AVAILABILITY OF REFERENCE MATERIALS
IN NRC PUBLICATIONS

NRC Reference Material

As of November 1999, you may electronically access NUREG-series publications and other NRC records at NRC's Public Electronic Reading Room at http://www.nrc.gov/reading-rm.html. Publicly released records include, to name a few, NUREG-series publications; *Federal Register* notices; applicant, licensee, and vendor documents and correspondence; NRC correspondence and internal memoranda; bulletins and information notices; inspection and investigative reports; licensee event reports; and Commission papers and their attachments.

NRC publications in the NUREG series, NRC regulations, and *Title 10, Energy*, in the Code of *Federal Regulations*, may also be purchased from one of these two sources:

1. The Superintendent of Documents
    U.S. Government Printing Office
    P.O. Box SSOP
    Washington, DC 20402-0001
    Internet: bookstore.gpo.gov
    Telephone: 202-512-1800
    FAX: 202-512-2250
2. The National Technical Information Service
    Springfield, VA 22161-0002
    www.ntis.gov
    1-800-553-6847 or, locally, 703-605-6000

A single copy of each NRC draft report for comment is available free, to the extent of supply, upon written request as follows:

Address: Office of the Chief Information Officer,
            Reproduction and Distribution
              Services Section
            U.S. Nuclear Regulatory Commission
            Washington, DC 20555-0001
E-mail: DISTRIBUTION@nrc.gov
Facsimile: 301-415-2289

Some publications in the NUREG series that are posted at NRC's Web site address http://www.nrc.gov/reading-rm/doc-collections/nuregs are updated periodically and may differ from the last printed version. Although references to material found on a Web site bear the date the material was accessed, the material available on the date cited may subsequently be removed from the site.

Non-NRC Reference Material

Documents available from public and special technical libraries include all open literature items, such as books, journal articles, and transactions, *Federal Register* notices, Federal and State legislation, and congressional reports. Such documents as theses, dissertations, foreign reports and translations, and non-NRC conference proceedings may be purchased from their sponsoring organization.

Copies of industry codes and standards used in a substantive manner in the NRC regulatory process are maintained at—

> The NRC Technical Library
> Two White Flint North
> 11545 Rockville Pike
> Rockville, MD 20852-2738

These standards are available in the library for reference use by the public. Codes and standards are usually copyrighted and may be purchased from the originating organization or, if they are American National Standards, from—

> American National Standards Institute
> 11 West 42nd Street
> New York, NY 10036-8002

ABSTRACT

New coupled neutron-gamma shielding libraries have been developed for use with the SCALE (Standardized Computer Analyses for Licensing Evaluation) code system. Two libraries have been generated based on the Evaluated Nuclear Data File/B Version VI (ENDF/B-VI) Release 8 (ENDF/B-VI.8) and ENDF/B-VII Release 0 (ENDF/B-VII.0) cross-section evaluations. Both libraries were generated using 200 neutron and 47 gamma groups. The neutron group structure is identical to the 199-group VITAMIN-B6 structure except an additional neutron group has been added to extend the top energy boundary to 20 MeV. In addition to the "fine-group" libraries, a "broad-group" ENDF/B-VII.0 library has been generated using a 27 neutron and 19 gamma group structure. In addition to the coupled cross-section library development, new shielding codes Monaco and MAVRIC (**M**onaco with **A**utomated **V**ariance **R**eduction using **I**mportance **C**alculations) have been developed for SCALE. This report documents the ENDF/B-VI.8 and ENDF/B-VII.0 cross-section library development and the benchmark testing of the new libraries with the new SCALE shielding transport codes Monaco and MAVRIC.

1   INTRODUCTION

Before development of Standardized Computer Analyses for Licensing Evaluation (SCALE) Version 6, coupled neutron-gamma cross-section libraries distributed with the code system were limited to U.S. Evaluated Nuclear Data File/B Version IV (ENDF/B-IV) data.[1] The latest version of the ENDF/B evaluation database that can be obtained from the National Nuclear Data Center (NNDC) at Brookhaven National Laboratory (BNL) is ENDF/B-VII.0 (Ref. 2). With the release of ENDF/B-VII in December 2006 (Ref. 3), the Oak Ridge National Laboratory (ORNL) initiated efforts to update the SCALE libraries for shielding applications to include both ENDF/B-VI Release 8 (ENDF/B-VI.8) and ENDF/B-VII.0 cross-section data. This report documents the cross-section library generation effort and the subsequent benchmark testing of the data libraries with SCALE.

In concert with the new cross-section library development activities, ORNL has developed new shielding capabilities for the SCALE code system. The Monaco shielding module is a new multigroup, fixed-source Monte Carlo transport code that can be used to perform shielding analyses for licensing applications. Monaco is the result of a modernization effort combining the multigroup neutron and photon physics of the well-known MORSE (Multigroup Oak Ridge Stochastic Experiment) Monte Carlo shielding code with the flexibility of the SCALE Generalized Geometry Package (SGGP) and cross-section processing. Monaco uses the same cross-section package as other SCALE modules. Available tallies in Monaco include point detectors, region-based flux tallies, and mesh tallies. Any Monaco tally can be folded with a response function, either user-entered or from a standard list available with each SCALE cross-section library. Mesh tally values and uncertainties can be viewed with a special Java viewer on all computer platforms that run SCALE. Monaco is implemented in SCALE through the MAVRIC (Monaco with Automated Variance Reduction using Importance Calculations) computational sequence. The MAVRIC sequence in SCALE combines the results of an adjoint calculation from the three-dimensional (3-D) deterministic code Denovo with Monaco. Both an importance map for weight windows and a biased source are automatically generated from the adjoint flux using the CADIS (Consistent Adjoint-Driven Importance Sampling) methodology. MAVRIC is completely automated— from a simple user input, it creates the cross sections (forward and adjoint), calculates the first collision source, computes the adjoint fluxes, creates the importance map and biased source, and executes Monaco. Users can start and stop the calculation at various points so that progress can be monitored and importance maps can be reused for similar problems. For simple problems that do not require the advanced variance reduction, the MAVRIC sequence is an easy way to compute problem-dependent cross sections and execute Monaco with a common user input. The MAVRIC/Monaco capability represents a significant radiation transport advancement for SCALE.

This report provides detailed computational results using the new shielding libraries and radiation transport capabilities of MAVRIC/Monaco.

2 LIBRARY GENERATION

2.1 AMPX Input File Generation

A flow diagram is presented in Fig. 2.1 to illustrate the automated procedure to generate the AMPX master library from ENDF/B evaluations.
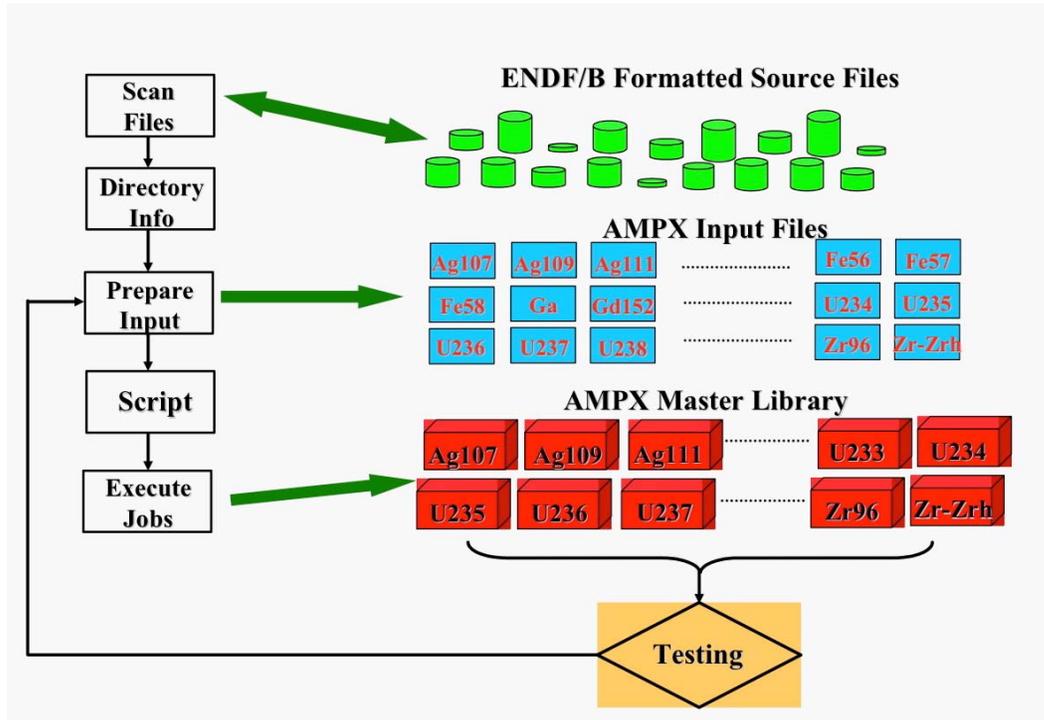

Fig. 2.1 Work flow for AMPX master library creation.

Input files are generated using an XML listing of the desired evaluations and XML templates. The XML listing of the desired evaluation is generated by a Java program that scans a directory tree of ENDF files and writes the relevant information to a file. A typical listing looks like the following.

```
<Material tag="al27
          endf="1325"
          za="13027"
          tape="/home/dw8/ampx/running/endf6/rev8/First.endf"

                    file7temps="296.0 400.0 500.0 600.0 700.0 800.0 1000.0 1200.0 1600.0 2000.0"
        />
```

XML templates used to create the AMPX input files are provided in Appendix A. The various templates can refer to the attribute values by name. For example *writeData(endf)* in the templates provided in Appendix A, will be substituted by the ENDF MAT number listed in the endf attribute. Table 2.1 lists some specialized additional values that can also be substituted.

In addition, the template reader reads a configuration file. The configuration file lists metastable isotopes, thermal moderator evaluations, and some special nuclei. In most cases the identifier (ID) used in SCALE is the ZA value; however, in the cases of metastable isotopes, thermal moderator evaluations, and some special nuclei, the SCALE ID is different. The configuration file allows supplying those special SCALE ID values. For the thermal moderators, one or more fast evaluations, identified by their endf numbers, are also supplied. The following is the configuration file used for the ENDF 6 data.

```
    <ConfigFile>

        <!-- metastable nuclei for which the scale id is different from the  real za value -->
        <metastable>
            <nuclei endf="9547" realza="95242" scaleza="95601"/> <!-- Am242m -->
            . . .
            <nuclei endf="5253" realza="52129" scaleza="52611"/> <!-- Te129m -->
            <nuclei endf="6153" realza="61148" scaleza="61601"/> <!-- Pm148m -->

        </metastable>

        <!-- nuclei for which the scale id is different from the  real za value -->
        <specialNuclei>
            <nuclei endf="1001" realza="1001" scaleza="1801"/>
            <nuclei endf="1002" realza="1001" scaleza="1802"/>
        </specialNuclei>

        <!-- thermal nuclei -  need to check the temperature stuff again  - these are the
    temperatures listed in file 7 -->
         <thermal>
            <nuclei endf="1" realza="101" scaleza="1001">  <!-- H_H20 -->
                <fastMat endf="125"/>  <!-- H -->
            </nuclei>
```

```
        . . .

    <nuclei endf="27" realza="127" scaleza="4509">    <!-- BEO -->
        <fastMat endf="425"/>     <!-- BE9 -->
        <fastMat endf="825"/>     <!-- 016 -->
    </nuclei>

    <nuclei endf="31" realza="131" scaleza="6312">    <!-- GRAPHITE -->
        <fastMat endf="600"/>     <!-- C -->
    </nuclei>
  </thermal>

</ConfigFile>
```

In addition to the attributes available directly from the above XML file, the tags listed in Table 2.1 can also be substituted.

Table 2.1 Substitution tags available for use in XML input templates

Attribute	Description
tag	The tag name of the material
version	The version of the evaluation
mod	The modification of the evaluation
rev	The revision of the evaluation
tape	The tape location of the evaluation
za	The ZA ID of the evaluation
a	The mass of the evaluation
z	The z value of the evaluation
scaleid or scaleidthermala1	The SCALE ZA ID. This is: endf + 10000 * mod + 1000000*version. If this is a thermal material, the ENDF MAT ID of the first thermal evaluation is used. Similarly, the mod number of the first thermal evaluation is used. The version is always of the current material.
scaleidthermal2	The SCALE ZA ID. This is: endf + 10000 * mod + 1000000*version. If this is a thermal material and a second thermal evaluation exists, the ENDF MAT ID of the second thermal evaluation is used. Similarly, the mod number of the first thermal evaluation is used. The version is always of the current material.
thermalscaleid	The same as scaleid but endf and mod value are from the current material, which is assumed to be a moderator.
changedza or changedzathermal1	For thermal, metastable, and some special material a changed ZA value is used in SCALE. This tag prints out the changed ZA value. If the ZA value does not need any changes, the original value is printed.
changedzatherml2	For thermal, metastable, and some special material a changed ZA value is used in SCALE. This tag prints out the changed ZA value for the second thermal evaluation.
Date	Prints the current date. The second argument optionally lists the date format.

The terms *fast1*, *fast2*, *or gamma* may be appended to all available attributes. If *fast1* is appended, the values of the attributes for the first fast thermal evaluation are printed. For example, in the case of graphite, appending *fast1* to the *writeData* attribute [*writeData(tagfast1)*] substitutes C, the tag for the first fast evaluation to be coupled with graphite. If *fast2* is appended, the values of the attributes for the second fast thermal evaluation are printed. For example, *writeData(endffast2)* for the case of BeO substitutes 825, the ENDF material for the second fast evaluation to be coupled with BeO. If *gamma* is appended, the value of the attribute pertaining to the coupled gamma evaluation is printed.

The *writeData(attribute)* function can optionally have two more parameters, the first of which gives the total length of the string to be printed and the second one the character to use for padding. Thus, in the case of graphite, the function *writeData(endf,10,*)* will print "*******600."

The templates are XML files with several special elements that allow looping over the various evaluations. The tags listed in Table 2.2 control the behavior of the templates. Templates for the input files used for the library creation effort are given in Appendix A.

Each restriction can contain more than one value and those values can be preceded by a plus (+) or a minus (−). A plus indicates that the indicated condition must be met, whereas a minus negates the indicated condition. For example, *restrict="+gamma + file2(yes)"* will only loop over evaluations that have a File 2 **and** have an associated gamma evaluation. However, *restrict="gamma file2(yes)"* will only loop over evaluations that have a File 2 **or** have an associated gamma evaluation. The restriction *restrict="−gamma +file2(yes)"* will only loop over evaluations that have a File 2 **and no** associated gamma evaluation.

The templates used to generate the various input files are given in Appendix A and should contain enough comments to serve as examples on how to use the input generator.

The template is parsed using a Java program where the program invocation is typically as follows.

```
java -jar ampx.jar -l Endf6.xml -c Config.xml -l template.xml
```

The argument for the −t option gives the file name of the template name, the argument for the −l option gives the file name containing the XML list of the ENDF evaluations, and the argument for the −c option lists the configuration file.

Table 2.2 Template control elements that allow looping over the evaluations

Tag			Description
loop			starts a loop over the various evaluations. It has the following optional attributes.
	restrict		Restricts the loop to special cases. Available values are as follows.
		thermal or thermal1	Only loops over materials that are moderators.
		thermal2	Only loops over materials that are moderators and have second fast evaluations.
		gamma or gammathermal1	Only loops over materials that have an associated gamma evaluation. In the case of moderators, the gamma evaluations need to exist for the first fast evaluation.
		gammathermal2	Only loops over materials that are moderators and have at least two fast evaluations and the second fast evaluation has a gamma evaluation associated with it.
		Metastable	Only loops over materials that are metastable.
			For any attribute listed in the XML file that has the associated value. For example *restrict="file2(yes),"* only loops over evaluations that contain a File 2.
	start		The index at which to start. Before the value is used, any *writeData* functions are substituted.
	stop		The index at which to stop. Before the value is used, any *writeData* functions are substituted.
	step		The index at which to stop the loop. Before the value is used, any *writeData* functions are substituted
	number		The number of times the loop should run. Before the value is used, any *writeData* functions are substituted.
openFile			With attribute name opens the indicated file for writing. The file name must be unique as it is used as the key.
closeFile			With attribute name closes a previously opened file.
writeFile			With attribute name writes data to the indicated file. Optionally it can contain an attribute restrict, which has the same function as for the loop element to restrict what gets written into the file. Any CDATA element and anything enclosed in a text element is written to the indicated file. Because a text element allows a restrict attribute with the same functionality as for the loop element, enclosure into this element allows writing different text depending on the particulars of the current evaluations.
noLast			Allows printing content if currently in a loop and if this is not the last time the loop will run.
first			Allows printing content if currently in a loop and if this is first time the loop will run.
noFirst			Allows printing content if currently in a loop and if this is not the first time the loop will run.

2.2 Processing

2.2.1 Group structure

The neutron group structure used is the 199-group VITAMIN-B6 structure with one extra group added to bring the upper group boundary to 20 MeV. The neutron group structure is listed in Table 2.3 and the gamma group structure in Table 2.4. For the broad-group library, 27 neutron groups and 19 gamma groups were used. The neutron group boundaries are listed in Table 2.5 and the gamma group boundaries in Table 2.6.

Table 2.3 Energy boundaries for the 200 neutron group structure

2.2.2 AMPX execution sequences for neutron and gamma-ray yield processing

The ORNL AMPX[4] processing system contains more than 100 distinct modules that can be used to perform various nuclear data processing functions. For generating a cross-section library, the specific modules needed to process a cross-section evaluation depend upon the data specified in the nuclide evaluation. For example, if the nuclide is a resonance nuclide, it will require more modules to be executed relative to a nonresonance nuclide. If the evaluation is a thermal moderator material, the AMPX execution sequence will be different because the final cross-section data will be a mixture of data from one evaluation above the thermal range and from another evaluation in the thermal range.

The general procedure to generate groupwise neutron cross-section data is outlined in Fig. 2.2. The flow chart to produce the coupled part of the library is depicted in Fig. 2.3.

11

The ENDF/B-VI.8 and ENDF/B-VII.0 cross-section evaluations were downloaded from the NNDC Web page.[2] Some of the ENDF/B-VI.8 evaluations contain incomplete evaluations preventing them from being used to generate a complete cross-section library for radiation transport calculations. These evaluations are excluded and are listed in Table 2.7. The ENDF/B-VI.8 evaluation for S (ENDF MAT 1600) does not list MT=18, fission, in File 3; therefore, the cross-section data for this reaction only extend from 1×10^{-5} eV to 1.0921×10^6 eV as derived from the resolved resonance data in File 2, which provides fission width data for some of the resonances. Clearly, the presence of fission width information for S in File 2 is not correct as S is not a fissionable nuclide.

Table 2.7 Evaluations excluded from the ENDF/B-VI.8 library

Evaluation	ENDF material	Reason for exclusion
^{40}Ar	1837	Evaluation is missing a file 3 and thus does not yield energy data above 500000.0 eV (end of resolved resonance data).
^{115}In	4931	File 3 only gives cross-section data for MT=51 and 102, corresponding to (z,n_1) and (z,γ).
^{41}K	1931	File 3 only gives cross-section data for MT=103, corresponding to (z,p).
^{24}Mg	1225	File 3 only gives cross-section data for MT=102, corresponding to (z,γ).
^{100}Mo	4249	File 3 only gives cross-section data for MT=102, corresponding to (z,γ).
^{98}Mo	4243	File only gives cross-section data for MT=102, corresponding to (z,γ).
^{92}Mo	4225	File 3 only gives cross-section data for MT=102, corresponding to (z,γ).
^{59}Ni	2828	File 3 only gives cross-section data for MT=102, 103, and 107, corresponding to (z,γ), (z,p), and (z,α).
^{46}Ti	2225	File 3 only gives cross-section data for MT=103.
^{47}Ti	2228	File 3 only gives cross-section data for MT=28 and 103, corresponding to (z,np) and (z,p).
^{48}Ti	2231	File 3 only gives cross-section data for MT=28, 103, and 107, corresponding to (z,np), (z,p), and (z,α).
^{50}Ti	2237	File 3 only gives data for MT=107 and (z,α).

In the case of the ENDF/B-VII.0 library, the thermal evaluations for $U(UO_2)$ and $O(UO_2)$ are excluded as there are some inconsistencies in the ENDF evaluations that prevent the AMPX module Y12 from processing the data.

2.2.2.1   Point-wise cross-section data

The following AMPX modules are used to create the point-wise neutron cross-section data.

POLIDENT

Whether cross sections are being prepared for continuous energy applications (CE-KENO or the CENTRM module in SCALE for resonance self-shielding) or for multigroup applications, the first module that will be executed is the POLIDENT module. For resonance nuclides, POLIDENT contains a procedure that determines a point energy mesh in the resolved resonance region and calculates the cross sections on the energy mesh. An analogous procedure is performed for nuclides having unresolved resonance data. For all nuclides, POLIDENT combines the resonance functions with the ENDF/B File 3 point data files to produce linearized cross-section functions. The combined data functions are written out in a standard AMPX tabular data format which is based on the ENDF/B TAB1 format.[5]

TGEL and DCON

One of the primary reasons to linearize the cross-section data is to produce internally consistent data sets. When all of the cross-section data are produced on a linear-linear grid, the sum of a group of linear functions is itself linear; however, simply linearizing the data that are given in an evaluation does not lead to this consistency. To ensure consistency, the total cross section and other "redundant" reactions (e.g., fission, inelastic) are formed by summing the partial values. The TGEL or DCON modules are used to ensure all redundant reactions are equal to the sum of the partial reactions. The output is written in the same tabular format that is used by POLIDENT.

BROADEN

Many applications, especially those dealing with reactors, need cross sections that vary as a function of temperature. The point cross sections can be Doppler broadened by a numerical treatment used in the BROADEN module. The output data from BROADEN are exported in an AMPX tabular format.

JERGENS

An energy-dependent weighting function is needed to produce multigroup cross sections. The JERGENS module provides a large variety of options for generating weighting spectra. JERGENS has options for calculating weighting spectra that may use point cross sections from POLIDENT. The output is written in an AMPX tabular format. To calculate the group-averaged infinite dilute cross sections, JERGENS was used to produce a "smooth" weighting spectrum that has the form of a Maxwellian—1/E—fission spectrum—1/E above 10 MeV. The weighting spectrum used for infinitely dilute group cross sections is shown in Fig. 2.4. The weighting spectrum is normalized with the factor $1/(\sigma_T + \sigma_0)$, where σ_T is the total cross section and σ_0 the background cross section.
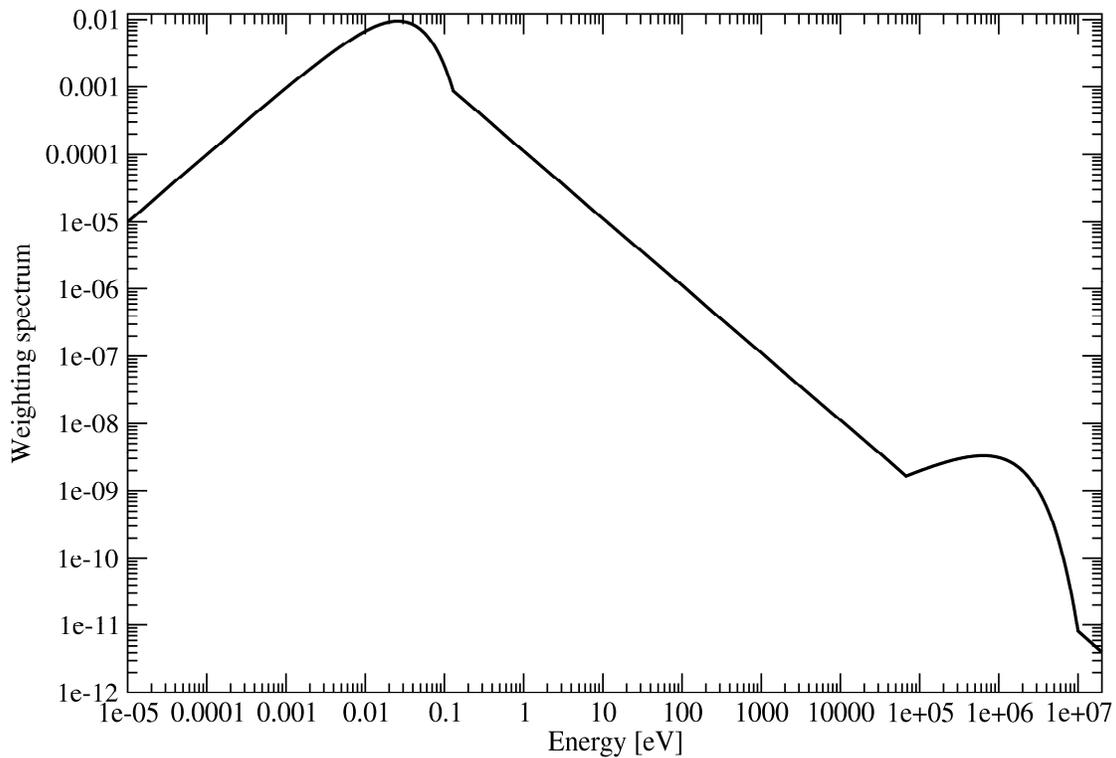

Fig. 2.4 Weighting spectrum generated by JERGENS.

Input template used

The input was generated using an XML template. The XML template used is given in Appendix A. The following is the generated AMPX input file for ^{235}U.

Input files have been processed on a DEC Alpha Tru64 machine, a 32-bit Linux machine, and a 64-bit Intel Mac. The differences, between the point-wise data from the different computing systems, are mostly smaller than 10^{-3}, the precision to which the energy grid was determined. In a few instances (^{148}Nd, ^{108}Cd, ^{239}Pu) larger differences are found due to rounding differences between the three platforms. For the final library, the data generated on the 64-bit Intel Mac were used.

The BROADEN module does not add additional points while performing Doppler broadening. This posed a problem at the boundary between the resolved and unresolved region and at the end of the unresolved range when generating Bondarenko factors. As the cross section in the unresolved region does not vary rapidly, normally relatively few energy points are needed to describe the point-wise cross-section data adequately. However, at the low energy end and the high energy range of the unresolved resonance region, the point-wise cross section may show discontinuities. This is an artifact of the evaluation. The ENDF formats and procedures[5] do not define the procedure for treating discontinuities. The BROADEN module incorrectly interprets these discontinuities as sharp resonances unless there is a sufficient number of energy points on either site of the discontinuity. Therefore, the module POLIDENT has been updated to add 10 additional energy points at both ends of the unresolved resonance range to correct the problem for BROADEN.

2.2.2.2   Comparison with NJOY

For verification purposes, the AMPX-processed data were compared to NJOY-generated data.[6] To investigate differences between the two programs that are relevant to the coupled library productions, we converted the point-wise data into group averaged data using a flux of Maxwellian 1/E fission spectrum—1/E above 10 MeV. Group averaged data were compared at 300 K because this temperature is used for the coupled library. Because AMPX leaves redundant reactions in the master library, whereas NJOY deletes them, these reactions are excluded from the comparison. Overall, the agreement with NJOY is good.

Differences are mostly due to the fact that the Doppler broadening module, BROADR, in NJOY adds additional data points whereas the AMPX BROADEN routine does not. As an example, we present the capture cross section in ^{140}Ce in Fig. 2.5.
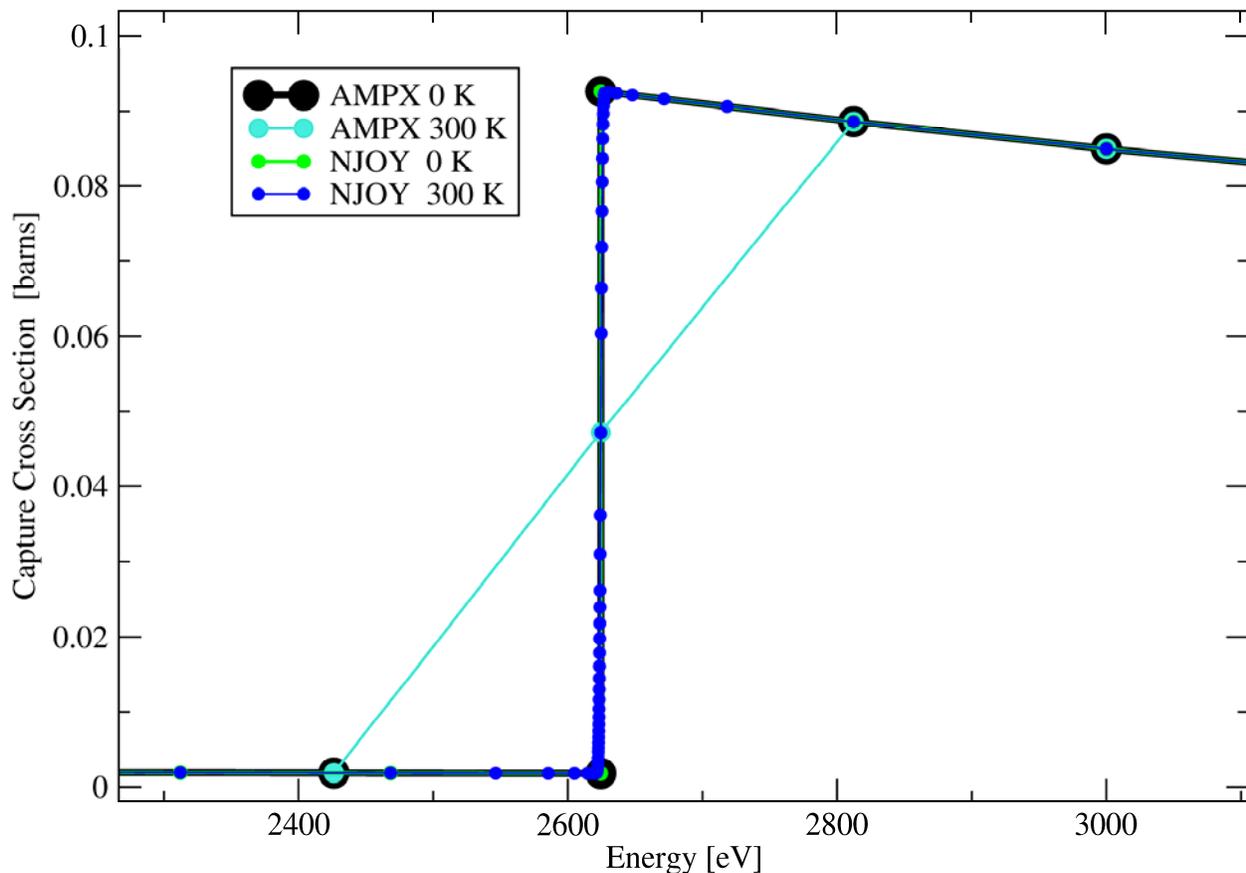

Fig. 2.5 Point-wise capture cross section as processed with AMPX and NJOY for ^{140}Ce.

2.2.2.3   Neutron and gamma yield processing

Fast neutron evaluation

Y12

A feature unique to the AMPX system is the Y12 module. This module reads an ENDF/B evaluation and produces tabular double-differential collision kinematics data for all reactions. The functions it produces tell what particles are produced and at what energies and directions when a reaction is encountered at some source energy point. The output from Y12 is an AMPX tabular kinematics file.

X10

The X10 module reads tabular point cross sections, a tabular weighting spectrum, and the tabular kinematics data file and uses these three files to produce group-averaged cross sections factors and group-to-group transfer matrices. This code contains no programming related to the physics of any reaction and is programmed in a manner that treats neutron data, gamma-ray data, or gamma-ray yield data. The output from X10 is a set of group cross sections that are written on a file in the AMPX master library format.

When a cross-section evaluation contains gamma-production data, either in ENDF File 6 or in the special Files 12, 13, 14, and 15, the kinematics data file produced by Y12, along with the point data files from POLIDENT and JERGENS are passed to X10 to produce gamma-ray yield transfer matrices. The gamma yield matrices tell where gamma rays are produced as a function of neutron reaction. The yield data are exported from X10 in an AMPX master library format. After the gamma transport data are processed in a separate AMPX sequence, the gamma yield data are coupled with the multigroup neutron and gamma-ray data.

Input files have been processed on a DEC Alpha Tru64 machine, a 32-bit Linux machine, and a 64-bit Intel Mac. For the final library, the data generated on the 64-bit Intel Mac were used.

2.2.2.4 Thermal neutron processing

FLANGE6

If the nuclide is a nonmoderator material, the FLANGE6 module is used to produce thermal scattering matrices at 300, 600, 900, 1200, and 2100 K based on the free-gas scattering model. The matrices are exported in the AMPX master library format.

JERGENS, Y12, and X10

If the nuclide is a moderator material with ENDF $S(\alpha,\beta)$ data (e.g., water-bound hydrogen, graphite), the thermal ENDF/B evaluations are processed by the Y12 module to produce thermal kinematics data as a function of temperatures provided in the ENDF/B evaluation. The thermal scatter kernel for other materials is represented as free gas. In addition, the Y12 module produces thermal point-wise cross-section data. The resulting thermal kinematics file and thermal point-wise cross-section file are passed to the X10 module, along with the JERGENS weighting spectrum, to produce a special thermal AMPX master library.

Special requirements for BeO

In all of the ENDF/B thermal scattering laws except BeO, the cross sections for the principal isotope in a compound can be isolated. For example, the thermal data for water gives the scattering law data for hydrogen in a manner that describes the specific binding effects for having hydrogen present in a water molecule. The file then specifies that oxygen should simply be treated by the free-gas model. This is very convenient because it allows one to produce a set of full-range cross sections for water-bound hydrogen by collecting together the thermal hydrogen values and combining them with the values from the fast neutron hydrogen evaluation. For BeO, it is not possible to separate the beryllium behavior (or oxygen) out of the data for the BeO molecule. The scattering law data are given for the molecule as a combined unit. There are several ways one can deal with this situation. The one that was chosen to be analogous to the water-bound hydrogen case was to couple the data from the fast neutron evaluation for Be with the thermal BeO data, and call this set "Be bound in BeO." For the oxygen component, a special set is prepared and called "O bound in BeO." For the O in BeO case, the oxygen data are prepared from the fast neutron evaluation without any thermal data (i.e., no thermal scattering data as would normally be present from a free-gas calculation by the FLANGE6 module).

Input for moderator data

The input was generated using an XML template. The XML template used is given in Appendix A. The following is the generated AMPX input file for hydrogen in H_2O.

end
=shell
cp ft41f001 ${RTNDIR}/../neutron/u235_flange6
end
```

Input files have been processed on a DEC Alpha Tru64 machine, a 32-bit Linux machine, and a 64-bit Intel Mac. The cross-section data produced on the 64-bit Intel Mac are used in the final coupled library.

Differences between the results on the three platforms exist, even if the Legendre coefficients are expanded and the real scattering matrices are compared. This is most likely due to rounding effects because mostly small scattering values are affected. The differences do not have significant impact on the library data.

2.2.2.5 *Generating full-range Bondarenko factors and thermal data*

To facilitate self-shielding calculations, full-range Bondarenko factors for several temperatures and background cross sections are supplied on the coupled library. The Bondarenko method is basically a self-shielding method that parameterizes cross sections for a nuclide as a function of temperature, T, and the "background" cross section, σ_0, of all the other nuclides mixed with the nuclide. Simplistically, given the temperature and background cross-section values, one determines self-shielded cross sections by interpolating in tables. Since self-shielding causes the "background" values that a nuclide sees to change, an iterative procedure involving all nuclides is used.

PRUDE

For nuclides with unresolved resonance data, the PRUDE module must be run to produce point "averaged" cross sections that are a function of temperature and "background" cross section. The background cross section is simply defined as the cross section per unit atom of a nuclide of the mixture (other than the nuclide itself) in which the nuclide is mixed. In the sequences that were prepared, temperatures of 300, 900, and 2100 K were chosen, along with background values of 10^{-6}, 1, 10, 100, 1000, 10^4, 10^5, 10^6, and 10^8. The cross sections are written out in an AMPX tabular file. This module can only be run for mono-isotopic evaluations.

FABULOUS

For all nuclides, the point data from PRUDE (if applicable) and POLIDENT are passed to the FABULOUS module with the weighting spectrum file from JERGENS. FABULOUS uses the same temperatures and background cross sections described for PRUDE to numerically Doppler broaden the functions exterior to the unresolved region, after which the functions are spliced together with the appropriate unresolved functions. These spliced functions are then used in a numerical scheme that calculates Bondarenko factors for all nuclides for elastic scattering, capture, fission, and total cross sections. The Bondarenko factors can be used in resonance self-shielding calculations.

Input files

The input was generated using an XML template. The XML template used is given in Appendix A. The following is the generated AMPX input file for ^{235}U.

Input files have been processed on a DEC Alpha Tru64 machine, a 32-bit Linux machine, and a 64-bit Intel Mac. The data generated on the 64-bit Intel Mac were used for the final library.

During the course of the library generation, several issues were discovered and corrected in PRUDE and FABULOUS. The PRUDE module calculates the point-wise cross sections for the unresolved resonance range for different values of σ_0, combining File 2 and File 3 data if necessary. The same calculation is done in the POLIDENT module for infinite dilution. The two modules produced inconsistent results because the combining was done in two different ways. The PRUDE module was updated to use the same methods as POLIDENT. The infinite diluted cross-section data are now consistent between the two modules.

Initially the FABULOUS module could not process all evaluations because some of the unresolved cross-section data are negative for lower values of σ_0 (i.e., highly self-shielded). This is most likely due to Single-Level Breit-Wigner (SLBW) approximation. Calculation of the "total" Bondarenko factor is given by

$$\frac{\int \dfrac{\phi\sigma_T}{\left(\sigma_T + \sigma_0\right)^2}}{\int \dfrac{\phi}{\left(\sigma_T + \sigma_0\right)^2}} \quad . \tag{2.1}$$

The value for $\left(\sigma_T + \sigma_0\right)$ can become negative. The NJOY[6] manual describes how the calculation in the UNRES function is done, which is similar to the PRUDE calculation. The manual states that for the higher actinides the approximation used in calculating this quantity can produce negative shielded cross-section data for lower values of σ_0. This should not be a problem as the higher actinides are rarely present in these quantities in a reactor. The affected evaluations are [238]Np, [242m]Am, [242]Am, and [253]Cf. In addition, an infinite loop was discovered in FABULOUS for [238]Np because the code tried to use a step-size smaller than the available computer precision. This problem and some overstepped bounds issues have been fixed.

Greater than expected differences were found between the Bondarenko factors calculated in Linux and on Tru64. These differences occurred because the Doppler broadening routine in FABULOUS converts the energy into velocity-like terms for the Bondarenko calculation. These terms are converted back to energy afterwards. On occasion, the end points of the unresolved resonance range may not be included in the

final point-wise cross-section data due to this conversion. The code has been updated to always include these end points. After these changes, good agreement is obtained for the Bondarenko factors calculated on the three platforms.

2.2.2.6 *Gamma processing*

The processing for gamma-ray interactions is much simpler in contrast to neutron interactions. Most of the important gamma-ray scattering reactions are due to interactions of the gamma ray with the electrons in a nucleus. Since the number of electrons in a nucleus is just the Z-value, the cross sections are calculated on a per electron basis and simply multiplied by Z to get the value for a nuclide. Since Z is the same for all isotopes of an element, one only has to calculate values for the elements. Furthermore, there are only two processes—incoherent (Klein-Nishina) and coherent (Rutherford) scattering—to be treated. There is only one exception to the number of processes, and this exception is the pair-production of two 0.511 MeV photons.

JERGENS

The JERGENS module is used to produce a weighting spectrum. For gamma-ray processing, the spectrum is typically a 1/E spectrum with "roll-offs" that account for significant absorption of the gamma rays because of photoelectric absorption. As before, the weighting spectrum is written out in a point-wise AMPX tabular file based on the ENDF/B TAB1 format.

Y12

The Y12 module produces a tabular kinematics file that describes coherent and incoherent scattering and pair production. In addition, Y12 produces a point-wise data file for all of these processes, and the point-wise file is exported in an AMPX tabular format.

X10

The tabular files from JERGENS and Y12 are passed to X10 with the tabular kinematics file. X10 produces a group-averaged AMPX master library for gamma-ray interactions.

RADE and PALEALE

The RADE module is used to perform internal consistency checks on the AMPX master library containing the gamma-ray interaction data. The PALEALE module is used to print the content of the library and allows data checking.

Gamma interaction data used

The Photo-Atomic interaction sublibrary of ENDF/B-VI.8 and ENDF/B-VII.0 were used in the library generation effort. In both cases data exist for the following 100 elements:

H He Li Be B C N O F Ne Na Mg Al Si P S Cl Ar K Ca Sc Ti V Cr Mn Fe Co Ni Cu Zn Ga Ge

As Se Br Kr Rb Sr Y Zr Nb Mo Tc Ru Rh Ce Pr Nd Pm Sm Eu Gd Tb Dy Ho Er Tm Yb Lu Hf

Ta W Re Os Ir Pt Au Hg Tl Pb Bi Po At Rn Fr Ra Ac Th Pa U Np Pu Am Cm Bk Cf Es Fm

Input used to process gamma cross-section data

The input was generated using an XML template. The XML template used is given in Appendix A.
The following is the generated AMPX input file for uranium.

Input files have been processed on a DEC Alpha Tru64 machine, a 32-bit Linux machine, and a 64-bit
Intel Mac. While the data processed on all three platforms were compared, no significant differences
were found, and the final library uses the data generated on the 64-bit Intel Mac.

Processing of gamma data

File 23 containing "smooth" photon interaction cross sections gives the data for MT=502, photon coherent scattering in the range from 1.0 eV to 1.0×10^{11} eV. These data need to be combined with form factors from File 27, MT=502 (form factor), MT=505 (imaginary scattering factor), and MT=506 (real scattering factor), which are given over the ranges 0.0 eV to 1.0×10^9 eV, 1.0 eV to 1.0×10^7 eV, and 1.0 eV to 1.0×10^7 eV, respectively. The program then tries to interpolate for energies listed for MT=502 and warns that the interpolation is outside the range. In the case of tungsten, the two values bracketing the 1.0×10^7 eV in MT=502 are 7.070513×10^6 eV and 2.135261×10^7 eV. The program gives a warning and assumes that the desired value is 0.0.

While the number of energy points in File 23 for MT=502 change for the various elements, the data for MT=505 and MT=506 in File 27 come in the range from 1.0 eV to 1.0×10^7 eV for all elements. Thus, the above problem is present for all elements used in the coupled library.

On Tru64, Y12 fails for hydrogen as the last two interpolation points for File 27 and MT=502 are given as $(1.0 \times 10^6; 8.18290 \times 10^{-27})$ and $(1.0 \times 10^9; 8.18290 \times 10^{-39})$. After the last two values are changed to 0.0 in the ENDF file, the calculation succeeds.

Data generated on Linux and on Tru64 show greater than expected differences in the scattering matrix for MT=504 for the lower energy groups. This is due to rounding effects in the calculations of the grid for the Klein-Nishina scattering, where Y12 reconstructs the point-wise scattering in terms of the scatter-cosine, which is given as a function of incident energy E and scattered energy E' as

$$\frac{e'}{e} = \frac{1}{1 + e(1 - \mu)} \quad , \tag{2.2}$$

where e and e' are the energy in terms of the electron mass unit $e = E / 0.5110034$. A function then calculates the cosine of the scattering angle from the above formula as

$$\mu = 1 + \frac{1}{e} - \frac{1}{e'} = 1 + \frac{5.110034 \times 10^5 \times (E' - E)}{E \times E'} \quad , \tag{2.3}$$

using the first approach after first calculating e and e', all in single precision. In single precision, the two forms of the equation can have two difference values. An example is $E = 1.0$ eV and $E' = 0.99999607$. In this case, the first form yields $\mu = -1.0186844$ and the second form $\mu = -1.0102476$. The later is consistent with the value calculated for both forms of the equation if calculation is done in double precision. This can lead to large differences. An example is silicon, where the largest difference is found scattering from group 41 to 41 in the fourth Legendre coefficient: single precision 4.0716E–02, double precision –1.6598E–01. For the final library, all calculations in the Y12 klein_nishina function were done internally in double precision and returned as single precision values.

After these changes, good agreement is obtained for gamma cross-section data generated on the three platforms.

Comparison with NJOY

For independent verification purposes, the AMPX-processed data were compared to NJOY-generated data.[6] The NJOY code was used to process the gamma evaluations. The groupwise ENDF files generated by GAMINR were converted to AMPX master files using SMILER. This module converts MT=522 to MT=527 and MT=525 to MT=1527—this feature is temporarily disabled to allow direct comparison. All NJOY files have the following one-dimensional (1-D) MT values: 501, 502, 504, 516, 522, 525, and 1599. The MT=1599 gives the flux and MT=525 is not defined in the ENDF-VI or ENDF-V reaction list. The NJOY manual states that this is the heating cross section defined in ENDF-V as 621.

AMPX writes out more reaction values because it keeps the redundant reactions.

The flux written by GAMINR is not normalized to the sum of the flux over all energy groups as is done for gamma processes in X10. SMILER has been changed to write out the normalized flux to allow a direct comparison between the results from AMPX and NJOY.

Summation over total and redundant reactions

X10 first calculates the group averages for all reactions listed in the ENDF file as translated by Y12. The following reactions are than treated in a special manner.

If MT=515 (pair production, electron field) or MT=517 (pair production, nuclear field) exists, the redundant reaction MT=516 (pair production) is created as the sum of the two, erasing all previous data in the reaction that might have been set by the ENDF evaluation. If MT=516 does not previously exist, it is **NOT** created, even if MT=515 or MT=517 exists.

If any MT in the range MT=534–572 (subshell photoelectric or electro-atomic cross section for various atomic levels) exist, then calculate

$$\text{MT=522} \quad = \quad \sum x_{MT} \qquad \qquad \text{Photoelectric absorption. (In version 5, this was MT=602.)}$$

$$\text{MT=602} \quad = \quad \sum x_{MT} \qquad \qquad \text{Photoelectric absorption.}$$

$$\text{MT=527} \quad = \quad \sum x_{MT} + x_{MT=602} \; ,$$

where x_{MT} is the group averaged cross section for the indicated reaction and the sum extends over reaction numbers MT=534–572. The total cross section is then recalculated as

$$\text{MT} \; = \; 501 \; = \; x_{MT \, = \, 502} \; + \; x_{MT \, = \, 504} \; + \; x_{MT \, = \, 516} \; + \; x_{MT \, = \, 522} \; .$$

(These calculations are done in the subroutine fixsums_g of X10).

Not all evaluations considered for the coupled library include MT=527 or MT=602, which are added by X10 as outlined above. All evaluations include MT=515, 516, and 517, and X10 will recalculate MT=516. All evaluations include MT=522, which will be erased by X10 and recalculated as outlined above. All evaluations include MT=501, which will be erased by X10 and recalculated as outlined above.

AMPX defines some special MT values. MT=527 is the sum of all gamma-ray absorption processes (in contrast to the ENDF defined value where it is defined as electro-atomic bremsstrahlung). MT=602 is still assumed to be photoelectric absorption, and the group-averaged cross-section data for MT=602 and

MT=522 are identical in the final library. MT=1527 is the gamma energy absorption coefficient or kerma factor. NJOY writes this into MT=527 in GAMINR.

One-dimensional processes

AMPX and NJOY results are compared for MT=501, 502, 504, 516, and 522 because these cross sections are directly comparable between the two programs. No significant differences were found.

Two-dimensional processes

To compare the two-dimensional (2-D) processes, we first compared the Legendre coefficients. If there was a big difference between NJOY and AMPX for these, we expanded the Legendre series and compared the scattering matrices directly. An example of the observed differences can be seen in Fig. 2.6 for MT=504 in hydrogen. Scattering is from group 1 to group 38.
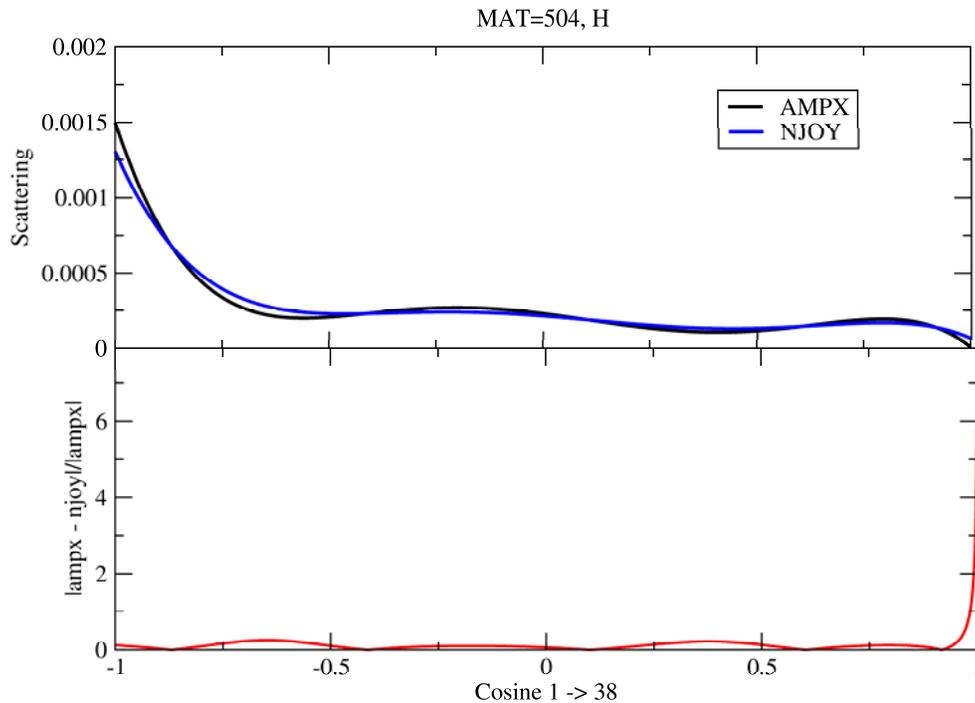

Fig. 2.6 AMPX and NJOY scattering data for MT=504 in hydrogen.   Scattering is from group 1 to group 38.

2.2.2.7   Creating the master library

Three steps are needed to create the final master library.

1. Create a master library for each evaluation containing the neutron data, Bondarenko shielding factors, and gamma data. In the case of moderator data, the fast evaluation also needs to be combined into this master library. The ENDF material ID needs to be changed to the SCALE ID.

2. Combine the master libraries for various evaluations into one master library.

3. Add dose data to the master library.

The steps are outlined in more detail below.

Create master library for each evaluation

The master library for nonmoderator data needs to contain gamma data, fast neutron data, neutron yield data, and Bondarenko data. In addition, several SCALE specific identifiers need to be set. Input files are generated from XML templates which are given in Appendix A. The following is the generated AMPX input for ^{235}U.

```
=shell
ln -sf  ${RTNDIR}/../neutron/u235_fast ft01f001
ln -sf ${RTNDIR}/../neutron/u235_yield ft02f001
ln -sf ${RTNDIR}/../neutron/u235_fabulous ft03f001
ln -sf ${RTNDIR}/../neutron/u235_flange6 ft04f001
ln -sf ${RTNDIR}/../gamma/u_master ft05f001
end
=simonize
Identifier=92235 master=20 source=endf

end
```

2.2.3 Adding dose data

The SCALE master library contains dose factor data as listed in Table 2.8. The same dose data are used for all three libraries (i.e., the ENDF/B-VI.8 fine-group library and the ENDF/B-VII.0 fine-group and broad-group libraries).

Table 2.8 Available dose functions on the coupled neutron-gamma libraries

Some gamma dose factors did not extend to higher energies and the JERGENS module needed to be changed to extend the dose factors. In these cases an extrapolation to higher energies was used as follows.

9503: Claiborne-Trubey conversion factors (rad/h)/(photons/cm^2/s)

We used an interpolation with five coefficients and interpolated from 6×10^6 eV to 1.48×10^7 eV. The interpolation was used for energies above 15 MeV. The following formula was used.

$$y = C_0 * \exp\left(C_1 + C_2 X + C_3 X^2 + C_4 X^3 + C_5 X^4\right)$$

$$X = \ln(E), \text{E in eV}$$

$$C_0 = 6.65922 \times 10^{-11}$$

$$C_1 = 2.91298$$

$$C_2 = 0.622646$$

$$C_3 = -0.00467212$$

$$C_4 = -0.00105295$$

$$C_5 = 6.73012 \times 10^{-5}$$

The interpolation is shown in Fig. 2.7.
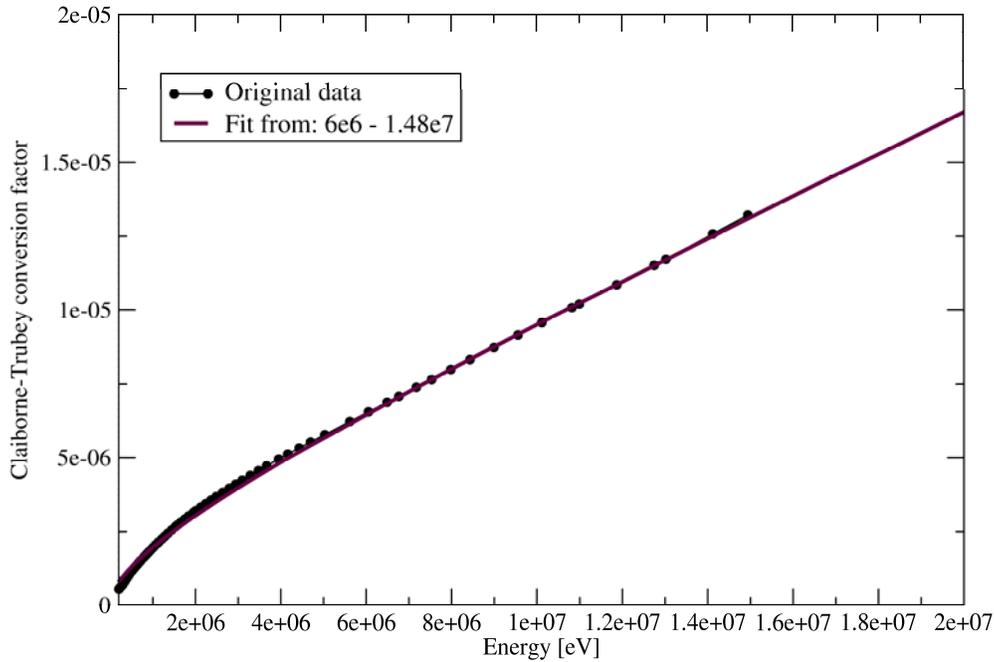

Fig. 2.7 Interpolation for Claiborne-Trubey gamma dose function.

9506 and 9507: International Commission on Radiation Units and Measurements, Report 57 (ICRU-57), Table A.21 (air) Kerma

We used an interpolation with five coefficients and interpolated from 4×10^6 eV to 1.0×10^7 eV. The interpolation was used for energies above 10 MeV. The formula is as follows.

$$y = C_0 * \exp\left(C_1 + C_2 X + C_3 X^2 + C_4 X^3 + C_5 X^4\right)$$

$$X = \ln(E), E \text{ in eV}$$

$$C_0 = 4.422278 \times 10^{-6}$$

$$C_1 = -0.898794$$

$$C_2 = 1.4646$$

$$C_3 = -0.0209916$$

$$C_4 = -0.00152315$$

$$C_5 = 6.80427 \times 10^{-5}$$

(The factor C_0 takes into account that the JERGENS module scales the internal results to obtain the results in (Gy/h)/(photons/cm^2/s) or (rad/h)/(photons/cm^2/s). The interpolation is shown in Fig. 2.8.
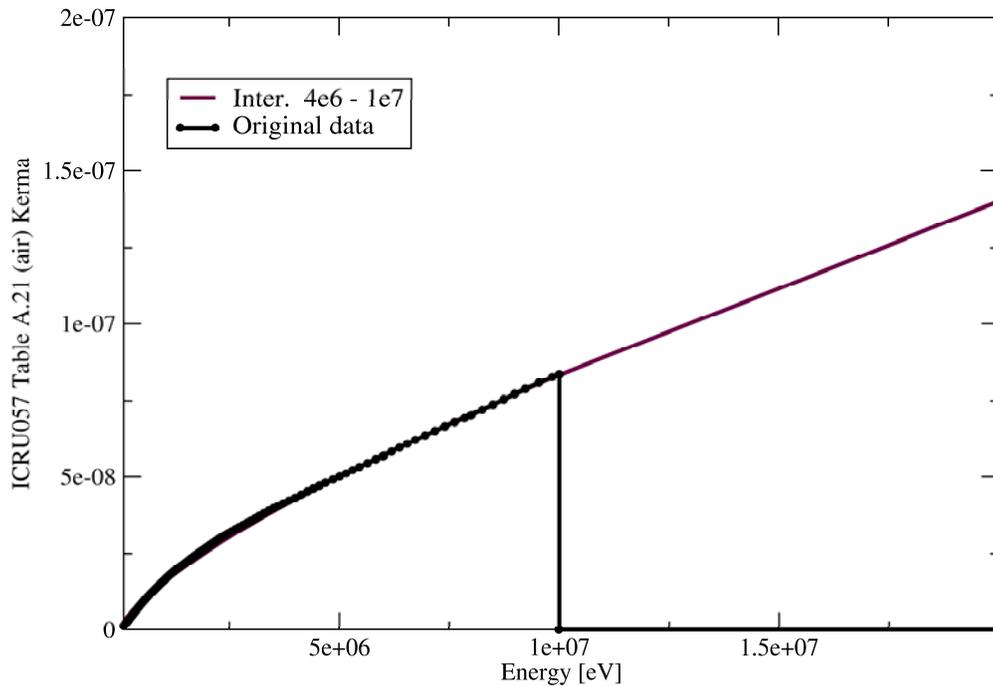

Fig. 2.8 Interpolation for ICRU-57, Table A.21 (air) Kerma gamma dose function.

9508 and 9509: Ambient dose equivalent (ICRU-57, Table A.21)

We used an interpolation with five coefficients and interpolated from 4×10^6 eV to 1.0×10^7 eV. The interpolation was used for energies above 10 MeV. The formula is as follows.

$$y \quad = \quad C_0 * \exp\left(C_1 + C_2 X + C_3 X^2 + C_4 X^3 + C_5 X^4\right)$$

$$X \quad = \quad \ln(E), \text{E in eV}$$

$$C_0 \quad = \quad 8.043111 \times 10^{-10}$$

$$C_1 \quad = \quad -11.8556$$

$$C_2 \quad = \quad 4.52715$$

$$C_3 \quad = \quad -0.0788323$$

$$C_4 \quad = \quad -0.0110208$$

$$C_5 \quad = \quad 0.000440013$$

(The factor C_0 takes into account that the JERGENS module scales the internal result to obtain the results in (Sv/h)/(photons/cm^2/s) or (rem/h)/(photons/cm^2/s). The interpolation is shown in Fig. 2.9.
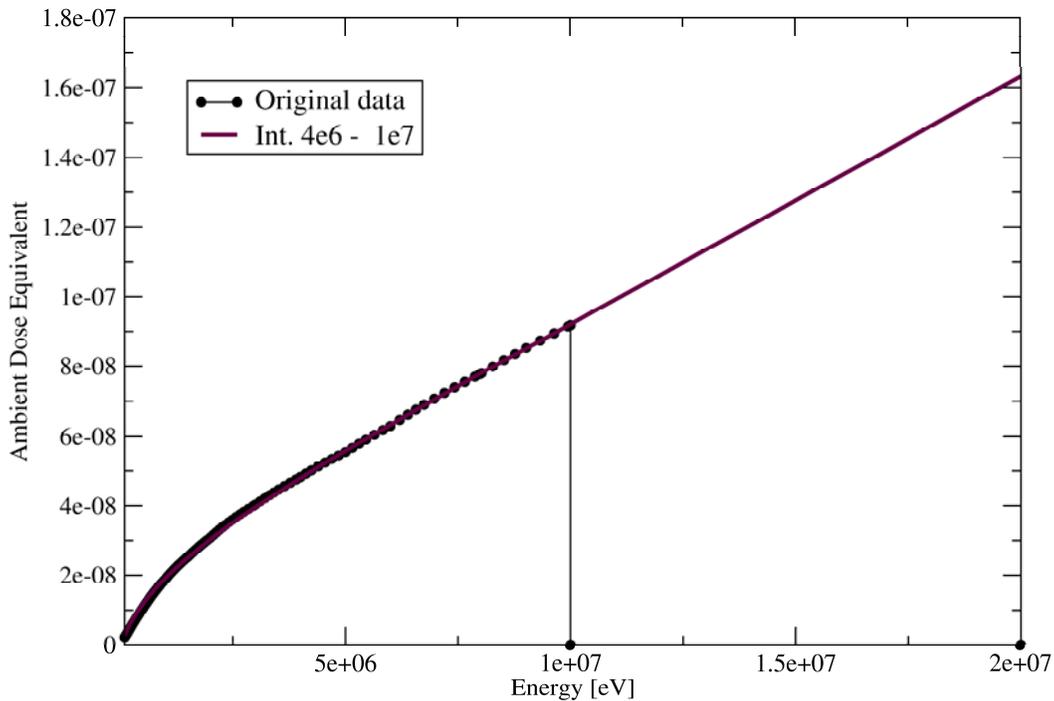

Fig. 2.9 Interpolation for ambient dose equivalent (ICRU-57, Table A.21).

9510 and 9511 Effective dose (ICRU-57, Table A.17) (Sv/h)/(photons/cm^2/s)

We used an interpolation with five coefficients and interpolated from 4×10^6 eV to 1.0×10^7 eV. The interpolation was used for energies above 10 MeV. The formula is as follows.

$$y \quad = \quad C_0 * \exp\left(C_1 + C_2 X + C_3 X^2 + C_4 X^3 + C_5 X^4\right)$$

$$X \quad = \quad \ln(E), E \text{ in eV}$$

$$C_0 \quad = \quad 2.154528\text{e-}5$$

$$C_1 \quad = \quad 4.74445$$

$$C_2 \quad = \quad 1.12057$$

$$C_3 \quad = \quad -0.0487202$$

$$C_4 \quad = \quad -0.00119816$$

$$C_5 \quad = \quad 0.000129643$$

(The factor C_0 takes into account that the JERGENS module scales the internal result to obtain the results in (Sv/h)/(photons/cm^2/s) or (rem/h)/(photons/cm^2/s). The interpolation is depicted in Fig. 2.10.
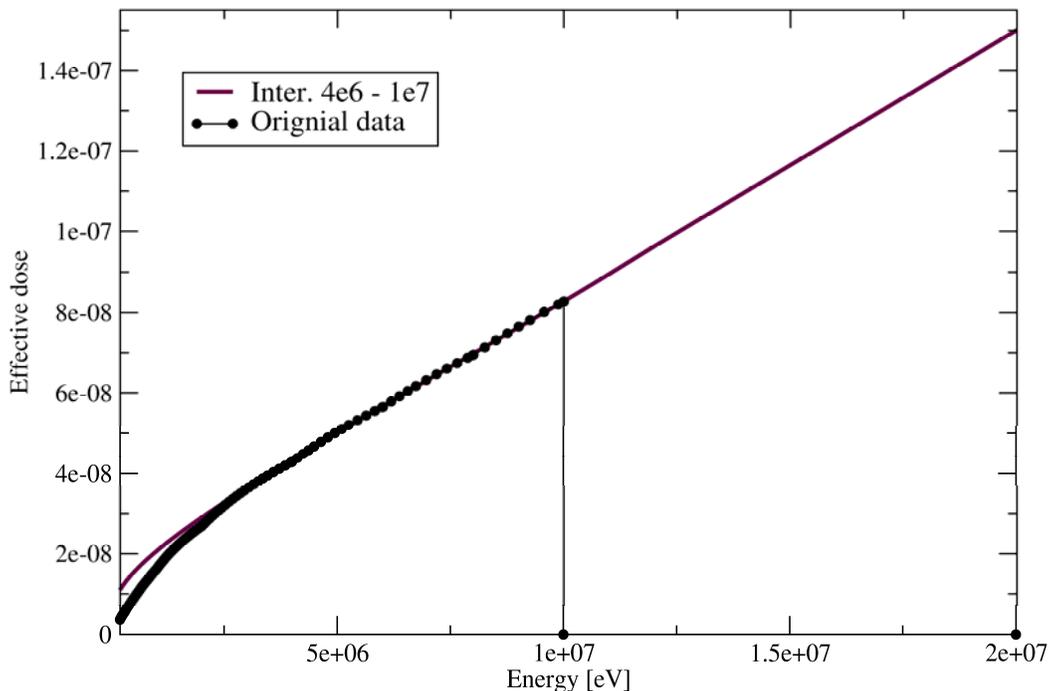

Fig. 2.10 Interpolation for effective dose (ICRU-57, Table A.17) .

Using AMPX, coupled neutron-gamma libraries were generated for ENDF/B-VI.8 and ENDF/B-VII.0. Complete listings of the ENDF/B-VI.8 and ENDF/B-VII.0 libraries are provided in Appendixes B and C, respectively.

3   BENCHMARK TESTING

As noted in the Introduction, new shielding capabilities have been developed for SCALE along with the ENDF/B-VI.8 and ENDF/B-VII.0 coupled library development. To this end, benchmark testing was performed to test both the new shielding transport capabilities and the new data libraries. As a result, the initial series of benchmark calculations have been used to compare the previous SCALE 5.1 Shielding Analysis Sequence Number 4 (SAS4) shielding sequence with the new MAVRIC sequence in SCALE 6. The SAS4-MAVRIC comparisons are used to verify the new transport capability relative to the previous SAS4 capability. These comparison calculations were performed using the ENDF/B-VI.8 coupled library. Because of this, the SAS4-MAVRIC calculations serve to verify the new shielding capability with the ENDF/B-VI.8 library. After the SAS4-MAVRIC comparisons, the ENDF/B-VI.8 and ENDF/B-VII.0 libraries are used with MAVRIC for benchmark calculations to validate the performance of MAVRIC and the ENDF/B-VI.8 and ENDF/B-VII.0 libraries.

3.1   SAS4 and MAVRIC Benchmark Comparison Calculations with ENDF/B-VI.8 Library

The new ENDF/B-VI.8 200 neutron group and 47 gamma group shielding library was tested by benchmarking the computational results against the results obtained with the previous SCALE shielding library, which was ENDF/B-IV with 27 neutron and 18 gamma groups. The computational results with the new library were also benchmarked against experimental measurements. The computations were performed using both the SAS4 and MAVRIC sequences of SCALE. SAS4 uses MORSE to perform Monte Carlo radiation transport along with XSDRN to create 1-D biasing parameters. MAVRIC uses Monaco to perform the Monte Carlo radiation transport and Denovo to create 3-D biasing parameters. Three sets of experimental measurements were selected for comparison purposes. All three consist of dose measurements on the outer surface of fully loaded spent nuclear fuel storage casks. Where feasible, SAS4 in the SCALE 5.1 release was used to model these storage casks with the new ENDF/B-VI.8 and the old ENDF/B-IV shielding libraries. MAVRIC, which is to be released as part of the SCALE 6 package, was also used to model each of these casks with the ENDF/B-VI.8 and ENDF/B-IV shielding libraries. Details about the storage casks, measurements, and previous validation calculations with SCALE 4.3 can be found in EPRI report TR-104329 (Ref. 7). A brief summary of the current verification and validation calculations for each cask and the computational results are presented in the following sections.

3.1.1 Cask descriptions

3.1.1.1 CASTOR-V/21

The CASTOR (**CA**sk for **S**torage and **T**ransport **O**f **R**adioactive material) cask was developed by Gesellschaft für Nuklear Service. This cask consists of a cast-iron body, and is 4.9 m tall and 2.4 m in diameter. Two concentric rows of polyethylene rods are incorporated in the cask wall to provide neutron shielding. The external surface consists of heat transfer fins oriented circumferentially around the cask surface. The fuel basket is configured to hold 21 pressurized water reactor (PWR) spent fuel assemblies and is constructed of stainless steel and borated stainless steel. The vertical and horizontal 2-D slices of the CASTOR geometry, as represented in Monaco using the SCALE Generalized Geometry Package (SGGP) are shown in Fig. 3.1. The green and pink rectangles and squares in Fig. 3.1 represent the homogenized fuel assemblies. The red regions in Fig. 3.1 above and below the fuel assemblies represents the end fittings where the ^{60}Co activation sources are located.

| Vertical Slice of CASTOR | Horizontal Slice of CASTOR |
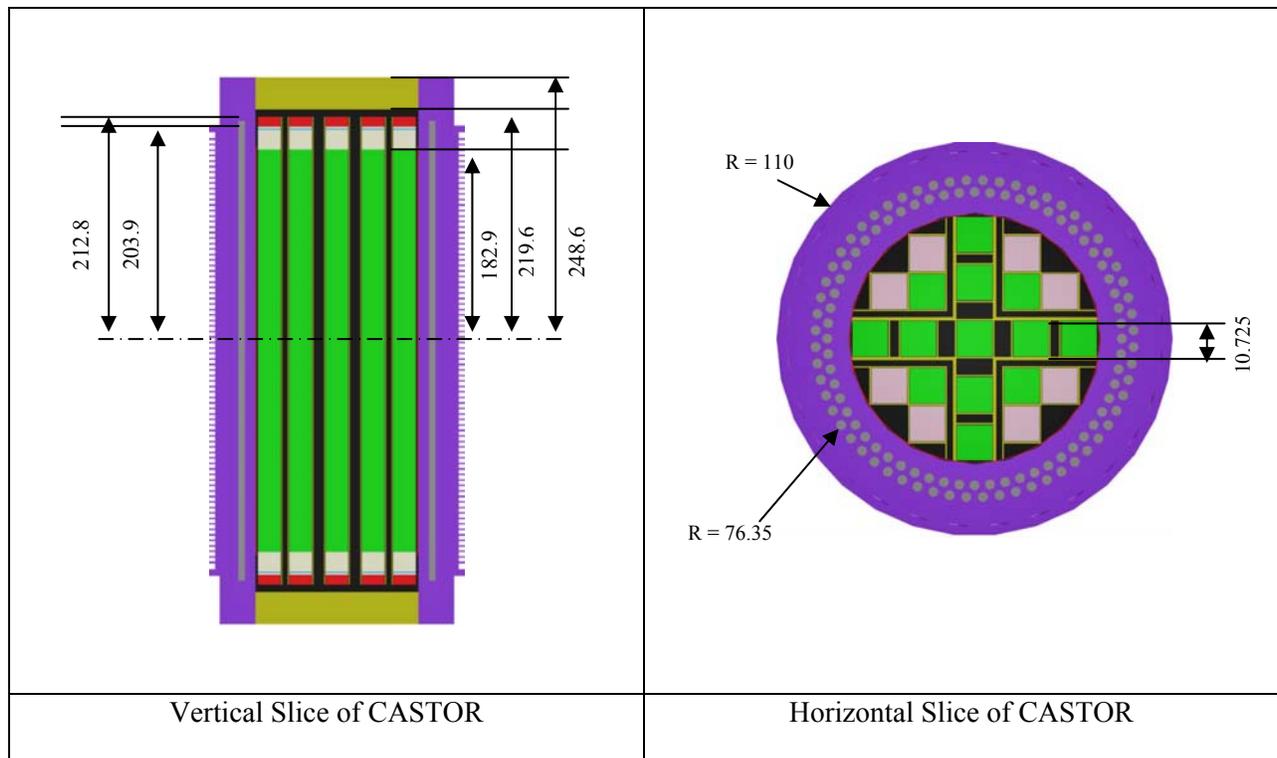

Fig. 3.1 Views of cask for storage and transport of radioactive material (CASTOR). (Dimensions in centimeters.)

3.1.1.2   *Westinghouse MC-10*

The Westinghouse MC-10 PWR spent fuel cask consists of a forged steel body. The cask is 4.8 m tall
and 2.7 m in diameter. Neutron shielding is provided by a layer of BISCO NS-3 on the outside of the
cask. The fuel basket is configured to hold 24 PWR spent fuel assemblies and is constructed of
aluminum. Each of the 24 basket locations contains a removable stainless steel enclosure and neutron
poison material for criticality control. Figure 3.2 shows 2-D slices of the MC-10 geometry as represented
in Monaco using SGGP. The green and magenta rectangles and squares in Fig. 3.2 represent the
homogenized fuel assemblies. The red regions above and below the fuel assemblies in Fig. 3.2 represents
the end fittings where the ^{60}Co activation sources are located.

| Vertical Slice of MC-10 | Horizontal Slice of MC-10 |
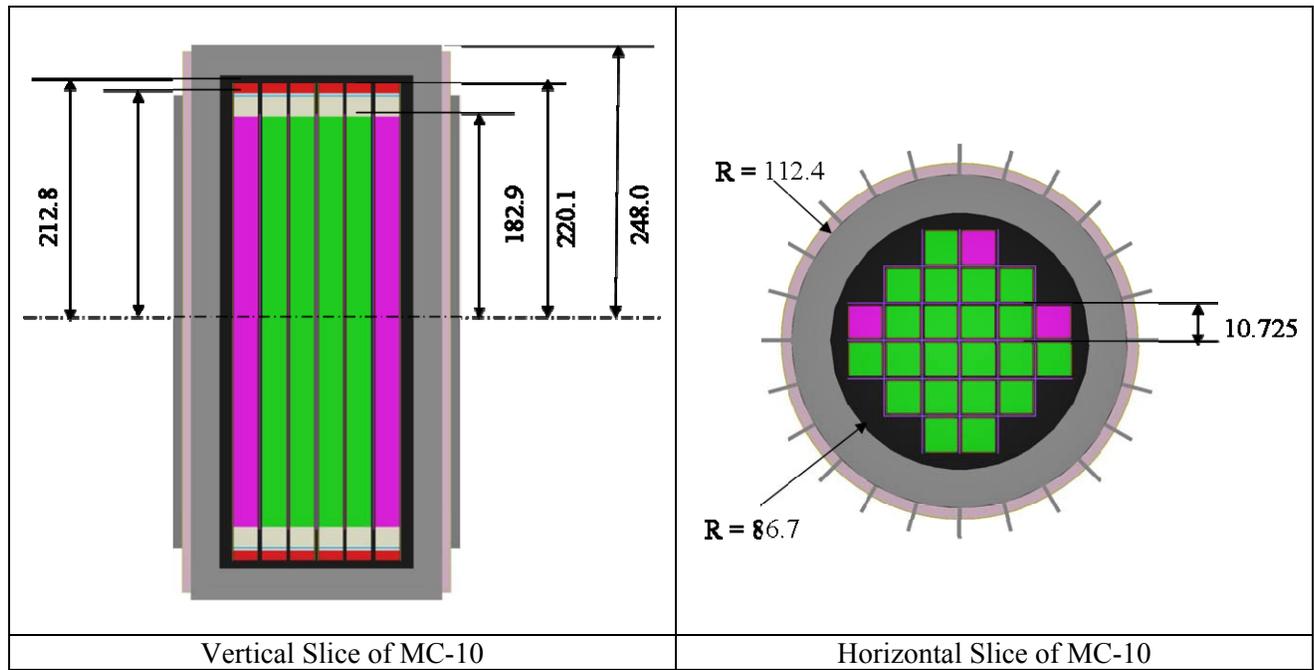

Fig. 3.2 Views of MC-10 cask. (Dimensions in centimeters.)

3.1.1.3   TN-24P

The TN-24P cask was developed by Transnuclear, Inc. The TN-24P cask also has a forged steel body, but is surrounded by a thin layer of resin enclosed in a steel outer shell. The resin is for neutron shielding. The TN-24P cask is 5 m tall and 2.3 m in diameter. The fuel basket will also hold 24 PWR spent fuel assemblies and is constructed of aluminum and boron plates. The vertical and horizontal 2-D slices of the TN-24P geometry, as represented in Monaco using the standard KENO-VI geometry package, are shown in Fig. 3.3. The dark blue and aquamarine rectangles and squares in Fig. 3.3 represent the homogenized fuel assemblies. The light blue above and below the fuel assemblies in Fig. 3.3 represents the end fittings where the ^{60}Co activation sources are located.

| Vertical Slice of TN-24P | Horizontal Slice of TN-24P |
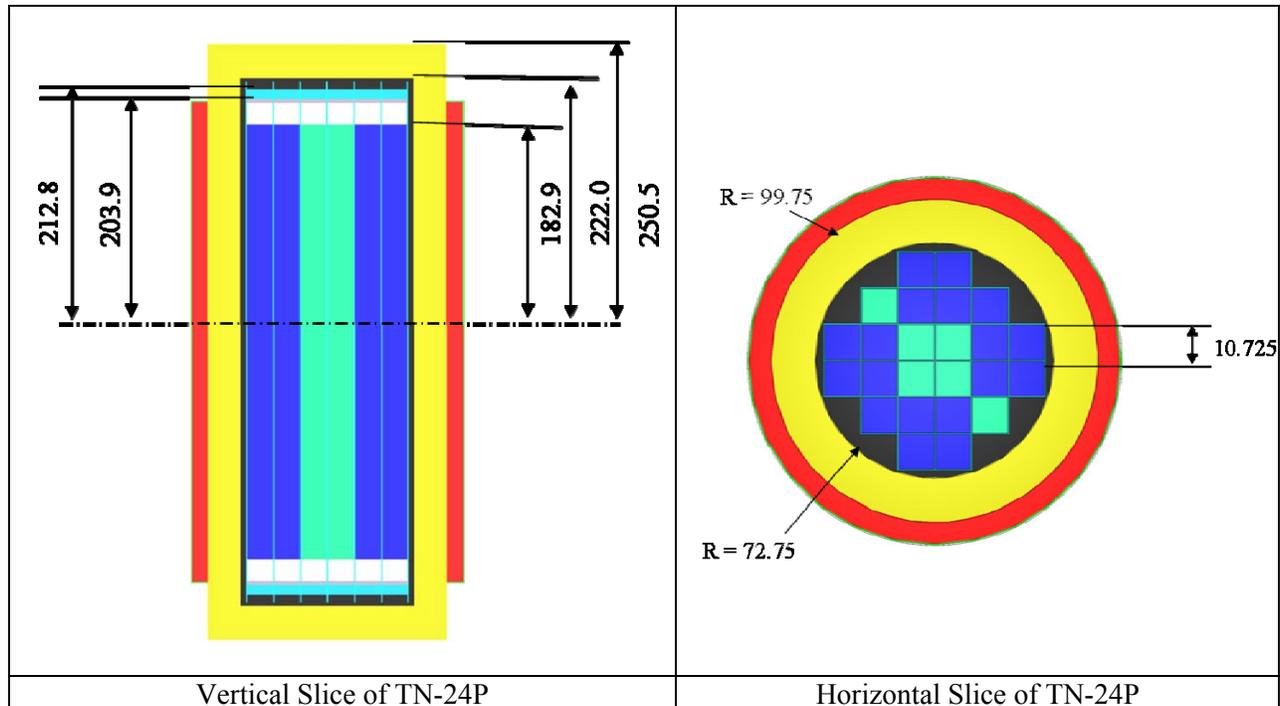

Fig. 3.3 Views of TN-24P cask. (Dimensions in centimeters.)

3.1.2   Calculations

Each cask was loaded with spent Westinghouse 15×15 fuel assemblies. The initial enrichment, burnup, and cooling times for all the fuel assemblies are described in Ref. 7. For the calculations with the ENDF/B-IV shielding library, the neutron and gamma sources from the spent fuel in the previous SCALE 4.3 SAS4 calculations were used. For the ENDF/B-VI.8 library, the data from Ref. 7, which described the life of the spent fuel assemblies, were entered into OrigenArp, and the neutron and photon sources from the spent fuel were calculated using the ENDF/B-VI.8 shielding library group structure. The version of OrigenArp that was used in this process is the version that was released with SCALE 5.1. The previous SCALE 4.3 SAS4 calculations most likely used the version of ORIGEN-S that was released with SCALE 4.3 to create the spent fuel sources, so this could be one source of differences in comparison of old and new calculated results. Similarly, the ^{60}Co sources previously used in the SCALE 4.3 SAS4 calculations were used again with the ENDF/B-IV library. For the ENDF/B-VI.8 shielding library, the 27 neutron-18 gamma group structure was converted to the new 200 neutron-47 gamma group structure. In this conversion, energy was conserved rather than number of particles.

Dose measurements were made at several different points on the top, bottom, and radial (near the fuel midplane) surfaces of each cask. SAS4 calculates dose averaged over a surface that represents the average of the measurements made at the different points on the surfaces of each cask. However, in the current version, Monaco does not yet have the capability of tallying on a surface. Therefore, very thin (1 mm thick) volume tallies were used instead of surface tallies. For the side or radial doses, the averaging surface is an outside cask surface (either the fin tips or the cask body) with an extent corresponding to the middle half of the fuel height. This is similar to the measurements made in Ref. 7. The top and bottom doses are on the top and bottom surfaces respectively, with radii also similar to those used in Ref. 7. These similarities allow for a more direct comparison between the calculations and experimental measurements.

SAS4 requires that the cask model be symmetric around the fuel midplane, so the geometries for the top and bottom doses vary slightly above and below the active fuel region. Since this variation is very small, either the top or bottom geometry could be used to calculate the radial doses. Therefore, the Monaco geometries were also modeled symmetric about the fuel midplane, instead of using the actual geometries, to be consistent with the SAS4 simulations. The source types referred to in Table 3.1, Table 3.3, and Table 3.5 are all spent fuel assemblies, except for Co source type, which is a ^{60}Co activation source. The same nomenclature as in Ref. 7 is used in this report to designate source or spent fuel assembly types. The full details about each spent fuel assembly and ^{60}Co source are given in Ref. 7, Section 3.

3.1.2.1   Computational results

The input summary for each cask and the computed results using MAVRIC and SAS4, where available, with the ENDF/B-VI.8 and ENDF/B-IV shielding cross sections are presented in the following tables. The computational results were benchmarked against measurements as well, and the results are presented at the end of this section.

Table 3.1 summarizes the geometry, source type, tally location, and particle type tallied for all the different TN-24P cask calculations.

Table 3.1 TN-24P calculations input summary

The ratio of the computed values using the new (ENDF/B-VI.8, 200 neutron and 47 gamma groups) and old (ENDF/B-IV, 27 neutron and 18 gamma groups) shielding libraries for all the TN-24P cask calculations are shown in Fig. 3.4. The corresponding geometries and source types for the case numbers were described in Table 3.1. In these figures red and blue points represent the computed ratios using SAS4 in SCALE 5.1 and MAVRIC, respectively. The error bars represent two sigma values.

As can be seen from the figures, the computed ratios using SAS4 in SCALE 5.1 and MAVRIC are in good agreement, within statistical fluctuations, for all tallies. Therefore, both codes show similar behavior when the same libraries are used. Furthermore, the ratios are above 1 (from a few percent up to 30%) for all the neutron tallies and below 1 (20% to 50%) for all the gamma tallies for both codes in a very consistent way. However, there are substantial differences in the response values computed with the two different versions of ENDF data.
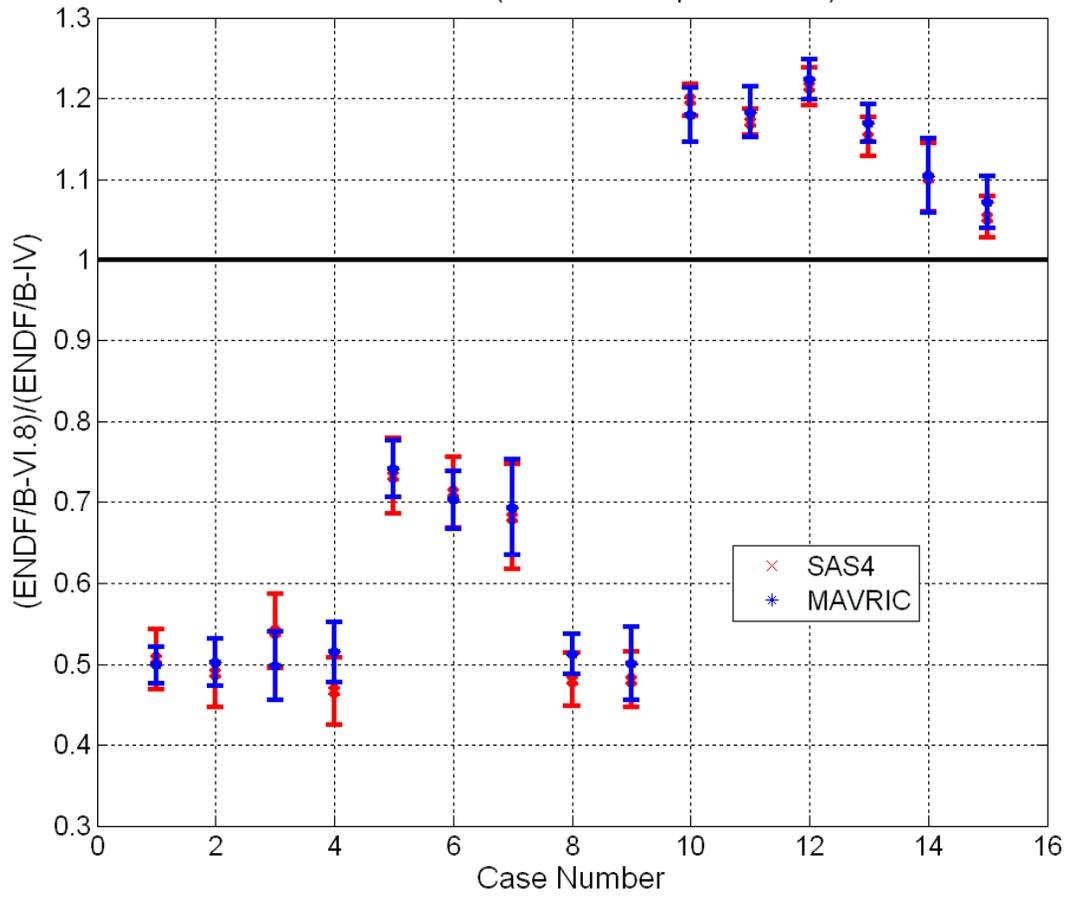

Fig. 3.4 The ratio of the computed TN-24P cask tallies using the ENDF/B-VI.8 and ENDF/B-IV shielding cross sections. The red and blue points represent the computed ratios using SAS4 in SCALE 5.1 and MAVRIC, respectively. The error bars represent two standard deviations.

For code comparison, the ratios of the computed values using MAVRIC and SAS4 in SCALE 5.1 with both the ENDF/B-VI.8 and ENDF/B-IV shielding libraries, for the results in Table 3.2, are shown in Fig. 3.5. As can be seen from the figures, the two codes are in agreement within ±20%.
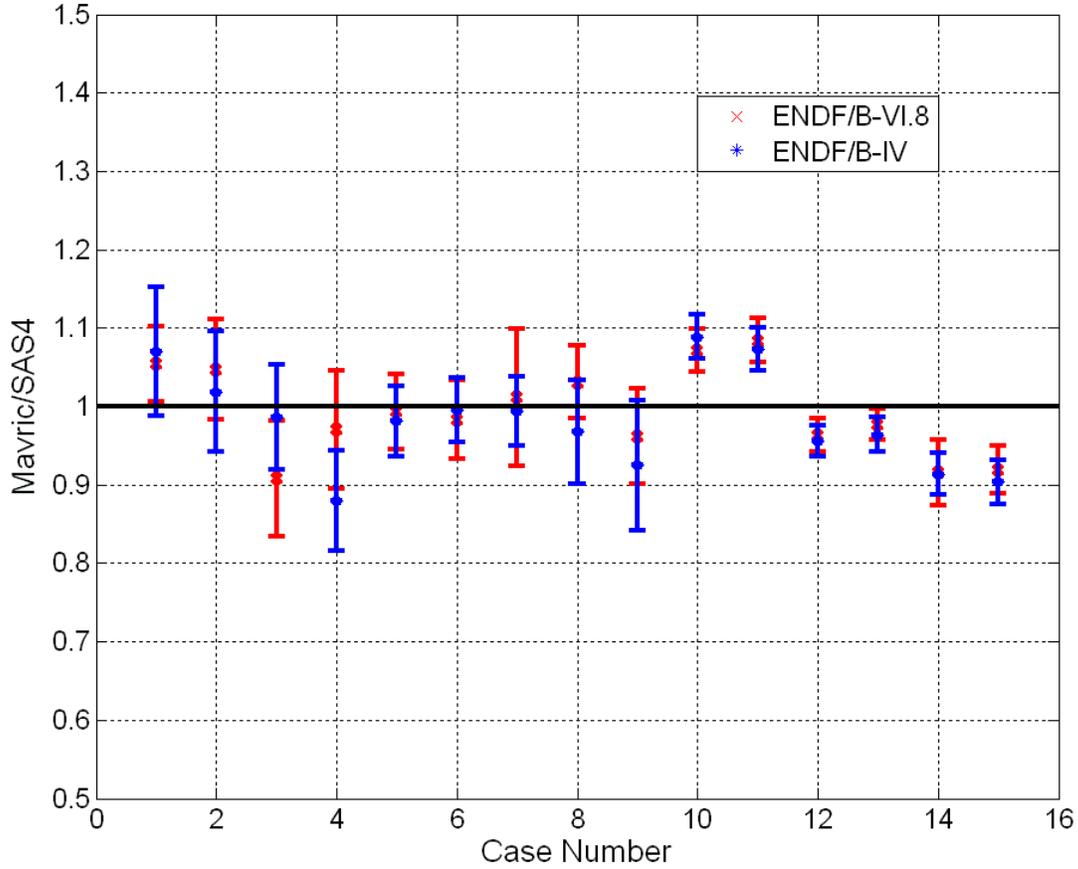

Fig. 3.5 The ratios of the computed TN-24P cask tallies using MAVRIC and SAS4. In this figure, the red and blue points represent the computed ratios using the ENDF/B-VI.8 (new) and ENDF/B-IV (old) cross sections, respectively. The error bars represent two standard deviations.

The geometry, source type, tally location, and particle type tallied for all the different MC-10 cask calculations are summarized in Table 3.3.

The ratio of the computed values using MAVRIC with the ENDF/B-VI.8 and ENDF/B-IV shielding libraries for all the CASTOR cask tallies are shown in Fig. 3.7. The corresponding geometries and source types for the case numbers were described in Table 3.5. In these figures, the error bars represent two sigma values.

As can be seen from the figures, the ratios are above 1 (up to 80%) for all the neutron tallies and below 1 (up to 50%) for all the gamma tallies.
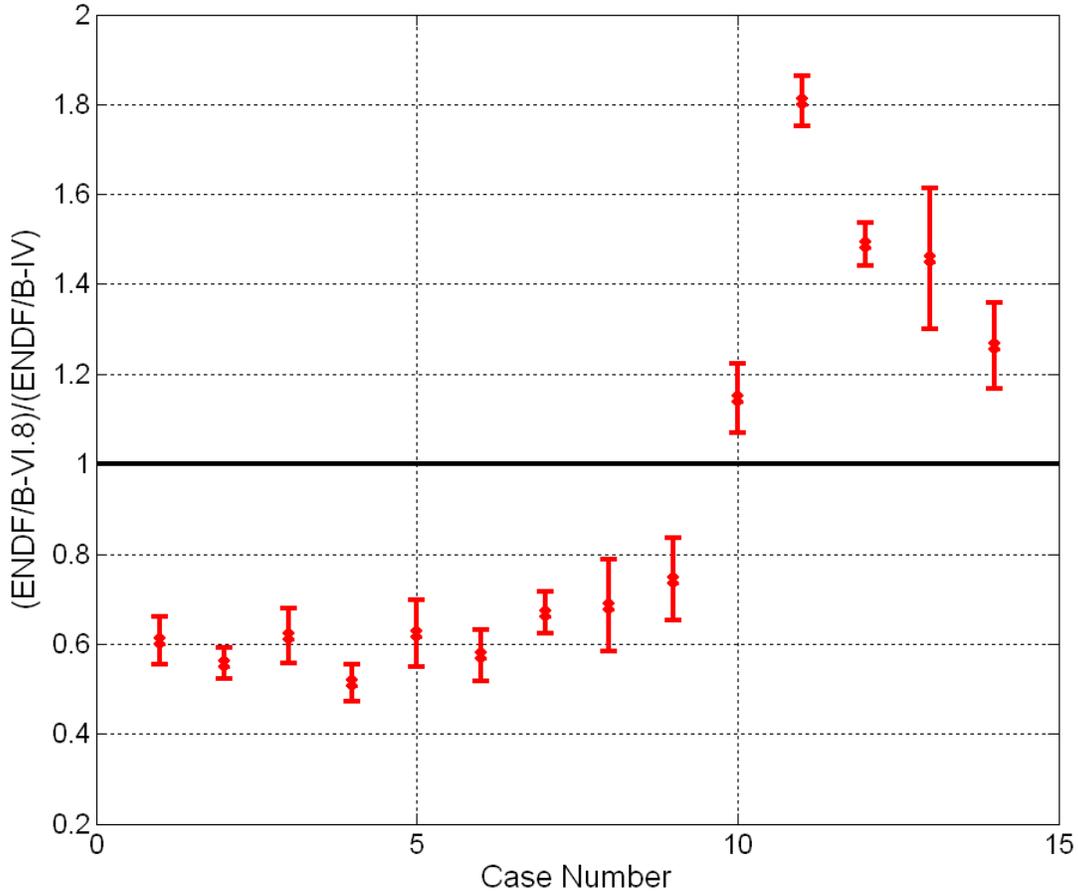

Fig. 3.7 The ratio of the computed CASTOR cask values using the ENDF/B-VI.8 and ENDF/B-IV shielding cross-section libraries with MAVRIC.

3.1.2.2   Benchmark against experimental measurement

The computational results using MAVRIC with both shielding libraries were benchmarked against the measured data points. The measured, computed (using both the ENDF/B-VI.8 and ENDF/B-IV libraries), and the ratio of computed to measured (C/M) data for neutron cases are presented in Table 3.7. The C/M ratios for the neutron cases for both the ENDF/B-VI.8 and ENDF/B-IV shielding libraries are plotted in Fig. 3.8.

As shown in Table 3.7 and Fig. 3.8, overall the computed values using the ENDF/B-VI.8 shielding library are higher than the values computed using the ENDF/B-IV shielding library. There is better agreement with the measured values using the ENDF/B-VI.8 library for cases 8 and 9. Since the uncertainties in the measured values are not available, it is not clear whether the change in the ratios is within the statistical uncertainty.

**Table 3.7 The measured and computed neutron dose rates and the ratio of
computed to measured (C/M) dose rates for each cask model**

Case no.	Cask type	Geometry	Meas. (mrem/h)	ENDF/B-IV (mrem/h)	ENDF/B-VI.8 (mrem/h)	C/M ENDF/B-IV	C/M ENDF/B-VI.8
1	TN24	Bottom	57.90	74.09	87.48	1.28	1.51
2		Side	2.80	1.45	1.76	0.52	0.63
3		Top	28.50	27.37	29.93	0.96	1.05

8		Side	11.40	7.76	12.75	0.68	1.12
9		Top	51.50	44.61	60.35	0.87	1.17
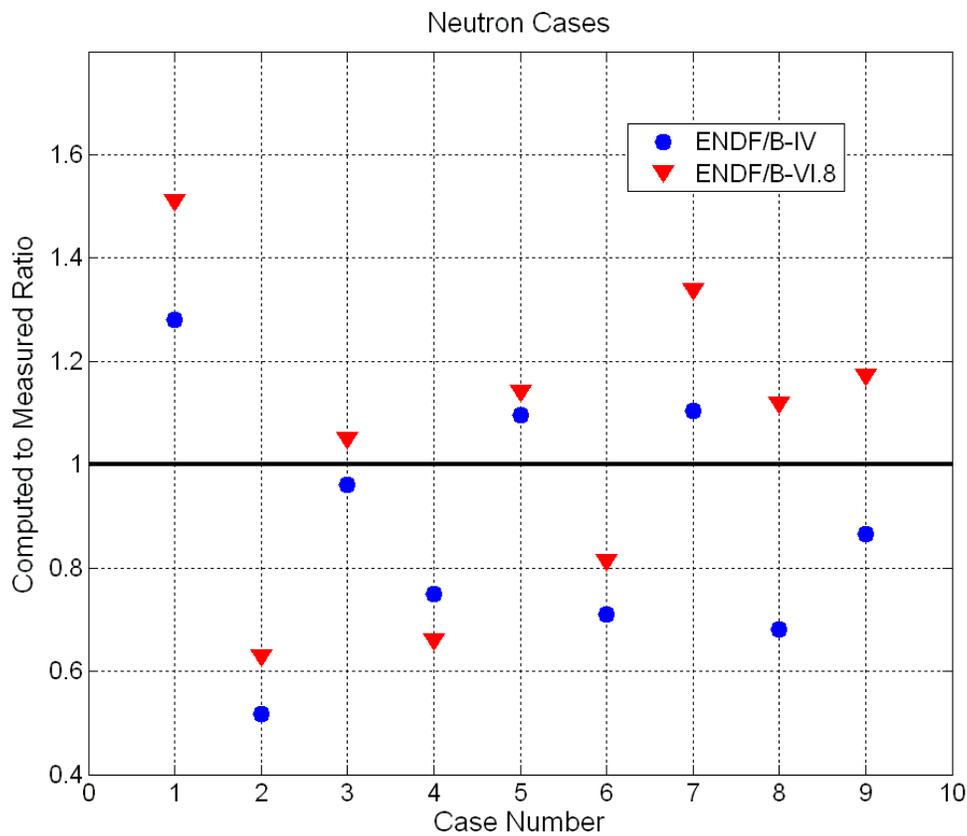

**Fig. 3.8 The ratio of the computed to measured values using MAVRIC with the
ENDF/B-VI.8 (new) and ENDF/B-IV (old) libraries for the neutron dose rates.**

The measured, computed (using both the ENDF/B-VI.8 and ENDF/B-IV shielding libraries), and C/M ratio data for the gamma cases are presented in Table 3.8. The C/M ratios for these cases for both the ENDF/B-VI.8 and ENDF/B-IV shielding libraries are plotted in Fig. 3.9. As presented in the table and figure, for the gamma cases, the computed values using the ENDF/B-VI.8 shielding library are lower than the values computed using the ENDF/B-IV shielding library. This trend was investigated further and found to be consistent with a neglect of coherent scattering at relatively low photon energies in the older library. Indeed it appears that the older library used gamma data that preceded ENDF/B-IV. The newer library has a much stronger theoretical basis. There is better agreement with the measured values using the ENDF/B-VI.8 library for case 6, and for cases 2, 5, and 8 even though the discrepancies for these cases are still between 40 and 50%. However for cases 1, 3, 4, 7, and 9, the agreement with the measured data was better with the ENDF/B-IV shielding library. Since the uncertainties in the measured values are not available, it is not clear whether the change in the ratios is within the experimental uncertainty.

3.2   MAVRIC Benchmark Calculations Using ENDF/B-VI.8 and ENDF/B-VII.0 Libraries

3.2.1   Neutron fields in three-section concrete labyrinth from ^{252}Cf source

3.2.1.1   Benchmark overview

Experimental measurements of the neutron flux from a ^{252}Cf source through an 18 m concrete labyrinth were made in Russia in 1982 to obtain benchmark data for code validation.[8]

Two sources were used: (1) a bare ^{252}Cf neutron source and (2) a ^{252}Cf neutron source encased in a polyethylene sphere.

Six labyrinths were constructed.

1. Empty, three-section labyrinth.
2. First corner is lined with polyethylene plates covered with cadmium.
3. First corner is lined with polyethylene plates without cadmium.
4. Two corners are lined with borated concrete.
5. Two polyethylene plates are installed in the second leg of the labyrinth (bare source only).

6. Dead end at the end of the first leg of the labyrinth.

Seven Bonner sphere detectors [with ^{6}LiI(Eu) crystal] were used.

1. 2 in. diameter, cadmium covered
2. 3 in. diameter, cadmium covered
3. 5 in. diameter, cadmium covered
4. 5 in. diameter, not covered
5. 8 in. diameter, cadmium covered
6. 10 in. diameter, cadmium covered
7. 12 in. diameter, cadmium covered.

The geometry of the labyrinth is shown in Fig. 3.10.
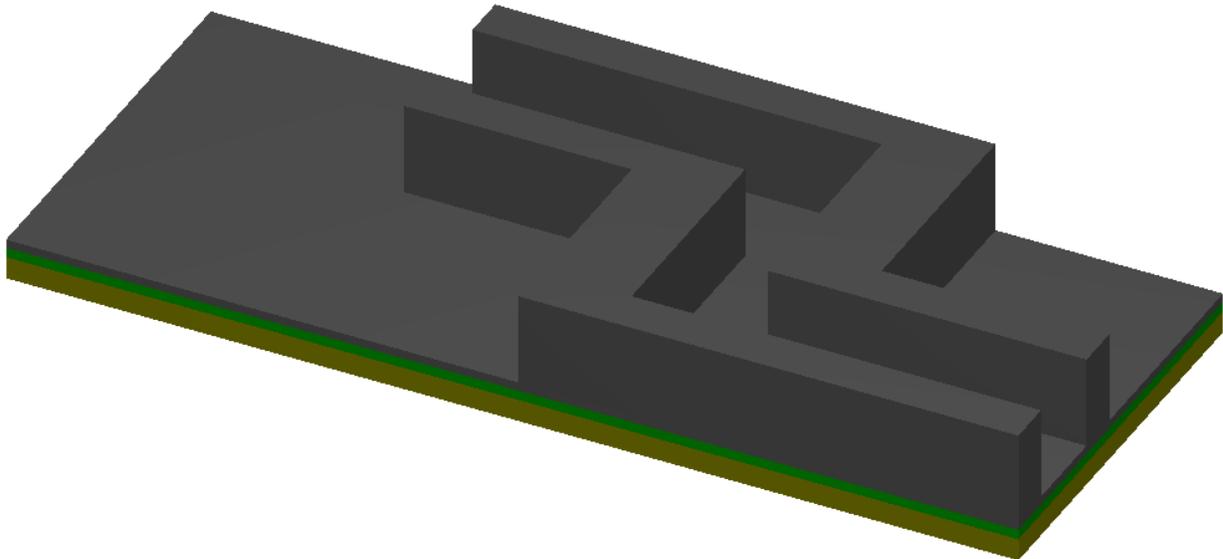

Fig. 3.10 Cutaway view of labyrinth model (ceiling removed)**.**

As part of the study in Ref. 8, benchmark calculations were performed with Monte Carlo N-particle (MCNP) code. Calculations were done in two steps: (1) the determination of the detector response in a free-field and (2) the transport of neutrons through the labyrinth, where computed fluxes were convolved with the response functions.

3.2.1.2 *Monaco/MAVRIC calculations*

Monaco and MAVRIC and the new ENDF/B-VI.8 200 neutron-47 gamma shielding library were used to compute the detector count rates measured by the various detectors for the first labyrinth design (empty, three section) using both the covered and uncovered californium (^{252}Cf) source. Calculations followed the benchmark instructions and were done in two steps.

1. Determination of the detector response function using Monaco—for each energy group, a Monaco calculation was done to find the integrated product of the ^{6}Li(n,t)^{4}He cross section and neutron flux

inside the crystal of the detector (Fig. 3.11). Monaco calculations were done for each energy group (200) incident on each detector (7).

2. MAVRIC, using the FW-CADIS method, was used to calculate neutron fluxes along the path through the labyrinth. FW-CADIS performs a quick forward discrete ordinates calculation and a quick adjoint discrete ordinates calculation to create an importance map and biased source distribution that, when used with Monaco, will give results for multiple tallies with nearly uniform statistical uncertainty. Each FW-CADIS calculation is optimized for a specific source and response, so calculations had to be done for each source (2) using each detector size (7).
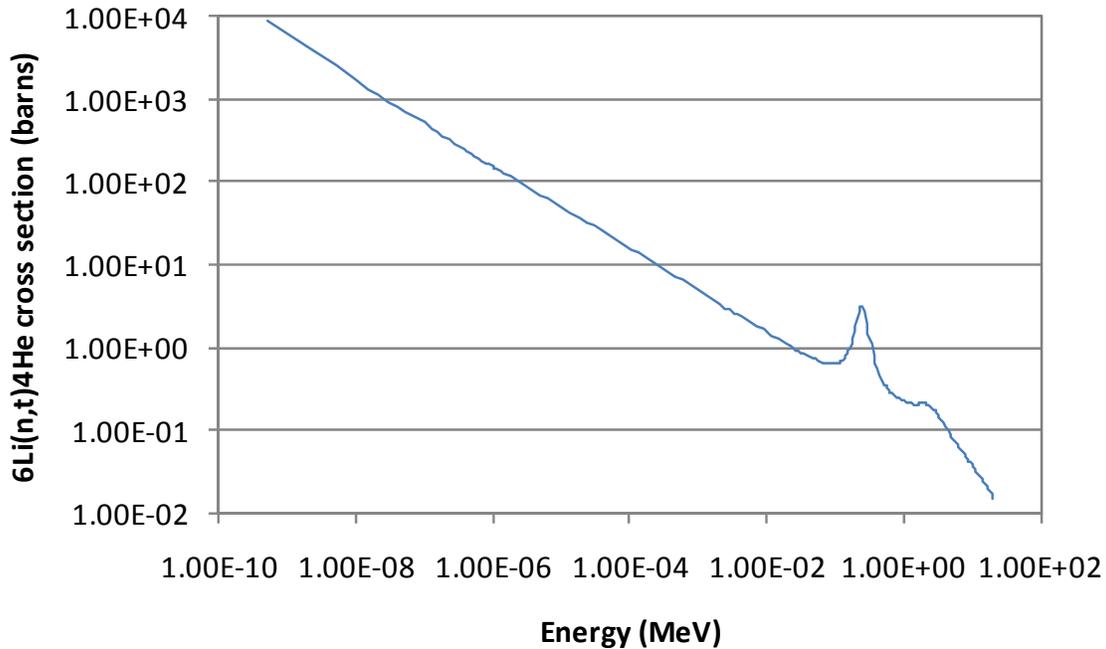

Fig. 3.11 ^{6}**Li(n,t)**^{4}**He cross section from the ENDF/B VI.8 200n/47g shielding library.**

3.2.1.3   *Detector response functions*

Seven Bonner spheres were used to measure the neutron flux through the labyrinths. Sizes were 2-, 3-, 5-, 8-, 10- and 12-inch diameters. Each was made of polyethylene ($\rho=0.92\pm0.03$ g/cm^3) with an 0.08-cm-thick cadmium layer ($\rho= 8.648$ g/cm^3). One other detector, 5 inches in diameter, had no cadmium cover. The crystal was a ^{6}LiI(Eu) cylinder, 1 cm in diameter and 1 cm high ($\rho=4.08$ g/cm^3), with a lithium enrichment of 90 at. %.

The benchmark model used by the experimental team for making detector response functions left out the europium content (since it was less than 0.3 wt %.). Source particles were started on the surface of a sphere with radius=160 cm, pointed inward striking the outer sphere of the detector model. The model of the detector is shown in Figure 20 of Ref. 8.

The Monaco model of the detector was a spherically symmetric model and included the following layers (outward, from center):

- 0.57235712 cm of LiI (to maintain volume of 0.7853982 cm³),
- 0.05 cm of TiO2,
- 0.03 cm of aluminum D16,
- 0.07 cm of void,
- 0.10 cm of aluminum D16,
- 0.05 cm of void, and
- polyethylene of the detector and its optional 0.08 cm cadmium cover.

For a detector response function, what is needed is the total number of ^{6}Li(n,t)^{4}He reactions occurring in the crystal (radius R_c) per unit flux for monoenergetic source neutrons. The count rate C(E) for incident neutrons of energy E is

$$C(E) = N_{6Li} V \int \sigma_{n,t}(E') \varphi(E') dE' \quad, \tag{3.1}$$

for a source strength S scaled such that the flux in an empty sphere the same size as the Bonner sphere (radius R_D) is unity. (This gives $S = \pi R_D^2$.)

$$C(E) = \left(\frac{1.66072 \times 10^{-2}}{b \ cm} \right) \left(\frac{4\pi}{3} R_C^3 \right) \int \sigma_{n,t}(E') \varphi(E') dE' \quad. \tag{3.2}$$

The volume of the crystal is $\frac{4\pi}{3} R_C^3 = 0.7853982 \ cm^3$.

For each detector (7), a series of 200 Monaco calculations were done (about 18 minutes each), and the responses for each incident neutron energy were determined as described above. As can be seen in Figs. 3.12–3.18, the computed detector response functions were similar to the response functions computed by MCNP in the benchmark report.
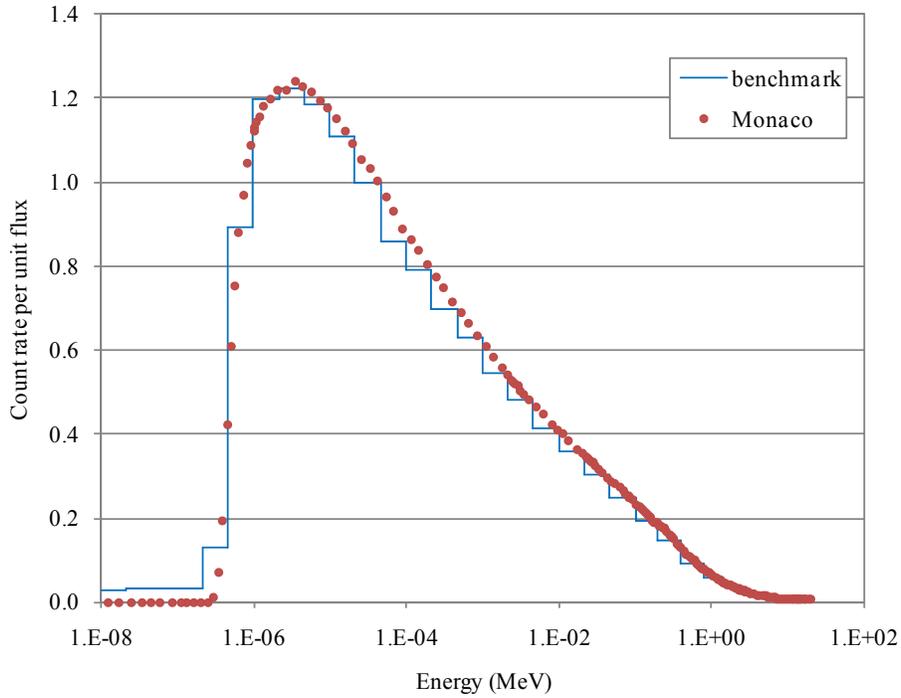

Fig. 3.12 Response (counts per unit flux) for the 2-inch diameter Bonner sphere (with cadmium cover). (Benchmark is computed function from Ref. 8.)
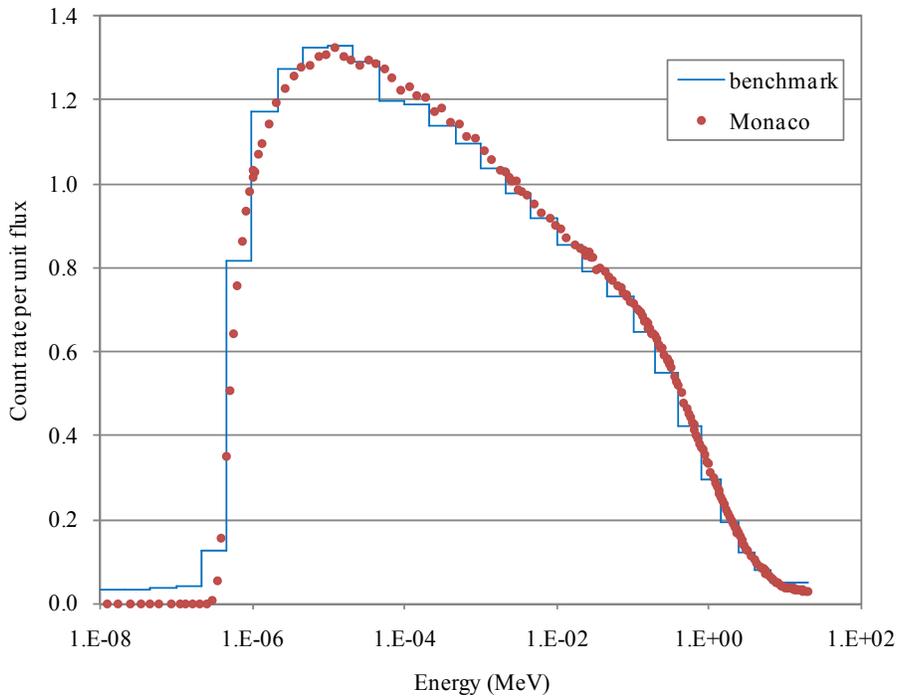

Fig. 3.13 Response (counts per unit flux) for the 3-inch diameter Bonner sphere (with cadmium cover). (Benchmark is computed function from Ref. 8.)
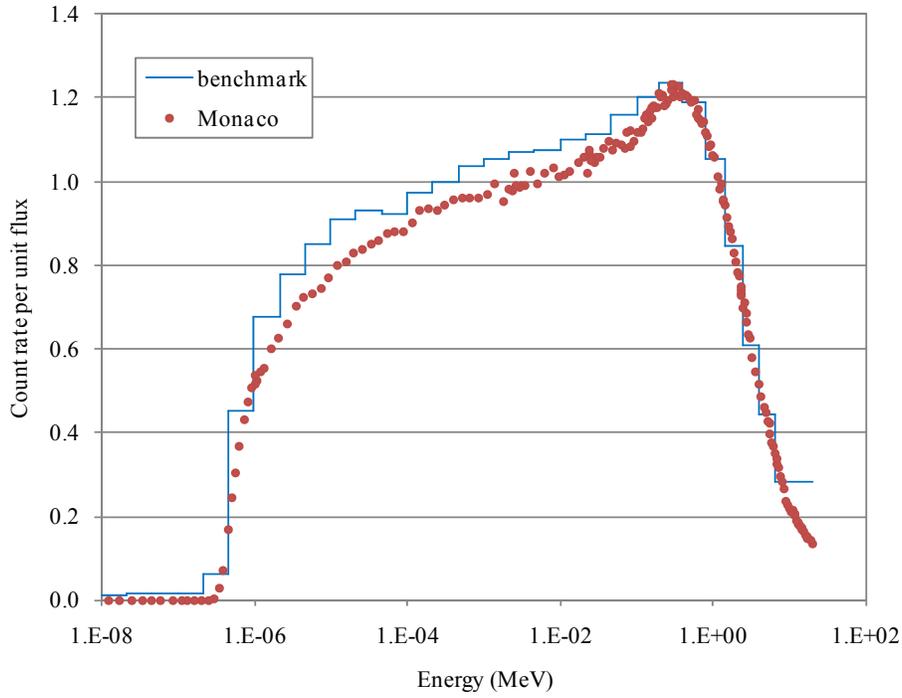

Fig. 3.14 Response (counts per unit flux) for the 5-inch diameter Bonner sphere (with cadmium cover). (Benchmark is computed function from Ref. 8.)
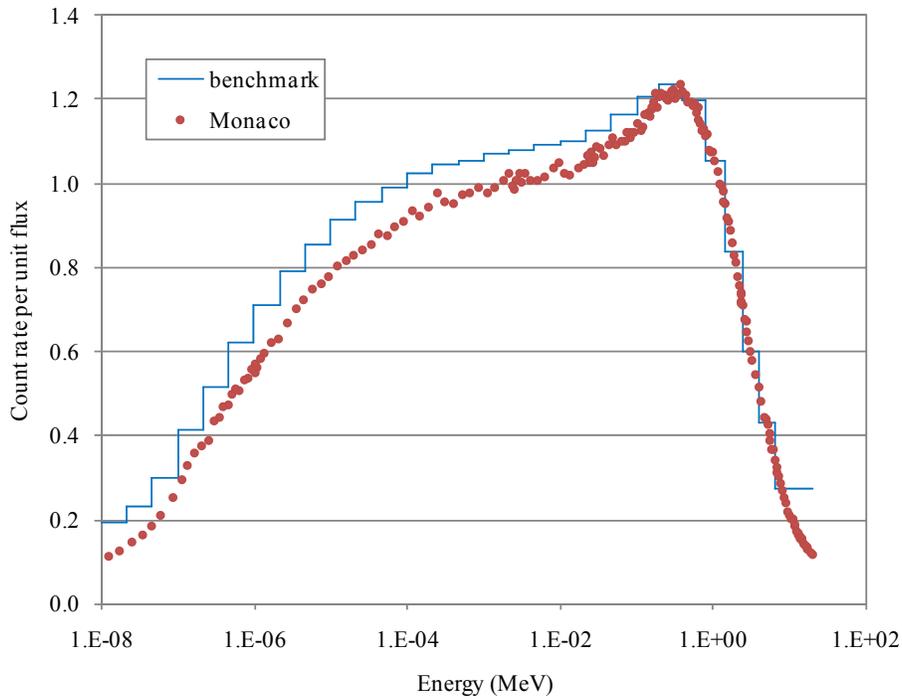

Fig. 3.15 Response (counts per unit flux) for the 5-inch diameter Bonner sphere (no cover). (Benchmark is computed function from Ref. 8.)
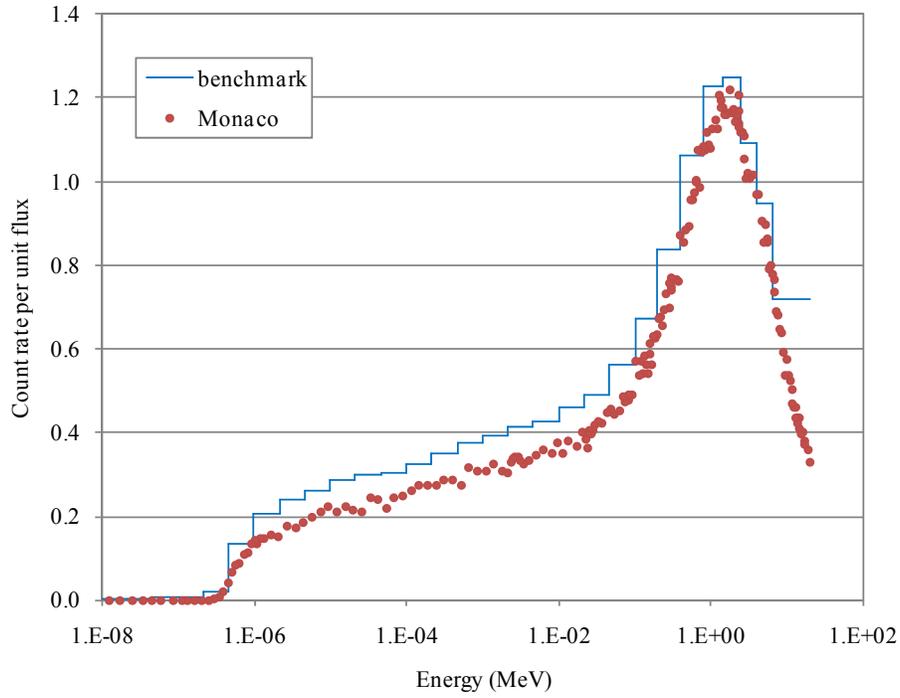

Fig. 3.16 Response (counts per unit flux) for the 8-inch diameter Bonner sphere (with cadmium cover). (Benchmark is computed function from Ref. 8.)
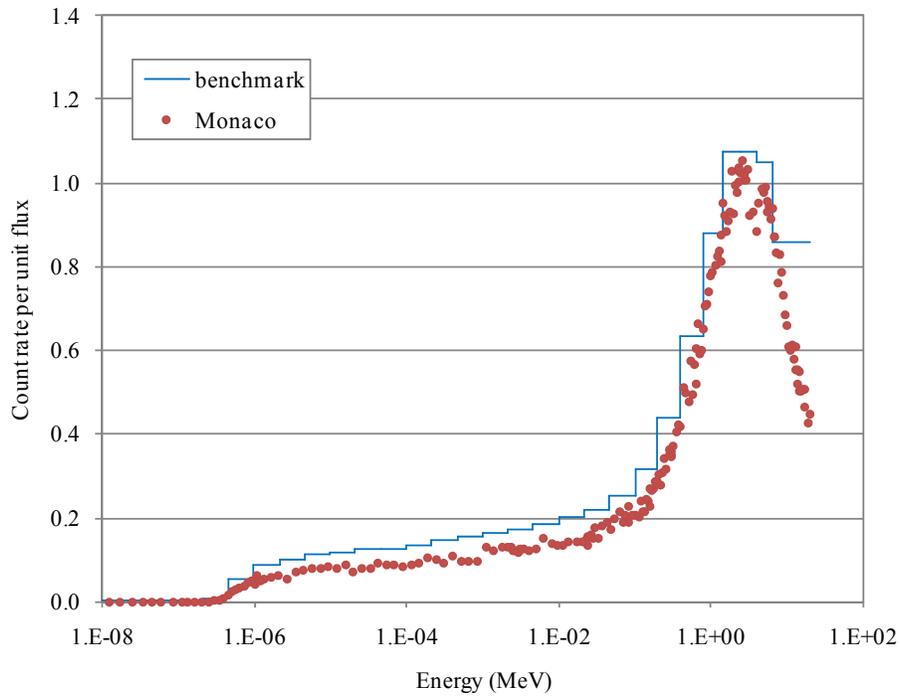

Fig. 3.17 Response (counts per unit flux) for the 10-inch diameter Bonner sphere (with cadmium cover). (Benchmark is computed function from Ref. 8.)
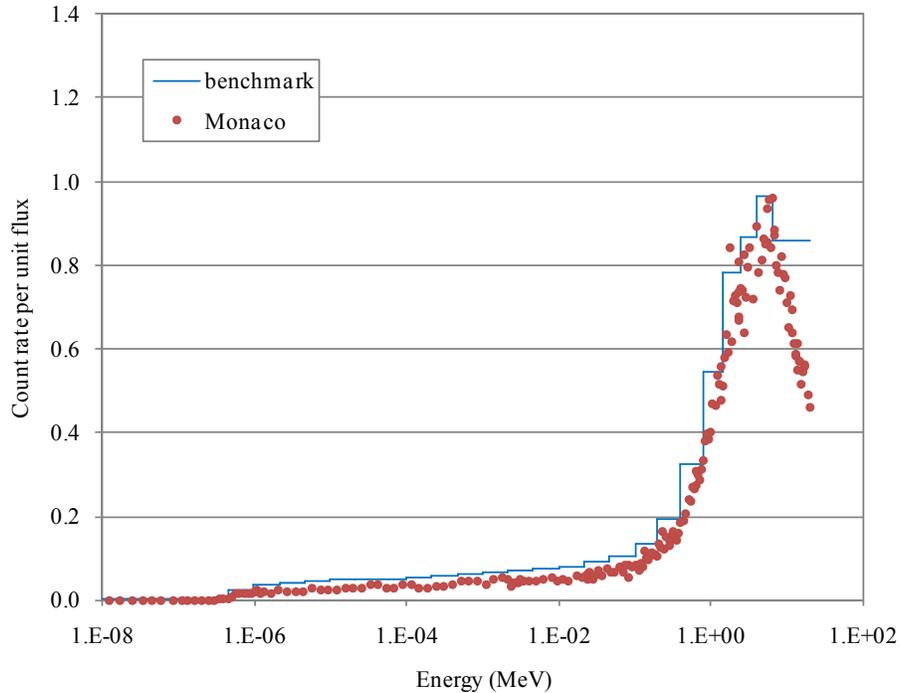

Fig. 3.18 Response (counts per unit flux) for the 12-inch diameter Bonner sphere (with cadmium cover). (Benchmark is computed function from Ref. 8.)

The Monaco-computed detector response functions compared well to the response functions computed by the benchmark team using MCNP. The results for the larger Bonner spheres show statistical noise in the Monaco results and could be reduced by longer run times. For these detectors, the Monaco responses are also a bit lower than the MCNP responses and could give lower total detector count rates.

3.2.1.4   Neutron transport through the labyrinth

The materials and labyrinth dimensions were taken from the benchmark report.[8] For each size detector (7) and for each type of source (2), MAVRIC and the FW-CADIS method were used to compute the detector count rates at all 10 detector locations for the first labyrinth design (empty, three-section labyrinth). Neutron flux spectra were computed at each location and then folded with the different detector response functions.

In the benchmark report, the authors computed the detector count rates with MCNP. For the 12-inch detector, the stated relative uncertainties ranged from 0.5% for the closest detector location to 2% for the furthest detector location.

The ratios of the calculated count rates to the experimentally measured count rates are shown for both the benchmark team using MCNP and MAVRIC in Figs. 3.19–3.32. The error bars in the C/E ratio are due almost entirely to the uncertainty in the experimental measurements. MAVRIC relative uncertainties were in the 1–2% range for the bare source and in the 2–3% range for the covered source.

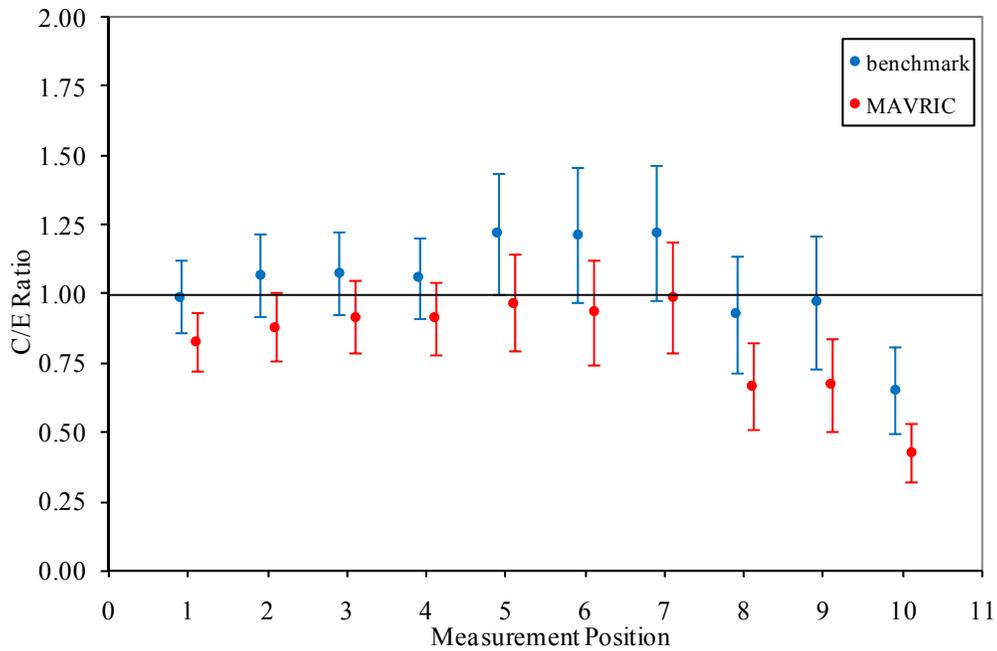

Fig. 3.30 Neutron count rate C/E for the 10-inch Bonner sphere (with cadmium) and the covered source.   (Benchmark is computer function from Ref. 8.)
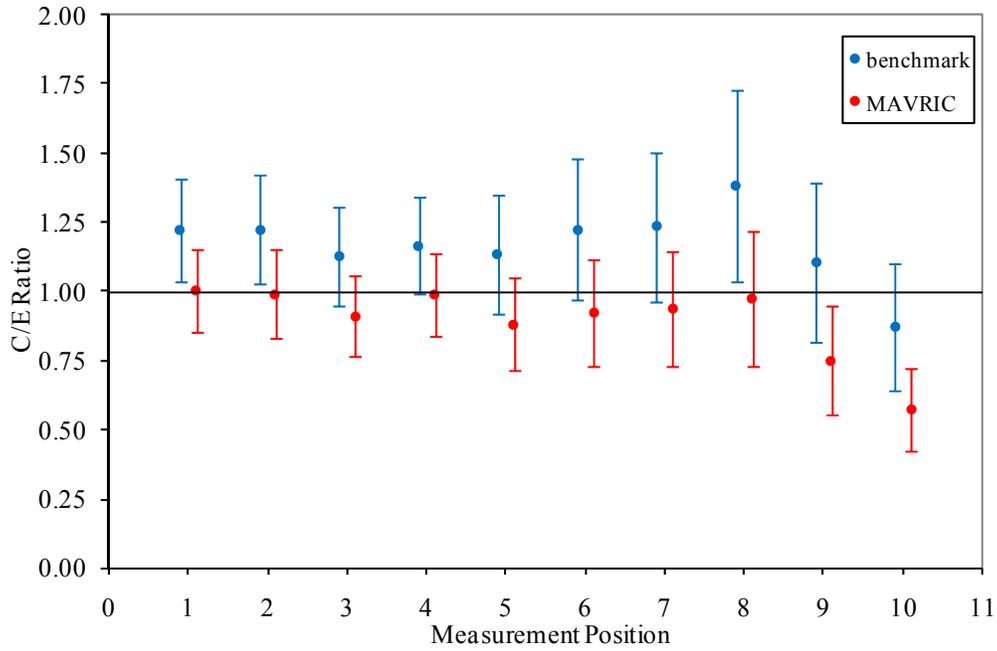

Fig. 3.31 Neutron count rate C/E for the 12-inch Bonner sphere (with cadmium) and the uncovered source. (Benchmark is computer function from Ref. 8.)
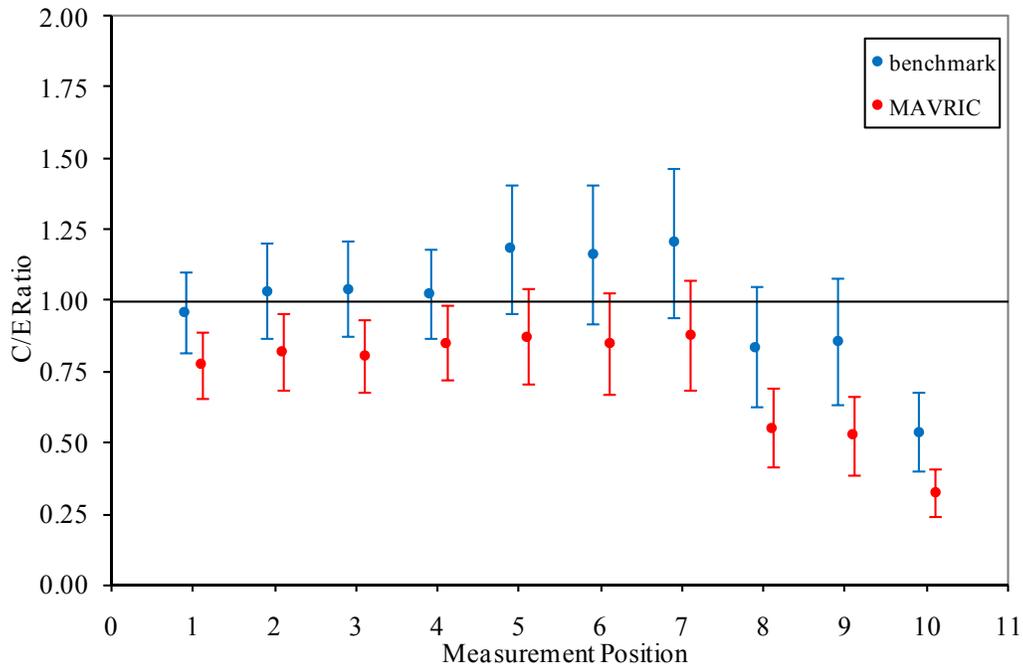

Fig. 3.32 Neutron count rate C/E for the 12-inch Bonner sphere (with cadmium) and the covered source. (Benchmark is computed function from Ref. 8.)

67

The MAVRIC count rates are all a bit lower than the benchmark MCNP count rates (due to lower detector response functions) but follow the MCNP C/E well for both the covered and uncovered sources for all seven detectors.

3.2.2 Neutron and photon leakage spectra from ^{252}Cf source at centers of six iron spheres of different diameters

3.2.2.1 Benchmark overview

Neutron and photon leakage spectra were measured from a ^{252}Cf source through iron spheres of various diameters in Russia during the 1980s. These data and instructions for benchmark calculations were presented in 2007 in an Organization for Economic Cooperation and Development report.[9]

Thirteen sets of experimental data are presented in the report—one for the bare source and one for each of six different diameters of iron shielding (20 cm, 30 cm, 40 cm, 50 cm, 60 cm, and 70 cm). Note that no photon measurement was made for the 20 cm shield. Each data set was the difference of two measurements—one with and one without a cone shaped shield between the source and detector. The experimental geometry is shown in Fig. 3.33.
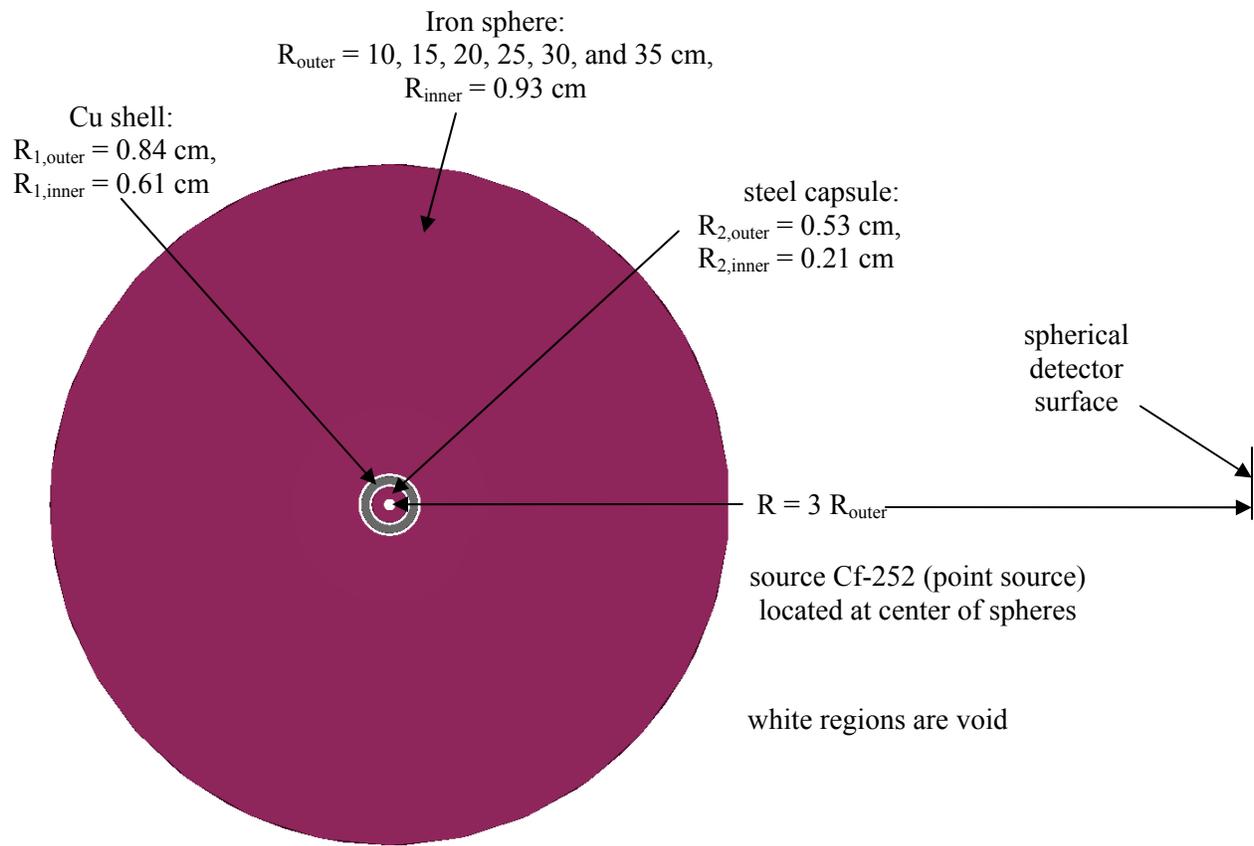

Fig. 3.33 Iron sphere experiments.

3.2.2.2   Monaco calculations

Monaco (SCALE 6) and the new ENDF/B-VI.8 fine-group shielding library were used to compute leakage spectra of both neutrons and photons according to the benchmark instructions.

For the Monaco neutron source, the experimentally measured neutron flux spectrum of the bare source was converted into a 200-group source specification. For the Monaco photon source, the experimentally measured photon flux spectrum of the bare source was converted into a 47-group source specification. Note that the "bare source" did include copper and steel canisters, so a small fraction of the measured photon flux could have come from secondary gammas from neutrons interacting in the source capsule. For every neutron emitted from the ^{252}Cf source, 3.82 photons were emitted. Monaco combined the sources into a single coupled neutron-photon source.

Benchmark results are listed in the above document in terms of $4\pi R^2\Phi(E)/Q$, where R is the radius of the detector (three times the radius of the shield, or 60 cm for the bare source) and Q is the neutron source strength. Experimental uncertainties ranged from 5% to 30%, so the experimental values are shown on the following plots as two lines, representing the values $\pm 1\sigma$.

Since the Monaco source was created from the bare source measurements, the Monaco simulation for these should match the experiment well, as shown in Figs. 3.34 and 3.35.
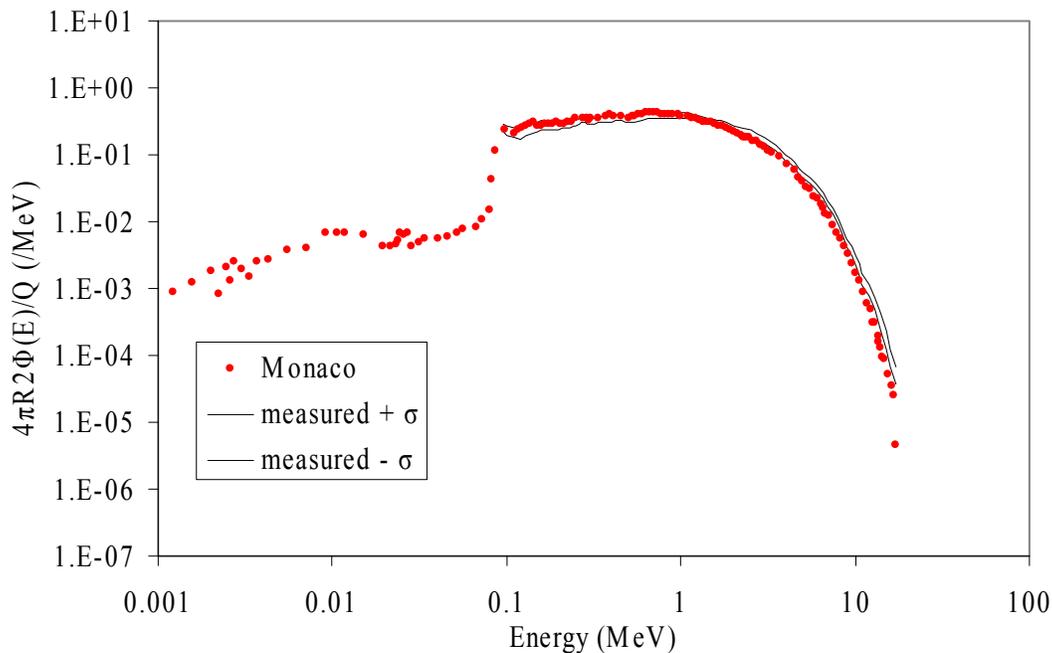

Fig. 3.34 Comparison of the neutron calculation to the measurement of the bare source.
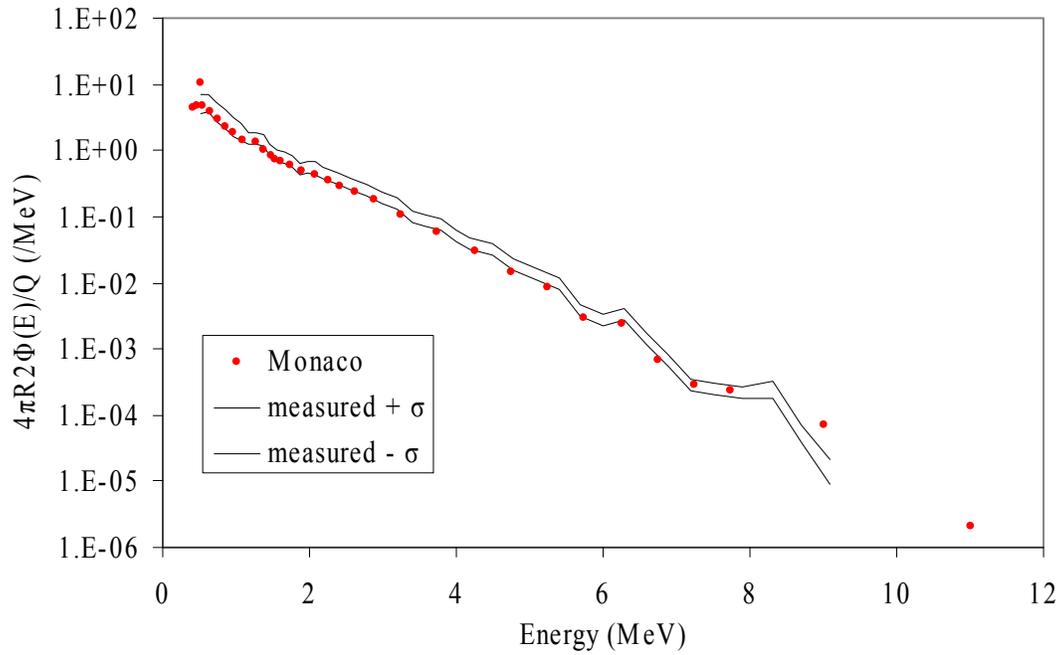

Fig. 3.35 Comparison of the photon calculation to the measurement of the bare source.

Neutron flux results for various shield thicknesses are shown in Figs. 3.36–3.41.

74
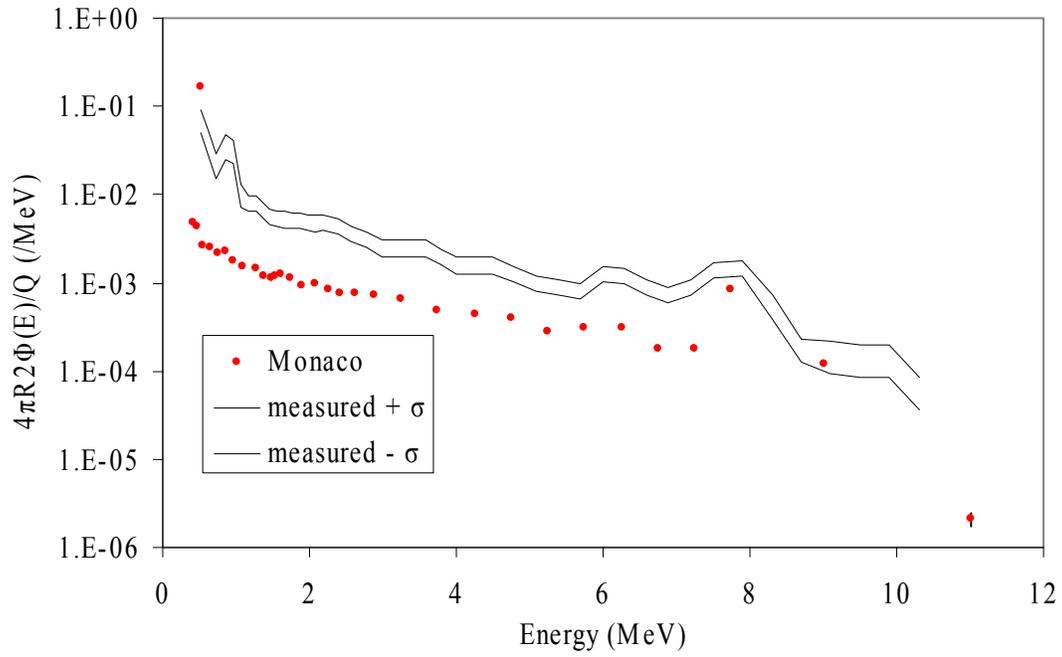

Fig. 3.45 Comparison of the photon calculation to the measurement of the 60 cm shield.
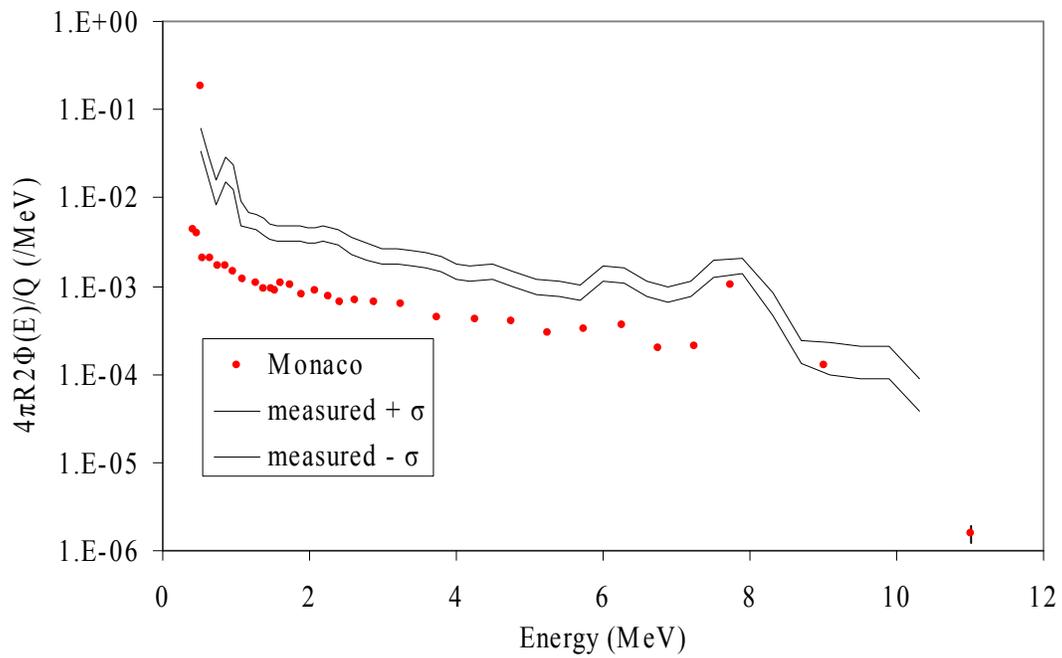

Fig. 3.46 Comparison of the photon calculation to the measurement of the 70 cm shield.

Photon fluxes are underpredicted by Monaco and MCNP5 as is depicted in Fig. 3.47.
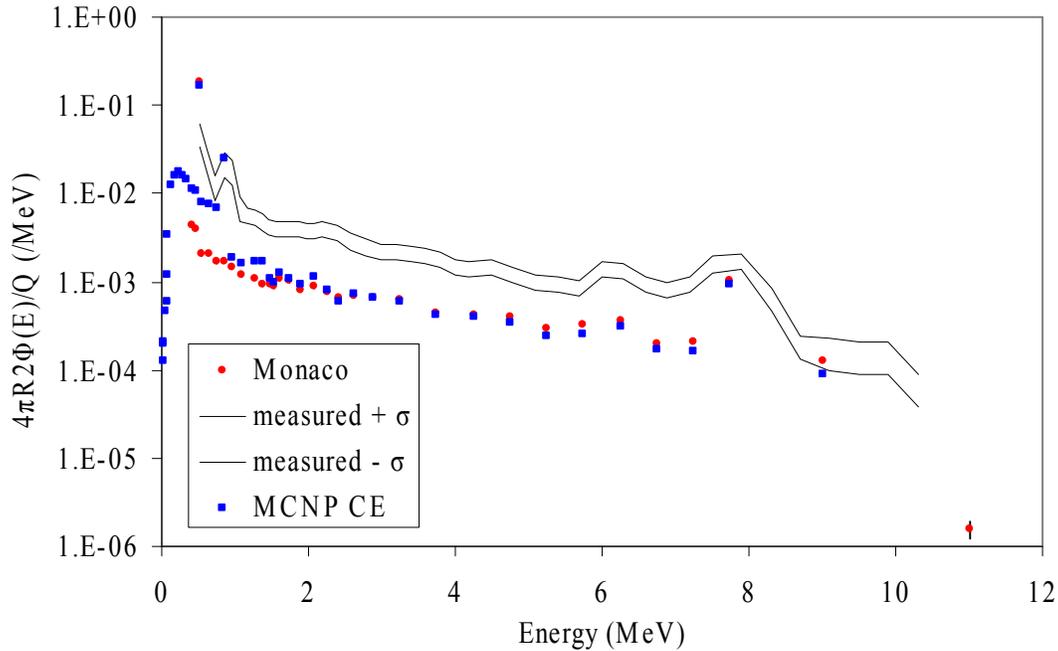

Fig. 3.47 Photon flux through the 70 cm shield as calculated by Monaco and MCNP5.

MCNP results in the benchmark study were similar to those shown in Fig. 3.47 (see Fig. 20 of Ref. 9).

3.2.3 Comparison of measured and calculated neutron transmission through heavy water for a ^{252}Cf source placed in the center of a 30 cm diameter sphere

3.2.3.1 Experiment overview

The transmission of ^{252}Cf neutrons through a sphere filled with heavy water was measured in Prague in the mid 1990s (Ref. 10). For each experiment, two measurements were made: one with an iron/polyethylene shield and one without the shield. The purpose of the shield was to block all direct particle transmission from the sphere to the detector. The difference in these two measurements accounts for scatter from the floor, walls, and ceiling (which is about a 5% effect for energies above 10 keV). A great amount of detail is given for the materials and geometry of the source holder, insertion tube, and detectors in Ref. 10. Two different assemblies holding the californium source were measured.

3.2.3.2 Monaco calculations

The Monaco SGGP geometry model consists of two nested spheres for the source and the heavy water. For the experiments where the iron/polyethylene shield is present, three borated polyethylene cylinders and one iron cylinder are placed between the sphere and the detector position (75,0,0). The experiment sat 2 m above the floor of an experimental hall that measured $10 \times 13 \times 25$ m. Here, the origin corresponds to the source at the center of the heavy water sphere. Neither of the two source holder assemblies was modeled in any detail. The geometry model is shown in Fig. 3.48.
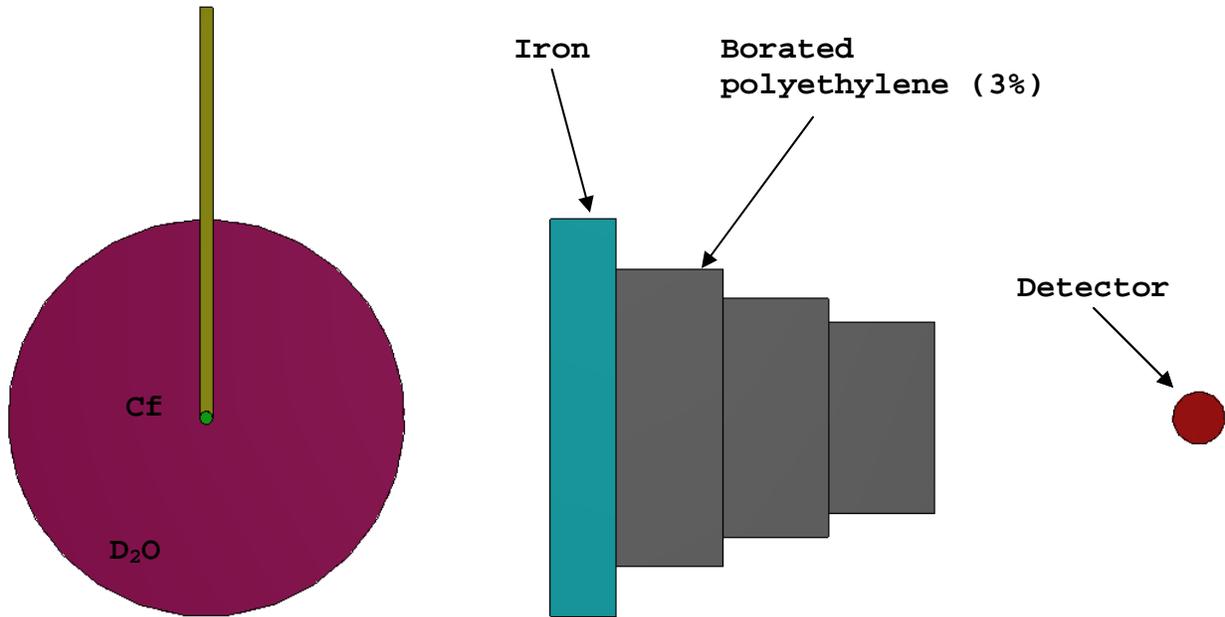

Fig. 3.48 Monaco model of ^{252}Cf source in heavy water experiment.

A second Monaco input file was created for the geometry without the 4 cylindrical shields in place.

For the source, the Watt spectrum with constants α =1.025 MeV, b =2.926/MeV was used.

$$p(E) = ce^{-E/\alpha} \sinh\left(\sqrt{bE}\right) . \tag{3.3}$$

The measurements listed in the paper were normalized such that the total flux at the detector (at r=75 cm) without the D_2O sphere or the shields would have been 1 n/cm^2/s. In Monaco, the source strength was set to a strength of $4\pi(75)^2 = 70686$ n/s. No biasing was used, other than implicit capture.

A point detector tally at the detector location was used to calculate the energy dependent neutron flux.

Results for the ENDF/B-VI.8 library are depicted in Figs 3.49 and 3.50. Results for ENDF/B-VII.0 are shown in Figs. 3.51 and 3.52.

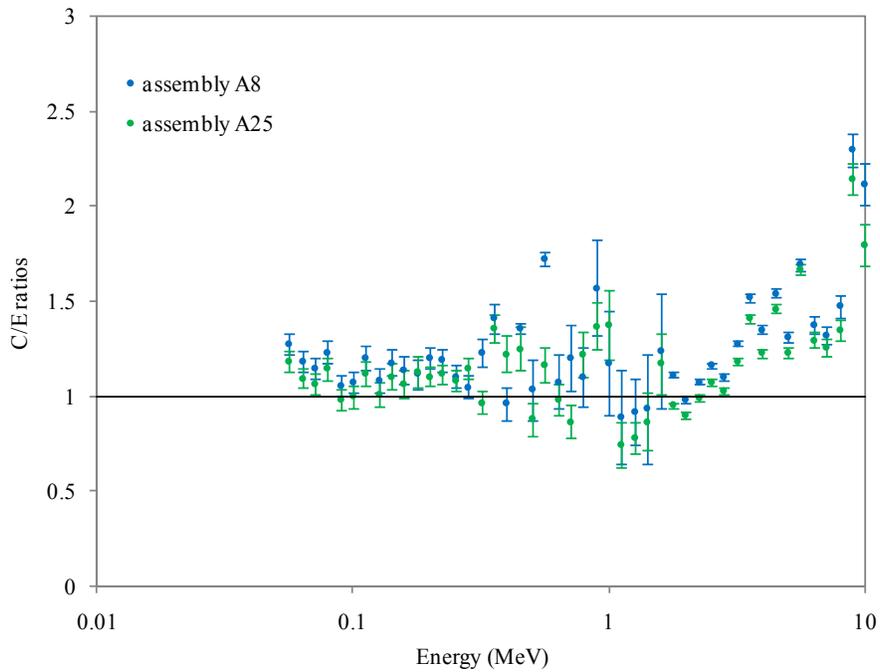

Fig. 3.52 Ratios of the Monaco (ENDF/B-VII.0 fine-group library) results and the measured data.

79

3.2.4 Comparison of measured and calculated neutron transmission through steel for a ^{252}Cf source

3.2.4.1 Experiment overview

In the early 1990s, several experiments measuring the transmission of ^{252}Cf neutrons through a sphere of iron were performed to benchmark ENDF/B-VI cross-section data. Two sets of measurements were made—one by the Czechoslovakian National Research Institute and the other by the Skoda Company.[11]

3.2.4.2 Monaco calculations

The Monaco model consists of just a point source and a spherical shell of iron. Two different tallies are used which should all give the same result: a region tally (for a thin spherical shell at radius=100 cm); a point detector tally at (x,y,z)=(100,0,0). For the source, the Watt spectrum with constants $\alpha = 1.025$ MeV, $b = 2.926$/MeV was used.

$$p(E) = ce^{-E/\alpha} \sinh\left(\sqrt{bE}\right) . \tag{3.4}$$

The measurements listed in the paper were normalized such that the total flux at the detector (at r=100 cm) without the iron shield would have been 1 n/cm^2/s. In Monaco, the source strength was set to a strength of $4\pi(100)^2 = 125664$ n/s. No biasing was used, other than implicit capture. The geometry is shown in Fig. 1 of Ref. 11.

Results for ENDF/B-VI.8 are depicted in Figs. 3.53 and 3.54. Results for ENDF/B-VII.0 are shown in Figs. 3.55 and 3.56.
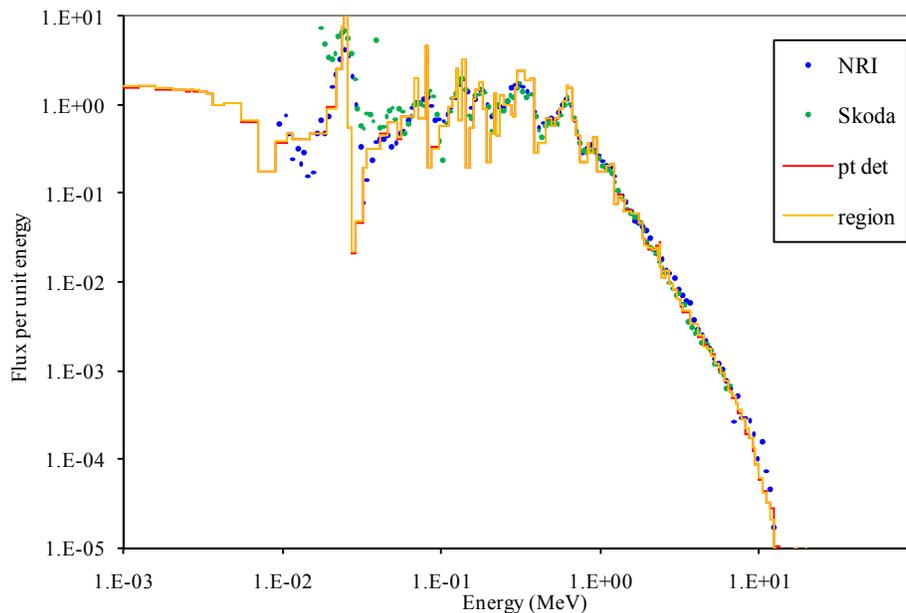

Fig. 3.53 Monaco output (ENDF/B-VI.8 fine-group library) for total flux at 10 cm using two different tallies compared to the two sets of measured data.
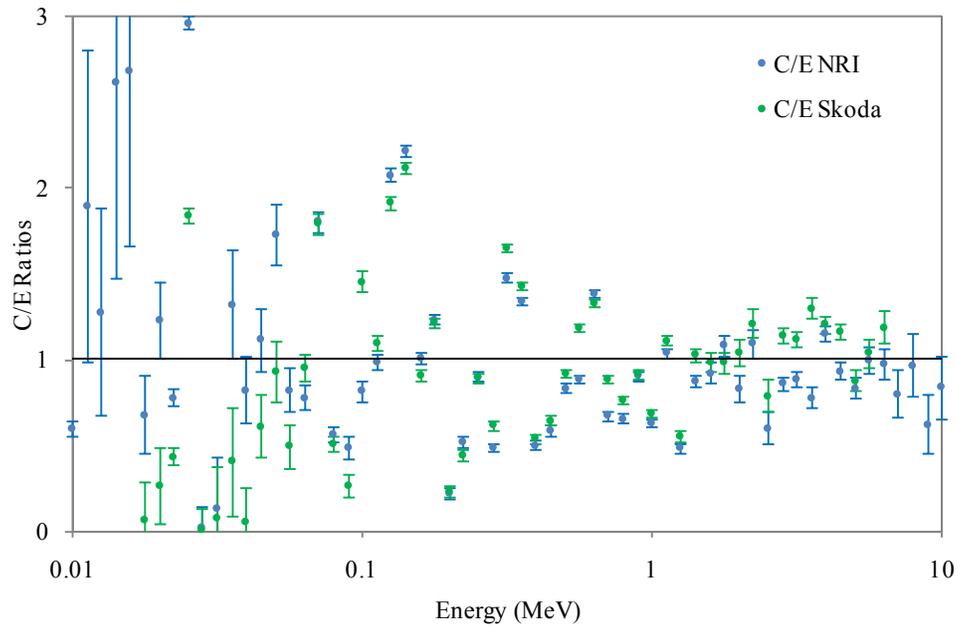

Fig. 3.54 Ratios of the Monaco (ENDF/B-VI.8 fine-group library) point detector tally to the measured fluxes.
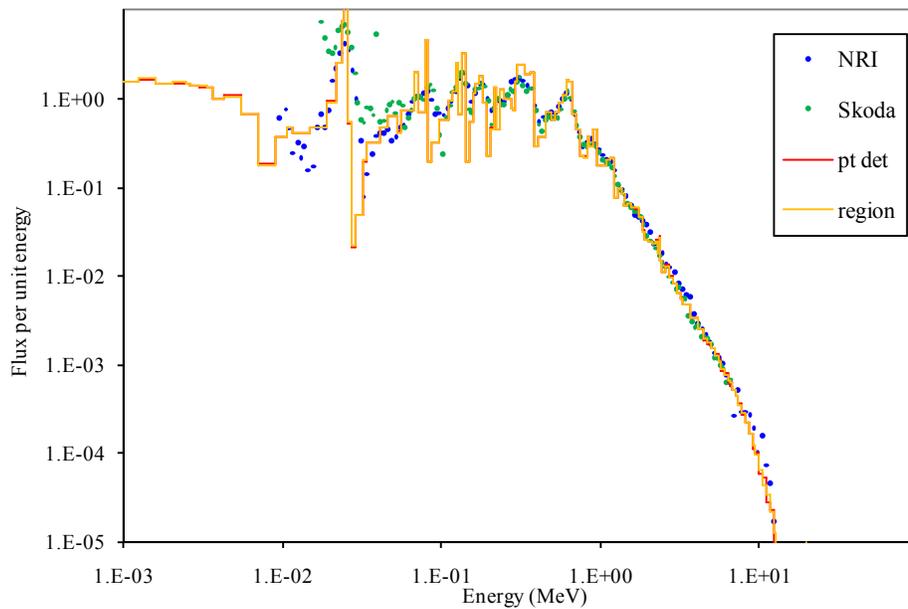

Fig. 3.55 Monaco output (ENDF/B-VII.0 fine-group library) for total flux at 10 cm using two different tallies compared to the two sets of measured data.

81

3.2.5   Systematic evaluation of neutron shielding effects for materials

3.2.5.1   Experimental overview

Transmission of neutrons from a [252]Cf source through different thicknesses of five different materials was measured to determine their shielding effectiveness.[12] Combinations of steel and polyethylene were also measured to determine the change in shielding effectiveness on the order of the materials. The detector used was an Aloka moderator-type survey meter, made of polyethylene, which is supposed to mimic the human dose response. The data presented by Ueki et al.[12] was corrected for room scatter. An example of one experiment is shown in Fig. 3.57.
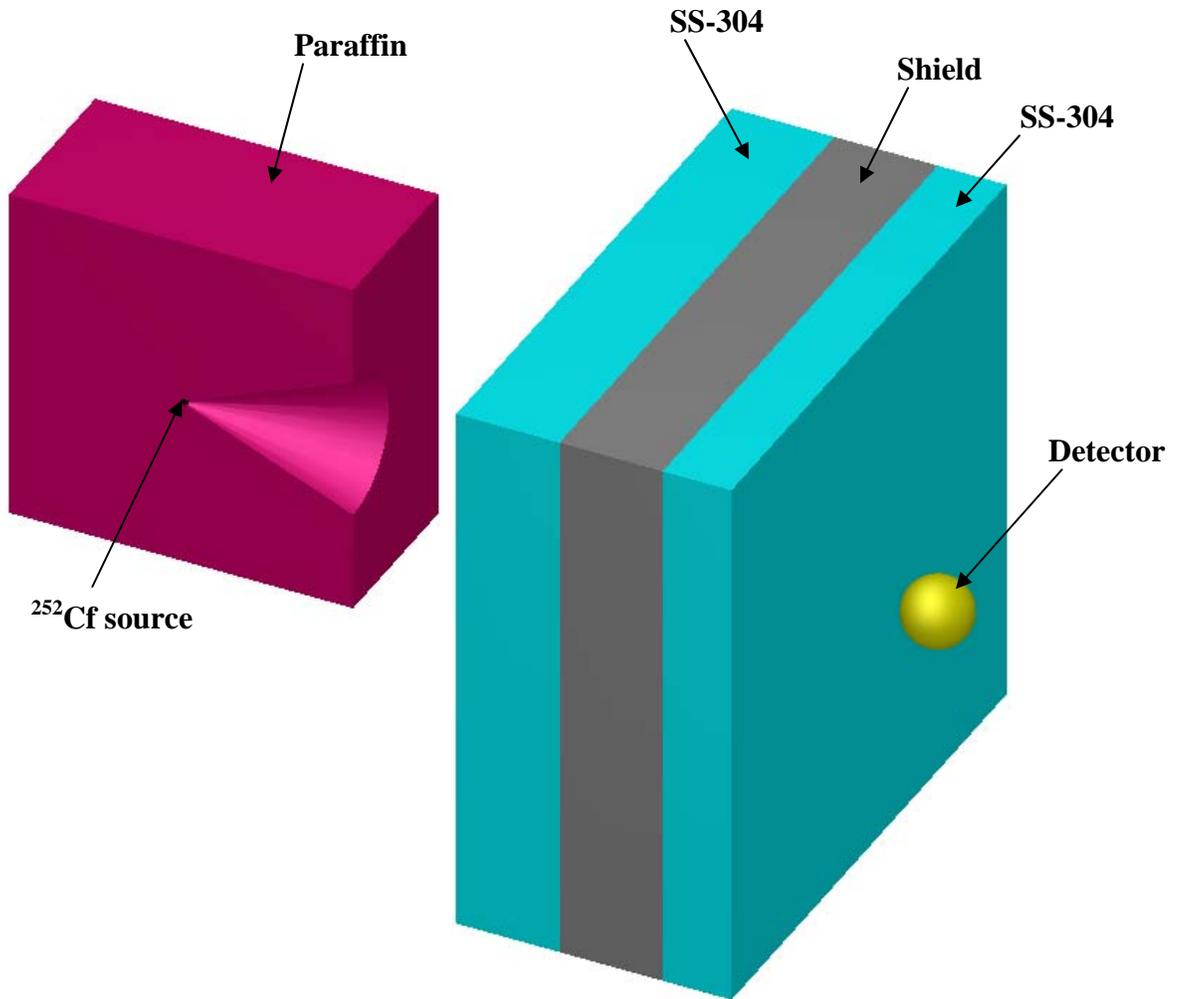

Fig. 3.57 Neutron shielding experiment example (half of paraffin removed to show source inside cone).

3.2.5.2 *MCNP simulations*

Polyethylene proved problematic for MCNP simulations. Reported results show good correlation with the findings of Ueki et al. for all materials except polyethylene.[13–15]

3.2.5.3 *MAVRIC calculations*

For penetration through thick shields, the MAVRIC sequence and the CADIS methodology were used. For each experiment, an adjoint calculation using GTRUNC/Denovo was performed using the new ENDF/B-VII.0 broad-group library. An importance map and a biased source distribution were calculated by MAVRIC from the adjoint fluxes. The Monaco simulation used the new ENDF/B-VI.8 fine-group shielding library and the importance map, but not the biased source distribution, so that the ^{252}Cf spectral shape would be better preserved with the fine-group library. Adjoint calculations typically took 6–10 minutes and the Monaco calculations typically took 10–13 minutes each, and all had less than 4% statistical uncertainties.

3.2.5.4   Results

MAVRIC calculations match the type 1 experiments (single shield) within ±20%, except for polyethylene. MAVRIC does not match the type 2 or type 3 experiments, probably due to the polyethylene component. Similar difficulties were observed with MCNP calculations.

Type 1 Experiment: Single material. Experiment geometries are shown in Fig. 1 of Ref. 12. Results are shown in Fig. 3.58.
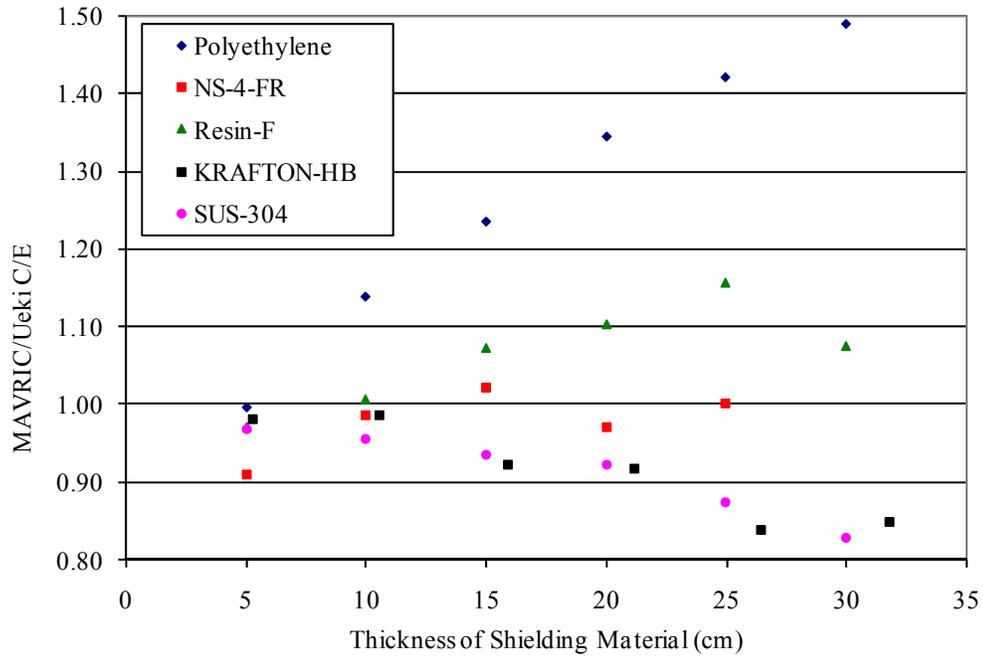

Fig. 3.58 Ratio of MAVRIC calculation of neutron detector dose rate to experimental measurement.

Type 2 Experiment: Stainless steel and polyethylene. Experiment geometries are shown in Ref. 12. Results are shown in Figs. 3.59 and . 3.60.
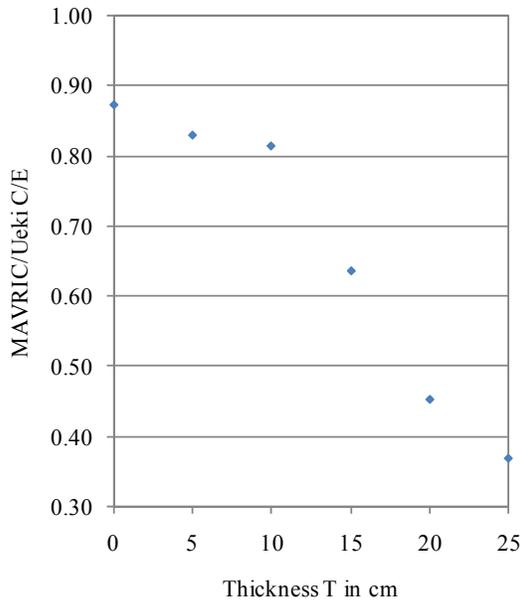

Fig. 3.59 Type 2a results—25 cm of stainless steel first, then polyethylene.
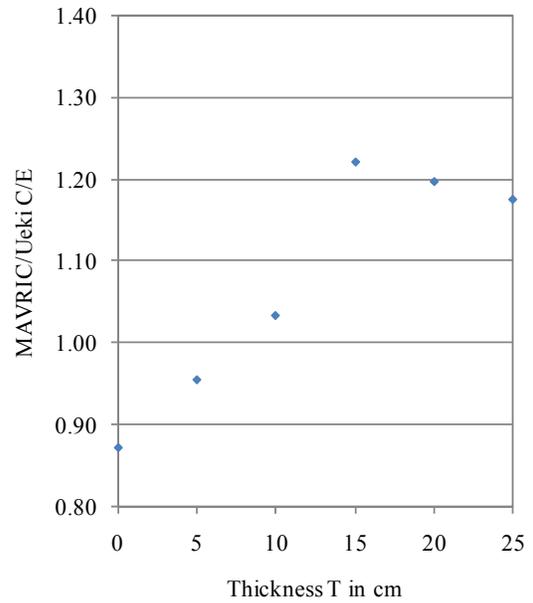

Fig. 3.60 Type 2b results—polyethylene, then 25 cm of stainless steel.

Type 3 Experiment: Polyethylene sandwiched in stainless steel. Experiment geometries are shown in Ref. 12. Results are depicted in Fig. 3.61.
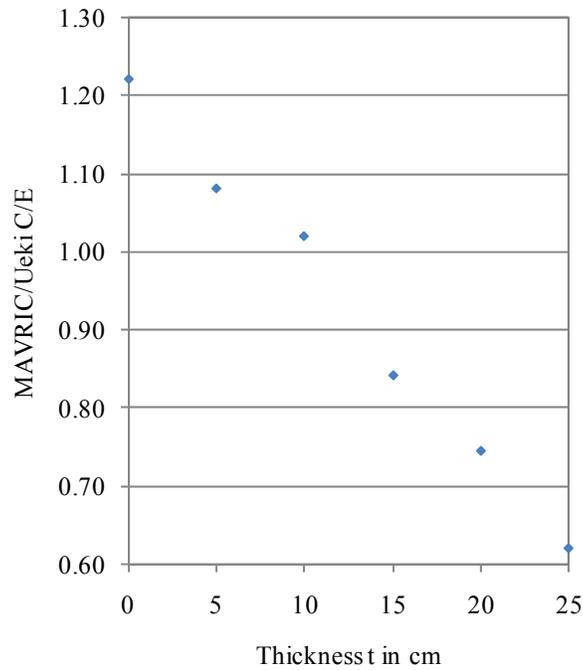

Fig. 3.61 Type 3 results for polyethylene fixed at a thickness of 15 cm.

4 SUMMARY

Coupled neutron-gamma libraries have been developed for SCALE based on ENDF/B-VI.8 and ENDF/B-VII.0 cross-section evaluations. The AMPX cross-section processing system was used for all library generation tasks for SCALE. ENDF/B-VI.8 and ENDF/B-VII.0 fine-group libraries were generated using 200 neutron and 47 gamma groups. The neutron group structure is identical to the 199-group VITAMIN-B6 structure except an additional neutron group has been added to extend the top energy boundary to 20 MeV. In addition to the fine-group libraries, a broad-group ENDF/B-VII.0 library has been generated using a 27 neutron and 19 gamma group structure. The broad-group library is primarily used to perform adjoint discrete ordinates calculations needed to prepare importance maps and a biased source distribution for biasing the forward Monte Carlo calculations. The SCALE shielding libraries have the following features.

- The multigroup neutron data were generated using a weighting function that has the form of a Maxwellian—1/E—fission spectrum—1/E above 10 MeV. This spectrum is consistent with the 238-group ENDF/B-VI library that was distributed with SCALE 5.1.

- Full-range Bondarenko factors are provided for all nuclides, thereby enabling faster neutron resonance self-shielding calculations using the narrow resonance approximation.

- Response functions consistent with previous SCALE libraries are maintained in the new shielding libraries.

As part of rigorous differential data testing activities, the AMPX code system was used to process all ENDF/B evaluations on three computing platforms: DEC Alpha Tru64, 32-bit Linux, and 64-bit Intel Mac. Because of the differences between compilers, experience has shown that different results can be obtained with different computing platforms. The use of the three platforms provided confirmatory checks of the cross-section processing calculations. In addition, independent verifications were performed between the AMPX results and results obtained with the NJOY code system for 1-D and 2-D processes. In general, the AMPX-NJOY comparisons show good agreement for the 1-D and 2-D processes. Although some differences have been observed between the independent processing systems, the overall agreement is good. The independent processing code comparisons provide additional verification checks for the differential cross-section data.

To complete the library testing effort, radiation transport calculations were performed with the SCALE shielding codes Monaco and MAVRIC using the coupled libraries to simulate several shielding benchmark calculations. Monaco/MAVRIC and the new ENDF/B-VI.8 and ENDF/B-VII.0 fine-group, coupled libraries matched experimental measurements well — in terms of transmission/attenuation values and spectral results. The ENDF/B-VII.0 broad-group library was not used in forward calculations but was used in creating importance maps for Monaco. Overall, the results obtained with MAVRIC/Monaco using the coupled libraries are good and demonstrate the effectiveness of the new SCALE methods and data capabilities for shielding applications.
