NOAA Technical Memorandum NMFS

The National Marine Fisheries Service's Alaska Fisheries Science Center uses the NOAA Technical Memorandum series to issue informal scientific and technical publications when complete formal review and editorial processing are not appropriate or feasible. Documents within this series reflect sound professional work and may be referenced in the formal scientific and technical literature.

The NMFS-AFSC Technical Memorandum series of the Alaska Fisheries Science Center continues the NMFS-F/NWC series established in 1970 by the Northwest Fisheries Center. The NMFS-NWFSC series is currently used by the Northwest Fisheries Science Center.

ABSTRACT

The eastern Bering Sea (EBS) bottom trawl survey has been conducted annually since 1975 by the National Marine Fisheries Service's Alaska Fisheries Science Center's Resource Assessment and Conservation Engineering Division. The purpose of this survey is to collect data on the distribution and abundance of crab and groundfish resources in the eastern Bering Sea. These data are used to estimate population abundances for the management of commercially important species in the region. In 2009, 376 standard stations were sampled and an additional 32 stations were resampled in Bristol Bay at the end of the standard survey to adequately account for female red king crab maturity. The 2009 point estimates (± 1.96 SE) for legal-sized males (millions of crab) of commercial crab stocks in the EBS were as follows:

<u>2009 legal-sized males</u>	
Bristol Bay District red king crab (<i>Paralithodes camtschaticus</i>)	8.5 ± 6.6
Pribilof District red king crab (<i>P. camtschaticus</i>)	0.7 ± 0.9
Pribilof District blue king crab (<i>P. platypus</i>)	0.07 ± 0.08
St. Matthew Island Section blue king crab (<i>P. platypus</i>)	1.4 ± 0.7
Southern Tanner crab (<i>Chionoecetes bairdi</i>), all Districts	6.9 ± 2.8
Snow crab (<i>C. opilio</i>), all Districts	371.8 ± 86.4
Snow crab (<i>C. opilio</i>), all Districts ≥ 4.0 inches	130.1 ± 42.4

INTRODUCTION

Survey History and Purpose

The eastern Bering Sea (EBS) bottom trawl survey has been conducted by the National Marine Fisheries Service's (NMFS), Resource Assessment and Conservation Engineering (RACE) Division of the Alaska Fisheries Science Center (AFSC) since 1971. Since 1975, annual surveys have been conducted and were expanded to include Bristol Bay and the majority of the Bering Sea continental shelf with the original purpose of assessing potential resource impacts of offshore oil development (Pereyra et al. 1976). The annual collection of data on the distribution and abundance of crab and groundfish resources provides fishery-independent estimates of population abundances and biological data for the management of commercially important species in the EBS. The crab species that have historically been assessed during the survey include: red king crab (*Paralithodes camtschaticus*), blue king crab (*P. platypus*), southern Tanner crab (*Chionoecetes bairdi*), snow crab (*C. opilio*), and hair crab (*Erimacrus isenbeckii*). The common name for *C. bairdi* has recently changed from Tanner crab to southern Tanner crab (McLaughlin et al. 2005); hereafter Tanner crab will be used to refer to *C. bairdi* in this document. Golden king crab (*Lithodes aequispina*) are periodically encountered on the bottom trawl survey, although the center of their distribution is at depths beyond the range of this survey. Since 1988, 376 standard stations have been included in the survey covering a 140,350 square nautical mile (nmi²) area of the EBS with station depths ranging from 20 to 150 m (Fig. 1).

In 2001 and from 2004 to 2006, an additional 29 stations were sampled northeast of the standard survey area to assess the northern distributions of snow crab and walleye pollock (*Theragra chalcogramma*). These data were not incorporated into the standard survey assessment in those years. These northeastern 29 stations were not sampled in 2009.

Beginning in the mid-1990s, a station producing ≥ 100 legal-sized male red king or Tanner crab has been considered a “hot spot”. At each hot spot, multiple tows were made within the station area and all crab species caught in tows were sampled identical to the standard survey tow protocol described in Methods section.

The annual EBS bottom trawl survey begins in the northeast section of Bristol Bay in early June. Approximately 10 to 12 stations are sampled each day from two vessels. The standard survey is completed in late July at the western edge of the survey grid northwest of St. Matthew Island. In some years when the reproductive cycle of red king crab has not progressed due to colder water temperatures, a small portion of the inner Bristol Bay area is resampled after the conclusion of the standard survey (see Results: Bristol Bay District Red King Crab section).

Eastern Bering Sea Crab Stock Assessment Process

Bering Sea and Aleutian Islands (BSAI) king and Tanner crabs included in the federal fisheries management plan in the eastern Bering Sea are managed by the Alaska Department of Fish and Game (ADF&G) with federal oversight by NMFS (NPFMC 1998). The annual Stock Assessment and Fishery Evaluation (SAFE) report prepared by the North Pacific Fishery Management Council's Crab Plan Team for the king and Tanner crab fisheries of the Bering Sea and Aleutian Islands region provides current biological and economic data associated with these species. The Crab Plan Team reviews the survey, biological, economic, and modeling data to recommend biological reference points associated with the status of stocks. Finally, NMFS determines the procedure for setting overfishing levels (OFLs) and ADF&G sets the annual Total Allowable Catch or Guideline Harvest Level for each crab stock. Crab stocks are defined by ADF&G management units for king crab and Tanner crab species (Bowers et al. 2008). Red king crab are split into Bristol Bay and Pribilof Islands stocks, blue king crab are split into Pribilof Islands and St. Matthew Island stocks for management purposes, while Tanner and snow crab are split into separate management units defined by the ADF&G Board of Fish using 166°W and 173°W as the boundary for each east and west unit, respectively. Results of the 2009 EBS bottom trawl survey are presented for these crab stocks as defined by the management units.

This report summarizes the 2009 survey results for commercially important crab resources in the EBS. Numbers presented are trawl survey estimates of relative population abundance and do not represent absolute abundance. More detailed survey design and fishing gear specifications in addition to the number and weights of the groundfish species sampled at each standard station during this survey will be reported in a separate NOAA Technical Memorandum (e.g., Lauth and Acuna 2009).

METHODS

Survey Area and Sampling Logistics

The 2009 survey was conducted onboard the chartered fishing vessels FV *Arcturus* and FV *Aldebaran*, beginning 2 June in Bristol Bay and moving westward to end at the shelf break on 19 July. The vessels sampled in close proximity during the standard survey and both returned to Bristol Bay to resample 32 stations between 27 and 30 July due to the delaying effects of cold water temperatures on the red king crab reproductive cycle (see Results: Bristol Bay District Red King Crab).

The survey stations are divided into multiple districts, which are defined by ADF&G commercial crab management units (Fig. 2). Management units are defined by registration areas and districts, which are further divided into sections which have standard or high station

densities. Standard-density sections have stations centered in 20×20 nmi (37.04×37.04 km) cells while high-density sections include additional stations at the corners of the 20×20 nmi cells. Total area calculations for each stock management unit uses an area of 401 nmi 2 for each 20×20 nmi cell due to the use of a spherical projection of the grid surface in an area as large as the EBS. The king crab Registration Area T in Bristol Bay (south of $58^\circ 39'N$ and east of $168^\circ W$) is $54,536$ nmi 2 and consists of 136 stations. The king crab Registration Area Q in the Bering Sea is divided into the Northern District (north of $58^\circ 39'N$) and the Pribilof District (south of $58^\circ 39'N$ and west of $168^\circ W$). The St. Matthew Island Section of the Northern District is divided into two sampling areas: 1) a high-density $7,218$ nmi 2 area with 28 stations and 2) a standard-density $60,551$ nmi 2 area with 151 stations. The stations in the Pribilof District are divided into two sampling areas: 1) a high-density $10,025$ nmi 2 area with 41 total stations and 2) a standard-density $14,436$ nmi 2 area with 36 stations.

The fishing gear used in 2009 was identical to that of EBS annual bottom trawl surveys since 1982 with both vessels fishing a standard 83-112 Eastern otter trawl with an 83 ft (25.3 m) headrope and a 112 ft (34.1 m) footrope (Lauth and Acuna 2009). The trawls on each vessel were rotated every 25 consecutive tows to mitigate potential impacts due to changes in net configuration from fishing. Each tow was approximately 0.5 h in duration and 1.5 nmi (2.8 km) in length at a speed of 3 knots (1.54 m/sec) and conducted in strict compliance with NMFS bottom trawl protocols established by the National Oceanic and Atmospheric Administration (Stauffer 2004).

Net mensuration equipment was used to monitor the net's fishing performance during each tow (Lauth and Acuna 2009). A bottom contact sensor (inclinometer) was attached to the center of the footrope to measure bottom contact of the net at 1-second intervals. The net mensuration system also consisted of an acoustic sensor attached to the headrope and two sensors attached to the port and starboard dandylines to measure net behavior (net height and width) during trawling operations. The bottom contact of the footrope and GPS data were used to calculate distance fished. Fishing power was assumed to be equal between the two vessels.

Surface and bottom water temperatures along with temperature-depth profiles were collected at 6-second intervals throughout the duration of each tow using a Seabird SBE-39 bathythermograph continuous data recorder (Sea-Bird Electronics Inc., Bellevue, WA) attached to the headrope of the net. The temperature measurement range of the SBE-39 is -5 to 35 ± 0.002 °C with pressure sensors measuring to $1,000 \pm 1$ m and calibrated every year by Sea-Bird Electronics. Bottom depth was also derived from this data by adding the net height from the net mensuration system to the headrope depth recorded by the SBE-39.

Biological Data Collection

All crab were removed from the catch, sorted by species and sex, and a total catch weight was obtained for each species. Tanner and snow crab hybrids are identified by a combination of characteristics including eyestalk color, curve of the epistome margin, and space between or shape of rostrum horns (Karinan and Hoopes 1971, Urban et al. 2002). Subsampling the total

catch of either *Chionoecetes* sp. crab occurred when an exceptionally large number of that species was caught in a tow. The weights of the sampled crab and non-sampled crab were recorded and an expansion factor was calculated to determine the final number of that species in the catch.

Individual crab carapaces were measured (± 1 mm) to provide a size-frequency distribution of each sample. Crab sizes are reported as carapace width excluding spines (CW) for Tanner and snow crab, and carapace length (CL) for all king crab and hair crab (Donaldson and Byersdorfer 2005). Carapace shell condition was assessed for each crab sampled and assigned to one of six classes according to specific criteria (0 = premolt or molting, 1 = soft and pliable, 2 = new hardshell both firm and clean, 3 = oldshell slightly worn, 4 = oldshell worn, 5 = very oldshell). All female crab abdomens were evaluated to determine reproductive condition based on the size of the egg clutch (0 = immature, 1 = mature female no eggs, 2 = trace to 1/8, 3 = 1/4, 4 = 1/2, 5 = 3/4, 6 = full) and the condition (0 = no eggs, 1 = uneyed, 2 = eyed, 3 = dead, 4 = empty egg cases) and color of the eggs (0 = no eggs, 2 = purple, 3 = brown, 4 = orange, 5 = purple-brown, 6 = pink).

Egg condition codes were assigned to assess the stage in the molt-mate cycle of mature female red king crab during the survey, where the presence of eyed embryos, empty egg cases, or absence of eggs (barren, hereafter) in mature sized females were indications of an incomplete cycle while mature females brooding uneyed embryos indicated completion of the cycle. The ratio of females with eyed embryos, empty egg cases, and old shell barren to uneyed embryos was derived as a measurement of the molt-mate cycle progression during the survey.

Chela height and carapace width measurements (± 0.1 mm) were collected from a subsample of male *Chionoecetes* spp. crab caught at each station to determine morphometric molt to functional maturity based on the chela height to carapace width ratio (Stevens et al. 1993, Tamone et al. 2007). Functional maturity in male *Chionoecetes* spp. can be separated into two morphometric groups, small claw and large claw. The historical dataset that defines functional maturity was updated with 1,300 *C. opilio* measurements in 2009.

All crab carapaces were scanned for evidence of bitter crab syndrome or black mat fungus, which was recorded when present, and crabs with bitter crab syndrome were set aside for further testing by the Fisheries Resource Pathology Laboratory at the AFSC in Seattle, WA.

Crab Abundance Estimates

Crab density (number/nmi²) was estimated at each station for legal, pre-recruit, and small males as well as large and small females of each stock (Table 1). The area swept by the trawl (nmi²) was calculated as the product of the distance traveled while the net had bottom contact by the mean net width over the duration of the tow. Prior to 2009, a fixed width of 50 ft (15.2 m; 0.008 nmi) was used in the area swept calculation to maintain consistency with historical calculations of crab abundance. The effective width of the trawl typically ranges from 48-60 ft when towing at a speed of 3 knots (Weinberg 2003), and changes with the depth of the tow due

to changes in scope of the trawl wire (Rose and Walters 1990). Beginning in 2009, crab densities were calculated using the mean net width recorded for the duration of each tow and a mean net width-inverse scope regression relationship was calculated when net width values were not recorded during a tow (Rose and Walters 1990). Distance traveled by the trawl was determined from ship positions recorded at the beginning and end of each tow using GPS equipment.

The crab population abundance within a district was estimated by averaging crab densities from all stations within the defined district and multiplied by the total area of the district specific to that stock. In this document, population abundance estimates are presented based on both the variable and fixed net width to compare with the historical estimates. Total population abundances were calculated using a stratified design based on management units (standard-density, high-density, and ADF&G defined districts). Population abundance estimates were calculated in each stratum and then summed among strata. Variance of the total population abundance estimate was calculated by summing the variance of each stratum. The 95% confidence intervals were calculated using the standard error of the total population multiplied by 1.96.

In the Bristol Bay District, two tows were completed at A04 due to the final position of the Z04 tow which only has limited area within the trawlable depth range. At stations with multiple tows (i.e., station A04 or hot spots), a single estimate of crab density was used by averaging all tows within the station prior to calculating total crab abundance.

In 2009, the additional data from stations resampled in Bristol Bay after the standard survey were handled differently for red king crab males and females. The total population abundance for males included the average of the original standard and the resampled stations. Due to the movements of females into the sampling area between the standard survey and the resampling event, only females from the resampled stations are included in total abundance estimate.

Note that population abundance estimates are point estimates and have substantial uncertainty due to the expanse of the area being sampled and the distributions of the resource. These point estimates are least precise for small crabs due to gear selectivity, and for females of some stocks due to differential crab behavior. However, for consistent analyses and due to a lack of available data, catchability is assumed to be near or equal to one.

Note that this report includes 2 revisions to the historical time series in Tables 3 and 5 through 10: 1) the 1997-2002 abundance estimates reported for all species are approximately 1-5% higher compared to values published prior to 2003 (Rugolo et al. 2003) as a result of a change in the total area specific to the district used in the abundance estimation and 2) a correction was made in the calculation of distance fished for the years 2001-2003 from a curved path to a straight line resulting in a negligible change in abundance estimates compared to values published prior to 2004 (Rugolo et al. 2006).

RESULTS

Survey Overview and Ancillary Data Collection

The 2009 EBS bottom trawl survey consisted of 408 bottom trawls (376 standard survey stations, and 32 resampled stations in Bristol Bay) conducted from 2 June to 30 July 2009 over an area of approximately 140,350 nmi². The latitude and longitude of the midpoint of each successful tow along with the duration (hr), distance fished (km), bottom depth (m) and bottom temperatures (°C) are listed in Appendix A. The mean distance fished was 1.56 nmi (2.88 km, SD = 0.21 nmi) with a range of 0.85 to 1.83 nmi (1.57 to 3.38 km) and the mean fishing time was 31.4 minutes (0.52 hr, SD = 0.04). The fishing depth of the 83/112 otter trawl net ranged from 19 to 171 m with a mean gear depth of 79 m (SD = 33.6). There were no hotspot protocols enacted on any station during the 2009 EBS bottom trawl survey.

Bottom temperatures measured during the survey ranged from -1.7° to 6.3°C (Fig. 3). These temperatures were collected at each station as the survey progressed from east to west, beginning on 2 June 2009 in the northeast corner of Bristol Bay and moving westward towards the shelf edge to finish at station N28 on 19 July 2009. A cold pool of water < 2°C was prevalent between the 50 m and 100 m isobaths in the middle shelf and Bristol Bay area with cool temperatures persisting at the nearshore stations along the Alaska Peninsula. Warmer bottom temperatures were evident at the shelf break in the southwestern area of the survey area and in shallow areas near Nunivak Island, while cold water temperatures persisted in the northwestern area between the 100 m and 200 m isobaths and the waters surrounding St. Matthew Island. In 2009, the mean bottom water temperature during the first survey leg (2 to 16 June 2009) was 1.5°C (SD = 0.5) which was colder than the mean bottom water temperature during the first survey leg in 2008 at 1.4°C (SD = 0.7), as well as 1.8°C (SD = 0.9) and 2.2°C (SD = 0.7) in 2007 and 2006, respectively. The mean water temperatures at the 32 stations resampled in July ranged from 2.3°C to 8.1°C, with an average of 4.5°C (SD = 1.5) (Fig. 4).

In 2009, the mean net width per tow ranged from 46 ft (14.0 m) to 66 ft (20.1 m) and the average mean net width for all 376 successful tows was 56.4 ft (17.2 m) with a standard deviation of 1.05. Only 18 of 376 successful standard tows completed on the 2009 EBS bottom trawl survey fished with a mean net width of 50 ft or less.

Seven special projects were conducted in addition to the assessment survey to collect specific biological data from particular crab species (Table 2). Five of the projects originated from the AFSC Shellfish Assessment Program; investigating the reproductive potential of female red king crab by evaluating egg loss and the presence of non-viable eggs during the incubation period, collecting specimens with rare or unusual pathological conditions, collecting hemolymph samples from *Paralithodes*, *Hyas*, and *Pagurus* spp. at randomly selected stations to monitor bitter crab syndrome and for population genetics, documenting any visual observations of bitter crab or black mat syndrome, and photographing invertebrate species to update the database for educational purposes. Data for two additional projects were collected for ADF&G and University of Alaska Southeast researchers to: 1) evaluate sperm reserves and clutch fullness in

Chionoecetes spp. as indicators of reproductive potential and 2) produce reproductive indices of male *C. opilio*.

A total of 132 egg clutches were collected and 41 live female red king crab were returned to the AFSC Kodiak Laboratory facility to evaluate seasonal and interannual variability in fecundity, assess clutch fullness indices as a tool for estimating fecundity, and determine if egg quality varies among females of different sizes. One *Telmessus cheiragonus* was collected for the rare pathological collection, while 311 male and female *Paralithodes* spp., 356 male and female *Hyas* spp., and 257 *Pagurus* spp. hemolymph samples were collected to monitor bitter crab syndrome and for population genetic assays. Black Mat was visually observed on 52 individual *C. bairdi* during the 2009 EBS trawl survey at stations A04, E18-E20, and G18 (Fig. 1), while digital photographs were taken throughout the survey of numerous invertebrate species for the digital imagery database. *Chionoecetes* spp. ($n = 1,037$) as well as immature male and female *C. opilio* ($n = 291$) and mature male *C. opilio* ($n = 43$) were collected for the ADF&G reproductive potential project to investigate growth and mating. Two hundred and seventy-seven *C. opilio* samples and 82 male *C. opilio* hemolymph samples were collected to support the University of Alaska Southeast crab reproduction project. All collections were completed within the guidelines stipulated by the ADF&G collection permits for each project.

Bristol Bay District Red King Crab

One objective of this multi-species bottom trawl survey is to assess the mature red king crab population by sampling after completion of the molt-mate cycle when mature females are carrying newly extruded, uneyed embryos (Otto 1986). Embryo development and larval hatching in female red king crab, followed by the molting and mating cycle, are delayed in years with cold bottom water temperatures (Shirley et al. 1990, Stevens and Swiney 2007). A delay in the molting and mating cycle is apparent in June, at the beginning of the EBS bottom trawl survey, by high numbers of oldshell mature females either brooding eyed embryos, which were fertilized from the previous season, or exhibiting pleopods with empty egg cases. In years with relatively warmer water temperatures, 94%-99% of the mature females in June carried uneyed embryos.

In years with colder than average bottom water temperatures, (1999, 2000, 2006, 2007, and 2008) a number of standard Bristol Bay stations were sampled in early June and again in late July to assess the percentage of ovigerous red king crab females which had recently completed the molting and mating cycle and extruded a new clutch of uneyed embryos. In 2009, it was necessary to resample 32 Bristol Bay stations in late July due to the low number of newly molted, ovigerous female with clutches of uneyed embryos encountered in early June. These resample stations were selected based on female red king crab abundance at these stations during the first sampling event and from expected distributions based on previous Bristol Bay surveys.

Red king crab were caught at 66 of the 136 stations in the Bristol Bay management district in 2009. The density of legal-sized male crab caught at a station ranged from 71 to 8,291 crab/nmi² (Appendix A). Legal-sized male Bristol Bay red king crab were caught at 48 stations (Appendix A), resulting in a total estimate of 8.5 ± 6.6 million crab in the Bristol Bay District

(Table 3). The majority of these males were concentrated in the central Bristol Bay area with some large catches in the southwest section of Bristol Bay, such as station B08 (Figs. 5 and 6). The 2009 estimate is lower than the 9.6 million crab average for the previous 20 years (Table 3).

Pre-recruit male red king crabs were encountered at 43 stations, estimated at 11.0 ± 7.3 million crab and represented 44% of the total male abundance in 2009 while the small male red king crab abundance estimate of 5.3 ± 2.5 million crab represented 21% of the total male abundance (Table 3). The majority of both size categories were centrally located in the Bristol Bay District, with a high number of pre-recruit and small males caught in the southeast nearshore stations (Figs. 5 and 6).

The 2007 male red king crab 100 to 105 mm CL cohort appears in 2008 at 110 to 115 mm CL and at approximately 125 to 130 mm CL size class in 2009 (Fig. 7). The 70 mm CL cohort of 2002, which grew to 140-150 mm CL range in 2007, declined in abundance in 2008 and aged as indicated by increasing old and older shell condition classes for 2008 and 2009. In 2009, one legal-sized male crab was in molting or softshell condition while 64% were hardshell crabs and 36% were oldshell and very oldshell crabs.

The 2009 large female red king crab abundance estimate of 36.1 ± 21.7 million crab represented 97% of the total female abundance with small female red king crab abundance estimated at 1.3 ± 0.9 million crab (Table 3). The majority of the large female red king crab were caught at depths less than 50 m while the small females were centrally located in the Bristol Bay District at deeper depths (Figs. 5 and 6).

Similar to the previous 3 years, the cold water temperatures in 2009 delayed the molting and mating cycle and only 52% of the 804 mature females sampled during the standard survey had extruded a new clutch of uneyed embryos. Among resurveyed female crab in late July of 2009, 94% were mature and 99% of these were new hardshell females that had extruded new, uneyed embryos (Fig. 8).

During years with colder than average bottom temperatures, such as 1999, 2000, 2006, 2007, 2008, and 2009, the ratio of eyed to uneyed embryos encountered on the EBS bottom trawl survey in June is high compared to years with warmer bottom temperatures (2001-2005). The eyed to uneyed embryo ratio ranges from 6.54 to 0.42 in cold years, compared to 0.06 to 0.01 in the warmer years, indicating a high number of females within the survey area have not completed the molting and mating cycle in early June. When the 32 Bristol Bay stations were resampled in late July of 1999, 2000, 2006, 2007, and 2008, the ratio of eyed to uneyed embryos decreases dramatically, ranging from 0.02 to 0.01, indicating the majority of mature females have completed the mating and molting cycle (Table 4).

Pribilof District Red King Crab

Historically, red king crab were not abundant in the Pribilof District and landings were taken incidentally during the blue king crab fishery. The red king crab fishery first opened in

1993 while fishing for blue king crab was closed. A combined fishery for red and blue king crab occurred in the Pribilof District from 1995 through 1998, but due to low abundance of blue king crab, the combined fishery and the red king crab fishery have both remained closed since the 1998/1999 season (Gish 2006).

Red king crab were caught at 7 of the 41 stations in the Pribilof District high-density sampling area in 2009. The density of legal-sized males caught at a station ranged from 66 to 1,745 crab/nmi² (Appendix A). Legal-sized male red king crab were caught at 6 stations in the Pribilof District high-density sampling area and were estimated at 0.7 ± 0.9 million crab, representing 73% of the total male abundance but below the average of 1.1 million crab from the previous 12 years (Table 5). The majority of the legal-sized males were distributed directly south of St. Paul Island at station G-21 (Figs. 9 and 10).

Pre-recruit males were encountered at 2 of the 41 stations with an abundance estimate of 0.3 ± 0.4 million crab which represents the remaining 27% of the total male abundance as no small male red king crab were captured on the 2009 survey. Pre-recruit males were distributed south and west of St. Paul Island in the nearshore shallow water stations (Table 5, Figs. 9 and 10).

Thirty percent of the legal-sized males were in molting or softshell condition while 53% were evaluated as new hardshell crabs and 17% as oldshell and very oldshell condition crabs. The 2009 size-frequency for red king crab males shows a decrease in the number of oldshell and very oldshell legal-sized males in comparison to the 2007 and 2008 shell conditions (Fig. 11).

The 2009 abundance estimate of large red king crab females was 0.3 ± 0.4 million crab, representing 100% of the total female abundance as no small red king crab females were caught on the 2009 survey (Table 5). Female abundance estimates are imprecise due to the limited number of tows with positive crab catches (Appendix A, Figs. 9 and 10). Less than one percent of the total female red king crab caught were immature while 75% of the mature females were brooding uneyed embryos, 24% were barren or had empty egg cases and no mature females were carrying eyed embryos. The majority of mature females with uneyed embryos were in the 140 mm CL to 160 mm CL size class (Fig. 12)

Pribilof District Blue King Crab

Blue king crab were caught at 6 of the 41 stations in Pribilof District high-density sampling area in 2009. Male abundance estimates are imprecise due to the limited number of tows with positive crab catches. Legal-sized males were caught at three stations east of St. Paul Island, with a density ranging from 73 to 131 crab/nmi² (Appendix A, Figs. 13 and 14). The 2009 abundance estimate of legal-sized males was 0.07 ± 0.08 million crab, representing 15% of the total male abundance and below the average of 0.56 million crab for the previous 20 years (Table 6).

Pre-recruit blue king crab males were caught at four stations in the Pribilof District high-density sampling area with an abundance estimate of 0.3 ± 0.4 million crab representing 51% of the total male abundance. Small male blue king crab were caught at four stations with an abundance estimate of 0.2 ± 0.3 million crab in 2009 representing the remaining 35% of the total male abundance (Table 6, Figs. 13 and 14).

Four legal-sized male blue king crab were captured on the 2009 survey in the Pribilof District; one in molting or softshell condition and one in new hardshell condition, while two were in very oldshell condition. The 2008 male blue king crab cohort at the 95 to 100 mm CL size class advanced to approximately the 125 to 130 mm CL size class in 2009 (Fig. 15).

Large female blue king crab were caught at three stations in the Pribilof District high-density sampling area with an abundance estimate of 0.6 ± 0.9 million crab representing 95% of the total female abundance (Table 6, Figs. 13 and 14). Small female blue king crab were caught at two stations northeast of St. Paul Island in the Pribilof District high-density sampling area with an abundance estimate of 0.07 ± 0.09 million crab for 2009 (Table 6, Figs. 13 and 14). Estimates of female abundance are imprecise due to the preference of these crab for rocky habitat which is not sampled well by trawls. Blue king crab females are predominantly biennial spawners with only a portion of the female population carrying eyed embryos in a given year, while the remainder is in a non-embryo-bearing phase (Somerton and MacIntosh 1985). Fourteen of the 29 large female blue king crab sampled during the survey were brooding uneyed or eyed embryos. Among sampled mature females, 24% were new hardshell crab all with newly extruded embryos while 76% were oldshell females of which 24% were brooding eyed embryos and 52% had empty egg cases (Fig. 16).

St. Matthew Island Section, Northern District Blue King Crab

Blue king crab were caught at 38 of the 56 total stations in the St. Matthew Island Section; 27 stations in the high-density sampling area and 11 stations in the standard-density sampling area. Abundance estimates in the St. Matthew Island Section are imprecise due to a large portion of the stock occupying inshore rocky untrawlable habitat. The density of legal-sized males caught at a station ranged from 60 to 739 crab/nmi² and were captured primarily south and west of St. Matthew Island (Appendix A, Figs. 17 and 18). Twenty legal-sized male blue king crab were caught in 2009 with an abundance estimate of 1.4 ± 0.7 million crab and representing 19% of the total male abundance but below the average of 1.9 million crab from the previous 20 years (Table 7).

In 2009, the pre-recruit male crab abundance estimate was 2.2 ± 1.5 million crab and represents 32% of the total male abundance, while the small male abundance estimate of 3.4 ± 2.0 million crab made up the remaining 49% of the total male abundance (Table 7). The majority of the pre-recruit and small male blue king crab were distributed southwest of St. Matthew Island (Figs. 17 and 18).

The 2007 100 mm CL mm male blue king crab cohort appears in 2008 at approximately 120 mm CL and is increasing in age in 2009 with old and older shell condition classes, although an 85 mm CL cohort from 2008 appears at approximately the 100 to 110 mm CL range in 2009 (Fig. 19). In 2009, 3 legal-sized male crab were in molting or softshell condition, 10 were new hardshell crabs and 7 were oldshell condition crabs while 59 of the 112 pre-recruit males were new hard shell crabs.

The 2009 large female blue king crab abundance estimate was 0.4 ± 0.3 million crab, representing 40% of the female abundance, while the small female blue king crab abundance estimate of 0.6 ± 0.6 million crab represented 60% of the female abundance (Table 7). Large and small females were primarily caught at stations southwest of St. Matthew Island (Figs. 17 and 18). Thirteen of the 18 mature females caught were in new hardshell condition and brooding uneyed embryos, while 1 mature female was softshell with newly extruded embryos and all within the 75 mm to 95 mm CL size class. The remaining 4 mature females were in oldshell condition with empty egg cases in both the 55 mm to 65 mm CL and 90 mm to 95 mm CL size classes (Fig. 20).

Tanner Crab

Tanner crab were caught at 183 of the 376 stations in the combined areas of the Bristol Bay District, Pribilof District, and Northern District. Tanner crab occurred at 41 stations in the Pribilof District high-density sampling area and 21 stations in the high-density sampling area of the St. Matthew Island Section in the Northern District (Appendix A).

Legal-sized male Tanner crab were caught at 64 stations, ranging from 63 to 1,992 crab/nmi² per tow (Appendix A). The 2009 abundance estimate for legal male Tanner crab was 6.9 ± 2.8 million crab, with high abundance regions occurring along the Alaska Peninsula in Bristol Bay District and west of St. Paul Island in the Pribilof District (Table 8, Figs. 21 and 22). Legal-sized male crab represented only 4% of the total male abundance in 2009 with 54% of legal males occurring east of 166°W in the ADF&G Eastern management district compared to 69% in 2008 and 45% in 2007 (Table 8).

Pre-recruit males represented 23% of the total male abundance with an estimate of 45.3 ± 13.2 million crab and the remaining 73% was comprised of small males with an abundance estimate of 144.0 ± 39.8 million crab (Table 8). High abundances of pre-recruit males occurred northwest and south of the Pribilof Islands and in the southwest area of the Bristol Bay District while small male Tanner crab were distributed throughout the eastern Bering Sea shelf (Figs. 21 and 22).

In 2008, a total of 1,783 male Tanner crab chela height and carapace width measurements were collected on the EBS bottom trawl survey. The scatterplot of the allometric relationship between chela height and carapace width graphically represents two distinct maturity groups; immature males (small claw) with a ratio of less than 0.17 and mature males (large claw) with a

ratio greater than or equal to 0.17 (Fig 23). The carapace widths for small claw males ranged from 17.0 to 145.8 mm compared to 59.5 to 166.8 mm for large claw males.

The 2006 male size-frequency revealed a prominent size class in the 70 mm CW range, which persisted to 90 to 95 mm CW in 2007, the 95 to 100 mm CW range in 2008, and appears at approximately the 110 to 120 mm CW in 2009 (Fig. 24). Old and very oldshell crab remain a relatively large proportion in the male size distribution at 80 mm carapace width and greater; these males will not molt to legal-size in the future. Morphometrically mature oldshell male *Chionoecetes* spp. crab will not molt again during their lifespan (Tamone et al. 2007).

The 2009 large female Tanner crab abundance estimate was 20.6 ± 9.8 million crab, representing 14% of the total female abundance while the small female Tanner crab abundance of 129.5 ± 41.3 million crab comprised the majority of the total female abundance (Table 8). Fifty-four percent of the large female population was distributed east of 166°W in the ADF&G Eastern management district in the southwest Bristol Bay District with a few large catches in the Pribilof Islands area, while the small females were distributed throughout the 50 to 200 m shelf of the eastern Bering Sea (Figs. 21 and 22). Among sampled mature females, 2% were softshells, 18% were new-hardshells, and 81% were oldshell and very oldshell. Eighty-two percent of the mature females carried newly extruded embryos while 13% had not produced a new clutch and 5% had were barren (Fig. 25).

Two small Tanner crab were caught at station I-26 that were too small to identify the gender. One was 11 mm in carapace width and one was 14 mm CW. The abundance estimate for these two crab was 0.03 million crab, less than 0.01% of the total Tanner crab population.

Snow Crab

Snow crab were caught at 277 of the 376 stations in the combined areas of the Bristol Bay District, Pribilof District, and Northern District. Snow crab occurred at 40 stations in the Pribilof District high-density sampling area, and 27 stations in the high-density sampling area of the St. Matthew Island Section of the Northern District (Appendix A).

Although the legal minimum size limit for male snow crab is 3.1 inches CW (78 mm), processors currently prefer a minimum size of 4.0 inches CW (102 mm). The abundance estimates reported for legal-sized male snow crab in this report combines both size groups (Table 9). The density of legal-sized male snow crab are listed by station in Appendix A and are separated into legal (≥ 3.1 in. CW) and preferred (≥ 4.0 in. CW) size categories.

Legal-sized male snow crab were caught at 247 stations, throughout all Districts combined, resulting in an abundance estimate of 371.8 ± 86.4 million crab and representing 30% of the total male abundance. Thirty-two percent of those legal males were ≥ 4 inches in carapace width, with an abundance estimate of 130.1 ± 42.4 million crab and approximately 79% of all legal male snow crab were east of 173°W in the ADF&G Eastern management district as

compared to 72% (265.4 million crab) in 2008. In 2009, 76% of the legal males were distributed between 166°W and 173°W with the remaining balance of 21% distributed west of 173°W. These legal-sized male snow crab were distributed throughout the eastern Bering Sea shelf with higher concentrations around the Pribilof Islands and southwest of St. Matthew Island (Table 9, Figs. 26 and 27).

The 2009 pre-recruit male snow crab abundance estimate of 879.9 ± 295.4 million crab, represented the remaining 70% of the total male abundance (Table 9). Fifty-two percent of these males were distributed east of 173°W in the ADF&G Eastern management district compared to 63% in 2008 (Table 9, Figs. 26 and 27). In 2009, less than 1% of the pre-recruit males were east of 166°W, 52% were distributed between 166°W and 173°W, and 48% were west of 173°W (Table 9).

In 2009, a total of 1,353 male snow crab chela height and carapace width measurements were collected on the EBS bottom trawl survey. The scatterplot of the allometric relationship between chela height and carapace width for snow crab graphically represents two distinct maturity groups; immature males (small claw) with a ratio of less than 0.20 and mature males (large claw) with a ratio greater than or equal to 0.20 (Fig 28). The carapace widths for small claw males ranged from 27.0 to 121.2 mm compared to 40.0 to 151.5 mm for large claw males.

The 50 to 55 mm CW size class of 2007 male crab recruited to the 60 to 65 mm CW in 2008 and appears at approximately the 70 to 75 mm CW size class in 2009. Among legal-sized male crab, 16% were in molting or softshell condition, 56% were in new-hardshell condition indicating a recent molt, and 28% were oldshell and very oldshell condition (Fig. 29).

The large female snow crab abundance estimate of 828.0 ± 340.7 million crab comprised 46% of the total female abundance and the small female crab abundance estimate of 979.5 ± 483.3 million crab comprised the remaining 54% of the total female abundance (Table 9). Fifty-three percent of the total abundance of small female crab and 75% of the total abundance of large female snow crab were caught east of 173°W in the ADF&G Eastern management district with 47% small females and 25% large females distributed west of 173°W (Table 9, Figs. 26 and 27). The female reproductive stock had high frequencies of old shell and very old shell condition crabs which is of concern in terms of expected reproductive output. Among sampled mature females; 27% were new-hardshells and 99% brooding newly extruded embryos, 73% were oldshell and very oldshell condition with 84% brooding new embryos, 7% had not produced a new clutch, and less than 1% of the mature females were barren (Fig. 30).

***Chionoecetes bairdi/opilio* hybrid**

Chionoecetes spp. hybrid crab were caught at 123 of the 165 stations in the combined areas of the Bristol Bay District, Pribilof District, and Northern District. *C.* hybrid crab occurred at 18 stations in the Pribilof District high-density sampling area, and 8 stations in the high-density sampling area of the St. Matthew Island Section of the Northern District (Appendix A).

In this document, *C. hybrid* crab size classes for legal males and large females are based on the size categories for snow crab (see snow crab section and Table 1). The abundance estimates reported in this report for legal-sized male *C. hybrid* crab combines both the preferred and legal size categories. The density of legal-sized male *C. hybrid* crab are listed by station in Appendix A and are separated into preferred (≥ 4.0 in. CW) and legal (≥ 3.1 in. CW) size categories.

Legal-sized male *C. hybrid* crab were caught at 48 stations, throughout all Districts combined, resulting in an abundance estimate of 10.0 ± 3.6 million crab. Fifty percent of those legal males were ≥ 4 inches in carapace width, with an abundance estimate of 5.0 ± 1.3 million crab and were primarily distributed between 50 and 100 m along the eastern Bering Sea shelf with large catches east and north of the Pribilof Islands (Figs. 31 and 32). The 2009 pre-recruit male *C. hybrid* crab abundance estimate for all Districts combined was 4.2 ± 2.5 million crab, were distributed between 50 and 100 m in the central area of the eastern Bering Sea shelf (Figs. 31 and 32).

The 2009 large female *C. hybrid* crab abundance estimate was 4.6 ± 2.4 million crab while the small female crab abundance estimate was 2.8 ± 2.2 million crab. The majority of the large females were distributed in the northwestern area of the EBS with a few large catches southeast of the Pribilof Islands, while small female hybrid crab were primarily distributed between 100 and 200 m of the northwestern area of the eastern Bering Sea (Figs. 31 and 32).

Other Crab Stocks and Species of Interest

Northern District Red King Crab

Red king crab were caught at 23 stations in the Northern District and do not occur in either of the management units where red king crab are commercially fished or managed (Fig. 2). The 2009 abundance estimates were calculated using an area of 9,223 nmi² based on the number of stations with positive catches of red king crab in the Northern District. Legal-sized males were caught at 10 of those stations. The density of legal-sized males caught at a station ranged from 75 to 154 crab/nmi² (Appendix A). The 2009 population abundance estimate of legal-sized males was 0.4 ± 0.2 million crab and the abundance estimate of pre-recruit and small males was 0.3 ± 0.2 million crab and 0.7 ± 0.5 million crab, respectively. The abundance estimate of large female red king crab was 1.1 ± 0.4 million crab while the abundance estimate of small females was 0.2 ± 0.2 million crab. Both legal males and large female red king crab were caught at stations south and west of Nunivak Island (Fig. 33).

Northern District Blue King Crab

Blue king crab were caught at two stations not included in the abundance estimates for the Pribilof District blue king crab or the St. Matthew Island section Northern District blue king crab. One small, oldshell male was caught at station N03 and one large, oldshell female was caught at station T29 (Appendix A, Fig. 34).

Hair Crab

In 2009, a total of 361 hair crab were captured at 71 of the 317 stations throughout all Districts combined on the EBS bottom trawl survey (Fig. 35). Historically, hair crab have been concentrated just north of the Alaska Peninsula and near the Pribilof Islands. In recent years, however, abundance of hair crab north of 58°N latitude has been increasing (Fig.35).

In this report, legal male hair crab are defined as > 3.25 inches CW (≥ 83 mm CL) which was specified in the previous Pribilof District fishery and the female hair crab abundance estimate is presented for all sizes combined regardless of carapace size. The 2009 density of legal male hair crab caught at a station ranged from 66 to 658 crab/nmi² resulting in an abundance estimate of 3.1 ± 1.2 million crab. Legal male hair crab were primarily concentrated in Bristol Bay and distributed along the 50 m isobath (Fig. 35).

The 2009 pre-recruit male hair crab abundance estimate was 3.6 ± 1.6 million crab and the female hair crab abundance estimate was 1.7 ± 0.9 million crab. The majority of pre-recruit male and female hair crab were distributed in Bristol Bay with a high number of pre-recruit males caught west of the Pribilof Islands and north of 58°N (Fig. 35).

The Pribilof District hair crab fishery has been closed since 2000 due to a shift in the distribution of legal males to the Northern District and, after one year of experimental fishing with minimal vessel participation, the Northern District fishery was closed in 2001 (Bowers et al 2008). In the last few years, the abundance estimates of both size classes of male hair crab have increased relative to 2006 and the 2009 abundance estimate for legal-sized male hair crab is higher than the 20-year average of 2.3 million crab (Table 10).

Golden King Crab

Two golden king crab, one new hardshell male at 156 mm CL and one oldshell female at 137 mm CL, were caught at station E-19 with an average depth of 128 m (Fig. 1). This species is managed by ADF&G in the Pribilof District of the Bering Sea king crab registration Area Q (Fig. 2). There has been limited commercial effort for this stock since the fishery began in 1982 and ADF&G does not currently survey this population nor estimate population abundances (Bowers et al. 2008). The annual EBS bottom trawl survey does not routinely encounter this species due to habitat and depth preferences outside of the surveyed area.

ACKNOWLEDGMENTS

We thank Glenn Sullivan and Jeff Boddington of the FV *Arcturus* and Norm Bakken of the FV *Aldebaran* and their crew without which the annual EBS crab and groundfish bottom trawl survey would not occur. We also thank the dedicated field party chiefs, deck bosses, and scientific crew from the AFSC and all those who volunteered to come out on the survey. The scientific personnel who made up the “crab crew” included; D. Benjamin (AFSC), J. Brogan (AFSC), E. Chilton (AFSC, Kodiak Lab), D. Dela Cruz (ADF&G), P. Cummiskey (AFSC, Kodiak Lab), M. Fox (UAS), J. Haaga (AFSC, Kodiak Lab), T. Hughes (AFSC, Kodiak Lab), E. Munk (AFSC, Kodiak Lab), L. Slater (ADF&G), S. Van Sant (AFSC, Kodiak Lab), and J. Webb (ADF&G).

Table 1. -- Definition of carapace size classes for crab species in the eastern Bering Sea.
 Carapace length (CL) is measured for *Paralithodes* species and *Erimacrus isenbeckii*,
 while carapace width (CW) is measured for *Chionoecetes* species.

	Small	Pre-recruit	Legal male or Large female
<i>Paralithodes camtschaticus</i>			
Bristol Bay District			
males	<110 mm	110-134 mm	≥ 135 mm CL or ≥ 6.5 in. CW
females	<90 mm		≥ 90 mm
Pribilof District			
males	<110 mm	110-134 mm	≥ 135 mm CL or ≥ 6.5 in. CW
females	< 90 mm		≥ 90 mm
<i>P. platypus</i>			
Pribilof District			
males	<110 mm	110-134 mm	≥ 135 mm CL or ≥ 6.5 in. CW
females	< 90 mm		≥ 90 mm
St. Matthew Island			
males	< 105 mm	105-119 mm	≥ 120 mm CL or ≥ 5.5 in. CW
females	< 80 mm		≥ 80 mm
<i>Chionoecetes bairdi</i>			
males	< 110 mm	110-137 mm	≥ 138 mm or ≥ 5.5 in. CW
females	< 85 mm		≥ 85 mm
<i>C. opilio</i>			
males		< 78 mm	≥ 78 mm ¹ or ≥ 3.1 in. CW
females	<50 mm		≥ 50 mm
<i>Erimacrus isenbeckii</i>			
males		<83 mm	≥ 83 mm ² CL or > 3.25 in. CW
females			

¹ The legal minimum size limit for *C. opilio* is 3.1 in. CW (78 mm), although processors currently prefer a minimum size of 4.0 in. CW (102 mm).

² Legal-sized male crab for *E. isenbeckii* are defined as those larger than a minimum size of 3.25 inches CW (≥ 83 mm CL) Alaska Department of Fish and Game permit guidelines in past years.

Table 10. --Time series of annual total abundance estimates (millions of crab) for hair crab (*Erimacrus isenbeckii*) from National Marine Fisheries Service bottom trawl surveys, all districts combined. From 1990 to 2008, a 50 ft net width (fixed) was used in the area swept calculation. In 2009 the mean net width (variable) was used and both are shown in this table.

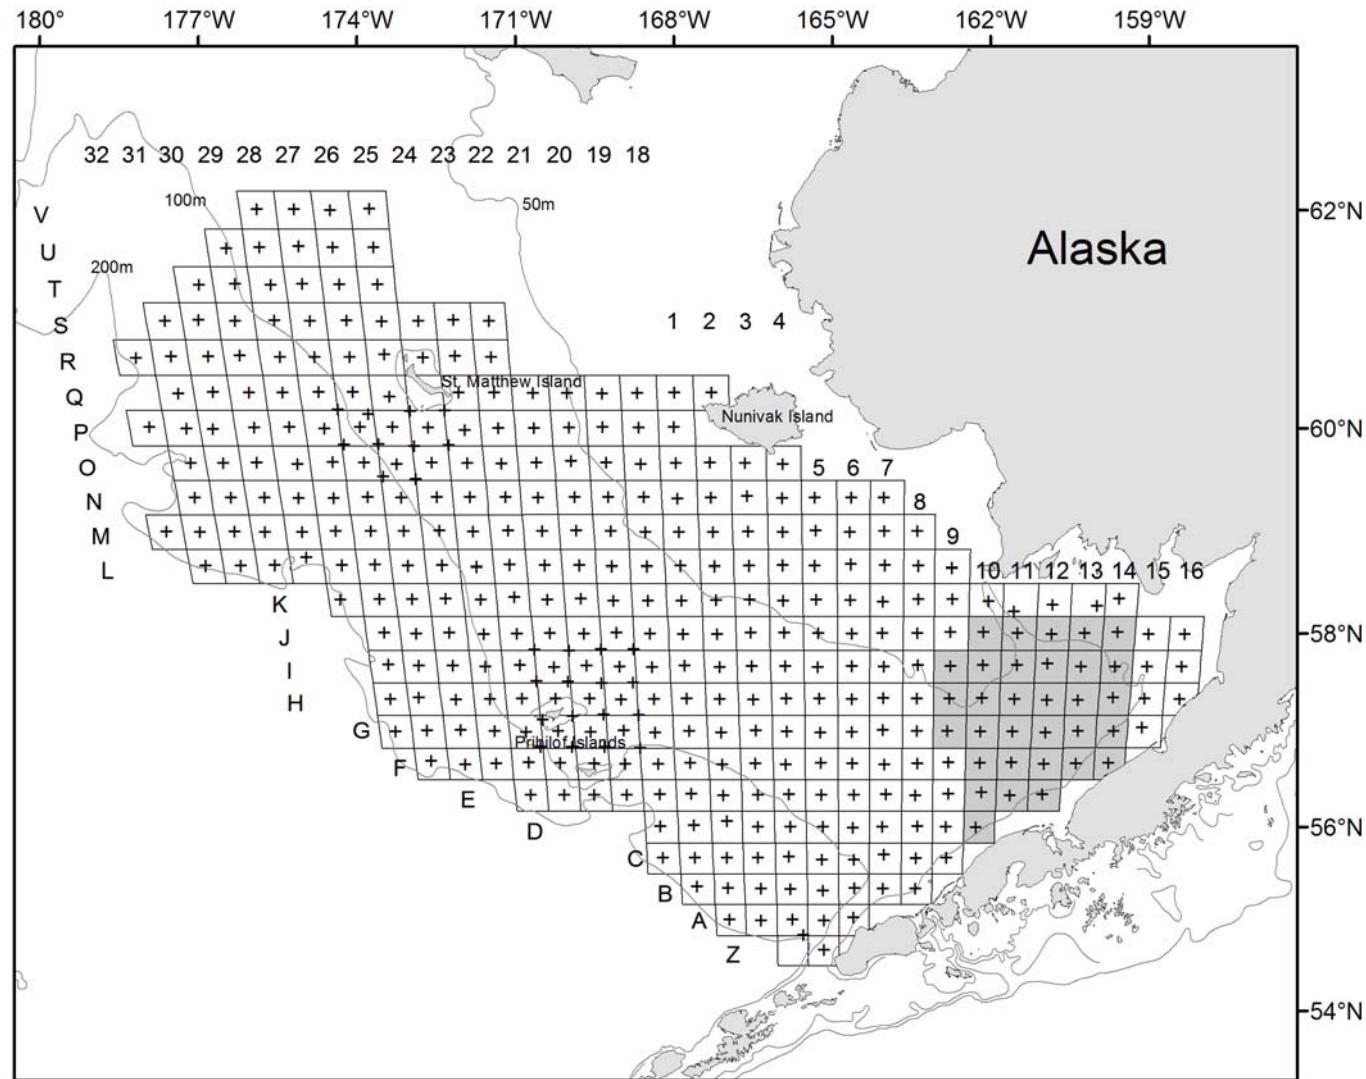

Figure 1. --National Marine Fisheries Service eastern Bering Sea bottom trawl area surveyed by FV *Arcturus* and FV *Aldebaran* from 2 June to 19 July 2009. Shaded area depicts Bristol Bay resample stations, 27 to 30 July 2009.

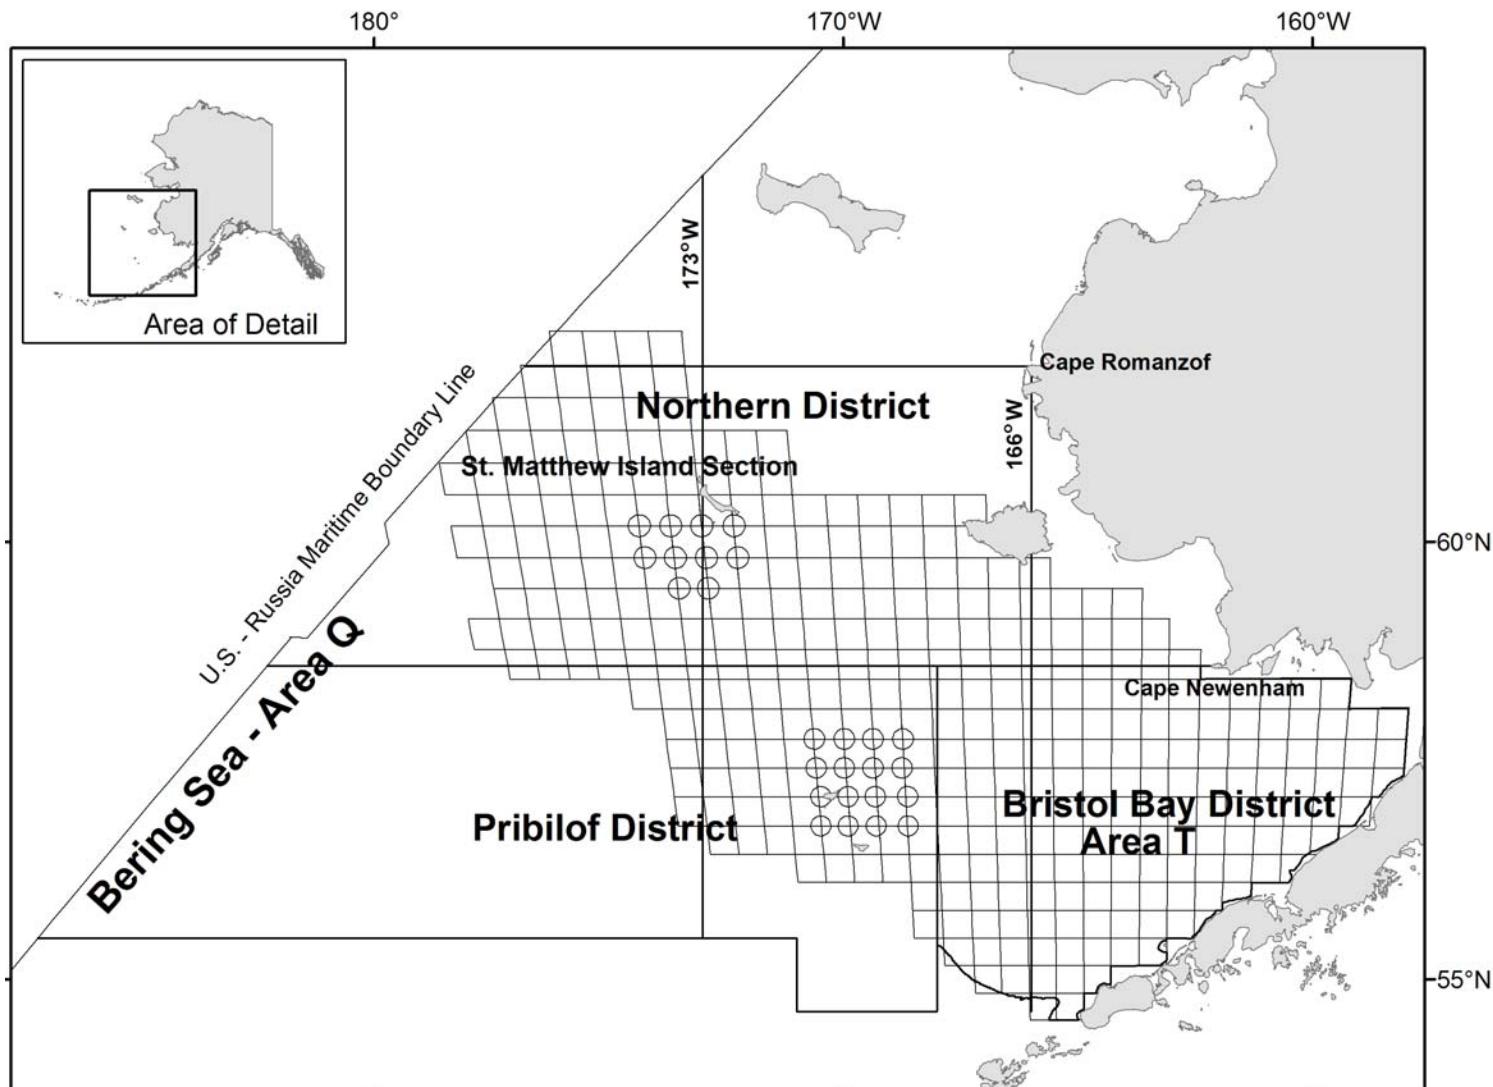

Figure 2. --Alaska Department of Fish and Game commercial crab management units within the 2009 eastern Bering Sea bottom trawl survey area. Circles represent the high-density sampling areas in the Pribilof District and St. Matthew Island Section.

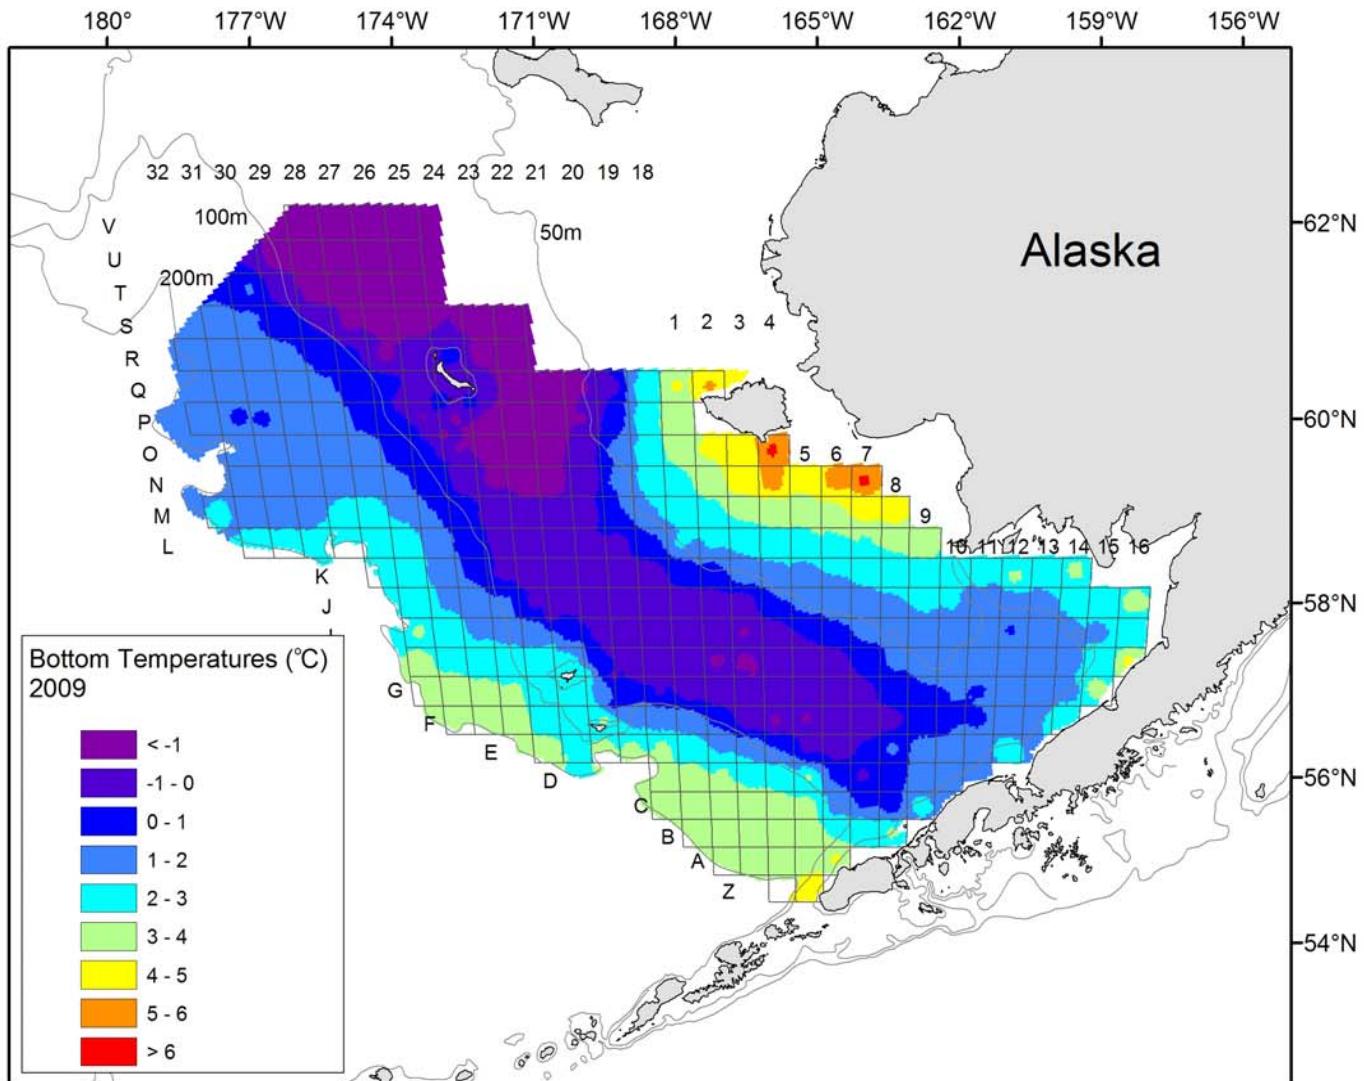

Figure 3. --Mean bottom temperatures ($^{\circ}\text{C}$) measured at stations from the National Marine Fisheries Service eastern Bering Sea bottom trawl survey, beginning 2 June 2009 in Bristol Bay and ending on 19 July 2009 at N28. This figure does not reflect the 32 resample stations in Bristol Bay, surveyed from 27 to 30 July 2009.

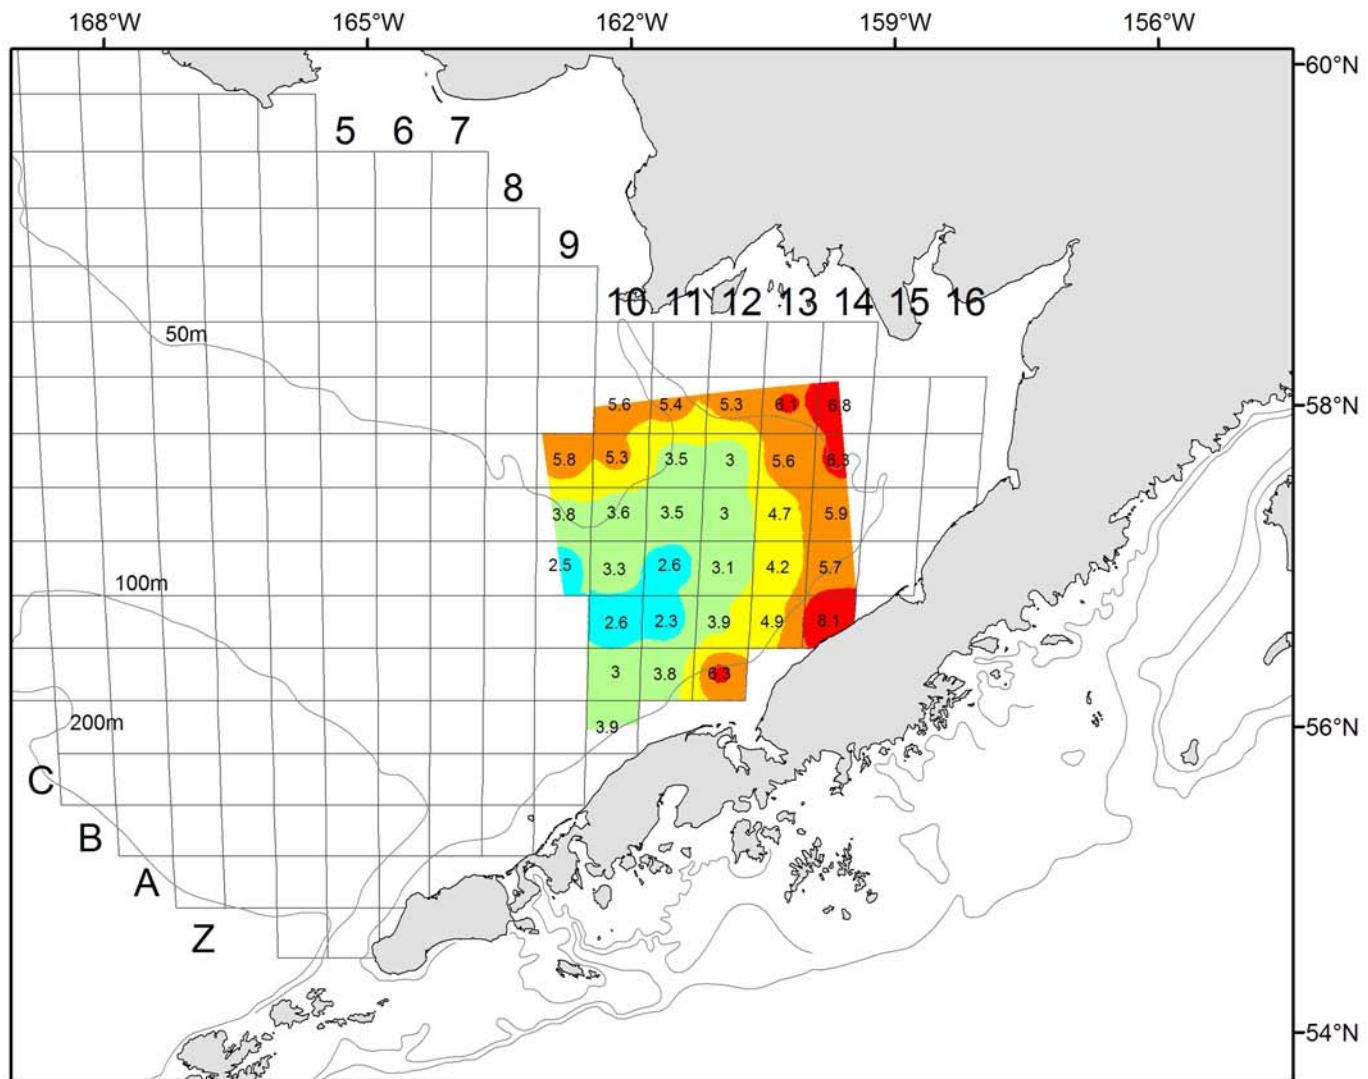

Figure 4. --Mean bottom temperatures ($^{\circ}\text{C}$) measured at the 32 resample stations in Bristol Bay, surveyed from 27 to 30 July 2009.

This page intentionally blank

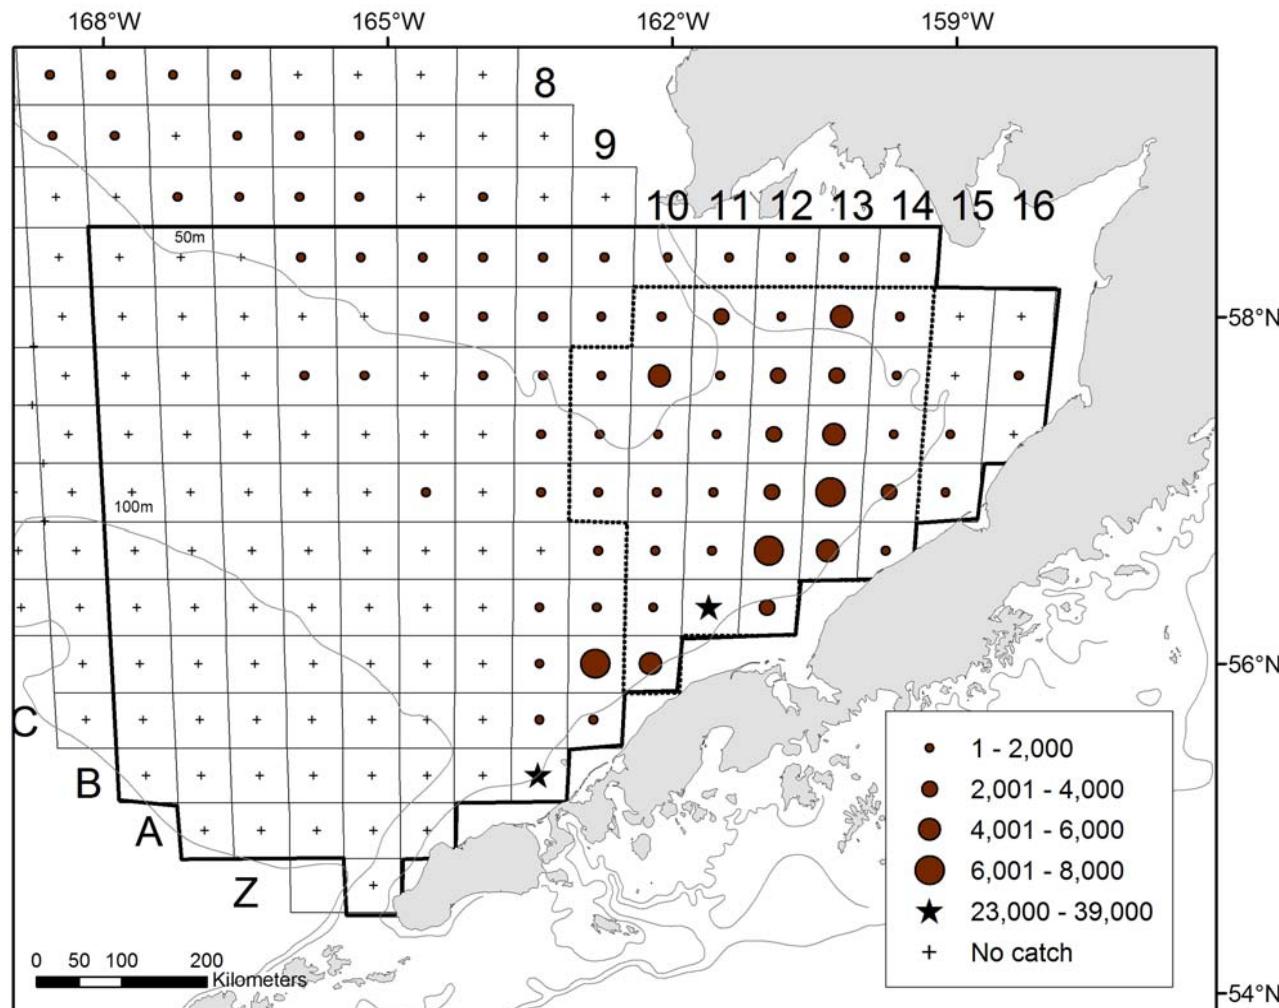

Figure 5. --Total density (number/nmi²) of red king crab (*Paralithodes camtschaticus*) at each station sampled in the Bristol Bay District in 2009. Data depicted by circles are equal interval densities, while stars are densities larger than the standard scale. Outlined area depicts the management district and dashed area depicts resurveyed stations which were included in abundance estimates by averaging male data and replacing female data collected in 3 to 7 June with data collected in 27 to 30 July at the 32 resampled stations.

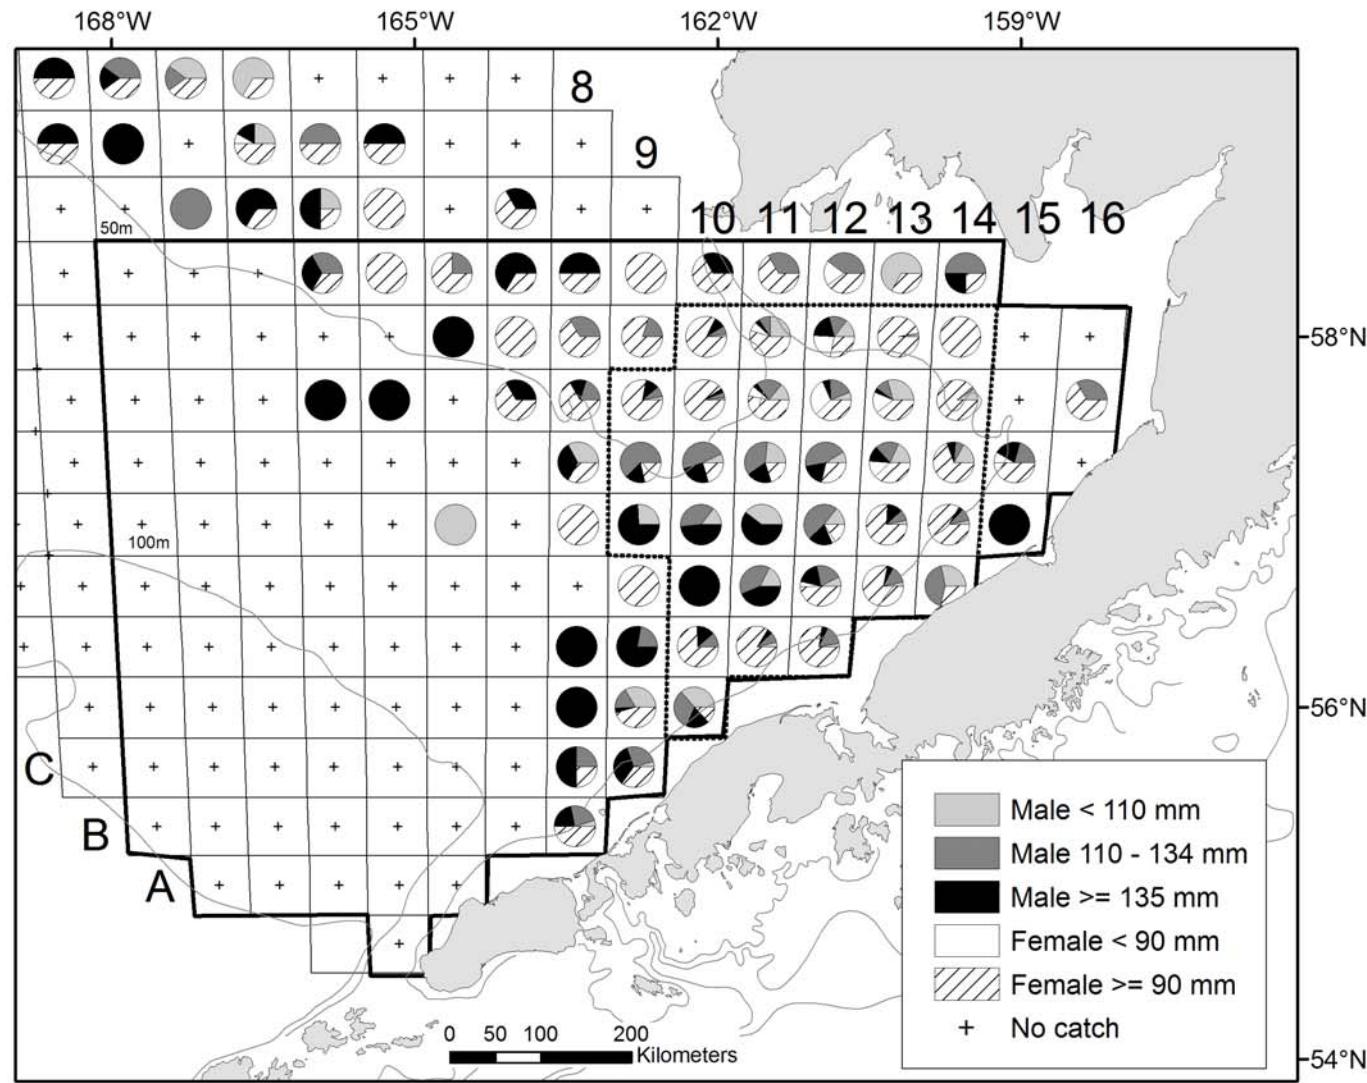

Figure 6. --Percentage of male and female red king crab (*Paralithodes camtschaticus*) size classes caught at each station in 2009. Outlined area depicts management district and dashed area depicts resurveyed stations.

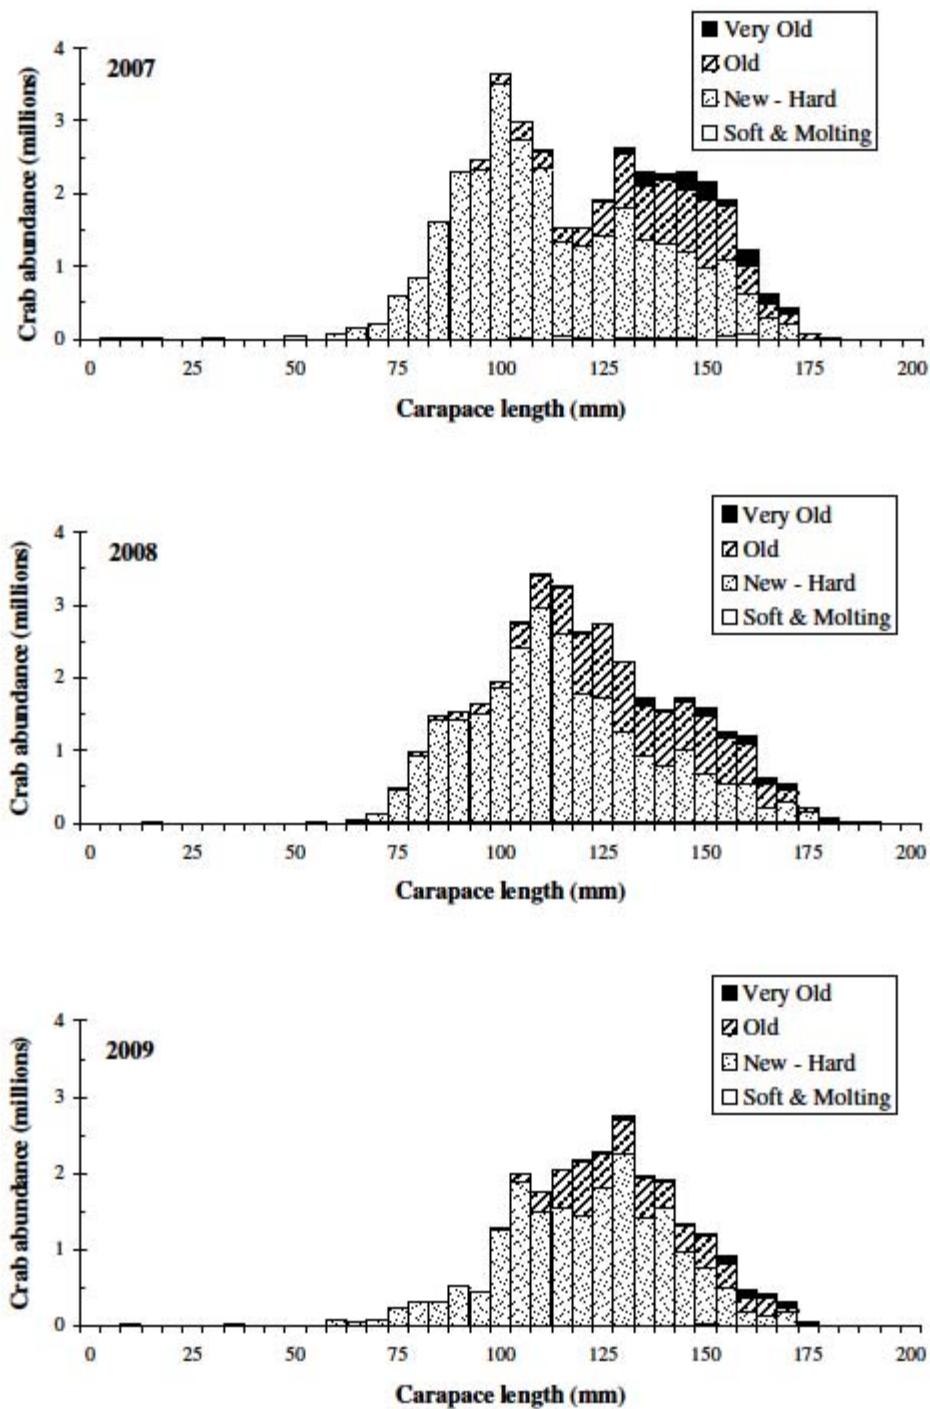

Figure 7. --Size-frequency of Bristol Bay District male red king crab (*Paralithodes camtschaticus*) by 5 mm length classes, 2007-2009.

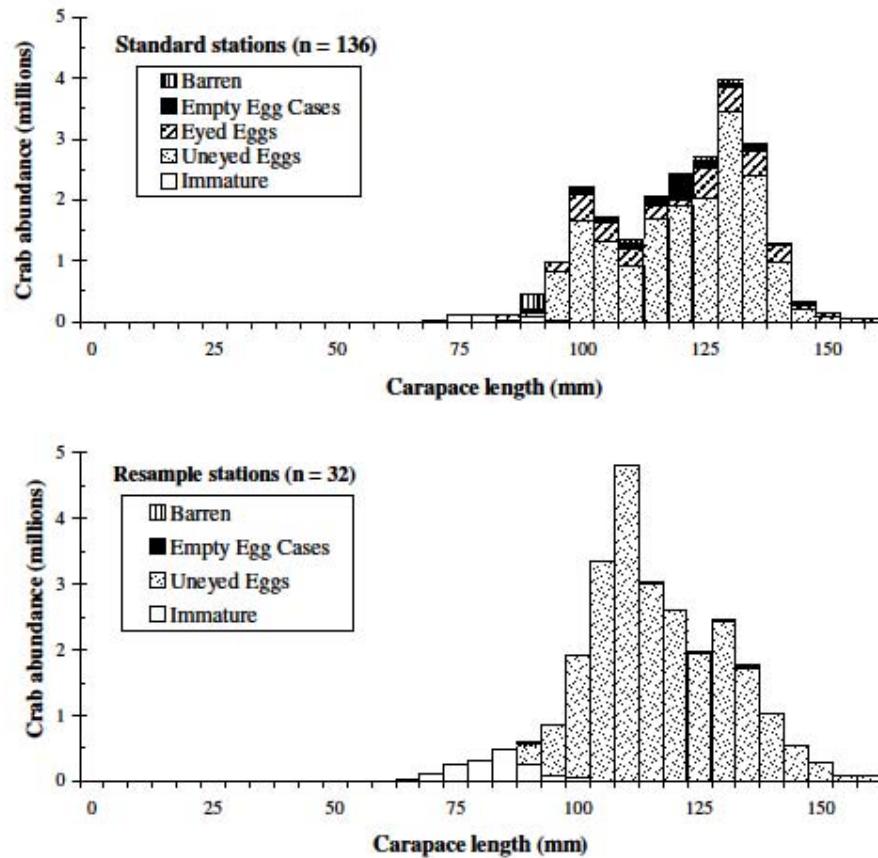

Figure 8. --Size-frequency and egg condition of Bristol Bay District female red king crab (*Paralithodes camtschaticus*) by 5 mm length classes in 2009.

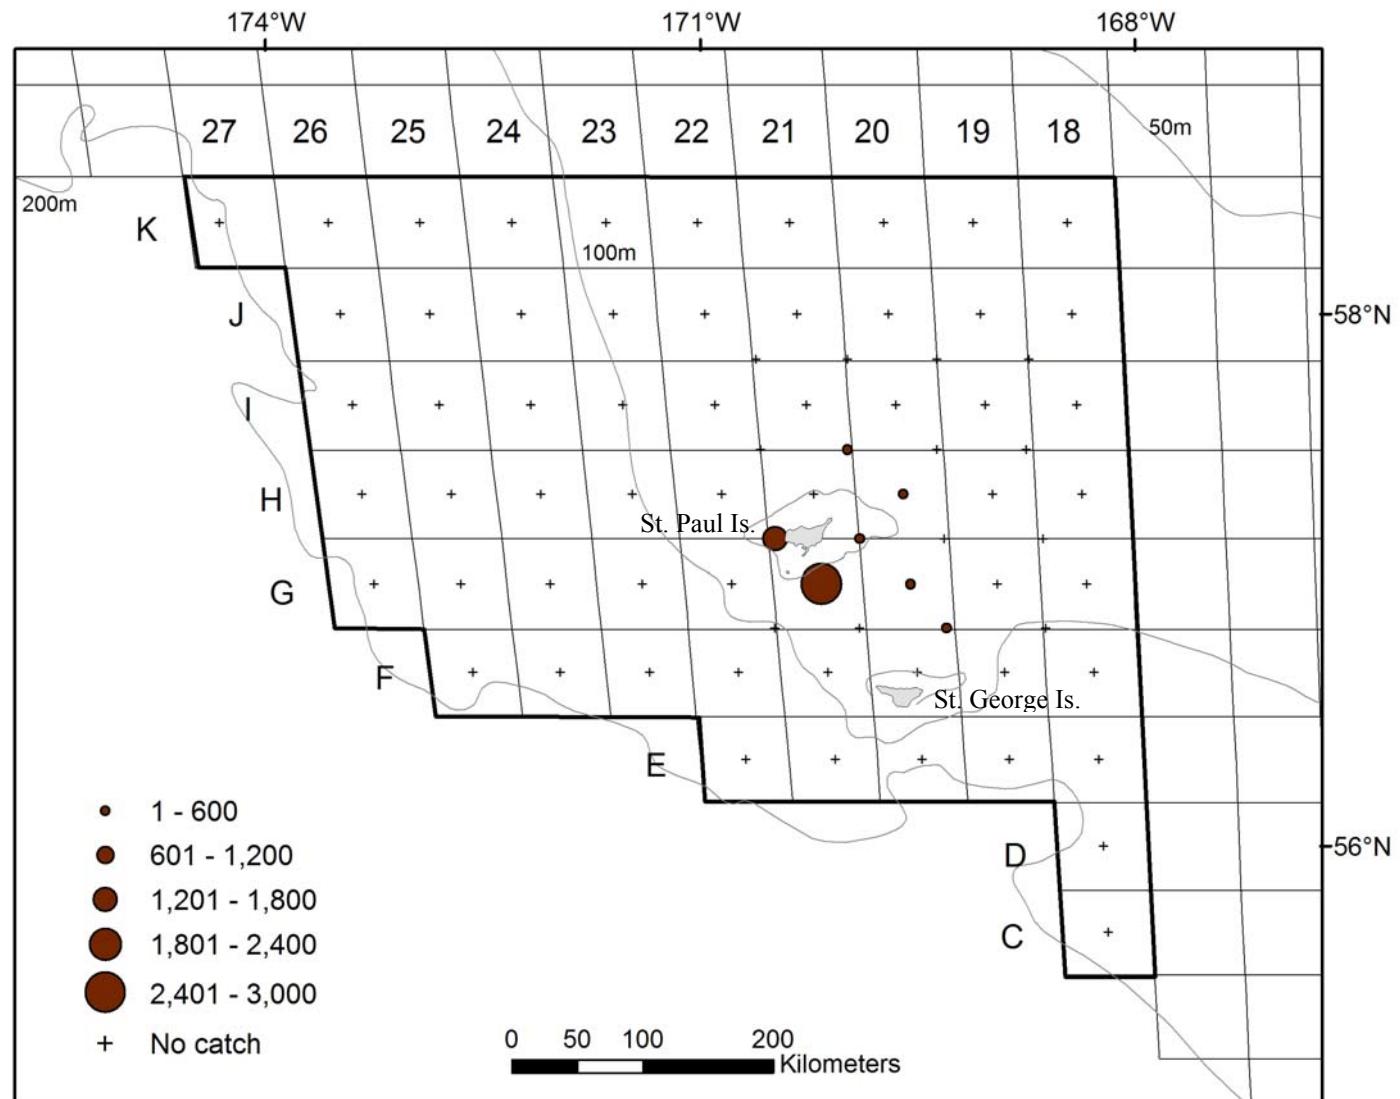

Figure 9. --Total density (number/nmi²) of red king crab (*Paralithodes camtschaticus*) at each station sampled in the Pribilof District in 2009. Data depicted by circles are equal interval densities and outlined area depicts stations within the management district.

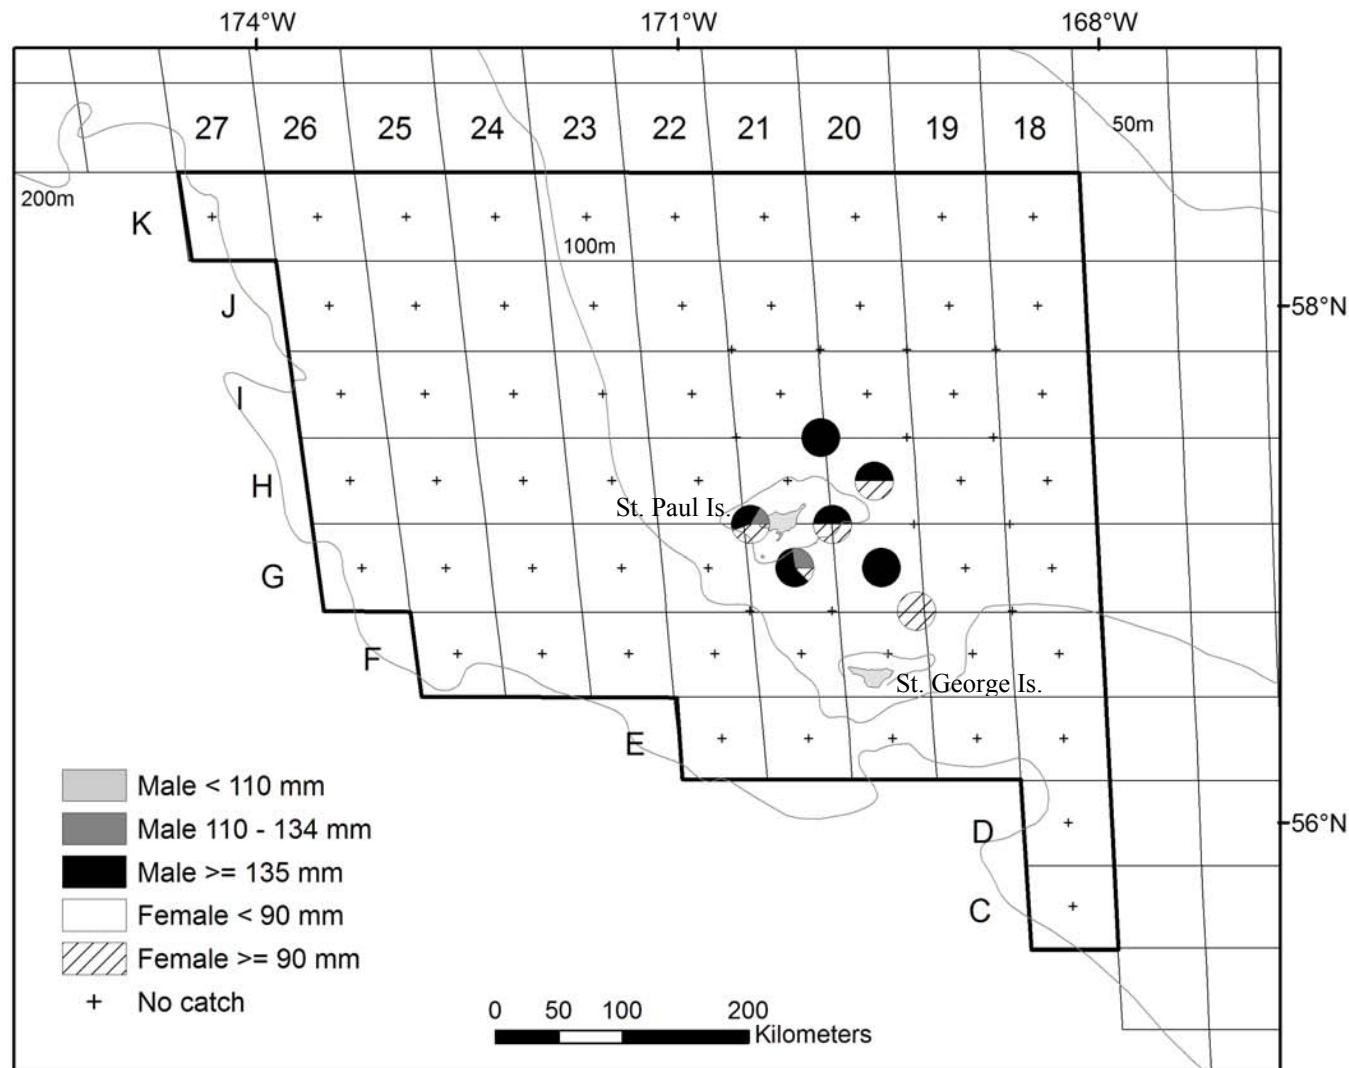

Figure 10. --Percentage of male and female red king crab (*Paralithodes camtschaticus*) size classes at each station of the Pribilof District in 2009. The outlined area depicts stations within the management district.

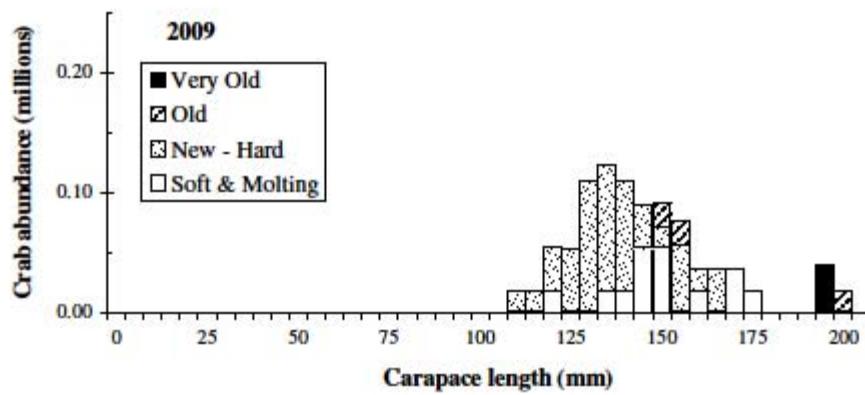

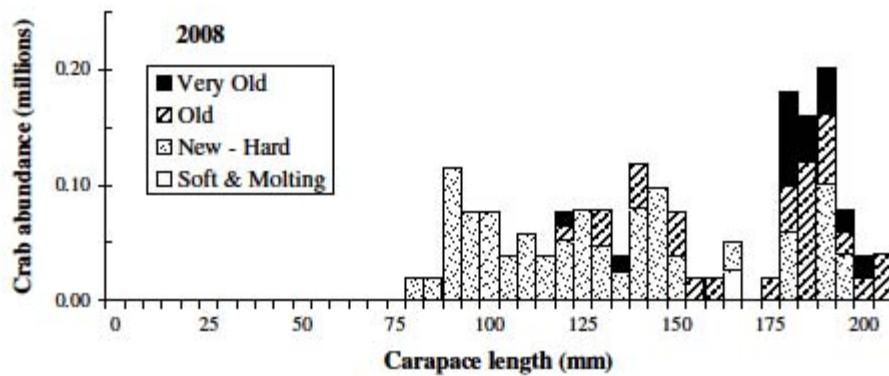

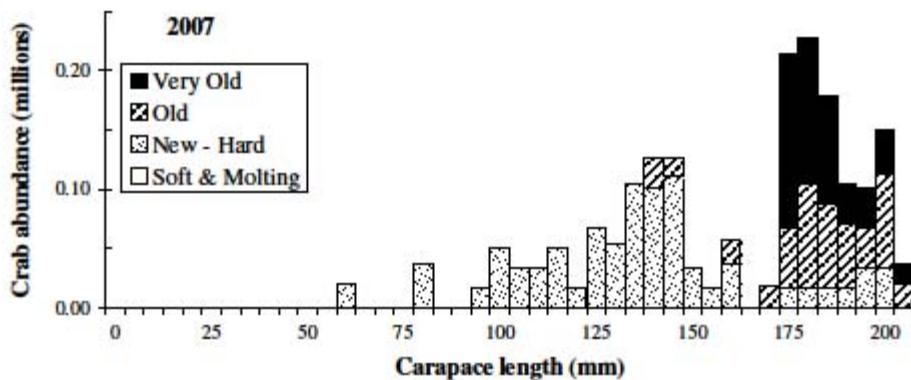

Figure 11. --Size-frequency of Pribilof District male red king crab (*Paralithodes camtschaticus*) by 5 mm length classes, 2007-2009.

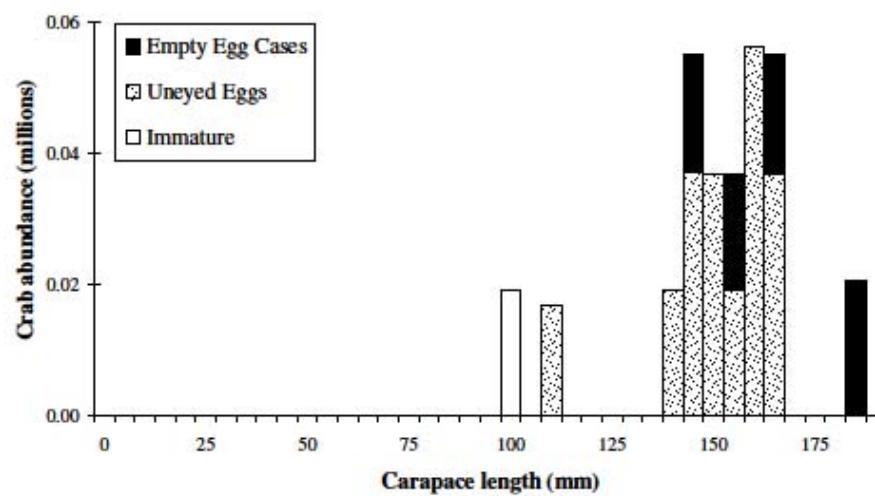

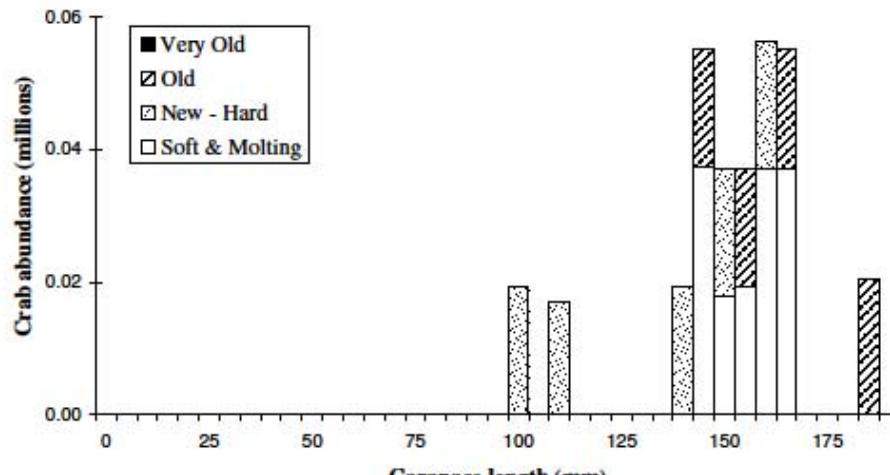

Figure 12. --Size-frequency, shell and egg condition of Pribilof District female red king crab (*Paralithodes camtschaticus*) by 5 mm length classes in 2009.

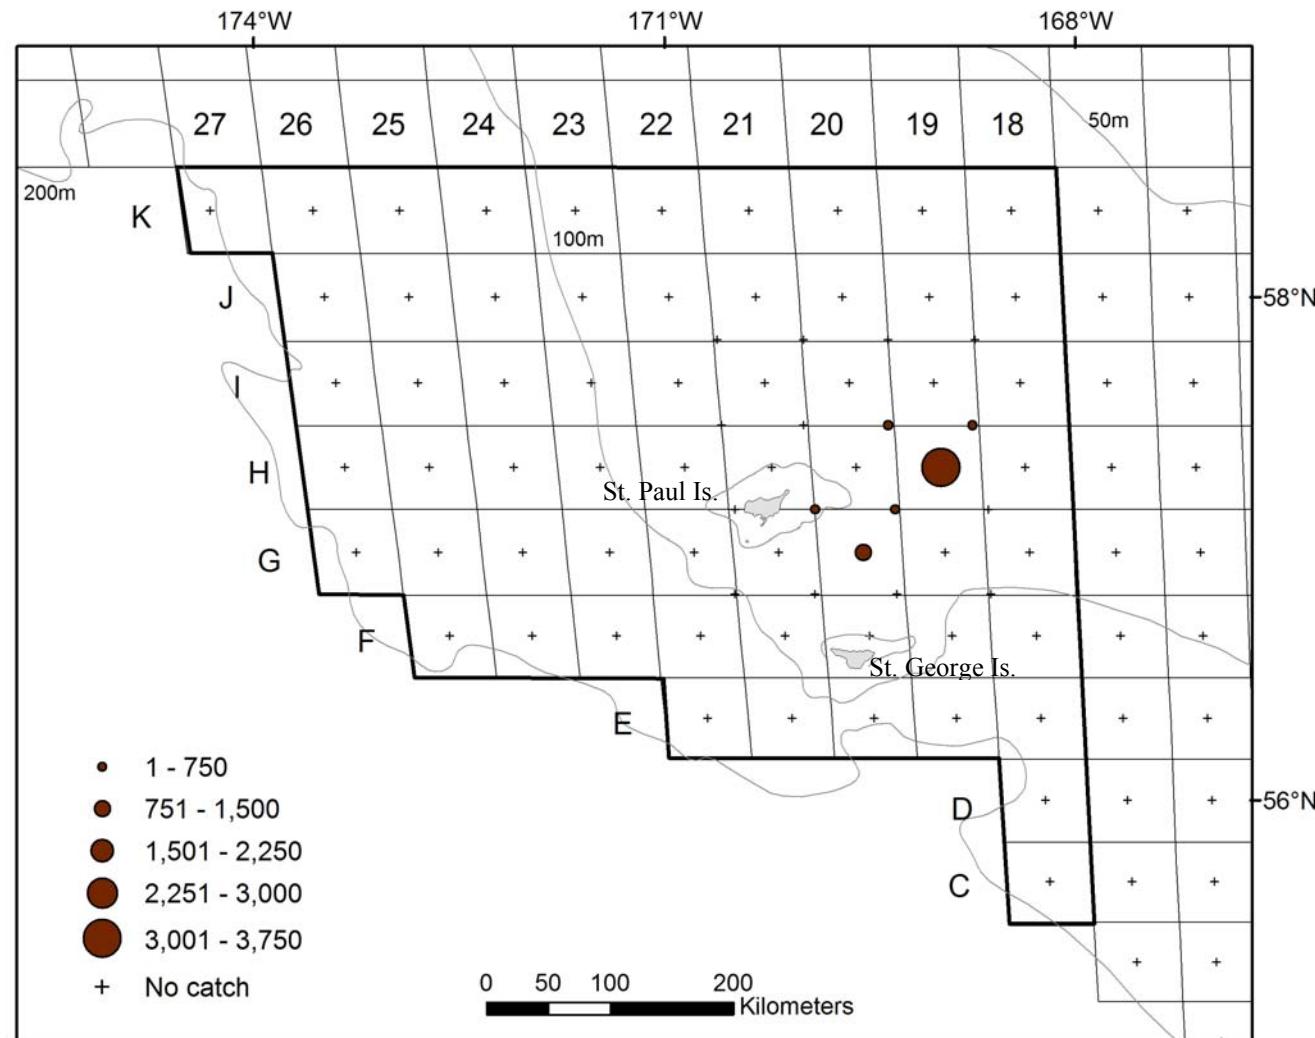

Figure 13. --Total density (number/nmi²) of blue king crab (*Paralithodes platypus*) at each station sampled in the Pribilof District in 2009. The outlined area depicts the management district.

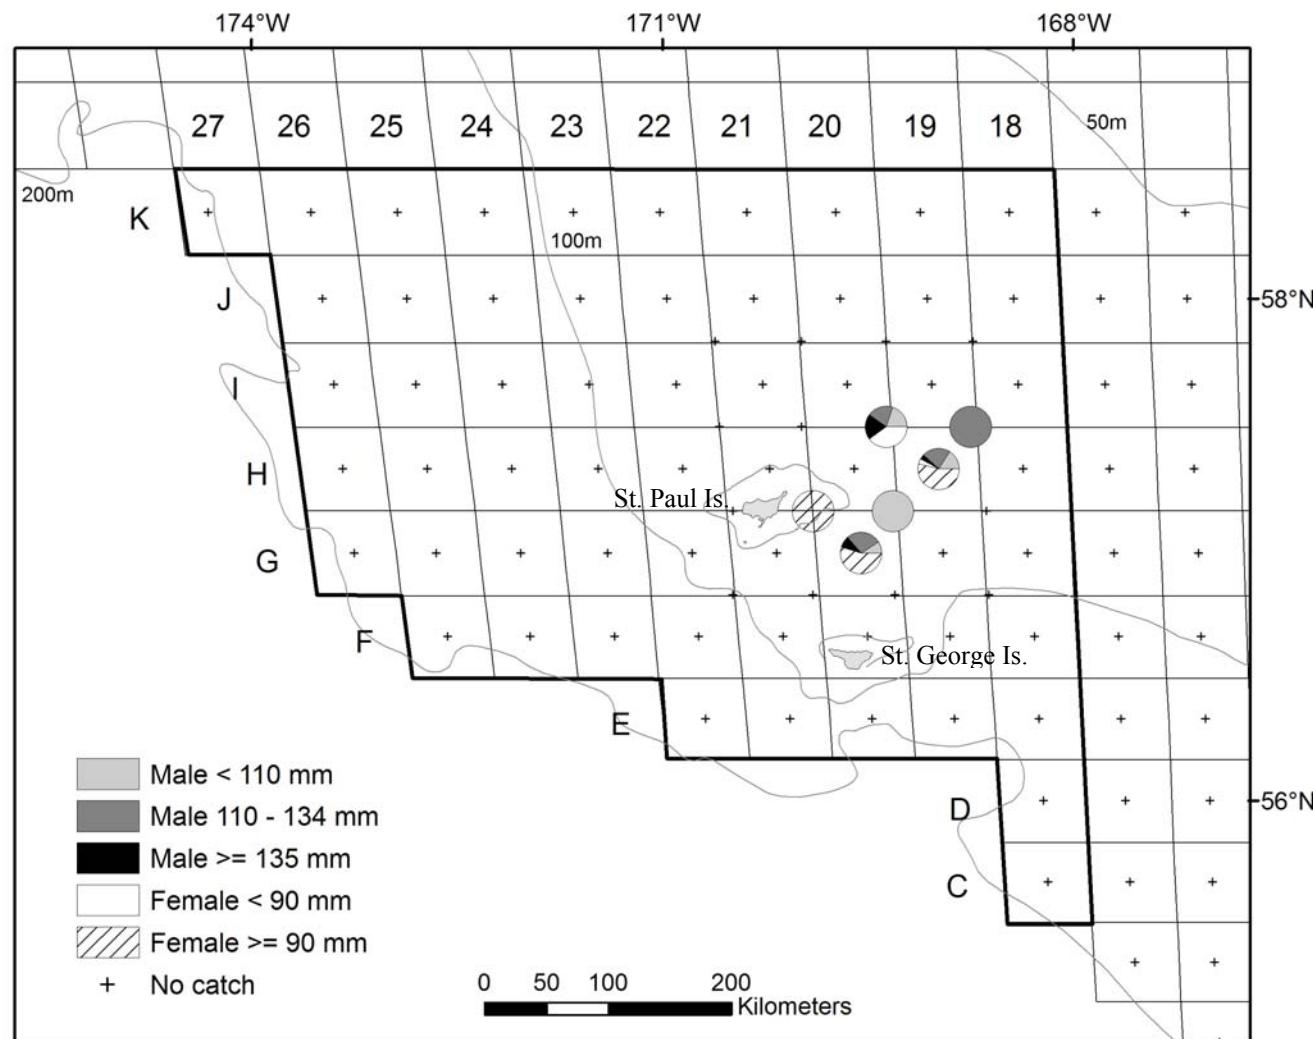

Figure 14. --Percentage of male and female blue king crab (*Paralithodes platypus*) size categories at each station of the Pribilof District in 2009. The outlined area depicts stations within the management district.

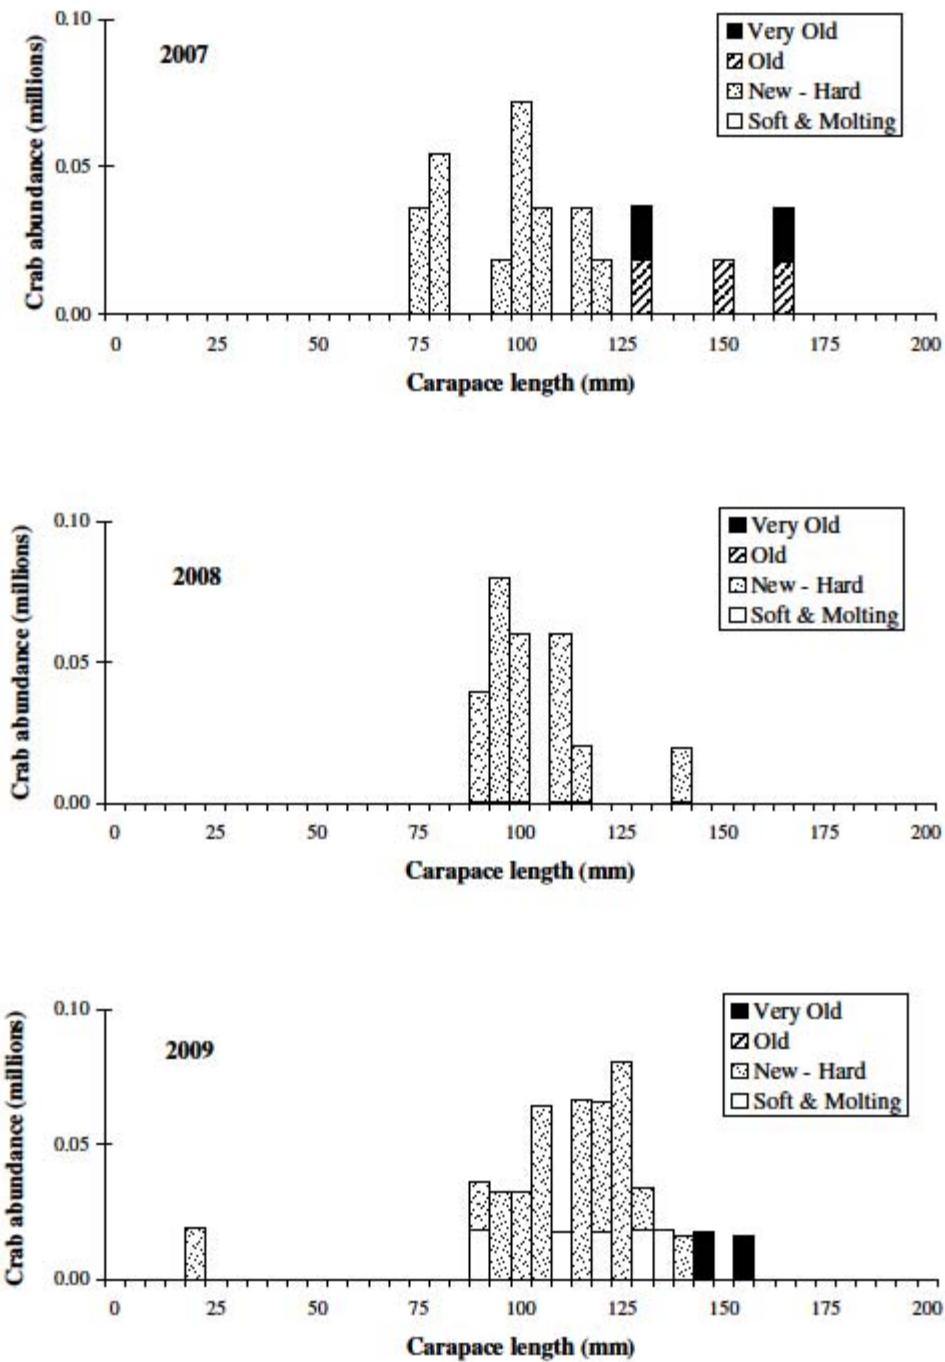

Figure 15. --Size-frequency of Pribilof District male blue king crab (*Paralithodes platypus*) by 5 mm length classes, 2007-2009.

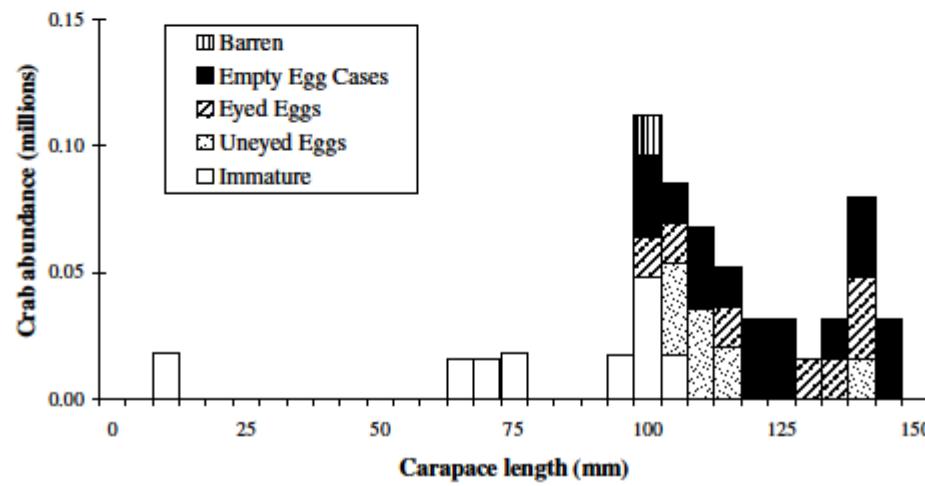

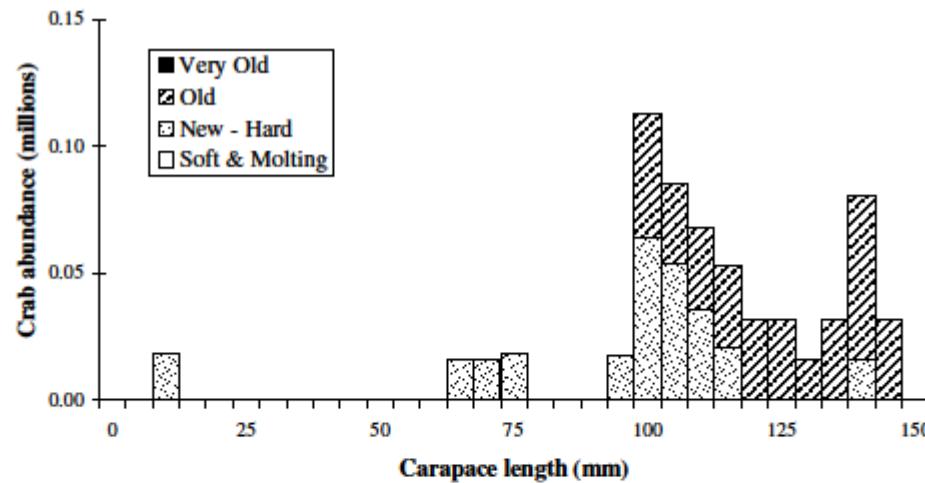

Figure 16. --Size-frequency, shell and egg condition of Pribilof District female blue king crab (*Paralithodes platypus*) by 5 mm length classes in 2009.

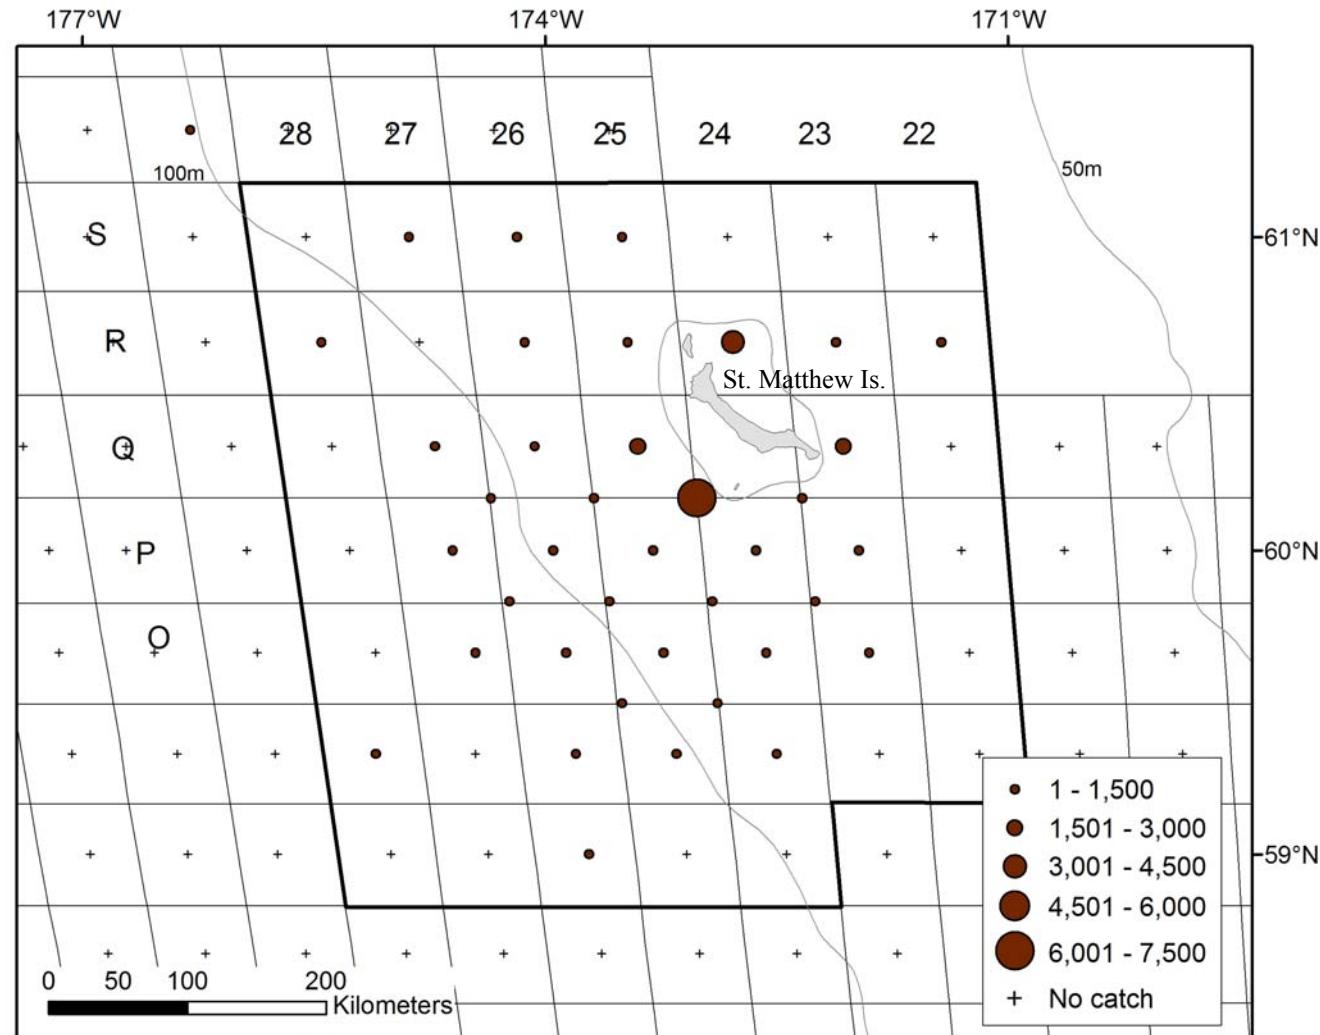

Figure 17. --Total density (number/nmi²) of blue king crab (*Paralithodes platypus*) at each station sampled in the St. Mathew Island Section of the Northern District in 2009. The outlined area depicts stations within the management district.

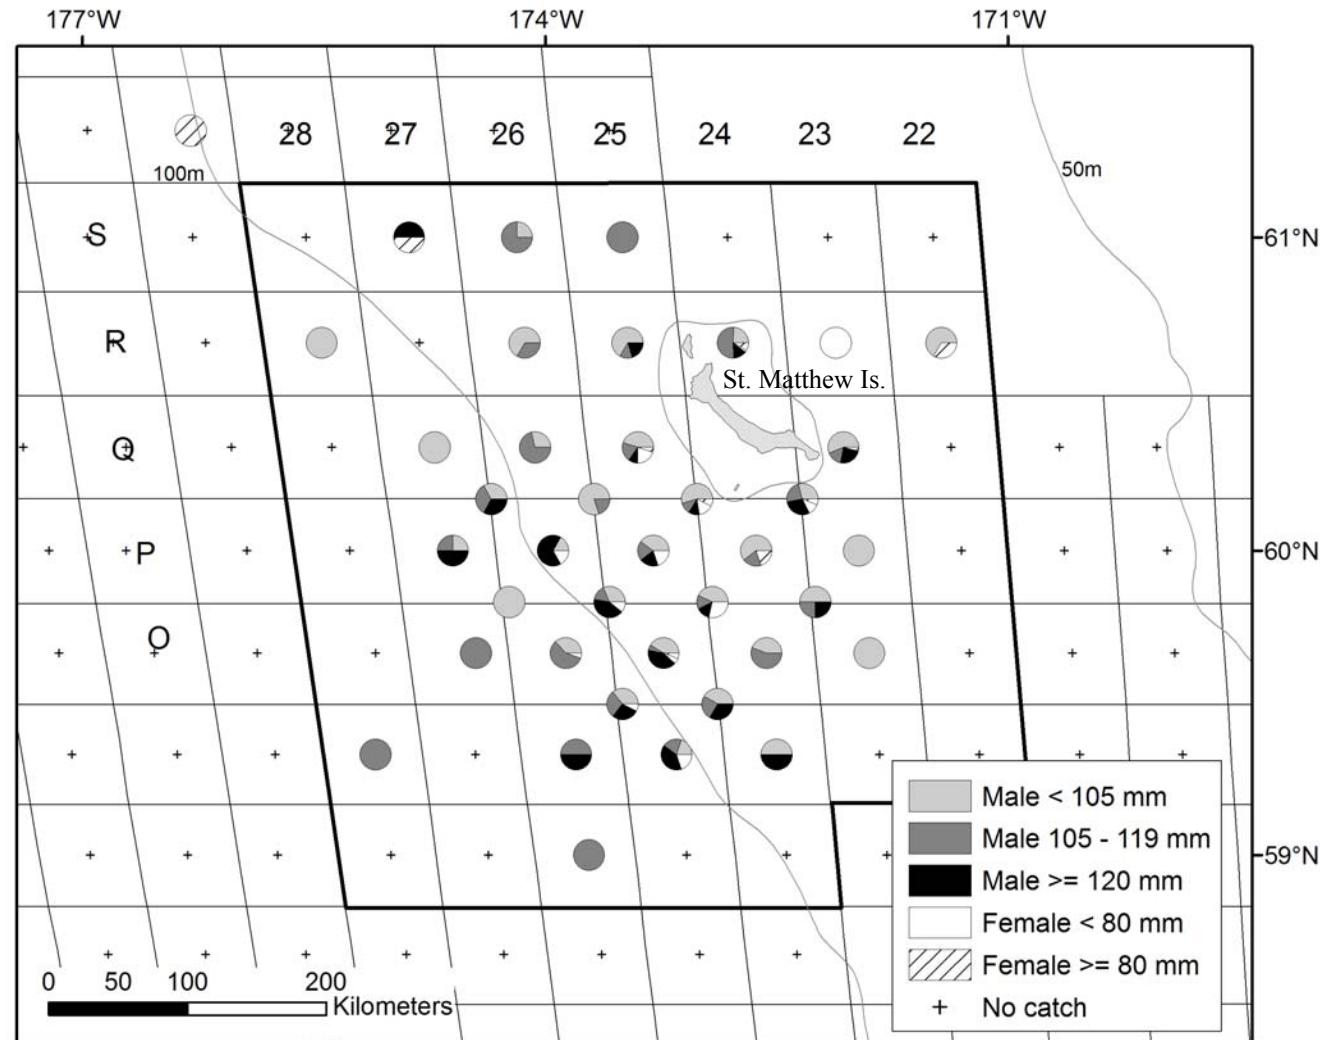

Figure 18. --Percentage of male and female blue king crab (*Paralithodes platypus*) size categories at each station of the St. Matthew Island Section of the Northern District in 2009. The outlined area depicts stations within the management district.

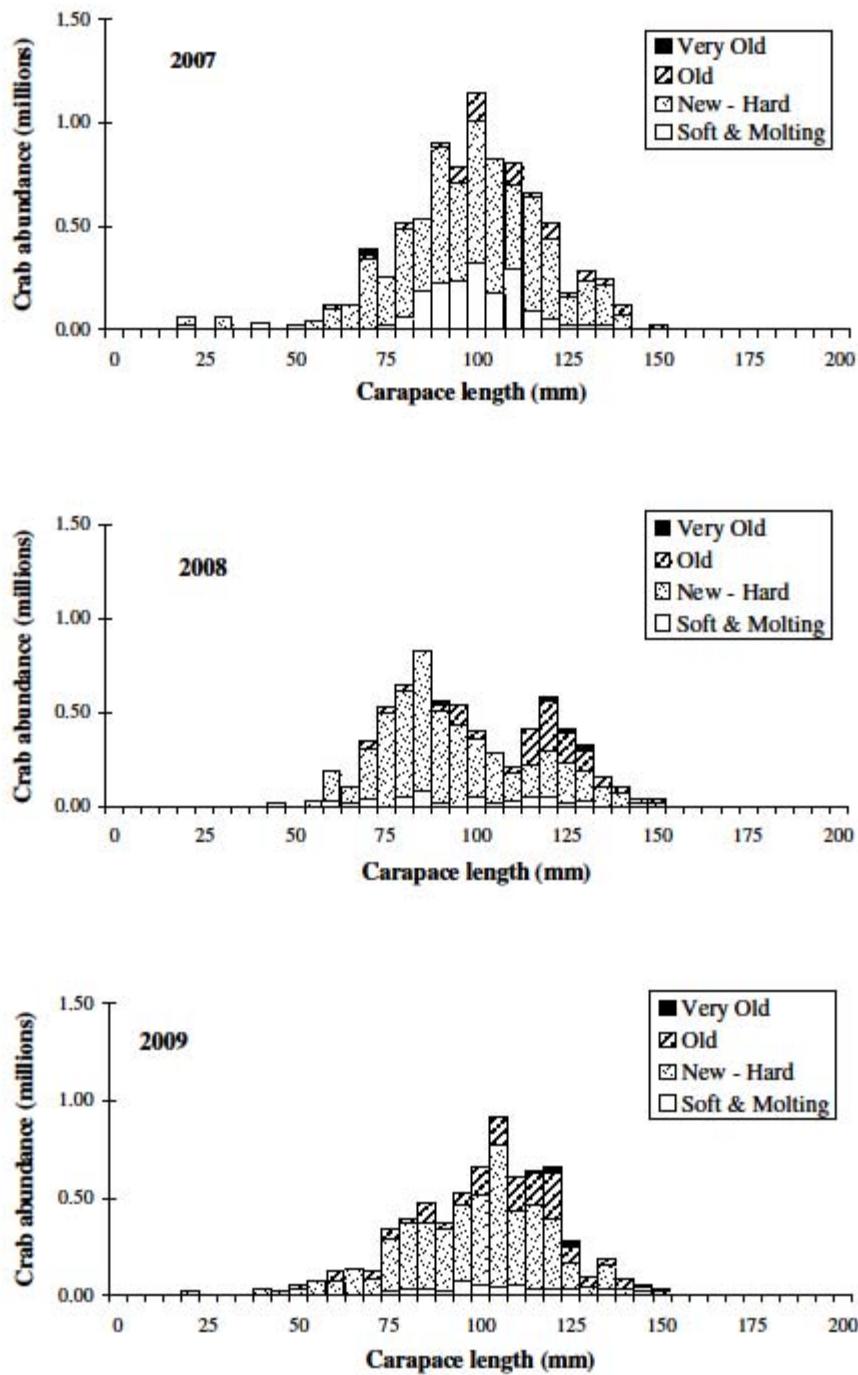

Figure 19. --Size-frequency of St. Matthew Island Section male blue king crab (*Paralithodes platypus*) by 5 mm length classes, 2007-2009.

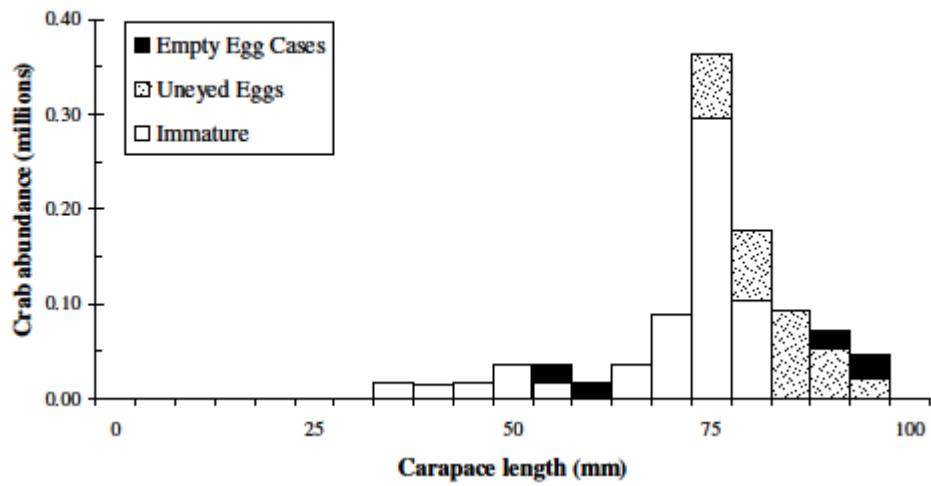

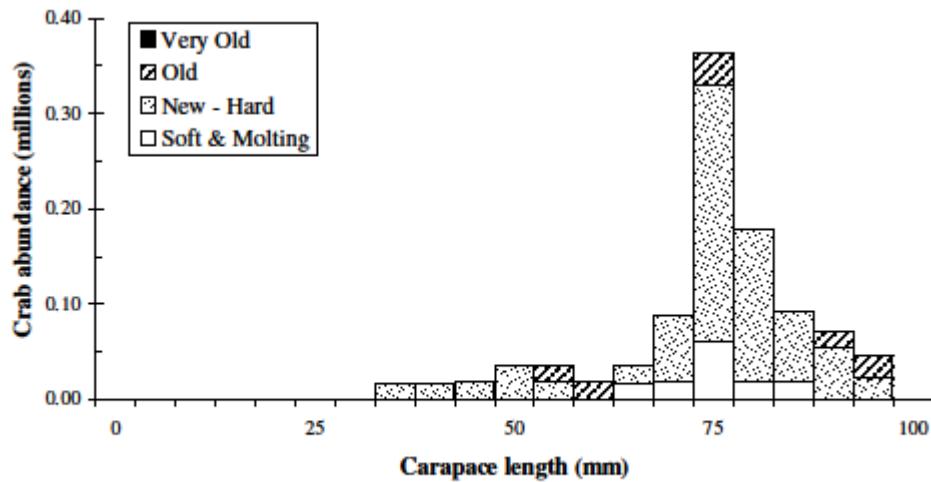

Figure 20. -- Size-frequency, shell and egg condition of St. Matthew Island Section female blue king crab (*Paralithodes platypus*) by 5 mm length classes, 2007-2009.

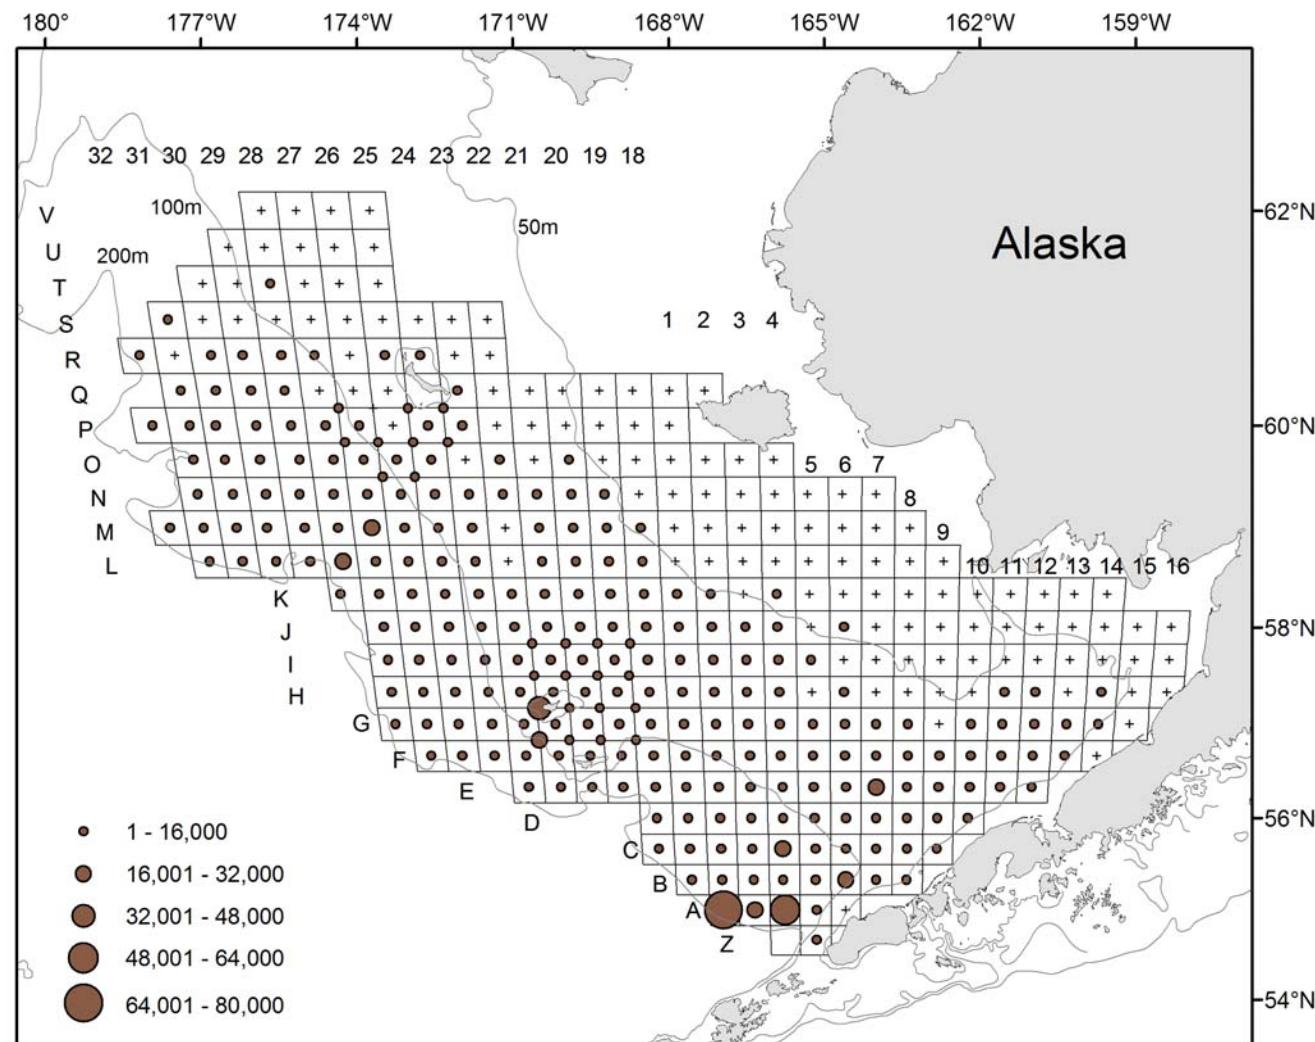

Figure 21. --Total density (number/nmi²) of Tanner crab (*Chionoecetes bairdi*) at each station sampled in 2009. Data depicted by circles are crab densities at equal intervals.

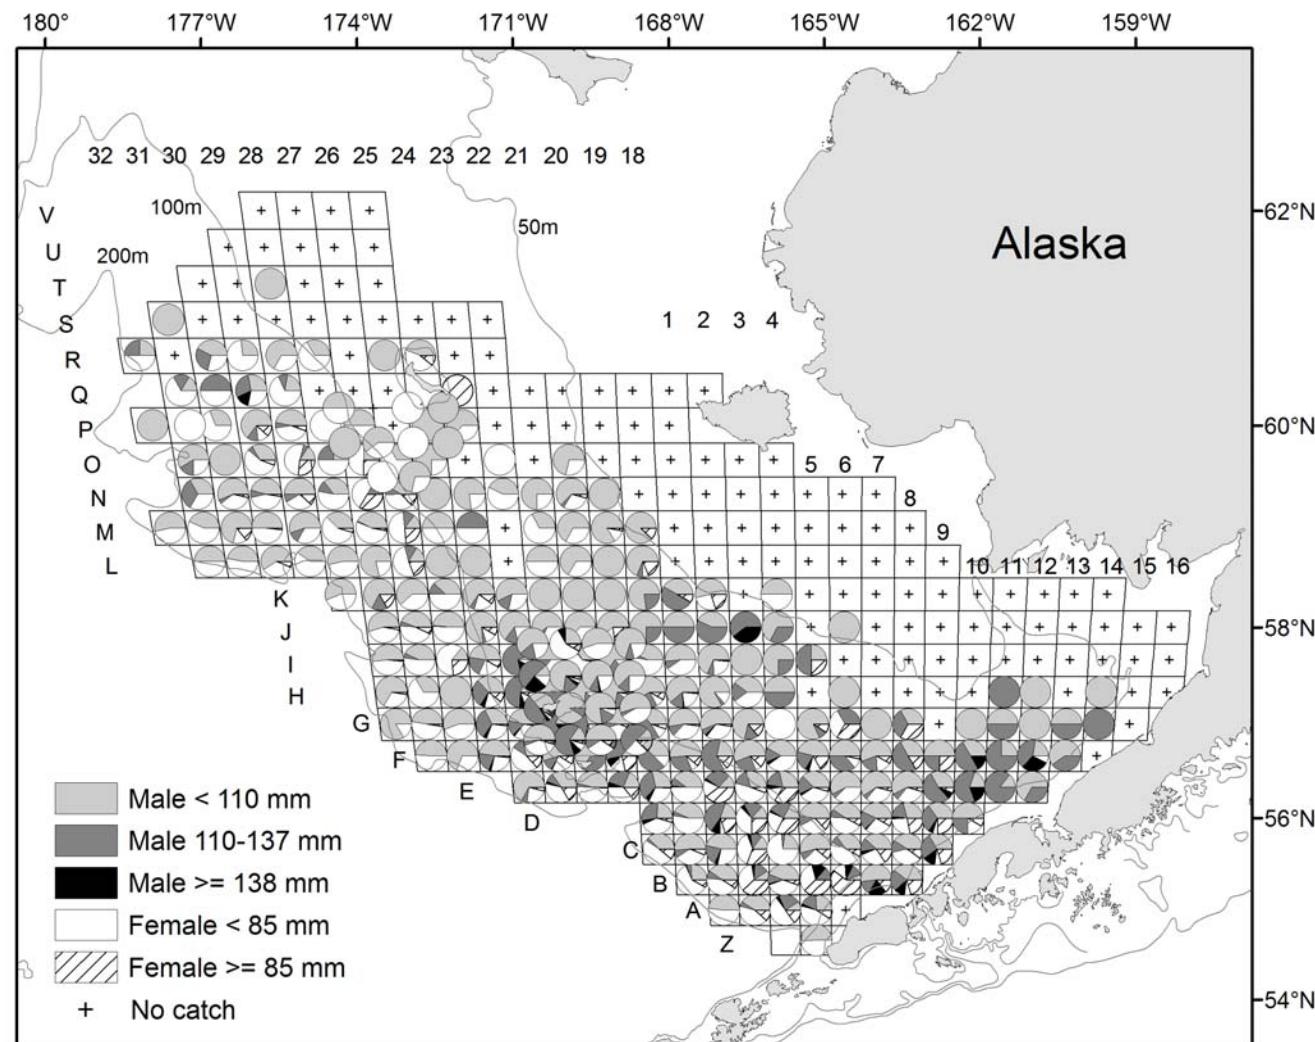

Figure 22. --Percentage of male and female Tanner crab (*Chionoecetes bairdi*) size categories at each station sampled in 2009.

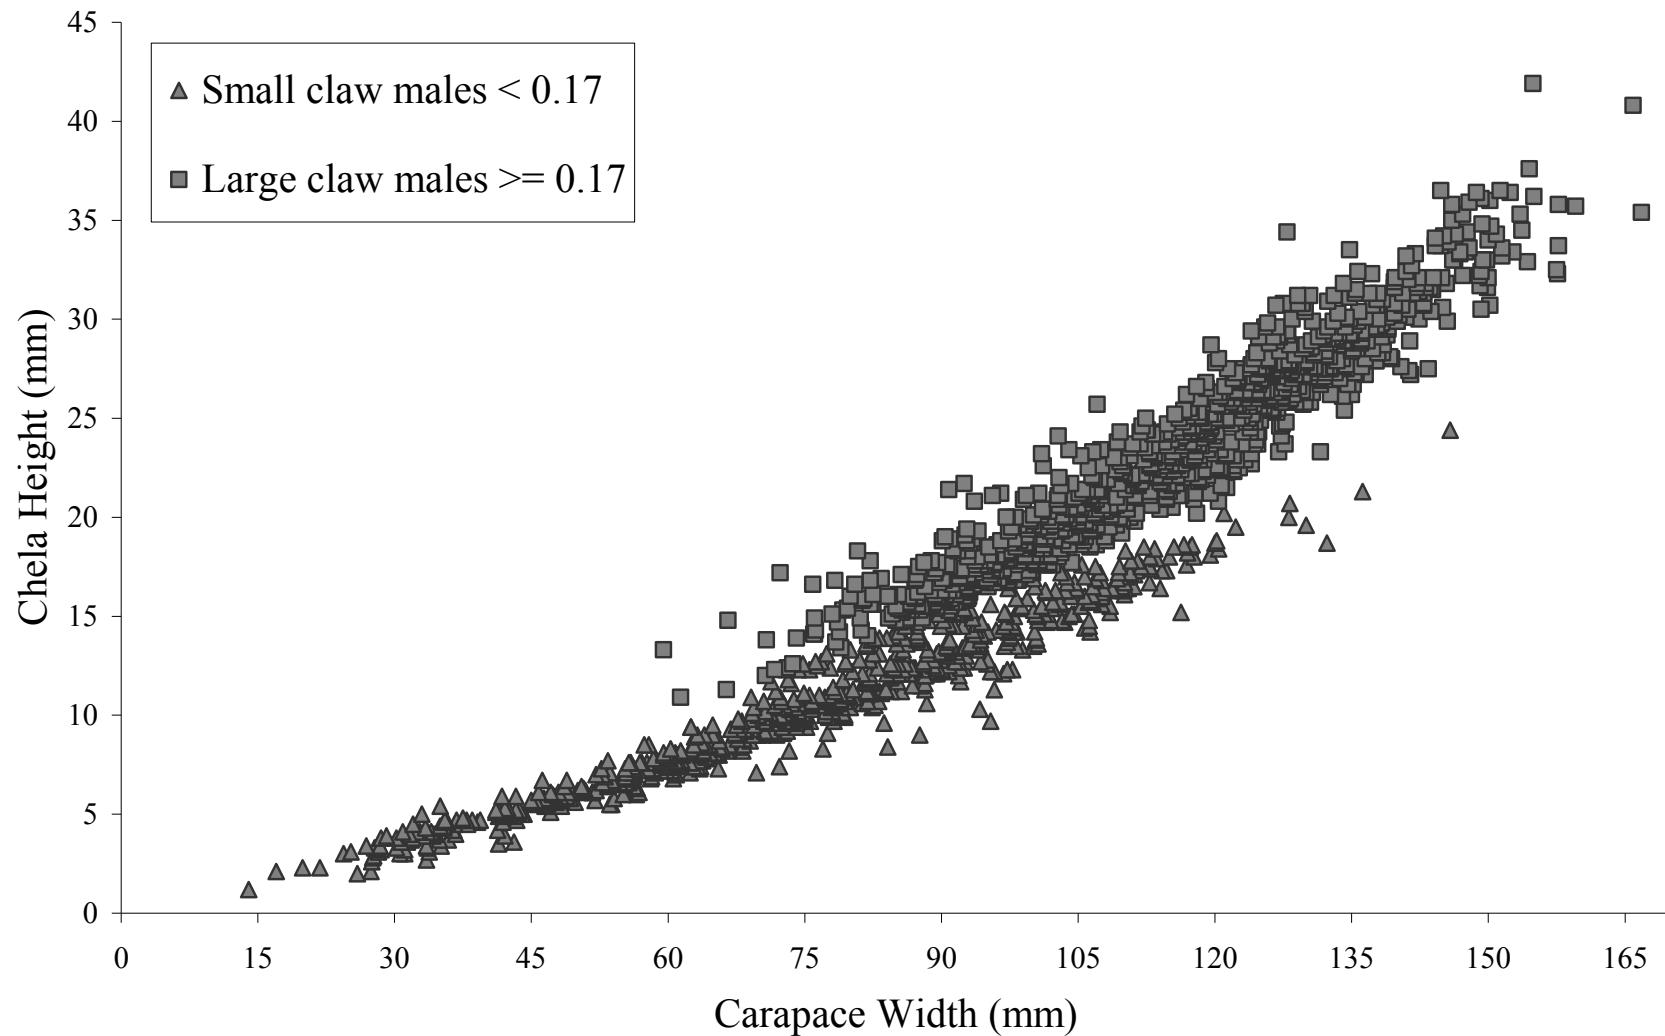

Figure 23. --Male Tanner crab (*Chionoecetes bairdi*) chela height versus carapace width measurements collected on the 2008 National Marine Fisheries Service eastern Bering Sea bottom trawl survey.

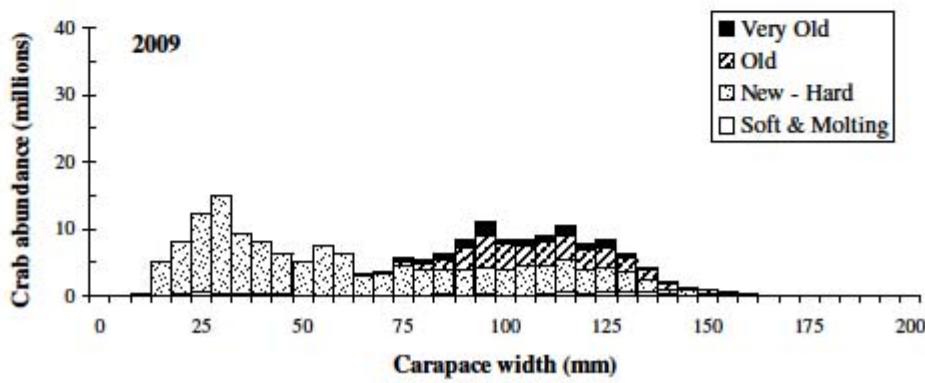

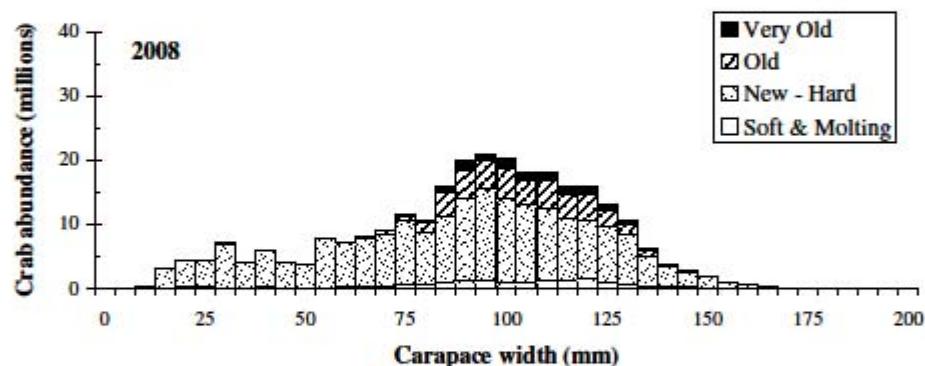

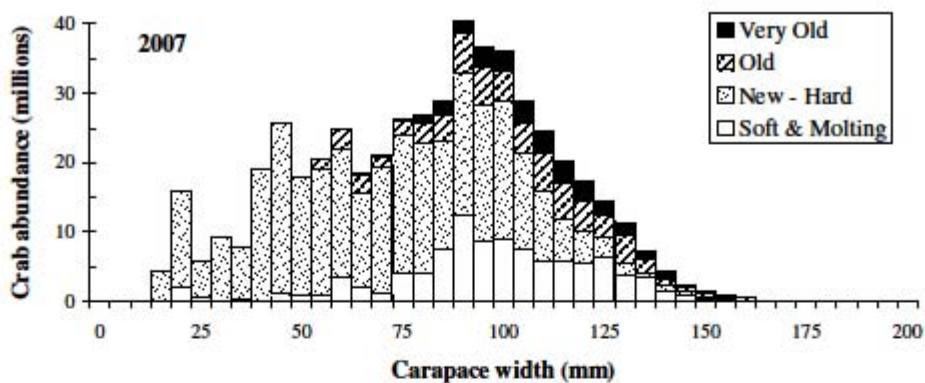

Figure 24. --Size-frequency of male Tanner crab (*Chionoecetes bairdi*) by 5 mm width classes of all districts combined, 2007-2009.

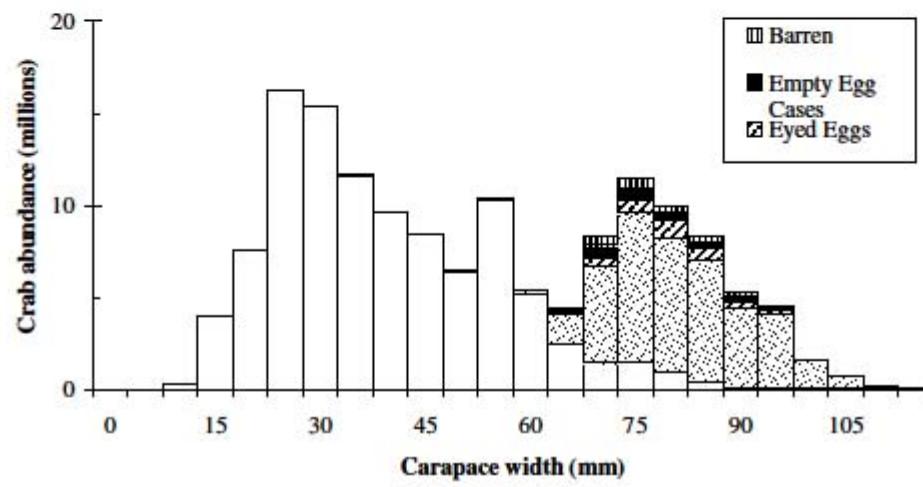

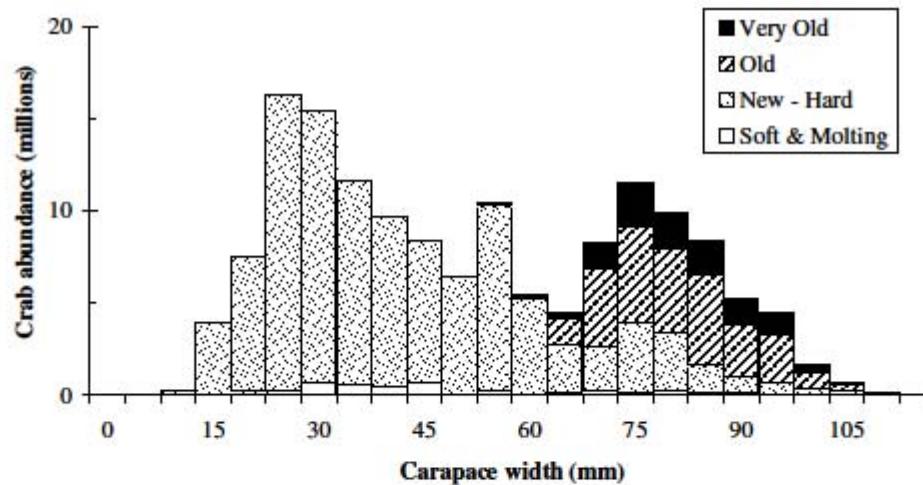

Figure 25. --Size-frequency, shell and egg condition of female Tanner crab (*Chionoecetes bairdi*) by 5 mm width classes of all districts combined in 2009.
