ABSTRACT

The eastern Bering Sea bottom trawl survey has been conducted annually since 1975 by the Resource Assessment and Conservation Engineering Division of the Alaska Fisheries Science Center, National Marine Fisheries Service. The purpose of this survey is to collect data on the distribution and abundance of crab, groundfish, and other benthic resources in the eastern Bering Sea. These data are used to estimate population abundances for the management of commercially important species in the region. In 2011, 376 standard stations were sampled on the eastern Bering Sea shelf and 20 stations were resampled in Bristol Bay at the end of the standard survey to account for female red king crab maturity. The 2011 biomass estimates reported in metric tons (t) and pounds (lb) with 95% confidence intervals (± 1.96 SE) for legal-sized males of commercial crab stocks in the eastern Bering Sea were as follows:

Commercial Crab Species	2011 Legal-sized Male	Biomass (± 95% CI) *
Bristol Bay District red king crab (*Paralithodes camtschaticus*)	15,412 (5,238) t	33,977,299.61 (11,547,788.81) lb
Pribilof District red king crab (*P. camtschaticus*)	3,751 (4,787) t	8,269,046.58 (10,554,038.49) lb
Pribilof District blue king crab (*P. platypus*)	399 (693) t	879,573.20 (1,528,179.24) lb
St. Matthew Island Section blue king crab (*P. platypus*)	5,788 (5,555) t	12,759,351.83 (12,246,469.72) lb
Southern Tanner crab (*Chionoecetes bairdi*), east 166° W	10,207 (5,880) t	22,503,103.69 (12,964,143.55) lb
Southern Tanner crab, east 166° W ≥ 5.5 inches	5,356 (4,344) t	11,807,249.93 (10,109,706.61) lb
Southern Tanner crab, west 166° W	23,278 (16,729) t	51,319,174.78 (36,880,898.03) lb
Southern Tanner crab, west 166° W ≥ 5.0 inches	15,676 (13,672) t	34,560,932.62 (35,029,759.51) lb
Snow crab, all Districts (*C. opilio*)	146,297 (32,652) t	322,525,931.00 (71,984,466.52) lb
Snow crab, all Districts ≥ 4.0 inches	94,763 (22,025) t	208,915,452.54 (48,556,399.29) lb

* Differences in metric ton biomass estimates compared to pound biomass estimates are due to rounding errors.

CONTENTS

INTRODUCTION

Survey History and Purpose

The eastern Bering Sea (EBS) bottom trawl survey has been conducted by the Resource Assessment and Conservation Engineering (RACE) Division of the Alaska Fisheries Science Center (AFSC), National Marine Fisheries Service (NMFS) since the early 1970s. Starting in 1975, annual surveys have been conducted and were expanded to include Bristol Bay along with the majority of the Bering Sea continental shelf with the original purpose of assessing potential resource impacts of offshore oil development (Pereyra et al. 1976). The annual collection of data on the distribution and abundance of crab and groundfish resources provides fishery-independent estimates of population abundances and biological data for the management of commercially important species in the EBS. The crab species that have historically been assessed during the survey include: red king crab (*Paralithodes camtschaticus*), blue king crab (*P. platypus*), southern Tanner crab (*Chionoecetes bairdi*), snow crab (*C. opilio*), and hair crab (*Erimacrus isenbeckii*). The common name for *C. bairdi* changed from Tanner crab to southern Tanner crab in 2005 (McLaughlin et al. 2005) but will be referred to as Tanner crab in this document.

Since 1988, 376 standard stations have been included in the survey covering a 140,350 square nautical mile (nmi^2) area of the EBS with station depths ranging from 20 to 150 m (Fig. 1). The annual EBS bottom trawl survey begins in the northeast section of Bristol Bay in early June and approximately 10 to 12 stations are sampled each day from two vessels. The standard survey is completed in late July at the western edge of the survey grid, northwest of St. Matthew Island. In some years when the reproductive cycle of red king crab is delayed due to colder water temperatures, a small portion of the inner Bristol Bay area is resampled after the conclusion of the standard survey (see Results: Bristol Bay District Red King Crab section).

Between 1994 and 2010, a survey station producing ≥ 100 legal-sized red king or Tanner crab males has been considered a "hot spot". At each hot spot, additional tows were made within the station area and all crab species caught were sampled identical to the standard survey tow protocol described in the Methods section. In 2011, there were no stations with ≥ 100 legal-sized red king crab and only one station, G-21, with ≥ 100 legal-sized Tanner crab.

Eastern Bering Sea Crab Stock Assessment Process

Crabs included in the federal Bering Sea and Aleutian Islands (BSAI) King and Tanner crab Fisheries Management Plan are managed by the Alaska Department of Fish and Game (ADF&G) with federal oversight by NMFS (NPFMC 1998). The annual stock assessment and fishery evaluation (SAFE) report prepared by the North Pacific Fishery Management Council's Crab Plan Team provides current biological, ecosystem, and economic data associated with these species. NMFS determines the procedure for setting overfishing levels and allowable biological catch while ADF&G sets the annual total allowable catch or guideline harvest level for each crab stock. Currently, the Crab Plan Team and the Council's Scientific and Statistical Committee review the assessment, biological, economic, and modeling data to recommend biological reference points associated with the status of crab stocks. Crab stock boundaries are defined by

ADF&G management units for king crab and Tanner crab species (Bowers et al. 2010). Red king crab are split into Bristol Bay and Pribilof Islands stocks, blue king crab are split into Pribilof Islands and St. Matthew Island stocks for management purposes, while Tanner and snow crab fisheries are considered single stocks but are split into separate management fishery units defined by the ADF&G Board of Fisheries using 166°W and 173°W as the boundary for each east and west unit, respectively.

This report summarizes the 2011 survey results for commercially important crab resources in the EBS. The results of the 2011 standard EBS bottom trawl survey are presented for these crab stocks as defined by the management units. Details of the survey design and fishing gear specifications in addition to the number and weights of the groundfish species sampled at each standard station during this survey will be reported in a separate NOAA Technical Memorandum (e.g., Lauth 2010).

METHODS

Survey Area and Sampling Logistics

The 2011 standard survey was conducted onboard the chartered fishing vessels FV *Alaska Knight* and FV *Aldebaran*, beginning 5 June in Bristol Bay and moving westward to end at station K-27 on 25 July. The vessels sampled in close proximity during the standard survey, with both vessels returning to Bristol Bay to resample 20 stations between 25 and 31 July. These stations were resampled due to the delaying effects of cold water temperatures on the red king crab reproductive cycle (see Results: Bristol Bay District Red King Crab).

The survey stations are divided into multiple districts, which are defined by ADF&G commercial crab management units (Fig. 2). Management units are defined by registration areas and districts, which are further divided into strata with standard or high station densities. Standard-density strata have stations centered in 20 × 20 nmi (37.04 × 37.04 km) cells while high-density strata include additional stations at the corners of the 20 × 20 nmi cells. Total area calculations for each stock strata uses an area of 401 nmi^2 for each 20 × 20 nmi cell due a spherical projection of the grid surface in an area as large as the EBS. The king crab Registration Area T in Bristol Bay (south of 58°39′N and east of 168°W) is 54,536 nmi^2 and consists of 136 stations within the stratum. The king crab Registration Area Q in the Bering Sea is divided into the Northern District (north of 58°39′N) and the Pribilof District (south of 58°39′N and west of 168°W). The stratum for the St. Matthew Island Section of the Northern District is divided into two sampling areas: 1) a high-density 7,218 nmi^2 area with 28 stations and 2) a standard-density 12,431 nmi^2 area with 29 stations creating a total of 57 stations within the St. Matthew Island Section stratum. The stratum of the Pribilof District is divided into two sampling areas: 1) a high-density 10,025 nmi^2 area with 41 total stations and 2) a standard-density 14,436 nmi^2 area with 36 stations creating a total of 77 stations within the stratum.

The fishing gear used in 2011 was identical to that of previous EBS annual bottom trawl surveys since 1982 with both vessels fishing a standard 83-112 Eastern otter trawl with an 83 ft (25.3 m) headrope and a 112 ft (34.1 m) footrope (Lauth 2010). The trawls on each vessel were rotated every 25-30 consecutive tows to mitigate potential impacts from changes in net

configuration due to fishing. Each tow was approximately 0.5 h in duration and 1.5 nmi (2.8 km) in length at a speed of 3 knots (1.54 m/sec) and conducted in strict compliance with NMFS bottom trawl protocols established by the National Oceanic and Atmospheric Administration (Stauffer 2004).

Net mensuration equipment was used to monitor the net's fishing performance during each tow (Lauth 2010). A bottom contact sensor was attached to the center of the footrope to measure bottom contact of the net at 1-second intervals. The net mensuration system also consisted of an acoustic sensor attached to the headrope and two sensors attached to the port and starboard dandylines to measure net height and width during trawling operations. The bottom contact of the footrope and GPS data were used to calculate distance fished. Fishing power was assumed to be equal between the two vessels.

Surface and bottom water temperatures along with temperature-depth profiles were collected at 6-second intervals throughout the duration of each tow using a Seabird SBE-39 bathythermograph continuous data recorder (Sea-Bird Electronics Inc., Bellevue, WA) attached to the headrope of the net. The temperature measurement range of the SBE-39 is -5 to 35 ± 0.002 °C with pressure sensors measuring to a maximum depth of 1,000 ± 1 m and are calibrated every year by Sea-Bird Electronics. Bottom depth was also derived from this data by adding the net height from the net mensuration system to the headrope depth recorded by the SBE-39.

Biological Data Collection

All crab were removed from the catch, sorted by species and sex, and a total catch weight was obtained for each species. Tanner and snow crab hybrids are identified by a combination of characteristics including curve of the epistome margin, eye color, carapace shape, and space between or shape of rostrum horns (Karinen and Hoopes 1971, Urban et al. 2002). Subsampling of the total catch occurred when an exceptionally large number (>300) of a species was caught in a tow. The weights of the sampled crab and non-sampled crab were recorded and an expansion factor was calculated to determine the final number of each species in the catch.

Individual crab carapaces were measured (± 1 mm) to provide a size-frequency distribution of each sample. Crab sizes are reported as carapace width (CW) excluding spines for Tanner and snow crab, and carapace length (CL) for all king crab and hair crab (Donaldson and Byersdorfer 2005). Carapace shell condition was assessed for each crab sampled and assigned to one of six classes according to specific criteria (0 = premolt or molting, 1 = soft and pliable, 2 = new hardshell both firm and clean, 3 = oldshell slightly worn, 4 = oldshell worn, 5 = very oldshell). All female crab abdomens were evaluated to determine reproductive condition based on the size of the egg clutch (0 = immature, 1 = mature female no eggs, 2 = trace to 1/8, 3 = 1/4, 4 = 1/2, 5 = 3/4, 6 = full), the condition of the eggs (0 = no eggs, 1 = uneyed, 2 = eyed, 3 = dead, 4 = empty egg cases), and color of the eggs (0 = no eggs, 2 = purple, 3 = brown, 4 = orange, 5 = purple-brown, 6 = pink).

Egg clutch and egg condition codes were used to assess the stage in the molt-mate cycle of mature female red king crab during the survey, where the presence of eyed embryos, empty egg cases, or absence of eggs (barren, hereafter) in mature-sized females were indications of an

incomplete cycle while mature females brooding uneyed embryos indicated completion of the cycle. The ratio of females with eyed embryos, empty egg cases, and old shell barren to uneyed embryos was derived as a measurement of the molt-mate cycle progression during the survey.

Chela height and carapace width measurements (± 0.1 mm) were collected from a subsample of male *Chionoecetes* spp. crab caught at each station to determine morphometric molt to functional maturity based on the chela height to carapace width ratio (Stevens et al. 1993, Tamone et al. 2007). Functional maturity in male *Chionoecetes* spp. can be separated into two morphometric groups, small claw and large claw based on the frequency distribution of the chela height to carapace width ratio in the large and small claw categories (Tamone et al. 2007).

All crab carapaces were scanned for evidence of bitter crab syndrome or black mat fungus and recorded when present. Crabs with bitter crab syndrome were set aside for further testing by the Fisheries Resource Pathology Laboratory at the AFSC in Seattle, WA.

Crab Biomass Estimates

Crab density (number/nmi^2) was estimated at each station for legal males, or sublegal males, as well as mature and immature males and females of each stock (Table 1). The area swept by the trawl (nmi^2) was calculated as the product of the distance traveled while the net had bottom contact by the mean net width over the duration of the tow. Prior to 2009, data reported in this annual document used a fixed width of 15.2 m (0.008 nmi) in the area swept calculation to maintain consistency with historical calculations of crab abundances. In this document, population biomass estimates are calculated using the variable net width based on net mensuration data. The effective width of the trawl typically ranges from 14.6 to 18.3 m when towing at a speed of 3 knots (Weinberg 2003, Fig. 3), and changes with the depth of the tow due to changes in scope of the trawl wire (Rose and Walters 1990). For 2011 and all historical data reported in this current document, crab densities were calculated using the mean net width recorded for the duration of each tow and a mean net width-inverse scope regression relationship was calculated when net width values were not recorded during a tow (Rose and Walters 1990). From 1975 to 1981, the net width estimates used for the area swept calculations were derived from a single width estimate calculated each year for a particular type of trawl used during the annual survey. From 1982 to 1987, the net width used in the area swept calculations was estimated using the inverse relationship between net scope and net width developed by Rose and Walters (1990). From 1988 to present, the net width is estimated using the net mensuration system described above, which measures the height and width of the net throughout the duration of the tow (Table 2, Fig. 3). Distance traveled by the trawl was determined from ship positions recorded at the beginning and end of each tow using GPS equipment.

All reported historical data and the current biomass estimates are calculated for the number of individual male and female crab species at each 1 mm size category using the weight-size relationships developed by the AFSC Kodiak Laboratory (Table 3). The weight-size relationships are described by the expression:

$$W = a\, L^b$$

where W is the total weight in grams, L is either CL or CW in millimeters, *a* is the intercept in log scale and *b* is the slope. Parameters *a* and *b* for the size-weight relationships are estimated from a linear regression fitted to log-transformed size-weight data.

The weights calculated at each 1 mm size category are summed within the legal male, sublegal male, mature and immature size categories for each species and sex caught at a station. The crab biomass within a district or section stratum was estimated by averaging crab densities from all stations within the defined district or section stratum and multiplied by the total area of the district or section stratum specific to that stock. Total biomass was calculated using a stratified design based on management units (standard-density, high-density, ADF&G defined districts, or section stratum). Population biomass estimates were calculated in each stratum and then summed among strata. Variance of the total biomass estimate for each size class was calculated by summing the variance of each stratum. The 95% confidence intervals were calculated using the standard error of the total population multiplied by 1.96. All biomass estimates and confidence intervals (± 95%) reported in this document are reported in metric tons (t) except in the Abstract where both metric tons and pounds are reported. Metric tons can be converted to pounds by multiplying the biomass in tons by 2,204.62 for comparison with ADF&G reported values of total allowable catch (TAC) and guideline harvest levels (GHL). Differences in metric ton biomass estimates compared to pound biomass estimates are due to rounding errors.

In the Bristol Bay District, two tows were completed at A-04 due to the final position of the Z-04 tow which only has limited area within the trawlable depth range. At stations with multiple tows (i.e., station A-04), a single estimate of crab density was used by averaging all tows within the station prior to calculating total crab biomass.

In years with colder than average bottom water temperatures, (1999, 2000, and 2006 - 2010) a small number of standard Bristol Bay stations sampled at the beginning of the survey were resampled in late July to accurately assess the percentage of ovigerous red king crab females which had extruded a new clutch of uneyed embryos. In 2011, it was necessary to resample 20 Bristol Bay stations in late July due to the low number of newly molted, ovigerous female with clutches of uneyed embryos encountered in early June. These resample stations were selected based on the density of female red king crab at these stations during the first sampling event and from expected distributions based on previous Bristol Bay surveys. The 2011 total population estimates for Bristol Bay red king crab males were calculated by averaging data collected at the original stations in early June with data collected at the 20 resample stations in late July. Bristol Bay female red king crab biomass estimates were calculated by replacing data collected at the original stations with data collected at the resample stations due to crab movement into the sampling area during the time between the standard survey and the resampling event.

The population biomass estimates reported in this document are point estimates and have substantial uncertainty due to the expanse of the area being sampled and the distributions of the resource. These point estimates are least precise for small crabs due to gear selectivity, and for females of some stocks due to crab behavior. However, for consistent analyses and due to a lack of available data, catchability is assumed to be near or equal to one.

RESULTS

Survey Overview

The 2011 EBS bottom trawl survey consisted of 396 bottom trawls (376 standard survey stations, and 20 resampled stations in Bristol Bay) conducted from 5 June to 31 July over an area of approximately 140,350 nmi^2 beginning in the northeast corner of Bristol Bay, moving northwest of St. Matthew Island and following the slope edge south to finish on 25 July at station K-27. The latitude and longitude of the midpoint of each successful tow along with the duration (hr), distance fished (km), bottom depth (m) and bottom temperatures (°C) are listed in Appendix A. The mean distance fished was 1.50 nmi (2.79 km, SD = 0.16 nmi) with a range of 0.54 to 1.87 nmi (1.00 to 3.46 km) and the mean fishing time was 30.5 minutes (SD = 3.1 min). The fishing depth of the 83-112 Eastern otter trawl ranged from 18 to 170 m with a mean gear depth of 77.5 m (SD = 33.4 m). The mean net width per tow ranged from 13.3 to 19.2 m and the average mean net width for all 396 successful tows was 16.4 m with a standard deviation of 0.9 m.

The mean bottom temperature at each station during the standard survey ranged from -1.6° to 6.5°C (Fig. 4). A cold pool of water < 2°C extended onto the middle shelf between the 50 and 100 m isobaths and into the western edge of Bristol Bay with cool temperatures persisting northeast of the Pribilof Islands. Warmer bottom temperatures were evident between the 100 and 200 m isobaths in the southwestern area of the survey area, at the nearshore stations along the Alaska Peninsula, and in shallow waters surrounding Nunivak Island. Cooler water temperatures persisted in the northwestern area between the 100 and 200 m isobaths and the waters surrounding St. Matthew Island. In 2011, the average mean bottom water temperature during the first survey leg (5 to 19 June 2011) was 2.6°C (SD = 1.0) which was warmer than the average mean bottom water temperature during the same time period in 2010 at 1.8°C (SD = 1.6) and in 2009 at 1.5°C (SD = 0.5), as well as 1.4°C (SD = 0.7) in 2008 and 1.8°C (SD = 0.9) in 2007. The mean bottom water temperatures at the 20 stations resampled in July ranged from 4.2°C to 7.7°C, with an average of 5.9°C (SD = 1.1) (Fig. 5).

The time series of mature male biomass, beginning in 1975, for six of the current commercial crab stocks highlights the fluctuations of each stock over the last 30 years with relative increases beginning in 2001 after a precipitous decline from 1997 to 2000 (Fig. 6).

Nine special projects were conducted in addition to the assessment survey to collect specific biological data from particular crab species (Table 4). Eight of the projects originated from the AFSC Shellfish Assessment Program: 1) investigate the effects of ocean acidification on the maternal condition and reproductive success as well as larval condition and survival in red king crab, 2) examine *Chionoecetes* spp. stomach contents, 3) collect specimens with rare or unusual pathological conditions, 4) collect hemolymph samples from *Paralithodes, Hyas, Pagurus,* and *Elassochirus* spp., and *E. isenbeckii* at randomly selected stations to monitor bitter crab syndrome and for population genetics, 5) define genetic population structure in EBS blue king crab, 6) investigate the effects of cold temperatures on crab survival using reflex assessment model predictor, 7) collect paired photographic and genetic documentation from *Chionoecetes* hybrid crab, and 8) evaluate adult and juvenile red king crab distribution at nearshore stations

along the Alaska Peninsula. Data for an additional project were collected to evaluate sperm reserves and clutch fullness in *Chionoecetes* spp. as indicators of reproductive potential for ADF&G.

A total of 55 live female red king crab with newly extruded embryos were collected and returned to the AFSC Kodiak Laboratory to measure the effects of ocean acidification on embryo viability, embryo development, hatching success, fecundity, and maternal condition, as well as the condition and survival of larvae. Over 200 stomachs from both male and female Tanner and snow crab were collected to investigate the diet of these species. Hemolymph samples were collected from 278 *P. camtschaticus*, 53 *Hyas lyratus,* 330 *H. coarctatus*, 81 *Pagurus spp.,* 6 *Elassochirus cavimanus*, 178 *E. isenbeckii,* and 110 *Telmessus cheiragonus* to monitor bitter crab syndrome. One hundred and seventeen hemolymph samples were also collected from both Pribilof Islands and St. Matthew Island blue king crab for population genetics and to monitor bitter crab syndrome. One hundred male snow crab were collected to investigate the effect of cold temperatures on crab metabolism and reflexes. One hundred and twenty hemolymph samples along with morphometric photographs were collected from *Chionoecetes* hybrid crab. Nine survey stations were added to the standard survey design to assess adult and juvenile red king crab distribution in the nearshore waters of Bristol Bay. All collections were completed within the guidelines stipulated by the ADF&G collection permit for each project.

Bristol Bay District Red King Crab

Red king crab were caught at 65 of the 156 stations in the Bristol Bay management district in 2011. The density of legal-sized male crab caught at a station ranged from 73 to 1,894 crab/nmi^2 (Appendix A). Legal-sized male Bristol Bay red king crab were caught at 56 stations (Table 5, Appendix A), resulting in a total biomass estimate (± 95% CI) of 15,412 ± 5,238 t in the Bristol Bay District (Table 6). The majority of these males were concentrated in the central and southwest section of Bristol Bay along the Alaska Peninsula (Figs. 7 and 8). The 2011 estimated biomass of legal-sized males is lower than the 20 year average of 24,464 ± 11,814 t (Table 6).

Red king crab mature males were encountered at 65 of the 156 surveyed stations; 136 Bristol Bay district stations and 20 resample stations (Fig. 9). One hundred percent of the 417 mature males caught were measured, while 43% of the 1,295 immature male red king crab caught were measured (Table 5). The estimated biomass of 19,599 ± 6,024 t for mature males represents 46% of the total male biomass in 2011 (Table 6) with immature male red king crab representing the remaining balance of 7,864 ± 5,517 (Table 5). The majority of both size categories were centrally located in the Bristol Bay District, with a high number of immature males caught at station G-15 in the nearshore waters of northeastern Bristol Bay (Figs. 7 and 8).

The male red king crab caught in 2009 from 125 mm to 135 mm CL grew to 140 mm to 150 mm CL in 2010 and 165 mm to 175 mm CL in 2011. In 2011 this cohort made up the old and very old shell condition classes. Juvenile recruitment appeared as the 40 mm to 50 mm CL size category in 2011 (Fig. 10). In 2011, 79% legal-sized male were hardshell crabs and 21% were oldshell and very oldshell crabs with the majority of oldshell males caught in central Bristol Bay and at depths of 50 m or less (Fig. 11).

One objective of this multi-species bottom trawl survey is to assess the mature red king crab population when mature females are carrying newly extruded, uneyed embryos after completion of the molt-mate cycle (Otto 1986). Embryo development and larval hatching in female red king crab, followed by the molting and mating cycle, are delayed in years with cold bottom water temperatures (Shirley et al. 1990, Stevens and Swiney 2007, Chilton et al. 2010). A delay in the molting and mating cycle is apparent at the beginning of the EBS bottom trawl survey by high numbers of oldshell mature females either brooding eyed embryos, which were fertilized from the previous season, or with pleopods exhibiting empty egg cases.

During years with colder than average bottom temperatures, (1999, 2000, and 2006 - 2010) the ratio of eyed to uneyed embryos encountered in mature females on survey in June was higher compared to years with warmer bottom temperatures (2001-2005). In years with relatively warmer water temperatures, more than 94% of the mature females in June carried uneyed embryos (Chilton et al. 2010). The eyed to uneyed embryo ratio ranges from 6.54 to 0.42 in cold years, compared to 0.06 to 0.01 in the warmer years, indicating a high number of females within the survey area did not complete the molting and mating cycle in early June. The ratio of eyed to uneyed embryos in mature females decreased dramatically when the Bristol Bay stations were resampled in cold years, ranging from 0.02 to < 0.01, and indicating the majority of mature females have completed the mating and molting cycle (Table 7). In 2011, the ratio of eyed to uneyed embryos decreased from 0.81 in early June during the standard survey to 0.06 in late July during the resampling event.

Similar to the previous 5 years, the cold water temperatures in 2011 delayed the molting and mating cycle in mature female red king crab and only 52% of the 450 mature females sampled during the standard survey had extruded a new clutch of uneyed embryos. In early June, the oldshell females with empty egg cases were distributed in the central and northern section of Bristol Bay while the new, hardshell females with uneyed embryos were primarily distributed along the Alaska Peninsula in the southeastern section of Bristol Bay (Fig. 12a). Among resurveyed female crab in late July, 93% were mature females and 94% of these were in new, hardshell condition with newly extruded uneyed embryos (Fig. 13). These new, hardshell females had molted and mated over the 6-week period between the first sampling event in early June samples and the resample in late July (Fig. 12b). The total density of mature female red king crab caught at the 20 resample stations in early June was 28,732 crab/nmi^2 compared to a total density of 63,897 crab/nmi^2 at those same resample stations in late July, indicating a number of the mature females were outside the central distribution area of Bristol Bay in early June (Figs. 12a and 12b).

The 2011 biomass estimates for female red king crab were calculated by replacing data collected at the original stations in early June with data collected at the resample stations in late July. The 2011 mature female red king crab biomass estimate of 37,486 ± 19,011 t represented 91% of the total female abundance (Table 6) with immature female red king crab biomass estimated at 3,760 ± 4,995 t (Table 5). The majority of the mature female red king crab were caught in the central area of Bristol Bay and along the Alaska Peninsula in shallow, nearshore waters while a high number of juvenile females were caught at station G-15 (Figs. 7 and 8).

Pribilof District Red King Crab

Historically, red king crab were not abundant in the Pribilof District and landings were taken incidentally during the blue king crab fishery. The red king crab fishery first opened in 1993 while fishing for blue king crab was closed. A combined fishery for red and blue king crab occurred in the Pribilof District from 1995 through 1998, but due to low abundance of blue king crab, the combined fishery and the red king crab fishery have both remained closed since the 1998/1999 season (Gish 2006).

Red king crab were caught at 7 of the 77 stations in the Pribilof District; 7 stations in the high-density sampling area and zero stations in the standard-density sampling area in 2011. The density of legal-sized males caught at a station ranged from 74 to 2,219 crab/nmi^2 (Appendix A). Legal-sized male red king crab were caught at 6 of the 77 stations in the Pribilof District; 6 stations in the high-density sampling area and zero stations in the standard-density sampling area, with a biomass estimate (± 95% CI) of 3,751 ± 4,787 t. Legal-size males represented 49% of the total male biomass but were below the average of 5,360 ± 5,961 t crab from the previous 20 years (Table 8). The majority of the legal-sized males were distributed south and west of St. Paul Island at stations G-21 and GH-2122 (Figs. 14 and 15).

Mature males were encountered at 6 of the 77 stations in the Pribilof District; 6 stations in the high-density sampling area (F-18 to J-22) and zero stations in the standard-density sampling area, and 100% of the 56 mature and 2 immature males caught were measured (Table 5, Fig. 16). The biomass estimate of mature males was 3,834 ± 4,872 t and represented 99% of the total male biomass (Table 8) with the remaining 1% represented by 44 ± 86 t of immature male red king crab (Table 5). Mature males were distributed ubiquitously around St. Paul Island in the nearshore shallow water stations and to the northeast of St. Paul Island (Figs. 14 and 15).

The 2011 size-frequency for red king crab males shows an increase in the number of oldshell and very oldshell legal-sized males in comparison to the 2009 and 2010 shell conditions (Fig. 17). In 2011, 17% of the legal-sized males were evaluated as new hardshell crabs and distributed northeast of St. Paul Island. Eighty-three percent of the legal-sized males were in oldshell and very oldshell condition and primarily distributed southeast of St. Paul Island (Fig 18).

The 2011 biomass estimate of mature-sized red king crab females was 814 ± 1,165 t, representing 99.9% of the total female biomass, with immature female red king crab biomass estimated at 3 ± 6 t (Table 8). Female biomass estimates are imprecise due to the limited number of tows with positive crab catches (Appendix A, Figs. 14 and 15). All of the mature females were carrying uneyed embryos with 96% of the mature females and 4% of the immature females in new hardshell condition. The majority of mature females with uneyed embryos were in the 130 mm to 140 mm CL size class (Fig. 19).

Pribilof District Blue King Crab

Blue king crab were caught at 5 of the 77 stations in the Pribilof District; 5 stations in the high-density sampling area and zero stations in the standard-density sampling area in 2011. Legal-sized males were caught at two stations east of St. Paul Island and one station north of St. George, with a density ranging from 74 to 454 crab/nmi^2 (Appendix A, Figs. 20 and 21). The 2011 biomass estimate (± 95% CI) of legal-sized males was 399 ± 693 t, representing 86% of the total male abundance and well below the average of 1,603 ± 1,293 t for the previous 20 years (Table 9).

Blue king crab mature males were caught at 3 of the 77 stations in the Pribilof District; 3 stations in the high-density sampling area and zero stations in the standard-density sampling area and 100% of the nine mature males caught were measured (Table 5, Fig. 22). The mature male biomass estimate of 461 ± 763 t represents 100% of the total male abundance since no immature male blue king crab were caught on the 2011 survey in the Pribilof District (Tables 5 and 9, Figs. 20 and 21).

The 2009 male blue king crab cohort at the 125 mm to 130 mm CL size class advanced to approximately the 145 mm to 155 mm CL size class in 2010 and appears in the 180 mm CL size class in 2011 (Fig. 23). Seven legal-sized male blue king crab were captured on the 2011 survey in the Pribilof District; five new hardshell males and one oldshell male were caught east of St. George Island at station H-19 while one legal-sized male was in new hardshell condition and caught northeast of St. Paul Island (Fig. 24).

One mature female blue king crab was caught in the Pribilof District high-density sampling area at station GF-2120 with a biomass estimate of 22 ± 43 t, and represents 60% of the total female biomass (Table 9, Figs. 20 and 21). Immature female blue king crab were caught at two stations north of St. Paul Island in the Pribilof District high-density sampling area with a biomass estimate of 15 ± 25 t for 2011 (Table 5, Figs. 20 and 21). Estimates of female biomass are imprecise due to the preference of these crab for rocky habitat which is difficult to sample with bottom trawls. Blue king crab females are predominantly biennial spawners with only a portion of the female population carrying eyed embryos in a given year, while the remainder is in a non-embryo-bearing phase (Somerton and MacIntosh 1985). One of the three female blue king crab sampled in the Pribilof District was brooding uneyed embryos, while one immature female was in new hardshell condition and the third crab was barren with a new hardshell (Fig. 25).

St. Matthew Island Section, Northern District Blue King Crab

The blue king crab fishery in the St. Matthew Island Section of the Northern District opened in 2009 after a 10-year rebuilding plan. Blue king crab were caught at 28 of the 57 total stations in the St. Matthew Island Section sampling strata; 18 stations in the high-density sampling area and 10 stations in the standard-density sampling area. The density of legal-sized males caught at a station ranged from 72 to 3,988 crab/nmi^2 and were captured primarily south and west of St. Matthew Island (Appendix A, Figs. 26 and 27). One hundred and thirty-two legal-sized male blue king crab were caught in 2011 with a biomass estimate (± 95% CI) of 5,701 ± 5,504 t

representing 52% of the total male biomass which was above the average of 2,997 ±1,468 t from the previous 20 years (Table 10).

Mature male blue king crab were caught at 23 of the 59 stations surveyed in the St. Matthew Island Section sampling strata and 100% of the 255 mature and 92 immature males caught were measured, respectively (Table 5, Fig. 28). The mature male biomass estimate in 2011 was 9,516 ± 10,167 t, representing 86% of the total male biomass (Table 10), while the immature male biomass estimate of 1,699 ± 2,064 t made up the remaining 14% of the total male biomass (Table 5). The majority of the immature male blue king crab were distributed in the shallow waters surrounding St. Matthew Island while a majority of the mature males were caught southwest of St. Matthew Island (Figs. 26 and 27).

The 2009 100 to 110 mm CL male blue king crab cohort grew to 115 mm to 120 mm CL in 2010 and 135-145 mm CL in 2011 with increasing oldshell and very oldshell condition classes (Fig. 29). In 2011, 60% of the legal-sized males were new hardshell crabs, with the majority distributed south of St. Matthew Island, followed by 28% in soft and molting condition while the remaining 12% were oldshell and very oldshell condition crabs (Fig. 30).

The 2011 mature female blue king crab biomass estimate was 51 ± 52 t, representing 38% of the female biomass (Table 10), and the immature female blue king crab biomass estimate was 104 ± 125 t (Table 5). Mature females were caught at two stations, Q-23 and PQ-2423 and immature females were caught at four stations, primarily southwest of St. Matthew Island (Figs. 26 and 27). One mature female was in new hardshell condition with uneyed embryos while one mature female was new hardshell with empty egg cases (see female Pribilof District Blue King Crab discussion above). The remaining 15 females were new hardshell and immature in the 64 to 89 mm CL size classes (Fig. 31).

Tanner Crab

In 2011, the ADF&G Board of Fish changed the legal-size limit of Tanner crab from ≥ 5.5 inches CW (138 mm, without spines) to ≥ 4.4 inches CW (110 mm, without spines) west of 166°W and ≥ 4.8 inches CW (120 mm, without spines) east of 166°W (Table 1). According to the regulatory harvest strategy of the State of Alaska (**5 AAC 35.508**), the annual TAC or GHL for Tanner crab in the area east of 166°W is determined by the biomass estimate of males ≥ 138 mm CW while the Tanner crab GHL in the area west of 166°W is determined by the biomass estimate of males ≥ 125 mm CW. The harvest strategy is based on the assumption that the commercial fishery will target these size categories (Zheng and Pengilly 2011), although the industry may self-impose retention of crab ≥ 5.5 inches CW and 5.0 inches CW (125 mm, without spines) east and west of 166°W, respectively. In this document, we have provided the 2011 abundance and biomass estimates the for the two legal-size categories as well as for ≥ 5.5 inches CW east of 166°W and ≥ 5.0 inches west of 166°W (Tables 5, 11 and 12).

Tanner crab were caught at 72 of the 121 stations east of 166°W and 162 of the 255 stations west of 166°W with Tanner crab occurring at 41 and 22 stations in the high-density area of the Pribilof District and St. Matthew Island Section sampling strata west of 166°W (Appendix A, Fig. 32).

Legal-sized Tanner crab were caught at 44 of the 121 stations east of 166°W and 99 of the 255 stations west of 166°W with one station, G-21, contributing ≥ 100 legal-sized males west of 166°W (Table 5, Fig. 33). Ninety-nine percent of the legal-sized males caught east of 166°W were measured while 74% of the legal-sized males caught west of 166°W were measured (Table 5). The 2011 biomass estimate (± 95% CI) for legal male Tanner crab east of 166°W was 10,201 ± 5,880 t and 52% of those were males ≥ 5.5 inches CW with a biomass estimate of 5,356 ± 4,344 t (Table 11). The 2011 biomass estimate for legal male Tanner crab west of 166°W was 23,259 ± 16,712 t and 67% of those were males ≥ 5.0 inches CW with a biomass estimate of 15,660 ± 13,658 t (Table 12). The majority of the Tanner males ≥ 138 mm CW east of 166°W were distributed in the northeast section of Bristol Bay and the majority of Tanner males ≥ 125 mm CW west of 166°W were distributed to the southwest of the Pribilof Islands while sublegal males were distributed throughout the EBS shelf with high abundances at stations F-07 and G-01 (Fig. 34).

In 2010, a total of 1,795 male Tanner crab chela height and carapace width measurements were collected on the EBS bottom trawl survey. The scatterplot of the allometric relationship between chela height and carapace width using the data collected in 2010 and in 2008 (n =1,783) graphically represents two distinct maturity groups; immature, small claw males with a ratio of less than 0.18 and mature, large claw males with a ratio greater than or equal to 0.18 (Fig. 35). The carapace widths for small claw males ranged from 14.0 to 137.3 mm compared to 66.6 to 175.2 mm for large claw males. Large claw males with carapace widths below the legal-size limit will not recruit to the fishery in the future, as morphometrically mature male *Chionoecetes* spp. crab will not molt again during their lifespan (Tamone et al. 2007).

The 2009 male size class of 55 to 65 mm CW appears at approximately the 85 to 95 mm CW size classes in 2010 and advanced into the 110 to 125 mm size classes in 2011 (Fig. 36). A high number of new hardshell males were caught in 2011 in the 30 to 50 mm and 60 to 70 mm CW size categories. Old and very oldshell males in the 90 to 130 mm CW size classes remain in the population, and are distributed in the southwest section of the EBS shelf at depths greater than 100 m as well as south and east of the St. Paul Island (Fig. 37).

The 2011 mature female Tanner crab biomass estimate east and west of 166°W was 1,727 ± 1,006 t and 5,125 ± 842 t, respectively, while the immature female Tanner crab biomass east and west of 166°W was 4,939 ± 3,242 t and 6,5556 ± 2,228 t, respectively (Tables 5, 11 and 12). Forty percent of the mature female population was distributed east of 166°W in the ADF&G Eastern management district in the central and southwestern area of the Bristol Bay District, while the immature females were distributed throughout the EBS shelf between the 50 and 200 m isobaths (Figs. 32 and 34). Among sampled mature females, 7% were softshell, 33% were new-hardshell, and 60% were oldshell and very oldshell. Eighty-four percent of the mature females carried newly extruded embryos while 5% were brooding eyed embryos, less than 1% had not produced a new clutch and 10% were barren (Fig. 38).

Snow Crab

Although the legal minimum size limit for male snow crab is 3.1 inches CW (78 mm), processors currently prefer a minimum size of 4.0 inches CW (102 mm). The density of legal-sized male snow crab is reported for both legal (≥ 3.1 in. CW) and preferred (≥ 4.0 in. CW) size categories and listed by station in Appendix A. The biomass estimates for male snow crab are reported for both legal and preferred size categories in this report (Table 13).

Snow crab were caught at 274 of the 376 stations in the combined areas of the Bristol Bay District, Pribilof District, and St. Matthew Island Section sampling strata. Snow crab occurred at 40 stations in the high-density area of the Pribilof District and 27 stations in the high-density area St. Matthew Island Section sampling strata (Appendix A). Legal-sized snow crab were caught at 231 of the 376 standard stations (Fig. 39) and 57% of the legal-sized males caught were measured (Table 5).

Legal-sized male snow crab were caught at 235 stations, throughout all Districts combined, resulting in a biomass estimate (± 95% CI) of 146,275 ± 32,651 t and representing 41% of the total male abundance. Thirty-nine percent of those legal males were ≥ 4.0 inches CW with a biomass estimate of 94,741 ± 22,022 t (Table 13), while the biomass estimate of sublegal males was 114,962 ± 36,799 t (Table 5). These legal-sized male snow crab were distributed throughout the EBS shelf with higher concentrations around the Pribilof Islands (Figs. 40 and 41). Approximately 89% of all legal male snow crab were east of 173°W in the ADF&G Eastern management district compared to 70% in 2010.

In 2011, a total of 1,130 male snow crab chela height and carapace width measurements were collected on the EBS bottom trawl survey. The scatterplot of the allometric relationship between chela height and carapace width using the data collected in 2011 and in 2009 (n = 1,303) graphically represents two distinct maturity groups for snow crab; immature males (small claw) with a ratio of < 0.20 and mature males (large claw) with a ratio of ≥ 0.20 (Fig. 42). The carapace widths for small claw males ranged from 21.3 to 121.2 mm compared to 40.6 to 151.6 mm for large claw males.

A high number of pre-recruit new hardshell males appeared in the 45 to 50 mm size category in 2010, and advanced into the 55 to 65 mm size category in 2011 (Fig. 43). Among legal-sized male crab, 4% were in molting or softshell condition while 69% were in new-hardshell condition indicating a recent molt and distributed between the 50 and 100 m isobaths in the middle shelf of the EBS survey area as well as between the 100 and 200m isobaths in the northwest area of the EBS shelf. Twenty-seven percent of the legal-sized males were oldshell and very oldshell condition crabs and primarily distributed in the southwestern section of the EBS shelf (Fig. 44).

The mature female snow crab biomass estimate of 236,886 ± 84,721 t was 77% of the total female biomass and the immature female crab biomass estimate was 72,308 ± 27,103 t (Tables 5 and 13). Among sampled mature females; 62% were in new-hardshell condition with 98% brooding newly extruded embryos, 37% were oldshell and very oldshell condition with 97% brooding new embryos, while less than 1% of the old and very old shell females had not produced a new clutch, and less than 1% of the mature females were barren (Fig. 45).

Chionoecetes bairdi/opilio hybrid

Chionoecetes spp. hybrid crab were caught at 163 of the 365 stations in the combined areas of the Bristol Bay, Pribilof, and Northern Districts. *Chionoecetes* hybrid crab occurred at 36 stations in the Pribilof District high-density sampling area, and 11 stations in the high-density sampling area of the St. Matthew Island Section of the Northern District (Appendix A).

In this document, *C.* hybrid crab size classes for legal males and mature females are based on the size categories for snow crab (see Snow Crab section and Table 1). The biomass estimates for legal-sized male *C.* hybrid crab combines both the preferred and legal size categories. The density of legal-sized male *C.* hybrid crab are listed by station in Appendix A and are separated into preferred (≥ 4.0 in. CW) and legal (≥ 3.1 in. CW) size categories.

Legal-sized male *C.* hybrid crab were caught at 126 stations, throughout all Districts combined, resulting in a biomass estimate (± 95% CI) of 4,225 ± 1,363 t and were primarily distributed northeast of the Pribilof Islands between 50 and 100 m (Figs. 46 and 47). Ninety-two percent of those legal males were ≥ 4 inches in carapace width, with a biomass estimate of 3,892 ± 1,321 t. The 2011 sublegal male *C.* hybrid crab biomass estimate for all Districts combined was 2,808 ± 1,421 t, were distributed throughout the northeastern Bering Sea shelf at depths greater than 50 m (Figs. 46 and 47).

The 2011 mature female *C.* hybrid crab biomass estimate was 3,084 ± 1,257 t and the immature female crab biomass estimate was 471 ± 229 t. The majority of the mature female hybrid crab were primarily distributed south of St. Matthew Island and between 100 and 200 m in the northwestern area of the eastern Bering Sea shelf (Figs. 46 and 47).

Other Crab Stocks and Species of Interest

Northern District Red King Crab

Red king crab were caught at 28 stations in the Northern District outside of the current management units where red king crab are commercially fished (Fig. 2). The 2011 biomass estimates were calculated using an area of 11,228 nmi^2 based on the number of stations with catches of red king crab in the Northern District. Legal-sized males were caught at 14 of those stations. The density of legal-sized males caught at a station ranged from 74 to 156 crab/nmi^2 (Appendix A). The 2011 biomass estimate (± 95% CI) of legal-sized males was 1,479 ± 620 t while the biomass estimate of mature and immature males was 2,047 ± 729 and 369 ± 208 t, respectively. The biomass estimate of mature female red king crab was 888 ± 392 t while the biomass estimate of immature females was 33 ± 45 t. The majority of both legal males and mature female red king crab were caught in depths < 50 m at stations south and west of Nunivak Island (Fig. 48).

Northern District Blue King Crab

Blue king crab were caught at three stations not included in the blue king crab biomass estimates for the Pribilof District or the St. Matthew Island section sampling strata of the Northern District. One immature, hardshell female was caught northeast of the Pribilof Islands at station I-02, while

one mature, hardshell male and one legal-sized, mature male in oldshell condition were caught northwest of St. Matthew Island at stations T-26 and V-27, respectively (Appendix A, Fig. 49).

Hair Crab

In 2011, a total of 620 hair crab were captured at 68 of the 317 stations throughout all Districts combined on the EBS bottom trawl survey (Fig. 50). Historically, hair crab have been concentrated just north of the Alaska Peninsula and near the Pribilof Islands. In recent years, abundance of hair crab north of 58°N has been increasing, particularly west of Nunivak Island (Fig. 50).

In this report, legal male hair crab are defined as > 3.25 inches CW (≥ 83 mm CL) which was specified in the previous Pribilof District fishery while the female hair crab biomass estimate is presented for all sizes combined. The 2011 density of legal male hair crab caught at a station ranged from 72 to 862 crab/nmi^2 resulting in a biomass estimate of 2,119 ± 239 t (Table 14). Legal male hair crab were primarily concentrated in the central Bristol Bay area, near St. Paul Island and distributed along the 50 m isobath near Nunivak Island (Fig. 50).

The 2011 pre-recruit male hair crab biomass estimate (± 95% CI) was 1,750 ± 170 t and the female hair crab biomass estimate was 375 ± 21 t (Table 14). A high number of pre-recruit males were caught west of Nunivak Island in the northeast section of the standard survey while the majority of female hair crab were caught in the central Bristol Bay area at depths > 50 m (Fig. 50). The density of both pre-recruit male and female hair crab has increased in these two areas over the last 4 years with an increasing number of females occurring west of Nunivak Island (Chilton et al. 2009 and 2011).

The Pribilof District hair crab fishery has been closed since 2000 due to a shift in the distribution of legal males to the Northern District and, after one year of experimental fishing with minimal vessel participation, the Northern District fishery was closed in 2001 (Bowers et al. 2010). In the last few years, the biomass estimates of both size classes of male hair crab have increased relative to 2006 with the 2011 biomass estimate for legal-sized male hair crab higher than the 20-year average of 1,780 ± 820 t (Table 14).

ACKNOWLEDGMENTS

We thank Captains Norm Bakken and Mike Wiggins of the FV *Aldebaran*, and Captain Jim Hampton of the FV *Alaska Knight* and all their crew without which the annual EBS bottom trawl survey would not occur. We also thank the dedicated field party chiefs, deck bosses, and scientific crew from AFSC and all those who volunteered to come out on the survey. The scientific personnel who made up the 2011 "crab crew" included; C. Armistead (AFSC, Kodiak Lab), E. Chilton (AFSC, Kodiak Lab), M. Dawson (AFSC Kodiak Lab), R. Foy (AFSC, Kodiak Lab), W. Gaeuman (ADF&G), J. Haaga (AFSC, Kodiak Lab), C. Long (AFSC, Kodiak Lab), E. Munk (AFSC, Kodiak Lab), N. Roberson (AFSC, Seattle), L. Slater (ADF&G), S. Tamone (UA Southeast), D. Urban (AFSC, Kodiak Lab).

Table 1. -- Definition of carapace size classes for crab species caught in National Marine Fisheries Service eastern Bering Sea standard survey. Carapace length (CL) is measured for *Paralithodes* spp. and *Erimacrus isenbeckii*, while carapace width (CW spines) is measured for *Chionoecetes* species.

	Immature	Mature	Legal male
Paralithodes camtschaticus			
Bristol Bay District			
males	<120 mm	≥ 120 mm	≥ 135 mm CL or ≥ 6.5 in. CW
females	<90 mm	≥ 90 mm	
Pribilof District			
males	<120 mm	≥ 120 mm	≥ 135 mm CL or ≥ 6.5 in. CW
females	< 90 mm	≥ 90 mm	
P. platypus			
Pribilof District			
males	<120 mm	≥ 120 mm	≥ 135 mm CL or ≥ 6.5 in. CW
females	< 100 mm	≥ 100 mm	
St. Matthew Island			
males	< 105 mm	≥ 105 mm	≥ 120 mm CL or ≥ 5.5 in. CW
females	< 80 mm	≥ 80 mm	
Chionoecetes bairdi			
East of 166° W			
males			≥ 120 mm or ≥ 4.8 in. CW[1]
females	< 85 mm	≥ 85 mm	
West of 166° W			
males			≥ 110 mm or ≥ 4.4 in. CW[1]
females	< 80 mm	≥ 80 mm	
Chionoecetes opilio	<50 mm	≥ 95 mm ≥ 50 mm	≥ 78 mm or ≥ 3.1 in. CW[2] ≥ 50 mm
Erimacrus isenbeckii			
males			≥ 83 mm[3] CL or > 3.25 in. CW
females			

[1] The 2011 legal minimum size limit for *C. bairdi* is ≥ 4.8 inches CW (120 mm) east of 166° W and ≥ 4.4 inches CW (110 mm) west of 166° W (ADF&G reg. **5 AAC 35.520(b)(1)**).

[2] The legal minimum size limit for *C. opilio* is 3.1 inches CW (78 mm), although processors currently prefer a minimum size of 4.0 inches CW (102 mm).

[3] Legal-sized male crab for *E. isenbeckii* are larger than a minimum size of 3.25 inches CW (≥ 83 mm CL) defined by Alaska Department of Fish and Game permit guidelines.

Table 2. --History of methods for determining trawl on bottom and estimating net width on National Marine Fisheries Service eastern Bering Sea bottom trawls.

Year	Net width (m)	Trawling methodology
1975		First and only year tow duration = 1 hour
1976-2011		Tow duration = 30 minutes
1975-1995		Brake set and haul back of winch drum wire defined trawl contact with seafloor (net on bottom)
1996-2011		Began using bottom contact sensors to determine trawl contact with seafloor
1975 - 1980	12.2	Mean width of 400-mesh eastern trawl*
1981	18.0	Mean width* of 83-112 eastern trawl for Vessel 1
1981	13.4 or 14.3	Mean width* of 400-mesh eastern trawl measurements different on haul 1-112 and 114-156 for Vessel 37*
1982 - 1987	Variable with each tow	Rose and Walters (1990) calculated the 83-112 net width based on an inverse relationship to net scope
1988 - 2001	Variable with each tow	All survey vessels used ScanMar acoustic sensors on the 83-112 trawl net
2001 - 2011	Variable with each tow	All survey vessels used NetMind acoustic sensors on the 83-112 trawl net

*Single value used for net width when calculating area swept.

Table 3. --Weight-size regression relationships used to calculate biomass of crab species caught in National Marine Fisheries Service eastern Bering Sea bottom trawl surveys.

Species	Number collected	*a*	*b*
Red king crab males	1086	0.000403	3.141334
Ovigerous red king crab	1010	0.003593	2.666076
Non-ovigerous RKC	201	0.000408	3.127956
Blue king crab males	409	0.000508	3.106409
Blue king crab females[2]	n/a	0.02065	2.2700
St. Matthew males	386	0.000502	3.107158
Tanner crab males	1030	0.00027	3.022134
Ovigerous Tanner crab	331	0.000441	2.898686
Non-ovigerous Tanner	487	0.000562	2.816928
Snow crab males	1107	0.000267	3.097253
Ovigerous snow crab	588	0.001158	2.827784

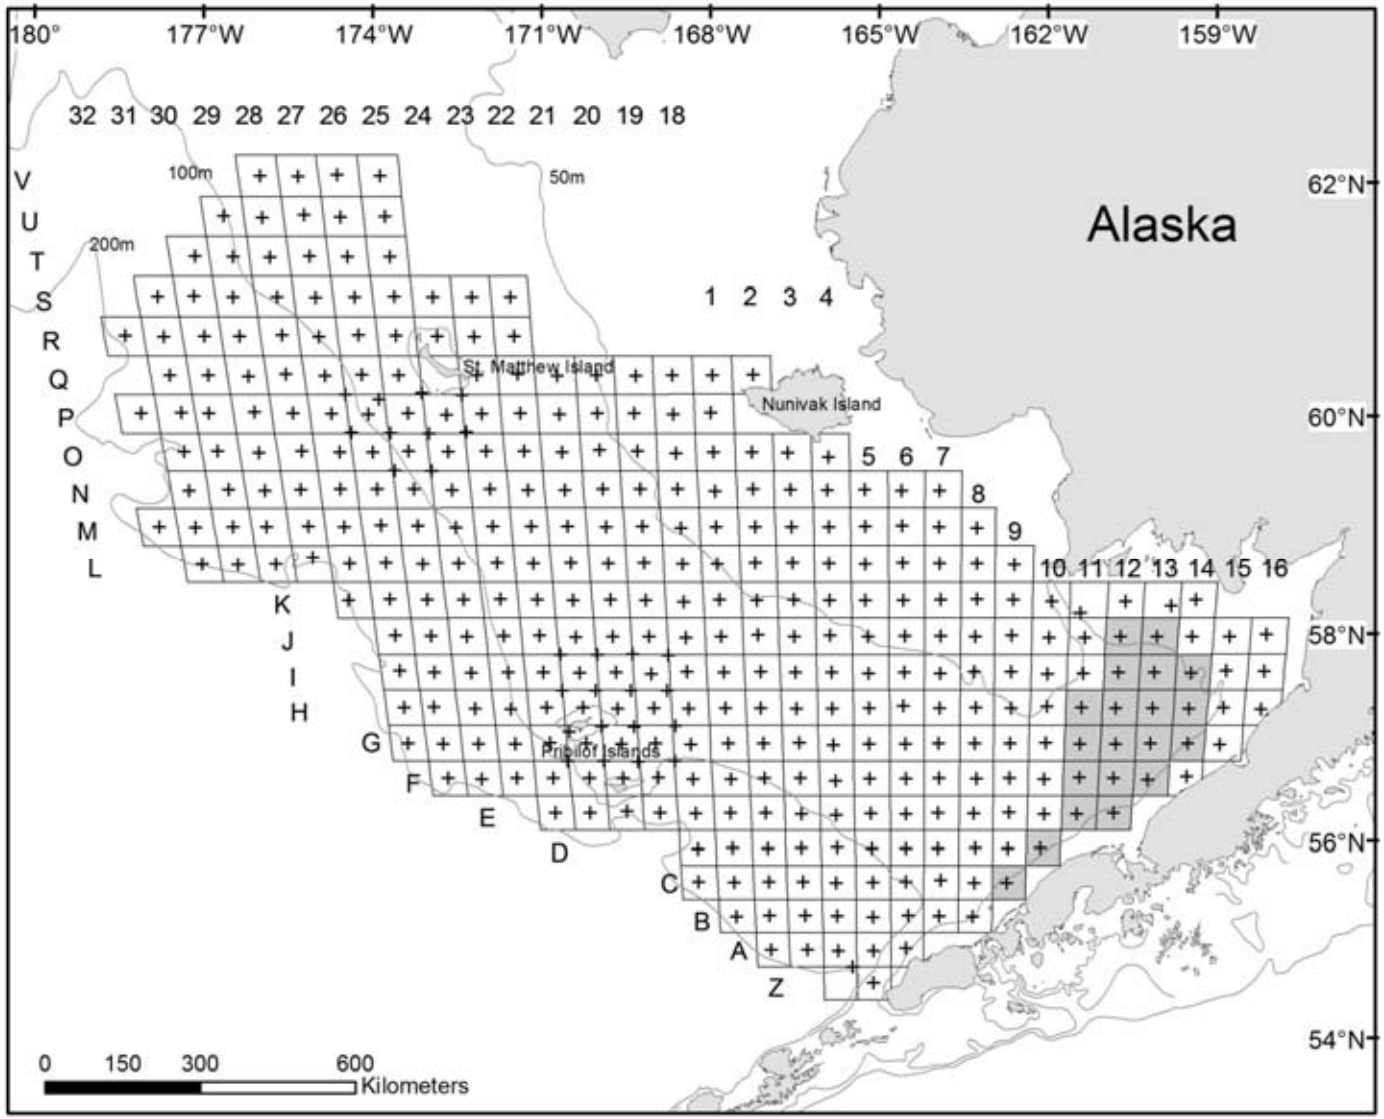

Figure 1. -- National Marine Fisheries Service eastern Bering Sea standard bottom trawl area surveyed by FV *Alaska Knight* and FV *Aldebaran* from 5 June to 31 July 2011. Shaded area depicts Bristol Bay resample stations, 25 to 31 July 2011.

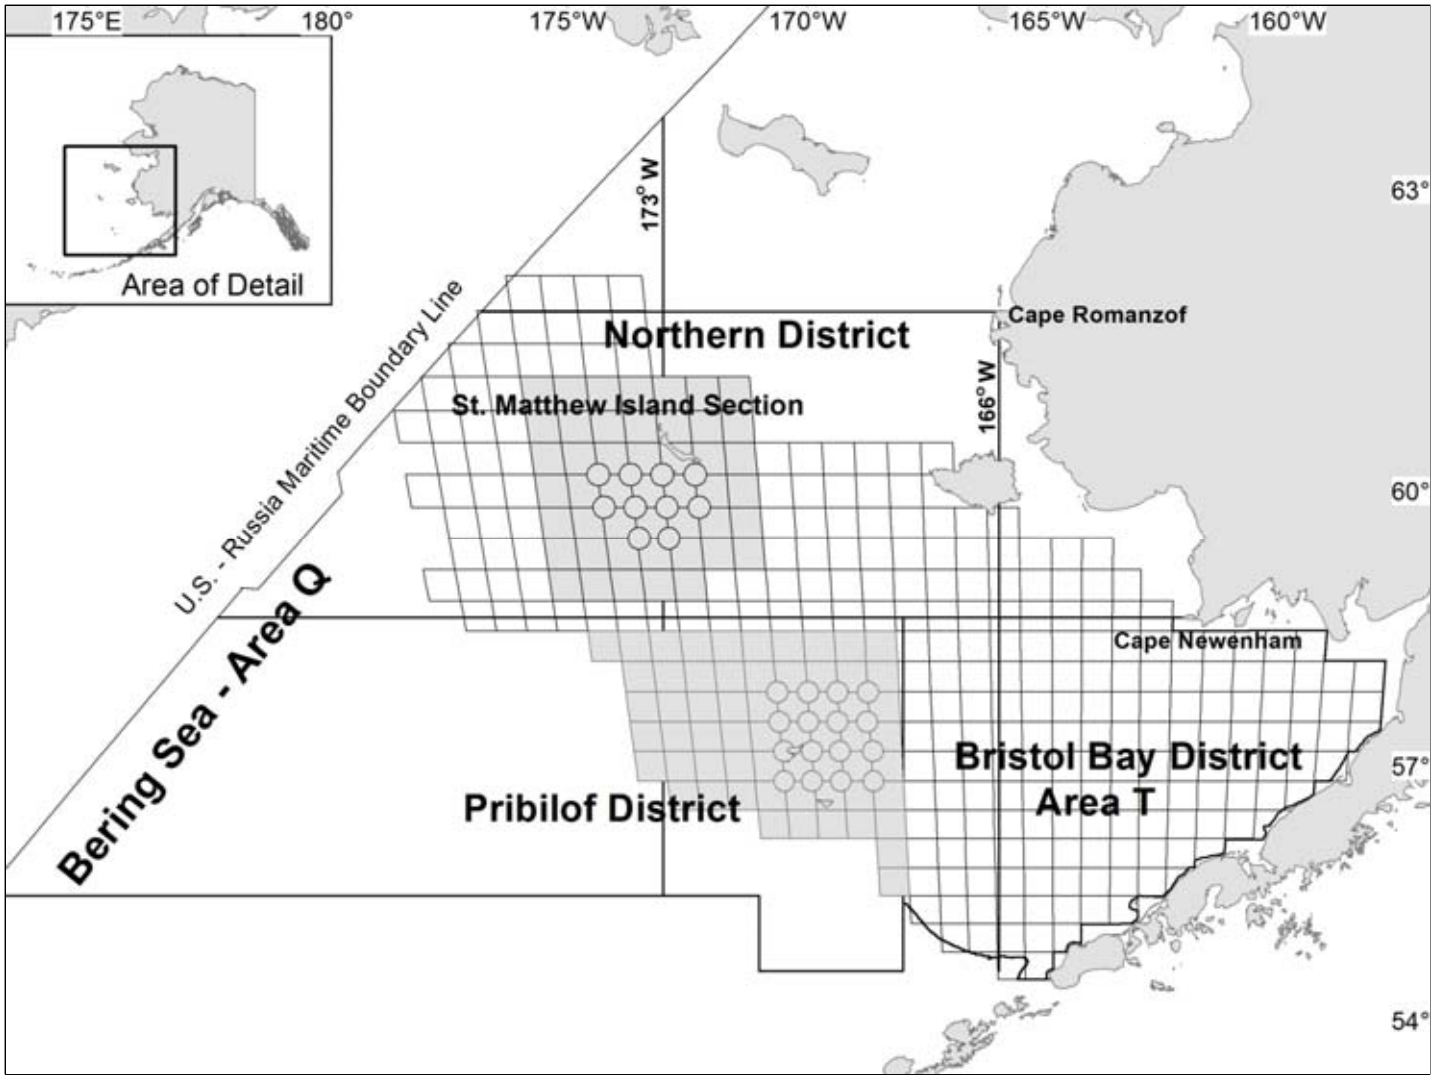

Figure 2. -- Alaska Department of Fish and Game commercial crab management units within the 2011 eastern Bering Sea bottom trawl survey area. Grey areas represent stations included in in the Pribilof District and St. Matthew Island Section, Northern District sampling strata and circles represent the high-density sampling areas.

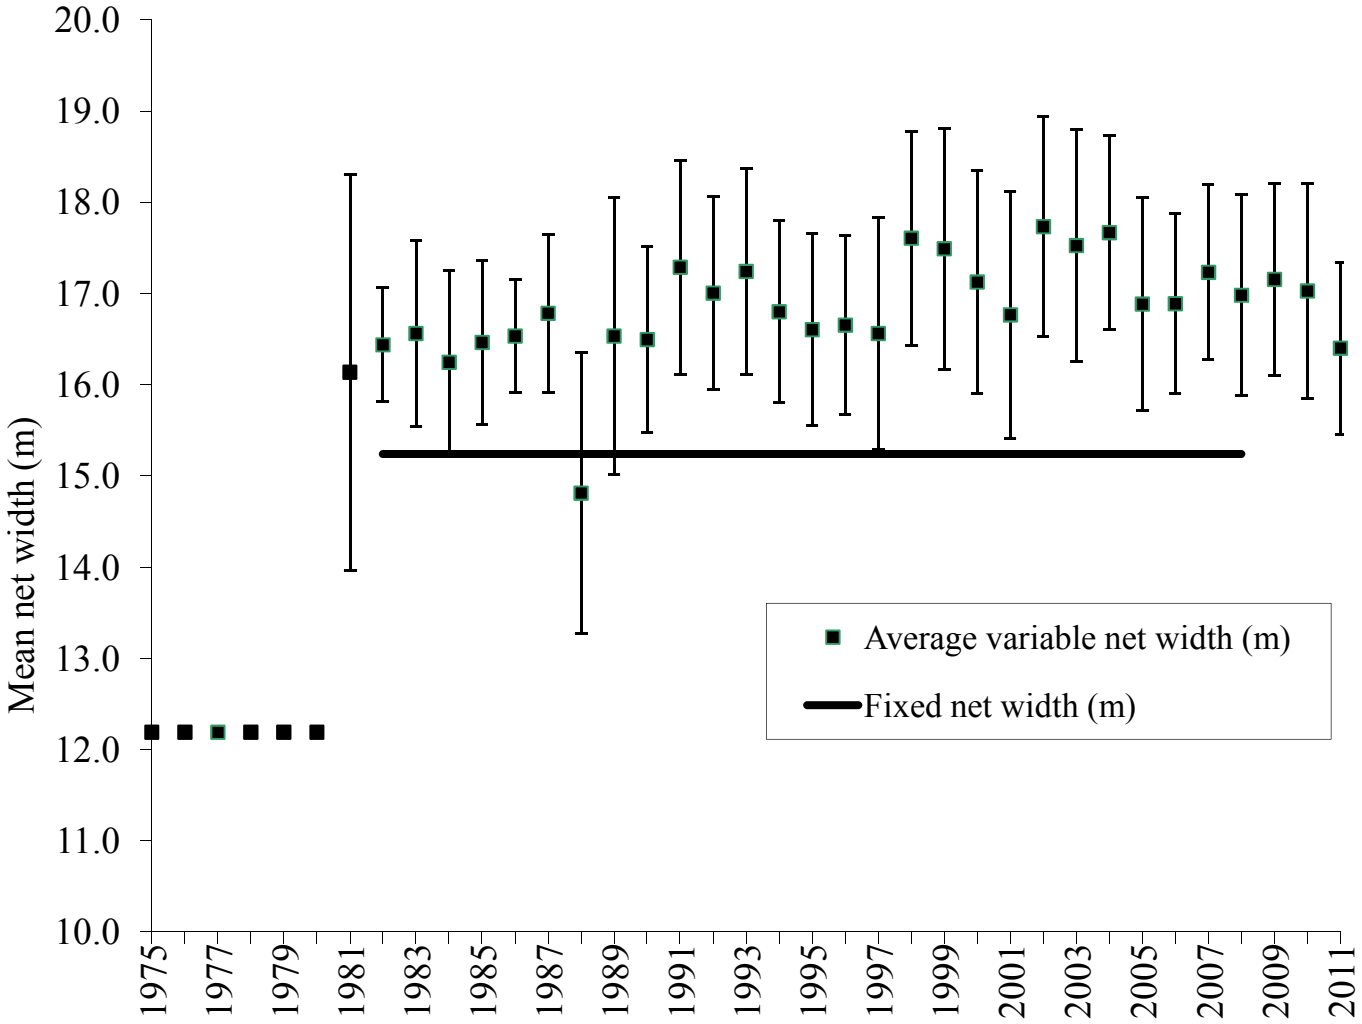

Figure 3. -- Fixed and average variable net widths (SD) used to calculate area swept by National Marine Fisheries Service eastern Bering Sea standard bottom trawls from 1975 to the present.

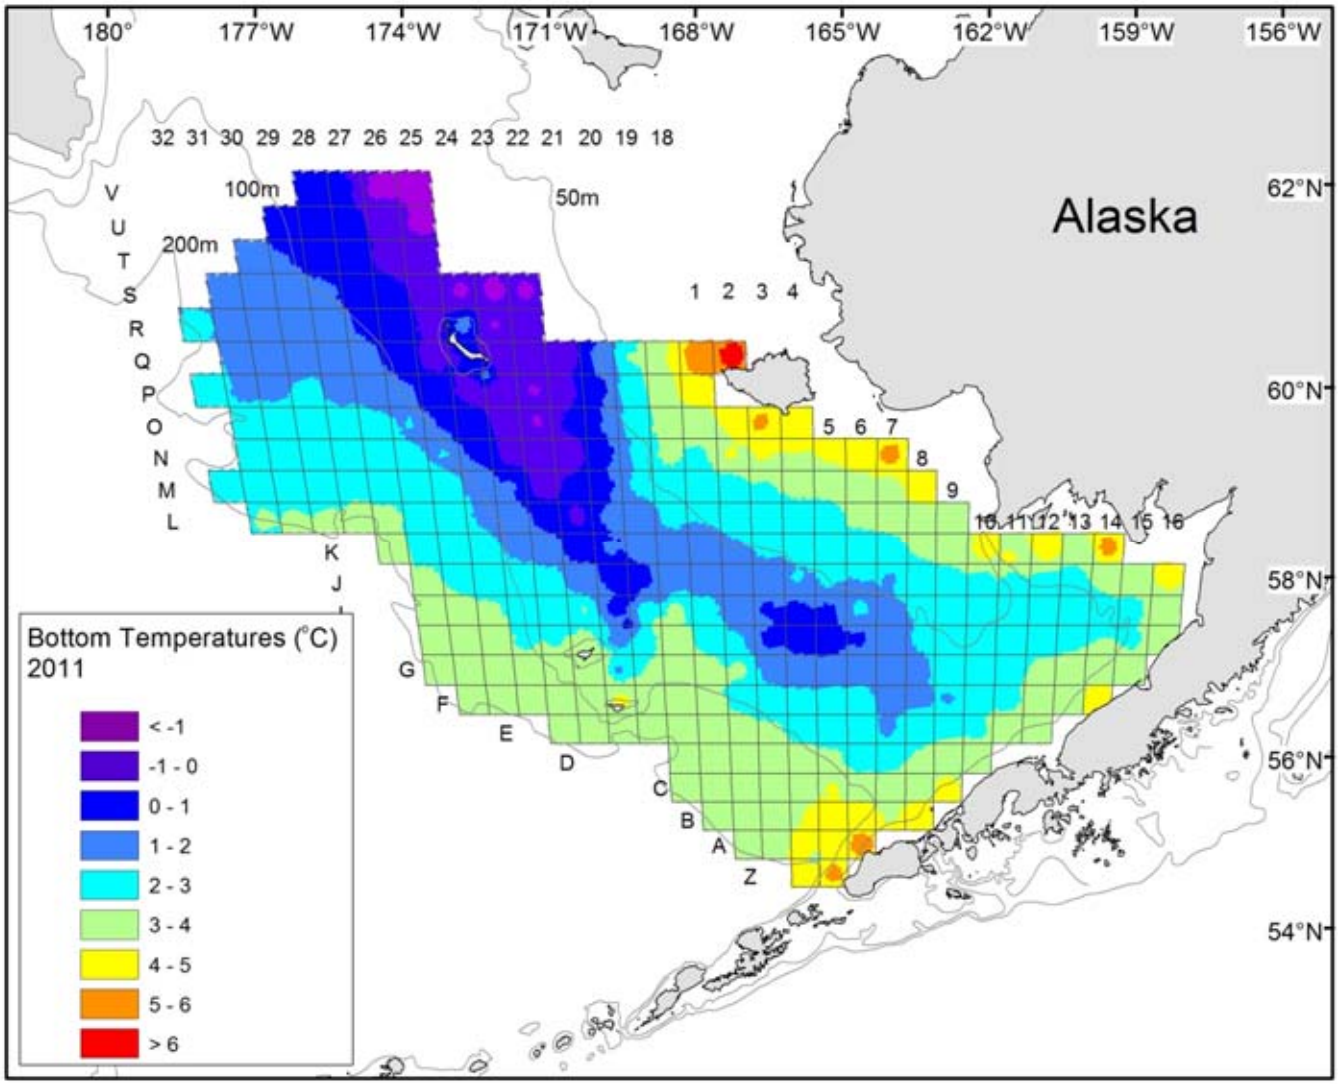

Figure 4. -- Mean bottom temperatures (°C) measured at stations from the National Marine Fisheries Service eastern Bering Sea bottom trawl survey, beginning 5 June 2011 in Bristol Bay and ending on 25 July 2011 at K-27. This figure does not reflect the 20 stations resampled in Bristol Bay from 25 to 31 July 2011.

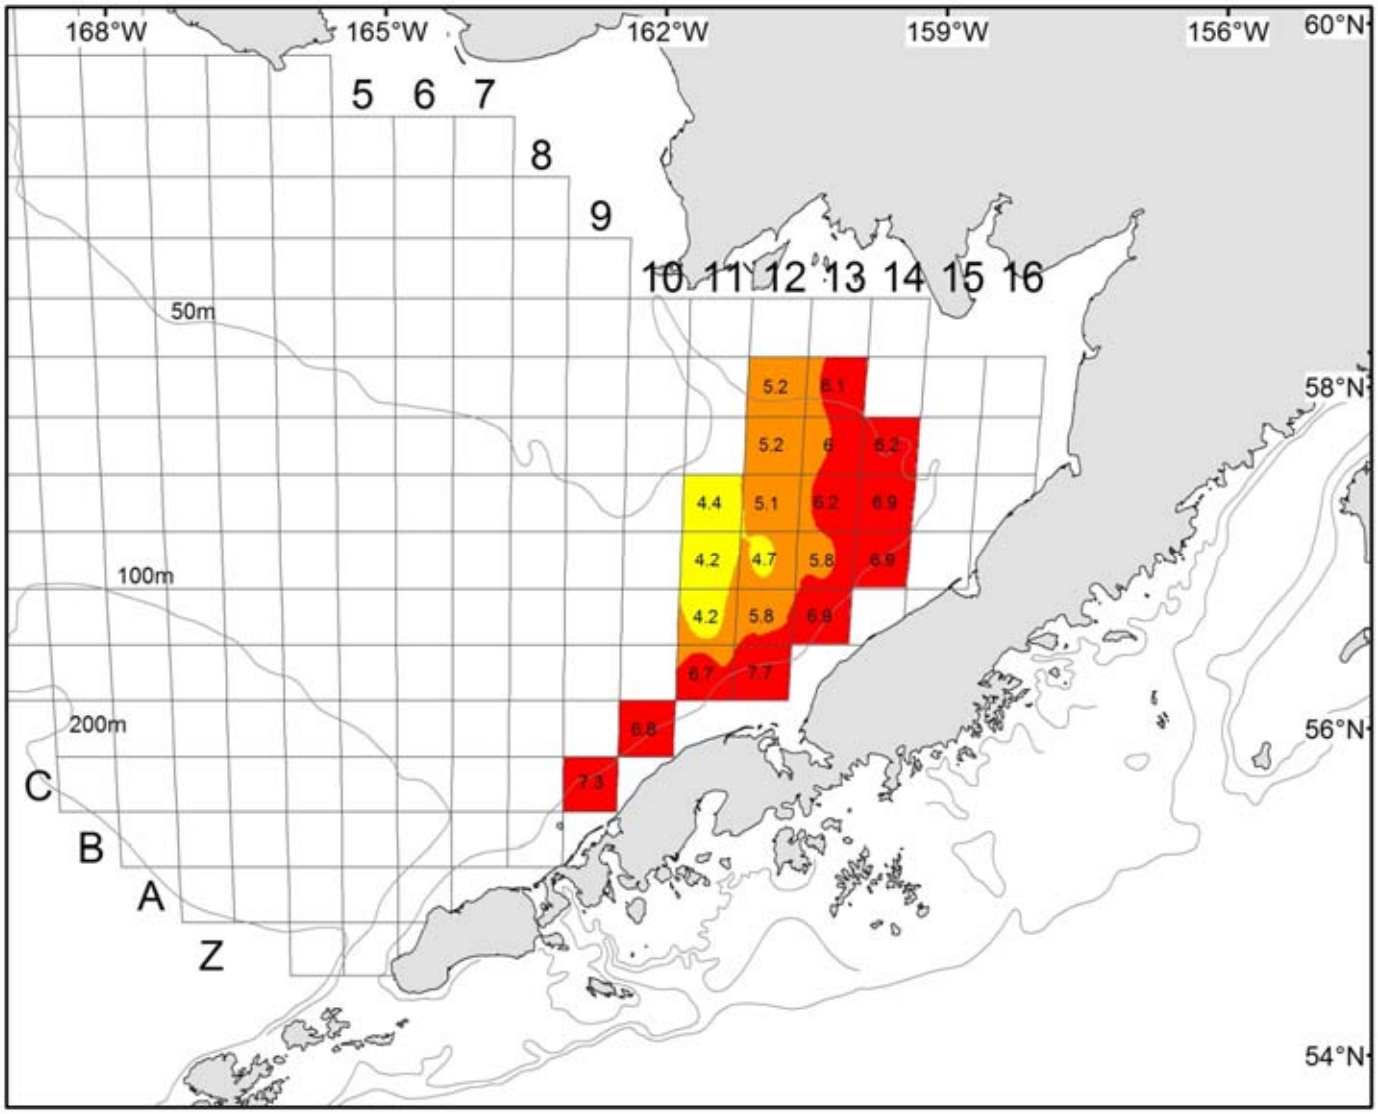

Figure 5. -- Mean bottom temperatures (°C) measured at the 20 resample stations in Bristol Bay, surveyed from 25 to 31 July 2011.

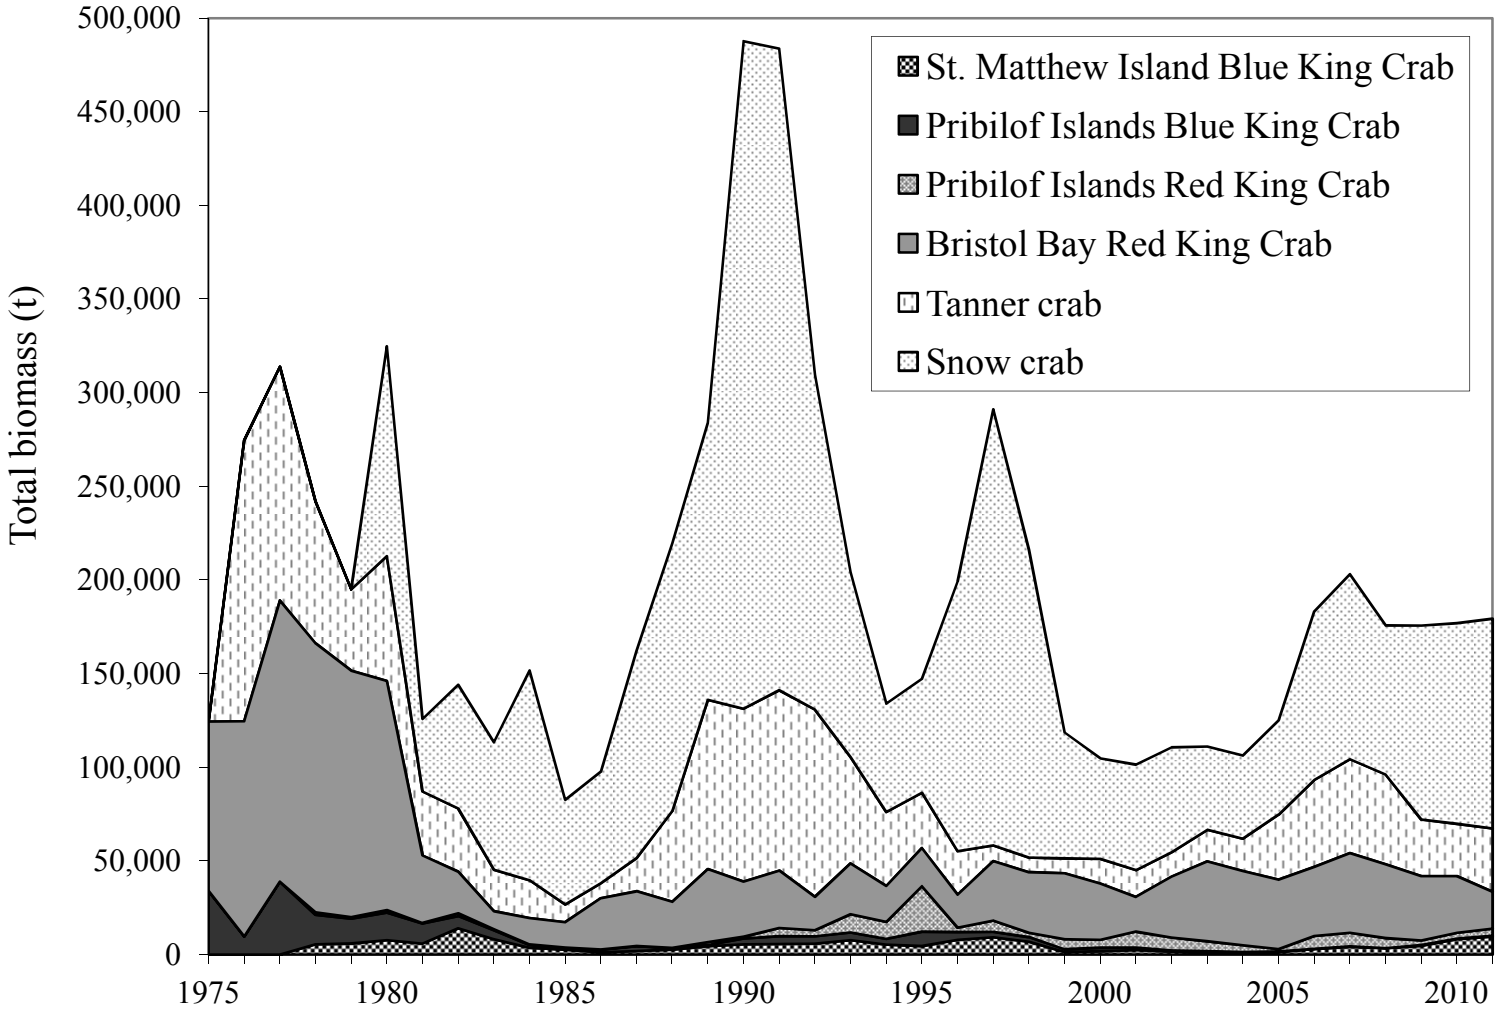

Figure 6. -- Historical mature male biomass for six commercial species caught on National Marine Fisheries Service eastern Bering Sea bottom trawl surveys.

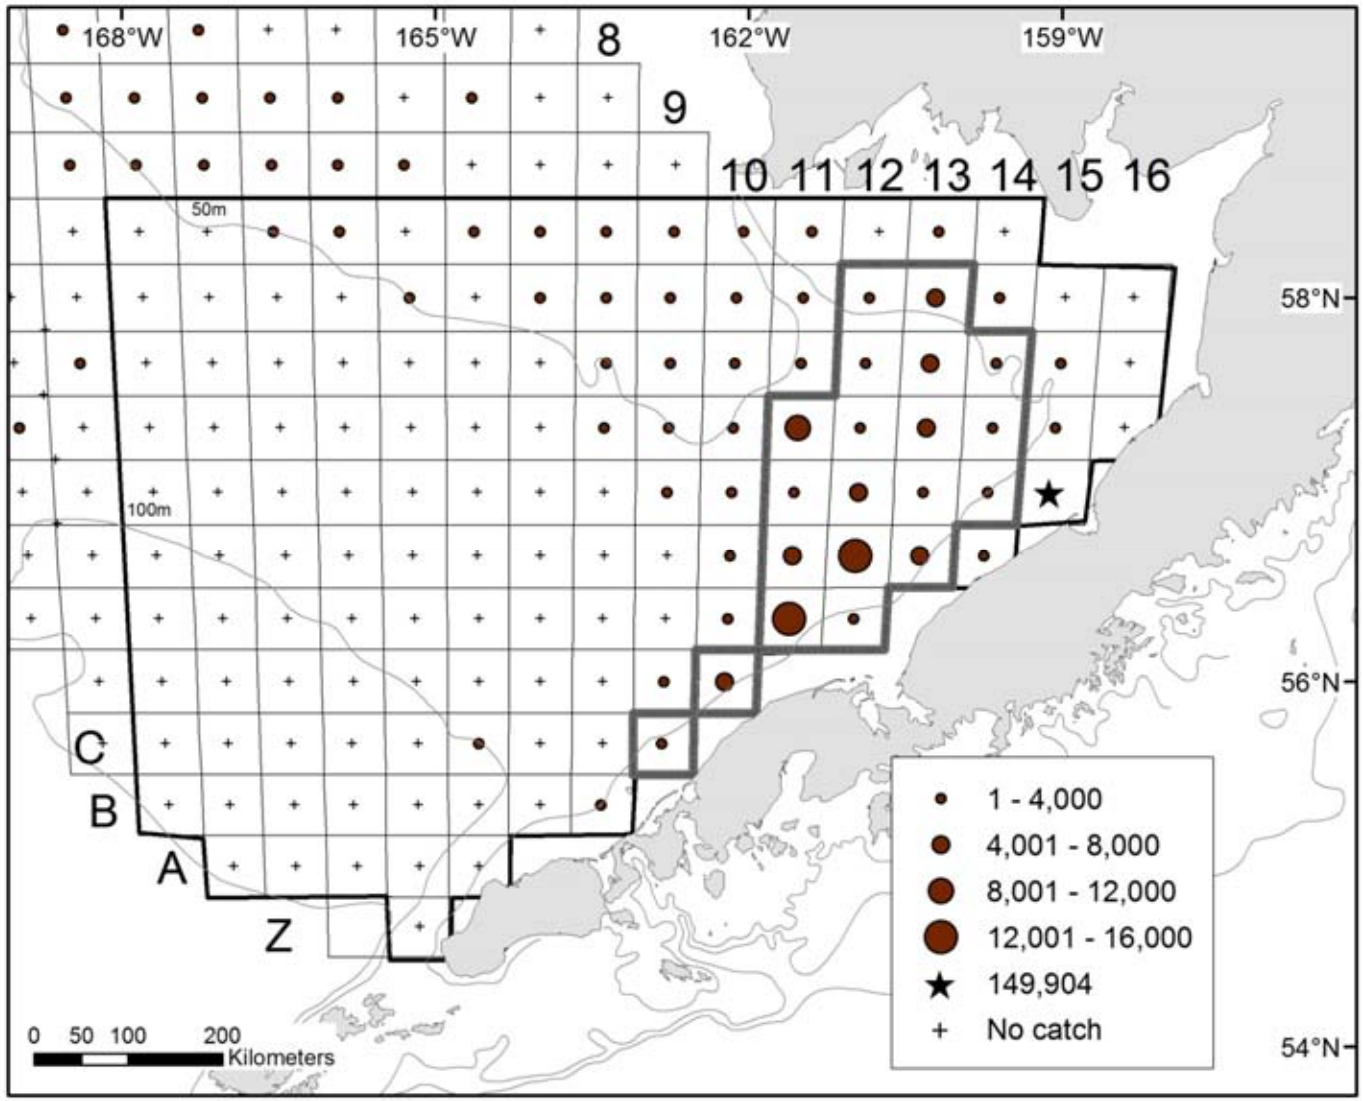

Figure 7. -- Total density (number/nmi^2) of red king crab (*Paralithodes camtschaticus*) at each station sampled in the 2011 Bristol Bay District. Data depicted by circles are equal interval densities, while stars are densities larger than the standard scale. Outlined area depicts the management district and the resurveyed stations outlined in grey within the management district.

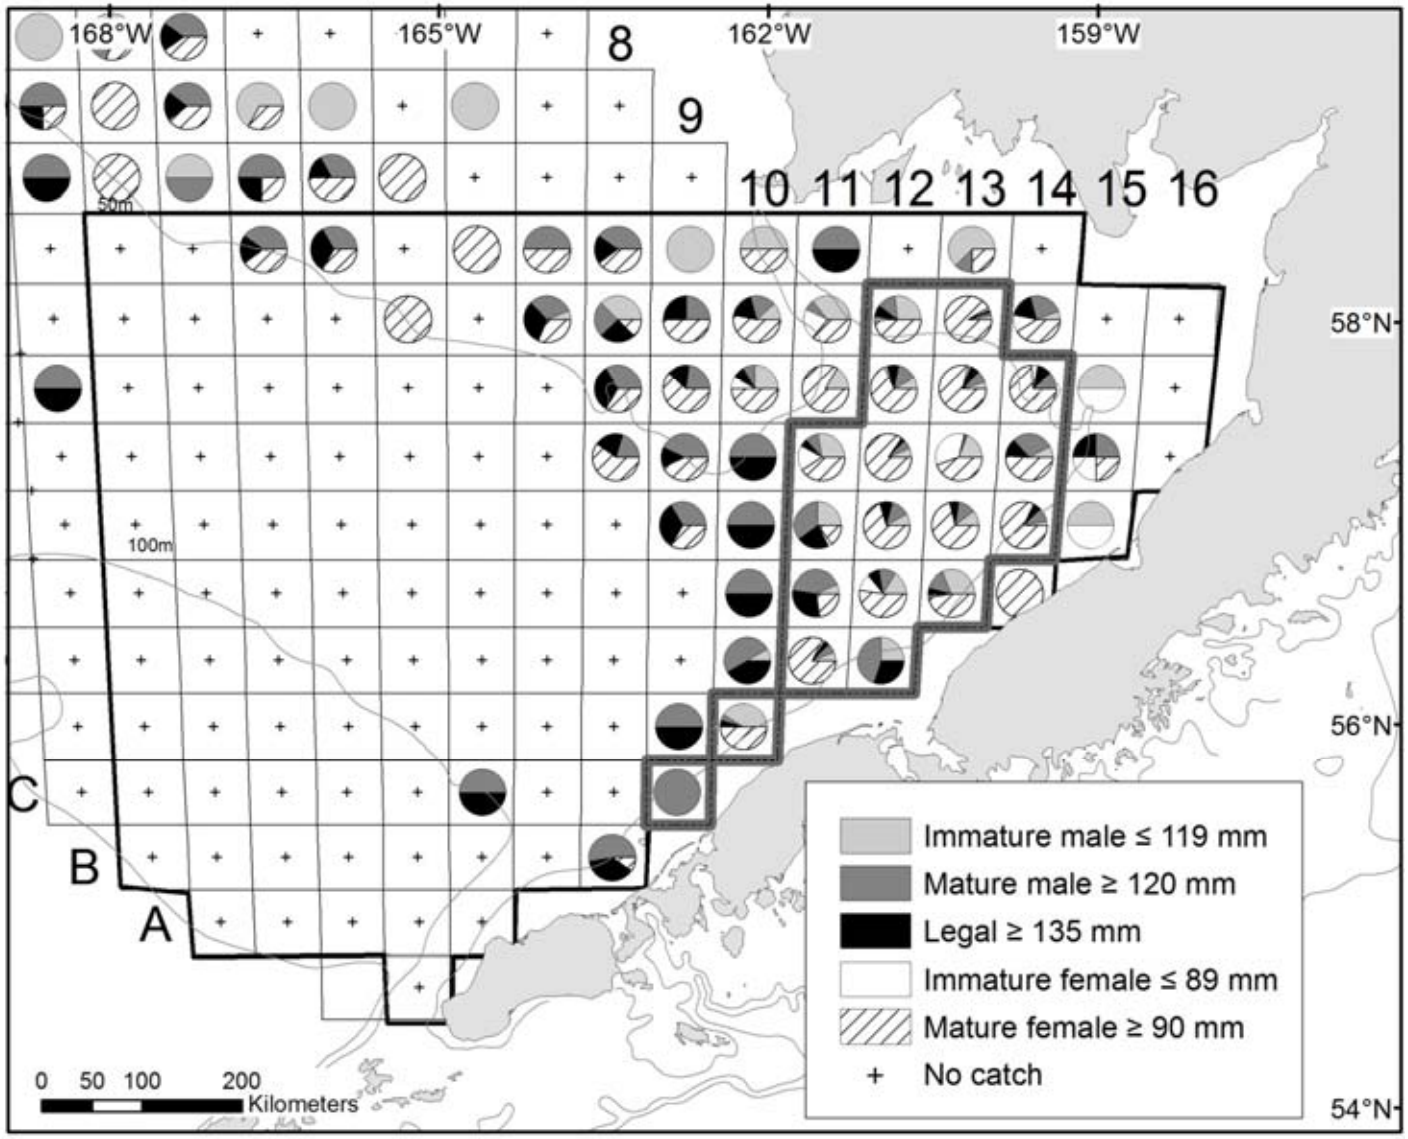

Figure 8. --Percentage of male and female red king crab (*Paralithodes camtschaticus*) size classes caught at each station of the Bristol Bay District in 2011. Outlined area depicts management district and the 20 resurveyed stations are outlined in grey.

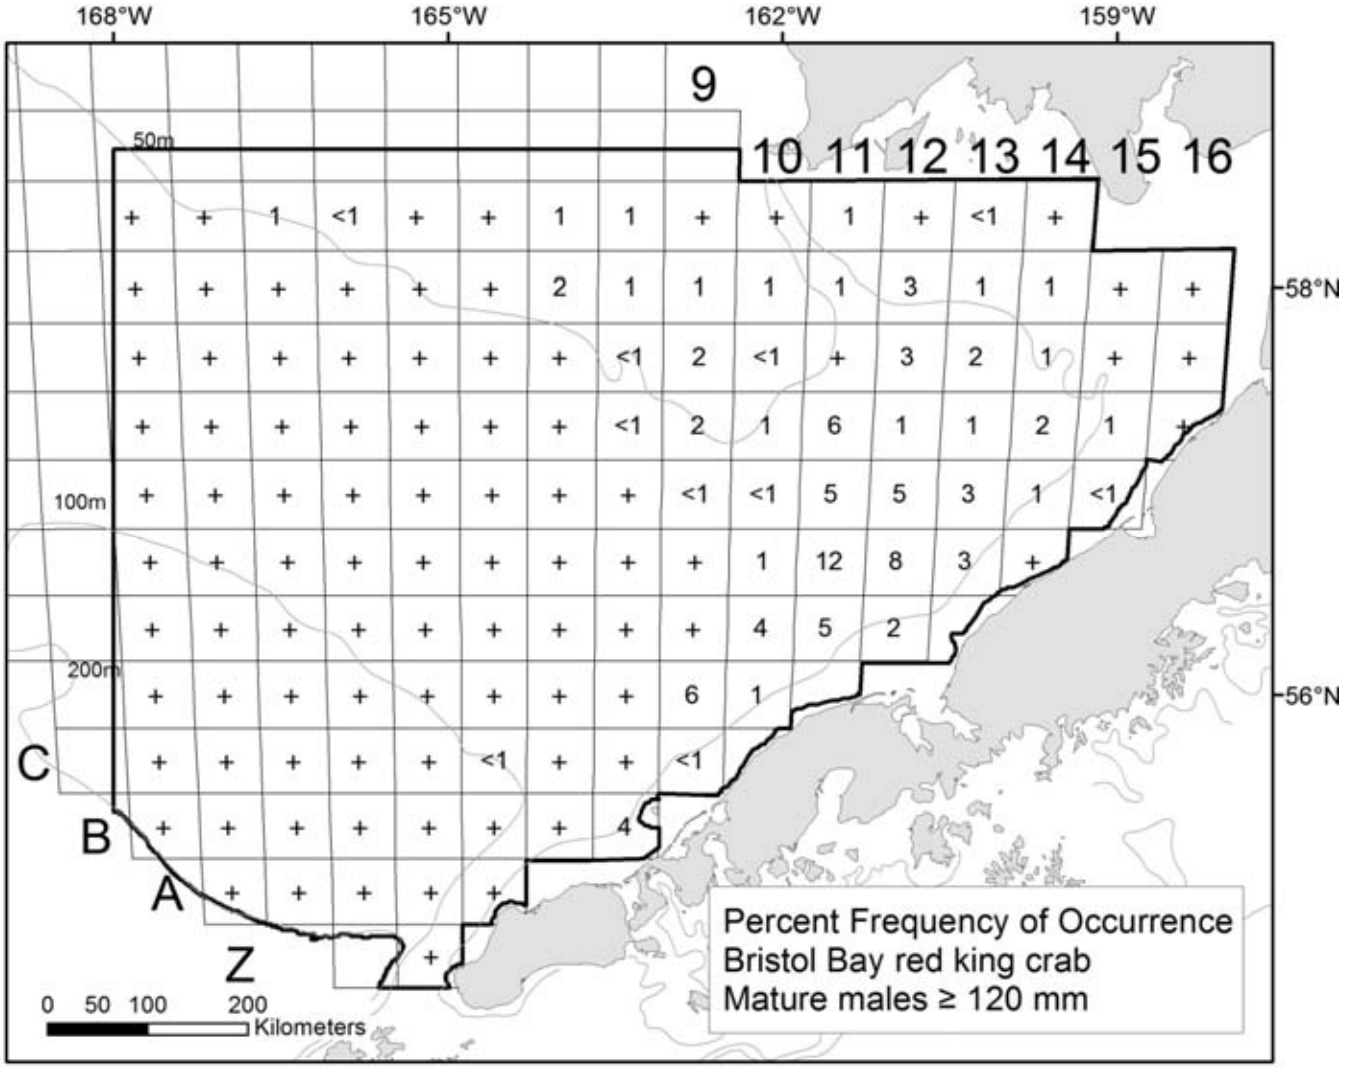

Figure 9. --Percent frequency of occurrence of mature male red king crab (*Paralithodes camtschaticus*) at stations sampled in the 2011 Bristol Bay District.

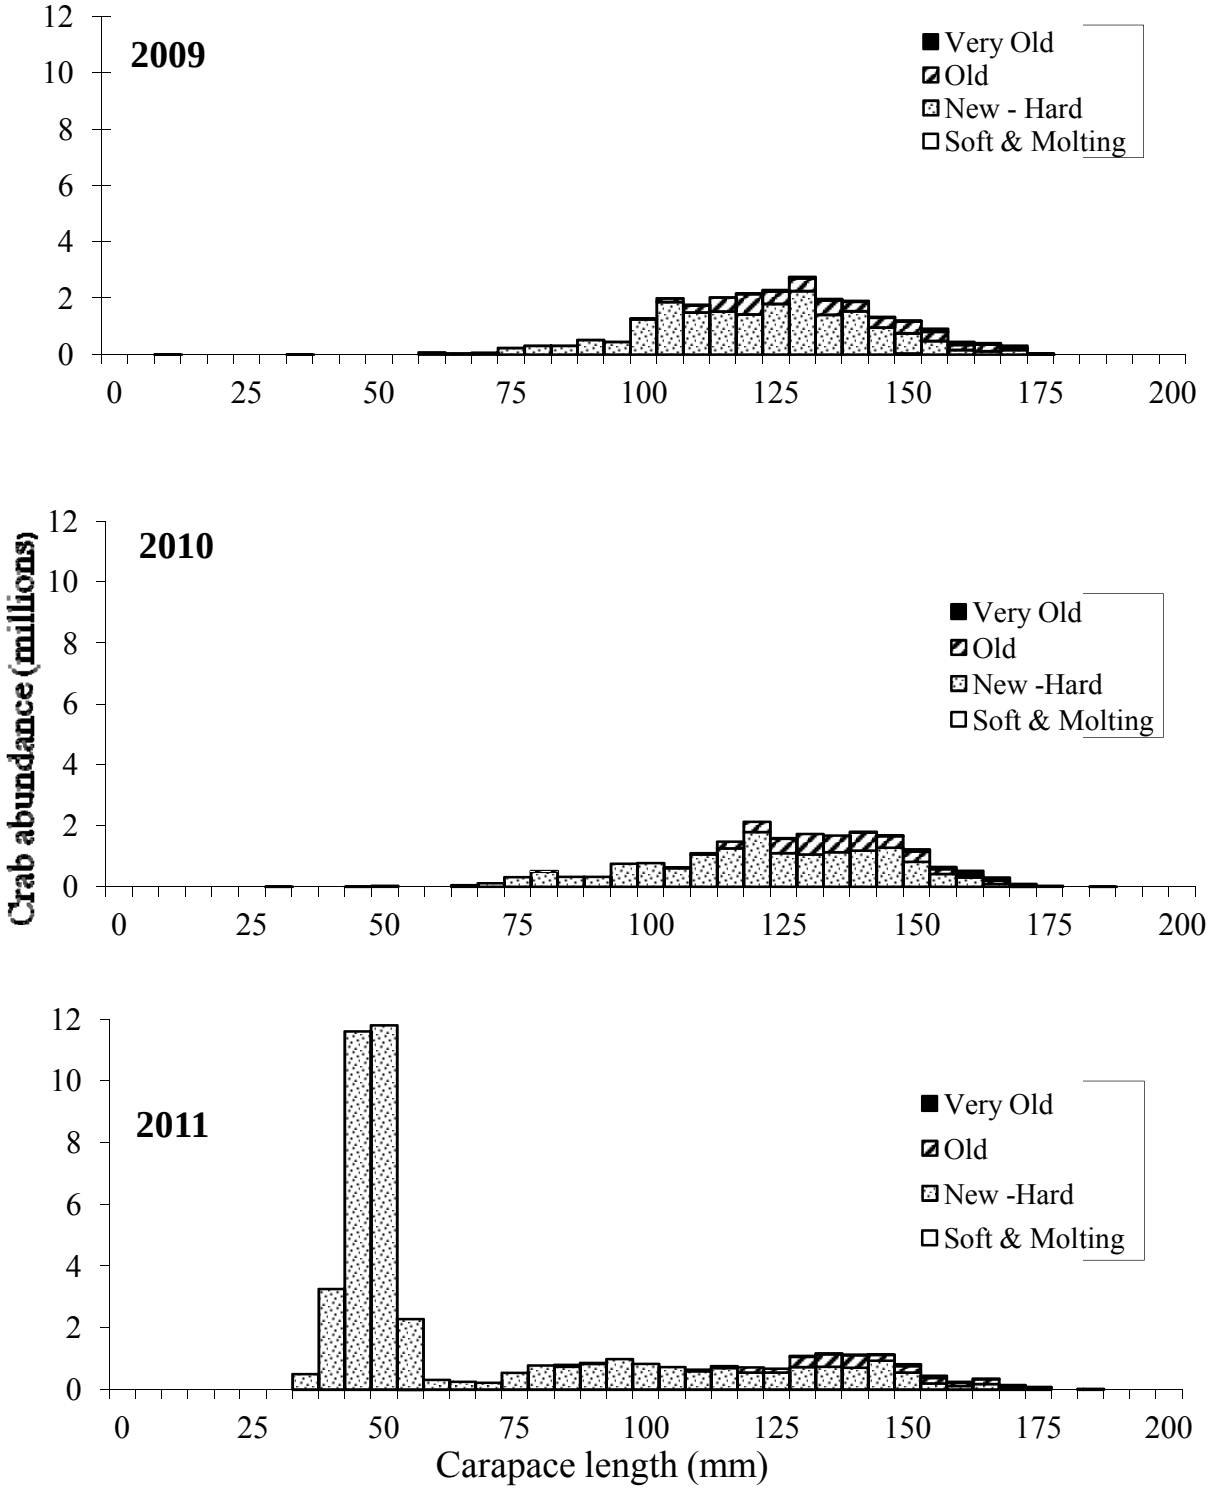

Figure 10. --Size-frequency of Bristol Bay District male red king crab (*Paralithodes camtschaticus*) by 5 mm length classes, 2009-2011.

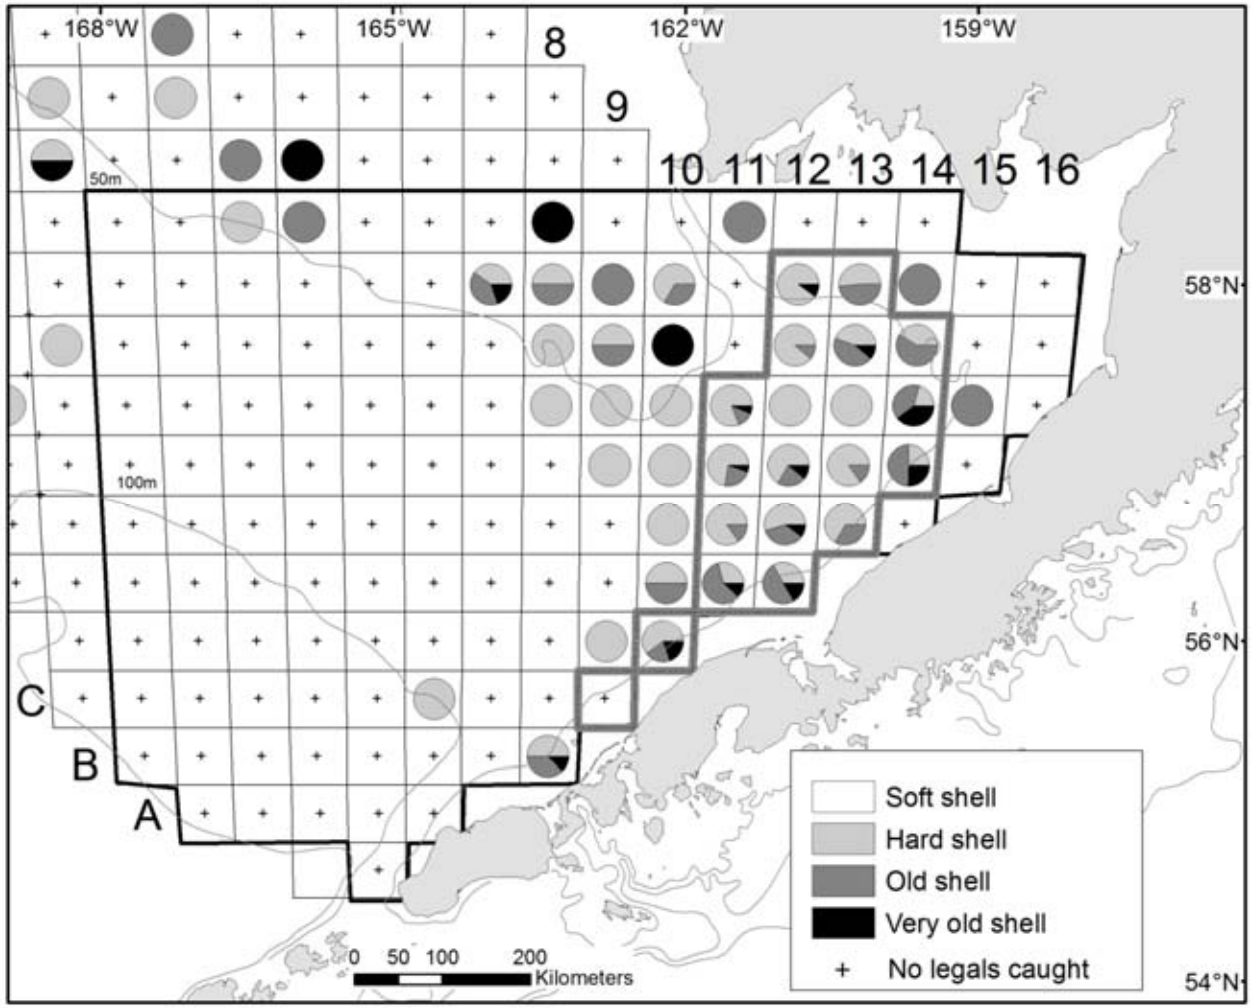

Figure 11. -- Distribution of legal-sized male red king crab (*Paralithodes camtschaticus*) caught at each station in the 2011 Bristol Bay District and distinguished by shell condition. Outlined area depicts management district and the 20 resurveyed stations are outlined in grey.

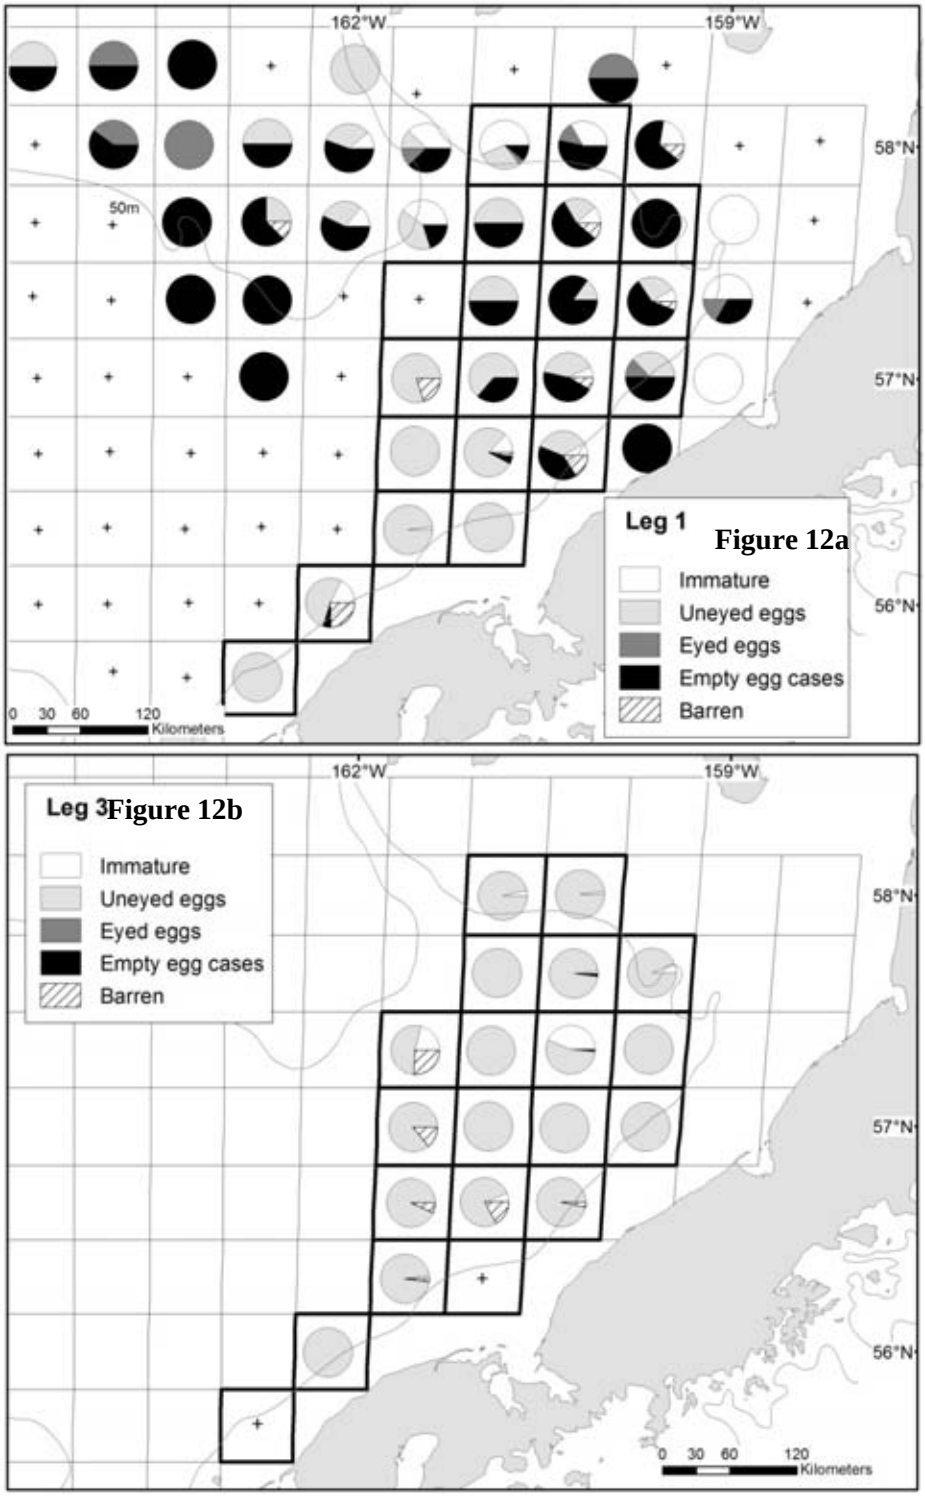

Figure 12. -- Changes in the distribution and egg condition of female red king crab (*Paralithodes camtschaticus)* caught (a) Leg 1 (5-17, June 2011) and (b) Leg 3 (25 to 31 July) in the Bristol Bay District. Outline depicts the 20 stations resampled in late July on Leg 3.

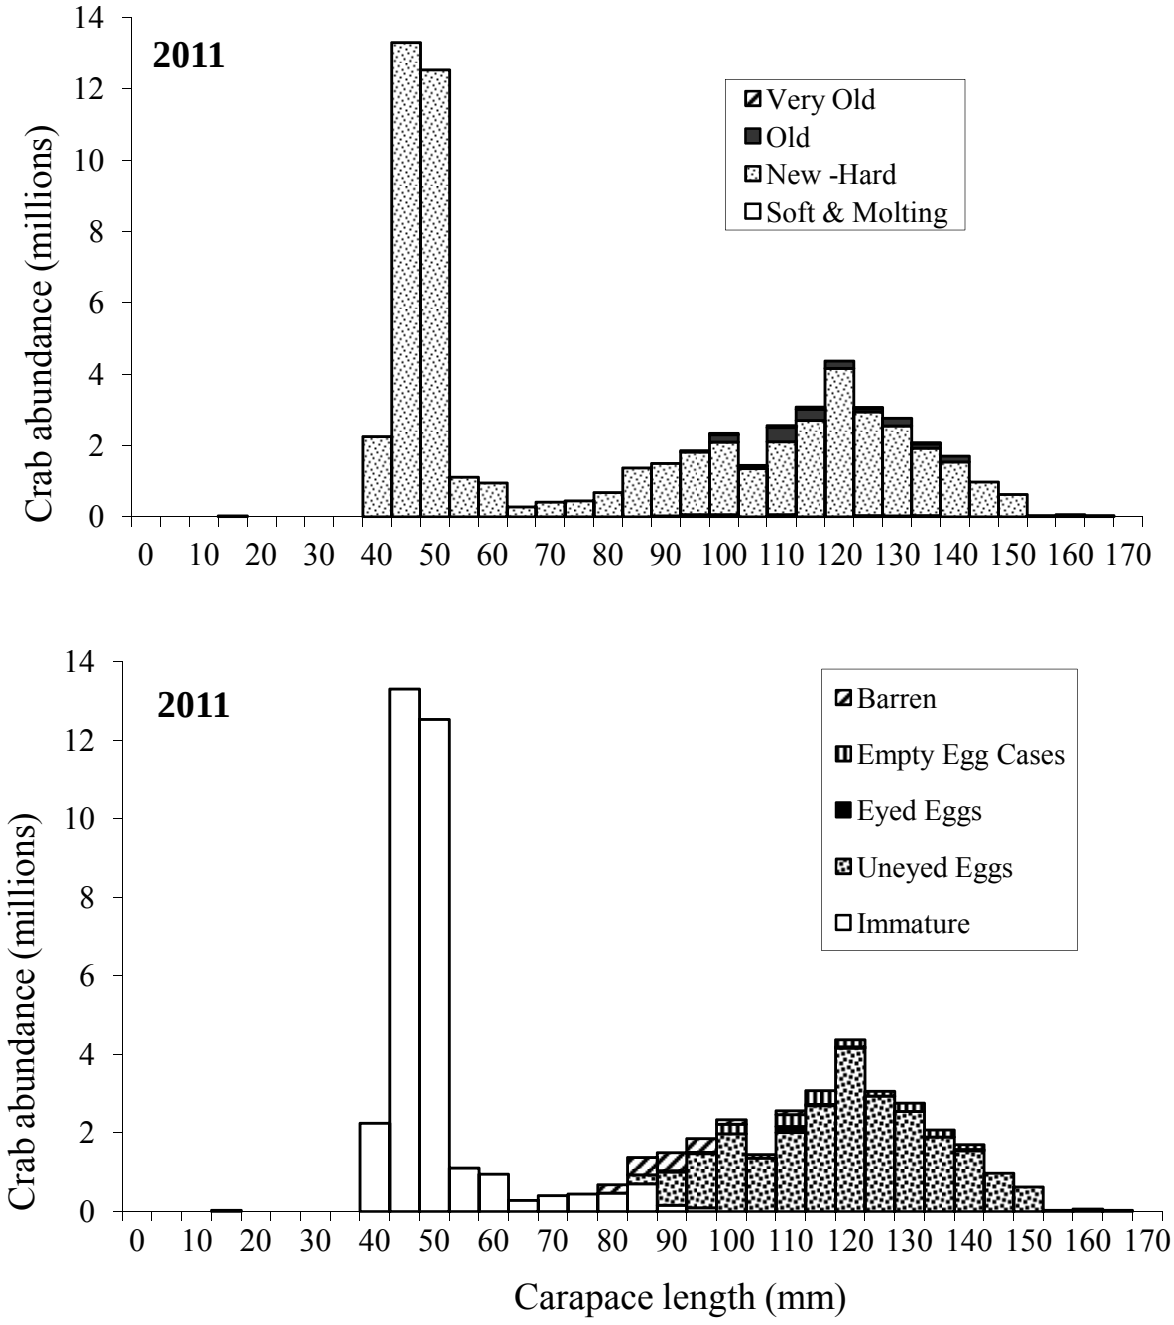

Figure 13. -- Size-frequency and egg condition of Bristol Bay District female red king crab (*Paralithodes camtschaticus*) by 5 mm length classes in 2011.

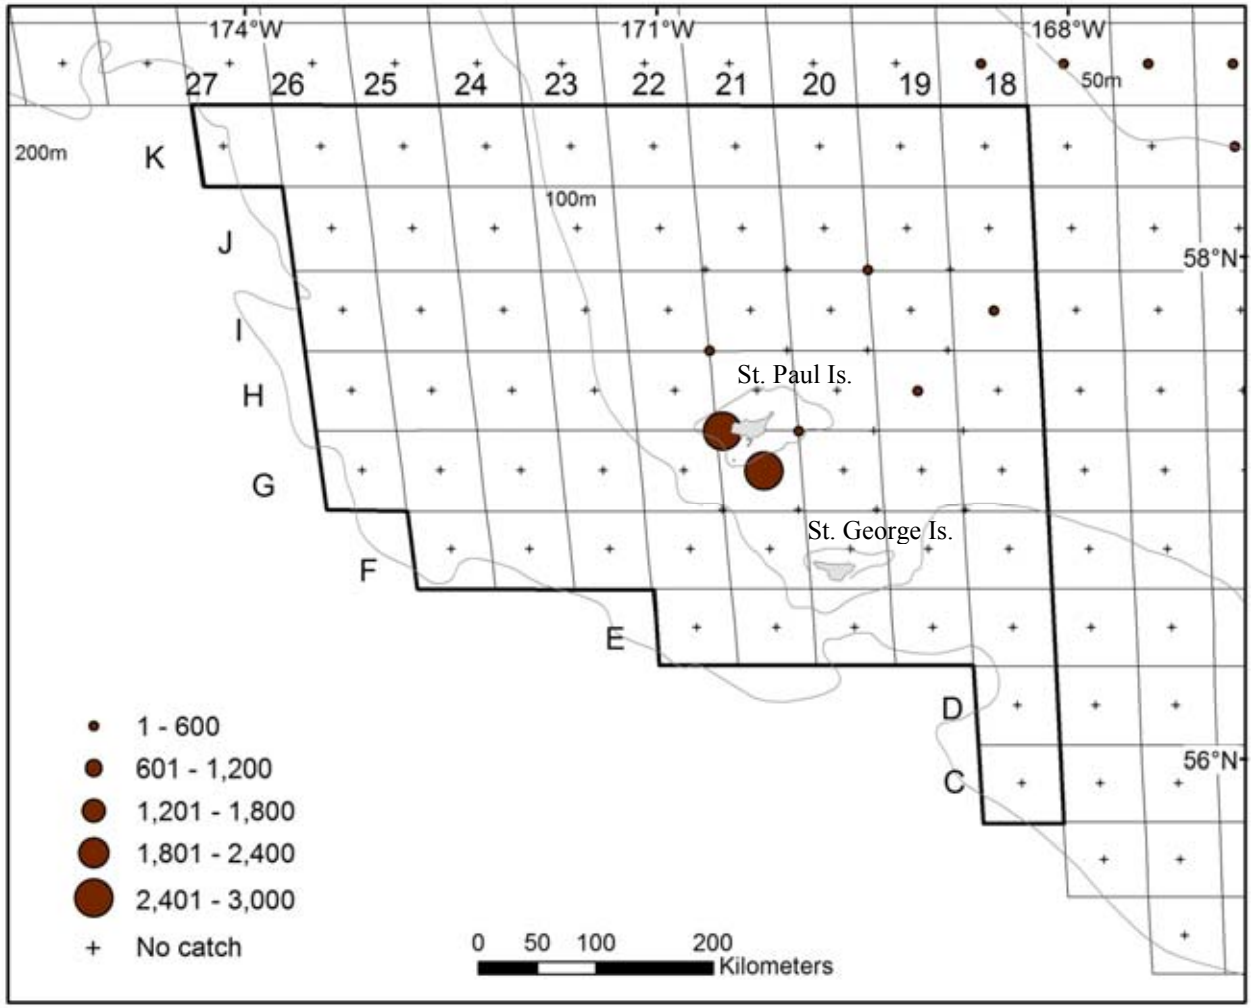

Figure 14. -- Total density (number/nmi^2) of red king crab (*Paralithodes camtschaticus*) at each station sampled in the Pribilof District in 2011. Data depicted by circles are equal interval densities and outlined area depicts stations within the management district.

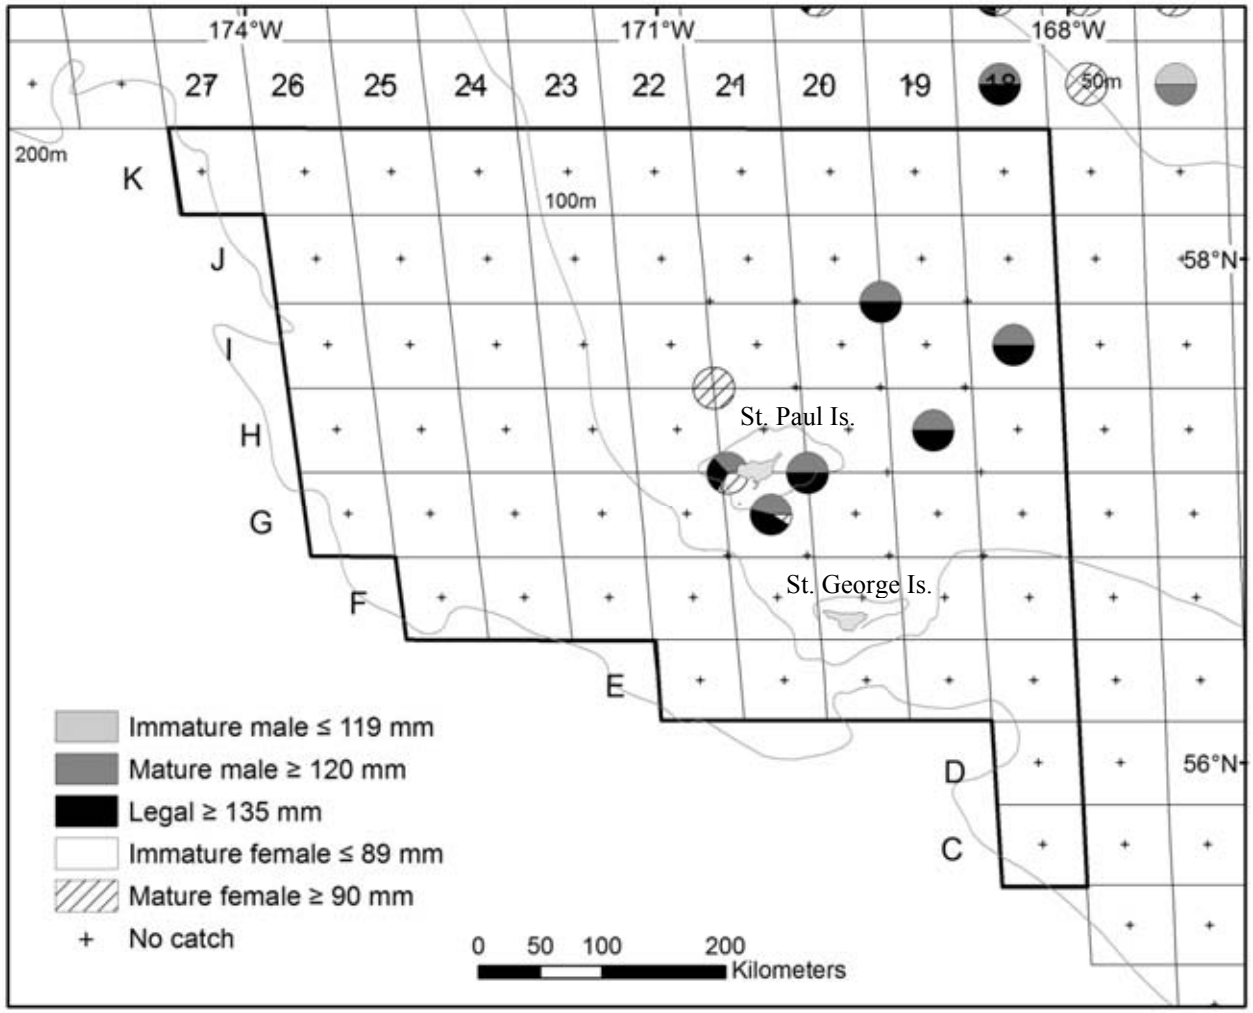

Figure 15. -- Percentage of male and female red king crab (*Paralithodes camtschaticus*) size classes at each station of the Pribilof District in 2011. The outlined area depicts stations within the management district.

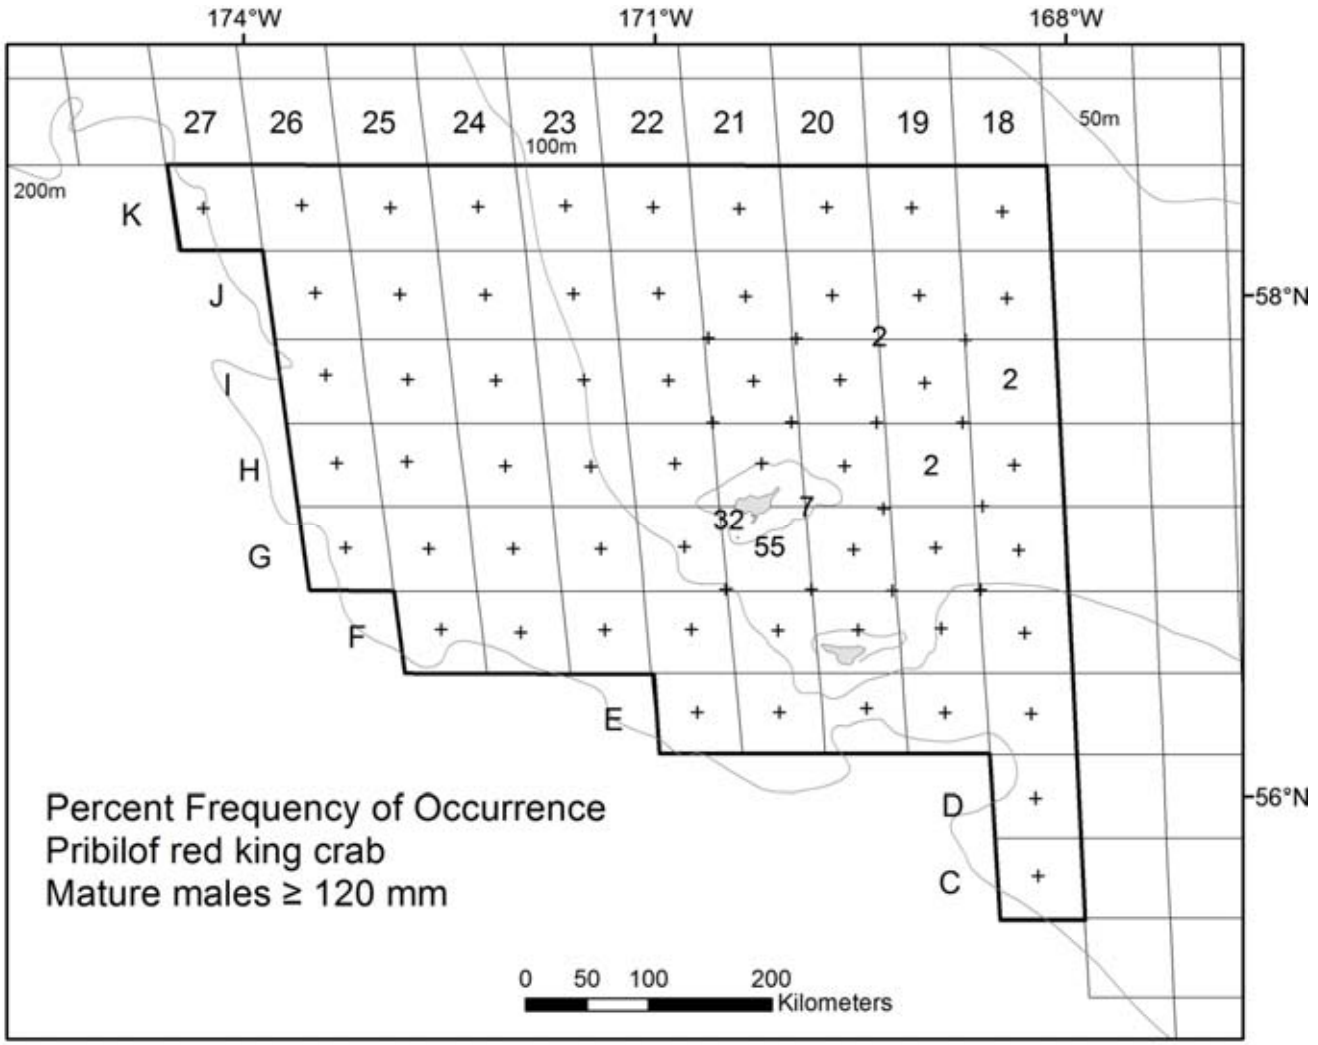

Figure 16. -- Percent frequency of occurrence of mature male red king crab (*Paralithodes camtschaticus*) at stations sampled in the 2011 Pribilof District.

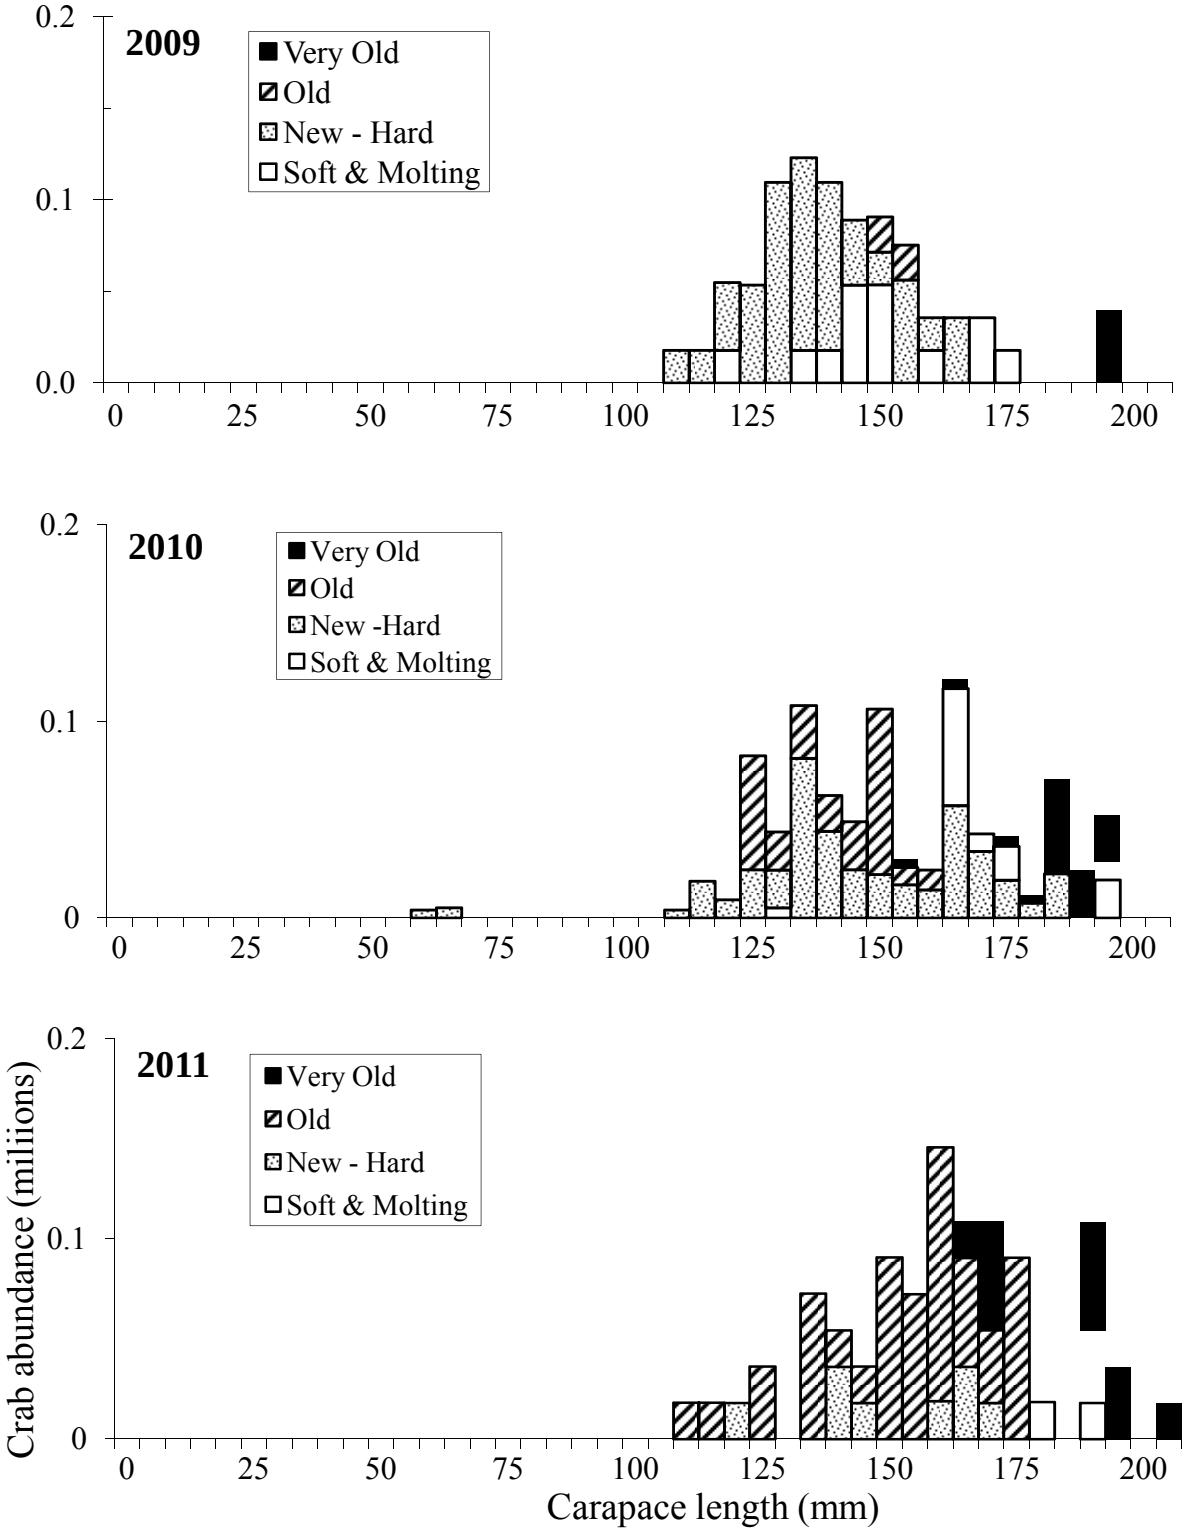

Figure 17. -- Size-frequency of Pribilof District male red king crab (*Paralithodes camtschaticus*) by 5 mm length classes, 2009-2011.

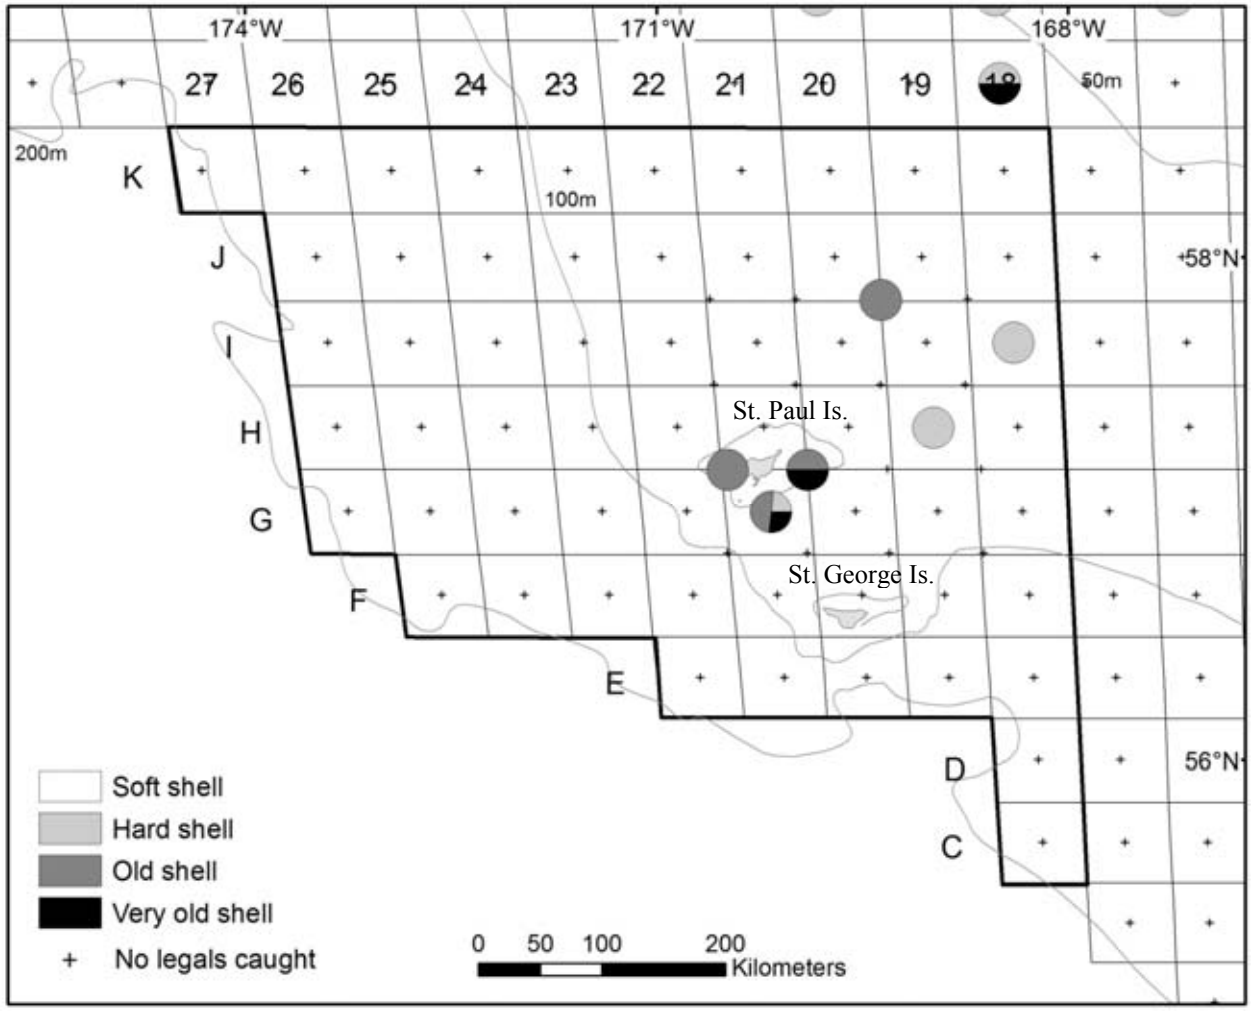

Figure 18. -- Distribution of legal-sized male red king crab (*Paralithodes camtschaticus*) caught at each station of the Pribilof District in 2011 and distinguished by shell condition. The outlined area depicts stations within the management district.

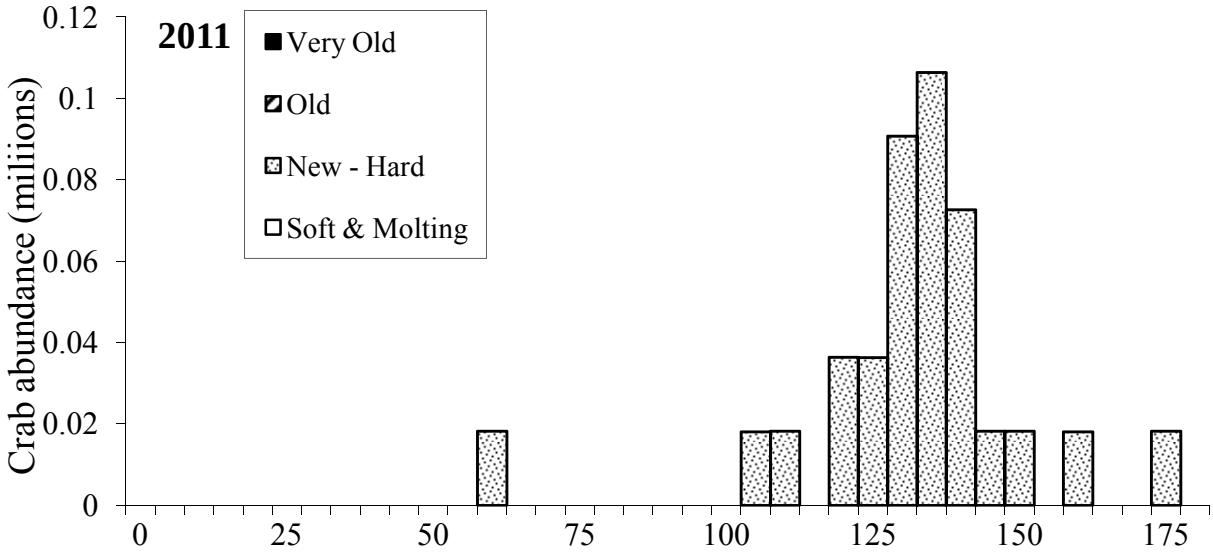

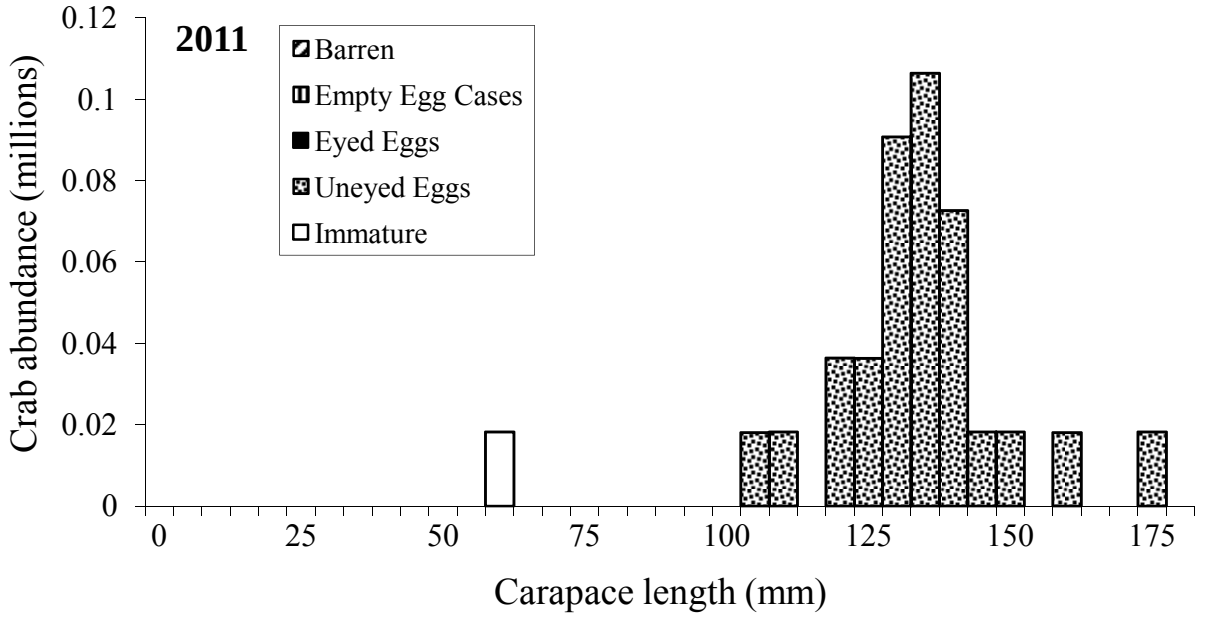

Figure 19. -- Size-frequency and egg condition of Pribilof District female red king crab (*Paralithodes camtschaticus*) by 5 mm length classes in 2011.

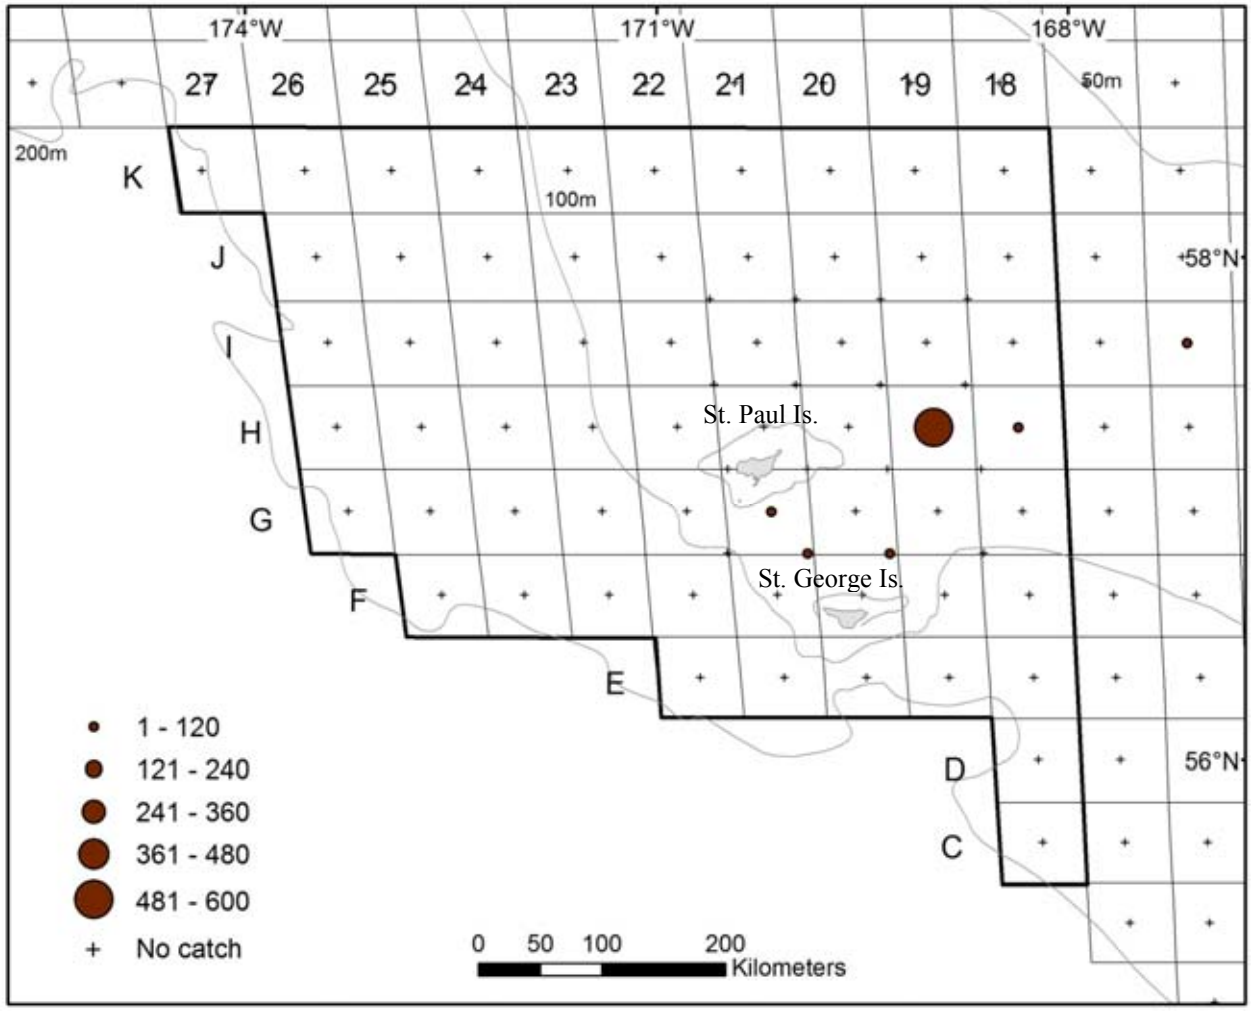

Figure 20. -- Total density (number/nmi^2) of blue king crab (*Paralithodes platypus*) at each station sampled in the Pribilof District in 2011.The outlined area depicts the management district.

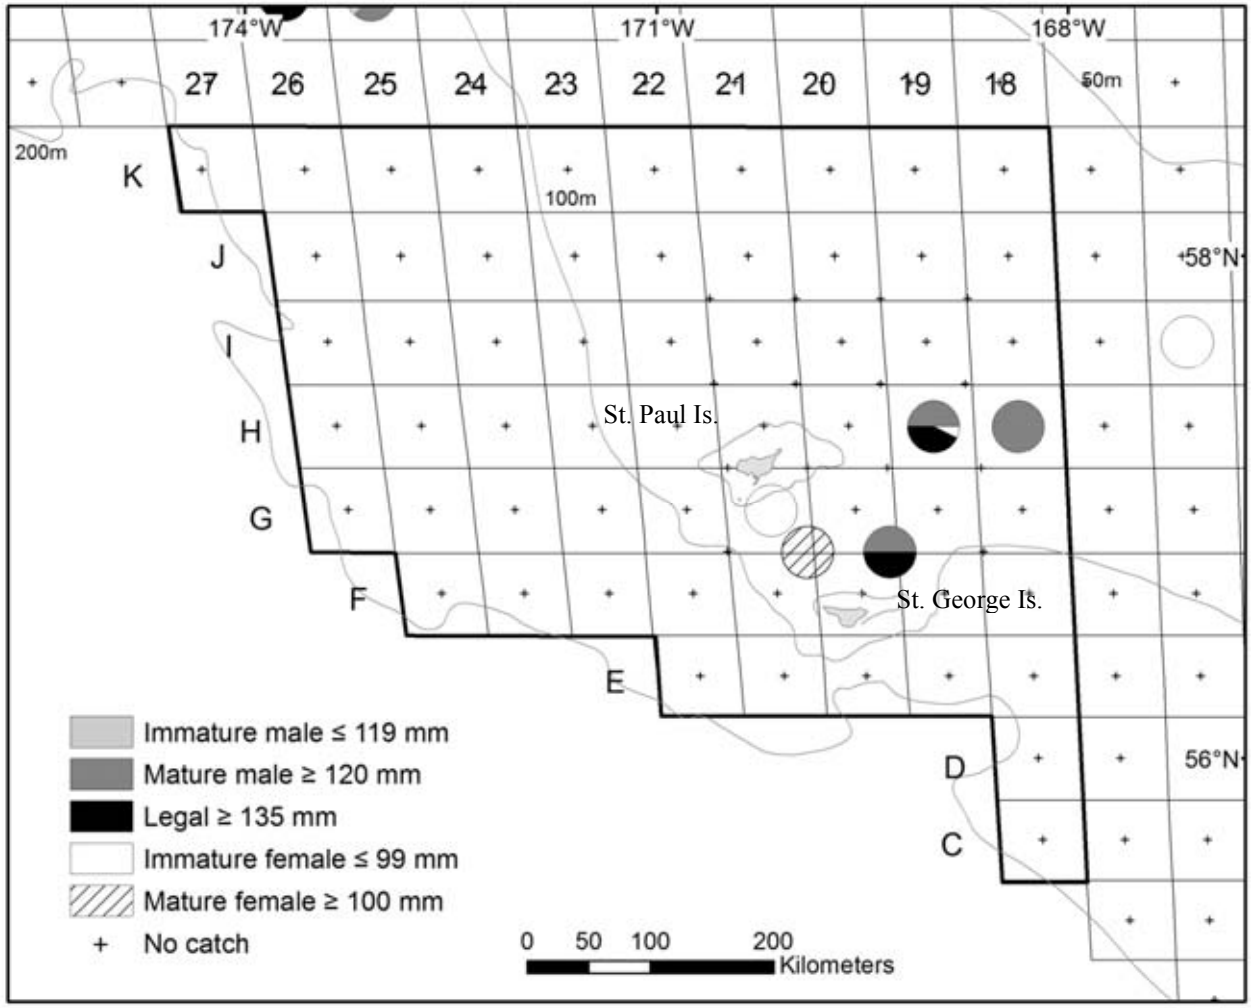

Figure 21. -- Percentage of male and female blue king crab (*Paralithodes platypus*) size categories at each station of the Pribilof District in 2011. The outlined area depicts stations within the management district.

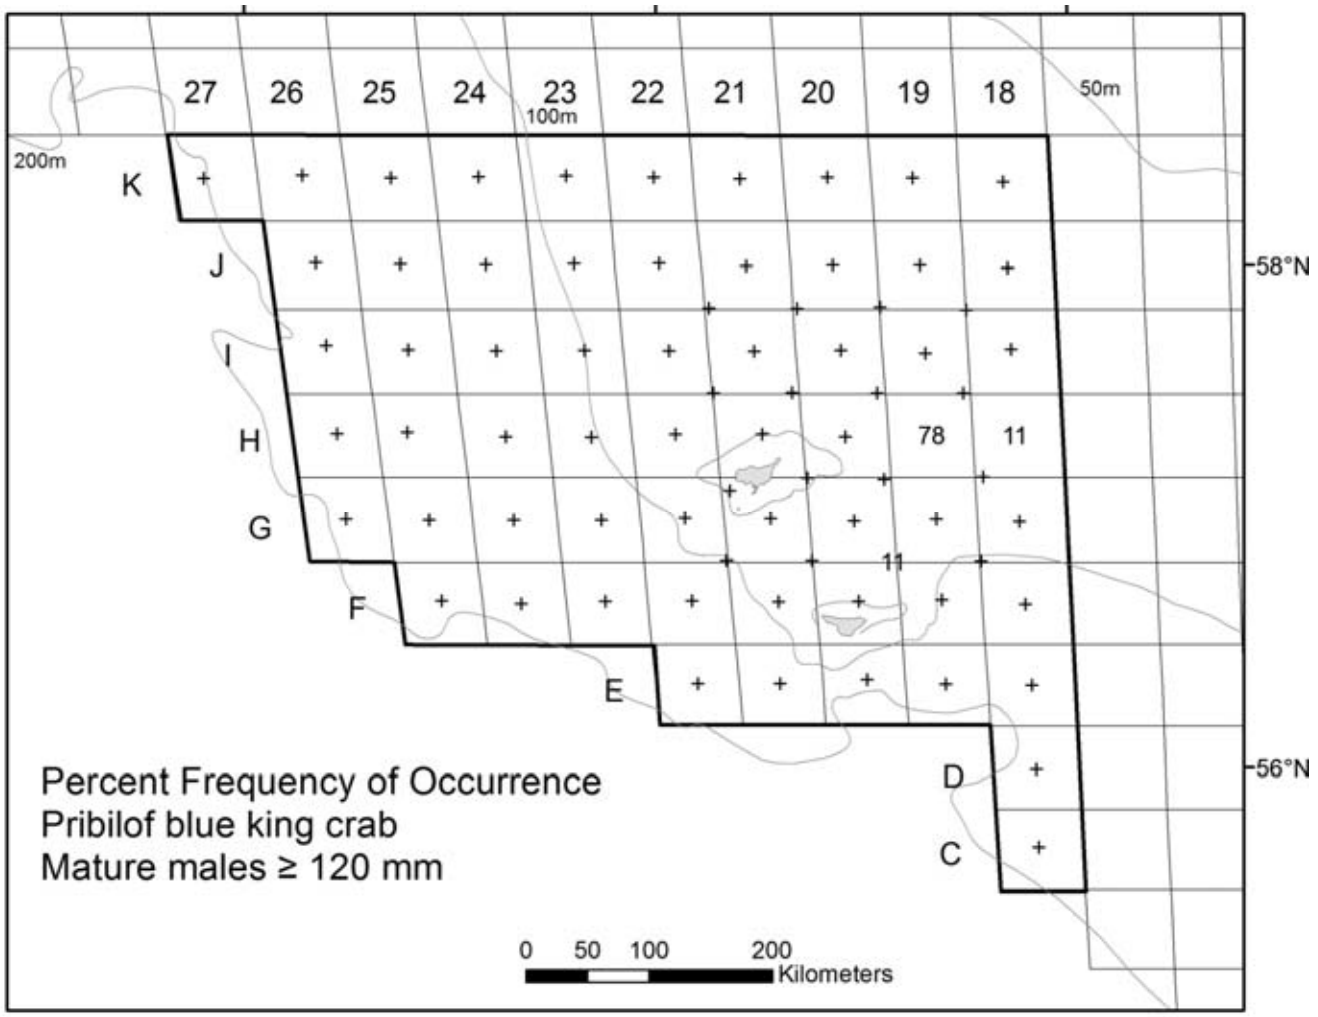

Figure 22. --Percent frequency of occurrence of mature male blue king crab (*Paralithodes platypus)* at stations sampled in the 2011 Pribilof District.

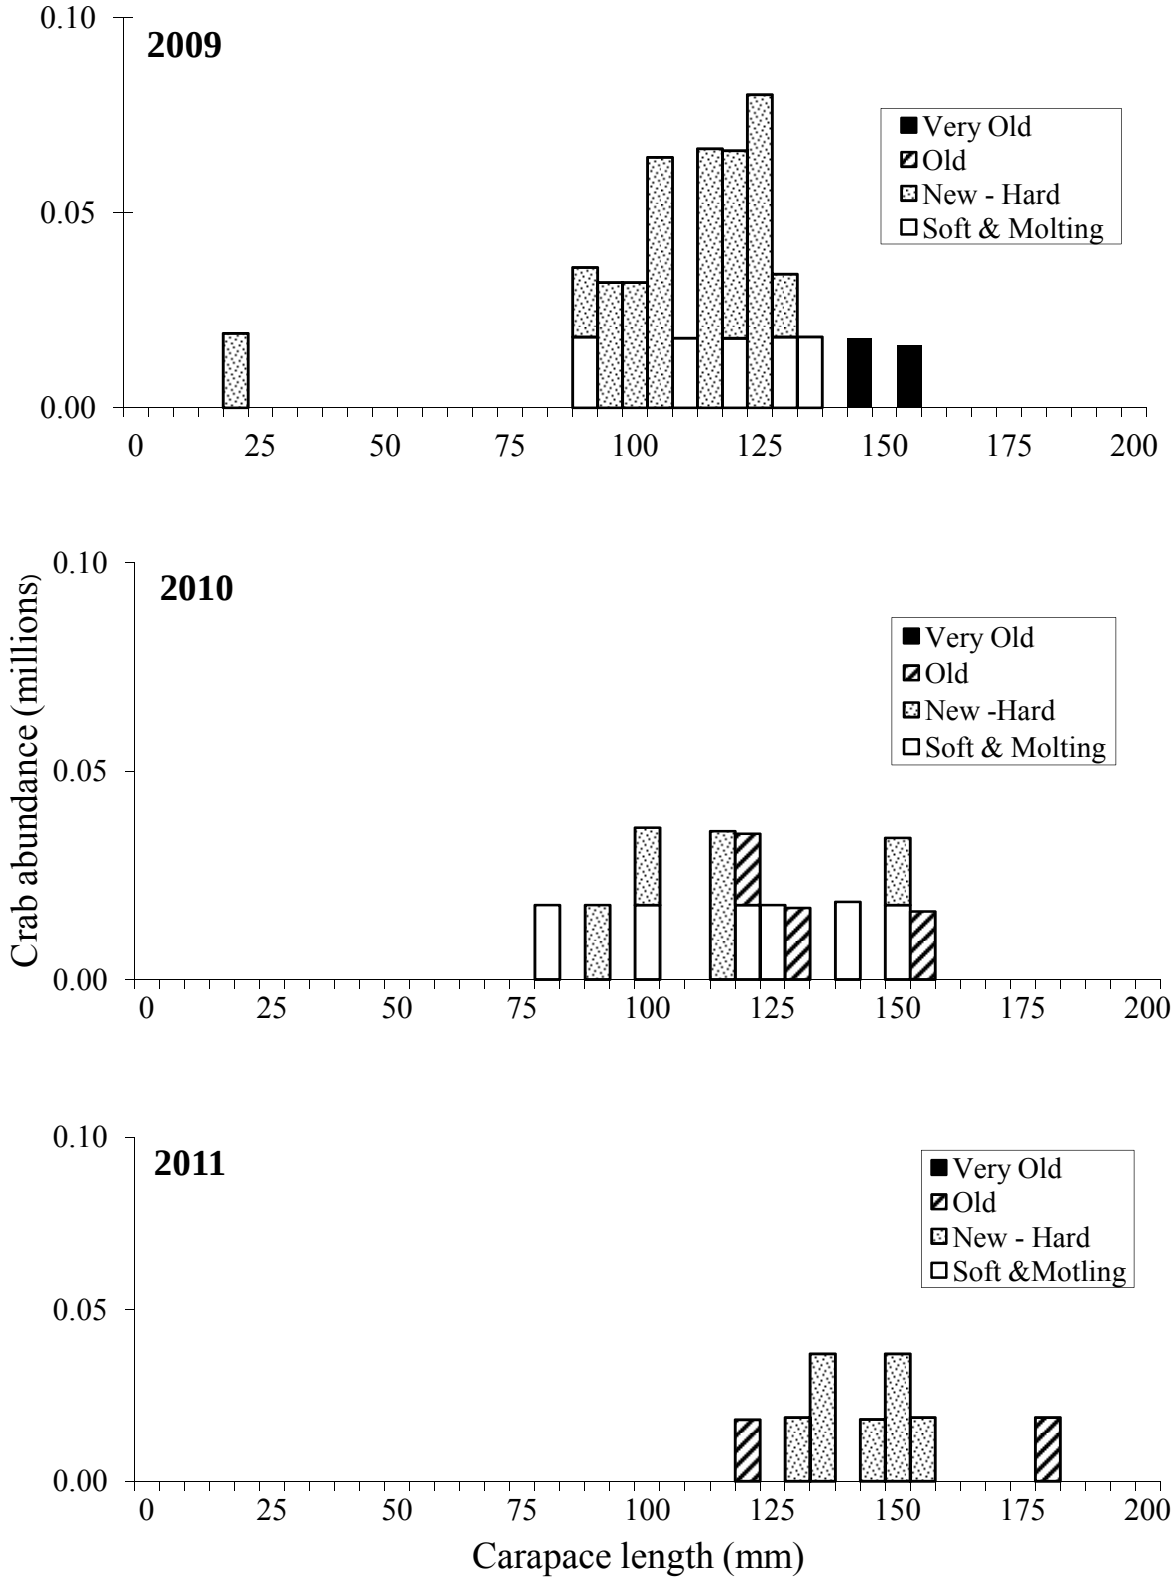

Figure 23. --Size-frequency of Pribilof District male blue king crab (*Paralithodes platypus*) by 5 mm length classes, 2009-2011.

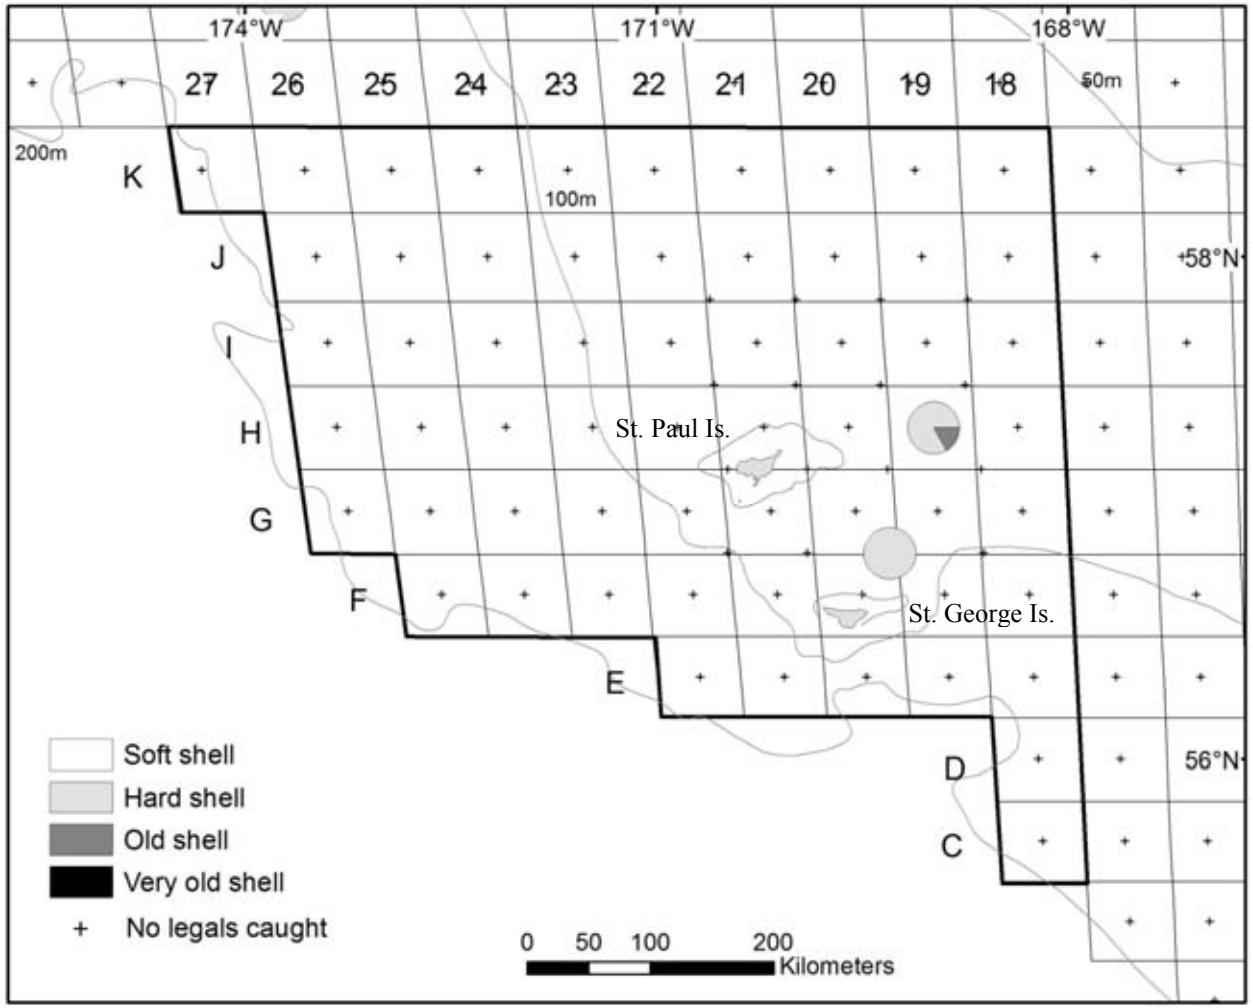

Figure 24. -- Distribution of legal-sized male blue king crab (*Paralithodes platypus*) caught at each station of the Pribilof District in 2011 and distinguished by shell condition. The outlined area depicts stations within the management district.

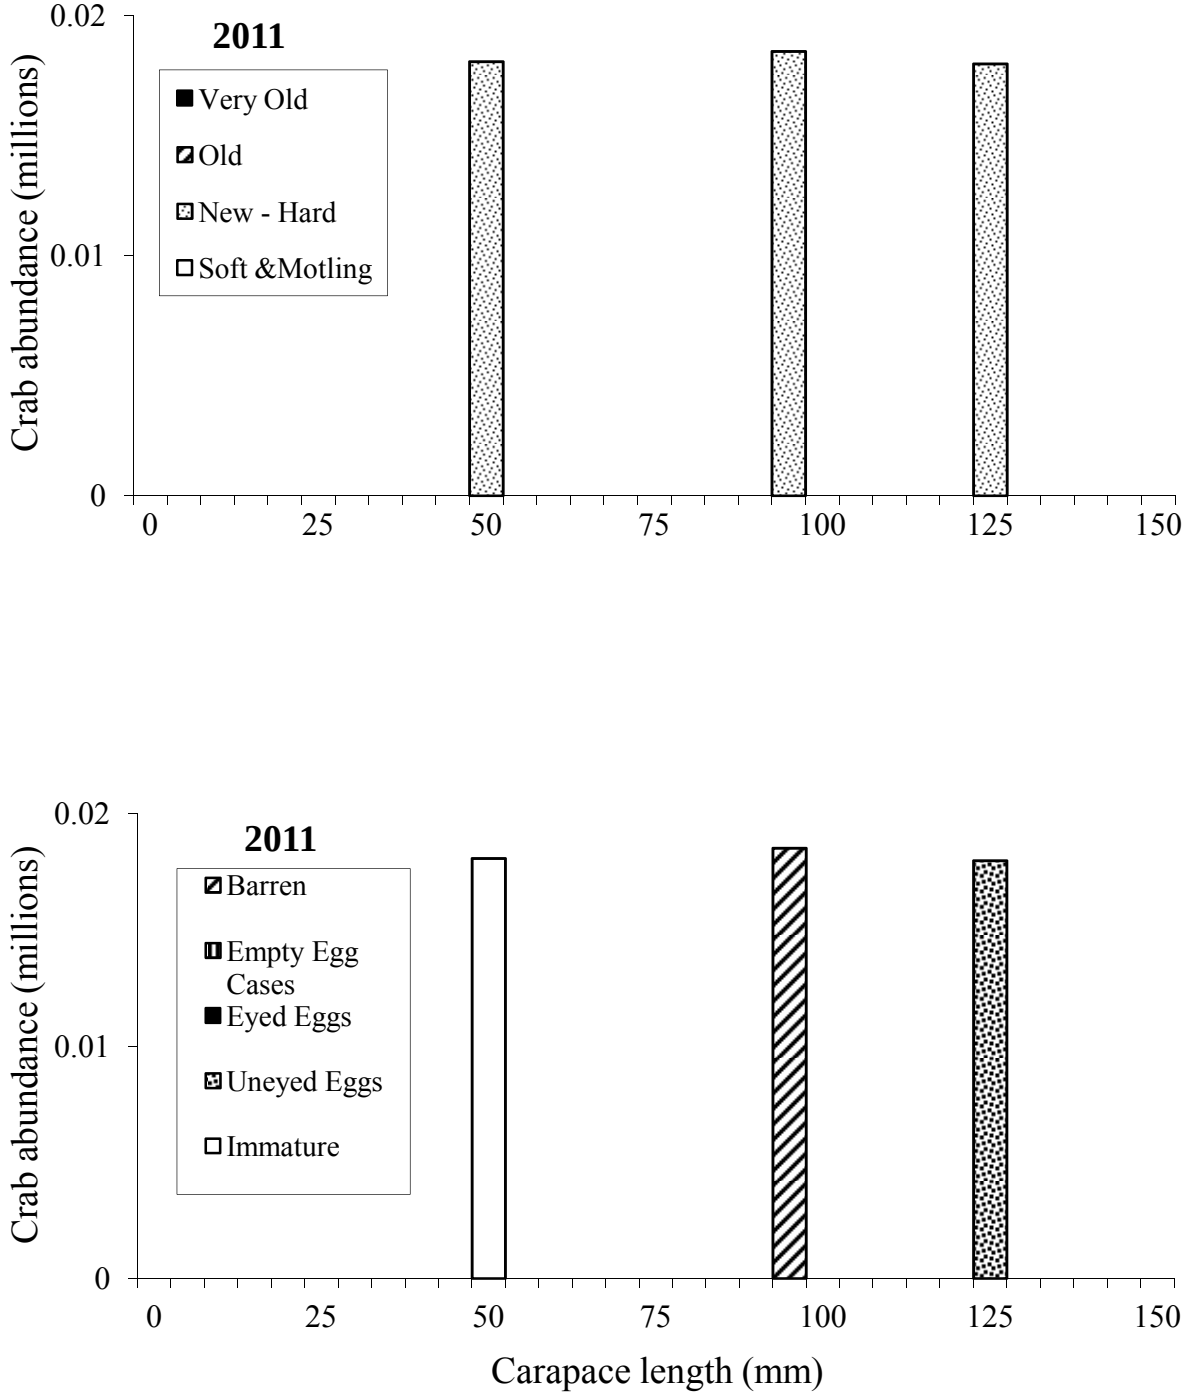

Figure 25. -- Size-frequency, shell and egg condition of Pribilof District female blue king crab (*Paralithodes platypus*) by 5 mm length classes in 2011.

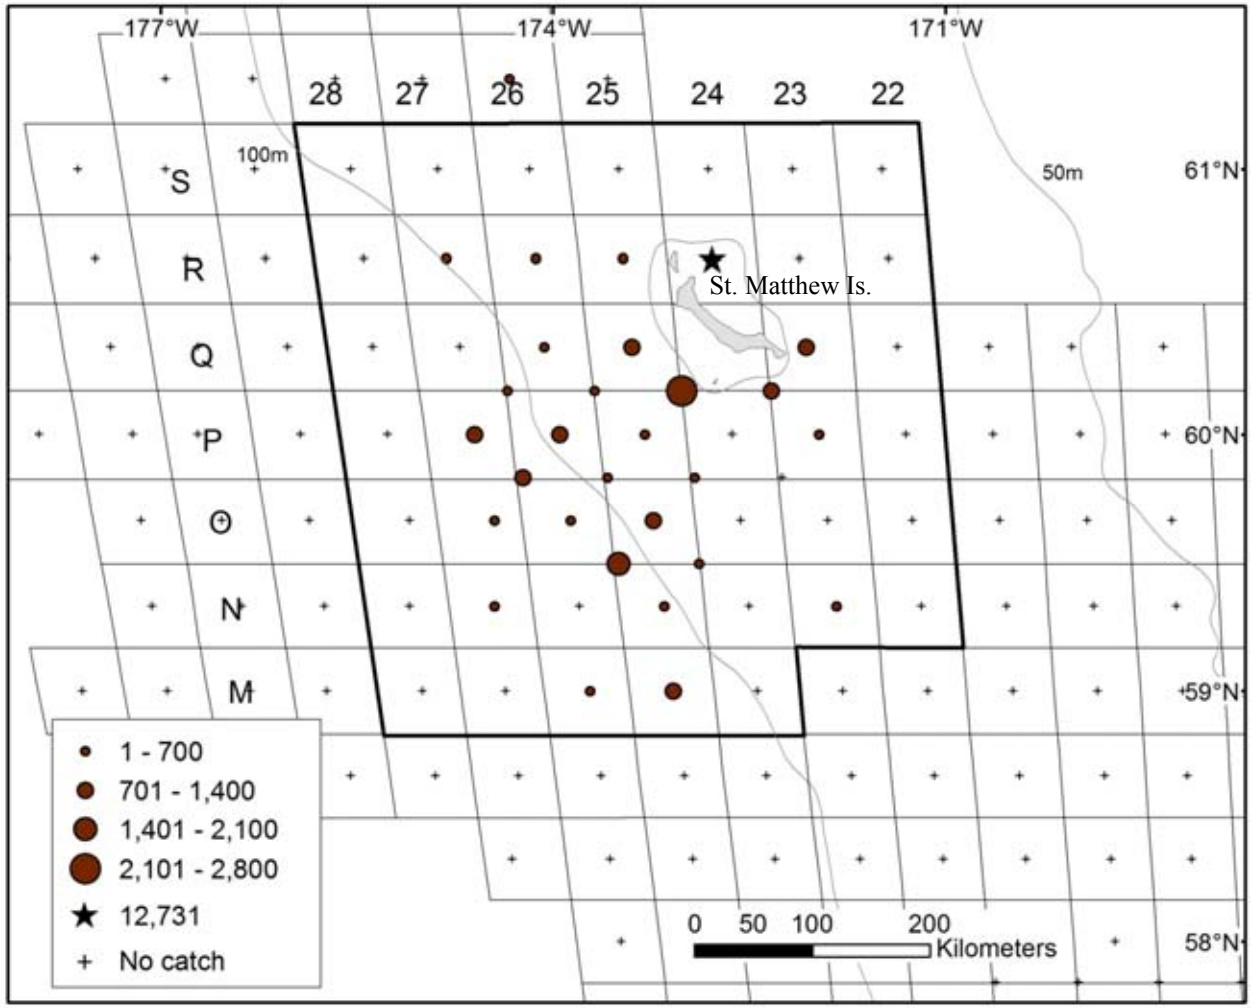

Figure 26. -- Total density (number/nmi^2) of blue king crab (*Paralithodes platypus*) at each station sampled in the St. Matthew Island Section of the Northern District in 2011. Data depicted by circles are equal interval densities, while stars are densities larger than the standard scale. The outlined area depicts stations within the St. Matthew Island Section sampling strata.

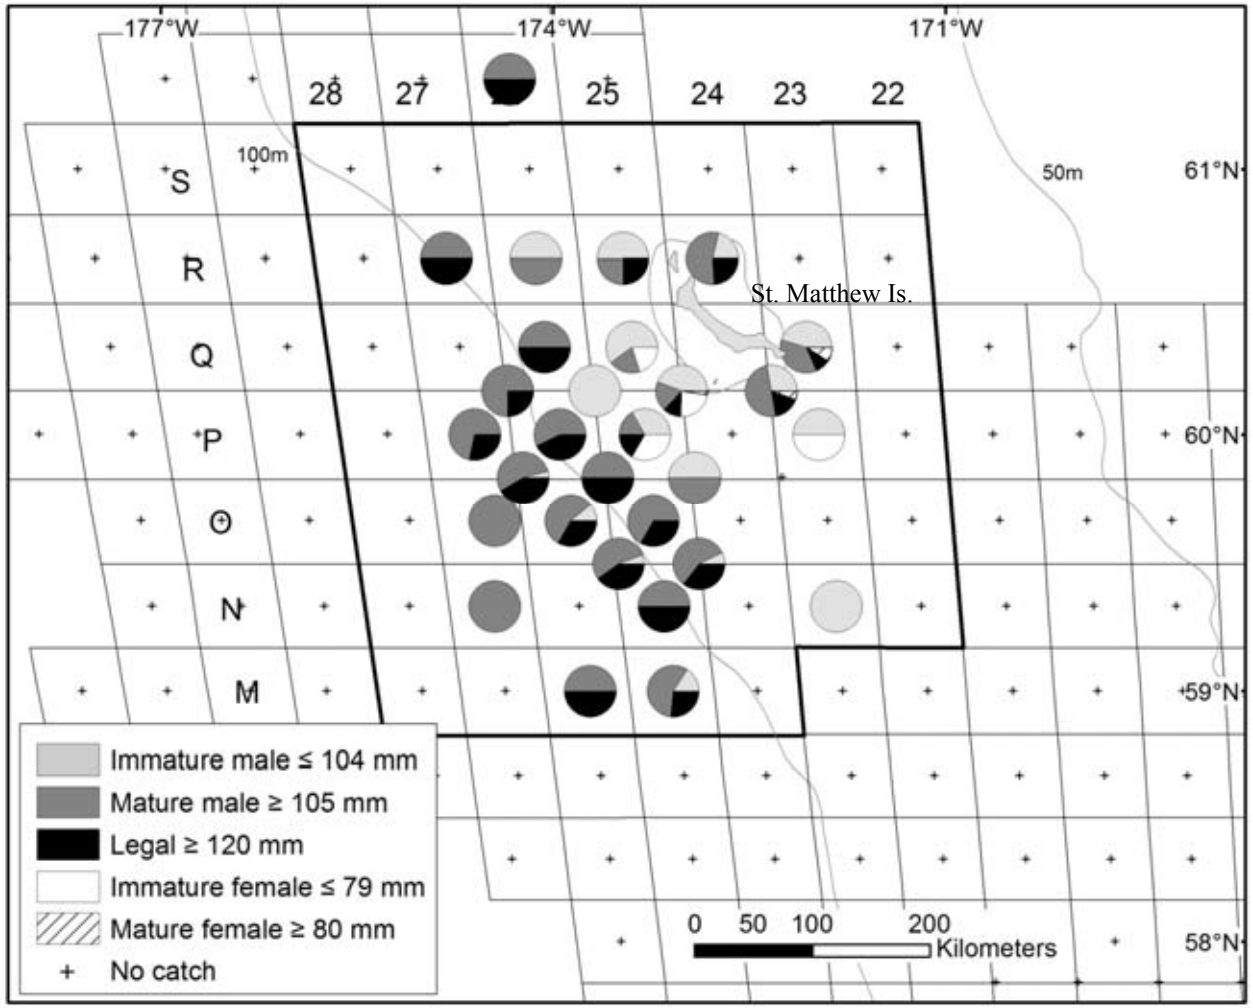

Figure 27. -- Percentage of male and female blue king crab (*Paralithodes platypus*) size categories at each station of the St. Matthew Island Section of the Northern District in 2011. The outlined area depicts stations within the St. Matthew Island Section sampling strata.

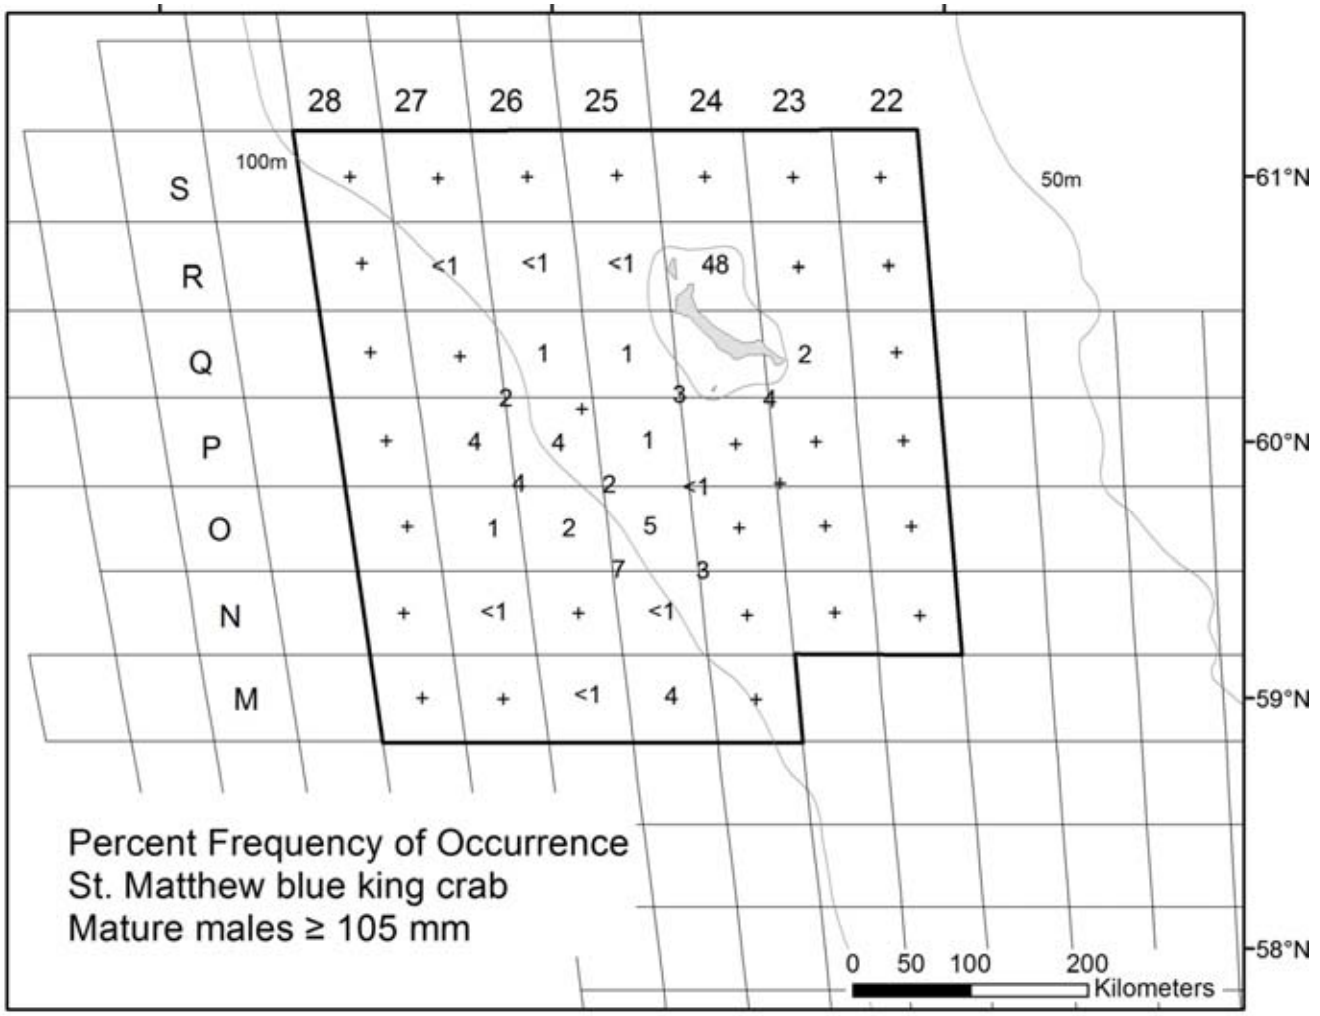

Figure 28. -- Percent frequency of occurrence of mature male blue king crab (*Paralithodes platypus)* at stations in the 2011 St. Matthew Island Section sampling strata of the Northern District.

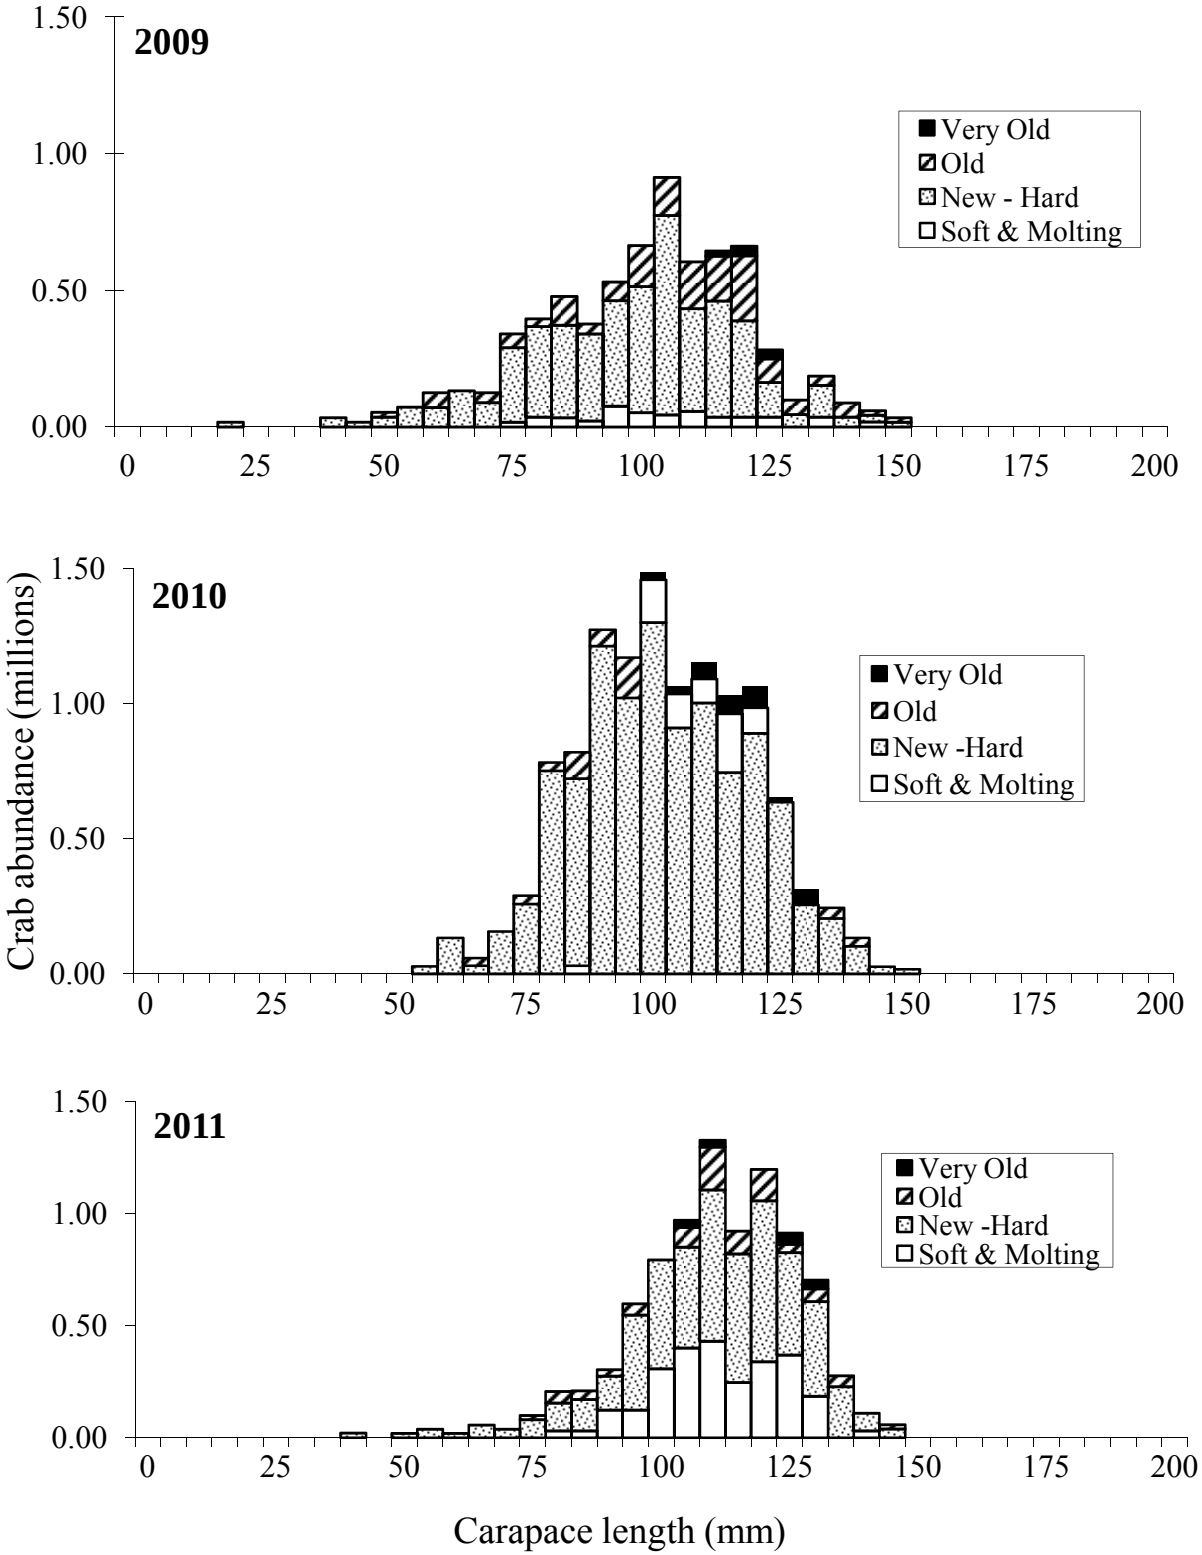

Figure 29. -- Size-frequency of St. Matthew Island Section male blue king crab (*Paralithodes platypus*) by 5 mm length classes, 2009-2011.

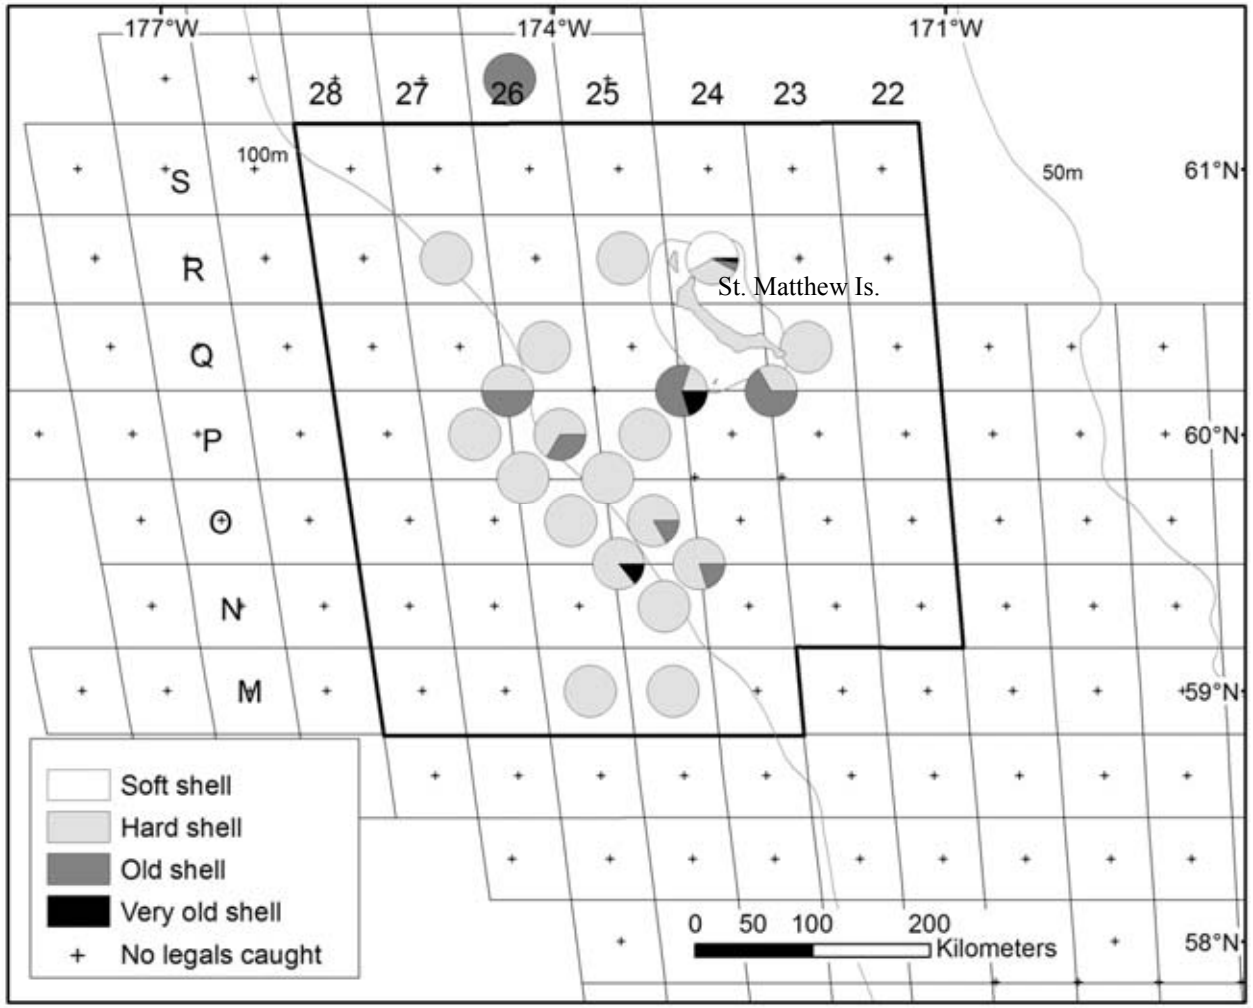

Figure 30. --Distribution of legal-sized male blue king crab (*Paralithodes platypus*) caught at each station of the St. Matthew Island Section of the Northern District in 2011 and distinguished by shell condition. The outlined area depicts stations within the St. Matthew Island Section sampling strata.

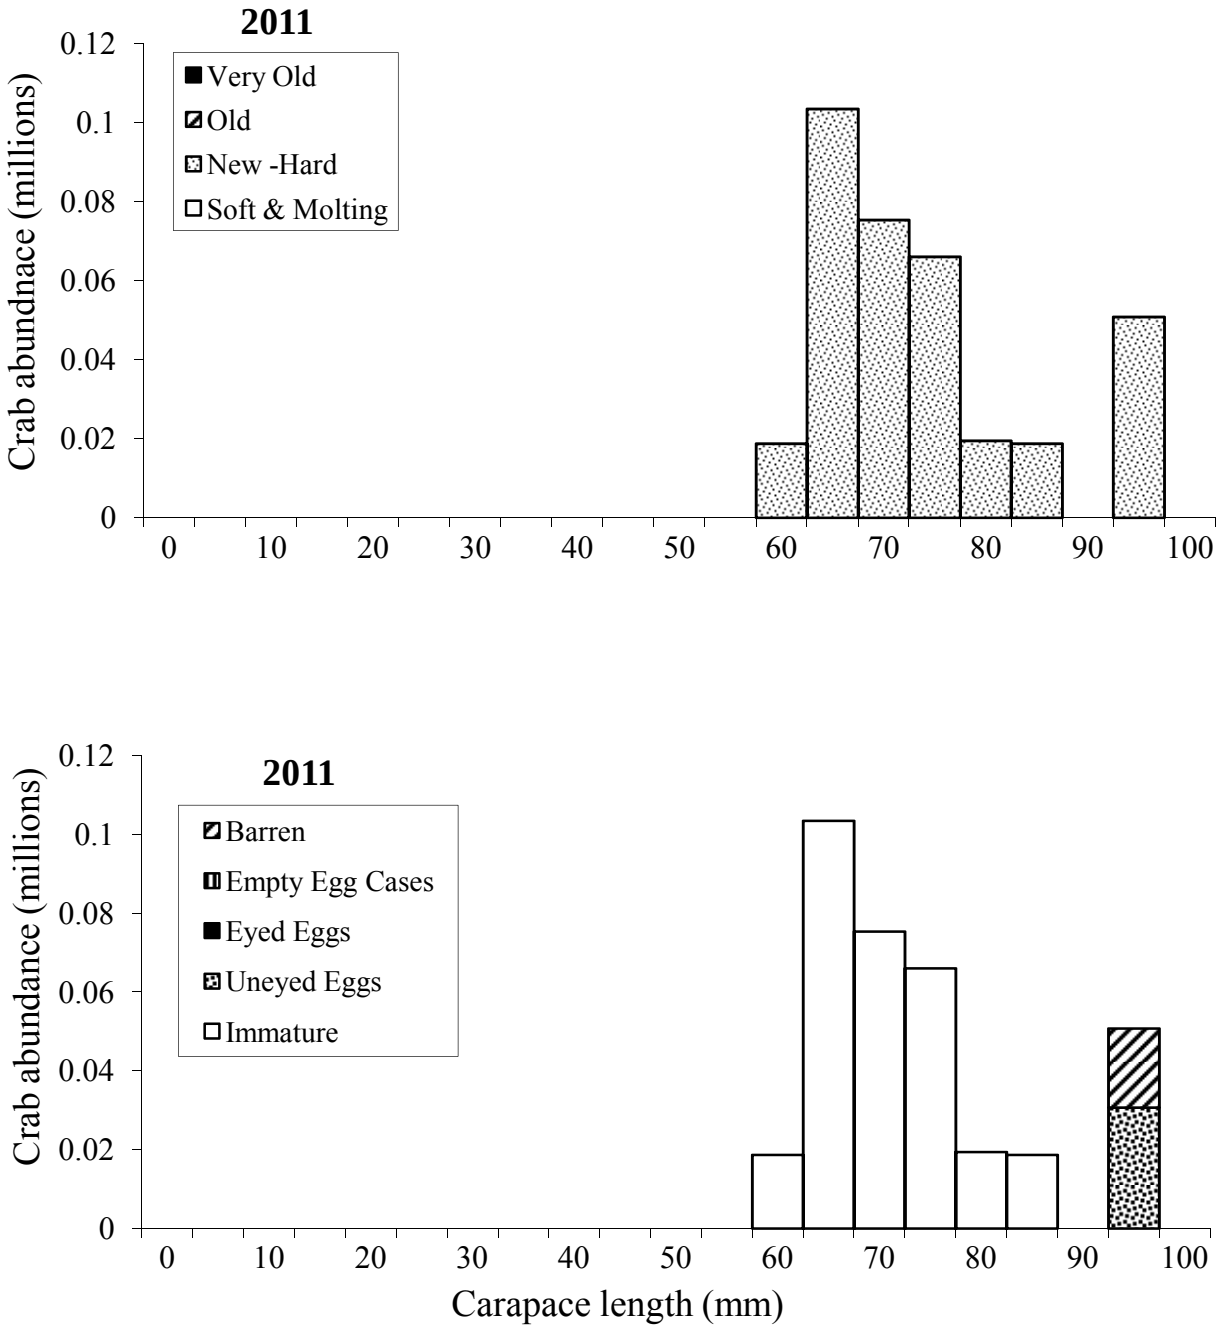

Figure 31. --Size-frequency, shell and egg condition of St. Matthew Island Section female blue king crab (*Paralithodes platypus*) by 5 mm length classes in 2011.

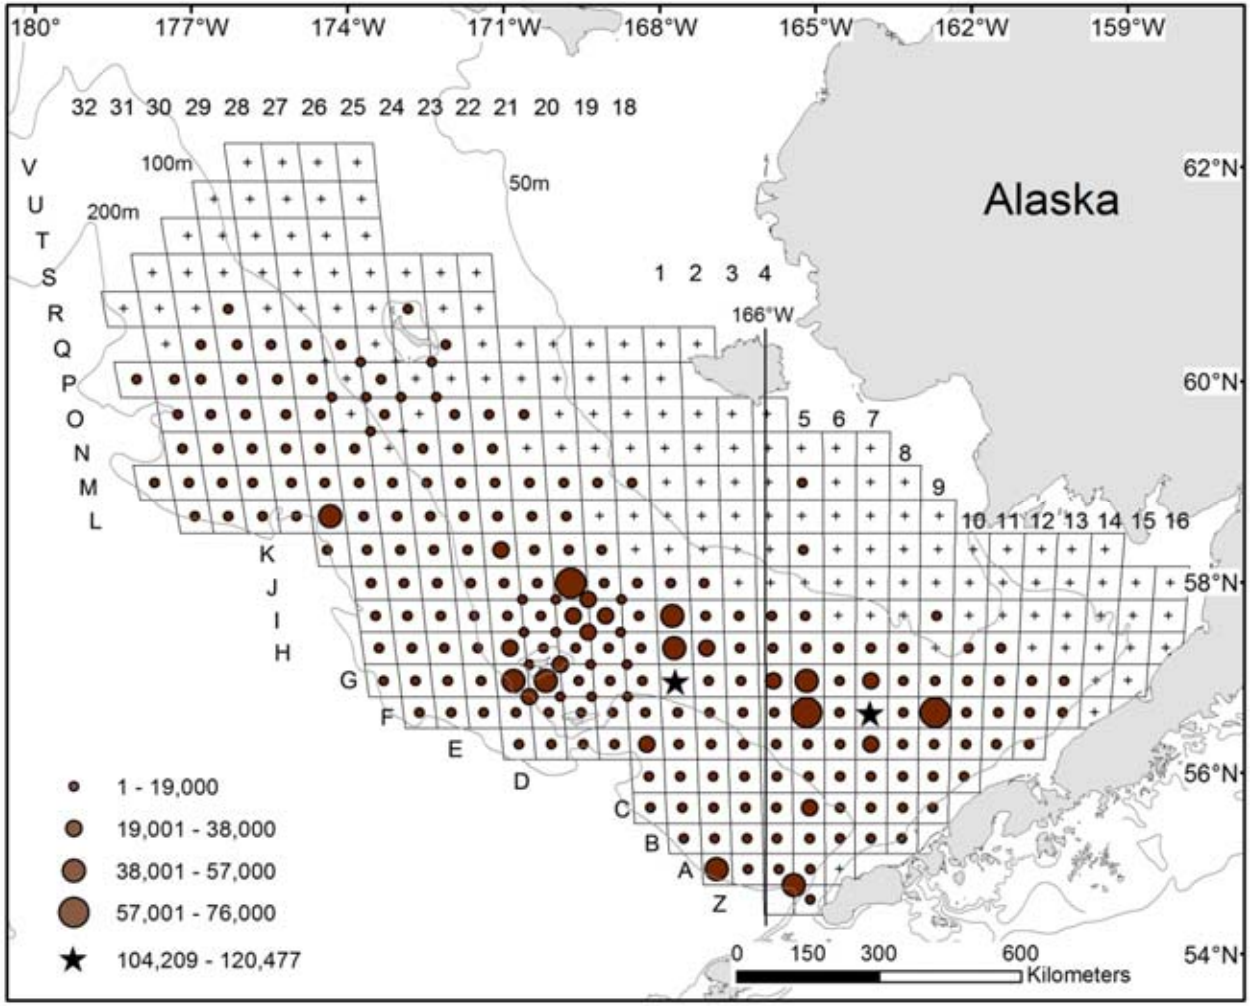

Figure 32. --Total density (number/nmi^2) of Tanner crab (*Chionoecetes bairdi)* at each station sampled in 2011. Data depicted by circles are crab densities at equal intervals, while stars are densities larger than the standard scale.

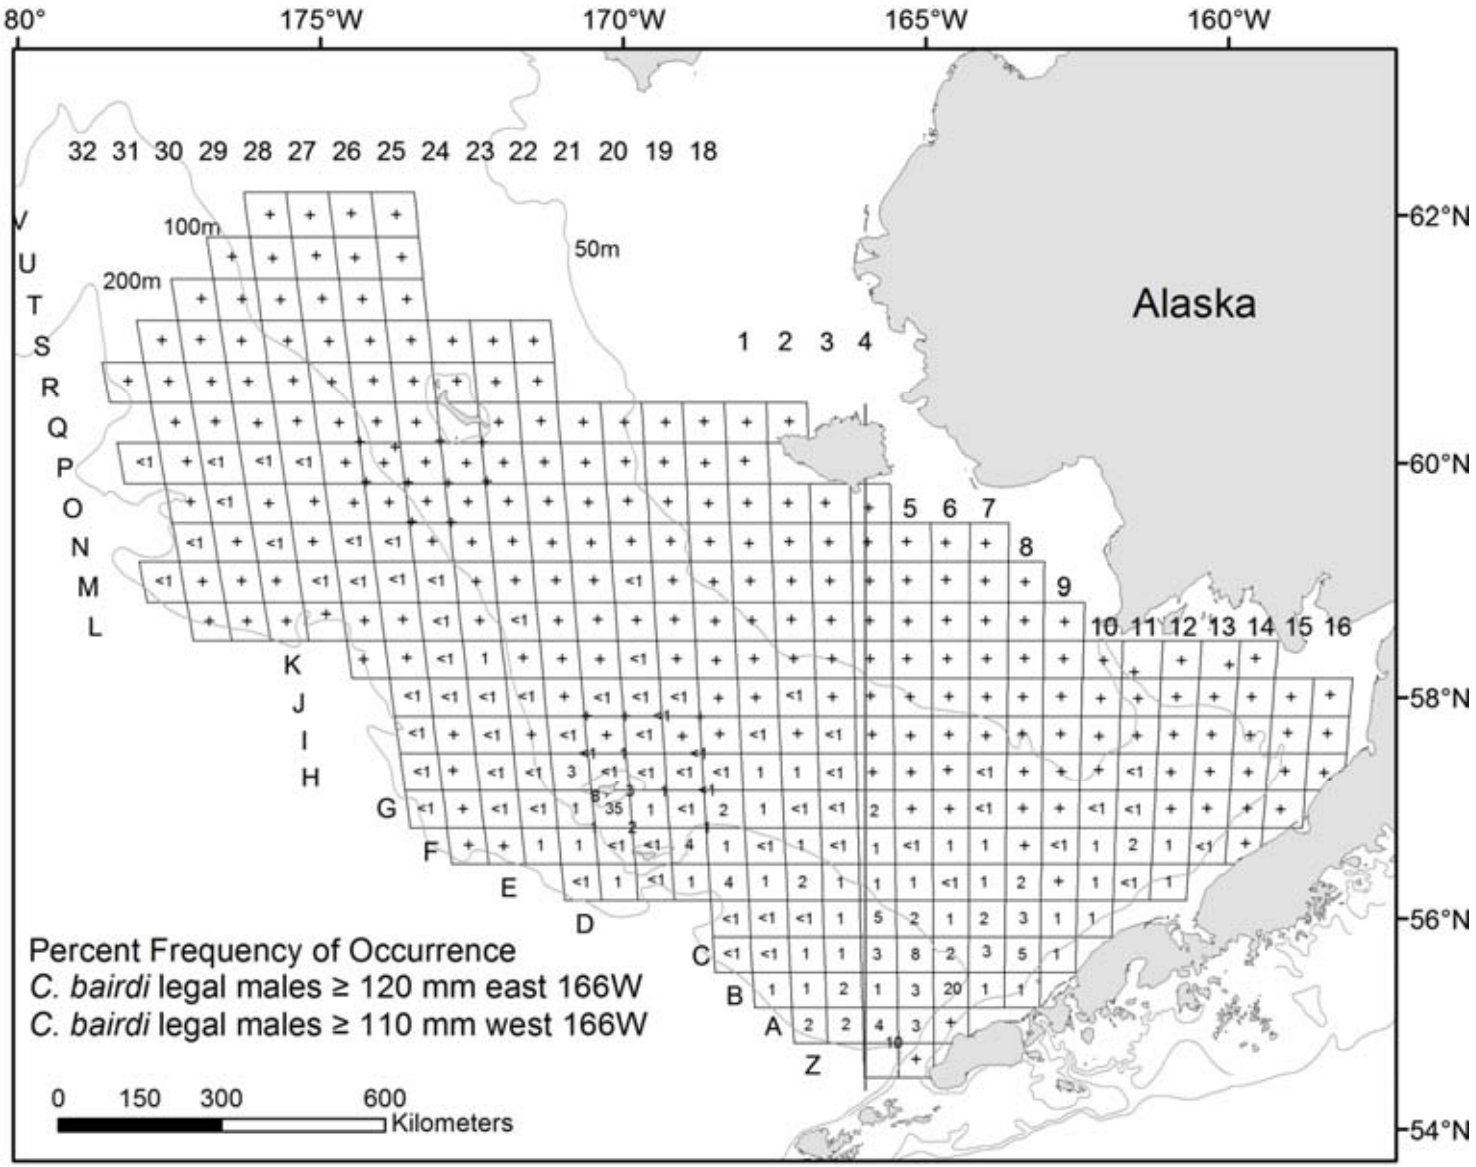

Figure 33. -- Percent frequency of occurrence of legal-sized male Tanner crab (*Chionoecetes bairdi)* at stations sampled in the 2011.

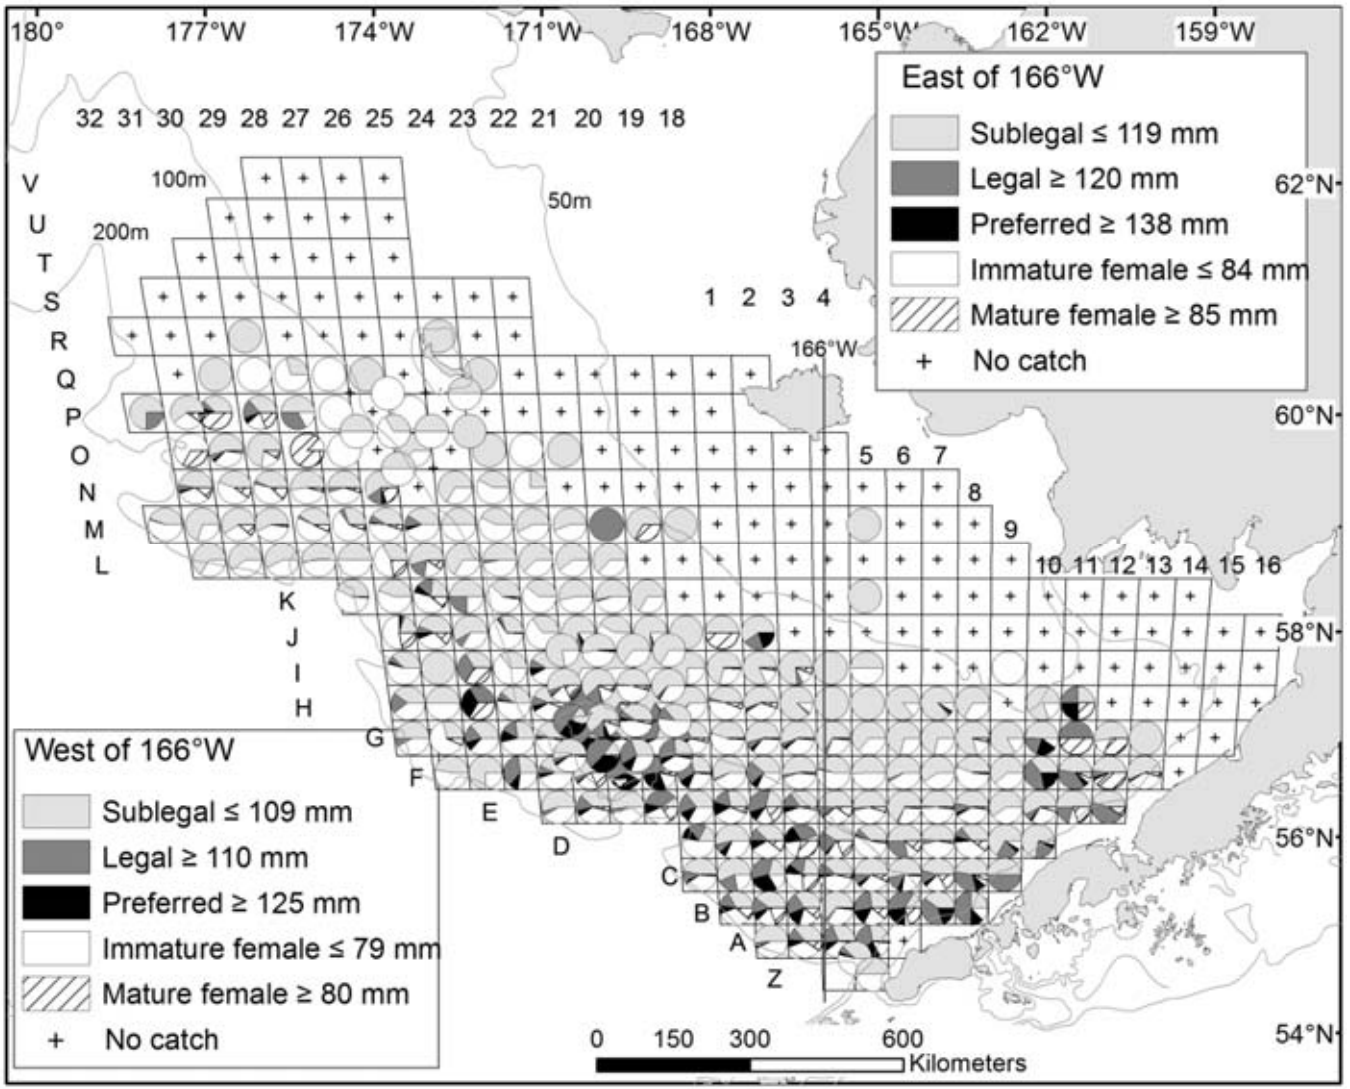

Figure 34. -- Percentage of male and female Tanner crab (*Chionoecetes bairdi*) size categories at each station sampled in 201. Tanner crab males ≥ 138 mm CW east of 166° W and ≥ 125 mm CW west of 166° W are preferred size categories while males ≥ 120 mm and ≥ 110 mm CW are the legal-size categories for east and west of 166° W, respectively.

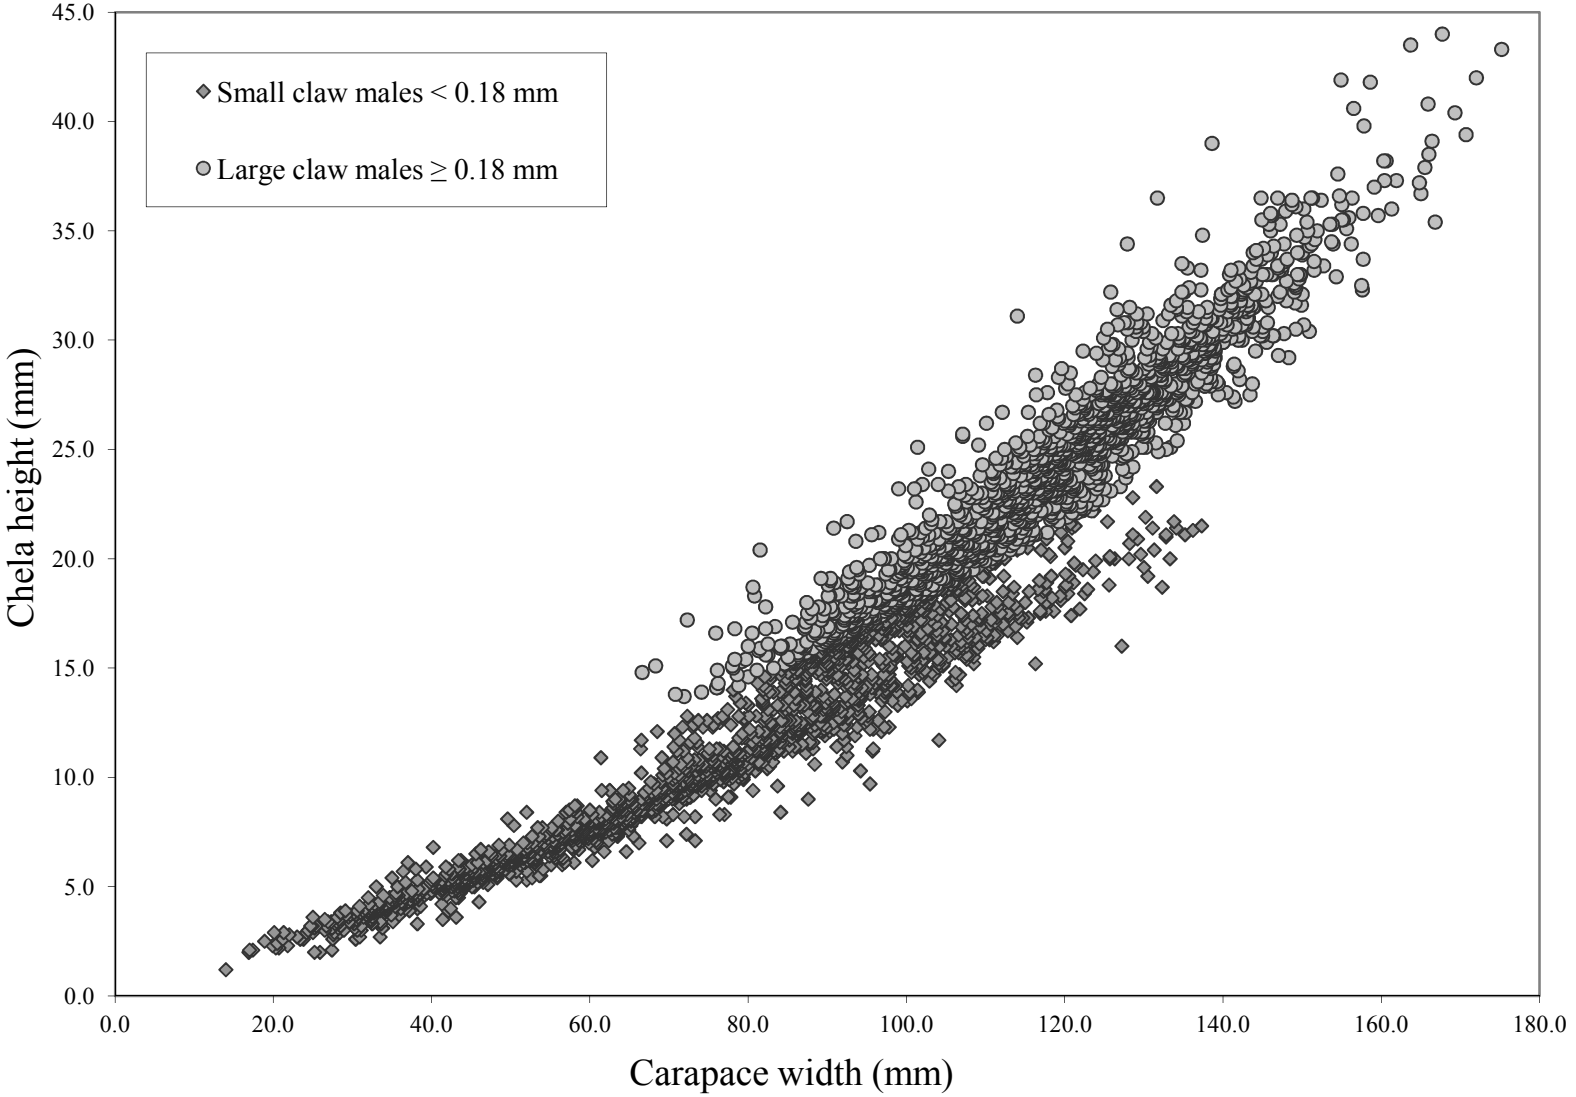

Figure 35. --Male Tanner crab (*Chionoecetes bairdi*) chela height versus carapace width measurements collected on the 2008 and 2010 National Marine Fisheries Service eastern Bering Sea bottom trawl surveys.

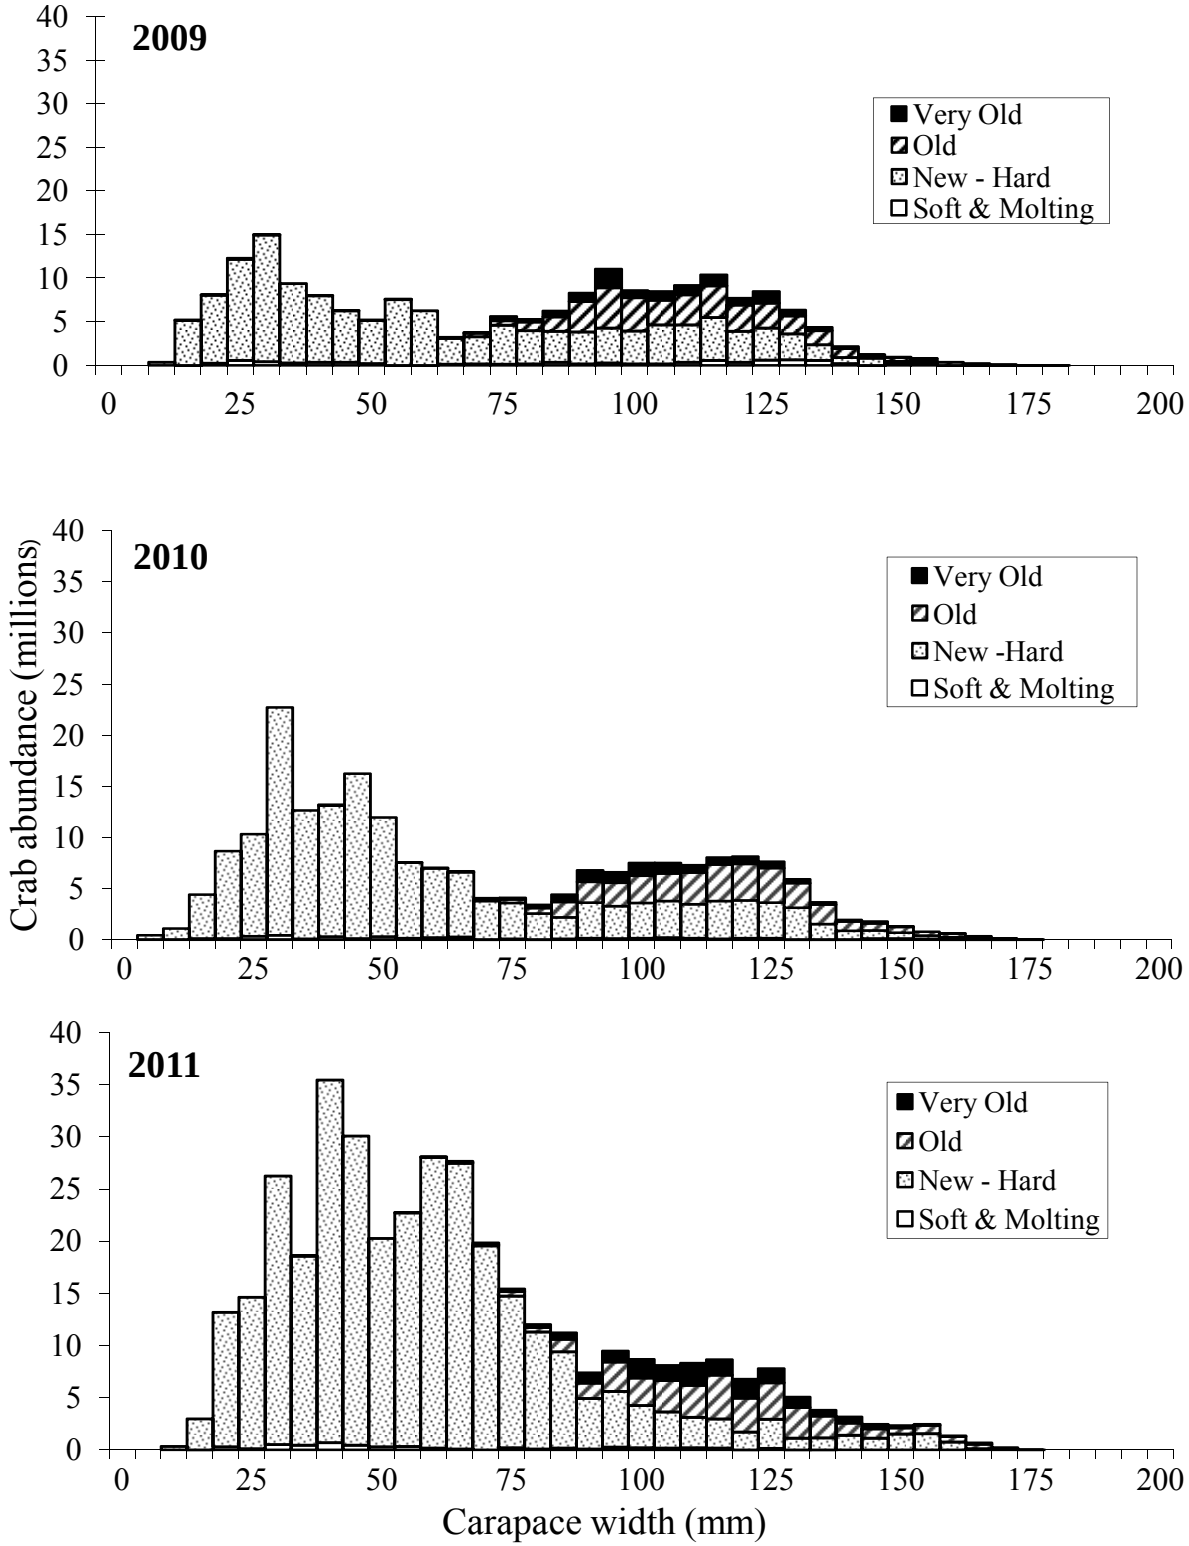

Figure 36. --Size-frequency of male Tanner crab (*Chionoecetes bairdi*) by 5 mm width classes of all districts combined, 2009-2011.

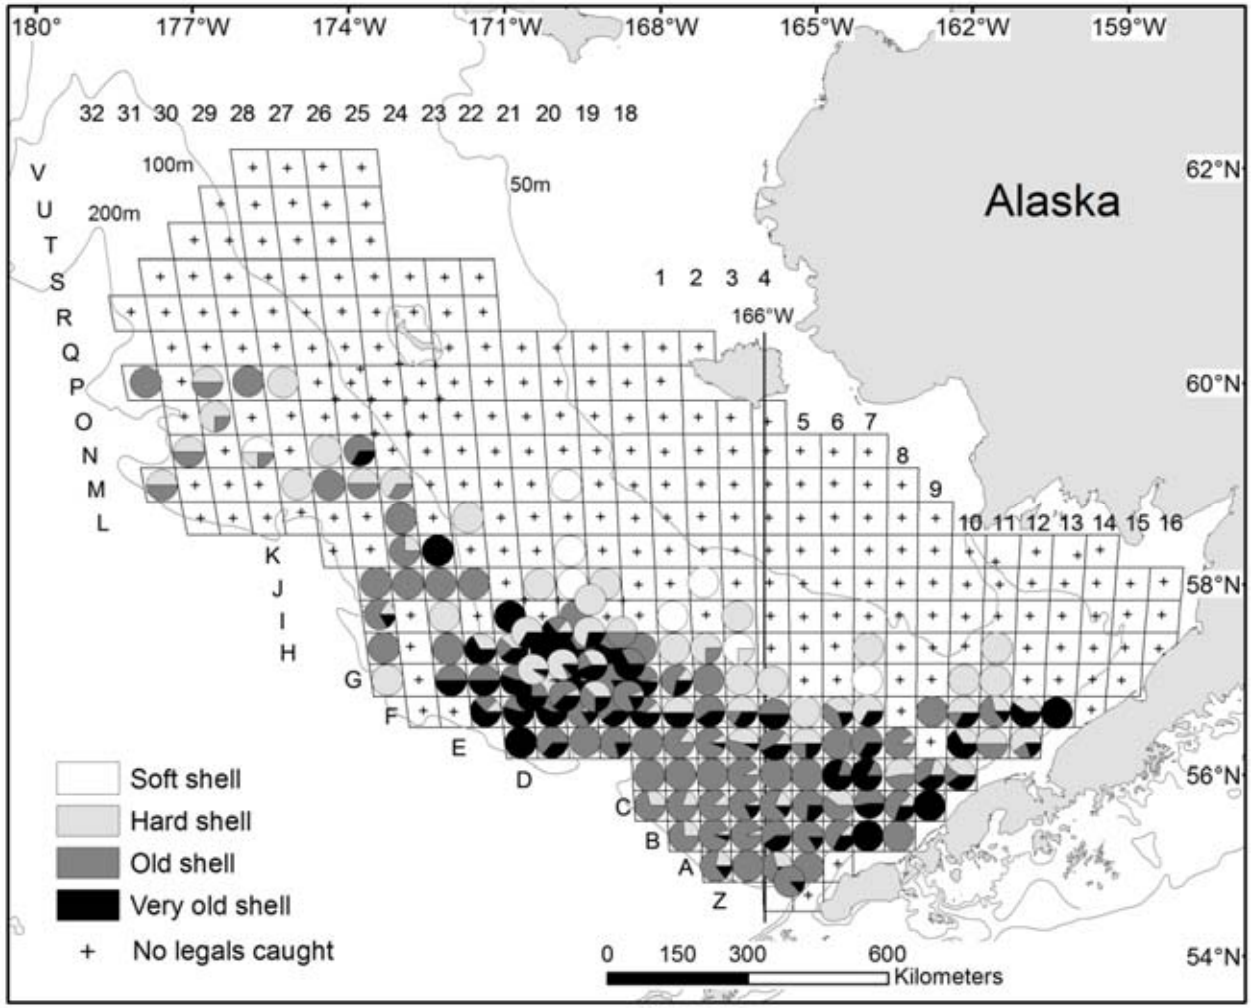

Figure 37. -- Distribution of legal-sized male Tanner crab (*Chionoecetes bairdi*) caught at each station in 2011 and distinguished by shell condition. Tanner male crab ≥ 120 mm and ≥ 110 mm CW are the legal-size categories for east and west of 166° W, respectively.

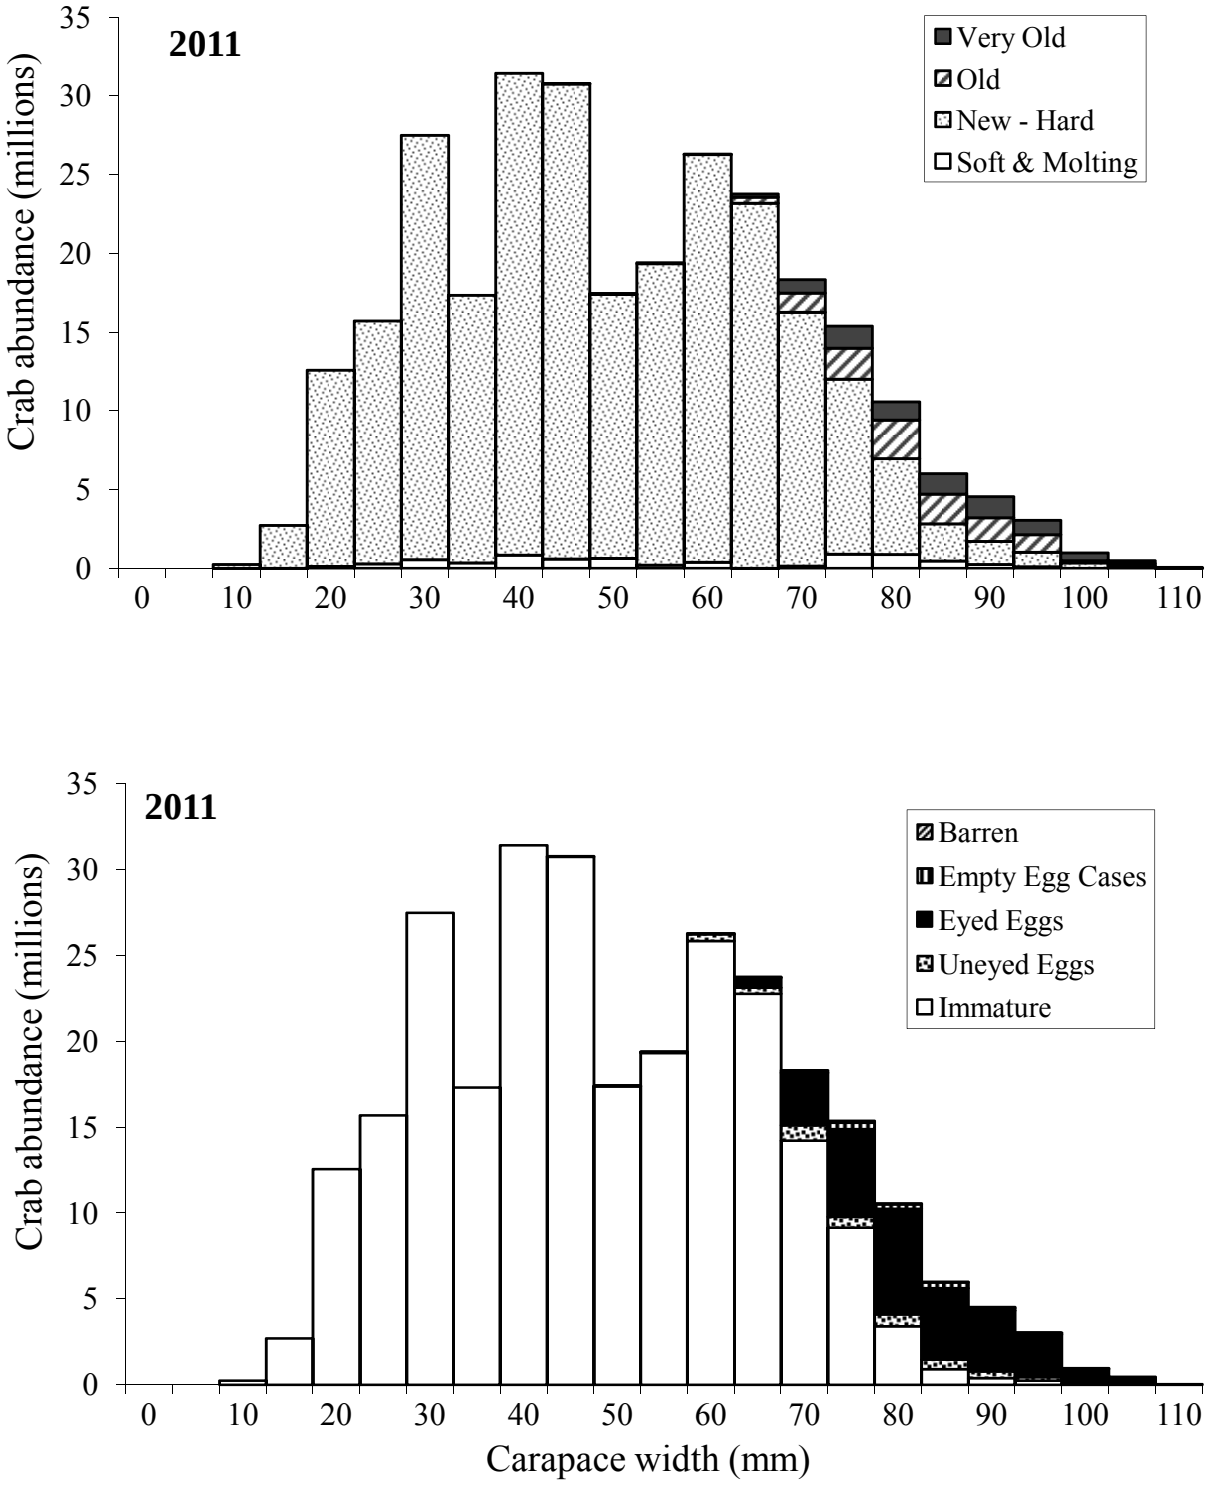

Figure 38. -- Size-frequency, shell and egg condition of female Tanner crab (*Chionoecetes bairdi*) by 5 mm width classes of all districts combined in 2011.

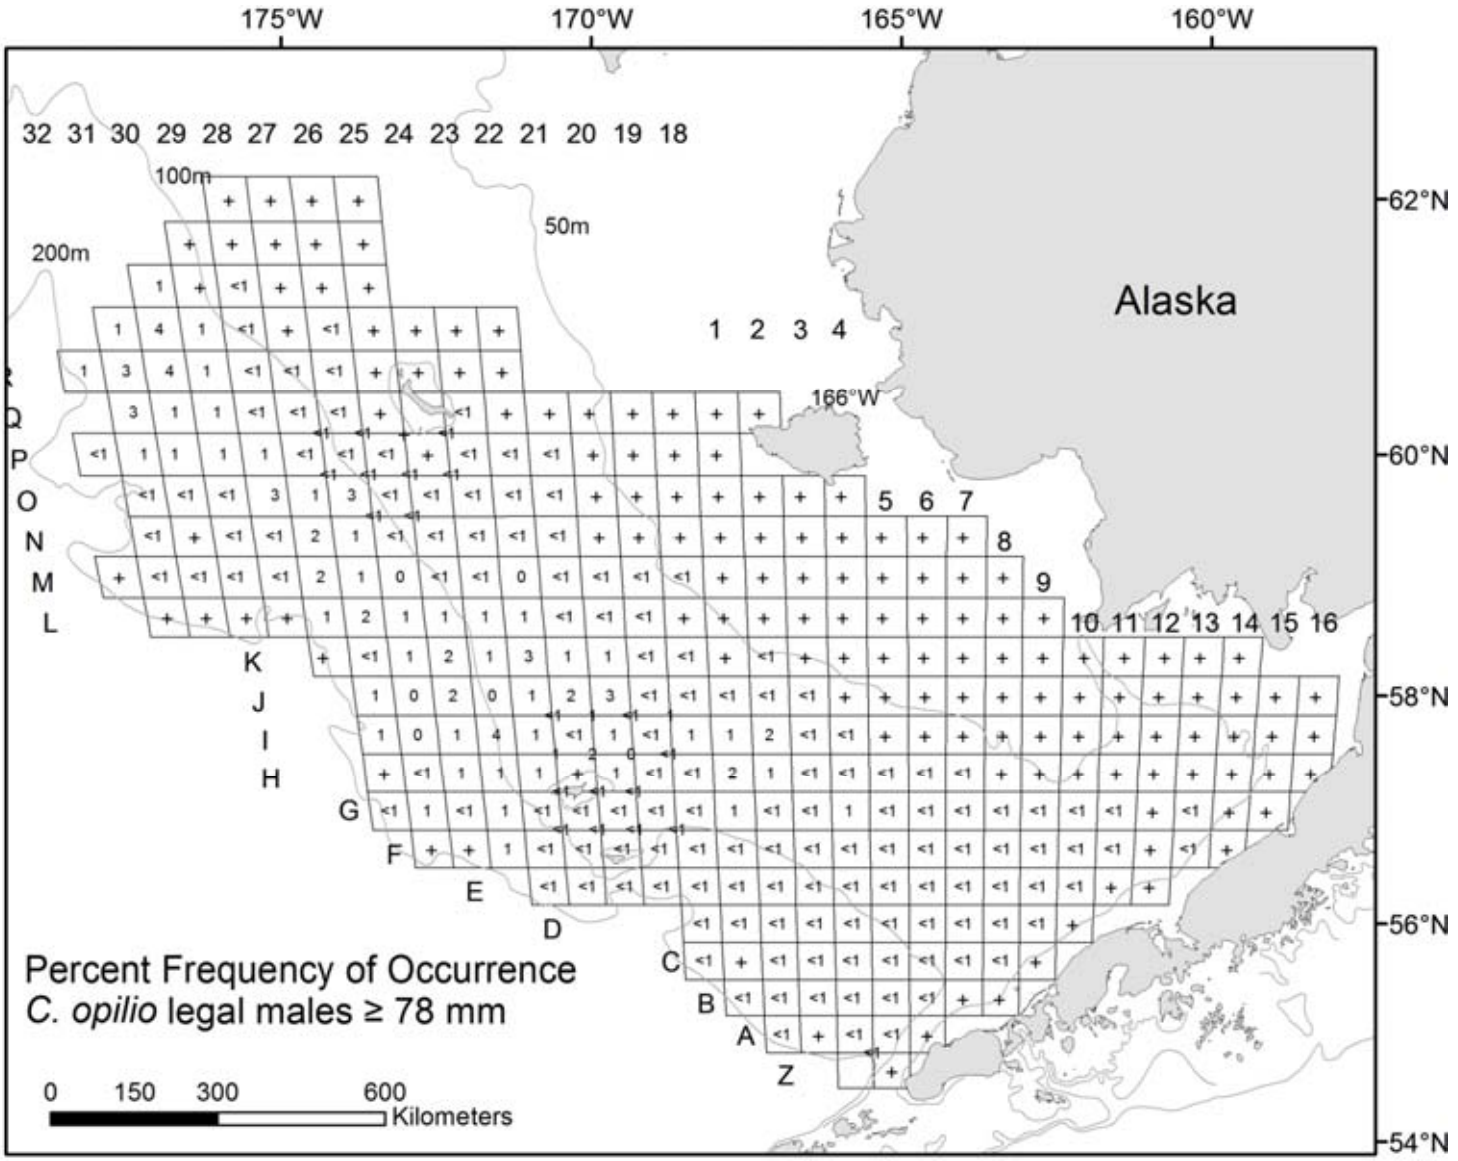

Figure 39. --Percent frequency of occurrence of legal-sized male snow crab (*Chionoecetes opilio*) at stations sampled in the 2011.

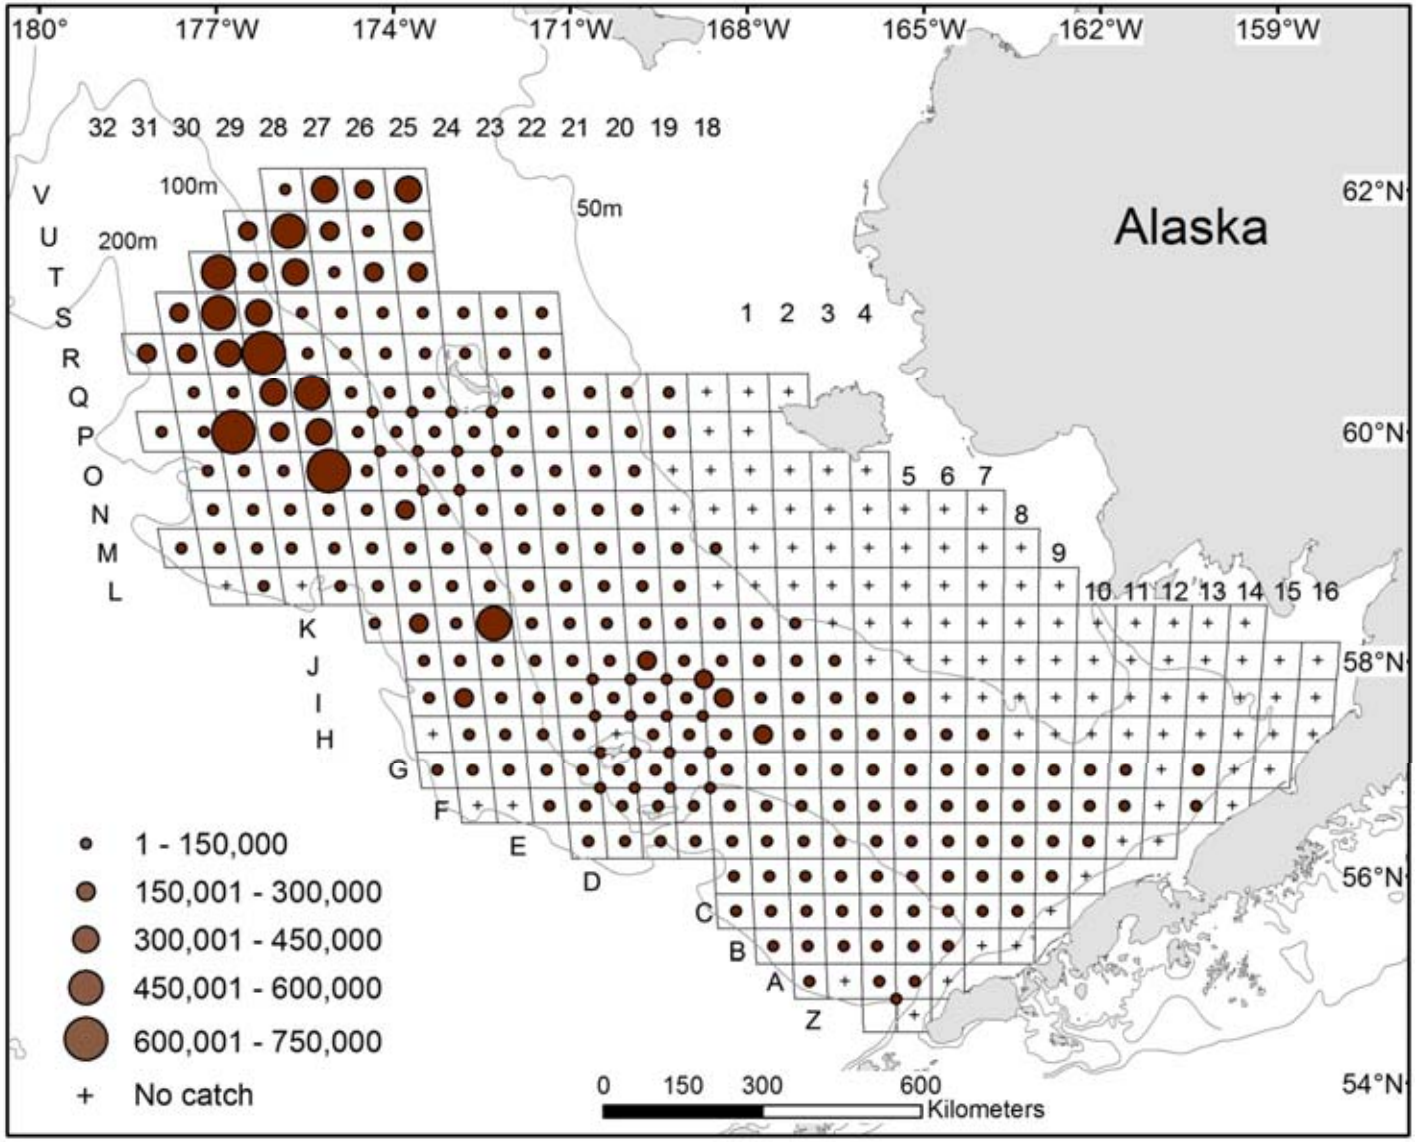

Figure 40. --Total density (number/nmi^2) of snow crab (*Chionoecetes opilio*) at each station sampled in 2011. Data depicted by circles are crab densities at equal intervals.

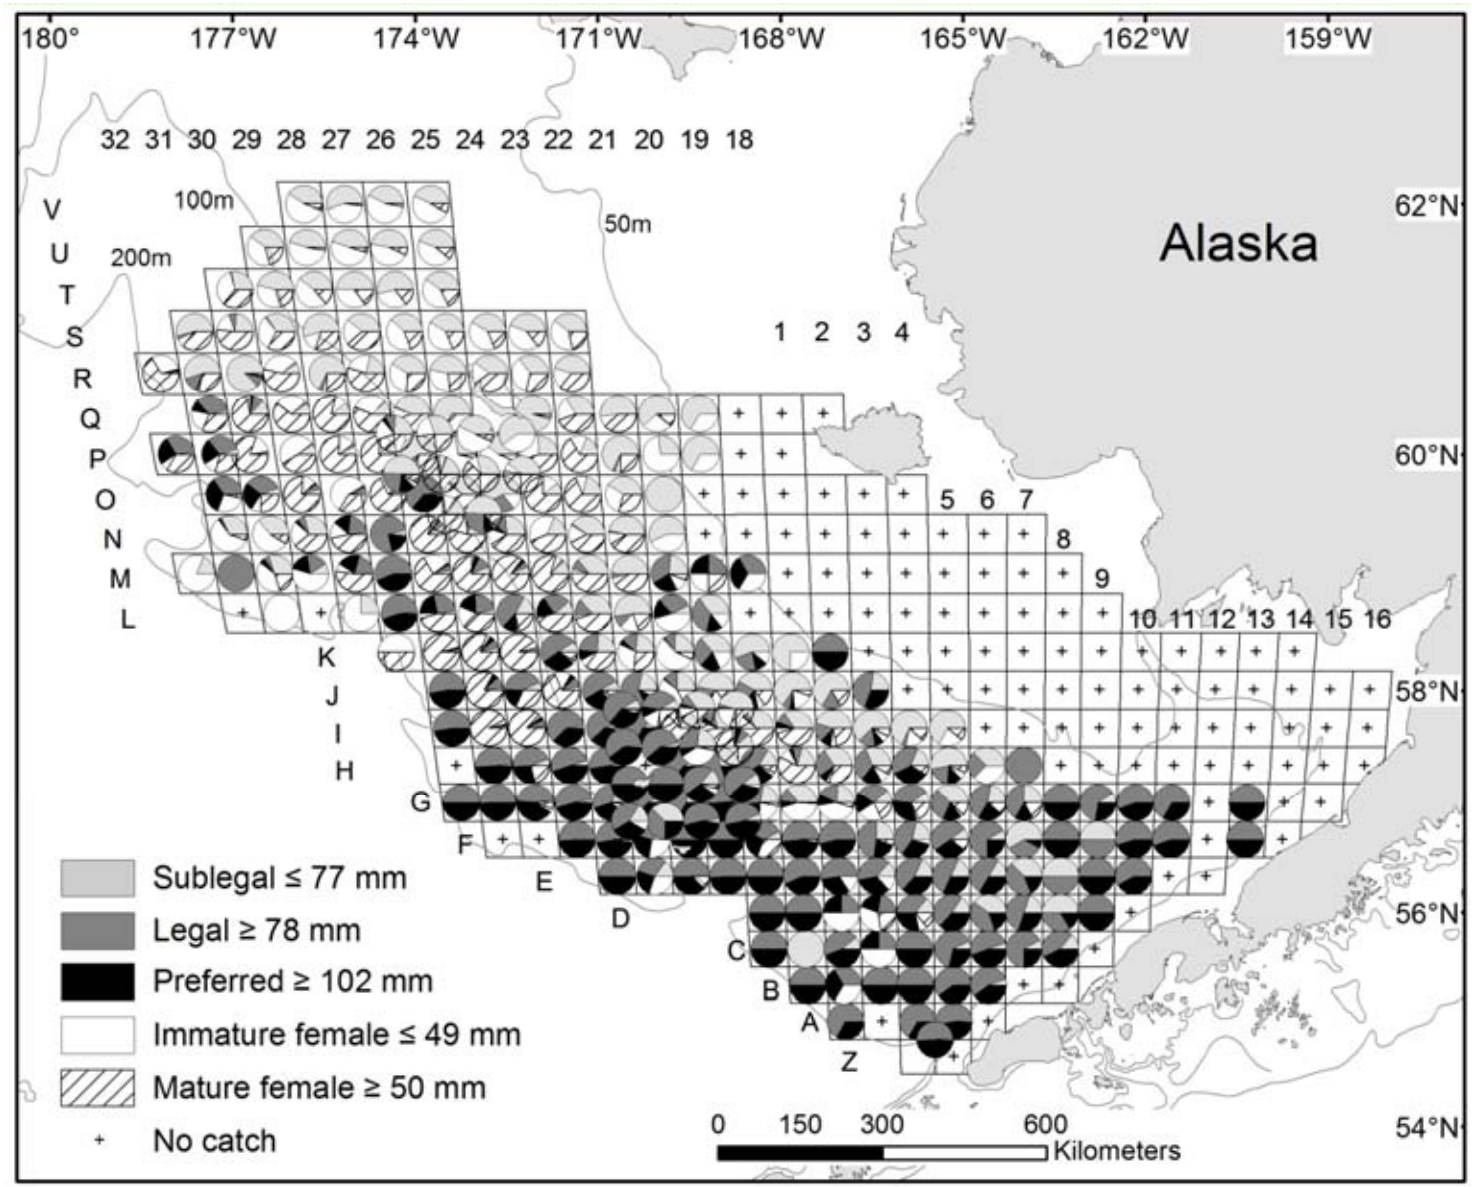

Figure 41. -- Percentage of male and female snow crab (*Chionoecetes opilio*) size categories at each station sampled in 2011.

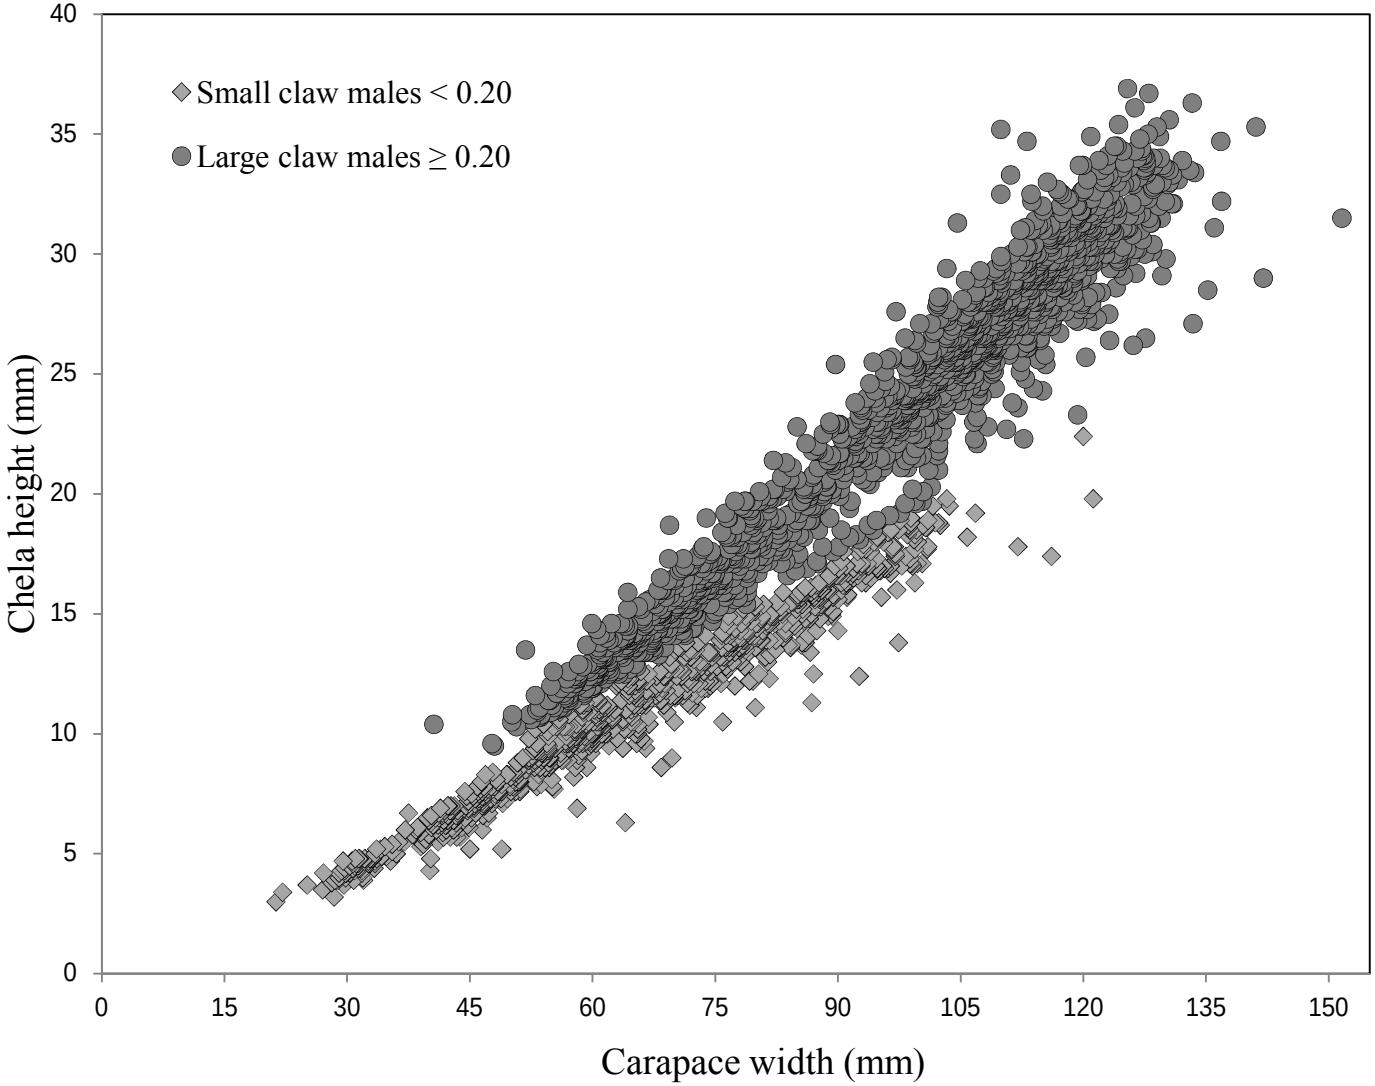

Figure 42. -- Male snow crab (*Chionoecetes opilio*) chela height versus carapace width measurements collected during the 2009 and 2011 National Marine Fisheries Service eastern Bering Sea bottom trawl surveys.

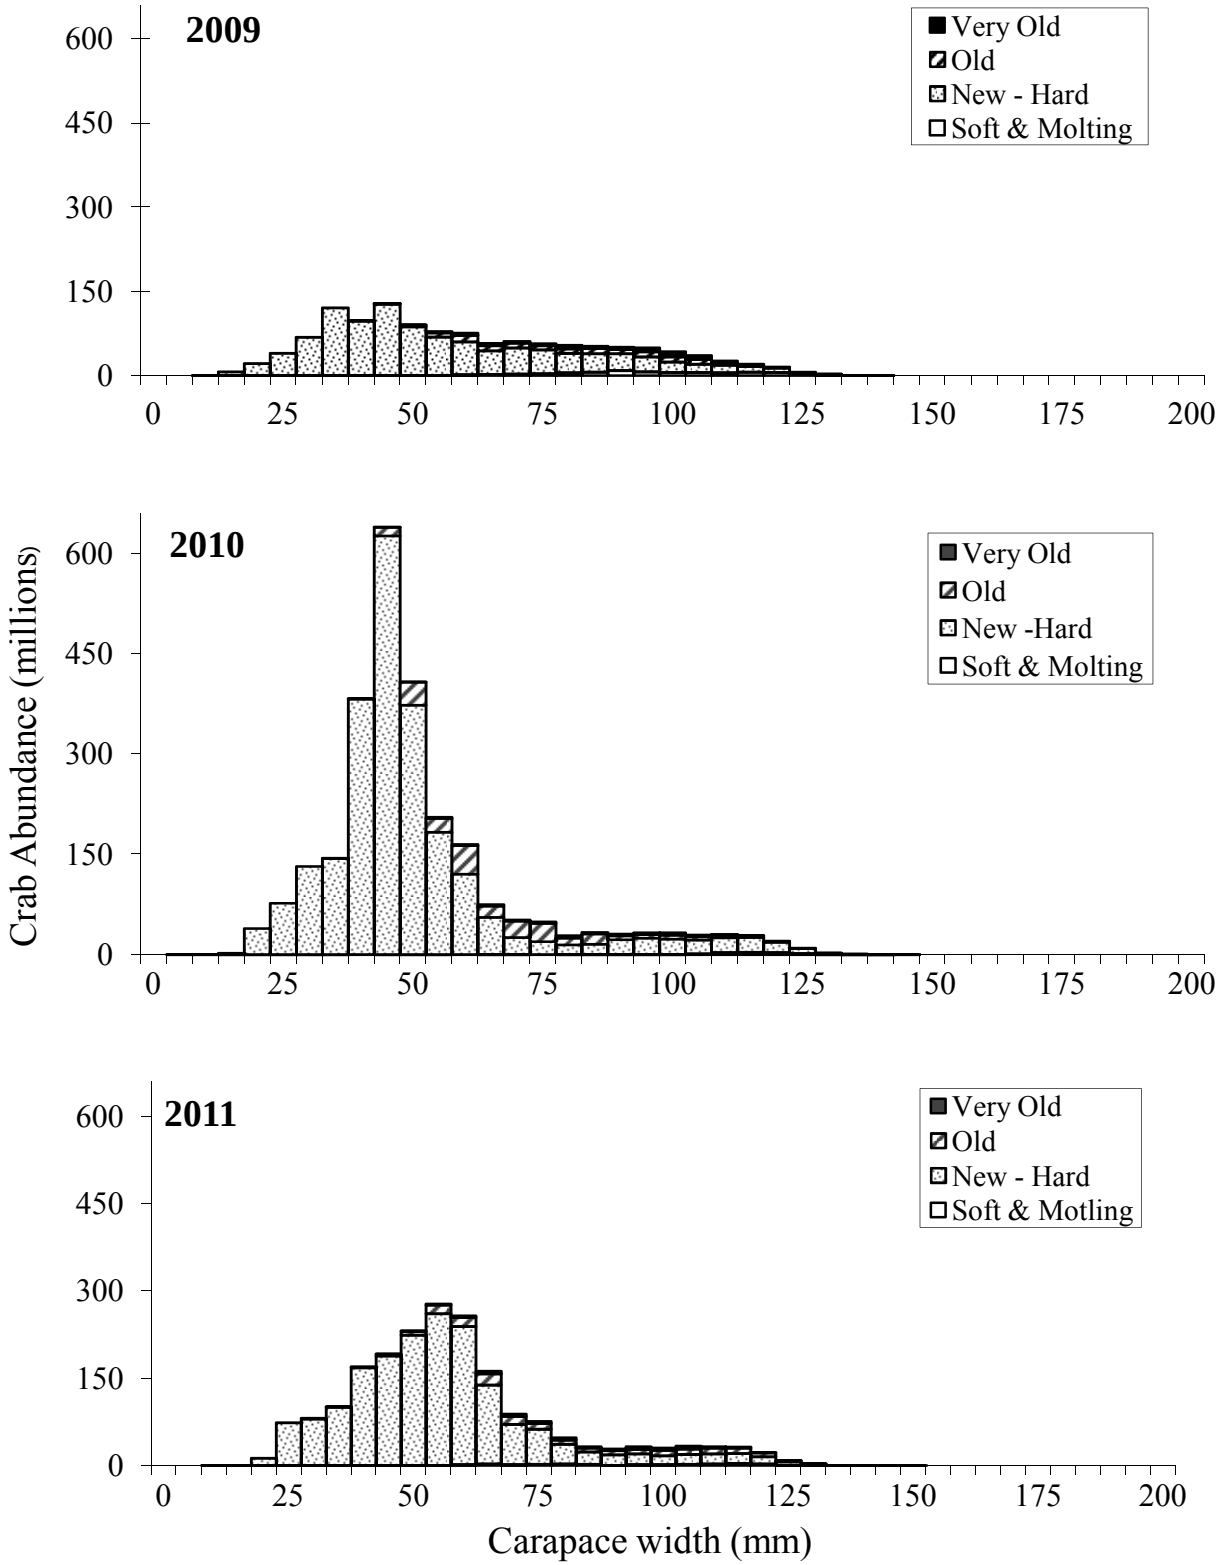

Figure 43. -- Size-frequency of male snow crab (*Chionoecetes opilio*) by 5 mm width classes of all districts combined, 2009-2011.

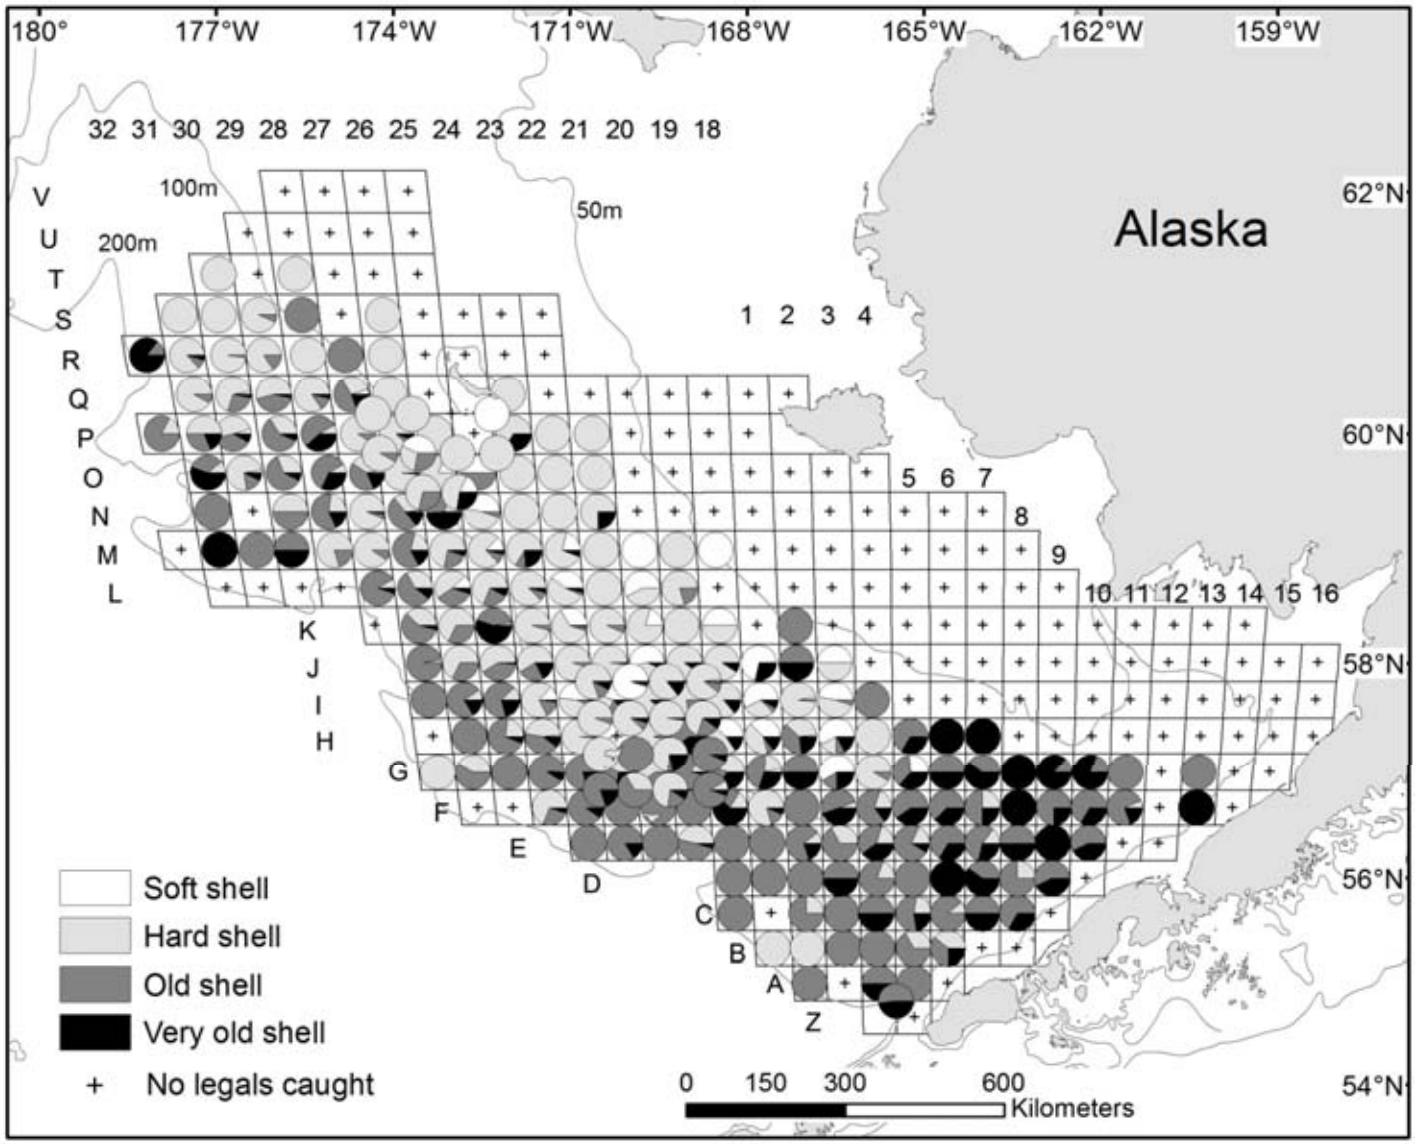

Figure 44. -- Distribution of legal-sized male snow crab (*Chionoecetes opilio*) caught at each station in 2011 and distinguished by shell condition.

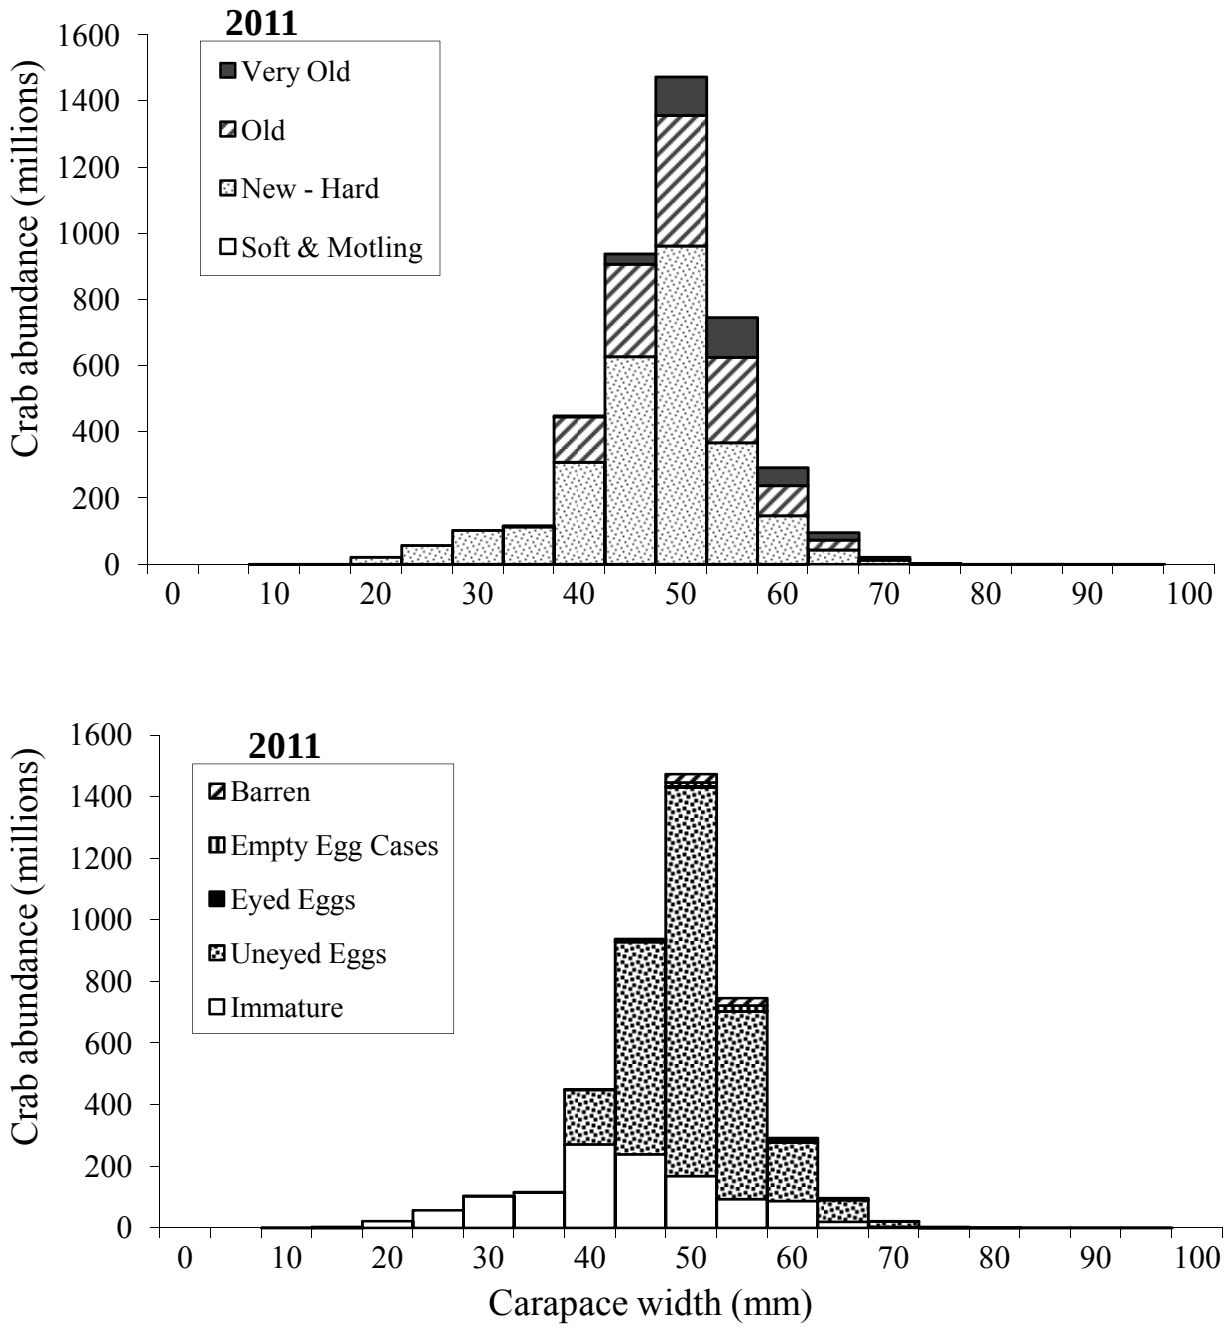

Figure 45. -- Size-frequency, shell and egg condition of female snow crab (*Chionoecetes opilio*) by 5 mm width classes of all districts combined in 2011.

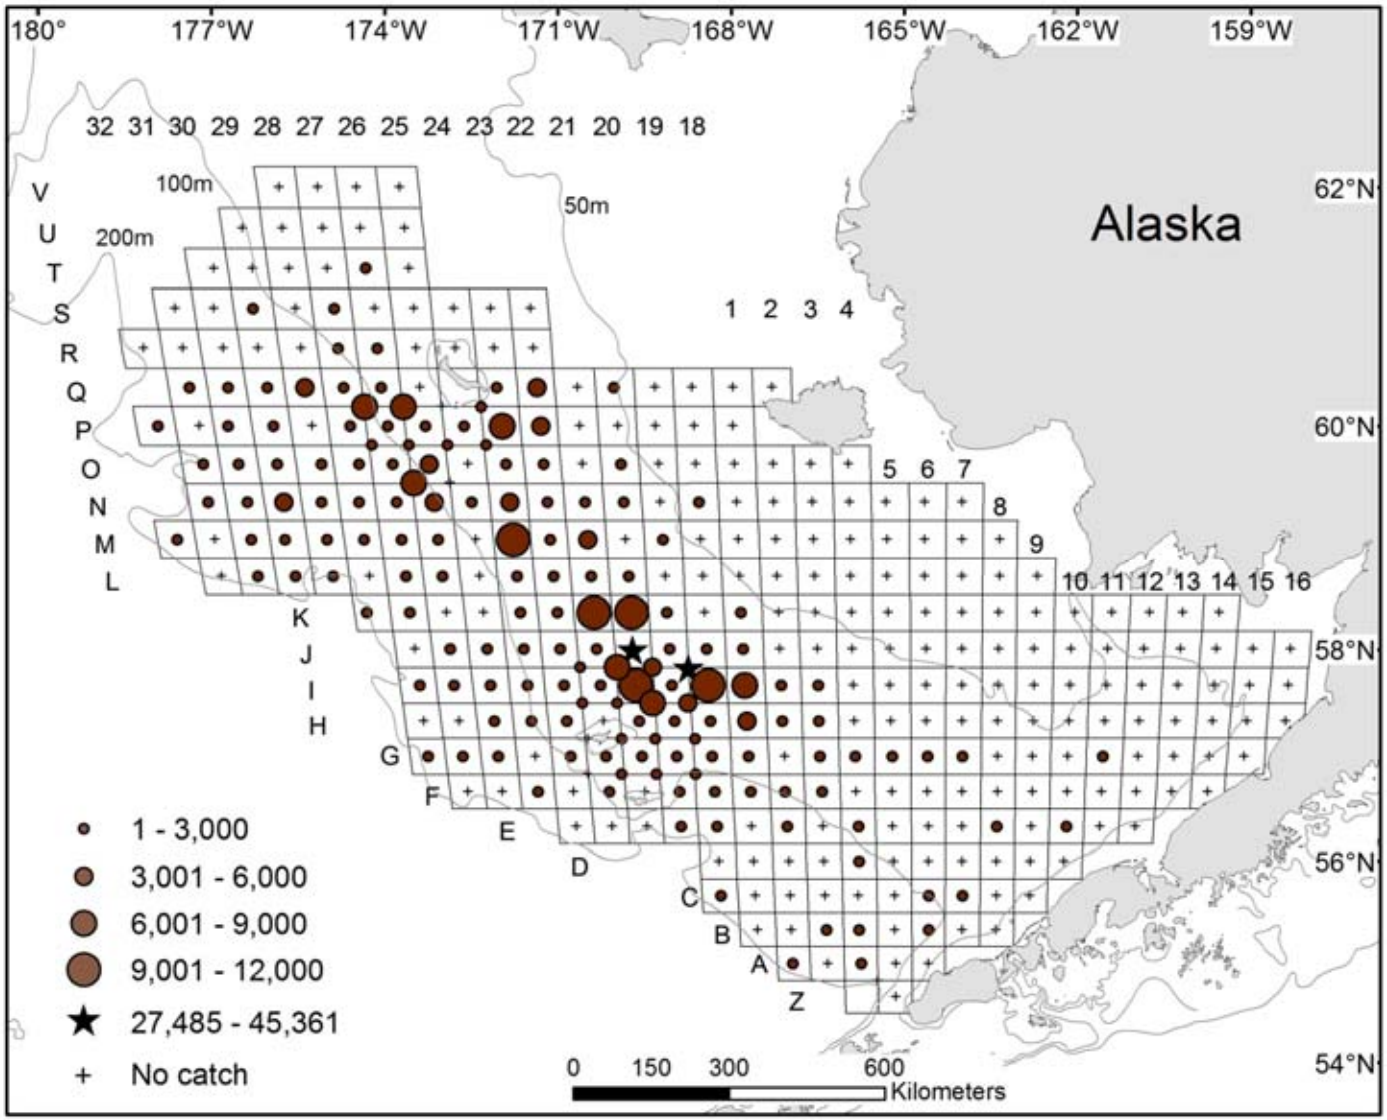

Figure 46. -- Total density (number/nmi^2) of *Chionoecetes bairdi/opilio* hybrid crab at each station sampled in 2011. Data depicted by circles are crab densities at equal intervals.

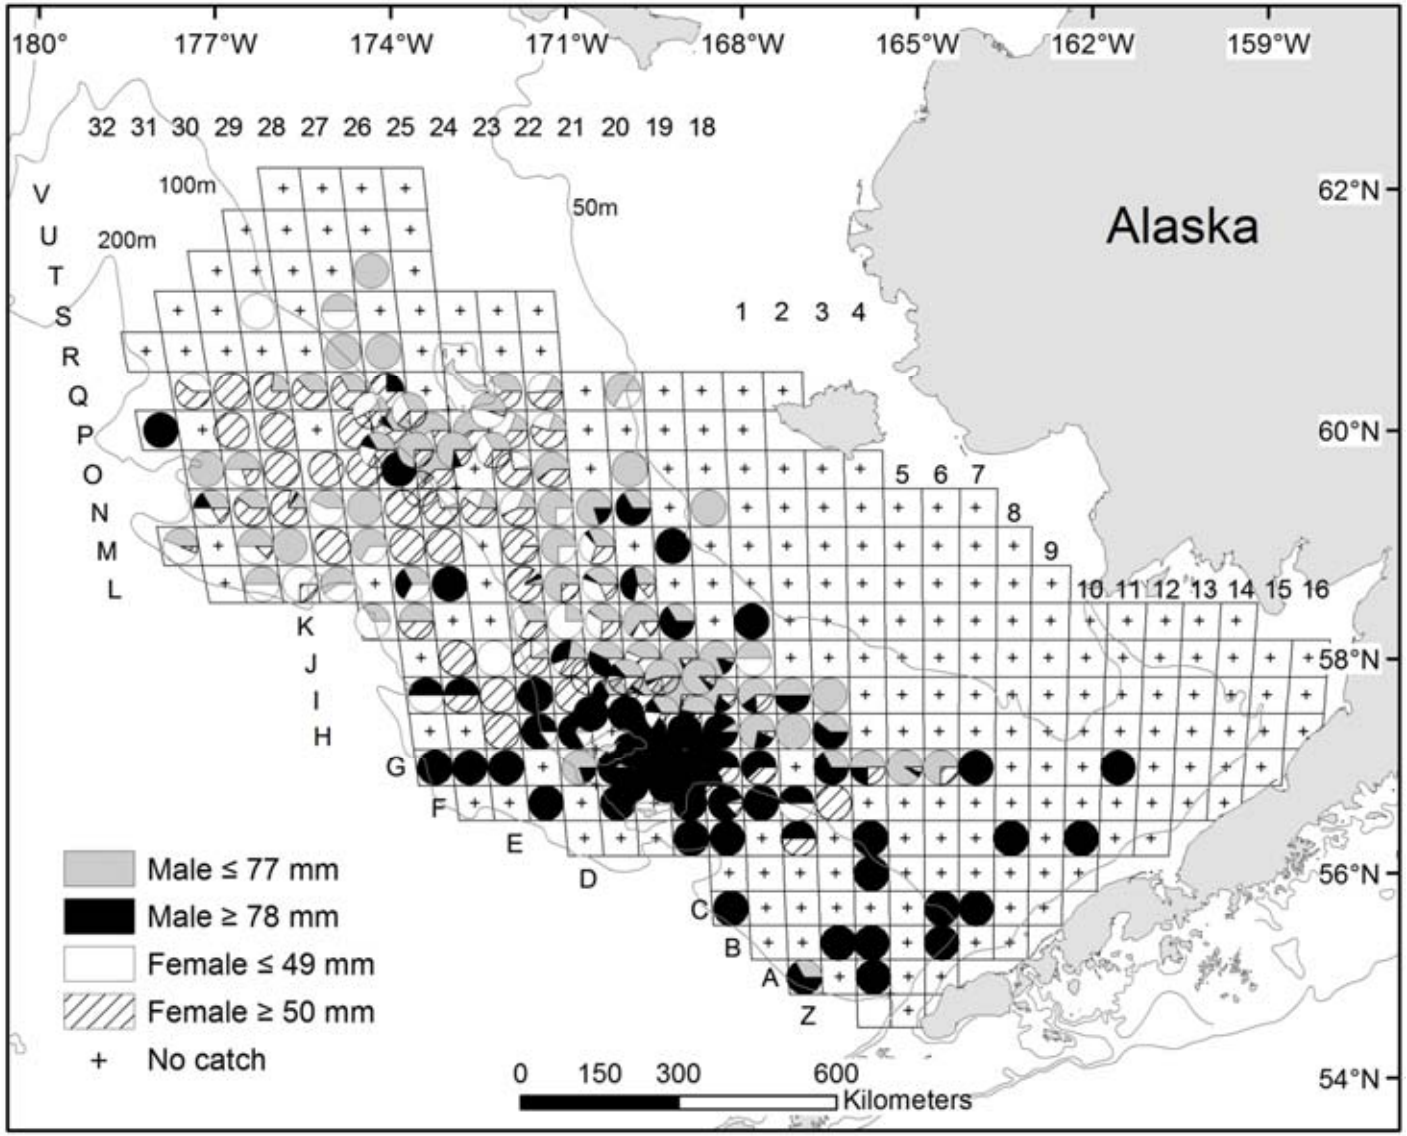

Figure 47. -- Percentage of male and female *Chionoecetes bairdi/opilio* hybrid crab size categories at each station sampled in 2011.

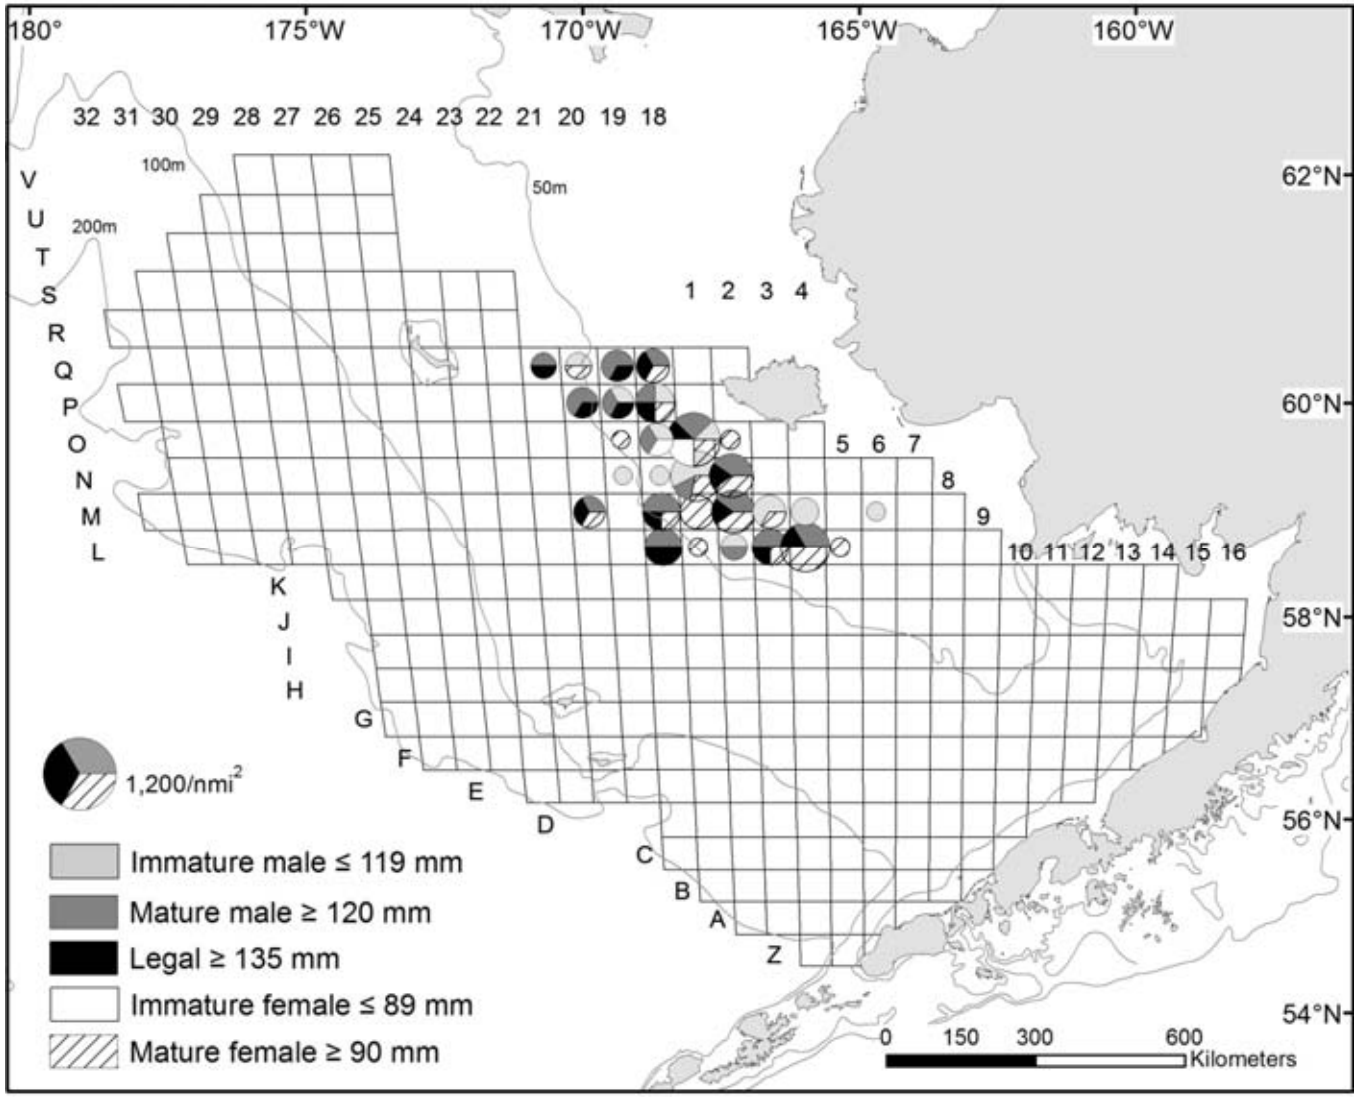

Figure 48. -- Total density (number/nmi^2) and percentage of male and female red king crab (*Paralithodes camtschaticus*) size categories at each station sampled in the Northern District in 2011.

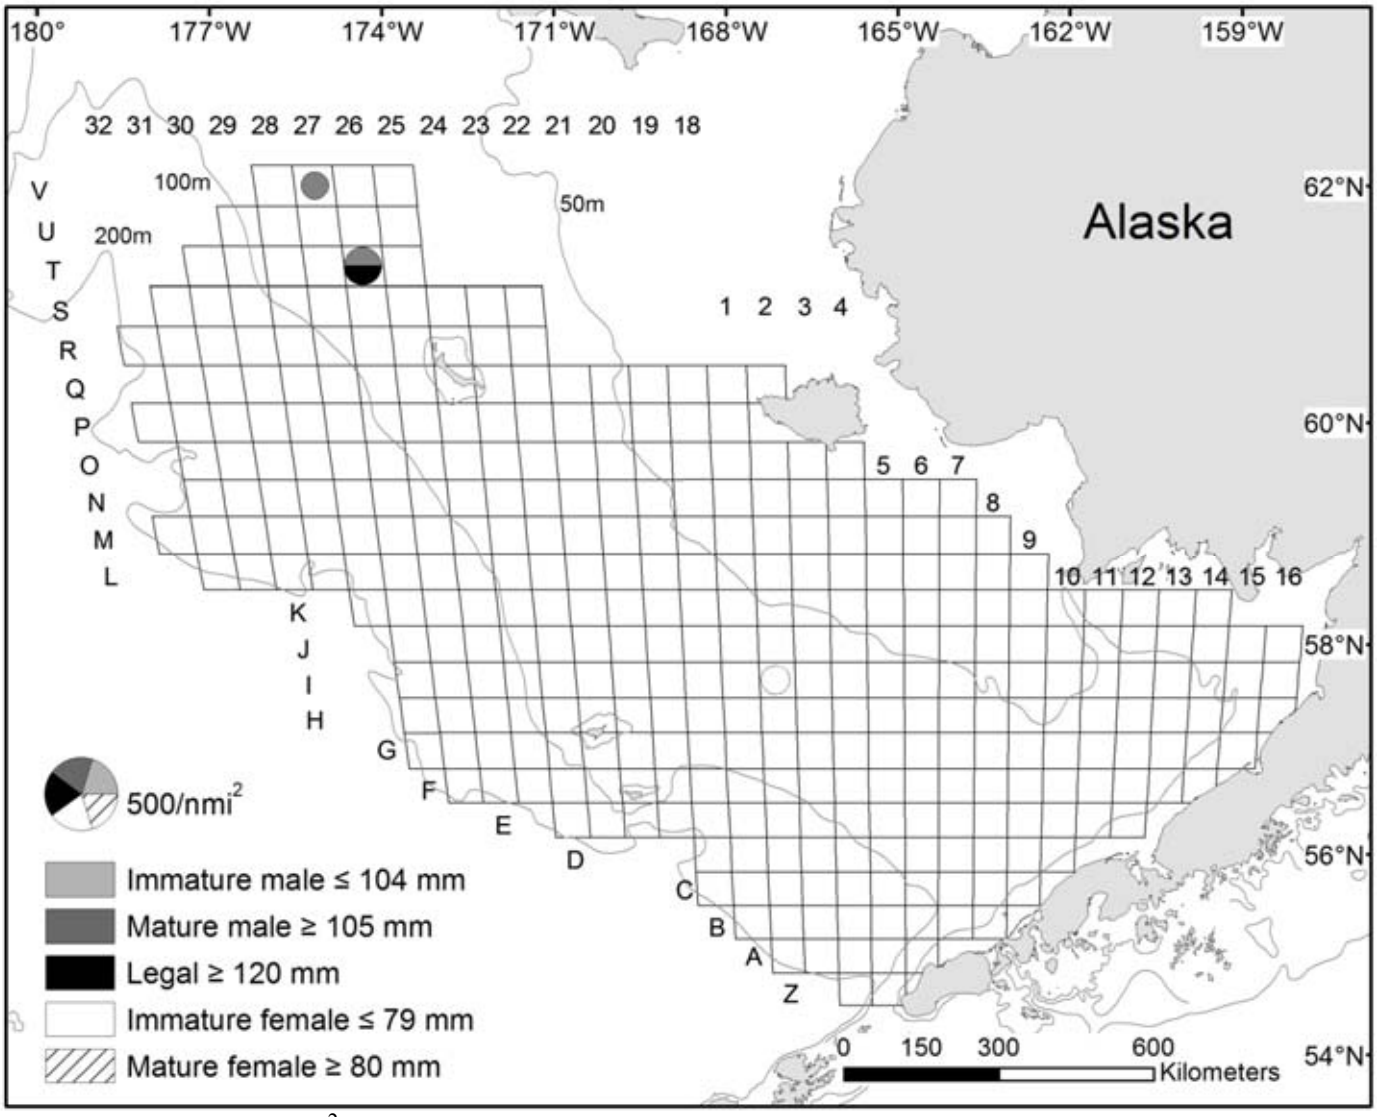

Figure 49. -- Total density (number/nmi^2) and percentage of male and female blue king crab (*Paralithodes platypus*) size categories at stations sampled outside of the Pribilof District and St. Matthew Island section of the Northern District in 2011.

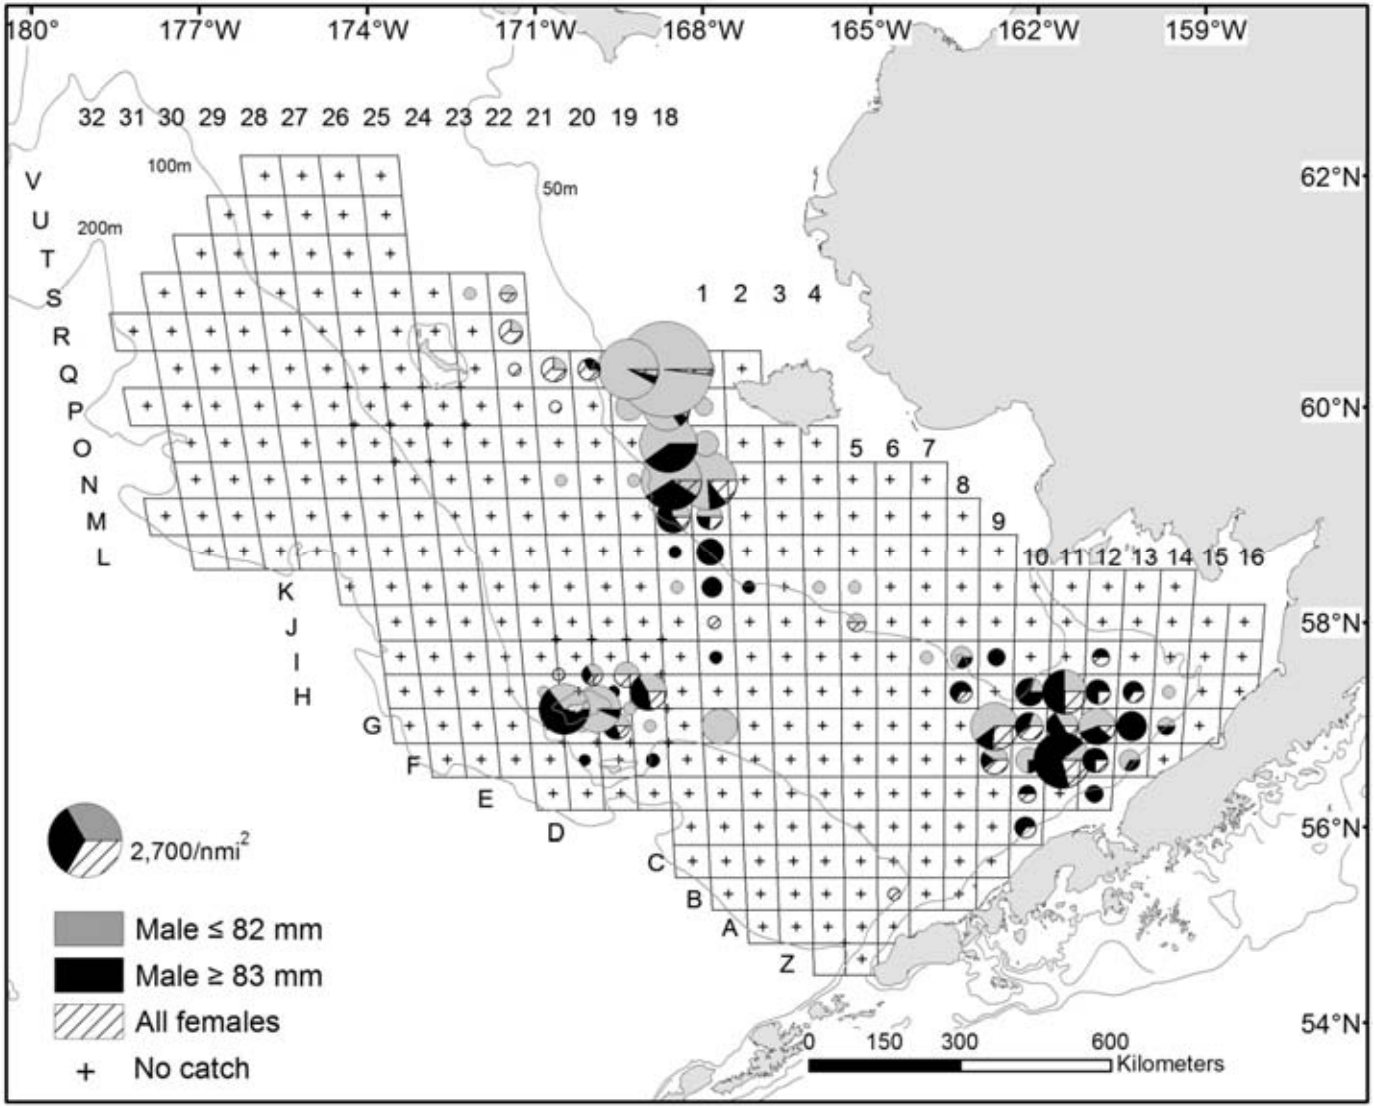

Figure 50. -- Total density (number/nmi^2) and percentage of male and female hair crab (*Erimacrus isenbeckii*) size categories at each station sampled in 2011.

Appendix. Tow details, crab density (number/nmi^2), and catch weight at successful stations on the 2011 eastern Bering Sea bottom trawl survey.
