portfolio itself because of other changes in the resource plan. This premium was deemed acceptable given TVA's objectives to increase reliance on cleaner and more environmentally responsible energy sources.

8.2.3 EEDR Portfolio

The modeling results were evenly split in selecting either the mid level EEDR portfolio (3,600 MW by 2020) or the larger portfolio (5,100 MW by 2020). For reference, the mid level portfolio was part of Strategy C, and the larger portfolio was included in Strategy E in the Draft IRP.

Given the uncertainty about the pace of customer participation and the implementation challenge for TVA associated with the larger portfolio, the mid level EEDR portfolio was used as the scorecard value. This selection also recognized there are similar non-quantified risks

associated with implementation of this mid level portfolio. Those risks were deemed to be sufficiently manageable to include the portfolio in the Recommended Planning Direction.

For a more complete discussion of the non-quantified risks that were part of TVA's assessment of the planning strategies, see Chapter 6 – Resource Plan Development and Analysis.

8.3 Recommended Planning Direction Development

8.3.1 Key Characteristics

After the key components of idled coal-fired capacity, EEDR and renewables were determined, the key characteristics of the strategies following the blended optimization were observed. These observations are shown in Figure 8-7.

| Component | Observations |
|-----------------------|---|
| Nuclear additions | Nuclear expansion is present in the majority of portfolios. Up to three ¹ units are added between 2013 and 2029 |
| Coal additions | New coal capacity is only selected after 2025 in scenarios with dramatic load growth |
| Natural gas additions | Expansion of natural gas is needed, but typically occurs after 2024 with simple-cycle combustion turbines. The dramatic load growth scenario is an exception as combined cycles and combustion turbines are chosen as early as 2015. Additional units may be required for reliability and/or grid stability |
| Renewable additions | Model results tend to favor the current wind contracts (1,500 MW) as the least cost plan. The renewable portfolio that delivers 2,500 MW by 2029 is selected in the dramatic load growth scenario |
| EEDR | Results evenly split in selecting either the 3,600 MW by 2020 portfolio and the 5,000 MW by 2020 portfolio |

1 - Included in number of nuclear units is TVA Board of Directors' approved project Watts Bar Unit 2

Figure 8-7 – Observations Developed from Preliminary Results

The remaining components of the Recommended Planning Direction were selected with consideration of these outcomes. Figure 8-8 is a tabular summary of the Recommended Planning Direction.

| Component | Guideline MW Range | Window of Time | Recommendations |
|------------------------------|---------------------------------------|----------------------|--|
| EEDR | 3,600-5,100 (11,400-14,400 GWh) | By 2020 ¹ | Expand contribution of EEDR in the portfolio |
| Renewable additions | 1,500-2,500 ² | By 2020 ¹ | Pursue cost-effective renewable energy |
| Coal-fired capacity idled | $2,400-4,700^3$ | By 2017 | Consider increasing amount of coal capacity idled |
| Energy storage | 850 ⁴ | 2020-2024 | Add pumped-storage capacity |
| Nuclear additions | 1,150-5,9005 | 2013-2029 | Increase contribution of nuclear generation |
| Coal additions | 0-9006 | 2025-2029 | Preserve option of generation with carbon capture |
| Natural gas additions | 900-9,3007 | 2012-2029 | Utilize natural gas as an intermediate supply source |

1 – This range includes EEDR savings achieved through 2010. The 2020 range for EEDR and renewable energy does not preclude further investment in these resources during the following decade

2 – TVA's existing wind contracts that total more than 1,600 MW are included in this range. Values are nameplate capacity. Net dependable capacity would be lower

3 – TVA has previously announced plans to idle 1,000 MW of coal-fired capacity, which is included in this range. MW values based on maximum net dependable capacity

4 - This is the expected size of a new pumped-storage hydro facility

5 – The completion of Watts Bar Unit 2 represents the lower end of this range

6 – Up to 900 MW of new coal-fired capacity is recommended between 2025 and 2029

7 - The completion of John Sevier combined cycle plant represents the lower end of this range

Figure 8-8 – Recommended Planning Direction

The above figure contains seven components that comprise the strategy and shows a range of the amount for each component as well as the timing of when these components would be added to the system.

8.3.2 Recommended Planning Direction Illustrative Portfolios

After the Recommended Planning Direction was defined, it was evaluated to determine if it represented an improvement over the strategies evaluated in the Draft IRP. A group of portfolios was developed and scored.

To produce the portfolios, the Recommended Planning Direction was tested in each of the eight scenarios. These portfolios were based on scorecard values for the key components of the Recommended Planning Direction (idled coal-fired capacity, EEDR and renewables) with optimized additions of the other resources that made up the capacity plans.

The resultant portfolios are illustrative in nature and based on the particular set of assumptions contained in each of the scenarios. Figure 8-9 is a tabular summary of the illustrative portfolios for the Recommended Planning Direction and shows the resource plans that result in each of the eight scenarios.

| Voor | Capacity Additions by Scenario | | | | | | | | | |

*Illustrative portfolios assume 4,000 MW of idled coal-fired capacity by 2015

| Additions | | | | | | | |
|-----------------|--|--------------|--|--|--|--|--|
| Natural Gas | | Pumped Hydro | | | | | |
| Coal | | Renewables | | | | | |
| Nuclear | | EEDR | | | | | |
| Purchased Power | | | | | | | |

Figure 8-9 – Illustrative Portfolios for the Recommended Planning Direction

After reviewing the resource plans in Figure 8-9, the following observations can be made about near-term and long-term additions:

- Near-term additions (0-5 years) were generally consistent across the scenarios, reflecting the addition of approved projects by the TVA Board of Directors, which include additions at John Sevier and Watts Bar. Resource additions in this time frame also included new natural gas plants and purchased power arrangements, depending on load growth
- Long-term additions (5-20 years) were somewhat more flexible. Nuclear capacity was a major component of the capacity plans in this period, with the first nuclear unit typically added between 2018 and 2020. Expansion of natural gas capacity often occurred after 2024

8.3.3 Recommended Planning Direction Validation

The Recommended Planning Direction was scored using the same ranking and strategic metrics utilized in the Draft IRP. The scorecard results of the Recommended Planning Direction were compared to the scorecard results of the strategies retained from the Draft IRP. Figure 8-10 is a fully populated scorecard for the Recommended Planning Direction, and Figures 8-11 and 8-12, respectively, show scorecards from the Draft IRP for Strategy C and Strategy E.

Figure 8-12 – Planning Strategy E – Updated Scorecard

Comparing the Recommended Planning Direction to the top two strategies from the Draft IRP (Strategy C and Strategy E) shows that the Recommended Planning Direction represents the most favorable blending of portfolio components. The performance of the Recommended Planning Direction across all scenarios implies that it is a more robust approach with a lower likelihood of regret. The following are additional observations based on the scorecard results:

- The Recommended Planning Direction was the top performer on total plan cost (PVRR) in six of the eight scenarios tested
- The Recommended Planning Direction was the top performer on the risk/benefit ratio metric in five of the eight scenarios
- The strategic metrics for the Recommended Planning Direction were improved from metrics for Strategy C (the top-ranked strategy from the Draft IRP), but were not as good as the strategic metrics for Strategy E
- The economic impact metrics for the Recommended Planning Direction were similar to the metrics for the strategies retained from the Draft IRP, indicating there was no significant difference among the strategies in terms of macroeconomic impacts

The Recommended Planning Direction provided a more effective balance between plan cost and financial risk, as shown in Figure 8-13. The graph presents a cost versus risk curve, and the Recommended Planning Direction provided the lowest combination of plan cost (PVRR) and financial risk of any of the strategies that were considered in this IRP.

Figure 8-13 – Plan Costs vs. Financial Risk

Figure 8-14, a risk trade-off graph that compares financial risk versus the risk/benefit ratio, reinforces the conclusion drawn from Figure 8-13. This shows that improved risk performance comes at a higher overall plan cost.

Figure 8-14 - Comparison of Financial Risks of Strategies

The uncertainty range in PVRR across the scenarios was another measure of performance used to assess the Recommended Planning Direction. Figure 8-15 is a tornado diagram of the variation in total plan cost (PVRR) from the stochastic analysis of the strategies in each of the eight scenarios. The width of the bars indicates the variation and uncertainty in plan cost. This figure shows that in most scenarios the Recommended Planning Direction (R) had the smallest range of cost uncertainty and that the expected value of the total plan cost was lower compared to the other strategies (C or E).

Figure 8-15 – PVRR (2010 \$B)

In addition to financial trade-offs, the Recommended Planning Direction also provided the best balance of plan cost and environmental footprint, represented by the graph of plan cost versus CO_2 tons shown in Figure 8-16.

Figure 8-16 – Plan Costs vs. Annual CO₂ Emissions

8.3.4 Other Considerations

The modeling results represented by the ranking and strategic metrics, along with other financial and risk assessments discussed in the preceding section, provided strong support for the Recommended Planning Direction. However, as indicated in Section 7.2.4 – Other Strategic Considerations, the analytics are not the only considerations that were factored into the selection of TVA's Recommended Planning Direction. Certain non-quantified risk concerns, also known as "no-regrets considerations," were included, either directly or indirectly, when making the selection. Figure 8-17 shows the key items of the "no-regrets considerations."

| Other Risk Considerations | Potential Implications | Potential Early Warning Signs | | |
|--|--|---|--|--|
| Establishing a successful partnership with distributor group to administer EEDR programs and deliver forecasted reductions | • Planning strategies with higher EEDR targets will have a greater exposure to this risk | • Delays in establishing formal agreement with distributors by end of FY 2012 | | |
| The ability of EEDR programs to stimulate customer participation and deliver forecasted reductions | • Planning strategies with higher EEDR targets will have a greater exposure to this risk | Measurement and verification data of actual reductions is significantly below forecast | | |
| The ability to achieve schedule targets for licensing/permitting, developing and constructing large baseload generation | Risks of meeting schedule targets will likely increase as the number and complexity of construction projects increase Projects with more extensive permitting requirements may have greater exposure to schedule risk | Critical internal resources for permitting, design, and construction are not maintained for upcoming projects Dramatic changes in licensing/ permitting requirements | | |
| The timely build-out of transmission and distribution (smart grid) infrastructure to support future resources | • Risks will likely increase as the amount of construction required increases; particularly if that construction is undertaken by entities other than TVA | Diminished availability of transmission design and construction resources Limited smart grid capability added to distribution system by 2015 | | |
| The ability to maintain appropriate operational flexibility after significant changes in resource mix | • Risks of limiting operational flexibility increase as the quantity of baseload, dispatchable, and non-dispatchable resources change | Prolonged increases in system load factor Emergence of barriers that delay addition of energy storage | | |

Figure 8-17 – Other Risk Considerations

The Recommended Planning Direction provides the most balanced approach to mitigating the risk associated with these non-quantified factors while providing the best performance in key metrics.

8.4 Conclusion

Based on the results of the analysis conducted in the Draft and final IRP, as well as the consideration of non-quantified risk factors, the Recommended Planning Direction positions TVA with the best balance of flexibility and "no-regrets" risk mitigation. A discussion of next steps and recommendations for implementation of this strategy is discussed in Chapter 9 – Next Steps.
