West Germans, Americans win

By **ARTHUR MAX**

Associated Press

STOCKHOLM, Sweden — Three Americans won the Nobel Prize in physics Wednesday for their work with subatomic particles, and three West Germans shared the chemistry prize for discoveries that may be critical in harnessing the sun's energy.

Americans Leon Lederman, Melvin Schwartz and Jack Steinberger shared the physics prize for capturing neutrinos in a high energy beam to probe the structure of atomic particles.

Chemists Johann Deisenhofer, Robert Huber and Hartmut Michel of West Germany were honored for their work in unraveling a mystery of photosynthesis. They were rewarded for work completed only three years ago, indicating the importance attached to their breakthrough by the awarding committee of the Royal Swedish Academy of Sciences.

Many recipients wait decades for recognition.

Committee chairman Bo Malmstrom said their work was an essential step toward artificial photosynthesis, which scientists hope will provide the key to converting the sun's energy to man's needs.

Producing Images

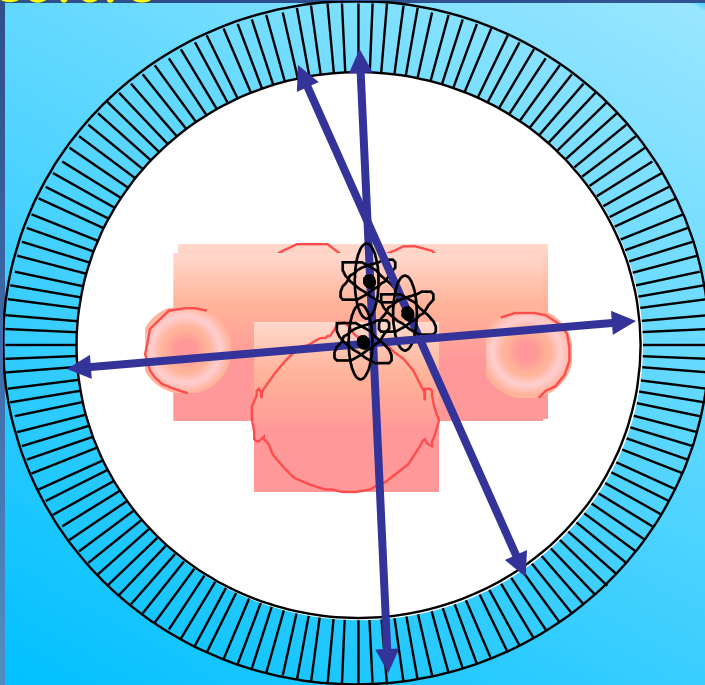

Rationale

- Spin-offs from the "big physics" projects are popular and expected by all the "stakeholders", even if not part of the main "mission"
- Scientists involved are to a large extent "normal" people sharing the concerns of the society
- Medical imaging was and is a natural spin-off from the particle physics community via:
 - Relevant technical expertise
 - Radiation detection instrumentation
 - Fast readout electronics and data acquisition systems
 - Fast computers
 - Computing algorithms, including simulations ("Monte Carlo")
- Special opening is in the dedicated organ specific imagers, where the technology advancements (compact, mobile, offer new opportunities to implement what particle physics is using or developed initially for the main mission.

Positron Emission Tomography (PET)

Ring of Photon Detectors

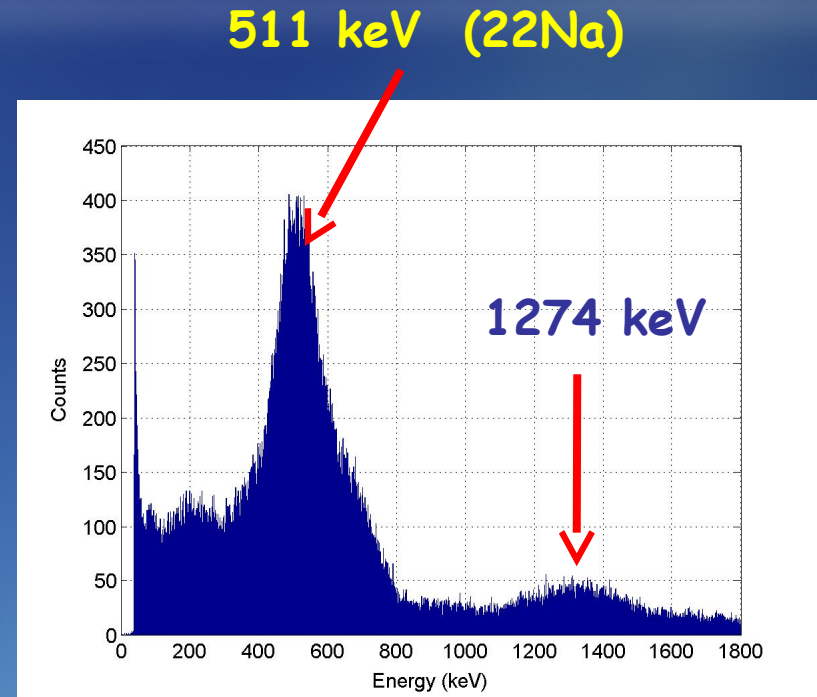

- Radionuclide decays by emitting a positron (β^+).
- β^+ annihilates with e^- from tissue, forming back-to-back 511 keV photon pair.
- 511 keV photon pairs detected via time coincidence.
- Positron lies on line defined by detector pair.

- Detects Pairs of Back-to-Back 511 keV Photons
 - No Collimator Needed \Rightarrow High Efficiency

Received 24 September 1982, in final form 7 February 1983

Abstract. Application of the Fourier space deconvolution algorithm to three-dimensional (3D) reconstruction problems necessitates the computation of a frequency space filter, which requires taking the 3D Fourier transform of the system response function. In this paper, it is shown that for system response functions of the specific form $d(\theta, \varphi)/r^2$, with $d(\theta, \varphi)$ an angular function describing the imaging system, the filter computation can always be reduced to a single integration which, in many cases, may be performed analytically. Complete expressions are derived for the general 3D filter, and two examples are given to illustrate the use of such expressions.

Three-dimensional filter computation

1015

equation (28) may be written

$$D(\Theta, \Phi) = \frac{1}{\cos \Theta} \int_{\varphi-\varphi_0}^{\varphi+\varphi_0} \int_{-\theta_0}^{\theta_0} \delta(\cos \varphi + \tan \theta \tan \Theta) d(\theta, \Phi - \varphi) d\theta d\varphi. \quad (32)$$

Setting $t = \cos \varphi + \tan \theta \tan \Theta$, $\theta = \tan^{-1}[(t - \cos \varphi)/\tan \Theta]$ equation (32) becomes

$$D(\Theta, \Phi) = \frac{\tan \Theta}{\cos \Theta} \int_{\varphi-\varphi_0}^{\varphi+\varphi_0} \int_{t_1}^{t_2} \delta(t) \frac{d(\tan^{-1}[(t - \cos \varphi)/\tan \Theta], \Phi - \varphi)}{\tan^2 \Theta + (t - \cos \varphi)^2} dt d\varphi \quad (33)$$

where

$$t_1 = \cos \varphi - \tan \theta_0 \tan \Theta$$

$$t_2 = \cos \varphi + \tan \theta_0 \tan \Theta.$$

Since

$$\int_a^b \delta(t)f(t) dt = \frac{1}{2} [\text{sign}(b) - \text{sign}(a)]f(0) \quad (34)$$

with $\text{sign}(0) = 0$, equation (33) may be written

$$D(\Theta, \Phi) = \int_{\varphi-\varphi_0}^{\varphi+\varphi_0} s(\varphi, \theta_0, \Theta) g(\varphi, \Theta, \Phi) d\varphi \quad (35)$$

for $0 < \Theta < \pi/2$, $0 \leq \Phi \leq \pi/2$ where the functions s and g are given by

$$s(\varphi, \theta_0, \Theta) = \frac{1}{2} [\text{sign}(\cos \varphi + \tan \theta_0 \tan \Theta) - \text{sign}(\cos \varphi - \tan \theta_0 \tan \Theta)] \quad (36)$$

$$g(\varphi, \Theta, \Phi) = \frac{\tan \Theta}{\cos \Theta} \frac{d(\tan^{-1}(\cos \varphi / \tan \Theta), \Phi - \varphi)}{\tan^2 \Theta + \cos^2 \varphi} \quad (37)$$

since $d(-\theta, \varphi) = d(\theta, \varphi)$. Equation (24) is thus reduced to a single integration, equation (35), with the functions s and g given by equations (36) and (37). Computer implementation of equation (35) may be made more efficient by a detailed analysis of equation (36). The function $s(\varphi, \theta_0, \Theta)$, with a value of $+1$, $+1/2$ or 0 , has the effect of segmenting Fourier space into at most four regions, as follows:

$$D(\Theta, \Phi) = 0 \quad 0 < \Theta < \pi/2 - \theta_0, 0 \leq \Phi < l - \varphi_0 \quad (38)$$

$$D(\Theta, \Phi) = \int_{\varphi-\varphi_0}^{\varphi+\varphi_0} g(\varphi, \Theta, \Phi) d\varphi \quad \begin{array}{l} \pi/2 - \theta_0 \leq \Theta < \pi/2 \\ 0 \leq \Phi \leq \pi/2 \end{array} \quad (39)$$

$$D(\Theta, \Phi) = \int_{-l}^l g(\varphi, \Theta, \Phi) d\varphi \quad \begin{array}{l} 0 < \Theta < \pi/2 - \theta_0 \\ |l - \varphi_0| \leq \Phi \leq \pi/2 \end{array} \quad (40)$$

$$D(\Theta, \Phi) = \int_{\varphi-\varphi_0}^{-l} g(\varphi, \Theta, \Phi) d\varphi + \int_l^{\varphi+\varphi_0} g(\varphi, \Theta, \Phi) d\varphi \quad \begin{array}{l} 0 < \Theta < \pi/2 - \theta_0 \\ 0 < \Phi < \varphi_0 - l \end{array} \quad (41)$$

with

$$a = \max(\Phi - \varphi_0, l)$$

$$b = \min(\Phi + \varphi_0, l - \pi/2)$$

and

$$l = \cos^{-1}(\tan \theta_0 \tan \Theta), \quad 0 \leq l \leq \pi/2.$$

$D/\Delta x \sim$ reduction in variance
or gain in sensitivity

(Joel Karp, U. Penn)

Impact of microcell size on PET timing resolution

$$PDE = Q.E. \times \Pr(\text{avalanche}) \times \text{fill factor}$$

Fill factor \propto Microcell size

Hamamatsu SiPM Microcell size (μm)	Hamamatsu SiPM Fill factor (%)
25	30.8
50	61.5
100	78.5

Expectation: PET detector using 100 μm SSPM should optimize timing resolution

Correlation with higher dark current

- Wider operational voltage range provided by 50um microcells with similar performance

Design Choice: Hamamatsu MPPC 4x6mm²

	1	2	3
element size(mm ²)	3x3	4x4	4x6
microcell pitch (um)	50	50	50
no of microcell/pixel	3600	6400	10375
gain	7.50E+05	7.50E+05	7.50E+05
fill factor	61.50%	61.50%	61.50%
PDE @ 440nm type	50%	50%	50%
capacitance/micro-cell (fF)	89	89	89
total capacitance (pF)	320	570	920
dark counts typ. (Mcps)	6	11	13

- 4x6mm² MPPC with 50μm provides the wider stable operational range
- larger area reduced number of readout channels to be processed

Detector Unit Design

4x3 LYSO array (4x5.3x25mm³)

2mm UV plastic

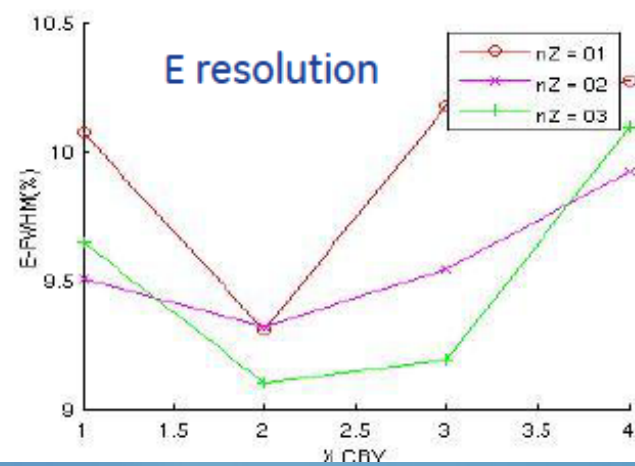

Timing Resolution - 350ps

Walk Correction - 340ps

Energy Resolution 9.7%

1_may9/6AZ_dev2_900mV_TPO50mV_16C_2mm_glass_4x3_after

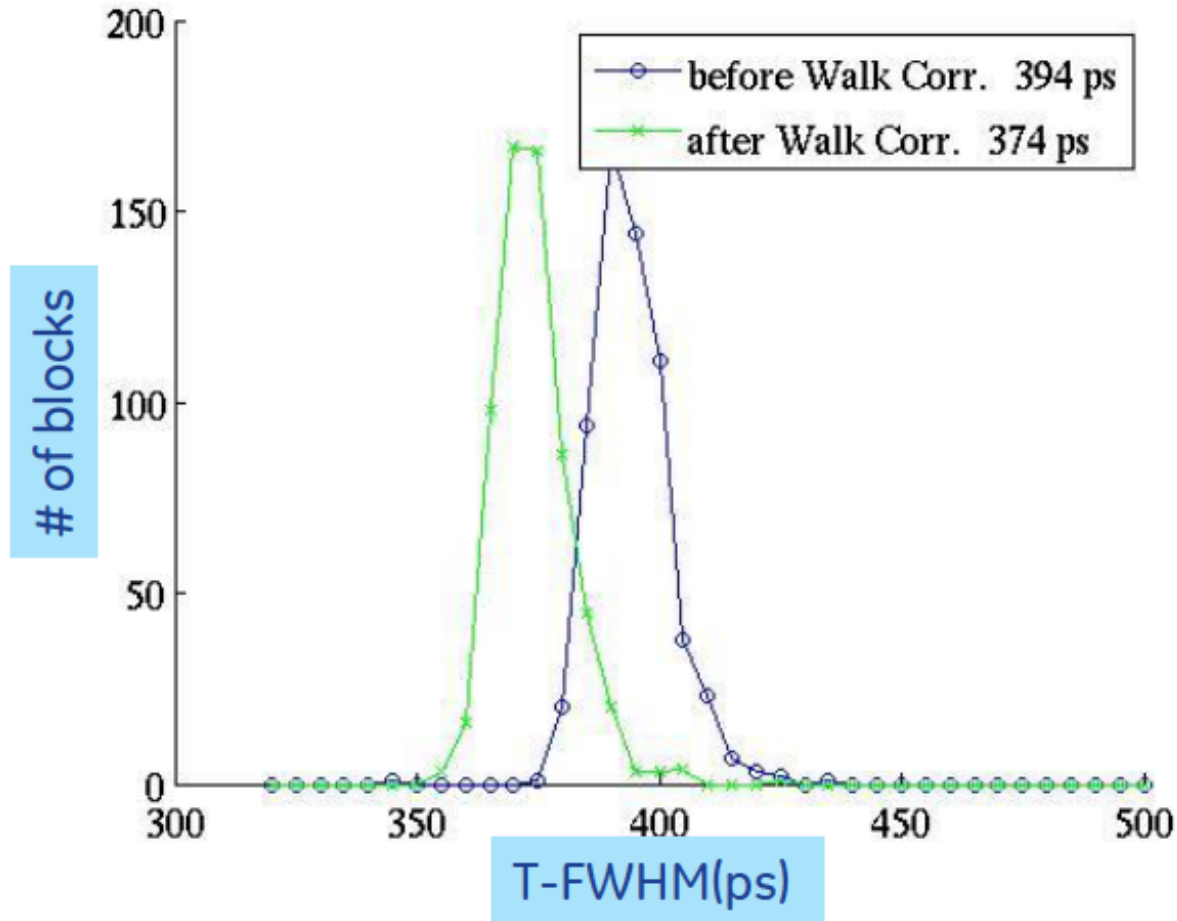

Tapered Light-guide Design

- Transition from crystal block $16 \times 16 \text{mm}^2$ to SiPM $12 \times 12 \text{mm}^2$
- 3x1 array of SiPMs \rightarrow 3x1 light-guide to cover $48 \times 16 \text{mm}^2$

Multiple Blocks Timing Resolution

- > 500 blocks were measured: Great consistency in performance among blocks
- Walk correction improves ~20ps in timing resolution

Dedicated Imaging Systems

Motivation for dedicated systems:

- Higher efficiency due to close geometry
- Possibility for low dose scans (repetitive - longitudinal studies, **screening ?**, children ?)
- Higher resolution (and efficiency via instrumentational Partial Volume Effect)
- Lower cost using small dedicated system as opposed to standard (also occupancy issue of the standard scanner)

Key technical choices:

- Choice of the PET detector technology
- Choice of the on-board readout: functionality, complexity, "compactness", **interference** with MRI
- DOI or not (always) necessary
- TOF or non-TOF

PET/MRI

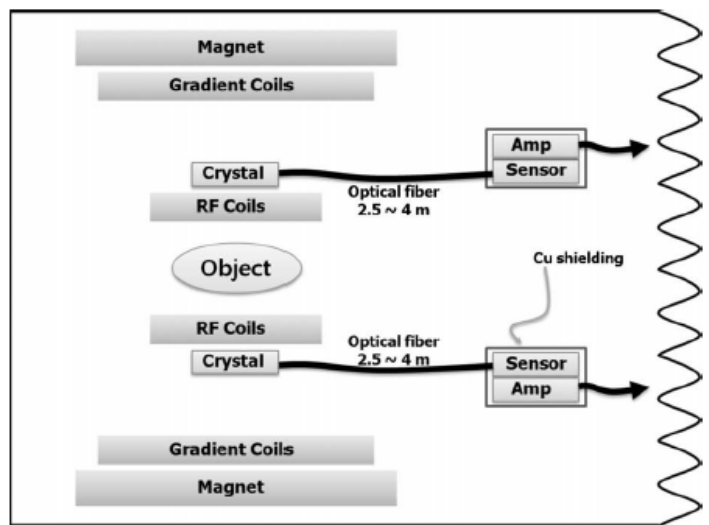

Methods to limit the PET-MRI interference: passive and active

- **Minimize on-board electronics**
- Place active components and photodetectors outside the MRI imaging volume (scintillation light coupling via optical light guides)
- Shielding of detectors and cabling
- RF noise filtering
- Placement of coils and integration of the PET insert with the RF coil
- Optical electronic signals coupling
- Selection of proper MRI sequences
- **Sequential imaging**

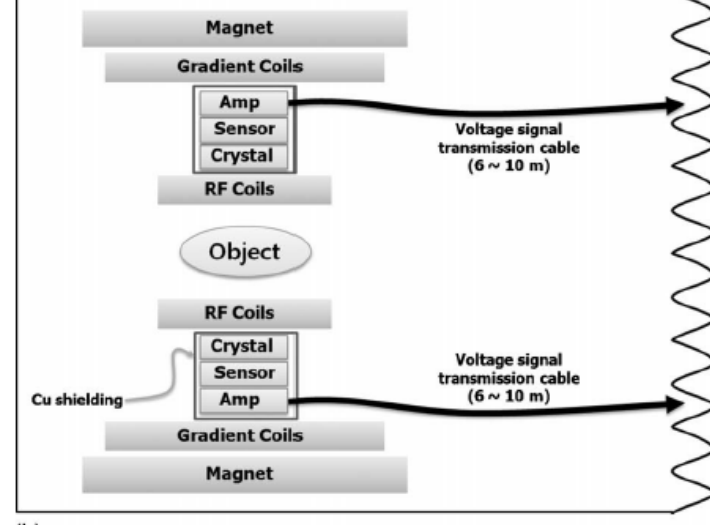

MRI compatible PET technologies:

- APDs
- SiPMs
- Scintillators
- Light guides
- CdTe, CdZnTe,

New cancer scanner halves radiation

Particle physicists have developed a new medical technology that combines PET and MRI in one. Benefit: Improved image quality and less radiation.

FIFTY PER CENT LESS RADIATION: The particle physicists Erlend Bolle, David Volgyes, Michael Rissi and Kim-Eigard Hines have developed a completely new technology that makes it possible to halve radiation from a PET scanner. The PET scanner is also built at such a small scale that it can be placed inside an MR scanner. This makes it possible to take the MR and PET images at the same time. Photo: Yngve Vogt

From calorimetry to medical imaging: a shining example of successful transfer!

A team at CERN has drawn inspiration from calorimetry methods developed for high-energy physics to create a new positron-emission tomography system for use in medical imaging, which they've dubbed **AX-PET**. With support from European and American laboratories*, the project is reaching fruition, as initial tests confirm its promise.

A traditional PET scanner showing the crystal layout.

The axial orientation of elongated crystals in AX-PET.

Snapshot of a "phantom", a test object, surrounded by the AX-PET photon detectors.

Some members of the project team: Christian Joram (CERN), Chiara Casella (ETH Zürich) and Matthieu Heller (CERN) pose behind AX-PET.

The AX-PET concept

Microcalcifications with Previous Benign Biopsy

Mammogram: right breast shows area of microcalcifications (see arrow). Previous needle biopsy of this area was negative.

BSGI:
demonstrated a high-uptake region highly suspicious and the patient was sent for open

Simultaneous PET-MRI Breast Imaging

Aurora Dedicated 1.5 T Breast MRI

Clinical Prototype

Need larger ID and flexibility in axial coverage

24 detector PET ring with a crystal wide gap on either side

PET ring is assembled in a plastic housing

Clinical Protocol - Taipei Medical University Hospital

Routine Breast MRI to find any lesions

18F-FDG Whole Body Scan*
(supine position)

Chest PET scan*
(prone position)

Simultaneous
PET/MRI

Delay phase prone
PET*

Biopsy

*Scans done on Siemens Accel

Patient 1 - Simultaneous PET-MRI

Future Directions

- Next generation is considerably larger both in radius and in length increasing our field of view
- This new design has only three cables coming out 1 power and 2 optical fibers

Things to Remember

- The power of PET and MRI lies in the ability to analyze the images, not in making nice pictures
- Think about kinetics as a way to better utilize PET and MRI data
- Think about ways to retrofit the 30,000 MR scanners in the world to make PET/MR available for the clinic

WVU HELMET PET BRAIN IMAGER

Examples of some possible situations with patients wearing the imager helmet: sitting in a chair (left), exercising (center), and laying down on a bed (right). Another option with a (helium) balloon supporting the weight of the helmet, allowing for even more movement freedom during imaging session, is not shown here. Except for the case of a patient on a bed, the helmet is suspended by a flexible harness /suspension attached to a hook on the helmet.

Each detector module is based on two 1"x1" Silicon Photomultiplier modules and a 1.0-1.5mm LYSO scintillation array (not shown). Status (5/2010): under construction, WVU.

Anticipated Applications Of The Helmet_PET Scanner

1. Stroke Patients - Diagnosis and recovery
2. Epilepsy Patients - Treatment
3. Dementia Patients

Examples of planned uses. Left: balancing patient tests using the computer controlled platform system. Center and Right: F18-PIB and F18-FDG PET images in Alzheimers.

New design: 100 MPPC Modules

MPPC array

Resistor board

Amplifiers
Power Supplies
Bias

No amplifiers on board

Left: Assembly of one ~5cm square compact module of the first Helmet PET prototype. Four Hamamatsu 25 MPPC arrays assembled on one resistive readout base from AiT Instruments. Four 1.5mm step 10mm thick LYSO arrays from Proteus coupled to form one compact module. There are **no amplifiers or other active components** on board the detector module, but in the distant (at the other end of the 2m cable) electronics board. There are 4 output channels per module.

WVU 12-Module Brain PET

The 12-module PET ring prototype after assembly. The ring can also fit outside the EEG cap in a PET/EEG hybrid configuration. PET/MRI/EEG is also possible.

Brain Phantom Images

Reconstructed images of a set of 10 1mm slices from a multi-layer multi-compartmental brain phantom (center) filled with 450 microCurie F18 activity. Left: from the 30 minute run. Right; 30 second run. The short run image showed basically the same overall distribution pattern.

Brain Phantom Images

Selected images of a 1mm slice of a brain phantom, left: with uniform activity, right: with increased activity in a section of the brain.

Left: Brain phantom inside the PET ring with a standard flexible MRI coil before insertion into the bore of a 3T MRI Siemens scanner. Right: MRI images of the phantom using MPRAGE sequencing and with the PET ring fully powered.

MRI images (2mm slices) of the brain phantom using T2 sequence. Left: obtained for comparison with the RF body coil only. Right: when using 3T Flex Large RF coil. In both cases the PET ring and PET DAQ/computer system was fully powered.

Upright Implementation

Setting of the upright system in preparation for pilot clinical trials.

Top: Left: An example of a schematic of a single imager PET ring, shown here with 12 individual MRI-compatible PET modules, divided into two parts, for easy placement and adjustment on the patient's head/brain/neck. Each of the modules is made from a matrix of pixellated LYSO crystals coupled to an array of solid-state Silicon Photo-Multipliers (SiPM). Center: example of an elongated ring – here built with 14 modules, better adapted to the shape of the human head. In the simplest variant only a single ring of modules is built. However, ultimately a three-ring system that will cover the whole brain in one position will be built as shown at right. Bottom: The two-ring variant with two rings spaced apart with an adjustable spacing, is the intermediate - so called "Open PET" type arrangement [Yamaya et al – Ref 5], that provides larger field of view at a reduced complexity and cost. In a special case one of the rings can be placed at the neck level, for example during first path dynamic blood flow imaging with the neck ring measuring the so called input function in the carotid artery. The MRI RF coils - not shown here - are placed inside all the rings.

Dual-sided SiPM readout for "high resolution" PET

Partial ring TOF PET for breast imaging

Lesion 1, 2, and 3 have 8:1 uptake relative to background, Lesion 4 is cold

TOF, 200ps

Non-TOF

In-situ dose verification for proton beam therapy

Full ring

Two-third ring

Non-TOF

Non-TOF

1000ps TOF

600ps TOF

300ps TOF

- 30-cm diameter cylinder irradiated by 4x4-cm² 125-MeV proton beam
- Isotope profile from GEANT4 simulation in skeleton muscle
- PET simulation performed in EGS4 and data written out in list-mode

Timing Resolution Measurement

- Setup: 3x3x15 mm³ LYSO crystals read out by Hamamatsu S10362 SiPMs
- coincidence timing resolution $\Delta T_1 - T_2 = 188$ ps FWHM
- coordinate resolution $\Delta x = c \cdot \Delta T_1 - T_2 / 2$ better than 3cm FWHM

Recovery of the Compton

- Read out 2 4x4 LYSO arrays with 4x4.5x15 mm LYSO crystals
- Select events with two hit pixels on one side, sum up the two charges

Recovery of the Compton

Highest energy deposition

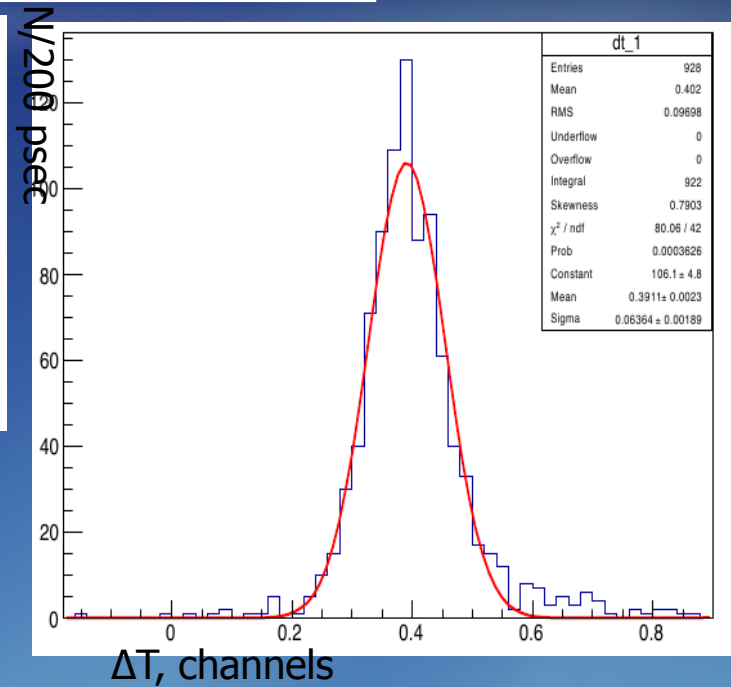

Events, recovered from the Compton tail

- Photopeak selection: number of events increases by $\sim 40\%$
- Observe SiPM saturation at a level of 15%
 - $\langle N \text{ photons} \rangle$ about 1000, $N \text{ cells} = 3600$

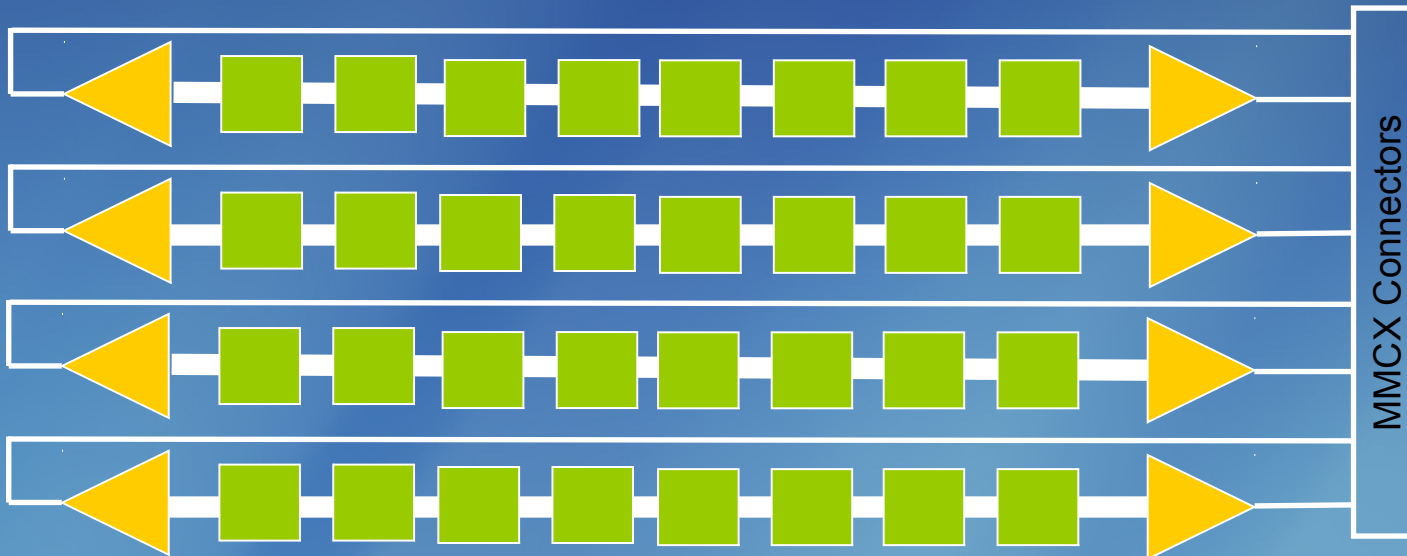

Multiplexed Readout to Reduce the Number of Channels

- Use the delay line with 8 SiPMs read out by 2 channels
- Reconstruct hit channel from the time difference $\Delta T = T1 - T2$
- Reduce the total number of readout channels by a factor of 4
- $\sigma_{T1-T2} \sim 30$ ps FWHM, or ~ 2.2 mm FWHM along the delay line
- For readout pitch of 4-5mm, individual crystals are well resolved

PET-TOF Strip Line Status

- Next SL prototype has 4 strings of 8xSiPMs
 - Design is for STM 10-contact 5.1x5.1 mm² package
 - Diode pitch is 5.2 mm
- Boards should arrive any time now, full component kit exists
 - First I plan to assemble 2 boards with a single line of diodes (solder)
 - Second step is to assemble a complete board, using anisotropic conductive film (will need 4x8 scintillator blocks for that – to push diodes against the board)
 - If conductive film does not work – will solder everything, and we have to learn how to ensure a good optical contact between scintillator and diodes

Strip Line Details

- Next SL prototype will have 4 strings of 8xSiPMs
 - Design is for STM 10-contact 5.1x5.1 mm² package (that is a rather challenging package for board layout)
 - Diode pitch is 5.2 mm
- I have a layout of an elementary cell, note two strip lines per row, the second one returns far end signal to the “digital end” of the board
 - GALI-S66+ amplifier from MiniCircuits (not an ideal package, but layout is possible)
power consumption 16mA@6V,
gain of x10@1GHz / x6.6@3GHz) relatively low

Diode cell layout

Amplifier cell layout

Signal Shape Simulations

- I have run a series of Spice simulations to get an idea of the pulse shape, and amplitude for various scenarios of diode interfacing, and pulse shaping
 - Light pulse shape:
 - 0.3ns rise time
 - 40ns fall time (LYSO time constant) -
 - Assumed 20ns of SiPM recovery timeLYSO light yield is 500 pe, and SiPM gain of $\times 10^6$ (easy to scale if different)
 - For shaping a simple C-R differentiating (“clipping”) circuit is used with time constant of the order of 1ns

SiPM output pulse shape for different pixel stray capacitance:
0.1%(green) 10%(red) 20%(blue)

Output Signals (after x10 amplifier and shaping)

- Signals shown at the two ends of the same transmission line (aligned in time):
 - Output 1 – near end
 - Output 2 – far end (lower peak amplitude)
- Pulse shapes are shown for different output capacitances of the SiPM buffer transistors:
 - Left - 0.5pf (previous SL board)
 - Right – 0.1pf (new SL board)

SiPM output pulse shape for different shaping capacitors: 10/30/100pf

Ring Designs – version 0

210 mm ID

210mm

Summary

- Particle physicists have played and still play substantial role in medical imaging: basic concepts, detectors, electronics, simulations, reconstructions. ...
- PET was invented many years ago but only in the last decade got full recognition for its unique clinical role when combined with CT and now with MRI
- PET imaging is providing critical assistance with patient diagnosis and treatment, as well as with work on understanding disease origin and cures (in small animal models)
- PET improvements are under way to reach the physical limits of the technique (again role for physicists !): TOF PET, partial angular coverage
- Many new technologies: scintillators, photodetectors, solid state materials - spin-offs from particle physics
- Organ-specific PET imagers-inserts in MRI is the new frontline
- Brain imaging - an obvious focus
- Challenge: ~35k MRI imagers to upgrade to PET/MR
- National laboratories are involved - Fermilab is involved !

Thank you !
