Foreword

The National Standard Reference Data System is a Government-wide effort to provide for the technical community of the United States effective access to the quantitative data of physical science, critically evaluated and compiled for convenience, and readily accessible through a variety of distribution channels. The System was established in 1963 by action of the President's Office of Science and Technology and the Federal Council for Science and Technology.

The responsibility to administer the System was assigned to the National Bureau of Standards and an Office of Standard Reference Data was set up at the Bureau for this purpose. Since 1963, this Office has developed systematic plans for meeting high-priority needs for reliable reference data. It has undertaken to coordinate and integrate existing data evaluation and compilation activities (primarily those under sponsorship of Federal agencies) into a comprehensive program, supplementing and expanding technical coverage when necessary, establishing and maintaining standards for the output of the participating groups, and providing mechanisms for the dissemination of the output as required.

The System now comprises a complex of data centers and other activities, carried on in Government agencies, academic institutions, and nongovernmental laboratories. The independent operational status of existing critical data projects is maintained and encouraged. Data centers that are components of the NSRDS produce compilations of critically evaluated data, critical reviews of the state of quantitative knowledge in specialized areas, and computations of useful functions derived from standard reference data. In addition, the centers and projects establish criteria for evaluation and compilation of data and make recommendations on needed modifications or extensions of experimental techniques.

Data publications of the NSRDS take a variety of physical forms, including books, pamphlets, loose-leaf sheets and computer tapes. While most of the compilations have been issued by the Government Printing Office, several have appeared in scientific journals. Under some circumstances, private publishing houses are regarded as appropriate primary dissemination mechanisms.

The technical scope of the NSRDS is indicated by the principal categories of data compilation projects now active or being planned: nuclear properties, atomic and molecular properties, solid state properties, thermodynamic and transport properties, chemical kinetics, colloid and surface properties, and mechanical properties.

An important aspect of the NSRDS is the advice and planning assistance which the National Research Council of the National Academy of Sciences-National Academy of Engineering provides. These services are organized under an overall Review Committee which considers the program as a whole and makes recommendations on policy, long-term planning, and international collaboration. Advisory Panels, each concerned with a single technical area, meet regularly to examine major portions of the program, assign relative priorities, and identify specific key problems in need of further attention. For selected specific topics, the Advisory Panels sponsor subpanels which make detailed studies of users' needs, the present state of knowledge, and existing data resources as a basis for recommending one or more data compilation activities. This assembly of advisory services contributes greatly to the guidance of NSRDS activities.

The NSRDS-NBS series of publications is intended primarily to include evaluated reference data and critical reviews of long-term interest to the scientific and technical community.

Theoretical Mean Activity Coefficients of Strong Electrolytes in Aqueous Solutions from 0 to 100 °C

Walter J. Hamer

In determining the activity coefficients of electrolytes in aqueous solutions from the freezing point to the boiling point of the solvent, various equations have been used in the treatment of the data. This paper gives values for activity coefficients of electrolytes of various valence types from 0 to 100 °C, and for ionic strengths from zero to 0.1 molal or 0.1 molar, as calculated by seven different equations based on the theory of interionic attraction. These equations are those of Debye and Hückel, Güntelberg, Davies, Scatchard, and Bjerrum, and what may be termed an extended Güntelberg equation and an extended Scatchard equation.

Key words: Activity coefficients, electrolytes, interionic attraction expressions.

1. Introduction

The mean activity coefficients, on a volume and weight basis, for 1-1, 1-2 (or 2-1), 1-3 (or 3-1), 1-4 (or 4-1 or 2-2), 2-3 (or 3-2), 2-4 (or 4-2), 3-3, 3-4 (or 4-3), and 4-4 completely dissociated electrolytes in aqueous solutions, as calculated by seven widely referred to theoretical equations are given for ionic strengths of 0.1 and less and for temperatures from 0 °C to 100 °C, inclusive. The theoretical equations employed are those of (1) Debye and Hückel, frequently referred to as the limiting law of Debye and Hückel, (2) Güntelberg, (3) Davies, (4) Scatchard, (5) Bjerrum, and what may be called a (6) modified or extended Güntelberg expression and a (7) modified or extended Scatchard expression. Although these equations reproduce experimental results exactly only in rare cases, they are of value as an aid in rapid interpretations of literature data where expressions, such as "activity coefficients were calculated by the limiting law of Debye and Hückel," or "activity coefficients were calculated by the Davies equation," or "Bjerrum ion sizes were used to calculate activity coefficients," or "Scatchard has suggested that a better average of the higher virial coefficients would be provided by a $1 + 1.5 m^{1/2}$ term" [1]¹ are encountered. They are also of use in estimating a value for an activity coefficient if an experimental value is not available.

2. Chemical Potentials, Activities, and Activity Coefficients

For closed isolated systems to which no matter is added or withdrawn thermodynamics give:

$$dU = TdS - pdV$$

where U is energy, T the absolute temperature, S the entropy, p the pressure, and V the volume.

For an open system to which matter may be added or withdrawn (for example, addition of a salt to water or removal of water from a salt solution by evaporation) Gibbs gave (Gibbs used different symbols):

$$dU = TdS - pdV + \mu_A dn_A + \mu_B dn_B + \dots + \mu_Z dn_Z$$

where n represents the number of moles of component A, B , etc., represented by subscripts and the μ 's represent the Gibbs' "chemical potentials" of the various components. Since from thermodynamic considerations,

$$G = U - TS + pV = \text{Gibbs energy}$$

$$H = U + pV = \text{Heat content}$$

$$F \text{ (or } A) = U - TS = \text{Helmholtz energy}$$

the Gibbs "chemical potentials" for component A , for example, may be defined in a multiplicity of ways as follows:

$$\begin{aligned} \mu_A &= (\partial U / \partial n_A)_{S, V, n'} = (\partial H / \partial n_A)_{S, p, n'} \\ &= (\partial F / \partial n_A)_{T, V, n'} = (\partial G / \partial n_A)_{T, p, n'} \end{aligned}$$

where n now represents the constancy of all components except component A . Thus, Gibbs' "chemical potentials" can be expressed in various ways depending on what conditions are held constant during an experiment. The last equality is the one generally used in defining the "chemical potential" in that experiments may easily be designed wherein the temperature and pressure are maintained constant. It is inconvenient to conduct experiments at constant volume and temperature, under which conditions the third equality applies; and it is indeed difficult to conceive of ways to conduct experiments either at constant entropy and volume (first equality) or at constant entropy and pressure (second equality).

¹ Figures in brackets indicate the literature references on page 5.

Since the energy, entropy, heat content, Helmholtz energy, and Gibbs energy are defined only by differential equations, we can determine only differences of these quantities between two states of a system containing the same quantity of matter. It is therefore customary to tabulate the differences from some standard state, which is equivalent to an arbitrary assumption that the various functions are each zero in the standard states. For general purposes it is customary to assume that the energy, or the heat content, of each element at some standard temperature, usually 25 °C, and some standard pressure, usually one atmosphere, and in its most stable form under these conditions is zero. This same standard state may be adopted for the entropy, Helmholtz energy, and Gibbs energy, although the entropy is sometimes taken as zero at absolute zero in accordance with the third law of thermodynamics. A knowledge of the individual heat capacities and volumes permits the calculation of these quantities under other conditions.

The same considerations apply to the chemical potential, i.e., only differences from an arbitrarily selected standard state can be determined. Throughout this evaluation the chemical potential shall be defined in terms of the partial molal Gibbs energy (fourth equality in equation above). The difference in chemical potential between two states (compositions) of an *ideal solution* is given by:

$$\mu_i - \mu'_i = RT \ln \frac{p_i}{p'_i} = RT \ln \frac{x_i}{x'_i}$$

where i = component i and p and x denote, respectively, the vapor pressure and mole fraction. If one of the compositions is the pure component with $x'_i = 1$, $p'_i = p_i^0$, and $\mu'_i = \mu_i^0$, then

$$\mu_i = \mu_i^0 + RT \ln \frac{p_i}{p_i^0} = \mu_i^0 + RT \ln x_i.$$

where the relative vapor pressure of component i is equal to the mole fraction of component i . For *real or nonideal solutions* this equation becomes

$$\mu_i = \mu_i^0 + RT \ln \frac{f_i}{f_i^0} = \mu_i^0 + RT \ln a_i$$

where a_i is the activity of component i and defined as the relative fugacity, where f denotes the fugacity or corrected pressure.

For solutions of electrolytes the standard state is usually chosen so that the ratio of the activity to the concentration is equal to unity at infinite dilution where the laws of ideal solutions are obeyed. G. N. Lewis [2] called this ratio the activity coefficient, thus $a = \gamma x$.

It is more usual, however, to express the composition of a solution either in terms of concentration (molarity), c , i.e., moles of solute per liter, or as molalities, m , in moles of solute per 1000 grams of solvent. In each of these cases, the numerical values

of the activity coefficient differ from those expressed on the basis of mole fraction; γ_c and γ_m are used here to denote the activity coefficient on the molarity and molality scales, respectively. The relations between γ_x , γ_c , and γ_m are given by:

$$\gamma_x = \gamma_c(d - 0.001 Mc + 0.001 M_s cv)/d_0$$

$$\gamma_x = \gamma_m(1 + 0.001 \nu m M_s)$$

$$c\gamma_c = d_0 m \gamma_m$$

where d = density of solution, d_0 = density of solvent, M_s = molecular weight of solvent, M = molecular weight of solute, and ν = the number of ions into which one molecule of the solute dissociates.

As electroneutrality must prevail in electrolytic solutions, the activity of an electrolyte that ionizes into ν_+ cations and ν_- anions is given by:

$$a_{\text{salt}} = a_2 = a_{+}^{\nu_+} \cdot a_{-}^{\nu_-} = a_{\pm}^{\nu}$$

where $\nu = \nu_+ + \nu_-$. Therefore, for an electrolytic solution, the mean activity of the ionized electrolyte, a_{\pm} , would be given by:

$$\mu = \mu^0 + \nu RT \ln a_{\pm}$$

Thus $a_{\pm} = \gamma_{\pm} m_{\pm}$ and $a_2 = (\gamma_{\pm} m_{\pm})^{\nu}$ where m_{\pm} and γ_{\pm} denote, respectively, the mean molality and mean activity coefficient of the electrolyte. The mean activity coefficient of the electrolyte is given by:

$$\gamma_{\pm} = (\gamma_{+}^{\nu_+} \gamma_{-}^{\nu_-})^{1/\nu}$$

and the mean ionic concentration (in molality, for example) by:

$$m_{\pm} = (\nu_+^{\nu_+} \nu_-^{\nu_-})^{1/\nu} m = X m$$

The properties of electrolytic solutions are, in general, directly related to the ionic strength of the solution, defined by:

$$I = 1/2 \sum_i z_i^2 m_i = Y m$$

where z is the ionic valence.

Values of Xm and Ym as well as γ_{\pm} and a_2 are given in table 1² for various valence types of electrolytes.

3. Theoretical Expressions for Activity Coefficients

Activity coefficients give a measure of the deviations of real solutions from ideality and include the magnitude of all effects that lead to these deviations.

² All tables are to be found at the end of the paper.

In dilute solutions the main effect is that of inter-ionic attraction, i.e., the attraction between electrical (ionic) charges of unlike sign, and for which Debye and Hückel [3] assuming that ions are point charges derived a solution which led to the following expression for the mean activity coefficient, γ_{\pm} , of an electrolyte (γ shall be used hereafter for γ_{\pm}):

$$\log \gamma_c = -z_+ z_- A_c \sqrt{I_c} \quad (1)$$

where the subscript c refers to concentrations on the volume basis and

$$A_c = \left(\frac{2\pi N}{1000}\right)^{1/2} \frac{e^3}{2.302585 k^{3/2}} \left(\frac{1}{T^{3/2} \epsilon^{3/2}}\right) = \frac{1.824829238 \times 10^6}{(T\epsilon)^{3/2}},$$

where the symbols have the following meanings and numerical values [4]:

N (or N_A) = Avogadro constant = $6.02252(28) \times 10^{23}$ mol⁻¹.

e = elementary charge (sometimes called the electronic or protonic charge) = $4.80298(20)$ esu.

k = Boltzmann constant = $1.38054(18) \times 10^{-16}$ erg K⁻¹.

T = absolute temperature in K (defined in the thermodynamic scale by assigning 273.16 K (Kelvin) to the triple point of water (freezing point of water, 273.15 K = 0 °C (Celsius). (The 13th General Conference on Weights and Measures in 1967 changed the unit of temperature and temperature interval from "degrees Kelvin" to simply "Kelvin," symbol: K.)

ϵ = dielectric constant of the solvent.

The values given in parentheses above represent established limits of error based on three standard deviations applied to the last digits in the listed value.

The following values of π and $\ln 10$ were used in the calculations:

$$\pi = 3.14159265$$

$$\ln 10 = 2.302585$$

A_m on the molality (or weight) basis is given by $A_m = A_c(d_0)^{1/2}$ where d_0 is the density of the solvent. Values of ϵ , the dielectric constant, and of d_0 , the density of water, from 0 to 100 °C, inclusive, are given in table 2 [5, 6]. Values of A_c and A_m for aqueous solutions from 0 to 100 °C, inclusive, are given in table 3.

Values of γ_c as calculated by equation (1) for 1-1, 1-2 (or 2-1), 1-3 (or 3-1), 1-4 (or 4-1 or 2-2), 2-3 (or 3-2), 2-4 (or 4-2), 3-3, 3-4 (or 4-3), and 4-4 electrolytes are given, respectively, in tables 4 to 12, inclusive, for ionic strengths of 0.1 and below and for temperatures from 0 to 100 °C, inclusive. Similar data for γ_m are given in tables 13 to 21, inclusive.

When the size, a_i , of the ions is taken into account, the Debye-Hückel equation becomes:

$$\log \gamma_c = \frac{-z_+ z_- A_c \sqrt{I_c}}{1 + B_c a_i \sqrt{I_c}}$$

where

$$B_c = \left(\frac{8\pi N}{1000}\right)^{1/2} \frac{e}{k^{1/2}} \left(\frac{1}{T^{1/2} \epsilon^{1/2}}\right) = \frac{50.29158649 \times 10^8}{(T\epsilon)^{1/2}}$$

in which the symbols have the significances given above. B_m on the molality (or weight) basis is given by $B_m = B_c(d_0)^{1/2}$. Values of B_c and B_m for aqueous solutions from 0 to 100 °C, inclusive, are given in table 3.

Güntelberg [7] suggested the simpler form

$$\log \gamma_c = \frac{-z_+ z_- A_c \sqrt{I_c}}{1 + \sqrt{I_c}} \quad (2)$$

which is equivalent to assigning a value of approximately 3Å as calculated by equation (2) to the ion size at all temperatures. Güntelberg values of γ_c for 1-1, 1-2 (or 2-1), 1-3 (or 3-1), 1-4 (or 4-1 or 2-2), 2-3 (or 3-2), 2-4 (or 4-2), 3-3, 3-4 (or 4-3), and 4-4 electrolytes are given, respectively, in tables 22 to 30, inclusive, for ionic strengths of 0.1 and below and for temperatures from 0 to 100 °C, inclusive. Güntelberg values for γ_m for these same valence types and ranges of ionic strength and temperature are given in tables 31 to 39, inclusive.

A modified or extended Güntelberg equation would be

$$\log \gamma_c = \frac{-z_+ z_- A_c \sqrt{I_c}}{1 + 3B_c \sqrt{I_c}} \quad (3)$$

where the denominator is now temperature dependent since B_c is a function of temperature. Extended Güntelberg values of γ_c as calculated by equation (3) for 1-1, 1-2 (or 2-1), 1-3 (or 3-1), 1-4 (or 4-1 or 2-2), 2-3 (or 3-2), 2-4 (or 4-2), 3-3, 3-4 (or 4-3), and 4-4 electrolytes are given, respectively, in tables 40 to 48, inclusive, for ionic strengths of 0.1 and below and for temperatures from 0 to 100 °C, inclusive. Extended Güntelberg values for γ_m for the same valence types and ranges of ionic strength and temperature are given in tables 49 to 57, inclusive.

These Güntelberg expressions for the activity coefficient give a fair representation of a number of electrolytes up to $I=0.1$. However, a better representation is obtained if a term linear in the ionic strength is added to the right side of the equations. Thus, Guggenheim [8] proposed the equation

$$\log \gamma_c = \frac{-z_+ z_- A_c \sqrt{I_c}}{1 + \sqrt{I_c}} + bI_c$$

where b is an adjustable parameter.

Davies [9] altered the Guggenheim equation by putting $b = 0.2Az_+z_-$, thus:

$$\log \gamma_c = \frac{-z_+z_-A_c\sqrt{I_c}}{1 + \sqrt{I_c}} + 0.2Az_+z_-I_c \quad (4)$$

where the denominator of the first term on the right is again independent of temperature. Davies values of γ_c as calculated by equation (4) for 1-1, 1-2 (or 2-1), 1-3 (or 3-1), 1-4 (or 4-1 or 2-2), 2-3 (or 3-2), 2-4 (or 4-2), 3-3, 3-4 (or 4-3), and 4-4 electrolytes are given, respectively, in tables 58 to 66, inclusive, for ionic strengths of 0.1 and below and for temperatures from 0 to 100 °C, inclusive. Davies values for γ_m for the same valence types and ranges of ionic strength and temperature are given in tables 67 to 75, inclusive.

Scatchard [10] suggested that a better average fit is obtained if $(1 + 1.5\sqrt{I})$ is used in the denominator of the first term on the right for the expression for $\log \gamma_c$, thus:

$$\log \gamma_c = \frac{-z_+z_-A_c\sqrt{I_c}}{1 + 1.5\sqrt{I_c}} \quad (5)$$

Scatchard actually used an additional linear term in I with an adjustable coefficient on the right side of the above equation but this additional term is omitted here. Scatchard values of γ_c as calculated by equation (5) for 1-1, 1-2 (or 2-1), 1-3 (or 3-1), 1-4 (or 4-1 or 2-2), 2-3 (or 3-2), 2-4 (or 4-2), 3-3, 3-4 (or 4-3), and 4-4 electrolytes are given, respectively, in tables 76 to 84, inclusive, for ionic strengths of 0.1 and below and for temperatures of 0 to 100 °C, inclusive. Scatchard values for γ_m for the same valence types and ranges of ionic strength and temperature are given in tables 85 to 93, inclusive.

A modified or extended Scatchard equation results if the denominator, $1 + 1.5\sqrt{I_c}$, in the above equation is made temperature dependent, thus:

$$\log \gamma_c = \frac{-z_+z_-A_c\sqrt{I_c}}{1 + 4.5B_c\sqrt{I_c}} \quad (6)$$

Extended Scatchard values for γ_c as calculated by equation (6) for 1-1, 1-2 (or 2-1), 1-3 (or 3-1), 1-4 (or 4-1 or 2-2), 2-3 (or 3-2), 2-4 (or 4-2), 3-3, 3-4 (or 4-3), and 4-4 electrolytes are given, respectively, in tables 94 to 102, inclusive, for ionic strengths of 0.1 and below and for temperatures from 0 to 100 °C, inclusive. Extended Scatchard values for γ_m for the same valence types and ranges of ionic strength and temperature are given in tables 103 to 111, inclusive.

Bjerrum [11] has shown that ion pairs (associated ions with charges of unlike sign) occur if the di-

ameter of the ion is less than

$$a_B = \frac{z_+z_-e^2}{2\epsilon kT}$$

Values of a_B for aqueous solutions from 0 to 100 °C, inclusive, are given in table 112. The Bjerrum expression for the activity coefficient is:

$$\log \gamma_c = \frac{-z_+z_-A_c\sqrt{I_c}}{1 + B_c a_B \sqrt{I_c}} \quad (7)$$

Bjerrum values of γ_c as calculated by equation (7) for 1-1, 1-2 (or 2-1), 1-3 (or 3-1), 1-4 (or 4-1 or 2-2), 2-3 (or 3-2), 2-4 (or 4-2), 3-3, 3-4 (or 4-3), and 4-4 electrolytes are given, respectively in tables 113 to 121, inclusive, for ionic strengths of 0.1 and below and for temperatures of 0 to 100 °C, inclusive. Bjerrum values for γ_m for the same valence types and ranges of ionic strength and temperature are given in tables 122 to 130, inclusive.

4. Uncertainties

The uncertainties in values of the activity coefficients of electrolytes of various valence types for an ionic strength of 0.1 arising from the established limits of error for the physical constants employed in the above theoretical relations for the activity coefficients are given in table 131 for temperatures of 0, 25, 50, 75, and 100 °C. Uncertainties at intermediate temperatures may be obtained by interpolation. Uncertainties for more dilute solutions may be obtained by interpolation of the uncertainties on a linear plot of the uncertainties versus \sqrt{I} between 0 (where the uncertainties are zero) and $\sqrt{0.1}$. In determining these uncertainties, the limits of error for the dielectric constant of water were taken to be zero.

Owen, Miller, Milner, and Cogan [12] in 1961, and Vidulich and Kay [13] in 1962 reported values for the dielectric constant of water from 0 to 70 °C and 0 to 40 °C, respectively. The values of Owen et al. differed from those of Malmberg and Maryott, used herein, by +0.18 percent, +0.08 percent, 0 percent, -0.16 percent, and -0.25 percent at 0, 25, 40, 70, and 100 °C, (Owen et al. values were calculated from their equation expressing the dielectric constant as a function of temperature), respectively, whereas those of Vidulich and Kay differed from those of Malmberg and Maryott by +0.17 percent, +0.08 percent, and +0.03 percent at 0, 25, and 40 °C, respectively. In table 132, values of the Debye-Hückel constants A_c , A_m , B_c , and B_m based on the dielectric constant of water determined by Owen et al. are given for temperatures from 0 to 100 °C. In table 133, values for the Bjerrum minimum ion parameter, based on the dielectric constant of water as determined by Owen et al., are given for tempera-

tures from 0 to 100 °C. The required Bjerrum values needed to give a smooth difference, as a function of temperature, between those calculated using the dielectric constant of water, as determined by Malmberg and Maryott [5] or Owen et al. [12] are given in the parentheses.

The differences in values of the activity coefficients of electrolytes of various valence types for an ionic strength of 0.1 from those given in the main tables, if the dielectric constant of water determined by Owen et al. [12] is used instead of the values of Malmberg and Maryott [5], are given in table 134 on a volume basis and in table 135 on a weight basis for temperatures of 0, 25, 50, 75, and 100 °C. Differences at intermediate temperatures may be obtained by interpolation. Differences for more dilute solutions may be obtained by interpolation of the differences on a linear plot of the differences versus \sqrt{I} between 0 and $\sqrt{0.1}$.

5. Other Theoretical Treatments

The theoretical equations considered here are all general and in principle apply to all completely dissociated electrolytes and differ only in the ionic valence or in the choice of a common ion-size parameter. Those treatments which require, a priori, a specific value for the ion-size parameter [11, 14–17], or hydration number [18, 19], or some physical model for the interaction of ions in order to obtain numerical results [20–28], cannot be treated in a general numerical way and obviously are not included here. Applications of these extended treatments rest with specific cases. The equations given here are especially valuable as aids in extrapolations.

The author is greatly indebted to Woodward G. Eicke, Jr., for writing the program for this work for FORTRAN IV.
