

The Intensity Frontier

André de Gouvêa

Northwestern University

Undergraduate Lecture Series – Fermilab

June 19, 2012

Outline

1. The Frontiers of Particle Physics
2. The Intensity Frontier
3. Neutrinos
4. Muons et al

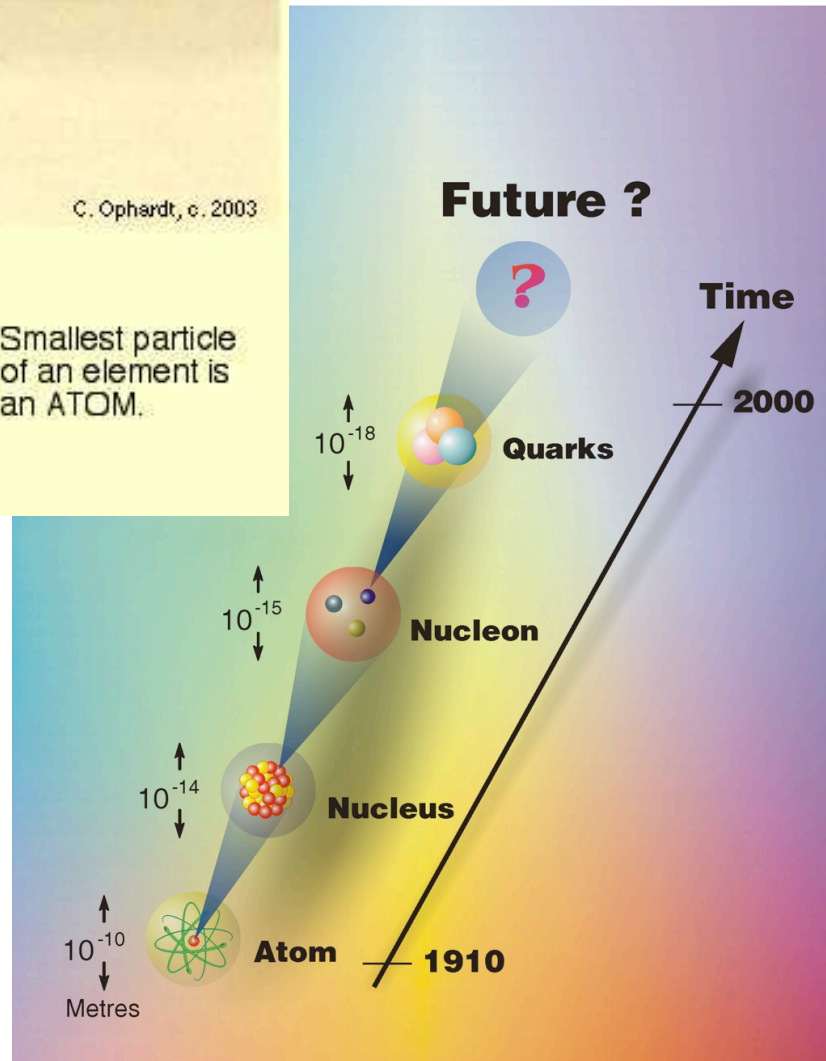

Carbon, C: Graphite

- What are basic ingredients of matter?
- How do they interact with one another?

Particle Physics

Questions:

- What are the most fundamental laws that describe all natural phenomena (at least in principle)?
- And several more pragmatic question:
 - how do stars shine?
 - heavy elements?
 - ...

Intensity Frontier

What We Know We Don't Know: A Few Solid Clues for What Lies Beyond

1. What is the physics responsible for electroweak symmetry breaking? → Higgs Boson (?)
2. What is most of the matter in the universe? → Dark Matter (?)
3. Where do *neutrino* masses come from?

The Research Frontiers of Particle Physics

There will be dedicated lectures on the **Energy Frontier** and the **Cosmic Frontier**. I am going to concentrate on the **Intensity Frontier**.

Boundaries are very fuzzy. To me,

“The **Intensity Frontier** consists of research efforts where one aims at probing nature through **precision studies of the properties and fundamental interactions of its basic constituents**. While many of these efforts – especially the ones pertinent to Fermilab – revolve around particle accelerators, **the energy of the accelerator is not ‘as high as possible’** but is rather dictated by the physics question one is interested in addressing. Instead, it is **the intensity and “quality”** (purity, time and space profile, etc) of the accelerated beam, that **determine the reach** of intensity frontier experiments. Past, current, and future Intensity Frontier experiments include studies of **neutrino oscillations**, searches for **rare muon, pion, and kaon processes**, precision measurements of **muon properties**, **heavy flavor** (charm and bottom) factories and the **LEP1** experiments (the energy was fixed at a special value, the Z -pole mass).”

[AdG, N. Saoulidou, *Ann. Rev. Nucl. Part. Sci.* 60, 513-538 (2010).]

around 100 billion go through
your thumb every second!

Also Closer to Home...

...And Much Further Away.

Supernova: 100 times more energy released in the form of neutrinos!

Neutrinos are Relics of the Big Bang:

Neutrinos are Everywhere

However, Neutrinos Are Really Hard To Detect:

Neutrinos have no charge (unlike, say, the electrons) and don't interact via the strong nuclear forces (unlike, say, a neutron).

They interact only via the WEAK force – which, as it turns out, is really weak.

You need a wall of lead as thick as the solar system in order to stop a neutrino produced in the Sun!

How did we get around this? With lots and lots of neutrinos, and really big detectors!

Until recently (~ 1998), this is how we pictured neutrinos:

- come in three flavors (see figure);
- interact only via weak interactions;
- have ZERO mass;
- 2 degrees of freedom:
 - left-handed state ν ,
 - right-handed state $\bar{\nu}$;
- neutrinos carry lepton number:
 - $L(\nu) = +1$,
 - $L(\bar{\nu}) = -1$.

Over the past decade, the picture changed dramatically. We have discovered that **neutrino masses** are **not zero**. In more detail, this is what we discovered:

- Neutrinos Mix.
- Neutrinos Oscillate. This means they can change their flavor after propagating a long distance (depends on the neutrino energy. Oftentimes, it is hundreds of miles).

Both of these phenomena occur only if the neutrino masses are not zero, and different from one another.

Mass-Induced Neutrino Flavor Oscillations

Neutrino Flavor change can arise out of several different mechanisms. The simplest one is to appreciate that, once **neutrinos have mass, leptons can mix**. If neutrinos have mass, there are two different ways to define the different neutrino states.

(1) Neutrinos with a well defined mass:

$$\nu_1, \nu_2, \nu_3, \dots \quad \text{with masses} \quad m_1, m_2, m_3, \dots$$

(2) Neutrinos with a well defined flavor:

$$\nu_e, \nu_\mu, \nu_\tau$$

These are related by a unitary transformation:

$$\nu_\alpha = U_{\alpha i} \nu_i \quad \alpha = e, \mu, \tau, \quad i = 1, 2, 3$$

U is a unitary mixing matrix.

The Propagation of Massive Neutrinos

Neutrino mass eigenstates are eigenstates of the free-particle Hamiltonian:

$$|\nu_i\rangle = e^{-i(E_i t - \vec{p}_i \cdot \vec{x})} |\nu_i\rangle, \quad E_i^2 - |\vec{p}_i|^2 = m_i^2$$

The neutrino flavor eigenstates are linear combinations of ν_i 's, say:

$$\begin{aligned} |\nu_e\rangle &= \cos\theta |\nu_1\rangle + \sin\theta |\nu_2\rangle. \\ |\nu_\mu\rangle &= -\sin\theta |\nu_1\rangle + \cos\theta |\nu_2\rangle. \end{aligned}$$

If this is the case, a state produced as a ν_e evolves in vacuum into

$$|\nu(t, \vec{x})\rangle = \cos\theta e^{-ip_1 x} |\nu_1\rangle + \sin\theta e^{-ip_2 x} |\nu_2\rangle.$$

It is trivial to compute $P_{e\mu}(L) \equiv |\langle \nu_\mu | \nu(t, z = L) \rangle|^2$. It is just like a two-level system from basic undergraduate quantum mechanics! In the ultrarelativistic limit (always a good bet), $t \simeq L$, $E_i - p_{z,i} \simeq (m_i^2)/2E_i$, and

$$P_{e\mu}(L) = \sin^2 2\theta \sin^2 \left(\frac{\Delta m^2 L}{4E_\nu} \right)$$

oscillation parameters: $\left\{ \begin{array}{l} \pi \frac{L}{L_{\text{osc}}} \equiv \frac{\Delta m^2 L}{4E} = 1.267 \left(\frac{L}{\text{km}} \right) \left(\frac{\Delta m^2}{\text{eV}^2} \right) \left(\frac{\text{GeV}}{E} \right) \\ \text{amplitude } \sin^2 2\theta \end{array} \right.$

NuMI Beamline

figure courtesy Ž. Pavlović

- 120 GeV P Beam → C target → π⁺ & K⁺
- ~35x10¹² protons on target (POT) per spill at 120 GeV with a beam power of 300-350 kW at ~0.5 Hz
- 2 horns focus π⁺ and K⁺ only (or π⁻ and K⁻)
- Mean E_ν increased by moving target and one horn
- π⁺ and K⁺ → μ⁺ν_μ
- Absorber stops hadrons not μ
- μ absorbed by rock, ν → detector

<http://www.particlezoo.net>

June 19, 2012

Intensity Frontier

- Result of over 50 years of particle physics theoretical and experimental research.
- Theoretical formalism based on the marriage of Quantum Mechanics and Special Relativity – Relativistic Quantum Field Theory.
- Very Powerful – once we specify the model ingredients: field content (matter particles) and the internal symmetries (interactions), the dynamics of the system is uniquely specified by a finite set of free parameters.

Given the known ingredients of the model and the known rules, we can predict that the neutrino masses are exactly zero.

Neutrino masses require new ingredients or new rules. We are still try to figure out what these new ingredients are.

On the plus side, we probably know what they could be...

The Muon Magnetic Dipole Moment

The magnetic moment of the muon is defined by $\vec{M} = g_\mu \frac{e}{2m_\mu} \vec{S}$.

The Dirac equation predicts $g_\mu = 2$, so that the anomalous magnetic moment is defined as (note: dimensionless)

$$a_\mu \equiv \frac{g_\mu - 2}{2}$$

In the standard model, the (by far) largest contribution to a_μ comes from the one-loop QED vertex diagram, first computed by Schwinger:

$$a_\mu^{QED}(1\text{-loop}) = \frac{\alpha}{2\pi} = 116,140,973.5 \times 10^{-11}$$

The theoretical estimate has been improved significantly since then, mostly to keep up with the impressive experimental reach of measurements of the $g - 2$ of the muon.

Spin Precession w.r.t. Momentum Vector

$$\vec{\omega}_a = -\frac{e}{m} \left[a_\mu \vec{B} - \left(a_\mu - \frac{1}{\gamma^2 - 1} \right) \frac{\vec{\beta} \times \vec{E}}{c} \right]$$

$$\gamma_{\text{magic}} = 29.3$$

$$p_{\text{magic}} = 3.09 \text{ GeV}/c$$

$$(g-2)/2$$

NOTE: $a_\mu^{LbL} = 105 \pm 26 \times 10^{-11}$

FIG. 9: Compilation of recent results for a_μ^{SM} (in units of 10^{-11}), subtracted by the central value of the experimental average [12, 57]. The shaded vertical band indicates the experimental error. The SM predictions are taken from: this work (DHMZ 10), HLMNT (unpublished) [58] (e^+e^- based, including BABAR and KLOE 2010 $\pi^+\pi^-$ data), Davier *et al.* 09/1 [15] (τ -based), Davier *et al.* 09/1 [15] (e^+e^- -based, not including BABAR $\pi^+\pi^-$ data), Davier *et al.* 09/2 [10] (e^+e^- -based including BABAR $\pi^+\pi^-$ data), HMNT 07 [59] and JN 09 [60] (not including BABAR $\pi^+\pi^-$ data).

[Davier *et al.*, 1010.4180]

Δa_μ : we need to dig a little more!

*This could be the greatest discovery of the century.
Depending, of course, on how far down it goes.*

Ever since it was established that $\mu \rightarrow e\nu\bar{\nu}$, people have searched for $\mu \rightarrow e\gamma$, which was thought to arise at one-loop, like this:

The fact that $\mu \rightarrow e\gamma$ did not happen, led one to postulate that the two neutrino states produced in muon decay were distinct, and that $\mu \rightarrow e\gamma$, and other similar processes, were forbidden due to symmetries.

To this date, these so-called individual lepton-flavor numbers seem to be conserved in the case of charged lepton processes, in spite of many decades of (so far) fruitless searching...

60+ Years of Searches for Charged-Lepton Flavor violation (μ and e)

SM Expectations?

In the old SM, the rate for charged lepton flavor violating processes is trivial to predict. It **vanishes** because **individual lepton-flavor number** is conserved:

- $N_\alpha(\text{in}) = N_\alpha(\text{out})$, for $\alpha = e, \mu, \tau$.

But individual lepton-flavor number are NOT conserved– ν oscillations!

Hence, in the ν SM (the old Standard Model plus operators that lead to neutrino masses) $\mu \rightarrow e\gamma$ is allowed (along with all other charged lepton flavor violating processes).

These are Flavor Changing Neutral Current processes, observed in the quark sector ($b \rightarrow s\gamma$, $K^0 \leftrightarrow \bar{K}^0$, etc).

Unfortunately, we do not know the ν SM expectation for charged lepton flavor violating processes → **we don't know the ν SM Lagrangian !**

One contribution known to be there: active neutrino loops (same as quark sector).
 In the case of charged leptons, the **GIM suppression is very efficient...**

$$\text{e.g.: } Br(\mu \rightarrow e\gamma) = \frac{3\alpha}{32\pi} \left| \sum_{i=2,3} U_{\mu i}^* U_{ei} \frac{\Delta m_{1i}^2}{M_W^2} \right|^2 < 10^{-54}$$

[$U_{\alpha i}$ are the elements of the leptonic mixing matrix,

$\Delta m_{1i}^2 \equiv m_i^2 - m_1^2$, $i = 2, 3$ are the neutrino mass-squared differences]

Principal Features of $\mu^+ \rightarrow e^+ \gamma$ Experiment

- Stop μ^+ in thin target
 - Measure energies of e^+ (E_e) and γ (E_γ)
 - Measure angle between e^+ and γ ($\Delta\theta$)
 - Measure time between e^+ and γ (Δt)

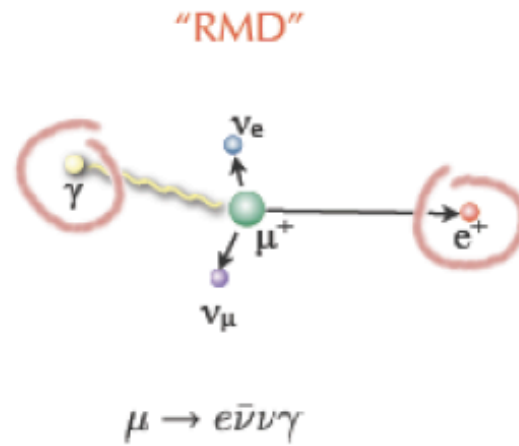

- Background from radiative decay – $\mu \rightarrow e \nu \nu \gamma$
 - Heavily suppressed for $E_\nu \rightarrow 0$, photon opposite electron
 - Not dominant background when rate high enough to reach 10^{-13} sensitivity
- Main source of background:
 - Accidental coincidences of e^+ from Michel decay ($\mu^+ \rightarrow e^+ \nu_e \nu_\mu$)
+ random γ from radiative decay or annihilation in flight
 - E_e distribution peaks near 53 MeV ($x = E_e / E_{\text{max}}$)
 - E_γ distribution in interval dy near $y=1$ given by $dN_\gamma \propto (1-y)dy$ ($y = E_\gamma / E_{\text{max}}$)

$$\Rightarrow \text{background/signal} \propto \Delta E_e \times (\Delta E_\gamma)^2 \times \Delta t \times (\Delta\theta)^2 \times \text{Rate}$$

The MEG Experiment

Dominant Background

$$\text{Br}(\mu \rightarrow e\gamma) < 2.4 \times 10^{-12} \text{ (90\% CL)}$$

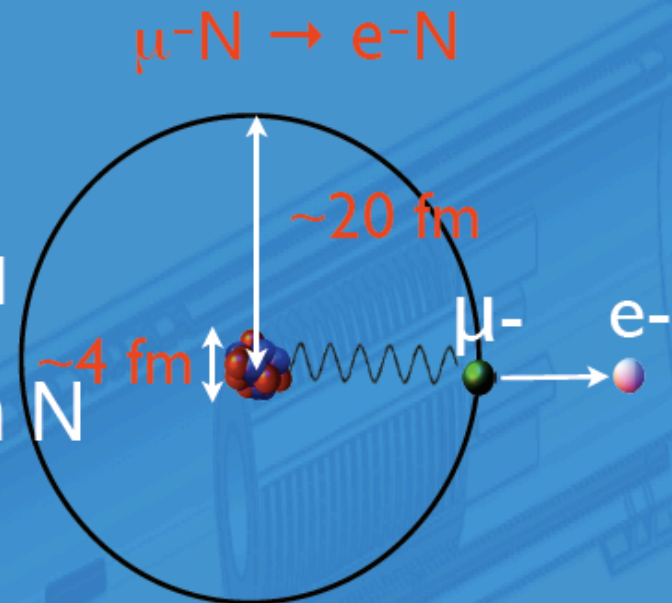

FIG. 1: Event distributions in the analysis region of (a) E_γ vs E_e and (b) $t_{e\gamma}$ vs $\cos\Theta_{e\gamma}$ for 2009 data and of (c) E_γ vs E_e and (d) $t_{e\gamma}$ vs $\cos\Theta_{e\gamma}$ for 2010 data. The contours of the PDFs (1-, 1.64- and 2- σ) are shown, and a few events with the highest signal likelihood are numbered for each year. (The two highest signal likelihood events in 2010 data appear only in (c) or (d).)

[MEG Coll. arXiv:1107.5547]

$\mu \rightarrow e$ Conversion

- $\mu^- + N$ form muonic atom
 - μ^- tightly bound in K shell
 - significant WF overlap with N
- μ^- converts coherently with N
 - e^- recoil is against N
 - N WF can participate in process
- Unique Experimental Signature
 - isolated, mono-energetic e^- with $P_e \cong m_\mu$

The Mu2e Experiment

- Experimental Goal: Measure the ratio $R_{\mu e}$

$$R_{\mu e} = \frac{\Gamma(\mu^- + (A, Z) \rightarrow e^- + (A, Z))}{\Gamma(\mu^- + (A, Z) \rightarrow \nu_\mu + (A, Z - 1))}$$

- 90% C.L. sensitivity to $R_{\mu e} > 6 \times 10^{-17}$
 - 4 orders of magnitude better than current limits
- Requires $\sim 10^{18}$ stopped muons
 - $\sim 4 \times 10^{20}$ protons on target (2 year run @ 25 KW)
- Requires negligible (< 1) background events
 - Many challenges for beamline and detector design

Mu2e Apparatus

← ~ 20 meters →

- Proton delivery beamline
- SC solenoids for muon collection, transportation, and analysis
- Primary (proton) and secondary (muon) targets
- Active devices: tracker, calorimeter, Cosmic Ray veto

Momentum Sensitivity

Signal and DIO Background

Shanker, Phys.Rev D25, 1847
(1982)

New calculation by Czarnecki et al
agrees within 30% arXiv:1106.4756v1

Beam Timing

- Prompt pions decay rapidly
 - $\tau = 26$ nsec
- Muons survive to reach the stopping target
 - Stopped muon lifetime on Al ~ 800 nsec

- The silicon detector is read out with 10 MHz (power consumption)
- Hundred electron tracks in one frame
- Can be resolved by scintillating fibre tracker
- Resolution ~ 100 ps - on average one electron

Backgrounds: $-\mu^+ \rightarrow e^+ \nu \nu \gamma^* (\rightarrow e^+ e^-)$
 $-\text{ accidentals (like } \mu \rightarrow e \gamma)$

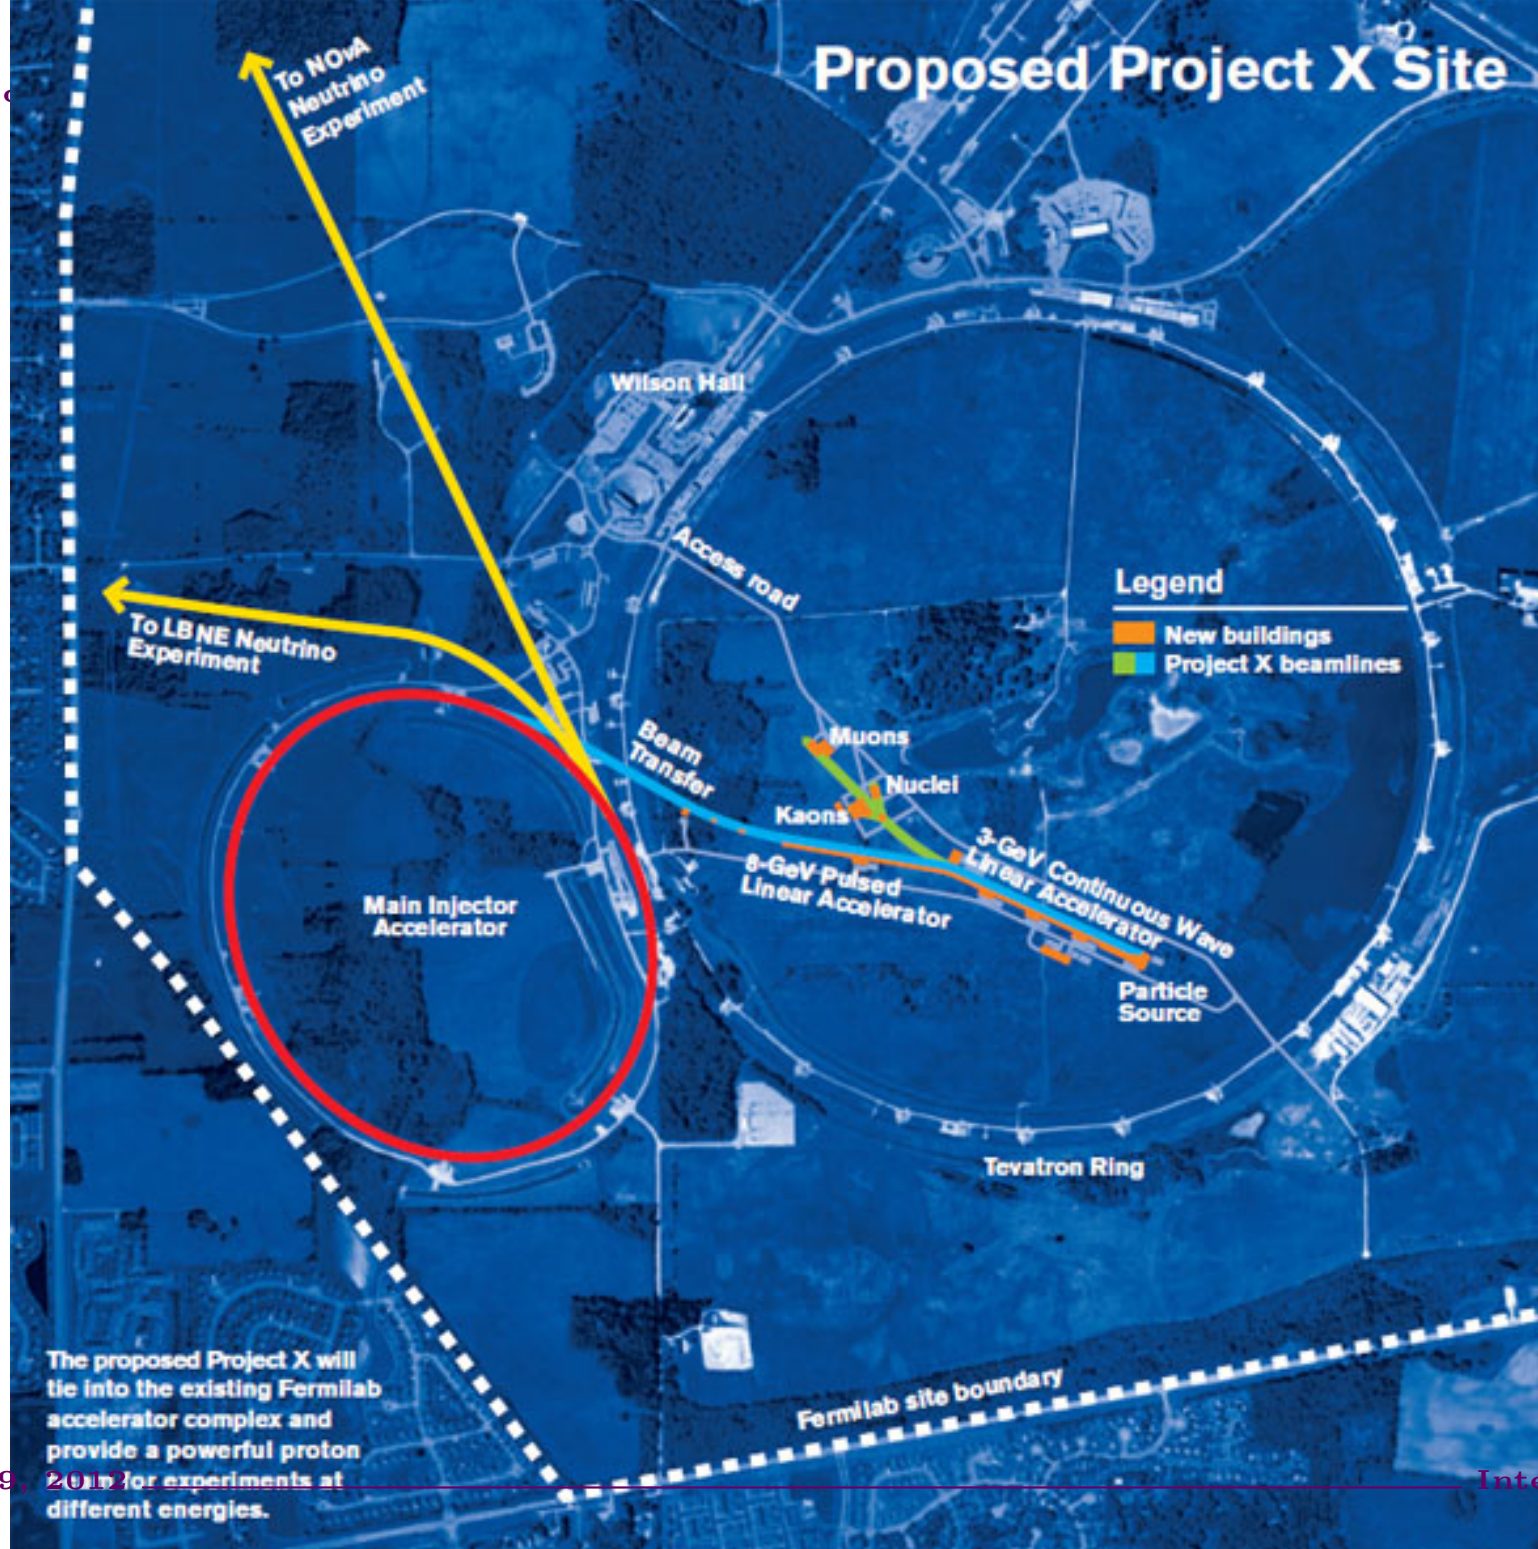

Handle: $-\text{ vertexing, needs excellent tracking}$

Yet to hit a wall. Proposal at PSI (?)

[N. Berger at NuFact'11]

What Will Happen in the Near Future ...

- Mu2e and COMET: $\mu \rightarrow e$ -conversion at 10^{-16} .
- $g - 2$ measurement a factor of 3–4 more precise.
- Project X-like: $\mu \rightarrow e$ -conversion at 10^{-18} (or precision studies?).
- Project X-like: deeper probe of muon edm.
- Muon Beams/Rings: $\mu \rightarrow e$ -conversion at 10^{-20} ? Revisit rare muon decays ($\mu \rightarrow e\gamma$, $\mu \rightarrow eee$) with new idea?

Intensity Frontier

The Kaon is bound state of a $s\bar{u}$ (charged Kaon) or $s\bar{d}$ (neutral Kaon)

Sensitivity Frontier of Kaon Physics Today

- CERN NA62: 100×10^{-12} measurement sensitivity of $K^+ \rightarrow e^+ \nu$
- Fermilab KTeV: 20×10^{-12} measurement sensitivity of $K_L \rightarrow \mu \mu e e$
- Fermilab KTeV: 20×10^{-12} search sensitivity for $K_L \rightarrow \pi \mu e, \pi \pi \mu e$
- BNL E949: 20×10^{-12} measurement sensitivity of $K^+ \rightarrow \pi^+ \nu \bar{\nu}$
- BNL E871: 1×10^{-12} measurement sensitivity of $K_L \rightarrow e^+ e^-$
- BNL E871: 1×10^{-12} search sensitivity for $K_L \rightarrow \mu e$

PRL 88, 041803 (2002)

E787

Two events above
the $K_{\pi 2}$ (pnn1)

$$B(K^+ \rightarrow \pi^+ \nu \nu) = 1.57^{+1.75}_{-0.82} \times 10^{-10}$$

Below $K_{\pi 2}$ (pnn2) limit:

1996: PL B537, 211 (2002)

1997: PR D70, 037102 (2004)

$140 < p_{\pi} < 195$ MeV/c

1 candidate event with an expected background of
 1.22 ± 0.24 events.

Background limited, with $S/N < 0.2$

Set an upper limit of $B(K^+ \rightarrow \pi^+ \nu \nu) < 22 \times 10^{-10}$

WIN09 September 18, 2009

Special Features of Measuring

Experimentally weak signature with background processes exceeding signal by $>10^{10}$

Determine everything possible about the K^+ and π^+

* π^+/μ^+ particle ID better than 10^6 ($\pi^+ - \mu^+ - e^+$)

Eliminate events with extra charged particles or *photons*

* π^0 inefficiency $< 10^{-6}$

Suppress backgrounds well below the expected signal ($S/N \sim 10$)

* Predict backgrounds *from data*: dual independent cuts

* Use “Blind analysis” techniques

* Test predictions with outside-the-signal-region measurements

Evaluate candidate events with S/N function

$K^+ \rightarrow \pi^+ \nu \bar{\nu}$ History

E787/E949 Final: 7 events observed

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) = 1.73^{+1.15}_{-1.05} \times 10^{-10}$$

Standard Model:

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) = (0.78 \pm 0.08) \times 10^{-10}$$

large data samples may teach us a lot ... depending on where we are late in this decade

$K \rightarrow \pi \nu \bar{\nu} \dots$ Past, Present, Future

Facility (Experiment)	Proton Power	Kaon Decay/stop rate	Kaon Properties	$K \rightarrow \pi \nu \bar{\nu}$ Sensitivity
BNL AGS (E787/E949):	50kW	1×10^6 K ⁺ /sec	Pure stopped K ⁺ source	7 events
CERN (NA62):	20kW	10×10^6 K ⁺ /sec	Un-separated 1- GHz K ⁺ /π ⁺ /p ⁺ beam	80 events
Fermilab: (ORKA):	75kW	9×10^6 K⁺/sec	Pure stopped K⁺ source	1000 events
Project-X K ⁺ → π ν $\bar{\nu}$	1500 kW	100×10^6 K ⁺ /sec	Pure stopped K ⁺ source	>1000 events

$K_L \rightarrow \pi^0 \nu \bar{\nu}$ has never been observed.

“nothing in – nothing out”. Very hard experimentally!

Figure 5: The K^0 TO detector.

Figure 6: The CV at E391a (left) and at K^0 TO (right).

goal of the KOTO experiment in J-PARC – around 50 events, assuming SM rate.

2012 Project X Physics Study

June 14 - 23, 2012 • Fermilab • Batavia, Illinois

The Project X Physics Study will engage theorists, experimenters, and accelerator scientists in establishing and documenting a comprehensive vision of the physics opportunities at Project X, and integrating these opportunities within a coherent plan for development of detector capabilities and the accelerator complex.
