Kingston Steam Plant - Ash Disposal Area Dikes Raising - Soils Investigation Report 11/3/75 and Evaluation

Herewith is the work copy of the report, marked for evaluation, roughly because virgin for design. Soils design values are marked on p. 4 of the report, and were sent to Hwy Group 11/11/75.

Also herewith:

1. Marked copy of the 6/26/74 investigation request. Proposed soil and ash investigation was unusual and notes are made on the parts of the investigation that were not done.

2. Evaluation of the soils report with comments on the investigation, on investigation results and on design and construction features. A copy of the commentary was sent to the Hwy Group 11/12/75.

This material is assembled in this binder as the Branch record on the investigation.

G. L. Buchanan, Chief, Civil Engineering and Design Branch, 418 UB-K (3)

Gene Farmer, Chief, Construction Services Branch, 305 NB-K

November 3, 1975

KINGSTON STEAM PLANT - ASH DISPOSAL AREA DIKE RAISING - SOIL INVESTIGATION

As requested in a memorandum of June 26, 1974, from W. W. Engle to me, our laboratory has completed sampling and testing for the dike raising at Kingston Steam Plant. The field work was completed between February 18 and March 12, 1975, using a CME-45 and a Mobile B-55 auger drill. Equal portions of the laboratory testing were done by Singleton Materials Engineering Laboratory and the soil laboratory of Law Engineering and Testing Company of Marietta, Georgia.

Foundation

As shown on laboratory drawing 604B602, a total of 24 standard penetration borings was drilled around the perimeter of the existing dike. The soil profile is shown on drawings 604K604 and 604K605 and reveals overburden depths in excess of 25 feet. In general the profile in the area between borings SS-1 and SS-10 consists of 8 to 26 feet of fill underlain by a stratified alluvium. The fill consists of soil overlain by 2 to 5 feet of ash. In scattered locations ash and soil are blended. Fill soils classified lean to fat clay, CL and CH, and silty to clayey sand, SM and SC. Throughout much of this fill, shaly gravel is interspersed with the fine-grained soils.

Standard penetration testing indicates the surficial materials are highly compacted but subsoils weaken as depth increases. In general, at the fill-ground contact, soils are of soft consistency with N≤4. The alluvium beneath the existing dike fill classifies lean to medium clay, CL, and silty clay and silt, ML-CL and ML, along with some silty sand, SM. These materials are of variable consistency with significant weaknesses established in borings SS-1, SS-4, SS-5, SS-6, SS-7, and SS-8 where N values of 4 or less are common. The water table varied between el. 735 and 750 over this portion of the dike.

In the area between borings SS-11 and SS-16, fill consists almost entirely of ash of silt to silty sand size. This ash is very dense at the surface to a depth of 5 to 8 feet. Below this depth its ~~relative~~ density decreases progressively. Below el. 740, the ash is very soft with N values consistently less than 4 and is underlain by alluvial lean clay, CL, and silty sand, SM. The water table varied between el. 749 and el. 756, ~~in this portion of the dike.~~

G. L. Buchanan
November 3, 1975

KINGSTON STEAM PLANT - ASH DISPOSAL AREA DIKE RAISING - SOIL INVESTIGATION

existing Dike C and Road Dike

Borings SS-17 through SS-24 were drilled in ash fill along the inside of the ~~dike~~ as shown on drawing 604B602. These standard penetration borings indicate the fairly coarse ash to be generally quite soft or loose with N values between 0 and 4. See drawing 604K606. This ash, being 4 to 24 feet thick, overlies the alluvial silt, silty sand, and lean clay, ML, SM, and CL. However, in borings SS-22 and SS-23, the ash and original ground were separated by 13 to 16 feet of soil fill. Groundwater in top of ash.

No. Generally sand + silt sizes.

Undisturbed samples were obtained of both the fill and foundation soils at of Dike C and Road Dike borings SS-1 and SS-7 for detailed testing. As shown on the attached "Summary of Laboratory Test Data" soils generally are of medium to high dry density. The natural moisture content mostly exceeds the plastic limit, and in some cases, approaches the liquid limit, accounting for the low penetration resistance. ?

Natural moisture Q

Unconsolidated-undrained triaxial compression tests disclose a wide range of strengths with the upper soil layers being of greater strength than the underlying materials. For those fine-grained soils with N values of 4 or less, a strength range of 2 to 5 degrees friction and 0.2 to 0.4 tsf cohesion was established. Consolidated-undrained triaxial compression tests at natural moisture content performed on foundation soils revealed medium to high strength with friction angles between 19 and 33 degrees and cohesion of 0.12 to 1.12 tsf. Back-pressure saturated triaxial compression R tests performed on fill soils were of medium shear strength. An exception is noted in boring US-1 at el. 739 where 16 degrees friction and 0.14 tsf cohesion was obtained.

Do not use.

Borrow

As shown on drawing 604B603, three areas designated A, B, and C were explored east of the plant. Profiles are presented on drawings 604K607, 604G608, 604K609, and 604G610. Each of these areas can supply from 10 to 25 feet of lean to fat clay, CL and CH, as well as a small amount of highly plastic silt, MH. Overall, about two million cubic yards of suitable fill material is available.

Laboratory compaction testing, in accordance with ASTM D698, established four soil classes as shown below:

Class I, representing 22 percent of the total borrow, classified sandy lean clay, CL, with an optimum moisture content of 19.7 percent and a maximum density of 104.5 pcf. The average natural moisture content of this material was 24.6 or 4.9 percent above optimum.

G. L. Buchanan
November 3, 1975

KINGSTON STEAM PLANT - ASH DISPOSAL AREA DIKE RAISING - SOIL INVESTIGATION

Class II, amounting to 22 percent of the total borrow, classified sandy medium clay, CH, with an optimum moisture content of 21.8 percent and a maximum density of 101.5 pcf. The average natural moisture content of this material was 27.5 percent or 5.7 percent above optimum.

Class III, accounting for 27 percent of the total classified fat clay, CH, with an optimum moisture content of 25.4 percent and a maximum density of 96.4 pcf. The average natural moisture content of this material was 29.1 or 3.7 percent above optimum.

Class IV, totaling 29 percent, also classified fat clay, CH, with an optimum moisture content of 29.6 percent and a maximum density of 90.4 pcf. The average natural moisture content of this material was 35.1 or 5.5 percent above optimum.

Each soil class was remolded to 95 percent of maximum density at 3 percent above and below optimum and subjected to triaxial compression Q and R tests. Results of these tests are presented in the attached "Summary of Laboratory Test Data - Borrow Soil Classes."

Summary

This investigation has shown the existing dike fill at Kingston Steam Plant to consist of ash and soil which are usually of stiff to hard consistency at the surface but are softening with increased depth. Below a depth of 10 feet, soils and ash often become soft with standard penetration blow counts of 4 or less. Portions of the underlying alluvial foundation soils are equally weak.

Sufficient quantities of impervious fill materials are available from the three borrow areas investigated east of the plant. While the investigation was carried out during a very wet period, it is likely borrow clays will require some drying prior to placement.

The following test values, based upon detailed laboratory testing are recommended for design purposes:

G. L. Buchanan

H. H. Mull, 707 UB-K
Lamar Parker, Tellico Dam

The strength values checked are acceptable.

① Do not use the natural moisture R. The old fill and fan of Dike C and Road Dike will have to be assumed saturated. The tests demonstrate the weakening effect of saturation of the soil with time as pondwater seeps into and saturates the foundation.

② Do not use the lab values $\phi = 15$ and $c = 0.4$ for fill. These values are from lab tests 3% wet. Lab tests 3% dry demonstrate erratic strengths (see note sheet with evaluation of dry-side compaction. Wet-side compac demonstrates more uniformity.
Use $\phi = 15°$, $c = 0.3$ tsf for general coverage of fill.

KINGSTON STEAM PLANT - ASH DISPOSAL AREA DIKE RAISING - SOILS EXPLORATION AND TESTING

We request that you arrange for the Materials Laboratory to make soil explorations and laboratory tests for the proposed raising of the dikes around the ash disposal area. Attached are three prints of study drawing 10SN100 which shows the ash disposal area. The road dike and dike "C" are to be raised while dike "B" will be new construction.

Road Dike and Dike "C"

The road dike and dike "C" existing fill and foundation are to be investigated by standard penetration split-spoon borings spaced approximately 1000 feet on centers. The locations of these borings are to be adjusted or additional borings made so the area where the former Swan Pond Creek channel underlies dike "C" will be explored. Also, the borings should be about 500 feet on centers along the southern portion of dike "C" that was originally built with ash (indicated on drawing 10SN100). All borings are to extend into the dike foundation a minimum depth equal to one-half the height of the overlying raised dike above the original ground, unless bedrock is encountered sooner. One undisturbed boring is to be made five feet from the split-spoon boring which penetrated the "softest" dike fill composed of earth. One undisturbed boring is to be made five feet from the split-spoon boring which penetrated the "softest" dike fill composed of ash. Another undisturbed boring is to be made five feet from the split-spoon boring that penetrated the "softest" dike foundation material. Regarding all the undisturbed borings, if the "softest" material is isolated, at the creek crossing or elsewhere, additional undisturbed borings are also to be made to sample more typical material. The "softest" and more typical are to be tested. These undisturbed borings are to extend into the foundation to the same elevation as the companion split-spoon borings. Undisturbed samples are to be taken the full depth of the borings.

Visual classification is required on all samples. Index tests are to be made on representative split-spoon and undisturbed samples. Triaxial compression Q and R tests are to be made on representative undisturbed samples as follows:

TVA-00000936

KINGSTON STEAM PLANT - ASH DISPOSAL AREA DIKE RAISING - SOILS EXPLORATION AND TESTING

1. All foundation borings (earth). Two Q and two R tests on each soil type at natural moisture content. *Done.*

2. Existing dike fill (earth and ash). If materials are reasonably uniform, three Q tests at natural moisture content and three R tests saturated prior to shear. If materials are variable, a minimum of two Q and two R tests on the major material types. *Done. There was no significant ash.*

All borings should be made at the inside shoulder of the original dike. All holes created by borings should be backfilled with tamped earth.

Dike "B" Foundation

Dike "B" will be parallel to Swan Pond Road, and it will be constructed in the wet on previously deposited ash. Due to the above conditions, foundation sampling and testing would be very difficult to perform; therefore, we are not requesting the foundation of dike "B" to be investigated.

The dike stability will be assisted by buttressing by the existing road fill shown on 10SN100, section E-E.

Borrow

1. Earth. Approximately 450,000 cubic yards of earth borrow will be required to raise the road dike and dike "C" to elevation 765. An additional 450,000 cubic yards of earth borrow will be required to construct dike "B" if ash of sufficient quality and quantity is not available. Please determine if this quantity of suitable earth borrow can be obtained from borrow areas located on the Kingston Steam Plant Reservation. *see * on p. 2*

The earth borrow materials are to be grouped by soil type. Each soil type is to have routine index tests and control curves for standard compaction. Each soil type is to have a minimum of two Q and two R triaxial shear tests. The "as molded" sample conditions should be at or very near 95 percent maximum dry density and at water contents approximately 3 percent above and 3 percent below optimum water content. R test specimens should be saturated prior to shear. *Done*

KINGSTON STEAM PLANT - ASH DISPOSAL AREA DIKE RAISING - SOILS EXPLORATION AND TESTING

2. Ash. If ash of sufficient quality and quantity is available, the base of dike "B" will be constructed of ash, and approximately 310,000 cubic yards of ash borrow will be required. The borrow areas for ash are located north of and adjacent to the north dike and on the inside of the road dike and dike "C." For the areas inside the road dike and dike "C," only that ash above elevation 746 and that ash which lies beyond the limits of the raised dike foundation will be available for borrow.

The ash is to be investigated by standard penetration split-spoon borings spaced approximately 1000 feet on centers along the road dike and dike "C" and approximately 400 feet on centers along the north dike. The spacings may be varied if necessary to more adequately cover the borrow areas. These borings are to extend to the original ground surface. | 1000' done | 400' done | Done

Since the ash fill base for dike "B" will be placed in the wet, final in-place densities are now uncertain. It is assumed that the ash fill base will be built by end dumping to minimum depth and compacting with tracked equipment. Therefore, in-place density tests are to be made on existing ash fills inside of dike "C" which have been constructed with comparable materials and by similar placement methods. These in-place density tests should be made in areas that have not been heavily traveled and at or below the saturation line in the ash. Density tests should be made in several locations to test various types of ash and can be done by undisturbed sampling or in open excavations. Laboratory permeability and shear tests are to be made on samples remolded to the low average density determined from these existing ash fills. | Nothing in report. See *

Each ash type is to have routine index tests, permeability tests, and a minimum of two Q, two R, and two S shear tests. The Q and R tests are to be made using the largest triaxial testing machine currently available at the Materials Laboratory. The S tests are to be made using the largest direct shear box currently available at the Materials Laboratory. The maximum ash particle size should be no more than 1/6 the diameter or thickness of the shear test specimen. All test specimens are to be saturated prior to shear.

These tests will provide information not only on the ash as borrow, but also on the present ash foundations of the road dike and dike "C" raising. inside the present dikes. (density, strength, perm) **

* Phone with Job (Childress) 11/10/75. Field now Commit and Hwy Group decided since plenty of earth is available for borrow and "ash is of poor quality," Dike B will be built all earth and ash borrow tests will not be made.

** UD samples from borings UD-1 and UD-7 were all earth. Result: there are no density or strength tests of ash foundation under DIKE C or ROAD DIKE raising, or replace same tests for ash as possible base for DIKE B.

KINGSTON STEAM PLANT - ASH DISPOSAL AREA DIKE RAISING - SOILS EXPLORATION AND TESTING

Graphic logs of all borings are to be prepared. Ground water, if encountered, is to be indicated on the logs. Grain size curves on ash are to be submitted, including those on shear test specimens that may have been altered to suit the laboratory equipment. A brief description of the methods used to determine in-place densities for the ash and the size of the shear testing equipment used on the ash are to be included in the report.

Costs for this work are to be charged to DPP suborder number 82-330.

If assistance is needed at the steam plant, please contact L. D. Kennedy, Assistant Superintendent at Kingston Steam Plant.

If umusual or unforeseen conditions develop, please contact the Civil Engineering and Design Branch (R. J. Bowman, telephone extension 2738).

The report of the soils investigation is scheduled to be completed by January 1, 1975, as outlined in the memorandum from you to Roy H. Dunham dated March 12, 1974.

Kingston Steam Plant - Ash Disposal Area Dike Raising - Soils Report 11/3/75 - Evaluation

Reference Study Dwg 36-C-4-105N100 with 6/26/74 soils investigation request.

1. Existing Dike C and Road Dike. Dikes to be raised on existing ash in the pond inside the dikes.

2. Investigation was done in accord with 6/26/74 request as concerns existing fdn and fill of both dikes. The request emphasized looking for and testing the "softest" soil, and testing more typical soil also. Penetration tests showed generally similar and generally "soft" soils in the existing dikes fdn and some in the existing fill. Therefore UD sampling and testing done in only holes 1 and 7 of the 10 dike holes is sufficient.

b. The request included information that the south 2000'± of existing Dike C was built with ash. Two of three 500'oc borings showed mostly soil, including UD sampled boring 7. No tests were made on ash.

c. Std penetr borings were made in the ash along the inside of Dike C and Road Dike as requested. Penetration values show the ash to be mostly silt size (minus 0.074 mm) and almost uniformly soft. See also 2.c.

2. New Dike B. "Inside" of existing county road embankment. To be built on existing ash in pond.
   a. Request said that since the area has present ash low and is under water, "fdn" exploration and testing is not requested. Instead,
   b. The request expected that "heavy ash" would be used as fill as "foundation" for Dike B to get above water, then complete dike with earth fill. The request asked for exploration and testing of ash above El 746 along the inside of Dike C and Road dike as "borrow," and to indefinite depth along the "inside" of existing North Dike where dry hauled heavy ash has reportedly been deposited.

Std penetr borings were made as requested along these areas. Part of the area inside existing Dike C and Road Dike has 1 or 2 feet of apparently coarse ash on top. There is little ash above El 746; it is reported as silty sand size (minus 3/16"). Pond water is at top of ash. Along the inside of existing North Dike, the dry haul deposit, two feet of coarse ash is indicated on top. Top is El 750 to 757. Water is at top of ash; does not drain out. About 10' is reported as silty sand size. Below

2. b. (cont)
this the ash is reported as mostly silt size, and soft by the low penetr values.
[The upper ash has higher penetr values, is therefore firm and more dense; but its weight has evidently not consolidated the finer lower ash under submerged conditions. The same applies along the inside of Dike C and Road Dike].

c. The request asked for in-place density tests of ash along the inside of Dike C and Road Dike, then strength tests of the ash. These would serve as strength tests for the "borrow" ash to be used under new Dike B, and strength tests of ash under Dike C and Road Dike raising. These tests were not made.

In phone discussion with SME it is stated that the field exploration crew discussed the ash exploration with Hwy Group personnel. The request said that ash "of suitable quality" would be used for Dike B fdn borrow, assuming that heavy ash would be found in the explored areas. Since the explored ash was of sand and smaller size, they

2.c. (cont)
decided that it could not be used for placing in water for Dike B foundation.

The decision included elimination of strength testing of the in-place ash along the inside of Dike C and Road Dike as foundation for raising these dikes.

So no ash has been tested anywhere.

3. Earth Borrow.
Three borrow areas were explored east of the plant. With estimated 2 million c.y. available for the request's estimated 900,000 c.y. required if Dike B is all earth without heavy ash base.
a. All borrow is reported averaging 4% to 5% wet of optimum, mostly CH, some CL.
b. Groundwater was not definitely established in borrow areas. But lab says borings were stopped when down to too wet soil.
c. Preference of borrow areas seems to be in order A, B, C.
(1) A is somewhat drier than B and C, and somewhat less CH.

3. c. (cont)

(2) A has 15' to 30' depth to too wet soil.
B " 15' to 25' " " " " " "
C has 3 of 6 holes only 10' to 15' to too wet soil.

(3) Report logs are depth not elevation, so I have no conception of the topo as regards borrow feasibility.

4. Design.

I am told that dikes design and construction is already very late. Design will have to proceed with present info.

a. Dike and Road Dike

(1) Use soil design values below

KINGSTON STEAM PLANT - ASH DISPOSAL AREA DIKE RAISING - SOIL INVESTIGATION

p. 4 of soils report

Lab Recommended Design Values

4.2. (cont)

The change in embankment saturated R cohesion is to account for soil drier than 3% wet of optimum, which may be encountered. Admittedly it may not be important; the number will be used ① for main "outslope" stability circle which only cuts up thru the new fill for a short part of its arc with most of arc in old dike fdn, and ② "inslope" circle on existing ash which has not been tested.

(2) Assume no strength in existing ash under dike raising. Assuming computer analysis, use "peculiar circles" to cover the slip possibilities on the "outslope." I see no sensible design for the "inslope" of new dike on ash. If it can be built it will have a safety of 1+ from vibration of earth hauling and compacting equipment. It can be improved by excav ash deeper than 746, placing fill, then "piling" ash along the inside to help support it. Can we assume the area has had traffic from ash haul and dump inside the dike? The top ash is firm.

4. (cont)
b. Dike B.

J.P.H. Stivers says the layout of Dike B is being studied again. It may be moved "out" to incorporate present county road embankment. These are exterior drainage problems the Hwy Group is struggling with. The soil in the road embankment and its foundation have not been tested.

The ash under presently proposed or under the above move is unknown. See 2. b. & c.

I make no suggestion on Dike B design. The problem of placing its base in water still exists. The explored ash inside Dike C, Road Dike and North Dike is probably too fine for placing in water. Is there not bottom ash or other "heavy" ash available in the original ash disposal area south of the North Dike?

Some of the preceding comments could deserve recognition or notes on dwgs.
