2011 Wind Energy Engineering Workshop
March 2, 2011*

Motivation - IWT Sensing and SHM

- Validate / update physics-based numerical models
- Estimate the current state of the blade, including detection of the onset and growth of damage
- Monitor / predict load characteristics to estimate remaining life in the presence of damage (prognostics)

Challenging Issues in Sensing System Design

- Critical state of damage is not well defined for wind turbine blades
- Low cost, low power solution with wireless capabilities
- Improved reliability in a robust electronics package
- Optimally configured and installed
 - Maximize observability while minimizing necessary hardware

IWT Structural Sensing System

- Multi-scale sensing for SHM and prognostic assessment
 - Local active sensing
 - Global passive sensing
- Piezoelectric transducers are used as sensors and actuators
 - Dual use reduces the total amount of installed hardware
- Develop an integrated hardware / software solution designed specifically for wind turbine applications

Piezoelectrics can serve as both sensors and actuators

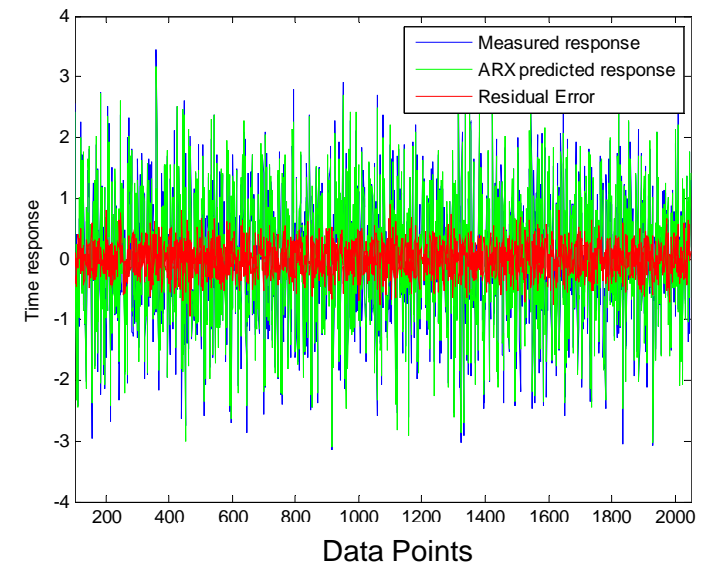

Hardware has evolved from previous experience in civil applications

Current prototype of the multi-scale sensing platform

Active Sensing SHM Techniques

- Lamb wave propagations
- High frequency response functions
- Time series predictive models
 - CX-100 turbine blade 1-m section
 - Introduced simulated damage

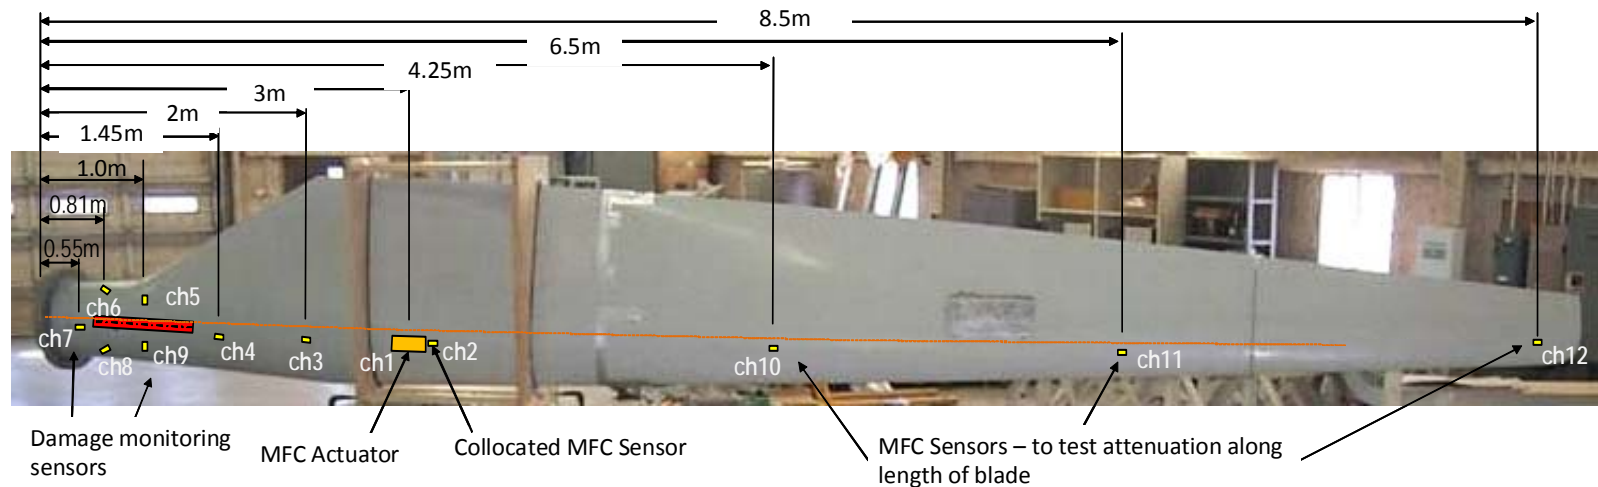

Active Sensing: Method Comparison

- **Lamb wave propagations**
 - Detect and locate damage
 - Requires higher electric power, extremely small propagating distance (< 0.5 m)
- **Frequency domain (up to 80 kHz)**
 - Damage localization capabilities
 - Moderate power and memory usage
- **Time series analysis**
 - Similar capabilities of FRF methods while requiring less measured data
 - Low power requirements
 - Electromagnetic interference

Sandia's Full-Scale Fatigue Test at NREL

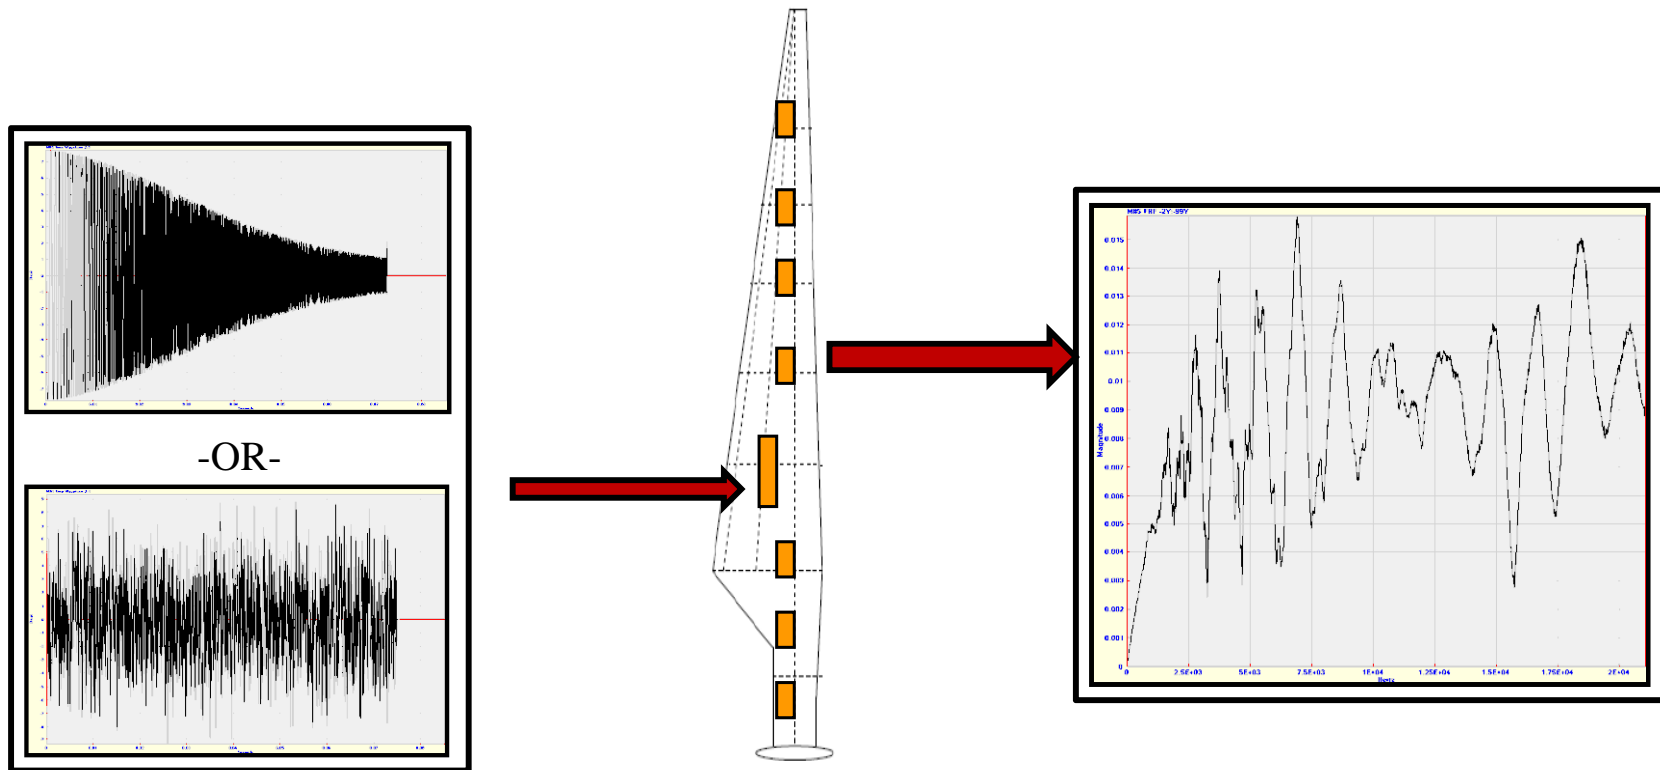

- After 2.3 M cycles, damage was identified visually in the root section
- Measurements were taken from multiple MFC sensors
- Several sensors (Ch. 6, 7, 10) became de-bonded during the test

Courtesy of SNL and NREL

Fatigue Test: Active Sensing SHM

- The MFC actuator was used to excite the system with band-limited (30 to 60kHz) signals
 - amplified sine chirp (30V peak to peak)
 - burst random signal (20V RMS)

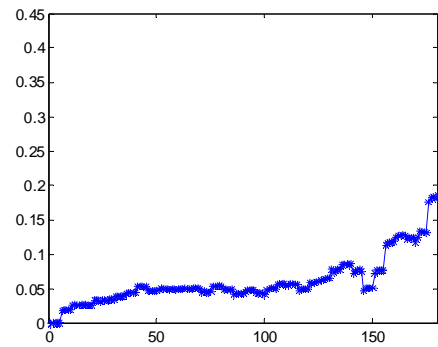

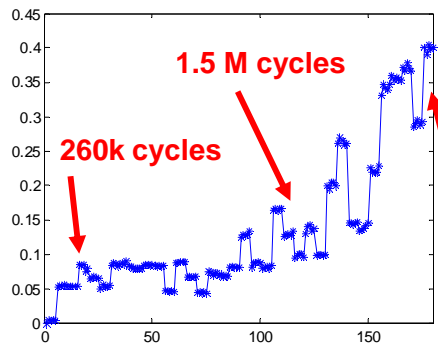

Fatigue Test: Active Sensing SHM

Fatigue damage was visually identified after 2.3 M cycles

Cross-Correlation of FRFs

RMS of Residual Errors

Fatigue Test: Active Sensing SHM

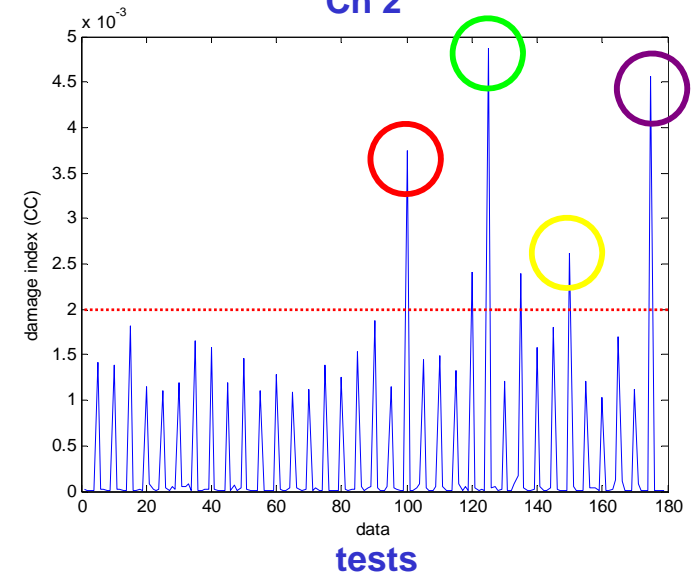

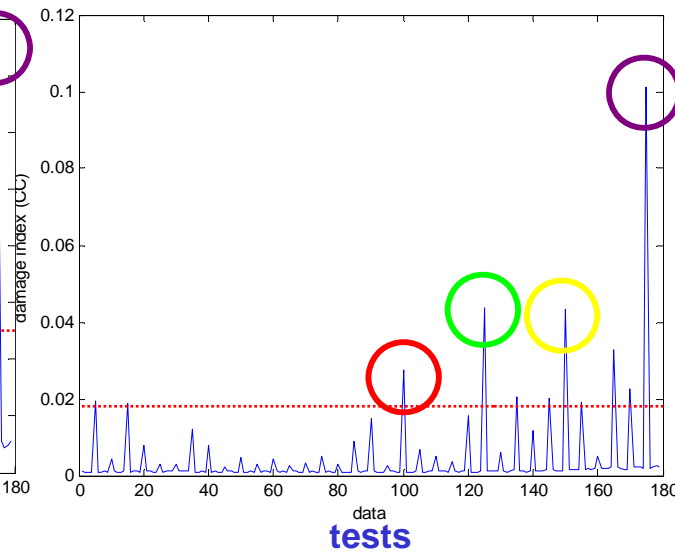

Cross-Correlation of FRFs

Ch 4

Ch 3

Ch 2

- Corresponds to 1.5 M cycles: acoustic emission systems also noticed changes in emission activities

Lessons Learned / Issues

- Demonstrated that piezoelectric active-sensors could detect and approximately locate damage in the blade.
- Sensors
 - Sensor / actuator locations could be optimized with model input
 - Reliability: three sensors were debonded / broken during the test
- Validation
 - No reference to assess the performance of the sensing system
 - Only high frequency responses - no attempt for multi-scale sensing
- We are planning to address these issues in the fatigue tests scheduled in 2011

Modal Test of Full-Scale Blade

- Tested a 9-m CX-100 blade with different boundary conditions
 - free-free, clamped-free
- Identified first several modes using accelerometers and passive piezoelectric sensors
- Roving hammer test

Modal Test of Full-Scale Blade

Mode	Freq. (Hz) by Accel.	Freq. (Hz) by PZT	Description
1	3.22	3.22	1 st Flap Bending
2	7.14	7.1	1 st Lag Bending
3	8.81	8.81	2 nd Flap Bending
4	16.89	16.89	2 nd Lag Bending
5	19.23	19.23	3 rd Flap Bending
6	30.96	30.91	4 th Flap Bending
7	44.11	44	1 st Torsion

Good correlation between natural frequency and mode shape measurements using accelerometer and piezoelectric sensors

Full-Scale Blade at LANL: Active Sensing

- Compare response at various points
 - Determine effective frequency range at points along length of blade (energy dissipation)
 - 2 actuators are needed to monitor the entire blade

Full-Scale Blade at LANL: Active Sensing

- Local stiffness changes were imposed through the use of a point load
- The location and intensity of damage can be assessed by the response characteristics of each sensor

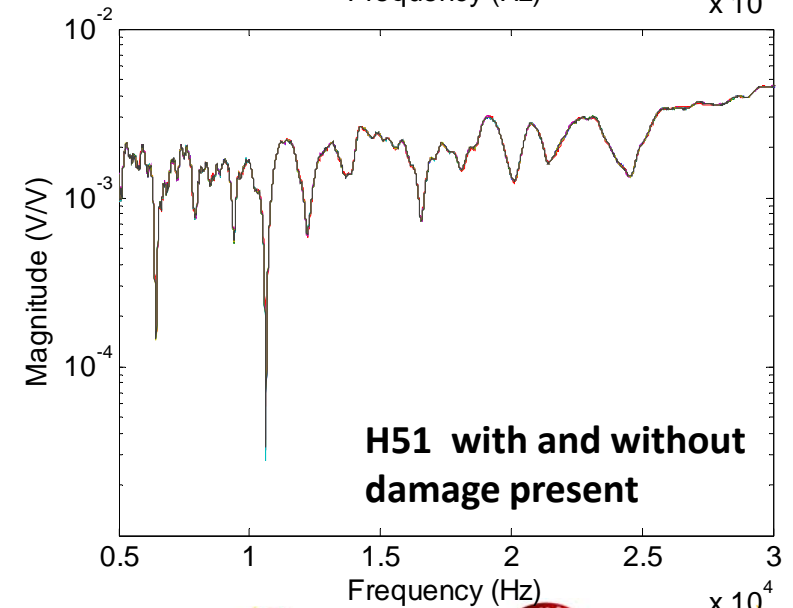

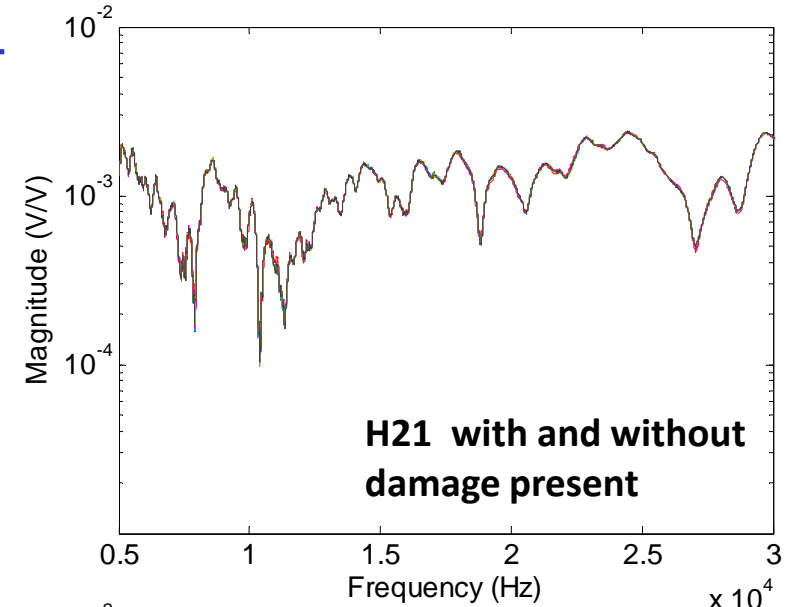

Load Frame used to Apply a Point Load to the Blade

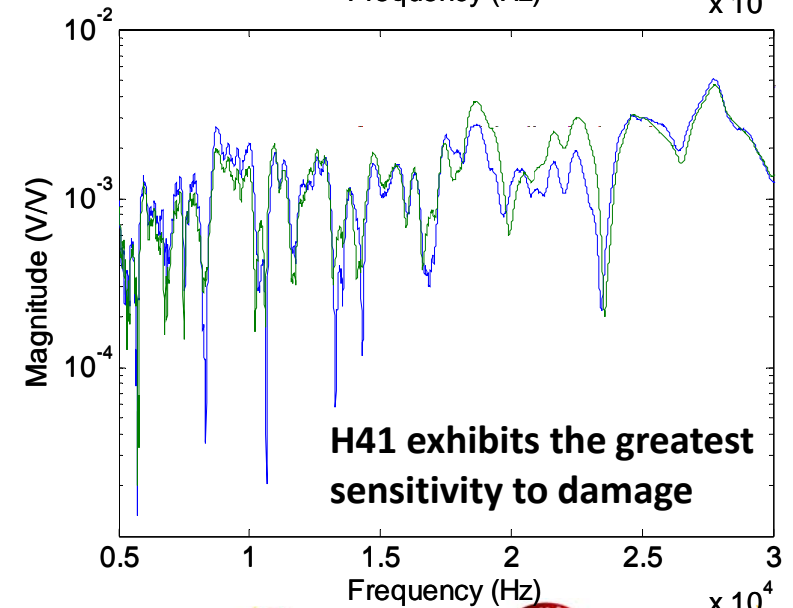

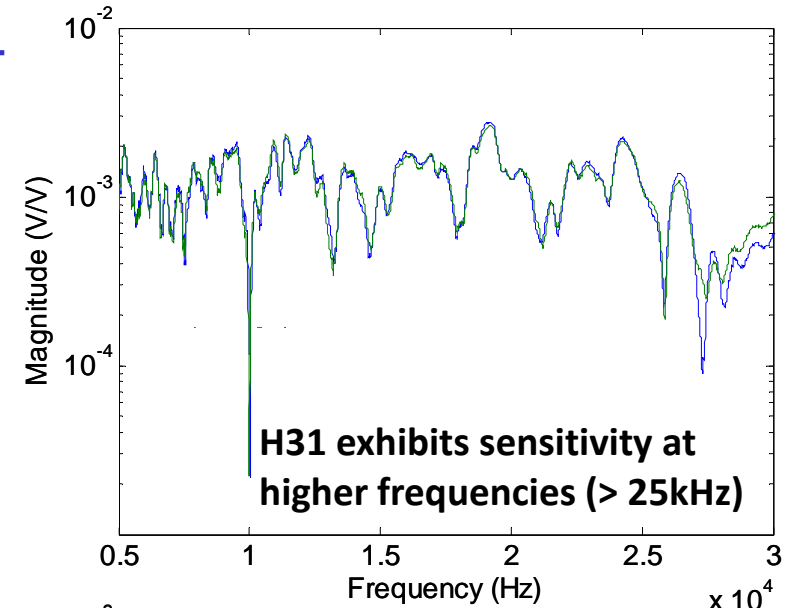

Simulated Damage – Active Sensing

- Damage was applied near PZT 3&4
- Measurements were collected for each of the sensor-actuator paths
 - PZTs 2 and 5 were insensitive to the applied damage

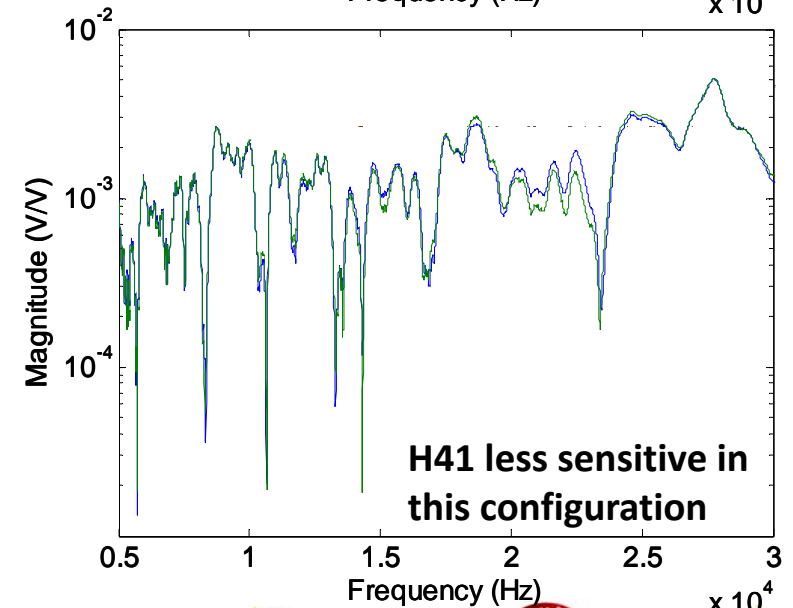

Simulated Damage – Active Sensing

- Damage was applied near PZT 3&4
- Measurements were collected for each of the sensor-actuator paths
 - PZTs 2 and 5 were insensitive to the applied damage
 - The influence of damage can be seen for PZT 3 at frequencies > 25 kHz
 - As expected PZT 4 is the most sensitive to the local stiffness change

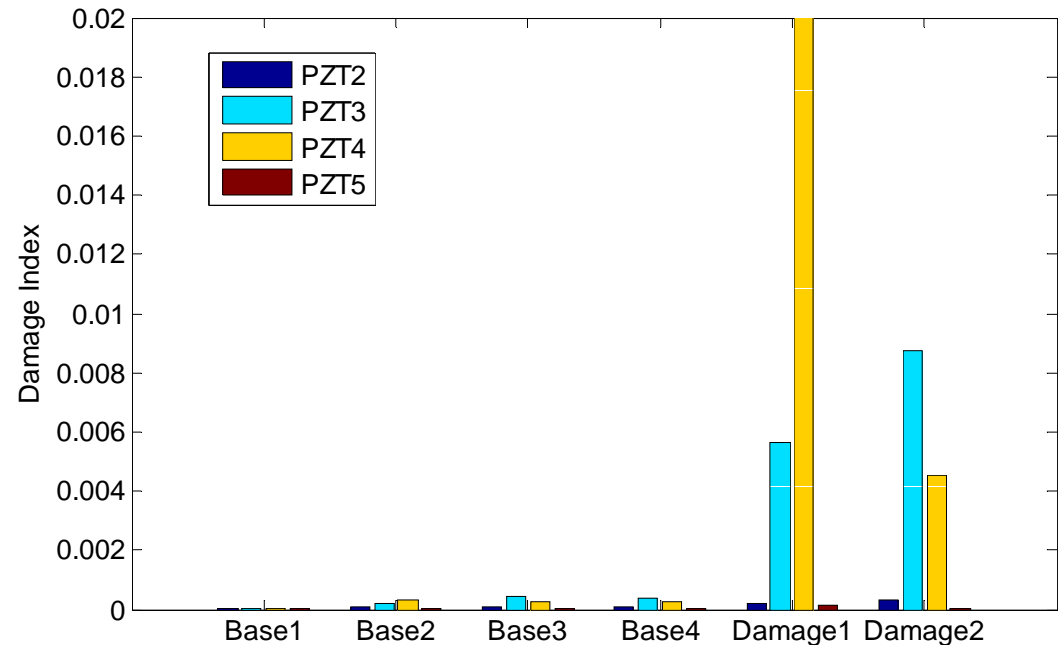

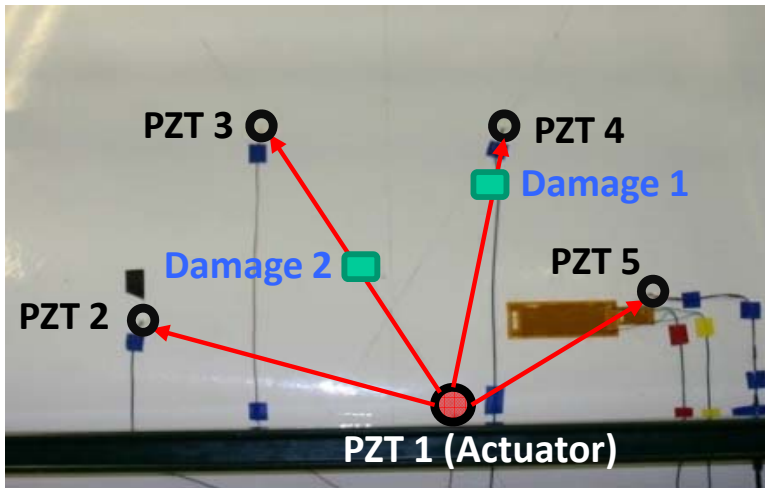

Simulated Damage – Active Sensing

- Damage was applied near PZT 3&4
- Measurements were collected for each of the sensor-actuator paths
 - PZTs 2 and 5 were insensitive to the applied damage
 - As we would expect – PZT 3 shows an increased sensitivity to damage in this location, whereas PZT4 is decreased

Simulated Damage – Active Sensing

- Demonstrated localization of damage using active-sensing
 - Sensing range: ~ 0.3 m radius for detecting the point load
- Extending this technique to identify damage along the spar cap and through the spar/shear web

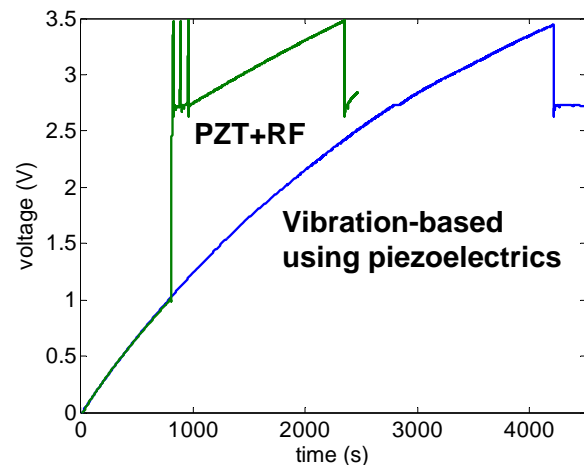

Hardware Development:

- Embedded Hardware for Multi-Scale Sensing
 - Active / passive capable up to 250 ksps
 - Frequency response, time series analysis, impedance methods
 - Sensor diagnostics
 - Accommodate multiple sensing modalities
 - Web-driven data acquisition
 - Higher (embedded) processing power

Powering Embedded Hardware

- Power demands will become a major design criteria for long term deployments
 - Currently we are investigating energy harvesting techniques to supplement onboard power sources
- Several sources are available on rotor blades
 - Solar, thermal, kinetic, electromagnetic, etc.
- To provide a robust power source, the harvesting system may need to extract energy from multiple sources

Charging response for civil infrastructure

Summary

- Several experimental investigations have demonstrated the potential of piezoelectric transducers for:
 - Structural Health Monitoring
 - Sensitive to small defects in blades
 - Immune to operational condition changes
 - Multi-scale sensing of wind turbine blades
 - Low-cost, low-power
- A wireless sensor node is being developed to integrate multi-scale sensing and SHM capabilities for damage prognosis

Plans for FY2011-12

FY-2011

- Full-scale fatigue tests of CX-100 (2011)
 - Collaboration with NREL, UMass-Lowell, SNL, Luna. We are currently open to other participants as well.
- NDE characterization of damage on fatigued CX-100 blade sections (2011)
 - Correlation with SHM results
- NREL's Gearbox CM round robin (2011)
- Fabrication of SHM Rotor Blade (2011)

FY-2011-12

- Integration with damage modeling and advanced data processing (2011-12)
 - Sensor location optimization
 - Prognostic analysis of blade condition
- Collaborative testing of SHM Rotor Blade with Sandia (2012)
 - Onboard SHM (LANL)
 - Operational Monitoring (SNL)
 - Large form PIV (LANL)

Acknowledgements

- We would like to thank
 - Mark Rumsey and Jon White from Sandia National Laboratory
 - Scott Hughes from National Renewable Energy Laboratory
 - Pete Avitabile and Chris Niezrecki from U.Mass, Lowellfor their collaborative support and guidance on this research
