- Hydrometeorology Group
- Ensemble, Data Assimilation and Verification Group
- Hydraulics Group

The Future of Hydrologic Forecasting at the NWS

- Enhanced use of **remotely sensed information** on a wide range of atmospheric and land-surface characteristics, from both active and passive satellite-based and/or airborne sensors;
- **Higher-resolution models**;
- Explicit consideration of the **uncertainty in the forcings and forecasts** (An ensemble approach is currently being pursued and will be fully implemented for short-, medium- and long-term forecasting);
- **Multi-model ensembles** to address the problem of uncertainty in the forecasts arising from structural errors in the models (These ensembles may be formed by combinations of lumped or distributed, conceptual or physically based models);
- Explicit consideration of the errors introduced by **sub-optimal parameter values and initial conditions**;
- **Data assimilation** of *in-situ* and remote-sensed state variables; and
- Verification of single-value (deterministic) and ensemble (probabilistic) forecasts.

The Future of Hydrologic Modeling

- Current Shortfalls of Physically Based Hydrologic Models
 - The models are typically based on small-scale hydrologic theory and thereby fail to account for larger-scale processes such as preferential flow paths;
 - The data necessary to estimate parameter values are not available at high enough resolution, certainty, or both;
 - The data necessary to drive the models are not available at high enough resolution, certainty or both; and
 - Despite the rapid increase in computer power and decrease in hardware costs, the computational demands are still a barrier, particularly for performing data assimilation and ensemble modeling in real-time.

How advances in predictability science transition to improved operational predictions

Hydrologic Models

- Continued research and development on physically based models offers the potential for:
 - More accurate forecasts in ungauged and poorly gauged basins;
 - More accurate forecasts after changes in land use and land cover, such as forest fires and other large-scale disturbances to soil and vegetation;
 - More accurate forecasts under non-stationary climate conditions;
 - Modeling of interior states and fluxes, which are critical for forecasts of water quality, soil moisture, land slides, groundwater levels, low flows, etc.; and
 - The ability to merge hydrologic forecasting models with those for weather and climate forecasting.

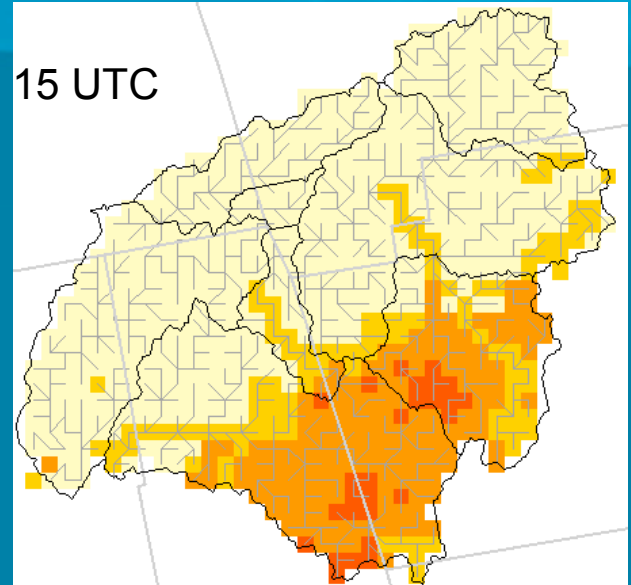

Hydrology Group

14 UTC

In these examples, frequencies are derived from routed flows, demonstrating the capability to forecast floods in locations downstream of where the rainfall occurred.

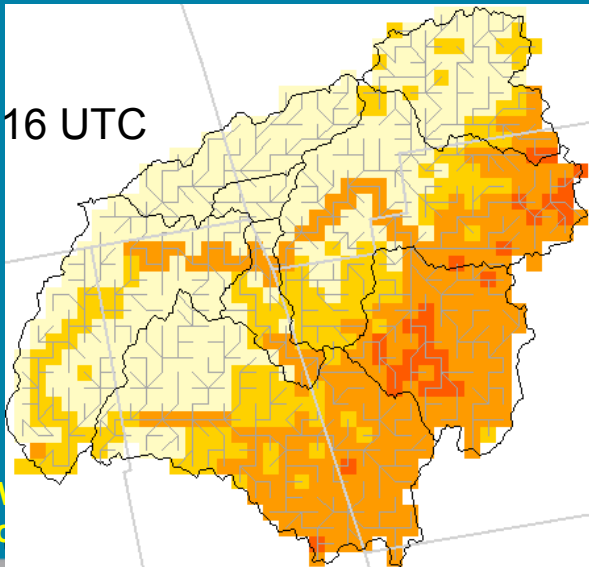

15 UTC

ARI (years)

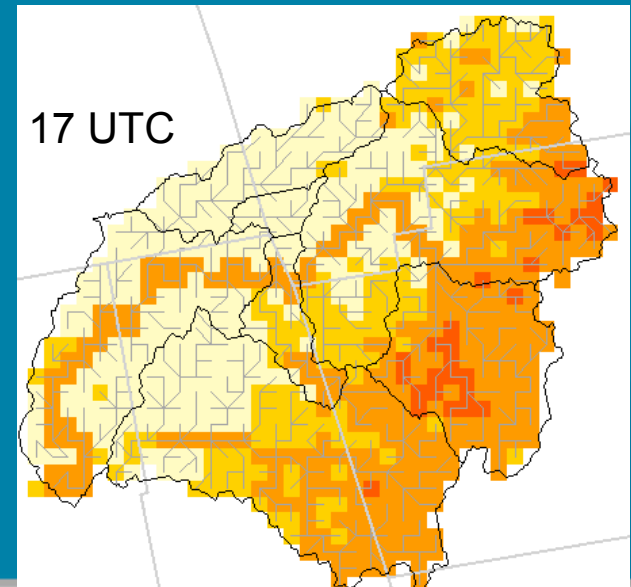

16 UTC

Flood frequencies are expressed in terms of the Average Recurrence Interval (ARI) associated with the annual maximum flood.

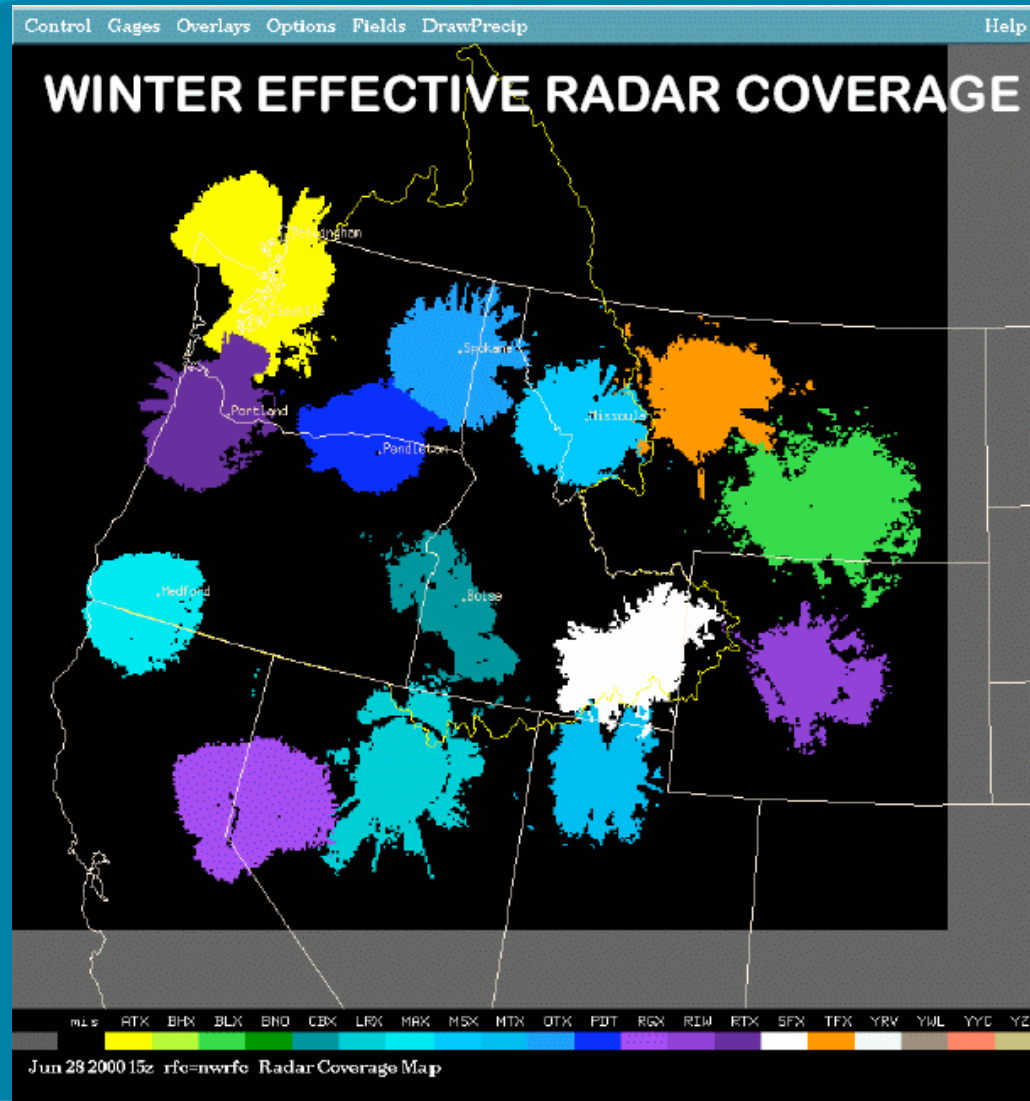

17 UTC

Precipitation Observations- Where we are

- Precipitation is the primary driver for streamflow, affecting discharge through surface runoff, subsurface flow, groundwater recharge, and snowmelt
- Varying time scale of the watershed response to precipitation input, depending on the watershed size and characteristics, from minutes to months.
- For areas well covered with radar and raingauges:
 - Multisensor Precipitation Estimator
 - USACE-developed P3 algorithm, enhanced and used at the ABRFC
 - Mountain mapper, developed at the CBRFC

Evaluation

Precipitation Observations- Where we want to be

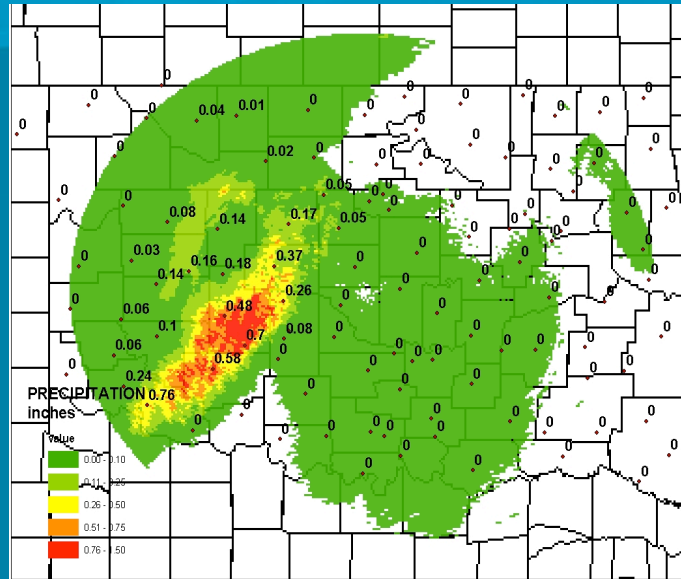

- Continuous, routine integration of all available sensor data and where needed, numerical prediction model estimates.
- Characterizations of the statistical distributions of estimation error will be used by the multisensor algorithms, and will be available to end users
- For radar:
 - implementation of dual-polarization algorithms
 - introduction of reflectivity profile and range corrections
 - automated selection of Z-R relationships
 - Spatial error understanding and modeling
 - Gap-filling radars in mountainous regions
- For satellite:
 - Implementation of algorithms for automatic real-time calibration of infrared temperature vs. rain-rate relationships based on collocated satellite and radar data
 - Anticipating the GPM deployment, OHD will explore applications of the Tropical Radar Rainfall Measurement Mission (TRMM) observations
 - Improved precipitation estimates by combining new satellite algorithms with numerical model prediction results (NOAA-CREST, Sayesteh Mahani)

Precipitation Forecasting- Where we are

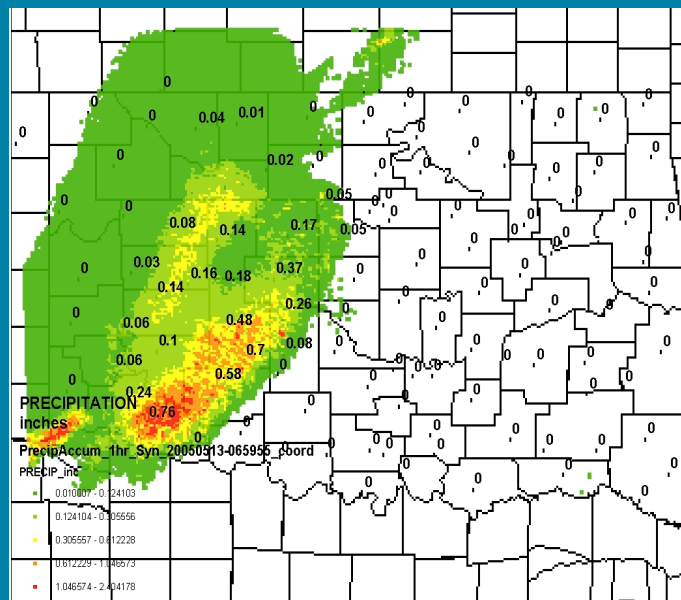

- Short-term nowcasting (< 3 hours)
- Near-term forecasting (3-12 hours) by a combination of radar-feature extrapolation and output from the Global Forecast System (GFS) and North American Mesoscale (NAM) models.
 - Manual modifications based on experience and physical logic are made to gridded precipitation fields by NCEP forecasters, and by HAS forecasters at RFCs. Output from the two models is subjectively weighted according to recent performance in the areas of interest.
 - Longer-term forecasts are based on GFS and NAM output

Hydrometeorology Group

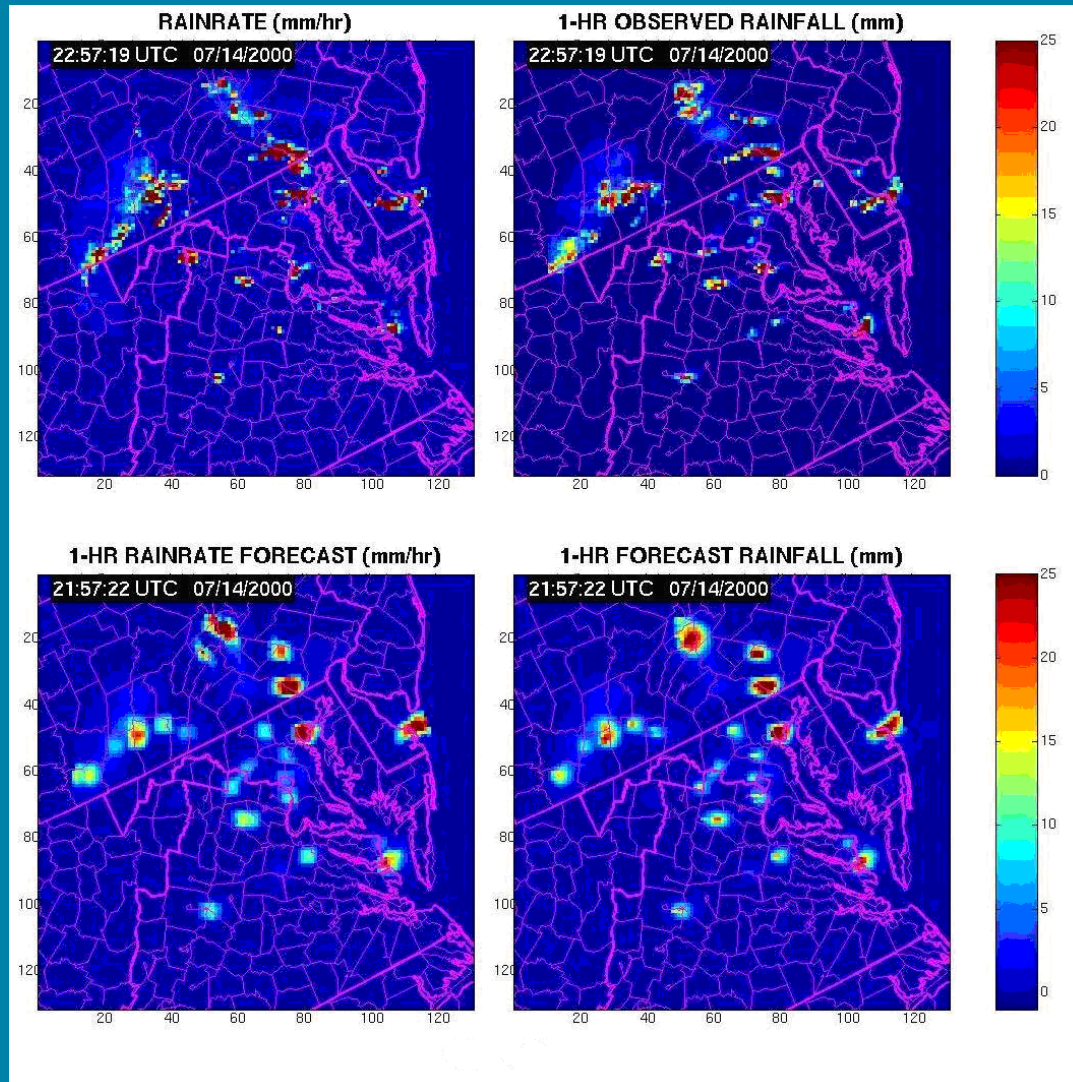

Current Radars (WSR88D)

New Radars (Dual Polarization)

High-resolution Precipitation Nowcaster

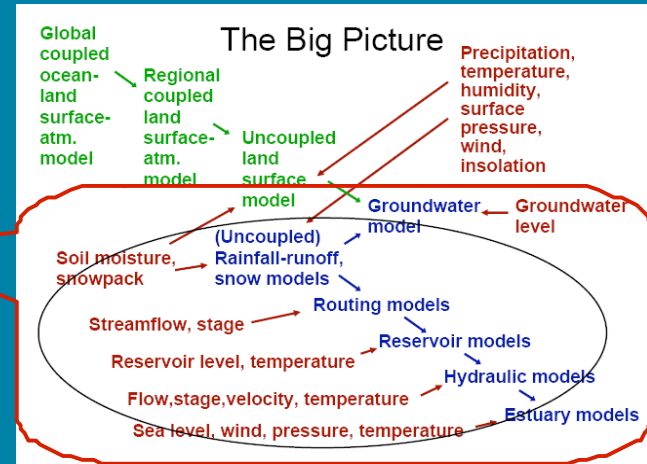

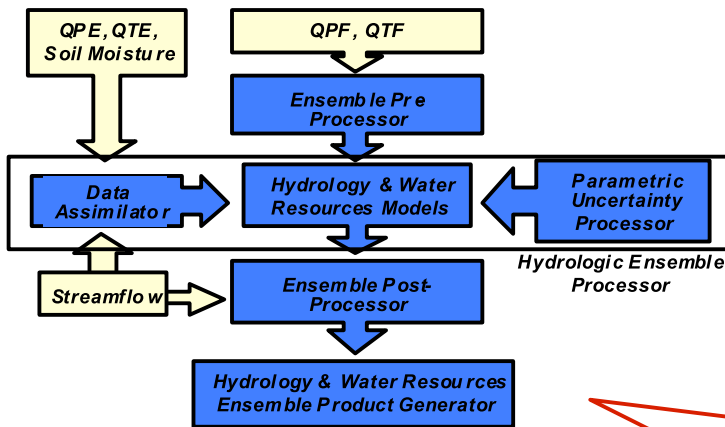

Ensemble Forecasting and Data Assimilation- Where we are

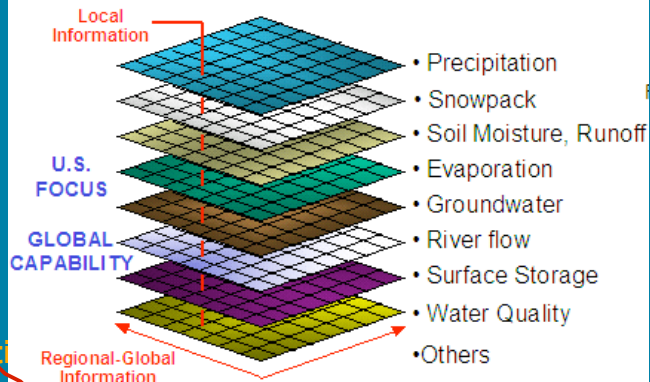

- Until now, operational ensemble forecast has been limited to Ensemble Streamflow Prediction (ESP) runs, essentially a long-range probabilistic forecast.
- Since AHPS, NWS is committed to generate streamflow forecasts at all time scales: customers and partners clearly indicate a need for short-term forecasts.
 - Ensemble pre-processor, to generate QPF and QTF short-term ensembles from single-value weather forecasts.
 - Ensemble post-processor to account for hydrologic uncertainty and river regulation
 - Hydrologic Ensemble Hindcaster, to support large-sample verification of streamflow ensembles
 - Ensemble Verification System for verification of precipitation, temperature and streamflow ensembles
- Partners: NCEP, HEPEX, Universities, RFCs, NASA Goddard, etc.

Ensembles- Where we want to be

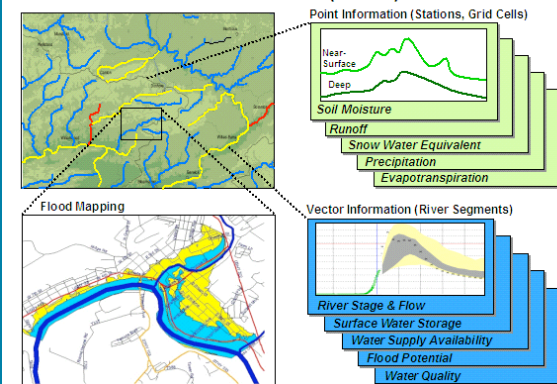

Hydrologic Ensemble Prediction System

a) NWS-NDFD High-Resolution Gridded Water Resources Product Suite (WRPS)

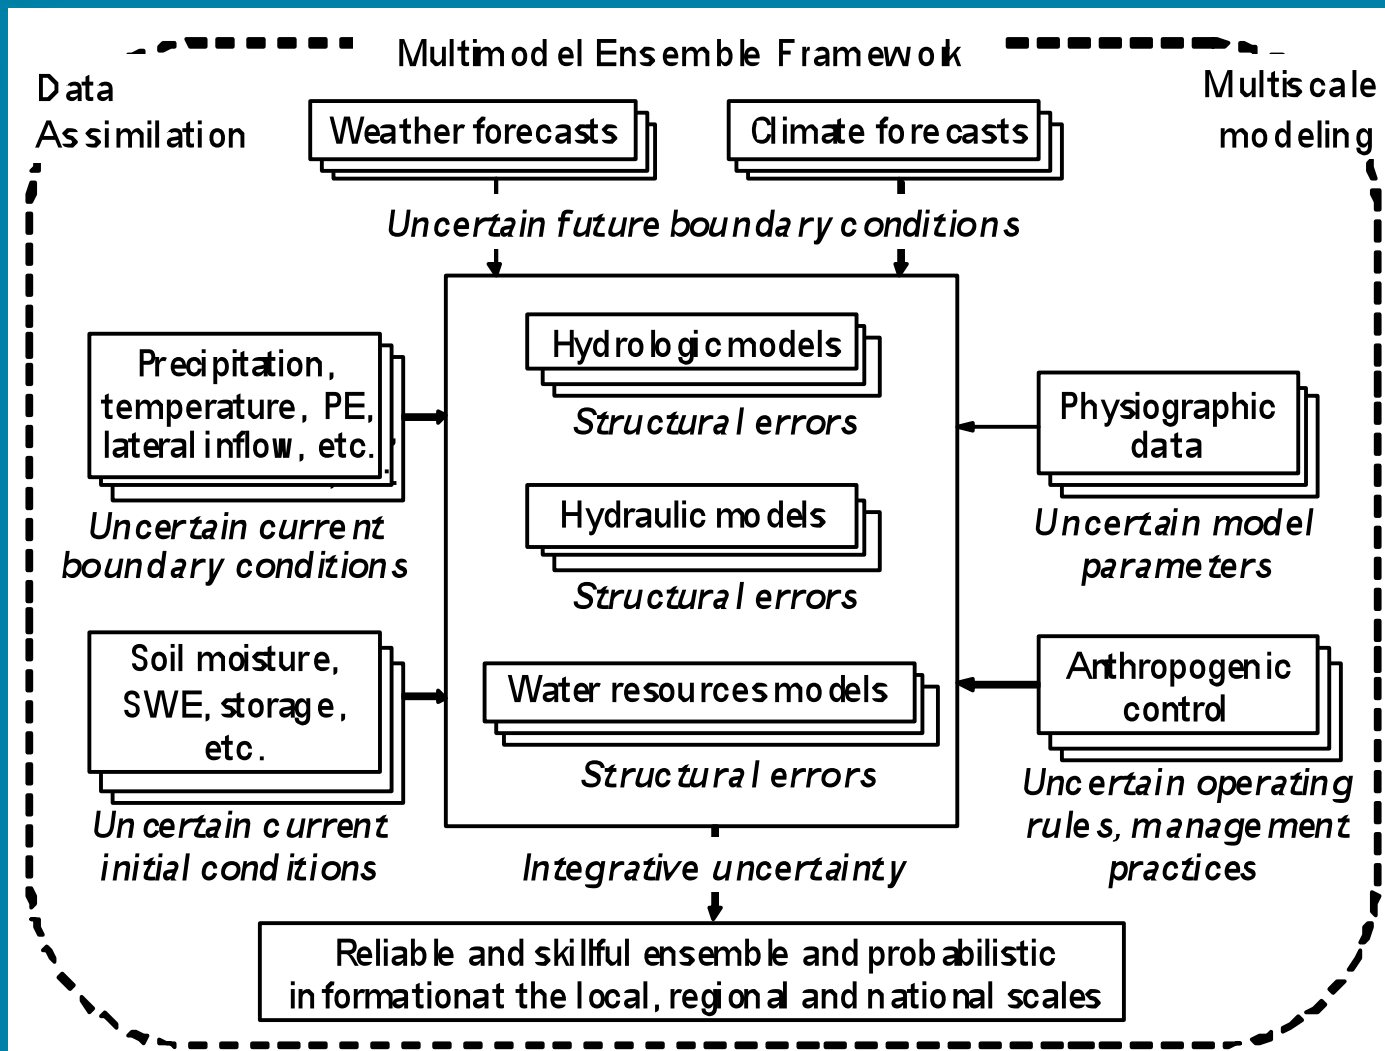

b) NWS-NDFD High-Resolution Geospatial Water Resources Product Suite (WRPS)

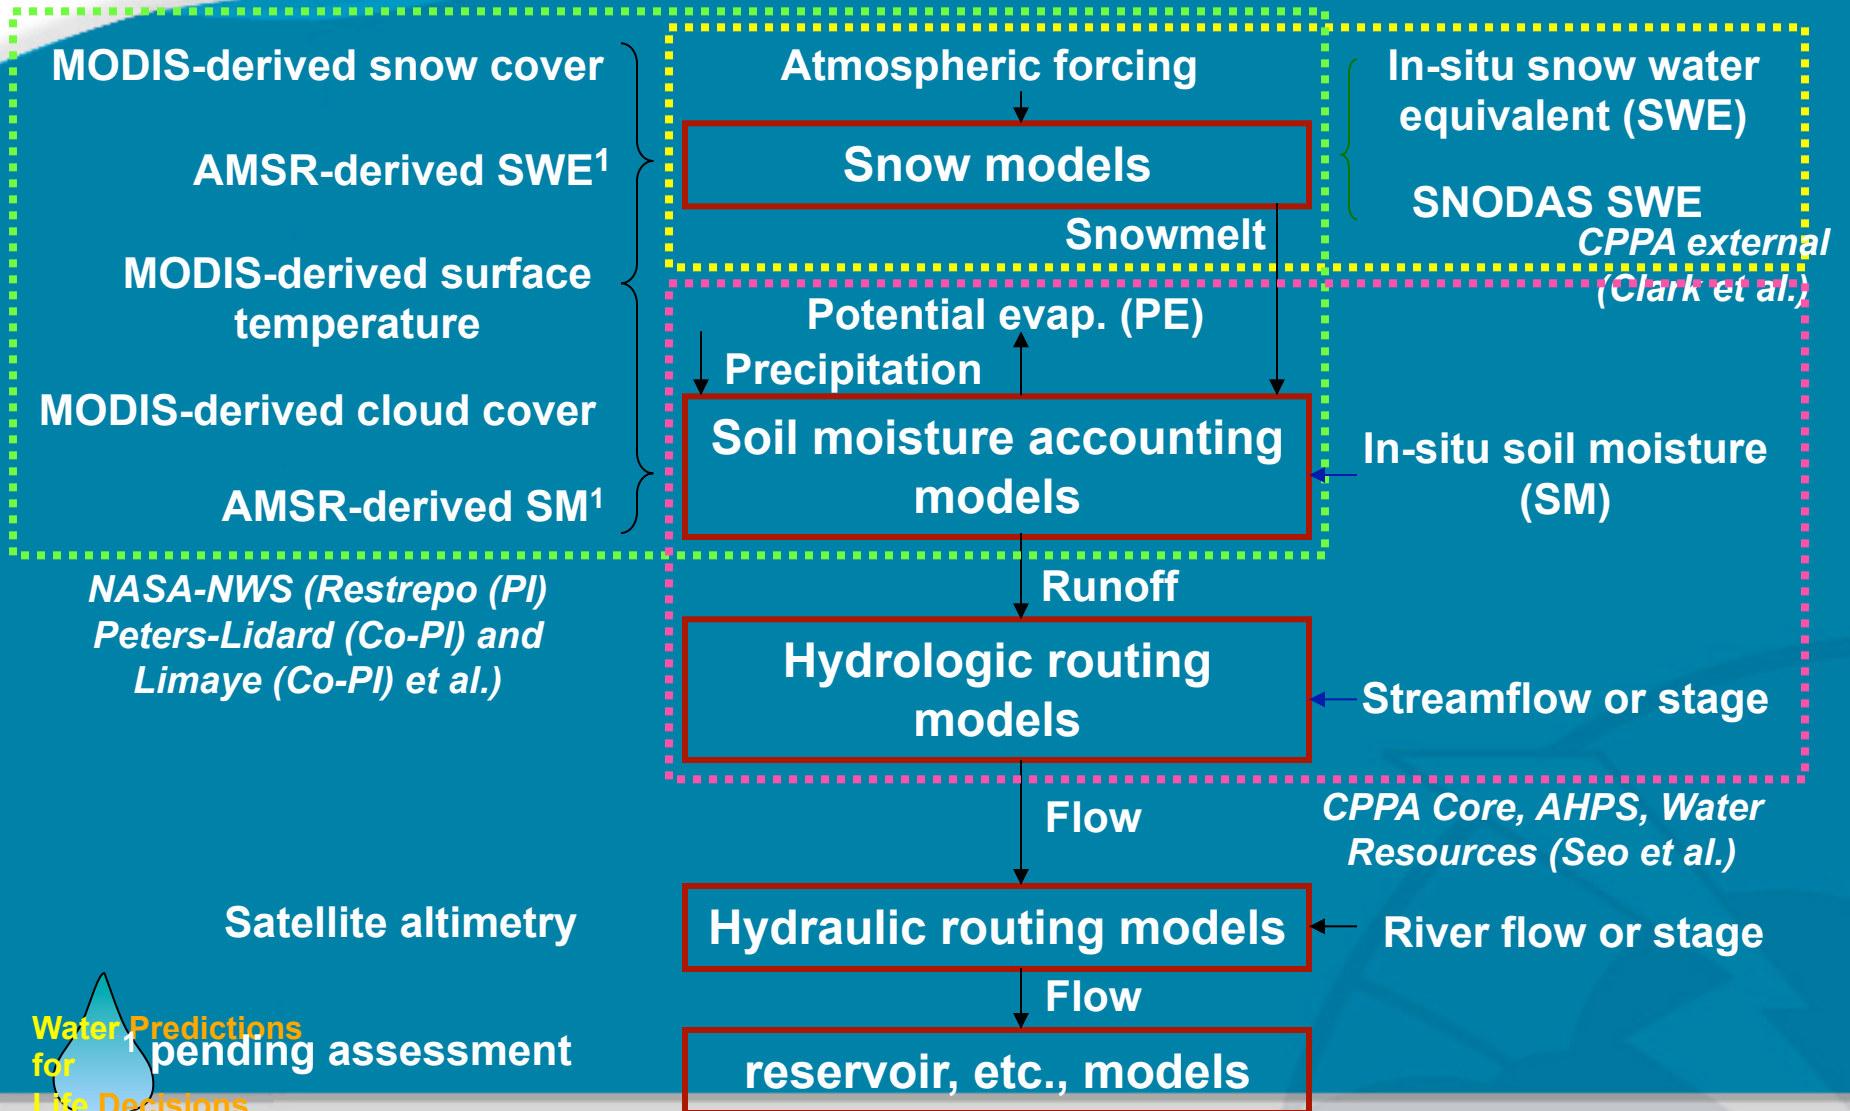

Improved accuracy,
Reliable uncertainty estimates,
Benefit-cost effectiveness maximized

Water Prediction for Life Decisions

Ensemble Kalman Filter Assimilation of SWE- U. of Colorado, NIWA

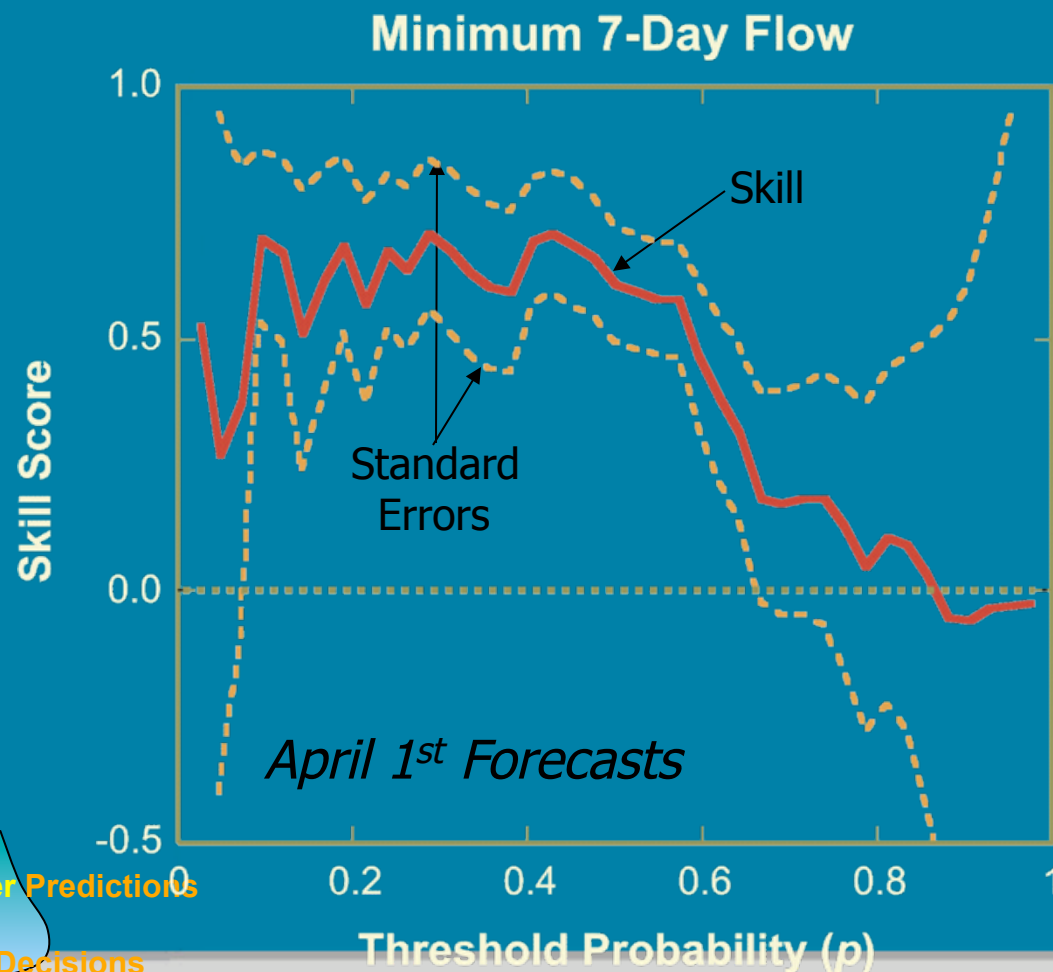

Ensemble Forecasting: Experimental Ensemble Forecasting System

Streamflow Forecast Verification

- The 2007 BAMS article by Welles *et al.* “Hydrologic Verification: a call for action and collaboration” clearly showed the need for hydrologic verification
- The Department of Commerce also requested a formal hydrologic verification program
- The only way to know if all the improvements to hydrologic forecasting mentioned earlier are paying off is by having a comprehensive verification system
- OHD, in collaboration with the U. of Iowa, is already developing such a system. It comprises
 - Data Archiving, including forecaster modifications
 - Computing Verification Metrics
 - Uncertainty Analysis
 - Diagnostic and Prognostic Verification
 - Communicating results

Ensemble Forecast Skill- Iowa Institute of Hydraulic Research

Skill depends on the threshold

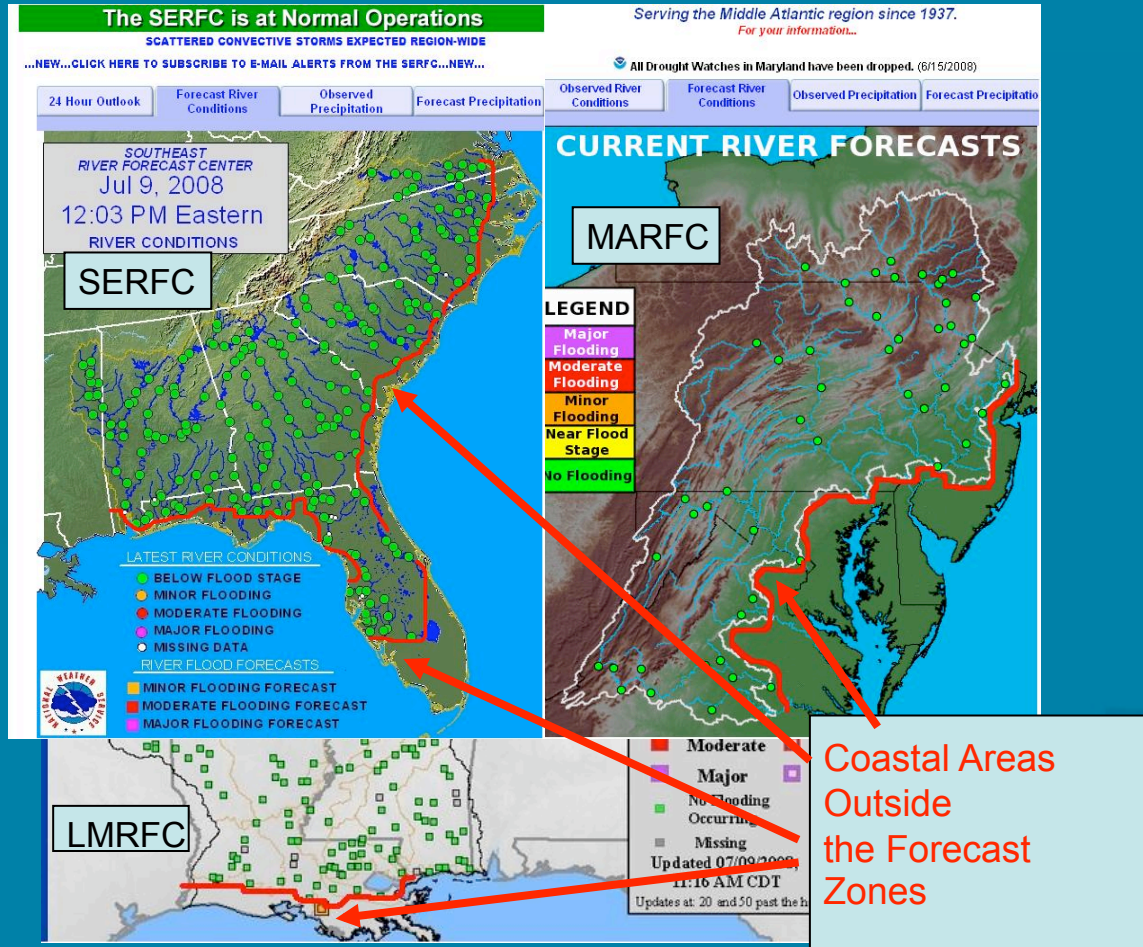

Uncertainty is greater for extremes

Summary measures describe attributes of the function

Hydraulics Group

- Where we want to be:
 - Integration of river models with estuary/ocean models
 - Use of 2Dimensional models where required
 - Coupled Surface-groundwater models
 - Water quality forecasting models: temperature, contaminants, nutrients

Hydrologic Forecasting in the Coastal zone

Part II: The Community Hydrologic Prediction System CHPS

Pedro Restrepo
Senior Scientist
Office of Hydrologic Development
National Weather Service

Earth Systems Research Laboratory
April, 2009

Why CHPS?

NWSRFS is a great architecture that was developed for use on mainframe computers

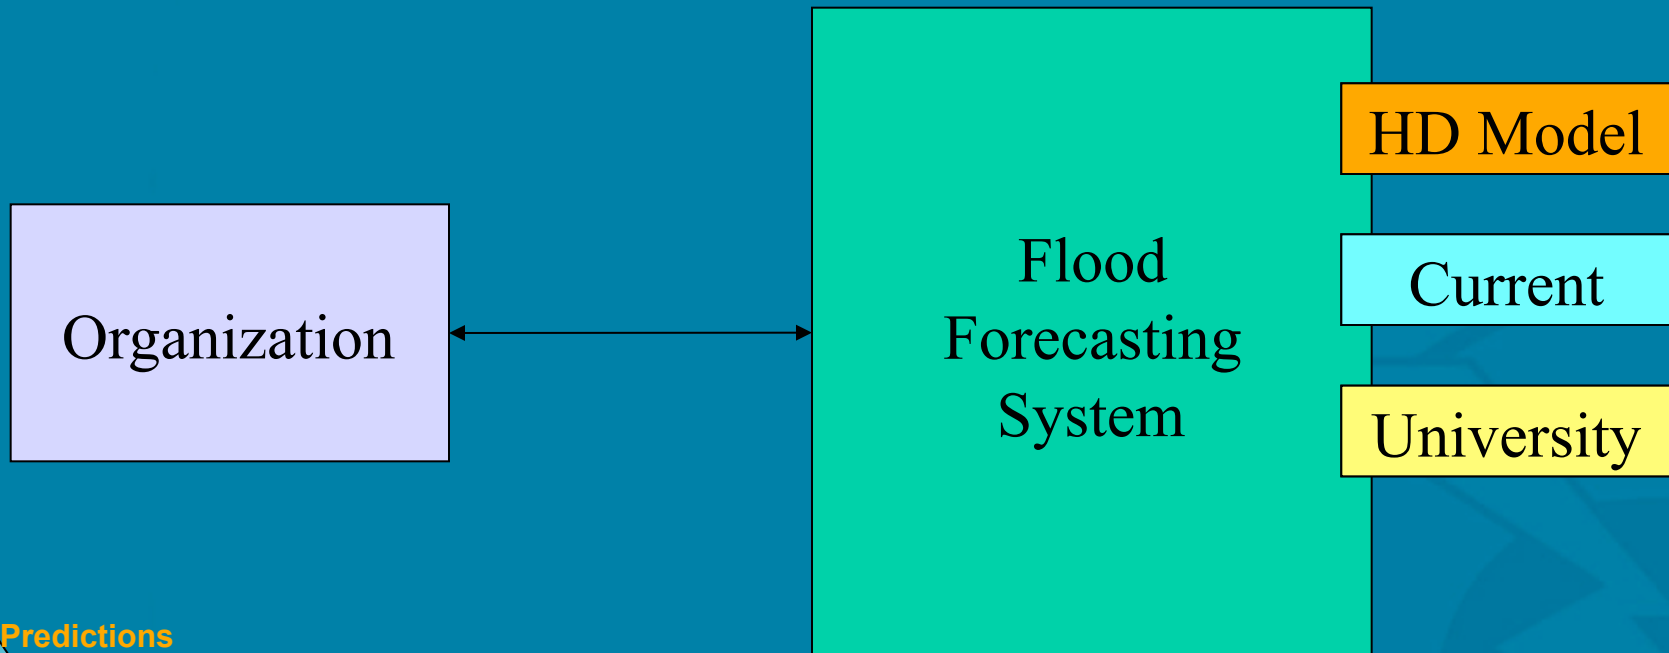

- lacks modern modularity
- difficult to add new models and techniques
- inhibits collaboration and research to operations
- very fast

CHPS will allow:

- greater ease in implementing new models
- greater collaboration with agency partners, universities, international community
- probably not as fast

Open System...

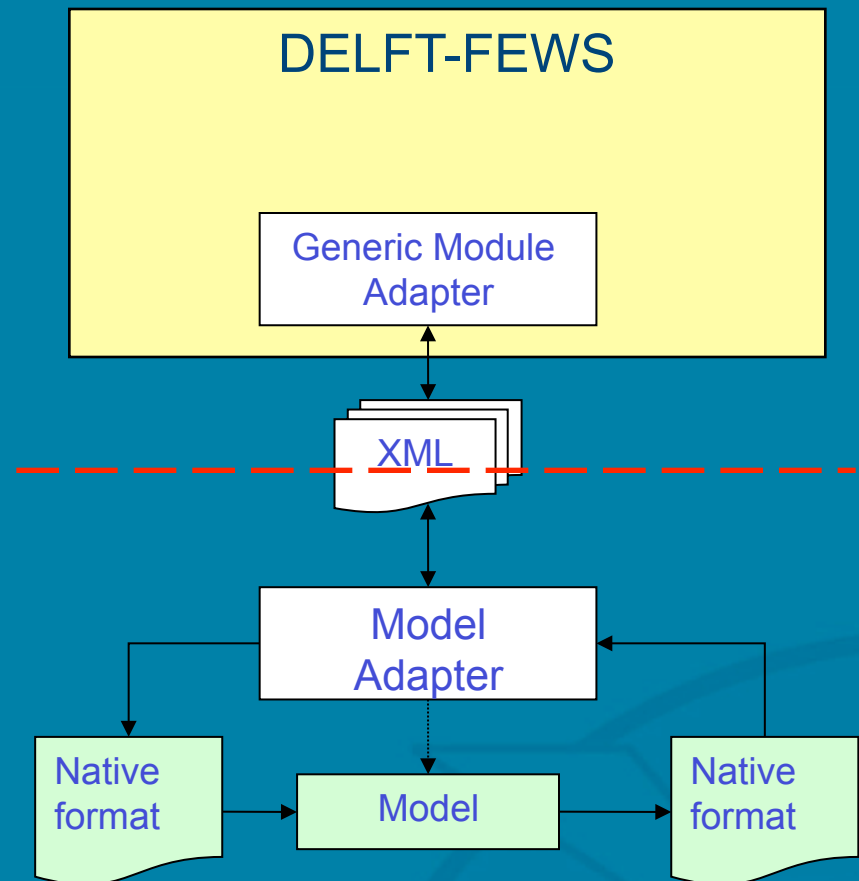

- No implications when introducing new model concepts
- Maintain current models/investments
- Easily introduce new advances

Open interface to models

No model intelligence in
DELFT-FEWS

Model intelligence vested in
model adapter

Implementation Strategy

Clear planning and execution

- Gap analysis for essential operations
 - Use of existing calibrated parameter sets is essential
- Preprocessing and post-processing utilities
- AWIPS II integration
- Staff training
- Change in conditions of work (NWSEO)
- Technical support
- RFC contributions (individual, groups, regions)
- Many others...

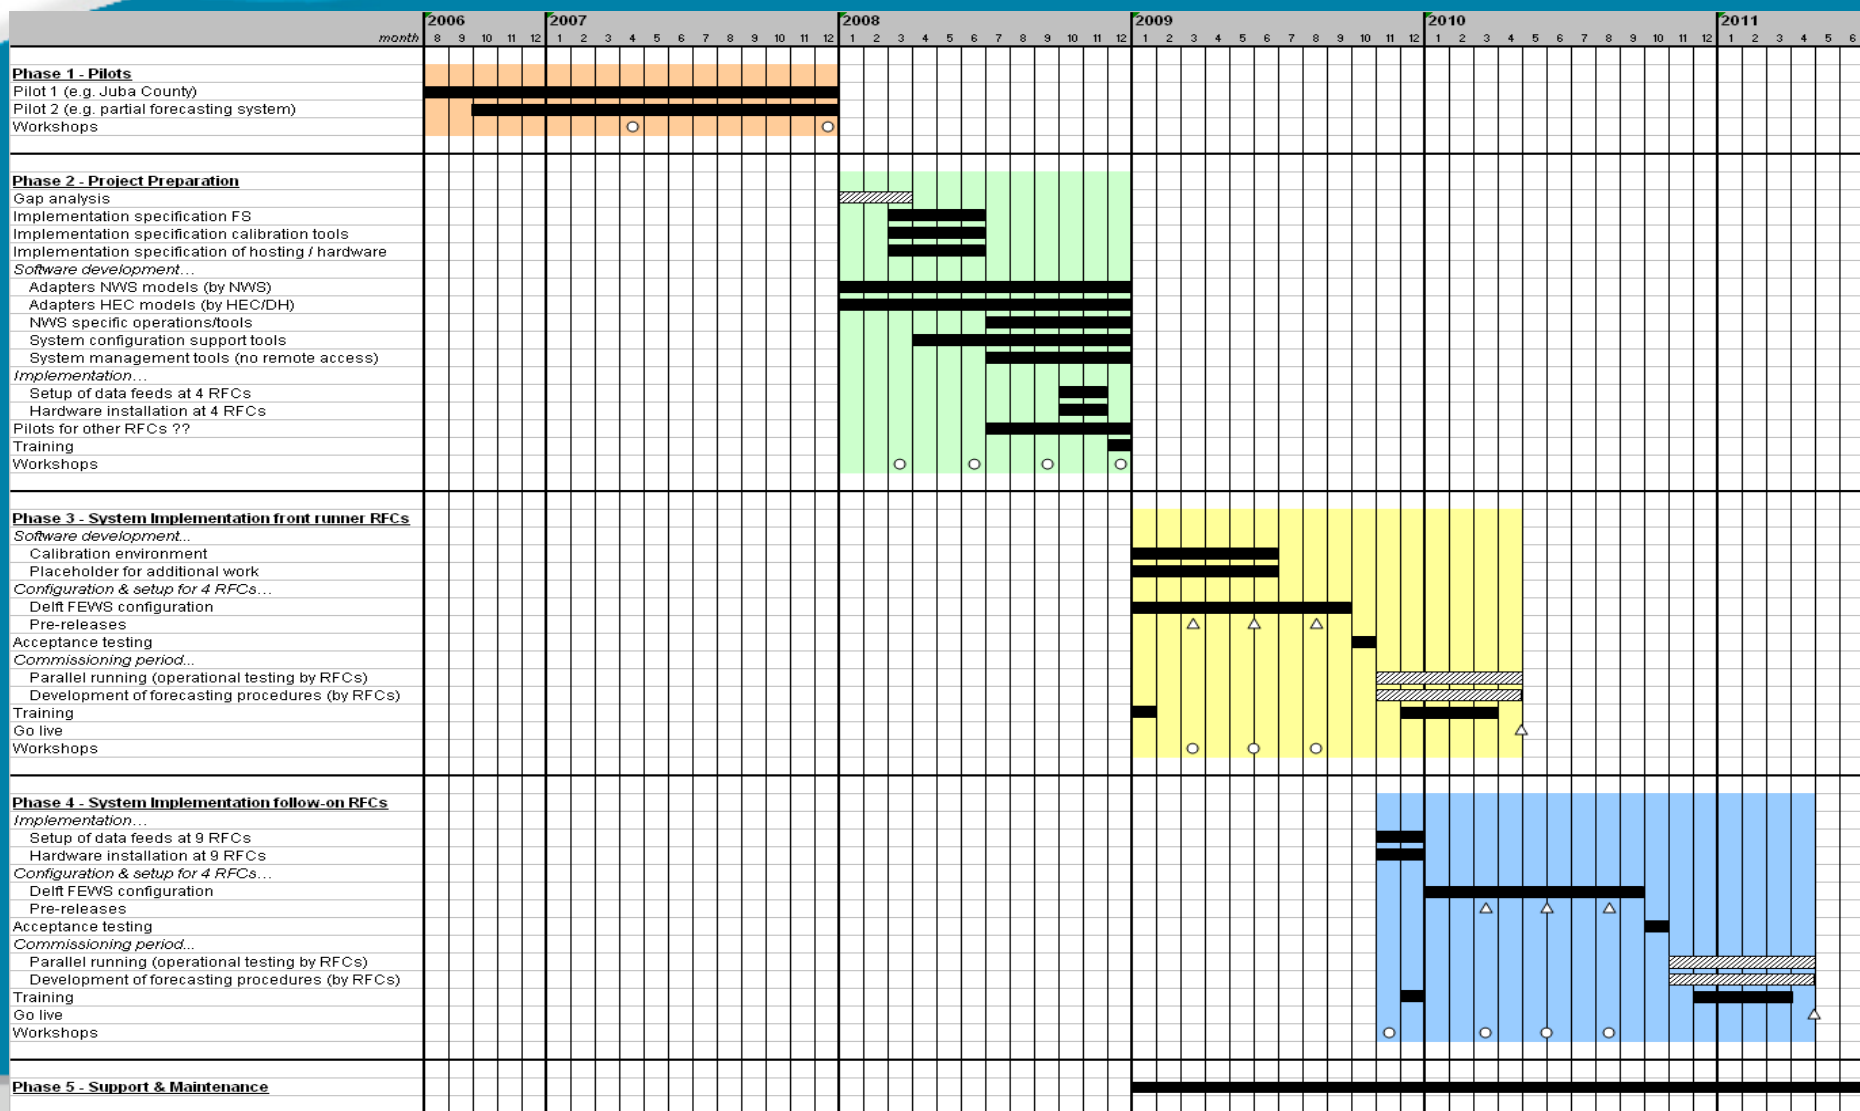

Implementation Strategy

Two tiers of deployment

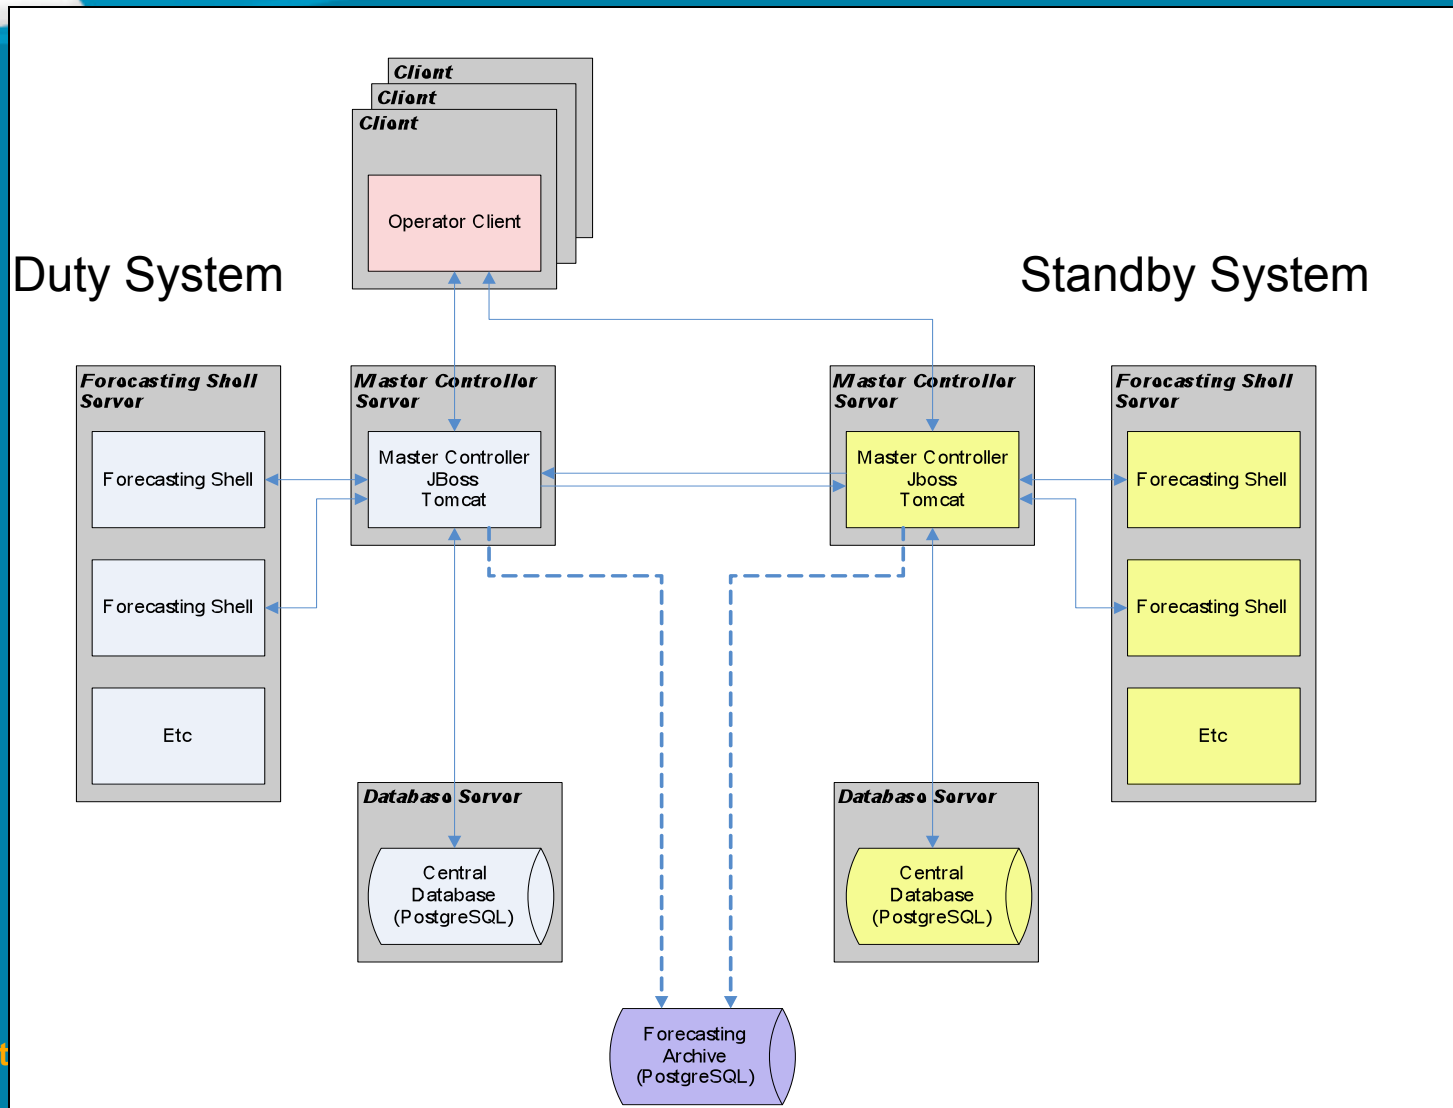

- CAT RFCs (AB, CN, NE, NW)
 - Initial hardware delivery in October 2008
 - Initial migration software and training in January 2009
 - Operational hardware delivery summer 2009
 - Parallel operations by October 2009
- Remaining 9 RFCs
 - Initial hardware delivery in October 2009
 - Migration/Systems training – Fall 2009
 - Migration begins January 2010
 - Parallel operations by October 2010

RFCs not required to drop NWSRFS until “fully ready”

National Weather Service

Backup Slides

National Research Council Reports

- *Assessment of Hydrologic and Hydrometeorological Operations and Services, (1996)*
 - Recommends that the NWS develop a formal, long-term plan for hydrologic science research, which is part of an ongoing dialogue between NWS headquarters and its field offices as to the most appropriate research and product development for hydrologic services.
- *Toward a new Advanced Hydrologic Prediction Service (AHPS) (2006)*
 - AHPS developers are encouraged to work closely with satellite precipitation groups to ensure that AHPS hydrologic requirements for precipitation are considered in other federal activities, such as the National Aeronautics and Space Administration's Global Precipitation Measurement mission.
 - The NWS should strengthen quantitative precipitation estimation (QPE) and quantitative precipitation forecasts (QPF) for hydrologic prediction through an end-to-end evaluation that assesses QPE/QPF quality and impacts on flood and streamflow products for basins of diverse size and topography.
 - The NWS should strengthen connections between DMIP Phase I/DMIP Phase II and AHPS goals.
 - The NWS should clarify the criteria and decision-making process for selecting the next generation of hydrologic model(s) for AHPS, using an advisory group that involves modeling experts from inside and outside of the NWS to ensure that the state-of-the-art modeling advances are incorporated objectively into NWSRFS.
 - The NWS should invest in the next generation of NWSRFS that includes a flexible framework that allows alternative models, methods, or features that can be tested, verified, and implemented expediently. A total redesign of the NWSRFS is needed for AHPS to fulfill its scientific and technical goals.

National Research Council Reports

- *Completing the Forecast: Characterizing and Communicating Uncertainty for Better Decisions Using Weather and Climate Forecasts. (2006)*
 - OHD should implement operational hydrology databases that span a large range of scales in space and time. The contribution of **remotely sensed and onsite data and the associated error measures** to the production of such databases should be delineated.
 - OHD should organize **workshops with participation from all sectors of the Enterprise** to design alternatives to the AHPS ensemble prediction system components and develop plans for intercomparisons through retrospective studies, demonstration with operational data, and validation, and for participation in testbed demonstration experiments.
 - OHD should develop methods for **seamlessly blending short-term (weather) with longer-term (climate) ensemble predictions** of meteorological forcing within the operational ensemble streamflow prediction system. This will require NCEP model output downscaling and bias adjustment, and real-time data availability.

Outline

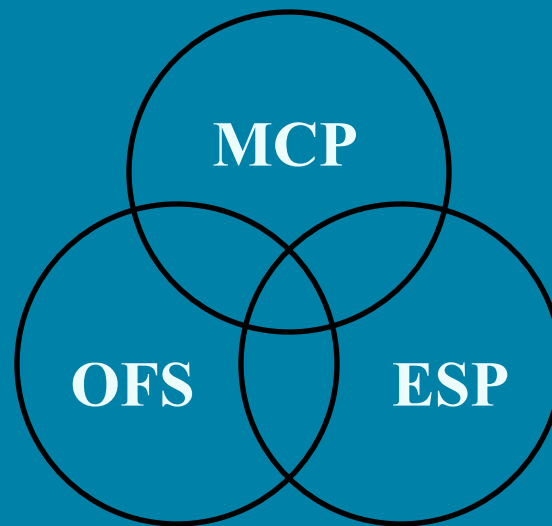

Background and history
Why are we doing this?
What are we doing?
How are we doing it?
When will we do it?
Samples of existing interface displays

How can this mesh with USACE efforts?

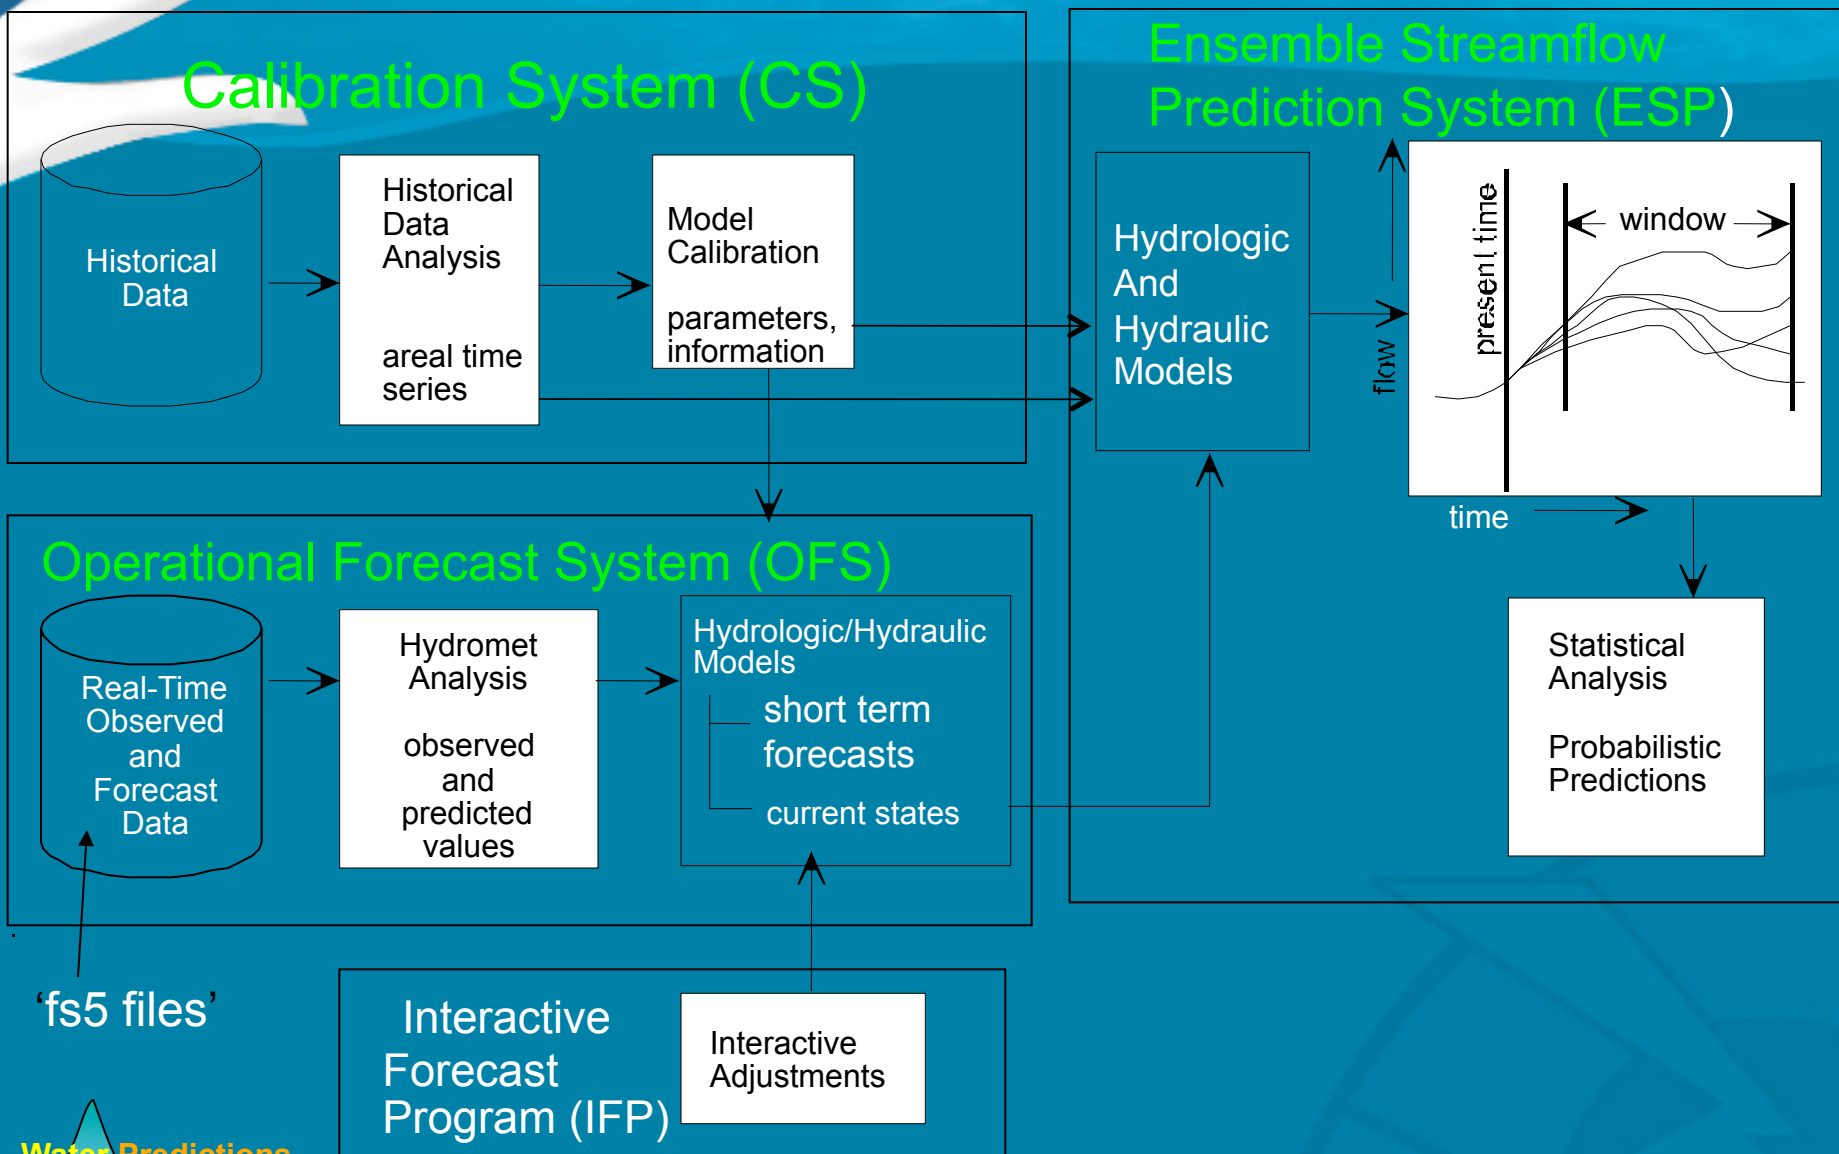

National Weather Service River Forecast System

Operates in 3 integrated modes.

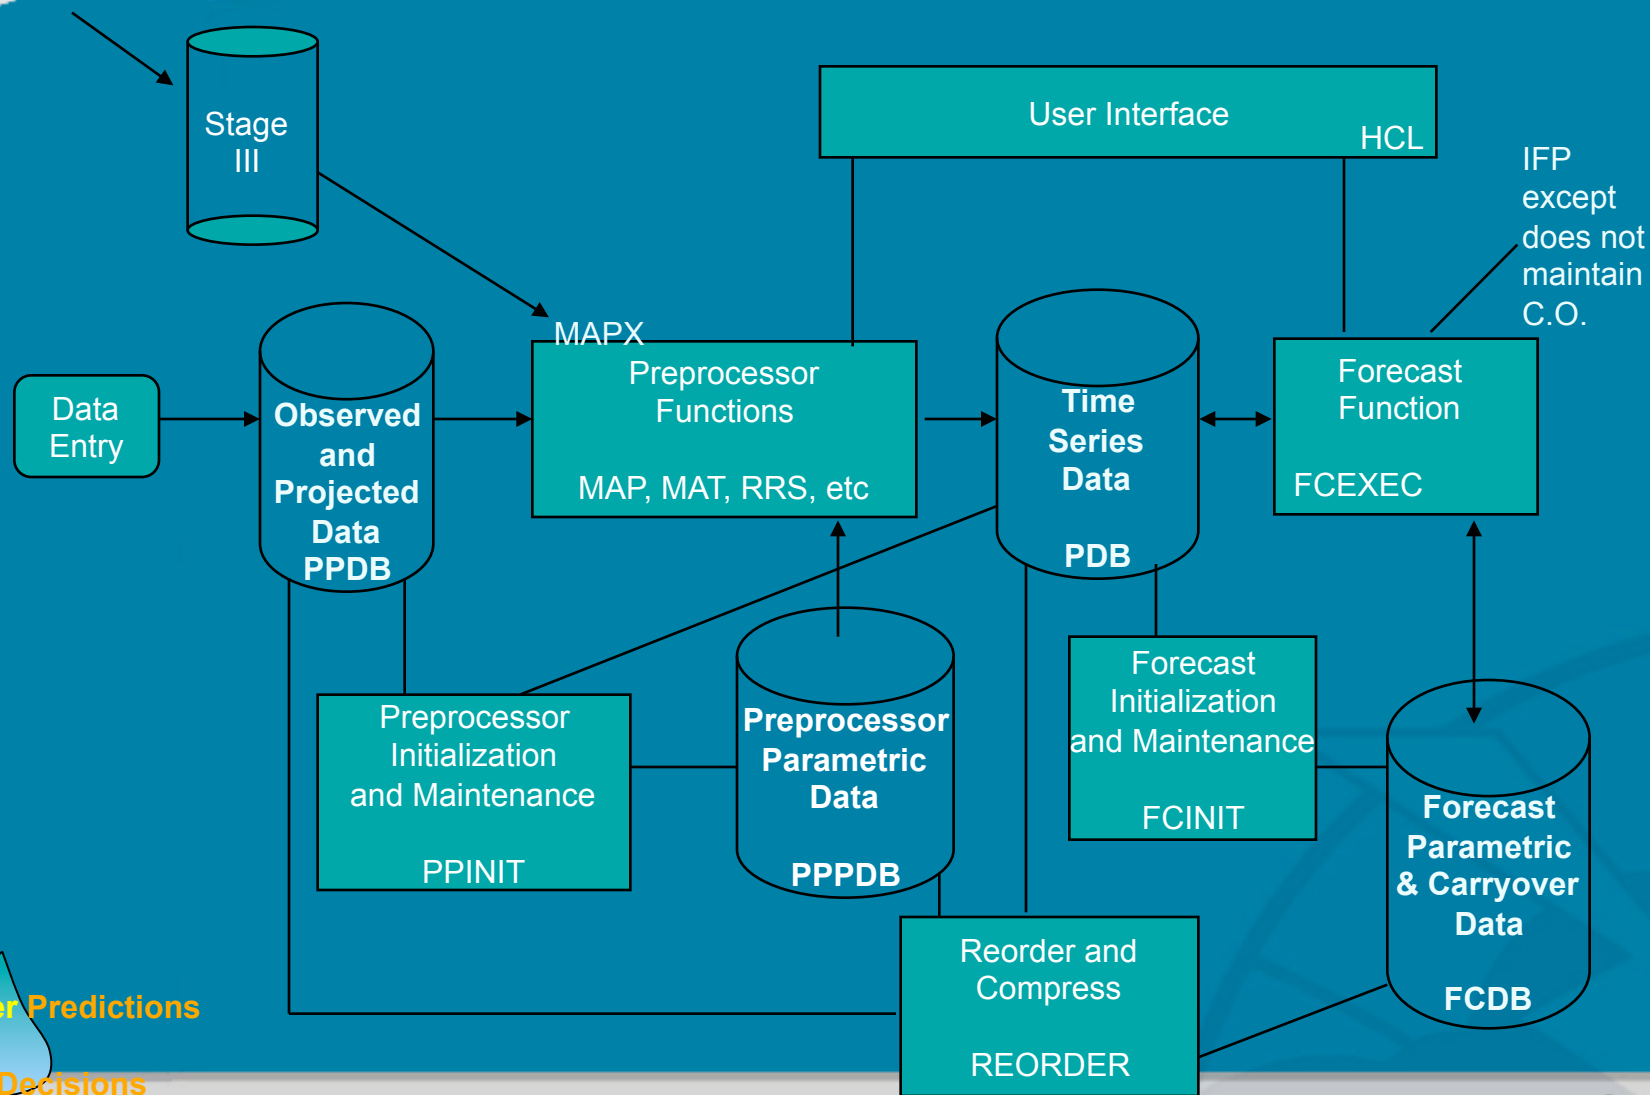

- Calibration <== parameter estimation
- Operational <== short term deterministic forecasts
- Ensemble <== longer term forecasts

NWSRFS

NWSRFS - OFS

Development Time Line

George Smith (NWS/OH) presented the IHFS (precursor to CHPS) at the April '96 DOH Workshop

OHD initiated exploration in '03

- Infrastructure analysis
- Several candidates considered including Delft-FEWS in Oct '05

CAT (CHPS Acceleration Team) formed at NHIC meeting in Jan '06 to accelerate pursuit of CHPS

- AB, NC, NW volunteered to work w/ OHD. CN later drafted.
- Criteria established through evaluation of NWSRFS strengths and weaknesses (Apex facilitation, available from HSEB)
- Evaluate Delft-FEWS as a CHPS candidate

Delft-FEWS Prototype Evaluation

Initiated Oct '06

- Facilitated by OHD, Apex, RTi, and WL-Delft Hydraulics
- NWRFC and NCRFC implementation
 - Strategy to include basic functionality (including SAC_SMA) but use surrogate FEWS models/functions/displays
- Apr '07 (NWRFC) workshop to review results
 - “Very promising”, but more evaluation needed...
 - » MODS-like capability
 - » Client-Server application
 - » Integration of SNOW-17
 - » Displays with English Units

FEWS Prototype Evaluation

Follow-on work to address Apr '07 concerns

- NW, NC, and AB RFCs. CN for ResSim project.
- Dec '07 (NCRFC) workshop to review results
 - Solid progress on MODs capability
 - Client-Server demonstrated
 - SNOW-17 integration easier than expected
 - Display units mostly taken care of
 - ESP capabilities demonstrated and discussed
 - Followed by training on FEWS configuration

FEWS is currently running and identically configured at AB, CN, NC, and NW RFCs.

CAT Recommendation

Approved by Gary Carter – January 17,

Proceed with implementation of Delft-FEWS as the CHPS software infrastructure.

Target operational use at all RFCs within 3 years.

Resource implications

- Major OHD focus
- Terminate “dead-end” NWSRFS enhancements
- Align/re-evaluate HSMB-oriented “Research to Operations” (RTO) projects

Retain CAT with a revised implementation charter

Implementation Strategy

Port models that require calibration

- BASEFLOW, SARROUTE, CONS_USE, LAG/K, LAY-COEF, TATUM,
- TIDEREV, MUSKROUT, RES-J, RSNWELEV, SNOW-17, CHANLOSS,
- STAGE-Q, SSARRESV, STAGEREV, UNIT-HG, RES-SNGL, SAC-SMA

Create adapters for several new models (e.g. HEC-RAS)

Rely existing data and display utilities with identified enhancements

- CLEAR-TS, CHANGE-T, ADD/SUB, SET-TS, MULT/DIV, NOMSNG, MERG-TS,
- MEAN-Q, WEIGHT-TS, LOOKUP3, LOOKUP, DELTA-TS, ADJUST-Q,
- ADJUST-H, ADJUST-T, PLOT-TS, PLOT-TUL

Implementation Strategy

Provide for forecaster run-time modifications

- IGNORETS, FMAP, SSARREG, MFC, RRICNG, SWITCHTS, TSCHNG,
- CHGBLEND, WECHNG, RAINSNOW, RRIMULT, WEADD, TSADD, SACCO,
- AESCHNG, ROMULT, SETMSNG, UADJ, ROCHNG, UHGCHNG, SETQMEAN,
- UHGDATE, QCSHIFT, QPSHIFT, HECRAS

Provide for existing level of ensemble operations, products, and services

- Port ESPADP to use FEWS architecture and data resources
