Effective Date:
March 10, 2009

SUBJ: United States Standard for Helicopter Area Navigation (RNAV)

These criteria are the Federal Aviation Administration (FAA) standards for developing helicopter area navigation (RNAV) instrument procedure construction based on Global Positioning System (GPS). This revision adds definitions, changes procedure identification from GPS to RNAV, provides specific holding pattern leg lengths, helicopter en route criteria, decreases navigation system error tolerance for along-track distance in the terminal area, and adds departure criteria, minimums, and requirements. The types of final approaches have been revised. They are Instrument Flight Rules (IFR) to an IFR heliport, IFR to a Visual Flight Rules (VFR) heliport (Proceed Visually), Point-in-Space (PinS) approach (Proceed VFR), and IFR to Runways with separate criteria for each.

The first step to increase helicopter IFR utility is the development of helicopter RNAV instrument procedures. Ongoing testing and criteria development by the FAA for application of the Wide Area Augmentation System (WAAS) will provide the next major step. WAAS with its increased integrity and 3-dimensional (3D) approach capability will allow narrower route widths and approaches with vertical guidance (APV).

Chapter 1. General Information

- 1. Purpose of This Order.** This order contains criteria for the formulation, review, approval, and publication of area navigation (RNAV) helicopter instrument procedures based on Global Positioning System (GPS) and Wide Area Augmentation System (WAAS) navigation.
- 2. Audience.** This order is distributed in Washington headquarters to the branch level offices of Airport Safety, Standards and Communications, and Navigation and Surveillance Systems; Air Traffic Organization (Safety, En Route and Oceanic Services, Terminal Services, System Operations Services, and Technical Operations Services); Flight Standards Services; National Flight Procedures Office and the Regulatory Standards Division (at the Mike Monroney Aeronautical Center); branch level in the regional Flight Standards and Airports Divisions; special mailing list ZVS-827, and Special Military and Public Addressees.
- 3. Where Can I Find This Order?** This information is also available on the FAA's Web site at <http://fsims.avs.faa.gov/fsims/fsims.nsf>.
- 4. What This Order Cancels.** Order 8260.42A, Helicopter Global Positioning System (GPS) Nonprecision Approach Criteria.
- 5. Explanation of Policy Changes.** This document has been completely revised for harmonization with FAA Order 8260.54, Area Navigation, incorporation of criteria policy documents, and to meet FAA Order 1320.1, FAA Directives Management, formatting requirements. These criteria were written for automated implementation. Formulas are presented in Math notation and standard text to facilitate programming efforts. Calculation examples were eliminated. Instead, an Adobe Acrobat version of the criteria document is available where each formula performs the calculation as an imbedded calculator.
- 6. Effective Date.** March 10, 2009

Chapter 2. General Criteria

Section 1. Basic Criteria Information

1. General. These criteria assume use of Global Positioning System (GPS) or Wide Area Augmentation System (WAAS) receivers approved for approach operations, in accordance with Advisory Circular (AC) 20-138, Airworthiness Approval of Global Navigation Satellite System (GNSS) Equipment; Technical Standard Order (TSO) C-129 Class A (1) systems; and AC 20-130, Airworthiness Approval of Navigation or Flight Management Systems Integrating Multiple Navigation Sensors, for GPS as part of a multi-sensor system meeting TSO-C129 Class C (1) System or pertinent military guidance. WAAS navigation equipment must be approved in accordance with the requirements specified in TSO-C145, Airborne Navigation Sensors Using the Global Positioning System (GPS) Augmented by the Wide Area Augmentation System (WAAS), or TSO-C146, Stand-Alone Airborne Navigation Equipment Using the Global Positioning System (GPS) Augmented by the Wide Area Augmentation System (WAAS).

Unless otherwise specified, Order 8260.3, United States Standard for Terminal Instrument Procedures (TERPS), applies. For public use procedures, the heliport must meet the guidance contained in AC 150/5390-2, Heliport Design. Obstacle clearance area dimensions are based on 90 knots indicated airspeed (KIAS) **maximum** in the initial and intermediate segments and 70 KIAS **maximum** in the final and missed approach segments until passing the missed approach holding fix. USA/USAF/USN/USCG only: procedures are designed for 90 KIAS in the final and missed approach segments.

The following FAA orders apply:

- 7130.3, Holding Pattern Criteria.
- 8260.3, United States Standard for Terminal Instrument Procedures (TERPS).
- 8260.19, Flight Procedures and Airspace.

Apply chapter 2, section 3 of Order 7130.3, Holding Pattern Criteria. Use pattern 4 for all helicopter holding (including climb-in-hold) up to and including 10,000 ft. Chart 4 nautical mile (NM) leg lengths.

The feeder, initial, intermediate, final, and missed approach criteria described in this order supersede the other publications listed above. See Order 8260.3, Volume 1, chapter 3 to determine visibility minima.

Formulas are numbered by chapter and depicted in standard mathematical notation and in standard text to aid in computer programming. Each formula contains a java script functional calculator.

The diagram illustrates a calculator interface for entering and calculating a formula. At the top, a red header reads "Formula x-x. Formula Title.". Below this, the formula $Y = \frac{X^2}{\tan\left(3 \cdot \frac{\pi}{180}\right)}$ is displayed in math notation. A callout box points to this formula with the text "Formula in math notation". Below the math notation, the text "where X = variable value" is shown. Underneath, the formula is entered in standard text notation as $x^2/\tan(3*\pi/180)$, with a callout box pointing to it that says "Formula in standard text notation". The calculator interface includes a "Calculator" section with a green "input value here" field and a grey "Click here to calculate" button. A callout box points to the input field with the text "Enter variable values in the green areas". Another callout box points to the "Click here to calculate" button with the text "Click here after entering input values to make the calculator function". Below the calculator, there are two rows: "X" and "Y". The "Y" row has a yellow "Calculated Result" field. A callout box points to this field with the text "The calculated answer is printed after the grey button is clicked".

2. Data Resolution. Perform calculations using an accuracy of at least 15 significant digits; i.e., floating point numbers must be stored using at least 64 bits. Do not round intermediate results. Round only the final result of calculations for documentation purposes. Required accuracy tolerance is 1 centimeter for distance and 0.002 arc-second for angles. The following list specifies the minimum accuracy standard for documenting data expressed numerically. This standard applies to the documentation of final results only; e.g., a calculated adjusted glidepath angle of 3.04178 degrees is documented as 3.05 degrees. The standard does not apply to the use of variable values during calculation. Use the most accurate data available for variable values.

a. Documentation Accuracy:

- (1) WGS-84 latitudes and longitudes to the nearest one hundredth (0.01) arc second; [nearest five ten thousandth (0.0005) arc second for Final Approach Segment (FAS) data block entries];
- (2) Flight Path Alignment Point (FPAP) mean sea level (MSL) elevation to the nearest foot;
- (3) FPAP height above ellipsoid (HAE) to the nearest tenth (0.1) meter;
- (4) Glidepath angle to the next higher one hundredth (0.01) degree;
- (5) Courses to the nearest one hundredth (0.01) degree; and
- (6) Course width at threshold to the nearest quarter (0.25) meter;
- (7) Distances to the nearest hundredth (0.01) unit [except for "length of offset" entry in FAS data block which is to the nearest 8 meter value].

b. Mathematics Convention. Formulas in this document as depicted are written for radian calculation.

Note: The value for 1 NM was previously defined as 6,076.11548 ft. For the purposes of RNAV criteria, 1 NM is defined as the result of the following calculation:

$$\frac{1852}{0.3048}$$

(1) Conversions:

- Degree measure to radian measure:

$$\text{radians} = \text{degrees} \cdot \frac{\pi}{180}$$

- Radian measure to degree measure:

$$\text{degrees} = \text{radians} \cdot \frac{180}{\pi}$$

- Feet to meters:

$$\text{meters} = \text{feet} \cdot 0.3048$$

- Meters to feet:

$$\text{feet} = \frac{\text{meters}}{0.3048}$$

- Feet to Nautical Miles (NM):

$$\text{NM} = \text{feet} \cdot \frac{0.3048}{1852}$$

- NM to feet:

$$\text{feet} = \text{NM} \cdot \frac{1852}{0.3048}$$

- NM to meters:

$$\text{meters} = \text{NM} \cdot 1852$$

- Meters to NM:

$$\text{NM} = \frac{\text{meters}}{1852}$$

- Temperature Celsius to Fahrenheit:

$$T_{\text{Fahrenheit}} = 1.8 \cdot T_{\text{Celsius}} + 32$$

- Temperature Fahrenheit to Celsius:

$$T_{\text{Celsius}} = \frac{T_{\text{Fahrenheit}} - 32}{1.8}$$

(2) Definition of Mathematical Functions and Constants:

$a + b$ indicates addition

$a - b$ indicates subtraction

$a \times b$ or ab or $a \cdot b$ or $a * b$ indicates multiplication

$\frac{a}{b}$ or a/b or $a \div b$ indicates division

$(a - b)$ indicates the result of the process within the parenthesis

$|a - b|$ indicates absolute value

\approx indicates approximate equality

\sqrt{a} or $a^{0.5}$ or $a^{.5}$ indicates the square root of quantity "a"

a^2 or a^2 indicates $a \times a$

$\ln(a)$ or $\log(a)$ indicates the natural logarithm of "a"

$\tan(a)$ indicates the tangent of "a" degrees

$\tan^{-1}(a)$ or $\text{atan}(a)$ indicates the arc tangent of "a"

$\sin(a)$ indicates the sine of "a" degrees

$\sin^{-1}(a)$ or $\text{asin}(a)$ indicates the arc sine of "a"

$\cos(a)$ indicates the cosine of "a" degrees

$\cos^{-1}(a)$ or $\text{acos}(a)$ indicates the arc cosine of "a"

e The constant **e** is the base of the natural logarithm and is sometimes known as Napier's constant, although its symbol (**e**) honors Euler. With the possible exception of π , **e** is the most important constant in mathematics since it appears in myriad mathematical contexts involving limits and derivatives. Its value is approximately 2.718281828459045235360287471352662497757...

r The TERPS constant for the mean radius of the earth for spherical calculations in feet. **r = 20890537**

(3) Operation Precedence (Order of Operations):

First: Grouping Symbols: parentheses, brackets, braces, fraction bars, etc.

Second: Functions: Tangent, sine, cosine, arcsine, and other defined functions

Third: Exponentiations: Powers and roots

Fourth: Multiplication and Division: Products and quotients

Fifth: Addition and subtraction: Sums and differences

e.g.,

$5 - 3 \times 2 = -1$ because multiplication takes precedence over subtraction

$(5 - 3) \times 2 = 4$ because parentheses take precedence over multiplication

$\frac{6^2}{3} = 12$ because exponentiation takes precedence over division

$\sqrt{9 + 16} = 5$ because the square root sign is a grouping symbol

$\sqrt{9} + \sqrt{16} = 7$ because roots take precedence over addition

$$\frac{\sin(30^\circ)}{0.5} = 1 \text{ because functions take precedence over division}$$

$$\sin\left(\frac{30^\circ}{0.5}\right) = 0.8660254 \text{ because parentheses take precedence over functions}$$

Notes on calculator usage:

1. Most calculators are programmed with these rules of precedence.
2. When possible, let the calculator maintain all of the available digits of a number in memory rather than re-entering a rounded number. For highest accuracy from a calculator, any rounding that is necessary should be done at the latest opportunity.

c. Geospatial Standards. The following standards apply to the evaluation of obstacle and terrain position and elevation data relative to RNAV OEAs and OCSs. Terrain and obstacle data are reported in NAD-83 latitude, longitude, and elevation relative to MSL in National Geodetic Vertical Datum of 1929 (NGVD-29) or North American Vertical Datum of 1988 (NAVD-88) vertical datum. Evaluate obstacles using their NAD-83 horizontal position and NAVD-88 elevation value compared to the WGS-84 referenced course centerline (along-track and cross-track), OEA boundaries, and OCS elevations as appropriate.

(1) WGS-84[G873] for Position and Course Construction. This reference frame is used by the FAA and the U.S. Department of Defense (DoD). It is defined by the National Geospatial-Intelligence Agency (NGA) (formerly the National Imagery and Mapping Agency, formerly the Defense Mapping Agency [DMA]). In 1986, the Office of National Geodetic Survey (NGS), redefined and readjusted the North American Datum of 1927 (NAD-27), creating the North American Datum of 1983 (NAD-83). The WGS-84 was defined by the DMA. Both NAD-83 and WGS-84 were originally defined (in words) to be geocentric and oriented as the Bureau International d'Heure (BIH) Terrestrial System. In principle, the three-dimensional (3D) coordinates of a single physical point should be the same in both NAD-83 and WGS-84 Systems; in practice; however, small differences are sometimes found. The original intent was that both systems would use the Geodetic Reference System of 1980 (GRS-80) as a reference ellipsoid. As it happened, the WGS-84 ellipsoid differs very slightly from GRS-80. The difference is 0.0001 meters in the semi-minor axis. In January 2, 1994, the WGS-84 reference system was realigned to be compatible with the International Earth Rotation Service's Terrestrial Reference Frame of 1992 (ITRF) and renamed WGS-84 (G730). The reference system underwent subsequent improvements in 1996, referenced as WGS-84 (G873) closely aligned with ITRF-94, to the current realization adopted by the NGA in 2001, referenced as WGS-84 (G1150) and considered equivalent systems to ITRF 2000.

(2) NAVD-88 for elevation values. NAVD-88 is the vertical control datum established in 1991 by the minimum-constraint adjustment of the Canadian-Mexican-U.S. leveling observations. It held fixed the height of the primary tidal bench mark, referenced to the new International Great Lakes Datum of 1985 local MSL height value, at Father Point/Rimouski, Quebec, Canada. Additional tidal bench mark elevations were not used due to the demonstrated variations in sea surface topography, (i.e., the fact that MSL is not the same equipotential surface at all tidal bench marks).

d. OEA Construction and Obstacle Evaluation Methodology.

(1) Courses, fixes, boundaries (lateral dimension). Construct straight-line courses as a WGS-84 ellipsoid geodesic path. If the course outbound from a fix differs from the course inbound to the fix (courses measured at the fix), then a turn is indicated. Construct parallel and trapezoidal boundary lines as a locus of points measured perpendicular to the geodesic path. (The resulting primary and/or secondary boundary lines do not display a “middle bulge” due to curvature of the ellipsoids surface since they are not geodesic paths.) NAD-83 latitude/longitude positions are acceptable for obstacle, terrain, and airport data evaluation. Determine obstacle lateral positions relative to course centerline/OEA boundaries using ellipsoidal calculations (see appendix B).

(2) Elevations (vertical dimension). Evaluate obstacles, terrain, and airport data using their elevation relative to their orthometric height above the geoid (for our purposes, MSL) referenced to the NAVD-88 vertical datum. The elevations of OCSs are determined spherically relative to their origin MSL elevation (NAVD-88). Department of Defense (DoD) procedure developers may use EGM-96 vertical datum.

e. Evaluation of Actual and Assumed Obstacles (AAO). Apply the vertical and horizontal accuracy standards in Order 8260.19, paragraphs 272, 273, 274, and appendix 3. (USAF, apply guidance per AFI 11-230)

Note: When applying an assumed canopy height consistent with local area vegetation, contact the FAA regional Flight Procedures Office (FPO) to verify the height value to use.

f. ATT Values. ATT is the value used (for segment construction purposes) to quantify position uncertainty of an RNAV fix. The application of ATT can; therefore, be considered “circular;” i.e., the ATT value assigned describes a radius around the plotted position of the RNAV fix (see figure 2-1 and table 2-1).

Note: Cross-track tolerance (XTT) values were considered in determining minimum segment widths, and are not considered further in segment construction.

Table 2-1. ATT Values.		
GPS	En Route Feeder, Initial, Intermediate, Missed Approach > 30 NM)	2.0 NM
	Terminal Feeder, Initial, Intermediate, Missed Approach ≤ 30 NM)	1.0 NM
	Approach (final)	0.3 NM
WAAS* (LP)	Approach (final)	40 meters

*Applies to final segment only. Apply GPS values to all other segments of the approach procedure.

3. Procedure Identification. GPS and WAAS are considered to be RNAV systems. The procedure identification begins with “COPTER RNAV (GPS).” The remainder of the identification is based on whether the landing site is a heliport or a runway.

a. U.S. Army (USA) Helicopter Runways. USA heliports that have helicopter runways chart the procedure with the letter H and the runway number. To differentiate between parallel runways, use the letter “L” or “R”; i.e., COPTER RNAV (GPS) RWY H22R.

b. IFR Approach to an IFR Runway (within 30 degrees alignment). Use the abbreviation “RWY” followed by the runway number. Examples: COPTER RNAV (GPS) RWY 22.

c. Point-in-Space (PinS) or IVH procedures to a VFR Runway. Use the magnetic bearing of the final approach course. Example: COPTER RNAV (GPS) 160°.

d. Multiple Procedures to the Same Runway. Where more than one approach, using the same final approach guidance is developed to the same location, identify each location/guidance combination with an alphabetical suffix beginning at the end of the alphabet; e.g., COPTER RNAV (GPS) Z RWY 22 (first procedure), COPTER RNAV (GPS) Y RWY 22 (second procedure), COPTER RNAV (GPS) X RWY 22 (third procedure). Identify the procedure with the lowest minimums will be identified with “Z” and the next lowest “Y.”

e. Special Approach Procedures. A procedure requires special authorization when it is an instrument flight rules (IFR) approach to a visual flight rules (VFR) heliport, reference chapter 4, paragraph 5, or one of the following conditions exists: (USAF/USA/USCG/USN not applicable).

- (1) A track change at the precise final approach fix (PFAF) exceeds 30 degrees.
- (2) Descent Gradient/Angle exceeds 600 ft/NM (5.64 degrees) on any IFR segment.
- (3) When raising the heliport crossing height (HCH) to greater than 10 ft in the visual segment.

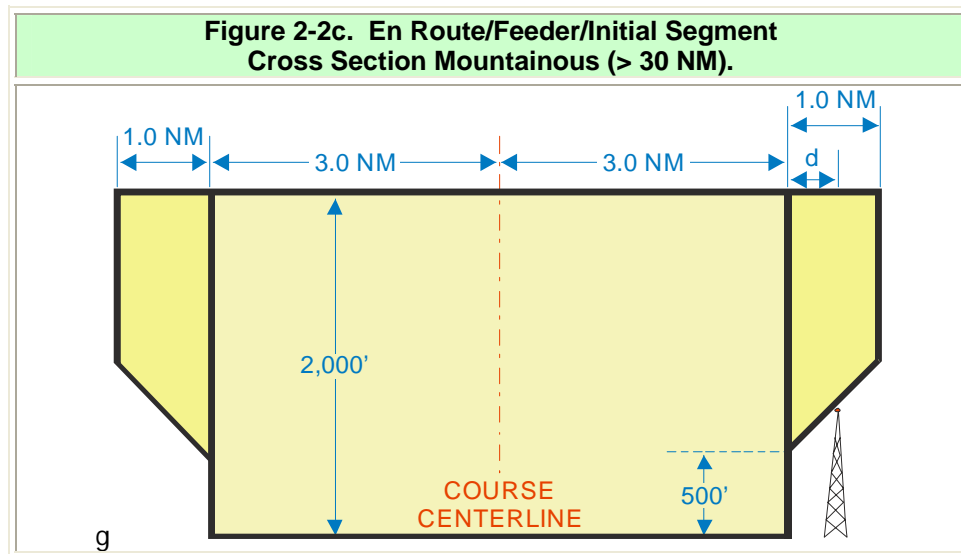

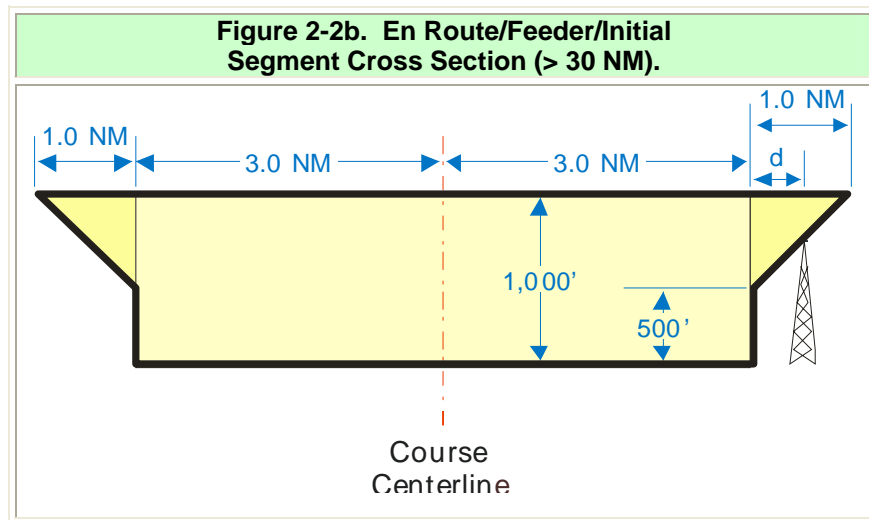

- (4) When a V_{mini} less than 70 knots indicated airspeed (KIAS) is applied.
- (5) Where a bank angle other than the standard is used.
- (6) When the missed approach point (MAP) to heliport distance is less than 3,342 ft (0.55 NM).

Note: This criterion applies only to an IFR to a VFR heliport (IVH) procedure.

4. Segment Width (General). Table 2-2 lists primary and secondary width values for all segments of an RNAV approach procedure. Where segments cross* a point 30 NM from airport reference point (HRP), segment primary area width increases (expansion) or decreases (taper) at a rate of 30 degrees relative to course to the appropriate width. Secondary area expansion/taper is a straight-line connection from the point the primary area begins expansion/taper to the point the primary area expansion/taper ends. Reference to route width values is often specified as NM values measured from secondary area edge across the primary area to the secondary edge at the other side. For example, route width for segments more than 30 NM from HRP is “1-3-3-1.” See figures 2-2b and 2-2c. For distances ≤ 30 NM, the width is “0.5-1.5-1.5-0.5.” See table 2-2 and figure 2-2a.

***Note:** Feeder segment width is 1-3-3-1 at all distances greater than 30 NM from HRP. A segment designed to cross within 30 NM of the HRP more than once does not taper in width until the 30 NM limit is crossed for approach and landing; i.e., crosses the limit for the last time before landing. A missed approach segment designed to cross a point 30 NM of the HRP more than once expands when it crosses the boundary the first time and remains expanded.

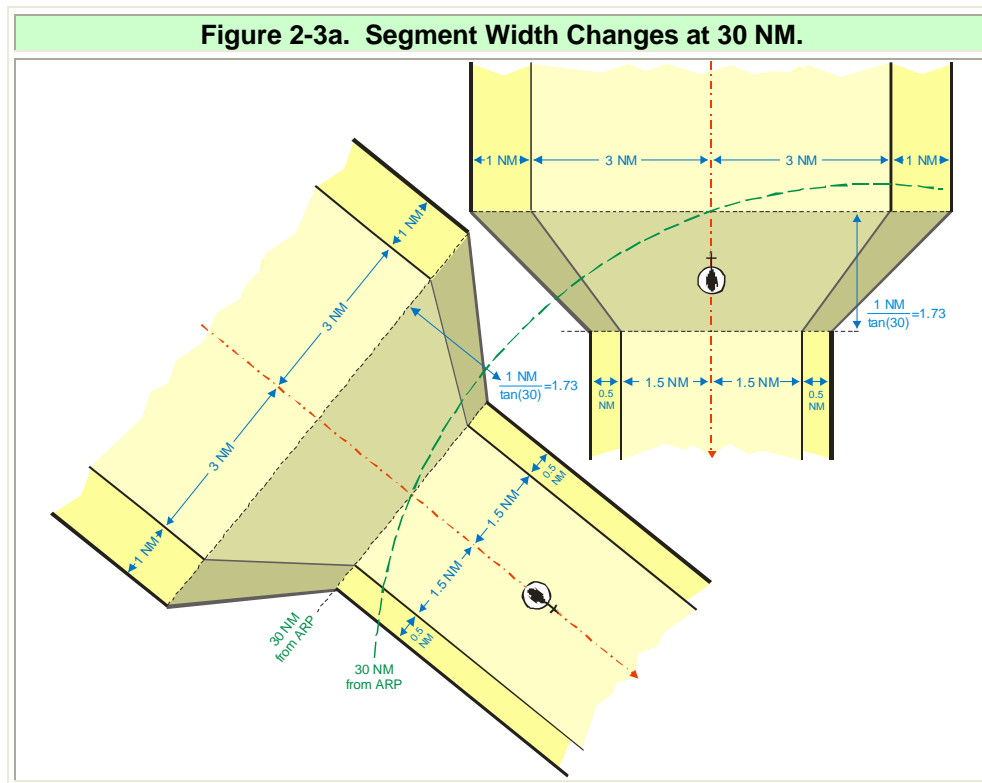

Table 2-2. RNAV Linear Segment Width (NM) Values.			
Segment		Primary Area Half-Width (p)	Secondary Area (s)
En Route, Feeder, Initial & Missed Approach	> 30 NM from ARP	± 3.00	1.00
		1-3-3-1	
Feeder, Initial, Missed Approach	≤ 30 NM from ARP	± 1.50	0.5
		0.5-1.5-1.5-0.5	
Intermediate		Continues initial segment width until 2 NM prior to PFAF. Then tapers uniformly to final segment width.	Continues initial segment width until 2 NM prior to PFAF. Then tapers to final segment width.

a. Width Changes at 30 NM from HRP/ARP.

(1) Width Changes at 30 NM from HRP (non-RF). Receiver sensitivity changes at 30 NM from HRP. From the point the designed course crosses 30 NM from HRP, the primary

OEA can taper inward at a rate of 30 degrees relative to course from ± 3 NM to ± 1.5 NM. The secondary area tapers from a 1 NM width when the 30 NM point is crossed to a 0.5 NM width abeam the point the primary area reaches the ± 1.5 NM width. The total along-track distance required to complete the taper is approximately 1.73 NM (10,524.14 ft). Segment width tapers regardless of fix location within the tapering section unless a turn is associated with the fix. Delay OEA taper until the turn is complete and normal OEA turn construction is possible (see figure 2-3a).

(2) Width Changes at 30 NM from HRP/ARP (RF). When the approach segment crosses the point 30 NM from airport reference point in an RF leg, construct the leg beginning at a width of 1-3-3-1 prior to the 30 NM point and taper to 0.5-1.5-1.5-0.5 NM width inside the 30 NM point. Calculate the perpendicular distance (B_{primary} , $B_{\text{secondary}}$) from the RF segment track centerline to primary and secondary boundaries at any along-track distance (specified as degrees of RF arc " α ") from the point the track crosses the 30 NM point using formula 2-1 (see figure 2-3b, apply formula 2-3c to find the RF arc radius).

Formula 2-1. RF Segment Taper Width.

$$D = \frac{3-1.5}{\tan\left(30 \cdot \frac{\pi}{180}\right)} \quad \alpha = \frac{180 \cdot D}{\pi \cdot R}$$

Calculates degrees of arc (α) to complete taper

$$B_{\text{primary}} = 3 - 1.5 \cdot \frac{\phi \cdot \pi \cdot R}{180 \cdot D}$$

$$B_{\text{secondary}} = 4 - 2 \cdot \frac{\phi \cdot \pi \cdot R}{180 \cdot D}$$

Where:

D = taper distance

R = RF leg radius

ϕ = degrees of arc (RF track)

Note: "D" will be in the same units as "R"

$$D = (3-1.5) / \tan(30 * \pi / 180)$$

$$\alpha = (180 * D) / (\pi * R)$$

$$B_{\text{primary}} = 3 - 1.5 * (\phi * \pi * R) / (180 * D)$$

$$B_{\text{secondary}} = 4 - 2 * (\phi * \pi * R) / (180 * D)$$

Calculator

B _{secondary}		

5. Calculating the Turn Radius (R). The design turn radius value is based on four variables: indicated airspeed, assumed tailwind, altitude, and bank angle. Calculate R using formula 2-3c. Apply the indicated airspeed from table 2-3 for the highest speed helicopter category that will be published on the approach procedure. Apply the highest expected turn altitude value. Apply the appropriate bank angle from table 2-4 and formula 2-2 to determine the vertical path altitude (VP_{alt}).

Formula 2-2. Vertical Path Altitude.		
$VP_{alt} = e^{\frac{D_z \cdot \tan\left(\frac{\theta - \pi}{180}\right)}{r}} \cdot (r + PFAF_{alt}) - r$		
Where:		
PFAF _{alt} = Designed PFAF MSL altitude		
θ = glidepath angle		
D _z = distance (ft) from PFAF to fix		
Note: If D _z is a NM value, convert to feet by multiplying NM by 1852/0.3048		
$e^{((D_z \cdot \tan(\theta \cdot \pi / 180)) / r) \cdot (r + PFAF_{alt})} - r$		
Calculator		
PFAF _{alt}		Click here to calculate
θ		
D _z		
VP _{alt}		

Note: Determine the highest altitude within a turn by:

For approach –calculate the vertical path altitude (VP_{alt}) by projecting a 3-degree vertical path from the PFAF along the designed nominal flight track to the turn fix.

For missed approach highest altitude in a turn, apply (a) or (b), and (c).

(a) Turn-At-A-Fix, project a vertical path along the nominal flight track from the SOC point and altitude to the turn fix, that rises at a rate of 400 ft/NM (Helicopter) or a higher rate if a steeper climb gradient is specified. Compare the vertical path altitude at the fix to the minimum published fix altitude, apply the higher of the two;

(b) Turn-At-An-Altitude, apply the climb-to-altitude;

(c) Plus an additive, (Turn-At-A-Fix (FO) and Turn-At-An-Altitude) based on a continuous climb of 400 ft per 12 degrees of turn [$\phi \cdot 400 / 12$]. The turn altitude must not be higher than the published missed approach altitude.

Helicopter example: 900 ft would be added for a turn of 27 degrees, 767 ft would be added for 23 degrees, 333 ft for 10 degrees of turn.

Step 1: Determine the true airspeed (KTAS) for the turn using formula 2-3a. Locate and use the appropriate knots indicated airspeed (KIAS) from table 2-3. Use the highest altitude within the turn.

Formula 2-3a. True Airspeed.		
$V_{KTAS} = \frac{V_{KIAS} \cdot 171233 \cdot \sqrt{(288 + 15) - 0.00198 \cdot alt}}{(288 - 0.00198 \cdot alt)^{2.628}}$		
where alt = aircraft MSL elevation V _{KIAS} = knots indicated airspeed		
$(V_{KIAS} * 171233 * ((288 + 15) - 0.00198 * alt)^{0.5}) / (288 - 0.00198 * alt)^{2.628}$		
Calculator		
V _{KIAS}		Click here to calculate
alt		
V _{KTAS}		

Table 2-3. Helicopter Indicated Airspeeds (Knots).		
Segment	Indicated Airspeed	
	Civil	Military
Feeder, Initial, Intermediate	140	140
Final, Missed Approach	70	90

Step 2: Calculate the appropriate tailwind component (V_{KTW}) using formula 2-3b for the highest altitude within the turn. EXCEPTION: If the MSL altitude is 2,000 ft or less above airport elevation, use 30 knots.

Formula 2-3b. Tailwind.		
$V_{KTW} = 0.00198 \cdot alt + 47$		
where alt = highest turn altitude		
Note: If "alt" is 2,000 or less above airport elevation, then V _{KTW} = 30		
$0.00198 * alt + 47$		
Calculator		
alt		Click here to calculate
V _{KTW}		

Note: Greater tailwind component values may be used where data indicates higher wind conditions are likely to be encountered. Where a higher value is used, it must be recorded in the procedure documentation.

Step 3: Calculate R using formula 2-3c.

Formula 2-3c. Turn Radius.		
$R = \frac{(V_{KTAS} + V_{KTW})^2}{\tan\left(\text{bank}_{\text{angle}} \cdot \frac{\pi}{180}\right) \cdot 68625.4}$		
where bank _{angle} = assumed bank angle (normally 11° or 14° for Helicopter)		
$(V_{KTAS} + V_{KTW})^2 / (\tan(\text{bank}_{\text{angle}} \cdot \pi / 180) \cdot 68625.4)$		
Calculator		
V _{KTAS}		Click here to calculate

R		

Note: Use formula 2-8 to verify the required bank angle does not exceed the design bank angle (11 or 14 degrees), see table 2-4.

Table 2-4. Bank Angles.		
Knots True Airspeed (KTAS)	< 90	≥ 90
Bank Angle (In degrees)	11.0	14.0

6. Turn Construction. If the outbound course from a fix differs by more than 0.03 degrees from the inbound course to the fix (courses measured at the fix), a turn is indicated.

a. Turns at Fly-Over Fixes (see figures 2-4 and 2-5).

(1) Extension for Turn Delay. Turn construction incorporates a delay in start of turn to account for pilot reaction time and roll-in time (rr). Calculate the extension distance in feet using formula 2-4a (terminal) or formula 2-4b (feeder and en route).

Formula 2-4a. Reaction & Roll Dist. (Terminal).		
$rr = 6 \cdot \frac{1852}{3600} \cdot V_{KTAS}$		
$6 \cdot 1852 / 0.3048 / 3600 \cdot V_{KTAS}$		
Calculator		
V _{KTAS}		Click here to calculate
rr		

Note: 6 second delay

Formula 2-4b. Turn Delay (En Route, Feeder).		
$rr = 8 \cdot \frac{1852}{3600} \cdot (V_{KTAS} + V_{KTW})$		
$8 \cdot (1852 / 0.3048 / 3600) \cdot (V_{KTW} + V_{KTAS})$		
Calculator		
V _{KTW}		Click here to calculate
V _{KTAS}		
rr (ft)		

Note: 8 second delay

Step 1: Determine **R**. See formula 2-3c.

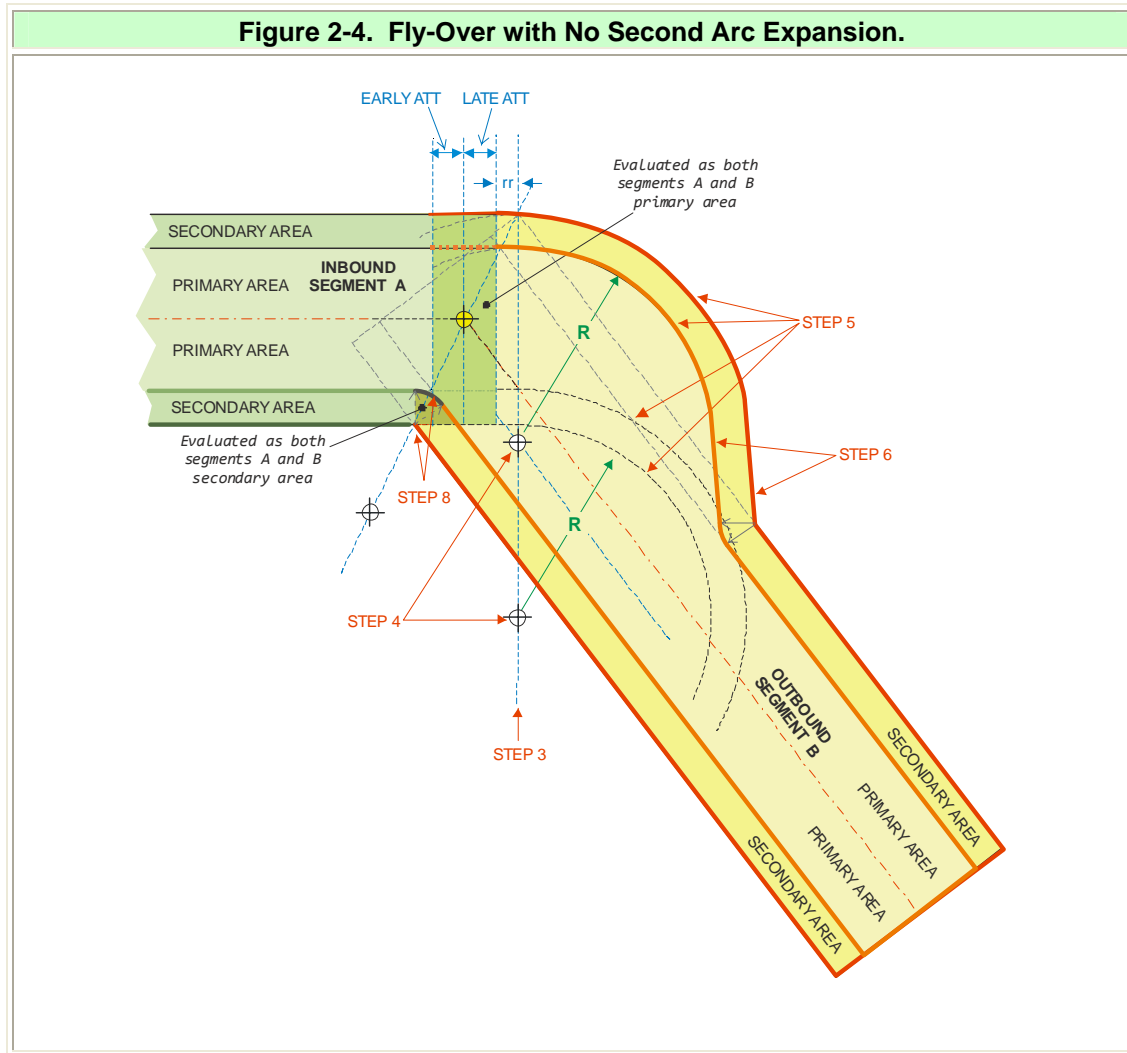

Step 2: Determine **rr**. See formula 2-4a or formula 2-4b.

Step 3: Establish the baseline for construction of the turn expansion area as the line perpendicular to the inbound track at a distance past the turn fix equal to (ATT+rr).

Step 4: On the baseline, locate the center points for the primary and secondary turn boundaries. The first is located at a distance R from the non-turning side primary boundary. The second is located at a distance R from the turning side secondary boundary (see figures 2-4 and 2-5).

Step 5: From these center points construct arcs for the primary boundary of radius R. Complete the secondary boundary by constructing additional arcs of radius (R+W_S) from the same center points. (W_S=width of the secondary). This is shown in figures 2-4 and 2-5.

Step 6: The arcs constructed in step 5 are tangent to the outer boundary lines of the inbound segment. Construct lines tangent to the arcs based on the first turn point tapering inward at an angle of 30 degrees relative to the outbound track that joins the arc primary and secondary boundaries. If both the inner and outer arcs lie outside subsequent segment boundary lines, but the resulting tapering line tangent points lie inside the subsequent segment boundary lines, consider the expanded boundary connection points to be the intersection of the arc and the subsequent segment boundary lines. If the arcs from the second turn point are inside the tapering lines as shown in figure 2-4, then they are disregarded and the expanded area construction is completed. If not, proceed to step 7.

Step 7: If both the inner and outer arcs lie outside the tapering lines constructed in step 6, connect the respective inner and outer arcs with tangent lines and then construct the tapering lines from the arcs centered on the second center point as shown in figure 2-5.

Step 8: The inside turn secondary boundary is the intersection of the preceding and succeeding segment secondary boundaries. The inside turn primary boundary is an arc of secondary-width radius joining the preceding and succeeding segment primary boundaries.

Evaluate the inbound-segment secondary area truncated by the arc as primary area by both segments. Both segments also evaluate the secondary area inside the arc (see figures 2-4 and 2-5)

The inbound OEA end (\pm ATT) is evaluated for both inbound and outbound segments.

(2) Minimum length of TF leg following a fly-over turn. The leg length of a TF leg following a fly-over turn must be sufficient to allow the aircraft to return to course centerline. Determine the minimum leg length (L) using DTA distance from formula 2-5 and formula 2-6.

Formula 2-5. Distance of Turn Anticipation.

$$DTA = R \cdot \tan\left(\frac{\phi}{2} \cdot \frac{\pi}{180}\right)$$

Where:
 R = turn radius from formula 2-3c
 φ = degrees of heading change

$R \cdot \tan(\phi/2 \cdot \pi/180)$

Calculator

R	<input type="text"/>	Click here to calculate
φ	<input type="text"/>	
DTA	<input type="text"/>	

Formula 2-6. TF Leg Minimum Length Following Fly-Over Turn.

If $\phi_1 < \frac{180}{\pi} \cdot \text{acos}(3^{0.5}-1)$, then

$$L = R1 \cdot \left(\sin(\phi_1) + 2 \cdot \sin\left(\text{acos}\left(\frac{(1+\cos(\phi_1))}{2}\right)\right) \right) + R2 \cdot \tan\left(\frac{\phi_2}{2}\right), \text{ else}$$

$$L = R1 \cdot \left(\sin(\phi_1) + 4 \cdot 3^{0.5} - 3^{0.5} \cdot \cos(\phi_1) \right) + R2 \cdot \tan\left(\frac{\phi_2}{2}\right)$$

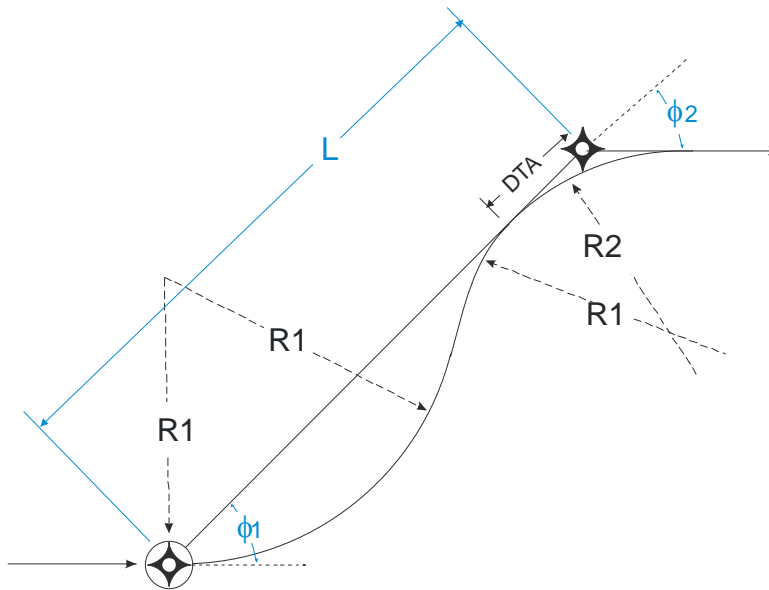

Where:

R1 = turn radius (NM) at the segment initial fix (formula 2-3c)

R2 = turn radius (NM) at the segment termination fix (zero if no fly-by turn)

ϕ_1 = turn magnitude at the segment initial fix

ϕ_2 = turn magnitude at the segment termination fix

If $\phi_1 < 180/\pi \cdot \text{acos}(3^{0.5}-1)$, then

$$R1 \cdot \left(\sin(\phi_1 \cdot \pi/180) + 2 \cdot \sin\left(\text{acos}\left(\frac{(1+\cos(\phi_1 \cdot \pi/180))}{2}\right)\right) \right) + R2 \cdot \tan\left(\frac{\phi_2/2}{180}\right), \text{ else}$$

$$R1 \cdot \left(\sin(\phi_1 \cdot \pi/180) + 4 \cdot 3^{0.5} - 3^{0.5} \cdot \cos(\phi_1 \cdot \pi/180) \right) + R2 \cdot \tan\left(\frac{\phi_2/2}{180}\right)$$

b. Fly-By Turn. See figure 2-6.

Step 1: Establish a line through the turn fix that bisects the turn angle. Determine Turn Radius (R). See formula 2-3c. Scribe an arc (with origin on bisector line) of radius R tangent to inbound and outbound courses. This is the designed turning flight path.

Step 2: Scribe an arc tangent to the inner primary boundaries of the two segment legs with a radius equal to $R + \frac{\text{Primary Area Half-width}}{2}$ (example: half width of 2 NM, the radius would be $R+1.0$ NM).

Step 3: Scribe an arc that is tangent to the inner secondary boundaries of the two segment legs using the origin and radius from step 2 minus the secondary width.

Step 4: Scribe the primary area outer turning boundary with an arc with a radius equal to the segment half width centered on the turn fix.

Step 5: Scribe the secondary area outer turning boundary with the arc radius from step 4 plus the secondary area width centered on the turn fix.

(1) Minimum length of track-to-fix (TF) leg following a fly-by turn. Calculate the minimum length for a TF leg following a fly-by turn using formula 2-7.

Formula 2-7. TF Leg Minimum Length Following Fly-by Turn.

$$L = R1 \cdot \tan\left(\frac{\phi_1}{2}\right) + R2 \cdot \tan\left(\frac{\phi_2}{2}\right)$$

Where:

- R1 = Turn radius at the segment initial fix (formula 2-3c)
- R2 = Turn radius at the segment termination (formula 2-3c)
- Note:** Zero when no turn
- ϕ_1 = turn magnitude at the segment initial fix
- ϕ_2 = turn magnitude, if any at the segment termination fix

$$R1 \cdot \tan(\phi_1/2 \cdot \pi/180) + R2 \cdot \tan(\phi_2/2 \cdot \pi/180)$$

c. Radius-to-Fix (RF) Turn. Incorporation of an RF segment may limit the number of aircraft served by the procedure. RF legs are used to control the ground track of a turn where obstructions prevent the design of a fly-by or fly-over turn, or to accommodate other operational requirements.* The curved leg begins tangent to the previous segment course at its terminating fix and ends tangent to the next segment course at its beginning fix (see figure 2-7). OEA construction limits turn radius to a minimum value equal-to or greater-than the OEA (primary and secondary) half-width. The RF segment OEA boundaries are parallel arcs.

***Note:** RF legs segments are not applicable to the final segment or section 1 of the missed approach segment. RF legs in the intermediate segment must terminate at least 2 NM prior to the PFAF. Where RF legs are used, annotate the procedure (or segment as appropriate) “RF Required.” Use Order 8260.52, table 1-3 for V_{KTW} values for radius calculations for RF legs.

Step 1: Determine the segment turn radius (R) that is required to fit the geometry of the terrain/airspace. Enter the required radius value into formula 2-8 to verify the resultant bank angle is ≤ 20 degrees (maximum allowable bank angle). Where a bank angle other than standard is used, annotate the value in the remarks section of the FAA Form 8260-9 or appropriate military procedure documentation form.

Formula 2-8. RF Bank Angle.		
$\text{bank}_{\text{angle}} = \arctan \left(\frac{(V_{KTAS} + V_{KTW})^2}{R \cdot 68625.4} \right) \cdot \frac{180}{\pi}$		
Where:		
V_{KTAS} = value from formula 2-3a V_{KTW} = value from Order 8260.52, table 1-3 R = required radius		
$\arctan((V_{KTAS} + V_{KTW})^2 / (R * 68625.4)) * 180 / \pi$

Segment _{length}		

Step 2: Turn Center. Locate the turn center at a perpendicular distance R from the preceding and following segments.

Step 3: Flight path. Construct an arc of radius R from the tangent point on the preceding course to the tangent point on the following course.

Step 4: Primary area outer boundary. Construct an arc of radius R+Primary area half-width from the tangent point on the preceding segment primary area outer boundary to the tangent point on the following course primary area outer boundary.

Step 5: Secondary area outer boundary. Construct an arc of radius R+Primary area half-width+secondary area width from the tangent point on the preceding segment secondary area outer boundary to the tangent point on the following course secondary area outer boundary.

Step 6: Primary area inner boundary. Construct an arc of radius R-Primary area half-width from the tangent point on the preceding segment inner primary area boundary to the tangent point on the following course inner primary area boundary.

Step 7: Secondary area inner boundary. Construct an arc of radius R-(Primary area half-width+secondary area width) from the tangent point on the preceding segment inner secondary area boundary to the tangent point on the following course inner secondary area boundary.

d. RNAV TF/VA/VI/CF leg followed by a DF Leg. Calculate minimum DF segment length using formula 2-9b.

Formula 2-9b. RNAV DF Leg Minimum Length following TF/VAVI/CF Legs.

If $\phi > 30$ then

$$L = 4 \cdot R \cdot \left(\sin\left(\frac{\phi + 30}{2}\right) \right)^2, \text{ else}$$

$$L = 2 \cdot R \cdot \sin(\phi)$$

Where:

R = turn radius (NM) at the segment initial fix (formula 2-3c)

ϕ = turn magnitude at the segment initial fix

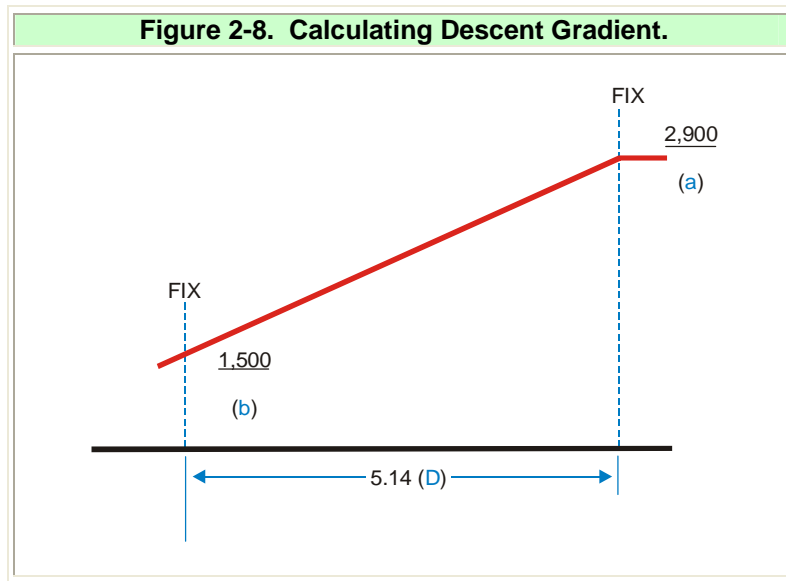

If $\phi > 30$ then
 $L = 4 \cdot R \cdot (\sin((\phi + 30) / 2 \cdot \pi / 180))^2$, else
 $L = 2 \cdot R \cdot \sin(\phi \cdot \pi / 180)$

7. Helicopter Initial and Intermediate Descent Gradient. The optimum descent gradient in the initial and intermediate segment is 400 ft/NM (6.58%, 3.77°); maximum is 600 ft/NM (9.87%, 5.64°). Where higher descent gradients are required, Order 8260.3, Volume 1, paragraph 1110 applies.

a. Calculating Descent Gradient (DG). Determine total altitude lost between the plotted positions of the fixes. Determine the distance (D) in NM. Divide the total altitude lost by D to determine the segment descent gradient using formula 2-10 (see figure 2-8).

Formula 2-10. Descent Gradient.

$$DG = \frac{r \cdot \ln\left(\frac{r+a}{r+b}\right)}{D}$$

Where:
 a = beginning altitude
 b = ending altitude
 D = distance (NM) between fixes

$r \cdot \ln((r+a)/(r+b))/D$

Calculator

a	<input type="text"/>	Click here to calculate
b	<input type="text"/>	
D	<input type="text"/>	
DG	<input type="text"/>	

8. Feeder Segment. When the initial approach fix (IAF) is not part of the en route structure, it may be necessary to designate feeder routes from the en route structure to the IAF. The feeder segment may contain a sequence of TF segments (and/or RF segments). The maximum course

change between TF segments is 90 degrees (70 degrees preferred). Formula 2-3c note applies. Chapter 2, paragraph 6 turn construction applies. The feeder segment terminates at the IAF (see chapter 2, figures 2-4, 2-5, and 2-6 for construction).

a. Length. The **minimum** length of a sub-segment is determined under chapter 2, paragraph 6a(2) or 6b(1) as appropriate. The **maximum** length of a sub-segment is 50 miles. The total length of the feeder segment should be as short as operationally possible.

b. Width. Primary area width is ± 3.0 NM from course centerline; secondary area width is 1.0 NM (1-3-3-1). These widths apply from the feeder segment initial fix to the approach IAF/termination fix.

c. Obstacle Clearance. The feeder segment OEA begins at the beginning fix early ATT and ends at the ending fix late ATT. The minimum ROC over areas not designated as mountainous under Federal Aviation Regulation (FAR) 95 is 1,000 ft. The minimum ROC within areas designated in FAR 95 as "mountainous" is 2,000 ft. Order 8260.3, Volume 1, paragraphs 1720b(1), 1720b(2), and 1721 apply. The published minimum feeder route altitude must provide at least the minimum ROC value and must not be less than the altitude established at the IAF. (Refer to figures 2-2a, 2-2b **and** apply formula 2-12a for standard secondary ROC.) Apply formula 2-12b for designated mountainous area calculations (formulas are applicable for en route, feeder, and initial).

Note: ROC additive, see 8260.3, Volume 1, paragraph 1720.

d. Descent Gradient, Helicopter (feeder, initial, intermediate segments). The optimum descent gradient in feeder, initial, and intermediate segments is 400 ft/NM (6.58%, 3.77°); maximum is 600 ft/NM (9.87%, 5.64°). Where higher descent gradients are required, Order 8260.3, Volume 1, paragraph 1110 applies.

e. Minimum Crossing Altitude (MCA). Establish an MCA when an obstacle prevents a normal climb to a higher minimum en route altitude (MEA). The normal climb gradient is shown in table 2-5. When a MCA is required, chart the required climb gradient and rate of climb on the procedure.

Table 2-5. Normal Helicopter En Route Climb Gradient.		
Gradient Level (MSL)	Gradient	OCS Slope
at or below 5,000 ft	300 ft per NM	20.25:1
5,001 ft through 10,000 ft	240 ft per NM	25.3:1

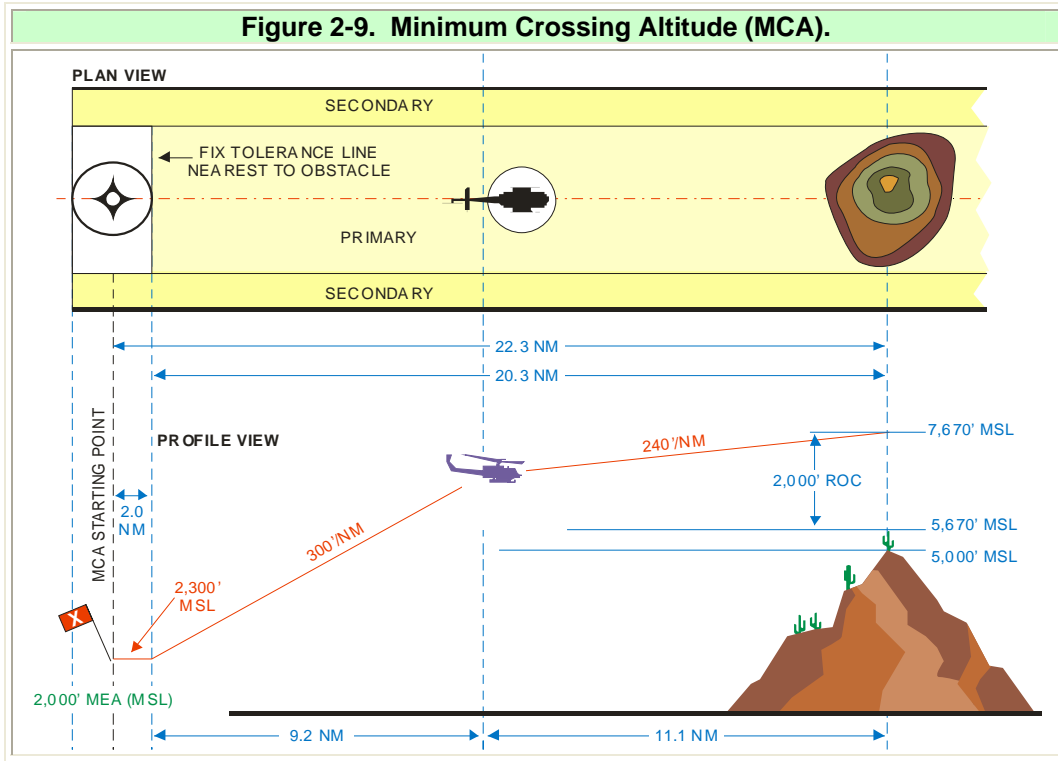

The MCA computation is based on the distance from the nearest fix displacement tolerance line to the obstacle. The computation is rounded to the next higher 100-ft increment (see figure 2-9 for an example MCA computation).

Note: The USA standard climb gradient is 400 ft/NM for all altitudes.

f. **Determine MCA.** Apply formula 2-11a, or 2-11b to determine MCA.

Formula 2-11a. MCA Sea Level to 5,000 ft MSL.		
$MCA = A - 300 \cdot L$		
Where: A = "Climb to" MSL Altitude L = Length of segment (NM)		
$A - 300 \cdot L$		
Calculator		
A		Click here to calculate
L		
MCA		

Formula 2-11b. MCA 5,000 - 10,000 ft MSL.		
$MCA = 5000 - 300 \left(L - \frac{A - 5000}{240} \right)$		
Where: A = "Climb to" MSL Altitude L = Length of segment (NM)		
$5000 - 300 \cdot \left(L - \frac{A - 5000}{240} \right)$		
Calculator		
A		Click here to calculate
L		
MCA		

Step 1: Add 2,000 ft mountainous ROC to MSL height of obstacle.

Step 2: Apply formula 2-11a or 2-11b to determine the MCA.

Chapter 2. General Criteria

Section 2. Terminal Segments

9. Initial Segment. The initial segment begins at the IAF and ends at the intermediate fix (IF). The initial segment may contain sequences of straight sub segments (see figure 2-10). Chapter 2, paragraphs 9b, 9c, 9d, and 9e apply to all sub segments individually. The total length of all sub segments must not exceed 50 NM. For descent gradient limits, see chapter 2, paragraph 8d.

a. Course Reversal. The optimum design incorporates either the basic Y or T configuration (see AIM or FHP for further BASIC T/Y information). This design eliminates the need for a specific course reversal pattern. Where the optimum design cannot be used and a course reversal is required, establish a holding pattern at the initial, or intermediate approach fix. See chapter 2, paragraph 9f(2). The maximum course change at the fix (IAF/IF) is to 90 degrees (70 degrees above FL 190).

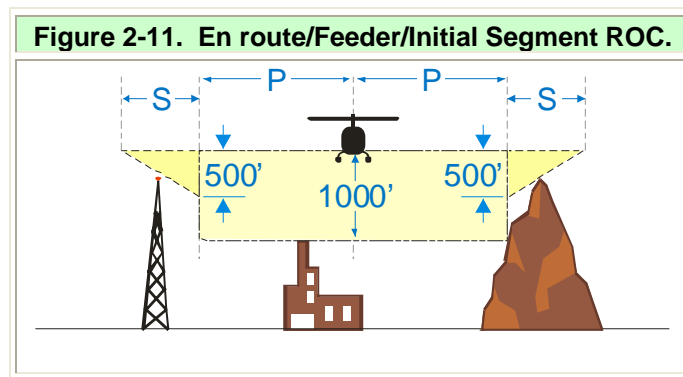

b. Alignment. Design initial/initial and initial/intermediate TF segment intersections with the smallest amount of course change that is necessary for the procedure. No course change is optimum. Where a course change is necessary, it should normally be limited to 70 degrees or less; 30 degrees or less is preferred. The maximum allowable course change between TF segments is 90 degrees.

Note: For USA, limit initial segment turn to a **MAXIMUM** of 60 degrees with a basic “Y” approach configuration for COPTER RNAV (GPS) procedures.

c. Area – Length. The **maximum** segment length (total of sub segments) is 50 NM. Minimum length of sub segments is determined as described in chapter 2, paragraphs 6a(2) and 6b(1).

d. Area – Width (see table 2-2).

e. Obstacle Clearance. The initial OEA begins at the segment beginning fix early ATT and ends at the segment ending fix late ATT. Apply 1,000 ft of ROC over the highest obstacle in the primary OEA. The ROC in the secondary area is 500 ft at the primary boundary tapering uniformly to zero at the outer edge (see figure 2-11).

Note: Allowance for precipitous terrain should be made as specified in Order 8260.3, Volume 1, paragraph 3.2.2b.

Calculate the secondary ROC values using formula 2-12a.

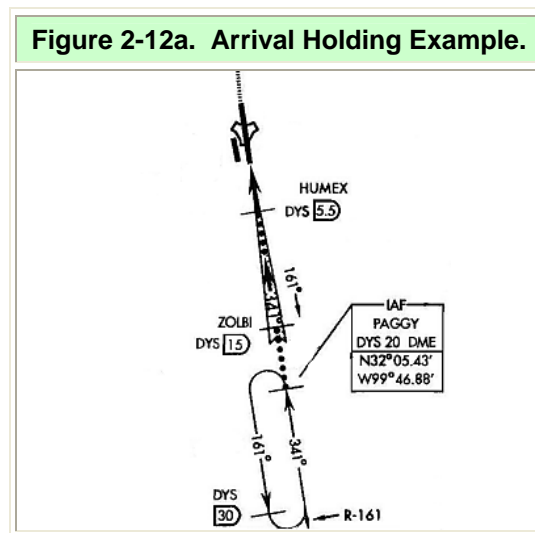

Formula 2-12a. En route/Feeder/Initial Secondary ROC (Standard).		
$ROC_{secondary} = 500 \cdot \left(1 - \frac{d}{D}\right)$		
Where:		
D = width (ft) of secondary		
d = distance (ft) from edge of primary area measured perpendicular to boundary

ROC _{secondary}		

f. Holding Pattern Initial Segment. A holding pattern may be incorporated into the initial segment procedure design where an operational benefit can be derived; e.g., arrival holding at an IAF, course reversal pattern at the IF, etc. See FAA Order 7130.3, Holding Pattern Criteria, for RNAV holding pattern construction guidance.

(1) Arrival Holding. Ideally, the holding pattern inbound course should be aligned with the subsequent TF leg segment (tangent to course at the initial fix of the subsequent RF segment). See figure 2-12a. If the pattern is offset from the subsequent TF segment course, the subsequent segment length must accommodate the resulting DTA requirement. Establish the minimum holding altitude at or above the IAF/IF (as appropriate) minimum altitude. MEA minimum altitude may be lower than the minimum holding altitude.

(2) **Course Reversal.** Ideally, establish the minimum holding altitude as the minimum IF fix altitude (see figure 2-12b). In any case, the published holding altitude must result in a suitable descent gradient in the intermediate segment: optimum descent gradient in the initial and intermediate segment is 400 ft/NM (6.58%, 3.77°); maximum is 600 ft/NM (9.87%, 5.64°). If the pattern is offset from the subsequent TF segment course, the subsequent segment length must accommodate the resulting DTA requirement. Maximum offset is 90 degrees.

10. Intermediate Segment. The intermediate segment primary and secondary boundary lines connect abeam the plotted position of the PFAF at the appropriate primary and secondary final segment beginning widths.

a. Alignment (Maximum Course Change at the PFAF). LNAV & LP. Align the intermediate course within 30 degrees of the final approach course (30 degrees maximum course change).

b. Length (Fix to Fix). The **minimum** Helicopter category segment length is 2 NM. Where turns over 30 degrees at the IF are required, the minimum is 3 NM. Where turns to and from the intermediate segment are necessary, determine minimum segment length using formula 2-6 or formula 2-7, as appropriate.

c. Width. The intermediate segment primary area tapers uniformly from ± 1.5 NM at a point 2 NM prior to the PFAF to the outer boundary of the X OCS abeam the PFAF (1 NM past the PFAF for LNAV). The secondary boundary tapers uniformly from 1 NM at a point 2 NM prior to the PFAF to the outer boundary of the Y OCS abeam the PFAF (1 NM past the PFAF for LNAV). See figure 2-13a.

If a turn is designed at the IF, it is possible for the inside turn construction to generate boundaries outside the normal segment width at the taper beginning point 2 miles prior to the PFAF. Where these cases occur, the inside (turn side) boundaries are a simple straight line connections as illustrated in figure 2-13b.

Maximum turn at the PFAF is 30 degrees. When a PFAF turn is constructed, **minimum** FAS length is 3 NM for turns greater than 15 degrees. Where the RNAV or LP intermediate course is not an extension of the FAC, use the following construction (see figure 2-13c).

(1) LNAV Offset Construction. Where LNAV intermediate course is not an extension of the final course, use the following construction (see figure 2-13c, upper graphic).

Step 1: Construct line A perpendicular to the intermediate course 2 NM prior the PFAF.

Step 2: Construct line B perpendicular to the intermediate course extended 1 NM past the PFAF.

Step 3: Construct the inside turn boundaries by connecting the points of intersection of line A with the turn side intermediate segment boundaries with the intersection of line B with the turn side final segment boundaries.

Step 4: Construct arcs centered on the PFAF of 1 NM and 1.5 NM radius on the non-turn side of the fix.

Step 5: Connect lines from the point of intersection of line A and the outside primary and secondary intermediate segment boundaries to tangent points on the arcs constructed in step 4.

Step 6: Connect lines tangent to the arcs created in step 4 that taper inward at 30 degrees relative to the FAC to intersect the primary and secondary final segment boundaries as appropriate.

The final segment evaluation extends to a point ATT prior to the angle bisector. The intermediate segment evaluation extends ATT past the angle bisector. Therefore, the area within ATT of the angle bisector is evaluated for both the final and intermediate segments.

(2) LP Offset Construction. Where LP intermediate course is not an extension of the final course, use the following construction (see figure 2-13c, lower graphic).

Step 1: Construct line A perpendicular to the intermediate course 2 NM prior the PFAF.

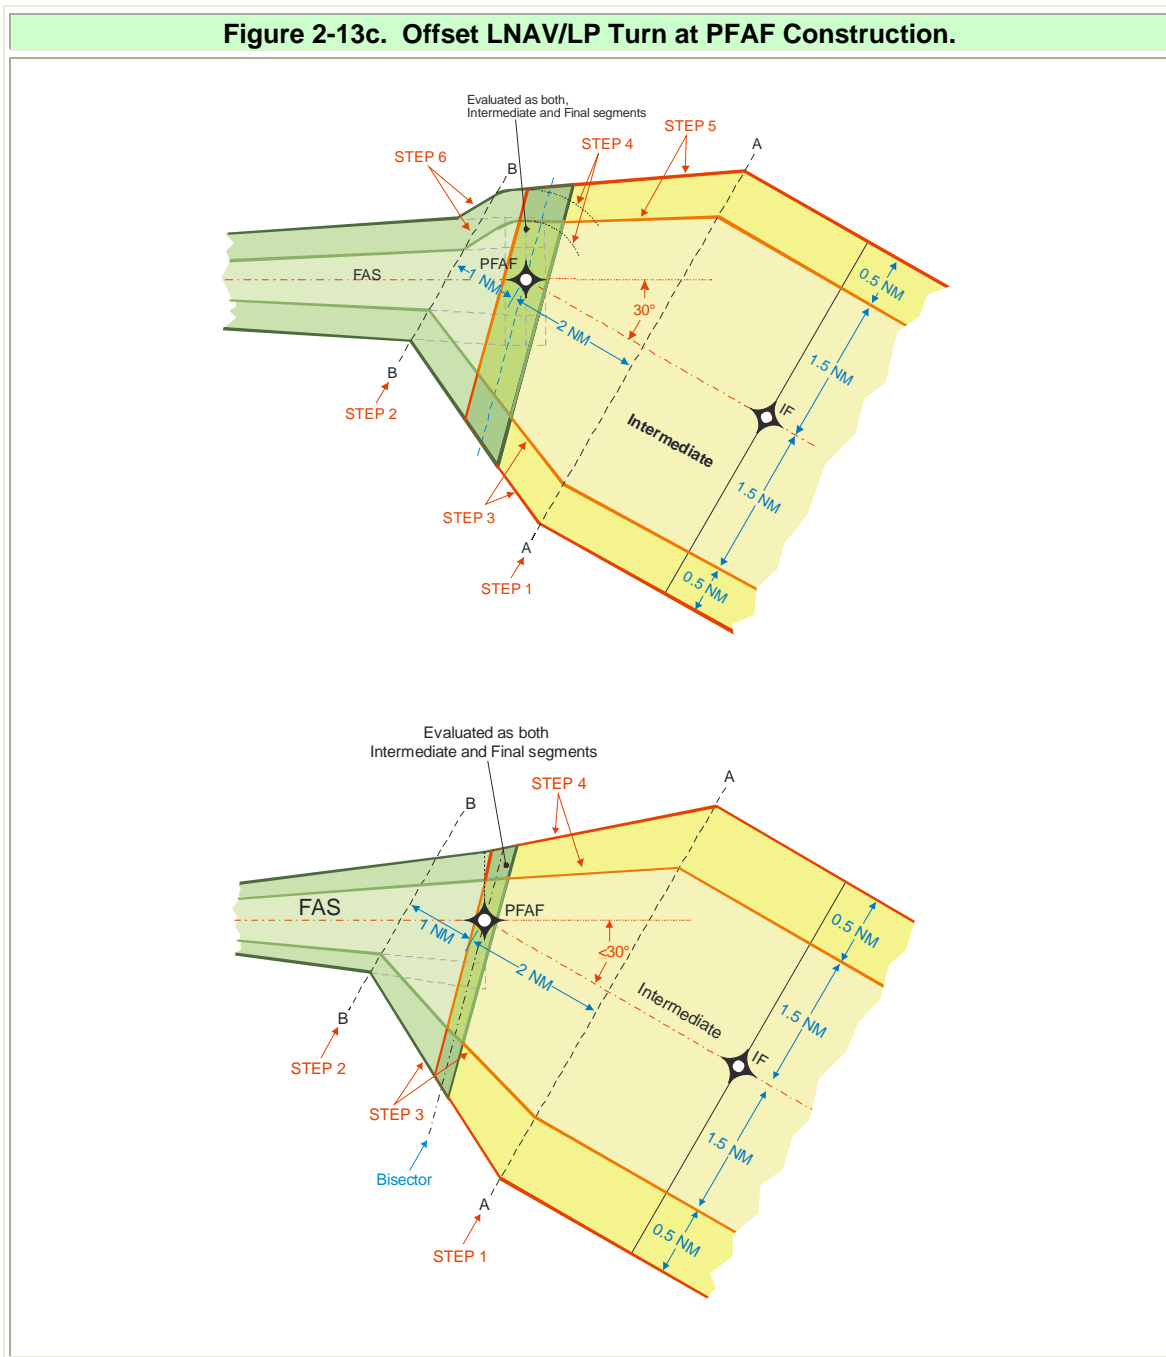

Step 2: Construct line B perpendicular to the intermediate course extended 1 NM past the PFAF.

Step 3: Construct the inside turn boundaries by connecting the points of intersection of line A with the turn side intermediate segment boundaries with the intersection of line B with the turn side final segment boundaries.

Step 4: Connect lines from the point of intersection of line A and the outside primary and secondary intermediate segment boundaries to the final segment primary and secondary final segment lines at a point perpendicular to the final course at the PFAF.

Note: DA must not occur at a greater distance from HRP than the turn-side point of intersection of the expanded outer boundary line with the final segment secondary boundary (intersection of line “B” with secondary boundary in figure 2-13c lower graphic). If a higher DA is required, then the degree of offset must be less.

The final segment evaluation extends to a point ATT prior to the angle bisector. The intermediate segment evaluation extends ATT past the angle bisector. Therefore, the area within ATT of the angle bisector is evaluated for both the final and intermediate segments.

(3) RF intermediate segments. **Reserved.**

d. Obstacle Clearance. The intermediate OEA begins at the segment beginning fix early ATT and ends at the segment ending fix late ATT. Apply 500 ft of ROC over the highest obstacle in the primary OEA. The ROC in the secondary area is 500 ft at the primary boundary tapering uniformly to zero at the outer edge (see figure 2-14).

Calculate intermediate secondary ROC values using formula 2-13.

Formula 2-13. Intermediate Secondary ROC.		
$ROC_{secondary} = (500 + adj) \cdot \left(1 - \frac{d_{primary}}{W_s}\right)$		
Where:		
$d_{primary}$ = perpendicular distance (ft) from edge of primary area W_s = Width (ft) of the secondary area adj = TERPS para 3.2.2 adjustments

Chapter 2. General Criteria

Section 3. Basic Vertically Guided Final Segment General Criteria

11. Determining Precise Final Approach Fix/Final Approach Fix (PFAF/FAF) Coordinates (see figure 2-15 fixed-wing example).

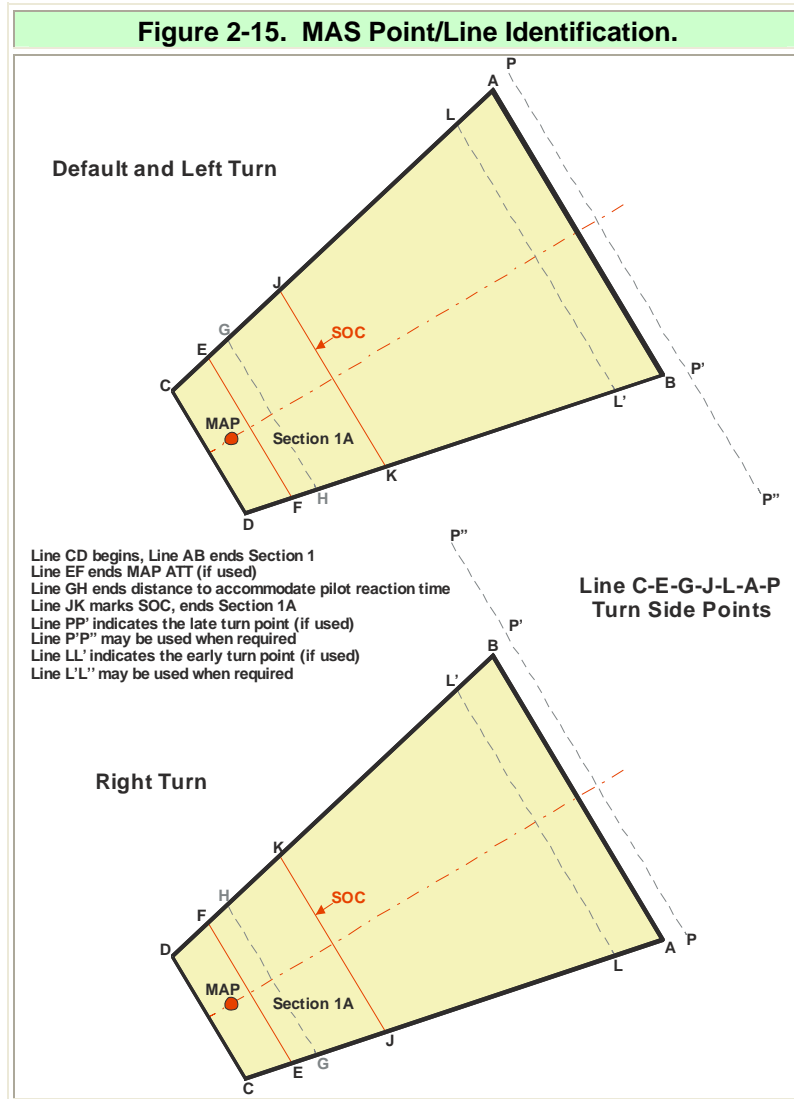

Geodetically calculate the latitude and longitude of the PFAF using the true bearing from the Heliport Reference Point (HRP) to the PFAF and the horizontal distance (D_{PFAF}) from the HRP to the point the glidepath intercepts the intermediate segment altitude. The LNAV (BaroVNAV) glidepath is a curved line (logarithmic spiral) in space. Calculation the PFAF distance from the HRP using formula 2-15 (calculates the LNAV PFAF distance from HRP; i.e., the point the curved line BaroVNAV based vertical path intersects the minimum intermediate segment altitude (see Order 8260.54A, chapter 2 for additional information).

Formula 2-15. LNAV PFAF.		
$D_{PFAF} = \frac{\ln\left(\frac{r + alt}{r + HRP_{elev} + HCH}\right) \cdot r}{\tan\left(\theta \cdot \frac{\pi}{180}\right)}$		
<p>where alt = minimum intermediate segment altitude HRP_{elev} = HRP MSL elevation HCH = Heliport Crossing Height value r = 20890537 θ = glidepath angle</p>		
$(\ln((r+alt)/(r+HRP_{elev}+HCH))*r)/\tan(\theta*\pi/180)$

D _{PFAF}	<input type="text"/>	

12-15. Reserved.

16. Common Fixes. Design all procedures published on the same chart to use the same sequence of charted fixes.

17. Missed Approach Segment (MAS) Conventions. Figure 2-16 defines the MAP point OEA construction line terminology and convention for section 1.

The missed approach obstacle clearance standard is based on a minimum helicopter climb gradient of 400 ft/NM, protected by a ROC surface that rises at 304 ft/NM. The MA ROC value is based on a requirement for a 96 ft/NM ($400 - 304 = 96$) increase in ROC value from the start-of-climb (SOC) point located at JK. The actual slope of the MA surface is $(1 \text{ NM in feet})/304 \approx 19.987$. In manual application of TERPS, the rounded value of 20:1 has traditionally been applied. However, this order is written for automated application; therefore, the full value (to 15 significant digits) is used in calculations. The nominal OCS slope ($MA_{OCSslope}$) associated with any given missed approach climb gradient is calculated using formula 2-16.

Formula 2-16. Helicopter Missed Approach OCS Slope.		
$MA_{OCSslope} = r \cdot \ln \left(\frac{\frac{1852}{0.3048 \cdot (CG - 96)} + r}{r} \right)$		
Where: CG = Climb Gradient (nominally 400 ft/NM)		
$r \cdot \ln((1852 / (.3048 * (CG - 96))) + r) / r$		
Calculator		
CG		Click here to calculate
MA _{OCSslope}		

a. Charted Missed Approach Altitude. Apply Order 8260.3, Volume 1, paragraphs 277d and 277f to establish the preliminary and charted missed approach altitudes.

b. Climb-In-Holding. Apply Order 8260.3, Volume 1, paragraph 277e for climb-in-holding guidance.

Chapter 3. Terminal Operations

1. Approach Configuration. The BASIC “Y” or “T” approach configuration should be the basis of procedure design. Segment length is affected by altitude to be lost, fix tolerances, and turn magnitude at the fixes. The **optimum** design incorporates a basic **Y** or **T** configuration. This design eliminates the need for a specific course reversal pattern. Where the **optimum** design cannot be used and a course reversal is required, establish a holding pattern at the initial or intermediate approach fix. Public procedures should not deviate from these shape and dimension configurations unless there is an operational advantage. Construct IAFs within 25 NM of the airport reference point/heliport reference point (ARP/HRP). See chapter 2, paragraph 9 for construction methods.

Note 1: Allowance for precipitous terrain should be made as specified in Order 8260.3, Volume 1, paragraph 3.2.2b.

Note 2: For USA, limit initial segment turn to a MAXIMUM of 60 degrees with a basic “Y” approach configuration for COPTER RNAV (GPS) procedures.

Table 3-1. Helicopter GPS MINIMUM Initial/Intermediate/Final Segment Lengths.	
Course Intercept Angle (Degrees)	Minimum Leg Length (NM)
00 – 30	2.0
> 30 - 90 *	3.0

* Final segment 30-degree MAXIMUM intercept angle for Global Positioning System (GPS) and Wide Area Augmentation System (WAAS) public procedures. Final segment 60-degree MAXIMUM intercept angle for GPS and WAAS special procedures. A turn exceeding 30 degrees at the precise final approach fix (PFAF) requires documentation of equipment capability.

a. Initial Approach Segment. The initial approach segment begins at the IAF and ends at the IF. The initial segment/subsegment obstacle evaluation area (OEA) begins at the early ATT of the segment beginning fix and ends at the late ATT of the segment/subsegment ending fix. If a special procedure requires a course change at the IAF that exceeds 90 degrees, a waiver is required and is noted on FAA Form 8260-9 (no course change exceeding 120 degrees is allowed). The IF may be identified as an along-track distance (ATD) from the PFAF. Course change at the IF must not exceed 90 degrees for public and special procedures. Construct the inbound leg of course reversal holding patterns within 30 degrees of the intermediate course (IF/IAF). Apply chapter 2, paragraph 9 for course reversal using holding pattern criteria. Do not establish a holding pattern in lieu of procedure turn at the PFAF. See chapter 2 for construction methods.

(1) Length. The initial segment begins at IAF and ends at the IF. The length should not exceed 10 NM unless operational requirements mandate a longer segment. Determine the **minimum** length using the greater distance from formulas 2-7, 2-8, and table 3-1.

(2) Width.

(a) Primary Area. 1.5 NM each side of the course centerline.

(b) Secondary Area. 0.5 NM on each side of the primary area.

(3) Obstacle Clearance. Provide a **minimum** of 1,000 ft of required obstacle clearance (ROC) in the primary area. In the secondary area, provide 500 ft of ROC at the inner edge, tapering uniformly to zero at the outer edge (see chapter 2, figure 2-12). Calculate the secondary ROC using chapter 2, formula 2-12a or formula 2-12b. Establish initial segment altitudes in 100-ft increments that meet or exceed minimum ROC.

(4) Descent Gradient for Initial Segments (see chapter 2, paragraph 7).

b. Intermediate Segment. The intermediate segment begins at the IF and ends at the PFAF. The intermediate segment OEA begins at the early ATT of the segment beginning fix and ends at the late ATT of the segment ending fix. The intermediate segment is used to prepare the helicopter speed and configuration for final approach segment entry; therefore, the gradient should be as flat as possible. At a point beginning 2.0 NM from the PFAF, construct a taper to join the final approach segment (FAS).

(1) Alignment. The **maximum** course change at the PFAF is 30 degrees. Course change more than 30 degrees requires Flight Standards approval.

(2) Area.

(a) Length. The intermediate segment begins at the IF and ends at the PFAF. The length should not exceed 5.0 NM (**optimum** length is 3.0 NM). Determine the **minimum** length using the greater distance from formulas 2-7, 2-8, and table 3-1.

(b) Width.

1 Primary Area. 1.5 NM each side of the segment centerline, beginning at the earliest IF position. The segment taper begins 2.0 NM prior to the plotted position of the PFAF to reach a ± 0.55 NM width at the PFAF plotted position (see chapter 2, figures 2-13a, 2-13b, and 2-13c).

2 Secondary Area. 0.50 NM on each side of the primary area.

Note: USAF/USA/USCG/USN operating at 90 KIAS: Change 0.55 NM to 0.70 NM.

(3) Obstacle Clearance. Provide a MINIMUM of 500 ft of ROC in the primary area. In the secondary area, provide 500 ft of ROC at the inner edge tapering to zero feet at the outer edge. Establish altitudes for each intermediate segment in 100-ft increments, and round to the

next higher 100-ft increment. Calculate the secondary ROC using chapter 2, formula 2-13 (see chapter 2, figure 2-14).

(4) Descent Gradient for Intermediate Segments (see chapter 2, paragraph 7).

Chapter 4. IFR Final and Visual Segments

1. General. The approach procedure type is determined by the visual segment. The instrument flight rule (IFR) final approach segment (FAS) applies to all five types of procedures. Use the criteria in chapter 3 for the construction of the initial and intermediate segments up to the precise final approach fix (PFAF), and chapter 5 criteria for the missed approach segment construction. Apply chapter 4, paragraph 3 criteria to LNAV IFR final segments, and chapter 4, paragraph 9 to WAAS LP IFR final segments.

Note: Chapter 4 graphics are not drawn to scale

a. Final Segment Stepdown Fix (SDF). An SDF may be applied where the MDA can be lowered 60 ft, or a visibility reduction can be achieved. Order 8260.3, Volume 1, paragraph 289 applies, with the following exceptions:

- (1) Establish step-down fix locations in 0.10 NM increments.
- (2) The minimum distance between stepdown fixes is 1 NM.
- (3) Establish stepdown fix altitudes using 20-ft increments, rounded to the next **higher** 20-ft increment. For example, 2104 becomes 2120.
- (4) Where a Remote Altimeter Setting Source (RASS) adjustment is in use, the published stepdown fix altitude must be established no lower than the altitude required for the greatest amount of adjustment (i.e., the published minimum altitude must incorporate the greatest amount of RASS adjustment required).
- (5) Descent gradient: Chapter 4, paragraphs 3a(3), 3a(4), and 3a(5) apply.
- (6) Obstacles eliminated from consideration (3.5:1 area) under this paragraph must be noted in the procedure documentation (see Order 8260.19).
- (7) Use formula 4-4 in chapter 4, paragraph 3a(6) concerning Order 8260.3, Volume 1, paragraph 289 to determine the OIS elevation at an obstacle and minimum fix altitude based on an obstacle height.
- (8) To mitigate surface penetrations:
 - Remove obstruction, or
 - Reduce obstruction height, or
 - Adjust the MDA, or
 - Combination of options.

2. Missed Approach. Construct the missed approach for all procedures using chapter 5 criteria.

3. The five procedure types are:

- IFR to an IFR Heliport
- IFR to a VFR Heliport (IVH) (Proceed Visually)
- IFR to a VFR Runway (IVR) (Proceed Visually)
- Point-in-Space (PinS) Approach (Proceed VFR)
- IFR to an IFR Runway

a. LNAV IFR Final Approach Segment (FAS). The IFR FAS begins at the PFAF and ends at the missed approach point (MAP) (see figure 4-1). This FAS construction is unique to helicopters. It applies trapezoidal rather than the linear construction used for fixed-wing applications. Locate LNAV PFAF using chapter 2, formula 2-15. MAP location should provide the best compromise of lowest visibility and visual segment descent angle (VSDA). The **optimum** distance for the “Proceed Visually” MAP is 0.65 nautical mile (NM) [3/4 statute mile (SM) visibility] from the heliport. For public procedures, the preferred approach paths should be aligned with the prevailing wind direction to avoid downwind and minimize crosswind operations. Other approach/departure paths should be based on the assessment of the prevailing winds or when this information is not available, the separation between such flight paths and the preferred flight path should be at least 135 degrees.

(1) Alignment. The IFR final segment connects the PFAF to the MAP. The course change at the PFAF from the intermediate course to the final approach course (FAC) must not exceed 30 degrees. The MAP is located on the FAC between the PFAF and a point no closer to the heliport than 0.3 NM from the visual segment reference line (VSRL). For a straight-in approach, the course change at the MAP must not exceed 30 degrees to an IFR heliport heliport **or** 30 degrees from a runway centerline (RCL) extended to an IFR runway threshold (RWT). Optimum alignment is coincident with the RCL. When the alignment exceeds 5 degrees the optimum alignment point is 1,500 ft from the RWT on RCL. Where circling approaches are required, apply Order 8260.3 Category A criteria.

(2) Area. The obstacle evaluation area (OEA) begins at the earliest PFAF along-track tolerance (ATT) and ends at the latest MAP ATT (see figure 4-1).

(a) Length. The IFR final approach segment begins at the PFAF and ends at the MAP. The length should not exceed 10 NM (**optimum** length is 3 NM). Determine the **minimum** length using the greater of descent distance, formula 2-7 or 2-8, and table 3-1.

(b) Width.

1 Primary Area. The primary area boundary begins 0.55 NM* each side of the final segment centerline at the earliest PFAF ATT. The width remains constant until the latest PFAF ATT. It then tapers to 0.40 NM* at the latest MAP ATT.

Note: USAF/USA/USCG/USN operating at 90 KIAS: Change 0.55 NM to 0.70 NM and 0.40 NM to 0.50 NM (primary area).

2 Secondary Area. The secondary area boundary is constant, 0.50 NM each side of the primary area. Calculate the primary half-width at any distance from latest MAP ATT using formula 4-1a.

(c) Required Obstacle Clearance. Primary area required obstacle clearance (ROC) is 250 ft. Secondary ROC is 250 ft at the edge of the primary area, tapering uniformly to zero at the outer edge. Calculate secondary ROC using formula 4-1b.

Formula 4-1a. Final Area Half-Width.(W _p)		
$W_p = P_{W2} + \left(\frac{P_{W1} - P_{W2}}{D_1} \right) \cdot D_2$		
Where P _{W1} = Primary Width, PFAF, (0.55 or 0.7) NM P _{W2} = Primary Width, latest MAP ATT, (0.4 or 0.5) NM D ₁ = PFAF to MAP distance (NM) D ₂ = Latest MAP ATT to desired point (NM) W _T = Final Total Width (ft) (WP+0.5NM)		
$P_{W2} + ((P_{W1} - P_{W2})/D_1) * D_2$

Formula 4-1b. Secondary Area ROC (ROC _{secondary}).		
$ROC_{secondary} = (250 + adj) \cdot \left(1 - \frac{d_{primary}}{W_s} \right)$		
Where adj = TERPS para 3.2.2 adjustments (ft) d _{primary} = distance (perpendicular to C/L from primary area (ft)) W _s = Secondary area width (ft)		
$(250 + adj) * (1 - d_{primary}/W_s)$		
Calculator		
adj	<input type="text"/>	Click here to calculate
d _{primary}	<input type="text"/>	
W _s	<input type="text"/>	
ROC _{secondary}	<input type="text"/>	

(3) Descent Gradient/Angle [IVH, PinS , and IVR] (R). The descent gradient/angle is measured from the plotted positions of the PFAF at PFAF altitude to the MAP at MDA. Calculate the final segment descent angle using formula 4-2. (Where required, calculate descent gradient using chapter 2, formula 2-10).

Formula 4-2. Final Approach Angle to MAP (DescentAngle).		
$\text{DescentAngle} = \text{atan}\left(\frac{r}{c} \cdot \ln\left(\frac{r+a}{r+b}\right)\right) \cdot \frac{180}{\pi}$		
Where:		
c = PFAF to MAP distance (ft)		
a = PFAF altitude MSL		
b = MDA at MAP MSL		
$\text{atan}(r/c \cdot \ln((r+a)/(r+b))) * 180/\pi$		
Calculator		
c		Click here to calculate
a		
b		
DescentAngle		

Note 1: USA **maximum** descent gradient/angle is 478 ft/NM (4.5 degrees) without a waiver. Descent gradient/angle waivers may be granted up to 800 ft/NM (7.5 degrees).

Note 2: The visual segment descent gradient is considered separately in approaches to VFR heliports or VFR runways.

(4) Descent Gradient/Angle to an IFR Runway or an IFR Heliport. Apply the same descent gradient/angle in chapter 4, paragraph 3a(3) for an IFR approach to an IFR runway, but the distance/elevation calculations begin at the PFAF and end at RWT/TCH elevation (see figure 4-2b). For an IFR approach to an IFR Heliport, the distance/elevation calculations begin at the PFAF and end at HCH (see figure 4-2c). Apply formula 4-3 for descent angle, and chapter 2, formula 2-10 for descent gradient:

Formula 4-3. Descent Angle to Runway or HCH (DescentAngle).

$$\text{DescentAngle} = \text{atan}\left(\frac{r}{c} \cdot \ln\left(\frac{r+a}{r+b}\right)\right) \cdot \frac{180}{\pi}$$

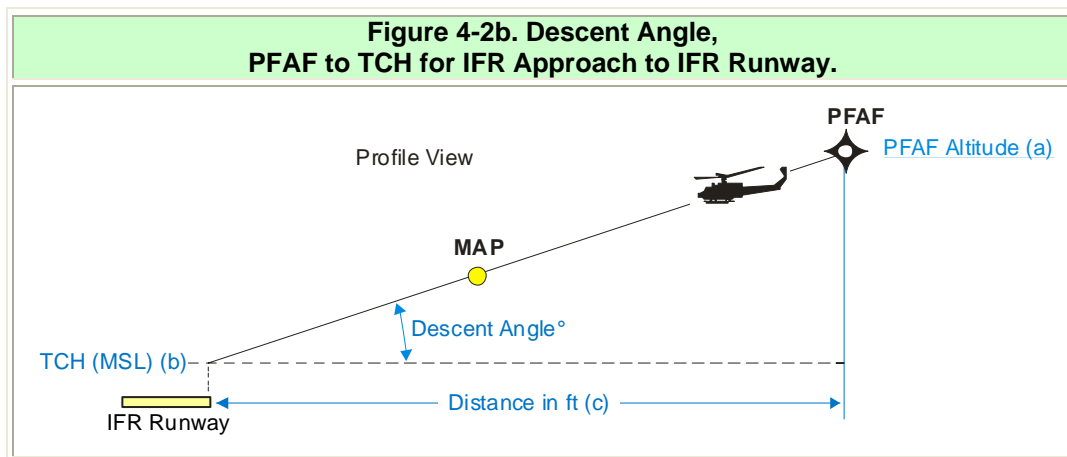

Where:

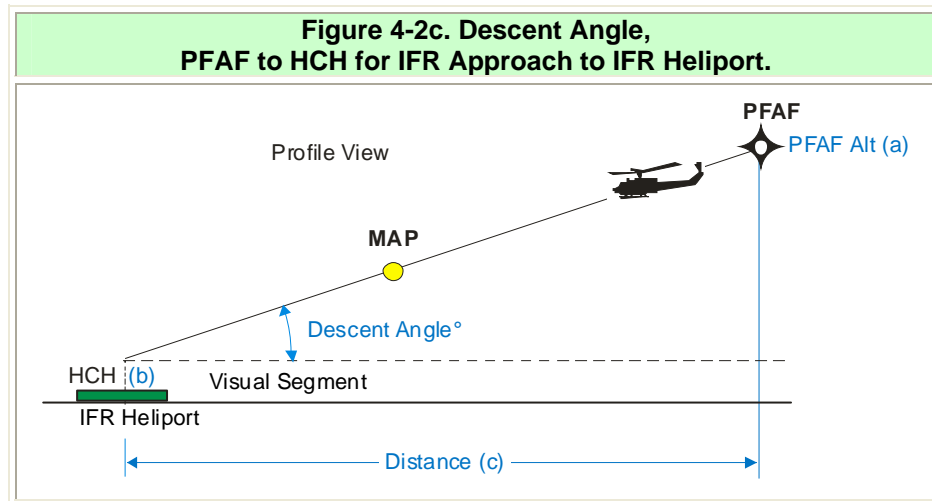

- c = PFAF to RWT/helipoint distance (ft)
- a = PFAF Altitude MSL
- b = TCH/HCH elevation at RWT or HCH

$\text{atan}(r/c \cdot \ln((r+a)/(r+b))) \cdot 180/\pi$

Calculator	
c	
a	
b	
DescentAngle	

Click here to calculate

(5) Stepdown Descent Gradient/Angle. When a stepdown fix is used, measure the descent gradient/angle from the PFAF at the PFAF altitude to the stepdown fix at the minimum fix altitude, then to the MAP at the MDA. For a stabilized approach, provide a constant gradient/angle from the PFAF to the MAP, (may require raising the PFAF altitude). A stepdown fix must be located no closer than 0.6 NM to the PFAF or MAP.

(6) Existing Obstacles Close to the PFAF or Stepdown Fix. If the segment descent gradient/angle is less than 800 ft/NM (7.5 degrees), Order 8260.3B, Volume 1, paragraph 289 may be applied substituting an OIS slope of 3.5:1 vice 7:1. Calculate the OIS Elevation and Minimum fix altitude using formula 4-4.

Formula 4-4. OIS Elevation & Minimum Fix Altitude (OIS_z & MFa).

$$OIS_z = (r + a - c) \cdot e^{\frac{-O_x}{3.5r}} - r$$

$$MFa = (r + O_z + c) \cdot e^{\frac{O_x}{3.5r}} - r$$

Where:

- a = MSL fix altitude (ft)
- c = ROC plus adjustments (Order 8260.3, Volume 1, para 3.2.2)
- O_x = Obstacle along-track distance (ft) from ATT prior to fix (1 NM max)
- O_z = MSL obstacle elevation (ft)
- MFa = Minimum Fix Altitude (rounded to next higher 100-ft increments)

$$OIS_z = (r + a - c) \cdot e^{(-O_x / (3.5 \cdot r))} - r$$

$$MFa = (r + O_z + c) \cdot e^{(O_x / (3.5 \cdot r))} - r$$

4. IFR Heliport Visual Segment. The IFR Heliport visual segment connects the MAP to the helipoint. The visual segment OCS starts at the VSRL and extends to the later of a point 250 ft below the MDA or the latest MAP ATT (see figures 4-3 and 4-4).

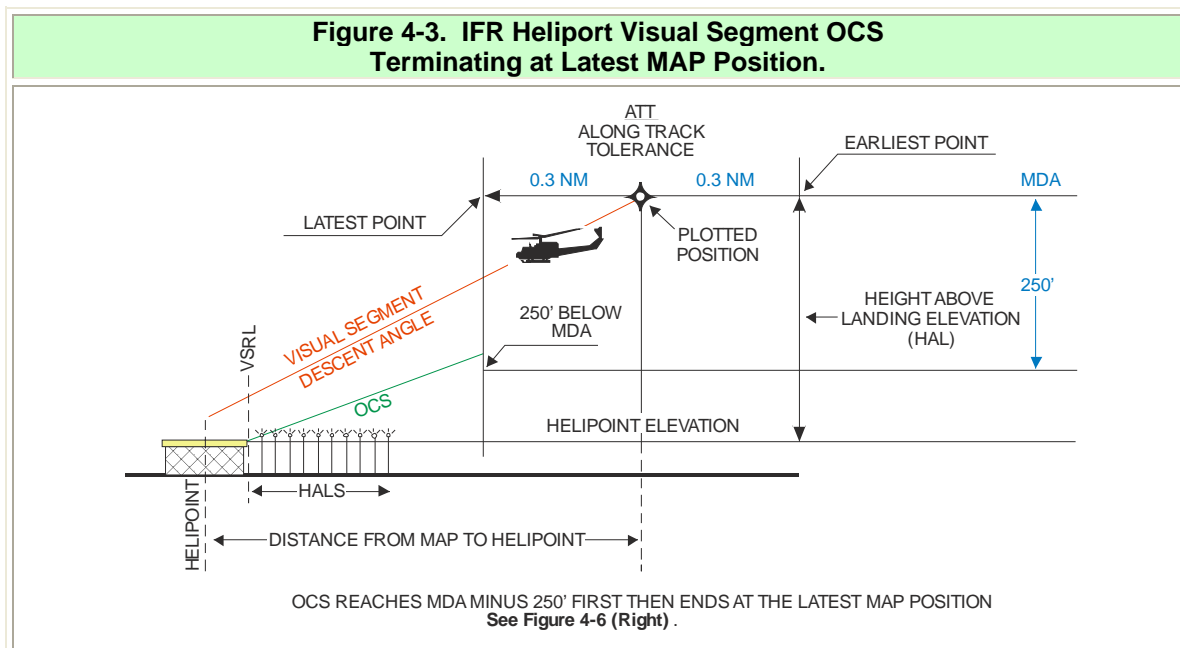

a. Alignment. The IFR Heliport visual segment connects the MAP to the helipoint. The course change at the MAP from the FAC must not exceed 30 degrees.

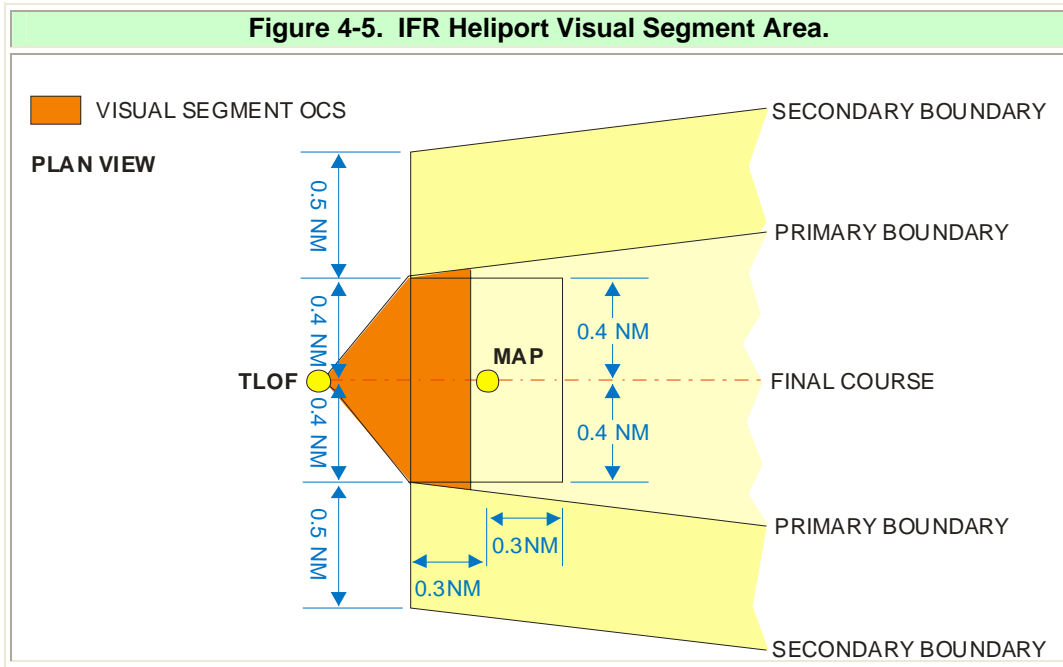

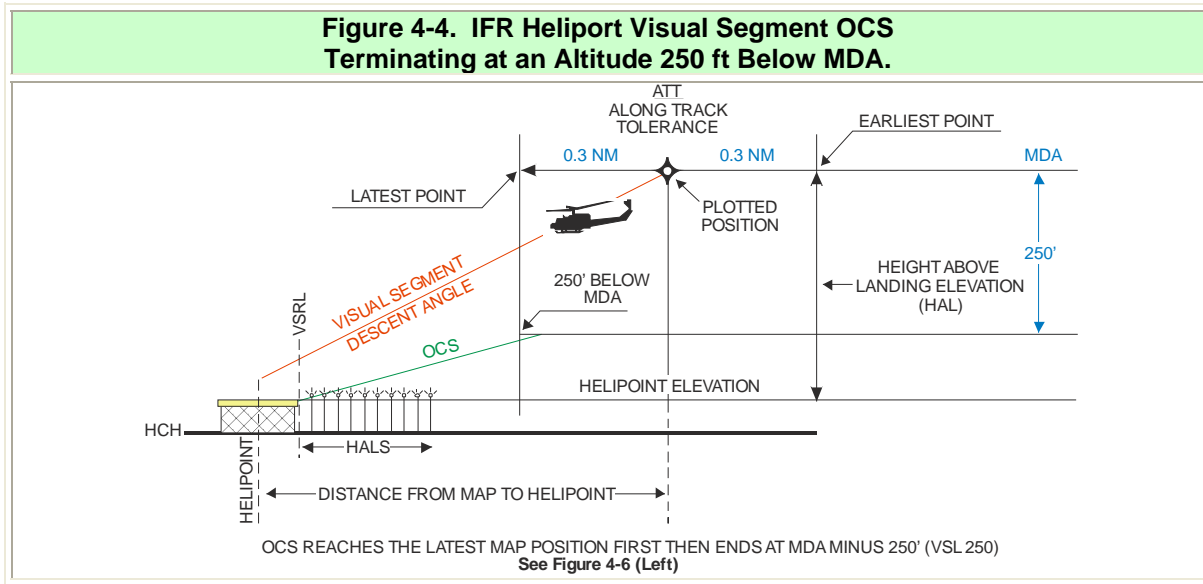

b. Area. The obstacle evaluation area (OEA) begins at the Visual Segment Reference Line (VSRL) and extends toward the MAP as defined below:

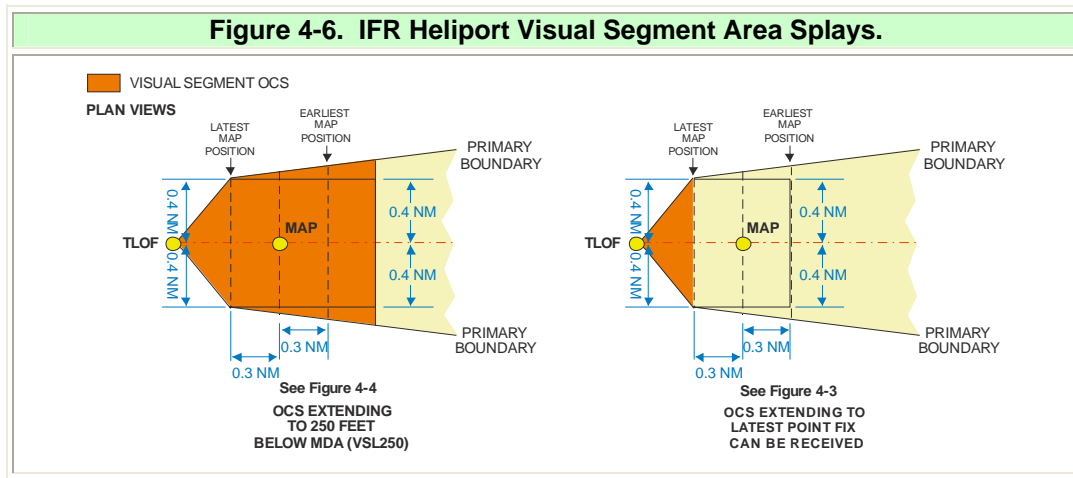

(1) Length. The IFR Heliport Visual segment begins at the MAP and ends at the Heliport (see profile figures 4-3 and 4-4).

(2) Width. The visual segment splay begins at the Visual Segment Reference Line (VSRL). It splays from the VSRL endpoints relative to the FAC to the latest FAS primary area width at the latest MAP ATT (see plan view figure 4-6 (right)). Where the OCS surface extends to a point 250 ft below the MDA, the boundary follows the primary area to its end point (see plan view figures 4-4 and 4-6 (left)).

c. Obstacle Clearance Surface. The OCS begins at the VSRL and extends 1.0 degree below the VSDA (see figures 4-3 and 4-4).

d. IFR Heliport with Visual Segment Descent Point (VSDP). A VSDP may be established for straight-in helicopter GPS procedures. Apply the VDP concepts in Order 8260.3, Volume 1, paragraph 253, except use heliport elevation vice RWT elevation and HCH vice TCH. The recommended descent angle from the VSDP is 6.0 degrees. The **maximum** angle is 7.5 degrees. Locate the VSDP on the FAC at the point where the visual glide slope indicator (VGSI) on-glide slope beam intersects the MDA. Publish the VSDP as an ATD from the MAP. Do not publish a VSDP where the VSDP falls between the MAP and the heliport. Where a VGSI is not established, calculate the VSDP to heliport distance along the FAC using formula 4-5:

Note: Where **no** VSDP has been established, refer to chapter 4, paragraph 4e, then proceed from chapter 4, paragraph 4d(1).

Formula 4-5. VSDP to Heliport Distance (VSDP_{dist}).

$$VSDP_{dist} = \frac{\left(r \cdot \ln \left(\frac{r + MDA}{r + HE + HCH} \right) \right)}{\tan \left(VSDA \cdot \frac{\pi}{180} \right)}$$

Where:

- MDA = Final Minimum Descent Altitude (MDA)
- HE = Heliport Elevation
- HCH = Heliport Crossing Height
- VSDA = descent angle (see formula 4-8)

(r*ln((r+MDA)/(r+HE+HCH))/tan(VSDA*pi/180))

VSDP _{dist}		

(1) Alignment. The VSDP-based visual segment connects the FAC/VSDP to the helipoint. No course change is allowed at the VSDP.

(2) Area. The obstacle evaluation area (OEA) begins at the VSDP and ends at the helipoint/VSRL (see figure 4-7).

(a) Length. The VSDP-based visual segment begins at the VSDP and ends at the helipoint/VSRL. Determine the VSDP-based visual segment length, VSDP-based descent angle, HAL, and VSRL to a point 250 ft below MDA (VSL_{250}) using the following steps (see figure 4-7).

(b) Width. The VSDP-based visual segment begins at the VSRL. It splays from the VSRL ends at a 10-degree angle relative the FAC until reaching the VSDP.

(3) Obstacle Clearance. No obstacle may penetrate the VSDP-based visual segment OCS (see figure 4-7). Calculate the OCS MSL elevation at any point between the VSRL and the VSDP using formula 4-6. Evaluate obstacles based on the shortest obstacle to surface origin distance (VSRL), measured parallel to the visual segment centerline. Calculate the OCS MSL elevation at a specified obstacle location using formula 4-6.

Formula 4-6. OCS Elevation (OCS_{elev}).		
$OCS_{elev} = (r + HE) \cdot e^{\frac{D \cdot \tan\left(\beta \cdot \frac{\pi}{180}\right)}{r}} - r$		
Where:		
HE = Helipoint elevation MSL		
D = Distance obstacle to VSRL (ft)		
β = OCS Angle

e. No Established VSDP. Where no VSDP has been established, apply the principles of Order 8260.3, Volume 1, paragraph 253. Locate the VSDP on the FAC at the point where the VGSI on-glide-slope beam intersects the MDA. The recommended VSDP on-glide-slope descent gradient/angle is 639 ft/NM (6 degrees). The **maximum** angle is 7.5 degrees (USA

maximum descent gradient/angle is 478 ft/NM (4.5 degrees) without a waiver). Where a VGSI facility is installed, the VSDP OCS inclines upward from the VSRL at an angle 1.0 degree below the aiming angle of the on-glide-slope beam. Where no VGSI facility is installed, the VSDP OCS rises 1 degree below the VSDA. Publish the VSDP as an ATD from the MAP. The **minimum** HCH is 5 ft. The **maximum** HCH is 20 ft unless approved by Flight Standards. Calculate the VSDP distance (D) from the heliport using formula 4-10.

Formula 4-10. Distance from Heliport (D).		
$D = \frac{\left(r \cdot \ln \left(\frac{r + HAL + HE}{r + HE} \right) \right)}{\tan \left(VSDA \cdot \frac{\pi}{180} \right)}$		
Where:		
HAL = Formula 4-7 output

5. Special IFR Approach to a VFR Heliport (IVH) (Proceed Visually). The special procedure provides a measure of obstruction protection/ identification along the visual track from a MAP to a specific VFR heliport. The visual segment is based on the premise that the pilot will maintain level flight at the MDA until the helicopter is in a position to initiate a descent to the heliport. Where obstacles preclude an immediate descent at the MAP to the FATO, establish an ATD fix to provide a descent point to the FATO. When an amended procedure no longer meets the criteria in this paragraph, a PinS procedure applying the criteria in chapter 4, paragraph 7 may be published. Compute the distance for the Remote Altimeter Setting Source (RASS) adjustment for the MDA and stepdown altitudes for the IVH approach procedures from the source to the MAP.

a. Alignment. The IVH visual segment connects the MAP to the heliport. The **optimum** IVH visual segment is aligned with the FAC. The course change at the MAP must not exceed 30 degrees.

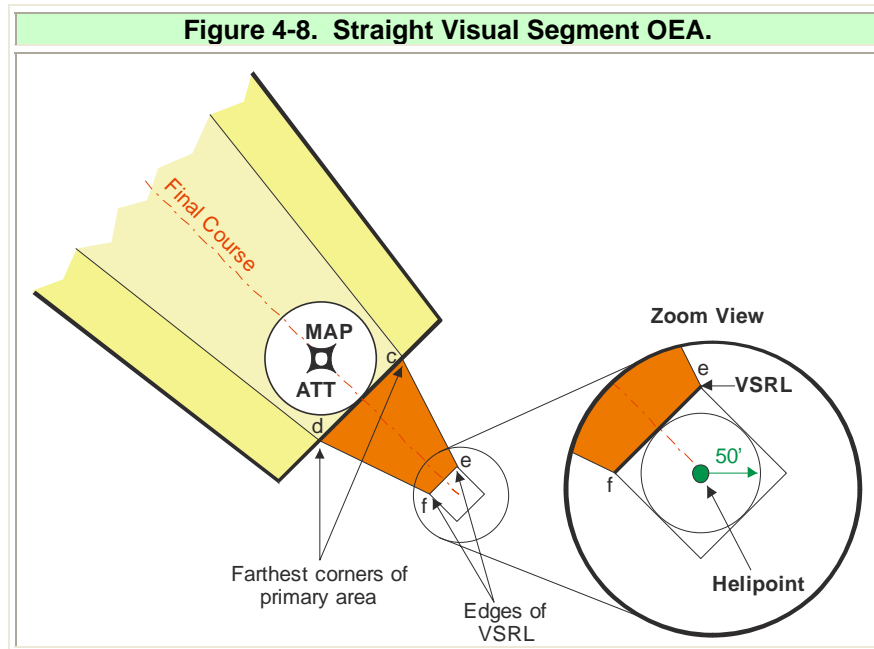

b. Area.

(1) Length. The IVH visual segment OEA begins at the earliest MAP ATT and ends at the VSRL. The IVH visual segment OEA **maximum** length is 10,560 ft (2 SM), measured from the MAP plotted position to the heliport. The **optimum** MAP/ATD fix to heliport distance is

3,949 ft (0.65 NM). The **minimum** distance from the MAP/ATD fix to the heliport is 3,342 ft (0.55 NM).

(2) Width. The IVH visual segment splay begins at the VSRL. It splays from the VSRL endpoints toward the MAP until the visual segment OEA reaches the appropriate construction width [see chapter 4, paragraph 5b(2)(a) or 5b(2)(b)].

(a) Straight Course Construction. Connect the final primary area outer edges (cd) to the VSRL outer edges (ef) (see figure 4-8).

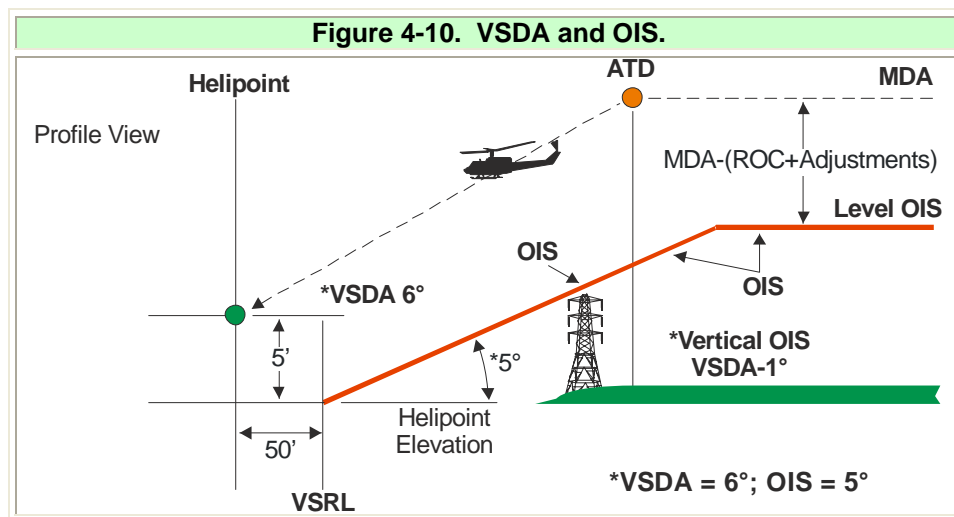

(b) Turn at the MAP Construction. Refer to figure 4-9, and connect the tangent on the turn side (b) of the MAP nearest the heliport to the VSRL at point (e). This connection extends the turn-side area and identifies whether final secondary areas lie within the visual OEA (The MDA must provide primary ROC within this area). Connect the non-turn-side primary area corner (d) to the VSRL at point (f).

(3) Visual Segment OIS Evaluation. Apply chapter 4, paragraph 3a for the IFR segment OCA and ROC. Apply chapter 4, paragraph 3a(3) in constructing the descent gradient/angle in the IFR segment.

c. Visual Segment Descent Angle (VSDA). The VSDA is a developer-specified angle extending from a point 5 to 20 ft directly above the helipoint to the MDA. The VSDA must cross the MDA between the helipoint and the MAP. The **maximum** VSDA is 7.5 degrees, **optimum** is 6.0 degrees, VSDA angles higher than 7.5 degrees require Flight Standards Service approval. (see figure 4-10).

d. Visual Segment OIS. The OIS begins at the VSRL and extends upward toward the MAP at an angle of (VSDA – 1 degree). The OIS rises to the point it reaches an altitude equal to the MDA minus the ROC and adjustments. Where the MAP is beyond this point, the OIS becomes a level surface to the MAP plotted position. Measure obstacles using the shortest distance to the VSRL. Obstacles should not penetrate the OIS; if they penetrate in the initial evaluation, take one of the following actions, listed in preferential order (see figure 4-11):

- (1) Remove or adjust obstacle location and/or height to eliminate the penetration, or

(2) Raise the VSDA to achieve an OIS angle that clears the obstacle, (7.5 degrees **maximum** without Flight Standards Service approval), or

(3) Identify the obstacle with the greatest penetration. Raise the MDA the penetration amount and round to the next higher 20-ft increment. Initiate action to have the obstacle marked and lighted, if feasible. Depict all obstacles on the approach chart that penetrate the OIS and include in required training.

(4) Raise the HCH to ≤ 20 ft provided the height is consistent with the helicopter's ability to hover out of ground effect. When this procedure is applied, raise the OIS origin above the heliport elevation by the amount that the HCH is increased (see figure 4-11).

6. Special IFR Approach to A VFR Runway (IVR) (Proceed Visually). This special procedure provides protection/identification along a visual track from the MAP to a specific point on a VFR runway (see figure 4-12 example). This procedure requires the training and equipment contained/specified in an OpSpec or letter of authorization (LOA). This procedure must meet all IVH (Proceed Visually) procedure requirements and the following additional requirements:

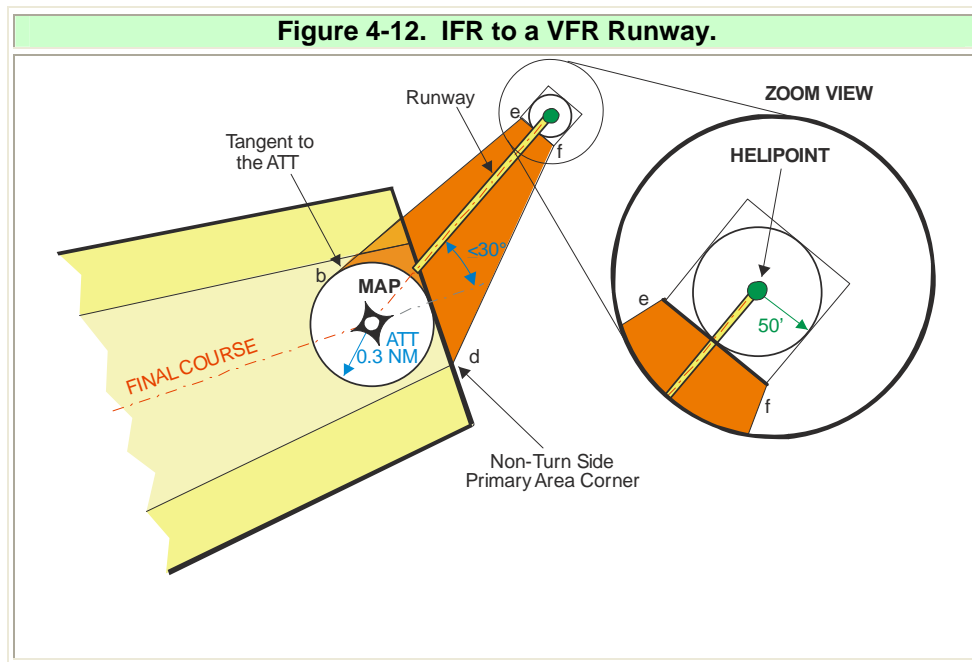

a. Location on the runway. The heliport (aiming point) may be located at any point on a runway centerline, but should be at least a distance of $(1.5 * \text{Rotor Diameter})$ from the end of the usable runway on centerline. The runway is not required to be marked with heliport markings. The visual track from the MAP to the final approach area heliport must be charted.

b. Alignment. The **optimum** FAC and visual flight path is aligned with the extended runway centerline, with the MAP at the threshold. The FAC must be aligned within 30 degrees of the extended runway centerline. See paragraph 5 and figures 4-8, 4-9 and 4-12 for OEA construction examples.

c. Day operations. An **'acceptable'** visual segment day flight evaluation for flyability and OIS obstacle penetration must be completed.

d. Night operations. An ‘acceptable’ visual segment night flight evaluation for flyability must be completed. This evaluation must confirm the runway lighting system is visible from the MAP.

e. Helipoint Location. The runway final approach area about the heliport must be clearly viewable from the MAP.

7. PinS Approach (Proceed VFR). The VFR segment on a PinS (Proceed VFR) approach procedure provides a measure of obstacle protection/identification to allow a safe transition from IFR to VFR flight. The area is not intended to support IFR descent.

Apply Order 8260.3, Volume 1, chapter 11 pertaining to PinS approach criteria, except no requirement exists for a MAP to be located beyond 2,600 ft of the heliport. A PinS (Proceed VFR) procedure may be developed to a heliport, multiple heliports, or a geographical area not associated with a specific heliport. Refer to chapter 2, paragraph 3 to determine whether procedures are ‘Specials.’ Compute the distance for the Remote Altimeter Setting Source (RASS) adjustment for the MDA and stepdown altitudes for the PinS approach procedures from the source to the MAP.

a. Alignment. The PinS visual segment is a 5,280 ft-radius arc segment centered at the FAC and the latest MAP ATT intersection.

b. Area. The PinS OEA is a 5,280 ft-radius arc segment centered at the FAC and the latest MAP ATT intersection. The arc segment is laterally bounded by 20 degree splay lines (relative the FAC-extended), originating at the FAS secondary boundaries and the latest MAP ATT (see figure 4-13).

c. Length. A 5,280 ft radius as described above.

d. **PinS visual segment OIS** (see chapter 4, paragraph 7e). This surface **must not** be penetrated **except** when a ‘special approach procedure’ MDA, not providing obstacle clearance in this area, is **mandatory** for mission completion. Obstacles that penetrate the special procedure surface must be charted and included in the required training (AAOs are not charted).

e. **Obstacle Clearance in the PinS VFR Segment.** Add 250 ft of ROC (minus adjustments) to the highest obstacle/terrain within the VFR area and (round to the next higher 20-ft increment). The final MDA is the higher of the MDAs calculated for the final and VFR segments. This does not apply to special approaches (see chapter 4, paragraph 7d).

f. **Visibility.** The **minimum** final segment visibility is $\frac{3}{4}$ SM for a height above surface (HAS) of 800 ft and below. Where a HAS exceeds 800 ft, the **MINIMUM** visibility is 1.0 SM.

8. IFR to an IFR Runway.

a. **Configuration and Alignment.** The MAP location should provide the best compromise of lowest visibility and VSDA. Except where the alignment is to the RWT, the mandatory MAP location is at the FAC and RCL intersection. Where the alignment is to the RCL, the optimum MAP location is at the RWT, with optional MAP location along the FAC between the PFAF and the RWT.

b. **Area.** The final OEA begins at the earliest PFAF ATT and ends at the latest MAP ATT, RWT, or a point abeam the RWT, whichever is farthest. Apply chapter 4, paragraph 3a criteria for the IFR segment OEA and ROC (see figure 4-1).

c. Descent Gradient/Angle. Calculate the FAS descent angle from the PFAF altitude at the plotted position of the PFAF to the TCH at RWT. Apply chapter 4, paragraph 3a(4).

d. Visual Segment. Apply Order 8260.3, Volume 1, paragraph 3.3.2.d. Establish a 40 ± 5 ft TCH for runways where no VGSI is installed. Where a VGSI is installed, a final descent gradient and VSDA may be established to coincide with the established gradients/angles for angles of 3.0 degrees or more. If the descent gradient/angle cannot be published coincident (within ± 0.20 degrees) and TCH values within 3 ft of the published VGSI glide slope angle, publish a note on the chart.

e. Visibility. See chapter 7, paragraph 1b. Apply Order 8260.3, Volume 1, paragraph 1127. Where obstacles penetrate Order 8260.3, Volume 1 paragraph 3.3.2.d. surfaces, add the chart note: Visibility Reduction by helicopters NA. See Order 8260.19, paragraph 854(i)(3).

Note: When a special procedure has a GPA greater than 5.7 degrees and a TCH higher than 45 ft, Order 8260.3, Volume 1, paragraph 1127 may be applied. Table 25 application is required.

9. WAAS LP Criteria. The WAAS LP criteria apply to the final approach only. For all other segments apply GPS criteria except where noted for a turn at the PFAF, and missed approach constructions that are different. This implementation of WAAS does not include a glidepath function for these procedures. Criteria in this chapter provide a narrower OEA in the IFR FAS and OIS in the visual segment. The segment lengths and descent rate/gradients are the same as chapter 4, paragraph 3. The intermediate segment begins with the same width at the GPS intermediate fix (IF), reference chapter 3, paragraph 1b, tailored to the beginning WAAS FAS width, reference chapter 4, paragraph 9d at the PFAF. Apply chapter 4, paragraph 5 through 7 to design approaches in the visual/visual flight rule (VFR) segments, and apply chapter 4, paragraphs 8 and 9 for the IFR FAS OEA and ROC. Apply an OIS, reference chapter 4, paragraph 5d, with the reduced width, reference chapter 4, paragraph 8d. Apply chapter 4, paragraph 5 for the analysis of the VFR area of a Point in Space (PinS) (Proceed VFR) approach.

Figure 4-17 depicts the basic configuration for determining the Flight Path Alignment Point (FPAP) and fictitious helipoint (FHP) coordinates. Locate the FHP 2,600 ft from the MAP. The FPAP is a point defined by the World Geodetic System 1984 (WGS-84) latitude, longitude, and is located 9,023 ft from the FHP.

a. Minimums. Apply chapter 7.

b. Use The Following Steps for WAAS LP Procedure Construction:

Step 1: Determine the FAS course alignment, MAP, FHP, and FPAP coordinates.

Step 2: Calculate the distance (ft) from the FHP to the PFAF (D_{PFAF}) using formula 4-11. Calculate the primary and secondary area widths at any distance from FHP to the earliest point the PFAF can be received using formulas 4-11 and 4-13 (see figure 4-14).

Formula 4-11. LP PFAF (D_{PFAF}).

$$D_{PFAF} = \frac{\ln\left(\frac{r + \text{alt}}{r + \text{FHP}_{\text{elev}} + \text{HCH}}\right) \cdot r}{\tan\left(\theta \cdot \frac{\pi}{180}\right)}$$

Where:

- alt = minimum intermediate segment altitude
- FHP_{elev} = FHP MSL elevation
- HCH = HCH value
- θ = glidepath angle

($\ln((r + \text{alt}) / (r + \text{FHP}_{\text{elev}} + \text{HCH})) * r$) / $\tan(\theta * \pi / 180)$

Calculator

FHP _{elev}	<input type="text"/>	Click here to calculate
HCH	<input type="text"/>	
θ	<input type="text"/>	
alt	<input type="text"/>	
D_{PFAF} (ft)	<input type="text"/>	

Step 3: After constructing the IFR final trapezoid area, analyze the FAS by determining the controlling obstacle within the IFR final segment by applying the ROC in chapter 4, paragraph 9b and determining the minimum descent altitude (MDA).

Step 4: When constructing an IFR to a VFR heliport procedure (IVH, Proceed Visually), or an IFR approach to a VFR runway procedure (IVR, proceed visually), apply chapter 4 criteria for the visual segment, but construct the narrower OIS in accordance with chapter 4, paragraph 9g.

Step 5: When constructing a PinS (Proceed VFR) approach, apply chapter 4 criteria for the VFR segment and adjust the MDA of the IFR segment after an analysis of the VFR segment if required.

Step 6: Construct the missed approach using chapter 5.

c. Determine FAS Course Alignment, FPAP and FHP Coordinates. The FAS course determines the positional relationship between the FPAP and the FHP. Calculate the FPAP latitude and longitude coordinates using the MAP as a starting point after determining the procedure final approach course (FAC). Use the direct program and extend the FAS course as an azimuth at a distance of 2,600 ft from the MAP to determine the FHP coordinates. Extend this course 9,023 ft beyond the FHP to calculate the FPAP coordinates (see figure 4-14 and table 4-1).

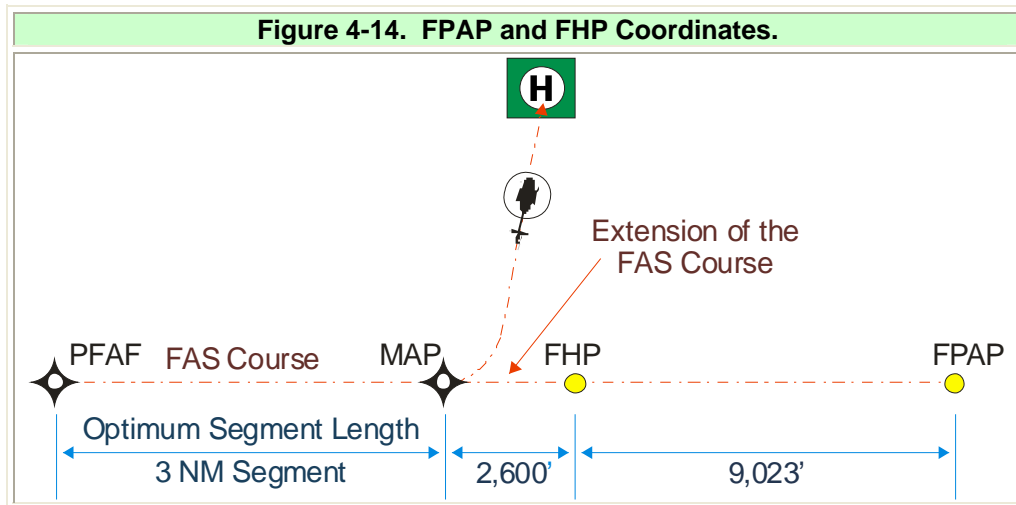

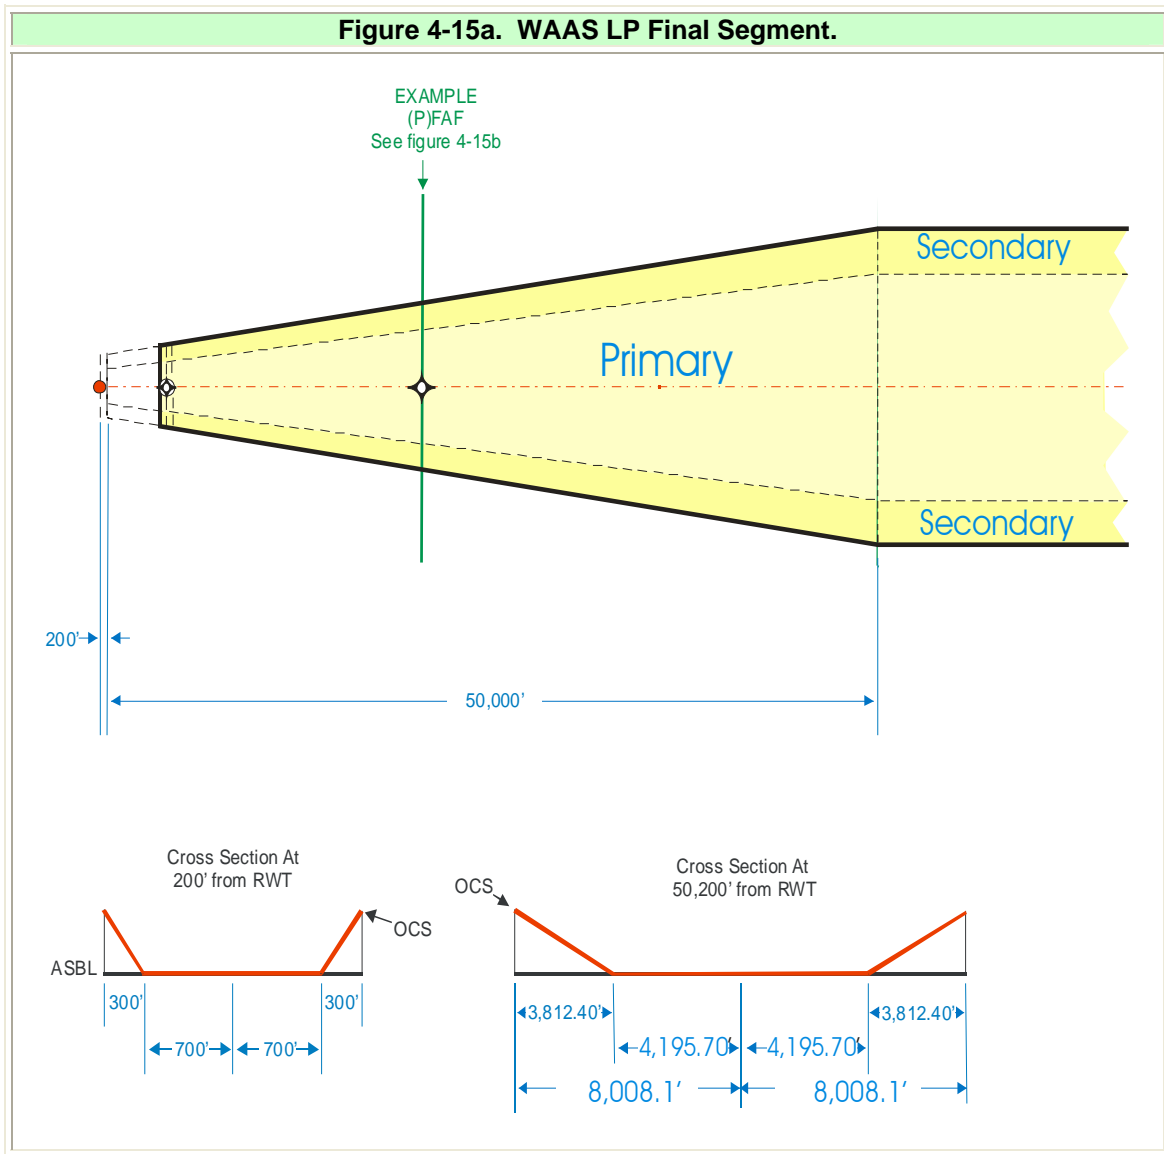

Table 4-1. FPAP Information.			
FPAP Distance from FHP	± Splay	± Width	Length Offset
9,023 ft	2.0°	350 ft (106.75 m)*	0

*Round result to the nearest 0.25 m.

d. Area. The FAS OEA begins at the earliest PFAF position and ends at the MAP latest ATT (see figure 4-16). The PFAF and MAP ATT is ±40 m. Apply 250 ft of ROC in the primary area. The secondary area ROC is 250 ft at the primary boundary tapering uniformly to zero at the outer edge. The beginning primary area width nearest the FHP is 867.79 ft, and the secondary areas are 468.60 ft (see figures 4-15b and 4-16). Calculate the primary and secondary widths at any point between FHP and PFAF using formulas 4-12 (primary) and 4-13 (secondary).

(1) Length. The **standard** IFR final segment length PFAF to MAP is 3 NM but is also determined by descent gradient. The **minimum** length is 2 NM and the **maximum** length is 50,000 ft. (see figure 4-15a).

(2) The primary area width (D_p) each side of FAC at its origin (2,600 ft from FHP) is 867.79 ft. The primary area expands uniformly to 3,495.70 ft from FAC at a point 50,200 ft from FHP. From 50,200 ft outward, the OEA is linear (boundaries parallel the centerline). The OEA begins at the earliest PFAF ATT and ends 2,600 ft from the FHP (MAP latest ATT). Calculate primary area half-width at any point in final using formula 4-12 (see figures 4-15a, 4-15b, and 4-16).

Calculate the perpendicular distance (ft) D_p from FAC to the primary area boundary at any distance (d_{FHP}) using formula 4-12:

Formula 4-12. $\frac{1}{2}$ Width of Primary (D_p).		
$D_p = \frac{1}{2}$ Primary Area Width (ft) = $0.0699139 (d_{FHP} - 200) + 700$		
d_{FHP} = Distance (ft) from FHP, along course		
$0.0699139 * (d_{FHP} - 200) + 700$		
Calculator		
d_{FHP}		Click here to calculate
D_p (ft)		

(3) The perpendicular distance from FAC to outer secondary boundary (D_s) is 1,336.39 ft at the origin, and expands uniformly to 7,008.1 ft at 50,200 ft from the FHP (see figures 4-15a, 4-15b, and 4-16). Calculate D_s (ft) using formula 4-13.

Formula 4-13. Perpendicular Distance (D_s).		
$D_s = \text{Secondary Boundary Dist. (ft)} = 0.140162 (d_{\text{FHP}} - 200) + 1000$		
Where:		
D_s = Course to Outer Secondary Distance (ft)		
d_{FHP} = Distance from FHP (ft), along course		
$0.140162 * (d_{\text{FHP}} - 200) + 1000$		
Calculator		
d_{FHP}		Click here to calculate
D_s (ft)		

e. **Required Obstacle Clearance (ROC).** Primary ROC is 250 ft. The MDA can be no lower than the controlling obstacle height adjusted for obstacle accuracy tolerance (see Order 8260.19, appendix 2) plus the ROC value plus adjustments rounded to the next higher 20 ft-increment. Calculate secondary area ROC using formula 4-14.

Formula 4-14. Secondary Area ROC ($ROC_{\text{secondary}}$).		
$ROC_{\text{secondary}} = (250 + \text{adj}) \cdot \left(1 - \frac{d_{\text{primary}}}{W_s} \right)$		
Where:		
adj = TERPS para 3.2.2 adjustments		
d_{primary} = perpendicular distance (ft) from primary area edge		
W_s = Secondary Area Width (ft)		
$(250 + \text{adj}) * (1 - d_{\text{primary}} / W_s)$		
Calculator		
adj		Click here to calculate
d_{primary} (ft)		
W_s (ft)		
$ROC_{\text{secondary}}$		

f. **FAS Descent Angle/Gradient.** Apply chapter 4, paragraphs 3a(4) and 3a(5).

g. **IFR Approach to a VFR Heliport (IVH) or IFR to a VFR Runway (IVR).** Apply chapter 4, paragraphs 5 through 7 and the criteria in this chapter for the IFR final segment OEA. Construct the IFR FAS by applying chapter 4, paragraph 9. The OIS width is like the IFR final segment primary area width at the latest point the MAP can be received (± 867.79 ft) then narrows to the VSRL width (see figure 4-17).

h. PinS Approach. Apply chapter 4, paragraph 9 to determine a preliminary MDA based on the FAS OEA. Apply chapter 4, paragraph 7 and 7e for the VFR segment analysis. The final MDA may require adjustment based on the VFR segment for a public procedure.

Chapter 5. Missed Approach

1. General.

a. Missed Approach (MA) Construction.

(1) Speed. Apply 70 KIAS for civil procedures (see chapter 2, paragraph 1) and 90 KIAS for military. Apply wind values (see chapter 2, formula 2-3b) and bank angles (see chapter 2, table 2-4).

(2) Optimum Flight Path. The missed approach segment ends at a holding point designated by a missed approach holding fix (MAHF). **Optimum** routing is straight ahead to a direct entry into holding at the MAHF. If the MA routing terminates at a “T” IAF, **optimum** MA holding pattern alignment is with the initial inbound course, with either a teardrop or direct entry into holding (see figure 5-1a).

Note: USA: Develop and annotate an alternate RNAV(GPS) MA procedure when requested.

b. Obstacle Clearance Standard. Calculate the nominal OCS slope ($MA_{OCS\text{SLOPE}}$) associated with a given missed approach climb gradient using chapter 2, formula 2-15. See chapter 2, paragraph 17 for Missed Approach Conventions.

c. Missed Approach Section 1 (MAS-1). Section 1 begins at earliest MAP along-track tolerance (ATT) and extends to the start-of-climb (SOC), or the point where the aircraft is projected to cross 400 ft above airport/heliport elevation, whichever is the greatest distance from MAP. See figure 5-1b for MA segment point and line designations. Figure 5-2 depicts the Section 1/Section 2 (partial), OCS plan and profile view beginning at an altitude of MDA minus 100 ft plus adjustments (see chapter 4 for greater final segment detail).

(1) Length.

(a) Flat Surface Length (FSL).

1 LNAV. Section 1 flat surface begins at CD (0.3 NM prior to the MAP) and extends (distance FSL feet) to JK.

2 LP. Section 1 flat surface begins at CD [40 meters prior to the MAP] and extends (distance FSL feet) to JK.

Step 1: Calculate the FSL value using formula 5-1. Use chapter 4, final segment formulas 4-1a, (LNAV primary and total), and 4-12 (LP primary), and 4-13 (LP Secondary distance) to determine MAS starting widths.

Formula 5-1. Flat Surface Length (FSL).		
$FSL = 8 \cdot \frac{1852}{3600} \cdot \left(\left(V_{KIAS} \cdot \frac{171233 \cdot \sqrt{(288 + 15) - 0.00198 \cdot MDA}}{(288 - 0.00198 \cdot MDA)^{2.628}} \right) + 10 \right) + 2 \cdot ATT$		
$8 \cdot (1852/0.3048/3600) \cdot ((V_{KIAS} \cdot (171233 \cdot ((288+15)-0.00198 \cdot MDA)^{0.5}) / (288-0.00198 \cdot MDA)^{2.628}) + 10) + 2 \cdot ATT$		
Calculator		
V _{KIAS}		Click here to calculate
MDA		
ATT (ft)		
FSL(ft)		

Note: FSL time is 3 seconds reaction, and 5 seconds delay.

(2) Section 1 end location (AB).

(a) MDA ≥ 400 ft above airport/heliport elevation. Locate AB coincident with JK.

(b) MDA < 400 ft above airport/heliport elevation. Locate AB at $\frac{1852}{(0.3048 \cdot CG)}$ feet

beyond JK for each foot of altitude needed to reach 400 ft above airport/heliport/surface elevation. The surface between JK and AB is a rising slope commensurate with the standard rate of climb (400 ft/NM). Find the appropriate CG-related slope using chapter 2, formula 2-15.

(c) Required/assigned turning altitude > 400 ft above airport/heliport elevation. Locate AB and apply the surface described in chapter 5, paragraph 1c(2)(b) until reaching the assigned turning altitude.

(3) Width. LNAV and LP.

(a) LNAV. Splay each secondary area outer boundary line outward 15 degrees relative to the missed approach course (MAC) from the secondary area outer edge at CD (0.3 NM prior to MAP) until it reaches a point 2 NM from MAC. Splay the primary area boundary uniformly outward from the primary area edge at CD to reach 1.5 NM from MAC at the same distance the secondary reaches full width. Calculate the distance from MAC to the MAS-1 OEA primary and outer secondary boundary at any distance from CD using formula 5-1a. Calculate final primary and secondary widths at CD using chapter 4, final formula 4-1a.

(b) LP. Splay each secondary area outer boundary line outward 15 degrees relative to the MAC from the secondary area outer edge at CD (40 meters prior to MAP) until it reaches a point 2 NM from MAC. Splay the primary area boundary uniformly outward from the primary area edge at CD to reach 1.5 NM from MAC at the same distance the secondary reaches full width. Calculate the distance (ft) from MAC to the MAS-1 OEA primary and outer secondary

boundary at any distance from CD using formula 5-1a. Calculate final primary and secondary widths at CD using chapter 4, final segment formulas 4-12 and 4-13.

Formula 5-1a. LNAV/LP Section 1 Primary & Secondary Width.		
$MAS_{Y_{primary}} = d \cdot \frac{\tan\left(15 \cdot \frac{\pi}{180}\right) \cdot (1.5 \cdot NM - W_p)}{2 \cdot NM - W_s} + W_p$ $MAS_{Y_{secondary}} = d \cdot \tan\left(15 \cdot \frac{\pi}{180}\right) + W_s$		
Where d = along-track distance (ft) from the cd line ≤ 45352.743 NM = 1852/0.3048 W _p = Primary Start Width (ft) (final formula) W _s = Secondary Start Width (ft) (final formula)		
$MAS_{Y_{primary}} = d \cdot ((\tan(15 \cdot \pi / 180) \cdot (1.5 \cdot 1852 / 0.3048 - W_p)) / (2 \cdot 1852 / 0.3048 - W_s)) + W_p$ $MAS_{Y_{secondary}} = d \cdot \tan(15 \cdot \pi / 180) + W_s$		
Calculator

MAS _{Y_{secondary}}		

(4) Obstacle Clearance Section 1.

(a) The nominal MAS-1 OCS is a flat surface. The MSL surface height (HMAS) is equal to the MDA minus 100 ft plus adjustments (see formula 5-1b). No obstacle may penetrate this surface.

(b) Where Section 1 extends beyond SOC (JK), no obstacle may penetrate the CG-associated OCS slope between SOC and AB. Find helicopter altitude at AB using formula 5-1c.

Formula 5-1b. HMAS.		
$HMAS = MDA - (100 + adj)$		
Where: adj = precipitous terrain, remote altimeter (only if full time), and excessive length of final adjustments

Copter _{AB}		

d. These criteria cover two basic MA constructions:

- Straight missed approach
- Turning missed approach

Note: These construction methods accommodate traditional combination straight and turning missed approaches.

(1) The section 2 obstacle evaluation area (OEA) splays 15 degrees relative to the nominal track to reach full width (see figure 5-3). The OEA ends at the MA Holding Fix (MAHF) latest ATT. Apply the Section 2 standard MA OCS slope beginning from AB. Calculate MA OCS slope values using chapter 2, formula 2-15.

Note: All references to ‘standard MA OCS slope’ and/or use of ‘20:1’ refer to chapter 2, formula 2-15 output, with an input climb gradient (CG) of 400 ft/NM.

(2) Where a higher than standard CG (400 ft/NM) is required, apply the CG and the CG-related OCS from the SOC. Apply secondary areas as specified in this chapter. Measure the 4:1 secondary OCS perpendicular to the nominal track, measured from the primary boundary, or perpendicular to the primary boundary when considering arcs, diagonal corner-cutters, etc.

(3) Locate the MAHF within 25 NM of the ARP/HRP. Determine **minimum leg length** for course changes following the first fix after the MAP using the greater distance from chapter 2, formulas 2-7, 2-8, and 2-9, climb distance required, and chapter 3, table 3-1.

(4) Design MA holding for 90 KIAS, or the appropriate restricted speed.

2. Straight Missed Approach. The straight missed approach course (MAC) is a continuation of the final approach course (FAC). The straight MA section 2 OEA begins at section 1 end (AB) and splays at 15 degrees relative to the nominal track until reaching full primary and secondary width (0.5-1.5-1.5-0.5). Apply the section 2 standard OCS, or the OCS associated with a higher CG, beginning at AB from the section 1 end OCS elevation. (When the increased CG is no longer required, revert to the section 2 standard OCS). Determine primary OCS elevation at an

obstacle by measuring the along-track distance from AB to a point at/abeam the obstacle. Where the obstacle is located in the secondary area, apply the primary OCS slope to a point abeam the obstacle, then apply the 4:1 secondary slope (perpendicular to the track) from the primary boundary to the obstacle (see chapter 5, figures 5-3, 5-4).

3. Turning Missed Approach. Apply turning criteria when requiring a turn at or beyond SOC. Where secondary areas exist in section 1, they continue to full width in section 2. Terminate turn-at-fix turn-side secondary areas not later than the early turn point. Do not apply turn-side secondary areas for turn-at-altitude construction. The terms 'inside turn' and 'outside turn' are used to reduce verbiage in describing turn associated construction and relationships. Where required, alternate construction steps (indicated by Step #ALT) are provided to supplement or replace the primary step.

There are two types of turn construction for the first MA turn:

- Turn at an altitude (see chapter 5, paragraph 3a):
 - Always followed by a DF leg ending with a DF/TF connection
- Turn at a fix (see chapter 5, paragraph 3b):
 - Always followed by a TF leg ending with a TF/TF connection.
 - May be followed by an RF leg (which requires advanced avionics) when the initial straight leg has reached full width, ending with an RF/TF or RF/RF connection. RF turn initial fix must be located where the aircraft is at least 500 ft above airport elevation.

Following a turn, the minimum segment length must be the greater of:

- The minimum length calculated using chapter 2, formulas 2-7, 2-8 and 2-9.
- The distance from previous fix to the intersection of the 30-degree converging outer boundary line extension and the nominal track, (plus segment end fix DTA).

Minimum DF leg length must accommodate 6 seconds (minimum) of flight time based on either 70 KIAS or 90 KIAS, as appropriate, applied between the wind spiral (WS)/direct-to-fix-line tangent point, and the earliest maneuvering point of the DF/TF fix. Convert to TAS using chapter 2, formula 2-3a and the MAHF altitude.

a. Turn At An Altitude. Apply turn-at-an-altitude construction unless the first MA turn is at a fix. Since pilots may commence the MA at altitudes higher than the MDA and helicopter climb rates differ, turn-at-an-altitude construction protects the large area where turn initiation is expected. This construction also provides protection for 'turn as soon as practicable' and combination straight and turning operations. When a required turning altitude exceeds the minimum turning altitude (typically 400 ft above the airport, heliport, or height above surface), specify the turning altitude in a 100-ft increment. Where operationally required, 20-ft increments may be applied.

Note: ‘Turn as soon as practicable’ includes, but is not limited to operational suitability, flight characteristics/capability, appropriate altitude, positioned at or beyond the MA early ATT, as well as the feasibility, workability, and viability of the intended maneuver.

When a turn at altitude MA, (low MDA, turn at less than 400 ft above airport/heliport or height above surface, etc.) is required, Flight Standards Approval is required.

Track guidance is assumed throughout the operation; therefore, dead reckoning (DR) segments are not considered. Apply turning MA criteria whenever the MAC differs from the FAC. The following applies:

- Section 1/Section 2 connection is depicted in chapter 5, figure 5-5 for a minimum altitude turn-at-altitude MA. The CD is the earliest the MAP can be received. AB is the SOC (chapter 5, figure 5-6 depicts higher than minimum altitude turns).
- Section 2 and section 1 connect at AB.
- Construct section 2 outside-turn boundaries using WS vice specified radii. Construct outside boundaries in relation to these WS and late turn track (see chapter 5, figures 5-9, 5-13, 5-15).
- Construct inside-turn boundaries in relation to the early turn track (see chapter 5, figures 5-5, 5-6).
- Apply the standard OCS slope (or the assigned CG-associated slope) beginning at AB at AB OCS height. The secondary 4:1 surface rises from the primary OCS.

(1) Turn Initiation Area (TIA). Construct the TIA, a portion of a straight MA, beginning from the earliest MA turn point (CD), and ending where the specified minimum turning altitude is reached, (AB or LL'). Base the TIA length on the climb distance required to reach the turning altitude. The TIA minimum length must place the aircraft at an altitude from which obstacle clearance is provided in section 2 outside the TIA. The TIA boundary varies with length, the shortest B-A-C-D, where AB overlies JK. Where the TIA is contained within section 1, B-A-J-C-D-K defines the boundary. Where the required turn altitude exceeds that supported by section 1, the TIA extends into section 2, (see figure 5-8 and Order 8260.54 for construction examples) and points L'-L-A-J-C-D-K-B define its boundary. In this case, L-L' is the early turn point based on the helicopter climbing at the prescribed CG. Calculate TIA length using chapter 5, formula 5-2a. A 4:1 secondary is depicted on the non-turning side of the primary (see chapter 5, figures 5-6, 5-8, and 5-9).

Step 1: Turn altitude. The turn altitude is either operationally specified (must be at or above altitude required by obstacles) or determined by obstacle evaluation. Evaluate the nominal OCS. If the OCS is penetrated, mitigate the penetration with one or a combination of the following:

- Raise MDA
 - Establish a climb gradient that clears the obstacle
 - Move MAP
 - If the penetration is outside the TIA, consider raising the climb-to altitude
- (a) Determine the helicopter required minimum turning altitude:
- Identify the controlling obstacle in section 2 (straight MA)
 - For straight OCS/CG/length options
 - Identify the controlling obstacle in section 2, (typically turn-side)
 - Find the shortest distance from the TIA lateral boundary to the obstacle
 - Apply this distance and the MA OCS slope to find the TIA-to-obstacle OCS rise
 - The minimum TIA boundary, (and OCS end elevation) equals the obstacle elevation minus OCS rise
 - The minimum turn altitude is the sum of (TIA OCS boundary elevation) and (final ROC), rounded to the next higher 100 ft-increment (where operationally required, 20-ft increments may be applied)

Note 1: TIA lateral boundary is the straight segment (portion) lateral boundary until the required minimum turn altitude and TIA length are established.

Note 2: Repeat Step 1 until acceptable results are obtained.

The specified altitude must equal or exceed the section 1 end altitude. Find section 1 end altitude using chapter 5, formula 5-1c.

Step 2: Calculate TIA length (ft) using chapter 5, formula 5-2a (see chapter 5, figures 5-6 and 5-8).

Formula 5-2a. TIA_{length}	
$TIA_{length} = FSL \cdot \frac{r}{(r + MDA)} + \frac{r}{CG} \cdot \frac{1852}{0.3048} \cdot \ln\left(\frac{r + turn_{alt}}{r + MDA}\right)$	
Where MDA = Final MDA CG = Climb Gradient (Standard 400 ft/NM) turn _{alt} = required turn altitude	
$FSL \cdot r / (r + MDA) + r / CG \cdot 1852 / 0.3048 \cdot \ln((r + turn_{alt}) / (r + MDA))$	
Calculator	
FSL (formula 5-1)	
MDA	
CG	
turn _{alt}	
TIA_{length} (ft)	
Click here to calculate	

Step 3: Locate the TIA end at a distance TIA length beyond CD (from **Step 2**) (LL') where the applied OCS reaches the required TIA end surface elevation (from **Step 1**).

Step 4: Locate the latest turn point, (PP') at distance rr (from chapter 2, formula 2-4a) beyond the TIA end (AB/LL'). See example chapter 5, figures 5-6 and 5-8.

(2) OEA Construction after TIA. The OEA includes areas to protect the earliest and latest direct tracks from the TIA to the fix. Construct the obstacle areas about each of the tracks as described below. See chapter 5, figures 5-9 through 5-15 for various turn geometry construction illustrations.

(a) Early Turn Track and OEA Construction. Where the early turn track from the FAC/CD intersection defines a turn less than or equal to 75 degrees relative to the FAC, the tie-back point is C (see chapter 5, figure 5-5); if the early track defines a turn greater than 75 degrees relative to the FAC, tie-back to point D (see chapter 5, figure 5-7). Where the early track represents a turn greater than 165 degrees (see chapter 5, figures 5-12 and 5-15), begin the early turn track and the 15-degree splay from the non-turn side TIA end + rr (chapter 2, formula 2-4a) (PP').

Step 1: Construct a line (defines the earliest-turn flight track), from the tie-back point to the fix. See chapter 5, figures 5-9, 5-10, 5-14, and 5-15.

Step 2: Construct the outer primary and secondary OEA boundary lines parallel to this line (0.5-1.5-1.5-0.5 segment width). See chapter 5, figures 5-9 and 5-10.

Step 3: From the tie-back point, construct a line splaying at 15 degrees to intersect the parallel boundary lines or segment end, whichever occurs earlier (see chapter 5, figures 5-9 and 5-10).

Note: Apply secondary areas only after the 15-degree splay line intersects the primary boundary line (see chapter 5, figures 5-9, 5-10, 5-13, etc).

Step 3Alt: Where **Step 3** construction provides less than full-width protection at the DF fix, construct the OEA inner boundary with a line splaying from the tie-back point at 15 degrees relative the direct-to-fix line, (or greater where required to provide full-width protection at the DF fix), until it intersects the parallel boundary lines (not later than tangent/tangent-extension to the full-width-arc about the fix), **and** provides full-width protection at or before the DF fix. DF secondary areas begin/exist only where full width primary exists. See chapter 5, figures 5-10, 5-14, and 5-15.

Note: Where excessive splay results (dependent upon various conditions but generally in the 20-25 degree range), consider modifying the segment to avoid protection and/or construction difficulties.

(b) Late Turn Track and OEA Construction. Apply WSs for late-turn outer boundary construction using the following calculations, construction techniques, and bank angles of 11 degrees or 14 degrees, as appropriate.

Step 1: Find the no-wind turn radius (R) using chapter 5, formula 5-2b.

Formula 5-2b. No-Wind Turn Radius (R).		
$R = \frac{(V_{KTAS} + 0)^2}{\tan(\text{Bank}_{\text{ANGLE}} \cdot \left(\frac{\pi}{180}\right)) \cdot 68625.4}$		
Where:		
V_{KTAS} = True Airspeed, formula 2-3a $\text{Bank}_{\text{ANGLE}}$ = Table 2-4 value		
$(V_{KTAS} + 0)^2 / (\tan(\text{Bank}_{\text{ANGLE}} * \pi / 180) * 68625.4)$		
Calculator		
V_{KTAS}		Click here to calculate
$\text{Bank}_{\text{ANGLE}}$		
R (NM)		

Note: Apply the appropriate indicated airspeed and minimum assigned turn altitude when converting to true airspeed for this application.

Step 2: Calculate the Turn Rate (TR) using chapter 5, formula 5-2c. Maximum TR is 3 degrees per second.

Formula 5-2c. Turn Rate (TR).		
$TR = \frac{3431 \cdot \tan\left(\text{Bank}_{\text{ANGLE}} \cdot \frac{\pi}{180}\right)}{\pi \cdot V_{KTAS}}$		
Where:		
$\text{Bank}_{\text{ANGLE}}$ = Table 2-4 V_{KTAS} = Formula 2-3a		
$(3431 * \tan(\text{Bank}_{\text{ANGLE}} * \pi / 180)) / (\pi * V_{KTAS})$		
Calculator		
$\text{Bank}_{\text{ANGLE}}$		Click here to calculate
V_{KTAS}		
TR (°/Sec)		

Step 2a: Calculate the Turn Magnitude (Turn_{Magnitude}) using the appropriate no-wind turn radius and the arc distance (degrees) from turn start (at PP) to the point of tangency with a line direct to the fix.

Step 2b: Calculate the highest altitude in the turn using chapter 5, formula 5-2d (MAHF altitude may be used). Determine subsequent fix altitudes using fix-to-fix direct measurement and 400 ft/NM, (or higher assigned) climb rate.

Formula 5-2d. Highest Altitude Gained (Total _{ALT}).	
$\text{HighestTurn} = \text{MDA}_{\text{ALT}} + (2R \cdot \pi \cdot \frac{\text{Turn}_{\text{Magnitude}}}{360} \cdot \text{CG})$	
<p>Where:</p> <p style="margin-left: 40px;">MDA_{ALT} = Procedure MDA</p> <p style="margin-left: 40px;">R = No-wind turn radius (NM), Formula 5-2b</p> <p style="margin-left: 40px;">Turn_{Magnitude} = Turn start to rollout (deg)</p> <p style="margin-left: 40px;">CG = Standard 400 ft/NM</p>	
$\text{MDA}_{\text{ALT}} + (2 \cdot R \cdot \pi \cdot \text{Turn}_{\text{Magnitude}} / 360 \cdot \text{CG})$

Total _{ALT}	<input type="text"/>
<div style="border: 1px solid gray; padding: 10px; width: fit-content; margin: auto;"> <p>Click here to calculate</p> </div>	

Step 3: Find the omni-directional wind component (V_{KTW}) for the highest altitude in the turn applying chapter 2, paragraph 5.

Step 4: Apply this common wind value (**Step 3**) to all first-turn wind spirals.

Note: Apply 30 knots for turn altitudes ≤ 2,000 ft above heliport/airport elevation.

Step 5: Calculate the wind spiral radius increase (ΔR) (relative R), for a given turn magnitude (φ) using chapter 5, formulas 5-2c and 5-2e.

Formula 5-2e. WS (ΔR).		
$\Delta R = \frac{V_{KTW} \cdot \phi}{3600 \cdot TR}$		
Where:		
V_{KTW} = Windspeed, formula 2-3b ϕ = Degrees of turn TR = Turn Rate, formula 5-2c		
$(V_{KTW} * \phi) / (3600 * TR)$

b. Turn-At-A-Fix. The first MA turn-at-a-fix may be a fly-by or fly-over fix. Use fly-by unless a fly-over is required for obstacle avoidance or where mandated by specific operational requirements. The turn fix early-turn-point must be at or beyond section 1 end.

(1) Early/Late Turn Points.

(a) The fly-by fix early-turn-point is located at (FIX-ATT-DTA) prior to the fix.

(b) The fly-by fix late-turn-point is located at a distance (FIX + ATT – DTA + rr) from the fix.

Fly-by fixes (see chapter 5, figure 5-16).

$$\text{Early}_{TP} = \text{Fix} - \text{ATT} - \text{DTA}$$

$$\text{Late}_{TP} = \text{Fix} + \text{ATT} - \text{DTA} + rr$$

(c) The fly-over early-turn-point is located at a distance (FIX - ATT) prior to the fix.

(d) The fly-over late-turn-point is located at a distance (FIX + ATT + rr) beyond the fix.

Fly-over fixes (see chapter 5, figure 5-16).

$$\text{Early}_{TP} = \text{Fix} - \text{ATT}$$

$$\text{Late}_{TP} = \text{Fix} + \text{ATT} + rr$$

(2) Turn-at-a-fix. (First MA turn) Construction. The recommended maximum turn is 70 degrees; the absolute maximum is 90 degrees. The first turn fix must be located on the final approach track extended.

Step 1: Calculate aircraft altitude at AB using chapter 5, formula 5-1c.

Step 2: Calculate fix distance based on minimum fix altitude. Where the first fix must be located at the point the helicopter reaches or exceeds a specific altitude, apply chapter 5, formula 5-2f (using the assigned/applied CG), to calculate fix distance (D_{fix}) (NM) from SOC (AB/JK) (see chapter 5, figures 5-17 through 5-20).

Formula 5-2f. Fix Distance (D_{fix}).		
$D_{fix} = \ln\left(\frac{Alt_{fix} + r}{Copter_{SOC} + r}\right) \cdot \frac{r}{CG}$		
Where:		
Alt _{fix} = Minimum altitude required at fix		
Copter _{SOC} = Copter <u>AB</u> (SOC) altitude		
CG = Climb Gradient (Standard 400 ft/NM)		
$\ln((Alt_{fix}+r)/(Copter_{SOC}+r)) * r / CG$		
Calculator		
Alt _{fix}		Click here to calculate
Copter _{SOC}		
CG		
D _{fix} (NM)		

Step 3: Calculate the altitude a helicopter climbing at the assigned CG would achieve over an established fix using chapter 5, formula 5-2g.

Formula 5-2g Altitude Achieved at Fix (Alt_{fix}).		
$Alt_{fix} = (r + Copter_{SOC}) \cdot e^{\left(\frac{CG \cdot D_{fix}}{r}\right)} - r$		
Where:		
Copter _{SOC} = Copter <u>AB</u> (SOC) altitude		
CG = Climb Gradient (Standard 400 ft/NM)		
D _{fix} = Distance (NM) from <u>AB</u> to fix		
$(r+Copter_{SOC}) * e^{(CG * D_{fix} / r)} - r$		
Calculator		
Copter _{SOC}		Click here to calculate
CG		
D _{fix} (NM)		
Alt _{fix}		

(3) Fly-By Turn Calculations and Construction. Consider direction-of-flight-distance positive, opposite-flight-direction distance negative.

(a) Fly-By Turn Calculations.

Step 1: Apply chapter 5, formula 5-2h for distance turn anticipation (DTA).

Formula 5-2h. Distance Turn Anticipation.

$$DTA = R \cdot \tan\left(\frac{\phi}{2} \cdot \frac{\pi}{180}\right)$$

Where:
 ϕ = Turn/Heading Change (Degrees)
 R = No-Wind Turn Radius, formula 5-2b

$R \cdot \tan(\phi/2 \cdot \pi/180)$

R		Click here to calculate
ϕ (Degrees)		
DTA (NM)		

Calculate the fix to early-turn distance (D_{earlyTP}) using chapter 5, formula 5-2i.

Formula 5-2i. Early Turn Distance (D_{earlyTP}).

$$D_{\text{earlyTP}} = \text{ATT} + \text{DTA}$$

Where:
 ATT = along-track tolerance (NM)
 DTA = Turn anticipation distance (NM), formula 5-2h

ATT+DTA

Calculator

ATT		Click here to calculate
DTA		
D_{earlyTP} (NM)		

(b) Early Turn Point (ETP) and Area construction.

Table 5-1. Inside Turn Expansion Guide.	
Outbound Segment Boundary Relative ETP Connections	Expansion Line Required
Secondary & Primary PRIOR ETP	15-Degree Line
Secondary Prior ETP	15-Degree Line
Primary Beyond ETP	$\phi/2$
Secondary & Primary Beyond ETP	$\phi/2$

Note: ETP = LL' early turn point connection, 15-degree line relative the outbound segment, $\phi/2$ = half turn-angle

(c) Inside turn (Fly-By) Construction is predicated on the location of LL' and primary/secondary boundary intersections (early turn connections), relative the outbound segment, see chapter 5, table 5-1. (See chapter 5, figures 5-17 and 5-18).

Where no inside turn secondary area exists in section 1, apply secondary areas only after the turn expansion line/s intersect the outbound segment boundaries.

Apply the same technique to primary and secondary area connections when both inbound segment connection points fall either outside the outbound segment, or inside the outbound segment primary area. When both inbound connection points are within the outbound segment secondary area or its extension, table 5-1 provides a connection method for each point.

Note: Where half-turn-angle construction is indicated, apply a line splaying at the larger of, half-turn-angle, or 15 degrees, relative the outbound track. Where a small angle turn exists and standard construction is suitable for one, but not both splays; connect the uncommon splay, normally primary, to the outbound primary boundary at the same along-track distance as the secondary connection. Maintain or increase primary area as required.

Step 1: Construct a baseline (LL') perpendicular to the inbound track at distance D_{earlyTP} (chapter 5, formula 5-2h) prior to the fix (see chapter 5, figures 5-17 and 5-18).

CASE 1: The outbound segment boundary, or its extension, is beyond the baseline (early-turn connection points are prior to the outbound segment boundary),

Step 1: Construct the inside turn expansion area with a line, drawn at one-half the turn angle from the inbound segment primary early turn connection point, to intercept the outbound segment primary boundary (see chapter 5, figure 5-18).

Step 2 (if required): Construct the inside turn expansion area with a line, drawn at one-half the turn angle, from the inbound segment secondary early turn connection point, to intercept the outbound segment secondary boundary (see chapter 5, figure 5-18).

CASE 2: The outbound segment secondary boundary or its extension is prior to the LL' baseline and outbound segment primary boundary or its extension is beyond the LL' baseline, (early-turn connection points are both **within** the outbound segment secondary area or its extension).

Step 1: Construct the inside-turn expansion area with a line splaying at 15-degree, (relative the outbound track) from the inbound segment secondary early turn connection point to intersect the outbound segment boundary.

Step 1Alt: Where the turn angle exceeds 75 degrees, begin the splay from L'.

Step 2: Construct the primary boundary with a line, drawn at one-half the turn angle, from the inbound segment primary early turn connection point to intercept the outbound segment primary boundary (see chapter 5, figure 5-17).

CASE 3: The outbound segment secondary and primary boundaries, or their extensions, are **prior** to the LL' baseline (primary early-turn connection point, or **both** connection points are **inside** the outbound segment primary area).

Step 1: Construct the inside turn expansion area with a line, splaying at 15-degree (relative the outbound track) from the more conservative point, (L') or (the intersection of LL' and the inbound segment inner primary boundary), to intersect the outbound segment boundaries.

Step 1Alt: Where the turn angle exceeds 75 degrees, begin the splay from L'.

In this case, terminate the inside turn secondary area at the outbound segment primary boundary, since it falls before the early turn points, LL' (see chapter 5, figure 5-18a).

(d) Outside Turn (Fly-By) Construction.

Step 1: Construct the outer primary boundary using a radius of 1/2 primary width (1.5 NM), centered on the plotted fix position, drawn from the inbound segment extended primary boundary until tangent to the outbound segment primary boundary. See chapter 5, figure 5-17.

Step 2: Construct the secondary boundary using a radius of one-half segment width (2 NM), centered on the plotted fix position, drawn from the inbound segment extended outer boundary until tangent to the outbound segment outer boundary (see chapter 5, figures 5-17, 5-18, and 5-18a). Where no inbound secondary exists, use an arc of radius one-half segment width from tangent to the outbound segment secondary boundary to terminate at the inbound segment boundary.

(3) Fly-Over Turn Construction.

(a) Inside Turn (Fly-Over) Construction.

Step 1: Construct the early-turn baseline (LL') at distance ATT prior to the fix, perpendicular to the inbound nominal track.

Step 2: Refer to chapter 5, paragraph 3b(3)(c), (skip **Step 1**).

(b) Outside Turn (Fly-Over) Construction.

Step 1: Construct the late-turn baseline (PP') at distance (ATT + rr) beyond the fix, perpendicular to the inbound nominal track. Calculate late turn distance using chapter 5, formula 5-2j (see chapter 5, figure 5-19).

Formula 5-2j. Late Turn Point Distance (D_{lateTP}).		
$D_{lateTP} = ATT + (rr \cdot \frac{0.3048}{1852})$		
Where:		
ATT = along-track tolerance (NM)		
rr = delay/roll-in formula 2-4a		
ATT + (rr * 0.3048 / 1852)		
Calculator		
ATT (NM)		Click here to calculate
rr (ft)		
D_{lateTP} (NM)		

Step 2: Apply wind spiral outer boundary construction for the first MA fly-over turn. See chapter 5, paragraph 3a(2)(b) for necessary data, using the higher of chapter 5, formula 5-2g output, or the assigned fix crossing altitude for TAS and turn radius calculations and chapter 5, paragraph 5 for wind spiral construction. A non-turn side secondary area may extend into the WS1 area.

(c) Obstacle Evaluations. See chapter 5, paragraph 3b(4)

(4) Section 2 Obstacle Evaluations.

(a) Turn at an Altitude Section 2. Apply the standard MA OCS slope, (or the assigned CG slope) to section 2 obstacles based on the shortest primary area distance (do) from the TIA boundary to the obstacle. Shortest primary area distance is the length of the shortest line kept within primary segments that passes through the early turn baseline of all preceding segments.

Step 1: Measure and apply the OCS along the shortest primary area distance (do) from the TIA boundary to the obstacle (single and multiple segments). See various obstacle measurement examples in chapter 5, figures 5-19 through 5-22.

Step 2: For obstacles located in secondary areas, measure and apply the OCS along the shortest primary area distance (do) from the TIA boundary to the primary boundary abeam the obstacle, then the 4:1 slope along the shortest distance to the obstacle, (taken perpendicular to the nominal track or in expansion areas, to the primary arc, the primary corner-cutter, corner apex, or other appropriate primary boundary). Where an obstacle requires multiple measurements (an obstacle is equidistant from multiple primary boundary points, or lies along perpendiculars from multiple primary boundary points, etc.), apply the more adverse result from each of the combined primary/secondary measurements. See chapter 5, figures 5-19 through 5-22.

(b) Turn at Fix Section 2. Apply an inclined OCS (MA OCS) slope, beginning at SOC at the inbound-segment end OCS height.

Step 1: Measure and apply the OCS along the shortest distance (do) from AB (parallel to track) to LL', the shortest primary distance to the obstacle (single and multiple segments). See chapter 5, figures 5-19 and 5-20, for various obstacle measurement examples.

Step 2: For obstacles located in secondary areas, measure and apply the OCS along the shortest primary area distance (do) from the TIA boundary to the primary boundary abeam the obstacle, then the 4:1 slope along the shortest distance to the obstacle, (taken perpendicular to the nominal track or in expansion areas, to the primary arc, the primary corner-cutter, corner apex, or other appropriate primary boundary). Where an obstacle requires multiple measurements (where an obstacle is equidistant from multiple primary boundary points, or lies along perpendiculars from multiple primary boundary points, etc.), apply the more adverse result from each of the combined primary/secondary measurements (see chapter 5, figure 5-21).

4. Turning Missed Approach (Second Turn).

a. DF/TF Turn (Second Turn, following turn-at-altitude). Turns at the DF path terminator fix will be fly-by or fly-over to a TF leg. In either case, the outer boundary provides fly-over protection, and the inner boundary provides fly-by protection. Maximum turn angle is 90 degrees (applicable to both tracks within the DF segment). This application provides that construction under chapter 2, or this chapter will apply, including cases where the inside and outside turn construction differs.

(1) DF/TF (Fly-By) Turn.

(a) Inside DF/TF (Fly-By) construction.

CASE 1: Full width inside secondary exists at the early turn point (LL').

Step 1: Construct a baseline (LL') perpendicular to the inbound track nearer the turn side boundary at distance D_{earlyTP} (chapter 5, formula 5-2h) prior to the fix.

Step 2: Apply chapter 2 criteria.

CASE 2: Less than full width inside secondary exists at (LL').

Step 1: Apply chapter 5, paragraph 3b(3)(c) criteria.

(b) Outside DF/TF (Fly-By) construction.

CASE 1: Full width outside secondary exists at the early turn point (L'L'').

Step 1: Construct a baseline (L'L'') perpendicular to the inbound track nearer the non-turn side boundary at distance D_{earlyTP} (chapter 5, formula 5-2h) prior to the fix.

Step 2: Apply chapter 2 criteria. See chapter 5, figures 5-21 through 5-22.

CASE 2: Less than full width outside secondary exists at (L'L'').

Step 1: Apply chapter 5, paragraph 3b(3)(d) criteria.

(2) DF/TF (Fly-Over) Turn.

(a) Inside DF/TF (Fly-Over) Turn Construction.

Step 1: Construct a baseline (LL') perpendicular to the inbound track nearer the turn side boundary at distance ATT prior to the fix (see chapter 5, figure 5-22).

Note: Where half-turn-angle construction is specified, apply a line splaying at the larger of half-turn-angle or 15 degrees relative the outbound track.

CASE 1: No inside secondary area exists at LL'.

Step 1: Create the OEA early-turn protection by constructing a line, splaying at the larger of one-half (1/2) the turn angle, or 15 degrees relative the outbound track, from the intersection of LL' and the inbound segment inner primary boundary to connect with the outbound TF segment boundaries.

The TF secondary area begins at the intersection of this diagonal line and the outbound segment boundary.

CASE 2: Partial width inside secondary area exists at LL'.

Step 1: Create the OEA early-turn primary area protection by constructing a line, splaying at the larger of one-half (1/2) the turn angle, or 15 degrees relative the outbound track, from the intersection of LL' and the inbound segment inner primary boundary to connect with the TF segment primary boundary.

Step 2: Create the OEA early-turn secondary protection by constructing a line, splaying at the larger of one-half (1/2) the turn angle, or 15 degrees relative the outbound track,

from the intersection of LL' and the inbound segment inner boundary to connect with the TF segment boundary.

CASE 3: Full width inside secondary area exists at LL'.

Step 1: Apply chapter 2 criteria. See chapter 5, figure 5-21.

(b) Outside DF/TF (Fly-Over) Turn Construction.

Step 1: Construct the late-turn baseline for each inbound track, (PP') for the track nearer the inside turn boundary, and (P'P'') for the outer track at distance (ATT + rr) beyond the fix, perpendicular to the appropriate inbound track. See chapter 5, figure 5-22.

Note: A DF/TF Fly-Over turn is limited to 90 degrees (both inbound tracks) and should require no more than one WS per baseline. Construct the outside track WS (WS1) on base line P'P'', then construct WS2 on baseline PP'.

Step 2: Apply wind spiral construction, see chapter 5, paragraph 3a(2)(b) for necessary data, and chapter 5, paragraph 5 for wind spiral construction. See chapter 5, figure 5-22.

b. TF/TF Turn (Second Turn, following turn-at-fix). Turns at the TF path terminator fix will be fly-by or fly-over to a TF leg. In either case, the outer boundary provides fly-over protection, and the inner boundary provides fly-by protection. Maximum turn angle is 90 degrees. This application provides that construction under chapter 2, or this chapter will apply, including cases where the inside and outside turn construction differs.

(1) TF/TF (Fly-By) Turn.

(a) Inside TF/TF (Fly-By) construction.

Step 1: Apply chapter 2 criteria.

(b) Outside TF/TF (Fly-By) construction.

Step 1: Apply chapter 2 criteria.

(2) TF/TF (Fly-Over) Turn.

(a) Inside TF/TF (Fly-Over) Turn Construction.

Step 1: Apply chapter 2 criteria.

(b) Outside TF/TF (Fly-Over) Turn Construction.

Step 1: Apply chapter 2 criteria.

5. Wind Spiral Cases. Wind Spiral (WS) construction applies to turn-at-an-altitude, turn-at-a-fix (Fly-Over) for the first MA turn, and DF/TF (Fly-Over) for the second turn. The late-turn line P' designator is typically placed where the baselines cross. Where baseline extension is required, mark each baseline inner end with P'. Additional WS examples are available in Order 8260.54.

Each WS has several connection options along its boundary. The chosen connection(s) must provide the more conservative reasonable track and protection areas (see chapter 5, figures 5-23 through 5-25 for examples).

- A 15-degree, (or greater*) splay line to join outbound segment outer boundaries, from:
 - WS/direct-to-fix tangent point
 - WS to WS tangent line origin
 - WS to WS tangent line end
 - WS/outbound segment parallel point (DF segment NA)
- A tangent line to join the next WS (see chapter 5, figure 5-25)
- A tangent line direct to the next fix (DF segment) (see chapter 5, figure 5-24)
- A tangent line, converging at 30 degrees to the segment track (TF segment) (see chapter 5, figure 5-20)

***Note:** See chapter 5, paragraphs 5b(1) and 5b(2) for alternate connection details.

Note: Where multiple WSs exist, a line from the earlier WS splaying at 15 degrees relative the tangent line between WSs may produce the more conservative construction.

Outbound segment type and turn magnitude are primary factors in WS application. Refer to chapter 5, table 5-2 for basic application differences. Calculate rr using chapter 2, formula 2-4a.

Table 5-2. MA First Turn Wind Spiral Application Comparison.		
	Turn At Fix (FO)	Turn At Altitude
WS1 Baseline (PP')	Fix + ATT + rr	TIA + rr
WS2 Baseline (PP')	Fix + ATT + rr	TIA + rr
WS3 Baseline (CD Ext)	NA	TIA + rr
WS Number	1 or 2	1, 2, or 3 *
Final WS Connection (Tangent line)	30° to outbound track	Direct to Fix

* Where a required turn exceeds that served by three wind spirals, consider adding fixes to avoid prohibitively large protection areas resulting from further wind spiral application.

a. Turn-at-Fix (FO) and Turn-at-Altitude WS Comparison. Three cases for outer-boundary wind spirals commonly exist:

- (Case 1), Small angle turns use one wind spiral (WS1);
- (Case 2), Turns near/exceeding 90° ~ use a second wind spiral (WS2); and
- (Case 3), turns near/exceeding 180° ~ use a third wind spiral (WS3).

(1) Turn-at-Altitude WS application concludes with a line tangent to the final WS direct to the next fix.

(2) Turn-at-Fix (FO) WS application concludes with a line tangent to the final WS converging at a 30-degree angle to the outbound segment nominal track. The intersection of this line with the nominal track establishes the earliest maneuvering point for the next fix. The minimum segment length is the greater of:

- The minimum length calculated using the chapter 2 formulas or,
- The distance from previous fix to the intersection of the 30-degree converging outer boundary line extension and the nominal track, (plus DTA). See chapter 5, paragraph 4a.

(3) Second MA Turn DF/TF Turn-at-Fix (FO) WS application concludes with a line tangent to the final WS converging at a 30-degree angle to the outbound segment nominal track. This construction requires two WS baselines, one for each inbound track. Each late turn baseline is located ($ATT + rr$) beyond the fix, oriented perpendicular to the specific track. The baseline for the inbound track nearer the inside turn boundary is designated PP', the baseline associated with the outside turn track is designated P'P'. For convenience P' is often placed at the intersection of the two baselines, but a copy properly goes with each baseline inner end if baseline extensions are required (see chapter 5, figure 5-22).

b. First MA Turn WS Construction. Find late turn point distance ($D_{late TP}$) using chapter 5, formula 5-2j.

(1) CASE 1: Small angle turn using 1 WS.

Step 1: Construct the WS1 baseline, (PP') perpendicular to the straight MA track at the late-turn-point (see chapter 5, table 5-2 for line PP' location). See chapter 5, figures 5-5 and 5-8.

Step 2: Locate the wind spiral center on PP' at distance R (no-wind turn radius, using chapter 5, formula 5-2b; see chapter 5, figure 5-8) from the intersection of PP' and the inbound-segment outer-boundary extension (see chapter 5, figures 5-8 and 5-9).

Step 3: Construct WS1 from this outer boundary point in the direction of turn until tangent to the WS/Segment connecting line from chapter 5, table 5-2 (see chapter 5, figure 5-9).

CASE 1-1: Turn-at-Altitude (WS1 ends when tangent to a line direct to fix).

Step 1: Construct the OEA outer primary and secondary boundary lines parallel to this track (0.5-1.5-1.5-.0.5 segment width). See chapter 5, figure 5-9.

Step 2: Construct a line from the WS1 tangent point, splaying at 15 degrees from the WS1-to-fix track until it intersects the parallel boundary lines or reaches the segment end (see chapter 5, figure 5-9).

Note: Consider 'full-width protection at the fix' to exist where the splay line is tangent to a full-width- radius- circle about the fix.

Step 2Alt: Where **Step 2** construction provides less than full-width protection at the DF fix, construct the OEA outer boundary with a line splaying from the WS1/direct-to-fix tangent point at 15 degrees relative the direct-to-fix line, (or greater where required to provide full-width protection at the DF fix), until it intersects the parallel boundary lines (not later than tangent/tangent-extension to the full width-arc about the fix), and provides full-width protection at or before the DF fix. DF secondary areas begin/exist only where full width primary exists (see chapter 5, figure 5-9).

Note: Where excessive splay (dependent upon various conditions generally in the 35-40 degree range), consider lengthening the segment, restricting the speed, category, etc. to avoid protection and/or construction difficulties.

CASE 1-2: Turn-at-Fix (FO) (WS1 ends when tangent to a 30-degree line converging to nominal track).

Step 1: Construct the OEA outer boundary line using WS1 and the tangent 30-degree converging line until it crosses the outbound segment boundaries (see chapter 5, figure 5-19).

Step 1a: Where WS1 lies within the outbound segment primary boundary, construct the OEA boundary using WS1 and a line (from the point WS1 is parallel to the outbound segment nominal track), splaying at 15 degrees relative the outbound segment nominal track until it intersects the outbound segment boundary lines.

Step 1b: Where WS1 lies within the outbound segment secondary boundary, construct the OEA boundary using WS1 and a line (from the point WS1 is parallel to the outbound segment nominal track), splaying at 15 degrees relative the outbound segment nominal track until it intersects the outbound segment boundary line. Continue WS1 and the tangent 30-degree converging line to establish the inner primary/secondary boundary (see chapter 5, similar figure 5-24).

(2) CASE 2: Larger turn using more than 1 WS. For turns nearing or greater than 90 degrees, WS2 may be necessary. See chapter 5, figure 5-20.

Step 1: To determine WS2 necessity, locate its center on baseline PP', at distance R from the inbound-segment inner-boundary extension.

Step 2: Construct WS2 from this inner boundary point in the direction of turn until tangent to the WS/WS, or WS/Segment connecting line from chapter 5, table 5-2. See chapter 5, figure 5-20.

Step 3: Where WS2 intersects, or is outside WS1 construction, (including the connecting and expansion lines where appropriate), include WS2 in the OEA construction. Otherwise revert to the single WS construction.

Step 3a: Connect WS1 and WS2 with a line tangent to both (see chapter 5, figure 5-20).

Note: The WS1/ WS2 tangent line should parallel a line between the WS center points.

CASE 2-1: Turn-at-Altitude (WS2 ends when tangent to a line direct to fix).

Step 1: Construct the OEA outer primary and secondary boundary lines parallel to this track (0.5-1.5-1.5.0.5 segment width).

Step 2: Construct a line from the WS2 tangent point, splaying at 15 degrees from the WS2-to-fix track until it intersects the parallel boundary lines or reaches the segment end (see chapter 5, figure 5-9).

Note: Consider 'full-width protection at the fix' exists where the splay line is tangent to a full-width- radius- circle about the fix.

Step 2Alt: Where **Step 2** construction provides less than full-width protection at the DF fix, construct the OEA outer boundary with a line splaying from the WS2/direct-to-fix tangent point at 15 degrees relative the direct-to-fix line, (or greater where required to provide full-width protection at the DF fix), until it intersects the parallel boundary lines (not later than tangent/tangent-extension to the full-width-arc about the fix), and provides full-width protection at or before the DF fix. Where the turn angle is ≤ 105 degrees, or the divergence angle between the WS/WS tangent line and the direct-to-fix line is ≤ 15 degrees, apply the splay line from the WS1/WS2 tangent line origin. DF secondary areas begin/exist only where full width primary exists (see chapter 5, figure 5-9).

Note: Where excessive splay exists (dependent upon various conditions but generally greater than 30 degrees), consider using an earlier splay origin point, lengthening the segment, restricting the speed, category, etc. to avoid protection or construction difficulties (see chapter 5, paragraph 5 for origin points).

CASE 2-2: Turn-at-Fix (FO): (WS2 ends when tangent to a 30-degree line converging to nominal track).

Step 1: Construct the OEA outer boundary line using WS2 and the 30-degree converging line until it crosses the outbound segment boundaries (see chapter 5, figure 5-20).

Step 1a: Where WS2 lies within the outbound segment primary boundary, construct the OEA boundary using WS1, WS2, and a line (from the point WS1 or WS2 is parallel to the outbound segment nominal track, the more conservative), splaying at 15 degrees relative the outbound segment nominal track until it intersects the outbound segment boundary lines.

Step 1b: Where WS2 lies within the outbound segment secondary boundary, construct the OEA boundary using WS1, WS2, and a line (from the point WS2 is parallel to the outbound segment nominal track), splaying at 15 degrees relative the outbound segment nominal track until it intersects the outbound segment boundary line. Continue WS2 and the tangent 30-degree converging line to establish the inner primary/secondary boundary.

(3) CASE 3: Larger turn using more than 2 WSs. (Not applicable to Turn-at-Fix due to 90 degree turn limit). For turns nearing or greater than 180 degrees (such as a missed approach to a holding fix at the IF),

Step 1: Construct the WS3 baseline perpendicular to the straight MA track along CD-extended toward the turn side. See chapter 5, figure 5-15.

Step 2: To determine WS3 necessity, locate its center on the WS3 baseline at distance R from point C. See chapter 5, figure 5-15.

Step 3: Construct WS3 from point C in the direction of turn until tangent to the WS/WS, or WS/Segment connecting line from chapter 5, table 5-2. See chapter 5, figure 5-15.

Step 4: Where WS3 intersects, or is outside WS2 construction, include WS3 in the OEA construction. Otherwise revert to the dual WS construction. See chapter 5, figure 5-15.

Step 5: Connect WS2 and WS3 with a line tangent to both. See chapter 5, figure 5-15.

Note: The WS2 & WS3 tangent line should parallel a line between the WS center points.

CASE 3-1: Turn-at-Altitude: (WS3 ends when tangent to a line direct to fix)

Step 1: Construct the OEA outer primary and secondary boundary lines parallel to this track (0.5-1.5-1.5-0.5 segment width). See chapter 5, figure 5-15.

Step 2: Construct a line from the WS3 tangent point, splaying at 15 degrees from the WS3-to-fix track until it intersects the parallel boundary lines or reaches the segment end. See chapter 5, figure 5-15.

(4) Outside Turn Secondary Area. Outbound segment secondary areas following wind spirals begin where either the 30-degree converging line crosses the secondary and primary boundaries from outside the segment, or the 15-degree splay line crosses the primary boundary from inside the segment.

c. Second MA Turn WS Construction (DF/TF FO). To accommodate the two inbound tracks in the DF leg, the second MA turn DF/TF (fly-over) construction uses two WS baselines, PP' and P'P''.

Note: Apply chapter 5, table 5-2 PP' location information for each baseline (formula is identical).

(1) CASE 1: Small angle turn using 1 WS for each inbound DF track.

Step 1: Construct the WS1 baseline, (P'P'') perpendicular to the DF track nearer the outside of the DF/TF turn, at the late-turn-point. See chapter 5, table 5-2 for line PP' location.

Step 1a: Construct the WS2 baseline, (PP') perpendicular to the DF track nearer the inside of the DF/TF turn, at the late-turn-point. See chapter 5, table 5-2 for line PP' location.

Step 2: Locate the WS1 center on P'P'' at distance R (no-wind turn radius, using chapter 5, formula 5-2b; see chapter 5, figure 5-5) from the intersection of P'P'' and the inbound-segment outer-boundary extension.

Step 2a: Locate the WS2 center on PP' at distance R (no-wind turn radius, using chapter 5, formula 5-2b; see chapter 5, figure 5-5) from the intersection of PP' and the inbound-segment inner-boundary extension.

Step 3: Construct WS1 from this outer boundary point in the direction of turn until tangent to the WS/Segment connecting line from chapter 5, table 5-2.

Step 3a: Construct WS2 from this inner boundary point in the direction of turn until tangent to the WS/Segment connecting line from chapter 5, table 5-2.

Step 4: Where WS2 intersects WS1 construction, include WS2 in the OEA construction, and connect WS1 to WS2 with a tangent line. Otherwise revert to the single WS construction.

CASE 1-1: WS1 and/or WS2 lie outside the outbound segment boundary.

Step 1: Construct the OEA outer boundary using WS1 and/or WS2 and the tangent 30-degree converging line until it crosses the outbound segment boundaries. See chapter 5, figure 5-22.

CASE 1-2: WS1 and WS2 lie inside the outbound segment boundary.

Step 1: Where WS1 and/or WS2 lie inside the outbound segment primary boundary, construct the OEA outer boundary using WS1 and/or WS2 and a line (from the point WS1 or WS2 is parallel to the outbound segment nominal track), splaying at 15 degrees relative the outbound segment nominal track until it intersects the outbound segment boundary lines.

Step 1a: Where WS1 and/or WS2 lie inside the outbound segment secondary boundary, construct the OEA outer boundary using WS1 and/or WS2 and a line (from the point WS1 or WS2 is parallel to the outbound segment nominal track), splaying at 15 degrees relative the outbound segment nominal track until it intersects the outbound segment boundary line. Continue the final WS and 30 degrees converging line to establish the primary/secondary boundary.

6. Missed Approach Climb Gradient. Where the MA standard OCS is penetrated and a CG is required, specify a missed approach CG to clear the penetrating obstruction. MA starting ROC is 100 ft (plus adjustments). ROC increases at 96 ft/NM, measured parallel to the MA track to TIA end (Turn-at-Altitude), or early-turn point (Turn-at-Fix), then shortest primary distance to the next fix. Apply fix-to-fix distance for subsequent segments. Where a part-time altimeter is in use, consider the helicopter SOC altitude to be the MDA associated with the local altimeter (ensures adequate CG is applied).

Step 1: Calculate the ROC, the altitude at which the ROC for the obstacle is achieved, and the required CG (ft/NM) using chapter 5, formula 5-13.

Step 2: Apply the CG to:

- The altitude which provides appropriate ROC, or
- The point/altitude where the subsequent MA OCS clears all obstacles.

Step 2a: Where a RASS adjustment is applicable for climb-to-altitude operations (prior to turn, terminate CG, etc.), apply the CG associated with the lower MDA (chapter 5, formula 5-3). Where there is a local altimeter, to establish the RASS-based climb-to-altitude, add the difference between the local altimeter-based MDA and the RASS-based MDA to the climb-to-altitude and round to the next higher 100-ft increment (see Order 8260.3, Volume 1, chapter 3 for further details).

Formula 5-3. ROC/CG/Minimum Altitude/OCS.		
STEP 1	<p style="text-align: center;">$ROC_{obs} = ROC_{start} + 96 \cdot d$</p> <p>Where: ROC_{start} = SOC ROC (100 ft for NVGP) d = distance (NM) CG origin (SOC) to obstacle</p>	
$ROC_{start} + 96 \cdot d$		
STEP 2	<p style="text-align: center;">$Alt_{min} = O_{elev} + ROC_{obs}$</p> <p>Where: ROC_{obs} = Step 1 result O_{elev} = Obstacle Elevation (MSL)</p>	
$O_{elev} + ROC_{obs}$		
STEP 3	<p style="text-align: center;">$CG = \frac{r}{d} \cdot \ln \left(\frac{(r + Alt_{min})}{(r + Copter_{SOC})} \right)$</p> <p>Where: Alt_{min} = Step 2 result $Copter_{SOC}$ = Helicopter altitude (MSL) at CG origin d = distance (NM), CG origin (SOC) to obstacle</p>	
$r/d \cdot \ln((r + ALT_{min}) / (r + Copter_{SOC}))$

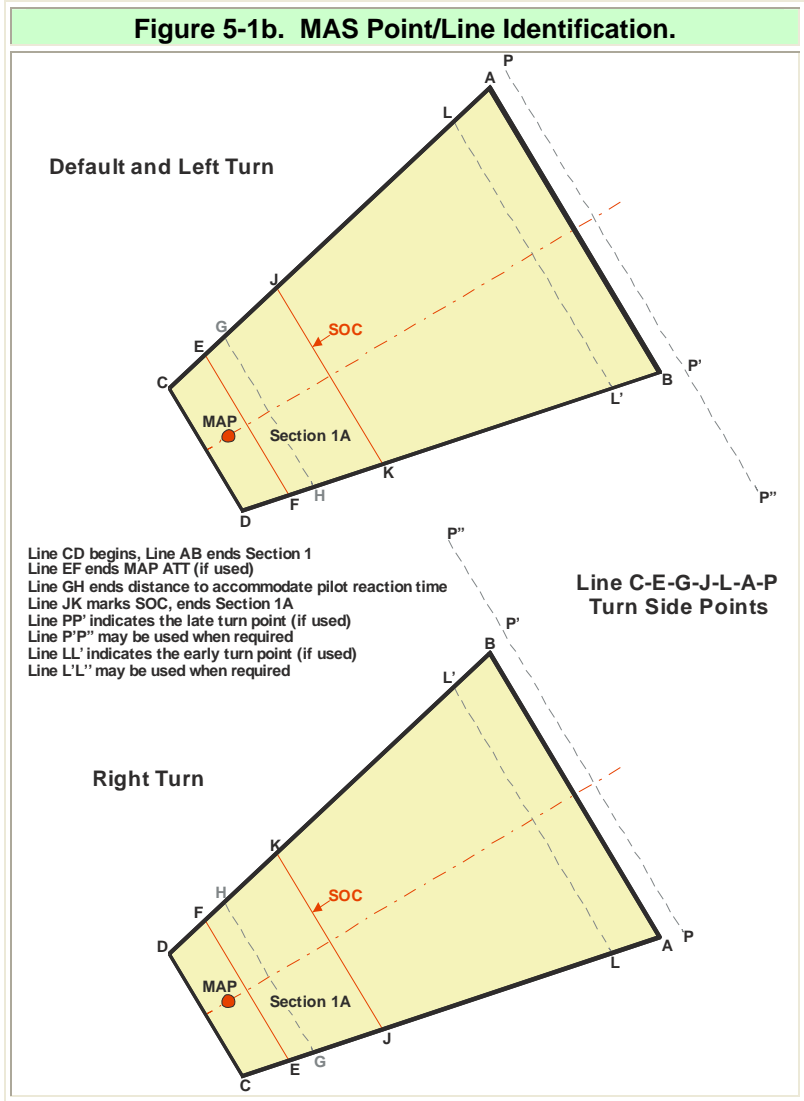

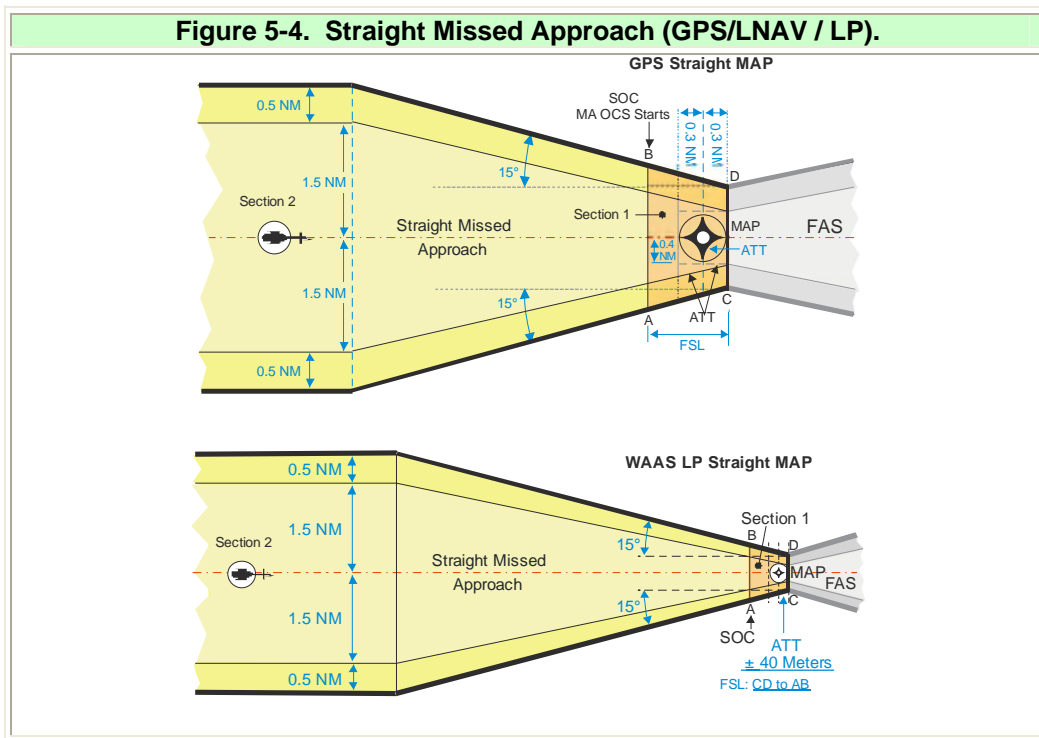

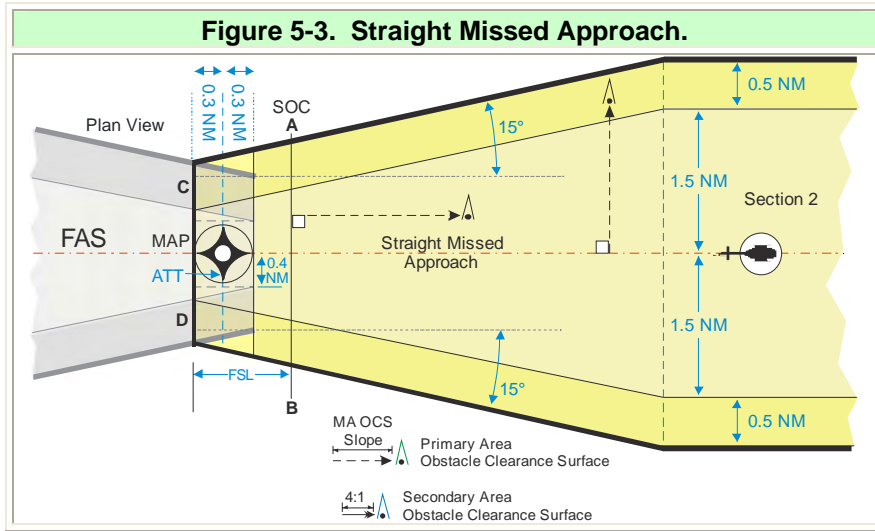

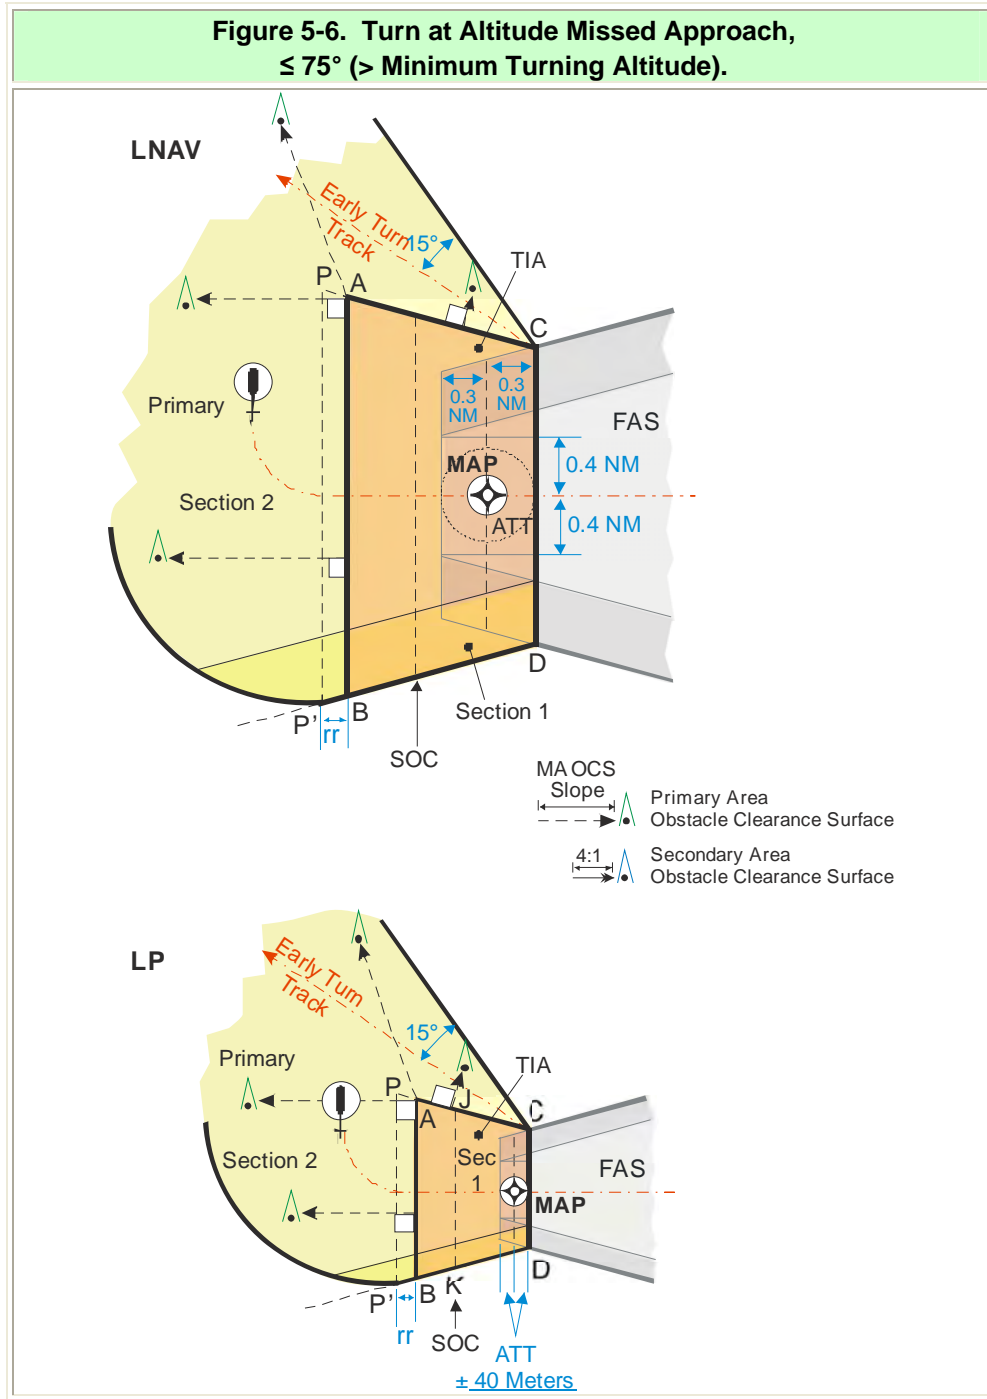

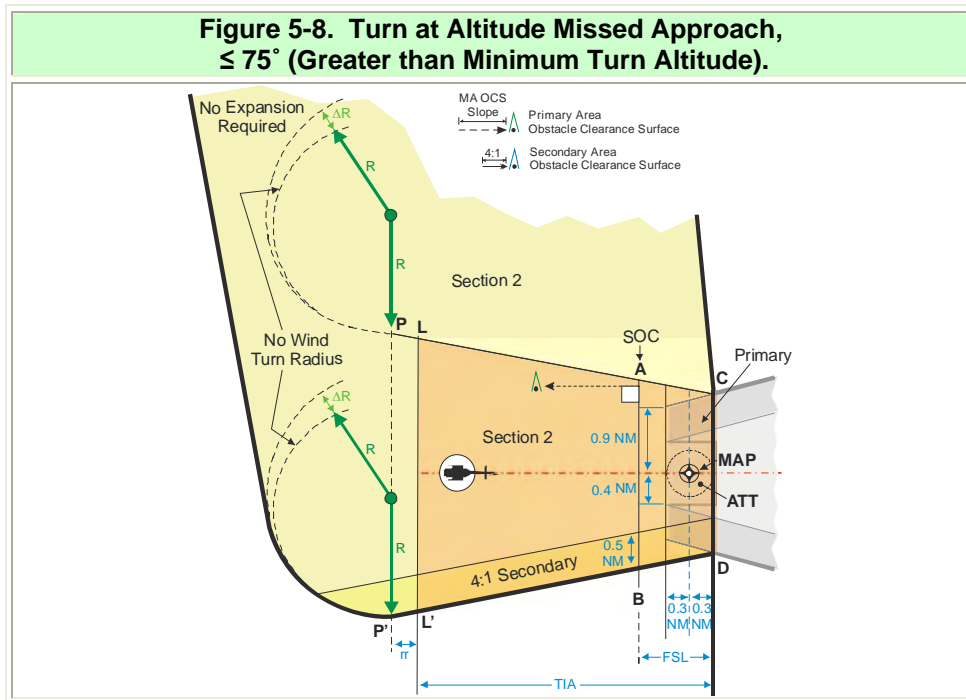

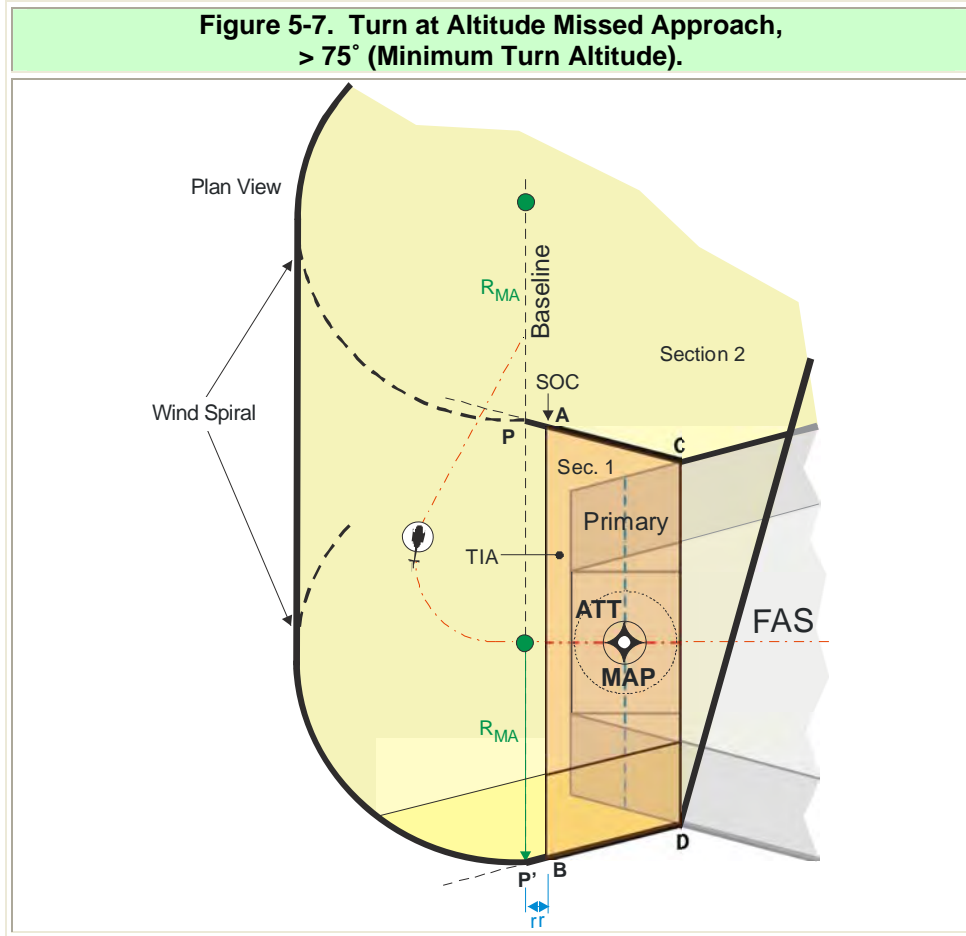

Figure 5-2. Missed Approach Section 1.

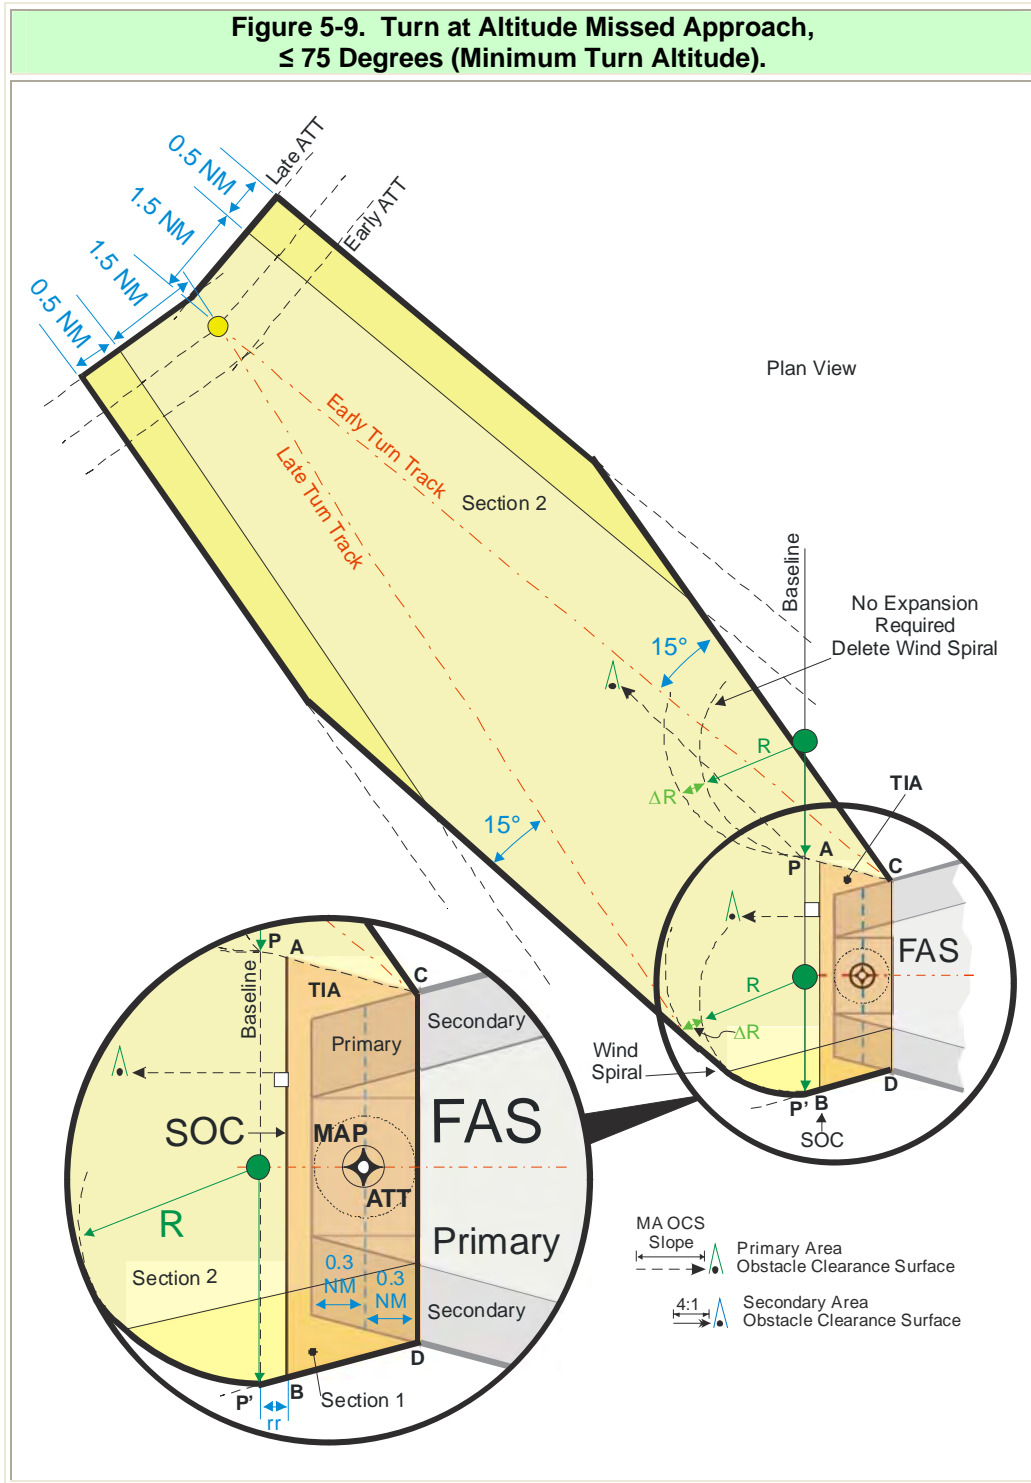

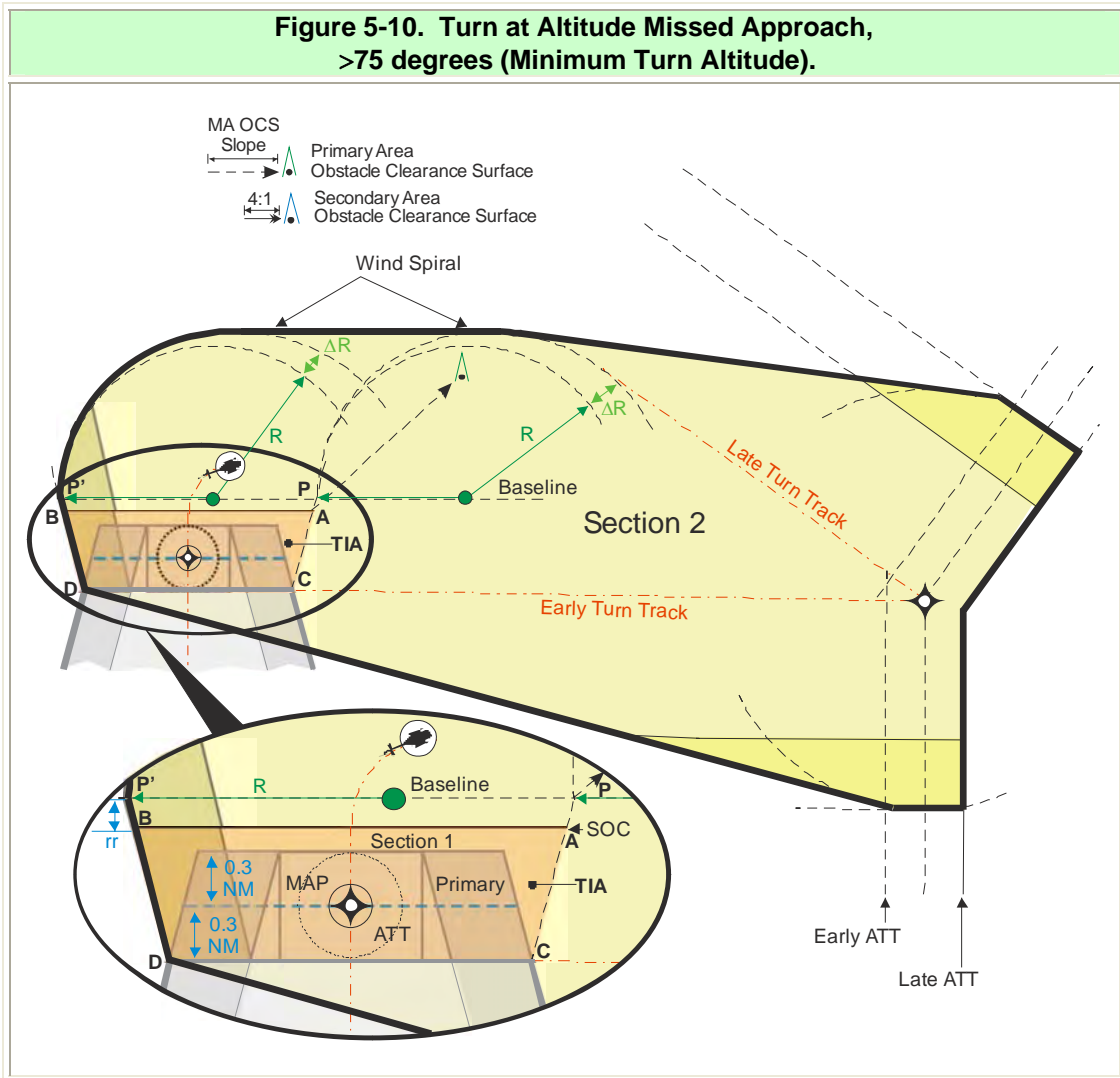

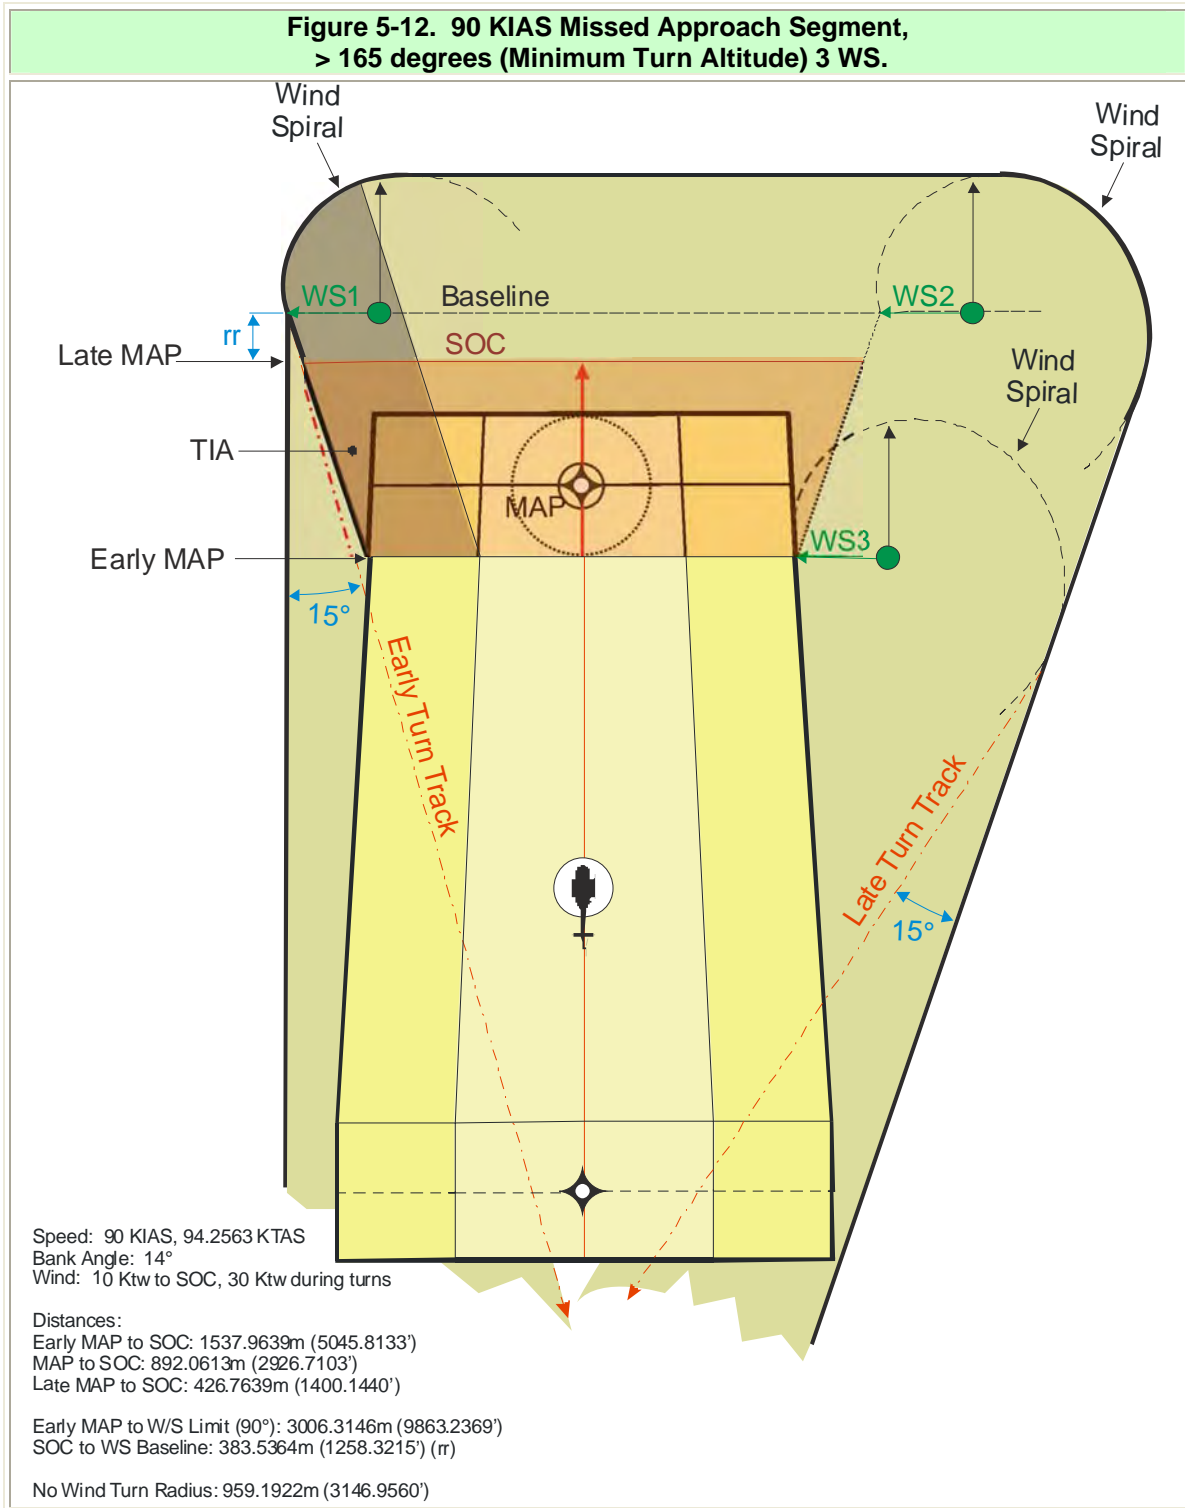

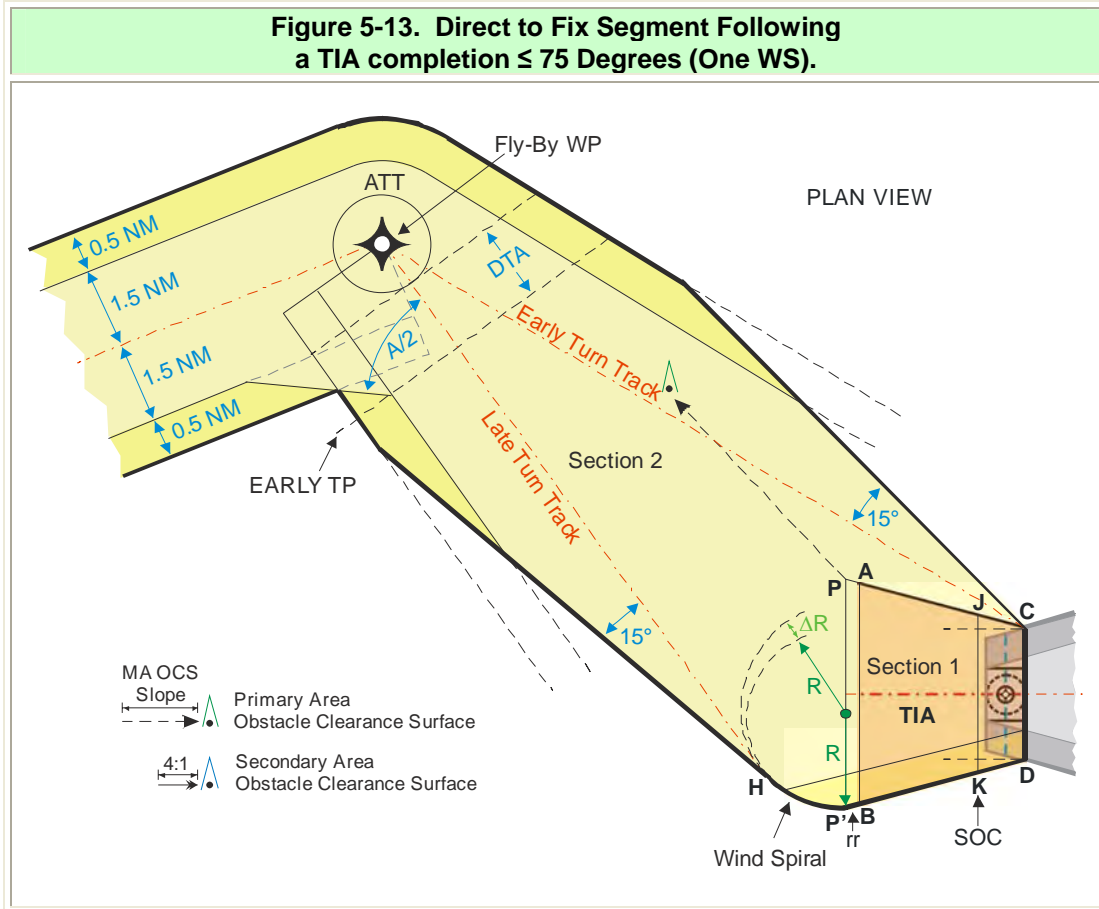

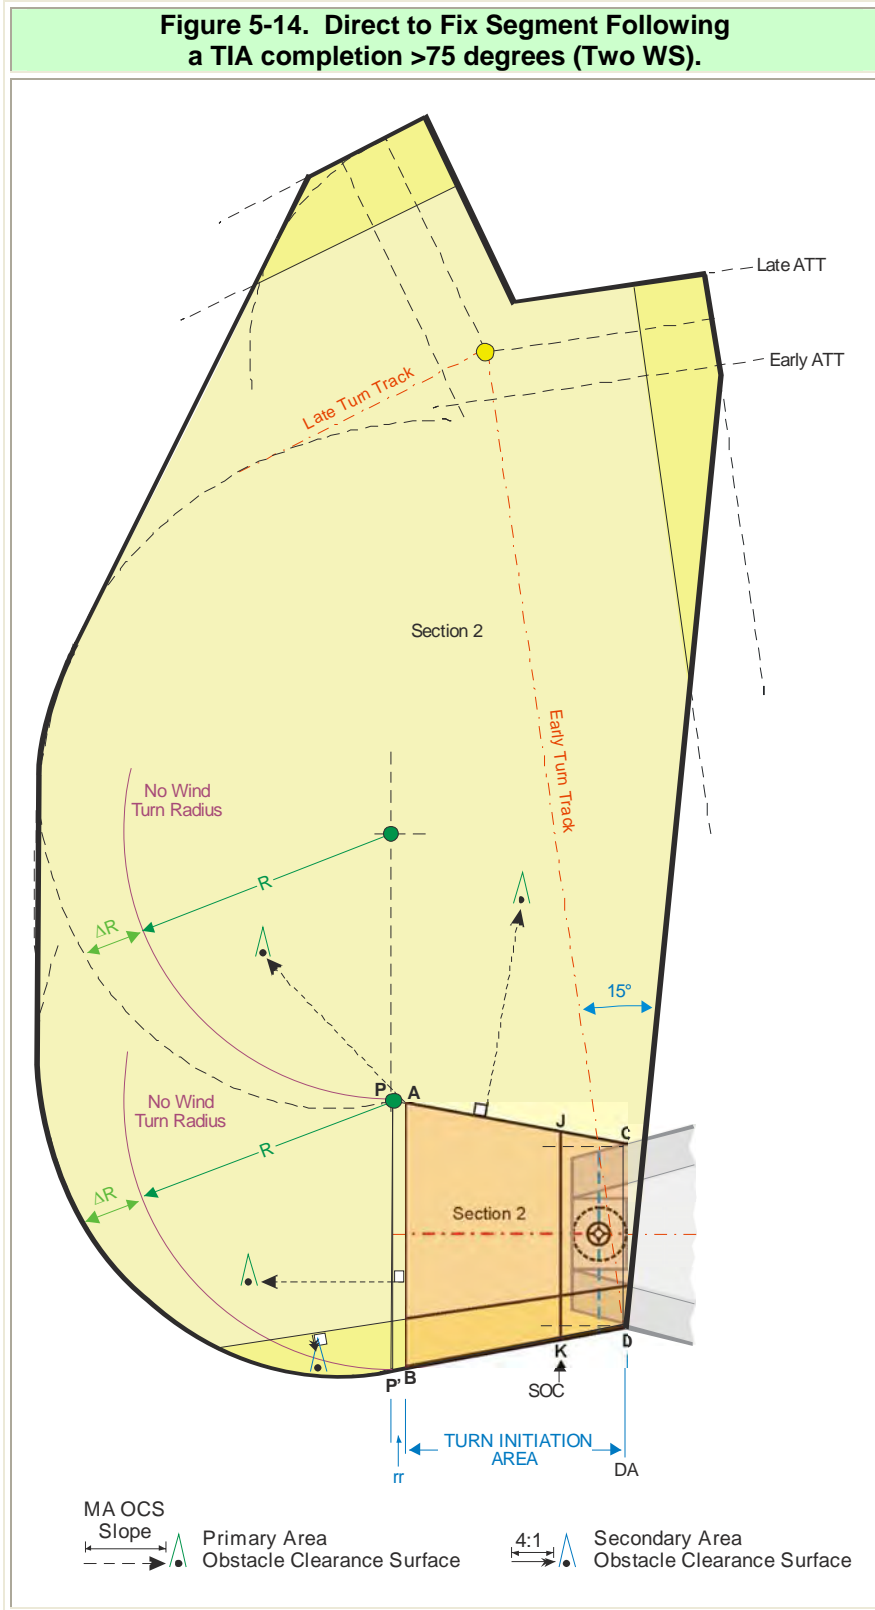

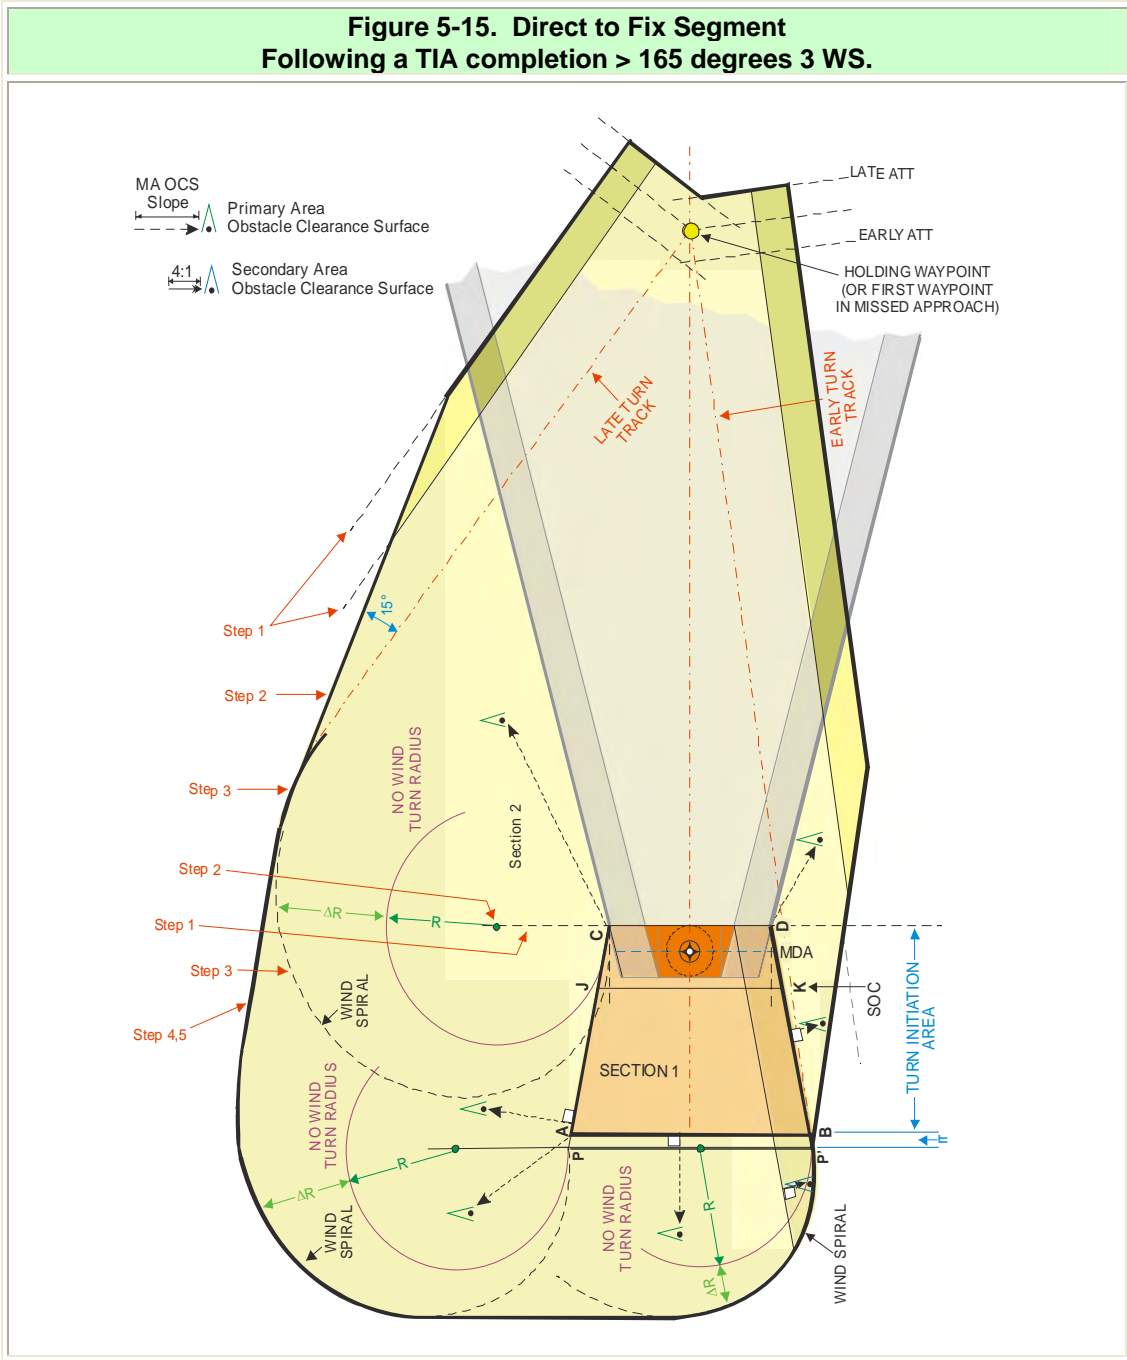

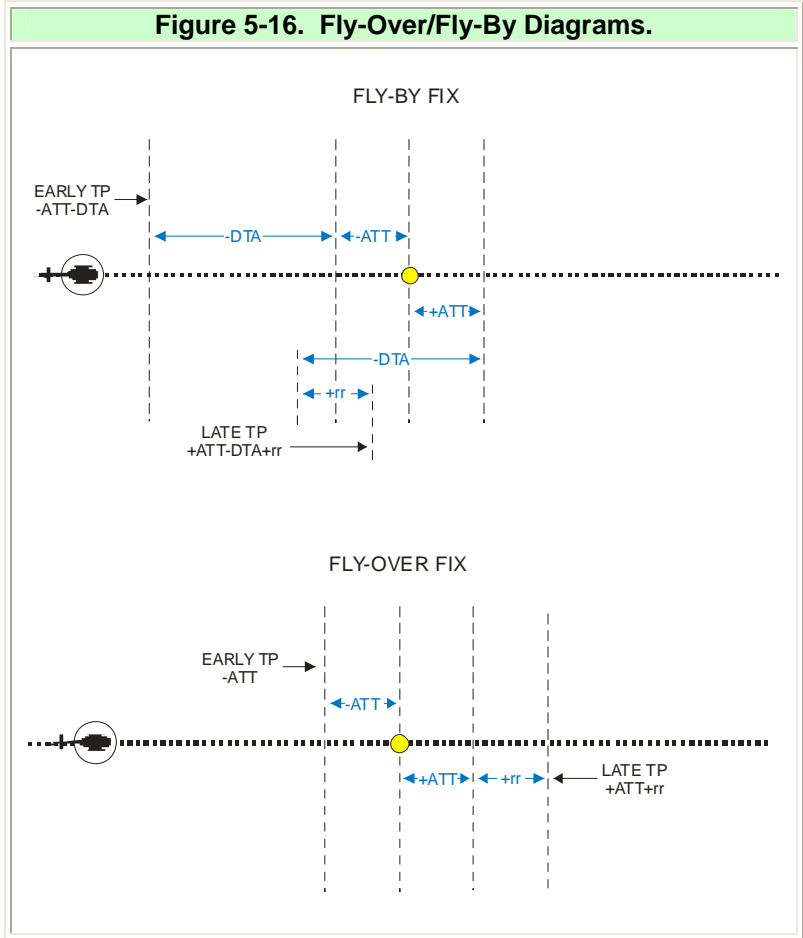

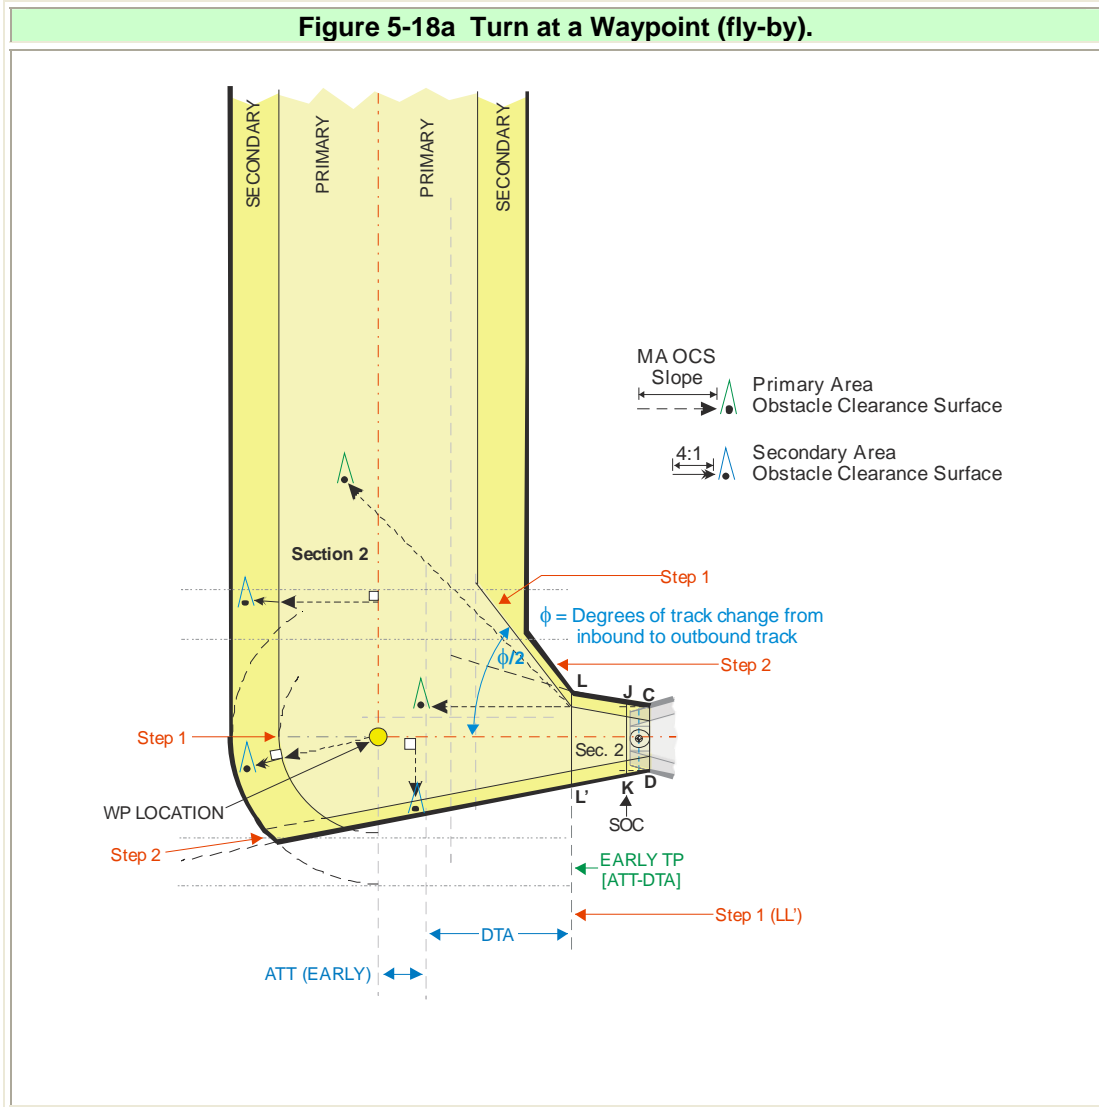

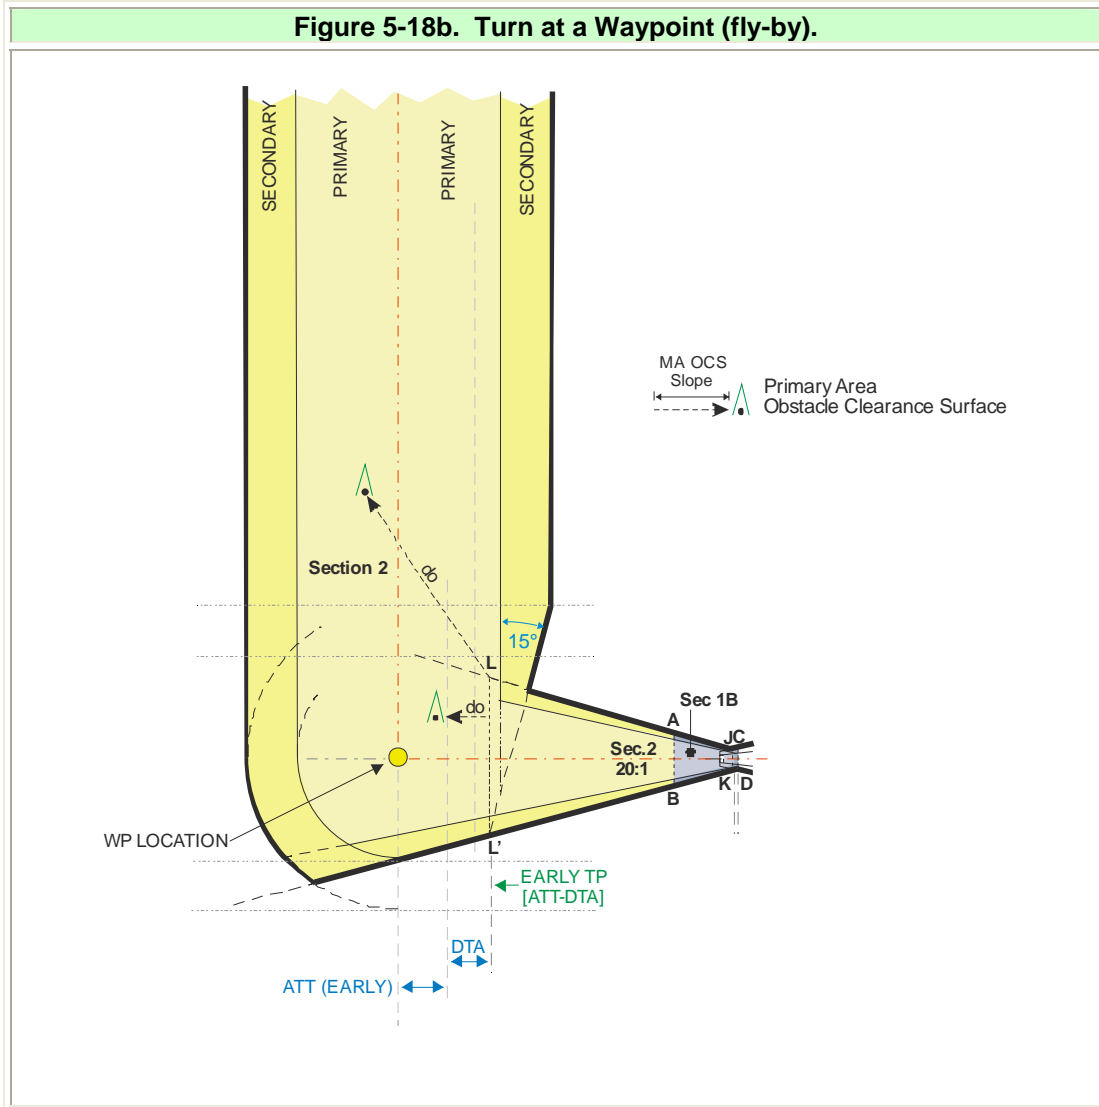

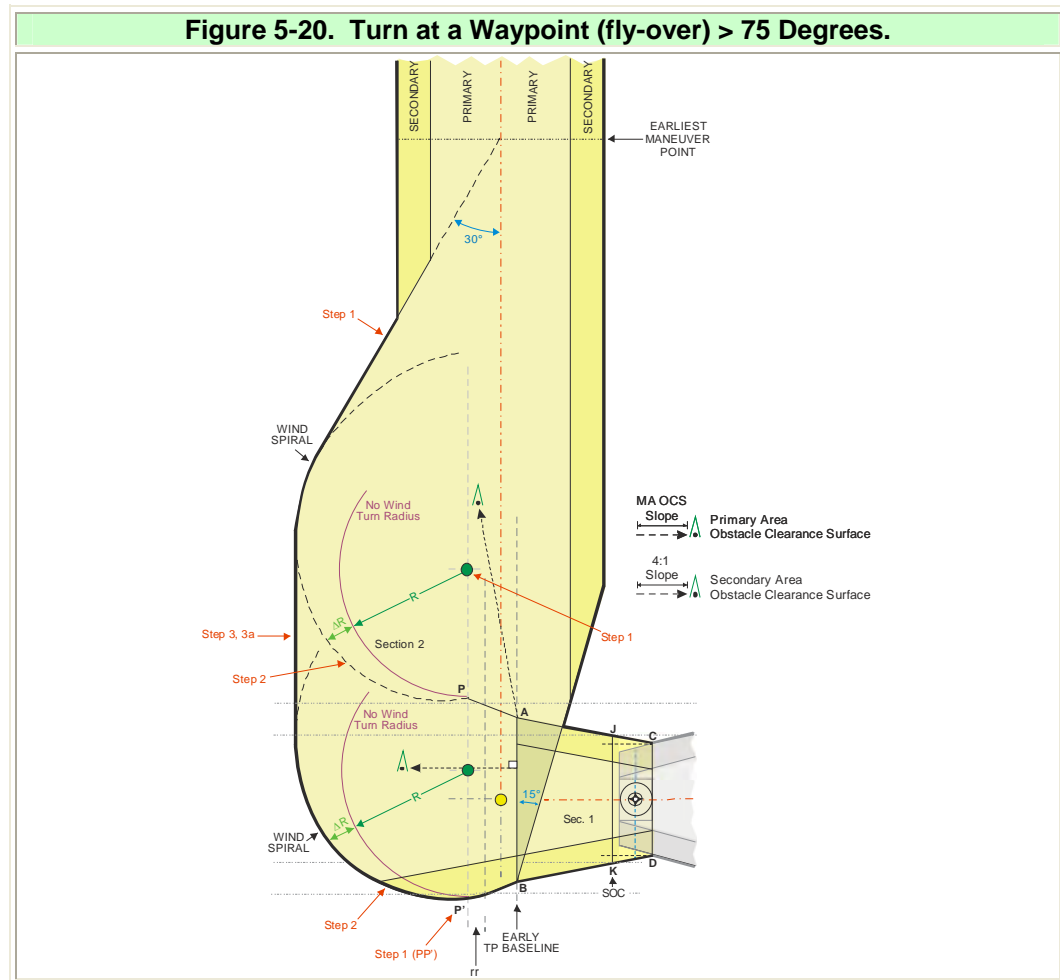

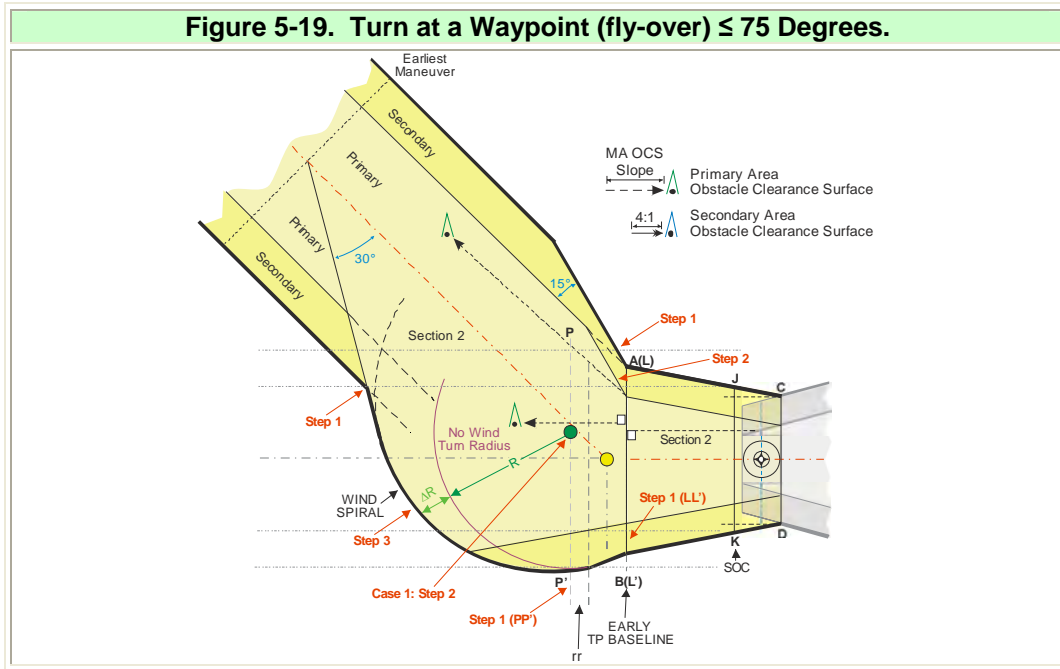

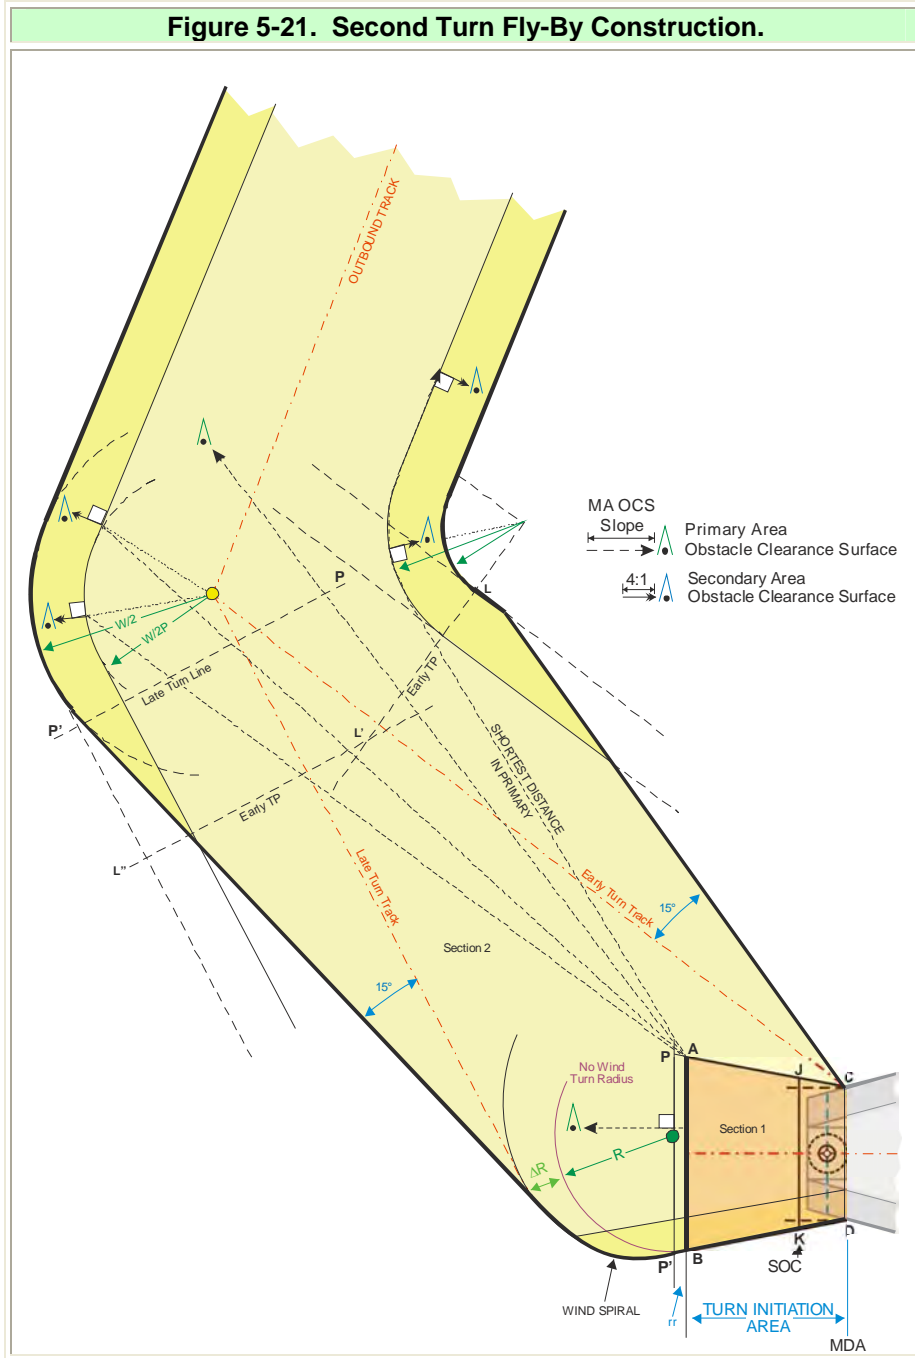

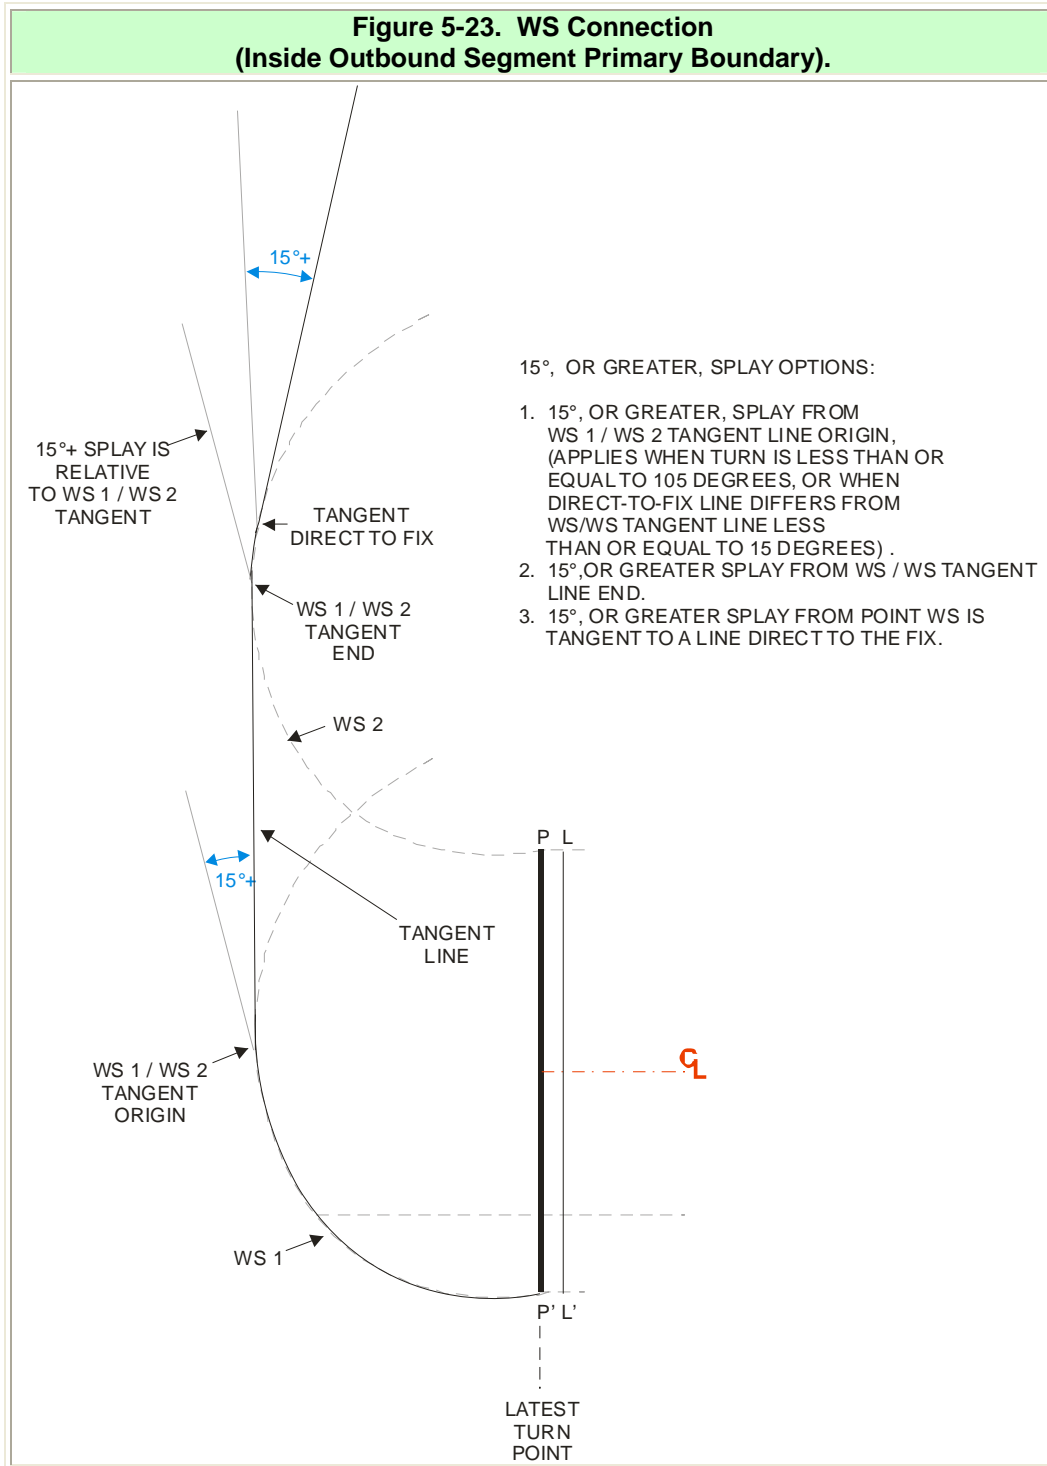

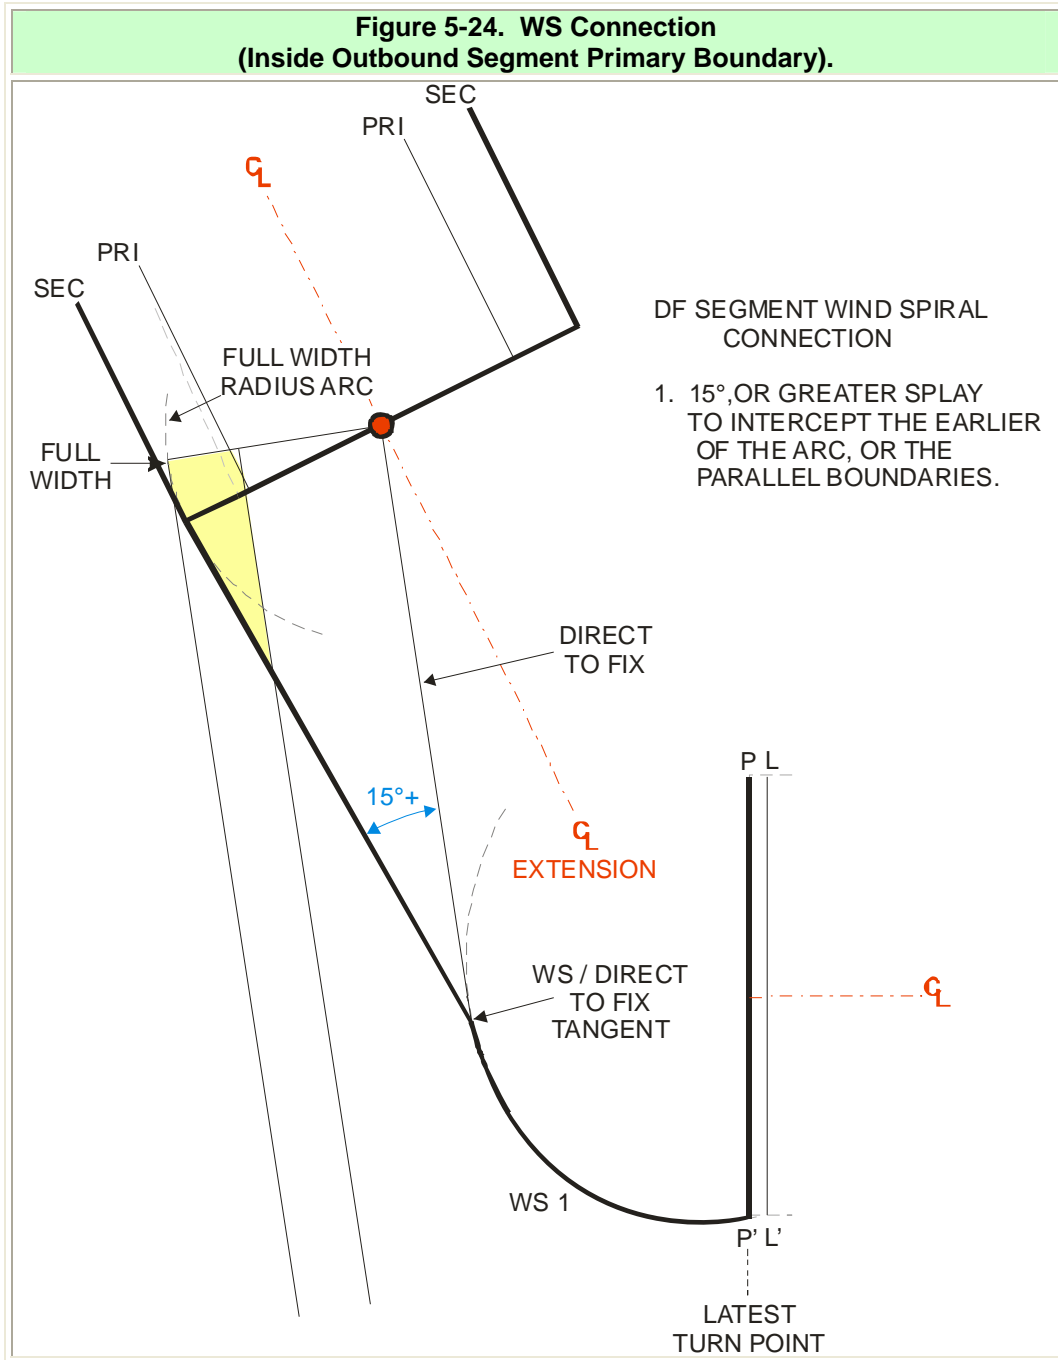

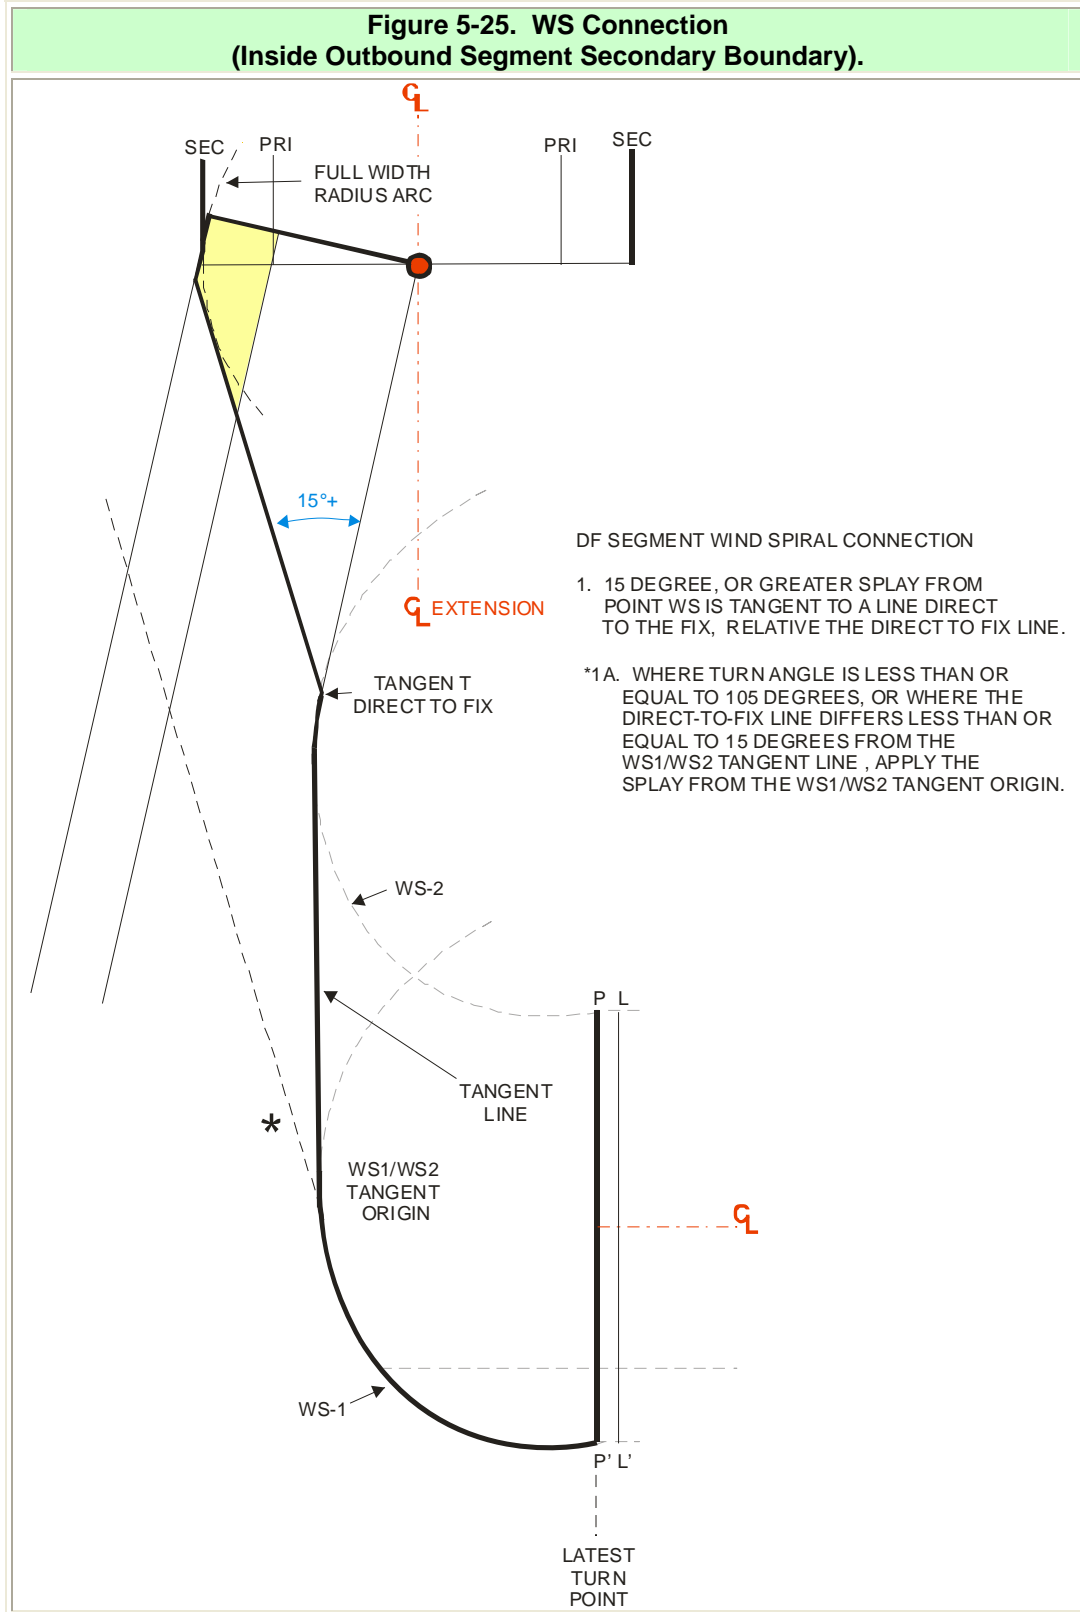

Chapter 6. Departure Criteria Special Procedures - RESERVED

Chapter 7. Minimums for Helicopter Nonprecision RNAV and WAAS Approaches

1. Application. Minimums specified for Category “A” aircraft in Order 8260.3, Volume 1, chapter 3, apply to helicopter RNAV procedures, except as follows: For helicopter procedures to heliports or heliports, substitute “heliport elevation” for “airport elevation” and “height above threshold (HATh)” for “heliport crossing height (HCH).”

a. Altitudes for IFR Approaches to IFR Heliports. Heliport minimums are referenced to the heliport elevation (HE).

b. Visibilities for IFR Approaches to IFR Heliports and Runways.

(1) Approaches to Lighted Heliports with a Heliport Approach Lighting System (HALS). Apply Order 8260.37, table 3. Apply Order 8260.3, Volume 1, chapter 3, table 3-5b for DoD helicopters.

(2) Approaches to Runways. Apply Order 8260.3, Volume 1, chapter 3, table 3-6 for civilian helicopters. The minimum visibility may be $\frac{1}{2}$ the computed values in table 3-6 but not less than $\frac{1}{4}$ sm/1.200 RVR. Apply Order 8260.3, Volume 1, chapter 3, table 3-5b for DoD helicopters.

Note 1: For all procedures where obstacles penetrate Order 8260.3, Volume 1, chapter 3, paragraph 3.3.2 visual surfaces, visibility credit for approach lighting systems must not reduce visibility to values less than the values specified by paragraph 3.3.2 ($\frac{3}{4}$ or 1 SM as appropriate).

Note 2: For USA, when analyzing the visual position of the final approach segment and a penalty is encountered when applying the basic criteria in Order 8260.3, Volume 1, paragraph 3.3.2, apply 20:1 vice 34:1 and 10:1 vice 20:1.

c. IFR to a VFR Heliport (IVH) IFR to a VFR Runway (IVR). (Proceed Visually). The **minimum** visibility is $\frac{3}{4}$ SM. If the height above surface (HAS) exceeds 800 ft, the **minimum** visibility is 1 SM. The **minimum** visibility must not be less than the distance from the plotted position of the MAP to the heliport. Nighttime Operations must be flight inspected and approved (see appendix A).

d. PinS Approach (Proceed VFR). The **minimum** visibility is $\frac{3}{4}$ SM. If the height above surface (HAS) exceeds 800 ft, the **minimum** visibility is 1 SM.

Appendix A. Conditions and Assumptions for IFR to VFR Heliport (IVH) (Proceed Visually) Approach Procedures

Before designing a special RNAV (GPS) IFR to a VFR heliport (IVH) approach procedure, ensure the heliport meets the following criteria:

1. **FAA Form 7480-1, Notice of Landing Area Proposal**, has been filed under Part 157.
2. **No penetration of the 8:1 surface in AC 150/5390-2 is permitted (see figure A-1).** Penetrations of either A or B areas but not penetrations of both areas are allowed if the obstructions are charted, and marked or lighted and if not considered a hazard. Use formula A-1 to determine height of the 8:1 surface.

Formula A-1. 8:1 OCS height (S_H).

$$S_H = (r + HE) \cdot e^{\frac{D}{8r}} - r$$

Where:
 D = C/L distance FATO edge to Obstacle
 HE = Heliport Elevation

$$(r + HE) \cdot e^{\frac{D}{(8 \cdot r)}} - r$$

Calculator

D (ft)		Click here to calculate
HE		
S _H		

3. **An acceptable onsite evaluation of the heliport for VFR use is required.** Order 8700.1, General Aviation Inspector’s Guide, chapter 61 is to be used for evaluation of the heliport. Based on the FAA determination, a procedure can be developed under the following conditions:

- a. **No objection.**

b. Conditional. Conditions have been resolved by the proponent, e.g., obstacle penetrations of the 8:1 approach area, transitional and lateral extension areas, or pertain to the minimum size of the FATO, TLOF, and Safety Area.

c. Objection. If an objection determination is issued, an IVH approach procedure is not authorized to be developed. A Point-in-Space (PinS) (Proceed VFR) approach procedure may be developed in accordance with chapter 5, paragraph 7.

4. An acceptable evaluation of the visual segment for flyability, obstacles, and visual references must be completed in both day and night flight conditions. The heliport or heliport visual references must be in clear view at the MAP, e.g., it cannot be completely obscured behind a building. A heliport is the area of land, water or a structure used or intended to be used for the landing and takeoff of helicopters, together with appurtenant buildings and facilities. Buildings and facilities associated with the heliport such as hangars, administration buildings, AWOS equipment, windsock, beacon, etc. located within 500 ft are acceptable visual references. Surrounding buildings and land marks are not allowable visual references, unless approved by Flight Standards. At least one of the following visual references must be visible or identifiable before the pilot may proceed visually:

- a. FATO or FATO lights.
- b. TLOF or TLOF lights.
- c. Heliport Instrument Lighting System (HILS).
- d. Heliport Approach Lighting System (HALS) or lead-in lights.
- e. Visual Glideslope Indicator (VGSI).
- f. Windsock or windsock light(s).*
- g. Heliport beacon.*
- h. Other facilities or systems approved by Flight Standards (AFS-400).

***Note:** Windsock lights and heliport beacons should be located within 500 ft of the TLOF.

5. IFR Approach to a VFR Heliport (IVH) Analysis. The following analysis must be performed for authorizing an IVH procedure. Obstacle clearance surface (OCS) areas are applied using concepts from Order 8260.3, Volume 1, chapter 2, paragraph 251a (1) with the following exceptions:

- a. **Alignment is always** centered on the visual segment centerline.

b. Length OCS-1 and OCS-2. The length of OCS-1 and OCS-2 begin from the edge of the FATO and extend to abeam the earliest point the MAP can be received (see figure A-2).

c. Area Width OCS-1 and OCS-2. OCS-1 splays outward 8.5 degrees from the outer edges of the FATO. OCS-2 splays outward 17 degrees from the outer edges of the FATO (see figure A-2).

Step 1: Calculate OCS-1 width (W_{OCS-1}) at distance (d) from the FATO edge using the formula A-2.

Formula A-2. OCS-1 Width (W_{OCS-1})		
$W_{OCS-1} = \left[\tan \left(8.5^\circ \cdot \frac{\pi}{180} \right) \cdot d \right] + .5 \cdot F_W$		
Where: W_{OCS-1} = Perpendicular distance from the flight path to the edge of the OCS-1 d = Distance (ft) from the FATO edge measured along the flight path F_W = FATO width		
$[(\tan(8.5 \cdot \pi/180) \cdot d)] + 0.5 \cdot F_W$		
Calculator		
d		Click here to calculate
F_W		
W_{OCS-1}		

Step 2: Calculate the OCS-2 width (W_{OCS-2}) at distance (d) from the FATO edge using the formula A-3.

Formula A-3. OCS-2 Width (W_{OCS-2})		
$W_{OCS-2} = \left[\tan \left(17^\circ \cdot \frac{\pi}{180} \right) \cdot d \right] + .5 \cdot F_W$		
Where: W_{OCS-2} = Perpendicular distance from the flight path to the edge of the OCS-2 d = Distance (ft) from the FATO edge measured along the flight path F_W = FATO width		
$[(\tan(17 \cdot \pi/180) \cdot d)] + 0.5 \cdot F_W$		
Calculator		
d		Click here to calculate
F_W		
W_{OCS-2}		

The slope of OCS-1 and OCS-2 is equal to the visual segment descent angle (VSDA) minus 1 degree measured from the FATO edge MSL elevation. Use formula A-4 to determine the MSL height of OCS-1 and OCS-2 at distance (D) from the FATO edge:

Formula A-4. OCS-1 and OCS-2 Slope (H _{OCS})		
$H_{OCS} = (r + HE) \cdot e^{\frac{D[\tan((VSDA-1)\frac{\pi}{180})]}{r} - r}$		
Where:		
VSDA - 1 = (VSDA minus 1 degree)		
H _{OCS} = OCS-1 and OCS-2 MSL height		
D = Distance (ft), FATO edge to obstacle		
HE = Heliport/FATO edge elevation (MSL)		
$(r + HE) \cdot e^{(D \cdot [\tan((VSDA-1) \cdot \pi / 180)] / r) - r}$		
Calculator		
D		Click here to calculate
VSDA		
HE		
H _{OCS}		

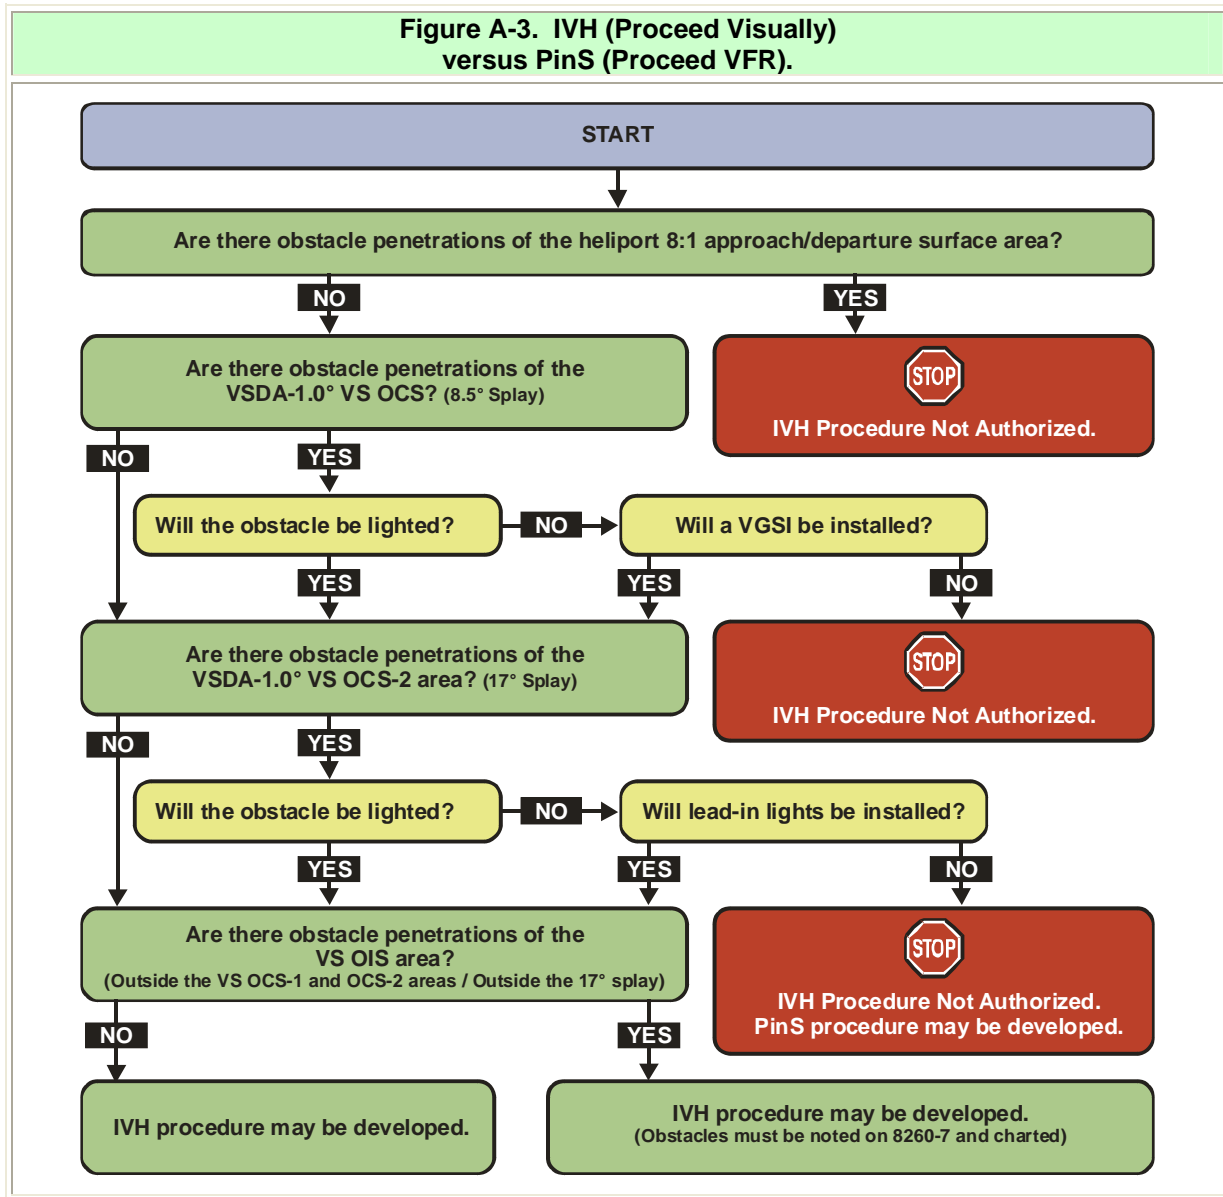

d. If an unlighted obstacle penetrates OCS-1, a VGSI is required to be installed at the heliport.

e. If an unlighted obstacle penetration is outside of OCS-1 but within OCS-2, the heliport must have lead-in lights to provide the pilot the visual cues to remain within the IVH OCS area.

f. The operational suitability of the lead in lights must be evaluated in accordance with appendix A, paragraph 4, during the night evaluation.

g. If there are obstacle penetrations outside of the OCS-1 and OCS-2 areas but within the OIS area (see chapter 5, paragraph 5, these obstacle penetrations must be noted on 8260-7 and charted.

6. If any of these conditions are not met, a PinS (Proceed VFR) procedure may be developed in accordance with chapter 5, paragraph 7 (see figure A-3).

Appendix 2. TERPS Standard Formulas for Geodetic Calculations

1.0 Purpose.

The ellipsoidal formulas contained in this document must be used in determining RNAV flight path (GPS, RNP, WAAS, LAAS) fixes, courses, and distance between fixes.

Notes:

Algorithms and methods are described for calculating geodetic locations (latitudes and longitudes) on the World Geodetic System of 1984 (WGS-84) ellipsoid, resulting from intersections of geodesic and non-geodesic paths. These algorithms utilize existing distance and azimuth calculation methods to compute intersections and tangent points needed for area navigation procedure construction. The methods apply corrections to an initial spherical approximation until the error is less than the maximum allowable error, as specified by the user.

Several constants are required for ellipsoidal calculations. First, the ellipsoidal parameters must be specified. For the WGS-84 ellipsoid, these are:

$$\begin{aligned} a &= \text{semi-major axis} = 6,378,137.0 \text{ m} \\ b &= \text{semi-minor axis} = 6,356,752.314245 \text{ m} \\ 1/f &= \text{inverse flattening} = 298.257223563 \end{aligned}$$

Note that the semi-major axis is derived from the semi-minor axis and flattening parameters using the relation $b = a(1 - f)$.

Second, an earth radius is needed for spherical approximations. The appropriate radius is the geometric mean of the WGS-84 semi-major and semi-minor axes. This gives

$$SPHERE_RADIUS (r) = \sqrt{ab} = 6,367,435.679716 \text{ m}.$$

Perform calculations with at least 15 significant digits.

For the purpose of determining geodetic positions, perform sufficient iterations to converge within 1 cm in distance and 0.002 arc seconds in bearing.

2.0 Introduction.

The algorithms needed to calculate geodetic positions on the earth for the purpose of constructing and analyzing Terminal Instrument Procedures (TERPS) require the following geodetic calculation process some of which are illustrated in figure B-1:

- Process 1: Find the destination latitude and longitude, given starting latitude and longitude as well as distance and starting azimuth (often referred to as the “direct” or “forward” calculation).
- Process 2: Compute the geodesic arc length between two points, along with the azimuth of the geodesic at either point (often referred to as the “inverse” calculation).
- Process 3: Given a point on a geodesic, find a second geodesic that is perpendicular to the given geodesic at that point.
- Process 4: Given two geodesics, find their intersection point. (Labeled “4”)
- Process 5: Given two constant-radius arcs, find their intersection point(s). (Labeled “5”)
- Process 6: Given a geodesic and a separate point, find the point on the geodesic nearest the given point. (Labeled “6”)
- Process 7: Given a geodesic and an arc, find their intersection point(s). (Labeled “7”)
- Process 8: Given two geodesics and a radius value, find the arc of the given radius that is tangent to both geodesics and the points where tangency occurs. (Labeled “8”)
- Process 9: Given an arc and a point, determine the geodesic(s) tangent to the arc through the point and the point(s) where tangency occurs. (Labeled “9”)
- Process 10: Given an arc and a geodesic, determine the geodesic(s) that are tangent to the arc and perpendicular to the given geodesic and the point(s) where tangency occurs. (Labeled “10”)
- Process 11: Compute the length of an arc.
- Process 12: Determine whether a given point lies on a particular geodesic.
- Process 13: Determine whether a given point lies on a particular arc.
- The following algorithms have been identified as required for analysis of TERPS procedures that use locus of points curves:
- Process 14: Given a geodesic and a locus, find their intersection point.

Process 15: Given a fixed-radius arc and a locus, find their intersection point(s). (Labeled “15”)

Process 16: Given two loci, find their intersection.

Process 17: Given two loci and a radius, find the center of the arc tangent to both loci and the points of tangency. (Labeled “17”)

The algorithm prototypes and parameter descriptions are given below using a C-like syntax. However, the algorithm steps are described in pseudo-code to maintain clarity and readability.

Numbers refer to the algorithm in the list above that would be used to solve for the point.

2.1 Data Structures.

2.1.1 Geodetic Locations.

For convenience, one structure is used for both components of a geodetic coordinate. This is referred to as an `LLPoint`, which is declared as follows using C syntax:

```
typedef struct {
    latitude;
    longitude;
} LLPoint;
```

2.1.2 Geodesic Curves.

A geodesic curve is the minimal-length curve connecting two geodetic locations. Since the planar geodesic is a straight line, we will often informally refer to a geodesic as a “line.” Geodesics will be represented in data using two LLPoint structures.

2.1.3 Fixed Radius Arc.

A geodetic arc can be defined by a center point and radius distance. The circular arc is then the set (or locus) of points whose distance from the center point is equal to the radius. If an arc subtends an angle of less than 360 degrees, then its start azimuth, end azimuth, and orientation must be specified. The orientation is represented using a value of ± 1 , with +1 representing a counterclockwise arc and -1 representing a clockwise arc. The distance between the start and end points must be checked. If it is less than a predetermined tolerance value, then the arc will be treated like a complete circle.

2.1.4 Locus of Points Relative to a Geodesic.

A locus of points relative to a geodesic is the set of all points such that the perpendicular distance from the geodesic is defined by a continuous function $w(P)$ which maps each point P on the geodesic to a real number. For the purposes of procedure design, $w(P)$ will be either a constant value or a linear function of the distance from P to geodesic start point. In the algorithms that follow, a locus of points is represented using the following C structure:

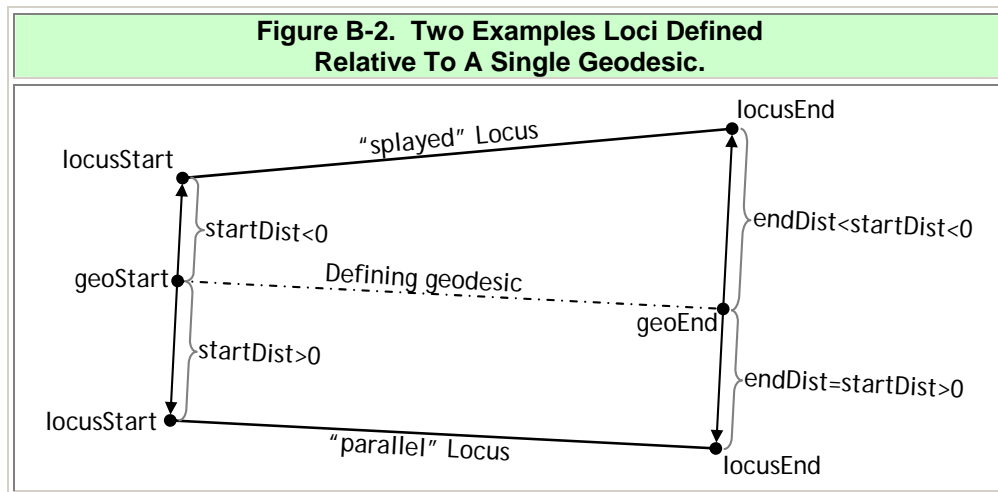

```
typedef struct {
    LLPoint geoStart; /* start point of geodesic */
    LLPoint geoEnd; /* end point of geodesic */
    LLPoint locusStart; /* start point of locus */
    LLPoint locusEnd; /* end point of locus */
    double startDist; /* distance from geodesic *
                       * to locus at geoStart */
    double endDist; /* distance from geodesic *
                    * to locus at geoEnd */
    int lineType; /* 0, 1 or 2 */
} Locus;
```

The startDist and endDist parameters define where the locus lies in relation to the defining geodesic. If endDist=startDist, then the locus will be described as being “parallel” to the geodesic, while if endDist≠startDist, then the locus is “splayed.” Furthermore, the sign of the distance parameter determines which side of the geodesic the locus is on. The algorithms described in this paper assume the following convention: if the distance to the locus is positive, then the locus lies to the

right of the geodesic; if the distance is negative, then the locus lies to the left. These directions are relative to the direction of the geodesic as viewed from the `geoStart` point. See figure B-2 for an illustration.

If memory storage is limited, then either the `startDist/endDist` or `locusStart/locusEnd` elements may be omitted from the structure, since one may be calculated from the other. However, calculating them once upon initialization and then storing them will reduce computation time.

The `lineType` attribute is used to specify the locus's extent. If it is set to 0 (zero), then the locus exists only between `geoStart` and `geoEnd`. If `lineType=1`, then the locus begins at `geoStart` but extends beyond `geoEnd`. If `lineType=2`, then the locus extends beyond both `geoStart` and `geoEnd`.

3.0 Basic Calculations.

3.1 Iterative Approach.

For most of the intersection and projection methods listed below, an initial approximation is iteratively improved until the calculated error is less than the required accuracy. The iterative schemes employ a basic secant method, relying upon a linear approximation of the error as a function of one adjustable parameter.

To begin the iteration, two starting solutions are found and used to initialize a pair of two-element arrays. The first array stores the two most recent values of the parameter being adjusted in the solution search. This array is named `distarray` when the search parameter is the distance from a known point. It is named `crsarray` when the search parameter is an angle measured against the azimuth of a known geodesic. The second array (named `errarray` in the algorithms below) stores the error values corresponding to the two most recent parameter values. Thus, these arrays store a

linear representation of the error function. The next solution in each iteration is found by solving for the root of that linear function using the `findLinearRoot` function:

```

static double findLinearRoot(double* x, double* y,
                             long* err) {
    if (x[0] == x[1]) {
        /* function has duplicate x values, no root */
        return x[0];
    }
    else if (y[0] == y[1]) {
        if (y[0]*y[1] == 0.0) {
            return x[0];
        }
        /* duplicate y values in root function */
        return 0.5*(x[0]+x[1]);
    }
    return -y[0]*(x[1]-x[0])/(y[1]-y[0]) + x[0]
}

```

This function returns the value of the search parameter for which the linear error approximation is zero. The returned root is used as the next value in the adjustable parameter and the corresponding error value is calculated. Then the parameter and error arrays are updated and another new root is found.

This iteration scheme works well for the algorithms described in this paper. Convergence is achieved very quickly because each starting solution is very close to the final solution, where the error is well approximated by a linear function.

3.2 Starting Solutions.

Starting solutions must be provided to start iterating toward a precise solution. Initial solutions may be found in all cases by using spherical triangles to approximate the geodetic curves being analyzed, and then solve for unknown distance and azimuth values using spherical trigonometry formulas.

3.2.1 Spherical Direction Intersect.

Given two points A and B and two bearings A to C and B to C, find C.

Run Inverse to find arc length from A to B and bearings A to B and B to A. Compute differences of bearings to find angles A and B of the spherical triangle ABC.

More than one valid solution may result. Choose the solution closest to the original points.

Apply the spherical triangle formulas to find the angle C and arc lengths from A to C and from B to C:

$$C = \cos^{-1} \left(-\cos(A) \cdot \cos(B) + \sin(A) \cdot \sin(B) \cos \left(\frac{c}{R} \right) \right),$$

$$a = R \cdot \cos^{-1} \left(\frac{\cos(A) + \cos(B) \cdot \cos(C)}{\sin(B) \cdot \sin(C)} \right), \quad b = R \cdot \cos^{-1} \left(\frac{\cos(B) + \cos(A) \cdot \cos(C)}{\sin(A) \cdot \sin(C)} \right).$$

Note: If distances a or b result from a reciprocal bearing, assign appropriate negative sign(s).

Run Direct from A to find C. Use given bearing and computed length b.

3.2.2 Spherical Distance Intersection.

Given A, B and distances AC and BC, find C₁ and C₂.

Run Inverse to find length and bearings between A and B.

Use spherical triangles to find angles A = BAC₁ = BAC₂, B = ABC₁ = ABC₂, and C = BC₁A = BC₂A:

$$A = \cos^{-1} \left(\frac{\cos\left(\frac{a}{R}\right) - \cos\left(\frac{b}{R}\right)\cos\left(\frac{c}{R}\right)}{\sin\left(\frac{b}{R}\right)\sin\left(\frac{c}{R}\right)} \right), \quad B = \cos^{-1} \left(\frac{\cos\left(\frac{b}{R}\right) - \cos\left(\frac{a}{R}\right)\cos\left(\frac{c}{R}\right)}{\sin\left(\frac{a}{R}\right)\sin\left(\frac{c}{R}\right)} \right),$$

$$\text{and } C = \cos^{-1} \left(\frac{\cos\left(\frac{c}{R}\right) - \cos\left(\frac{a}{R}\right)\cos\left(\frac{b}{R}\right)}{\sin\left(\frac{a}{R}\right)\sin\left(\frac{b}{R}\right)} \right).$$

Run Direct from A to find C_1 and C_2 .

To compute the bearing from A to C_1 , start with the bearing from A to B and subtract angle A.

To compute the bearing from A to C_2 , start with the bearing from A to B and add angle A.

Use Inverse and spherical triangle formulas to get remaining bearings.

3.2.3 Spherical Tangent Point.

In both cases of the tangent point, distances are signed according to the following sign legend:

Where the arrow indicates the bearing from the first point A to the target point D.

3.2.4 Two Points and a Bearing Case.

Given two points, A and C, and a bearing from the first point (A). Find the point D along the given bearing extended which is closest to C.

Run Inverse to find length and bearings between A and C.

Find difference in bearings to compute angle A.

Use right spherical triangles to calculate y and x:

$$y = R \sin^{-1} \left(\sin\left(\frac{r}{R}\right) \sin(A) \right),$$

$$x = R \cos^{-1} \left(\cos\left(\frac{r}{R}\right) / \cos\left(\frac{y}{R}\right) \right).$$

Run Direct from A to find D using given bearing and computed length x.

3.2.5 Given Three Points Case.

Given three points (A, B, C), find the point (D) on the geodesic line from the first two points which is the perpendicular foot from the third point.

Use Inverse to determine bearing from A to B.

Use Inverse to determine bearing and length from A to C.

Find the difference in bearings to determine angle A.

Use right spherical triangles to find the lengths x and y :

$$y = R \sin^{-1} \left(\sin\left(\frac{r}{R}\right) \sin(A) \right),$$

$$x = R \cos^{-1} \left(\cos\left(\frac{r}{R}\right) / \cos\left(\frac{y}{R}\right) \right).$$

Use Direct to calculate D from A using the computed bearing from A to B and computed distance x .

3.3 Tolerances.

Two different convergence tolerances must be supplied so that the algorithms cease iterating once the error becomes sufficiently small. The first tolerance parameter is used in the forward and inverse routines; it is referred to as `eps` in the algorithm descriptions. The second parameter, labeled `tol`, is used in the intersection and projection routines to limit the overall error in the solution. Since the intersection and projection routines make multiple calls to the inverse and forward algorithms, the `eps` parameter should be several orders of magnitude smaller than the `tol` parameter to ensure that the iteration methods return correct results. Empirical studies have shown that `eps = 0.5e-13` and `tol = 1.0e-9` work well.

Finally, a maximum iteration count and convergence tolerances must be supplied to ensure that no algorithms can remain in an infinite loop if convergence is not reached. This parameter can be set by the programmer, but should be greater than five to ensure that all of the algorithms can reach convergence.

3.4 Direct and Inverse Algorithms.

The Direct and Inverse cases utilize formulae from T. Vincenty's, Survey Review XXIII, No. 176, April 1975: Direct and Inverse Solutions of Geodesics on the Ellipsoid with Application of Nested Equations.

Vincenty's notation is annotated below:

- a, b , major and minor semi axes of the ellipsoid.
- f , flattening = $\frac{a-b}{a}$.
- ϕ , geodetic latitude, positive north of the equator.
- L , difference in longitude, positive east.
- s , length of the geodesic.

α_1, α_2 , bearings of the geodesic, clockwise from north; α_2 in the direction P_1P_2 produced.

α , bearing of the geodesic at the equator.

$$u^2 = \frac{a^2 - b^2}{b^2} \cos^2 \alpha.$$

U , reduced latitude, defined by $\tan U = (1 - f) \tan \phi$.

λ , difference in longitude on the auxiliary sphere.

σ , angular distance P_1P_2 , on the sphere.

σ_1 , angular distance on the sphere from the equator to P_1 .

σ_m , angular distance on the sphere from the equator to the midpoint of the line.

3.4.1 Vincenty's Direct Formula.

$$\tan \sigma_1 = \frac{\tan U_1}{\cos \alpha_1} \quad (1)$$

$$\sin \alpha = \cos U_1 \sin \alpha_1. \quad (2)$$

$$A = 1 + \frac{u^2}{16384} \left\{ 4096 + u^2 \left[-768 + u^2 (320 - 175u^2) \right] \right\} \quad (3)$$

$$B = \frac{u^2}{1024} \left\{ 256 + u^2 \left[-128 + u^2 (74 - 47u^2) \right] \right\} \quad (4)$$

$$2\sigma_m = 2\sigma_1 + \sigma \quad (5)$$

$$\Delta\sigma = B \sin \sigma \left\{ \cos(2\sigma_m) + \frac{1}{4} B \left[\cos(\sigma) (2 \cos^2(2\sigma_m) - 1) - \frac{1}{6} B \cos(2\sigma_m) (4 \sin^2 \sigma - 3) (4 \cos^2(2\sigma_m) - 3) \right] \right\} \quad (6)$$

$$\sigma = \frac{s}{bA} + \Delta\sigma \quad (7)$$

Equations (5), (6), and (7) are iterated until there is a negligible change in σ . The first approximation of σ is the first term of (7).

Note 1: For 1 cm accuracy, σ can change no more than 1.57e-009.

$$\tan \phi_2 = \frac{\sin U_1 \cos \sigma + \cos U_1 \sin \sigma \cos \alpha_1}{(1-f) \left[\sin^2 \alpha + (\sin U_1 \sin \sigma - \cos U_1 \cos \sigma \cos \alpha_1)^2 \right]^{\frac{1}{2}}} \quad (8)$$

$$\tan \lambda = \frac{\sin \sigma \sin \alpha_1}{\cos U_1 \cos \sigma - \sin U_1 \sin \sigma \cos \alpha_1} \quad (9)$$

$$C = \frac{f}{16} \cos^2 \alpha \left[4 + f(4 - 3 \cos^2 \alpha) \right] \quad (10)$$

$$L = \lambda - (1-C) f \sin \alpha \left\{ \sigma + C \sin \sigma \left[\cos(2\sigma_m) + C \cos \sigma (2 \cos^2(2\sigma_m) - 1) \right] \right\} \quad (11)$$

$$\tan \alpha_2 = \frac{\sin \alpha}{-\sin U_1 \sin \sigma + \cos U_1 \cos \sigma \cos \alpha_1} \quad (12)$$

The latitude is found by computing the arctangent of (8) and α_2 is found by computing the arctangent of (12).

3.4.2 Vincenty's Inverse Formula.

$$\lambda = L \text{ (first approximation)} \quad (13)$$

$$\sin^2 \sigma = (\cos U_2 \sin \lambda)^2 + (\cos U_1 \sin U_2 - \sin U_1 \cos U_2 \cos \lambda)^2 \quad (14)$$

$$\cos \sigma = \sin U_1 \sin U_2 + \cos U_1 \cos U_2 \cos \lambda \quad (15)$$

$$\tan \sigma = \frac{\sin \sigma}{\cos \sigma} \quad (16)$$

$$\sin \alpha = \frac{\cos U_1 \cos U_2 \sin \lambda}{\sin \sigma} \quad (17)$$

$$\cos(2\sigma_m) = \cos \sigma - \frac{2 \sin U_1 \sin U_2}{\cos^2 \alpha} \quad (18)$$

λ is obtained by equations (10) and (11). This procedure is iterated starting with equation (14) until the change in λ is negligible. See Note 1.

$$s = bA(\sigma - \Delta\sigma) \quad (19)$$

Where $\Delta\sigma$ comes from equations (3), (4), and (6)

$$\tan \alpha_1 = \frac{\cos U_2 \sin \lambda}{\cos U_1 \sin U_2 - \sin U_1 \cos U_2 \cos \lambda} \quad (20)$$

$$\tan \alpha_2 = \frac{\cos U_1 \sin \lambda}{\cos U_1 \sin U_2 \cos \lambda - \sin U_1 \cos U_2} \quad (21)$$

The inverse formula may give no solution over a line between two nearly antipodal points. This will occur when λ , as computed by (11), is greater than π in absolute value. To find α_1, α_2 , compute the arctangents of (20) and (21).

The remainder of this appendix will assume the direct and inverse use the following named functions:

Long WGS84Dest (LLPoint, origin, double course, double distance, LLPoint* dest, double eps) returns an LLPoint representing the destination point, where the inputs are:

LLPoint origin	=	Starting LLPoint with lat/lon in radian
Double course	=	Azimuth of geodesic at origin in radians
Double distance	=	Distance to desired point (in NM)
LLPoint* dest	=	Reference to LLPoint that will be updated with lat/lon of destination
Double eps	=	Maximum error allowed in computation

Long WGS84Inverse (LLPoint origin, LLPoint dest, double* crs, double* bcrs, double* dist, double eps) returns course and distance where the inputs are:

LLPoint origin	=	Coordinates of starting point
LLPoint dest	=	Coordinates of destination point
Double* crs	=	Reference to double that will be updated with course at origin in radians
Double* bcrs	=	Reference to double that will be updated with reciprocal course at destination in radians
Double* dist	=	Reference to return value that will contain the distance between origin and dest
Double eps	=	Maximum error allowed in computation

3.5 Geodesic Oriented at Specified Angle.

In TERPS procedure design, it is often required to find a geodesic that lies at a prescribed angle to another geodesic. For instance, the end lines of an obstacle evaluation area (OEA) are typically projected from the flight path at a prescribed angle. Since the azimuth of a geodesic varies over the length of the curve, the angle between two geodesics must be measured by comparing the azimuth of each geodesic at the point where they intersect. The following pseudo-code represents an algorithm that will calculate the correct azimuth at any point on a geodesic described by its start and end points. This azimuth can easily be extended to find the azimuth of an intersecting geodesic at the point if the angle of intersection is known.

3.5.1 Input/Output.

`double WGS84GeodesicCrSAtPoint(LLPoint startPt, LLPoint endPt, LLPoint testPt, int length, double* startCrS, double* revCrS, double* distToPt, long* err, double tol, double eps)` returns a `double` representing the azimuth of the intersecting geodesic, where the inputs are:

<code>LLPoint startPt</code>	=	Coordinates of start point of given geodesic
<code>LLPoint endPt</code>	=	Coordinates of end point of geodesic
<code>LLPoint testPt</code>	=	Point at which course of geodesic is to be determined
<code>double* startCrS</code>	=	Azimuth of geodesic at <code>startPt</code> in radians
<code>double* revCrS</code>	=	Reciprocal azimuth of geodesic at <code>endPt</code> in radians
<code>double* distToPt</code>	=	Distance from <code>startPt</code> to <code>testPt</code> in NM
<code>double tol</code>	=	Accuracy tolerance for intersection calculation
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

3.5.2 Algorithm Steps.

STEP 1: Use the `WGS84PtIsOnLine` algorithm to check that `testPt` actually lies on geodesic defined by `startPt` and `endPt`.

STEP 2: Use Inverse algorithm to determine course and distance from `testPt` to `startPt`. Denote course as `crSToStart`.

STEP 3: Use Inverse algorithm to determine course and distance from `testPt` to `endPt`. Denote course as `crsToEnd`.

STEP 4: If `testPt` lies on geodesic between `startPt` and `endPt`, then the correct azimuth is `crsToEnd`.

STEP 5: If `testPt` lies on the geodesic beyond `endPt`, then the correct azimuth is `crsStart + π` .

STEP 6: Return the calculated azimuth.

Note that if `angle` is positive, then the new geodesic will lie to the right of the given geodesic (from the perspective of standing at the start point and facing toward the end point); otherwise, the new geodesic will lie to the left.

3.6 Determine If Point Lies on Geodesic.

This algorithm returns a true value if a point lies on and within the bounds of a given geodesic. The bounds of the geodesic are specified by two pieces of information: the end point coordinates and an integer length code. If the length code is set to 0, then the geodesic is understood to exist only between its start and end points, so a value of true will be returned only if the test point also lies between the start and end points. If the length code is set to 1, then the geodesic is understood to extend beyond its end point to a distance of one half of earth's circumference from its end point. If the length code is set to 2, then the geodesic is understood to extend beyond both the start and end points.

Note that this algorithm relies on the concept of equality for two `LLPoint` structures. This will be defined to mean that the distance between the two `LLPoints`, as calculated using the inverse algorithm, is less than `tol`.

3.6.1 Input/Output.

`int WGS84PtIsOnLine(LLPoint startPt, LLPoint endPt, LLPoint testPt, LineType lengthCode, double tol, double eps)` returns an integer value indicating whether `testPt` lies on geodesic, where the inputs are:

<code>LLPoint startPt</code>	=	Geodetic coordinate of line start point
<code>LLPoint endPt</code>	=	Geodetic coordinate of line end point
<code>LLPoint testPt</code>	=	Geodetic coordinate of point to test
<code>LineType lengthCode</code>	=	Integer that specifies extent of line. 0: geodesic exists only between <code>startPt</code> and <code>endPt</code> . 1: geodesic extends beyond <code>endPt</code> . 2: geodesic extends behind <code>startPt</code> .
<code>double tol</code>	=	Maximum difference allowed in distance
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

3.6.2 Algorithm Steps.

See figure B-4 for an illustration of the variables.

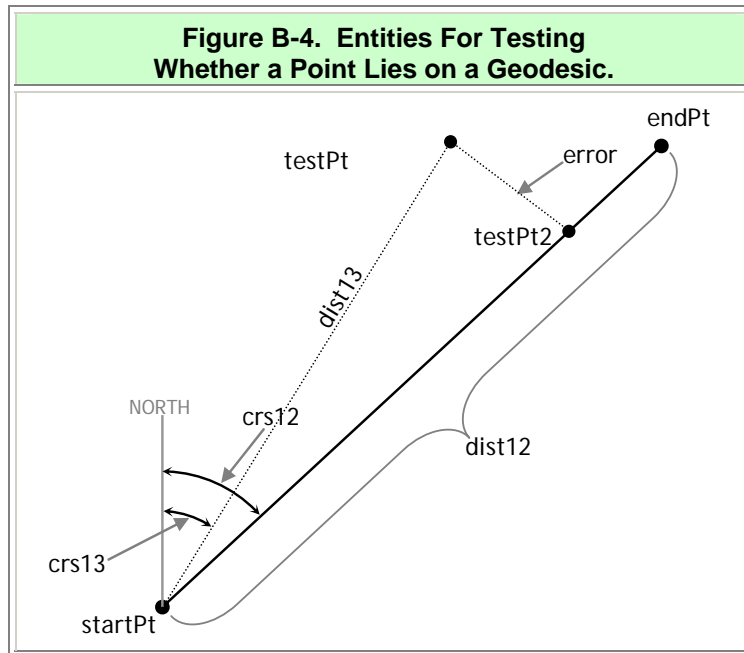

STEP 1: Use inverse algorithm to calculate the azimuth and distance from `startPt` to `endPt`. Denote these values by `crs12` and `dist12`, respectively.

STEP 2: Use `WGS84PtIsOnCrs` algorithm to determine if `testPt` lies on geodesic given by `startPt` and `endPt`.

1. Use inverse algorithm to calculate the distance from `startPt` to `testPt`. Denote this value by `tmpDist1Test`.
2. Use direct algorithm to project a point from `startPt`, along `crs12`, a distance equal to `tmpDist1Test`. Denote this point by `comparePt`.
3. Use `WGS84PointsAreSame` algorithm to determine if `testPt` is equal to `comparePt`.

STEP 3: Examine `error` to determine whether `testPt` lies on the geodesic within `tol` as follows:

1. If (`error` \leq `tol`) then
 - a. If (`lengthCode` $>$ 0) or (`dist13`-`dist12` \leq `tol`) then
 - (1) `onLine` = true
 - b. else
 - (1) `onLine` = false
2. end if
3. Else if (`lengthCode` = 2)
 - a. Use the direct algorithm to project point from `startPt`, along `crs12+ π` a distance `dist13`. Again, denote this point again by `testPt2`
 - b. Use the inverse algorithm to recalculate `error`, which is the distance from `testPt` to `testPt2`.
 - c. If (`error` \leq `tol`) then `onLine` = true
 - (1) Else `onLine` = false
4. End if
5. Else
 - a. `onLine` = false
6. End if

3.7 Determine If Point Lies on Arc.

This algorithm returns a non-zero (true) value if the sample point lies on and between the bounds of the given arc. The arc is defined by its center point, radius, start azimuth, end azimuth, and orientation. A positive orientation parameter indicates that the arc is traversed in a counterclockwise sense, while a negative orientation parameter indicates that the arc is traversed clockwise. This algorithm is used in conjunction with the arc intersection functions (Algorithms 4.2, 4.3, and 4.6) to determine whether the computed intersections lie within the bounds of the desired arc.

3.7.1 Input/Output.

`int WGS84PtIsOnArc(LLPoint center, double radius, double startCrs, double endCrs, ArcDirection orientation, LLPoint testPt, double tol)` returns an integer value indicating whether `testPt` lies on arc, where the inputs are:

<code>LLPoint center</code>	=	Geodetic coordinates of arc center
<code>double radius</code>	=	Arc radius
<code>double startCrs</code>	=	True azimuth from center to start of arc
<code>double endCrs</code>	=	True azimuth from center to end of arc
<code>ArcDirection orientation</code>	=	Orientation of the arc [+1 for counter-clockwise; -1 for clockwise]

LLPoint testPt	=	Geodetic coordinate of point to test
double tol	=	Maximum error allowed in solution
double eps	=	Convergence parameter for forward/inverse algorithms

3.7.2 Algorithm Steps.

See figure B-5 for an illustration of the variables.

STEP 1: Use inverse algorithm to calculate distance and azimuth from center to testPt. Denote values as `dist` and `crs`, respectively.

STEP 2: If $(\text{abs}(\text{dist} - \text{radius}) > \text{tol})$ then testPt is not correct distance from center.

a. `onArc = false.`

STEP 3: else.

a. Use Algorithm 6.0 - Calculate Angular Arc Extent to calculate the angle subtended by the full arc. Denote this value by `arcExtent`.

b. If $(\text{arcExtent} = 360^\circ)$ then

(1) `onArc = true.`

c. else.

(1) Use the inverse algorithm to calculate the azimuth from center to testPt. Denote this value by `testCrs`.

(2) Use Algorithm 6.0 - Calculate Angular Arc Extent to calculate the angle subtended by and arc starting at `startCrs`, but ending at `testCrs`, with the same orientation. Denote this value by `subExtent`.

(3) If $(-.002 \leq \text{subExtent} \leq \text{arcExtent} + .002)$ then traversing arc from `startCrs` to `endCrs`, one would encounter testPt, so it must lie on arc.

(a) `onArc = true.`

d. end if.

STEP 4: end if.

3.8 Calculate Length of Fixed Radius Arc.

A fixed radius arc on an ellipsoid does not generally lie in a plane. Therefore, the length of the arc cannot be computed using the usual formula for the circumference of a circle. The following algorithm takes the approach of dividing the arc into many sub-arcs. Three points are then calculated on each sub-arc. Since any three points in space uniquely determine both a plane and an arc, the three points on each sub-arc are used to calculate the radius and subtended angle of the planar arc that contains all three points. The length of the approximating planar arc is then calculated for each sub-arc. The sum of the sub-arc lengths approaches the length of the original arc as the number of sub-arc increases (and each sub-arc's length decreases).

A simpler method that is sufficiently accurate for arcs with radius less than about 300 nautical miles (NM) is described in section 6.4.

3.8.1 Input/Output.

`double WGS84DiscretizedArcLength (LLPoint center, double radius, double startCrs, double endCrs, int orient, int *n, double tol)` returns a double precision value representing the length of the arc, where the inputs are:

<code>LLPoint center</code>	=	Geodetic coordinates of arc center
<code>double radius</code>	=	Arc radius
<code>double startCrs</code>	=	True azimuth from center to start of arc
<code>double endCrs</code>	=	True azimuth from center to end of arc
<code>int orient</code>	=	Orientation of the arc [+1 for counter-clockwise; -1 for clockwise]
<code>int *n</code>	=	Reference to integer used to return number of steps in discretized arc
<code>double tol</code>	=	Maximum allowed error
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

3.8.2 Algorithm Steps.

See figure B-6 for an illustration of the variables.

STEP 1: Set initial number of sub-arcs to use. The fixed value $n = 16$ has been found through trial-and-error to be a good starting value. Alternatively, the initial value of n may be calculated based on the arc's subtended angle and its radius (i.e., its approximate arc length).

STEP 2: Convert `center` point to Earth-Centered, Earth-Fixed (ECEF) coordinates, `v0` according to Algorithm 6.1.

STEP 3: Compute subtended angle, `subtAngle`, using Algorithm 6.0.

STEP 4: Set iteration count, $k = 0$.

STEP 5: Do while $k = 0$ or $((\text{error} > \text{tol}) \text{ and } (k \leq \text{maximumIterationCount}))$.

- a. Calculate subtended angle of each sub-arc, $d\theta = \text{subtAngle}/n$.
- b. Use direct algorithm from `center`, using `startCrs` and distance `radius`, to project start point of arc. Denote this point by `p1`.
- c. Convert `p1` to ECEF coordinates. Denote this vector by `v1`.

- d. Initialize $\text{arcLength} = 0$.
- e. For $i = 0$ to n .
- (1) Compute azimuth from arc center to end point of sub-arc number i :
 $\text{theta} = \text{startCrs} + i * \text{dtheta}$.
 - (2) Use direct algorithm from center, using azimuth $\text{theta} + 0.5 * \text{dtheta}$ and distance radius , to project middle point of sub-arc. Denote this point by $p2$.
 - (3) Convert $p2$ to ECEF coordinate $v2$.
 - (4) Use direct algorithm from center, using azimuth $\text{theta} + \text{dtheta}$ and distance radius , to project endpoint of sub-arc. Denote this point by $p3$.
 - (5) Convert $p3$ to ECEF coordinate $v3$.
 - (6) Subtract $v2$ from $v1$ to find chord vector between $p1$ and $p2$. Denote this vector by chord1 . Compute $x1 = |\text{chord1}|$.
 - (7) Subtract $v2$ from $v3$ to find chord vector between $p3$ and $p2$. Denote this vector by chord2 . Compute $x2 = |\text{chord2}|$.
 - (8) Compute dot product of chord1 and chord2 . Denote this value as d .
 - (9) Use the following calculation to compute the length L of the sub-arc: (see figure B-7)
 - (a) $x_i = d / (x1 * x2)$
 - (b) $\text{sigma} = \text{sqrt}(1 - x_i^2)$
 - (c) $R = (x2 * \text{sqrt}((x1/x2 - x_i)^2 + \text{sigma}^2)) / (2 * \text{sigma})$
 - (d) $A = 2(\pi - \arccos(x_i))$
 - (e) $L = R * A$

$$\xi = \frac{d}{x_1 x_2}$$

$$\sigma = \sqrt{1 - \xi^2}$$

$$R = \frac{x_2 \sqrt{(x_1/x_2 - \xi)^2 + \sigma^2}}{2\sigma}$$

$$A = 2(\pi - \cos^{-1} \xi)$$

$$L = R \cdot A$$

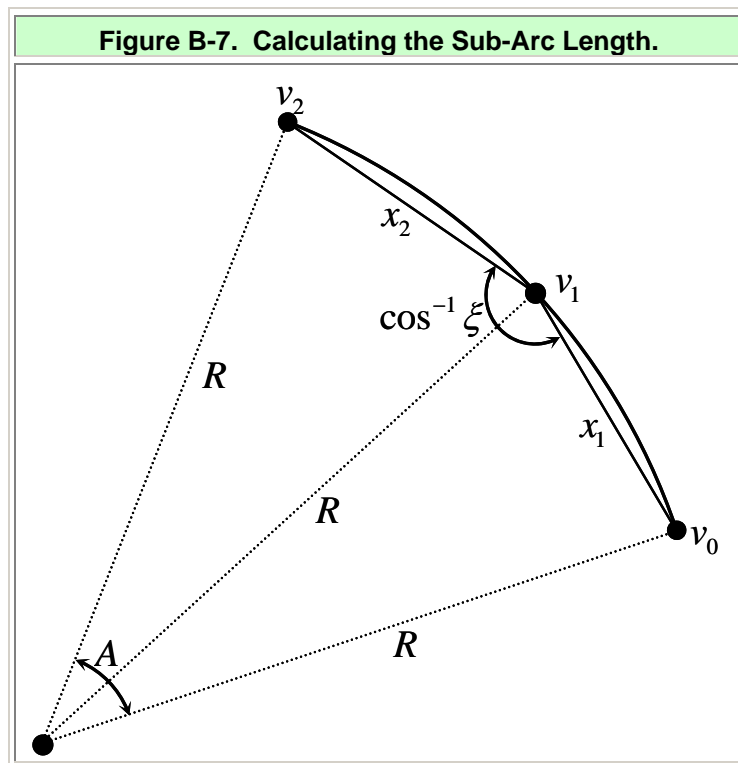

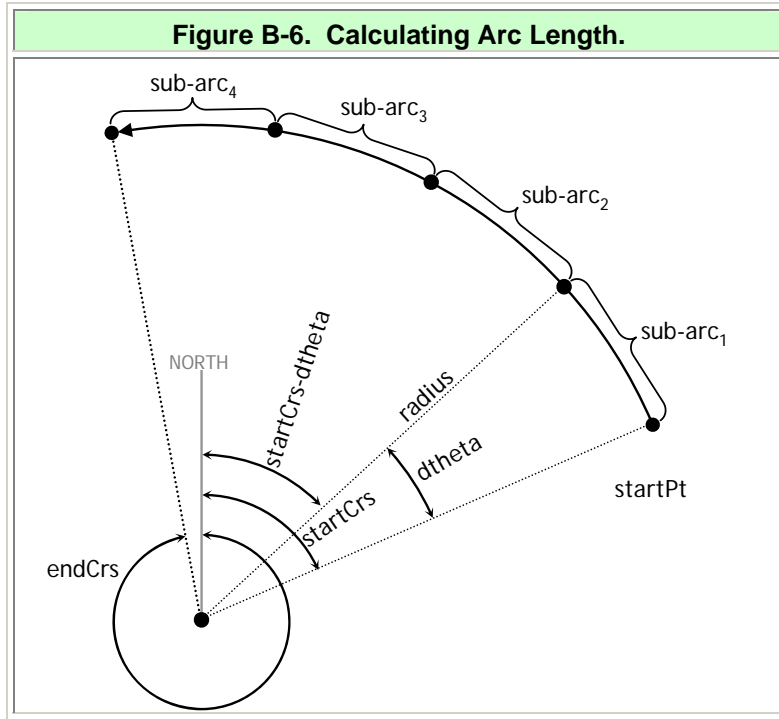

Note that since the arc length is a planar (not geodetic) calculation, the subtended angle A is not equal to d theta.

(10) Add L to cumulative length to get total length of sub-arcs through sub-arc number i : $\text{length} = \text{length} + L$.

- f. end for loop.
- g. Compute error, which is the change in length calculation between this iteration and the last: $\text{error} = \text{abs}(\text{length} - \text{oldLength})$.
- h. Increment the iteration count: $k = k+1$.
- i. Double the number of sub-arcs: $n = 2 * n$.
- j. Save the current length for comparison with the next iteration: $\text{oldLength} = \text{length}$.

STEP 6: End while loop.

STEP 7: Return length.

3.9 Find Distance from Defining Geodesic to Locus.

When computing a position on a locus of points, it is necessary to solve for the distance from the defining geodesic to the locus. This distance is constant if the locus is

designed to be “parallel” to the defining geodesic. However, it is necessary to allow the locus distance to vary linearly with distance along the geodesic, since in some cases the locus will splay away from the defining geodesic. To account for this, we have included `startDist` and `endDist` attributes in the `Locus` structure defined above. For a given point on the geodesic (or given distance from the geodesic start point), the distance to the locus can then be calculated.

The two algorithms described below carry out the computation of locus distance for different input parameters. If the distance from the geodesic start point to the point of interest is known, then `WGS84DistToLocusD` may be used to calculate the locus distance. If instead a point on the defining geodesic is given, the `WGS84DistToLocusP` may be used. The latter algorithm simply computes the distance from the geodesic start point to the given point and then invokes the former algorithm. Therefore, steps are described for `WGS84DistToLocusD` only.

3.9.1 Input/Output.

`double WGS84DistToLocusD (Locus loc, double distance)`
returns the distance from the defining geodesic to the locus at the given distance from `loc.geoStart`, where the inputs are:

`Locus loc` = Locus of interest

`double distance` = Distance from locus start point to point where distance is to be computed

`double WGS84DistToLocusP (Locus loc, LLPoint geoPt, double *faz, double tol, double eps)` returns the distance from the defining geodesic to the locus at the given point, where the inputs are:

`Locus loc` = Locus of interest

`LLPoint geoPt` = Point on defining geodesic

`double *faz` = Pointer used to return forward azimuth of geodesic at `geoPt`. This is needed if `geoPt` is not between `geoStart` and `geoEnd`.

`double tol` = Maximum allowable error

`double eps` = Convergence parameter for forward/inverse algorithm

3.9.2 Algorithm Steps.

The following steps are followed if the distance from `loc.geoStart` is given. If a point on the geodesic (`geoPt`) is given instead, then first use the inverse algorithm to compute the distance from `geoPt` to `loc.geoStart` and then follow the following steps (note that distance must be signed negative if the locus's line type is 2 and `geoPt` is farther from `geoEnd` than it is from `geoStart`):

STEP 1: Use the inverse function to compute the length of the locus's defining geodesic. Denote this value as `geoLen`.

STEP 2: If (`geoLen = 0`) then `distToLoc = 0.0`

STEP 3: Else:

$$\text{distToLoc} = \text{loc.startDist} + \frac{\text{distance}}{\text{geoLen}} * (\text{loc.endDist} - \text{loc.startDist})$$

STEP 4: End if

STEP 5: Return `distToLoc`

3.10 Project Point on Locus from Point on Defining Geodesic.

Given a point on the defining geodesic, this algorithm computes the corresponding point on the locus.

3.10.1 Input/Output.

`LLPoint WGS84PtOnLocusP (Locus loc, LLPoint geoPt, LLPoint* ptonloc, double* perpCrs, double tol, double eps)`
returns the point on the locus that is abeam the given point, where the inputs are:

<code>Locus loc</code>	=	Locus of Interest
<code>LLPoint geoPt</code>	=	Point on defining geodesic
<code>LLPoint* ptonloc</code>	=	Pointer to <code>LLPoint</code> , updated with coordinates of point on locus abeam given point.
<code>double* perpCrs</code>	=	Pointer to double, updated with azimuth from point on geodesic to point on locus.
<code>double tol</code>	=	Maximum allowable error
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

3.10.2 Algorithm Steps.

STEP 1: Use Algorithm 3.9 (with point input) to determine the distance from `geoPt` to the locus. Denote this distance as `distp`.

STEP 2: If (`distp = 0`) return `geoPt`

STEP 3: Use the inverse algorithm to compute the course from `geoPt` to the start point of the defining geodesic. Denote this value as `fcrs`.

STEP 4: If (`distp > 0.0`) then the locus lies to the right of the geodesic. Let
`*perpCrS = fcrs + $\pi/2$`

STEP 5: Else, the locus lies to the left of the geodesic. Let

`*perpCrS = fcrs - $\pi/2$`

STEP 6: End if

STEP 7: Use the direct algorithm to project a point along `*perpCrS`, distance `abs(distp)` from `geoPt`. Denote the point as `ptonLoc`.

STEP 8: Return `ptonLoc`.

3.11 Determine if Point Lies on Locus.

This algorithm compares the position of a given point with the position of the corresponding point on the locus. The corresponding point on the locus is found by projecting the given point onto the locus's defining geodesic curve, computing the correct distance from there to the locus, and then projecting a point at that distance perpendicular to the geodesic. If distance from the corresponding point to the given point is less than the error tolerance, then a reference to the projected point on the geodesic is returned. Otherwise a null reference is returned.

An alternative implementation could simply return true or false, rather than references. However, it is more efficient to return the projected point as this is often needed in subsequent calculations.

3.11.1 Input/Output.

`int WGS84PtIsOnLocus (Locus loc, LLPoint testPt, LLPoint* ptOnGeo, double tol, double eps)` returns a reference to the projection of `testPt` on the locus's defining geodesic if `testPt` lies on the locus and `NULL` otherwise, where the inputs are:

`Locus loc` = Locus of Interest

<code>LLPoint testPt</code>	=	Point to test against locus
<code>LLPoint* ptOnGeo</code>	=	Pointer to <code>LLPoint</code> , updated with point on defining geodesic abeam the given point on the locus.
<code>double tol</code>	=	Maximum allowable error
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

3.11.2 Algorithm Steps.

See figure B-8 for an illustration of the variables.

STEP 1: If `testPt` is the same as `loc.geoStart` or `loc.geoEnd` then return a reference to `ptOnGeo` containing the appropriate point.

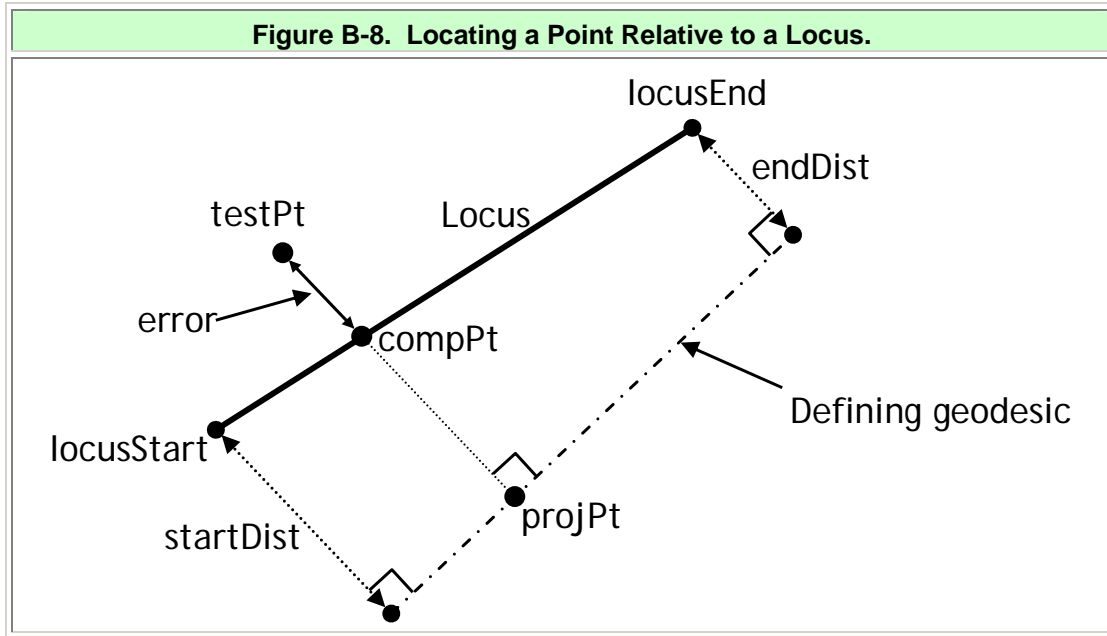

STEP 2: Use Algorithm 5.1 to project `testPt` onto the locus's defining geodesic. Denote the projected point as `ptOnGeo`.

STEP 3: Use Algorithm 3.6 to determine whether `ptOnGeo` lies on the locus's defining geodesic. This will account for an infinite or semi-infinite locus. If it does not, then return `0` (false).

STEP 4: Use the Inverse Algorithm to find the course between `loc.geoStart` and `testPt`. Use this course to determine which side of the locus `testPt` falls. Apply the appropriate sign to this distance, `distFromPoint`.

STEP 5: Use Algorithm 3.9 to calculate the correct expected locus distance, `locDist`.

STEP 6: If `abs(distFromPoint - locDist) <= tol`, then the point is on the locus. Return a reference to the projection on the defining geodesic.

3.12 Compute Course of Locus.

This algorithm is analogous to the inverse algorithm for a geodesic. It is used by other locus algorithms when the direction of the locus is needed.

3.12.1 Input/Output.

`double WGS84LocusCrsAtPoint (Locus loc, LLPoint testPt, LLPoint* geoPt, double* perpCrs, double tol)` returns the course of the locus at the given point. Also sets values of calculation byproducts, including the corresponding point on the locus's geodesic and the course from the given point toward the geodesic point, where the inputs are:

<code>Locus loc</code>	=	Locus of Interest
<code>LLPoint testPt</code>	=	Point at which course will be calculated
<code>LLPoint* geoPt</code>	=	Projection of <code>testPt</code> on defining geodesic
<code>double* perpCrs</code>	=	Course for <code>testPt</code> to <code>geoPt</code>
<code>double tol</code>	=	Maximum allowable error
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

3.12.2 Algorithm Steps.

See figure B-9 for an illustration of the variables.

STEP 1: Use Algorithm 3.11 to determine whether `testPt` lies on `loc`. This same step will return a reference to the projection of `testPt` onto the defining geodesic. Denote this reference as `geoPt`.

STEP 2: If (`geoPt = NULL`) then `testPt` is not a valid point at which to calculate the locus's course. Return `-1.0`. (Valid course values are in the range $[0, 2\pi]$.)

STEP 3: Use the inverse algorithm to calculate the course and distance from `testPt` to `geoPt`, denoted by `perpCrS` and `perpDist`, respectively.

STEP 4: Use Algorithm 3.9 to calculate `distToLoc`, the distance from the geodesic to the locus at `geoPt`. This step is required to determine which side of the geodesic the locus lies on because `perpDist` will always be positive.

STEP 5: Calculate the slope of the locus relative to the geodesic:

$$\text{slope} = \frac{(\text{loc.endDist} - \text{loc.startDist})}{\text{geoLen}}$$

STEP 6: Convert the slope to angular measure in radians:

$$\text{slope} = \text{atan}(\text{slope})$$

STEP 7: Adjust the value of the perpendicular course by `slope`. This accounts for how the locus is approaching or receding from the geodesic:

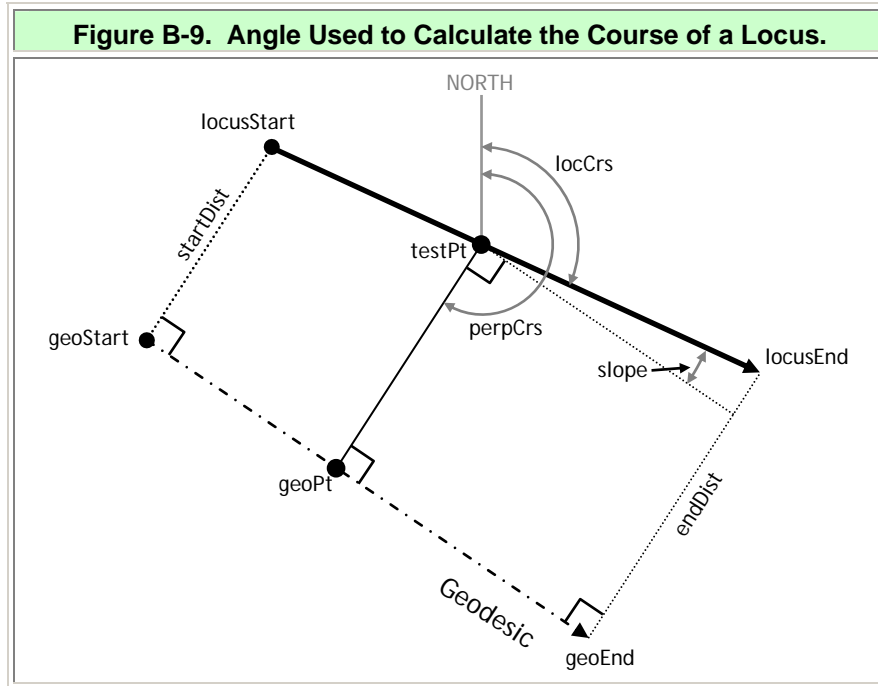

$$\text{perpCrS} = \text{perpCrS} + \text{slope}$$

STEP 8: If (`distToLoc < 0`), then `testPt` lies to the left of the geodesic, so `perpCrS` points to the right of the locus's course:

$$\text{locCrS} = \text{perpCrS} - \pi/2$$

STEP 9: Else, `testPt` lies to the right of the geodesic so `perpCrS` points to the left of the locus's course: $\text{locCrS} = \text{perpCrS} + \pi/2$

STEP 10: Return `locCrS`

4.0 Intersections.

4.1 Intersection of Two Geodesics.

The following algorithm computes the coordinates where two geodesic curves intersect. Each geodesic is defined by its starting coordinates and azimuth at that coordinate. The algorithm returns a single set of coordinates if the geodesics intersect and returns a null solution (no coordinates) if they do not.

4.1.1 Input/Output.

`long WGS84CrsIntersect(LLPoint pt1, double crs13, double* crs31, double* dist13, LLPoint pt2, double crs23, double* crs32, double* dist23, LLPoint* intx, double tol)` returns a reference to an `LLPoint` structure that contains the intersection coordinates, where the inputs are:

<code>LLPoint pt1</code>	=	Start point of first geodesic
<code>double crs13</code>	=	Azimuth from <code>pt1</code> to intersection point
<code>double* crs31</code>	=	Reference to azimuth from intersection point to <code>pt1</code>
<code>double* dist13</code>	=	Reference to distance from <code>pt1</code> to intersection
<code>LLPoint pt2</code>	=	Start point of second geodesic

double crs23	=	Azimuth from pt2 to intersection point
double* crs32	=	Reference to azimuth from intersection to pt2
double* dist23	=	Reference to distance between pt2 and intersection point
LLPoint* intx	=	Reference to intersection point
double tol	=	Maximum error allowed in solution
double eps	=	Convergence parameter for forward/inverse algorithms

4.1.2 Algorithm Steps.

See figure B-10 for an illustration of the variables.

STEP 1: Use inverse algorithm to calculate distance, azimuth and reverse azimuth from pt1 to pt2. Denote these values by dist12, crs21 and crs12, respectively. Run a check to see if pt1 lies on the geodesic defined by pt2 and crs23 and if pt2 lies on the geodesic defined by pt1 and crs13.

a. If pt1 falls on geodesic 2 and pt2 falls on geodesic 1.

(1) Return an error. Courses are collinear. There are infinite intersections.

b. If pt1 falls on geodesic 2.

(1) Return intersection = pt1.

c. If pt2 falls on geodesic 1.

(1) Return intersection = pt2.

STEP 2: Calculate the signed azimuth difference in angle between crs12 and crs13, denoted by angle1.

STEP 3: Calculate the signed azimuth difference in angle between crs21 and crs23, denoted by angle2.

STEP 4: If $(\sin(\text{angle1}) * \sin(\text{angle2}) < 0)$ then the courses lay on opposite sides of the pt1-pt2 line and cannot intersect in this hemisphere. Use reciprocal course so that the nearest intersection may be found.

- a. If $\text{abs}(\text{angle1}) > \text{abs}(\text{angle2})$
- (1) $\text{angle1} = (\text{crs13} + \pi) - \text{crs12}$
- b. Else
- (1) $\text{angle2} = \text{crs21} - (\text{crs23} + \pi)$

STEP 5: End if.

STEP 6: Locate the approximate intersection point, intx , using a spherical earth model. See the documents referenced in section 2.2 methods to accomplish this.

STEP 7: The following steps describe the function `iterateLineIntersection` which is called once the initial approximation, intx , of the line intersection is found. The purpose of the `iterateLineIntersection` function is to further refine the solution.

STEP 8: Use the inverse algorithm to calculate dist13 , the distance from pt1 to intx .

STEP 9: Use the inverse algorithm to calculate dist23 , the distance from pt2 to intx .

STEP 10: If $\text{dist13} < \text{tol}$, then the intersection point is very close to pt1 . Calculation errors may lead to treating the point as if it were beyond the end of the geodesic. Therefore, it is helpful to move pt1 a small distance along the geodesic.

1. Use the direct algorithm to move pt1 from its original coordinates 1 nm along azimuth $\text{crs13} + \pi$.
2. Use the inverse algorithm to calculate the azimuth acrs13 for the geodesic from the new pt1 .

STEP 11: Repeat steps 10, 10(1), and 10(1) for pt2 and crs23 .

STEP 12: If $(\text{dist23} < \text{dist13})$ then the intersection point is closer to pt2 than pt1 . In this case, the iterative scheme will be more accurate if we swap pt1 and pt2 . This is because we iterate by projecting the approximate point onto the geodesic from pt1 and then calculating the error in azimuth from pt2 . If the distance from pt2 to the intersection is small, then small errors in distance can correspond to large errors in azimuth, which will lead to slow convergence. Therefore, we swap the points so that we are always measuring azimuth errors farther from the geodesic starting point.

- a. `newPt = pt1`
- b. `pt1 = pt2`
- c. `pt2 = newPt`
- d. `acrs13 = crs13`
- e. `crs13 = crs23`
- f. `crs23 = acrs13`
- g. `dist13 = dist23`; We only need one distance so the other is not saved
- h. `swapped = 1`; This is a flag that is set so that the solutions can be swapped back after they are found.

STEP 13: End if

STEP 14: Initialize the distance array: `distarray[0] = dist13`. Errors in azimuth from `pt2` will be measured as a function of distance from `pt1`. The two most recent distances from `pt1` are stored in a two element array. This array is initialized with the distance from `pt1` to `intx`:

STEP 15: Use the direct algorithm to project `intx` onto the geodesic from `pt1`. Use `pt1` as the starting point, and a distance of `distarray[0]` and azimuth of `crs13`.

STEP 16: Use the inverse algorithm to measure the azimuth `acrs23` from `pt2` to `intx`.

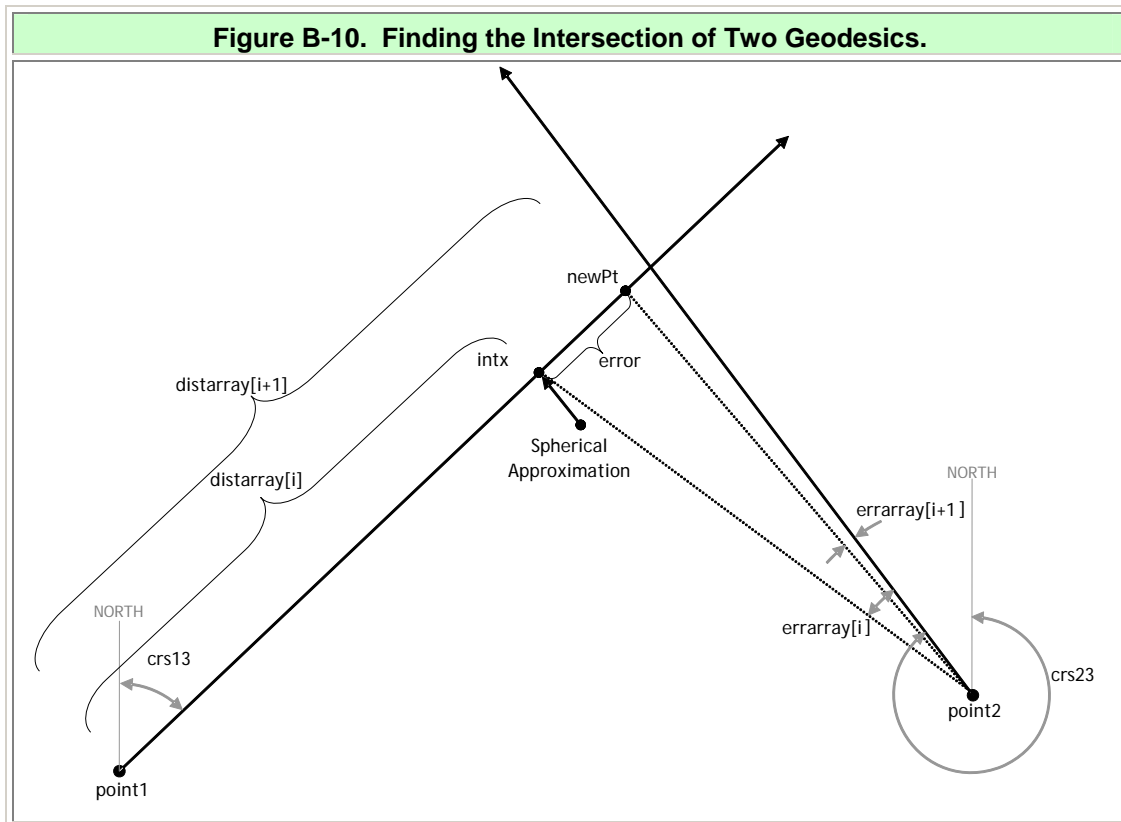

STEP 17: Initialize the error array:
`errarray[0] = signedAzimuthDifference(acrs23, crs23)`.
`signedAzimuthDifference` function; `errarray[0]` will be in the range $(-\pi, \pi]$.

STEP 18: Initialize the second element of the distance array using a logical guess:
`distarray[1] = 1.01 * dist13`.

STEP 19: Use the direct algorithm to project the second approximation of `intx` onto the geodesic from `pt1`. Use `pt1` as the starting point, and a distance of `distarray[1]` and azimuth of `crs13`.

STEP 20: Use the inverse algorithm to measure the azimuth `acrs23` from `pt2` to `intx`.

- STEP 21: Initialize the error array:
`errarray[1] = signedAzimuthDifference(acrs23, crs23).`
- STEP 22: Initialize $k = 0$
- STEP 23: Do while ($k=0$) or ($(\text{error} > \text{tol})$ and ($k \leq \text{MAX_ITERATIONS}$))
- a. Use linear approximation to find root of `errarray` as a function of `distarray`. This gives an improved approximation to `dist13`.
 - b. Use the direct algorithm to project the next approximation of the intersection point, `newPt`, onto the geodesic from `pt1`. Use `pt1` as the starting point, and a distance of `dist13` (calculated in previous step) and azimuth of `crs13`.
 - c. Use inverse algorithm to calculate the azimuth `acrs23` from `pt2` to `intx`.
 - d. Use the inverse algorithm to compute the distance from `newPt` to `intx` (the previous estimate). Denote this value as the `error` for this iteration.
 - e. Update `distarray` and `errarray` with new values:
`distarray[0] = distarray[1]`
`distarray[1] = dist13`
`errarray[0] = errarray[1]`
`errarray[1] = signedAzimuthDifference(acrs23, crs23)`
 - f. Increment k : $k = k + 1$
- STEP 24: End while loop
- STEP 25: Check if k reached `MAX_ITERATIONS`. If so, then the algorithm may not have converged, so an error message should be displayed.
- STEP 26: The distances and azimuths from `pt1` and `pt2` to `intx` are available at the end of this function, since they were calculated throughout the iteration. It may be beneficial to return them with the `intx` coordinates, since they may be needed by the calling function. If this is done, and if `swapped = 1`, then the original identities of `pt1` and `pt2` were exchanged and the azimuths and distances must be swapped again before they are returned.
- STEP 27: Return `intx`.

4.2 Intersection of Two Arcs.

The following algorithm computes the intersection points of two arcs. Each arc is defined by its center point coordinates and radius. The algorithm will return a null solution (no points) if the arcs do not intersect; it will return a single set of coordinates if the arcs intersect tangentially; and it will return two sets of coordinates if the arcs overlap.

4.2.1 Input/Output.

`long WGS84ArcIntersect(LLPoint center1, double radius1, LLPoint center2, double radius2, LLPointPair intx, int* n, double tol)` returns a reference to an LLPoint structure array that contains the coordinates of the intersection(s), where the inputs are:

<code>LLPoint center1</code>	=	Geodetic coordinates of first arc center
<code>double radius1</code>	=	Radius of first arc in nautical miles
<code>LLPoint center2</code>	=	Geodetic coordinates of second arc center
<code>double radius2</code>	=	Radius of second arc in nautical miles

<code>LLPointPair intx</code>	=	Two-element array of <code>LLPoint</code> objects that will be updated with intersections' coordinates
<code>int* n</code>	=	Reference to integer number of intersection points returned
<code>double tol</code>	=	Maximum error allowed in solution
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

4.2.2 Algorithm Steps.

See figure B-11 for an illustration of the variables.

This algorithm treats the arcs as full circles. Once the intersections of the circles are found, then each intersection point may be tested and discarded if it does not lie within the bounds of the arc.

STEP 1: Use inverse algorithm to calculate the distance and azimuth between `center1` and `center2`. Denote these values as `dist12` and `crs12`, respectively.

STEP 2: If $(\text{radius1} + \text{radius2} - \text{dist12} + \text{tol} < 0)$ or $(\text{abs}(\text{radius1} - \text{radius2}) > \text{dist12})$ then the circles are spaced such that they do not intersect. If the first conditional is true, then the arcs are too far apart. If the second conditional is true, then one arc is contained within the other.

a. Return no intersections.

STEP 3: Else if $(\text{abs}(\text{radius1} + \text{radius2} - \text{dist12}) \leq \text{tol})$ then the circles are tangent to each other and intersect in exactly one point.

a. Use direct algorithm to project point from `center1`, along `crs12`, distance `radius1`.

b. Return projected point.

STEP 4: End if

STEP 5: Calculate approximate intersection points, `intx[0]` and `intx[1]`, according to section 3.2.

STEP 6: Iterate to improve approximation to `pt`:

a. `k = 0`

- b. Use inverse algorithm to find azimuth from `center2` to `pt`, denote this value as `crs2x`.
- c. Use direct algorithm to move `pt` along `crs2x` to circumference of `circle 2`. Use `center2` as starting point, `crs2x` as azimuth, `radius2` as distance.
- d. Use inverse algorithm to compute distance and azimuth from `center1` to `pt`. Denote these values as `dist1x` and `crs1x`, respectively.
- e. Compute error at this iteration step: `error = radius1 - dist1x`.
- f. Initialize arrays to store error as function of course from `center1`:
`errarray[1] = error`
`crsarray[1] = crs1x`
- g. While (`k ≤ maximumIterationCount`) and (`abs(errarray[1]) > tol`), improve approximation
 - (1) Use direct function to move `pt` along `crs1x` to circumference of `circle1`. Use `center1` as starting point, `crs1x` as azimuth, and `radius1` as distance. Note that `crs1x` was calculated as last step in previous iteration.
 - (2) Use inverse function to find azimuth from `center2` to `pt`, `crs2x`.
 - (3) Use direct function to move `pt` along `crs2x` to circumference of `circle2`. Use `center2` as starting point, `crs2x` as azimuth, and `radius2` as distance.
 - (4) Use inverse algorithm to compute distance and azimuth from `center1` to `pt`. Denote these values as `dist1x` and `crs1x`, respectively.
 - (5) Update function arrays:
`crsarray[0] = crsarray[1]`
`crsarray[1] = crs1x`
`errarray[0] = errarray[1]`
`errarray[1] = error`
 - (6) Use linear root finder to find the azimuth value that corresponds to zero error. Update the variable `crs1x` with this root value.

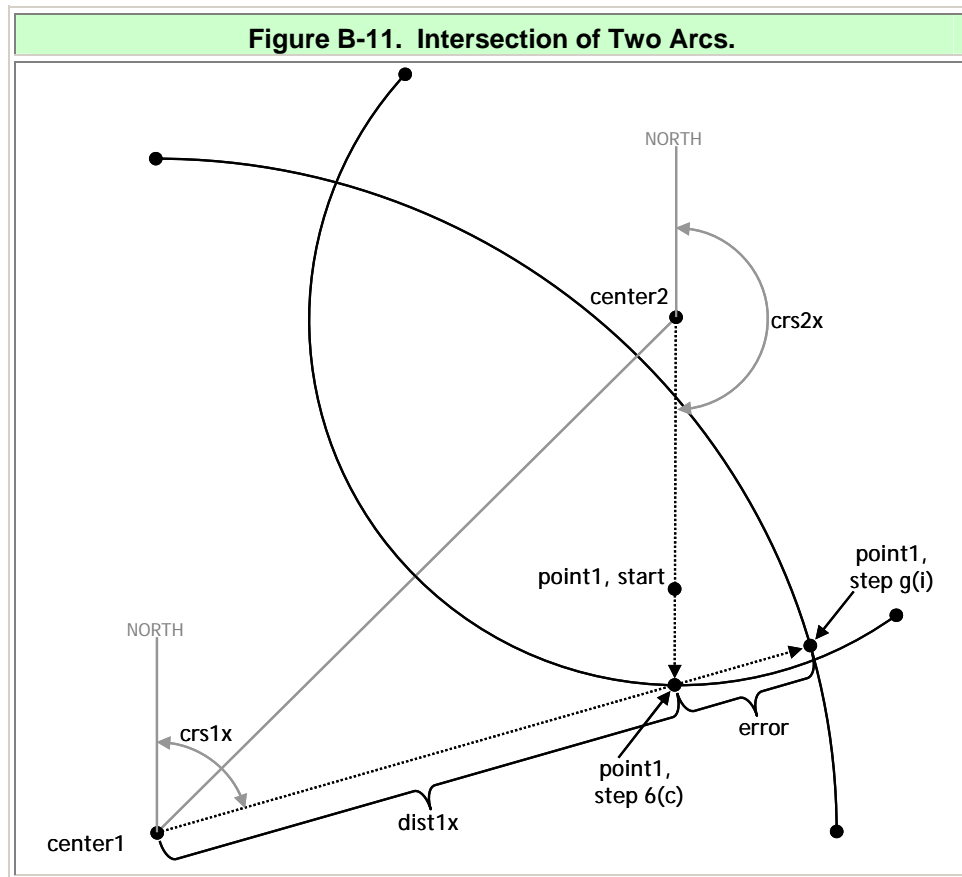

(7) Increment k : $k = k + 1$

h. End while loop.

STEP 7: Store point in array to be returned: $\text{intx}[0] = \text{point}$.

STEP 8: Repeat step 6 for approximation $\text{intx}[1]$.

STEP 9: Return array intx .

4.3 Intersections of Arc and Geodesic.

The following algorithm computes the point where a geodesic intersects an arc. The geodesic is defined by its starting coordinates and azimuth. The arc is defined by its center point coordinates and radius. The algorithm will return a null solution (no points) if the arc and geodesic do not intersect; it will return a single set of coordinates if the arc and geodesic intersect tangentially; and it will return two sets of coordinates if the arc and geodesic overlap.

4.3.1 Input/Output.

`long WGS84LineArcIntersect(LLPoint pt1, double crs1, LLPoint center, double radius, LLPointPair intx, int* n, double tol)` returns a reference to an `LLPoint` structure array that contains the coordinates of the intersection(s), where the inputs are:

<code>LLPoint pt1</code>	=	Geodetic coordinates of start point of geodesic
<code>double crs1</code>	=	Initial azimuth of geodesic at start point
<code>LLPoint center</code>	=	Geodetic coordinates of arc center point
<code>double radius</code>	=	Arc radius in nautical miles
<code>LLPointPair intx</code>	=	Two-element array of <code>LLPoint</code> objects that will be updated with intersections' coordinates
<code>int* n</code>	=	Reference to number of intersection points returned
<code>double tol</code>	=	Maximum error allowed in solution
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

4.3.2 Algorithm Steps.

This algorithm treats the arc and geodesic as unbounded. Once intersection points are found, they must be tested using Algorithms 3.6 and 3.7 to determine which, if any, lie within the curves' bounds. This algorithm fails if the arc and geodesic describe the same great circle. A test for this case is embedded in step 7. See figure B-12 for an illustration of the variable names.

- STEP 1:** Use Algorithm 5.1 to find the perpendicular projection point from arc center point (`center`) to the geodesic defined by starting point `pt1` and azimuth `crs1`. Denote this point by `perpPt`. Denote the distance as `perpDist`.
- STEP 2:** Use inverse Algorithm to calculate the azimuth of the geodesic at `perpPt`. Denote the azimuth from `perpPt` to `pt1` as `crs`.
- STEP 3:** If $(\text{abs}(\text{perpDist} - \text{radius}) < \text{tol})$, then the geodesic is tangent to the arc and intersection point is at `perpPt`.
- a. Return `intx[0] = perpPt`
- STEP 4:** Else if $(\text{perpDist} > \text{radius})$ then geodesic passes too far from center of circle; there is no intersection.

- a. Return empty array.

STEP 5: End if

STEP 6: Use spherical triangle approximation to find distance from `perpPt` to one intersection points. Since the spherical triangle formed from `center`, `perpPt`, and either intersection point has a right angle at the `perpPt` vertex, the distance from `perpPt` to either intersection is:

$$\text{dist} = \text{SPHERE_RADIUS} * \text{acos}(\text{cos}(\text{radius} / \text{SPHERE_RADIUS}) / \text{cos}(\text{perpDist} / \text{SPHERE_RADIUS}))$$

where `SPHERE_RADIUS` is the radius of the spherical earth approximation.

Note that a test must be performed so that if $\text{cos}(\text{perpDist} / \text{SPHERE_RADIUS}) = 0$, then no solution is returned

STEP 7: Find ellipsoidal approximation `intx[0]` to first intersection by starting at `perpPt` and using direct algorithm with distance `dist` and azimuth `crs`. This will place `intx[0]` on the geodesic.

STEP 8: Initialize iteration count `k = 0`.

STEP 9: Use inverse algorithm to calculate the distance from `center` to `intx[0]`. Denote this value by `radDist`. In the same calculation, calculate azimuth from `intx[0]` to `center`. Denote this value by `rcrs`; it will be used to improve the solution.

STEP 10: Calculate error for this iteration: `error = radius - radDist`

STEP 11: Initialize arrays that will hold distance and error function values so that linear interpolation may be used to improve approximation:
`distarray[0] = dist`
`errarray[0] = error`

STEP 12: Do one iterative step using spherical approximation near intersection point (see figure B-13).

- a. Use the inverse algorithm to calculate the azimuth from `intx[0]` to `perpPt`. Denote this value by `bcrs`.
- b. Compute the angle between the arc's radial line and the geodesic at `intx[0]`. This is depicted by `B` in figure B-13:

$$B = \text{abs}(\text{signedAzimuthDifference}(\text{bcrs}, \text{rcrs}))$$

- c. Calculate the angle opposite the radial error:

$$A = \arccos[\sin(B) * \cos(\text{abs}(\text{error}) / \text{sphereRad})]$$
- d. If $(\text{abs}(\sin(A)) < \text{eps})$ then the triangle is nearly isosceles, so use simple formula for correction term c : $c = \text{error}$
- e. Else, if $(\text{abs}(A) < \text{eps})$ then the error is very small, so use flat approximation: $c = \text{error} / \cos(B)$
- f. Else, use a spherical triangle approximation for c :

$$c = \text{sphereRad} * \arcsin[\sin(\text{error} / \text{sphereRad}) / \sin(A)]$$
- g. End if
- h. If $(\text{error} > 0)$, then $\text{intx}[0]$ is inside the circle, so approximation must be moved away from perpPt : $\text{dist} = \text{dist} + c$
- i. Else $\text{dist} = \text{dist} - c$
- j. End if
- k. Use the direct algorithm to move $\text{intx}[0]$ closer to solution. Use perpPt as the starting point with distance dist and azimuth crs .
- l. Use the inverse algorithm to calculate the distance from center to $\text{intx}[0]$. Denote this value again as radDist .
- m. Initialize second value of distarray and errarray :

$$\text{distarray}[1] = \text{dist}$$

$$\text{errarray}[1] = \text{radius} - \text{radDist}$$

STEP 13: Do while $(\text{abs}(\text{error}) > \text{tol})$ and $(k < \text{maximumIterationCount})$

- a. Use a linear root finder to find the distance value that corresponds to zero error. Update the variable dist with this root value.
- b. Use the direct algorithm again to move $\text{intx}[0]$ closer to solution. Use perpPt as the starting point with distance dist and azimuth crs .
- c. Use the inverse algorithm to calculate the distance from center to $\text{intx}[0]$. Denote this value radDist .
- d. Update distarray and errarray with the new values:

$$\text{distarray}[0] = \text{distarray}[1]$$

$$\text{errarray}[0] = \text{errarray}[1]$$

$$\text{distarray}[1] = \text{dist}$$

$$\text{errarray}[1] = \text{error}$$

- e. Increment the iteration count: $k = k + 1$

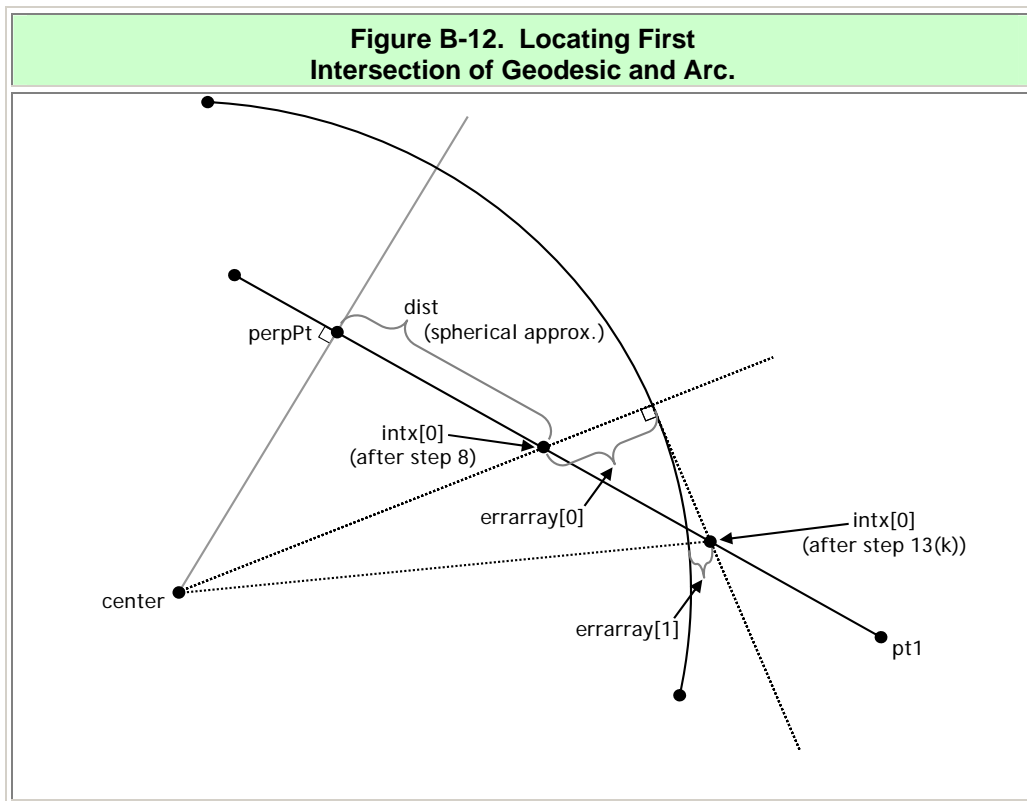

STEP 14: End while loop

STEP 15: Prepare variables to solve for second solution, $\text{intx}[1]$.

- Second solution lies on other side of perpPt , so set $\text{crs} = \text{crs} + \pi$.
- Use direct algorithm to find $\text{intx}[1]$. Start at perpPt , using crs for the azimuth and dist for the distance, since the distance from perpPt to $\text{intx}[0]$ is a very good approximation to the distance from perpPt to $\text{intx}[1]$.
- Use inverse algorithm to calculate radDist , the distance from center to $\text{intx}[1]$.
- Initialize the error function array:
 $\text{errarray}[0] = \text{radius} - \text{radDist}$.

STEP 16: Repeat steps 13 - 14 to improve solution for $\text{intx}[1]$

STEP 17: Return $\text{intx}[0]$ and $\text{intx}[1]$

4.4 Arc Tangent to Two Geodesics.

This algorithm is useful for finding flight path arcs, such as fitting a fly-by turn or radius-to-fix (RF) leg between two track-to-fix (TF) legs. Note that for the arc to be tangent to both the incoming and outgoing geodesics, the two tangent points must be different distances from the geodesics' intersection point.

4.4.1 Input/Output.

`long WGS84TangentFixedRadiusArc(LLPoint pt1, double crs12, LLPoint pt3, double crs3, double radius, ArcDirection* dir, double tol)` returns a reference to an `LLPoint` structure array that contains the coordinates of the center point and both tangent points of the arc that is tangent to both given geodesic, where the inputs are:

<code>LLPoint pt1</code>	=	Geodetic coordinates of start point of first geodesic
<code>double crs12</code>	=	Azimuth of first geodesic at <code>pt1</code>
<code>LLPoint pt3</code>	=	Geodetic coordinates of end point of second geodesic
<code>double crs3</code>	=	Azimuth of second geodesic at <code>pt3</code>
<code>double radius</code>	=	Radius of desired arc

ArcDirection* dir = Reference to an integer that represents direction of turn.

dir = 1 for left hand turn
dir = -1 for right hand turn

double tol = Maximum error allowed in solution

double eps = Convergence parameter for forward/inverse algorithms

4.4.2 Algorithm Steps.

See figure B-14 for an illustration of the variable names.

STEP 1: Use Algorithm 4.1 to locate the intersection point of the given geodesics. The first geodesic has azimuth `crs12` at `pt1`, while the second geodesic has azimuth `crs3` at `pt3`. Denote their intersection point by `pt2`.

STEP 2: If intersection point `pt2` is not found, then no tangent arc can be found.

a. Return empty array.

STEP 3: End if

STEP 4: Use the inverse algorithm to calculate the distance from `pt1` to `pt2` (denoted by `dist12`). Also calculate the azimuth at `pt2` to go from `pt2` to `pt1`. Denote this value by `crs21`.

STEP 5: Use the inverse algorithm to compute the azimuth at `pt2` to go from `pt2` to `pt3`. Denote this value by `crs23`.

STEP 6: Calculate angle between courses at `pt2` (see Algorithm 6.2). Denote this value by `vertexAngle`:

$$\text{vertexAngle} = \text{signedAzimuthDifference}(\text{crs21}, \text{crs23})$$

STEP 7: If $\text{abs}(\sin(\text{vertexAngle})) < \text{tol}$, then either there is no turn or the turn is 180 degrees. In either case, no tangent arc can be found.

a. Return empty array.

STEP 8: Else if `vertexAngle > 0` then course changes direction to the right:
`dir = -1`

STEP 9: Else, the course changes direction to the left: `dir = 1`

STEP 10: End if

STEP 11: Use spherical triangle calculations to compute the approximate distance from `pt2` to the points where the arc is tangent to either geodesic. Denote this distance by `distToStart`:

- a. `B=vertexAngle/2`
- b. If (`radius > sphereRad*B`) then no arc of the required radius will fit between the given geodesics
 - (1) Return empty array
- c. End if
- d. Calculate `distToStart` using the approximate formula from Napier's Rule of Circular Parts.

$$\text{distToStart} = \text{sphereRad} * \text{asin}(\tan(\text{radius}/\text{sphereRad}) / \tan(B))$$

STEP 12: Initialize the iteration count: `k = 0`

STEP 13: Initialize the error measure: `error = 0.0`

STEP 14: Do while (`k = 0`) or (`(abs(error) > tol)` and (`k ≤ maximumIterationCount`))

- a. Adjust the distance to tangent point based on current error value (this has no effect on first pass through, because `error = 0`):

$$\text{distToStart} = \text{distToStart} + (\text{error} / \sin(\text{vertexAngle}))$$

- b. Use the direct algorithm to project `startPt` distance `distToStart` from `pt1`. Use `pt1` as the starting point with azimuth of `crs12` and distance of `distToStart`.
- c. Use the inverse algorithm to compute azimuth of geodesic at `startPt`. Denote this value by `perpCrs`.
- d. If (`dir < 0`), then the tangent arc must curve to the right. Add $\pi/2$ to `perpCrs` to get the azimuth from `startPt` to center of arc:

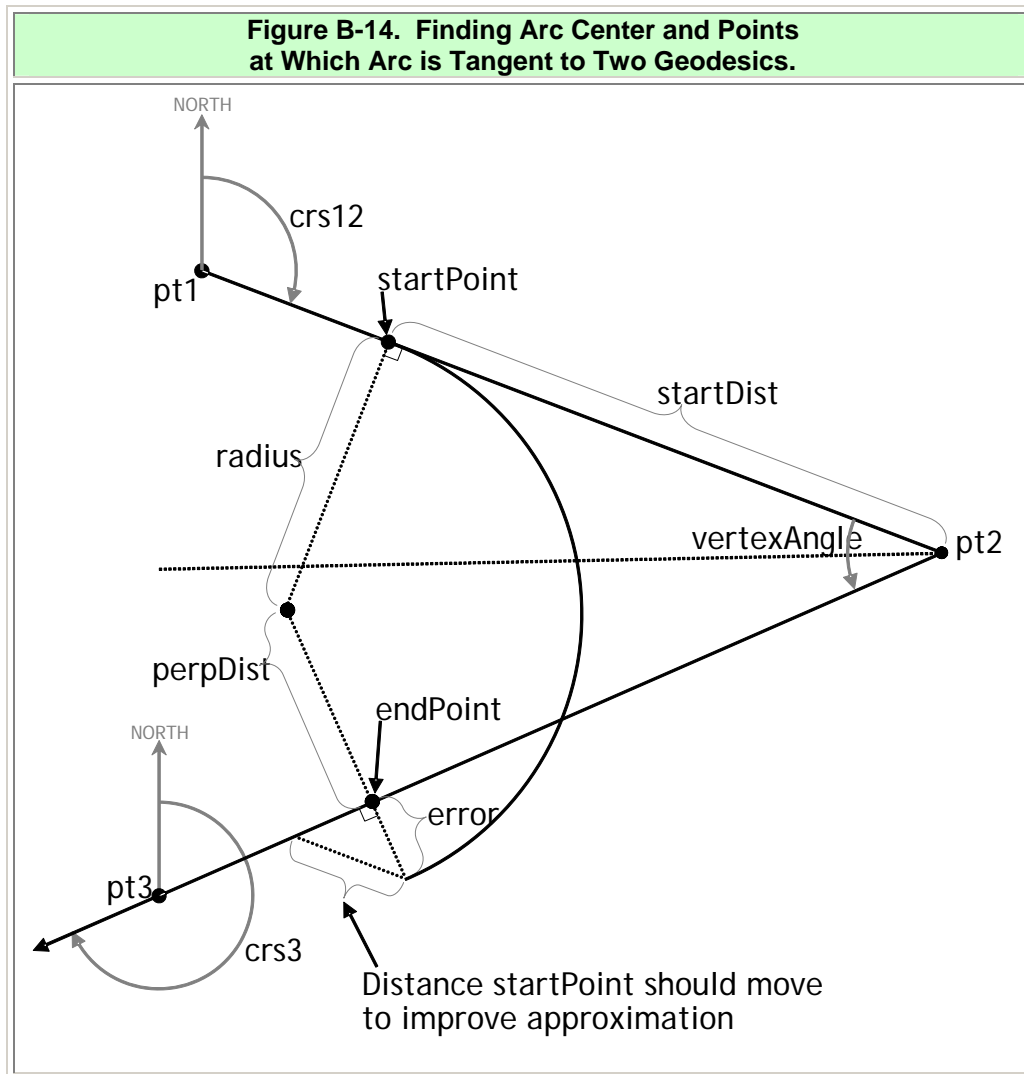

$$\text{perpCrs} = \text{perpCrs} + \pi/2$$

- e. Else, the tangent arc must curve to the left. Subtract $\pi/2$ from `perpCrs` to get the azimuth from `startPt` to center of arc:

$$\text{perpCrs} = \text{perpCrs} - \pi/2$$
- f. End if.
- g. Use the direct algorithm to locate the arc center point, `centerPoint`. Use `startPt` as the starting point, `perpCrs` for the azimuth, and radius for the distance.
- h. Use Algorithm 5.1 to project `centerPoint` to the second geodesic. Denote the projected point by `endPt`. This is approximately where the arc will be tangent to the second geodesic. Denote the distance from `centerPoint` to `endPoint` as `perpDist`.
- i. Calculate the tangency error: $\text{error} = \text{radius} - \text{perpDist}$. This error value will be compared against the required tolerance parameter. If its magnitude is greater than `tol`, then it will be used to adjust the position of `startPoint` until both `startPoint` and `endPoint` are the correct distance from `centerPoint`.

STEP 15: End while.

STEP 16: Return the values for `centerPoint`, the center of the arc, `startPoint`, the tangent point on the first geodesic, and `endPoint`, the tangent point of second geodesic.

4.5 Intersections of Geodesic and Locus.

This algorithm is useful for finding the corner points of TF sub-segment's OEA, where a parallel (represented as a locus of points) intersects the geodesic end line.

4.5.1 Input/Output.

`long WGS84GeoLocusIntersect(LLPoint geoSt, LLPoint geoEnd, LLPoint* pint, Locus loc, double tol)` returns a reference to an `LLPoint` structure array that contains the coordinates of the intersection point., where the inputs are:

`LLPoint geoSt` = Geodetic coordinates of start point of geodesic

`LLPoint geoEnd` = Geodetic coordinates of end point of geodesic

<code>Locus loc</code>	=	Structure defining locus of points
<code>LLPoint* pint</code>	=	Reference to <code>LLPoint</code> that will be updated with intersection coordinates.
<code>double tol</code>	=	Maximum error allowed in solution
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

4.5.2 Algorithm Steps.

See figure B-15 for an illustration of the variable names.

- STEP 1: Use the geodesic intersection algorithm (Algorithm 4.1) to find a first approximation to the point where the given geodesic and locus intersect. Use the start and end coordinates of the locus along with the start and end coordinates of given geodesic as inputs to the geodesic intersection algorithm. This will erroneously treat the locus as a geodesic; however, the calculated intersection will be close to the desired intersection. The geodesic intersection algorithm will return the approximate intersection point, `pt1`, along with the courses and distances from the `pt1` to the start points of the locus and given geodesic. Denote these courses and distances as `crs31`, `dist13`, `crs32`, `dist23`, respectively.
- STEP 2: If `pt1` is not found, then the locus and geodesic do not intersect.
- Return empty point.
- STEP 3: End if
- STEP 4: Use the inverse algorithm to calculate the course from `geoSt` to `geoEnd`. Denote this value as `fcrs`. This value is needed by the direct algorithm to locate new points on the given geodesic.
- STEP 5: Use the inverse algorithm to calculate the distance and course from `pt1` to `geoSt`. Denote these values as `distBase` and `crsBase`, respectively.
- STEP 6: Obtain the forward course of the locus's defining geodesic. This course is stored as `loc.geoAz`. Denote this course as `tcrs`. This value is needed to project the approximate point onto the defining geodesic in order to calculate the appropriate locus distance.
- STEP 7: Use Algorithm 5.1 to project `pt1` onto the locus's defining geodesic. Use `pt1`, `loc.geoStart`, and `tcrs` as inputs. Denote the returned point as

pInt, the returned course as crsFromPt, and the returned distance as distFromPt.

STEP 8: Use Algorithm 3.9 to calculate the distance from the defining geodesic to the locus at pInt. Denote this value as distLoc. Note that distLoc may be positive or negative, depending on which side of defining geodesic the locus lays.

STEP 9: Calculate the distance from pt1 to the locus. This is the initial error:
errarray[1] = distFromPt - abs(distLoc).

STEP 10: Save the initial distance from geoSt to the approximate point:
geodarray[1] = distBase. We will iterate to improve the approximation by finding a new value for distBase that makes errarray zero.

STEP 11: Calculate a new value of distBase that will move pt1 closer to the locus. This is done by approximating the region where the given geodesic and locus intersect as a right Euclidean triangle and estimating the distance from the current pt1 position to the locus (see figure B-16).

- a. Calculate the angle between the geodesic from pt1 to pInt and the geodesic from pt1 to geoSt:

$$\text{theta} = \text{abs}(\text{signedAzimuthDifference}(\text{crsFromPt}, \text{crsBase}))$$

- b. Calculate a new value for distBase:
newdistbase = distbase - errarray[1] / cos(theta)

STEP 12: Initialize the iteration count: k = 0.

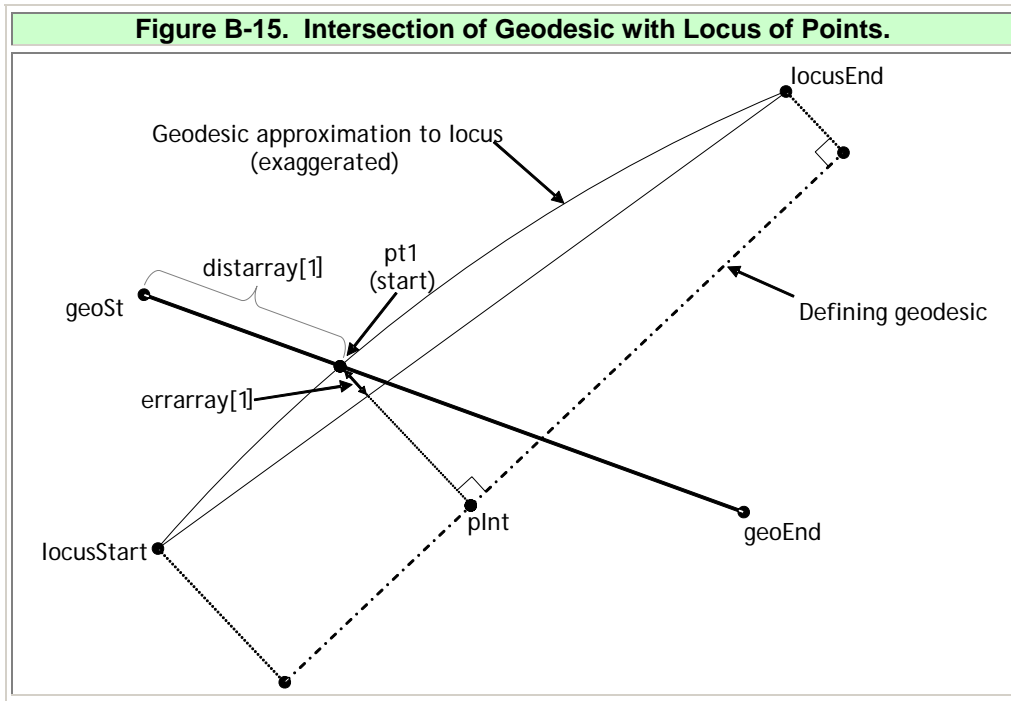

STEP 13: Do while (abs(errarray[1] > tol) and (k < maxIterationCount))

- a. Use geoSt, fcrs, and newDistBase in the direct algorithm to update the value of pt1.
- b. Save the current values of errarray and geodarray:
errarray[0] = errarray[1]
geodarray[0] = geodarray[1]
- c. Set geodarray[1] = newDistBase.
- d. Repeat steps 7, 8, and 9 to calculate the distance from pt1 to the locus, distloc, and the corresponding update to errarray[1].

- e. Use a linear root finder with `geodarray` and `errarray` to find the distance value that makes the error zero. Update `newDistBase` with this root value.

STEP 14: End while

STEP 15: Return `pint=pt1`.

4.6 Intersections of Arc and Locus.

This algorithm solves for the intersection of a fixed radius arc and a locus. It is very similar to Algorithm 4.3, which computes the intersections of an arc and a geodesic. It begins by treating the locus as a geodesic and applying Algorithm 4.3 to find approximate intersection points. The approximation is improved by traveling along the locus, measuring the distance to the arc center at each point. The difference between this distance and the given arc radius is the error. The error is modeled as a series of linear functions of position on the locus. The root of each function gives the next approximation to the intersection. Iteration stops when the error is less than the specified tolerance.

4.6.1 Input/Output.

`long WGS84LocusArcIntersect(Locus loc, LLPoint center, double radius, LLPointPair intx, int* n, double tol)` returns a reference to an `LLPoint` structure array that contains the coordinates of the intersection(s), where the inputs are:

<code>Locus loc</code>	=	Locus of interest
<code>LLPoint center</code>	=	Geodetic coordinates of arc
<code>double radius</code>	=	Arc radius

<code>LLPointPair intx</code>	=	Two-element array of <code>LLPoint</code> that will be updated with intersection coordinates.
<code>int* n</code>	=	Number of intersections found
<code>double tol</code>	=	Maximum error allowed in solution
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

4.6.2 Algorithm Steps.

See figure B-17 for an illustration of the variables.

- STEP 1: Initialize number of intersections: $n = 0$
- STEP 2: Use the inverse algorithm to compute the course from `loc.locusStart` to `loc.locusEnd`. Denote this value as `fcrs`.
- STEP 3: Use Algorithm 5.2 to project the center of the arc to the locus. Denote the projected point as `locpt`. Denote the distance and course from center to `locpt` as `distFromPoint` and `crsFromPoint`, respectively. If `locpt` is on or within the radius of the arc, then it will be used to find the intersection(s) of the locus and the arc, `intx`.
- STEP 4: If (`distFromPoint > radius`), then no approximate intersections were found. Return NULL.
- STEP 5: End if.
- STEP 6: Else if `distFromPoint` is equal to `radius` within tolerance level, then:
- Locus is tangent to arc. One intersection exists.
 - `intx[0]=locpt`
- STEP 7: End if.
- STEP 8: Otherwise, `distFromPoint` must be less than `radius`, meaning there are two possible intersections. These two approximate intersections are found using spherical trigonometry and the direct algorithm. Denote the approximate intersections as `intx[0]` and `intx[1]`.
- STEP 9: Use the inverse algorithm to compute the forward and reverse course from `loc.geoStart` to `loc.geoEnd`. Store these values as `fcrs1` and `bcrs`, respectively.

STEP 10: For $i=0, i < n1$

- a. Use Algorithm 5.1 to project `intx[0]` to the locus's defining geodesic. Denote the projected point as `perpPt`.
- b. Use the inverse algorithm to calculate `distbase`, the distance from `perpPt` to `loc.geoStart`.
- c. Use Algorithm 3.10 to project `locPt` onto the locus from `perpPt`.
- d. Use the inverse algorithm to calculate `distCent`, the distance from `locPt` to center.
- e. Calculate the error and store it in an array:
`errarray[1] = distCent - radius`
- f. If `(abs(errarray[1]) < tol)`, then `locPt` is close enough to the circle. Set `intx[n] = locPt`, `n = n+1`, and continue to the end of the for loop, skipping steps g through m below.
- g. Save the current value of `distbase` to an array: `geodarray[1] = distbase`
- h. Initialize the iteration count: `k = 0`
- i. Perturb `distbase` by a small amount to generate a second point at which to measure the error: `newDistbase = 1.001*distbase`.
- j. Do while `(k < maxIterationCount)` and `(abs(errarray[1]) > tol)`
- k. Project `Pt1` on the defining geodesic a distance `newDistbase` along course `fcrs1` from `loc.geoStart`.
 - (1) Use Algorithm 3.10 to project `locPt` onto the locus from `Pt1`.
 - (2) Use the inverse algorithm to calculate `dist1`, the distance from `locPt` to center.
 - (3) Calculate the error: `error = dist1 - radius`
 - (4) Update the distance and error arrays:
`geodarray[0] = geodarray[1]`
`geodarray[1] = newDistbase`
`errarray[0] = errarray[1]`
`errarray[1] = error`

(5) Use a linear root finder with `geodarray` and `errarray` to find the distance value that makes the error zero. Update `newDistbase` with this root value.

- l. End while.
- m. If `locPt` is on the locus according to Algorithm 3.11, then
 - (1) Copy `locPt` to the output array: `intx[n] = locPt`.
 - (2) Update the count of intersection points found: `n = n + 1`.

STEP 11: End for loop

STEP 12: Return `intx`

4.7 Intersections of Two Loci.

4.7.1 Input/Output.

`long WGS84LocusIntersect(Locus loc1, Locus loc2, LLPoint* intx, double tol)` returns a reference to an `LLPoint` structure array that contains the intersection coordinates, where the inputs are:

`Locus loc1` = First locus of interest

`Locus loc2` = Second locus of interest

LLPoint* intx = Reference to LLPoint that will be updated with intersection coordinates.

Double tol = Maximum error allowed in solution

Double eps = Convergence parameter for forward/inverse algorithms

4.7.2 Algorithm Steps.

See figure B-18 for an illustration of the variables and calculation steps.

- STEP 1:** Use the inverse algorithm to calculate the course of the geodesic approximation to loc1. Use loc1.locusStart and loc1.locusEnd as start and end points. Denote this course as crs1.
- STEP 2:** Use the inverse algorithm to calculate the course of the geodesic approximation to loc2. Use loc2.locusStart and loc2.locusEnd as start and end points. Denote this course as crs2.
- STEP 3:** Use loc1.locusStart, crs1, loc2.locusStart, and crs2 as input to Algorithm 4.1 to calculate an approximate solution to the locus intersection. Denote the approximate intersection point at p1.
- STEP 4:** If (p1 = NULL), then the loci do not intersect, so return NULL.
- STEP 5:** Use the inverse algorithm to calculate the course of loc1's defining geodesic. Use loc1.geoStart and loc1.geoEnd as the start and end points, and denote the course as tcrs1.
- STEP 6:** Project p1 to the geodesic of loc1 using Algorithm 5.1 with loc1.geoStart and tcrs1 as input parameters. Store the projected point as pint1.
- STEP 7:** If (pint1 = NULL), then no projected point was found so return NULL.
- STEP 8:** Use the inverse algorithm to calculate distbase, the distance from loc1.geoStart to pint1.
- STEP 9:** Initialize iteration counter: k = 0
- STEP 10:** Do while (k = 0) or ((k < maxIterationCount) and (abs(error) > tol))
- a. If (k > 0) then apply direct algorithm to project new pint1 on loc1. Use starting point loc1.geoStart, course tcrs1, and distance distbase.

- b. Use Algorithm 3.10 to project a point on `loc1` from the current `pint1`. Denote the projected point as `ploc1`.
- c. Project `ploc1` to the geodesic of `loc2` using Algorithm 5.1 with `loc2.geoStart` and `tcrs2` as input parameters. Store the projected point as `pint2`.
- d. Use Algorithm 3.10 to project a point on `loc2` from `pint2`. Denote the projected point as `ploc2`. If `ploc1` were truly at the intersection of the `loci`, then `ploc2` and `ploc1` would be the same point. The distance between them measures the error at this calculation step.
- e. Compute the error by using the inverse algorithm to calculate the distance between `ploc1` and `ploc2`.
- f. Update the error and distance arrays and store the current values:

```
errarray[0] = errarray[1]
errarray[1] = error
distarray[0] = distarray[1]
distarray[1] = distbase
```
- g. If ($k = 0$), then project `ploc2` onto `loc1` to get a new estimate of `distbase`:
 - (1) Project `ploc2` to the geodesic of `loc1` using Algorithm 5.1 with `loc1.geoStart` and `tcrs1` as input parameters. Store the projected point as `pint1`.
 - (2) Use the inverse algorithm to calculate `distbase`, the distance from `loc1.geoStart` to `pint1`.
- h. Else
 - (1) Use a linear root finder with `distarray` and `errarray` to find the distance value that makes the error zero. Update `distbase` with this root value. This is possible only after the first update step because two values are required in each array.
- i. End if
- j. Increment iteration count: $k = k + 1$

STEP 11: End while

LLPoint* centerpoint	=	Reference to LLPoint that will contain arc's center coordinates.
LLPoint* startPoint	=	Reference to LLPoint that will contain arc's start point coordinates.
LLPoint* endpoint	=	Reference to LLPoint that will contain arc's endpoint coordinates.
ArcDirection* dir	=	Reference to an integer that represents direction of turn. dir = 1 for left hand turn dir = -1 for right hand turn
double tol	=	Maximum error allowed in solution
double eps	=	Convergence parameter for forward/inverse algorithms

4.8.2 Algorithm Steps.

See figure B-19.

- STEP 1:** Use inverse algorithm to calculate `crs12`, the course from `loc1.locusStart` to `loc1.locusEnd`.
- STEP 2:** Use inverse algorithm to calculate `gcrs1` and `geoLen1`, the course and distance from `loc1.geoStart` to `loc1.geoEnd`.
- STEP 3:** Use inverse algorithm to calculate `crs32`, the course from `loc2.locusEnd` to `loc2.locusStart`. Convert `crs32` to its reciprocal: $crs32 = crs32 + \pi$.
- STEP 4:** Apply Algorithm 4.4 to find the arc tangent to the geodesic approximations to `loc1` and `loc2`. Use `loc1.locusStart`, `crs12`, `loc2.locusEnd`, `crs32`, and `radius` as input parameter. Denote the array of points returned as `intx`. `intx[0]` will be the approximate arc center point, `intx[1]` will be the tangent point near `loc1`, and `intx[2]` will be the tangent point near `loc2`. Also returned will be the direction of the arc, `dir`.
- STEP 5:** If (`intx = NULL`) then there is no tangent arc. Return `NULL`.

STEP 6: Calculate the approximate angle at the vertex where `loc1` and `loc2` intersect. This will be used only to estimate the first improvement to the tangent point `intx[1]`. Thus we use an efficient spherical triangles approximation (see figure B-20):

- a. Use the spherical inverse function to calculate the `rcrs1`, the course from `intx[0]` (the approximate arc center) to `intx[1]` (the approximate tangent point on `loc1`).
- b. Use the spherical inverse function to calculate the `rcrs2`, the course from `intx[0]` to `intx[2]` (the other approximate tangent point).
- c. Calculate the angle difference between `rcrs1` and `rcrs2`:

$$\text{angle} = \text{abs}(\text{signedAzimuthDifference}(\text{rcrs1}, \text{rcrs2}))$$
- d.
$$\text{vertexAngle} = 2 * \text{acos} \left(\sin \left(\frac{\text{angle}}{2} \right) \cos \left(\frac{\text{radius}}{\text{SPHERE_RADIUS}} \right) \right)$$

STEP 7: Calculate the inclination angle of `loc1` relative to its geodesic:

$$\text{locAngle} = \text{atan} \left[\frac{(\text{loc1}.\text{endDist} - \text{loc1}.\text{startDist})}{\text{geoLen1}} \right]$$

STEP 8: Initialize `distbase = 0.1`

STEP 9: Initialize the iteration count: `k = 0`

STEP 10: Do while (`k = 0`) or (`(k < maxIterationCount) and abs(error) > tol`))

- a. Use direct algorithm with starting point `loc1.geoStart`, course `gcrs1`, and distance `distbase` to project point `geoPt`.
- b. Use Algorithm 3.10 to project a point on `loc1` from the current `geoPt1`. Denote the projected point as `intx[1]`.
- d. Use Algorithm 3.12 to calculate `lcrs1`, the course of `loc1` at `intx[1]`.
- e. Convert `lcrs1` into the correct perpendicular course toward the arc center (note that `dir > 0` indicates a left-hand turn):

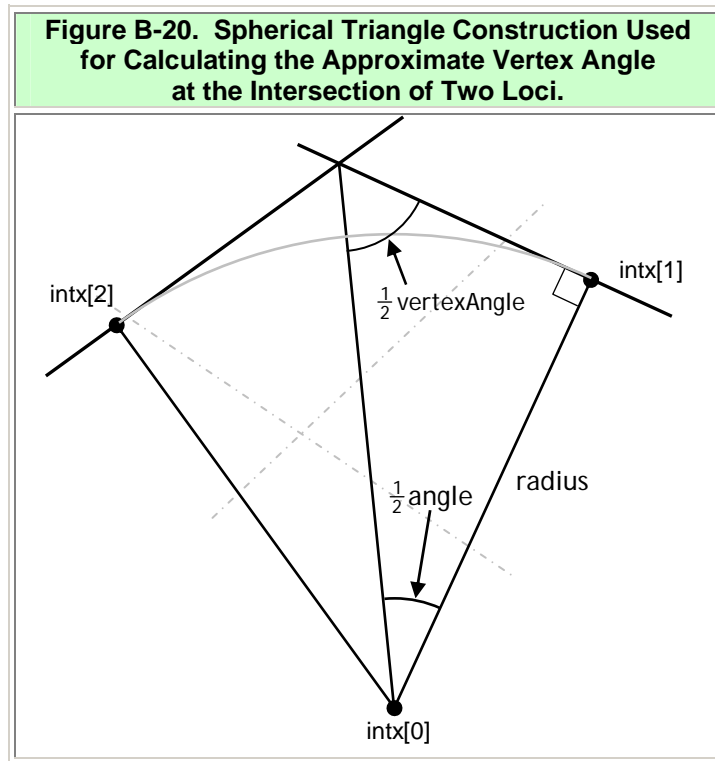

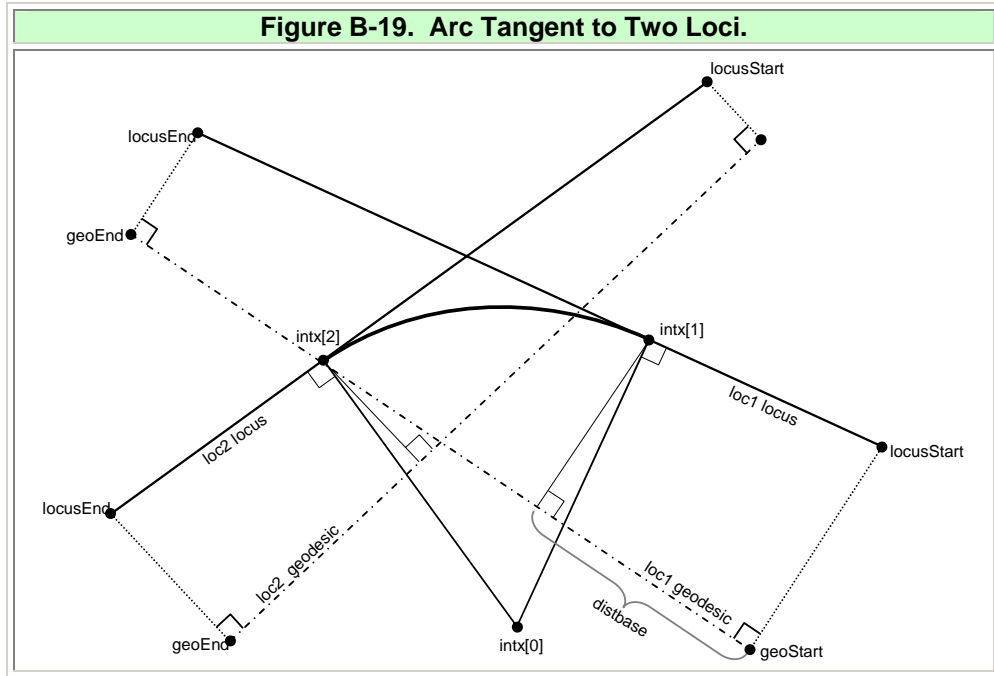

$$\text{lcrs1} = \text{lcrs1} - \text{dir} * \frac{\pi}{2}$$

- f. Use the direct algorithm with starting point `intx[1]`, course `lcrs1`, and distance `radius` to project the arc center point, `intx[0]`.
- g. Use Algorithm 5.2 to project `intx[0]` onto `loc2`. Reassign `intx[2]` as the projected point.
- h. Use the inverse algorithm to calculate `r2`, the distance from `intx[0]` to `intx[2]`
- i. Calculate the error: `error = r2 - radius`
- j. Update the distance and error function arrays:
`distarray[0] = distarray[1]`
`distarray[1] = distbase`
`errarray[0] = errarray[1]`
`errarray[1] = error`
- k. If (`k = 0`), then estimate better `distbase` value using spherical approximation and calculated error:

$$\text{distbase} = \text{distbase} + \text{error} * \frac{\cos(\text{locAngle})}{\sin(\text{vertexAngle})}$$
- l. Else, use a linear root finder with `distarray` and `errarray` to find the distance value that makes the error zero. Update `distbase` with this root value.
- m. End if

STEP 12: End while

STEP 13: Return `intx`.

5.0 Projections.**5.1 Project Point to Geodesic.**

This algorithm is used to determine the shortest distance from a point to a geodesic. It also locates the point on the geodesic that is nearest the given point.

5.1.1 Input/Output.

`long WGS84PerpIntercept(LLPoint pt1, double crs12, LLPoint* pt2, LLPoint pt3, double* crsFromPoint, double* distFromPoint, double tol)` returns a reference to an `LLPoint` structure that contains the coordinates of the projected point, where the inputs are:

<code>LLPoint pt1</code>	=	Coordinates of geodesic start point
<code>double crs13</code>	=	Initial azimuth of geodesic at start point
<code>LLPoint pt3</code>	=	Coordinates of point to be projected to geodesic
<code>LLPoint* pt2</code>	=	Reference to <code>LLPoint</code> that will be updated with coordinates of projected point.
<code>double* crsFromPoint</code>	=	Reference to azimuth of geodesic from <code>pt3</code> to projected point, in radians.
<code>double* distFromPoint</code>	=	Reference to distance from <code>pt3</code> to projected point, in radians.
<code>double tol</code>	=	Maximum error allowed in solution
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

5.1.2 Algorithm Steps.

This algorithm treats the geodesic as unbounded, so that projected points that lie “behind” the geodesic starting point `pt1` will be returned. If it is desired to limit solutions to those that lie along the forward direction of the given geodesic, then step 4g may be modified to return a `NULL` solution (see figure B-21).

STEP 1: Use the inverse algorithm to calculate the distance, azimuth, and reverse azimuth from `pt1` to `pt3`. Denote these values as `crs13`, `crs31`, and `dist13`, respectively.

STEP 2: Calculate the angle between the given geodesic and the geodesic between pt1 and pt3. This is accomplished using signedAzimuthDifference function (see Algorithm 6.2)

```
angle=abs(signedAzimuthDifference(crs13, crs12))
```

STEP 3: If (dist13 <= tol), then pt2 is the same point as pt1.

STEP 4: If $\pi/2 - \text{angle} < \text{tol}$, then the projected point pt2 is very close to or behind pt1 (the start of the geodesic), so extend the geodesic backward far enough to catch the projection. Use a spherical triangle approximation to calculate the needed extension distance.

- a. B=angle
- b. a=dist13/sphereRad
- c. b=asin(sin(B)sin(a))
- d. dist12=2*sphereRad*atan(tan(0.5*(a-b))*sin(0.5*(A-B)))
- e. If abs(dist12) < tol, then the projected point is identical to pt1 to within the required accuracy.
 - (1) crsFromPoint = crs31;
 - (2) distFromPoint = dist13;
 - (3) Return pt2 = pt1
- f. End if.
- g. Use the direct algorithm to move pt1 along reverse geodesic course. Use 1.1*dist12 for the distance, crs12+ π for the azimuth, and then store the new location in the temporary variable newPt1. A distance greater than dist12 is used to compensate for possible errors in the spherical approximation.
- h. Use the inverse algorithm to calculate the azimuth from newPt to pt1. This value replaces the original azimuth value crs12.
 - (1) Rename newPt1 as pt1: pt1 = newPt1.

STEP 5: Calculate the approximate distance from `pt1` to the projected point using the spherical triangle formula from steps 4(a) through 4(d). Denote the approximate distance found as `dist13`.

STEP 6: Use the direct algorithm to project a point on the given geodesic distance `dist13` from `pt1`. Use `pt1` for the starting point, `dist12` for distance, and `crs12` for azimuth. Denote the computed point by `pt2`.

STEP 7: Use the inverse algorithm to calculate the azimuth `crs21` from `pt2` to `pt1`.

STEP 8: Use the inverse algorithm to calculate the azimuth `crs23` and distance `dist23` from `pt3` to `pt2`

STEP 9: Calculate the angle between the geodesics that intersect at `pt3`, and cast that angle into the range $[0, \pi]$ using the following formula (see Algorithm 5.1):

```
angle=abs(signedAzimuthDifference(crs21, crs23))
```

STEP 10: Calculate the error and store it as the first element in the error function array: `errarray[0] = angle - $\pi/2$`

STEP 11: Store the current distance from `pt1` to `pt2` in the distance function array: `distarray[0] = dist12`

STEP 12: A second distance/error value must be calculated before linear interpolation may be used to improve the solution. The following formula may be used:

```
distarray[1]=distarray[0]+errarray[0]*dist23
```

STEP 13: Use the direct algorithm to project point on the given geodesic distance `distarray[1]` from `pt1`. Use `pt1` for the starting point, `distarray[1]` for distance, and `crs12` for azimuth. Denote the computed point by `pt2`.

STEP 14: Use the inverse algorithm to calculate the azimuth `crs21` from `pt2` to `pt1`.

STEP 15: Use the inverse algorithm to calculate the azimuth `crs23` from `pt2` to `pt3`.

STEP 16: Calculate the error in angle (see Algorithm 5.1):

```
errarray[1]=abs(signedAzimuthDifference(crs21, crs23))- $\pi/2$ 
```

STEP 17: Initialize the iteration count: $k = 0$

STEP 18: Do while ($k = 0$) or ($(\text{error} > \text{tol})$ and ($k < \text{maxIterationCount}$))

- a. Use linear approximation to find root of `errarray` as a function of `distarray`. This gives an improved approximation to `dist12`.
- b. Use the direct algorithm to project point on the given geodesic distance `dist12` from `pt1`. Use `pt1` for the starting point, `dist12` for distance, and `crs12` for azimuth. Denote the computed point by `pt2`.
- c. Use the inverse algorithm to calculate the azimuth `crs21` from `pt2` to `pt1`.
- d. Use the inverse algorithm to calculate the distance `dist23`, azimuth `crs32`, and reverse azimuth `crs23` from `pt3` to `pt2`.
- e. Update `distarray` and `errarray` with the new values:

```
distarray[0] = distarray[1]
errarray[0] = errarray[1]
distarray[1] = dist13
errarray[1]=abs(signedAzimuthDifference(crs21,
crs23))-π/2
```
- f. Calculate the difference between the two latest distance values. This serves as the error function for measuring convergence:

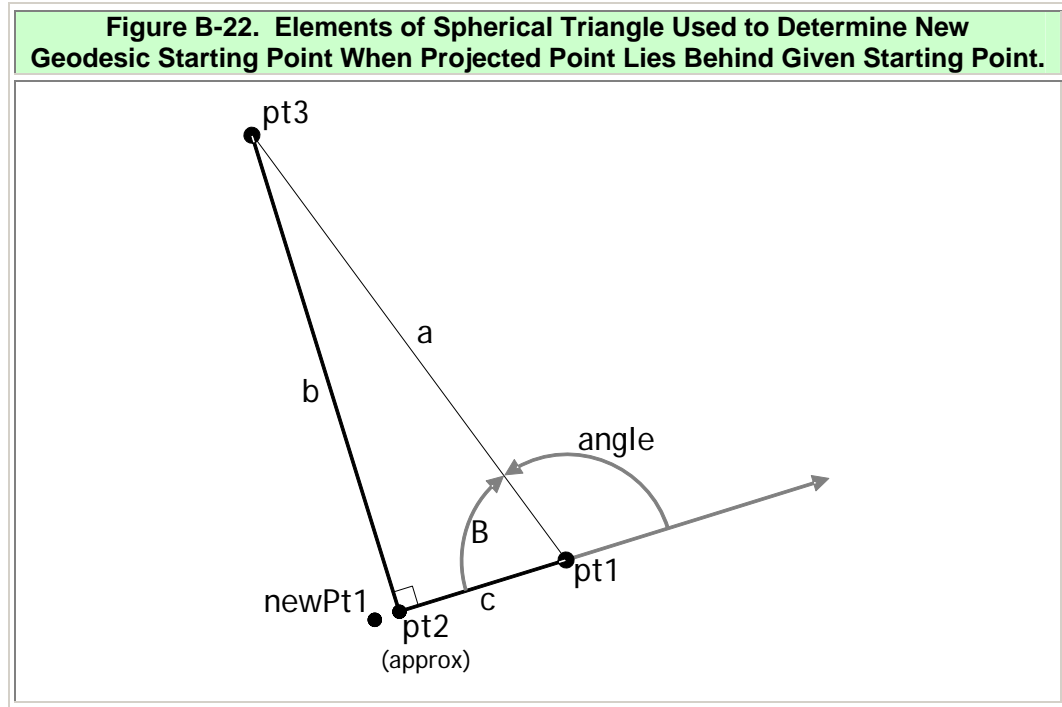

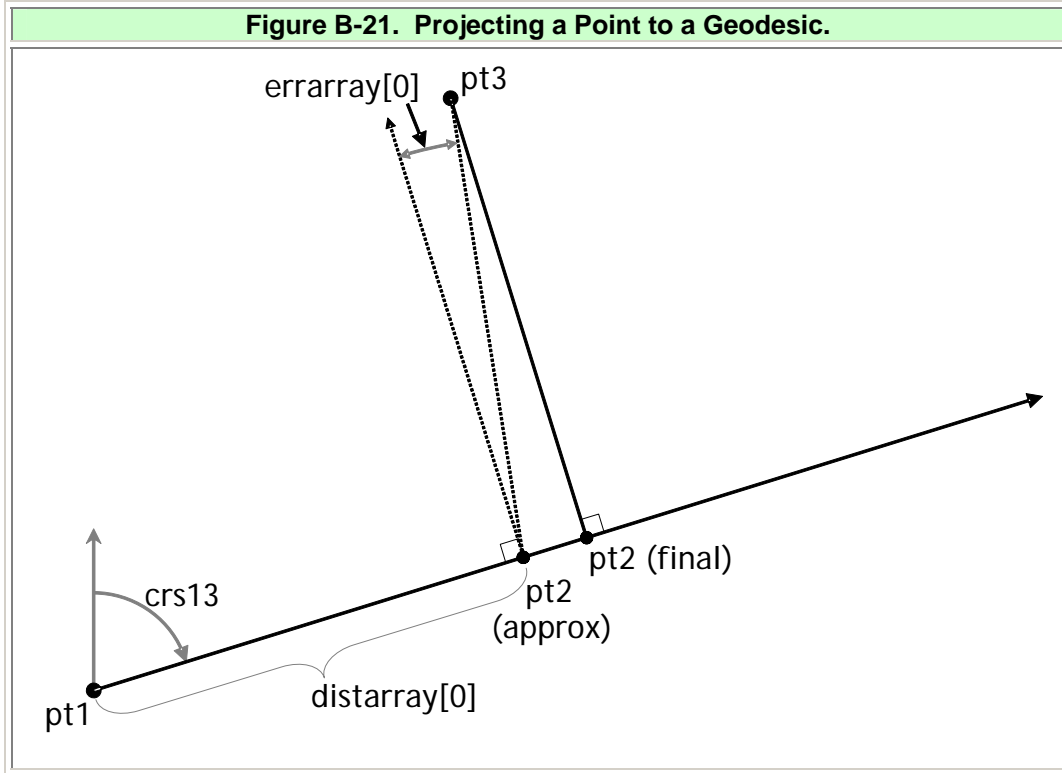

```
error=abs(distarray[1]-distarray[0])
```

STEP 19: End while

STEP 20: Set `crsToPoint = crs32`

STEP 21: Set `distToPoint = dist23`

STEP 22: Return `pt2`

5.2 Project Point to Locus.

This algorithm returns the point on a locus nearest the given sample point. It is used in Algorithm 4.8 to calculate an arc tangent to two loci.

5.2.1 Input/Output.

`LLPoint* WGS84LocusPerpIntercept(Locus loc, LLPoint pt2, double* crsFromPoint, double* distFromPoint, double tol)`
returns a reference to an `LLPoint` structure that contains the coordinates of the projected point, where the inputs are:

<code>Locus loc</code>	=	Locus structure to which point will be projected
<code>LLPoint pt2</code>	=	Coordinates of point to be projected to locus
<code>double* crsFromPoint</code>	=	Reference to value that will store the course from <code>pt2</code> to projected point
<code>double* distFromPoint</code>	=	Reference to value that will store the distance from <code>pt2</code> to projected point
<code>double tol</code>	=	Maximum error allowed in solution
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

5.2.2 Algorithm Steps.

See figure B-23 for an illustration of the variables.

STEP 1: Define the course and distance from `loc.geoStart` to `loc.geoEnd` as `gcrs` and `gdist`, respectively. This course and distance is a part of the locus structure.

- a. `gcrs=loc.geoAz`
- b. `gdist=loc.geoLength`

STEP 2: If $(\text{abs}(\text{loc.startDist} - \text{loc.endDist}) < \text{tol})$, then the locus is "parallel" to its defining geodesic. In this case, the projected point on the locus will lie on the geodesic joining `pt2` with its projection on the defining geodesic, and the calculation is simplified:

- a. Apply Algorithm 5.1 to project `pt2` onto the defining geodesic of `loc`. Use `loc.geoStart`, `gcrs`, and `pt2` as input parameters. The intersection point, `perpPt`, will be returned along with the course and distance from `pt2` to `perpPt`. Denote the course and distance values as `crsFromPoint` and `distFromPoint`, respectively.

- b. Use Algorithm 3.10 to project a point `locPt` on the locus from `perpPt` on the geodesic.
- c. Use the inverse algorithm to recalculate `distFromPoint` as the distance between `pt2` and `locPt`.
- d. Return `locPt`.

STEP 3: End If.

STEP 4: Use the inverse algorithm to compute `lcrs`, the course from `loc.locusStart` to `loc.locusEnd`.

STEP 5: Use Algorithm 5.1 to project `pt2` onto the geodesic approximation of the locus. Pass `loc.locusStart`, `lcrs`, and `pt2` as parameters. Denote the computed point as `locPt`. (In general, this point will not exactly lie on the locus. We will adjust its position so that it is on the locus in a subsequent step.)

STEP 6: Calculate the locus inclination angle, relative to its geodesic:

$$\text{locAngle} = \text{atan}((\text{loc.startDist} - \text{loc.endDist}) / \text{gdist})$$

STEP 7: Use Algorithm 5.1 to project `locPt` onto the locus's defining geodesic. Pass `loc.geoStart`, `gcrs`, and `locPt` as parameters. Denote the computed point as `geoPt`.

STEP 8: Use the inverse function to calculate the distance from `loc.geoStart` to `geoPt`. Store this value as `distarray[1]`.

STEP 9: Initialize the iteration count: `k = 0`

STEP 10: Do while (`k = 0`) or (`abs(errarray[1]) > tol`) and (`k < maxIterationCount`)

- a. Use Algorithm 3.10 with `distarray[1]` to project a point onto the locus. Reassign `locPt` as this point.
- b. Use Algorithm 3.12 to recompute `lcrs`, the course of the locus at `locPt`.
- c. Use the inverse algorithm to compute `crsToPoint` and `distToPoint`, the course and distance from `locPt` to `pt2`.

- d. Compute the signed angle between the locus and the geodesic from locPt to pt2:

```
angle=signedAzimuthDifference(lcrs, crsToPoint)
```

- e. Store the approximate error as:

```
errarray[1]=-distToPoint*cos(angle)
```

This converts the error in angle into an error in distance which can be compared to tol.

- f. If ($k = 0$) then a direct calculation is used to improve the approximation:

```
newDist=distarray[1]+errarray[1]*cos(locAngle)
```

- g. Else, use a linear root finder with distarray and errarray to solve for the distance value that makes the error zero. Denote this value as newDist.

- h. End If

- i. Update the distance and error arrays:

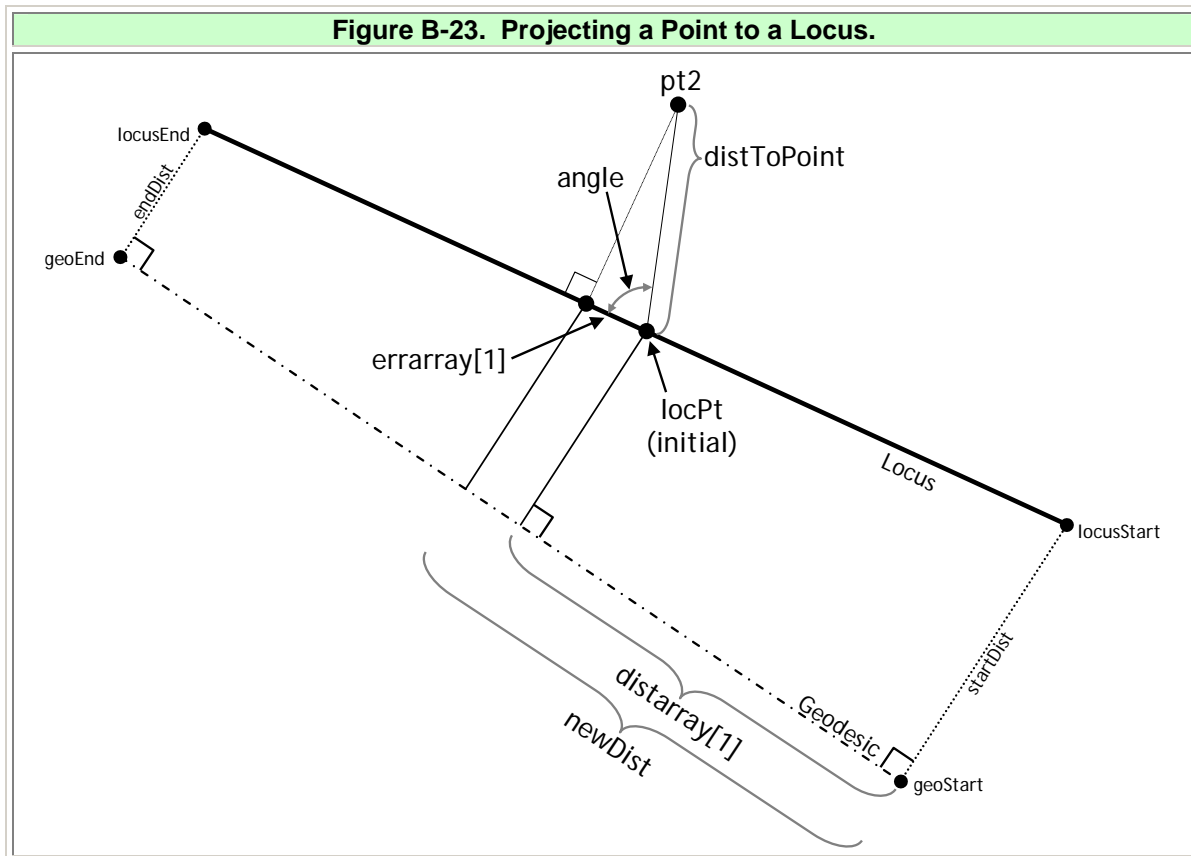

```
distarray[0] = distarray[1]
```

```
errarray[0] = errarray[1]
```

```
distarray[1] = newDist
```

STEP 11: End while

STEP 12: Return locPt

5.3 Tangent Projection from Point to Arc.

This projection is used in obstacle evaluation when finding the point on an RF leg or fly-by turn path where the distance to an obstacle must be measured.

5.3.1 Input/Output.

`long WGS84PointToArcTangents(LLPoint point, LLPoint center, double radius, LLPointPair tanPt, int* n, double tol)` returns a reference to an `LLPoint` structure that contains the coordinates of the points where geodesics through `point` are tangent to arc, where the inputs are:

<code>LLPoint point</code>	=	Point from which lines will be tangent to arc
<code>LLPoint center</code>	=	Geodetic centerpoint coordinates of arc
<code>double radius</code>	=	Radius of arc
<code>LLPointPair tanPt</code>	=	Two-element array of <code>LLPoint</code> objects that will be updated with tangent points' coordinates

<code>int* n</code>	=	Reference to number of tangent points found (0, 1, or 2)
<code>double tol</code>	=	Maximum error allowed in solution
<code>double eps</code>	=	Convergence parameter for forward/inverse algorithms

5.3.2 Algorithm Steps.

This algorithm treats the arc as a complete circle, so either zero or two tangent points will be returned. If the arc is bounded and two tangent points are found, then each point must be tested using Algorithm 3.7 to determine whether they lie within the arc's bounds. (See figure B-24)

STEP 1: Use the inverse algorithm to calculate the distance, azimuth, and reverse azimuth from point to center. Denote these values by `crsToCenter`, `crsFromCenter`, and `distToCenter`, respectively.

STEP 2: If $\text{abs}(\text{distToCenter} - \text{radius}) < \text{tol}$, then point lies on the arc and is a tangent point.

- a. Set `n = 1`
- b. Return `tanPt = point`

STEP 3: Else, if $\text{distToCenter} < \text{radius}$, then point lies inside of the arc and no tangent points exist.

- a. Return no solution.

STEP 4: End if

STEP 5: There must be two tangent points on the circle, so set `n = 2`

STEP 6: Use spherical trigonometry to compute approximate tangent points.

- a. $a = \text{distToCenter} / \text{SPHERE_RADIUS}$
- b. $b = \text{radius} / \text{SPHERE_RADIUS}$
- c. $c = a \cos(\tan(b) / \tan(a))$.

This is the approximate angle between the geodesic that joins `point` with `center` and the geodesic that joins `center` with either tangent point.

STEP 7: Initialize iteration count: $k = 0$

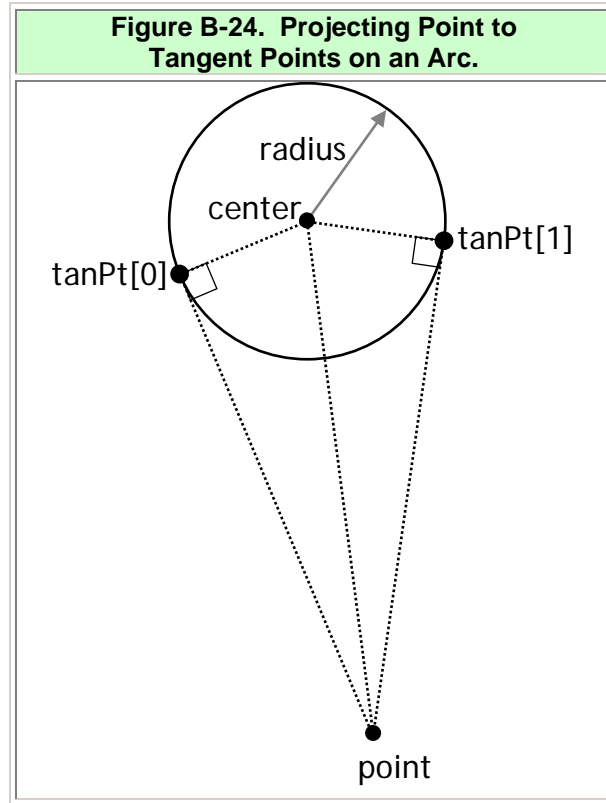

STEP 8: Do while ($k = 0$) or ($\text{abs}(\text{error}) > \text{tol}$ and $k < \text{maxIterationCount}$)

- a. Use the direct algorithm to locate $\text{tanPt}[0]$ on arc. Use center as the starting point, radius as the distance, and $\text{courseFromCenter} + C$ as the azimuth.
- b. Use the inverse algorithm to calculate the azimuth from $\text{tanPt}[0]$ to center. Denote this value as radCrs .
- c. Use the inverse algorithm to calculate the azimuth from $\text{tanPt}[0]$ to point. Denote this value as tanCrs .
- d. Use the function in Algorithm 6.2 to calculate the angle between the two courses and cast it into the range $(-\pi, \pi]$:
 $\text{diff} = \text{signedAzimuthDifference}(\text{radCrs}, \text{tanCrs})$
- e. Compute the error: $\text{error} = \text{abs}(\text{diff}) - \frac{\pi}{2}$
- f. Adjust the value of C to improve the approximation: $C = C + \text{error}$
- g. Increment the iteration count: $k = k + 1$

STEP 9: End while loop.

STEP 10: Repeat steps 7-9 to solve for $\text{tanPt}[1]$. In each iteration; however, use $\text{crsFromPoint} - C$ for azimuth in step 8(a).

STEP 11: Return $\text{tanPt}[0]$ and $\text{tanPt}[1]$

5.4 Project Arc to Geodesic.

This algorithm is used for obstacle evaluation when finding a point on the straight portion of TF leg where distance to an obstacle must be measured.

5.4.1 Input/Output.

`long WGS84PerpTangentPoints(LLPoint lineStart, double crs, LLPoint center, double radius, LLPointPair linePts, LLPointPair tanPts, double tol)` updates geodesic intercepts, but returns no output, where input values are:

<code>LLPoint lineStart</code>	=	Start point of geodesic to which arc tangent points will be projected
<code>double crs</code>	=	Initial course of geodesic
<code>LLPoint center</code>	=	Geodetic coordinates of arc center
<code>double radius</code>	=	Arc radius
<code>LLPointPair linePts</code>	=	Two-element array of projected points on Geodesic

LLPointPair tanPts	=	Two-element array of tangent points on arc
double tol	=	Maximum error allowed in solution
double eps	=	Convergence parameter for forward/inverse algorithms

5.4.2 Algorithm Steps.

See figure B-25 for an illustration of the variable names.

STEP 1: Use the inverse algorithm to calculate the distance, azimuth, and reverse azimuth from `lineStart` to center. Denote these values as `distStartToCenter`, `crsStartToCenter`, and `crsCenterToStart`, respectively.

STEP 2: Compute the angle between the given geodesic and the geodesic that joins `lineStart` to center (see Algorithm 6.2):
`angle1 = signedAzimuthDifference(crs, crsStartToCenter)`

STEP 3: If `abs(distStartToCenter * (crsStartToCenter - crs)) < tol`, then center lies on the given geodesic, which is a diameter of the circle. In this case, the tangent points and project points are the same.

- a. Use the direct algorithm to compute `tanPts[0]`. Use `lineStart` as the starting point, `crs` as the azimuth, and `distStartToCenter - radius` as the distance.
- b. Use the direct algorithm to compute `tanPts[1]`. Use `lineStart` as the starting point, `crs` as the azimuth, and `distStartToCenter + radius` as the distance.
- c. Set `linePts[0] = tanPts[0]`
- d. Set `linePts[1] = tanPts[1]`
- e. Return all four points.

STEP 4: End if

STEP 5: Use Algorithm 5.1 to project center to the geodesic defined by `lineStart` and `crs`. Denote the projected point by `perpPt`.

STEP 6: Use the inverse algorithm to calculate the distance, azimuth, and reverse azimuth from `perpPt` to `lineStart`. Denote these values by `dist12` and `crs21`, respectively.

STEP 7: Set $\delta = \text{radius}$

STEP 8: Initialize iteration count: $k = 0$

STEP 9: Do while ($k = 0$) or ($\text{abs}(\text{error}) > \text{tol}$ and $k < \text{maxIterationCount}$)

- a. Use the direct algorithm to compute $\text{linePts}[0]$. Use perpPt as the starting point, δ as the distance, and $\text{crs}21 + \pi$ as the azimuth.
- b. Use the inverse algorithm to calculate the course from $\text{linePts}[0]$ to perpPt . Denote this value by strCrs .
- c. Calculate the azimuth, perpCrs , from $\text{linePts}[0]$ to the desired position of $\text{tanPts}[0]$. The azimuth depends upon which side of the line the circle lies, which is given by the sign of angle1 :
 - (1) If the circle lies to the right of the line:
 $\text{perpCrs} = \text{strCrs} + \pi/2$
 - (2) If the circle lies to the left of the line:
 $\text{perpCrs} = \text{strCrs} - \pi/2$
- d. Use Algorithm 5.1 to project center onto the geodesic passing through $\text{linePts}[0]$ at azimuth perpCrs . Algorithm 5.1 will return the projected point, $\text{tanPts}[0]$, along with the distance from center to $\text{tanPts}[0]$. Denote this distance by radDist .
- e. Calculate the error, the amount that radDist differs from radius :
 $\text{error} = \text{radDist} - \text{radius}$
- f. Adjust the distance from lineStart to $\text{linePts}[0]$:
 $\delta = \delta - \text{error}$
- g. Increment the iteration count: $k = k + 1$

STEP 10: End while loop.

STEP 11: Repeat steps 7-10 to solve for $\text{linePts}[1]$ and $\text{tanPts}[1]$. In each iteration; however, use $\text{crs}21$ for azimuth in step a). Note that using the final δ value for the first iteration in the search for $\text{linePts}[1]$ will make the code more efficient (i.e., don't repeat step 7).

STEP 12: Return $\text{linePts}[0]$, $\text{linePts}[1]$, $\text{tanPts}[0]$, and $\text{tanPts}[1]$.

Attachment A - Useful Functions.**6.0 Calculate Angular Arc Extent.**

When calculating the angle subtended by an arc, one must take into account the possibility that the arc crosses the northern branch cut, where $\theta^\circ = 360^\circ$. The following algorithm accounts for this case.

Input/Output.

`double WGS84GetArcExtent(double startCrs, double endCrs, int orientation, double tol)` returns a double precision value containing the arc's subtended angle, where the input values are:

`double startCrs` = Azimuth from center to start point of arc

`double endCrs` = Azimuth from center to end point of arc

`int orientation` = Integer that indicates the direction in which the arc is traversed to go from `startCrs` to `endCrs`.

`orientation` = 1 if the arc is traversed counter-clockwise,

`orientation` = -1 if the arc is traversed clockwise.

`double tol` = Maximum error allowed in calculations

6.01 Algorithm Steps.

STEP 1: If `(abs(startCrs-endCrs) < tol)` return $2*\pi$

STEP 2: If `orientation < 0`, then orientation is clockwise. Cast the arc into a positive orientation (counter-clockwise) so only one set of calculations is required

a. `temp = startCrs`

b. `startCrs = endCrs`

c. `endCrs = temp`

STEP 3: End if

STEP 4: If `startCrs > endCrs`, then `angle = startCrs - endCrs`

STEP 5: Else angle = $2*\pi + \text{startCrs} - \text{endCrs}$

STEP 6: End if

STEP 7: If orientation < 0, then angle = -angle

STEP 8: Return angle

6.1 Converting Geodetic Latitude/Longitude to ECEF Coordinates.

Geodetic coordinates may be converted to rectilinear ECEF coordinates using the following formulae¹. Given geodetic latitude φ , geodetic longitude θ , semi-major axis a and flattening parameter f , calculate the square of the eccentricity

$$e^2 = f(2 - f) \text{ and the curvature in the prime vertical: } N = \frac{a}{\sqrt{1 - e^2 \sin^2 \varphi}}.$$

The ECEF coordinates are then

$$x = N \cos \varphi \cos \theta$$

$$y = N \cos \varphi \sin \theta$$

$$z = N(1 - e^2) \sin \varphi$$

6.2 Signed Azimuth Difference.

It is often necessary to calculate the signed angular difference in azimuth between two geodesics at the point where they intersect. The following functions casts the difference between two geodesics into the range $[-\pi, \pi)$:

$$\text{signedAzimuthDifference}(a_1, a_2) = \text{mod}(a_1 - a_2 + \pi, 2\pi) - \pi$$

This function returns the angle between the two geodesics as if the geodesic that is oriented along azimuth a_1 were on the positive x -axis and the geodesic oriented along azimuth a_2 passed through the origin. In other words, if

$\text{signedAzimuthDifference}(a_1, a_2) > 0$ azimuth a_2 is to the left when standing at the geodesics' intersection point and facing in the direction of azimuth a_1 .

The mod function in the definition of `signedAzimuthDifference` must always return a non-negative value. Note that the C language's built in `fmod` function does not have this behavior, so a replacement must be supplied. The following code suffices:

```
double mod(double a, double b) {
  a = fmod(a, b);
  if (a < 0.0) a = a + b;
  return a;
}
```

¹ Dana, Peter H., "Coordinate Conversion Geodetic Latitude, Longitude, and Height to ECEF, X, Y, Z", <http://www.colorado.edu/geography/gcraft/notes/datum/gif/llhxyz.gif>, 11 February, 2003

6.3 Approximate Fixed Radius Arc Length.

Algorithm 3.8 describes a method for computing the length of an arc to high precision. The following algorithm provides a solution accurate to 1 centimeter for an arc whose radius is less than about 300 nautical miles (NM). This algorithm approximates the ellipsoid at the center of the arc in question with a “best fit” sphere, whose radius is computed as the geometric mean of the meridional and prime-vertical curvatures at the arc’s center.

Given the arc center’s latitude θ , the ellipsoidal semi-major axis a and flattening f , compute the local radius of curvature R as follows:

$$e^2 = f(2 - f)$$

$$M = \frac{a(1 - e^2)}{(1 - e^2 \sin^2 \theta)^{\frac{3}{2}}}$$

$$N = \frac{a}{\sqrt{1 - e^2 \sin^2 \theta}}$$

$$R = \sqrt{MN}$$

If the radius and subtended angle of the of the constant radius arc are r and A , respectively, then the length of the arc is given by:

$$L = AR \sin\left(\frac{r}{R}\right).$$

Attachment C**7.0 Sample Function Test Results.**

The following pages provide test inputs with expected outputs. This data is included here to make it easy to verify that an independent implementation of these algorithms produces the same results. All of these results were obtained using the tolerance parameter $\text{tol} = 1.0e-9$ and forward/inverse convergence parameter $\text{eps} = 0.5e-13$.

Test results are not included for those algorithms that are fairly straightforward applications of other algorithms, such as 3.9, 3.10, and 3.11.

Appendix C. Administrative Information

1. Distribution.

2. Background. The analysis of GPS/WAAS navigation flight test data provides the basis for these criteria. A significant difference exists between approach procedures to runways and approach procedures to heliports. Approaches to runways terminate in relatively obstacle-free environments. Approaches to heliports commonly terminate in areas of dense population and large buildings. Speed limitations incorporated in these criteria provide the smallest obstacle clearance areas, the shortest segment lengths, and the lowest ceiling and visibility minimums. *The graphic illustrations in this order are not to scale.* The guidance published in this directive supersedes previous guidance concerning helicopters published in Terminal Instrument Procedures (TERPS) Instruction Letters (TILs) and other correspondence.

3. Definitions.

a. Approach Procedure Types using RNAV (GPS).

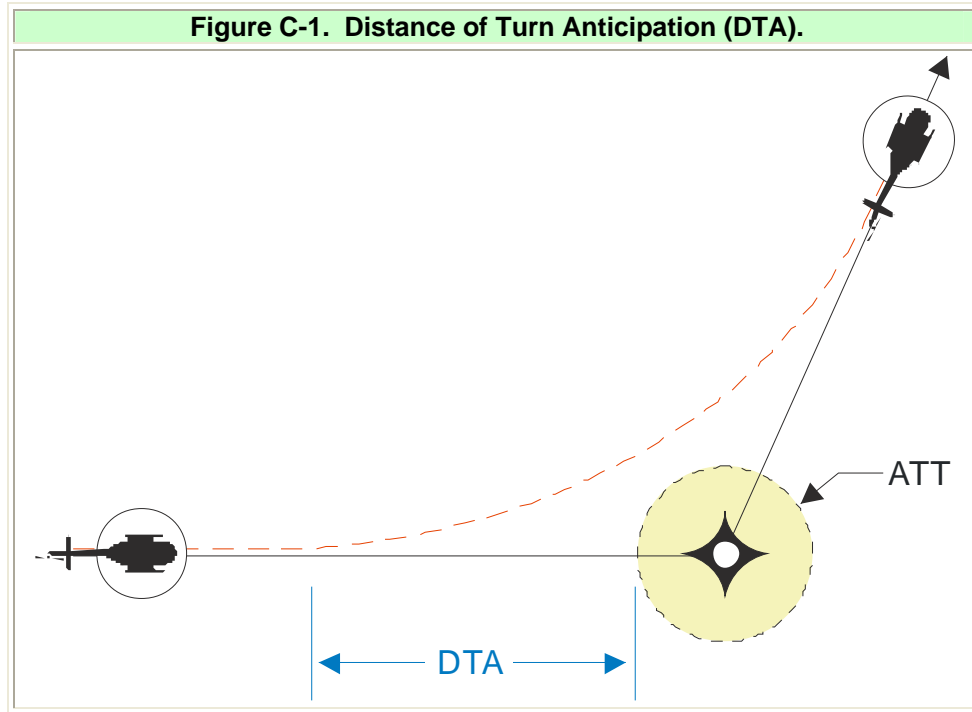

(1) **IFR to an IFR Heliport** (Public and Special). An IFR approach to a heliport that meets Advisory Circular (AC) 150/5390-2, Heliport Design, standards for an IFR heliport.

(2) **IVH (Proceed Visually)** (Special). An IFR approach to a VFR heliport that meets AC 150/5390-2 standards. This procedure requires flight standards approval. The phrase “Proceed Visually” is charted on the procedure for the visual segment from the MAP to the heliport. IVR applies IVH criteria to an approach to a VFR runway.

(3) **PinS Approach (Proceed VFR)** (Public and Special). An IFR PinS approach to one or more VFR heliports. The phrase “Proceed VFR” is charted on the procedure for the VFR segment following the MAP.

(4) **IFR to a Runway**(Public and Special). An IFR helicopter approach procedure to a runway.

b. Distance of Turn Anticipation (DTA). DTA represents the maximum distance prior to a fly-by-fix that a helicopter is expected to start a turn to intercept the course of the next segment. The along-track tolerance (ATT) value, associated with a fix, is added to the DTA value when DTA is applied (see figure C-1 and formula 2-6).

$$\text{DTA} = \text{Radius} \times \tan (\text{degrees of turn} \div 2)$$

- c. **Fly-By Fix.** ✦ A fly-by fix is a waypoint where a turn is initiated prior to reaching it.
- d. **Fly-Over Waypoint (WP).** ⦿ A fly-over WP is a waypoint over which an aircraft is expected to fly before one turn is initiated.
- e. **Final Approach and Takeoff Area (FATO).** A defined area over which the final phase of the approach to a hover, or a landing, is completed and from which the takeoff is initiated. The guidance for a FATO is published in AC 150/5390-2.
- f. **Fictitious Helipoint (FHP).** The FHP is located 2,600 ft beyond the MAP and 9,023 ft in front of the flight path alignment point (FPAP). It is used to establish the approach course width for the WAAS.
- g. **Flight Path Alignment Point (FPAP).** The FPAP is a 3-dimensional (3D) point defined by World Geodetic System of 1984/North American Datum of 1983 (WGS-84/NAD-83) latitude, longitude, MSL elevation, and WGS-84 Geoid height. The FPAP is used in conjunction with the FHP and the geometric center of the WGS-84 ellipsoid to define the final approach azimuth (LPV glidepath's vertical plane, where used) associated with an LP or LPV final course.
- h. **Flight Technical Error (FTE).** FTE is the measure of the pilot or autopilot's ability to control an aircraft so that its indicated position matches the desired position.

i. Geoid Height (GH). The GH is the height of the Geoid relative to the WGS-84 ellipsoid. It is a positive value when the Geoid is above the WGS-84 ellipsoid and negative when it is below. The value is used to convert an MSL elevation to an ellipsoidal or geodetic height - the height above ellipsoid (HAE).

Note: The Geoid is an imaginary surface within or around the earth that is everywhere normal to the direction of gravity and coincides with mean sea level (MSL) in the oceans. It is the reference surface for MSL heights.

j. Heliport Approach Lighting System (HALS). The HALS is a distinctive approach lighting configuration designed to prevent it from being mistaken for an airport runway approach lighting system. HALS consists of ten bars of lights at 100-ft increments and has a length of 1,000 ft (305 m). HALS provides a visibility credit of 1/4 statute mile (SM). for nonprecision approaches.

k. Height Above Landing Area Elevation (HAL). The HAL is the height of the minimum descent altitude (MDA) above heliport elevation.

l. Height Above Surface (HAS). HAS is the height of the MDA above the highest terrain/surface within a 5,200-ft radius of the MAP in the PinS procedure.

m. Heliport Crossing Height (HCH). The HCH is the height of the vertical guidance path above the heliport elevation at the heliport.

n. Heliport. The heliport is the aiming point for the visual segment and is normally centered in the touchdown and lift-off area (TLOF). The TLOF is normally centered in the FATO.

o. Heliport. An area of land, water, or structure used or intended to be used for helicopter landings and takeoffs and includes associated buildings and facilities. IFR and VFR heliports are described in AC 150/5390-2.

p. Heliport Elevation (HE). For heliports without a precision approach, the heliport elevation is the highest point of the FATO expressed as the distance above mean sea level (MSL).

q. Heliport Reference Point (HRP). The geographic position of the heliport, measured at the center of the FATO or the central point of multiple FATOs, expressed as (WGS-84/NAD-83) latitude and longitude to the nearest hundredth of a second. The HRP elevation is equal to the heliport elevation.

r. Initial Departure Fix (IDF). The first fix on a PinS departure procedure where application of IFR obstruction protection and air traffic separation standards are provided.

s. IFR Heliports. Facility specifications for IFR Heliports are described in chapters 6 or 7 as appropriate of Advisory Circular 150/5390-2, Heliport Design. Chapter 6 of

AC 150/5390-2 relates to paragraph 5.3 of this order for nonprecision IFR approach procedures to IFR heliports.

t. Landing and Takeoff Site. The area of intended landing and takeoff. It can be a heliport, helistop, vertiport, or other point of landing designated for a PinS approach.

u. Proceed Visually. This phrase requires the pilot to acquire and maintain visual contact with the FATO or elements associated with the FATO such as heliport lighting, precision approach path indicator (PAPI), etc. at or prior to the MAP. Obstacle and terrain avoidance from the MAP to the FATO is the responsibility of the pilot. A missed approach procedure is not provided between the MAP and the landing FATO.

v. Proceed VFR. For PinS procedures, this phrase requires the pilot to proceed from the MAP to the selected landing area on the approach chart with no less than the visibility and ceiling required on the approach chart. For flights that do not terminate at the selected landing area on the approach chart, the pilot is required to proceed from the MAP under the applicable VFR for ceiling and visibility required by the applicable Code of Federal Regulations (14 CFR) but no less than the visibility required on the approach chart, operations specifications (OpSpec), or letter of agreement (LOA). The pilot is responsible for obstacle and terrain avoidance from the MAP to the landing site. A missed approach procedure is not provided between the MAP and the landing site. The landing site is not required to be in sight from the MAP.

w. Touchdown and Lift-Off Area (TLOF). A TLOF is a load bearing, generally paved area, normally centered in the FATO, on which the helicopter lands or takes off (see AC 150/5390-2).

x. United States Air Force (USAF).

y. United States Army (USA).

z. United States Coast Guard (USCG).

aa. United States Navy (USN).

bb. VFR Heliports. Standards and recommendations for VFR and IFR heliports are described in chapters 2 through 5 and chapter 8 of AC 150/5390-2, Heliport Design. Paragraph 5.4 of this order relates to VFR heliports.

cc. Minimum instrument meteorological condition airspeed (V_{mini}). V_{mini} means instrument flight minimum speed, utilized in complying with minimum limit speed requirements for instrument flight. This is the certified minimum airspeed that a specific helicopter is approved to enter instrument meteorological flight conditions.

dd. Visual Segment Descent Angle (VSDA). The angle of descent in the visual segment.

ee. Visual Segment Descent Point (VSDP). The descent point within the visual segment of a helicopter instrument approach to an IFR heliport or runway.

ff. Visual Segment Reference Line (VSRL). A line perpendicular to the final course at a distance of 75 ft (22.9 m) from the heliport for public use heliports and 50 ft (15.27 m) from the heliport for heliports with special instrument procedures. It extends 75 ft (22.9 m) on each side of the final course centerline for public use heliports and 50 ft (15.27 m) on each side of the final course centerline for heliports with special instrument procedures. For IFR procedures the line is 75 ft (22.9 m) from the heliport and it extends 75 ft (22.9 m) on each side of the final approach course.

gg. Wide Area Augmentation System (WAAS) Localizer Performance (LP). The LP approach applies lateral-only WAAS guidance (and reduced OEA) within the FAS to a PinS.

4. Data Resolution. See chapter 2, paragraph 2.

5. Related Publications. All directives in this order refer to the latest editions:

- Advisory Circular 150/5390-2, Heliport Design
- Order 7130.3, Holding Pattern Criteria
- Order 8260.3, United States Standard for Terminal Instrument Procedure (TERPS)
- Order 8260.19, Flight Procedures and Airspace
- Order 8260.40, Flight Management System Instrument Procedures Development
- Order 8260.45, Terminal Arrival Area (TAA) Design Criteria
- Order 8260.54, United States Standards for Area Navigation (RNAV)

6. Information Update. For your convenience, FAA Form 1320-19, Directive Feedback Information, is included at the end of this order to note any deficiencies found, clarifications needed, or suggested improvements regarding the contents of this order. When forwarding your comments to the originating office for consideration, please use the "Other Comments" block to provide a complete explanation of why the suggested change is necessary.

THIS PAGE INTENTIONALLY LEFT BLANK

Directive Feedback Information

Please submit any written comments or recommendation for improving this directive, or suggest new items or subjects to be added to it. Also, if you find an error, please tell us about it.

Subject: Order _____

To: Directive Management Officer, _____

(Please check all appropriate line items)

- An error (procedural or typographical) has been noted in paragraph _____ on page _____ .
- Recommend paragraph _____ on page _____ be changed as follows:
(attached separate sheet if necessary)
- In a future change to this order, please include coverage on the following subject
(briefly describe what you want added):

Other comments:

I would like to discuss the above. Please contact me.
