ABSTRACT

The Resource Assessment and Conservation Engineering (RACE) Division of the Alaska Fisheries Science Center (AFSC) has been conducting annual bottom trawl surveys of the eastern Bering Sea (EBS) continental shelf since 1982. The quality and specificity of field identifications for many taxa have fluctuated over the history of the surveys due to changing priorities and resources. Historical trends in identification quality for the EBS shelf survey have not been documented. This report includes an identification confidence matrix for all fishes and invertebrates identified from the EBS shelf survey from 1982 through 2008. The matrix lists a confidence level for each taxon for each survey year, and is intended to serve as a general guideline for data users interested in assessing the relative reliability of historical species identifications on this survey.

INTRODUCTION

The Resource Assessment and Conservation Engineering (RACE) Division of the Alaska Fisheries Science Center (AFSC) has been conducting bottom trawl surveys of the eastern Bering Sea continental shelf since the early 1970s. A grid of 356 stations (Fig. 1) has been sampled annually since 1982 for the purpose of tracking population trends in the fish and invertebrate resources of the eastern Bering Sea. Information gathered from the summer survey provides fisheries-independent population trends that are invaluable for stock assessments and development of management strategies for commercially exploited fish and invertebrate species in the region. In addition to their utility as a management tool, data collected on these surveys have been used by a variety of constituents to examine spatial and temporal trends in the fish and invertebrate fauna of the eastern Bering Sea.

Throughout the history of the survey, changing priorities and limited resources have led to fluctuations in the quality and specificity of field identifications for taxa that are not of direct commercial importance. For some taxa, species identification quality is limited by the state of taxonomic knowledge, which for some groups has changed considerably over the course of the time series. For others, identification characteristics that can be reliably used in the field are not known or have only recently become widely recognized. Another factor influencing the quality and specificity of field identifications is the suite of identification tools available to survey participants, which has evolved dramatically over the course of the survey and continues to improve with increasing knowledge of the Bering Sea fauna. In addition to changes in field identification tools, the training level and experience of scientists participating in the survey have varied widely over the years, which may have had profound and unpredictable influence on the consistency and reliability of field identifications for some taxa.

Trends in species identification quality and specificity have not routinely been documented during the AFSC Bering Sea bottom trawl survey and have generally not been taken into account by data users. However, as an increasing number of users request access to survey data for use in a broad diversity of studies, we feel that it is now more important than ever to provide users with a tool to help assess the confidence level that should be assigned to identifications of each taxon throughout the history of the survey.

Recent efforts to help track and stabilize field identifications have included the production of a series of durable field guides for use at sea and a specimen voucher program. Over the past decade, the ongoing development of a series of field guides to the fishes and benthic macroinvertebrates of the region has encouraged the consistent application of identification characteristics and taxonomy among vessels and legs within a survey year and among survey years. The specimen voucher program encourages the collection of rare or unusual specimens of fishes and invertebrates encountered on groundfish surveys as well as specimens of uncertain identity. Specimens collected on the surveys are returned to the AFSC in Seattle, where they are recorded and verified. Fish specimens are then shipped to the University of Washington fish collection, where they are curated and permanently stored, while invertebrates are shipped to the California Academy of Sciences, where they are examined by various experts and curated. The tables in this report are intended to further these efforts by providing a rough estimate of identification quality for each taxon in each survey year from 1982 through 2008.

MATERIALS AND METHODS

An identification confidence index was established for each taxon for each survey year for both fishes (Table 1) and invertebrates (Table 2). These tables refer only to data collected during the annual surveys of the eastern Bering Sea continental shelf conducted by the AFSC from 1982 through 2008 during May-August. The index is unavoidably subjective, but was influenced by several factors, including relevant taxonomic literature, available field identification tools, interannual reporting trends, and examination of collected specimens. The identification confidence index codes used in this table are defined as follows:

- 1 – High confidence and consistency. Taxonomy is stable and reliable at this level, and field identification characteristics are well known and reliable.
- 2 – Moderate confidence. Taxonomy may be questionable at this level, or field identification characteristics may be variable and difficult to assess consistently.
- 3 – Low confidence. Taxonomy is incompletely known, or reliable field identification characteristics are unknown, or the occurrence of this taxon in the Bering Sea is doubtful and survey records have not been verified.

The tables included in this data report are intended to serve as a general guideline to assist data users in assessing the relative historical reliability of the species identification data in this time series, and do not necessarily reflect the reliability of each individual record. A taxon-by-taxon list of the reasoning behind the coding for each taxon is well beyond the scope of this report, and data users are encouraged to contact AFSC staff for further clarification on specific taxa or individual records.
