EE-14	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Constraints	The GRR will be compliant with all applicable laws and statues, including the Wild and Scenic Rivers Act, which is discussed throughout the GRR's companion document, the EIS/EIR. Compliance with law and policy is assumed in every study. Planning Constraints are project specific items that are not addressed by either law or policy that would limit planning efforts in some way. At this time, no other planning constraints have been identified beyond the restriction of additional bird habitat near the Sacramento International Airport.

EE-15	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Folsom Dam Operations/ Water Control Manual	The ARCF study used a conservative characterization of future flood management operations at Folsom Dam assuming the Joint Federal Project (JFP) is complete. The Folsom Dam future operations reflected in the ARCF study are based on the operations identified in the Folsom Dam Modification and Folsom Dam Raise Projects PACR (2007). The purpose of the Folsom Dam and Lake Water Control Manual Update (WCM Update) is to carry out a more detailed analysis of how to revise operation rules for Folsom Dam to reduce flood risk based on the capabilities of the JFP, to reflect operation capabilities created by improved weather forecasts, and to potentially reduce the volume of flood control reservation in Folsom Lake at any particular time in comparison to the operations that have been in effect since 1995. Any proposed refinements to operation rules at Folsom identified in the WCM Update are being evaluated on their effectiveness in meeting the flood risk management objectives as well as on their effects to the other project purposes of Folsom Dam. Those other project purposes are: water supply (agricultural and M&I), hydropower, water quality, sustain fish and wildlife resources, and recreation. The WCM Update is evaluating potential effects to these other project purposes on a local and regional basis. Because Folsom Dam and Lake is a key facility in the Central Valley Project, the WCM Update is utilizing the CalSim II model and outputs to measure effects within the larger CVP/SWP system. Along the lower American River and beyond its confluence with the Sacramento River, the WCM Update will be evaluating resource effects to a greater level of detail, utilizing HEC ResSim and RAS models and output to measure changes in flow frequency, duration, rate, and stage, among other variables, on a sub-monthly timestep. The expectation of the WCM Update is that, through an iterative modeling process, operation rules at Folsom Dam will be refined to be able to not only meet the flood risk management objectives of the JFP, but to also minimize, avoid, or possibly provide incidental beneficial effects to the other Folsom Dam project purposes. Results of the WCM Update will be used to better-inform the detailed design of the ARCF selected plan.
EE-16	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Auburn Dam	The assumptions regarding Auburn Dam as discussed in the GRR were based on the Corps' 1996 Supplemental Information Report. Further studies by other agencies have occurred, however, those agencies have analyzed the dam based on other project purposes such as water supply and hydropower. The purpose of the ARCF GRR is Flood Risk Management, and, therefore, the 1996 SIR was adequate for the purposes of this study.
EE-17	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	The two largest floods on record are 1986 and 1997 which are post hydrologic design of all the reservoirs in the system. This is not the main driver on why reoperation of upstream reservoirs was screened out but is part of the story. Location plays a key part and the presence of many unregulated water courses entering the Sac River system. Clarifying text was added to this section.
EE-18	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	A statement was added citing the 1991 study for further information on why the alternative was screened.
EE-19	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project History	The design of the overall Sacramento River Flood Control Project was based on historic floods (1907, 1909, and 1927 for the most part). On many segments of river throughout the Sacramento Valley, flows experienced in 1955, 1964, 1986, and 1997 exceeded the design of those reaches. A clarifying statement was added to section 3-6.
EE-20	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Comment noted.

EE-21	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Alternatives	Concur. Table 3-6 in the GRR has been modified to reflect that the Maximum Plan does not meet the acceptability criteria.
EE-22	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Alternatives	The added uncertainty for large events beyond the 200-Year event are included in the larger range of Folsom Releases described in the Hydrologic Appendix to the GRR.
EE-23	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	WRRDA 2014 Section 3013 requires a review of the levee vegetation policy. The review is still in progress, therefore no new policies have been established at this time and the Corps is making no assumptions about what the policy will consist of. However, WRRDA 2014 Section 3013(g)(1) also requires that vegetation removal not be a condition or requirement for the approval of funding of a project or any other action, unless the specific vegetation has been demonstrated to present an unacceptable safety risk. In line with this provision, under the ARCF GRR a study was conducted to determine the acceptability of the safety risk associated with the vegetation on the levees in the study area. This study is described in Section 1.4.5 of the draft EIS/EIR. The study resulted in a determination that it was an acceptable assumption that a variance to the vegetation policy is appropriate under this study, and therefore waterside vegetation can remain on the levees. Additionally, the sponsor has sent the Corps a Letter of Intent to apply for a SWIF for the levees in the study area. The combination of the SWIF and the variance allows the Corps to leave all vegetation outside of the construction footprint in place. As a result, the project is in compliance with Section 3013(g)(1), because compliance with the vegetation policy is not a factor in funding or approving the ARCF GRR. The presence of wildflowers and native grasses on the levees is not in conflict the ETL. The Corps is supportive of the presence of California's State flower on our levee slopes!
EE-24	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project Design	USACE coordinated with the Lower American River Task Force during the previous design and construction of flood risk reduction features in the parkway. This effort resulted in successful implementation of these features and USACE welcomes the opportunity to work together again with the Task Force on this next generation of flood risk reduction features.
EE-25	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Sacramento Weir Operations	The operation of the new Sacramento Weir would be refined during the design and construction phase in conjunction with the project sponsors and the operators of the facility. This refinement would take in consideration other regional efforts to reduce flood risk and optimize the operation of the weir in light of these efforts.
EE-26	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	The project will comply with the Wild and Scenic Rivers Act. The EIS/EIR has been updated to include further discussion of this law and potential effects to the values under which the American River is regulated under this Act.
EE-27	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Compliance	The GRR will be compliant with all applicable laws and statues, including the Wild and Scenic Rivers Act and WRRDA 2014.
EE-28	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Geologic Resources	Further discussion of liquefaction potential is included in the Geotechnical Appendix (Appendix C, Attachment C) to the GRR.

EE-29	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Editorial	Concur. Edits have been made to the EIS/EIR accordingly.
EE-30	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Parkway Plan	Citations have been added to the EIS/EIR to quote, reference, and indicate compliance with the American River Parkway Plan.
EE-31	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project Design	The ARCF GRR is being planned using principles the Corps' SMART Planning initiative, as required by Section 1001 of WRRDA 2014. As a result, the planning phase relied heavily on existing information to drive the decision making process due to the size of the study area and the scope of the project. Under this process it was not possible to conduct site-specific analysis during the planning phase. These analyses will occur during the preconstruction design phase to confirm the assumptions that drove the planning phase.
EE-32	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The Corps concurs that the vegetation and aesthetic resources of the Parkway should not be unnecessarily sacrificed. The ARCF GRR is a public safety project and all measures proposed are to reduce the risk of life loss and damages from a catastrophic flood event. Additionally, the effects analyzed in the EIS/EIR are a worst-case scenario based on a maximum footprint. In the preconstruction engineering and design phase of the project, the Corps will conduct site-specific analysis to refine the proposed construction footprint and anticipates that there is a strong possibility of minimizing the effects that are disclosed in this study.
EE-33	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Regulatory Setting	The State and Federal Wild and Scenic Rivers Acts were added to the Regulatory Setting. The National Park Service provided comments on the draft EIS/EIR and the Corps is addressing their concerns in this final EIS/EIR. Further coordination with the National Park Service will occur throughout the design phase of the project.
EE-34	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project Area	Thank you for your comment. The ARN and ARS basins and the levee reaches described in the study documents are defined based on existing conditions and not historic (pre-leveed) conditions.
EE-35	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The ARCF GRR used a conservative characterization of future flood management operations at Folsom Dam assuming the JFP auxiliary spillway and control structure are complete. The Folsom Dam future operations reflected in the ARCF GRR are based on the operations identified in the Folsom Dam Modification and Folsom Dam Raise Projects Post Authorization Change Report (2007) (JFP PACR).
EE-36	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The operation of the Sacramento Weir is currently based on the gauge at the I Street Bridge. Operations will be refined during the design and construction phase in conjunction with the project sponsors and the operators of the facility. This refinement would take in consideration other regional efforts to reduce flood risk and optimize the operation of the weir in light of these efforts.
EE-37	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Editorial	Thank you for pointing the error out. We have fixed this for the final EIS/EIR.
EE-38	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The Corps is committed to reducing impacts to the maximum extent possible during the design phase. The impacts presented in this EIS/EIR were intended to be a worst-case scenario. When site-specific analysis is conducted during the design phase, we expect to be able to minimize impacts from those presented in this document.

EE-39	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Erosion	Independent External Peer Review was conducted on the feasibility report and its technical appendices including the erosion assumptions. Additionally, a 60-day public review period occurred and allowed for external review of the proposed alternatives. The Corps of Engineers is committed to working with stakeholders during the design and construction process. Previous bank protection constructed working with the Lower American River Task Force is a good example that the Corps is supportive of using as a working model.
EE-40	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Regulatory Setting	The State and Federal Wild and Scenic Rivers Acts were added to the Regulatory Settings.
EE-41	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Under the ARCF GRR a study was conducted to determine the acceptability of the safety risk associated with the vegetation on the levees in the study area. This study is described in Section 1.4.5 of the draft EIS/EIR. The study resulted in a determination that it was an acceptable assumption that a variance to the vegetation policy is appropriate under this study, and therefore waterside vegetation can remain on the levees. Additionally, the sponsor has sent the Corps a Letter of Intent to apply for a SWIF for the levees in the study area. The combination of the SWIF and the variance allows the Corps to leave all vegetation outside of the construction footprint in place. As a result, the project is in compliance with WRRDA 2014 Section 3013(g)(1), because compliance with the vegetation policy is not a factor in funding or approving the ARCF GRR. While the SWIF does assume long-term compliance with the current ETL policies, it also allows for flexibility in adjusting to any change in vegetation policies that may occur.
EE-42	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Compliance	The National Park Service was added to the list of agencies that the Corps is coordinating with on this project.
EE-43	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Cumulative Effects	Concur. Changes in the BDCP were announced after public release of this EIS/EIR. The description of the BDCP has been updated for the final EIS/EIR.
EE-44	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation Impacts	The Corps is committed to reducing impacts to the maximum extent possible during the design phase. The impacts presented in this EIS/EIR were intended to be a worst-case scenario. When site-specific analysis is conducted during the design phase, we expect to be able to minimize impacts from those presented in this document.
EE-45	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	While this comparison may be helpful, the project features are based on a design flow of 160,000 cfs not necessarily a frequency or historical based event. Also, this comparison is best conducted under that Folsom Water Control Manual Update. The Water Control Manual EIS/EIR is tentatively scheduled for release in summer 2016.
EE-46	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Comments	All comments submitted are addressed in this appendix as part of the public review process.
EE-47	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	American River proposed measures would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.

EE-48	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
EE-49	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Editorial	The uncertainty in this statement is primarily related to how much erosion would occur, and how much bank would be lost in a single event. As stated in the No Action Alternative, because we cannot predict when and how large events will occur it would be speculative to assume at which time the berms will erode.
EE-50	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Filling in eroded portions of the bank would be necessary in cases where the bank has eroded away and could potentially undermine the levee foundation. This condition is more typical on the Sacramento River than the American River because there is less berm between the waterway and the levee.
EE-51	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Typically when we are referring to large vegetation vs small vegetation we are referring to trees versus shrubs or grasses.
EE-52	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Site specific designs for erosion protection will be completed in the design phase of this study, including any necessary hydraulic design of the bank protection sites.
EE-53	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The Corps will plant new trees as part of self-mitigating features on bank protection sites. New trees could be planted over time if the sites are not meeting their restoration criteria during the monitoring period, as established in the Mitigation and Monitoring Plan. Once the monitoring period has concluded, natural lifecycle processes are expected to occur.
EE-54	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Trees left in place are not expected to die. The Corps has been protecting trees in place as part of bank protection construction under the Sacramento River Bank Protection Project and the trees at these sites have had successful survival rates over the last decade.
EE-55	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The proposed project only impacts vegetation in the construction footprint, and proposes to protect existing trees in place whenever possible. Additionally, all trees removed from the construction footprint would be compensated for, in the case of the Parkway, on-site to the maximum extent practicable. As a result, while there would be a significant short term impact from vegetation removal, long-term vegetation in the parkway is expected to recover. As a result of these proposed measures, the conclusions presented in the draft EIS/EIR are appropriate.
EE-56	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Access ramps may not be needed in cases when there are already existing ramps developed that could be used during construction.
EE-57	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	A large berm made of large rocks. See Engineering Appendix for more details on the size and scope of the bank protection design.

EE-58	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Concur. The Corps will update figure 1 to ensure that the planting berm is shown.
EE-59	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Editorial	Thank you for pointing the error out. We have fixed this for the final EIS/EIR.
EE-60	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Editorial	Concur. The Corps has updated Figure 1 to ensure that the planting berm is shown.
EE-61	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	A design objective for the launchable rock trench was to reduce the launch distance and increase the reliability of the design. The proposed placement near bottom of the vadose zone does this and helps to reduce the overall rock quantity needed for this design.
EE-62	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The trench design will have soil placed with rock, however, it will not be thoroughly mixed due to the adverse affects to launching capability. Additionally, a geotextile wrap around the trench is proposed to limit the infiltration of soil into rock voids. Aspects to design features such as these will be refined in PED phase.
EE-63	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Excess fill that could not be used for project features would become available for borrow site mitigation or infill purposes at other restoration sites. Future coordination would be performed during PED phase.
EE-64	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Shrubs would be considered appropriate if it does not put undue burden on maintaining agencies, and if it is in locations that do not interfere with channel conveyance capacity.
EE-65	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The trench areas do have limitations as noted, however, they still offer an opportunity to partially/fully mitigate impacts. More specific analysis and coordination with maintenance agencies will be performed during PED phase to determine the mitigation capabilities of these sites.
EE-66	Friends of the River, Habitat 2020, and Save the American River Association	Letter	No Action	Yes, the No Action Alternative is based on past experience and is a forecast of what could transpire with large magnitude flood events.
EE-67	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The trench width is a function of existing topography, trench slopes, depth, and quantity of launchable rock. These aspects of the design will be analyzed in more detail within PED phase. For the purposes of this study and description of impacts, the 70 feet trench width, is considered to be conservative when applied to the extents shown in plates 3 and 4.
EE-68	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The acreage of impact was based on the construction footprint, including some additional areas like ramps and roads in the vegetation and wildlife section. Staging areas have not been determined at this time, because of the potential for changing conditions between this study and the implementation of the project, therefore this acreage was not included in current project estimates. Following authorization when site-specific design occurs, staging areas will be determined and if the impacts associated with those staging areas increase the environmental impacts disclosed in this EIS/EIR, then supplemental NEPA analysis would occur.

EE-69	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	For launchable rock trench, vegetation can not be deep rooted so that it does not interfere with the deployment (launching) of rock, plus, any vegetation other than grass and small shrubs needs to be placed 15 feet or more away from the waterside toe. Within the American River Parkway, this construction area is a very small percentage of the total area. On-site mitigation will be implemented to the maximum extent practicable.
EE-70	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The Corps anticipates restoring riparian vegetation both on and offsite, depending on site conditions and mitigation requirements. Plant establishment takes time. Typically most mitigation sites require up to 10 years of monitoring to ensure establishment that meets the restoration metrics established in the mitigation and monitoring plan. If sites are not meeting those criteria, they could require replanting, which could extend the establishment period. The only option for immediate mitigation/compensation would be purchasing credits at an off-site mitigation bank, which is an option being considered for some of the mitigation associated with the ARCF GRR.
EE-71	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-72	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Land Use	There is no permanent conversion of Parkway lands associated with the ARCF GRR. It is anticipated that all of the proposed erosion protection sites within the Parkway would remain a part of the Parkway, and would continue to be used by the public. This discussion regarding mitigation for permanent loss of Parkway lands has been removed from the final EIS/EIR.
EE-73	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Modeling results are a summarization of a Sacramento Bank Protection Regional Sediment Study. This is a challenging issue. In general, in the absence of bedrock or other erosion resistant materials, the LAR is degradational in nature down to about RM 4. Downstream of this location, the river is slightly aggradational. The erosion resistant layer has only been mapped between river miles 5.5 and 11.5 (approximate RM's). The vertical location of the resistant layer is unknown for the remainder of the river below Nimbus Dam. Despite the general trends, zones of local aggradation and degradation are observed to occur in both the prototype river channel as well as in numerical modeling simulations (e.g., HEC-6T). In the zone where the erosion resistant layer has been identified, it appears that continued wholesale lowering of the channel thalweg is unlikely; however, other portions of the channel cross section (e.g., channel terraces or berms) may continue to degrade over time.
EE-74	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The degradation analysis report did look at nick points developing into full head cuts that would move upstream and jeopardize levee stability. This study found that the only place that this was somewhat probable was in the vicinity of the Guy West bridge. That is the reason that study only recommended grade control in that vicinity. Further site specific design in PED will relook at this, likely in consultation with local stakeholder groups.
EE-75	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Draft results for the long-term simulation indicate that about 263,000 cy would be eroded for the without-project condition during the period simulated. For the without-project conditions, a volume of 304,000 cy would be eroded along the 22-mile study reach of the American River.

EE-76	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	When sediment is mobilized from along the American River or other rivers, it washes downstream. Ultimately, this sediment finds its way to the Suisun, San Pablo, and San Francisco Bay and ultimately to the Pacific Ocean.
EE-77	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Considerable sea level rise would be required to significantly impact the sediment transport ability of the reach of river in question. There are conditions where high stage on the Sacramento River causes backwater effects on the American River in the RM 5-7 stretch, but then there are other conditions where the backwater effect is not present but there are still significant flows coming down the American River causing higher rates of sediment transport including in the RM 5-7 range. Significant sea level rise would need to occur before the sediment transport capability of this reach of river would greatly reduce. However, this will be further studied in PED in consultation with local stakeholder groups.
EE-78	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	It is possible that if these rates of degradation are experienced, that hydraulic mining debris has been exhausted, but it does not have to occur that way. If this amount of degradation occurs, it will likely be because a nick point turns into a full head cut that moves upstream. This will further be analyzed however in PED in consultation with local stakeholder groups.
EE-79	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	We concur that naturally, upstream of RM 8 it is not a braided channel. But, artificially, because of the multiple channels associated with historic gravel mining, upstream of RM 8, sediment transport occurs as if it were a braided channel, which is why it is characterized this way. Further analysis in PED will address this further, likely in consultation with local stakeholder groups.
EE-80	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	In general, in the absence of bedrock or other erosion resistant materials, the American River is degradational in nature down to about River Mile 4. Downstream of this location, the river is slightly aggradational. The conclusions are not contradicting, but are referring to different reaches of the river. The erosion resistant layer has only been mapped between approximately River Miles 5.5 and 11.5. The vertical location of the resistant layer is unknown for the remainder of the river below Nimbus Dam. Despite the general trends, zones of local aggradation and degradation are observed to occur in both the prototype river channel as well as in numerical modeling simulations (e.g., HEC-6T). In the zone where the erosion resistant layer has been identified, it appears that continued wholesale lowering of the channel thalweg is unlikely; however, other portions of the channel cross section (e.g., channel terraces or berms) may continue to degrade over time.
EE-81	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Reference to RM 9.0R was only made as an example of where erosion is actively occurring, even at low discharges such as 7,000 cfs. The concern regarding the erosive trends in the LAR are not predicated on just this one location. A review of the performance of the LAR channel with regards to erosion reveals that multiple locations of the channel have experienced damaging erosion and have required repair following significant discharge event. The GRR and Section 3.4 of the EIS/EIR have been updated to show a comparison of erosion conditions in the channel at both the narrow RM 9 reach, and other lower velocity reaches.
EE-82	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Reference to RM 9.0R was only made as an example of where erosion is actively occurring, even at low discharges such as 7,000 cfs. The concern regarding the erosive trends in the LAR are not predicated on just this one location. A review of the performance of the LAR channel with regards to erosion reveals that multiple locations of the channel have experienced damaging erosion and have required repair following significant discharge event. The GRR and Section 3.4 of the EIS/EIR have been updated to show a comparison of erosion conditions in the channel at both the narrow RM 9 reach, and other lower velocity reaches.
EE-83	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Reference to RM 9.0R was only made as an example of where erosion is actively occurring, even at low discharges such as 7,000 cfs. The concern regarding the erosive trends in the LAR are not predicated on just this one location. A review of the performance of the LAR channel with regards to erosion reveals that multiple locations of the channel have experienced damaging erosion and have required repair following significant discharge event. The GRR and Section 3.4 of the EIS/EIR have been updated to show a comparison of erosion conditions in the channel at both the narrow RM 9 reach, and other lower velocity reaches.

EE-84	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Given the magnitudes of local shear and velocity along portions of the lower American River banks makes bio-engineering or other soft approaches for providing bank protection very challenging. Nonetheless, site specific designs for bank and erosion protection will be developed in the design phase of the study. As part of the Folsom Water Control Manual, additional Channel Stability Analyses are being conducted to further refine the designs.
EE-85	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	It is possible that sewer main undercrossing is contributing to the erosion concerns at RM 7. However, looking at the Ayres' velocity plots - the velocity at this location is high enough to be of concern with or without the sewer main undercrossing. Site specific designs for erosion protection will be completed in the design phase of this study and the sewer main undercrossing will be evaluated.
EE-86	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	It is possible that sewer main undercrossing is contributing to the erosion concerns at RM 7. However, looking at the Ayres' velocity plots - the velocity at this location is high enough to be of concern with or without the sewer main undercrossing. Site specific designs for erosion protection will be completed in the design phase of this study known as Preconstruction, Engineering and Design (PED) and the sewer main undercrossing will be evaluated. Given the magnitudes of local shear and velocity along portions of the lower American River banks makes bio-engineering or other soft approaches for providing bank protection very challenging. Nonetheless, site specific designs for bank and erosion protection will be developed in the next phase of the study (PED Phase). As part of the Folsom Water Control Manual, additional Channel Stability Analyses are being conducted to further refine the designs.
EE-87	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Concur, this text has been removed and the section has been reassessed.
EE-88	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The text has been revised to clarify that the discussion refers to surface runoff conditions, which are not expected to be impacted by implementation of the project. Erosion conditions will be addressed by the proposed measures.
EE-89	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	For the purposes of this study, the project features were designed with a flow of 160,000 cfs which is currently estimated to be a 200-year event.
EE-90	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The ARCF GRR used a conservative characterization of future flood management operations at Folsom Dam assuming the JFP auxiliary spillway and control structure are complete. The Folsom Dam future operations reflected in the ARCF GRR are based on the operations identified in the Folsom Dam Modification and Folsom Dam Raise Projects Post Authorization Change Report (2007) (JFP PACR). Evaluation of how the flow regime has changed to get to the Spillway and Dam raise in place is being done under the Folsom Water Control Manual Update.
EE-91	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Manual Update	The Folsom Dam Water Control Manual Update Draft Supplemental EIS/EIR is tentatively scheduled for release in the summer of 2016.
EE-92	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Use of launchable rock results in a layer of rock which provides erosion protection if/when the rock is launched. The design ensures that sufficient volume of rock is available to provide protection and takes into consideration that the layer is formed, underwater, primarily by gravity. Given the size and depth of the LAR, the layer of "launched" rock would not significantly impact the hydraulic conditions.

EE-93	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Use of launchable rock results in a layer of rock which provides erosion protection if/when the rock is launched. The design ensures that sufficient volume of rock is available to provide protection and takes into consideration that the layer is formed, underwater, primarily by gravity. Given the size and depth of the LAR, the layer of "launched" rock would not significantly impact the hydraulic conditions.
EE-94	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Tree surveys were conducted using the Sacramento County standards for tree measurements. Tree survey data is contained within GIS shape files and is available upon request from the Corps.
EE-95	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Thank you for your comment. The assumption that natural environments can be easily disturbed by heavy use is a standard methodology applied to impact assessment.
EE-96	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Thank you for your comment. Special-status species in the study area, such as the valley elderberry longhorn beetle, benefit from habitat connectivity, which can be achieved through the restoration of larger natural areas. Smaller restoration areas can fragment the habitat and provide less habitat values through most habitat assessment methodologies, than larger stands of natural habitat.
EE-97	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Section 1508.20 of NEPA defines mitigation as a term that encompasses: (1) Avoiding, (2) Minimizing, (3) Rectifying, (4) Reducing, or (5) Compensating for an impact. Compensation would consist of replacing impacted habitat.
EE-98	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Substantial effects are considered to be significant, unmitigatable effects, as described throughout Sections 3.6.4 and 3.6.5. Conflicting with a plan indicates not complying with the relevant goals and policies of that plan.
EE-99	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Citation to this reference from the Parkway Plan was added to the Final EIS/EIR.
EE-100	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Section 3.6 of the EIS/EIR has been updated to clarify habitat impacts under the proposed study.
EE-101	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
EE-102	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.

EE-103	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Footprints were developed for internal use only during the study process, primarily because they are intended to be the largest possible footprint and likely do not represent the refined/reduced footprint that will actually be implemented when the project reaches the construction phase. As site-specific designs are refined post-authorization, these more accurate footprints will be available for coordination and consultation purposes.
EE-104	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	65 acres of riparian habitat are estimated to be impacted by construction of the launchable rock trenches within the American River Parkway.
EE-105	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-106	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
EE-107	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-108	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.

EE-109	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Analysis was intended to address a worst-case scenario, therefore we should not be assuming more impacts than a potential worst-case scenario. If there are greater impacts than what is stated in the NEPA document, then a supplemental NEPA document would be required to address those increased impacts, and further coordination would be required under that supplemental analysis. Therefore, yes, increased impacts would require additional coordination.
EE-110	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The preferred alternative for erosion protection is a combination of both measures, based on site-specific conditions. Site specific designs for erosion protection will be completed in the design phase of this study.
EE-111	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The EIS/EIR assesses impacts and mitigation, including short term and long term impacts. The Mitigation and Monitoring Plan, which is appended to the Final EIS/EIR also includes more information regarding mitigation planning.
EE-112	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Trees left in place are not expected to die. The Corps has been protecting trees in place as part of bank protection construction under the Sacramento River Bank Protection Project and the trees at these sites have had successful survival rates over the last decade.
EE-113	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Trees left in place are not expected to die. The Corps has been protecting trees in place as part of bank protection construction under the Sacramento River Bank Protection Project and the trees at these sites have had successful survival rates over the last decade.
EE-114	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The planting berm/trench is discussed in the draft EIS/EIR Section 2.3.1 under "Bank Protection" in the 2nd and 4th paragraphs. Concur. The Corps will update figure 1 to ensure that the planting berm is shown.
EE-115	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Mitigation was estimated using a maximized footprint of potential impacts, which would be refined during the design phase of the project. The footprint was not minimized or reduced by any proposed mitigation, such as planting berms.
EE-116	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Design based on site-specific hydraulic and environmental conditions would occur during the design phase of the project to determine which erosion protection measure is appropriate at each location.
EE-117	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	A mitigation and monitoring plan was prepared and will be appended to the final EIS/EIR.
EE-118	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The Corps has conducted internal assessments during the planning phase to determine the feasibility of all mitigation commitments. The Corps has confidence that all American River vegetation impacts can be mitigated within the Parkway without compromising the integrity of the flood management system. The proposed alternatives have been designed in accordance with the American River Parkway Plan Flood Control Policies. During the preconstruction engineering and design phase of the project, site-specific designs will be conducted for each segment of the project, and will include the final design of all mitigative features, which would be implemented during project construction. If the Corps determines that proposed onsite mitigation is not feasible, credits may be purchased at a mitigation bank.

EE-119	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Trenches would be buried within the existing berm footprint and would not change the elevation of the berm in any way. Mitigation proposed for the trench surface would compensate for impacts from construction of the trench and would attempt to recreate similar habitat to the maximum extent practicable.
EE-120	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Mitigation proposed for the trench surface would compensate for impacts from construction of the trench and would attempt to recreate similar habitat to the maximum extent practicable. If habitat removed is not compatible with the trench, then offsite mitigation in the vicinity of the trench would be sought.
EE-121	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The launchable rock trench size was estimated as a conservative design based on a forecast of the potential for degradation of the channel and bank during a flood event. During the preconstruction engineering and design phase of the project this design will be refined based on site-specific conditions.
EE-122	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	130 acres of riparian mitigation is based on the 65 acre impact, mitigated on a 2:1 basis.
EE-123	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-124	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	An assumption was made for the purposes of mitigation planning that all elderberry shrubs are riparian because the Corps was evaluating effects based on a maximum impact scenario and riparian shrubs have more stringent mitigation requirements than non-riparian shrubs. During site-specific designs, each elderberry shrub will be evaluated on an individual basis and the mitigation will be adjusted, as needed, based on the existing conditions prior to construction.
EE-125	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	An assumption was made for the purposes of mitigation planning that all elderberry shrubs are riparian because the Corps was evaluating effects based on a maximum impact scenario and riparian shrubs have more stringent mitigation requirements than non-riparian shrubs. During site-specific designs, each elderberry shrub will be evaluated on an individual basis and the mitigation will be adjusted, as needed, based on the existing conditions prior to construction.
EE-126	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	The surveys were conducted prior to project design and include only 15 feet from the levee, both landside and waterside. There is the potential that there are more trees impacted by the trench than the survey results showed, which is why the impact associated with the trench is an acreage rather than a tree count. The footprint of the trenches is a maximum of 65 acres.
EE-127	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	The associated natives are based on the requirements established in the USFWS Conservation Guidelines for the Valley Elderberry Longhorn Beetle (USFWS, July 1999). The guidelines list and establish a number of species that are appropriate for VELB mitigation sites, including various species of willows, cottonwoods, oaks, box elder, etc.

EE-128	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Impacts to vegetation and wildlife within the project area are evaluated based on data collected from the tree surveys conducted in 2011, site visits, Google Earth, and the American River Parkway Plan. Engineering provided estimated construction footprints overlayed on aerial photos of the project area. The estimated acreage of impacts shown in the Final EIS/EIR was determined by overlaying the largest possible footprint of the erosion repair work proposed onto aerial photographs of the study area and calculating the habitat within the footprint. Additionally, the habitat maps appended to the Final EIS/EIR were reviewed to determine what other habitat types such as wetlands might be present.
EE-129	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
EE-130	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	The surveys were conducted prior to project design and include only 15 feet from the levee, both landside and waterside. There is the potential that there are more trees impacted by the trench than the survey results showed, which is why the impact associated with the trench is an acreage rather than a tree count. The footprint of the trenches is a maximum of 65 acres.
EE-131	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Effects	Analysis was intended to address a worst-case scenario, therefore we should not be assuming more impacts than a potential worst-case scenario. If there are greater impacts than what is stated in the NEPA document, then a supplemental NEPA document would be required to address those increased impacts, and further coordination would be required under that supplemental analysis. Therefore, yes, increased impacts would require additional coordination.
EE-132	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Yes, the tree surveys were conducted in 2011.
EE-133	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The launchable rock trench size was estimated as a conservative design based on a forecast of the potential for degradation of the channel and bank during a flood event. During the preconstruction engineering and design phase of the project this design will be refined based on site-specific conditions.
EE-134	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	The associated natives are based on the requirements established in the USFWS Conservation Guidelines for the Valley Elderberry Longhorn Beetle (USFWS, July 1999). The guidelines list and establish a number of species that are appropriate for VELB mitigation sites, including various species of willows, cottonwoods, oaks, box elder, etc.
EE-135	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.

EE-136	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Specific mitigation plans, including any lands needed, will be developed during the site-specific design process following Congressional authorization. It is possible that more Parkway lands could be needed for mitigation, however locations haven't been selected yet. Any decisions on locations of mitigation for this project would be developed in coordination with the Sacramento County Department of Parks and Recreation.
EE-137	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	See new impact summary tables in EIS/EIR Section 3.6. Sacramento River has greater impacts. American River effects are double counted in some locations because site-specific design won't occur until PED. Impacts were maximized to account for either erosion protection scenario.
EE-138	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Hawk Mitigation	On page 146 of the draft EIS/EIR, it states that a 0.25-mile buffer would be established between construction activities and active nests.
EE-139	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Proposed vegetation establishment at bank protection sites is applicable to all bank protection sites proposed within the study area, including the American River. The specific details of the vegetation establishment in the planting berm would be designed on a site-specific basis in the design phase of the project.
EE-140	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	On page 30 of the draft EIS/EIR in Section 2.3.1, the planting berm is described as follows: After revetment placement has been completed, a small planting berm would be constructed in the rock where feasible to allow for some revegetation of the site, outside of the vegetation free zone as required by ETL 1110-2-583. This vegetation will be designed on a site specific basis to minimize the O&M responsibility of the LMA and in such a way to not impact the hydraulic conveyance of the channel.
EE-141	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Riparian mitigation would include planting of a variety of species associated with this habitat type, including oaks, cottonwoods, willows, box elder, elderberries, etc. All plantings within the Parkway would be established in coordination with County Parks and per the approved Parkway plant list. Woodlake/Cal Expo could be used for riparian mitigation, however it is not a preferred location for mitigation within the Parkway, due to continued problems with wildfires in this portion of the Parkway. The Corps is not likely to support additional mitigation sites at this location.
EE-142	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	The removal of riparian habitat for construction would likely also include the removal of some trees (as described in Section 3.6.4) that provide nesting habitat for Swainson's Hawk.
EE-143	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Page 147 of the draft EIS/EIS states that 134 acres of riparian habitat supporting Swainson's hawks would be removed.
EE-144	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Coordination would occur between the Corps and County Parks to determine the appropriateness and availability of mitigation opportunities within the Parkway. The Corps and County Parks have a history of collaborating in this way (e.g, the creation of a number of existing restoration sites within the Parkway, including Cal Expo, Sailor Bar, and River Bend Park, among others).
EE-145	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Coordination	Coordination would occur between the Corps and County Parks to determine the appropriateness and availability of mitigation opportunities within the Parkway. The Corps and County Parks have a history of collaborating in this way for the creation of a number of existing restoration sites within the Parkway, including Cal Expo, Sailor Bar, and River Bend Park, among others. Mitigation for Swainson's hawk is guaranteed to occur due to stipulations in the USFWS Biological Opinion, which requires compensation for the removal of riparian trees due to impacts to the Western yellow-billed cuckoo.

EE-146	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Impacts	Typically, impacts from construction are considered to be temporary and short-term, because construction only occurs for a limited amount of time. In this case, since construction is proposed over a number of years, although in different parts of the parkway, the temporary disruption from construction is treated differently than a typical less-than-significant short term impact. This is why the determination resulted in a significant, unmitigatable effect on recreation.
EE-147	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Impacts	"Eliminate" indicates a permanent loss of recreation. "Restrictions" indicate more of a limitation in what recreation activity could occur. "Disruption" is more related to the impacts that occur to present recreationists using the facility, such as noise or dust from construction.
EE-148	Friends of the River, Habitat 2020, and Save the American River Association	Letter	No Action	The Parkway Plan has specifically identified policies for Flood Control project implementation. The Flood Control policies identified in Chapter 4 of the Parkway Plan are the relevant regulations for this action. Implementation of the project is consistent with these policies. Allowing the Parkway to erode away over time, as is assumed in the No Action Alternative, would not be consistent with these policies.
EE-149	Friends of the River, Habitat 2020, and Save the American River Association	Letter	No Action	Citations for the Parkway Plan quotes have been added to the Final EIS/EIR.
EE-150	Friends of the River, Habitat 2020, and Save the American River Association	Letter	No Action	The Parkway Plan has specifically identified policies for Flood Control project implementation. The Flood Control policies identified in Chapter 4 of the Parkway Plan are the relevant regulations for this action. The project is in compliance with these policies, as identified throughout the various sections of this EIS/EIR. This discussion has been expanded for the final report.
EE-151	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Recreation	Section 3.14 evaluates the effects of the project on recreational resources and establishes that significant effects from detours and possible closures of portions of the parkway during construction would conflict with the Parkway Plan.
EE-152	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Recreation	Section 3.14 evaluates the effects of the project on recreational resources and establishes that significant effects from detours and possible closures of portions of the parkway during construction would conflict with the Wild and Scenic Rivers Act.
EE-153	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Recreation	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-154	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Aesthetics	Concur. The Visual Resources No Action alternative has been updated to include full berm loss as a significant impact.

EE-155	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project Area	There is a total of 11 miles of erosion protection proposed for the Parkway.
EE-156	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The planting berm/trench is discussed in the draft EIS/EIR Section 2.3.1 under "Bank Protection" in the 2nd and 4th paragraphs. Concur. The Corps will update figure 1 to ensure that the planting berm is shown.
EE-157	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	There would be no planting berm under the launchable rock trench measure. The planting berm is only associated with bank protection measures. Under the trench scenario, on-site plantings would be above the trench.
EE-158	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Mitigation proposed for the trench surface would compensate for impacts from construction of the trench and would attempt to recreate similar habitat to the maximum extent practicable. If habitat removed is not compatible with the trench, then offsite mitigation in the vicinity of the trench would be sought.
EE-159	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	Elderberry shrubs estimated to be impacted by the project are contained within the acreage of riparian that are estimated to be mitigated. Elderberry mitigation requires the planting of associated riparian native plants. Mitigating for these two habitat types together is an effective and reasonable assumption for the project.
EE-160	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	An assumption was made for the purposes of mitigation planning that all elderberry shrubs are riparian because the Corps was evaluating effects based on a maximum impact scenario and riparian shrubs have more stringent mitigation requirements than non-riparian shrubs. During site-specific designs, each elderberry shrub will be evaluated on an individual basis and the mitigation will be adjusted, as needed, based on the existing conditions prior to construction.
EE-161	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	Elderberry shrubs removed from the riparian corridor are considered to be riparian, and on-site mitigation associated with these impacts would be designed to contribute to the riparian corridor.
EE-162	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Mitigation proposed for the trench surface would compensate for impacts from construction of the trench and would attempt to recreate similar habitat to the maximum extent practicable. If habitat removed is not compatible with the trench, then offsite mitigation in the vicinity of the trench would be sought.
EE-163	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Mitigation proposed for the trench surface would compensate for impacts from construction of the trench and would attempt to recreate similar habitat to the maximum extent practicable. If habitat removed is not compatible with the trench, then offsite mitigation in the vicinity of the trench would be sought.

EE-164	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	The Visual Resources No Action alternative has been updated to include full berm loss as a significant impact. Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-165	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Concur. The Corps will update figure 1 to ensure that the planting berm is shown.
EE-166	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The repair shown is a conceptual design that reflects actual construction on the American River as part of the Sac Bank sites repair. In PED, site specific design will occur that will take into account the hydraulic, geotechnical, topographical, environmental, and cultural aspects of each site. The Corps, in conjunction with stakeholders will address the constraints at individual sites to come up with the best design alternative for each site.
EE-167	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The repair shown is a conceptual design that reflects actual construction on the American River as part of the Sac Bank sites repair. In PED, site specific design will occur that will take into account the hydraulic, geotechnical, topographical, environmental, and cultural aspects of each site. The Corps, in conjunction with stakeholders will address the constraints at individual sites to come up with the best design alternative for each site.
EE-168	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The repair shown is a conceptual design that reflects actual construction on the American River as part of the Sac Bank sites repair. In PED, site specific design will occur that will take into account the hydraulic, geotechnical, topographical, environmental, and cultural aspects of each site. The Corps, in conjunction with stakeholders will address the constraints at individual sites to come up with the best design alternative for each site.
EE-169	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The Corps concurs that rock will be visible, even after revegetation has been established, particularly during low water years. It is anticipated that over time, as new vegetation establishes, the visibility of rock revetment will be greatly reduced. Section 3.15 of the EIS/EIR has been updated to acknowledge that rock will be visible.
EE-170	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The Corps concurs that rock will be visible, even after revegetation has been established, particularly during low water years. It is anticipated that over time, as new vegetation establishes, the visibility of rock revetment will be greatly reduced. Section 3.15 of the EIS/EIR has been updated to acknowledge that rock will be visible.
EE-171	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The Corps concurs that rock will be visible, even after revegetation has been established, particularly during low water years. It is anticipated that over time, as new vegetation establishes, the visibility of rock revetment will be greatly reduced. Section 3.15 of the EIS/EIR has been updated to acknowledge that rock will be visible.

EE-172	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The Sac Bank site shown is a worst case scenario with regards to the amount of bank protection being required and the revegetation that is included in the design. It is anticipated that during site specific design, the quantity of rock needed at most sites will be less than at this site. With this reduction in rock, and the ability to work around most existing vegetation, the extent of environmental impacts is expected to be reduced.
EE-173	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
EE-174	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
EE-175	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Impacts for the American River are as described in the document throughout Section 3.6. As described above, this estimate is based on the impacts to vegetation in the construction footprint and the level of impact would not change under a variance. American River proposed measures would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
EE-176	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Typically when we are referring to large vegetation vs small vegetation we are referring to trees versus shrubs or grasses.
EE-177	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Bank protection will be placed around large trees. If necessary, select trees will need to be removed for construction purposes such as the ability of a hydraulic excavator to place bank protection. Launchable rock protection will require complete removal of vegetation within the footprint of the trench. In all cases, vegetation is being removed for construction purposes and not because of hydraulic analysis.
EE-178	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Trees left in place are not expected to die. The Corps has been protecting trees in place as part of bank protection construction under the Sacramento River Bank Protection Project and the trees at these sites have had successful survival rates over the last decade.
EE-179	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Trees left in place are not expected to die. The Corps has been protecting trees in place as part of bank protection construction under the Sacramento River Bank Protection Project and the trees at these sites have had successful survival rates over the last decade.
EE-180	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The proposed project only impacts vegetation in the construction footprint, and proposes to protect existing trees in place whenever possible. Additionally, all trees removed from the construction footprint would be compensated for, in the case of the Parkway, on-site to the maximum extent practicable. As a result, while there would be a significant short term impact from vegetation removal, long-term vegetation in the parkway is expected to recover. As a result of these proposed measures, the conclusions presented in the draft EIS/EIR are appropriate.

EE-181	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	A large berm made of large rocks. See Engineering Appendix for more details on the size and scope of the bank protection design.
EE-182	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Concur. The Corps will update figure 1 to ensure that the planting berm is shown.
EE-183	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Design based on site-specific hydraulic and environmental conditions would occur during the design phase of the project to determine which erosion protection measure is appropriate at each location.
EE-184	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Shallow rooted trees could be planted on the trench surface. Trench configuration is described in Chapter 2 of the EIS/EIR.
EE-185	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Vegetation would be removed only from the construction footprint of the project. To the maximum extent practicable, mitigation would be conducted on site with the ultimate goal of returning on-site conditions to as close to pre-project conditions as possible. Further information on proposed mitigation is included in the Mitigation and Monitoring Plan, which is appended to the final EIS/EIR.
EE-186	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Site specific erosion protection analysis to be completed during the design phase could identify locations where better long term resource results and may be able to minimize short term impacts. These additional measures may have less substantial effects that result from site specific design.
EE-187	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Mitigation proposed for the trench surface would compensate for impacts from construction of the trench and would attempt to recreate similar habitat to the maximum extent practicable. If habitat removed is not compatible with the trench, then offsite mitigation in the vicinity of the trench would be sought.
EE-188	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The trench width is a function of existing topography, trench slopes, depth, and quantity of launchable rock. These aspects of the design will be analyzed in more detail within PED phase. For the purposes of this study and description of impacts, the 70 feet trench width, is considered to be conservative when applied to the extents shown in plates 3 and 4.
EE-189	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Concur. Under the No Action Alternative, with erosion not addressed, full berm loss in a major flood event is assumed, and this is considered to be a significant impact.
EE-190	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	The Corps has updated the No Action Alternative sections to indicate that full berm loss during a major flood event is considered to be a significant impact.

EE-191	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-192	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-193	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The planting berm/trench is discussed in the draft EIS/EIR Section 2.3.1 under "Bank Protection" in the 2nd and 4th paragraphs. Planting berms are associated with the bank protection design and not the launchable rock trench design. Trenches will be designed on a site-specific basis and would include shallow-rooted tree species.
EE-194	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	There would be no planting berm under the launchable rock trench measure. The planting berm is only associated with bank protection measures. Under the trench scenario, on-site plantings would be above the trench.
EE-195	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Section 2.3.1 includes revegetation through the planting berm at bank protection sites, and through planting shallow-rooted species on the surface of the trenches. This is consistent with the visual mitigation discussion. It should be noted that the conclusion of the visual resources section is that effects are significant and cannot be fully mitigated. This conclusion is primarily due to the temporal loss of vegetation while the new vegetation is establishing.
EE-196	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project Area	There is a total of 11 miles of erosion protection proposed for the Parkway.
EE-197	Friends of the River, Habitat 2020, and Save the American River Association	Letter	No Action	The No Action Alternative is based on past experience and is a forecast of what could transpire with large magnitude flood events in the future. It is based on best available information, but does not include specific qualitative estimates.

EE-198	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-199	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The trench width is a function of existing topography, trench slopes, depth, and quantity of launchable rock. These aspects of the design will be analyzed in more detail within PED phase. For the purposes of this study and description of impacts, the 70 feet trench width, is considered to be conservative when applied to the extents shown in plates 3 and 4.
EE-200	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	The acreage of impact was based on the construction footprint, including some additional areas like ramps and roads in the vegetation and wildlife section. Staging areas have not been determined at this time, because of the potential for changing conditions between this study and the implementation of the project, therefore this acreage was not included in current project estimates. Following authorization when site-specific design occurs, staging areas will be determined and if the impacts associated with those staging areas increase the environmental impacts disclosed in this EIS/EIR, then supplemental NEPA analysis would occur.
EE-201	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Modeling results are a summarization of a Sacramento Bank Protection Regional Sediment Study. This is a challenging issue. In general, in the absence of bedrock or other erosion resistant materials, the LAR is degradational in nature down to about RM 4. Downstream of this location, the river is slightly aggradational. The erosion resistant layer has only been mapped between river miles 5.5 and 11.5 (approximate RM's). The vertical location of the resistant layer is unknown for the remainder of the river below Nimbus Dam. Despite the general trends, zones of local aggradation and degradation are observed to occur in both the prototype river channel as well as in numerical modeling simulations (e.g., HEC-6T). In the zone where the erosion resistant layer has been identified, it appears that continued wholesale lowering of the channel thalweg is unlikely; however, other portions of the channel cross section (e.g., channel terraces or berms) may continue to degrade over time.
EE-202	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The degradation analysis report did look at nick points developing into full head cuts that would move upstream and jeopardize levee stability. This study found that the only place that this was somewhat probable was in the vicinity of the Guy West bridge. That is the reason that study only recommended grade control in that vicinity. Further site specific design in PED will relook at this, likely in consultation with local stakeholder groups.
EE-203	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Draft results for the long-term simulation indicate that about 263,000 cy would be eroded for the without-project condition during the period simulated. For the without-project conditions, a volume of 304,000 cy would be eroded along the 22-mile study reach of the American River.
EE-204	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	When sediment is mobilized from along the American River or other rivers, it washes downstream. Ultimately, this sediment finds its way to the Suisun, San Pablo, and San Francisco Bay and ultimately to the Pacific Ocean.

EE-205	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Considerable sea level rise would be required to significantly impact the sediment transport ability of the reach of river in question. There are conditions where high stage on the Sacramento River causes backwater effects on the American River in the RM 5-7 stretch, but then there are other conditions where the backwater effect is not present but there are still significant flows coming down the American River causing higher rates of sediment transport including in the RM 5-7 range. Significant sea level rise would need to occur before the sediment transport capability of this reach of river would greatly reduce. However, this will be further studied in PED in consultation with local stakeholder groups.
EE-206	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	We concur that naturally, upstream of RM 8 it is not a braided channel. But, artificially, because of the multiple channels associated with historic gravel mining, upstream of RM 8, sediment transport occurs as if it were a braided channel, which is why it is characterized this way. Further analysis in PED will address this further, likely in consultation with local stakeholder groups.
EE-207	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	This is a challenging issue. In general, in the absence of bedrock or other erosion resistant materials, the LAR is degradational in nature down to about RM 4. Downstream of this location, the river is slightly aggradational. The erosion resistant layer has only been mapped between river miles 5.5 and 11.5 (approximate RM's). The vertical location of the resistant layer is unknown for the remainder of the river below Nimbus Dam. Despite the general trends, zones of local aggradation and degradation are observed to occur in both the prototype river channel as well as in numerical modeling simulations (e.g., HEC-6T). In the zone where the erosion resistant layer has been identified, it appears that continued wholesale lowering of the channel thalweg is unlikely; however, other portions of the channel cross section (e.g., channel terraces or berms) may continue to degrade over time.
EE-208	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Reference to RM 9.0R was only made as an example of where erosion is actively occurring, even at low discharges such as 7,000 cfs. The concern regarding the erosive trends in the LAR are not predicated on just this one location. A review of the performance of the LAR channel with regards to erosion reveals that multiple locations of the channel have experienced damaging erosion and have required repair following significant discharge event.
EE-209	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Reference to RM 9.0R was only made as an example of where erosion is actively occurring, even at low discharges such as 7000 cfs. The concern regarding the erosive trends in the LAR are not predicated on just this one location. A review of the performance of the LAR channel with regards to erosion reveals that multiple locations of the channel have experienced damaging erosion and have required repair following significant discharge event.
EE-210	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	It is possible that sewer main undercrossing is contributing to the erosion concerns at RM 7. However, looking at the Ayres' velocity plots - the velocity at this location is high enough to be of concern with or without the sewer main undercrossing. Site specific designs for erosion protection will be completed in the design phase of this study known as Preconstruction, Engineering and Design (PED) and the sewer main undercrossing will be evaluated. Given the magnitudes of local shear and velocity along portions of the lower American River banks makes bio-engineering or other soft approaches for providing bank protection very challenging. Nonetheless, site specific designs for bank and erosion protection will be developed in the next phase of the study (PED Phase). As part of the Folsom Water Control Manual, additional Channel Stability Analyses are being conducted to further refine the designs.

EE-211	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	It is possible that sewer main undercrossing is contributing to the erosion concerns at RM 7. However, looking at the Ayres' velocity plots - the velocity at this location is high enough to be of concern with or without the sewer main undercrossing. Site specific designs for erosion protection will be completed in the design phase of this study known as Preconstruction, Engineering and Design (PED) and the sewer main undercrossing will be evaluated. Given the magnitudes of local shear and velocity along portions of the lower American River banks makes bio-engineering or other soft approaches for providing bank protection very challenging. Nonetheless, site specific designs for bank and erosion protection will be developed in the next phase of the study (PED Phase). As part of the Folsom Water Control Manual, additional Channel Stability Analyses are being conducted to further refine the designs.
EE-212	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The significance criteria in the Hydrology and Hydraulics section is based on the environmental checklist in Appendix G of the State CEQA Guidelines. Hydraulic effects are discussed throughout the section and the determination is that there would be no significant hydraulic effects associated with the project.
EE-213	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	Design based on site-specific hydraulic and environmental conditions would occur during the design phase of the project to determine which erosion protection measure is appropriate at each location.
EE-214	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The text has been revised to clarify that the discussion refers to surface runoff conditions, which are not expected to be impacted by implementation of the project. Erosion conditions will be addressed by the proposed measures. If trenches have launched, significant berm has been lost and channel geometry was highly altered by a major flood event. The launched trench would protect the levee. Erosion of the berm is not considered an impact of the project as it is part of the existing condition. Addressing the changed geometry post-flood event would be part of a collaborative effort during the recovery period.
EE-215	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	For the purposes of this study, the project features were designed with a flow of 160,000 cfs which is currently estimated to be a 200-year event. The ARCF GRR used a conservative characterization of future flood management operations at Folsom Dam assuming the JFP auxiliary spillway and control structure are complete. The Folsom Dam future operations reflected in the ARCF GRR are based on the operations identified in the Folsom Dam Modification and Folsom Dam Raise Projects Post Authorization Change Report (2007) (JFP PACR). Evaluation of how the flow regime has changed to get to the Spillway and Dam raise in place is being done under the Folsom Water Control Manual Update.
EE-216	Friends of the River, Habitat 2020, and Save the American River Association	Letter	H&H	The significance criteria in the Hydrology and Hydraulics section is based on the environmental checklist in Appendix G of the State CEQA Guidelines. Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.

EE-217	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The comment is unclear. Site-specific designs will be coordinated with County Parks during the PED phase of the project.
EE-218	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The EIS/EIR assesses impacts and mitigation, including short term and long term impacts. The Mitigation and Monitoring Plan, which is appended to the Final EIS/EIR also includes more information regarding mitigation planning.
EE-219	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Trees left in place are not expected to die. The Corps has been protecting trees in place as part of bank protection construction under the Sacramento River Bank Protection Project and the trees at these sites have had successful survival rates over the last decade.
EE-220	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Mitigation plans have been refined since the preparation of the draft EIS/EIR and are evaluated in more detail in the Mitigation and Monitoring Plan, which is appended to the Final EIS/EIR. These plans will be further evaluated in PED during site-specific engineering design and selection of any off-site mitigation sites. Some riparian plantings will occur on the trenches, however, at this time the Corps anticipates that not all required mitigation will occur on-site.
EE-221	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-222	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-223	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	An assumption was made for the purposes of mitigation planning that all elderberry shrubs are riparian because the Corps was evaluating effects based on a maximum impact scenario and riparian shrubs have more stringent mitigation requirements than non-riparian shrubs. During site-specific designs, each elderberry shrub will be evaluated on an individual basis and the mitigation will be adjusted, as needed, based on the existing conditions prior to construction.

EE-224	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	Mitigation requirements for VELB are established in the USFWS Conservation Guidelines for the Valley Elderberry Longhorn Beetle (USFWS, July 1999). The guidelines require that elderberries are planted along with a ratio of associated native plants. The Conservation Guidelines list and establish a number of species that are appropriate for VELB mitigation sites, including various species of willows, cottonwoods, oaks, box elder, etc.
EE-225	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	Trench footprints are part of the riparian corridor. They primarily consist of riparian forest and oak woodland habitat types. In some cases they would also impact ruderal herbaceous habitat areas. The acreage of impacts will be refined during the design phase and a more accurate assessment of the habitat impacts will be conducted at that time. It is not anticipated that trenches would impact SRA habitat.
EE-226	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	Existing mitigation sites within the American River Parkway contribute to the riparian corridor and therefore are generally considered to be riparian. When these sites reach full maturity they are expected to provide riparian habitat.
EE-227	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	The relationship between these mitigation types has not been established at this time. There is some overlap between the riparian mitigation and the required "associated natives " that must be planted for VELB mitigation. The final acreage of mitigation will be determined prior to construction and will be based on the recommendations in the USFWS CAR and the requirements of the Biological Opinion, as well as through coordination with County Parks.
EE-228	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-229	Friends of the River, Habitat 2020, and Save the American River Association	Letter	VELB	Elderberry impacts were based on the 2011 surveys. Because habitat will grow and could change significantly between 2011 and implementation of construction, surveys and counts will be conducted again prior to construction and mitigation implemented would be coordinated with USFWS prior to construction. Mitigation estimates were based on best available information during the planning phase. The project's cost estimate includes contingency costs to allow for potential future increases in mitigation. However, the expectation is that project footprints would decrease during construction and that impacts overall would likely be reduced.
EE-230	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
EE-231	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The draft EIS/EIR does not propose planting levee slopes. Smaller vegetation such as grasses and shrubs must be removed in order to construct bank protection sites, but large trees can be protected in place. Bank protection sites would include the establishment of a planting berm on the waterside toe of the levee. Figures in Chapter 2 will be updated for clarity and will show the planting berms in the Final EIS/EIR.

EE-232	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Smaller vegetation such as grasses and shrubs must be removed in order to construct bank protection sites, but large trees can be protected in place. Bank protection sites would include the establishment of a planting berm on the waterside toe of the levee. Figures in Chapter 2 will be updated for clarity and will show the planting berms in the Final EIS/EIR.
EE-233	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Design based on site-specific hydraulic and environmental conditions would occur during the design phase of the project to determine which erosion protection measure is appropriate at each location. Planting berms would include a soil cap to allow for establishment of new vegetation and long-term revegetation (see Figures 8-10 of the EIS/EIR showing vegetative features in bank protection sites near CSU Sacramento).
EE-234	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Design based on site-specific hydraulic and environmental conditions would occur during the design phase of the project to determine which erosion protection measure is appropriate at each location.
EE-235	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	The Corps has worked very closely with National Marine Fisheries Service under the Sacramento River Bank Protection Project (SRBPP) over the last 10-15 years to design self-mitigating bank protection sites, which include various types of planting berms to account for impacts to SRA habitat. Under the ARCF GRR, the Corps proposes to evaluate each bank protection site during the design phase to apply the appropriate SRBPP design to minimize and mitigate for effects to habitat.
EE-236	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	An estimate of impacts and mitigation for the American River erosion protection work is included in the EIS/EIR in Sections 3.6 and 3.8 and in the Mitigation and Monitoring Plan, which is appended to the Final EIS/EIR. The final mitigation acreage will be coordinated following authorization once site-specific surveys and designs have been completed. At that time, coordination with County Parks and the resource agencies would occur and the final required mitigation would be established.
EE-237	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	The removal of riparian habitat for construction would likely also include the removal of some trees (as described in Section 3.6.4) that provide nesting habitat for Swainson's Hawk.
EE-238	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Woodlake/Cal Expo could be used for Swainson's/riparian mitigation, however it is not a preferred location for mitigation within the Parkway, due to continued problems with wildfires in this portion of the Parkway. The Corps is not likely to support additional mitigation sites at this location.
EE-239	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Habitat impacts have been clarified in Section 3.6 and 3.8 of the Final EIS/EIR. Additional information is also included in the Mitigation and Monitoring Plan, which is appended to the Final EIS/EIR.
EE-240	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.

EE-241	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Project Area	There is a total of 11 miles of erosion protection proposed for the Parkway.
EE-242	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The planting berm/trench is discussed in the draft EIS/EIR Section 2.3.1 under "Bank Protection" in the 2nd and 4th paragraphs. Concur. The Corps updated Figure 1 to show the planting berm.
EE-243	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	There would be no planting berm under the launchable rock trench measure. The planting berm is only associated with bank protection measures. Under the trench scenario, on-site plantings would be above the trench.
EE-244	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	Deep-rooted trees would not be permitted on the trench, but shallow-rooted trees and shrubs could be planted in these areas.
EE-245	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	There would be no planting berm under the launchable rock trench measure. The planting berm is only associated with bank protection measures. Under the trench scenario, on-site plantings would be above the trench.
EE-246	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Mitigation	Elderberry impacts are included within the riparian impacts estimated. These two habitat types are inter-related and would be mitigated in coordination with one another.
EE-247	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Environmental Effects	The Visual Resources No Action alternative has been updated to include full berm loss as a significant impact. Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
EE-248	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Vegetation	Figures throughout Chapter 2 will be updated to include planting berms. During site-specific design, the Corps will evaluate each site and determine which planting berm designs is appropriate based on existing conditions. The Corps anticipates being able to implement some level of vegetative features at every bank protection site. If a planting berm is infeasible, this could include planting willow poles, or installing IWM for fish habitat.

EE-249	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The repair shown is a conceptual design that reflects actual construction on the American River as part of the Sac Bank sites repair. In PED, site specific design will occur that will take into account the hydraulic, geotechnical, topographical, environmental, and cultural aspects of each site. The Corps, in conjunction with stakeholders will address the constraints at individual sites to come up with the best design alternative for each site.
EE-250	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The repair shown is a conceptual design that reflects actual construction on the American River as part of the Sac Bank sites repair. In PED, site specific design will occur that will take into account the hydraulic, geotechnical, topographical, environmental, and cultural aspects of each site. The Corps, in conjunction with stakeholders will address the constraints at individual sites to come up with the best design alternative for each site.
EE-251	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Design	The repair shown is a conceptual design that reflects actual construction on the American River as part of the Sac Bank sites repair. In PED, site specific design will occur that will take into account the hydraulic, geotechnical, topographical, environmental, and cultural aspects of each site. The Corps, in conjunction with stakeholders will address the constraints at individual sites to come up with the best design alternative for each site.
EE-252	Friends of the River, Habitat 2020, and Save the American River Association	Letter	Visual	The Corps concurs that rock will be visible, even after revegetation has been established, particularly during low water years. It is anticipated that over time, as new vegetation establishes, the visibility of rock revetment will be greatly reduced. Section 3.15 of the EIS/EIR has been updated to acknowledge that rock will be visible.
FF-1	Save the American River Association	Letter	Design	It is agreed that the reach of the American River between Howe Ave. and Paradise Beach is the worst stretch of the river with regards to the applied velocity. This reach however is not an anomaly with regards to erosion. Erosion has occurred in this reach and has been repaired (Sac Bank site 4, ARCF site 6.4L, 6.9L, and site 7.0R). Erosion has also occurred downstream and upstream of this reach and has been repaired (Sac Bank sites 1, 2, 3, and 5, ARCF sites 1.8L, 4.0L, 10.0L 10.2R, plus the 1986 emergency repair upstream of the Capital City Freeway). The velocity within the Howe to Paradise Beach reach is 12 to 13 fps for flows ranging from 115,000 cfs to 160,000 cfs. Upstream and downstream of this reach, velocities are often in the 6 to 7 fps range. Bare soil can withstand 1.5 to 2.5 fps and soil with a good turf cover can withstand 3.5 to 8 fps depending on the class of turf. The American River does not offer good turf conditions. This is a reason why we have experienced erosion in reaches downstream and upstream of the Howe to Paradise Beach reach. Text to explain conditions both upstream and downstream of the Howe to Paradise Beach reach has been added to section 2.3.1 of the GRR and Section 3.4 of the EIS/EIR.
FF-2	Save the American River Association	Letter	Design	It is agreed that the reach of the American River between Howe Ave. and Paradise Beach is the worst stretch of the river with regards to the applied velocity. This reach however is not an anomaly with regards to erosion. Erosion has occurred in this reach and has been repaired (Sac Bank site 4, ARCF site 6.4L, 6.9L, and site 7.0R). Erosion has also occurred downstream and upstream of this reach and has been repaired (Sac Bank sites 1, 2, 3, and 5, ARCF sites 1.8L, 4.0L, 10.0L 10.2R, plus the 1986 emergency repair upstream of the Capital City Freeway). The velocity within the Howe to Paradise Beach reach is 12 to 13 fps for flows ranging from 115,000 cfs to 160,000 cfs. Upstream and downstream of this reach, velocities are often in the 6 to 7 fps range. Bare soil can withstand 1.5 to 2.5 fps and soil with a good turf cover can withstand 3.5 to 8 fps depending on the class of turf. The American River does not offer good turf conditions. This is a reason why we have experienced erosion in reaches downstream and upstream of the Howe to Paradise Beach reach. Text to explain conditions both upstream and downstream of the Howe to Paradise Beach reach has been added to section 2.3.1 of the GRR and Section 3.4 of the EIS/EIR.

FF-3	Save the American River Association	Letter	Design	Figure 4-5 has been modified to include the previously installed erosion repair sites.
FF-4	Save the American River Association	Letter	Design	The cross sections shown in all documents are conceptual and do not represent exactly what will occur at any given site. Design will occur at individual sites and will take into account the geotechnical, hydraulic, environmental constraints at the site. Covering rock with soil is now an established practice. To the extent practicable, rock placed above the normal summer water surface will be covered with soil.
FF-5	Save the American River Association	Letter	Engineering Appendix History	Agree that history should be updated in said attachment. However, the Mayhew improvements from 2008 addressed levee height and seepage/stability, and not erosion protection. Our study indicates that Mayhew area is in need of an erosion protection to handle the future without project conditions which the Mayhew seepage/stability and raise project did not account for. However, the necessity of bank protection and the design details of this feature will be further analyzed in PED.
FF-6	Save the American River Association	Letter	Design	Figure 2-6 has been updated to reflect the more current understanding of the potential erosion sites which corresponds with the recommended erosion protection sites.
FF-7	Save the American River Association	Letter	Design	The following text has been added to Chapter 2 of the GRR to describe how areas were identified for erosion protection. Additionally, maps showing the velocity contours of the entire leveed reach of the lower American River have been added to further illustrate this analysis. "Figure 2-7 shows the velocities for a discharge of 115,000 cfs which average about 6 to 8 ft/sec in the channel with maximum velocities ranging up to about 12 ft/sec. Figure 2-8 shows the velocities for a discharge of 160,000 cfs which average about 5 to 9 ft/sec in the channel with maximum velocities ranging up to about 13 ft/sec. Of concern in both of these figures are the proximities of the relatively high velocities to the levees along the Lower American River. Additionally, the range of the computed velocities is of concern since the magnitude of the velocities is great enough to erode many of the relatively fine grained material present in the channel lining. The results of the analysis indicate that the large discharge events are capable of eroding the material typically found lining the Lower American River channel." Additionally, the following language has been added to Chapter 4: "The rationale used to determine where erosion protection was required involved consideration of several factors. The most important factors included: 1) the velocity computed by the hydraulic modeling (Ayres 2004) for a discharge of 160,000 cfs, 2) the erodibility of the material near the levee prism, and 3) the past performance of the levee segment with respect to erosion."
FF-8	Save the American River Association	Letter	Alternatives	The recommended plan in the GRR has identified areas along the American River where potential high flow velocities are within a proximity to the levee which would cause concern for potential levee failure. This footprint of erosion work represents the largest area that the initial studies have identified. These sites will be further investigated during the design phase and the extent of levee work would possibly be reduced as a result of the future analysis. Additionally, the recommendations in the GRR would be constructed in a worst-first sequence, meaning that the areas considered to be the highest risk would be constructed first. Since the GRR would need to wait for both authorization and then annual appropriations from Congress, it could be many years until the funding is in place for construction for those areas considered to be lower risk.

FF-9	Save the American River Association	Letter	General	A description of the final report approval process has been added to Chapter 4 of the GRR. That approval process is as follows: The Project Delivery Team (PDT) has responded to the comments on the Draft GRR & EIS/EIR and Appendices received during concurrent Public Review, Agency Technical Review (ATR), Independent External Peer Review (IEPR) and HQUSACE Policy Review and revised the documents as appropriate. The Final GRR &EIS/EIR and Appendices are transmitted to the South Pacific Division (SPD) for endorsement and then forwarded to HQUSACE. Once the documents are received at HQUSACE, a Civil Works Review Board (CWRB) is convened. The purpose of the CWRB is to determine if the final GRR &EIS/EIR and appendices, along with the proposed Report of the Chief of Engineers, are ready to be released for State and Agency review, as required by the Flood Control Act of 1944, as amended (33U.S.C. 701-1). Upon a successful conclusion of the CWRB meeting, the Deputy Commanding General for Civil and Emergency Operations (DCG-CEO) will approve release of the documents for State and Agency review and final NEPA review. After State and Agency review, comments are incorporated in to the documents as appropriate and a Final Chief's Report will be signed by the Chief of Engineers. The Chief's Report will then be sent to the chairpersons of the Senate Committee in Environment and Public Works and the House of Representative Committee on Transportation and Infrastructure. The Chief's Report, along with the GRR, EIS/EIR and appendices will then be sent to the Assistant Secretary of the Army for Civil Works (ASA(CW)) for review and approval. After approval by the ASA(CW), the documents will be sent to the Office of Management and Budget (OMB) for review.
FF-10	Save the American River Association	Letter	LPP	The acronym "LPP" has been added to the list of acronyms at the front of the report. The LPP was developed by the project delivery team which consists of USACE and sponsor staff. It has been endorsed by USACE Headquarters, the Assistant Secretary of the Army for Civil Works (ASA(CW)), the Central Valley Flood Protection Board and the SAFCA Board of Directors.
GG-1	James Morgan	Letter	NEPA	During the preconstruction engineering and design phase of the project, the Corps will be designing each phase of the project on a site-specific basis. During this site-specific design, an analysis will be conducted to determine whether the impacts are consistent with those described in this EIS/EIR or whether supplemental NEPA analysis would need to occur.
GG-2	James Morgan	Letter	Alternatives	A lot of levee improvement work has already taken place along the American River. The remaining problem is the potential for erosion to cause a levee failure. Sites have been identified along the American River where high velocity flows could cause potential levee erosion. Several different construction techniques have been identified to address the erosion potential. These techniques will be refined on a site specific basis during the design phase.
GG-3	James Morgan	Letter	Communication	The information presented at the Lower American River Task Force was meant to highlight the risk of erosion in the length of river between Paradise Beach and Watt Ave. We regret any misunderstanding this might have caused.
GG-4	James Morgan	Letter	Alternatives	The recommended plan in the GRR has identified areas along the American River where potential high flow velocities are within a proximity to the levee which would cause concern for potential levee failure. This footprint of erosion work represents the largest area that the initial studies have identified. These sites will be further investigated during the design phase and the extent of levee work would possibly be reduced as a result of the future analysis. Additionally, the recommendations in the GRR would be constructed in a worst-first sequence, meaning that the areas considered to be the highest risk would be constructed first. Since the GRR would need to wait for both authorization and then annual appropriations from Congress, it could be many years until the funding is in place for construction for those areas considered to be lower risk.
GG-5	James Morgan	Letter	Design	Concur, the bank protection graphic on page 32 should have soil cover for the rocks areas which are above the summer mean water surface elevation.

HH-1	Gay Jones	E-mail	Coordination	The Corps of Engineers is committed to working with stakeholders during the design and construction process. Previous bank protection constructed working with the LARTF is a good example that the Corps is supportive of using as a working model.
HH-2	Gay Jones	E-mail	Scope	As part of the ongoing effort to reduce the flood risk for the City of Sacramento, many studies have been conducted to gain a better understanding of the nature of the risk and possible ways to reduce the risk. These efforts have greatly expanded the understanding of the extent of the risk, including the potential for erosion of not only the banks of the American River, but the levees as well.
HH-3	Gay Jones	E-mail	Alternatives	The recommendations included in the GRR will be refined during the design phase of the project, at which time, site specific surveys and details would be taken into account.
HH-4	Gay Jones	E-mail	Alternatives	The levees along the American and Sacramento River could fail during a flood event due to four main factors. These factors include 1) flood water seeping through and under the levee, 2) levee instability, 3) flood waters overtopping a levee during a flood event, and 4) erosion of the levee. The first three factors have been addressed by prior work along the American River, however, the risk of significant levee erosion still remains as a possible cause of levee failure. Several erosion sites have been repaired and this work, along with all the other previous work, was accounted for during the development of the recommended plan for the GRR. The analysis conducted as part of the GRR identified additional areas where there is a high likelihood of erosion during large flood events.
HH-5	Gay Jones	E-mail	Parkway Plan	The majority of the Parkway Plan quotes in the document are directly out of Chapter 4 of the Parkway Plan, which identifies the goals and regulations for flood control actions in the Parkway. The EIS/EIR has been updated with citations to Chapter 4 of the Parkway Plan.
HH-6	Gay Jones	E-mail	Vegetation	The Corps does not propose to construct any new levees under the ARCF GRR. The project proposes to improve known problems in the existing levee system that could lead to a failure, damages, and loss of life. In order to complete this important public safety project, there would be significant impacts on the environment. The mitigation proposed in the EIS/EIR is expected to provide a similar habitat value long-term, however the short-term effects would be significant and unavoidable. The Corps intends to do what it can in site-specific design to minimize these significant effects, however, protecting habitat is not the purpose of the project.
II-1	State Water Resources Control Board	Letter	Alternatives	A wide variety of possible alternatives was analyzed as part of the study. Because the levees surrounding the City are in such poor condition, the study concluded that the most effective way to reduce the flood risk for the City of Sacramento is to improve the levees. A setback levee with a seepage berm is recommended for the Sacramento Bypass north levee which would approximately double the width of the floodplain area in the Sacramento Bypass. The remainder of the levees are adjacent to urban development with little to no available land for a levee setback.
II-2	State Water Resources Control Board	Letter	Water Quality	The CVRWQCB Basin Plan for the Sacramento and San Joaquin River Basins is referred to throughout Section 3.5, and the thresholds identified within the Basin Plan are cited throughout as the regulatory level applicable to the project for various water quality issues such as dissolved oxygen, water temperature, pH, and turbidity. Mitigation is proposed to comply with these thresholds, and monitoring would be conducted during in-water work to ensure that these thresholds are not exceeded. Further coordination with the CVRWQCB would occur during the design phase prior to construction to ensure that all appropriate permits (i.e., Section 401 Water Quality Certification) is met and any additional mitigation required will be coordinated with the board through that process.
II-3	State Water Resources Control Board	Letter	Water Quality	The Corps will ensure that prior to initiation of construction, a Section 401 Water Quality Certification is obtained, as necessary, for impacts to waters of the U.S. Through the Water Quality Certification process, the Corps will consult with the Water Boards, as required.
II-4	State Water Resources Control Board	Letter	Water Quality	Section 3.5 of the EIS/EIR has been updated to identify beneficial uses of surface waters and to analyze the impacts that could occur to these water uses.

II-5	State Water Resources Control Board	Letter	Alternatives	A wide variety of possible alternatives was considered, including features throughout the watershed, to find ways to reduce the flood risk to the City of Sacramento. USACE has developed a hydraulic model of the Sacramento River which allows us to analyze the effects of modifications to the flood management system. Because the levees surrounding the City are in such poor shape, the analysis showed that most effective plan to reduce the flood risk is to improve the existing levees. A setback levee is recommended for the north levee of the Sacramento Bypass which would approximately double it's floodplain area. The remainder of the levees are adjacent to urban development with little to no available land for a levee setback. The ongoing Central Valley Integrated Flood Management Study (CVIFMS) is a multi-purpose watershed study that is considering the larger, regional scale benefits associated with flood risk management, ecosystem restoration and other water resource related purposes. SAFCA is a local cost sharing partner on the study and has been in close coordination with USACE on the development of the GRR and the proposed work along the Sacramento River and the North Area Streams. The recommendations of the GRR are considered integral to the Lower Sacramento River Feasibility Study that is being developed as part of the Central Valley Flood Protection Plan (CVFPP).
II-6	State Water Resources Control Board	Letter	Vegetation	As detailed in Section 1.4.5 of the EIS/EIR, the Corps has conducted an analysis to determine the feasibility of acquiring a vegetation variance. The analysis determined that receipt of a variance is a reasonable assumption for the project and therefore all effects analyses assumed the variance is in place. If a variance is not granted by USACE HQ, then the Corps will conduct further NEPA/CEQA analysis at that time to analyze the effects of compliance with ETL 1110-2-583. The variance application process will be conducted following Congressional authorization during the preconstruction engineering and design phase of the project.
II-7	State Water Resources Control Board	Letter	SAFCA projects	SAFCA has informed the Corps that they will be seeking both permission to alter the Federal Flood Management Project (Section 408) and Credit Consideration (Section 221) for levee improvement work they intend on constructing prior to implementation of the ARCF GRR recommended project. Section 221 of the Flood Control Act of 1970 as amended by Section 2003 of the Water Resources Development Act (WRDA) of 2007 (42 U.S.C. 1962d-5b) allows the sponsor to seek credit for the study, design and construction of Federally authorized water resources development projects that are carried out after the execution of an agreement with the ASA(CW). Where there is a cost sharing agreement, the sponsor may provide in-kind contributions in accordance with the terms of the applicable agreement. The sponsor has indicated that they intend to construct portions of the levee improvements recommended by the GRR that are considered the highest risk areas and seek credit for those improvements. These actions will not be considered part of the without project condition however, in order that the sponsor may receive credit consideration in the future.
II-8	State Water Resources Control Board	Letter	Water Quality	Section 3.5 of the EIS/EIR has been updated to identify beneficial uses of surface waters and to analyze the impacts that could occur to these water uses.
II-9	State Water Resources Control Board	Letter	Vegetation	If a variance is not granted by USACE HQ, then the Corps will conduct further NEPA/CEQA analysis at that time to analyze the effects of compliance with ETL 1110-2-583.
II-10	State Water Resources Control Board	Letter	Vegetation	The variance application process will be conducted following Congressional authorization during the preconstruction engineering and design phase of the project.
II-11	State Water Resources Control Board	Letter	Vegetation	The SWIF Plan will be prepared by the local sponsors. It is anticipated that this will be acknowledged within the SWIF plan, as it is a key assumption associated with the vegetation variance and SAFCA's ongoing vegetation management efforts under the Levee Accreditation Program.
II-12	State Water Resources Control Board	Letter	Vegetation	The regulatory setting sections refer to the laws and regulations that are applicable to the proposed projects. These laws are further described in Chapter 5, including details on which agencies must be consulted with and what actions the Corps must take in order to achieve full compliance.

II-13	State Water Resources Control Board	Letter	Wetlands	The second bullet in the Significance Criteria for Section 3.6 states: "Substantial effects on a sensitive natural community, including Federally protected wetlands and other waters of the U.S., as defined by Section 404 of the Clean Water Act.".
II-14	State Water Resources Control Board	Letter	Water Quality	In Section 3.6, the EIS/EIR acknowledges the significant impacts that result from the temporal loss of vegetation, including riparian trees. Additionally, in Section 1.4.5 the EIS/EIR describes the project's approach to vegetation removal and protection under the Corps' levee safety policies. Section 1.4.5 describes the vegetation variance, which will allow the Corps to leave mature vegetation in place along the waterways, preserving the SRA habitat in the study area. Additionally, the Corps proposes to plant additional waterside habitat through the construction of planting berms at bank protection sites. Through these measures, the project would not result in a significant impact on water temperature. The Water Quality section will be updated for the final EIS/EIR to include this analysis.
II-15	State Water Resources Control Board	Letter	Mitigation	Mitigation planning efforts are ongoing and are discussed in greater detail in the Mitigation and Monitoring Plan, which is appended to the Final EIS/EIR.
II-16	State Water Resources Control Board	Letter	Mitigation	Mitigation planning efforts are ongoing and are discussed in greater detail in the Mitigation and Monitoring Plan, which is appended to the Final EIS/EIR.
II-17	State Water Resources Control Board	Letter	Mitigation	The Corps will comply with all applicable State and Federal regulations. Further coordination with the CVRWQCB will occur following project authorization to ensure that the Corps is conducting all mitigation and monitoring in accordance with the applicable guidance.
II-18	State Water Resources Control Board	Letter	Vegetation	As detailed in Section 1.4.5 of the EIS/EIR, the Corps has conducted an analysis to determine the feasibility of acquiring a vegetation variance. The analysis determined that receipt of a variance is a reasonable assumption for the project and therefore all effects analyses assumed the variance is in place. If a variance is not granted by USACE HQ, then the Corps will conduct further NEPA/CEQA analysis at that time to analyze the effects of compliance with ETL 1110-2-583. The variance application process will be conducted following Congressional authorization during the preconstruction engineering and design phase of the project.
JJ-1	Sacramento County	Letter	Environmental Effects	The Final EIS/EIR has been updated with an effort to be more specific about habitat impacts.
JJ-2	Sacramento County	Letter	Recreation	Recreational access points, boat launches, parks, and recreation sites such as the Campus Commons Golf Course would remain open to the greatest extent practicable. If construction equipment and material delivery requires full closure of revenue generating facilities, compensation would be discussed during PED phase when such closures are determined to be required.
JJ-3	Sacramento County	Letter	Recreation	Impacts to the Golf Course will be included in the Final EIS/EIR.
JJ-4	Sacramento County	Letter	Recreation	Construction of the project would not take place in all areas of the Parkway at one time, and there may be viable detours for equestrians during construction. However, communication about where the construction would take place would enable equestrian riders to determine the best route to take in order to avoid equestrian startlement and confusion. These efforts would be further discussed during PED phase.
JJ-5	Sacramento County	Letter	Recreation	Construction of the project would not take place in all areas of the Parkway at one time. There is the potential for bank-side access points near construction sites to be closed or limited during construction, but construction would not substantially limit the ability for recreationists to do water-based activities.
JJ-6	Sacramento County	Letter	Recreation	Closures and detours of the recreational trail could impact multiple events such as Eppie's Great Race, the American River Parkway Half Marathon, the Jed Smith Ultra Classic, and multiple other fun runs and events. Coordination during PED phase would reduce impacts to these events to the greatest extent practicable. Recreational access points, boat launches, parks, and recreation sites such as the Campus Commons Golf Course would remain open to the greatest extent practicable. If any construction would require full closure, compensation of lost revenue would be considered during the design phase.

JJ-7	Sacramento County	Letter	Recreation	Construction contractors are required to restore the area to pre-construction conditions. If unofficial public trails are created due to project impacts, the eroded areas would be included in project impacts and restored to pre-construction conditions.
JJ-8	Sacramento County	Letter	Recreation	Coordination with Park staff would be conducted during design phase in order to reduce impacts to recreation to the greatest extent practicable. If detours, closures, and other disturbances to recreation are determined to be necessary in order to complete the project, public outreach would be conducted in conjunction with State and local outreach efforts.
JJ-9	Sacramento County	Letter	Borrow	Thank you, we will consider in PED phase.
JJ-10	Sacramento County	Letter	Borrow	The Corps or its contractor would acquire all appropriate permits prior to the initiation of project construction.
JJ-11	Sacramento County	Letter	Vegetation	Typically when we are referring to large vegetation vs small vegetation we are referring to trees versus shrubs or grasses.
JJ-12	Sacramento County	Letter	Vegetation	Design based on site-specific hydraulic and environmental conditions would occur during the design phase of the project to determine which erosion protection measure is appropriate at each location.
JJ-13	Sacramento County	Letter	Vegetation	More information about vegetation habitats has been included in the Final EIS/EIR and the Mitigation and Monitoring Plan.
JJ-14	Sacramento County	Letter	Vegetation	Trees left in place are not expected to die. The Corps has been protecting trees in place as part of bank protection construction under the Sacramento River Bank Protection Project and the trees at these sites have had successful survival rates over the last decade.
JJ-15	Sacramento County	Letter	Design	Concur. The Corps will update figure 1 to ensure that the planting berm is shown.
JJ-16	Sacramento County	Letter	Vegetation	Proposed measures on the American River would only impact vegetation within the construction footprint. For the launchable rock trench measure, the construction footprint includes the lower waterside slope. Since the vegetation variance only applies to the lower waterside slope, it cannot be applied to this measure. The bank protection measure on the American River does not involve the levee slope, and therefore, a vegetation variance is not necessary. The Corps will minimize impacts to vegetation in the Parkway to the maximum extent possible during construction.
JJ-17	Sacramento County	Letter	Vegetation	Impacts for the American River are as described in the document throughout Section 3.6. As described above, this estimate is based on the impacts to vegetation in the construction footprint and the level of impact would not change under a variance. No ETL compliance is necessary for the measures proposed under this project on the American River. It remains the responsibility of the local maintaining agency.
JJ-18	Sacramento County	Letter	Vegetation	The appropriateness of where replantings occur would be determined on a site-specific basis during the preconstruction engineering and design phase of the project. For example, following construction on the Sacramento River levees, new trees would not be installed in the levee prism, as it would conflict with State and Federal vegetation policies, but they would be installed in planting berms, while levees would be reseeded with native grasses.
JJ-19	Sacramento County	Letter	No Action	As part of the Folsom Water Control Manual update, additional Channel Stability Analyses are being conducted to further refine channel widening and deepening.
JJ-20	Sacramento County	Letter	Design	The trench width (top) is a function of existing topography, trench slopes, depth, and quantity of launchable rock. These aspects of the design will be analyzed in more detail within PED phase. For the purposes of this study and description of impacts, the 70 feet trench width is considered to be conservative when applied to the extents shown in plates 3 and 4.

JJ-21	Sacramento County	Letter	Design	Berm erosion is part of the existing condition and is not an impact of project implementation or operation. Additionally, since a combination of bank protection and trench is proposed, the project does prevent the full berm loss that is considered significant under the No Action alternative. Erosion of the bank/berm is a natural process that is continually occurring, but is exacerbated when extreme precipitation results in high releases from Folsom Dam. The decision to construct launchable rock trench as opposed to bank protection does not change these erosion conditions, but rather prevents the erosion from causing a levee failure. The construction of a trench rather than bank protection in some locations also allows for some natural sediment transport processes to continue. The balance of these two measures reduces the potential significant impacts that would occur if either one was implemented on its own. During PED, a more substantial design analysis will be conducted, working with stakeholders. This more substantial design analysis will look at site specific conditions to better inform the decision on bank protection versus launchable rock.
JJ-22	Sacramento County	Letter	NEPA	Section 1.1 of the EIS/EIR describes the process for evaluating site-specific conditions in the design phase of the project and determining whether any supplemental NEPA/CEQA analysis will need to be conducted prior to construction.
JJ-23	Sacramento County	Letter	Coordination	As part of the ongoing coordination for the ARCF GRR, site-specific designs would be shared when they are developed during the Design Phase.

DEPARTMENT OF DEFENSE

Department of the Army; Army Corps of Engineers

Notice of Intent To Prepare an Environmental Impact Statement for 408 Permission and 404 Permit to Three Rivers Levee Improvement Authority for the Feather River Levee Repair Project, California, Segment 2

AGENCY: Department of the Army, U.S. Army Corps of Engineers, DoD.

ACTION: Notice of intent.

SUMMARY: The action being taken is the preparation of an Environmental Impact Statement (EIS) for the issuance of both the 408 permission to the Central Valley Flood Protection Board and 404 Permit to Three Rivers Levee Improvement Authority (TRLIA) for their work on the Feather River Levee Repair Project (FRLRP). Under 33 U.S.C. 408, the Chief of Engineers grants permission to alter an existing flood control structure if it is not injurious to the public interest and does not impair the usefulness of such work. Under section 404 of the Clean Water Act, the District Engineer permits the discharge of dredged or fill material into waters of the United States if the discharge meets the requirements of the Environmental Protection Agency's 404(b)(1) guidelines and is not contrary to the public interest. The FRLRP is located in Yuba County, CA. TRLIA is requesting this permission and permit in order to complete construction along the east levee of the Feather River.

DATES: A public scoping meeting will be held March 10, 2008, 6:30 to 8:30 at the Yuba County Government Center, 915 8th Street, Marysville, CA. Send written comments by April 9, 2008 to the address below.

ADDRESSES: Send written comments and suggestions concerning this study to Mr. John Suazo, U.S. Army Corps of Engineers, Sacramento District, Attn: Planning Division (CESPK–PD–R), 1325 J Street, Sacramento, CA 95814. Requests to be placed on the mailing list should also be sent to this address.

FOR FURTHER INFORMATION CONTACT: Questions about the proposed action and EIS should be addressed to John Suazo at (916) 557–6719, e-mail: *john.suazo@usace.army.mil* or by mail to (see **ADDRESSES**).

SUPPLEMENTARY INFORMATION:

1. *Proposed Action.* The U.S. Army Corps of Engineers is preparing an EIS to analyze the impacts of the work proposed by TRLIA from the implementation of the FRLRP, Segment 2. The FRLRP, Segment 2 is being constructed by TRLIA to improve flood protection to portions of Yuba County and Reclamation District (RD) 784.

2. *Alternatives.* The EIS will address an array of flood control improvement alternatives along Segment 2. Alternatives analyzed during the investigation will include a combination of one or more flood protection measures. These measures include seepage berms, stability berms, setback levees, seepage cutoff walls, and relocation of a pump station.

3. *Scoping Process.* a. The Corps has initiated a process to involve concerned individuals, and local, State, and Federal agencies. A public scoping meeting will be held on March 10, 2008 to present information to the public and to receive comments from the public.

b. Significant issues to be analyzed in depth in the EIS include effects on hydraulic, wetlands and other waters of the U.S., vegetation and wildlife resources, special-status species, cultural resources, land use, fisheries, water quality, air quality, transportation, and socioeconomics; and cumulative effects of related projects in the study area.

c. The Corps is consulting with the State Historic Preservation Officer to comply with the National Historic Preservation Act, and the National Marine Fisheries Service and the U.S. Fish and Wildlife Service to comply with the Endangered Species Act. Coordination with the National Marine Fisheries Service has been completed; coordination with U.S. Fish and Wildlife Service is still ongoing.

d. A 45-day public review period will be provided for individuals and agencies to review and comment on the draft EIS. All interested parties are encouraged to respond to this notice and provide a current address if they wish to be notified of the draft EIS circulation.

4. *Availability.* The draft EIS is scheduled to be available for public review and comment in early 2008.

Dated: February 22, 2008.

Thomas C. Chapman,

COL, EN, Commanding.

DEPARTMENT OF DEFENSE

Department of the Army; Army Corps of Engineers

Notice of Intent To Prepare an Environmental Impact Statement for the American River Common Features General Reevaluation Report, Sacramento, CA

AGENCY: Department of the Army, U.S. Army Corps of Engineers; DOD.

ACTION: Notice of intent.

SUMMARY: The action being taken is the preparation of an environmental impact statement (EIS) for the American River Common Features General Reevaluation Report (GRR). The Common Features Project GRR will re-evaluate the currently authorized plan as well as develop and evaluate other viable alternatives, including a locally-preferred plan, with the goal of identifying a comprehensive plan that will lower the risk of flooding in and around the City of Sacramento. The Common Features Project GRR is located in Sacramento, Sutter and Yolo Counties, CA.

DATES: A series of public scoping meetings will be held as follows:

1. March 5, 2008, 5 to 7 p.m. at The Elk's Lodge.
2. March 6, 2008, 5 to 7 p.m. at Arden Park Community Center, Room A.
3. March 10, 2008, 3 to 6 p.m. at The Library Galleria East Meeting Room.
4. March 13, 2008, 5 to 7 p.m. at The Sierra Health Foundation.

Send written comments by April 11, 2008 to the address below.

ADDRESSES: Written comments and suggestions concerning this study may be submitted to Ms. Elizabeth Holland, U.S. Army Corps of Engineers, Sacramento District, Attn: Planning Division (CESPK–PD–R), 1325 J Street, Sacramento, CA 95814. Requests to be placed on the mailing list should also be sent to this address. The location of the public meetings is as follows; The Elks Lodge, 6446 Riverside Blvd., Sacramento, CA; Arden Park Community Center, 1000 La Sierra Drive, Sacramento, CA; Library Galleria, 828 ''I'' Street, Sacramento, CA; and Sierra Health Foundation, 1321 Garden Highway, Sacramento, CA.

FOR FURTHER INFORMATION CONTACT: Questions about the proposed action and EIS should be addressed to Liz Holland at (916) 557–6763, e-mail *Elizabeth.g.holland@usace.army.mil* or by mail to (see **ADDRESSES**).

SUPPLEMENTARY INFORMATION:

1. *Proposed Action.* The U.S. Army Corps of Engineers is preparing an EIS

to analyze the impacts of a range of alternatives that would lessen the risk of flooding in and around the City of Sacramento.

2. *Alternatives.* The EIS will address an array of flood control improvement alternatives that are intended to reduce flood risk within the project area. Alternatives analyzed during the investigation will include a combination of one or more flood protection measures. These measures include levee improvements (e.g., seepage berms, adjacent setback levees, seepage wells, seepage cutoff walls), revisions to system hydraulics through setbacks, levee raises, and/or more diversion of flow into the bypass system, and possible use of upstream lands for detention.

3. *Scoping Process.* a. A series of public scoping meeting will be held in early March, 2008 to present information to the public and to receive comments from the public. These meetings are intended to initiate the process to involve concerned individuals, and local, State, and Federal agencies.

b. Significant issues to be analyzed in depth in the EIS include effects on hydraulics, wetlands and other waters of the U.S., vegetation and wildlife resources, special-status species, esthetics, cultural resources, recreation, land use, fisheries, water quality, air quality, transportation, and socioeconomics; and cumulative effects of related projects in the study area.

c. The Corps is consulting with the State Historic Preservation Officer to comply with the National Historic Preservation Act and the U.S. Fish and Wildlife Service and National Marine Fisheries Service to comply with the Endangered Species Act. The Corps is also coordinating with the U.S. Fish and Wildlife Service to comply with the Fish and Wildlife Coordination Act.

d. A 45-day public review period will be provided for individuals and agencies to review and comment on the draft EIS. All interested parties are encouraged to respond to this notice and provide a current address if they wish to be notified of the draft EIS circulation.

4. *Availability.* The draft EIS is scheduled to be available for public review and comment in spring 2010.

Dated: February 15, 2008.

Department of the Navy

Meeting of the Ocean Research and Resources Advisory Panel

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: The Ocean Research and Resources Advisory Panel (ORRAP) will meet to discuss National Ocean Research Leadership Council (NORLC) and Interagency Committee on Ocean Science and Resource Management Integration (ICOSRMI) activities. All sessions of the meeting will be open to the public.

DATES: The meeting will be held on Tuesday, April 15, 2008 from 8 a.m. to 5:30 p.m. and Wednesday, April 16, 2008 from 8 a.m. to 1:30 p.m.

ADDRESSES: The meetings will be held at the Consortium for Ocean Leadership located at 1201 New York Ave, Suite 420, Washington, DC.

FOR FURTHER INFORMATION CONTACT: Dr. Charles L. Vincent, Office of Naval Research, 875 North Randolph Street, Suite 1425, Arlington, VA 22203–1995, telephone: 703–696–4118.

SUPPLEMENTARY INFORMATION: This notice is provided in accordance with the provisions of the Federal Advisory Committee Act (5 U.S.C. App. 2). The meeting will include discussions on ocean research to applications, ocean observing, professional certification programs, and other current issues in the ocean science and resource management communities. In order to maintain the meeting time schedule, members of the public will be limited in their time to speak to the Panel. Members of the public should submit written comments at least one week prior to the meeting to Dr. Charles L. Vincent, Office of Naval Research, 875 North Randolph Street, Suite 1425, Arlington, VA 22203–1995, telephone: 703–696–4118.

Dated: February 22, 2008.

T.M. Cruz,

Lieutenant, Office of the Judge Advocate General, U.S. Navy, Federal Register Liaison Officer.

Privacy Act of 1974; System of Records

AGENCY: Department of the Navy, DoD.

ACTION: Notice to Amend a System of Records.

SUMMARY: The Department of the Navy is amending a system of records notice in its existing inventory of record systems subject to the Privacy Act of 1974, (5 U.S.C. 552a), as amended.

DATES: This proposed action will be effective without further notice on March 31, 2008 unless comments are received which result in a contrary determination.

ADDRESSES: Send comments to the Department of the Navy, PA/FOIA Policy Branch, Chief of Naval Operations (DNS–36), 2000 Navy Pentagon, Washington, DC 20350–2000.

FOR FURTHER INFORMATION CONTACT: Mrs. Doris Lama at (202) 685–6545.

SUPPLEMENTARY INFORMATION: The Department of the Navy systems of records notices subject to the Privacy Act of 1974, (5 U.S.C. 552a), as amended, have been published in the **Federal Register** and are available from the address above.

The specific changes to the record system being amended are set forth below followed by the notice, as amended, published in its entirety. The proposed amendments are not within the purview of subsection (r) of the Privacy Act of 1974, (5 U.S.C. 552a), as amended, which requires the submission of a new or altered system report.

Dated: February 25, 2008.

L.M. Bynum,

Alternate OSD Federal Register Liaison Officer, Department of Defense.

08SAC0046
03-SAC- 5 / 160 / 50 / 51 / 80
American River Common Features General Evaluation Report
Notice of Preparation
SCH# 2005072046

Ms. Annalena Bronson
Central Valley Flood Protection Board
3310 El Camino Avenue, Room LL-40
Sacramento, CA 95821

Dear Ms. Bronson:

We have reviewed the American River Common Features General Re-evaluation Report Notice of Preparation documentation. Our comments are as follows:

- Caltrans' prior comments in our letters of July 27, 2005 and October 3, 2002 (copies enclosed) are still valid.

- In carrying out this project's levee improvement activities, it is very likely that truck haul routes used in transporting soil, rock, borrow and cleared vegetation disposal materials to and from the various proposed sites along the American and Sacramento Rivers and Natomas Cross Canal and Natomas East Main Drainage Canal could involve the use of Interstate 5, State Route (SR) 160, U.S. 50, SR51, and I-80. We note on page 2 in the "Study Area" discussion and on Page 6's map of the project levee areas that this "project's" scope is quite large. Clarification should be made regarding which of the multiple levee improvement areas will use trucks and which will use waterside barges to transport work materials.

- If off-site levee materials are being transported by truck to these work sites to modify levee bank areas and are using adjoining State roadway facilities, a project Traffic Management Plan (TMP) will be necessary. The TMP should be prepared for our review and include appropriate strategies to mitigate construction traffic impacts to the nearby roadway intersections, freeway interchanges, and mainlines. Truck haul routes and points of access to State roadway facilities used should be clarified in the plan. If Garden Highway will be used as an access to some of the improvement areas, the TMP should explain how Garden Highway is to be accessed, whether from I-5 or via a local road network. The project's individual levee site work plan dates should also be provided, if known, and the truck trip volumes. We recommend truck-hauling operations avoid peak traffic periods (6-10 AM and 3-7 PM) whenever possible. The Caltrans TMP Guidelines are enclosed for your use. For assistance, please contact Paul Wilkinson, the Caltrans District 3 Traffic Manager (DTM), at (916) 859-7978.

- If electronic warning signs are provided within State right-of-way at work sites to alert the traveling public of trucks entering or leaving State highways, an encroachment permit will be required. For permit assistance, please contact Julio Elvir at (530) 741-4204.

- Caltrans is interested in the work zone proximity of this project's planned levee improvements on the Sacramento River near the system of relief wells and piezometer installations near the downtown Sacramento I-5 freeway and within State property. Freeway Post Mile locations may have been established for these well and piezometer locations when they were installed to help prevent levee seepage near the subgrade section of Interstate 5 (more commonly called, "the Boat Section"). The distance of well locations from freeway bridge footings might have been specified as well to help locate where they are. We understand that Encroachment Permit # 0304-NMC-0918 was obtained from Caltrans District 3 in prior years when this installation work was done. Caltrans wishes to make sure that these wells and piezometer locations are not disturbed during the levee bank work. Preliminary planning installation maps, showing where the wells and piezometers were located in relation to our right-of-way lines and freeway facilities, and "As Built" maps, were prepared for Caltrans to update its right of way records of the Interstate 5 freeway corridor.

If you have any questions regarding these comments, please contact Ken Champion at (916) 274-0615.

Sincerely,

Dawn Cheser, Office Chief
Office of Transportation Planning - South

Ms. Annalena Bronson
The Reclamation Board
3310 El Camino Avenue, Room 110
Sacramento, CA 95821

Dear Ms. Bronson:

We have reviewed the Sacramento River East and Natomas Cross Canal Levee Modifications Project Notice Of Preparation documentation. We look forward to reviewing the draft Environmental Impact Report. Our comments are as follows:

- Our comments provided in our letter of October 3, 2002 (copy enclosed) are still valid.

- The document map of the Sacramento River work site shows Elverta and Power Line Roads as potential access roadways. If off-site levee materials are being transported by truck to this work site to modify these levees and are using adjoining State roadway facilities, a project Traffic Management Plan (TMP) will be necessary. The TMP should be prepared for our review and include appropriate strategies to mitigate construction traffic impacts to the nearby State Route 99/Elverta Road intersection and other nearby freeway interchanges. The TMP should also clarify whether Interstate 5 would be used via Power Line Road. The Caltrans TMP Guidelines are enclosed for your use. Truck haul routes and points of access to State roadway facilities used should be clarified in the plan. The planned project initiation and completion dates should also be noted, as well as truck trip volumes, daily hours of operations, and whether electronic warning signs are provided to alert the traveling public. We recommend truck hauling operations during non-peak traffic periods.

Please provide our office with a copy of the draft TMP requested above. If you have any questions regarding these comments, please contact Ken Champion at (916) 274-0615.

Sincerely,

KATHERINE EASTHAM, Chief
Office of Transportation Planning - Southwest

Sacramento, CA 95814

Dear Ms. Enstrom:

Thank you for the opportunity to comment on the above mentioned project. Our comments are as follows:

- The project documentation should provide a map (s) describing the project "activity areas" and any nearby State highway facilities in order to clarify the scope of project and potential impacted highway and bridge structure areas.

- Any flood control improvements and protection measures located near State right-of-way should be identified and Caltrans should be notified. Any work conducted within State right-of-way will require an encroachment permit. For assistance, Bruce Capaul at (530) 741-4408 should be contacted.

- Haul routes for transporting soil and construction materials and any State highways used should be provided in the project discussion.

Please provide our office with the requested information, a copy of the DEIR, copies of draft mitigation measures, and any further action regarding this project. If you have any questions regarding these comments, please contact Ken Champion at (916) 274-0615.

Posters from March 2008 Scoping Meetings

About the Re-evaluation Report

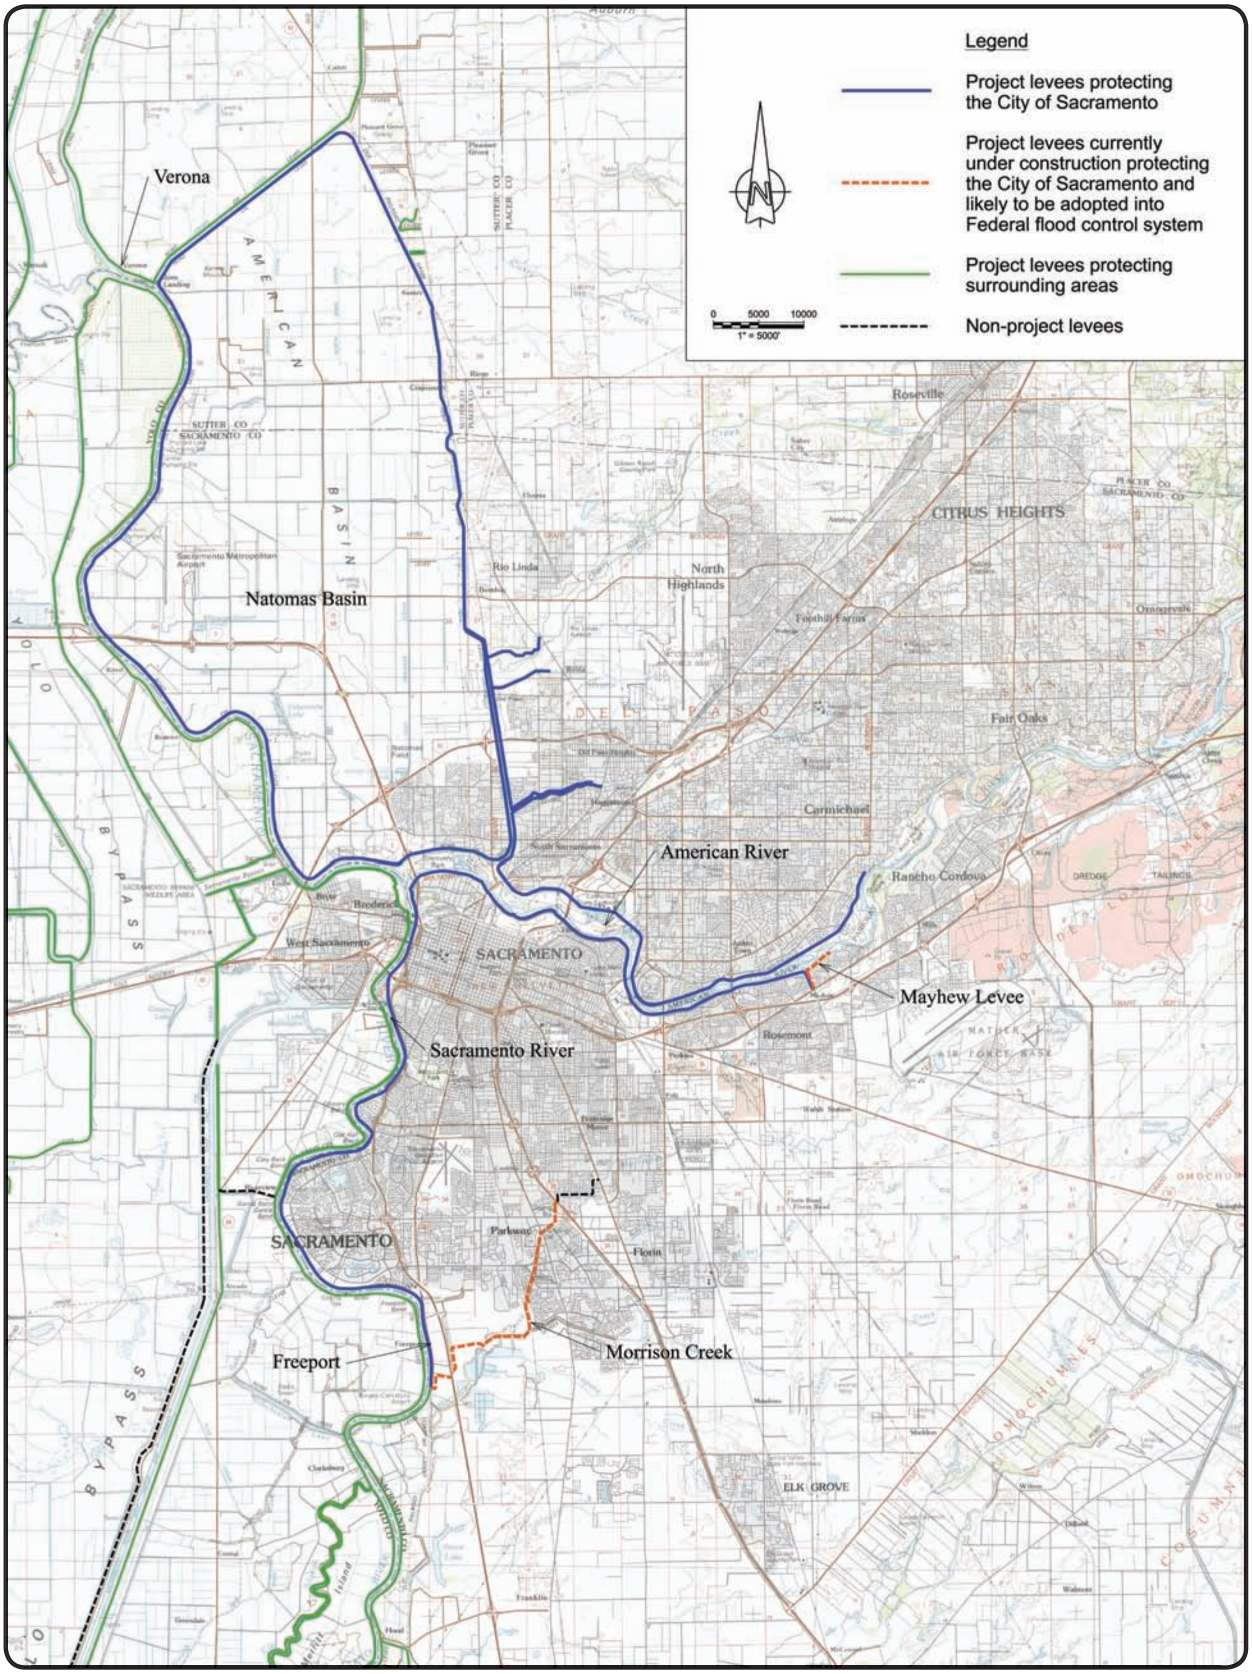
Flooding is a long-standing problem facing the Sacramento area. The recent floods of 1986 and 1997 devastated several communities, including homes, businesses, orchards and farmlands. In 1996 the Water Resources Development Act authorized the American River Common Features Project (CFP), designed to lessen flood risks in Sacramento. Since the authorization of the CFP 12 years ago, a great deal of progress has been made to improve the flood control system. However, new information and issues have been identified and new engineering standards have been instituted. As a result, there are continuing concerns about the integrity of Sacramento's flood control management system.

As a result, the U.S. Army Corps of Engineers plans to conduct a re-evaluation report called the American River Common Features General Re-evaluation Report (Common Features GRR) that will look at the existing CFP with the purpose of identifying alternatives to lower the risk of flooding to the City of Sacramento. The Common Features GRR will examine the City's flood management system as a whole, rather than on a site-by-site, project-by-project basis.

The purpose of the Common Features GRR is to review the CFP with the aim of making recommendations for changes or additions that will effectively and efficiently reduce flood risks within the American River Watershed. This includes the flood control features along the American and Sacramento Rivers that provide protection to the City of Sacramento and surrounding areas.

In a separate effort, the Sacramento Area Flood Control Agency (SAFCA) is currently working on a flood control program specific to Natomas to provide the area with 100-year flood protection as soon as possible, and ultimately, in cooperation with this study, 200-year protection. These improvements could be completed before the Common Features GRR is conducted because of the high risk of catastrophic flooding in Natomas. It is anticipated that SAFCA's program will eventually be incorporated into the Common Features GRR.

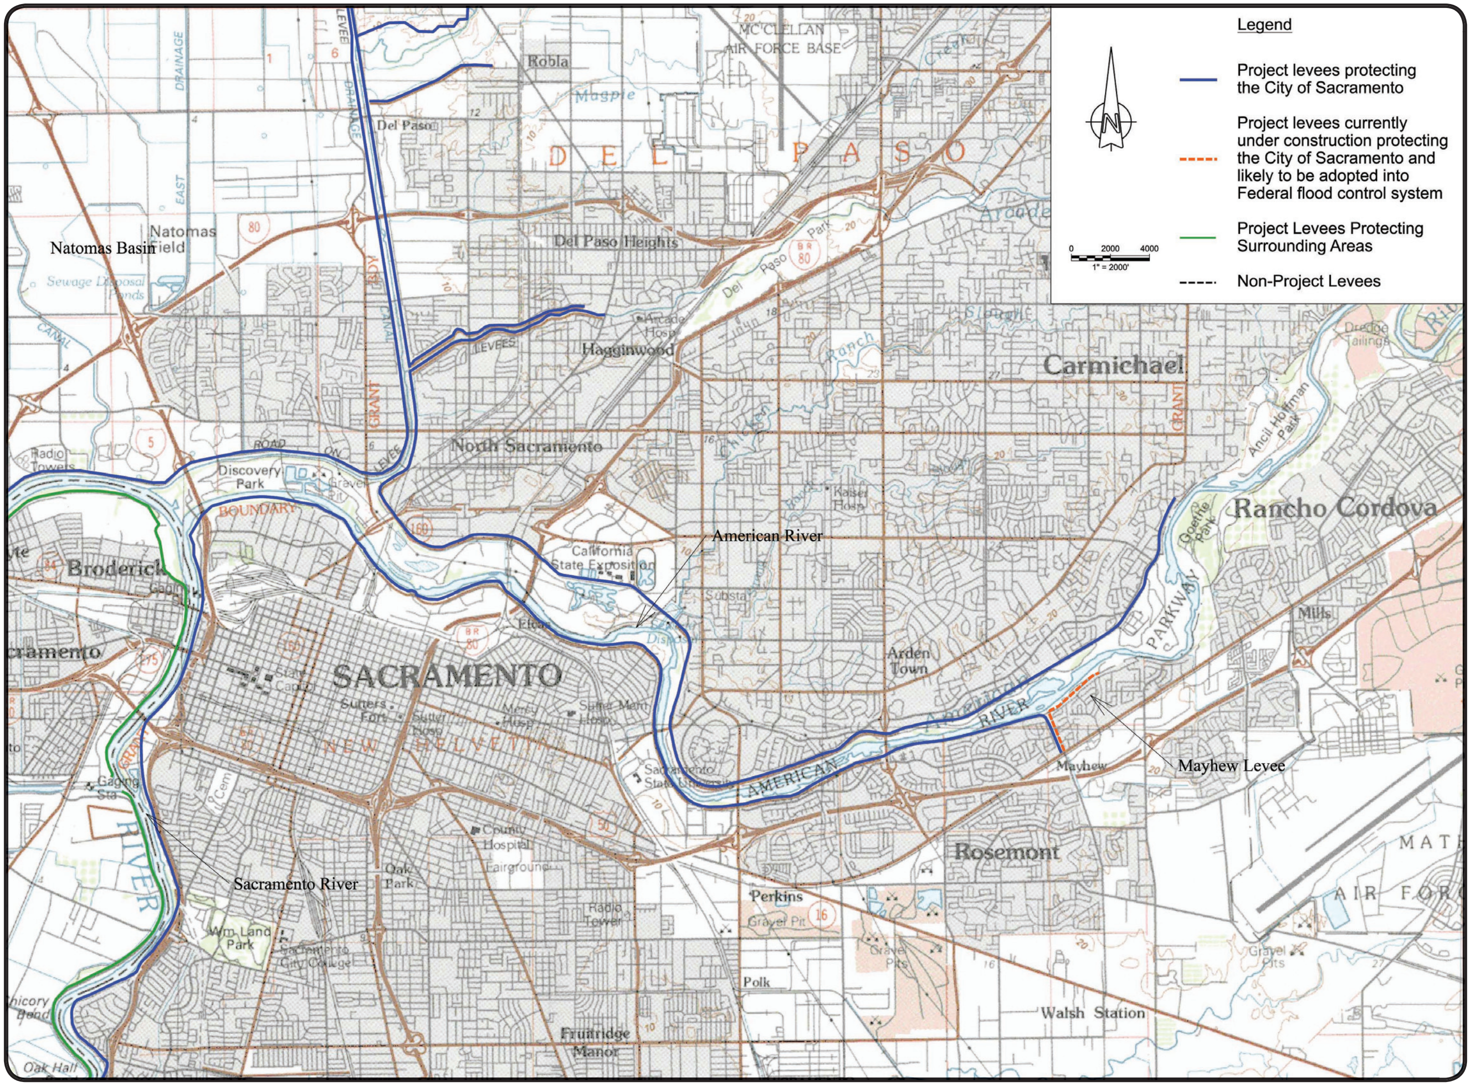
Study Area



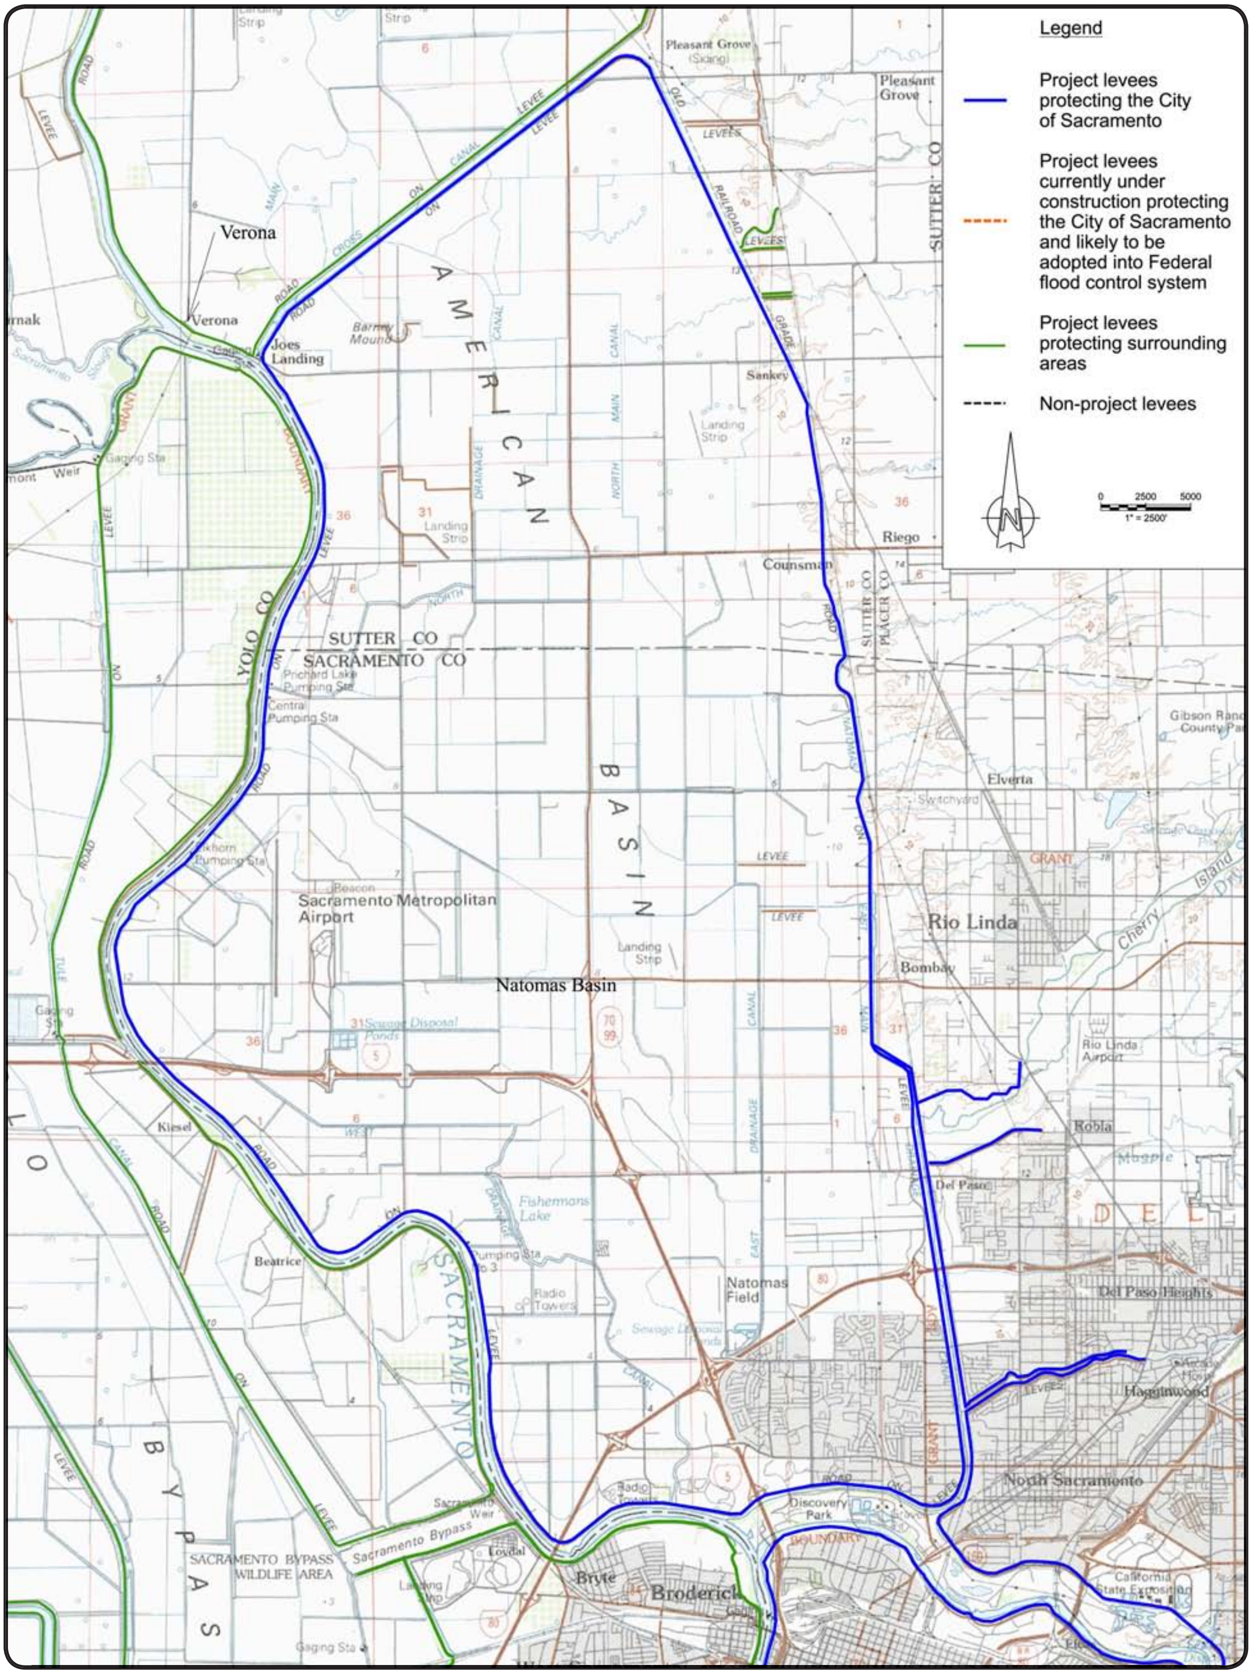
US Army Corps of Engineers Sacramento District

SAFCA

Lower American River



Natomas Basin



Sacramento River from American River to Freeport

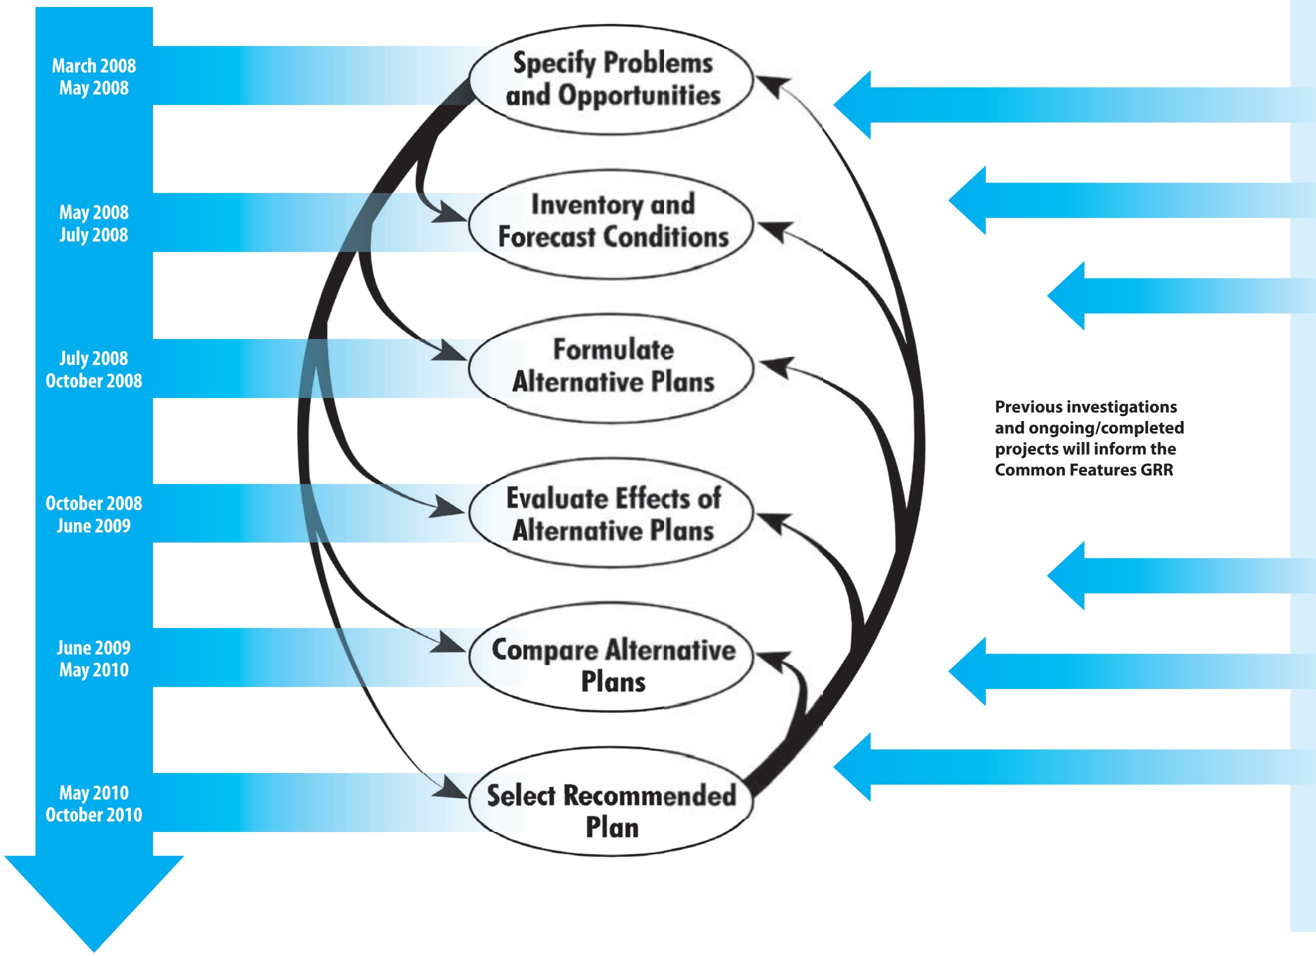
US Army Corps of Engineers
Sacramento District

SAFCA

Planning Process

The Corps' "Beehive" diagram represents the six planning steps and the iterative process of Corps project planning.

Corps decision making is generally based on the accomplishment and documentation of all of these steps. It is important to stress the iterative nature of this process. As more information is acquired and developed, it may be necessary to reiterate some of the previous steps. The six steps, though presented and discussed in a sequential manner for ease of understanding, usually occur iteratively and sometimes concurrently. Iterations of steps are conducted as necessary to formulate efficient, effective, complete and acceptable plans.



Completed and Ongoing Projects

A great deal of progress has been made since the major flood events in 1986 and 1997. The projects listed below are examples of recent efforts to increase the level of flood protection in the Sacramento area. These efforts will inform and be coordinated with the Common Features GRR planning process.

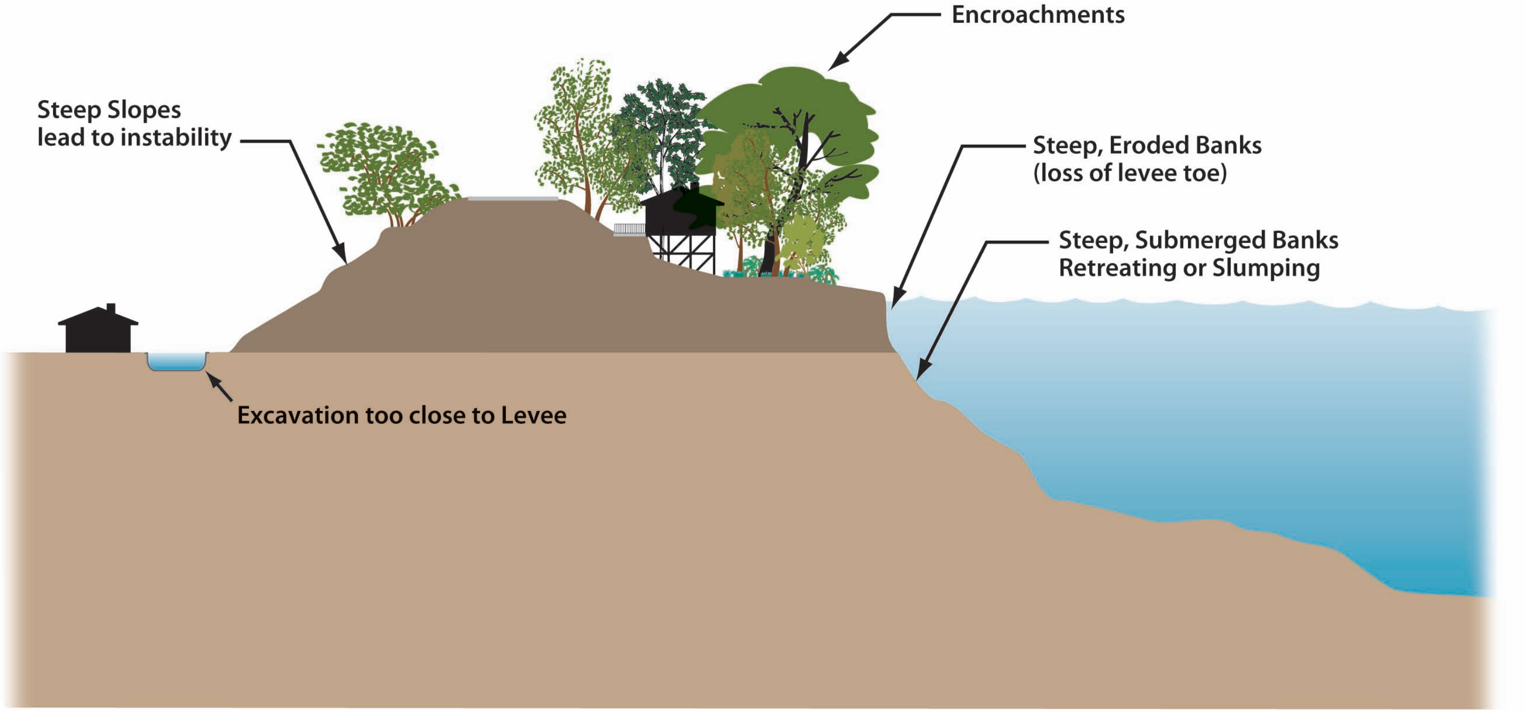
American River Common Features Projects

- Slurry Wall Construction along the Lower American River (24 miles completed)
- Upstream Telemetry Gages (completed)
- Erosion Protection (4 sites completed)
- Jet Grouting/Alternative Methods (ongoing)
- Seepage Remediation along the Sacramento River (completed)
- Mayhew Levee Raise and Drain Closure (under construction)
- Levee Raising and Strengthening (various sites remaining)

Other Major Flood Protection Projects

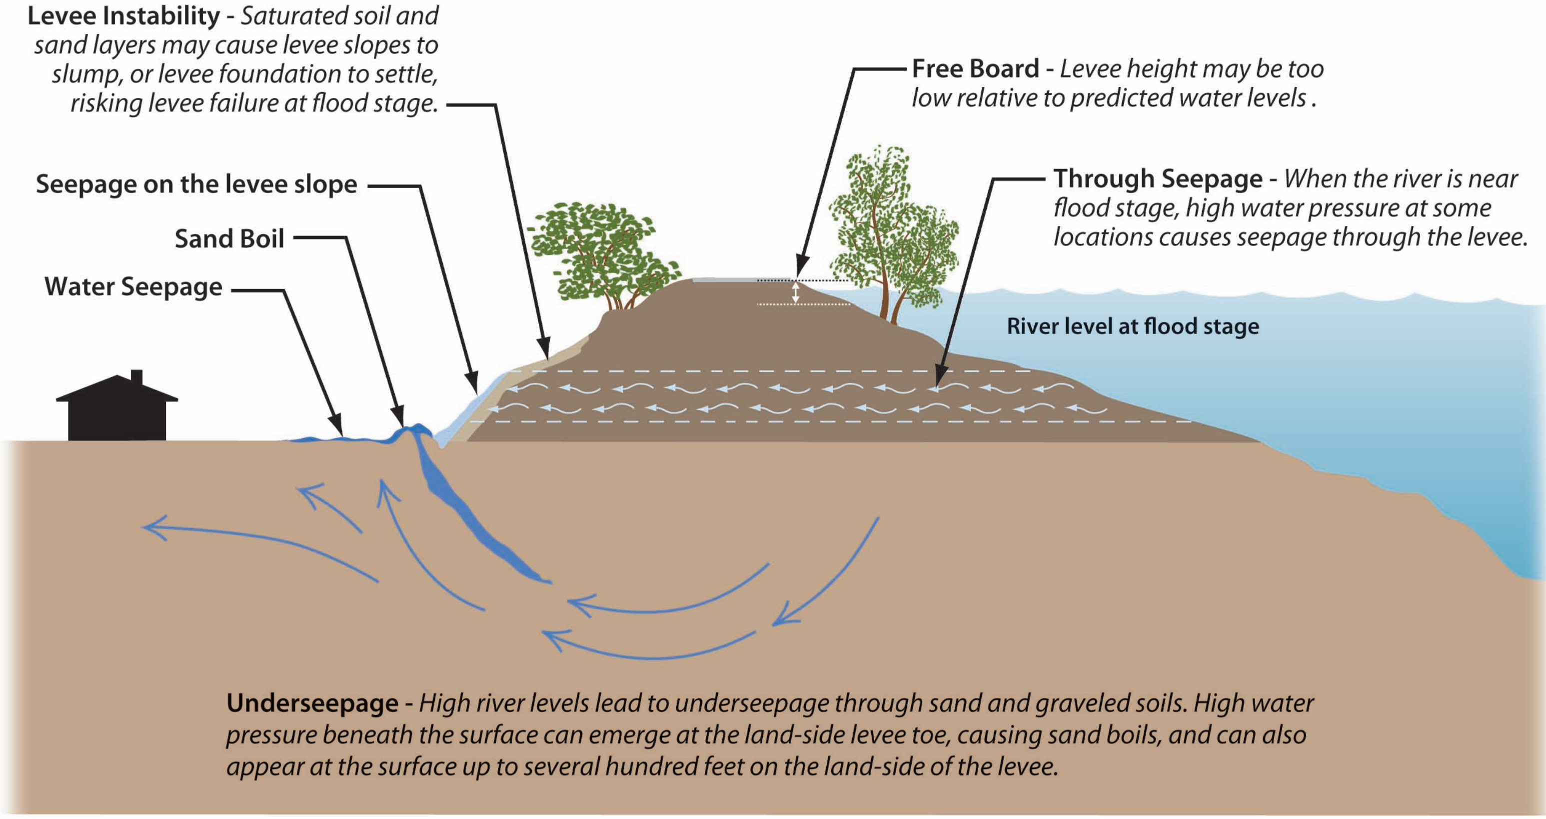
- Folsom Dam Reoperation (ongoing)
- Natomas Levee Improvement Project (ongoing)
- Sacramento River Bank Protection Project (Corps/ CVFPB) (ongoing)
- West Sacramento Levee Improvement Project (Corps/City of West Sacramento) (ongoing)
- South Sacramento Streams Group Project (Corps/ SAFCA) (ongoing)
- Joint Federal Project at Folsom Dam (Corps/Bureau of Reclamation/CVFPB/SAFCA)

Encroachments, Unstable Slopes, Erosion



- Unstable Slopes - irregular or overly steep slopes compromise the levee structure
- Encroachments including pools, homes, vegetation
- Erosion - water flow, wakes and waves, remove soil material, degrading the levee

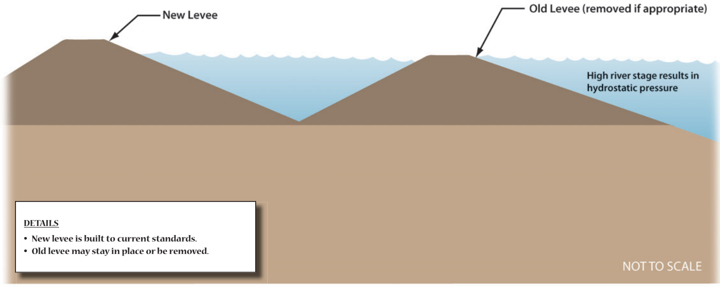
Seepage and Inadequate Freeboard



- Inadequate Freeboard - levee height may be too low relative to predicted water levels

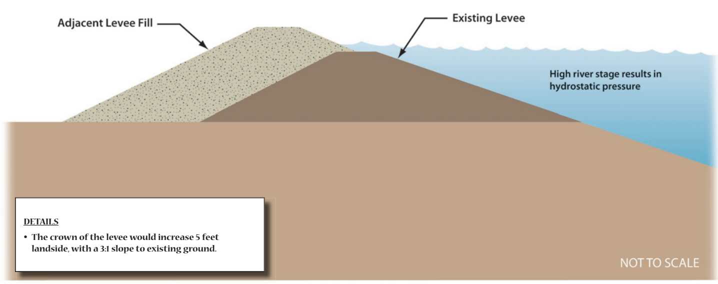
IMPROVEMENTS TO FLOOD CONTROL FEATURES THAT ADDRESS STABILITY, EROSION AND FREEBOARD

Setback Levee (stability, seepage, & freeboard)



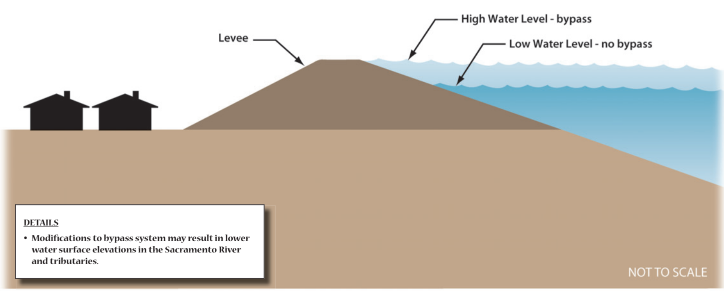
Concept:
A new levee is built toward the landside of an existing levee where the existing levee is not readily repairable or where more flooding capacity is desired.

Adjacent Levee Raise (stability, seepage, & freeboard)



Concept:
A new embankment strengthens the existing levee and enlarges the slopes.

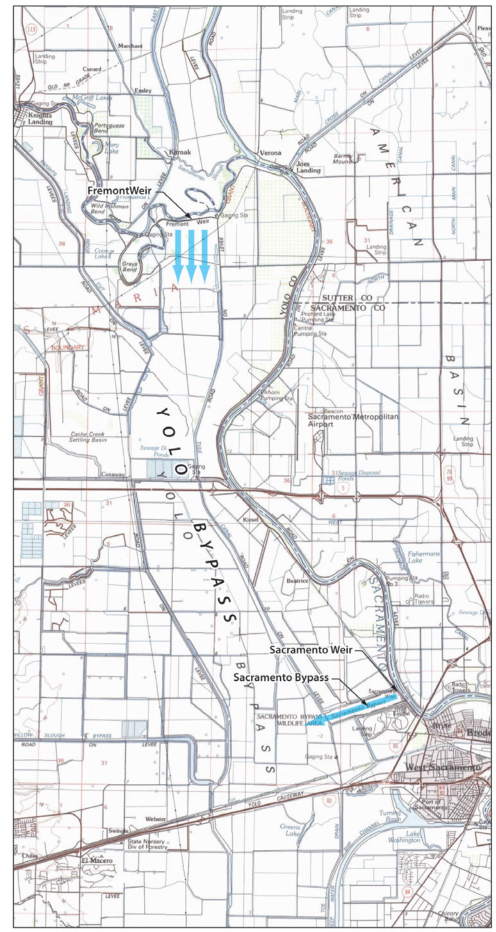
Diversion to Bypass System (seepage, stability, & freeboard)



Concept:
Reducing water surface elevations by modifying diversion to the bypass system may also reduce seepage and stability issues by reducing hydrostatic pressure. Lower water surface elevations will also alleviate freeboard issues.

Diversion to Bypass System

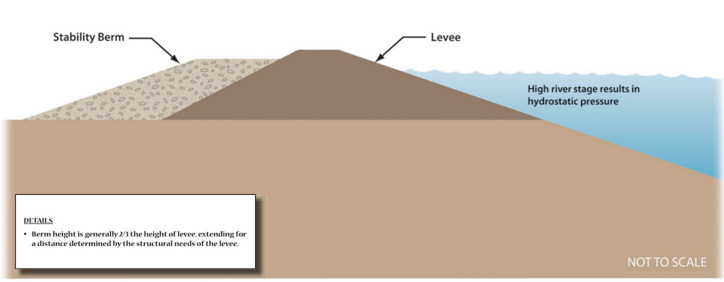
(seepage, stability, & freeboard)



Potential Solutions

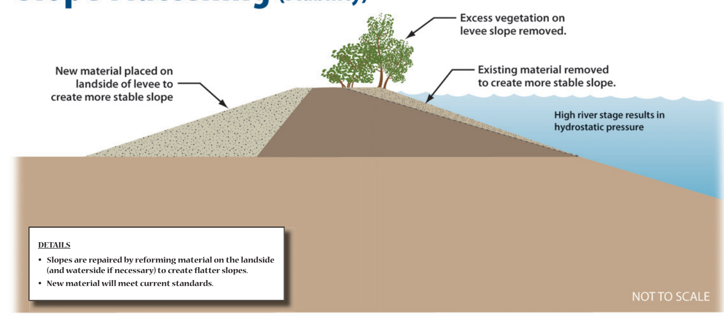
IMPROVEMENTS TO LEVEES THAT ADDRESS STABILITY, EROSION AND FREEBOARD

Stability Berm (stability)



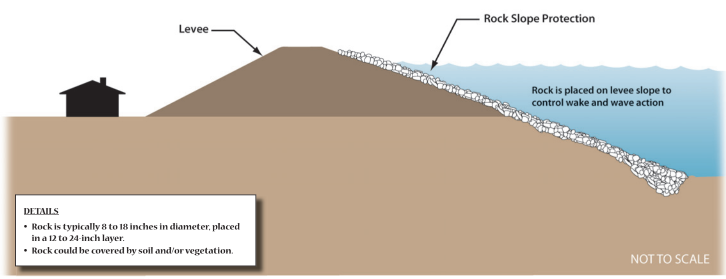
Concept:
Provides additional support to levee to increase strength.

Slope Flattening (stability)



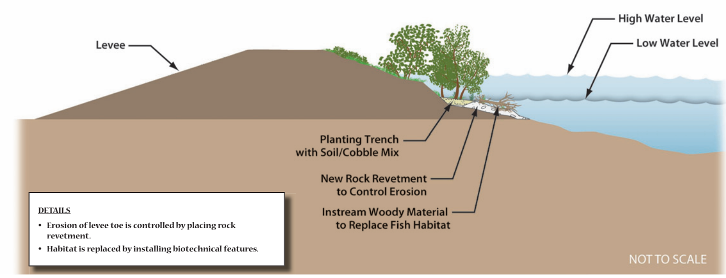
Concept:
Flatter slopes are more stable and less susceptible to erosion. Excess vegetation may inhibit levee maintenance and performance monitoring.

Rock Slope Protection (erosion)



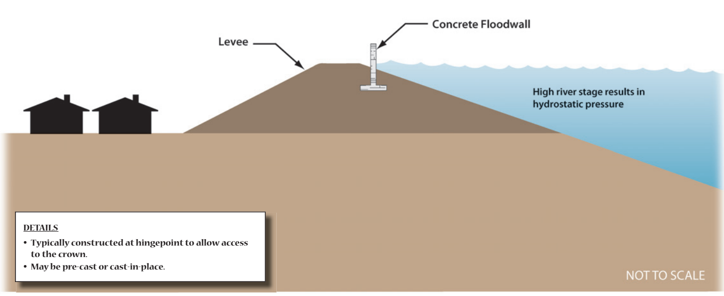
Concept:
Water-side erosion is prevented by placement of rock.

Biotechnical Erosion Protection (erosion)



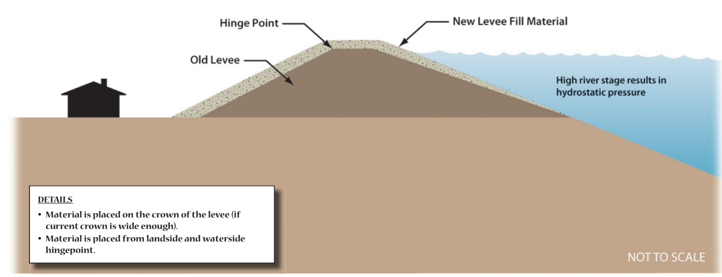
Concept:
Placing rock revetment at toe of eroding levee controls erosion. Installing biotechnical features replaces habitat and further controls erosion.

Flood Wall (freeboard)



Concept:
Additional levee height may be achieved through construction of a concrete wall on the levee crown.

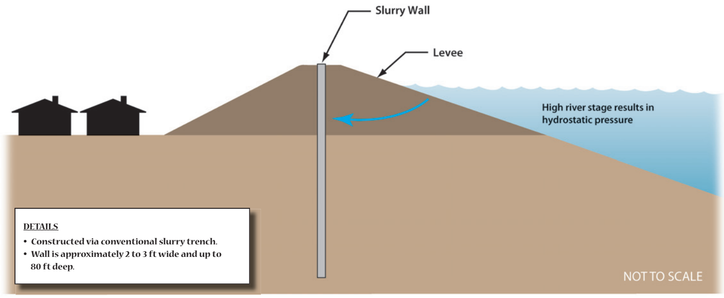
In-Place Levee Raise (freeboard)



Concept:
Flood protection is increased by adding material to crown and levee slope (land or water side).

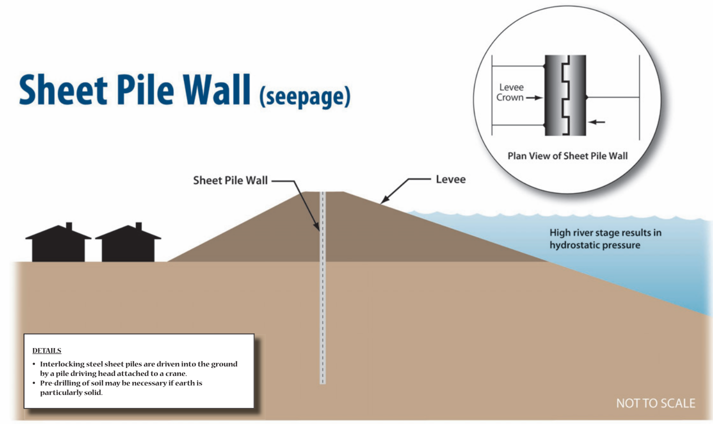
IMPROVEMENTS TO LEVEES THAT ADDRESS SEEPAGE

Slurry Wall (seepage)



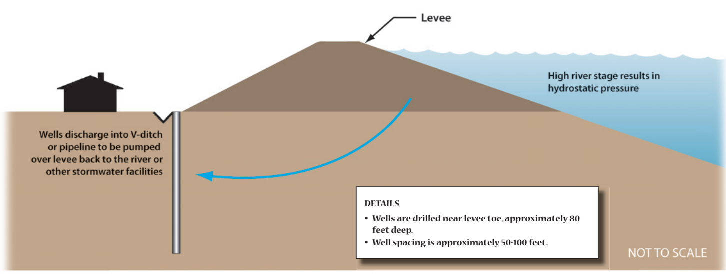
Concept:
Water pressure is contained and dispersed by a low-permeability wall constructed within the levee cross section.

Sheet Pile Wall (seepage)



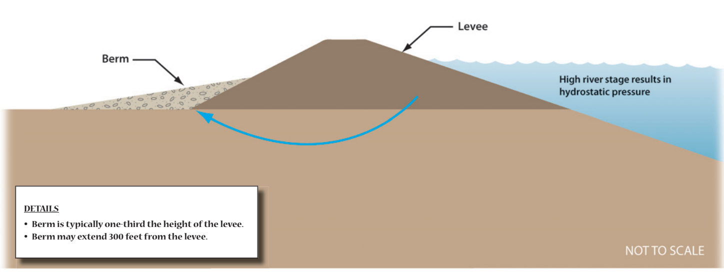
Concept:
Steel panels are driven into the levee core to provide a seepage barrier.

Relief Well (seepage)



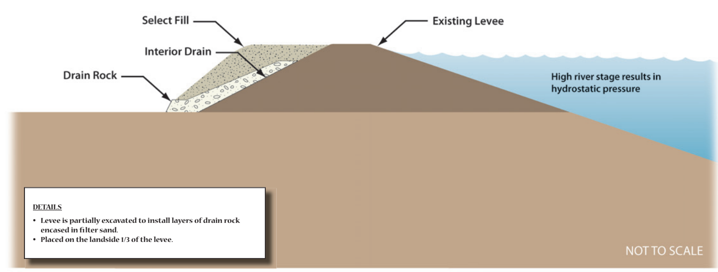
Concept:
Water pressure is relieved via passive wells, which control water discharge into a collection system.

Seepage Berm (seepage)



Concept:
Water pressure is contained and dispersed by a thickened soil layer.

Interior Drain (seepage)



Concept:
Capture any through-seepage and direct it away from the face of the levee.

U.S. Army Corps of Engineers

SAFCA

The process of determining the scope, focus and content of an EIS/EIR is known as "scoping". Scoping is a part of the NEPA/CEQA process in which the general public, interested agencies and stakeholders provide comments to the Lead Agency to help identify the key issues, range of actions, alternatives, and environmental affects to be analyzed in the EIS/EIR.

The following issues related to this project have been identified to date:

- Riparian vegetation and habitat effects;
- Cultural resources;
- Flood control and river hydraulic effect;
- Location of flood control infrastructure and effects on land use and access;
- Construction related effects such as those related to transportation, noise, and air quality;
- Economic issues

NEPA/CEQA Compliance

What is an EIS/EIR?

An EIS (Environmental Impact Statement) and an EIR (Environmental Impact Report) are documents that are required to comply with the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA), respectively. The purpose of these documents is to analyze and disclose a project's potential effects on the natural and human environment and identify conservation measures and alternatives to avoid significant effects.

An EIS is prepared when there is Federal involvement in the project and an EIR is prepared when the project is subject to State or local jurisdiction. A joint document, an EIS/EIR, may be prepared when both a Federal and State agency are involved. The major steps to complying with both acts are outlined below.

NEPA (Environmental Impact Statement)		CEQA (Environmental Impact Report)
Notice of Intent	Official notice that an environmental document is being prepared	Notice of Preparation
Scoping	Defines the scope of the study by identifying issues and soliciting comments from the general public, agencies, and jurisdictions.	Scoping
Draft EIS	Describes the purpose and need/proposed project; alternatives considered; alternatives rejected or accepted; and a comprehensive evaluation of the environmental impacts that the alternatives would likely cause, and conceptual mitigation.	Draft EIR
EPA Filing: Federal Register		State Clearinghouse
Public and Agency Review	At least a 45-day period during which the public and agencies review the draft document and submit comments to the lead agencies.	Public and Agency Review
		Preparation of Response to Comments
Final EIS	Addresses the comments on the draft document and from any public hearing, presents the final evaluation of project-induced environmental impacts and ways to mitigate unavoidable impacts.	Final EIR
EPA Filing: Federal Register Notice		
Agency Decision/ Record of Decision	Lead agency uses information from the final document and the project record to issue a decision and document commitments and mitigation.	Agency Decision/Findings, Statement of Overriding Consideration, Mitigation Monitoring

American River Common Features Project
North Sacramento Streams Levee Improvement Project
Biological Assessment

1.0 Introduction

The U.S. Army Corps of Engineers (Corps) is requesting consultation with the National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS) under Section 7 of the Federal Endangered Species Act (ESA) to evaluate, on a biological assessment (BA) level, potential effects associated with levee modifications proposed under the American River Common Features (ARCF) General Reevaluation Report (GRR) Project. In addition, the Sacramento Area Flood Control Agency (SAFCA) is proposing to implement some segments of the ARCF GRR in advance of the Federal project. This BA addresses the overarching ARCF GRR project, and SAFCA's North Sacramento Streams Levee Improvement Project (NSS), a subset of the ARCF GRR. The purpose of this BA is to meet Section 7 consultation requirements as well as requirements of the Magnuson-Stevens Fishery Conservation and Management Act of 1997 (NMFS 1997). This BA was prepared in accordance with the Corps' Engineering Regulation 1105-2-100 (Corps 2000a).

Section 7 of the ESA requires Federal agencies to conserve listed species and their critical habitat, and to consult with USFWS and NMFS (the Services) to ensure that actions they fund, authorize, or perform do not jeopardize the existence of any listed species or result in the destruction or adverse modification of their designated critical habitat. The actions covered in this BA are associated with future levee modifications proposed for the ARCF GRR Project (Figure 1).

The Magnuson-Stevens Fishery Conservation and Management Act of 1997 (MSA) governs the conservation and management of commercially harvested ocean fisheries. The purpose of the Act is to take immediate action to conserve, protect, and manage U.S. coastal fishery resources, anadromous species, and Essential Fish Habitat (EFH). EFH is the aquatic habitat (water and substrate) that is necessary for fish to spawn, breed, feed, or mature, and that allows production levels needed to: (1) support a long-term, sustainable commercial fishery, and (2) contribute to a healthy ecosystem (NMFS 1997). The ARCF study area is designated as EFH habitat for Pacific salmon under Section 305(b)(2) of the MSA. Species to be addressed in this BA include:

- Fish species with designated EFH under the MSA;
- Listed species under the Federal Endangered Species Act; and
- Species with designated critical habitat under the ESA.

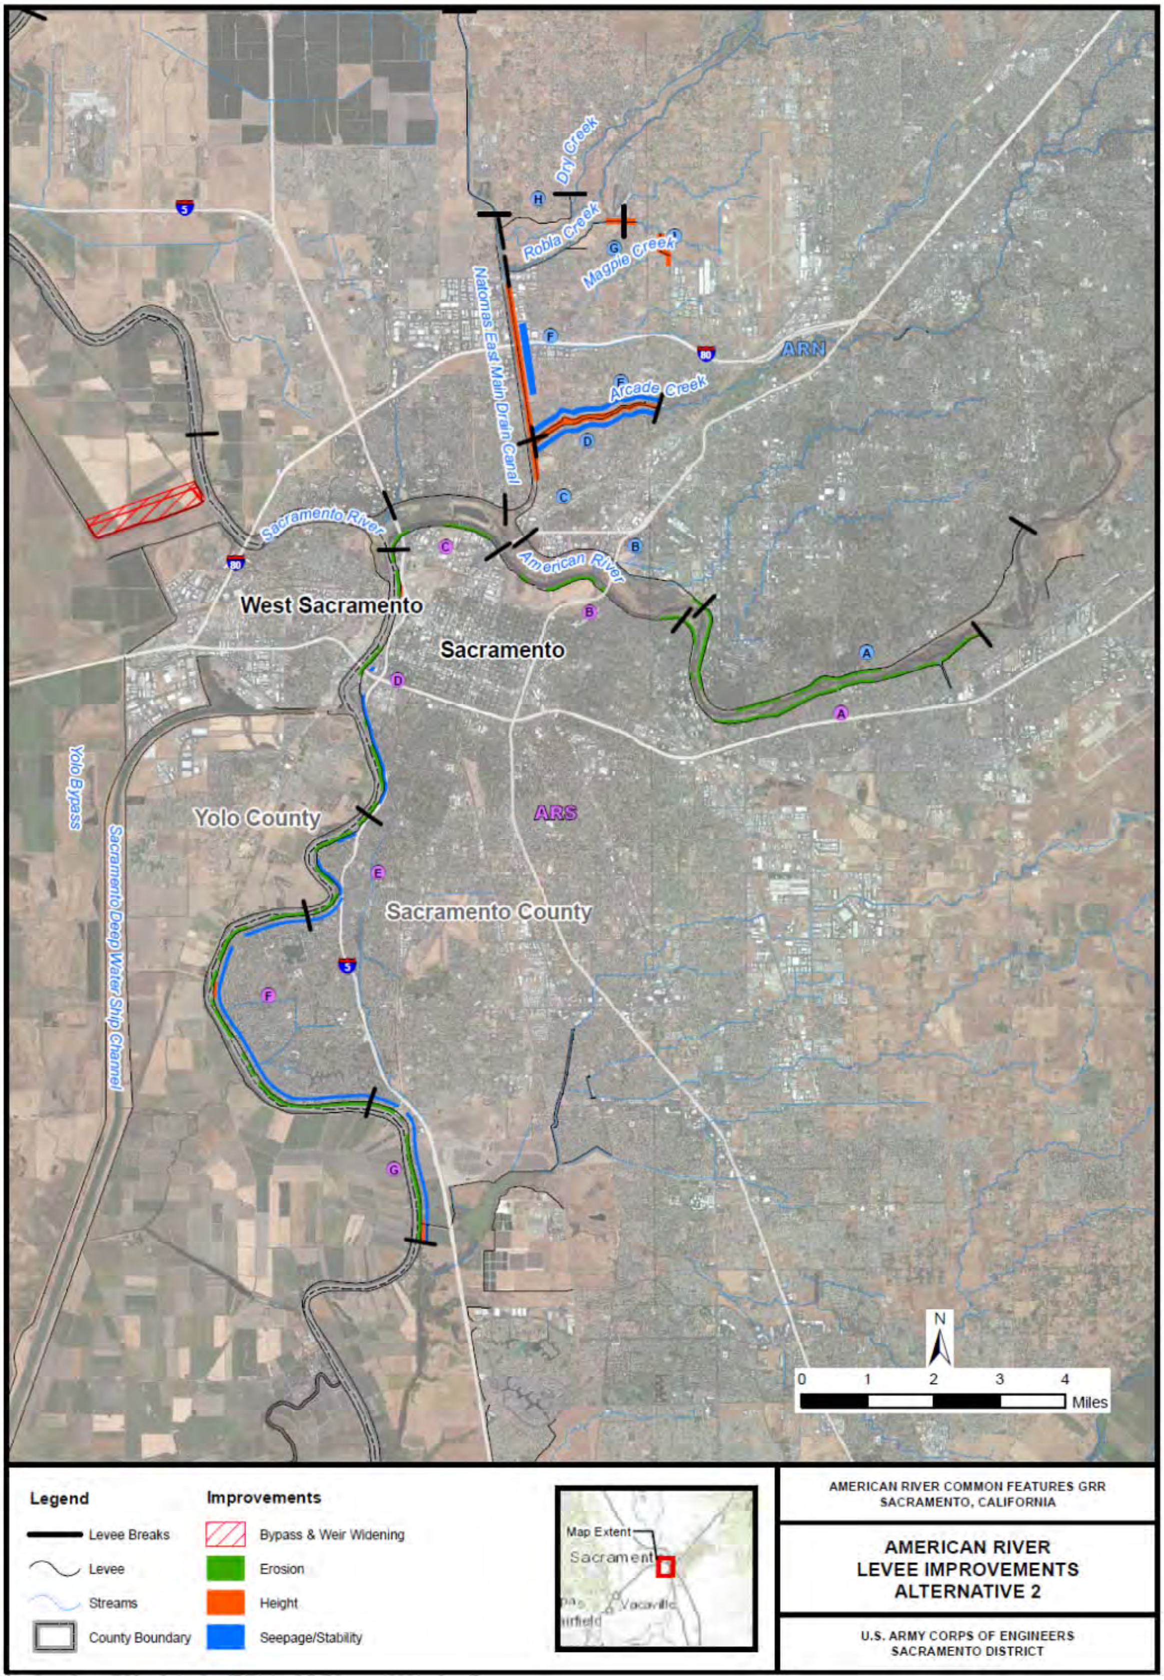

Figure 1. American River Common Features Study Area.

1.1 American River Common Features Study Area and Action Area

The study area is located within the Sacramento and American River Watersheds. The Sacramento River watershed covers approximately 26,000 square miles in central and northern California. Major tributaries of the Sacramento River include the Feather, Yuba, and American Rivers. The American River Watershed covers about 2,100 square miles northeast of the city of Sacramento and includes portions of Placer, El Dorado, Alpine, and Sacramento counties. The American River watershed includes Folsom Dam and Reservoir; inflowing rivers and streams, including the North, South, and Middle forks of the American River; and the lower American River downstream of Folsom Dam to its confluence with the Sacramento River in the city of Sacramento. The Sacramento and American Rivers, in the Sacramento area, form a flood plain covering roughly 110,000 acres at their confluence. The flood plain includes most of the developed portions of the city of Sacramento. Figure 1 shows the study area.

The city of Sacramento is the capitol of California, and thus is the government center for the state, which by itself has the 9th largest economy in the world. Many state offices located in downtown Sacramento, including the State Capitol building, are in areas that could be affected by flood events. Disruption of government services, and effects to emergency services and transportation corridors could have far ranging effects including life safety.

The ARCF study area includes: (1) approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; (2) the east bank of the Natomas East Main Drainage Canal (NEMDC), Dry, Robla, and Arcade Creeks and the Magpie Creek Diversion Channel (collectively referred to as the East Side Tributaries); (3) the east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee, the southern defense for Sacramento; and (4) the Sacramento Weir and Bypass, located along the north edge of the city of West Sacramento (Figure 1). This BA analyzes the effects of repairing the levees in the Sacramento area and widening the Sacramento Weir and Bypass to divert more flows into the Yolo Bypass and alleviate the need to raise levees along the Sacramento River downstream of the bypass.

The action area for the ARCF GRR project includes the American River from below Folsom Dam to the confluence with the Sacramento River and the Sacramento River from the Sacramento Bypass down to below Freeport. In addition the action area includes the East Side Tributaries: the NEMDC, Dry, Robla, and Arcade Creeks, and the Magpie Creek Diversion Channel. The SAFCA NSS project includes approximately 5 miles of Arcade Creek and NEMDC, as well as an associated borrow site and staging areas. More information about these sites is included in the project description below.

The erosion repairs within the project area is likely to somewhat reduce the sediment supply for riverine reaches directly downstream because the erosion repair is holding the bank or levee in place. However, from a system sediment perspective, the bank material we are protecting in the project reaches is not a major source of sediment compared to the upstream reaches of the Sacramento, Feather and especially the Yuba River systems. All of the available sediment in the American River watershed is being contained behind Folsom Dam. For velocity, the site specific designs will be constrained from allowing any velocity increases outside the erosion repair site. Sediment impacts due to the bypass widening are not known at this time, except to say that the study would constrain the design to minimize impacts to sediment transport. Further studies associated with the Bypass widening would be conducted during the preconstruction engineering and design phase of the project, and any impacts to listed species that are discovered during these studies would be coordinated with the resource agencies at that time. The action area for the project is directly related to the study area where construction activities would occur.

The project is designed to allow for the release of 160,000 cubic feet per second (cfs) from Folsom Dam. The levees along the American River are unable to withstand these maximum flows for extended periods of time without increased risk of erosion and potential failure. The exact location where erosion would occur and to what extent erosion would occur during any given event is unknown. Erosion within the American River Parkway is being addressed as part of the Folsom Dam Water Control Manual Update currently under evaluation and a biological assessment is being prepared to initiate Section 7 consultation with both USFWS and NMFS. Therefore, the affects of erosion due to changes in operations from Folsom Dam are not analyzed in this BA because construction of the American River and Sacramento Bypass measures for the ARCF GRR, which are dependant on releases from Folsom Dam, would not occur until after a Biological Opinion is received for the Water Control Manual Update. Sacramento River and East Side Tributaries measures would be necessary to improve the flood risk management system in the Sacramento area regardless of the change in operation at Folsom Dam and are not dependant on Folsom Dam operations for their implementation. As a result, construction in these areas could occur regardless of the Folsom Dam Water Control Manual Update schedule.

The American River Common Features General Reevaluation Report (ARCF GRR) is being completed in accordance with the principles that have been outlined in the Corps' SMART Planning Guide (May 2012). SMART Planning requires that all feasibility studies should be completed within a target of 18 months (to no more than three years at the greatest), at a cost of no more than $3 million, utilizing 3 levels of vertical team coordination, and of a "reasonable" report size. The SMART Planning methodology and framework were developed to facilitate more efficient, effective, and consistent delivery of Planning Decision Documents. As a result of this effort, team members and decision makers are required to accept a lower level of detail and higher level of uncertainty during the pre-authorization study phase. All designs associated with this project are therefore preliminary, with the largest footprint considered for analysis of maximum affects to listed species and designated critical habitat. As design refinements and more site specific data becomes available, where practicable, it is anticipated that there will be reductions in effects to listed species and designated critical habitat.

On-going coordination with the Services will occur as the project progresses to the preliminary engineering design phase to ensure compliance with Section 7. The Corps would coordinate potential design refinements with the Services to avoid, minimize, and compensate for affects to listed species and reinitiate consultation if necessary. The study area includes the protected species and critical habitat listed in Table 1, as well as fall-/late fall–run Chinook salmon, which has EFH within the study area.

Table 1. Federally Protected Species and Critical Habitat Addressed in this Biological Assessment.

Common Name	Scientific Name	Federal Status
Threatened and Endangered Species		
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*	T
Sacramento River winter-run Chinook salmon ESU	*Oncorhynchus tshawytscha*	E/MSA
Central Valley spring-run Chinook salmon ESU	*Oncorhynchus tshawytscha*	T/MSA
Central Valley steelhead DPS	*Oncorhynchus mykiss*	T
Delta smelt	*Hypomesus transpacificus*	T
Green sturgeon southern DPS	*Acipenser medirostris*	T
Giant garter snake	*Thamnophis gigas*	T
Vernal pool fairy shrimp	*Branchinecta lynchi*	T
Vernal pool tadpole shrimp	*Lepidurus packardi*	E
Western yellow-billed cuckoo	*Coccyzus americanus occidentalis*	T
Critical Habitat		
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*	
Sacramento River winter-run Chinook salmon ESU	*Oncorhynchus tshawytscha*	
Central Valley spring-run Chinook salmon ESU	*Oncorhynchus tshawytscha*	
Central Valley steelhead DPS	*Oncorhynchus mykiss*	
Delta smelt	*Hypomesus transpacificus*	
Green sturgeon southern DPS	*Acipenser medirostris*	

Note: ESU = Evolutionarily Significant Unit, DPS = Distinct Population Segment, T = Threatened, E = Endangered, MSA = Magnuson-Stevens Fishery Conservation and Management Act.

1.2 Project Background and Authority

1.2.1 Authority

The ARCF project was authorized by Section 106(a)(1) of the Water Resources Development Act (WRDA) of 1996, (Public Law [PL] 104-303) (110 Stat. 3658, 3662-3663), as amended by Section 130 of the Energy and Water Development and Related Agencies Appropriations Act of 2008, (PL 110-161) (121 Stat. 1844, 1947). Additional authority was provided in Sections 366 and 566 of WRDA 1999, (PL 106-53), (113 Stat. 269, 319-20). Section 366 directed the Secretary to include specific levee improvement features in the overall project and Section 566(b) directed the Secretary to undertake additional study of American and Sacramento River levee modifications. Significant changes to the project cost were recommended in the Supplemental Information Report of March 2002. This report was submitted to the Assistant Secretary of the Army for Civil Works, but before it could be forwarded to Congress, Section 129 of the Energy and Water Development Appropriations Act of 2003, (PL 108-137), (117 Stat. 269, 1839) increased the authorized total cost of the project to $205,000,000. The current estimated cost of the authorized project is $274,100,000. In accordance with Section 902 of WRDA 1986 (Pub. L. 99-662, § 902, Nov. 17, 1986, 100 Stat. 4183), the allowable cost limit is $284,000,000.

To implement the NSS Levee Improvements Project, SAFCA would request permission from the Corps for:

- Alteration of Federal project levees, pursuant to Section 14 of the Rivers and Harbors Act of 1899 (33 USC 408, referred to as "Section 408"); and
- Placement of fill in jurisdictional waters of the United States, pursuant to Section 404 of the Clean Water Act (33 USC 1344, referred to as "Section 404").

1.2.2 Background

After the flood of 1986, Congress directed the Corps to investigate the feasibility of reducing flood risk of the city of Sacramento. The Corps completed feasibility studies in 1991 and 1996, recommending a concrete gravity flood detention dam on the north fork of the American River at the Auburn site along with levee improvements downstream of Folsom Dam. Other plans evaluated in the report were Folsom Dam improvements and a stepped release plan for Folsom Dam releases. These additional plans also included levee improvements downstream of Folsom Dam. Congress recognized that levee improvements were "common" to all candidate plans in the report and that there was a Federal interest in participating in these "common features." Thus, the ARCF Project was authorized in WRDA 1996 and a decision on Auburn Dam was deferred to a later date. Major construction components for ARCF in the WRDA 1996 authorization include construction of seepage remediation along approximately 22 miles of American River levees and construction of levee strengthening and raising of 12 miles of Sacramento River levee in Natomas.

Following the flood of 1986, significant seepage was experienced on the Sacramento River from Verona (upstream end of Natomas) at River Mile (RM) 79 to Freeport at RM 45.5. In addition, both the north and south bank of the American River from RM 0 to approximately RM 11.4 experienced seepage. Seepage on the Sacramento River was so extensive that Congress, soon after the 1986 flood event, funded remediation in the Sacramento Urban Levee Improvement Project (Sac Urban). The Sac Urban Project constructed shallow seepage cutoff walls from Powerline Road in Natomas at approximately RM 64 down to Freeport.

Shortly thereafter, the Sacramento Valley experienced a flood event in 1997. Considerable seepage occurred on the Sacramento River as well as on the American River. Seepage on the American River was to be expected because remediation had yet to be constructed, but the occurrence of significant seepage on the Sacramento River in the reach remediated as part of the Sac Urban project was alarming and confirmed that deep underseepage was also of significant concern. As a result of this conclusion, seepage remediation on the American River (then in the late 1990s in the design phase) would need to be designed to remediate both through- and deep underseepage.

In 1999, Congress decided not to authorize Auburn Dam but instead to authorize improvements for Folsom Dam. By doing this, improvements to levees downstream of Folsom Dam could be fine tuned to work closely with the Folsom Dam improvements being discussed by Congress. Therefore, the ARCF project was modified by WRDA 1999 to include additional necessary features for the American River so that it could safely convey the proposed emergency release of 160,000 cfs from Folsom Dam. Major construction components for the ARCF project in the WRDA 1999 authorization include construction of seepage remediation and levee raises along four stretches of the American River, and construction of levee strengthening and raising of 5.5 miles of Natomas Cross Canal levee in Natomas. All American River features authorized in WRDA 1996 and 1999 have been constructed or are in design analysis for construction within a year or two.

Because of the considerable cost increase of seepage remediation on the American River, all funds appropriated by Congress throughout the late 1990s and the early part of the 2000s were used for construction activities on the American River instead of for design efforts in the Natomas Basin. Combining this with the recognition that all work in the Natomas Basin would also require significantly more effort than was anticipated at the time of authorization, it was decided in 2002 that a general reevaluation study would be required for at least the Natomas Basin portion of the ARCF project. This general reevaluation started in 2006.

At approximately the same time that the reevaluation study was beginning, the Folsom Dam Post Authorization Change report (PAC) was being completed by the Sacramento District. Results of this study showed that additional levee improvements were needed on the American River and on the Sacramento River below the American River in order to truly capture the benefits of the Folsom Dam projects. These levee improvements consisted primarily of addressing erosion concerns on the American River and seepage, stability, erosion, and height concerns on the Sacramento River below the American River. However, the full extent of the levee improvements necessary to address these concerns was not known. With the construction of the Sac Urban project, it was thought that the seepage and stability problems had been addressed. However, the 1997 flood event proved otherwise. Because of this, it was realized that additional reevaluation studies are also needed to include the additional two basins comprising the city of Sacramento, as well as the Natomas Basin.

The purpose of the ARCF project is to reduce the flood risk for the city of Sacramento. The following problems were identified within the Sacramento levee system:

- Seepage and Underseepage;
- Levee Erosion;
- Levee Stability;
- Levee Overtopping;
- Access for Maintenance and Flood Fighting;
- Vegetation and Encroachments;
- Releases from Folsom Dam;
- Floodplain Management; and
- Additional Upstream Storage from Existing Reservoirs.

1.3 Future Consultation Approach

In order to evaluate the maximum affects to listed species this BA looks at the largest foreseeable footprint. The Corps will consult on Alternative 2 (Proposed Alternative) which is the tentatively selected plan and the Locally Preferred Plan. Following project authorization as the Corps begins the design phase of the project, footprint refinements will likely reduce the effects to listed species. Coordination with the resource agencies will continue into the design phase to obtain input to avoid, minimize, or compensate for affects to listed species. The Corps would consult with the resource agencies of any project footprint changes, including potential reductions of impacts prior to the initiation of construction. This future coordination would attempt to reduce any mitigation required for the project and also would determine if additional consultation is needed for the project.

In addition, SAFCA, the project's local sponsor, is proposing to implement some reaches of the ARCF GRR in advance of the Federal project. SAFCA would seek permission from the Corps pursuant to 33 USC §408 (Section 408) for alteration of the Federal levee system. Additionally, SAFCA would seek credit from the Corps under Section 221 of the Flood Control Act of 1970. This BA supports implementation of SAFCA's NSS Levee Improvement Project.

2.0 Description of the Action and Project Evaluation Approach

2.1 Introduction

The ARCF GRR has identified a number of problems associated with the flood risk management system protecting the city of Sacramento and surrounding areas. There is a high probability that flows in the American and Sacramento Rivers will stress the network of levees protecting Sacramento to the point that levees could fail. The consequences of such a levee failure would be catastrophic, since the area inundated by flood waters is highly urbanized and the flooding could be up to 20 feet deep.

The majority of the Sacramento River levee within the study area requires seepage, slope stability, height, and erosion improvements in order to meet Corps criteria. Construction of the levee improvement measures will require complete vegetation removal within the construction footprint required to install the cutoff wall and raise the levee for approximately one mile. On the waterside, where construction does not remove vegetation, on the lower one-half of the slope to 15 feet waterward of the waterside levee toe, the vegetation will be left in place and a Vegetation Variance (VV) will be sought by the Sacramento District. To show that the safety, structural integrity, and functionality of the levee would be retained, an evaluation of underseepage and waterside embankment slope stability was completed given that a tree fell resulting in scouring of the root ball area.

An analyses section/index point was chosen for the VV analyses which was considered to be representative of the most critical channel and levee geometry and the without project analyses showed the section does not meet underseepage and slope stability criteria. The cross-section geometry of the index point incorporated tree fall and scour by using a maximum depth of scour for cottonwoods as approximately 11.0 feet; the associated soil removed was projected at a 2:1 slope from the base of the scour toward both the landside, and waterside slopes. The base scour width was equal to the maximum potential diameter at breast height (dbh) of cottonwoods (12.0 feet) projected horizontally at a depth of 11.0 feet below the existing ground profile. The results show that the tree fall and scour did not significantly affect levee performance and that the levee meets Corps seepage and slope stability criteria considering the seepage and stability improvement measures are in place (“with project” conditions). Therefore, it is a reasonable conclusion that a VV to allow vegetation to remain would not jeopardize the safety, structural integrity, and functionality of the Sacramento River levee. The Sacramento Weir and Bypass levees would be constructed in compliance with the Corps ETL as these would be new levees. No vegetation removal would be required within the existing or expanded Sacramento Bypass. Table 2 below summarizes the project reaches and whether or not a variance would be requested outside of the construction footprint.

Table 2. Summary of ETL Compliance Method by Waterway.

	Vegetation Variance	SWIF
Sacramento River (lower ½ of levee slope which is outside construction footprint)		
Waterside	X	
Landside		X
American River		
Trench Landside[1]		X
Bank Protection		X
North Area Tributaries[2]		
NEMDC	X	X
Dry/Robla Creeks	X	X
Arcade Creek	X	X
Magpie Creek[3]	X	X

1 The waterside footprint for the trench construction would require removal of vegetation and therefore compliance with the ETL.
2 A variance is included for these tributaries waterside slopes outside of the construction footprint, and a SWIF would be prepared by the non-Federal partners for the landside slopes and access.
3 The new levee constructed along Raley Boulevard would be constructed in compliance with the ETL.

2.1.1 Alternative Formulation and Screening

A wide variety of management measures were developed to address the planning objectives. These measures were evaluated and then screened using the Corps planning process. Formulation strategies were then developed to address various combinations of the planning objectives and planning constraints. Based upon these strategies, various combinations of the measures were assembled to form an array of preliminary plans. The preliminary plans were then evaluated, screened and reformulated, resulting in a final array of alternatives.

The formulation strategies used to address the objectives and constraints included:

- Measures to reduce flood stages;
- Measures to address seepage and underseepage;
- Measures to address stability;
- Measures to achieve the urban levee level of protection;
- Measures to address erosion;
- Measures to address maintenance and emergency response access; and
- Non-structural measures.

Approximately 35 different measures were developed to address these formulation strategies. The measures then went through a preliminary screening process prior to combining them into alternatives. This screening was done by evaluating the measures against the four planning criteria established in the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies: completeness, efficiency, effectiveness, and acceptability. In addition, the local sponsor identified a planning criterion of ability to implement the project.

2.1.2 Measures Considered, But Eliminated From Future Consideration

Some measures originally identified that could contribute to addressing Sacramento's flood problems and needs were reviewed and dropped from further consideration. These measures included:

- Upstream storage on the American River (Auburn Dam);
- Transitory storage in upstream basins;
- Yolo Bypass improvements;
- Reoperation of upstream reservoirs: and
- Construction of a diversion structure just upstream of the existing I Street Bridge on the Sacramento River.

The Corps has a long history of studying upstream storage on the American River. Auburn Dam was proposed for authorization by the Corps in both 1991 and 1996, with no authorization granted by Congress. Since that time, Congress has consistently directed the Corps to focus on downstream elements rather than upstream storage under the scope of this study, as levee improvements are considered to be the first increment necessary to improve the overall system. As a result, this alternative was eliminated from consideration under this study. However, upstream storage may be considered to be a viable measure to further reduce the level of risk to the flood risk management system under future studies.

The I Street Bridge diversion structure was proposed to limit flood flows through the city of Sacramento and push excess flows into the Yolo Bypass in order to limit the need for levee repairs downstream of the structure. This measure was not carried forward for a variety of reasons. The estimated implementation time would leave the urban Sacramento River at risk for an unacceptably long period of time. Operation of the structure would inundate the Yolo Bypass more frequently than current operations, causing an unknown disruption to the Yolo County agricultural economy. In addition, the construction of a permanent structure in the Sacramento River channel is inconsistent with the goals and objectives of the Central Valley Flood Protection Plan, a key planning effort by the State of California; moving forward with a measure that is inconsistent with this plan could risk the partnership between the Corps and the State for the ARCF GRR.

The remaining three measures listed above include upstream transitory storage, Yolo Bypass improvements, and reoperation of upstream reservoirs. These three measures were all eliminated from further consideration because none would reduce flood stages to a low enough level to eliminate the need for downstream levee repairs. As a result, the downstream levee repairs remain the common element between these measures and remain the primary focus of Alternative 2, the tentatively selected plan, detailed in Section 2.2 below.

In addition, some non-structural measures were considered, and eliminated, including flood proofing individual structures, relocating residents out of the flood plain, and raising structures to above the floodplain. All of these non-structural measures were eliminated because the sheer number of residents in the floodplains, particularly in the American River South study area in the Pocket and Meadowview neighborhoods, made this alternative cost-prohibitive when compared to the proposed alternatives.

2.2 Alternative 2 – Improve Levees and Widen the Sacramento Weir and Bypass

Alternative 2, the tentatively selected plan, involves the construction of fix-in-place levee remediation measures to address seepage, stability, erosion, and height concerns identified for the American River levees, NEMDC, Arcade, Dry/Robla, and Magpie Creeks. The levees along the Sacramento River would be improved to address identified seepage, stability, erosion, and a minimal amount of height concerns. Most height concerns along the Sacramento River would be addressed by a widening of the Sacramento Weir and Bypass to divert more flows into the Yolo Bypass. A summary of the measures proposed under this study are included in Table 3.

Table 3. Proposed Measures for the American River Common Features Project.

Waterway/Location	Extent of Action	Proposed Measure
American River	North and south levees from the confluence with the Sacramento River upstream for approximately 12 miles.	• Construct bank protection or launchable rock trenches
Sacramento River	East levee from the American River to Morrison Creek.	• Install cutoff walls • Construct bank protection • Construct levee raise
NEMDC	East levee from Dry/Robla Creek to the American River	• Install cutoff walls • Construct floodwalls
Arcade Creek	North and south levees from NEMDC to Marysville Boulevard	• Install cutoff walls • Raise floodwalls
Dry/Robla Creek		• Raise floodwalls
Magpie Creek Diversion Canal	Upstream of Raley Boulevard	• Construct floodwalls
Magpie Creek area	South of Raley Boulevard	• Construct new levee
Magpie Creek area	East of Raley Boulevard	• Acquire property to create a flood detention basin • Widen the Raley Boulevard/Magpie Creek bridge and raise the elevation of the roadway • Remove the Don Julio Creek culvert
Sacramento Weir and Bypass	North bypass levee to 1,500 feet north.	• Widen the Sacramento Weir and Bypass by approximately 1,500 feet • Construct a new section of weir and levee • Remove the existing Sacramento Bypass north levee

All proposed measures are detailed in Sections 2.2.1 through 2.2.4 below. Due to the urban nature and proximity of existing development within the American River North and South basins, Alternative 2 proposes fix in place remediation. The purpose of this alternative would be to improve the flood damage reduction system to safely convey flows to a level that maximizes net benefits. Table 4 summarizes the levee problems discussed above and the proposed measure for each waterway.

Table 4. Alternative 2 - Proposed Remediation Measures by Waterway.

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[1]	---	---	Bank Protection, Launchable Rock Trench	---
Sacramento River	Cutoff Wall	Cutoff Wall	Bank Protection	Sacramento Bypass and Weir Widening, Levee Raise
NEMDC	Cutoff Wall	Cutoff Wall	---	Floodwall
Arcade Creek	Cutoff Wall	Cutoff Wall	---	Floodwall
Dry/Robla Creeks	---	---	---	Floodwall
Magpie Creek[2]	---	---	---	Floodwall, Levee Raise

1 American River seepage, stability, and overtopping measures were addressed in the American River Common Features, WRDA 1996 and 1999 construction projects.
2 In addition to the Floodwall, Magpie Creek will include construction of a new levee along Raley Boulevard south of the creek, and construction of a detention basin on both sides of Raley Boulevard. In addition, some improvements would need to occur on Raley Boulevard, including widening of the Magpie Creek Bridge, raising the elevation of the roadway, and removing the Don Julio Creek culvert.

2.2.1 Vegetation and Encroachments

In addition to the proposed levee improvements measures shown in Table 3, the following measures and policies would be addressed during construction:

- Utility encroachments will be brought into compliance with Corps policy as a part of project construction activities. Utilities that penetrate the levee would be removed during excavation of the levee and replaced with one of two fixes as construction commences. These two fixes include: (1) a surface line over the levee prism, or (2) a through-levee line equipped with positive closure devices.
- Private encroachments such as fences and stairs in the levee shall be removed by the non-federal sponsor prior to construction.

The Corps' Engineering Technical Letter (ETL) 1110-2-583, Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures, calls for the removal of wild growth, trees, and other vegetation, which might impair levee integrity or flood-fighting access in order to reduce the risk of flood damage. The vegetation requirements include a 15 foot waterside, landside, and vertical vegetation-free zone. In certain instances, to further enhance environmental values or to meet state or Federal laws and/or regulations, a variance can be requested from the standard vegetation guidelines set forth in this ETL.

The ARCF GRR has identified significant and extensive seepage, stability, overtopping, and erosion problems with the levees that increase the risk of flooding for the Sacramento area. Due to the potential for catastrophic consequences associated with a levee failure in this urban area, all identified problems, including vegetation and encroachments, require correction in order to reduce the flood risk to an acceptable level. However, risk reduction measures must be implemented in a "worst first" manner in order to immediately maximize the amount of risk reduction for each increment of investment. The engineering analysis conducted to date generally indicates that seepage and erosion concerns pose a significantly higher risk of levee failure than those associated with vegetation and encroachments. However, specific instances of vegetation and encroachment problems have been identified as high risk and require resolution concurrent with other high risk issues.

In the case of construction associated with the recommended plan, vegetation and encroachment removal is secondary to the primary flood risk management measures (i.e. seepage cutoff barrier, levee raise, slope flattening). In an effort to modernize the levee system to meet current engineering standards, vegetation and encroachment issues (including landside levee access) in the study area will be resolved through a combination of construction actions associated with implementation of the recommended plan and formal agreements. The formal agreements involve the integrated use of a SWIF agreement with the local maintaining agency (LMA) and a variance from vegetation standards in ETL 1110-2-583, Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures.

System Wide Improvement Framework

The SWIF is an agreement between the Corps and the non-Federal sponsor that allows the LMA to defer compliance with ETL 1110-2-583. Under the SWIF agreement, the LMA would address landside vegetation and encroachment issues (including landside levee access) through the implementation of their standard operation and maintenance (O&M) actions over time. Therefore, vegetation not impacted by project construction would be addressed by the LMA in accordance with the State's Levee Vegetation Management Strategy in the Central Valley Flood Protection Plan (CVFPP) over the next 20 to 40 years. The SWIF will be planned and implemented by the non-Federal sponsor and includes the following criteria:

- An engineering inspection and evaluation shall be conducted to identify trees and other woody vegetation (alive or dead) on the levee and within 15 feet of the levee toe that pose an unacceptable threat to the integrity of the levee. Identified trees shall be removed and associated root balls and roots shall be appropriately remediated. Based on the engineering inspection and evaluation, trees and other woody vegetation that do not pose an unacceptable threat need not be removed.

- In cases of levee repair or improvement projects, vegetation within the project footprint shall be removed as part of construction activities.
- Trees and other woody vegetation that are not removed must be monitored as part of routine levee maintenance to identify changed conditions that cause any of these remaining trees and other woody vegetation to pose an unacceptable threat to levee integrity. Otherwise, such trees and woody vegetation are to be maintained according to the levee vegetation management criteria included in the CVFPP which establish a vegetation management zone (including the landside levee slope, crown and upper 1/3 of the waterside slope) in which trees are trimmed up to 5 feet above the ground (12-foot clearance above the crown road) and thinned for visibility and access while brush, trees and other woody vegetation less than four inches in diameter at breast height, weeds or other such vegetation over 12 inches high are to be removed in an authorized manner.

Vegetation Variance

A vegetation variance would be sought during the preconstruction engineering and design phase before construction to allow vegetation to remain on the lower 2/3 of the waterside slope and out 15 feet from the waterside toe. If granted, the variance would allow for vegetation to remain in these areas. To show that the safety, structural integrity, and functionality of the levee would be retained with a variance, an evaluation of underseepage and waterside embankment slope stability was completed by Corps geotechnical engineers.

This evaluation was completed for the section/index point at levee mile (LM) 5.92 on the Sacramento River. This index point was chosen for the variance analyses because it was considered to be representative of the most critical channel and levee geometry, underseepage and slope stability conditions, and vegetation conditions. The cross-section geometry of the index point incorporated tree fall and scour by using maximum potential diameter at breast height (dbh) of cottonwoods (12.0 feet) projected horizontally at a depth of 11.0 feet below the existing ground profile. The results show that the tree fall and scour did not significantly affect levee performance and that the levee meets Corps seepage and slope stability criteria considering the seepage and stability improvement measures are in place (“with project” conditions). Therefore, it is a reasonable conclusion that by allowing vegetation to remain as stated above, the safety, structural integrity, and functionality of the Sacramento River levee would be retained.

The vegetation variance request would be developed during the design phase to allow for vegetation to remain on the lower portion of the waterside levee slope (Figures 8 and 9). Vegetation on the upper waterside levee slope would be removed as part of project construction. If a variance is not approved, the recommendations for this portion of the project will be reformulated and further environmental compliance efforts would be required.

Construction of Alternative 2 is proposed to take approximately 13 years. The construction reaches have been prioritized based on a variety of factors, including the condition of the levee, the potential damages that would occur due to levee failure, and construction feasibility considerations, such as the availability of equipment at any given time. The tentative schedule of construction is shown in Table 5. The project reaches are shown in Figure 2 below.

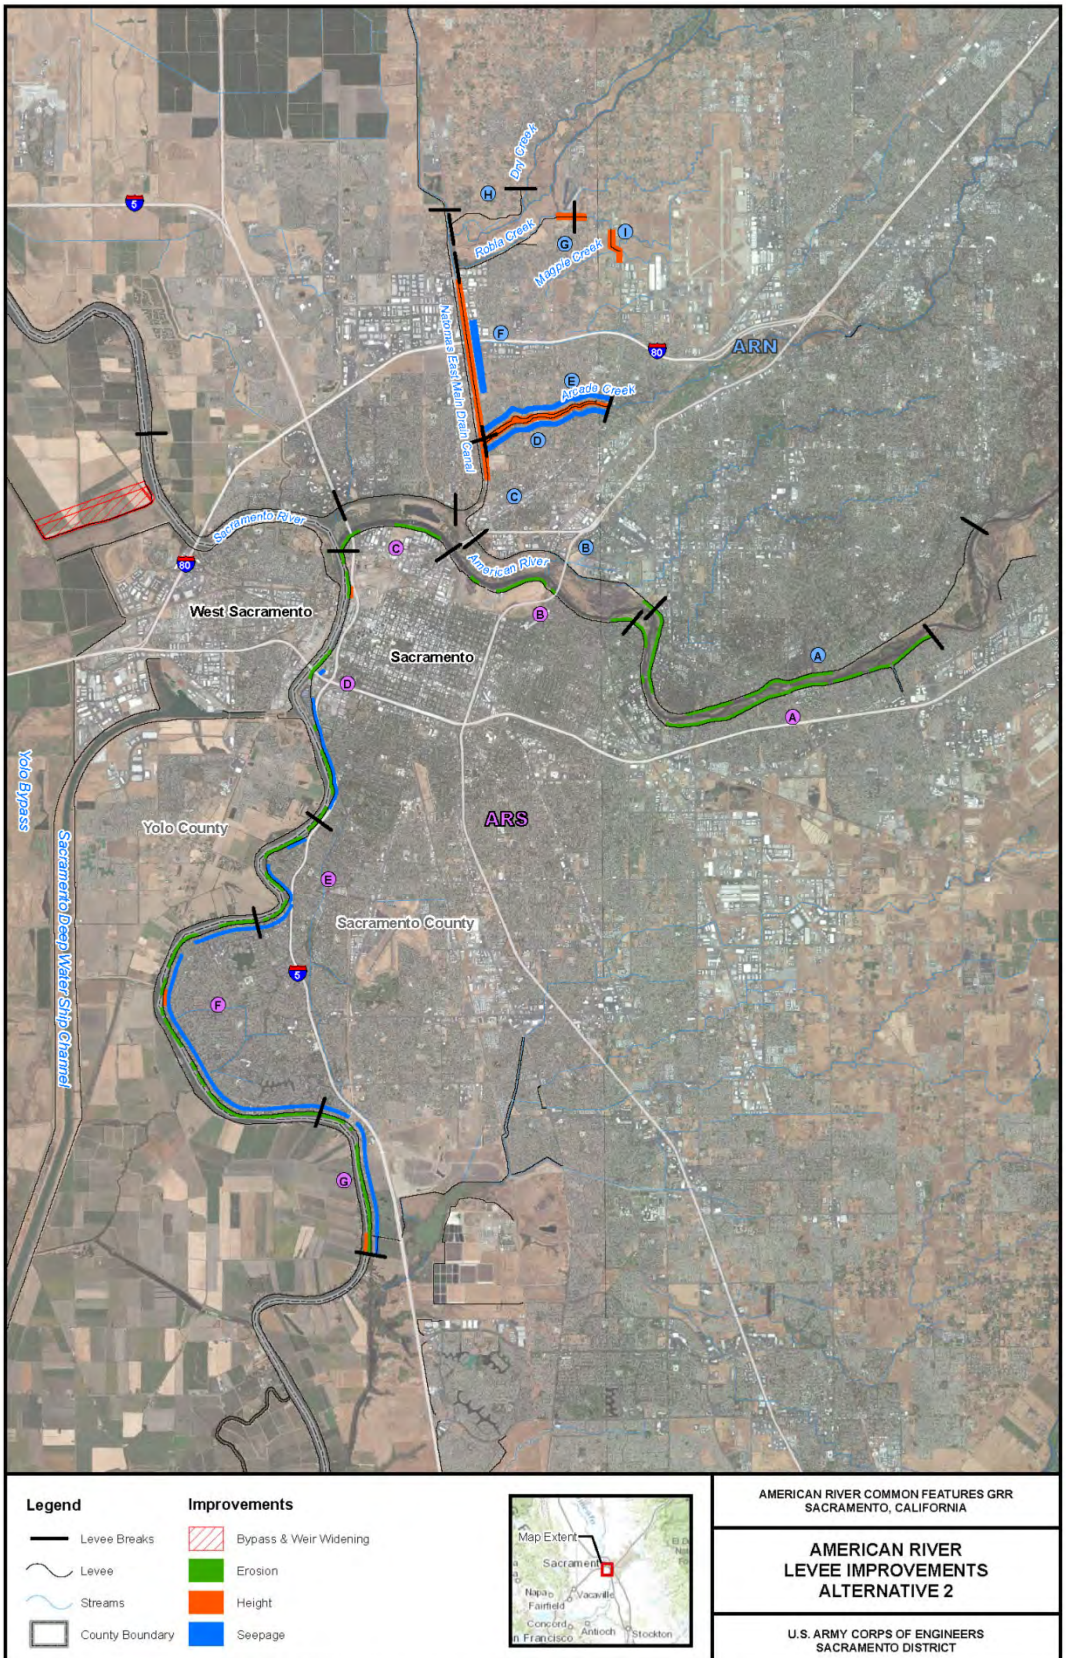

Figure 2. Individual Reach Identification in the ARCF Study Area.

Table 5. Tentative Construction Schedule for Alternative 2.

PRIORITY	WATERWAY	REACH[1]	YEAR OF PROJECT CONSTRUCTION

2.2.2 Borrow Sites, Haul Routes, and Staging Areas

Borrow Sites

It is estimated that a maximum of 1 million cubic yards (cy) of borrow material could be needed to construct the project. Because this project is in the preliminary stages of design, detailed studies of the borrow needs have not been completed. Actual volumes exported from any single borrow site would be adjusted to match demands for fill. Borrow sites would be selected that do not cause an impact to endangered species or their habitat and therefore, consultation for borrow sites is not required.

To identify potential locations for borrow material, soil maps and land use maps were obtained for a 20-mile radius surrounding the project area. These potential borrow locations are shown on Figure 3. Borrow sites would be lands that are the least environmentally damaging and would be obtained from willing sellers. The criteria used to determine potential locations were based on current land use patterns and soil types from the Natural Resources Conservation Service (NRCS). The data from land use maps and NRCS has not been field verified, therefore, to ensure that sufficient borrow material would be available for construction the Corps looked at all locations within the 20 miles radius for 20 times the needed material. This would allow for sites that do not meet specifications or are not available for extraction of material.

The excavation limits on the borrow sites would provide a minimum buffer of 50 feet from the edge of the borrow site boundary. From this setback, the slope from existing grade down to the bottom of the excavation would be no steeper than 3H:1V. Excavation depths from the borrow sites would be determined based on available suitable material. The borrow sites would be stripped of top material and excavated to appropriate depths. Once material is extracted, borrow sites would be returned to their existing use whenever possible, or these lands could be used to mitigate for project impacts, if appropriate.

Clean rock would be commercially acquired in order to construct the American and Sacramento River bank protection sites. For the Sacramento River, it is assumed that the rock would be acquired from a commercial source in the Bay Area and barged up the Sacramento River to the construction sites. Rock for the American River sites would be acquired from a commercial source within a 50-mile radius and would be hauled in trucks to the construction sites.

Haul routes would be determined during the design phase and would be dependant on what borrow sites and staging areas are selected for project construction. To the maximum extent feasible, haul routes would be selected based on existing commercial haul routes and levee roads and would avoid impacts to Federally listed species.

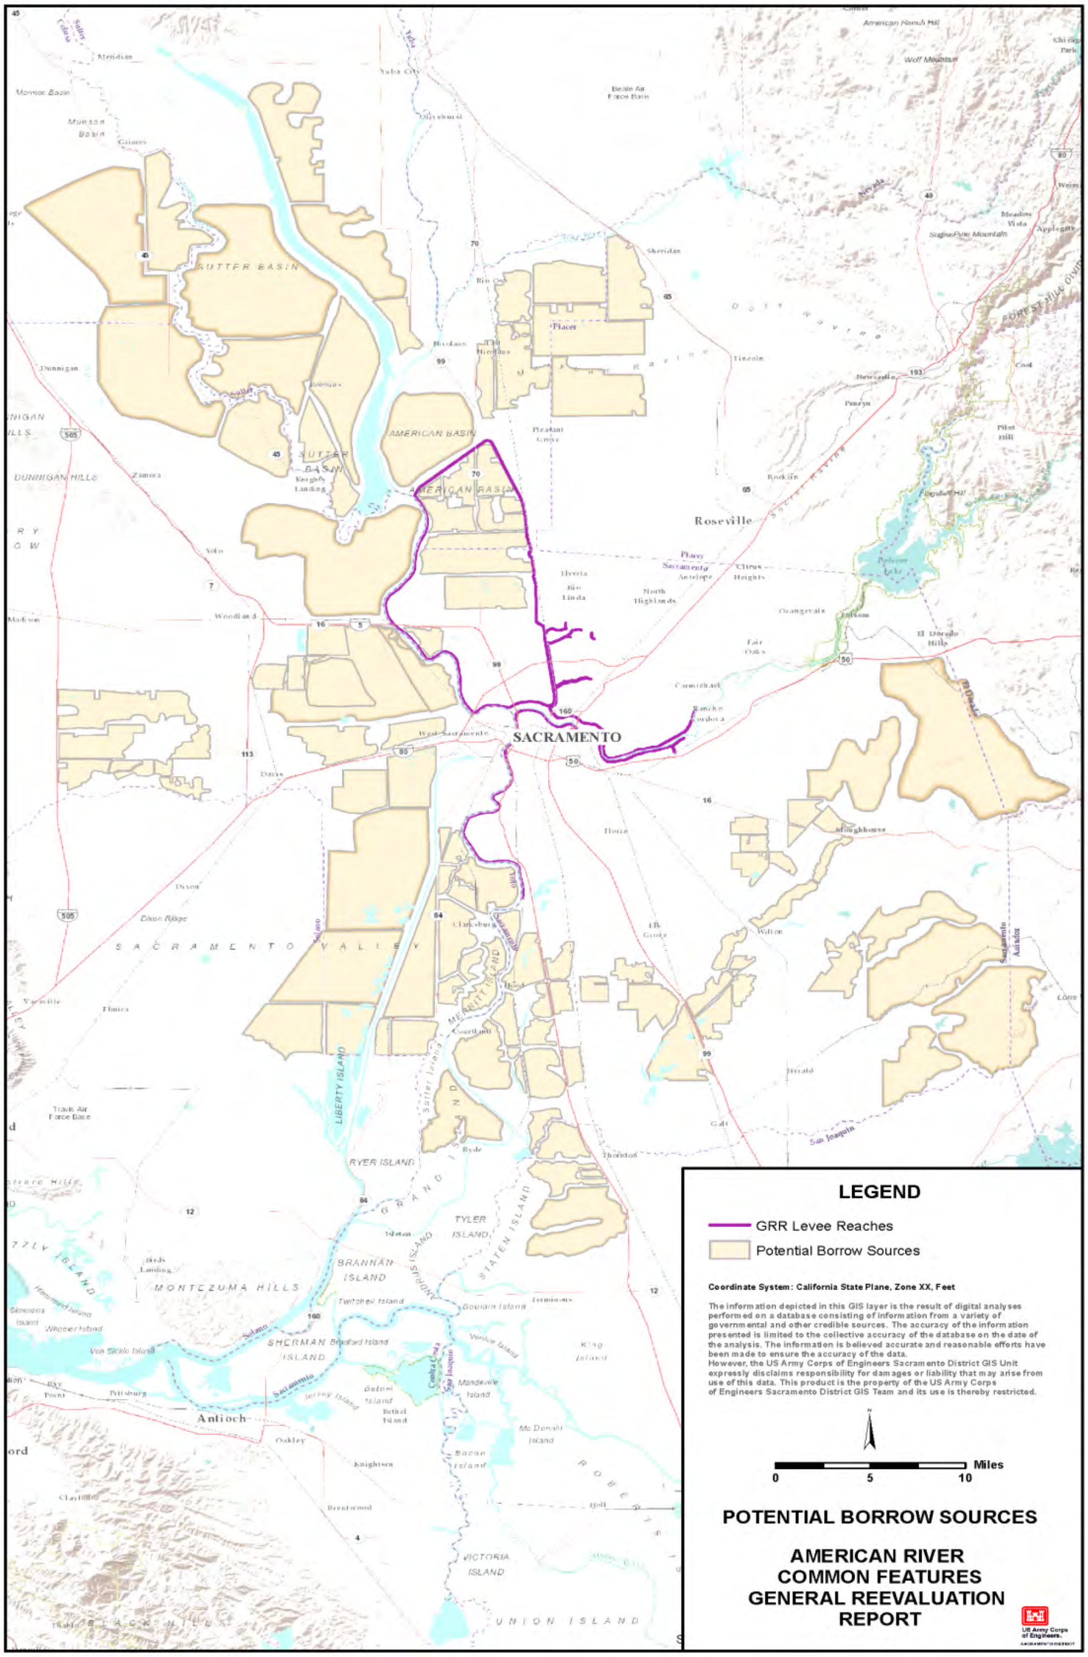

Figure 3. Potential Borrow Sites within 20-miles of Study Area.

SAFCA has selected a borrow site to provide suitable material for the NSS Levee Improvements based on proximity to the project area. The preferred borrow source, Borrow Site 2/Site 2K is shown in Figure 4. Approximately 27,000 cy of material will be excavated from the 5.5-acre borrow site in order to construct the levee improvements. Borrow Site 2 would be returned to pre-project conditions following construction activities.

SAFCA's goal in selecting haul routes is to use existing levee crowns for hauling wherever possible (Figure 5). However, there are locations where hauling on paved public roads is the best available option because the levee crown is already paved for public use or because there is inadequate room on the waterside of the levee to develop a temporary toe road without affecting standing water or low flow channels. Final haul routes would be selected based on constraints, the construction schedule, and in coordination with the City.

Borrow Site 2 is in close proximity to the NEMDC levee and East Levee Road located on the levee crown. From these two sites, haul trucks would use East Levee Road from the borrow site down to a point just north of the existing Del Paso/Main Avenue Bridge over NEMDC. At this point, haul trucks would divert off the road, down the levee slope, and pass under the bridge on an existing road. Just downstream of the Del Paso/Main Avenue Bridge, a short span temporary bridge would cross a narrow section of the low flow NEMDC channel. A temporary culvert crossing of the low flow channel is also possible. From the temporary bridge (or culvert) crossing, the haul trucks would proceed up a new sloping ramp constructed on the waterside of the NEMDC east levee to the levee crown. Trucks would then continue down the levee crown to the Arcade Creek north levee. At the Arcade Creek north levee, trucks would cross the existing Union Pacific Railroad (UPRR) tracks at the existing at-grade crossing and proceed along the north levee crown to the improvement sites.

To access the Arcade Creek south levee and the work proposed on the NEMDC east levee, haul trucks would continue south following an access ramp down the levee slope to Arcade Creek. At the creek, a short temporary bridge would be constructed to cross the low flow channel. A temporary culvert crossing of the low flow channel is also possible. From the temporary bridge (or culvert) crossing, the haul trucks would proceed up a new sloping ramp constructed on the waterside of the NEMDC east levee to the levee crown in the vicinity of the existing railroad at-grade crossing near the existing City of Sacramento Pump Station. Trucks would then proceed up the Arcade Creek south levee crown, or south to the improvement sites on the NEMDC east levee south of Arcade Creek.

Figure 4. North Sacramento Streams Borrow Site 2/Site 2K.

Figure 5. North Sacramento Streams Haul Routes.

Along the proposed haul routes, there are many opportunities to make use of existing undeveloped toe roads or develop new toe roads without affecting channel areas to facilitate truck passage and to avoid active work sites. Several temporary bridge crossings of the low-flow channel may also be needed to connect the north and south side levee waterside toe roads on Arcade Creek to facilitate movement of material and equipment around active work areas. Railroad car undercarriages on temporary abutment supports would be one option for temporary bridge crossings. Spans of up to 85 feet are possible. Locations for toe roads, ramps on levee slopes, and temporary bridge crossings would be finalized as part of final project design. Gravel on levee crowns along haul routes would be maintained as needed during periods of hauling, including watering for dust control and periodic grading to control rutting.

Storm Water Pollution Prevention Plan (SWPPP) requirements would apply to haul routes during construction. Following construction, temporary ramps would be removed, temporary bridges and abutments would be removed, and all disturbed areas would be revegetated.

Staging Areas

While staging areas have not been identified at this point in the planning phase, sites will be selected that do not require the removal of large vegetation or habitat that is valuable for endangered species. Staging areas would be selected that do not cause an impact to federally listed species or their habitat and therefore, this BA does not address staging areas and consultation for staging areas is not anticipated. Prior to construction, any staging areas would be cleared, grubbed, and stripped.

For SAFCA's NSS project, four potential staging areas have been identified for potential use to support construction (Figure 6). Several of these areas have been used previously to support levee improvements along Arcade Creek. The areas would require little preparation other than surface stripping, and temporary connection roads and ramps to the levee crown. The primary use for the staging areas would be for temporary trailers, parking, and material staging and for stockpiling and blending of excavated soils with imported borrow to make the excavated soils suitable for use in levee reconstruction. This would involve stockpiles of material to be processed, a processing area where excavated soils and imported soils would be spread out and processed to mix and moisture condition the material, and stockpiles of processed material. Importing, processing, and exporting material for levee reconstruction would all be continuous activities once the work flow is established during the start of the construction season. Other disturbed areas would be also be stabilized. Staging areas would be returned to pre-project conditions following construction activities unless the owner agrees to some grade raising to help dispose of excess construction soils.

Figure 6. North Sacramento Streams Staging Areas.

The following sections contain more detailed information on the specific measures proposed under this alternative for the American River North and South study areas.

2.2.3 American River

Levees along the American River under Alternative 2 require improvements to address erosion. The proposed measures for these levees consist of waterside armoring to prevent erosion to the river bank and levee, which could potentially undermine the levee foundation. There are two measures proposed for the American River levees: (1) a maximum of 31,000 linear feet (LF) of bank protection, and (2) a maximum of 65 acres/45,000 LF of launchable rock trench. Both of these measures are described in detail in the subsections below. These numbers are maximized because there is some overlap identified to account for the uncertainty of site-specific conditions. For example, for some reaches both bank protection and launchable rock trench impacts were estimated even though both measures would not be constructed in the same reach. Figure 7 shows the erosion protection locations on the American River.

Bank Protection

The Corps conducts ongoing erosion repairs to sites on the Sacramento River levees under the Sacramento River Bank Protection Project (SRBPP). As part of the SRBPP NMFS Biological Opinions, the Corps is required to conduct post-construction monitoring in order to evaluate the relative success of on-site habitat features that are incorporated into the repairs. Under the SRBPP, bank protection designs have been constantly evolving, as the results of the monitoring help inform engineers to adapt the designs to optimize for site-specific conditions in meeting the objective of the habitat features. The Corps will use the best available information and SRBPP design templates as a basis for designing site-specific bank protection repairs for this project. As a result, the bank protection measure described below is a basic example of a typically designed bank protection site.

This measure consists of placing rock revetment on the river's bank to prevent erosion. This measure entails installing revetment along the stream bank based on site-specific analysis (Figure 7). When necessary, the eroded portion of the bank would be filled and compacted prior to the rock placement. The sites would be prepared by clearing and stripping of loose material and understory growth prior to construction. In most cases large vegetation would be permitted to remain at these sites. Temporary access ramps would be constructed, if needed, using imported borrow material that would be trucked on site.

The placement of rock onto the bank will occur from a land based staging area using long reach excavators and loader. The loader brings the rock from a permitted source and stockpiles it near the levee in the construction area. The excavator then moves the rock from the stockpile to the water side of the levee.

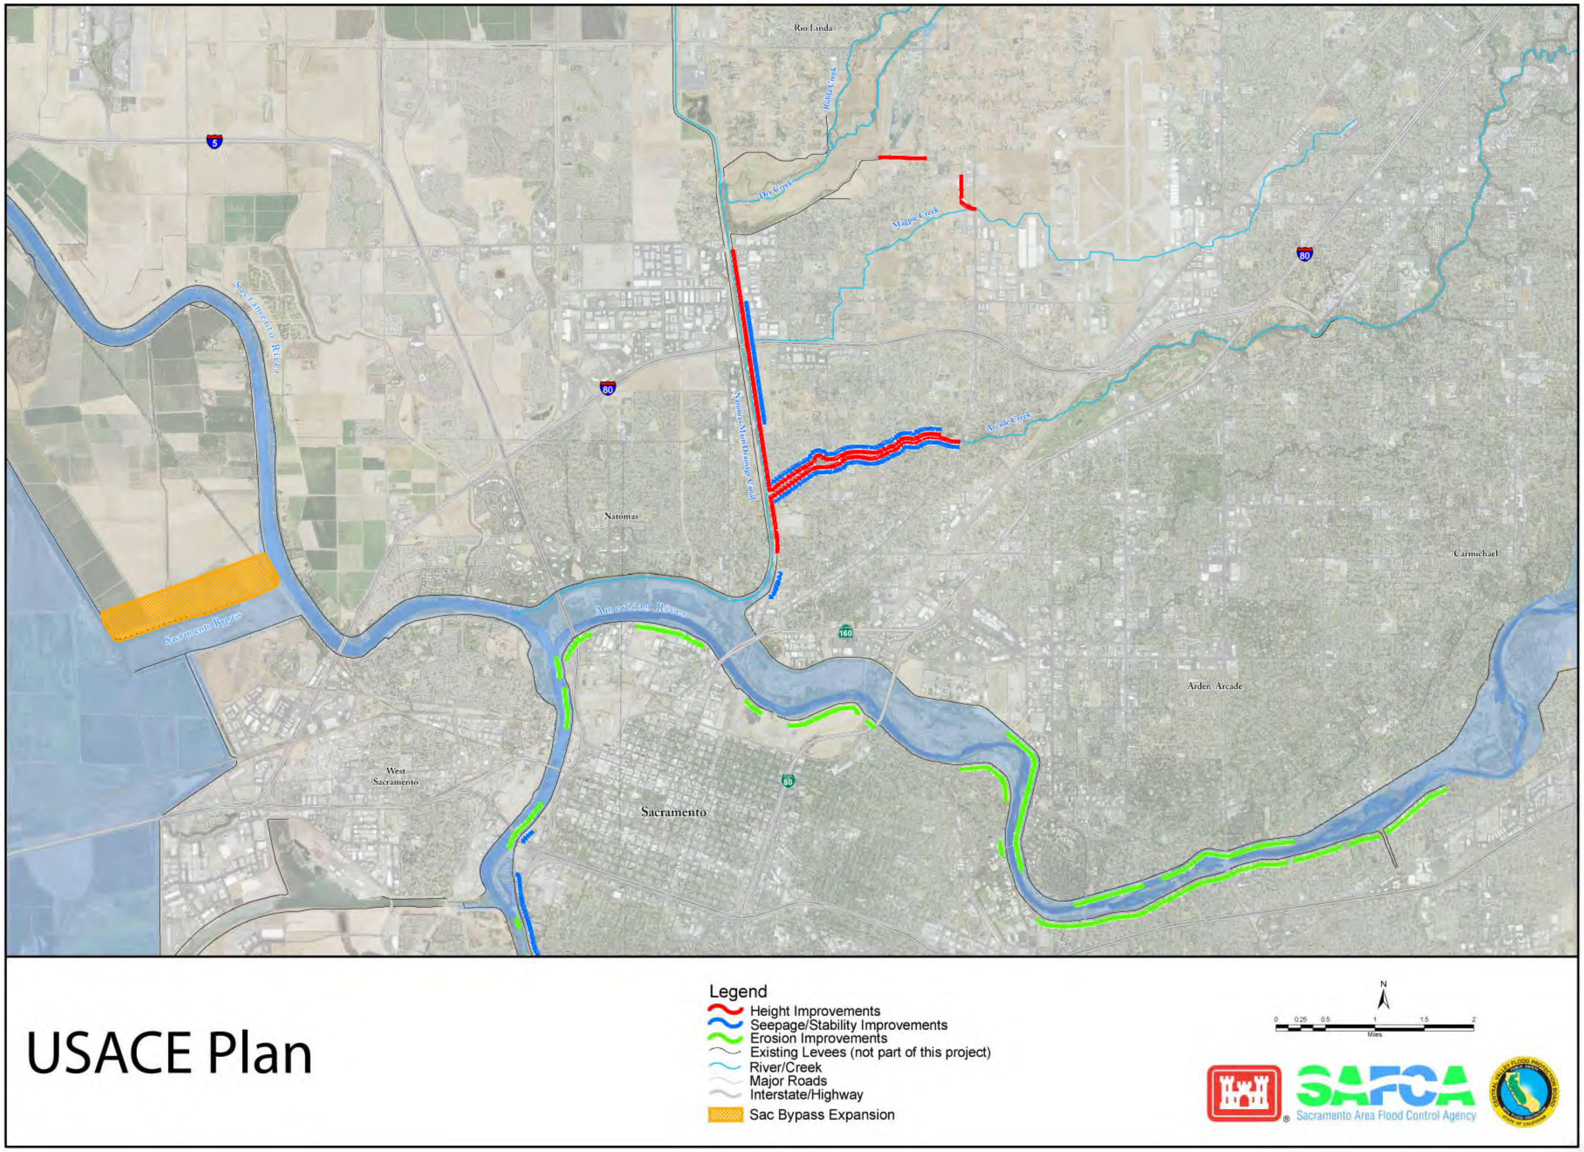

Figure 7. American River and East Side Tributaries Proposed Measures.

The revetment would be placed on the existing bank at a slope varying from 2V:1H to 3V:1H depending on site specific conditions. After revetment placement has been completed, a planting berm would be constructed in the rock to allow for revegetation of the site. The planting berm varies in width from 5 to 15 feet (Figure 8). In all cases the planting will occur outside the vegetation free zone as required by the ETL.

Riparian vegetation installed on the planting berm would include large woody species such as Fremont cottonwood (*Populus fremontii*), California sycamore (*Platanus racemosa*), and valley oak (*Quercus lobata*), white alder (*Alnus rhombifolia*), and box elder (*Acer negundo var. californicum*); shrub-scrub species such as elderberry (*Sambucus* spp.), redbud (*Cercis Canadensis*), and coyote brush (*Baccharis pilularis*); and understory species such as California rose (*Rosa californica*), California blackberry (*Rubus ursinus*), and wild grape (*Vitus californica*); and native grasses such as annual fescue (*Vulpia* spp.), California brome (*Bromus carinatus*), blue wildrye (*Elymus glaucus*), and needle grass (*Nassella* spp.).

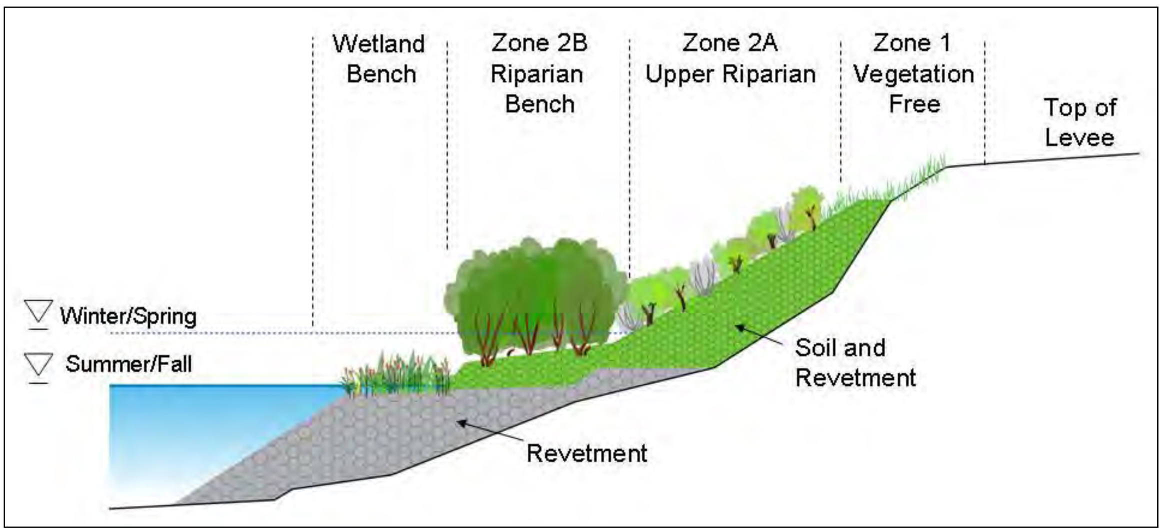

Figure 8. Planting Berms with Vegetation and Wetland Bench.

<u>Launchable Rock Trench</u>

This measure includes construction of a launchable rock filled trench, designed to deploy once erosion has removed the bank material beneath it (Figure 9). All launchable rock trenches would be constructed outside of the natural river channel. The vegetation would be removed from the footprint of the trench and the levee slope prior to excavation of the trench. The trench configuration would include a 2:1 landslide slope and 1:1 waterside slope and would be excavated at the toe of the existing levee. All soil removed during trench excavation would be stockpiled for potential reuse. The bottom of the trench would be constructed close to the summer mean water surface elevation in order to reduce the rock launching distance and amount of rock required.

After excavation, the trench would be filled with revetment that would be imported from an offsite location. After rock placement the trench would be covered with a minimum of 3 feet of the stockpiled soil for a planting berm. Rock placed on the levee slope would be covered with 2 feet of stockpiled soil. All disturbed areas would be reseeded with native grasses and small shrubs where appropriate. Trees and shrubs could be permitted on the berm if planted outside the specified vegetation free zone as required by the ETL. This alternative would not increase flows in the American River that would cause additional erosion along the banks. If flow changes occur that could cause loss of floodplain between the levee and the existing natural channel (the Parkway land) it will be addressed under the Folsom Reoperation Biological Assessment and EIS/EIR if applicable.

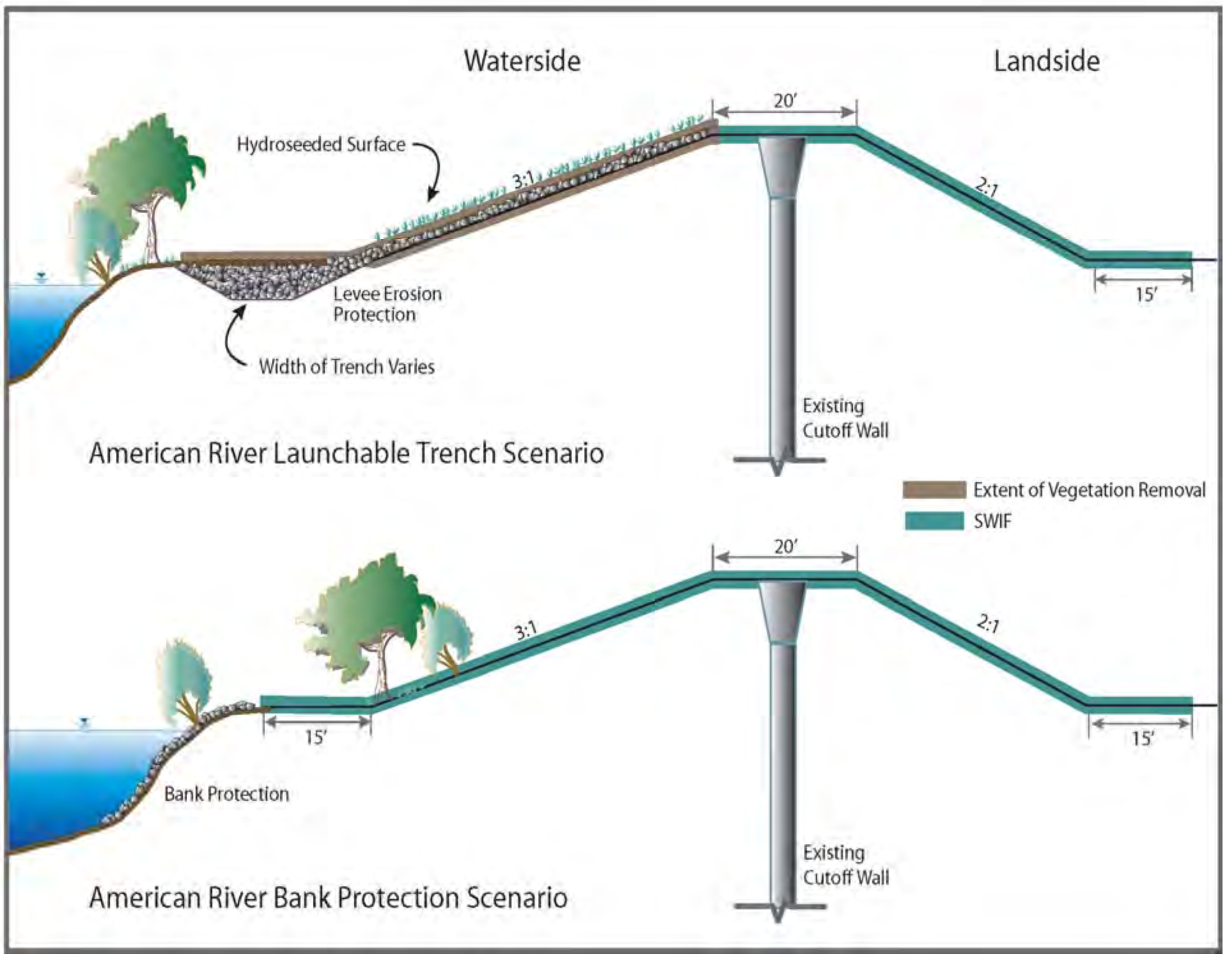

Figure 9. Erosion Protection – Launchable Rock Trench and Bank Protection Scenarios.

2.2.4 Sacramento River

Levees along the Sacramento River require improvements to address seepage, stability, and erosion. Approximately 50,300 LF of bank protection and cutoff wall or slope stability work is proposed for the Sacramento River. In addition, these levees require a total of one mile of intermittent height improvements in order to convey additional flows that exceed current design levels. Figure 10 shows the proposed measures for the Sacramento River.

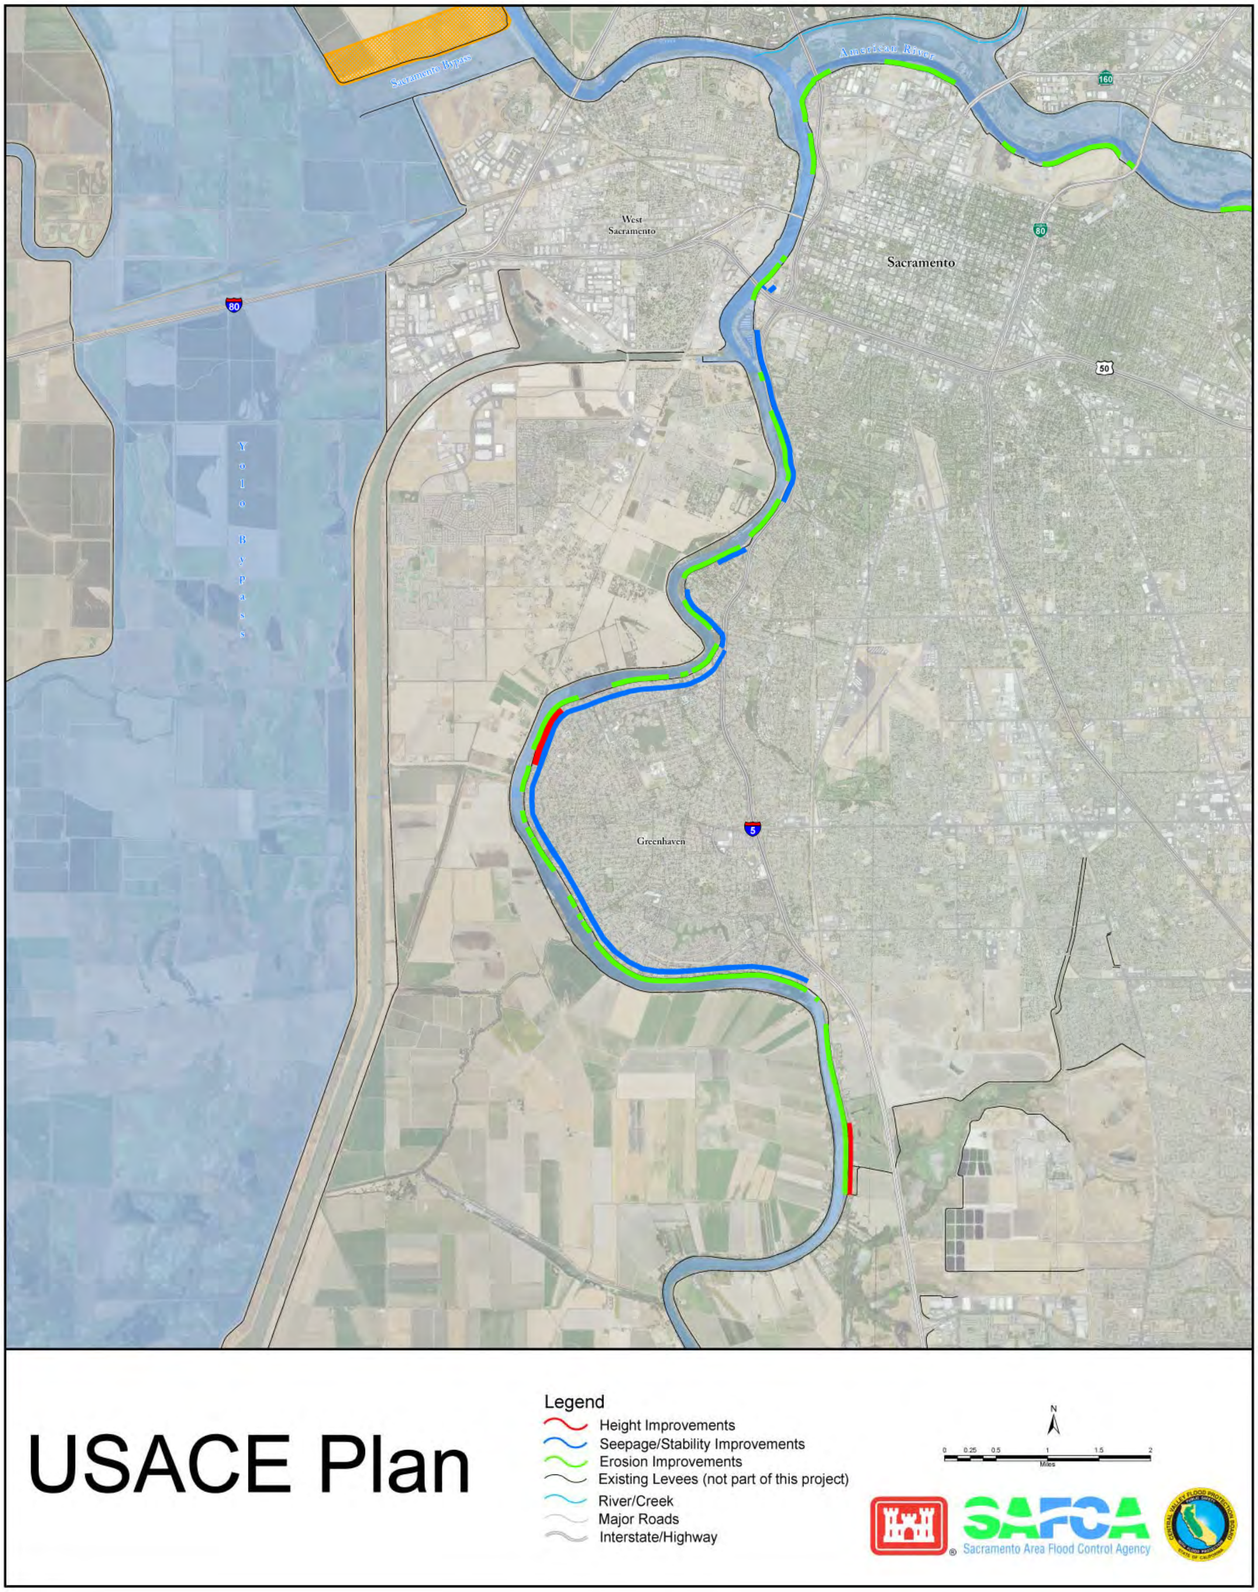

Figure 10. Sacramento River Proposed Measures.

Where the existing levee does not meet the levee design requirements, as discussed in Section 2.2 above, slope flattening, crown widening, and/or a minimal amount of levee raise is required. This improvement measure addresses problems with slope stability, geometry, height and levee crest access and maintenance. To begin levee embankment grading, loose material and vegetation understory would be cleared, grubbed, stripped, and, where necessary, portions of the existing embankment would be excavated to allow for bench cuts and keyways to tie in additional embankment fill. Excavated and borrow material (from nearby borrow sites) would be stockpiled at staging areas. Haul trucks and front end loaders would bring borrow materials to the site, which would then be spread evenly and compacted according to levee design plans.

The levee would be raised approximately 1 to 3 feet which would result in the levee footprint extending out a maximum of 5 feet on the landside from the existing levee. The levee crown patrol road would be re-established at the completion of construction. A typical design for these levees is shown in Figure 11 below.

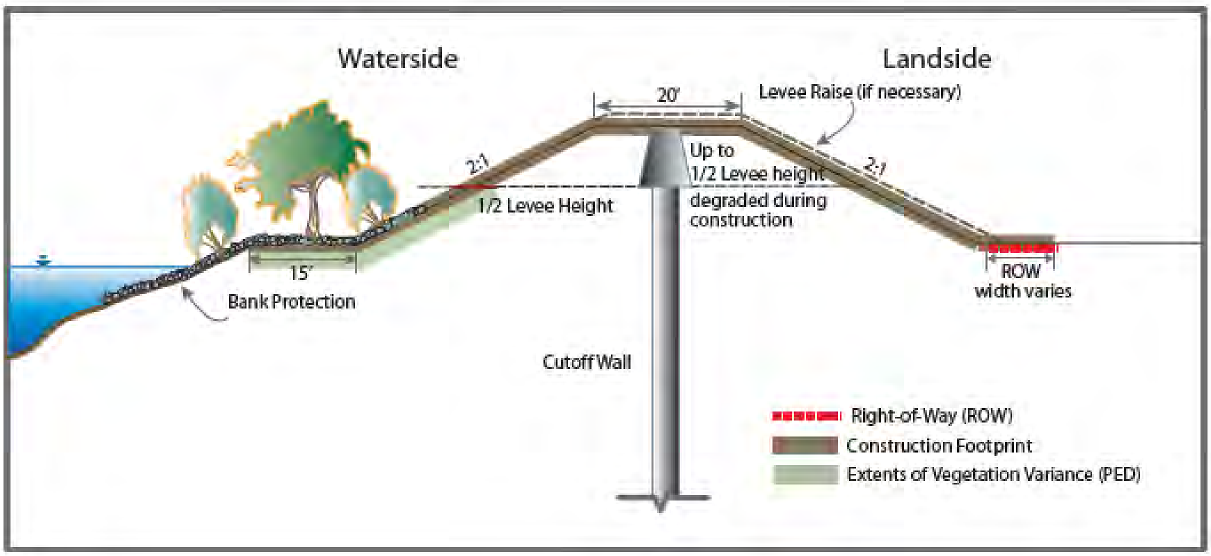

Figure 11. Fix-In-Place with Cutoff Wall and Levee Raise.

__Cutoff Walls__

To address seepage concerns, a cutoff wall will be constructed through the levee crown (Figure 9). The cutoff wall would be installed by one of two methods: (1) conventional open trench cutoff walls, or (2) deep soil mixing (DSM) cutoff walls. The method of cutoff wall selected for each reach would depend on the depth of the cutoff wall needed to address the seepage. The open trench method can be used to install a cutoff wall to a depth of approximately 85 feet. For cutoff walls of greater depth the DSM method would be utilized.

Prior to construction of either method of cutoff wall, the construction site and any staging areas would be cleared, grubbed, and stripped. The levee crown would be degraded up to half the levee height to create a large enough working platform (approximately 30 feet) and to reduce the risk of hydraulically fracturing the levee embankment from the insertion of slurry fluids. This method of slurry wall installation will also reduce the risk of slurry mixture following seepage paths and leaking into the river or into landside properties.

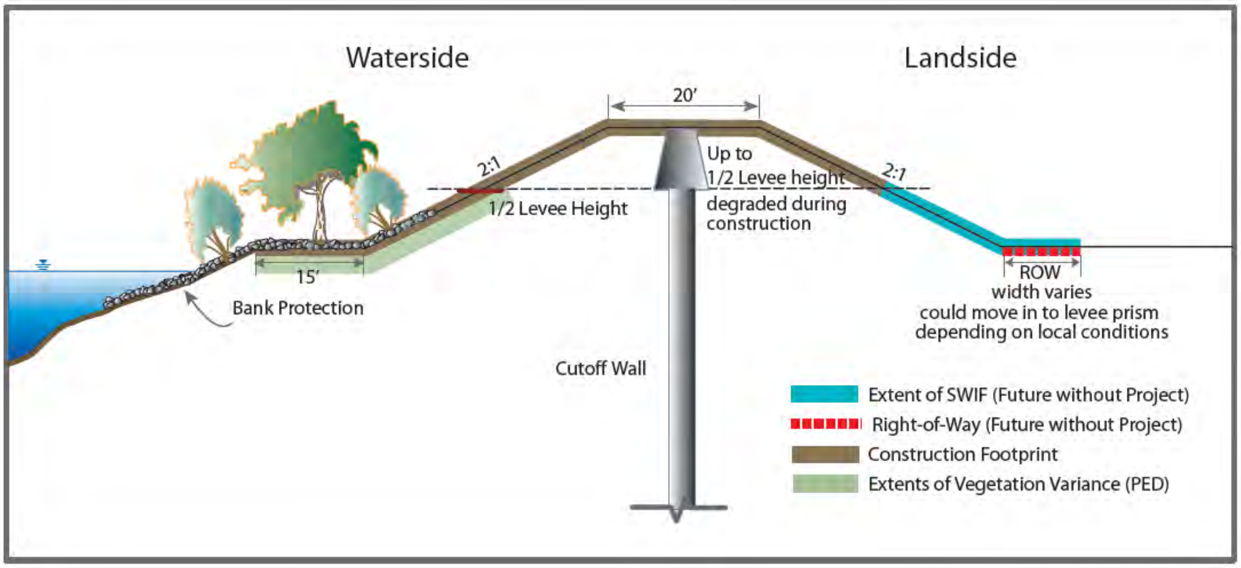

Figure 12. Fix-In-Place with Cutoff Wall and No Levee Raise.

Open Trench Cutoff Wall

Under the open trench method, a trench approximately 3 feet wide would be excavated at the top of levee centerline and into the subsurface materials up to 85 feet deep with a long boom excavator. As the trench is excavated, it is filled with low density temporary bentonite water slurry to prevent cave in. The soil from the excavated trench is mixed nearby with hydrated bentonite, and in some applications cement. The soil bentonite mixture is backfilled into the trench, displacing the temporary slurry. Once the slurry has hardened, it would be capped and the levee embankment would be reconstructed with impervious or semi-impervious soil.

DSM Cutoff Wall

The DSM method involves a crane supported set of two to four mixing augers used to drill through the levee crown and subsurface to a maximum depth of approximately 140 feet. As the augers are inserted and withdrawn, a cement bentonite grout would be injected through the augers and mixed with the native soils. An overlapping series of mixed columns would be drilled to create a continuous seepage cutoff barrier. A degrade of up to one half the levee height would be required for construction of the DSM wall. For both methods, once the slurry has hardened it would be capped and the levee embankment would be reconstructed with impervious or semi-impervious soil.

Bank Protection

Bank protection on the Sacramento River would be addressed via either the launchable rock trench method described for the American River in Section 2.2.1 above, or by standard bank protection with planting berm (Figure 9). The standard bank protection measure for the Sacramento River consists of placing rock protection on the bank to prevent erosion. This measure entails filling the eroded portion of the bank, where necessary, and installing revetment along the waterside levee slope and streambank from streambed to a height determined by site-specific analysis. Large trees on the lower 1/2 slope will be protected in place to retain SRA habitat. The sites would be prepared by removing vegetation along the levee slopes at either end of the site for construction of a temporary access ramp, if needed. The ramp would then be constructed using imported borrow material that would be trucked on site.

The placement of rock onto the levee slope would occur from atop the levee and/or from the water side by means of barges. Rock required within the channel, both below and slightly above the water line at the time of placement, would be placed by an excavator located on a barge. Construction would require two barges: one barge would carry the excavator, while the other barge would hold the stockpile of rock to be placed on the channel slopes. Rock required on the upper portions of the slopes would be placed by an excavator located on top of the levee. Rock placement from atop the levee would require one excavator and one loader for each potential placement site. The loader brings the rock from a permitted source and stockpiles it near the levee in the construction area. The excavator then moves the rock from the stockpile to the water side of the levee.

The revetment would be placed via the methods discussed above on existing bank at a slope varying from 2V:1H to 3V:1H depending on site specific conditions. After revetment placement has been completed, a small planting berm would be constructed in the rock to allow for revegetation of the site (Figure 13).

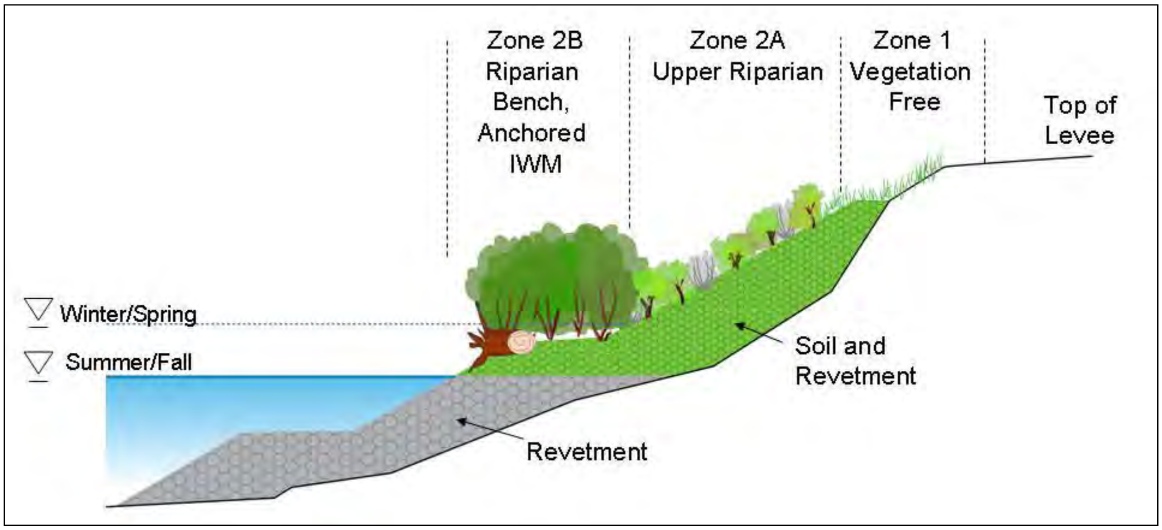

Figure 13. Planting Berm with Vegetation and Woody Material.

2.2.5 East Side Tributaries

The East Site Tributaries include measures proposed for the Natomas East Main Drain Canal (NEMDC), Arcade Creek, Dry/Robla Creek, and Magpie Creek. Arcade Creek and portions of NEMDC are included in the North Sacramento Stream Project, SAFCA's early implementation action on the ARCF GRR. The proposed measures for the East Side Tributaries under the ARCF GRR are shown on Figure 7 above.

Natomas East Main Drain Canal (NEMDC)

The east levee of the NEMDC requires 6,000 LF of improvements to address seepage and stability at locations where historic creeks had intersected the current levee alignment. A conventional open trench centerline cutoff wall would be constructed at these locations to address the seepage and stability problems (Figure 14). The open trench cutoff walls would be constructed as described for the Sacramento River levee in Section 2.2.2 above.

In addition, SAFCA is proposing to address seepage and stability in advance of the Federal project on a 1,700 foot reach of the NEMDC from Station 3028+00 to Station 3051+00, just south of the Arcade Creek south levee. For this reach, SAFCA proposes to construct a cement bentonite (CB) slurry cutoff wall at the waterside toe of the levee. This measure is described in greater detail in the Arcade Creek discussion below.

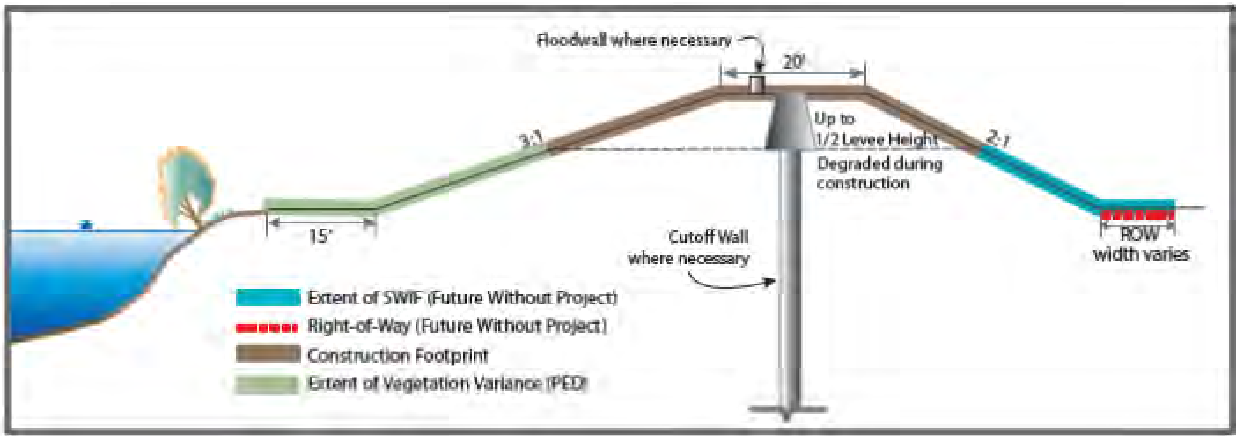

Figure 14. Conventional Open Trench Cutoff Wall or Floodwall Scenario.

Arcade Creek

The Arcade Creek levees require improvements to address seepage, slope stability, and overtopping when the event exceeds the current design. A centerline cutoff wall would be constructed to address seepage along 22,000 feet of the levee (Figure 12). There is a ditch adjacent to the north levee at the landside toe which provides a shortened seepage path, and could affect the stability of the levee. The ditch would be replaced with a conduit or box culvert and then backfilled. This would lengthen the seepage path and improve the stability of the levee (Figure 12). The majority of the Arcade Creek levees have existing floodwalls which vary in height from 1 to 4 feet, however there remains a height issue in this reach. A 1 to 4-foot floodwall raise would allow the levees to pass flood events greater than the current design level. The new floodwall or added height would result in a total floodwall height of approximately 4 to 6 feet. The floodwall would be placed at the waterside hinge point of the levee and would be designed to disturb a minimal amount of waterside slope and levee crown for construction (Figure 14). The waterside slope would be re-established to its existing slope and the levee crown would grade away from the wall and be surfaced with aggregate base.

SAFCA's NSS project is primarily focused on addressing seepage and slope stability concerns on Arcade Creek. Figure 15 below shows Arcade Creek in detail, broken down into Arcade Creek North (ACN) and Arcade Creek South (ACS) reaches. The NSS project includes centerline cutoff walls for most of the Arcade Creek levees (ACS A, ACS B, and ACN B). For the ACS C and ACN C reaches, stretching generally from Rio Linda Boulevard to Marysville Boulevard, SAFCA proposes to construct a CB slurry cutoff wall at the waterside toe of the levee, rather than a centerline cutoff wall. In addition, on the ACN C reach, SAFCA proposes to reconstruct the waterside slope from Station 5075+00 to Station 5100+00, and from Station 5100+00 to Marysville Boulevard, SAFCA proposes to construct a sheet pile cutoff wall at the centerline of the levee, rather than the waterside toe cutoff wall. For the ACN A reach, SAFCA proposes to install pressure relief wells along the landside toe of the levee. The waterside toe slurry cutoff walls and sheet pile walls are described in greater detail below.

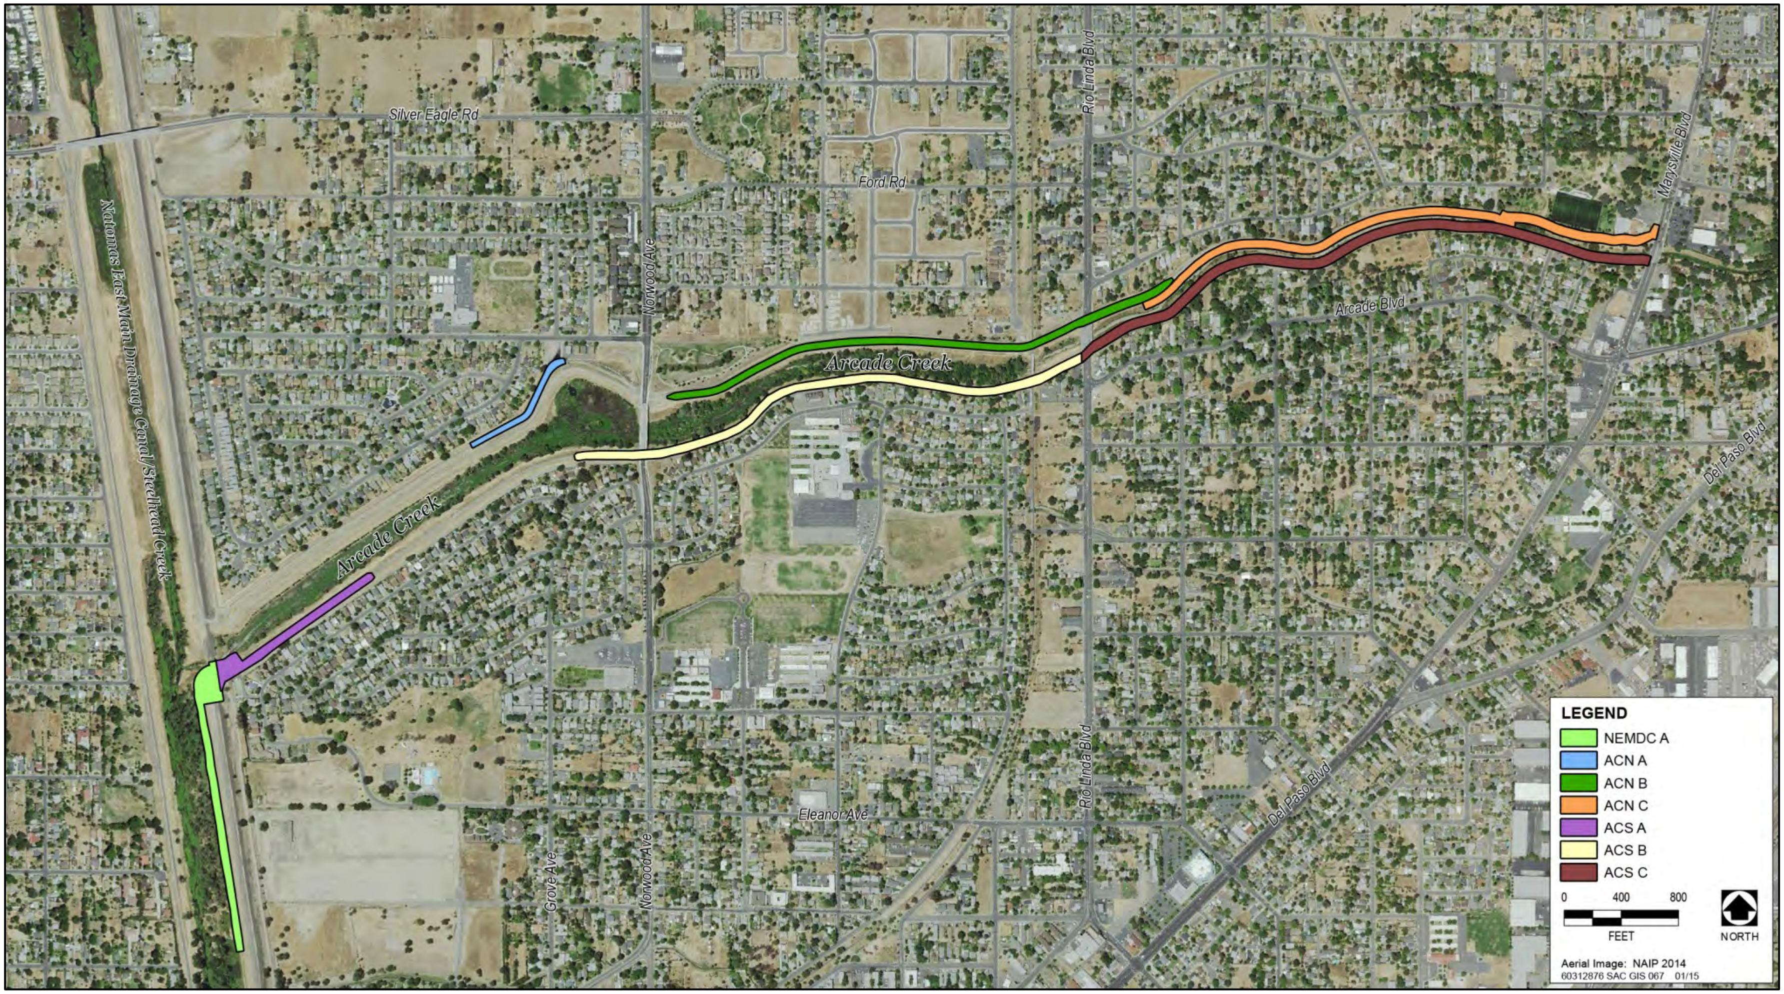

Figure 15. North Sacramento Streams Levee Improvement Project Area Reaches.

Toe Slurry Cutoff Wall Construction

Construction of the toe CB slurry cutoff walls to depths ranging from 15 to 30 feet along the existing waterside levee toe would be accomplished primarily with small- to medium-size excavators depending on required wall depth. This equipment and the associated sequence of excavation and placement of the centerline CB material into the trench, would require constructing a work bench along the toe. The bench elevation would be selected based on existing topography, required working room for cutoff wall installation, optimizing earthwork, and minimizing the need for bench elevation changes along the levee that could complicate slurry wall construction.

Excavations for the bench would extend deep enough below existing grade to remove organic material and soft, unsuitable foundation soils. Some dewatering and groundwater control is anticipated in connection with this excavation. Bench excavation would also extend into the existing waterside slope of the levee as needed to ensure that new selected bench fill material is integrated effectively with existing low permeability blanket material on the levee slope. This provides an integral seepage barrier with the cutoff wall over the full height of the levee. To the fullest extent possible, all excavated non-organic soil suitable for reuse would be processed and used for reconstruction to minimize off-hauling materials.

Some portions of ACN C reach, as described above, would require a more substantial excavation and reconstruction of the waterside slope to provide a low permeable seepage levee slope barrier, which may not currently exist. Here again, the bench fill material would be integrated with the slope reconstruction fill to provide an integral seepage barrier with the cutoff wall over the full height of the levee slope.

After the foundation has been excavated and accepted, properly moisture conditioned embankment materials would be placed in accordance with accepted levee construction standards and compacted to create the bench working surface for slurry wall construction. Each lift would be moisture-conditioned and compacted to the specified density using suitable tamping foot compactors.
After backfilling to the working surface for cutoff wall construction, the CB wall would be installed. For CB centerline wall construction, it is assumed that 50 percent of the material from the trench can be salvaged and processed with other excavated soil or borrow material for reuse in levee reconstruction. The remaining material from the trench excavation is assumed unsuitable for reuse and would be disposed of as described previously.

After installation of the cutoff wall, properly moisture-conditioned embankment materials would be placed to complete the bench construction to a minimum height of approximately 3 feet over the top of the cutoff wall and complete reconstruction of cuts on the waterside slope. Embankment material would be blended and processed material suitable for reuse. Each lift would be moisture-conditioned and compacted to the specified density using suitable tamping foot compactors.
After the bench is completed, the top and waterside slope would be covered with rip rap to control erosion over the completed cutoff wall. Above the bench, all disturbed construction areas would be revegetated. Gravel surfacing on the levee crown would be supplemented or replaced within the levee repair limits wherever damaged by haul vehicles and other construction-related traffic.

Sheet Pile Cutoff Walls

Sheet pile cutoff walls are installed with a crane and hydraulic ram that hammers or pushes the sheet pile into the ground to the desired depth. In levee reach ACN C near Marysville Boulevard where the wall would be located along the approximate existing levee crown centerline, the asphalt concrete surfacing would be removed prior to sheet pile placement. No levee degradation is needed except to develop an access platform for the crane of sufficient width. A 3-foot-wide by 3-foot-deep trench would be excavated along the sheet pile alignment. The sheet piling would be driven in the trench. The trench would then be backfilled with suitable levee fill materials placed on both sides and over the top of the completed wall. After backfilling the trench the existing asphalt-concrete pavement would be reconstructed.

Dry and Robla Creeks

The Dry and Robla Creeks levees require improvements to address overtopping for when flood events exceed the design level. Height improvements would be made with a new floodwall constructed to a height of 4 to 6 feet along 2,500 LF of the south levee. The floodwall would be placed at the waterside hinge point of the levee and would be designed to disturb a minimal amount of waterside slope and levee crown for construction (Figure 16). Construction of the floodwall would be consistent with the description for NEMDC, above. The waterside slope would be re-established to its existing slope and the levee crown would grade away from the wall and be surfaced with aggregate base.

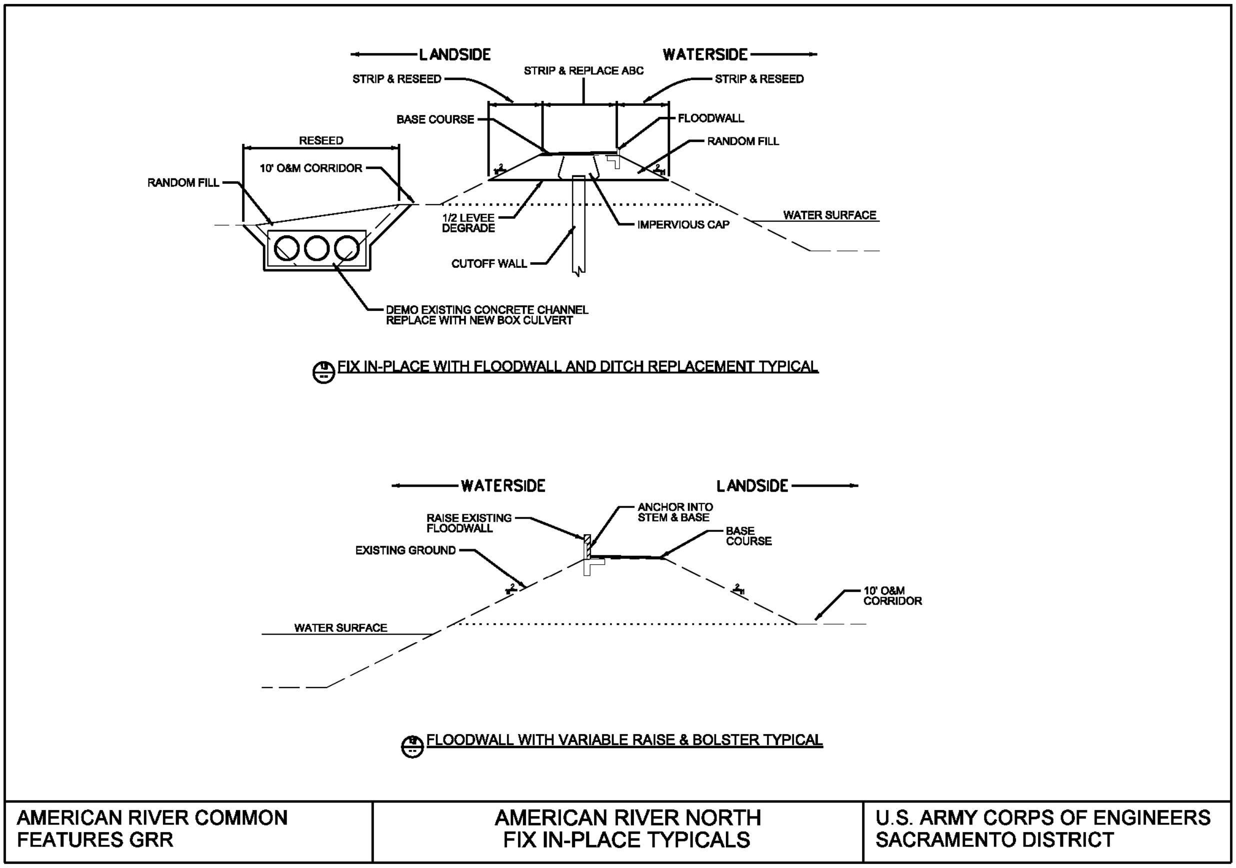

Figure 16. Floodwall with Variable Raise and Bolster Typical.

Magpie Creek Diversion Canal

A number of features are proposed for the Magpie Creek Diversion Canal. The existing project levee on the diversion canal would be raised by approximately 3 to 4 feet for a distance of approximately 2,100 feet. Construction of the raise would be similar to the levee raise described for the Sacramento River above. Additionally, a new, approximately 1,000-foot-long levee would be constructed adjacent to Raley Boulevard, south of the Magpie Creek bridge. The footprint of the existing and new levee is shown on Figure 17.

In addition to the above levee improvements, an approximately 79-acre flood detention basin would be created for the overflow of flood waters in the Magpie Creek area. The flood detention basin would mostly be created through the acquisition of property in the floodplain that is currently flooded during high water events. The flood detention basin would be located on both sides of Raley Boulevard near Magpie Creek. The frequency of flooding of this property would not change with implementation of the proposed measures, however, there would be a increase in surface elevation on the property during these events and the property may remain flooded for longer durations.

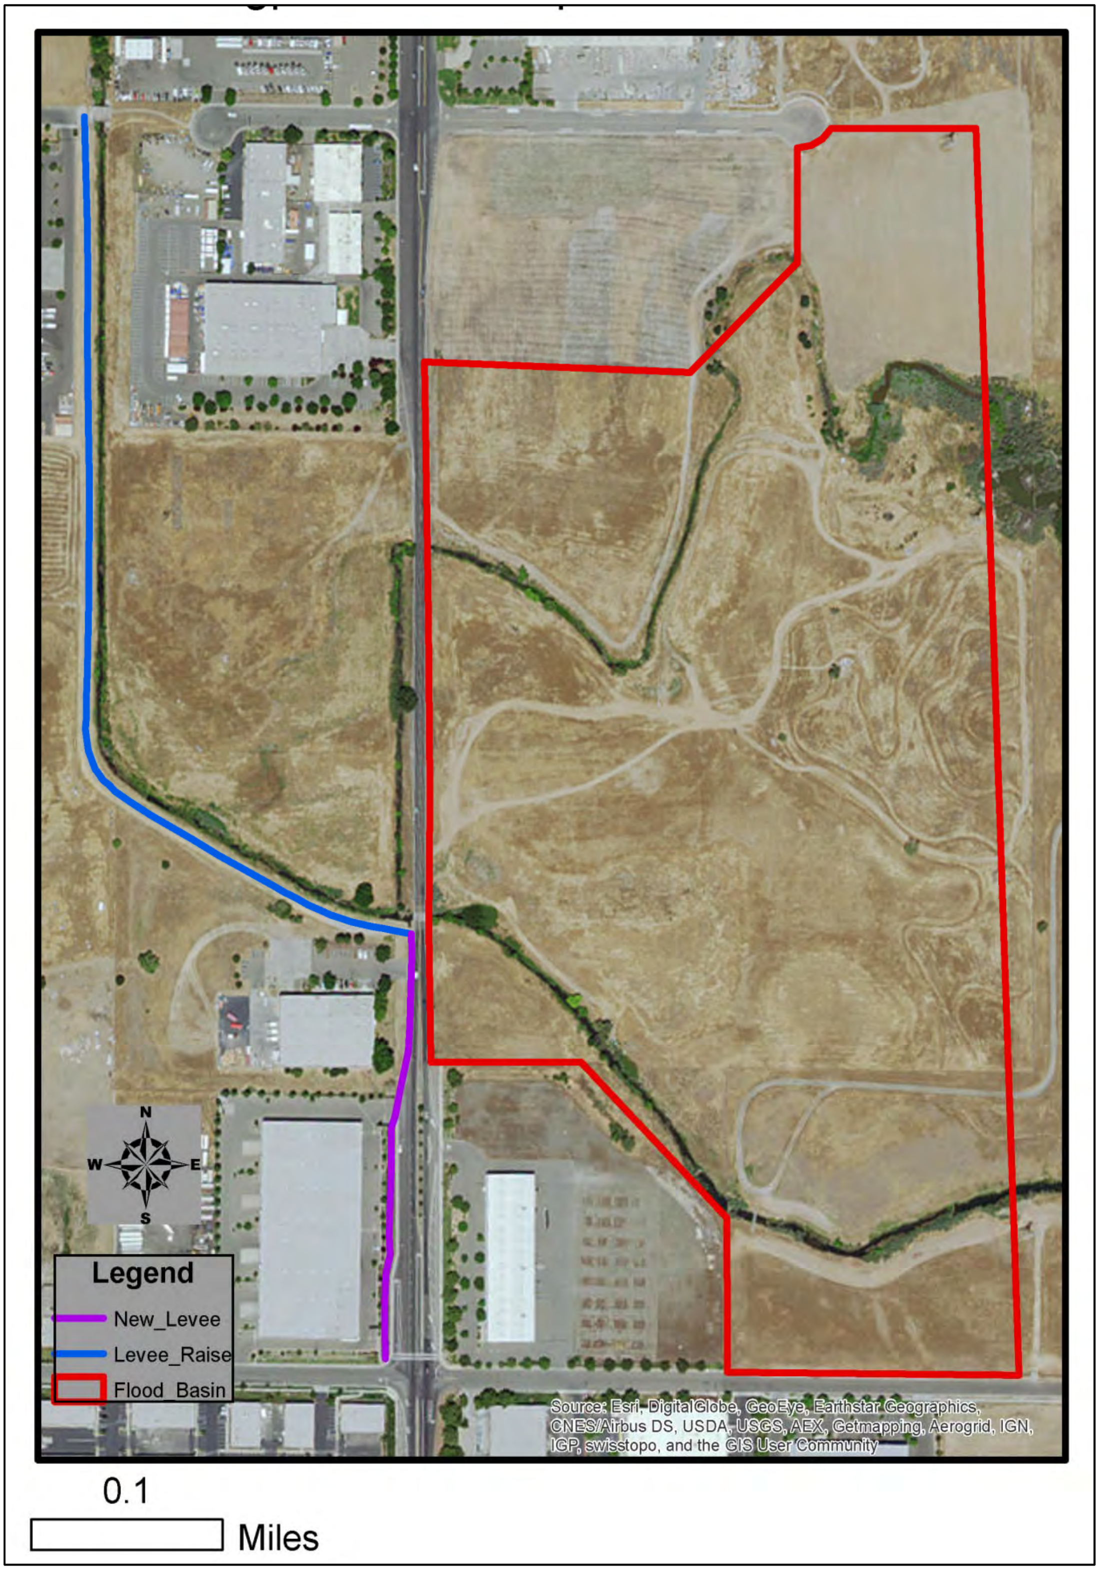

Figure 17. Magpie Creek Proposed Measures.

The features and design proposed for Magpie Creek were originally associated with a separate project, the Magpie Creek Flood Control Project, which was planned and designed by the Corps and SAFCA in 2004. In September 2004, USFWS issued a Biological Opinion to the Corps on the Magpie Creek Flood Control Project (Appendix E). Since the design has not changed at this time from the 2004 project, the 2004 Biological Opinion is considered to be valid and addresses the potential impacts associated with this portion of the ARCF GRR. These effects are summarized throughout this BA, as appropriate.

2.2.6 Sacramento Weir and Bypass

The Sacramento Weir was completed in 1916. It is the only weir that is manually operated – all others overflow by gravity on their own. It is located along the right bank of the Sacramento River approximately 4 miles upstream of the Tower Bridge, and about 2 miles upstream from the confluence with the American River. Its primary purpose is to protect the city of Sacramento from excessive flood stages in the Sacramento River channel downstream of the American River. The weir limits flood stages (water surface elevations) in the Sacramento River to project design levels through the Sacramento/West Sacramento area. Downstream of the Sacramento Weir, the design flood capacity of the American River is 5,000 cfs higher than that of the Sacramento River. Flows from the American River channel during a major flood event often exceed the capacity of the Sacramento River downstream of the confluence. When this occurs, floodwaters flow upstream from the mouth of the American River to the Sacramento Weir.

The project design capacity of the weir is 112,000 cfs. It is currently 1,920 feet long and consists of 48 gates to divert floodwaters to the west through the mile-long Sacramento Bypass to the Yolo Bypass. Each gate has 38 vertical wooden plank "needles" (4 inches thick by 1 foot wide by 6 feet long). It is cumbersome and expensive to operate, and questions have long been asked about whether this 1916 design is appropriate for today’s water management needs (DWR 2010).

Though the weir crest elevation is 24.75 feet, the weir gates are not opened until the river reaches 27.5 feet at the I Street gage with a forecast to continue rising. This gage is about 1,000 feet upstream from the I Street Bridge and about 3,500 feet upstream from the mouth of the American River. The number of gates to be opened is determined by the National Weather Service /Department of Water Resources (DWR) river forecasting team to meet either of two criteria: (1) to prevent the stage at the I Street gage from exceeding 29 feet, or (2) to hold the stage at the downstream end of the weir to 27.5 feet (DWR 2010). The weir gates are then closed as rapidly as practicable once the stage at the weir drops below 25 feet. This provides "flushing" flows to re-suspend sediment deposited in the Sacramento River between the Sacramento Weir and the American River during the low flow periods when the weir is open during the peak of the flood event (DWR 2010).

Under Alternative 2, the Sacramento Weir and Bypass would be expanded to roughly twice their current width to accommodate increased bypass flows. The existing north levee of the Sacramento Bypass would be degraded and a new levee would be constructed approximately 1,500 feet to the north. The existing Sacramento Weir would be expanded to match the wider bypass. At this time, it is not known whether the new segment of weir would be constructed consistent with the 1916 design described above, or whether it would be designed to be a gravity-type weir. The new north levee of the bypass would be designed to be consistent with the existing Sacramento Bypass north levee, however, it would also include a 300-foot-wide seepage berm on the landside with a system of relief wells. A hazardous, toxic, and radiological waste (HTRW) site near the existing north levee would be remediated by the non-Federal sponsor prior to construction.

To avoid potential effects to the Yolo Bypass, the new segment of the Sacramento Weir would be operated only during high water situations, when flows from Folsom Dam exceed 115,000 cfs. Operation of the existing Sacramento Weir and Bypass would remain the same, as described above. While not specifically modeled, there are not expected to be any water quality impacts. The approximate change in water diversions, which are shown in Table 6 below, would vary based on the size of the flood event. The frequency of water diversion is expected to be the same, which is to use the current Sacramento Weir operation based on a stream gage at the I Street Bridge (Schlunegger 2014). Under these operation assumptions, Alternative 2 would result in a diversion of flows from the Sacramento River to the Yolo Bypass that would slightly raise water surface elevations in the Yolo Bypass when flows in the American River exceed 115,000 cfs.

With the Folsom Dam improvements in place, releases from Folsom Dam would be above 115,000 cfs for flood events greater than 1/100 ACE event. Therefore, for events up to and including the 1/100 ACE event, only the existing weir will be operated per the criteria previously established. For events greater than the 1/100 ACE event when the release from Folsom Dam will go above 115,000 cfs, the new weir will be opened. With the increased flood storage space and anticipatory releases at Folsom Dam, this translates into a reduction of flows into the Yolo Bypass with Alternative 2 in place compared to the existing conditions. See Table 6 for a comparison of the flows at various locations for the Existing Condition, the Future Without Project Condition (Folsom Dam improvements), and Future With Project Condition (Alternative 2) in place. For the 1/100 ACE event and greater, the benefits of the Folsom Dam improvements would be realized in the form of reduced flows compared to the existing condition.

Table 6. Comparison of 10, 100 and 200 year Frequency Flows under Various Conditions.

10 year event	**Existing Condition**	**Future Without Project Condition with JFP**	**Future With Project Condition (Alternative 2)**
American River	43,000cfs	72,000cfs	72,000cfs
Sacramento Bypass	50,000cfs	66,000cfs	66,000cfs
Yolo Bypass below Sac Bypass	270,000cfs	296,000cfs	296,000cfs
100 year event	**Existing**	**Future Without Project and Alt. 1**	**Alt. 2 (TSP)**
American River	145,000cfs	115,000cfs	115,000cfs
Sacramento Bypass	131,000cfs	115,000cfs	115,000cfs
Yolo Bypass below Sac Bypass	555,000cfs	535,000cfs	535,000cfs
200 year event	**Existing**	**Future Without Project and Alt. 1**	**Alt. 2 (TSP)**
American River	320,000cfs	160,000cfs	160,000cfs
Sacramento Bypass	183,000cfs	149,000cfs	164,000cfs
Yolo Bypass below Sac Bypass	656,000cfs	631,000cfs	643,000cfs

The widening of the Sacramento Weir and Bypass diverts flood flows from the Sacramento and American River into the Yolo Bypass. At a 10-year level event, the Yolo Bypass is already flooded with water from levee toe to levee toe. By the time flows in the American River exceed 115,000 cfs, water would be approximately 5 to 6 feet below the top of the Yolo Bypass levees. As a result, to avoid impacts to the Yolo Bypass, the widened portion of the weir will only be operated when flood releases from Folsom Dam are above the existing objective release of 115,000 cfs which would occur during flood events greater than 1/100 ACE event. Therefore, for events up to the 1/100 ACE event, there would be no change in flow conditions in the Sacramento and Yolo Bypasses.

For flood events greater than 1/100 ACE event when releases from Folsom Dam would go above 115,000 cfs (such as a 1/200 ACE event in which the Folsom release goes up to 160,000 cfs), there would be an increase in flows in the Sacramento Bypass of approximately 15,000 cfs. In the Yolo Bypass, this equates to an increase of approximately 0.10-foot of water surface elevation. During the 200-year event, the Yolo Bypass is already flooded from levee to levee with depths of up to 21 feet. The addition of these flows would equate to approximately one or two tenths of a foot, which would amount to less than 1 foot of additional width on both levee slopes. This amounts to a total addition of approximately 4.8 acres of flooded area along the existing levee slopes of the Yolo Bypass.

2.2.7 Additional North Sacramento Streams Project Components

Erosion Protection

The only erosion protection currently envisioned includes placement of rip rap on waterside benches where waterside toe slurry walls are constructed. Following construction, levee slopes and other areas disturbed by construction would be revegetated and brought back to pre-project conditions. Locations where erosion is identified along the waterside levee slope and riverbank have been evaluated to determine whether levee integrity or stability may be affected. Insufficient embankment protection may cause a levee to be undermined by erosive forces due to wave action and/or high flow velocities along the levee bank. In many cases, the placement of embankment protection material, such as engineered armoring (rip-rap), would dissipate wave and velocity forces and reduce the potential for erosion to occur. Other factors to be considered prior to installing embankment protection material include grading the levee waterside slope to address stability issues, and environmental impacts within the vicinity of the embankment repair site.

Utility Relocation

SAFCA prepared an inventory and assessment of existing encroachments and penetrations within the NSS Levee Improvements Project area. Known utilities that cross or are adjacent to the levee include gas pipelines; storm drainage and pump station discharge pipes; and numerous water supply mains, culverts, electrical conduits, and sanitary sewers. The construction contractor can work around many of these utilities. However, some utilities may need to be temporarily removed or relocated prior to construction. Temporary bypass pumping may be required for sanitary sewers. SAFCA and the construction contractor would coordinate closely with utility owners to manage the utilities in advance of construction. Disturbed utilities would be restored after construction consistent with CVFPB requirements. Coordination between SAFCA and the utility owner would be required for those utilities that do not currently have CVFPB encroachment permits.

Stormwater Pollution Prevention

Temporary erosion/runoff best management control measures would be implemented during construction to minimize stormwater pollution resulting from erosion and sediment migration from the construction, borrow, and staging areas. These temporary control measures may include implementing construction staging in a manner that minimizes the amount of area disturbed at any one time; secondary containment for storage of fuel and oil; and the management of stockpiles and disturbed areas by means of earth berms, diversion ditches, straw wattles, straw bales, silt fences, gravel filters, mulching, revegetation, and temporary covers as appropriate. Erosion and stormwater pollution control measures would be consistent with National Pollutant Discharge Elimination System (NPDES) permit requirements and would be included in a Stormwater Pollution Prevention Plan (SWPPP).

After completion of construction activities, the temporary facilities (construction trailers and batch plants) would be removed and the site would be restored to pre-project conditions. Site restoration activities for areas disturbed by construction activities, including borrow areas and staging areas, will include a combination of regrading, reseeding, constructing permanent diversion ditches, using straw wattles and bales, and applying straw mulch and other measures deemed appropriate.

Proposed Sequence of Project Construction

It is anticipated that the North Sacramento Streams levee improvements would be implemented in one construction season (2016). The construction season would take place from April 15 to November 1. An approximate construction sequence includes the following:

- **Mobilization:** Mobilization would include setting up construction offices and the slurry batch plant and transporting heavy earthmoving equipment to the site. These activities may take up to 1 month.
- **Vegetation and encroachment removal:** Trees and other encroachments that impact remedial measures would be removed consistent with established SAFCA policies regarding vegetation and encroachments. These activities may take 1–4 weeks depending upon the reach being remediated.
- **Levee degradation for cutoff wall installation:** Beginning of levee degradation would follow vegetation and encroachment removal and precede cutoff wall installation. Degradation would take a total of about 4 months but it would not likely be conducted in one simultaneous operation. Rather, levee reaches would be degraded for specific lengths of cutoff wall to minimize the total length of degraded levee at any one time. Construction would take approximately 3 months.
- **Cutoff wall installation:** This activity would begin with construction of the work pad once a sufficient length of levee was degraded and was available for construction. Assuming four headings, construction would take approximately 4 months.
- **Drainage blanket construction:** Drainage blanket would be constructed prior to placing overlying slope reconstruction fill. Portions of drainage blanket extending up levee cut slopes would be placed as the adjacent slope reconstruction material is placed. Construction would take approximately 1 month since such construction is a small part of the proposed project.
- **Toe cutoff wall erosion protection:** Toe cutoff wall rip rap erosion protection would be placed after the toe cutoff wall bench has been completed to final lines and grades. Construction would take approximately 2 months.

- **Utility relocation:** Any required utility relocation would be conducted concurrent with the levee degradation, toe cutoff wall bench construction, and reconstruction operations. Construction would take approximately 4 months.
- **Levee reconstruction:** Levee reconstruction would begin once there was sufficient length completed cutoff wall to efficiently begin reconstructing the levee embankment. Total time estimated for levee reconstruction is about 6 months.
- **Seepage Wells:** Seepage wells can be installed at any time during the construction season. Installation and development of relief wells and reconstruction of paved channel and basin inverts would likely take about 2 month.
- **Site restoration and demobilization:** Upon completion of the main construction activities, the levee patrol road would be resurfaced, disturbed areas would be revegetated, staging and borrow areas would be restored, and the contractor would demobilize the site(s). These activities are expected to take about 2 months.

Construction would be staged and sequenced with the appropriate stakeholders: the City, County, Reclamation District, utility and service providers, biological resource construction work windows, and other environmental and land use/real estate constraints, to the greatest extent practical to minimize impacts and effects on the community.

High Hazard Levee Encroachment and Vegetation Removal

Encroachment Management

The National Flood Insurance Program (NFIP) standards for levee accreditation and the State's ULDC both require removal or modification of encroachments that pose an unacceptably high risk to the performance and safety of a levee either by undermining its structural integrity or by interfering with necessary inspection, operation, and maintenance activities. To address this requirement, SAFCA has identified and evaluated all of the encroachments in the NSS Levee Improvements area. Each of these encroachments has been evaluated to determine whether it constitutes an unacceptably high risk to the performance of the levee either by undermining the stability of the levee or by interfering with necessary patrolling, operation, and maintenance activities. Based on this evaluation, the encroachments have been classified as either:

- High-risk – poses a threat to levee integrity, removable prior to the levee being accredited;
- High-risk – impedes operation, maintenance, and inspection, removable within 3 years after the levee is accredited; or
- Low-risk – not identified as high hazard.

In the NSS Levee Improvements area, high-risk encroachments to be removed are limited to residential landscaping located at approximately 10 locations along the landside of the south and north levees of Arcade Creek (mainly between Marysville Boulevard and Rio Linda Boulevard) and along the Robla Creek South Levee, east of Rio Linda Boulevard.

Vegetation Management

The levee accreditation element of the proposed project also includes a vegetation management component. Although the NFIP does not identify specific standards for managing vegetation on levees, ULDC provides criteria that reflect the underlying risk management objectives of the NFIP. Under these criteria, vegetation on levees must be modified or removed if it presents an unacceptable risk to the structural integrity or impedes operation and maintenance of the levee.
In the NSS Levee Improvements area, approximately 8 high-risk trees along Arcade Creek have been identified for removal. All of the trees are either nonnative (7) or snags (3). Five are located on the waterside of the levees. These trees are in addition to any trees that would be removed as a result of implementation of levee improvements in the NSS Levee Improvements area.

2.3 Operation and Maintenance

Operation and maintenance (O&M) of the levees in the Sacramento area are the responsibility of the local maintaining agencies, including the American River Flood Control District, Maintenance Area 9, the California Department of Water Resources, and the City of Sacramento. The applicable O&M Manual for the Sacramento area levees is the Standard Operation and Maintenance Manual for the Sacramento River Flood Control Project. Typical levee O&M in the Sacramento area currently includes the following actions:

- Vegetation maintenance up to four times a year by mowing or applying herbicide.
- Control of burrowing rodent activity monthly by baiting with pesticide.
- Slope repair, site-specific and as needed, by re-sloping and compacting.
- Patrol road reconditioning up to once a year by placing, spreading, grading, and compacting aggregate base or substrate.
- Visual inspection at least monthly, by driving on the patrol road on the crown and maintenance roads at the base of the levee.
- Post-construction, groundwater levels would be monitored using the piezometers.

Following construction, the O&M manual for these reaches would be adjusted to reflect the vegetation variance and the SWIF plan. Under the adjusted O&M manual, large trees that are protected in place under the variance would be allowed to remain on the waterside slopes, but smaller shrubs would be removed and grasses would be regularly mowed to allow for inspection and access.

Vegetation maintenance includes keeping maintenance roads clear of overhanging branches. Some of the vegetation along the levees includes elderberry shrubs. As part of long-term O&M, elderberry shrubs will be trimmed by the three levee maintenance districts. The following table describes the maximum amount of elderberry acreage that will be trimmed each year as a result of O&M. Trimming consists of cutting overhanging branches along the levee slopes on both the landside and waterside. Some shrubs may be located adjacent to the levee with branches hanging over the levee maintenance road. Up to a third of a shrub will be trimmed in a single season. Trimming will occur between November 1 and March 15. Loss of habitat will be offset through the development of a conservation area as described in the conservation measures below. Each year the local maintaining authority will document the amount of valley elderberry longhorn beetle habitat that they have trimmed and report that number to the Corps to ensure compliance with this biological opinion. If the local maintaining agency has a need to exceed the amount of valley elderberry longhorn beetle habitat which needs to be trimmed or affected due to routine maintenance then they will request the Corps reinitiate consultation on this biological opinion for those actions.

2.4 Full Consultation Biological Assessment Approach

The description of baseline conditions and the evaluation of potential impacts have been organized by waterway, which includes the American River, Sacramento River, NEMDC, Arcade Creek, Dry/Robla Creek, Magpie Creek, and the Sacramento Weir/Bypass areas. For species that are described and covered in this consultation, habitat preferences and distributions are based on published data, agency documents, and review of the California Natural Diversity Database (CNDDB) (CDFW 2013a). Species distributions were assessed throughout the ARCF study area, and where appropriate, within specific regions.

Descriptions of baseline conditions are based on information published in peer-reviewed scientific literature, resource agency publications, as well as aerial photography viewed in Google Earth Pro within the project area. Baseline conditions are described with a focus on features that affect habitat conditions for threatened and endangered species, including Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley steelhead, delta smelt, green sturgeon, giant garter snake, valley elderberry longhorn beetle, vernal pool fairy shrimp, vernal pool tadpole shrimp, western yellow-billed cuckoo, and other special status bird species.

Table 7 summarizes the species addressed in this Biological Assessment and where the Corps assumes their habitat is present within the study area.

Table 7. Presence of Listed Species within the Study Area.

	Valley Elderberry Longhorn Beetle	Vernal Pool Fairy Shrimp	Vernal Pool Tadpole Shrimp	Giant Garter Snake	Winter-run Chinook Salmon	Spring-run Chinook Salmon	Central Valley Steelhead	Green Sturgeon	Delta Smelt	Western Yellow-billed Cuckoo
American River	Yes	No	No	No	Yes	Yes	Yes	Critical Habitat to Highway 160	No	Yes
Sacramento River	Yes	No	No	No	Yes	Yes	Yes	Yes	Yes	Yes
Natomas East Main Drainage Canal	Yes	No	No	No	No	No	Yes	No	No	No
Arcade Creek	Yes	No	No	No	No	No	No	No	No	No
Dry/Robla Creek	Yes	No	No	No	No	No	Yes	No	No	No
Magpie Creek	Yes	Yes	Yes	No	No	No	No	No	No	No
Sacramento Bypass	Yes	No	No	Yes	Yes	Yes	Yes	Yes	Yes	No

2.5 Proposed Conservation and Mitigation Measures

2.5.1 Compensation Timing

Compensation timing refers to the time between the initiation of construction at a particular site and the attainment of the habitat benefits to protected species from designated compensation sites. In general, compensation time is the time required for on-site plantings to provide significant amounts of shade or structural complexity from instream woody material recruitment. Significant long-term benefits have often been considered as appropriate to offset small short-term losses in habitat for listed species in the past, as long as the overall action contributes to recovery of the listed species. The authority to compensate prior to or concurrent with project construction is given under WRDA 1986 (33 United States Code [USC] § 2283).

2.5.2 Valley Elderberry Longhorn Beetle Conservation and Mitigation Measures

The following is a summary of measures that would be implemented during construction based on the *Conservation Guidelines for the Valley Elderberry Longhorn Beetle* (Conservation Guidelines) (USFWS 1999a). These measures will be implemented to minimize any potential effects on valley elderberry longhorn beetles or their habitat, including restoration and maintenance activities, long-term, protection, and compensation if shrubs cannot be avoided. If shrubs cannot be avoided, compensation shall be implemented as shown in Tables 10 and 11 below. These measures could be adjusted in compliance with the most current guidance at the time of construction.

- The Corps assumes complete avoidance of the valley elderberry longhorn beetle when a 100-foot (or wider) buffer is established and maintained around elderberry shrubs.
- When work will occur within the 100-foot buffer, a setback of 20 feet from the dripline of each elderberry shrub will be maintained whenever possible.
- During construction activities, all areas to be avoided will be fenced and flagged.
- Contractors will be briefed on the need to avoid damaging elderberry shrubs and the possible penalties for not complying with these requirements.
- Signs will be erected every 50 feet along the edge of the avoidance area, identifying the area as an environmentally sensitive area.
- Any damage done to the buffer area will be restored.
- Buffer areas will continue to be protected after construction.

- No insecticides, fertilizers, or other chemicals that might harm the beetle or its host plant will be used in the buffer areas.
- Elderberry shrubs that cannot be avoided would be transplanted to an appropriate riparian area at least 100 feet from construction activities.
- If possible, elderberry shrubs would be transplanted during their dormant season (approximately November, after they have lost their leaves, through the first two weeks in February). If transplantation occurs during the growing season, increased mitigation will apply.
- Elderberry compensation would be planted in the American River Parkway. The Corps has six existing sites which are offsetting previous Corps flood control projects along the lower American River and near Folsom Dam. The Corps will find areas within the lower American River parkway which will either expand existing compensation areas or provide for connectivity between conserved valley elderberry longhorn beetle habitat. Sites within the Parkway will be coordinated with County Parks and the Service during the design phase of the project. Sites will be designed and developed prior to any effects to valley elderberry longhorn beetle habitat. The Corps will create 69.91 acres of riparian habitat which supports valley elderberry longhorn beetle within the lower American River parkway.
- The Corps will work to develop compensation areas prior to or concurrent with any take of valley elderberry longhorn beetle habitat.
- Management of these lands will include all measures specified in USFWS's conservation guidelines (1999a) related to weed and litter control, fencing, and the placement of signs.
- Monitoring will occur for ten consecutive years or for seven non-consecutive years over a 15-year period. Annual monitoring reports will be submitted to USFWS.
- Off-site areas will be protected in perpetuity and have a funding source for maintenance (e.g., endowment).

2.5.3 Giant Garter Snake Conservation and Mitigation Measures

The following measures will be implemented to minimize effects on giant garter snake habitat that occurs within 200 feet of any construction activity. These measures are based on USFWS guidelines for restoration and standard avoidance measures included as appendices in USFWS (1997).

- Unless approved otherwise by USFWS, construction will be initiated only during the giant garter snakes' active period (May 1–October 1, when they are able to move away from disturbance).
- Construction personnel will participate in USFWS-approved worker environmental awareness program.

- A giant garter snake survey would be conducted 24 hours prior to construction in potential habitat. Should there be any interruption in work for greater than two weeks, a biologist would survey the project area again no later than 24 hours prior to the restart of construction.
- Giant garter snakes encountered during construction activities will be allowed to move away from construction activities on their own.
- Movement of heavy equipment to and from the construction site will be restricted to established roadways. Stockpiling of construction materials will be restricted to designated staging areas, which will be located more than 200 feet away from giant garter snake aquatic habitat.
- Giant garter snake habitat within 200 feet of construction activities will be designated as an environmentally sensitive area and delineated with signs or fencing. This area will be avoided by all construction personnel to the maximum extent feasible.
- Habitat temporarily affected for one season (the 5.5 acre borrow site along the NEMDC and the 75 acres along the toe drain of the Sacramento Bypass levee) will be restored after construction by applying appropriate erosion control techniques and replanting/seeding with appropriate native plants. If for any reason construction extends into another active season the Corps will replace the habitat on-site and purchase credits at a ratio of 1:1 at a Service approved conservation bank.
- Habitat temporarily affected for more than three or more seasons will be restored and twice as much habitat will be created.
- Habitat permanently affected in the Sacramento Bypass in the form of drainage ditches and irrigation canals will be compensated for through the purchase of 135 acres of credits at a USFWS-approved conservation bank.
- One year of monitoring will be conducted for the 80.5 acres that are temporarily affected.
- The Corps will purchase credits at a conservation bank prior to any permanent disturbance of giant garter snake habitat.

For SAFCA's NSS project, the following measures are additionally proposed to reduce impacts to GGS from use of Borrow Site 2:

- A biological monitor shall be on-site during all ground-disturbing activities at Borrow Site 2.
- At least 10 days prior to the commencement of ground disturbing activities and after May 1, exclusionary fencing will be erected around the perimeter of Borrow Site 2K. Prior to fencing installation, the fence line shall be mowed (with a minimum height of 6 inches) in order to conduct a surface survey of potential burrows. Fencing shall be installed with a minimum of 6 inches buried in the ground and a minimum of 24 inches above ground. Fence staking shall

be installed on the inside of the exclusion area. One-way escape funnels shall be installed every 50 to 100 feet and sealed along the fence line, to provide an escape for any giant garter snake that may be within the exclusion area. The fencing shall enclose the entirety of the site, or additional exclusionary fencing can be extended 200 to 400 feet beyond the proposed entrance area. The fencing will be inspected before the start of each work day and maintained by the project proponents until completion of the project. The fencing will be removed only when project activities within Borrow Site 2 are completed.

2.5.4 Vernal Pool Crustacean Conservation and Mitigation Measures

The following measures from the 2004 Biological Opinion from the Magpie Creek Flood Control Project would be implemented to avoid and minimize impacts to potential vernal pools in the vicinity of the Magpie Creek construction area:

- Preservation component: For every acre of habitat directly or indirectly affected, at least two vernal pool credits will be dedicated within a Service-approved ecosystem preservation bank or, based on Service evaluation of site-specific conservation values, three acres of vernal pool habitat may be preserved on the project site or another nonbank site as approved by the Service.
- Creation component: For every acre of habitat directly affected, at least one vernal pool creation credit will be dedicated within a Service-approved habitat creation bank or, based on Service evaluation of site-specific conservation values, two acres of vernal pool habitat will be created and monitored on the project site or another non-bank site as approved by the Service.
- Listed vernal pool crustacean habitat and associated uplands utilized as on-site compensation will be protected from adverse effects and managed in perpetuity or until the Corps, the applicant, and the Service agree on a process to exchange such areas for credits within a Service-approved conservation banking system. Off-site conservation at a Service-approved non-bank location will be protected and managed in perpetuity through a Service-approved conservation easement, Service-approved management plan, and a sufficient endowment fund to manage the site in perpetuity in accordance with the management plan.
- If habitat is avoided (preserved) on site, then a Service-approved biologist (monitor) will inspect any construction-related activities at the proposed project site to ensure that no unnecessary take of listed species or destruction of their habitat occurs. The biologist will have the authority to stop all activities that may result in such take or destruction until appropriate corrective measures have been completed. The biologist also will be required to immediately report any unauthorized impacts to the Service and the California Department of Fish and Game.

- Adequate fencing will be placed and maintained around any avoided (preserved) vernal pool habitat to prevent impacts from vehicles.
- All on-site construction personnel will receive instruction regarding the presence of listed species and the importance of avoiding impacts to these species and their habitat.
- The applicant will ensure that activities that are inconsistent with the maintenance of the suitability of remaining habitat and associated on-site watershed are prohibited. This includes, but is not limited to: (i) alteration of existing topography or any other alteration or uses for any purposes, including the exploration for or development of mineral extraction; (ii) placement of any new structures on these parcels; (iii) dumping, burning, and/or burying of rubbish, garbage, or any other wastes or fill materials; (iv) building of any new roads or trails; (v) killing, removal, alteration, or replacement of any existing native vegetation; (vi) placement of storm water drains; (vii) fire protection activities not required to protect existing structures at the project site; and (viii) use of pesticides or other toxic chemicals.

The proposed project will result in 0.25 acre of indirect effects to vernal pools/swales of potentially suitable vernal pool shrimp and vernal pool tadpole shrimp habitat. The applicant has identified and agreed to purchase 0.5 vernal pool preservation credits at a Service-approved conservation bank or Service-approved fund. Credits will be purchased prior to the effect on any vernal pool habitat. The agreed upon conservation responsibilities of the applicant are as follows:

- Prior to any earth-moving activities at the proposed project site, the applicant shall purchase at least 0.5 vernal pool preservation credits within a Service-approved ecosystem preservation bank or fund account.

2.5.5 Western Yellow-Billed Cuckoo Conservation Measures

The following measures would be implemented to avoid and minimize impacts to potential yellow-billed cuckoo habitat in the study area:

- Prior to construction, surveys will be conducted to determine the presence of yellow-billed cuckoos within the project area in accordance with any required Service survey protocols and permits at the time of construction.
- If surveys find cuckoos in the area, vegetation removal will be done outside of the cuckoo nesting season.
- Riparian habitat that is removed due to project construction along the American River will be replanted within the American River Parkway. The Corps intends to expand existing conserved riparian lands within the parkway that could support the yellow-billed cuckoo. The design of replacement riparian areas will be coordinated with the Service to ensure that the habitat benefits both valley elderberry longhorn beetle and yellow-billed cuckoos.

2.5.6 Fisheries Conservation and Mitigation Measures

Green Sturgeon

The Corps proposes to develop a green sturgeon habitat, mitigation, and monitoring plan (HMMP) to address the long-term negative impacts to green sturgeon designated critical habitat with the specific elements that are described below:

- The green sturgeon HMMP shall be developed in coordination with the Interagency Ecological Program (IEP) green sturgeon project work team and consulted on with NMFS prior to the construction of any work within the designated critical habitat of sDPS green sturgeon related to the ARCF GRR.
- The Corps shall either refine the SAM or develop an alternative green sturgeon survival and growth response model based on using and updating the existing Hydrologic Engineering Center Ecosystem Function Model (HEC-EFM) that reflects green sturgeon's preference for benthic habitat.
- The green sturgeon HMMP shall also be developed with measurable objectives for completely offsetting all adverse impacts to all life stages of sDPS green sturgeon (as modeled using refined approaches described above and considering design refinements that occur in the PED phase of project implementation.
- The HMMP shall also, restore or compensate for the number of acres of soft bottom benthic substrate for sDPS green sturgeon permanently lost to project construction. This mitigation shall be coordinated with the Interagency Working Group (IWG) or a Bank Protection Working Group (BPWG) and must be carried out within the lower Sacramento River/North Delta in order to offset the adverse modification to designated critical habitat.
- Mitigation actions shall be initiated prior to the construction activities affecting sDPS green sturgeon and their critical habitat.
- The sDPS green sturgeon HMMP will include measurable performance standards at agreed upon intervals and will be monitored for a period of at least ten years following construction.

The following additional conservation measures would be implemented to reduce the adverse effects to listed Chinook, steelhead, delta smelt, and green sturgeon:

- In-water construction activities (e.g., placement of rock revetment) will be limited to the work window of August 1 through November 30. If the Corps wants to work outside of this window they will consult with USFWS and NMFS.
- The Corps will purchase 42 acres of delta smelt credits from a USFWS-approved conservation bank to off-set the loss of 14 acres of shallow water habitat.
- The Corps will purchase an additional 32 acres of delta smelt credits from a USFWS-approved conservation bank to off-set the loss of spawning habitat due to the placement of riprap on the river bed.
- Erosion control measures (BMPs), including Storm Water Pollution Prevention Program and Water Pollution Control Program, that minimize soil or sediment from entering the river. BMPs shall be installed, monitored for effectiveness, and maintained throughout construction operations to minimize effects to Federally listed fish and their designated critical habitat.
- Screen any water pump intakes, as specified by NMFS and USFWS screening specifications. Water pumps will maintain an approach velocity of 0.2 feet per second or less when working in areas that may support delta smelt.
- No grading or altering of the lands within the existing Sacramento Bypass will occur as part of the project.
- The Corps shall participate in an existing IWG or work with other agencies to participate in a new BPWG to coordinate stakeholder input into future flood risk reduction actions associated with the ARCF GRR.
- The Corps shall coordinate with NMFS during PED as future flood risk reduction actions are designed to ensure conservation measures are incorporated to the extent practicable and feasible and projects are designed to maximize ecological benefits.
- The Corps shall include as part of the Project, a Riparian Corridor Improvement Plan with the overall goal of maximizing the ecological function and value of the existing levee system within the Sacramento Metropolitan Area.
- The Corps shall develop a HMMP with an overall goal of ensuring the conservation measures achieve a high level of ecological function and value. The HMMP shall include:
    - Specific goals and objectives and a clear strategy for maintaining all of the project conservation elements for the life of the project.
    - Measures to be monitored by the Corps for 10 years following construction and shall update their O&M manual to ensure the HMMP is adopted by the local

sponsor to ensure the goals and objectives of the conservation measures are met for the life of the project.

- o Include specific goals and objectives and a clear strategy for achieving full compensation for all project-related impacts to listed fish species.
- o The Corps shall continue to coordinate with NMFS during all phases of construction, implementation, and monitoring by hosting annual meetings and issuing annual reports throughout the construction period as described in the HMMP.
- o The Corps shall host an annual meeting and issue annual reports for five years following completion of project construction.

- The Corps shall ensure that, for salmon and steelhead, the maximum SAM WRI deficits for each seasonal water surface elevation as determined appropriate with input from the IWG or the BPWG are fully offset through the purchase of credits at a NMFS approved conservation bank (as described in this BA).
- The Corps shall minimize the removal of existing riparian vegetation and IWM to the maximum extent practicable, and where appropriate, removed IWM will be anchored back into place or if not feasible, new IWM will be anchored in place.
- The Corps shall ensure that the planting of native vegetation will occur as described in the HMMP. All plantings must be provided with the appropriate amount of water to ensure successful establishment.
- The Corps shall provide a copy of the BO, or similar documentation, to the prime contractor, making the prime contractor responsible for implementing all requirements and obligations included in the documents and to educate and inform all other contractors involved in the project as to the requirements of the BO.
- A NMFS-approved Worker Environmental Awareness Training Program for construction personnel shall be conducted by the NMFS-approved biologist for all construction workers prior to the commencement of construction activities. Written documentation of the training will be submitted to NMFS within 30 days of the completion of training.
- The Corps shall consider installing IWM along future flood risk reduction projects associated with the ARCF GRR at 40 to 80 percent shoreline coverage at all seasonal water surface elevations in coordination with the IWG or the BPWG. The purpose is to maximize the refugia and rearing habitats for juvenile fish.
- The Corps shall protect in place all riparian vegetation on the lower waterside slope of any levee unless removal is specifically approved by NMFS.
- The Corps shall develop a Vegetation Variance for all elements of the ARCF GRR that are adjacent to habitat that is occupied by federally listed salmon, steelhead and green sturgeon, including the main channel of the Sacramento River (as proposed) and the Sacramento Bypass.
- Additional mitigative concerns, not considered in a SAM analysis, will be included in the MMP (See Appendix I) along the Sacramento Bypass reach, including potential adult and

juvenile passage issues, loss of shoreline riparian vs. gain in floodplain, and contradicting ESA species habitat requirements. These issues will be considered and appropriate actions will be taken where possible in coordination with other agencies.

For SRA habitat impacted by construction, the following measures would be implemented to compensate for the habitat loss:

- Compensation timing refers to the time between the initiation of construction at a particular site and the attainment of the habitat benefits to protected species from designated compensation sites. In general, compensation time is the time required for on-site plantings to provide significant amounts of shade or structural complexity from instream woody material recruitment. Significant long-term benefits have often been considered as appropriate to offset small short-term losses in habitat for listed species in the past, as long as the overall action contributes to recovery of the listed species. The authority to compensate prior to or concurrent with project construction is given under WRDA 1986 (33 United States Code [USC] §§ 2201–2330).
- For identified designated critical habitat, where feasible all efforts will be made to compensate for impacts where they have occurred or in close proximity. Impacts to designated critical habitat, SRA and instream components combined and the compensation value of replacement habitat will be based on the interagency approved Standard Assessment Model (SAM) used throughout the Sacramento River basin and Delta flood control system.
- Compensation sites would be monitored and vegetation would be replaced as necessary based on performance standards in the Mitigation Monitoring Plan (MMP) as detailed in Appendix I of the EIS/EIR.

Depending on the species of interest (e.g., delta smelt), the severity of the short- term habitat losses due to bank erosion repair actions may not be compensated by long-term gains, whereas longer lived species (e.g., steelhead, Chinook) have longer periods for compensation to be provided. The following compensation time periods (based loosely on life expectancy) should be considered as guidelines for compensation:

- Green sturgeon, 15 years;
- Chinook salmon, 5 years;
- Central Valley steelhead, 4 years; and
- Delta smelt, 1 year.

2.5.7 Additional Minimization and Conservation Measures

- Obtain an ETL approved vegetation variance exempting sites from vegetation removal prior to final design and construction phase for the Sacramento River.
- Minimize the removal of existing vegetation in the proposed project area. Any disturbance or removal of vegetation will be replaced with native riparian vegetation, outside of the vegetation-free zone, as established in the ETL. Compensation for impacts to native riparian habitat will occur on a 2:1 basis on-site or in close proximity to the impact area. Riparian vegetation impacted under the SAFCA 408/404 actions will be replaced on a 3:1 canopy acreage basis.
- Erosion control measures (BMPs) including Storm Water Pollution Prevention Program and Water Pollution Control Program that minimize soil or sediment from entering the river. BMPs shall be installed, monitored for effectiveness, and maintained throughout construction operations to minimize effects to Federally listed fish and their designated critical habitat.
- Implement BMPs to prevent slurry seeping out to river and require piping system on land side only.
- Stockpile construction materials such as portable equipment, vehicles, and supplies, at designated construction staging areas and barges, exclusive of any riparian and wetlands areas.
- Stockpile all liquid chemicals and supplies at a designated impermeable membrane fuel and refueling station with a 110% containment system.
- Construction will be scheduled when listed terrestrial and aquatic species would be least likely to occur in the project area. If construction needs to extend into the timeframe that species are present, then coordination/reinitiation with the resource agencies will need to occur.
- Site access will be limited to the smallest area possible in order to minimize disturbance. Litter, debris, unused materials, equipment, and supplies will be removed from the project area daily. Such materials or waste will be deposited at an appropriate disposal or storage site.
- To minimize ground and vegetation disturbance during project construction, project limits shall be clearly marked, including the boundaries of designated equipment staging areas; ingress and egress corridors; stockpile areas for spoils disposal, soil, and materials; and equipment exclusion zones.
- Project-related vehicles shall observe a 20-mile-per-hour speed limit within construction areas, except on County roads and on State and Federal highways.Immediately (within 24 hours) cleanup and report any spills of hazardous materials to the resource agencies. Any

such spills, and the success of the efforts to clean them up, shall also be reported in post-construction compliance reports.

- Designating a Service-approved biologist as the point-of-contact for any contractor who might incidentally take a living, or find a dead, injured, or entrapped threatened or endangered species. This representative shall be identified to the employees and contractors during an all employee education program conducted by the Corps.

Furthermore, the Corps will seek to avoid and minimize construction effects on listed species and their critical habitat to the extent feasible. A number of measures will be applied to the entire project or specific actions, and other measures may be appropriate at specific locations within the study area. Avoidance activities to be implemented during final design and construction may include, but are not limited to, the following:

- Identifying all habitats containing, or with a substantial possibility of containing, listed terrestrial, wetland, aquatic, and/or plant species in the potentially affected project areas. To the extent practicable efforts will be made to minimize effects by modifying engineering design to avoid potential direct and indirect effects.
- Incorporating sensitive habitat information into project bid specifications.
- Incorporating requirements for contractors to avoid identified sensitive habitats into project bid specifications.
- Minimizing vegetation removal to the extent feasible.
- Minimizing, to the extent possible, grubbing and contouring activities.
- Where feasible compensating for impacts close to where impacts have occurred.

2.5.8 Summary of Environmental Commitments

Items below present a general summary of environmental commitments that the Corps will adhere to as part of the ARCF GRR.

If habitat compensation efforts for listed species or designated critical habitat do not perform, or adequately compensate for habitat losses per established guidelines, then the Corps will purchase compensation at a mitigation bank approved by the USFWS and/or NMFS or work with the Services to determine where appropriate mitigation can be created.

- The Corps will obtain an ETL-approved vegetation variance exempting the Sacramento River sites from vegetation removal in the lower third of the waterside of the levee prior to final construction and design phase. The Corps will be complying with the ETL on the American River via a SWIF. Full ETL compliance would occur on the East Side Tributaries sites. This approval process is in alignment with the Corps' Levee Safety Program's goal of maintaining public safety as the primary objective and assuring application of consistent and well-documented approaches.

- The Corps will use a rock soil mixture to facilitate re-vegetation of the proposed project area. A (70:30) rock to soil ratio would be implemented. The soil-rock mixture would be placed on top of the of the rock revetment to allow native riparian vegetation to be planted to insure that SRA habitat lost is partially replaced or enhanced. Alternatively, a rock lined soil trench approach could be taken.
- In addition to an approved vegetation variance, the Corps will minimize the removal of existing vegetation in the proposed project area. Disturbance or removal of trees or larger woody vegetation will be replaced with native riparian species, outside of the vegetation-free zone, as established in the ETL.
- Vegetation removal, particularly tree removal, shall be conducted between September 16 and January 31, to the extent feasible, to minimize potential loss of active bird nests and bat maternity roosts.
- Construction will be scheduled when listed terrestrial and aquatic species would be least likely to occur in the project area, approximately May or June through October, depending on the species present on a site-specific basis. If construction needs to extend into the timeframe that species are present coordination with the resource agencies will occur.

The Corps is committed to implementing project compensation and mitigation as detailed above, however site selection and real estate coordination has not occurred at this time and would be determined during the design phase of the project. A draft mitigation and monitoring plan will accompany the final EIS/EIR, and would be updated throughout the design phase as detailed design efforts allow for finalizing the mitigation plans. The mitigation and monitoring plan would be coordinated with the Services during the design phase. The Corps would go through the following process in order to determine sites for implementing compensation for impacts to riparian habitat, including VELB and yellow-billed cuckoo compensation sites:

- The Corps would assess opportunities for on-site compensation to the maximum extent practicable. This assessment would include considering site-specific conditions, including whether the site is protected from future erosion by bank protection, or remains at risk of berm and vegetation loss due to the launchable rock trench.
- If on-site compensation is not possible, the Corps would evaluate opportunities to expand existing Corps mitigation sites within the American River Parkway, such as the River Bend Park mitigation site.
- If the Corps requires additional lands for compensation, the Corps would evaluate other opportunities within the American River Parkway in coordination with County Parks, USFWS, NMFS, and the ARFCD.

- If the above three opportunities are exhausted and further compensation is still required, the Corps would seek credits at a USFWS-approved mitigation bank.

SAFCA will mitigate for impacts to riparian habitat caused by levee improvements along Arcade Creek, and for removal of high-hazard trees that may affect the performance and reliability of existing levees on the Arcade Creek. SAFCA has identified some locations where native riparian vegetation could be established. Planting locations were selected to increase the patch size, improve habitat connectivity, and expand age class and species diversity of woodland habitat. These improvements would enhance nesting opportunities for native bird species.

Arcade Creek Habitat Improvements

Impacts caused by levee improvements and high-hazard tree removal along Arcade Creek would be mitigated on-site to the extent feasible by improving and expanding native wetland and riparian habitat adjacent to the low-flow channel within the reach between Rio Linda Boulevard and Marysville Boulevard, which is currently dominated by nonnative annual grasses and broadleaf weeds. Following construction, native wetland vegetation (e.g., Santa Barbara sedge, Baltic rush) would be planted along the banks of Arcade Creek, and one row of large riparian tree species (e.g., valley oak) would be planted along each bank of the low-flow channel. The tree spacing would be determined by the capacity of the floodplain to accommodate vegetation without impacting the desired flood performance. The dense, high overhead canopy of the trees as they mature would provide important shade to the low-flow channel and bank, cover for small mammals and a connected migration corridor for flying and gliding animals (both vertebrates and invertebrates). The SRA habitat along the active channel would benefit water quality by keeping temperatures lower (cooler water retains higher levels of dissolved oxygen needed to sustain native fish and aquatic invertebrates), and provide leaf drop and other organic material to support aquatic food webs. In addition, shade from streamside trees would help suppress some growth of dense red sesbania and willows in the understory to maintain flood conveyance, and prevent new colonization of invasive species.

Robla Creek Habitat Improvements

Replacement riparian woodlands are proposed either on Robla Creek Mitigation Site A, approximately 6 acres north of Rio Linda Boulevard, or on Robla Creek Mitigation Site B (approximately 7.1 acres south of Rio Linda Boulevard). Both sites are adjacent to and west of Robla Creek (Figure 18). Site A is a previous borrow site and is at a lower elevation making this area better suited for wetland mitigation. Site B is connected to the Robla Creek floodplain and is the site of a future multi-use recreational trail. SAFCA would provide right-of-way for future construction of the trail.

Figure 18. North Sacramento Streams Potential Robla Creek Mitigation Sites.

3.0 Federally Protected Species and Critical Habitat

Federally protected species and critical habitat that may be affected by the proposed action within the ARCF study area were determined through consultation with USFWS and NMFS. The Central Valley fall-/late fall–run Chinook salmon, which is an Evolutionarily Significant Unit (ESU) of special concern but is not Federally listed, is included because the project's effects on EFH must also be assessed.

3.1 Plants

Federally listed plant species are associated with habitat such as, salt marsh, dunes, or cismontane woodland/valley and foothill grasslands. Salt marsh habitat and cismontane woodland/valley and foothill grasslands are also very unlikely to occur along or adjacent to the levees. Due to the general lack of supporting habitat, potential impacts to Federally listed plants are not considered in this BA.

3.2 Invertebrates

3.2.1 Valley Elderberry Longhorn Beetle

Status and Distribution

The valley elderberry longhorn beetle is listed as a threatened species under the ESA (USFWS 1980). USFWS previously issued a proposed rule and a 12-month review finding on October 2, 2012 (77 FR 60238), to remove the valley elderberry longhorn beetle from the Federal endangered species list and to remove the designation of critical habitat for this species. In a proposed rule issued on September 17, 2014 (79 FR 55874), the USFWS withdrew the proposed rule to delist the species based on the best scientific and commercial data available and evaluation that indicated that threats to the species and its habitat have not been reduced such that removal of the species from the Federal endangered species list is appropriate and warranted.

The valley elderberry longhorn beetle's range extends from southern Shasta County to Fresno County (Talley et al. 2006). Along the eastern edge of the species' range, adult beetles have been found in the foothills of the Sierra Nevada at elevations up to 2,220 feet, and beetle exit holes have been located on elderberry plants at elevations up to 2,940 feet. Along the western edge of the species' range, adult beetles have been found on the eastern slopes of the Coast Ranges at elevations of up to

500 feet, and beetle exit holes have been detected on elderberry plants at elevations up to 730 feet (Barr 1991).

Critical habitat for the valley elderberry longhorn beetle occurs in two locations near the city of Sacramento (USFWS 1980). One area is enclosed by the Western Pacific railroad tracks and Highway 160, approximately one-half mile north of the American River near its confluence with the Sacramento River. The second site is located along the south bank of the American River at River Bend Park, just upstream of RM 13. Both of these areas are within the study area, however they would not be impacted by the proposed project. No bank protection measures are proposed in the area near Highway 160, and River Bend Park is upstream of the termination of the American River levees.

Life History and Habitat Requirements

Because historic loss of riparian habitat in the study area has already occurred, the rate of riparian habitat loss has slowed significantly over the last 30 years. During this period, incidental take of habitat has been authorized primarily for urbanization, transportation, water management, and flood control, on the order of 10,000 to 20,000 acres. Several habitat conservation plans are being developed to allow for continued urbanization of the Sacramento Valley (Talley et al. 2006).

Approximately 50,000 acres of existing riparian habitat in the Central Valley, primarily in the Sacramento Valley, have been protected by Federal, State, and local agencies as well as private organizations. Within the study area, large parcels of suitable habitat for the valley elderberry longhorn beetle have been protected, along the American River Parkway. Restoration of more than 5,000 acres of habitat has been initiated throughout the beetle's range (Talley et al. 2006). Mitigation for previous Corps projects has planted within the American River Parkway through agreements with Sacramento County Parks. Additional lands are currently available for mitigation that may be required for this project.

Valley elderberry longhorn beetle is only found in close association with its host plant, elderberry shrubs (*Sambucus* spp.). Elderberry shrubs are found in or near riparian and oak woodland habitats. The valley elderberry longhorn beetle's life history is assumed to follow a sequence of events similar to those of related taxa. Female beetles deposit eggs in crevices in the bark of living elderberry shrubs. Presumably, the eggs hatch shortly after they are laid, and the larvae bore into the pith of the trunk or stem. When larvae are ready to pupate, they move through the pith of the plant, open an emergence hole through the bark, and return to the pith for pupation. Adults exit through the emergence holes and can sometimes be found on elderberry foliage, flowers, or stems or on adjacent vegetation. The entire life cycle of the valley elderberry longhorn beetle is thought to encompass 1 or 2 years, from the time eggs are laid and hatch until adults emerge and die (USFWS 1984).

The presence of exit holes in elderberry stems indicates previous valley elderberry longhorn beetle habitat use. Exit holes are cylindrical and approximately 0.25 inch in diameter. Exit holes can be found on stems that are 1 or more inches in diameter. The holes may be located on the stems from a few inches to about 9 to 10 feet above the ground (Barr 1991).

Factors Affecting Abundance

The valley elderberry longhorn beetle distribution decline is most likely related to the extensive loss of riparian forests in the Central Valley, which has reduced the amount of available habitat for the species, and has most likely decreased and fragmented the species' range (USFWS 1984).

Insecticide drift from cultivated fields and orchards adjacent to elderberry plants may affect valley elderberry longhorn beetle populations, if drift occurs at a time when adults are present on the shrubs (Barr 1991). Herbicide drift from agricultural fields and orchards can likewise affect the health of elderberry plants, thereby reducing their quantity and quality as valley elderberry longhorn beetle habitat.

The invasive Argentine ant (*Linepithema humile*) has been spreading in riparian habitats and may affect survival of the valley elderberry longhorn beetle. Argentine ants may predate valley elderberry longhorn beetle eggs although this interaction needs further exploration (Huxel 2000). The spread of invasive exotic plants (e.g., giant reed [*Arundo donax*] may also negatively affect the valley elderberry longhorn beetle by affecting supporting riparian habitats. The presence of giant reed promotes a more frequent fire cycle and homogenous plant community (Talley et al. 2006).

3.2.2 Vernal Pool Fairy Shrimp

Status and Distribution

The vernal pool fairy shrimp is listed as a threatened species under the ESA (59 FR 48136). Fairy shrimp are endemic to vernal pools in the Central Valley, coast ranges, and a limited number of sites in the Transverse Range and Santa Rosa Plateau of California. . The most accurate indication of the distribution and abundance of vernal pool fairy shrimp is the number of inhabited vernal pool complexes. There are 32 known populations of the vernal pool fairy shrimp, extending from the Stillwater Plain in Shasta County through the Central Valley to Pixley in Tulare County. In addition, the shrimp occur along the central Coast Range from northern Solano County to Pinnacles National Monument in San Benito County.

Critical habitat for the vernal pool fairy shrimp is designated in the vicinity of the study area on lands surrounding Mather Field. There is no critical habitat for vernal pool fairy shrimp in the study area.

Life History and Habitat Requirements

Vernal pool fairy shrimp live in vernal pools, an ephemeral freshwater habitat. None are known to occur in riverine waters, marine waters, or other permanent bodies of water. They are ecologically dependent on seasonal fluctuations in their habitat, such as absence or presence of water during specific times of the year, duration of inundation, and other environmental factors that include specific salinity, conductivity, dissolved solids, and pH levels. Water chemistry is one of the most important factors in determining the distribution of fairy shrimp (Belk 1977).

Fairy shrimp and tadpole shrimp play an important role in the community ecology of many ephemeral water bodies (Loring et al. 1988). They are fed upon by waterfowl and other vertebrates, such as western spadefoot toad (*Scaphiopus hammondi*) tadpoles (Ahl 1991).

Fairy shrimp have delicate elongate bodies, large stalked compound eyes, no carapace, and 11 pairs of swimming legs. They swim or glide gracefully upside down by means of complex beating movements of the legs that pass in a wavelike, anterior-to-posterior direction. Nearly all fairy shrimp feed on algae, bacteria, protozoa, rotifers, and bits of detritus. Female shrimp drop their eggs to the pool bottom or eggs remain in the brood sac until the female dies and sinks. The "resting" or "summer" eggs are capable of withstanding heat, cold, and prolonged desiccation. When the pools refill in the same or subsequent seasons some, but not all, of the eggs may hatch. The egg bank in the soil may be comprised of the eggs from several years of breeding (Donald 1983). The eggs hatch when the vernal pools fill with rainwater. The early stages of the fairy shrimp develop rapidly into adults. These non-dormant populations often disappear early in the season long before the vernal pools dry up.

Vernal pools form in regions with Mediterranean climates where shallow depressions fill with water during fall and winter rains and then evaporate in the spring (Collie and Lathrop 1976). Downward percolation is prevented by the presence of an impervious subsurface layer, such as a claypan, hardpan, or volcanic stratum (Holland 1976, 1988). Due to local topography and geology, the pools are usually clustered into pool complexes (Holland and Jain 1988). Pools within a complex typically are separated by distances on the order of meters and may form dense, interconnected mosaics of small pools or a more sparse scattering of larger pools. Temporary inundation makes vernal pools too wet during the wetted period for adjacent upland plant species adapted to drier soil conditions, while rapid drying during late spring makes pool basins unsuitable for typical marsh or aquatic species that require a more permanent source of water. However, many indigenous plant and aquatic invertebrate species have evolved to occupy the extreme environmental conditions found in vernal pool habitats.

Factors Affecting Abundance

Vernal pools are in danger due to a variety of human-caused activities, including urban development, water supply and flood control activities, and conversion of land to agricultural use. Changes in hydrologic pattern, overgrazing, and off-road vehicle use also imperil this aquatic habitat . Habitat loss occurs from direct destruction and modification of pools by filling, grading, discing, leveling, and other activities. Vernal pools can also be indirectly impacted when modifications of the surrounding uplands alter the vernal pool watershed (USFWS 1992b). Diversion of watershed runoff feeding the pools can result in premature pool dry-down before the life cycle of the fairy shrimp is complete. The fairy shrimp is also intolerant of flowing water that washes away the egg bank. Supplemental water from outside the natural watershed into vernal pools can change the habitat into a marsh-dominated or a permanent aquatic community that is unsuitable for the
vernal pool shrimp.

Other secondary impacts associated with urbanization include disposal of waste materials into habitat for the four species included in this final rule (Bauder 1986, 1987). Disposal of concrete, tires, refrigerators, sofas, and other trash adversely affects these animals by eliminating habitat, disrupting pool hydrology or, in some cases, through release of toxic substances. Dust and other forms of air or water pollution from commercial development or agriculture projects also may be deleterious to these animals. Introduction of the bullfrog (*Rana catesbeiana*) to areas inhabited by the vernal pool tadpole shrimp appears to increase the threat of predation facing this crustacean.

3.2.3 Vernal Pool Tadpole Shrimp

Status and Distribution

The vernal pool tadpole shrimp is listed as an endangered species under the ESA (59 FR 48136). They are endemic to vernal pools in the Central Valley, coast ranges, and a limited number of sites in the Transverse Range and Santa Rosa Plateau of California. The most accurate indication of the distribution and abundance of the vernal pool tadpole shrimp is the number of inhabited vernal pool complexes. There are 18 known populations of vernal pool tadpole shrimp in the Central Valley, ranging from east of Redding in Shasta County south to the San Luis National Wildlife Refuge in Merced County.

Critical habitat for the vernal pool tadpole shrimp is designated in the vicinity of the study area on lands surrounding Mather Field. There is no critical habitat for vernal pool fairy shrimp in the study area.

Life History and Habitat Requirements

The life history of the vernal pool tadpole shrimp is linked to the phenology of the vernal pool habitat. None are known to occur in riverine waters, marine waters, or other permanent bodies of water. After winter rainwater fills the pools, the populations are reestablished from diapaused eggs that lie dormant in the dry pool sediments (Ahl 1991). Tadpole shrimp are primarily benthic animals that swim with their legs down. They climb or scramble over objects, as well as plow along in bottom sediments. Their diet consists of organic detritus and living organisms, such as fairy shrimp and other invertebrates (Pennak 1989).

A female surviving to large size may lay up to six clutches of eggs, totaling about 861 eggs in her lifetime (Ahl 1991). The eggs are sticky and readily adhere to plant matter and sediment particles (Simovich and Fugate 1992). A portion of the eggs hatch immediately and the rest enter diapause and remain in the soil to hatch during later rainy seasons (Ahl 1991). Ahl (1991) found that eggs in one pool hatched within three weeks of inundation and maturated to sexually reproductive adults in another three to four weeks. Simovich and Fugate (1992) reported sexually mature adults occurred in another pool three to four weeks after the pools had been filled. The vernal pool tadpole shrimp matures slowly and is a long-lived species (Ahl 1991). Adults are often present and reproductive until the pools dry up in the spring (Ahl 1991; Simovich et al. 1992).

Factors Affecting Abundance

Vernal pools are in danger due to a variety of human-caused activities, including urban development, water supply and flood control activities, and conversion of land to agricultural use. Changes in hydrologic pattern, overgrazing, and off-road vehicle use also imperil this aquatic habitat . Habitat loss occurs from direct destruction and modification of pools by filling, grading, discing, leveling, and other activities. Vernal pools can also be indirectly impacted when modifications of the surrounding uplands alter the vernal pool watershed (USFWS 1992b). Diversion of watershed runoff feeding the pools can result in premature pool dry-down before the life cycle of the tadpole shrimp is complete. The tadpole shrimp is also intolerant of flowing water that washes away the egg bank. Supplemental water from outside the natural watershed into vernal pools can change the habitat into a marsh-dominated or a permanent aquatic community that is unsuitable for the vernal pool tadpole shrimp.

Other secondary impacts associated with urbanization include disposal of waste materials into habitat for the four species included in this final rule (Bauder 1986, 1987). Disposal of concrete, tires, refrigerators, sofas, and other trash adversely affects these animals by eliminating habitat, disrupting pool hydrology or, in some cases, through release of toxic substances. Dust and other forms of air or water pollution from commercial development or agriculture projects also may be deleterious to these animals. Introduction of the bullfrog (*Rana catesbeiana*) to areas inhabited by the vernal pool tadpole shrimp appears to increase the threat of predation facing this crustacean.

3.3 Fish

Six fish species' ESUs or Distinct Population Segments (DPSs) and critical habitats are addressed below. These include Sacramento River winter-run Chinook salmon ESU, Central Valley spring-run Chinook salmon ESU, Central Valley fall-/late fall–run Chinook salmon ESU, Central Valley steelhead DPS, delta smelt, and green sturgeon southern DPS.

3.3.1 Sacramento River Winter-Run Chinook Salmon Evolutionarily Significant Unit

Status and Distribution

The Sacramento River winter-run Chinook salmon ESU (*Oncorhynchus tshawytscha*) was listed as threatened under the Federal ESA on August 4, 1989 (NMFS 1989). NMFS subsequently upgraded the Federal listing to endangered on January 4, 1994 (NMFS 1994). NMFS designated critical habitat for Sacramento River winter-run Chinook salmon on June 16, 1993 (NMFS 1993a). The ESU includes all naturally spawned populations of winter-run Chinook in the Sacramento River and its tributaries, as well as populations from two artificial propagation programs, one at the Livingston Stone National Fish Hatchery and the other at Bodega Marine Laboratory (NMFS 2005a).

Prior to construction of Shasta Dam, winter-run Chinook salmon spawned in the upper reaches of the Sacramento River, the McCloud River, and the lower Pit River. Spawning is now restricted to approximately 44 miles of the mainstem Sacramento River, immediately downstream of Keswick Dam (Yoshiyama et al. 1998). The abundance of winter-run Chinook salmon in the Sacramento River before Shasta Dam was constructed, is unknown. Some biologists believe the run was relatively small, possibly consisting of a few thousand fish (Slater 1963). Others, relying on anecdotal accounts, believe the run could have numbered more than 200,000 fish (NMFS 1993b). During the mid-1960s, more than 20 years after the construction of Shasta Dam, the population exceeded 80,000 fish (USBR 1986). The population declined substantially during the 1970s and 1980s.

In 1988, winter-run Chinook salmon escapement was estimated at 696 adults. Escapement continued to decline, diminishing to an estimated 430 fish in 1989 and 211 fish in 1990 (CDFW 2013b). The rapid decline in escapement during the late 1980s and early 1990s prompted listing of the winter-run Chinook salmon as endangered under the California ESA and the Federal ESA. Escapement in 1991 was estimated to be 1,240 fish, indicating good survival of the 1988 class. NMFS data indicates that the population has increased during the late 1990s through 2001. In 1995, returning spawners numbered 1,337 fish and in 2012, returning adults were estimated to be 6,123 (CDFW 2013b). Despite increased efforts to maintain and enhance the population of winter-run Chinook salmon by various entities, in their final listing determination of June 28, 2005, NMFS again found "that the Sacramento River winter-run Chinook salmon ESU in total is in danger of extinction throughout all or a significant portion of its range" and concludes that the ESU continues to warrant listing as an endangered species under the Federal ESA (NMFS 2005a).

Life History

Winter-run Chinook salmon spend 1 to 3 years in the ocean. Adult winter-run Chinook salmon leave the ocean and migrate through the Delta into the Sacramento River from December through July with peak migration in March. Adults spawn from mid-April through August (Moyle 2002). Egg incubation continues through October. The primary spawning habitat in the Sacramento River is above the Red Bluff Diversion Dam (RBDD) at RM 243, although spawning has been observed downstream as far as RM 218 (NMFS 2001). Spawning success below RBDD may be limited primarily by warm water temperatures (Hallock and Fisher 1985; Yoshiyama et al. 1998).

Downstream movement of juvenile winter-run Chinook salmon begins in August, soon after fry emerge. The peak abundance of juveniles moving downstream at Red Bluff occurs in September and October (Vogel and Marine 1991). Juvenile Chinook salmon move downstream from spawning areas in response to many factors, which may include inherited behavior, habitat availability, flow, competition for space and food, and water temperature. The numbers of juveniles that move and the timing of movement are highly variable. Storm events and their resulting high flows and turbidity appear to trigger downstream movement of substantial numbers of juvenile Chinook salmon.

Winter-run Chinook salmon smolts (i.e., juveniles that are physiologically ready to enter seawater) may migrate through the Delta and San Francisco Bay to the ocean from November through May (Yoshiyama et al. 1998). The Sacramento River channel is the main migration route through the Delta. However, the Yolo Bypass also provides significant outmigration passage during higher flow events.

During winter in the Sacramento–San Joaquin system, juveniles rear on seasonally inundated floodplains. Sommer et al. (2001) found higher growth and survival rates of juvenile Chinook salmon reared on the Yolo Bypass floodplain, than those that reared in the mainstem Sacramento River.

Factors Affecting Abundance

One of the main factors in the decline of Chinook salmon is habitat loss and degradation. On the Sacramento River, Shasta Dam blocked access to historical spawning and rearing habitat. Other factors affecting abundance include the effects of reservoir operations on water temperature, harvesting and fishing pressure, entrainment in diversions, contaminants, predation by non-native species, and interaction with hatchery stock (Corps 2000b).

In the Sacramento River, operation of the Central Valley Project (CVP) and State Water Project (SWP) influences river flow. Low flows can reduce habitat area and adversely affect water quality. The resulting warm water temperatures and low dissolved oxygen levels can stress incubating eggs and rearing juvenile winter-run Chinook salmon. Low flow may affect migration of juveniles and adults through increased water temperature or reduced velocity that slows downstream movement of juveniles. Low flow, in combination with diversions, may result in higher entrainment losses at the State and Federal pumping plants in the south Delta (Corps 2000b).

In the Delta, flow drawn through the Delta Cross Channel (DCC) and Georgiana Slough transports some percentage of downstream migrating salmon into the central Delta. The number of juveniles entering the DCC and Georgiana Slough is assumed to be proportional to the flow volume diverted from the Sacramento River (CDFG 1987). Survival of juvenile Chinook salmon that are drawn into the central Delta is lower than survival of juvenile Chinook salmon that remain in the Sacramento River channel.

<u>Critical Habitat/Essential Fish Habitat</u>

Within the ARCF GRR study area, the Sacramento River and Sacramento Bypass is considered to be critical habitat for winter-run Chinook salmon. Critical habitat includes the water column, river bottom, and adjacent riparian zone which fry and juveniles use for rearing (NMFS 2006b). The conservation value of critical habitat in the study area is high because it supports both recruitment and survival of juveniles and adults (NMFS 2006a).

EFH is defined as those waters and substrate necessary for spawning, breeding, feeding, or growth to maturity. EFH includes currently and historically accessible habitat. All reaches within the ARCF study area are considered to be essential fish habitat for winter-run Chinook salmon.

3.3.2 Central Valley Spring-Run Chinook Salmon Evolutionarily Significant Unit

<u>Status and Distribution</u>

The Central Valley spring-run Chinook salmon ESU (*Oncorhynchus tshawytscha*) was Federally listed as threatened on September 16, 1999 (NMFS 1999). Their threatened status was reaffirmed in NMFS's final listing determination issued on June 28, 2005 (NMFS 2005a). Critical habitat for Central Valley spring-run Chinook salmon was designated by NMFS on September 2, 2005 (NMFS 2005b). The ESU includes all naturally spawned spring-run Chinook salmon in the Sacramento River and its tributaries. Naturally spawned fish of hatchery origin in the Feather and Yuba Rivers as well as hatchery spawned fish in the Feather River are also included as a part of this ESU (NMFS 2005a).

Spring-run Chinook salmon may have once been the most abundant of Central Valley Chinook salmon (Mills and Fisher 1994), historically occupying the upstream reaches of all major river systems in the Central Valley where there were no natural barriers. Central Valley spring-run Chinook salmon are now restricted to the upper Sacramento River downstream of Keswick Dam; the Feather River downstream of Oroville Dam; the Yuba River downstream of Englebright Dam; several perennial tributaries of the Sacramento River (e.g., Deer, Mill, and Butte creeks); and the Delta.

The abundance of Central Valley spring-run Chinook salmon escapement, as measured by the number of adults returning to spawn from 1960 to 2013, averaged 10,236 adults for in-river natural spawners and 2,364 average adults returning to hatcheries (CDFW 2013b). Spring-run Chinook salmon spawn in the early fall and have interbred with fall-run Chinook salmon in the Sacramento and Feather Rivers. Genetically uncontaminated populations may exist in Deer Creek, Mill Creek, Butte Creek, and other eastside tributaries of the Sacramento River.

<u>Life History</u>

Adult spring-run Chinook salmon enter the mainstem Sacramento River from March through September, with the peak upstream migration occurring from May through June (Yoshiyama et al. 1998). Adults generally enter tributaries from the Sacramento River between mid-April and mid-June (Lindley et al. 2006 as cited in NMFS 2006b). Spring-run Chinook salmon are sexually immature during upstream migration, and adults hold in deep, cold pools near spawning habitat until spawning commences in late summer and fall. Spring-run Chinook salmon spawn in the upper reaches of the mainstem Sacramento River and tributary streams (USFWS 1995), with the largest tributary runs occurring in Butte, Deer, and Mill Creek's (Yoshiyama et al. 1998). Spawning typically begins in late August and may continue through October. Juveniles emerge in November and December in most locations but may emerge later when water temperature is cooler. Newly emerged fry remain in shallow, low-velocity edgewater (CDFG 1998).

Juvenile spring-run Chinook salmon typically spend up to one year rearing in fresh water before migrating to sea as yearlings, but some may migrate downstream as young-of-year juveniles. Rearing takes place in their natal streams, the mainstem of the Sacramento River, inundated floodplains (including the Sutter and Yolo bypasses), and the Delta. Based on observations in Butte Creek and the Sacramento River, young-of-year juveniles typically migrate from November through May. Yearling spring-run Chinook salmon migrate from October to March, with peak migration in November (Cramer and Demko 1997; Hill and Webber 1999). Downstream migration of yearlings typically coincides with the onset of the winter storm season, and migration may continue through March (CDFG 1998).

<u>Factors Affecting Abundance</u>

Main factors in the decline of spring-run Chinook salmon populations are habitat loss and degradation. Dams have blocked access to historical spawning and rearing habitat. Other factors affecting abundance of spring-run Chinook salmon include harvest, entrainment in diversions, contaminants, predation by non-native species, and interbreeding with fall-run Chinook salmon and hatchery stocks (Corps 2000b).

In the Sacramento River and its major tributaries, operation of the CVP and SWP controls river flow. Low flows limit habitat area and adversely affect water quality, such as warm water temperature and low dissolved oxygen that stress incubating eggs and rearing juveniles. Low flow may affect migration of juveniles and adults through inadequate water depth to support passage, or through reduced velocity that slows the downstream movement of juveniles. Low flow, in combination with diversions, may result in higher entrainment losses (Corps 2000b).

In the Delta, flow drawn through the DCC and Georgiana Slough transports some portion of downstream migrants into the central Delta. The number of juveniles entering the DCC and Georgiana Slough is assumed to be proportional to the flow volume diverted from the Sacramento River (CDFG 1987). Survival of juvenile Chinook salmon that are drawn into the central Delta is lower than survival of juvenile Chinook salmon that remain in the Sacramento River channel.

Critical Habitat/Essential Fish Habitat

Critical habitat for spring-run Chinook salmon includes all river channels and sloughs within the ARCF GRR study area on the Sacramento River and on the American River from the confluence to the Watt Avenue bridge. (NMFS 2006b). Critical habitat includes the stream channels and the lateral extent as defined by the ordinary high-water line or bank-full elevation. Primary constituent elements (PCEs) of critical habitat in the study area include: (1) freshwater rearing sites that have adequate water quality and quantity, floodplain connectivity, and natural cover that supports juvenile growth and mobility, and (2) freshwater migration corridors that support adequate water quantity and quality as well as natural cover to provide food and migration pathways for juveniles as well as adults. (NMFS 2005e, 2006b). The conservation value of critical habitat in the study area is high because it supports both recruitment and survival of juveniles and adults (NMFS 2006a).

EFH is defined as those waters and substrate necessary for spawning, breeding, feeding, or growth to maturity. EFH includes currently and historically accessible habitat. All reaches within the ARCF study area are considered to be EFH for spring-run Chinook salmon.

3.3.3 Central Valley Fall-/Late Fall–Run Chinook Salmon Evolutionarily Significant Unit

Status and Distribution

The Central Valley fall-/late fall–run Chinook salmon ESU (*Oncorhynchus tshawytscha*) is not listed under the Federal ESA. On March 9, 1998, NMFS issued a proposed rule to list fall-run Chinook salmon as threatened (NMFS 1998a). However, on September 16, 1999, NMFS determined that the species did not warrant listing (NMFS 1999). On April 15, 2004, NMFS classified Central Valley fall-/late fall–run Chinook salmon as a species of concern (NMFS 2004). However, EFH is designated for this species.

The Central Valley fall-/late fall–run Chinook salmon ESU includes all naturally spawned populations of fall-run Chinook salmon in the Sacramento and San Joaquin river basins and their tributaries. Central Valley fall-/late fall–run Chinook salmon are currently the most abundant and widespread salmon runs in California (Mills et al. 1997), representing about 80% of the total Chinook salmon produced in the Sacramento River drainage (Kjelson et al. 1982). The most abundant spawning populations of fall-/late fall–run Chinook salmon occur in the Sacramento, Feather, Yuba, and American rivers (Mills and Fisher 1994). Fall-run Chinook salmon in the Sacramento, Feather, and American rivers have a relatively large hatchery component, from 1952 to 2013 the average was 57,508 fish. The average escapement in-river on the Sacramento and San Joaquin system from 1960 to 2013 was 264,475 (CDFW 2013b).

Life History

Adult fall-run Chinook salmon migrate into the Sacramento River and its tributaries from June through December in mature condition and spawn from late September through December, soon after arriving at their spawning grounds (Yoshiyama et al. 1998). The spawning peak occurs in October and November. Emergence occurs from December through March, and juveniles migrate downstream to the ocean soon after emerging, rearing in fresh water for only a few months. Smolt outmigration typically occurs from March through July (Yoshiyama et al. 1998).

Late fall–run Chinook salmon migrate upstream before they are sexually mature, and hold near spawning grounds for 1 to 3 months before spawning. Upstream migration takes place from October through April and spawning occurs from late January through April, with peak spawning in February and March (Yoshiyama et al. 1998). Fry emerge from April through June. Juvenile late fall–run Chinook salmon rear in their natal streams during the summer, and in some streams they remain throughout the year. Smolt outmigration can occur from November through May (Yoshiyama et al. 1998).

Factors Affecting Abundance

Factors affecting abundance of fall-/late fall–run Chinook salmon are similar to factors affecting abundance of winter- and spring-run Chinook salmon, i.e., habitat loss and degradation. Fall-run Chinook salmon, however, typically use spawning habitat farther downstream than the spawning habitat used by spring- and winter-run Chinook salmon. The effect of dams on spawning habitat area for fall-run Chinook salmon is not as severe as for other runs, although access to substantial spawning habitat area has been blocked by dams.

Critical Habitat/Essential Fish Habitat

Critical habitat is not designated for fall-/late fall–run Chinook salmon, however EFH is designated for this species. EFH is defined as those waters and substrate necessary for spawning, breeding, feeding, or growth to maturity. EFH includes currently and historically accessible habitat. All reaches within the ARCF GRR study area are considered to be EFH for fall-/late fall-run Chinook salmon.

3.3.4 Central Valley Steelhead Distinct Population Segment

Status and Distribution

The Central Valley steelhead (*Oncorhynchus mykiss*) DPS was Federally listed as threatened on March 19, 1998 (NMFS 1998b). The threatened status of Central Valley steelhead was reaffirmed in NMFS's final listing determination on January 5, 2006 (NMFS 2006a); at the same time NMFS also adopted the term DPS, in place of ESU, to describe Central Valley steelhead and other population segments of this species. NMFS originally designated critical habitat for Central Valley steelhead on February 16, 2000 (NMFS 2000). However, following a lawsuit (*National Association of Home Builders et al. v. Donald L. Evans, Secretary of Commerce, et al.*), NMFS decided to rescind the listing and re-evaluate how to classify critical habitat for several DPSs of steelhead.

Critical habitat for Central Valley steelhead was re-designated by NMFS on September 2, 2005 (NMFS 2005b). The DPS includes all naturally spawned populations of steelhead in the Sacramento and San Joaquin rivers and their tributaries, excluding steelhead from San Francisco and San Pablo Bays and their tributaries. Artificially propagated fish from the Coleman and Feather River hatcheries are included in the DPS (NMFS 2006a).

Steelhead ranged throughout the tributaries of the Sacramento and San Joaquin rivers prior to dam construction, water development, and watershed perturbation dating from the 19th and 20th centuries. Wild stocks are now mostly confined to the upper Sacramento River downstream of Keswick Dam; upper Sacramento River tributaries such as Deer, Mill, and Antelope creeks; and the Yuba River downstream of Englebright Dam. Populations may also exist in Big Chico and Butte Creeks and a few wild steelhead are produced in the American and Feather rivers (McEwan and Jackson 1996). The abundance of naturally reproducing Central Valley steelhead, as measured by the number of adults returning to spawn, is largely unknown. Natural escapement in 1995 was estimated to be about 1,000 adults each for Mill and Deer creeks and the Yuba River (S. P. Cramer and Associates 1995). Hatchery returns have averaged around 10,000 adults (Mills and Fisher 1994). The most recent annual estimate of adults spawning upstream of RBDD is less than 2,000 fish (NMFS 2006a).

Life History

Central Valley steelhead have one of the most complex life histories of any salmonid species, exhibiting both anadromous and freshwater resident life histories. Freshwater residents typically are referred to as rainbow trout, and those exhibiting an anadromous life history are called steelhead (NMFS 1999). Steelhead exhibit highly variable life history patterns throughout their range but are broadly categorized into winter and summer reproductive ecotypes. Winter steelhead are the most widespread reproductive ecotype and the only type currently present in Central Valley streams (McEwan and Jackson 1996). Winter steelhead become sexually mature in the ocean, enter spawning streams in summer, fall or winter, and spawn a few months later in winter or late spring (Meehan and Bjornn 1991; Behnke 1992).

In the Sacramento River, adult winter steelhead migrate upstream during most months of the year, beginning in July, peaking in September, and continuing through February or March (Hallock 1987). Spawning occurs primarily from January through March, but may begin as early as late December and may extend through April (Hallock 1987). Individual steelhead may spawn more than once, returning to the ocean between each spawning migration.

Juvenile steelhead rear a minimum of one and typically two or more years in fresh water before migrating to the ocean as smolts. Juvenile migration to the ocean generally occurs from December through August. The peak months of juvenile migration are January to May (McEwan 2001). The importance of main channel and floodplain habitats to steelhead in the lower Sacramento River and upper Delta is not well understood. Steelhead smolts have been found in the Yolo Bypass during the period of winter and spring inundation (Sommer 2002), but the importance of this and other floodplain areas in the lower Sacramento River and upper Delta is not yet clear.

Factors Affecting Abundance

The decline in steelhead populations is attributable to changes in habitat quality and quantity. The availability of steelhead habitat in the Central Valley has been reduced by as much as 95% or more due to barriers created by dams (NMFS 1996a). Populations have been most severely affected by dams blocking access to the headwaters of all major tributaries; consequently, most runs are maintained through artificial production. The decline of naturally produced Central Valley steelhead has been more precipitous than that of hatchery stocks. Populations in the range’s southern portion have experienced the most severe declines (NMFS 1996b). Other factors contributing to the decline of steelhead in the Central Valley are mining, agriculture, urbanization, logging, harvest, hatchery influences, flow management (including reservoir operations), hydropower generation, and water diversion and extraction (NMFS 1996a).

Critical Habitat/Essential Fish Habitat

Habitat for endangered or threatened anadromous fish is designated as critical habitat under the ESA and as EFH under the MSA. EFH has been designated for Chinook salmon, but not for steelhead. Critical habitat for Central Valley steelhead includes the stream channels and the lateral extent as defined by the ordinary high-waterline or bank-full elevation in the designated stream reaches of the Sacramento and American River, NEMDC and Dry/Robla creek portions of the ARCF GRR. Primary constituent elements of critical habitat are as described for spring-run Chinook salmon (NMFS 2006b).

3.3.5 Delta Smelt

Status and Distribution

Delta smelt (*Hypomesus transpacificus*) was Federally listed as threatened on March 5, 1993 (USFWS 1993) and critical habitat was designated on December 19, 1994 (USFWS 1994). Population trends and abundance of delta smelt are poorly understood due to their short life span (1 year). Based on data from 21 years of monthly sampling in Suisun Marsh, delta smelt appear to be experiencing long-term declines (Matern et al. 2002). Summer tow-net and fall/mid-water trawl data show fluctuating annual abundance from 1991 through 1996, with an increasing trend in the late 1990s, followed by an overall decline in abundance since 1999 (Bryant and Souza 2004).

Life History

Delta smelt are endemic to the Sacramento–San Joaquin estuary and are found seasonally in Suisun Bay and Suisun Marsh. They typically are found in shallow water (less than 10 feet) where salinity ranges from 2 to 7 parts per thousand (ppt), although they have been observed at salinities between 0 and 18.4 ppt. Delta smelt have relatively low fecundity and most live for 1 year. They feed on planktonic copepods, cladocerans, amphipods, and insect larva (Moyle 2002).

Delta smelt are semi-anadromous. During their spawning migration, adults move into the freshwater channels and sloughs of the Delta between December and January. Spawning occurs between January and July, with peak spawning from April through mid-May (Moyle 2002). Spawning locations in the Delta have not been identified and are inferred from larval catches (Bennett 2005). Larval fish have been observed in Montezuma Slough; Suisun Slough in Suisun Marsh; the Napa River estuary; the Sacramento River above Rio Vista; and Cache, Lindsey, Georgiana, Prospect, Beaver, Hog, Sycamore, and Barker sloughs (Wang 1986, Moyle 2002, Stillwater Sciences 2006, and USFWS 1996). Spawning was also observed in the Sacramento River up to Garcia Bend (RM 51) during drought conditions, as a result of increased saltwater intrusion that moved delta smelt spawning and rearing farther inland (Wang and Brown 1993).

Laboratory experiments have found eggs to be adhesive, demersal, and usually attached to substrate composed of gravel, sand, or other submerged material (Moyle 2002, Wang 1991). Hatching takes approximately 9 to 13 days, and larvae begin feeding 4 to 5 days later. Newly hatched larvae contain a large oil globule that makes them semi-buoyant and allows them to stay near the bottom. As their fins and swim bladder develop, they move higher into the water column and are transported downstream to the open waters of the estuary (Moyle 2002).

Factors Affecting Abundance

Diversions and Delta inflow and outflow may affect survival of delta smelt. In water exported at the South Delta CVP and SWP export facilities, estimates of delta smelt entrainment suggest a population decline in the early 1980s, mirroring the decline indicated by mid-water trawl, summer tow-net, Kodiak trawl, and beach seine data (Bennett 2005). Diversions and upstream storage, including operation of the CVP and SWP, control Delta inflow and outflow during most months. Reduced Delta flow may inhibit or slow movement of larvae and juveniles to estuarine rearing habitat and into deeper and narrower channels of the Delta, resulting in lower prey availability and increased mortality from predators (Moyle 2002). Low Delta flow also may increase entrainment in diversions, including entrainment at the CVP and SWP export pumps (Moyle 2002). Additional factors affecting delta smelt abundance include extremely high river outflow that increases entrainment at export facilities, changes in prey abundance and composition, predation by nonnative species, toxic substances, disease, and loss of genetic integrity through interbreeding with the introduced Wagasaki smelt (Moyle 2002; CDFG 2000; Bennett 2005).

Critical Habitat/Essential Fish Habitat

Critical habitat for delta smelt consists of all water and all submerged lands below ordinary high water and the entire water column bounded by and contained in Suisun Bay (including the contiguous Grizzly and Honker bays); the length of Goodyear, Suisun, Cutoff, First Mallard (Spring Branch), and Montezuma sloughs; and the contiguous waters in the Delta (USFWS 1994). Critical habitat for delta smelt is designated in the following California counties: Alameda, Contra Costa, Sacramento, San Joaquin, Solano, and Yolo (USFWS 2003). Critical habitat in the ARCF GRR study area includes the Sacramento River up to the I Street Bridge and the Yolo Bypass just above Interstate 80 at the railroad tracks. Primary constituent elements of critical habitat determined to be essential to the conservation of the species include: physical habitat, water, river flow, and salinity concentrations required to maintain delta smelt habitat for spawning, larval and juvenile transport, rearing, and adult migration (USFWS 2006a).

3.3.6 Green Sturgeon Southern Distinct Population Segment

Status and Distribution

On January 23, 2003, NMFS determined that green sturgeon (*Acipenser medirostris*) are comprised of two populations, a northern and a southern DPS (NMFS 2003). The northern DPS includes populations extending from the Eel River northward, and the southern DPS includes populations south of the Eel River to the Sacramento River. The Sacramento River supports the southernmost spawning population of green sturgeon (Moyle 2002). On April 6, 2005, NMFS determined that the northern DPS does not warrant listing under the ESA, but it remains on the Species of Concern List (NMFS 2005c). On April 7, 2006, NMFS determined that the southern DPS of green sturgeon was threatened under the Federal ESA (NMFS 2006c). On October 9, 2009, NMFS (74 CFR 52300) designated critical habitat for the green sturgeon southern DPS throughout most of its occupied range.

Green sturgeon were classified as a Class 1 Species of Special Concern by CDFG in 1995 (Moyle et al. 1995). Class 1 Species of Special Concern are those that conform to the state definitions of threatened or endangered and could qualify for addition to the official list. On March 20, 2006, emergency green sturgeon regulations were put into effect by CDFG requiring a year-round zero bag limit of green sturgeon in all areas of the state (CDFG 2006).

Life History

The green sturgeon is anadromous, but it is the most marine-oriented of the sturgeon species and has been found in near shore marine waters from Mexico to the Bering Sea (NMFS 2005c). The southern DPS has a single spawning population in the Sacramento River (NMFS 2005d) and more recently spawning has been observed in the lower Feather River, a tributary of the Sacramento River (Seesholtz et al. 2012). Adults typically migrate upstream into rivers between late February and late July. Spawning occurs from March to July, with peak spawning from mid-April to mid-June. Green sturgeon are believed to spawn every 3 to 5 years, although recent evidence indicates that spawning may be as frequent as every 2 years (NMFS 2005c). Little is known about the specific spawning habitat preferences of green sturgeon. Adult green sturgeon are believed to broadcast their eggs in deep, fast water over large cobble substrate, where the eggs settle into the interstitial spaces (Moyle 2002). Spawning is generally associated with water temperatures from 46 to 57 degrees Fahrenheit (°F). In the Central Valley, spawning occurs in the Sacramento River upstream of Hamilton City, perhaps as far upstream as Keswick Dam (Adams et al. 2002) and the lower Feather River (Seesholtz et al. 2012).

Green sturgeon eggs hatch in approximately 8 days at 55°F (Moyle 2002). Larvae begin feeding 10 days after hatching. Metamorphosis to the juvenile stage is complete within 45 days of hatching. Juveniles spend 1 to 4 years in fresh and estuarine waters and migrate to salt water at lengths of 300 to 750 millimeters (mm) (NMFS 2005c).

Little is known about movements, habitat use, and feeding habits of green sturgeon. Green sturgeon have been salvaged at the state and Federal fish collection facilities in every month, indicating that they are present in the Delta year-round. Juveniles and adults are reported to feed on benthic invertebrates, including shrimp and amphipods, and small fish (NMFS 2005c).

<u>Factors Affecting Abundance</u>

The historical decline of the southern DPS of green sturgeon has been largely attributed to the reduction of spawning habitat area. Keswick and Shasta Dams on the Sacramento River and Oroville Dam on the Feather River are impassable barriers that prevent green sturgeon from accessing what were likely historical spawning grounds upstream of these dams. Other potential migration barriers or impediments include the Sacramento Deep Water Ship Channel locks, Fremont Weir, Sutter Bypass, the Delta Cross Channel, and Shanghai Bench and Sunset Pumps on the Feather River. Other factors that have been identified as potential threats to green sturgeon are reductions in freshwater outflow in the Delta during larval dispersal and rearing, high water temperatures during spawning and incubation, entrainment by water diversions, contaminants, predation and other impacts by introduced species, and poaching (NMFS 2005c).

<u>Critical Habitat/Essential Fish Habitat</u>

There is no EFH designated for green sturgeon. Designated critical habitat for the southern DPS of green sturgeon includes the Sacramento River downstream of Keswick Dam, the Feather River downstream of Oroville Dam, and the Yuba River downstream of Daguerre Dam; portions of Sutter and Yolo Bypasses; the legal Delta, excluding Five Mile Slough, Seven Mile Slough, Snodgrass Slough, Tom Paine Slough and Trapper Slough; and San Francisco, San Pablo, and Suisun bays. Freshwater habitat of green sturgeon of the southern DPS varies in function, depending on location within the Sacramento River watershed. Spawning areas currently are limited to accessible reaches of the Sacramento River upstream of Hamilton City and downstream of Keswick Dam (CDFG 2002) and portions of the Feather River (Seesholtz et al. 2012). Preferred spawning habitats are thought to contain large cobble in deep and cool pools with turbulent water (CDFG 2002; Moyle 2002; Adams et al. 2002). Sufficient flows are needed to sufficiently oxygenate and limit disease and fungal infection of recently laid eggs (Deng et al. 2002). Within the Sacramento River, spawning appears to be triggered by large increases in water flow during spawning (Brown and Michniuk 2007).

3.4 Amphibians

Two protected amphibian species were identified in the USFWS database records: the California red-legged frog (*Rana draytonii*) and the California tiger salamander (*Ambystoma californiense*) Amphibians are generally associated with smaller creeks, lentic habitats, and/or vernal pools. These aquatic habitats are generally not found along the ARCF reaches or in adjacent areas. Additionally, there are no known occurrences of these species in the action area. No suitable habitat for the salamander is present in the action area, and the action area is outside of the frog's extant range. Therefore, these listed amphibians are not considered further in this BA.

3.5 Reptiles

Two protected reptile species were identified in USFWS database records: the Alameda whipsnake (*Masticophis lateralis euryxanthus*) and giant garter snake (*Thamnophis gigas*). The range of the Alameda whipsnake is limited to Contra Costa and Alameda counties, which is not within the ARCF study area; therefore, Alameda whipsnake is dismissed and not discussed further in this BA.

3.5.1 Giant Garter Snake

Status and Distribution

The giant garter snake (*Thamnophis gigas*) is Federally listed as a threatened species under the ESA. Currently, this species is only known from 13 isolated population clusters within the Central Valley, from Chico to an area just southwest of Fresno (USFWS 1997). Giant garter snake populations that occur within the ARCF study area are within and adjacent to the Sacramento Bypass, which includes both small canals and rice fields. Additionally GGS is known to occur in the NEMDC north of the pump station at the Dry Creek north levee, however this is north of the ARCF GRR action area. SAFCA's Borrow Site 2 is located north of Dry Creek, so there is some potential for impacts to GGS in the NEMDC area.

Life History

The giant garter snake inhabits agricultural wetlands and associated waterways, including irrigation and drainage canals, rice fields, marshes, sloughs, ponds, low- gradient streams, and adjacent uplands. They have also been observed to use revetment as cover (Wylie et al. 2002). Giant garter snakes are believed to be most numerous in rice-growing regions (USFWS 1999b). Giant garter snakes are typically absent from the larger rivers; wetlands with sand, gravel, or rock substrates; and riparian areas lacking suitable basking sites or suitable prey populations (Hansen and Brode 1980; Brode 1988; USFWS 1999b). The giant garter snake hibernates from October to March in abandoned burrows of small mammals located above prevailing flood elevations (Fisher et al. 1994), and breeds during March and April.

Factors Affecting Abundance

Giant garter snakes have been reduced in distribution and abundance due to habitat loss and degradation throughout the Central Valley. Several factors may degrade habitat for giant garter snakes, including upstream watershed modifications, water storage and diversion projects, and urban and agricultural development. Contamination from agricultural runoff may also have detrimental effects. On-going agricultural practices such as tilling, grading, harvesting and operation of other equipment may also result in mortality and increased rates of predation. Clearing and maintenance of irrigation canals and draining of rice fields may also result in mortality and degradation of habitat (USFWS 1999b).

3.6 Birds

3.6.1 Western Yellow-Billed Cuckoo

The western yellow-billed cuckoo (*Coccyzus americanus occidentalis*) is was Federally listed as threatened in October 2014. Nesting western yellow-billed cuckoos no longer occur on the Sacramento River south of Colusa as the river has been channelized and riprapped from that point into the Sacramento-San Joaquin River Delta. However, nesting western yellow-billed cuckoo do occur south of the Sacramento area, and north of the Sacramento area, so there is some potential for migrant individuals to use the riparian habitats along the American River Parkway as they move between nesting habitat areas. As a result, this species is discussed in greater detail below.

Prior to construction activities, surveys would be conducted within the study area to determine where potential nest sites occur. The surveys would be conducted annually in close proximity to construction locations and within one-half mile of any anticipated construction. If any special status bird species are found, coordination with the resource agencies would occur and appropriate avoidance and minimization measures would be established prior to the start of construction.

Status and Distribution

Over the last 100 years, western cuckoo population declined dramatically due to extensive loss of suitable breeding habitat, primarily riparian forests and associated bottomlands dominated by willow (Salix spp.), cottonwood (Populus spp.), or mesquite (Prosopis spp.) (Gaines and Laymon 1984, Laymon and Halterman 1987, Hughes 1999). Once considered a common breeder in California, by 1940 the yellow-billed cuckoo suffered severe population reduction (Grinnell and Miller 1944) and by 1987 was estimated to occupy only 30 percent of its historical range (Laymon and Halterman 1987). California statewide surveys conducted in 1977 (Gaines and Laymon 1984), 1986/1987 (Laymon and Halterman

1987), and 1999 (Halterman et. al 2001) found yellow-billed cuckoo populations were concentrated mostly along the Sacramento River from Red Bluff to Colusa, along the South Fork of the Kern River, and portions of the Lower Colorado River. Population estimates on the Sacramento and Kern Rivers from the 1999 surveys were similar to those of the 1986/1987 surveys, but lower when compared to the 1977 survey. The Lower Colorado River population appeared to suffer severe declines in the 12 years from the 1986/87 to the 1999 surveys.

In 2001, USFWS determined that western yellow-billed cuckoos represent a Distinct Population Segment (DPS), and as such became a candidate for protective listing under the Endangered Species Act (USFWS 2001). In 2002, the listing was determined to be warranted but precluded by higher priority listing actions (due to limited resources) (USFWS 2002). In 2013, USFWS formally proposed that the Western DPS be listed as Threatened under the Endangered Species Act. On October 3, 2014, the proposed rule became effective and finalized the USFWS determination for listing the western yellow-billed cuckoo, but not its critical habitat.

Life History

Yellow-billed cuckoos are among the latest-arriving Neotropical migrants. They arrive on their breeding grounds in Arizona and California by June (Hughes 1999). Diet during the breeding season consists primarily of large insects such as grasshoppers, katydids, caterpillars, praying mantids, and cicadas; also tree frogs and small lizards (Hamilton and Hamilton 1965, Laymon 1980, Laymon et al. 1997). Nesting usually occurs between late June and late July, but can begin as early as late May and continue until late September (Hughes 1999). Nests consist of a loose platform of twigs, which are built by both sexes and take one to two days to build (Hughes 1999), though occasionally the nest of another species is used (Jay 1911, Bent 1940, Payne 2005). Clutch size is 1 to 5 (Payne 2005), though up to 8 eggs have been found in one nest due to more than one female laying in the nest (Bent 1940). Eggs are generally laid daily until clutch completion (Jay 1911), and incubation begins once the first egg is laid, lasting 9 to 11 days (Hughes 1999). Young hatch asynchronously and are fed mostly large insects (Laymon and Halterman 1985, Laymon et al. 1997, Halterman et al. 2009) similar to the adult diet. Young fledge after 5 to 9 days (6 days average), but may be dependent on adults for at least three weeks (Laymon and Halterman 1985).

Fall migration is thought to begin in late August, with most birds gone by mid-September (Hughes 1999); however on the Lower Colorado River some individuals appear to begin migrating in early August (McNeil et al. 2011). Their non-breeding range is believed to be the western side of the Andes (Hughes 1999), though little information exists on migration routes and non-breeding range in South America where they can be confused with the endemic pearly-breasted cuckoo (C. euleri), their closest relative (Payne 2005).

Factors Affecting Abundance

Habitat losses associated with manmade flood control and water management features that alter watercourse hydrology have contributed to the decline of the species. The natural processes that sustained riparian habitat in western North America have greatly diminished. Loss and degradation of habitat has occurred as a result of livestock overgrazing and encroachment from agriculture. These losses are exacerbated by the conversion of native habitat to predominantly nonnative vegetation. Habitat losses result in additional effects such as increased predation and reduced dispersal potential. These effects are associated with small and widely separated habitat patches. These threats are particularly persistent where small habitat patches are within proximity to human-altered landscapes, especially agricultural fields, resulting in the potential for pesticides to poison individual western yellow-billed cuckoos and reduce their prey base.

4.0 Environmental Baseline

This section describes the physical conditions and general vegetation, wildlife, and fisheries resources present within the ARCF action area. These conditions are first presented generally throughout the ARCF action area and then site specific SRA is analyzed as well as affected species in the ARCF action area. The environmental baseline provides information necessary to determine if the proposed action would jeopardize the continued existence of species being considered, and if the project can support long-term survival of these species in the action area.

The ARCF action area includes the mainstem Sacramento River from Freeport (RM 46) in the Delta upstream to the American River confluence (RM 60). The region also includes the lower American River from the confluence with the Sacramento River upstream to RM 11, NEMDC, Arcade Creek, Dry/Robla Creeks and Magpie Creek.

Downstream from the American River confluence, the Sacramento River is moderately sinuous (average sinuosity of 1.3), with the channel confined on both sides by man-made levees enhanced by decades of man-made additions. The channel in this reach is of uniform width, is not able to migrate, and is typically narrower and deeper relative to the upstream reach due to scour caused by the concentration of shear forces acting against the channel bed (Brice 1977). Channel migration is similarly limited along the lower American River because of man-made levees and regulated flows from Folsom Dam.

The natural banks and adjacent floodplains of both rivers are composed of silt- to gravel-sized particles with poor to high permeability. Historically, the flow regimes caused the deposition of a gradient of coarser to finer material, and longitudinal fining directed downstream (sand to bay muds). The deposition of these alluvial soils historically accumulated to form extensive natural levees and splays along the rivers, 5 to 20 feet above the floodplain for as far as 10 miles from the channel (Thompson 1961). The present day channels consist of fine-grained cohesive banks that erode due to natural processes as well as high flow events (Corps 2012).

Seasonal high flows enter the adjacent Yolo Bypass from this reach of the Sacramento River via the Sacramento Bypass (RM 63). Tidal influence emanating from Suisun Bay extends up the Sacramento River for 80 miles to Verona, with greater tidal variations occurring downstream during low river stages in summer and fall.

NEMDC is an approximately 13.3-mile, human-made, partially leveed drainage channel that provides drainage from Sankey Road and connects streams of the American Basin (Dry, Robla, and Arcade Creeks) to the American River. South of the confluence with Arcade Creek, the east and west levees of NEMDC are dominated by wild oats grasslands, while the channel is characterized by Fremont cottonwood forest, with smaller amounts of valley oak woodland, smart-weed cocklebur patches, and perennial rye grass fields.

The approximately 16.2-mile-long channel of Arcade Creek extends east-to-west from Orangevale to the American River, via NEMDC. The north and south levees are dominated by wild oats grasslands. Valley oak woodland is the main riparian vegetation type along Arcade Creek, but Fremont cottonwood forest occurs in small patches along the easternmost reach of Arcade Creek near NEMDC. Hardstem bulrush marsh is found within Arcade Creek near Norwood Avenue while water primrose wetlands are predominant within the channel of Arcade Creek from approximately the confluence with NEMDC to Norwood Avenue. East of Norwood Avenue, the creek channel becomes narrower, and dominated by a shaded canopy of valley oak woodland.

The environmental baseline in the ARCF GRR action area also includes the sites completed under the WRDA 1996 and WRDA 1999 authorizations for the project. The WRDA 1996 construction included installing slurry walls in the American River levees to address seepage and slope stability concerns. The WRDA 1999 construction included shape and slope improvements to specific reaches of the American River levee system, and some segments of the Sacramento River levees. Consultation has occurred on these sites throughout the construction period on an as-needed basis to ensure compliance with the ESA. The original project construction was coordinated with USFWS as the American River Watershed (Common Features) Project, Sacramento County, California. The Biological Opinions for these sites are on file with USFWS under Reference # 1-1-99-F-0078.

4.1 Vegetation

The ARCF study area consists of primarily riparian forest, valley oak woodland, riparian scrub-shrub habitat, and typically non-native annual grassland. Scrub-shrub generally refers to areas where the woody riparian canopy is composed of young trees or shrubs less than 20 feet high. Species that are typically found in riparian forest, valley oak woodland, and scrub habitats include cottonwood, several willow species, sycamore valley oak, black walnut, Oregon ash, white alder, boxelder, blue elderberry, buttonbush, Himalaya blackberry, wild grape, and poison oak. Understory vegetation may consist of an herbaceous layer of sedges, rushes, grasses, and forbs.

Riparian forest typically has a dominant overstory of cottonwood, California sycamore, black walnut, black willow, or valley oak. Dominant species found in the sub canopy may also include alder, ash and box elder. Layers of climbing vegetation make up part of the subcanopy, with wild grape being a major component, but wild cucumber and clematis vines are also found in riparian communities.

Several species of invasive non-native trees, shrubs and vines may be present in some riparian locations, predominantly red sesbania, Himalayan blackberry, tamarix, false bamboo, tree-of-heaven, eucalyptus, and ivy.

The herbaceous ruderal groundcover, primarily nonnative annual grassland, is found on most levees along the Sacramento River. It occurs on the levees and also within gaps in the riparian habitats. Plant species include wild oats, soft chess, ripgut brome, red brome, wild barley, Bermuda grass, and foxtail fescue. Common forbs include broadleaf filaree, red stem filaree, turkey mullein, clovers, and many others. The majority of these plants are not native to the project area.

4.1.1 Historical Human Resource Use and Current Riparian Vegetation

Historical precipitation and runoff patterns resulted in the Sacramento River being bordered by up to 500,000 acres of riparian forest, with valley oak woodland covering the higher river terraces (Katibah 1984). However, human activities of the 1800s and 1900s have substantially altered the hydrologic and fluvial geomorphic processes that create and maintain riparian forests within the Sacramento basin, resulting in both marked and subtle effects on riparian communities. Riparian recruitment and establishment models (Mahoney and Rood 1998; Bradley and Smith 1986) and empirical field studies (Scott et al. 1997, 1999) emphasize that hydrologic and fluvial processes play a central role in controlling the elevational and lateral extent of riparian plant species. These processes are especially important for pioneer species that establish in elevations close to the active channel, such as cottonwood and willows (*Salix* spp.). Failure of cottonwood recruitment and establishment is attributed to flow alterations by upstream dams (Roberts et al. 2001) and to isolation of the historic floodplain from the river channel. In addition, many of these formerly wide riparian corridors are now narrow and interrupted by levees and weirs. Finally, draining of wetlands, conversion of floodplains to agricultural fields, and intentional and unplanned introduction of exotic plant species have altered the composition and associated habitat functions of many of the riparian communities that are able to survive under current conditions.

4.1.2 Site-Specific Analysis of Riparian Vegetation

Analysis of total linear feet (lf) of SRA was conducted using Google Earth Pro for the reaches only associated with bank protection on the American and Sacramento Rivers in the ARCF action area (Table 8). However, site specific conditions at proposed bank protection sites will evaluate SRA habitat values using the SAM method of analysis to determine impacts and onsite compensation value based on actual designs. The East Side Tributaries were not evaluated because no bank erosion protection is planned. It should be noted however that there is minimal, if any, SRA associated with the tributaries in the reaches where construction is proposed, except Arcade Creek. Approximately 8 acres of trees along the Sacramento River would be removed to construct the new 1,500 foot Sacramento Weir. Additionally, in the area proposed to be incorporated into the Sacramento Bypass, there is approximately 236 acres of newly planted nut orchard trees as of summer 2015. In order to construct the widened bypass, these trees would be removed.

Identification of individual reaches in the ARCF action area can be seen in Figure 2. American River North (ARN) reaches A through I includes the north side of the American River and the East Side Tributaries. American River South (ARS) reaches A through G includes the south side of the American River and the east side of the Sacramento River.

Table 8. Summary of Reach-Specific SRA Analysis.

American River		Sacramento River	
Reach	**Linear Feet (lf) of SRA**	**Reach**	**Linear Feet (lf) of SRA**
ARN A	19,000	D	9,200
ARS A	6,850	E	8,850
ARS B	875	F	21,100
ARS C	3,800	G	11,150
Total	30,525	Total	50,300

4.2 American River Hydraulic Baseline

The American River levee system was originally intended to convey a discharge of 115,000 cfs. When the Joint Federal Project (JFP) is completed at Folsom Dam, in combination with levee repairs currently being completed under the Common Features Project (and other authorities) and the dam 3.5 foot raise, the intent is for the river to be able to convey a discharge of 160,000 cfs, assuming that the levees do not fail from one or more of the potential failure modes (i.e., seepage, stability, insufficient height, or erosion).

In addition, modifications of Folsom Dam operations will shift the way floods are released into the lower river from Folsom Dam. Specifically, frequent flood events, that is, floods which occur say once in every ten to twenty-five years, will have a larger peak discharge compared to those under current dam operations.

4.2.1 Folsom Dam Operations

In 2017, the Folsom Joint Federal Project (JFP) auxiliary spillway at Folsom Dam will be completed and a new water control manual will be adopted. This includes a 400,000 acre-feet to 600,000 acre-feet (400/600) variable flood space operation that takes incidental storage space in upstream reservoirs into consideration when determining flood storage requirements at Folsom Dam during the flood season. The JFP will allow dam operators to release larger quantities of water at lower reservoir stages and more efficiently utilize flood space in the reservoir.

While the JFP and new water control manual are not in place, these projects will be in operation prior to any construction occurring on the ARCF project. As a result, including the operation of the JFP as a part of the baseline condition of this project is a reasonable assumption for the ARCF GRR. Therefore, the ARCF GRR assesses the impacts associated with the increase in water within the Yolo Bypass that results from the widening of the Sacramento Weir and Bypass. Additional changes in flows from the operation of the JFP will be addressed in the forthcoming Folsom Dam Water Control Manual Update consultation. However, these flows are represented throughout this BA as a part of the Future Without Project Condition.

Table 9 lists a sample of the current and future peak discharges for a range of flood events. It is anticipated that the values will be updated as part of the Folsom Water Control Manual Update evaluation.

Table 9. Comparison of Peak Discharges in the American River between Current and Future Events.

	Current Conditions	Future Conditions
50% (1/2) ACE (2-year)	30,200	25,200
10% (1/10) ACE (10-year)	43,100	71,700
4% (1/25) ACE (25-year)	99,700	115,000
2% (1/50) ACE (50-year)	115,000	115,000
1% (1/100) ACE (100-year)	145,000	115,000
0.5% (1/200) ACE (200-year)	320,000	160,000

4.2.2 American River Erosion Susceptibility

The Lower American River, Erosion Susceptibility Analysis for Infrequent Flood Events, evaluated the potential for erosion of grass-covered levees and overbanks in response to different stream discharges resulting from releases of various magnitudes from Folsom Dam (Ayers, 2004). This study concluded that the river system is degrading under present operating conditions because the lower American River is starved of sediments by Folsom Dam and Nimbus Dam. Hardpan has been reached in the channel bottom as far downstream as Guy West Bridge (RM 7.0), and this hardpan is slowing further degradation. With the river starved for sediment and unable to further scour its channel the river is now eroding laterally to satisfy its need for sediment. Erosion of the riverbank is occurring even at low flow conditions of 7,000 cfs, which was the peak flow from the 2003 runoff season. Ongoing erosion has scarred the channel banks leaving them susceptible to further erosion, especially during high flow events. Lateral erosion is further reducing the amount of berm separating the main channel from the levee. The loss of vegetation on the berm and bank is leaving bare soil, which is more susceptible to erosion at a lower velocity than if the berm or bank was covered with vegetation.

Figure 19 shows the velocities for a discharge of 115,000 cfs, which average about 6 to 8 feet per second in the channel with maximum velocities ranging up to about 12 feet per second. Figure 20 shows the velocities for a discharge of 160,000 cfs which average about 6 to 9 feet per second in the channel with maximum velocities ranging up to about 13 feet per second. Of concern in both of these figures are the proximities of the relatively high velocities to the levees along the Lower American River. Additionally, the range of the computed velocities is of concern since the magnitude of the velocities is great enough to erode many of the relatively fine grained material present in the channel lining. The results of the analysis indicate that the large discharge events are capable of eroding the material typically found along the Lower American River channel.

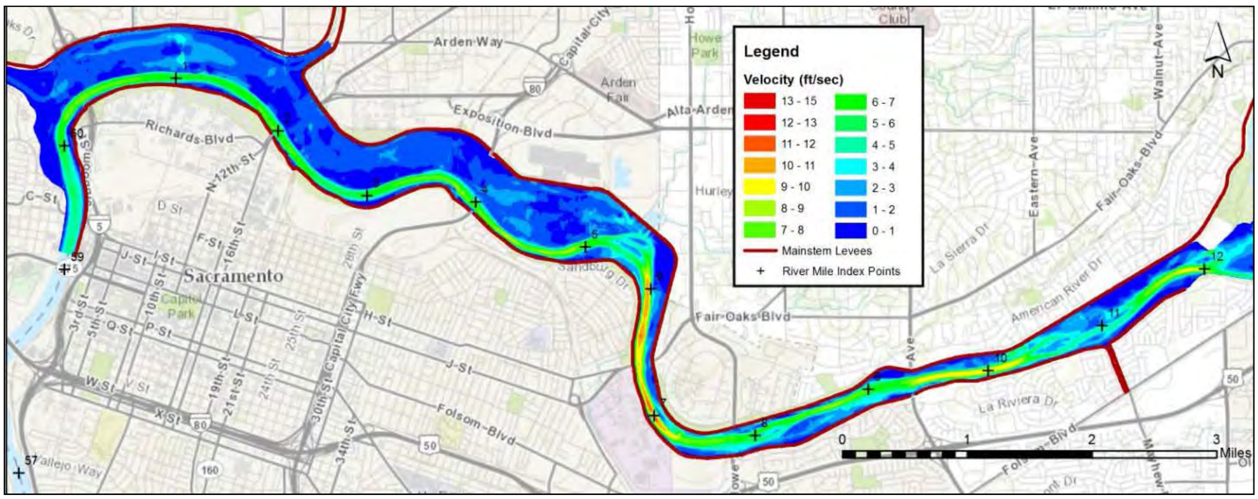

Figure 19. Velocities in the Lower American River at 115,000 cfs.

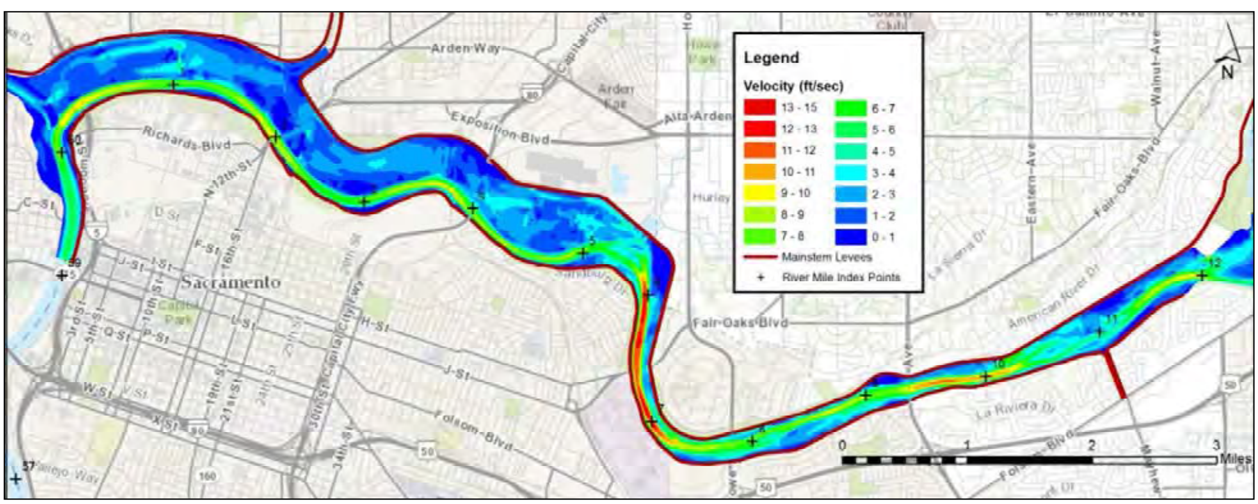

Figure 20. Velocities in the Lower American River at 160,000 cfs.

Figure 21 shows velocity contours in the area where erosion is greatest, between RM 6 and RM 7.5. As can be seen in Figure 21, velocities reach 11 feet per second for flows of 115,000 cfs, and get as high as 14 feet per second for 160,000 cfs. The study concluded that a flow of 145,000 cfs could cause damage at most of the study's identified priority sites, and could cause a levee failure to occur for at least one of the sites (Ayers, 2004). This reach of river represents the worst conditions regarding velocity (11 to 14 feet per second). Downstream and upstream of this reach, velocities in general for the same peak releases average in the 6 to 9 feet per second range.

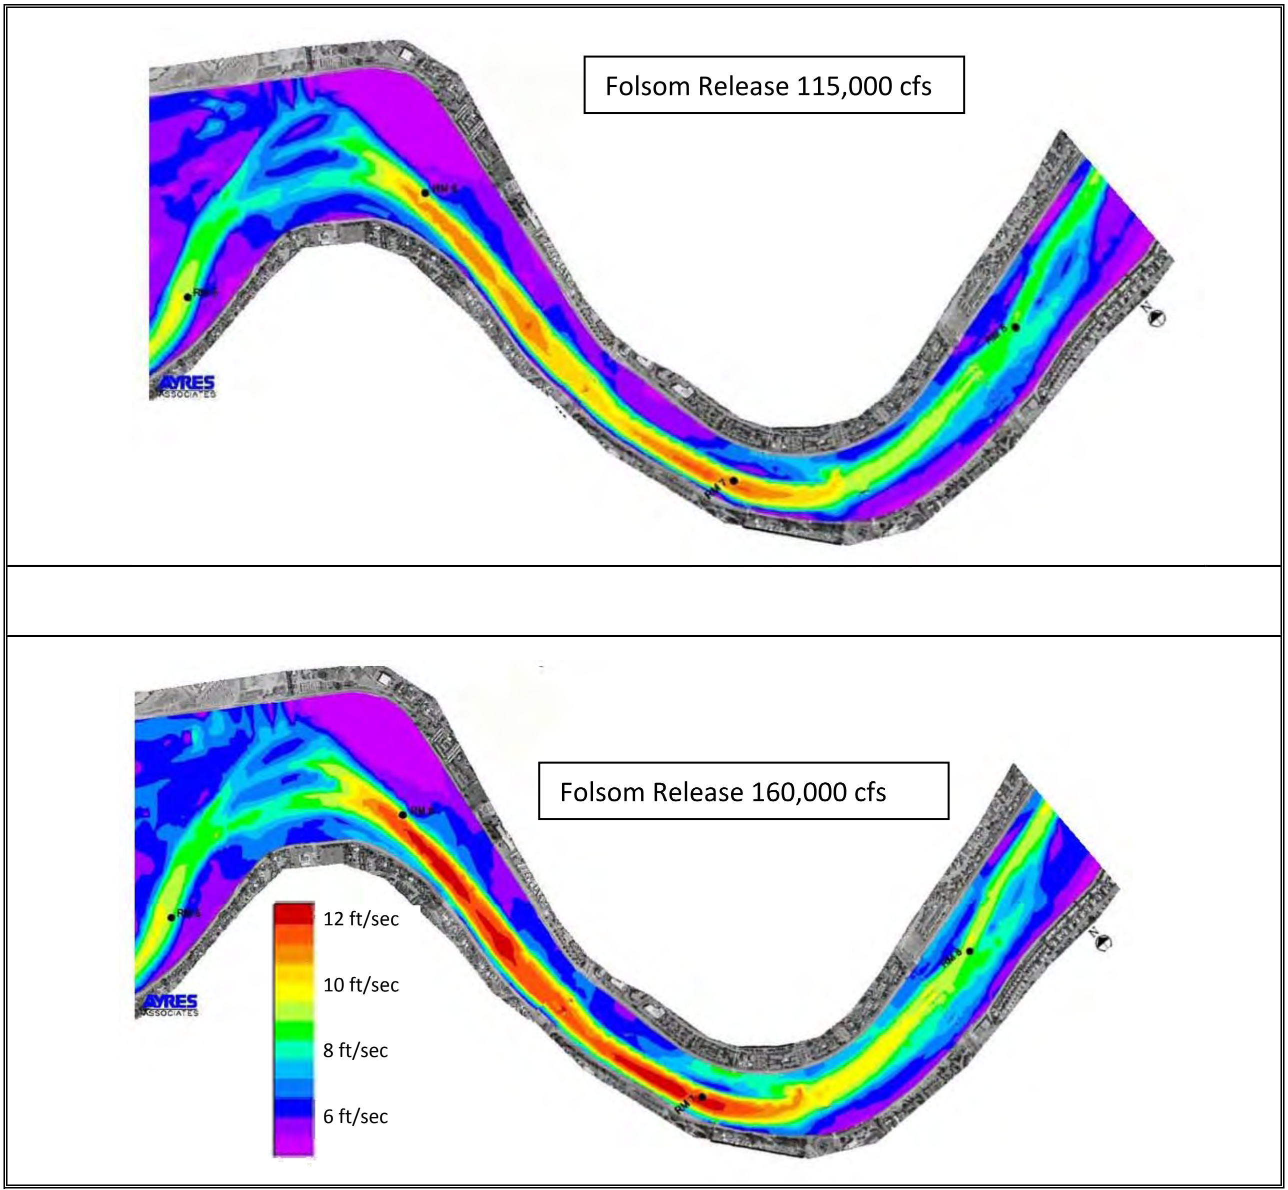

Figure 21. American River Velocity Contours.

Bare soil can withstand approximately 1.5 to 2.5 feet per second. Soil with good turf cover can withstand between 3.5 to 8 feet per second. The conditions of grass cover along the American River are not good and erosion occurs at velocities much less than the 11 to 14 feet per second in the RM 6 to RM 7.5 reach. This is illustrated by the fact that emergency erosion repairs have needed to occur as far downstream as near Highway 160 (RM 1.8) and as far upstream as between Watt Avenue and the Mayhew Drain (RM 10.2).

4.3 Affected Species in the Action Area

4.3.1 Valley Elderberry Longhorn Beetle

The valley elderberry longhorn beetle is listed as a threatened species under the ESA (USFWS 1980). The valley elderberry longhorn beetle's range extends from southern Shasta County to Fresno County (Talley et al. 2006). Along the eastern edge of the species' range, adult beetles have been found in the foothills of the Sierra Nevada at elevations up to 2,220 feet, and beetle exit holes have been located on elderberry plants at elevations up to 2,940 feet. Along the western edge of the species' range, adult beetles have been found on the eastern slopes of the Coast Ranges at elevations of up to 500 feet, and beetle exit holes have been detected on elderberry plants at elevations up to 730 feet (Barr 1991).

Valley elderberry longhorn beetle is only found in close association with its host plant, elderberry (Sambucus spp.). Elderberry plants are found in or near riparian and oak woodland habitats. The valley elderberry longhorn beetle's life history is assumed to follow a sequence of events similar to those of related taxa. Female beetles deposit eggs in crevices in the bark of living elderberry plants. Presumably, the eggs hatch shortly after they are laid, and the larvae bore into the pith of the trunk or stem. When larvae are ready to pupate, they move through the pith of the plant, open an emergence hole through the bark, and return to the pith for pupation. Adults exit through the emergence holes and can sometimes be found on elderberry foliage, flowers, or stems or on adjacent vegetation. The entire life cycle of the valley elderberry longhorn beetle is thought to encompass 2 years, from the time eggs are laid and hatch until adults emerge and die (USFWS 1984).

The presence of exit holes in elderberry stems indicates previous valley elderberry longhorn beetle habitat use. Exit holes are cylindrical and approximately 0.25 inch in diameter. Exit holes can be found on stems that are 1 or more inches in diameter. The holes may be located on the stems from a few inches to about 9 to 10 feet above the ground (Barr 1991).

The valley elderberry longhorn beetle distribution decline is most likely related to the extensive loss of riparian forests in the Central Valley, which has reduced the amount of available habitat for the species, and has most likely decreased and fragmented the species' range (USFWS 1984). Insecticide drift from cultivated fields and orchards adjacent to elderberry plants may affect valley elderberry longhorn beetle populations, if drift occurs at a time when adults are present on the shrubs (Barr 1991). Herbicide drift from agricultural fields and orchards can likewise affect the health of elderberry plants, thereby reducing their quantity and quality as valley elderberry longhorn beetle habitat.

The invasive Argentine ant (*Linepithema humile*) has been spreading in riparian habitats and may affect survival of the valley elderberry longhorn beetle. Argentine ants may predate valley elderberry longhorn beetle eggs although this interaction needs further exploration (Huxel, 2000). The spread of invasive exotic plants (e.g., giant reed [*Arundo donax*] may also negatively affect the valley elderberry longhorn beetle by affecting supporting riparian habitats. The presence of giant reed promotes a more frequent fire cycle and homogenous plant community (Talley et al. 2006).

Critical habitat for the valley elderberry longhorn beetle occurs in two locations near the City of Sacramento (USFWS 1980). One area is enclosed by the Western Pacific railroad tracks and Highway 160, approximately one-half mile north of the American River near its confluence with the Sacramento River. The second site is located along the south bank of the American River at Goethe Park, just upstream of RM 13.

VELB are known to occur throughout the ARCF GRR study area. The Corps conducted surveys in 2011 of the levee systems within the action area. The survey area consisted of the levee structures and 15 feet on both the waterside and landside; where access was available. The survey located elderberry clusters, however, actual shrubs, stem size, nor exit hole presence were determined. The surveys found the greatest amount of clusters on the south side of the American River and determined that both basins contain shrubs. All shrubs are considered to be in a riparian zone. Within the East Side Tributaries surveys were conducted identical to the American and Sacramento River. The only area where shrubs were located was along Arcade Creek, which contained two clusters of shrubs.

The American River Parkway has been the focus of a number of mitigation efforts from the confluence of the American and Sacramento Rivers (mitigation site 0.9, located at river mile [RM] 0.9 on the right side of the American River) up to Lake Natoma (Sailor Bar mitigation site located at RM 21 on the right side of the American River), elderberry mitigation sites create connectivity for potential translocation of valley elderberry longhorn beetles.

Additional VELB habitat within the Parkway has been created as part of previous Corps construction efforts, including:

- Site 0.9 on the right bank of American River at RM 0.9.
- Cal Expo: three distinct mitigation sites located between RM 3 and RM 4 on the right side of the American River.
- Site 11.5: elderberry mitigation site located near RM 11.5 on the right side of the American River.

- Mayhew: elderberry mitigation site located near RM 11 on the left side of the American River.
- River Bend Park: multiple mitigation sites located near RM 14 on the on the left side of the American River.
- Sailor Bar: mitigation site located near RM 21 on the right side of the American River.

These sites are currently being monitored and maintained by the Corps with annual reports provided to USFWS. Both the critical habitat are located in areas Operated and Maintained by the American River Flood Control District. The mitigation sites are maintained by SAFCA. Habitat maps of the American River Parkway showing locations of elderberry shrubs are included as Appendix F of the BA. Existing mitigation sites in the Parkway are identified in the maps in Appendix G of the BA.

Additional sites established by other agencies also exist along both sides of the American River, increasing connectivity to existing areas of critical habitat for the VELB. Additionally, future plans of restoration and mitigation could increase connectivity in large areas such as Woodlake, Bushy Lake, and Rossmoor. Smaller sites along the American River, including restoration efforts within the ARCF GRR construction footprint, would increase connectivity between these larger sites and the existing habitat within the American River Parkway. These additional sites would be assessed during the design phase of the ARCF GRR project for viability of future compensation efforts associated with this action.

4.3.2 Chinook Salmon and Steelhead

Four distinct runs of Chinook salmon occur in the ARCF action area: winter-run, spring-run, fall-run, and late fall–run. The runs are named after the season of adult migration, with each run having a distinct combination of adult migration, spawning, juvenile residency, and smolt migration periods. In general, fall- and late fall-run Chinook salmon spawn soon after entering their natal streams, while spring- and winter-run Chinook salmon typically hold in their natal streams for up to several months before spawning. Central Valley Steelhead also occurs in the ARCF action area. Immigration of adult steelhead in the Sacramento and American River's peaks in late September and October (Moyle 2002). The steelhead spawning season typically stretches from December through April. After several months, fry emerge from the gravel and begin to feed. Juveniles rear in fresh water from 1 to 4 years (usually 2 years), then migrate to the ocean as smolts in the spring (March through June).

During higher winter flow events in the East Side Tributaries there is suitable habitat in NEMDC, Arcade Creek and Dry/Robla Creek for the presence of fall/late-fall salmon. Central Valley steelhead are expected to occur in NEMDC as adults, migrating upstream to their spawning habitat, and as juveniles and smolts, rearing and migrating toward the ocean. Central Valley steelhead would not typically occur in Arcade Creek or Robla Creek, as these streams regularly lacks water quality conditions for spawning. NEMDC includes critical habitat for Central Valley steelhead, which uses this locations for juvenile rearing, juvenile migration, and adult migration (NMFS 2014). There is no critical fish habitat designation for Arcade and Robla Creeks.

During the intermittent years when the Sacramento Bypass is flooded in the winter and spring all four runs of juvenile Chinook salmon and steelhead can potentially use the floodplain for rearing and migration.

4.3.3 Green Sturgeon

Green sturgeon are known to occur in the lower reaches of large rivers, including the Sacramento River (Moyle 2002) and more recently spawning has been observed in the lower Feather River, a tributary of the Sacramento River (Seesholtz et al. 2012). Adults of this species tend to be associated with marine environments more than the more common white sturgeon, although spawning populations have been identified in the Sacramento and Klamath Rivers (Corps 1993). Juvenile rearing (natal stream to estuary) can occur year round in the Sacramento River action area.

Critical habitat for the green sturgeon extends into the American River upstream to the Highway 160 bridge where there is a potential to encounter adults and/or rearing juvenile green sturgeon. The Sacramento Bypass, when flooded, can support juvenile green sturgeon during downstream migration and rearing.

4.3.4 Delta Smelt

Adult delta smelt begin spawning migration into the upper Delta in December or January. Migration may continue over several months. Spawning occurs between January and July, with peak spawning during April through mid-May (Moyle 2002). Spawning occurs along the channel edges in the upper Delta, including the Sacramento River above Rio Vista, Cache Slough, Lindsey Slough, and Barker Slough. Spawning has been observed in the Sacramento River up to Garcia Bend below the confluence of the American River on the Sacramento River action area during drought conditions, possibly attributable to adult movement farther inland in response to saltwater intrusion (Wang and Brown 1993). The typical pattern is for delta smelt to inhabit the oligohaline to freshwater portion of the estuary for much of the year until late winter and early spring, when many migrate upstream to spawn (Sommer et al. 2011). There is evidence that some may not migrate to spawn. After hatching, their larvae and post-larvae subsequently migrate downstream in spring towards the brackish portion of the estuary (Dege and Brown 2004; Sommer and Mejia 2013).

Key progress in our understanding of delta smelt is that they are strongly associated with turbid water (Feyrer et al. 2007). Their results showed that, during fall, delta smelt are only present at locations where Secchi depth is less than 1 meter. This finding is consistent with Grimaldo et al. (2009), who found that delta smelt were not present in upstream areas when turbidities were less than about 12 NTU

(Sommer and Mejia 2013). It is likely that the lack of turbidity in the American River would be unsuitable for delta smelt.

The general pattern is that delta smelt cannot tolerate temperatures higher than 25 °C (Swanson et al. 2000). Hence, the 25 °C is used as a general guideline to assess the upper limits for delta smelt habitat (Wagner et al. 2011; Cloern et al. 2011). Downstream of the Delta, the smallest channel where adults and juveniles have been reported is Spring Branch Slough in Suisun Marsh, which averages about 15-m wide (Meng et al. 1994; Matern et al. 2002; Sommer and Mejia 2013). Due to higher temperatures and lack of suitable channel width the East Side Tributaries would not be suitable habitat for the delta smelt.

The northern-most reach of delta smelt critical habitat in the study area includes the Sacramento River up to the I Street Bridge on the east side and on the west side the critical habitat extends up the Yolo Bypass to the Union Pacific Railroad tracks just below the Sacramento Bypass along the I-80 corridor.

4.3.5 Giant Garter Snake

The giant garter snake inhabits agricultural wetlands and other waterways such as irrigation and drainage canals, sloughs, ponds, small lakes, low gradient streams, and adjacent uplands in the Central Valley. Because of the direct loss of natural habitat, the giant garter snake relies heavily on rice fields in the Sacramento Valley, but also uses managed marsh areas in Federal National Wildlife Refuges and State Wildlife Areas. Habitat loss and fragmentation, flood control activities, changes in agricultural and land management practices, predation from introduced species, parasites, water pollution, and continuing threats are the main causes for the decline of this species.

Rice fields and their adjacent irrigation and drainage canals serve an important role as aquatic habitat for giant garter snake as is the case adjacent to the Sacramento Bypass. The land proposed to be incorporated into the Sacramento Bypass is currently agricultural fields producing row crops and nut orchards. The associated drainage ditches and farm canals in this area are considered aquatic GGS habitat.

Habitat elements for GGS do occur along the east side of the NEMDC and other waterways of the east side tributaries, however, due to current habitat conditions, such as close proximity to urban development, high levels of human disturbance, scarcity of upland habitat, and riparian vegetation along the banks of most channel reaches, giant garter snakes are unlikely to occur in the Arcade, Dry/Robla, and Magpie Creek and the southern portion of NEMDC below Dry/Robla Creek. Large waterways, such as the Sacramento and American Rivers, do not provide suitable habitat for giant garter snake.

4.3.6 Vernal Pool Fairy Shrimp

The vernal pool fairy shrimp lives in vernal pools and swales containing clear to turbid water and grassy bottoms in unplowed grasslands. The shrimp is ecologically dependent on seasonal fluctuations in its habitat, such as presence or absence of water during specific times of the year, duration of water, temperature, and quantities of dissolved oxygen (USFWS 1992b).

There are 32 known populations of the vernal pool fairy shrimp, extending from the Stillwater Plain in Shasta County through the Central Valley to Pixley in Tulare County. In addition, the shrimp occur along the central Coast Range from northern Solano County to Pinnacles National Monument in San Benito County. Critical habitat is designated for a number of sub-populations of fairy shrimp throughout California. The closest critical habitat to the action area is a sub-population of vernal pool fairy shrimp in vernal pools near Mather Field in south-eastern Sacramento County. In the action area, vernal pools are known to occur near Magpie Creek, and there are recorded occurrences of vernal pool fairy shrimp in the CNDDB from 1995 (CNDDB 2015).

Vernal pool habitat is known to occur near Magpie Creek. Alongside the Magpie Creek Diversion Canal, there are some lands which could support vernal pools or vernal pool fairy shrimp that would be impacted by project construction. At this time, a wetland delineation has not been conducted to verify the occurrence of vernal pools; however, a wetland delineation would occur prior to project construction. Since the ARCF GRR is adopting the design of the 2004 Magpie Creek Flood Control Project, the impacts to vernal pools at this time were assessed based on that project's consultation. The proposed project would result in 0.25-acre of indirect effects to vernal pools/swales of potentially suitable vernal pool fairy shrimp habitat.

Seasonal wetlands, which may provide suitable habitat for vernal pool invertebrates, occur in the vicinity of the NSS project's Robla woodland mitigation site A, however any vernal pools in this area would be avoided by these activities. With the implementation of at 250-foot buffer between vernal pools and construction activities there would be no direct or indirect impacts from activities at Robla woodland mitigation site A. As a result, any mitigation efforts at the Robla woodland mitigation site would are not likely to adversely affect vernal pool fairy shrimp.

4.3.7 Vernal Pool Tadpole Shrimp

The vernal pool tadpole shrimp lives in vernal pools and swales containing clear to highly turbid water. The shrimp is ecologically dependent on seasonal fluctuations in its habitat, such as presence or absence of water during specific times of the year, duration of water, temperature, and quantities of dissolved oxygen (USFWS 1992b).

There are 18 known populations of vernal pool tadpole shrimp in the Central Valley, ranging from east of Redding in Shasta County south to the San Luis National Wildlife Refuge in Merced County. In the action area, vernal pools are known to occur near Magpie Creek, and there are recorded occurrences of vernal pool tadpole shrimp in the CNDDB from 1998 (CNDDB 2015).

Vernal pool habitat is known to occur near Magpie Creek. Alongside the Magpie Creek Diversion Canal, there are some lands which could support vernal pools or vernal pool tadpole shrimp that would be impacted by project construction. At this time, a wetland delineation has not been conducted to verify the occurrence of vernal pools; however, a wetland delineation would occur prior to project construction. Since the ARCF GRR is adopting the design of the 2004 Magpie Creek Flood Control Project, the impacts to vernal pools at this time were assessed based on that project's consultation. The proposed project would result in 0.25-acre of indirect effects to vernal pools/swales of potentially suitable vernal pool tadpole shrimp habitat.

Seasonal wetlands, which may provide suitable habitat for vernal pool invertebrates, occur in the vicinity of the NSS project's Robla woodland mitigation site A, however any vernal pools in this area would be avoided by these activities. With the implementation of at 250-foot buffer between vernal pools and construction activities there would be no direct or indirect impacts from activities at Robla woodland mitigation site A. As a result, any mitigation efforts at the Robla woodland mitigation site would are not likely to adversely affect vernal pool tadpole shrimp.

4.3.8 Western Yellow-Billed Cuckoo

Western yellow-billed cuckoo is Federally listed as threatened. The cuckoo is typically found in riparian forests with dense deciduous trees and shrubs. Over the last 100 years, western cuckoo population declined dramatically due to extensive loss of suitable breeding habitat, primarily riparian forests and associated bottomlands dominated by willow (Salix spp.), cottonwood (Populus spp.), or mesquite (Prosopis spp.) (Gaines and Laymon 1984, Laymon and Halterman 1987, Hughes 1999, Halterman et al. 2001). Once considered a common breeder in California, by 1940 the Yellow-billed Cuckoo suffered severe population reduction and by 1987 was estimated to occupy only 30 percent of its historical range (Laymon and Halterman 1987).

Nesting usually occurs between late June and late July, but can begin as early as late May and continue until late September (Hughes 1999). Nests consist of a loose platform of twigs, which are built by both sexes and take one to two days to build (Hughes 1999), though occasionally the nest of another species is used (Jay 1911, Bent 1940, Payne 2005). There are no recent CNDDB occurrences in the vicinity of the action area, but migrant individuals are likely to pass through the area in transit to breeding sites along the Sacramento River north of Colusa. Cuckoos are unlikely to nest in the study area, although potential dispersal and foraging habitat is present in the American River Parkway and along the Sacramento River.

5.0 Effects of the Proposed Action

5.1 Invertebrates

5.1.1 Valley Elderberry Longhorn Beetle

Effects to valley elderberry longhorn beetle may occur if elderberry shrubs are incidentally damaged by construction personnel or equipment. Impacts may also occur if elderberry shrubs need to be transplanted because they are located in areas that cannot be avoided by construction activities. During the design phase of the project, a site-specific assessment would occur in coordination with County Parks, project stakeholders, and the Services to determine which erosion protection measure is appropriate for each location in the Parkway. This assessment would take into account hydraulic conditions as well as environmental conditions of the site and would avoid and minimize impacts to riparian habitat and elderberry shrubs to the maximum extent practicable within the framework of the proposed project. Impacts that cannot be avoided or minimized would be mitigated, as described in Section 2.5 above.

Potential impacts due to damage or transplantation include direct mortality of beetles and/or disruption of their lifecycle. Since the project would occur over a 10 year period and construction would occur during beetle flight season, there could be direct mortality caused by construction activities. Elderberry shrubs that cannot be avoided would be transplanted between November and mid-February when the plants are doormat. Transplanting procedures will comply with the Conservation Guidelines for the Valley Elderberry Longhorn Beetle, USFWS, 9 July 1999.

Along the American River portion of the project, there is approximately 65 acres of riparian habitat that would be impacted, which includes elderberry shrubs. In this 65 acres, approximately 250 shrubs would be transplanted within the American River Parkway outside of the 15 foot vegetation free zone. The habitat maps in Appendix F show the locations of elderberry shrubs within the Parkway in 2013. Impacts to shrubs would be limited to approximately 40-feet waterward of the levee in most places. While impacts to these 250 shrubs would likely result in adverse effects to VELB, the majority of the shrubs in the Parkway, including the mitigation and restoration sites delineated on the maps in Appendix G, would not be impacted by the project. The majority of the impacts to VELB would occur on the stretch of the American River between Howe and Watt Avenues. Without implementation of compensation within this reach, connectivity of VELB habitat could be adversely impacted by the proposed measures.

Seedlings and native plants could be planted on top of the constructed trench to create similar connectivity as the existing conditions, or on the protected berms above bank protection sites. However, temporal loss of habitat may occur due to transplantation of elderberry shrubs. With transplants, new shrubs, and associated natives installed on the surface of the launchable rock trenches between Howe and Watt Avenues, and other compensation proposed in Section 2.5, connectivity for the beetle would be similar to the existing condition. Although compensation measures include restoration and creation of habitat, mitigation plantings would likely require one or more years to become large enough to provide supporting habitat. Furthermore, associated riparian habitats may take 25 years or longer to reach their full value.

Along the Sacramento River reach of the project, there is approximately 110 acres of riparian habitat that would be impacted, which includes elderberry shrubs. In this 110 acres, approximately 13 elderberry shrubs would be transplanted between November and mid-February. These shrubs would be transplanted to the River Bend Park mitigation site within the American River Parkway, or a new site coordinated with County Parks during the design phase of the project. Additionally, there is some potential for shrubs to be transplanted on site, where space is available, or to potential future mitigation sites in the Sacramento River corridor. Connectivity for the beetle could be affected by the reduction in shrubs if on-site compensation is not possible; however, impacts along this reach of the project are limited to the top half of the levee, which would be degraded in order to construct the slurry wall. The majority of the shrubs in this reach would likely not be located on the levee prism and would remain in place and provide sufficient connectivity.

For the NSS project, elderberry shrubs were not observed along Arcade Creek, NEMDC, or Borrow Site 2 during field surveys. Encroachment removal along Robla Creek would be limited to trimming back residential landscaping from a fence line and would have no potential for adverse impact to any elderberry shrubs, if present nearby. Elderberry shrubs could be present adjacent to potential woodland mitigation sites, including along Robla Creek. However, tree mitigation efforts would occur on open grassland areas and avoid disturbance of elderberry shrubs that may be nearby. Buffers would be established around elderberry shrubs in these areas as described in Section 2.5 above and would be maintained during all encroachment removal and mitigation installation activities. Further, implementation of the avoidance and minimization measures listed in Section 2.5 above would avoid the potential for direct and indirect effects on elderberry shrubs through the establishment of appropriate buffers.

Elderberry surveys done in 2011 by the Corps looked at the project area including the levee itself and 15 feet landside and 15 feet waterside. Only the locations of the shrubs were surveyed in order to get an idea of the magnitude of potential impacts. In order to determine affects to the beetle, detail elderberry shrub surveys from previous projects within the American River Parkway are being used as a representative sample for this project. The previous surveys were completed for other ARCF Projects along the American River Parkway within the project vicinity. These representative samples take into effect all project-related impacts to elderberry shrubs that would require mitigation, including incidental trimming of full stems for the purposes of providing access for project activities. The representative sample calculations are as follows; each shrub contains 13 stems measuring between 1 and 3 inches with no exit holes; 5 stems between 3 and 5 inches with .02 exit holes; and 2 stems greater than 5 inches with .07 exit holes. All shrubs are assumed to be in riparian habitat. Tables 10 and 11 include calculations of stems that would be affected with the implementation of this project and proposed compensation.

Operation and Maintenance

As part of long-term O&M, elderberry shrubs will be trimmed by the three levee maintenance districts. Table 12 describes the maximum amount of elderberry acreage that will be trimmed each year as a result of O&M. Trimming consists of cutting overhanging branches along the levee slopes on both the landside and waterside. Some shrubs may be located adjacent to the levee with branches hanging over the levee maintenance road. Up to a third of a shrub will be trimmed in a single season. Trimming will occur between November 1 and March 15. Loss of habitat will be offset through the development of a conservation area as described in the conservation measures below. Each year the local maintaining authority will document the amount of valley elderberry longhorn beetle habitat that they have trimmed and report that number to the Corps to ensure compliance with this biological opinion. If the local maintaining agency has a need to exceed the amount of valley elderberry longhorn beetle habitat which needs to be trimmed or affected due to routine maintenance then they will request the Corps reinitiate consultation on this biological opinion for those actions.

Table 12. O&M Elderberry Shrub Effects and Compensation.

O&M Agency	Annual Acreage Trimmed[1]	Life of Project Acreage[2]
American River Flood Control District	0.5 acre	25 acres
Maintenance Area 9	0.2 acre	10 acres
City of Sacramento	0.1 acre	5 acres

[1] Acreage was estimated based on a measurement of 0.009-acre per every 1/3[rd] of a shrub trimmed.
[2] Life of project is estimated to be 50 years.

5.1.2 Vernal Pool Fairy Shrimp

Effects to vernal pool fairy shrimp associated with the ARCF GRR's proposed Magpie Creek measures were addressed in the 2004 Biological Opinion for the Magpie Creek Flood Control Project (Appendix E).

For the NSS project, seasonal wetland habitat is present in annual grassland north of Robla Creek, including in the eastern portion of Robla woodland mitigation site A. Although riparian planting activities would not directly affect the seasonal wetland habitat, these activities could indirectly affect potentially suitable habitat for vernal pool invertebrates in this area by altering hydrology and/or degrading water quality. These effects could result in temporary loss of individuals, but the population could persist if the habitat is restored to its prior condition. However, implementation of the avoidance and minimization measures listed in Section 2.5 above would avoid and minimize the potential for indirect effects on suitable habitat for vernal pool invertebrates through the establishment of appropriate buffers.

5.1.3 Vernal Pool Tadpole Shrimp

Effects to vernal pool tadpole shrimp associated with the ARCF GRR's proposed Magpie Creek measures were addressed in the 2004 Biological Opinion for the Magpie Creek Flood Control Project (Appendix E).

For the NSS project, seasonal wetland habitat is present in annual grassland north of Robla Creek, including in the eastern portion of Robla woodland mitigation site A. Although riparian planting activities would not directly affect the seasonal wetland habitat, these activities could indirectly affect potentially suitable habitat for vernal pool invertebrates in this area by altering hydrology and/or degrading water quality. These effects could result in temporary loss of individuals, but the population could persist if the habitat is restored to its prior condition. However, implementation of the avoidance and minimization measures listed in Section 2.5 above would avoid and minimize the potential for indirect effects on suitable habitat for vernal pool invertebrates through the establishment of appropriate buffers.

5.2 Fish Species

The assessment of effects on fish considers the potential occurrence of protected species and life stages relative to the location, magnitude, timing, frequency, and duration of project actions. Species habitat attributes potentially affected by project implementation include spawning habitat area and quality, rearing habitat area and quality, migration habitat conditions, and water quality.

Short-term construction related effects on fish species include effects on individuals (e.g., displacement, disruption of essential behaviors, mortality) and immediate, short-term effects on habitat. These short-term effects are evaluated qualitatively and generally mitigated through the use of construction BMPs and limitations on construction windows.

Long-term effects typically last months or years, and generally involve physical alteration of the bank and riparian vegetation adjacent to the water's edge, with consequent impacts upon SRA cover, nearshore cover, and shallow water habitat (Fris and DeHaven 1993).

The operation and maintenance of the bank protection sites would include allowing the vegetation to grow to maturity and provide SRA habitat. There would be no sediment removal or clearing of vegetation along the planted bench after construction. The following statements will be added to the O&M manual once construction is completed to ensure sustainability of the created habitat. Therefore, affects from O&M activities would not be affect listed fish species and are not discussed in detail below.

Trees, either preserved or planted, on the berm within the project footprint of the bank protection site shall not be removed as part of normal maintenance as long as they remain healthy. As unhealthy trees are removed or fall over, any subsequent cavities in the rock must be filled in a timely manner with rock material equal to the surrounding repair. Leave the fallen trees in place.

Mitigation plantings installed on this site shall be left in a natural state. Following successful establishment of the habitat, no additional maintenance such as irrigation or mowing shall be required as a part of normal maintenance.

Soil placed on/in rock as a part of the original repair and all associated vegetation (grasses & woody shrubs/trees) within the footprint of the bank protection site does not require replacement as a part of normal maintenance. In other words if the soil is washed out it does not need to be replaced and re-vegetated.

During typical summer-fall conditions, focus fish species which include salmon, steelhead, green sturgeon, and delta smelt are generally absent in the Sacramento and Yolo Bypass. During winter-spring conditions, assuming inundation, the Yolo Bypass provides a large amount of available floodplain habitat for migration and rearing. Under the "worst case scenario" assumptions, project actions along the Sacramento Bypass levee reach would result in the removal of all trees and vegetation; due to the abundance of floodplain habitat during increased inundation with the widening of the Sacramento Bypass, it is highly unlikely that the loss of these shoreline habitat features would impact overall habitat that would be available and most likely utilized by salmon, steelhead, green sturgeon, and delta smelt in the Sacramento Bypass during winter-spring conditions.

5.2.1 Sacramento River Winter-Run Chinook Salmon

Potential project effects from the actions are described below for each life stage and its habitat. Effects on designated critical habitat are addressed via description of habitat effects for each applicable species.

Construction-Related Effects

Adult Migration

Construction activities may affect but are not likely to adversely affect winter-run adults because construction will avoid the primary migration period (December through July), will be restricted to the channel edge, and will include implementation of the avoidance and minimization measures described in Section 2.5. The work windows for all listed fish species that could be impacted by the project are shown on Table 13 below.

Spawning

Winter-run Chinook salmon do not spawn in the ARCF GRR action area. Therefore, the project will have no effect on winter-run Chinook salmon spawning or spawning habitat.

Juvenile Rearing and Migration

Rearing and emigrating juveniles and smolts may be found in the action area during the fall, winter, and spring. The abundance of juvenile winter-run Chinook salmon moving downstream peaks at Red Bluff in September and October and continues until mid March in drier years (Vogel and Marine 1991). Downstream migration may be triggered by storm events and the resulting high flow and turbidity, although the relative importance of various outmigration cues remains unclear.

Implementation of the bank erosion protection measures may result in adverse effects to juvenile and smolt winter-run Chinook salmon and their critical habitat. Construction activities that increase noise, turbidity, and suspended sediment may disrupt feeding or temporarily displace fish from preferred habitat. Rearing or outmigrating salmon may not be able to readily move away from nearshore areas that are directly affected by construction activities such as placement of rock revetment; these effects could result in stress, injury, or mortality. Take of juvenile or smolt winter-run Chinook salmon could therefore occur via mortality or injury during construction activity, or by the impairment of essential behaviors such as feeding or escape from predators. Substantial increases in suspended sediment could temporarily bury substrates that support benthic macroinvertebrates, an important food source for juvenile salmonids. However, due to the limited duration and spatial extent of project actions, effects on salmonid feeding are expected to be minimal. In addition, spills or leakage of gasoline, lubricants, or other petroleum products from construction equipment or storage containers could result in physiological impairment or mortality to rearing or outmigrating salmon in the vicinity of the project sites. With implementation of best management practices, the impacts due to spills should be minimal.

Restricting in-water activities to the August 1 through November 30 work window (beginning on July 1 for sites upstream of RM 60) and implementing the avoidance and minimization measures described in Section 2.5 will minimize, but may affect and is likely to adversely affect potential construction-related effects on juveniles and smolts.

Long-Term Effects

The ARCF GRR action area does not support spawning habitat for winter-run Chinook salmon, therefore the projects long-term effects will have no effect to spawning habitat.

Winter-run Chinook salmon are expected to show a long term positive response to project actions in the Sacramento River Standard Assessment Methodology (SAM) and American River SAM analysis reach over the lifetime of the project (Appendix B). Figures 22 through 24 below show the long term condition changes at a typical bank protection site over 10 years. Chinook salmon should exhibit a positive response by year 5. Short term habitat deficits are expected within the recommended recovery period for Chinook salmon. The maximum habitat deficit identified is -1,291 ft for the juvenile migration life stage of Spring-run Chinook salmon in the fall of year 11. Short term habitat deficits will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions.

Winter-run Chinook salmon are expected to show a small long term negative response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project. Winter-run Chinook salmon should exhibit a negative response by year 1. The maximum habitat deficit identified is -188 ft for the juvenile migration life stage of Winter-run Chinook salmon in the spring of year 2. Short term and long term habitat deficits will result from the loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions during and after the construction of the extension to the Sacramento Bypass Weir.

Figure 23. Bank Protection Site 4R in 2005

Figure 24. Bank Protection Site 4R in 2010.

5.2.2 Central Valley Spring-Run Chinook Salmon

Potential project effects for spring-run Chinook salmon are described below for each life stage and its habitat, including effects on designated critical habitat.

<u>Construction-Related Effects</u>

Adult Migration

Adult spring-run Chinook salmon migrate up the Sacramento River from March through September although most individuals have entered tributary streams by mid-June and will not be affected by construction activities. Therefore, potential for construction-related ARCF GRR project effects will be similar to that described for winter-run Chinook salmon.

Spawning

Spring-run Chinook salmon do not spawn in the ARCF GRR action area. Therefore, the project will have no effect on spring-run Chinook salmon spawning or spawning habitat.

Juvenile Rearing and Migration

Similar to winter-run Chinook salmon, spring-run Chinook salmon typically spend up to 1 year rearing in fresh water before migrating to sea. Therefore, potential for construction-related effects will be similar to that described for winter-run Chinook salmon above.

Restricting in-water activities to the August 1 through November 30 work window and implementing the avoidance and minimization measures described in Section 2.5 will minimize, but may affect and is likely to adversely affect potential construction-related effects on juveniles and smolts.

<u>Long-Term Effects</u>

The ARCF GRR area does not support spawning habitat for spring-run Chinook salmon, therefore the projects long-term effects will have no effect to spawning habitat.

Spring-run Chinook salmon are expected to show a long term positive response to project actions in the Sacramento River SAM and American River analysis reaches over the lifetime of the project (Appendix B). Figures 22 through 24 show the long term condition changes at a typical bank protection site over 10 years. Spring-run Chinook salmon should exhibit a positive response by year 5. Short term habitat deficits are expected within the recommended recovery period for spring-run Chinook salmon. The maximum habitat deficit identified is -1,440 feet for the juvenile migration life stage of spring-run Chinook salmon in the summer of year 10. Short term habitat deficits will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions. For juvenile spring-run Chinook salmon, the bank protection measures will generally provide long-term increases in bank shading at project sites. The plantings of native grasses and willows are designed to benefit juvenile Chinook salmon by increasing the availability (habitat area) and quality (shallow water and instream cover) of nearshore aquatic habitat and SRA relative to current conditions. Long term effects may affect but are not likely to adversely affect critical habitat for spring-run Chinook salmon juvenile rearing and migration.

Spring–run Chinook salmon are expected to show a small long term negative response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project. Chinook salmon should exhibit a negative response by year 1. The maximum habitat deficit identified is -188 feet for the juvenile migration life stage of spring-run Chinook salmon in the spring of year 2. Short term and long term habitat deficits will result from the loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions during and after the construction of the extension to the Sacramento Bypass Weir.

5.2.3 Central Valley Steelhead

Potential project effects for steelhead are described below for the relevant life stages and their habitat, including effects on designated critical habitat.

Construction-Related Effects

The levees along NEMDC are devoid of any tall vegetation or instream woody material and subsequently, construction activities would be approximately 100 feet from the east levee toe, outside of the wetted channel. As a result, the NSS levee improvements would not result in construction-related effects to steelhead.

Adult Migration

In the Sacramento River, adult steelhead migrate upstream during most months of the year, beginning in July, peaking in September, and continuing through February or March. Adults use the river channel in the action area as a migration pathway to upstream spawning habitat, and may also use deep pools with instream cover as resting and holding habitat. The potential for construction-related effects on migrating adult steelhead would be similar to that described above for adult winter-run Chinook salmon with the determination being that the construction-related activities may affect but are not likely to adversely affect adult migration.

Spawning

Within the ARCF GRR action area, potential spawning habitat is present in the American River, NEMDC, and Dry/Robla Creek. Steelhead spawn in late winter and late spring outside of the August 1-November 30 construction window; therefore, construction-related effects may affect but are not likely to adversely affect steelhead spawning or their spawning habitat.

Juvenile Rearing and Migration

Central Valley steelhead rear year-round in the cool upstream reaches of the mainstem Sacramento River and its major tributaries. Juveniles and smolts are most likely to be present in the action area during their downstream migration to the ocean, which may begin as early as December and peaks from January to May. The importance of main channel and floodplain habitats in the lower Sacramento River to rearing steelhead is becoming more understood.

Steelhead smolts have been found in the Yolo Bypass during the period of winter and spring inundation (Sommer 2002). Sommer et al. (2001) found that Juvenile Chinook salmon that reared within a large, engineered floodplain of the Sacramento River (the Yolo Bypass) had higher rates of growth and survival than fish that reared in the main-stem river channel during their migration. For purposes of this analysis, rearing juvenile steelhead are assumed to use nearshore and off-channel habitat in the action area. The potential for construction-related effects on steelhead juveniles and smolts and their habitat will therefore be similar to that described above for winter-run Chinook salmon which may affect and is likely to adversely affect.

Long-Term Effects

Steelhead are expected to show a long term positive response to project actions in the Sacramento River SAM and American River SAM analysis reaches over the lifetime of the project (Appendix B). Figures 22 through 24 show the long term condition changes at a typical bank protection site over 10 years. Steelhead should exhibit a positive response by year 5. Short term habitat deficits are expected within the recommended recovery period for Steelhead. The maximum habitat deficit identified is -1,330 ft for the juvenile migration life stage of Steelhead in the fall of year 11. Short term habitat deficits will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions.

Steelhead are expected to show a small long term negative response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project. Steelhead should exhibit a negative response by year 1. The maximum habitat deficit identified is -174 ft for the juvenile migration life stage in the spring of year 2. Short term and long term habitat deficits will result from the loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions during and after the construction of the extension to the Sacramento Bypass Weir.

The NSS project would result in long-term indirect effects on steelhead through modification of riparian and aquatic habitat, including channel bed and bank substrate. Additionally, SRA habitat would be impacted through the removal of approximately 5 trees. These impacts would be unlikely to adversely affect steelhead with the implementation of the measures described in Section 2.5 above.

5.2.4 Delta Smelt

Primary Constituent Elements

In determining which areas to designate as critical habitat, the Service considers those physical and biological features that are essential to a species' conservation (50 CFR 424.12[b]). The Service is required to list the known primary constituent elements together with a description of any critical habitat that is proposed. Such physical and biological features (i.e., primary constituent elements) include, but are not limited to, the following:

- Space for individual and population growth, and for normal behavior;
- Food, water, air, light, minerals, or other nutritional or physiological requirements;
- Cover or shelter;
- Sites for breeding, reproduction, rearing of offspring, germination, or seed dispersal; and
- Generally, habitats that are protected from disturbance or are representative of the historic geographical and ecological distributions of a species.

The primary constituent elements essential to the conservation of the delta smelt are physical habitat, water, river flow, and salinity concentrations required to maintain delta smelt habitat for spawning, larval and juvenile transport, rearing, and adult migration (NMFS 1994a).

Spawning Habitat

Delta smelt adults seek shallow, fresh or slightly brackish backwater sloughs and edgewaters for spawning. To ensure egg hatching and larval viability, spawning areas also must provide suitable water quality (i.e., low concentrations of pollutants) and substrates for egg attachment (e.g., submerged tree roots and branches and emergent vegetation). Specific areas that have been identified as important delta smelt spawning habitat include Barker, Lindsey, Cache, Prospect, Georgiana, Beaver, Hog, and Sycamore sloughs and the Sacramento River in the Delta, and tributaries of northern Suisun Bay. The spawning season varies from year to year and may start as early as December and extend until July (NMFS 1994a).

Larval and Juvenile Transport

To ensure that delta smelt larvae are transported from the area where they are hatched to shallow, productive rearing or nursery habitat, the Sacramento and San Joaquin Rivers and their tributary channels must be protected from physical disturbance (e.g., sand and gravel mining, diking, dredging, and levee or bank protection and maintenance) and flow disruption (e.g., water diversions that result in entrainment and in-channel barriers or tidal gates). Adequate river flow is necessary to transport larvae from upstream spawning areas to rearing habitat in Suisun Bay. Additionally, river flow must be adequate to prevent interception of larval transport by the State and Federal water projects and smaller agricultural diversions in the Delta. To ensure that suitable rearing habitat is available in Suisun Bay, the 2 ppt isohaline must be located westward of the Sacramento-San Joaquin River confluence during the period when larvae or juveniles are being transported, according to the historical salinity conditions which vary according to water-year type. Reverse flows that maintain larvae upstream in deep-channel regions of low productivity and expose them to entrainment interfere with these transport requirements. Suitable water quality must be provided so that maturation is not impaired by pollutant concentrations. The specific geographic area important for larval transport is confined to waters contained within the legal boundary of the Delta, Suisun Bay, and Montezuma Slough and its tributaries. The specific season when habitat conditions identified above are important for successful larval transport varies from year to year, depending on when peak spawning occurs and on the water-year type. The Service identified situations in the biological opinion for the delta smelt (1994) where additional flows might be required in the July-August period to protect delta smelt that were present in the south and central Delta from being entrained in the State and Federal project pumps, and to avoid jeopardy to the species. The long-term biological opinion on CVP-SWP operations will identify situations where additional flows may be required after the February through June period identified by EPA for its water quality standards to protect delta smelt in the south and central Delta (USFWS 1994).

Rearing Habitat

Maintenance of the 2 ppt isohaline according to the historical salinity conditions described above and suitable water quality (low concentrations of pollutants) within the Estuary is necessary to provide delta smelt larvae and juveniles a shallow, protective, food-rich environment in which to mature to adulthood. This placement of the 2 ppt isohaline also serves to protect larval, juvenile, and adult delta smelt from entrainment in the State and Federal water projects. An area extending eastward from Carquinez Strait, including Suisun Bay, Grizzly Bay, Honker Bay, Montezuma Slough and its tributary sloughs, up the Sacramento River to its confluence with Three Mile Slough, and south along the San Joaquin River including Big Break, defines the specific geographic area critical to the maintenance of suitable rearing habitat. Three Mile Slough represents the approximate location of the most upstream extent of tidal excursion when the historical salinity conditions described above are implemented. Protection of rearing habitat conditions may be required from the beginning of February through the summer (USFWS 1994).

Adult Migration

Adult delta smelt must be provided unrestricted access to suitable spawning habitat in a period that may extend from December to July. Adequate flow and suitable water quality may need to be maintained to attract migrating adults in the Sacramento and San Joaquin River channels and their associated tributaries, including Cache and Montezuma sloughs and their tributaries. These areas also should be protected from physical disturbance and flow disruption during migratory periods (USFWS 1994).

Construction-Related Effects

Delta smelt in the Sacramento River have been documented upstream as far as the city of Sacramento (RM 60) (Moyle 2002), and may be present throughout their life cycle. Potential project effects are described below for relevant life stages and their habitats, including effects on designated critical habitat.

Adult Migration

Adult Delta smelt migrate upstream between December and January and spawn between January and July, with a peak in spawning activity between April and mid-May (Moyle 2002). Potential construction-related effects to physical habitat, water, river flow, and salinity concentrations for migrating adult Delta Smelt will be avoided or minimized by restricting in water construction activities on the Sacramento River to the August 1 through November 30 work window allowing for unrestricted access to suitable and important spawning habitat. If there is any change in effect due to construction constraints outside the work window, consultation will be initiated. Construction-related effects may affect but are not likely to adversely affect adult migration.

Spawning

Potential spawning habitat includes shallow channel edge waters in the Delta and Sacramento River. Specific areas that have been identified below the ARCF GRR project area as important delta smelt spawning habitat include Barker, Lindsey, Cache, Prospect, Georgiana, Beaver, Hog, and Sycamore sloughs and the Sacramento River in the Delta, and tributaries of northern Suisun Bay. As a result, potential construction-related effects to delta smelt physical habitat would include disruption of spawning activities, disturbance or mortality of eggs and newly hatched larvae, alteration of spawning and incubation habitat, and loss of shallow water habitat for spawning.

The erosion repair is likely to somewhat reduce the sediment supply for riverine reaches directly downstream because the erosion repair is holding the bank or levee in place. However, from a system sediment prospective, the bank material we are protecting in the project reaches is not a major source of sediment compared to the upstream reaches of the Sacramento, Feather, and especially the Yuba River systems. All of the available sediment in the American River watershed is being contained behind

Folsom Dam. The site specific designs will be constrained from allowing any velocity increases outside the erosion repair site (Schlunegger 2014).

In response to a USFWS request for more data on July 23, 2014, the Corps conducted an analysis of existing shallow water habitat in the ARCF GRR project area, and the effect of the proposed project on that habitat. The results of this analysis are included as Appendix C to this report. This analysis was based on a cross section geometry with the assumption that the sediment or sand will be converted to rock revetment. The conclusion of the analysis was that approximately 14 acres of shallow water habitat would be permanently lost as a result of implementation of the ARCF GRR with 46 acres of spawning habitat being affected by a long-term change in substrate from sand to rock. The footprint could be minimized as site-specific designs are developed during the PED phase of the project and will be further coordinated with USFWS at that time. Compensation would involve the purchase of 42 credits of shallow water habitat replacement and 32 credits to compensate for the permanent change in spawning substrate at a USFWS-approved mitigation bank.

Construction-related effects on delta smelt spawning and incubation will be minimized by restricting in-water construction activities on the Sacramento River and Sacramento Weir and Bypass to the August 1 through November 30 work window, thereby avoiding the seasons when spawning is most likely to occur, however construction activities may affect and is likely to adversely affect delta smelt spawning habitat.

Juvenile Rearing and Migration

Juvenile delta smelt may be subject to disturbance or displacement caused by construction activities that would alter physical habitat, water, and river flow in the form of increased noise, turbidity, and suspended sediment. Delta smelt may not be readily able to move away from channel or nearshore areas that are directly affected by construction activities (i.e., removal or placement of instream woody material, placement of rock revetment). Larvae may be disrupted during summer months as they migrate downstream to rear in the Delta. Incidental take of delta smelt may occur from direct mortality or injury during a construction activity, or by the impairment of essential behavior patterns (i.e., feeding, escape from predators). Salinity concentrations would not be affected by the construction activity. Construction-related effects on delta smelt rearing and migration will be minimized by restricting in-water construction activities on the Sacramento River to the August 1 through November 30 work window, thereby avoiding the seasons when these life stages are most likely to occur. Construction-related activities may affect and is likely to adversely affect juvenile rearing and migration.

Long-Term Effects

Non-native species may exploit the warmer water temperature in the shallow bench habitat created as an on-site mitigation feature and prey on delta smelt eggs and larvae; however, bench habitat would most likely not bring in more predatory fish that don't already exist in the project area. A 2013 long-term aquatic monitoring program draft report by FishBio for the Corps noted that Black bass (largemouth and smallmouth bass) have the highest probability of habitat occupancy at both Sacramento River Bank Protection Project (SRBPP) sites with bench features and sites with no bench features. Unlike previous years, when highest bass abundance was typically associated with wetland trench designs (not included in the suite of monitored sites in 2013), the highest likelihood of encountering black bass was observed at no bench and bench sites, in particular those near rivermile 70, well above the project area (Corps 2013b). Proposed planting of emergent vegetation will enhance habitat complexity by providing cover and incubation habitat, especially during high winter and spring flows.

5.2.5 Green Sturgeon

Potential project effects are described below for each life stage of green sturgeon and its habitat. An accurate assessment of potential project effects on green sturgeon and its habitat is difficult due to the limited information available on distribution, seasonal abundance, habitat preferences, and other life history requirements of this species.

Construction-Related Effects

Adult Migration

Adult green sturgeon are believed to move upstream through the Sacramento River ARCF action area from February through late July (NMFS 2005c). Construction activities occurring outside of these time periods are not likely to affect migrating green sturgeon adults. Construction activities during July, however, may have adverse impacts on any adult green sturgeon that are still migrating upstream. Because construction activities will largely avoid the peak migration period, will be restricted to the channel edge, and will implement the avoidance and minimization measures described in Section 2.5, construction-related activities may affect but are not likely to adversely affect adult migration.

Spawning

Spawning migrations of Green Sturgeon typically occur during the months of March through June (Thomas et al. 2013). The Sacramento River downstream of Knights Landing (RM 90) is not believed to have suitable spawning habitat for green sturgeon, primarily due to lack of suitable coarse bottom substrate such as large cobbles (Corps 2012). Therefore, the ARCF GRR project will have no affect on spawning green sturgeon or their habitat.

Juvenile Rearing and Migration

Based on general knowledge of green sturgeon life history, larvae may occur in the Sacramento River and Delta shortly after spawning, from February through late July (peak spawning from April through June) (Emmett et al. 1991 as cited in Moyle 2002). Restricting in-water construction activities to the August 1 through November 30 work window and implementing the avoidance and minimization measures described in Section 2.5, will minimize potential impacts of in-water construction activities on green sturgeon larvae. However, if larvae or juveniles are present during construction, in-water activities could result in localized displacement and possible injury or mortality to individuals that do not readily move away from the channel or nearshore areas. Project actions associated with bank protection measures may increase sediment, silt, and pollutants, which may affect and is likely to adversely affect rearing habitat or reduce food production, such as aquatic invertebrates, for larval and juvenile green sturgeon.

Widening of the weir and bypass will increase the entrainment and stranding exposure and rates of juveniles. When the weir is overtopping and water is flowing down the bypass, adult fish are attracted to the flow and follow it upstream in an attempt to reach their holding and spawning habitat. Widening the weir and bypass would increase the amount of water going over the weir and increase the attraction rate of sturgeon, salmon, and steelhead. Without fish passage in place, the stranding rates of these fish would increase. This is significant, especially for sturgeon. Population viability modeling, funded in part by the Corps, concluded that without the fish rescue that took place, the loss of the green sturgeon stranded behind the Fremont and Tisdale weirs in 2011 would have significantly reduced the viability the species and increased their extinction risk (Thomas, et. al, 2013). We believe that because of its location and design, the Sacramento weir poses a similar risk and widening the weir would add to the effect. Given that green sturgeon are long-lived species that have the strongest upstream migration and cohort replacement rates during wet water years and especially after high river flow conditions, the effect of the stranding occurring only two to three times over a 50 year period could adversely impact juvenile green sturgeon.

Long-Term Effects

SRBPP onsite mitigative features were designed to maximize habitat response for salmonid species. SAM values for green sturgeon generally indicate a negative response or no response to typical onsite mitigative features. Green sturgeon are expected to show long term negative response to project actions in the Sacramento River SAM analysis reach for several life stages at all seasonal habitat conditions over the lifetime of the project. Project actions in the American River SAM analysis reach will also mimic SRBPP repair site onsite mitigative features. SRBPP onsite mitigative features were designed to maximize habitat response for salmonid species; green sturgeon will exhibit a negative response for juvenile rearing in the summer/fall to these onsite mitigative features. However, during the winter/spring green sturgeon juvenile rearing life stages will exhibit a positive response to these onsite mitigative features. Green Sturgeon are expected to show a long term positive response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project for the fry and juvenile rearing life stages in the winter/spring/summer/fall of year 1 (See Appendix B of the ARCF GRR BA for a more detailed analysis).

Long-term changes in nearshore habitat are expected to have negligible effects on adult green sturgeon because adult sturgeon use deep, mid-channel habitat during migration. If juvenile green sturgeon use nearshore areas of the Sacramento River as foraging habitat or refuge from predators, the general long-term effects of bank protection on nearshore habitat values may affect, and is likely to adversely affect rearing juvenile green sturgeon critical habitat.

5.3 Giant Garter Snake

Much of the project area is unlikely to provide GGS aquatic habitat because it consists of larger rivers and flood control features, often surrounded by riparian vegetation and steep banks. GGS have not been documented in the east side tributaries (CDFW 2014), and historical habitat conditions are thought to have limited dispersal of the species east of NEMDC (E. Hansen, pers. comm., 2015). Based on these factors and current habitat conditions, such as close proximity to urban development, high levels of human disturbance, scarcity of upland habitat, and riparian vegetation along the banks of most channel reaches, GGS are unlikely to occur in the east side tributaries and the southern portion of NEMDC. Therefore, all proposed project elements that would occur in these areas are unlikely to directly or indirectly impact GGS or adversely affect habitat occupied by the species.

The quality of habitat for GGS improves along NEDMC north of Dry Creek, where aquatic habitat is more extensive, very little riparian vegetation is present, urban development is less extensive, and large areas of open grasslands are present landside of the levees. GGS are known to occur in rice fields, associated canals, and managed marshes in the Natomas Basin. Additionally, the Sacramento Bypass is considered GGS habitat.

<u>Short-Term Effects</u>

There is the potential for short-term effects to GGS upland habitat during construction of the Sacramento Bypass widening. Construction activities could disturb GGS due to vibration, noise, and dust. During construction, equipment could possibility harm or kill a snake if the snakes are present. In addition to these short-term construction related effects, there would be temporary impacts to approximately 25 acres of aquatic GGS habitat and 50 acres of upland habitat from the relocation of the Sacramento Bypass levee toe drain. To minimize potential impacts to GGS, the avoidance and minimization measures discussed in Section 2.5 above would be implemented. These short-term effects are anticipated to occur over a single construction season and would return to the pre-existing conditions once completed. If construction were to occur in GGS habitat areas for more than one construction season, then additional mitigation would be required in accordance with the measures discussed in Section 2.5 above.

Based on habitat conditions and known occurrences of giant garter snake, NSS project's Borrow Site 2 is located immediately east of NEMDC and supports suitable upland habitat for GGS. If GGS are present during borrow activities, these activities would result in direct and indirect effects to this species. Approximately 5.5 acres of GGS upland habitat would be impacted by the borrow activities. Ground disturbing activities at Borrow Site 2, where uplands adjacent to suitable aquatic habitat would be disturbed, could result in direct displacement, injury, or death of snakes if the habitat is used for basking, hibernating, or aestivating. Indirect effects could occur if snakes are displaced from occupied habitat or disturbed by nearby construction activities. Displacement and disturbance resulting from human activity, construction noise, and equipment vibrations could affect the ability of snakes to conduct essential life history functions, such as dispersal, movement, or foraging, and could result in increased competition for food and space and vulnerability to predation.

However, all project-related impacts at Borrow Site 2 would occur within one active season and, therefore, are considered temporary. Borrow Site 2 would be restored/enhanced and re-graded to a condition that exceeds the pre-project condition by lowering the land surface closer to the low flow channel elevation and through establishment of a more diverse mosaic of aquatic and wetland habitat components. Additionally, with the implementation of the proposed avoidance and minimization measures discussed in Section 2.5, the use of Borrow Site 2 may affect, but is not likely to adversely affect GGS.

Table 14. Impacts to Giant Garter Snake Habitat.

Location	**Area of Impact (acres) / Impact Type**
NEMDC/NSS Borrow Site 2	5.5 acres / Temporary Upland
Sacramento Bypass Drainage Ditches/Irrigation Canals	15 acres / Permanent Aquatic 30 acres / Permanent Upland
Sacramento Bypass Levee Toe Drain	25 acres / Temporary Aquatic 50 acres / Temporary Upland
Total Impacts to GGS Habitat	**Permanent Aquatic - 15 acres** **Permanent Upland – 30 acres** **Temporary Aquatic – 25 acres** **Temporary Upland – 55.5 acres**

Long-Term Effects

GGS habitat at the NSS Borrow Site 2 would be restored to pre-project conditions, resulting in no long-term loss of upland GGS habitat in this portion of the project area. The Borrow Site will be planted to create freshwater marsh and seasonal wetland habitat, which will provide mitigation for potential unavoidable impacts to jurisdictional wetland habitat occurring during the North Sacramento

Streams Levee Improvement Project. Upland areas disturbed during borrow activities will be seeded with native perennial grasses.

In the Sacramento Bypass, there would be a permanent loss of approximately 15 acres of GGS aquatic habitat from the removal of the drainage ditches and farm canals in the extended Bypass area and approximately 30 acres of associated upland habitat. Compensation would occur through the purchase of credits at a USFWS-approved mitigation bank. This compensation would be in accordance with the ratios established in Section 2.5.

Additionally, since the land within the expanded bypass area would be removed from agricultural production and added to the wildlife area, there is the potential for wetlands to form in this area, which could improve the habitat conditions of the area long term. Long-term adverse impacts could result from O&M activities. These activities include mowing, rodent control, and grouting any new rodent holes that form in the new levee. Additionally, driving near habitat could disturb GGS due to vibration, noise, and dust. Maintenance activities would occur during the GGS active season to reduce impacts to the snake. Overall, these activities are considered less than significant, because they are short term activities and because O&M reduces the potential impacts associated with future levee repairs.

Operation of the expanded Sacramento Weir and Bypass was described in Section 2.2.6 above, and would result in an increase of water surface elevation of approximately 0.5-foot on the levee slopes on either side of the Yolo Bypass. However, when this increase would occur, during a 200-year flood event, the Yolo Bypass levees already contain water up to a 21 foot depth. As a result, GGS burrows would likely already be saturated before the additional water associated with the widened Sacramento Bypass is a factor. The additional 0.5-foot resulting from this action would not significantly change the timing or duration of this flooding and would not result in further impacts to GGS habitat. As a result, operation of the widened Sacramento Weir and Bypass may affect, but is not likely to adversely impact the GGS.

5.4 Western Yellow-Billed Cuckoo

The project area is unlikely to support western yellow-billed cuckoo nesting habitat. However, migrant individuals are likely to pass through the area in transit to breeding sites along the Sacramento River north of Colusa. Overall, cuckoos are unlikely to occur in the action area, although potential dispersal and foraging habitat is present in the American River Parkway and along the Sacramento River.

Short-Term Effects

Prior to construction, surveys would be conducted to determine the presence of cuckoos within the project area in accordance with any required USFWS survey protocols and permits at the time of construction. If cuckoos are determined to be present, there is the potential for short term, temporary impacts during construction from dust, noise, and vibration. However, since construction would occur in the summer months when the cuckoo is nesting (June 1 through September 30), and cuckoos are unlikely to be nesting in the study area, these effects would not adversely effect the species. If cuckoos are determined to the present prior to construction, the Corps would reinitiate consultation in order to coordinate the appropriate avoidance and minimization measures that should be implemented in order to reduce impacts to the cuckoo.

Long-Term Effects

Potential long-term effects to the cuckoo could result from the loss of 65 acres of riparian habitat in the footprint of the rock trench sites within the American River Parkway. For the American River, impacts to trees would be the width of the launchable rock trenches (currently proposed at approximately 40-feet wide) for a total of approximately 65 acres. This habitat is suitable for the yellow-billed cuckoo due to the significant width of the riparian corridor along the American River Parkway, ranging from approximately 75 feet in some of the more narrow stretches to over 1,000 feet in other locations. The Corps would compensate for riparian vegetation removed as a result of construction within the Parkway and on-site to the maximum extent practicable. There would remain a significant temporal loss of riparian habitat for the cuckoo during their migration, however in time it is anticipated that with the implementation of the compensation proposed by the Corps, the riparian corridor would recover and would provide a suitable level of habitat for the cuckoo long-term.

Additionally, approximately 70 acres of riparian habitat would be impacted along the Sacramento River; however the Sacramento River's riparian corridor is very narrow (approximately 100 feet wide in most locations) and would not likely provide quality habitat for the cuckoo, who require a minimum of 20 hectares of riparian corridor to nest. However, they are expected to use this area as a migration corridor. Impacts to riparian vegetation along the Sacramento River could remove approximately a 60-foot wide segment of the 100-foot wide riparian corridor. However, with the implementation of on-site mitigative features associated with the construction of the bank protection, as described in Section 2.2.3, the project would add an additional 25-foot wide corridor of SRA/riparian vegetation along the river bank. The result would be a remaining impact of approximately 35 feet of riparian corridor loss, or approximately 40 acres. This remaining impact would be compensated either through the creation of off-site mitigation near the Sacramento River, or through the purchase of credits from a USFWS-approved mitigation bank. With the implementation of compensation for the loss of riparian habitat, the long-term effect of the removal of riparian vegetation along the Sacramento and American Rivers may affect, but is not likely to adversely affect the western yellow-billed cuckoo.

5.5 Ongoing Project Actions

As described in Section 2.5, in-water construction work will be completed during established work windows for salmonids and delta smelt. Maintenance activities may occur year-round in the dry areas. Effects from on-going activities (e.g., maintenance) are expected to be similar to effects described in Section 5.2, although the effects' magnitudes will be less.

5.6 Effects on the Environmental Baseline

Effects of the proposed action include reductions in nearshore aquatic and riparian habitat that is used by aquatic and terrestrial species. Placement of revetment on earthen banks alters natural fluvial processes that sustain high-value nearshore and floodplain habitats in alluvial river systems.

5.7 Effects on Essential Elements of Critical Habitat

The project actions may adversely modify designated critical habitat for the valley elderberry longhorn beetle, Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley steelhead, and green sturgeon. Any project action within the Sacramento River waterway from the confluence of the American River downstream to Freeport RM 46 may also affect designated critical habitat for delta smelt (USFWS 2003). Potential impacts of the project actions on critical habitat for listed species are discussed separately for each species in the effects analysis discussion above (Sections 5.1 to 5.3).

5.8 Cumulative Effects

5.8.1 ESA Cumulative Effects Analysis

The ESA requires the action agency, NMFS, and USFWS to evaluate the cumulative effects of the proposed actions on listed species and designated critical habitat, and to consider cumulative effects in formulating Biological Opinions (USFWS and NMFS 2002c). The ESA defines cumulative effects as "those effects of future State or private actions, not involving Federal activities that are reasonably certain to occur within the action area" of the proposed action subject to consultation (USFWS and NMFS 2002b). Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to Section 7 of the Federal ESA. For the purposes of this BA, the area of cumulative effects analysis is defined as the Sacramento River watershed.

A number of other commercial and private activities, including hatchery operations, timber harvest, recreation, as well as urban and rural development, could potentially affect listed species in the Sacramento River basin. Levee maintenance activities by state agencies and local reclamation districts are likely to continue, although any effects on listed species will be addressed through Section 10 of the ESA. Ongoing non-federal activities that affect listed salmonids, green sturgeon, delta smelt, valley elderberry longhorn beetle, giant garter snake and their habitat, will likely continue in the short-term, at intensities similar to those of recent years. However, some activities associated with the State's proposed Central Valley Flood Protection Plan or state or local efforts to implement the ETL could result in increased effects on listed species. The extent and pace of those activities are not yet known.

Cumulative effects may also include non-federal rock revetment projects. Some non-federal rock revetment projects carried out by State or local agencies (e.g., reclamation districts) that do not fill wetlands or occur above the ordinary high water line will not need Section 404 (Clean Water Act) permits from the Corps and resulting Section 7 (ESA) consultation, but any effects on listed species should be addressed through Section 10 of the ESA. These types of actions are possible at many locations throughout the ARCF action area and could contribute to cumulative impacts to waters of the U.S. These impacts could include similar effects to those associated with the ARCF proposed bank protection measure, including loss of Delta smelt shallow water and spawning habitat, loss of green sturgeon benthic habitat, loss of SRA habitat, and loss of riparian habitat along the Sacramento and American River corridors. Without appropriate mitigation, these effects would contribute to an adverse effect on these species. However, since the ARCF project is proposing to restore impacted SRA and riparaian habitat and compensate for any permanent loss of in-water habitat, the ARCF project would not be expected to combine to create an adverse cumulative effect with these actions.

Potential cumulative effects on fish may include any continuing or future non-federal diversions of water that may entrain adult or larval fish or that may incrementally decrease outflows, thus changing the position of habitat for these species. Water diversions through intakes serving numerous small, private agricultural lands and duck clubs in the Delta, upstream of the Delta, and in Suisun Bay contribute to these cumulative effects. These diversions also include municipal and industrial uses and power production. Several new diversions are in various stages of action. The introduction of exotic species may also occur under numerous circumstances. Exotic species can displace native species that provide food for larval fish.

Potential cumulative effects on all species addressed in this BA could include: wave action in the water channel caused by boats that may degrade riparian and wetland habitat and erode banks; dumping of domestic and industrial garbage; land uses that result in increased discharges of pesticides, herbicides, oil, and other contaminants; and conversion of riparian areas for urban development. In addition, routine vegetation clearing and mowing associated with agricultural practices may affect or remove habitat for the valley elderberry longhorn beetle and giant garter snake.

5.8.2 Federal Cumulative Effects Analysis

While cumulative effects analyses in ESA consultations are specifically to address non-federal actions as explained above, the following cumulative analysis of Federal actions is being provided to inform the agencies of federal actions affecting listed species in the general local area. The Corps has initiated consultation with USFWS and NMFS on four different Federal actions which could create a cumulative effect on listed species in the Sacramento area. These four projects include the West Sacramento Project, the Southport Early Implementation Project, the American River Common Features Project (including the North Sacramento Streams project), and the Sacramento River Bank Protection Project (SRBPP).

The purpose of the West Sacramento Project is to investigate and determine the extent of Federal interest in plans that reduce flood risk to the City of West Sacramento. The proposed alternative for this project consists of levee improvements to 50 miles of existing levees surrounding the city and extending down along the Sacramento Deep Water Ship Channel to address identified seepage, stability, and erosion concerns through the construction of slurry walls and bank protection. In addition, the project proposes to set back the Sacramento River levee in the Southport area of West Sacramento. The West Sacramento Project includes the geographic area and project features that are also being considered in the Southport Early Implementation Project. The Southport Early Implementation Project is being proposed by the West Sacramento Area Flood Control Agency and the State of California to provide 200-year protection consistent with the State's goal for urbanized areas, as well as to provide opportunities for ecosystem restoration and public recreation. The Southport Early Implementation Project's proposed alternative includes the Sacramento River setback levee in the Southport area of West Sacramento. The Southport project is planned to begin construction in 2015.

The SRBPP was authorized to protect the existing levees and flood control facilities of the SRFCP. The SRBPP is a long-range program of bank protection authorized by the Flood Control Act of 1960. The SRBPP directs the Corps to provide bank protection along the Sacramento River and its tributaries, including that portion of the lower American River bordered by Federal flood control project levees. Beginning in 1996, erosion control projects at five sites covering almost two miles of the south and north banks of the lower American River have been implemented. Additional sites at RM 149 and 56.7 on the Sacramento River totaling one-half mile have been constructed since 2001. During 2005 through 2007, 29 critical sites totaling approximately 16,000 linear feet were constructed under the Declaration of Flood Emergency by Governor Schwarzenegger. This is an ongoing project, and additional sites requiring maintenance will continue to be identified indefinitely until the remaining authority of approximately 24,000 linear feet is exhausted over the next 3 years. WRDA 2007 authorized an additional 80,000 linear feet of bank. For implementation of the 80,000 additional linear feet of bank protection, the Corps has submitted a biological assessment and initiated formal consultation with NMFS and USFWS.

Potential cumulative impacts from the combination of these projects to each of the listed species included in this consultation are below. The construction periods and related effects from these projects could all occur simultaneously. For the ARCF and West Sacramento projects, this means that similar construction-related effects such as rock placement or tree removal could be occurring at the same time for the stretch of the projects from the I Street Bridge to the Stone Locks. During preconstruction engineering and design, the Corps designs will avoid impacts to special status species, where possible, or otherwise minimize effects to each of these species including designs to have negligible effects on velocities. There may be localized effects; the change in bank composition to rock may result in short term slight increase of velocities, but installation of vegetation on site would result in a much greater long-term reduction of velocities. The site would be designed to ensure that any increase in velocity does not extend downstream of the sites. Additionally, the two projects would coordinate to ensure that construction sites are offset from each other (i.e., sites directly across the Sacramento River from each other where there is bank protection being installed, specifically from the I-Street Bridge downstream to the Barge canal, would not be constructed in the same construction season). These are also different styles of bank protection. The West Sacramento side has some berm between the levee and the channel, and therefore it is really a "bank" fix, while the ARCF side has levee toe underwater and includes rock berm.

Valley Elderberry Longhorn Beetle

Concurrent construction of multiple projects over the next 10 to 15 years within the Sacramento Metropolitan area would likely cause mortality to beetles due to construction operations. Construction activities for the multiple projects would occur each year during the flight season of beetles. Since construction activities would be adjacent to known VELB locations it is likely that some mortality may occur. No designated critical habitat would be affected with the construction of any of the projects.

Shrubs within the each project footprint would be transplanted to areas in close proximately to the current locations. Additionally, compensation would be located within the vicinity of impacted shrubs. Transplanting of shrubs and planting of seedlings and natives within the project vicinity would provide connectivity for the beetle within the American River Parkway. Connectivity is a primary cause of the beetle decline and an important element in the recovery and sustainability for the beetle. Habitat maps of the Parkway that show individual shrub locations are included in Appendix F. Appendix G includes maps of the Corps' existing compensation sites within the Parkway. The Corps would coordinate with County Parks to determine appropriate locations for newly established elderberry mitigation sites within the Parkway, with connectivity being one of the goals in site selection. The transplanting of shrubs and compensation within the same area as the potential impacts would result in effects to the beetle but not result in jeopardy to the valley elderberry longhorn beetle.

Salmon, Steelhead, and Sturgeon

The proposed projects could adversely modify critical habitat or contribute to the loss or degradation of sensitive habitats for listed species such as the Sacramento River winter-run Chinook salmon, Central Valley steelhead, Central Valley spring-run Chinook salmon, and green sturgeon in the greater project vicinity. However, with site specific erosion repair designs, retention of SRA through vegetation variances, and the installation of riparian plantings and instream large woody material, the proposed projects are expected to increase habitat values over time by increasing the amount of riparian habitat, SRA cover, and floodplain habitat available to listed fish over a broad range of flows.

The erosion repair activities of these combined projects would likely reduce the sediment supply for riverine reaches directly downstream because the erosion repair is holding the bank or levee in place. However, from a system sediment perspective, the bank material we are protecting in the project reaches is not a major source of sediment compared to the upstream reaches of the Sacramento, Feather, and especially the Yuba River systems. All of the available sediment in the American River watershed is being contained behind Folsom Dam. The site specific designs will be constrained from allowing any velocity increases outside the erosion repair site (Schlunegger 2014).

Site specific designs such as setback levees, IWM, and shallow bank slopes within the SRBPP, Common Features, West Sacramento, and Southport EIP projects would be incorporated to address erosion repair while including features for increasing habitat for listed fish. The levee setback component of the Southport EIP and West Sacramento projects would result in the restoration of historical Sacramento River floodplain in the project areas, with a diverse mosaic of seasonal floodplain, wetland, riparian, and upland habitat. The goals of the offset area restoration designs are to increase river-floodplain connectivity, restore ecologically functional floodplain habitat, and meet the flood risk–reduction objectives of the projects. Based on the SAM, establishing connectivity of the floodplain to the river will result in large and rapid gains in habitat quantity and quality that will fully compensate for initial habitat deficits on the existing levee and result in significant long-term species benefits (improved growth and survival) relative to existing conditions. Although not addressed by the SAM, these benefits will be enhanced over time by revegetation of the floodplain and development of a diverse mosaic of wetland, riparian and upland plant communities that will further improve the habitat and ecosystem functions of the restored floodplain. In addition to increasing the amount of structural cover available to fish along the shoreline, the installation of IWM is also expected to promote sediment deposition on the rock bench as observed at locations where similar designs have been used to address the compensation needs of listed fish species. Project actions are unlikely to result in long-term habitat losses to Sacramento River winter-run Chinook salmon, Central Valley steelhead, Central Valley spring-run Chinook salmon, and green sturgeon.

The American River Common Features and West Sacramento Projects would have initial cover losses due to project actions but will be partially offset by installing riparian plantings and native grasses along the lower slopes. These features will increase the availability of high quality shallow water habitat for juvenile Chinook salmon and steelhead, and possibly juvenile green sturgeon during the annual high-flow period (late fall, winter, and spring). Because of the vegetation variance that the Corps will be seeking, tree removal would be limited to no more than the upper one-half of the waterside of the levees therefore leaving the lower one-half or more of the trees in place on the Sacramento River within the study area. SRA would not be compromised, thus maximizing existing SRA values in the study area. The establishment and growth of planted riparian vegetation is expected to increase habitat values over time by increasing the extent of overhead cover available to listed fish species.

<u>Delta Smelt</u>

The proposed projects, with the implementation of site specific designs and purchase of credits at a USFWS-approved mitigation bank, would provide long-term net benefits to delta smelt as explained above in for the other fish species. However, there are four specific significant threats to the delta smelt that have been identified by the USFWS: direct entrainments by State and Federal water export facilities, summer and fall increases in salinity, summer and fall increases in water clarity, or effects from introduced species (USFWS 2015). Bank protection has also been identified as a significant threat to delta smelt shallow water habitat for spawning, incubation, and rearing within the Sacramento River portion of the ARCF project area.

Implementation of the various projects would not affect direct entrainments by State and Federal water export facilities. The ARCF project would release of more water down the Sacramento Bypass into the Yolo Bypass during high water events. The excess water that would normally be moving downriver through the Sacramento area would enter the system farther down in the Delta area. Since adult delta smelt are moving up the system to spawn at this time this would not affect entrainment in the water export facilities.

Summer and fall increases in salinity is driven more by low flow drought years and water releases in the Sacramento tributaries then site specific designs for erosion protection in the project areas. Summer and fall increases in water clarity are associated with, among other factors, invasive non-native clam species and non-native plant species, which are generally located down in the Delta below the project areas, that are filtering out vital chlorophyll and plankton that would normally increase turbidity which helps the delta smelt avoid predators. However, as mentioned above, the erosion repair component of the ARCF, West Sacramento, and SRBPP would likely reduce the sediment supply for riverine reaches directly downstream because the erosion repair is holding the bank or levee in place. However, as explained above, from a system sediment perspective, the bank material we are protecting in the project reaches is not a major source of sediment compared to the upstream reaches of the Sacramento, Feather, and especially the Yuba River systems.

Increases of bank substrate size over sand and sediment resulting in reductions in instream habitat are assumed to reduce the availability and suitability of habitat for spawning, incubation, and rearing. As a result, potential cumulative effects include disruption of spawning activities, disturbance or mortality of eggs and newly hatched larvae. A permanent loss of approximately 14 acres with an additional 46 affected acres of sandy shallow water spawning and incubation habitat in the ARCF GRR project area would result from sand to rock conversion and would eliminate areas for successful egg deposition and survival due to the change in preferred substrate. However, the ARCF project would mitigate for the loss of shallow water habitat through the purchase of credits at a USFWS-approved mitigation bank. As a result, the cumulative impact of these projects may affect, but is not likely to adversely affect the Delta Smelt.

Giant Garter Snake

The giant garter snake could be affected by multiple projects being constructed within the Sacramento Metropolitan area over the next 10 to 15 years. Primarily habitat loss would occur on the West Sacramento side of the Sacramento River adjacent to the Sacramento Bypass and the West Sacramento and Southport construction areas. Short term impacts would occur for a single construction season along haul routes and within borrow sites. To minimize potential impacts to snakes work within giant garter snake habitat would be conducted between May 1 and October 1 when snakes are active and can move out of the construction area. Snake mortality could occur during construction along haul routes, however, the snakes are mobile and would likely move out of the way from construction equipment. There would be a permanent loss of a few irrigation canals in the Sacramento Bypass and some existing wetlands adjacent to the levees in the West Sacramento study area.

Western Yellow-Billed Cuckoo

Concurrent construction of the ARCF, West Sacramento, and SRBPP projects over the next 10 to 15 years within the Sacramento Metropolitan area could result in adverse effects to Western yellow-billed cuckoo through the removal of trees within the riparian corridors. Construction activities for the multiple projects would occur each year during nesting season, which could disrupt nesting birds, if present. However, the cuckoo is not known to nest in the Sacramento River or its tributaries below Colusa, therefore the tree removal would not effect Western yellow-billed cuckoo nesting habitat. Additionally, any tree removal would likely occur outside of the nesting season. No designated critical habitat would be affected with the construction of any of the projects.

Prior to construction, each project would be required to conduct surveys to determine the presence of the cuckoo. Nesting birds are not expected to be present, but migrating cuckoos could use riparian habitat in these reaches as they pass through the area. If cuckoos are found during surveys, additional measures would be proposed by each of the projects, which may include biological monitoring.

Planting of seedlings and native trees within the project vicinity would mitigate for the loss of trees within the riparian corridor and would likely improve the habitat in the area long-term by filling gaps in the riparian canopy. While the short term impact would be significant, over time these compensation measures within the same area as the potential impacts would result in less than significant effects to the cuckoo. Since the cuckoo is not likely to be nesting within the area, and while the cumulative impact to the riparian corridor from tree removal would be significant, there still remains a significant amount of trees that could be used by the cuckoo, particularly in the American River Parkway, as described in Section 5.9.5 above. As a result, the cumulative effect from these projects may affect, but is not likely to adversely affect the yellow-billed cuckoo.

5.9 Conclusion and Effects Determination for Listed Species

5.9.1 Valley Elderberry Longhorn Beetle

The project construction would result in the transplanting of a maximum of 270 elderberry shrubs during the 13 year construction timeframe. Compensation for the transplanting of the shrubs would be on-site where possible and within the same region when off-site. The replacement plantings would result in habitat connectivity for the beetle within the project area. In consideration of this information, the project actions are unlikely to result in long-term habitat losses to valley elderberry longhorn beetle, as long as the applicable mitigation and compensation measures are implemented. However, ARCF GRR project actions may adversely affect valley elderberry longhorn beetles due to potential take during construction.

Additionally, approximately 90 shrubs could be trimmed each year by the maintaining agencies for O&M activities. The trimming are not expected to reduce the habitat overall for the beetle as the shrubs would remain in the existing location. The maintaining agencies would purchase credits in a mitigation bank to offset any potential affects that may occur due to trimming.

5.9.2 Fish

Anadromous Fish Species

The ARCF GRR is expected to result in adverse short-term, construction- and O&M-related effects on Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, California Central Valley steelhead, southern DPS North American green sturgeon, and their designated critical habitat. Project effects may include localized incidental take due to disturbance, displacement, or impairment of feeding or other essential behaviors of adult and juvenile salmon, steelhead, and green sturgeon during construction and operations and maintenance (O&M) activities. Injury or mortality of juvenile salmonids, and green sturgeon, could occur, if individuals are unable to readily move away from channel or nearshore areas directly affected by construction activities. Accidental discharge of toxic substances during construction could cause physiological impairment or mortality of listed fish and other aquatic species at or immediately downstream of project sites. Other potential stressors include noise, suspended sediment, turbidity, and sediment deposition generated during in-water construction activities. These effects could also occur in areas downstream of project sites, because noise and sediment may be propagated downstream. Restricting in-water activities to the August 1 through November 30 work window, and implementing BMPs, will minimize the potential for adverse effects.

Long-term project effects on the habitat of listed fish species include instream and overhead cover, and substrate conditions along the seasonal low- and high-flow shorelines of the erosion sites. Implementation of the project will result in temporary losses of instream structure and riparian vegetation along the summer-fall and winter-spring shorelines and will also limit long-term fluvial functioning necessary for the development and renewal of SRA habitat in the future.

Initial cover losses due to project actions will be partially offset by installing riparian plantings and native grasses along the lower slopes. These features will increase the availability of high quality shallow water habitat for juvenile Chinook salmon and steelhead, and possibly juvenile green sturgeon during the annual high-flow period (late fall, winter, and spring). Because we will not be removing any trees on the lower one-third of the waterside of the levees in the Sacramento River area, SRA will not be compromised thus maximizing existing SRA values in the action area. The establishment and growth of planted riparian vegetation is expected to increase habitat values over time by increasing the extent of overhead cover available to listed fish species.

These features will increase the availability of high quality shallow water habitat for juvenile Chinook salmon and steelhead, incubating delta smelt, and possibly juvenile green sturgeon during the annual high-flow period (late fall, winter, and spring). Because we will not be removing any trees on the lower one-third of the waterside of the levees in the Sacramento River area, SRA will not be compromised thus maximizing existing SRA values in the action area. The establishment and growth of planted riparian vegetation is expected to increase habitat values over time by increasing the extent of overhead cover available to listed fish species.

In consideration of the above information, the project actions are not likely to result in long-term habitat losses to Sacramento River winter-run Chinook salmon, Central Valley steelhead, Central Valley spring-run Chinook salmon, delta smelt, and green sturgeon as long as the applicable mitigation and compensation measures are implemented. This conclusion is based on the Corps' commitment to: (1) minimize temporary habitat losses through the incorporation of on-site mitigation features (e.g., vegetated riparian and wetland benches, riparian plantings, and no planned tree removal) in the project area measures; and (2) implementation of off-site habitat compensation measures (e.g., riparian planting, rock removal) prior to or concurrent with project construction. However, project actions may adversely affect these focus species due to: (1) incidental take during construction and; (2) fragmentation of existing natural bank habitats due to the placement of revetment; and (3) the potential loss of long-term fluvial functioning necessary for the development and renewal of shaded riverine aquatic habitat.

Determinations

Section 7 of the Endangered Species Act requires that Federal agencies ensure, in consultation with the U.S. Fish and Wildlife Service, that any action they authorize, fund, or carry out is not likely to result in the destruction or adverse modification of critical habitat. Effects to critical habitat are discussed for each fish species in Section 5.2. Based on those assessments, project actions:

- May affect, likely to adversely affect designated critical habitat for Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley steelhead, and Green sturgeon;
- May affect, likely to adversely affect designated critical habitat for delta smelt within the ARCF GRR project area which includes the Sacramento River upstream to approximately RM 60 (U.S. Fish and Wildlife Service 2003a).

5.9.3 Giant Garter Snake

To minimize the potential for adverse effects on GGS in the Sacramento Bypass, GGS habitat will be designated as an environmentally sensitive area delineated with signs or fencing, and if possible, avoided by all construction personnel. Additional measures and habitat compensation as outlined in Section 2.5.3 will also be implemented to avoid and minimize potential temporary effects to GGS during construction. There would be approximately 15 acres of GGS aquatic habitat permanently removed due to removal of the drainage canals within the widened bypass. Compensation for this loss would occur in accordance with the measures discussed in Section 2.5.3. Temporary effects during construction would disturb approximately 30 acres of upland GGS habitat for one construction season. Compensation for these temporary impacts would occur in accordance with the measures discussed in Section 2.5.3.

In consideration of the above information, the project actions are unlikely to result in long-term habitat losses to the giant garter snake, as long as the applicable mitigation and compensation measures are implemented. However, even with on-site mitigation and off-site compensation, the project actions may adversely affect giant garter snakes due to: (1) take during construction and O&M activities; and (2) habitat fragmentation. Ground disturbing activities at NSS Borrow Site 2 could result in direct displacement, injury, or death of snakes. These effects, which could affect the ability of snakes to conduct essential life history functions, such as dispersal, movement, or foraging, would be temporary (occurring during one active season). Construction activities could temporarily degrade aquatic habitat, but the overall result of implementing the proposed site restoration at Borrow Site 2 would be an enhancement of habitat quality.

5.9.4 Vernal Pool Fairy Shrimp and Vernal Pool Tadpole Shrimp

Approximately 0.25-acre of vernal pool habitat has the potential to be indirectly impacted by project construction near Magpie Creek. The Corps proposes to either purchase 1 acre of credits at a mitigation bank, or compensate for the loss of 1 acre of habit through enhancement of the habitat in the 79 acres of land being acquired under this project as a flood overflow area. The project actions are unlikely to result in long-term habitat losses to the vernal pool fairy shrimp and vernal pool tadpole shrimp, with the implementation of the mitigation and compensation measures proposed. As a result, the project actions may affect, but are not likely to adversely affect the vernal pool fairy shrimp and vernal pool tadpole shrimp.

5.9.5 Western Yellow-billed Cuckoo

Potential long-term effects to the cuckoo could result from the loss of 175 acres of riparian habitat. However, this long term effect would be significantly reduced with the receipt of a vegetation variance and implementation of the SWIF. There would remain a significant temporal loss of riparian habitat for the cuckoo during their migration, however in time it is anticipated that the riparian corridor would recover with the implementation of the compensation proposed by the Corps. While the removal of trees from the construction footprint is a significant effect, the majority of the trees within the cuckoo's migration corridor would not be impacted by construction activities, particularly within the American River Parkway. In the Parkway, the maximum footprint of impact would be 65 feet from the levee toe, while portions of the Parkway include a corridor of150 to 500 feet wide. As a result, the long-term effect of the removal of riparian vegetation may affect, but is not likely to adversely affect the western yellow-billed cuckoo.

5.10 Effects of the Proposed Action on Essential Fish Habitat

The Magnuson-Stevens Fishery Conservation and Management Act (MSA), as amended (U.S.C. 180 et seq.), requires that Essential Fish Habitat (EFH) be identified and described in Federal fishery management plans. Federal action agencies must consult with NMFS on any activity that they fund, permit, or carry out that may adversely affect EFH. NMFS is required to provide EFH conservation and enhancement recommendations to the Federal action agencies.

EFH of Pacific salmon pursuant to Section 305 (b) (2) of the MSA appropriate determinations for EFH as either; (1) will not adversely effect, or (2) may adversely affect. Important components of EFH for Chinook salmon spawning, rearing, and migration include:

- Freshwater spawning sites with water quantity and quality conditions and substrate supporting spawning, incubation and larval development;
- Freshwater rearing sites with:
    a) Water quantity and floodplain connectivity to form and maintain physical habitat conditions and support juvenile growth and mobility;
    b) Water quality and forage supporting juvenile development; and
    c) Natural cover such as shade, submerged and overhanging large wood, log jams and beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks.

- Freshwater migration corridors free of obstruction and excessive predation with water quantity and quality conditions and natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, side channels, and undercut banks supporting juvenile and adult mobility and survival.
- Estuarine areas free of obstruction and excessive predation with:
    a) Water quality, water quantity, and salinity conditions supporting juvenile and adult physiological transitions between fresh- and saltwater;
    b) Natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, side channels; and
    c) Juvenile and adult forage, including aquatic invertebrates and fishes, supporting growth and maturation.

The ARCF GRR includes habitat on the Sacramento River, American River, and the Sacramento Bypass that have been designated as EFH for Chinook salmon, a major contributor to Pacific Coast salmon fisheries. The Pacific Coast salmon fishery EFH extends along the Pacific Coast from Washington to Point Conception in California. Freshwater EFH includes all habitats currently and historically accessible to salmon and is based on descriptions of habitat used by coho and Chinook salmon. The EFH excludes areas above naturally occurring barriers such as waterfalls, which have been present for several hundred years, and impassible dams identified on large rivers (NMFS 1997). The following analysis of EFH does not include effects to the fish species, just the species habitat as defined in the MSA. Results for the effects of EFH for winter-run, spring-run, and fall/late-fall-run Chinook salmon in the ARCF GRR action area were based on the SAM analysis detailed in Appendix B.

5.10.1 Effects of the Proposed Action on EFH

Site specific project designs were unavailable for the ARCF GRR project reach at the time of this SAM analysis. The following data sources were used to characterize SAM habitat conditions (as defined by bank slope, floodplain availability, substrate size, instream structure, aquatic vegetation, and overhanging shade) within the ARCF GRR project area under existing or pre-project conditions:

- The Corps' Sacramento River revetment database – This database was used to stratify the project reach into subreaches that encompass relatively uniform bank conditions based on their general physical characteristics (USACE 2007). This database was used to characterize existing habitat conditions within individual subreaches where more recent data were unavailable.
- Aerial images of the ARCF GRR project reach (Google™ Earth), provided current and historical images of bank conditions that were used to address gaps or uncertainties related to existing cover characteristics within individual subreaches.

The SAM employs six habitat variables to characterize near-shore and floodplain habitats of the winter-run, spring-run, and fall/late-fall-run Chinook species:

- Bank slope—average bank slope of each average seasonal water surface elevation;
- Floodplain availability—ratio of wetted channel and floodplain area during the 2-year flood, to the wetted channel area during average winter and spring flows;
- Bank substrate size—the median particle diameter of the bank (i.e., D50) along each average seasonal water surface elevation;
- Instream structure—percent of shoreline coverage of instream woody material along each average seasonal water surface elevation;
- Aquatic vegetation—percent of shoreline coverage of aquatic or riparian vegetation along each average seasonal water surface elevation; and
- Overhanging shade—percent of the shoreline coverage of shade along each average seasonal water surface elevation.

Sacramento River SAM EFH Analysis

The Sacramento River SAM analysis reach includes the entire left bank (east side) of the Sacramento River from the American River confluence to approximately 4,020 linear feet (lf) below the Freeport Bridge.

Short Term

Short term construction activities may adversely affect Chinook EFH. Short term habitat deficits will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions most positively associated with fry and juvenile rearing and migration.

Long Term

Long term construction actions will not adversely affect EFH on the Sacramento River portion of the ARCF GRR action area. EFH is expected to show a long term positive response to project actions in the Sacramento River SAM analysis reach over the lifetime of the project. Positive EFH response would be most likely associated with long term growth of SRA (overhanging shade) and aquatic vegetation.

American River SAM EFH Analysis

The American River SAM analysis (ARN A-B and ARS A-C) reaches include portions of the right and left bank of the American River from Goethe Park to the confluence of the Sacramento. It also includes portions of NEMDC, Arcade Creek, Magpie Creek, and Dry/Robla Creek.

Short Term

Short term construction activities may adversely affect Chinook EFH. Short term habitat deficits will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions most positively associated with fry and juvenile rearing and migration.

Long Term

Long term construction actions will not adversely affect EFH on the Sacramento River portion of the ARCF GRR action area. EFH is expected to show a long term positive response to project actions in the American River SAM (Appendix B) analysis reach over the lifetime of the project. Positive EFH response would be most likely associated with long term growth of SRA (overhanging shade) and aquatic vegetation.

Sacramento Bypass SAM EFH Analysis

The Sacramento Bypass SAM analysis reach includes the right bank (north side) of the Sacramento Bypass levee in its entirety from the confluence of the Sacramento River to its termination at the Yolo Bypass.

Short Term

Short term construction activities may adversely affect Chinook EFH. Short term habitat deficits will result from the initial loss of aquatic vegetation and over hanging shade at the portion of the Sacramento Bypass associated with the removal of the SRA habitat to allow expansion of the Sacramento Bypass Weir. There is no planned vegetation removal for the levee widening.

Long Term

Chinook salmon are expected to show a small long term negative response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project. Chinook salmon should exhibit a negative response by year 1. The maximum habitat deficit identified is -188 ft for the juvenile migration life stage of spring-run and winter-run Chinook salmon in the spring of year 2. Long term habitat deficits would be associated with the permanent removal of SRA habitat for the expansion of the weir portion of the project not the levee portion.

Sacramento Fish & Wildlife Office

Federal Endangered and Threatened Species that Occur in or may be Affected by Projects in the Counties and/or U.S.G.S. 7 1/2 Minute Quads you requested

Document Number: 141222022932

Current as of: December 22, 2014

Quad Lists

CLARKSBURG (497A)

Listed Species

Invertebrates

Branchinecta conservatio

Conservancy fairy shrimp (E)

Branchinecta lynchi

vernal pool fairy shrimp (T)

Desmocerus californicus dimorphus

valley elderberry longhorn beetle (T)

Lepidurus packardi

vernal pool tadpole shrimp (E)

Fish

Acipenser medirostris

green sturgeon (T) (NMFS)

Hypomesus transpacificus

Critical habitat, delta smelt (X)
delta smelt (T)

Oncorhynchus mykiss

Central Valley steelhead (T) (NMFS)
Critical habitat, Central Valley steelhead (X) (NMFS)

Oncorhynchus tshawytscha

Central Valley spring-run chinook salmon (T) (NMFS)
Critical Habitat, Central Valley spring-run chinook (X) (NMFS)
Critical habitat, winter-run chinook salmon (X) (NMFS)
winter-run chinook salmon, Sacramento River (E) (NMFS)

Amphibians

Ambystoma californiense

California tiger salamander, central population (T)

Rana draytonii

California red-legged frog (T)

Reptiles

Thamnophis gigas

giant garter snake (T)

Birds

Coccyzus americanus occidentalis
Western yellow-billed cuckoo (T)

RIO LINDA (512B)
Listed Species

Invertebrates

Branchinecta lynchi
vernal pool fairy shrimp (T)

Desmocerus californicus dimorphus
valley elderberry longhorn beetle (T)

Lepidurus packardi
vernal pool tadpole shrimp (E)

Fish

Hypomesus transpacificus
delta smelt (T)

Oncorhynchus mykiss
Central Valley steelhead (T) (NMFS)
Critical habitat, Central Valley steelhead (X) (NMFS)

Oncorhynchus tshawytscha
Central Valley spring-run chinook salmon (T) (NMFS)
winter-run chinook salmon, Sacramento River (E) (NMFS)

Amphibians

Ambystoma californiense
California tiger salamander, central population (T)

Rana draytonii
California red-legged frog (T)

Reptiles

Thamnophis gigas
giant garter snake (T)

SACRAMENTO EAST (512C)
Listed Species

Invertebrates

Branchinecta lynchi
vernal pool fairy shrimp (T)

Desmocerus californicus dimorphus
Critical habitat, valley elderberry longhorn beetle (X)
valley elderberry longhorn beetle (T)

Lepidurus packardi
vernal pool tadpole shrimp (E)

Fish

Acipenser medirostris
green sturgeon (T) (NMFS)

Hypomesus transpacificus
delta smelt (T)

Oncorhynchus mykiss
- Central Valley steelhead (T) (NMFS)
- Critical habitat, Central Valley steelhead (X) (NMFS)

Oncorhynchus tshawytscha
- Central Valley spring-run chinook salmon (T) (NMFS)
- Critical Habitat, Central Valley spring-run chinook (X) (NMFS)
- winter-run chinook salmon, Sacramento River (E) (NMFS)

Amphibians

Ambystoma californiense
- California tiger salamander, central population (T)

Rana draytonii
- California red-legged frog (T)

Reptiles

Thamnophis gigas
- giant garter snake (T)

Birds

Coccyzus americanus occidentalis
- Western yellow-billed cuckoo (T)

SACRAMENTO WEST (513D)
Listed Species

Invertebrates

Branchinecta lynchi
- vernal pool fairy shrimp (T)

Desmocerus californicus dimorphus
- valley elderberry longhorn beetle (T)

Lepidurus packardi
- vernal pool tadpole shrimp (E)

Fish

Acipenser medirostris
- green sturgeon (T) (NMFS)

Hypomesus transpacificus
- Critical habitat, delta smelt (X)
- delta smelt (T)

Oncorhynchus mykiss
- Central Valley steelhead (T) (NMFS)
- Critical habitat, Central Valley steelhead (X) (NMFS)

Oncorhynchus tshawytscha
- Central Valley spring-run chinook salmon (T) (NMFS)
- Critical Habitat, Central Valley spring-run chinook (X) (NMFS)
- Critical habitat, winter-run chinook salmon (X) (NMFS)
- winter-run chinook salmon, Sacramento River (E) (NMFS)

Amphibians

Ambystoma californiense
- California tiger salamander, central population (T)

Rana draytonii

California red-legged frog (T)

Reptiles

Thamnophis gigas

giant garter snake (T)

Birds

Coccyzus americanus occidentalis

Western yellow-billed cuckoo (T)

Vireo bellii pusillus

Least Bell's vireo (E)

County Lists

No county species lists requested.

Key:

(E) *Endangered* - Listed as being in danger of extinction.

(T) *Threatened* - Listed as likely to become endangered within the foreseeable future.

(P) *Proposed* - Officially proposed in the Federal Register for listing as endangered or threatened.

(NMFS) Species under the Jurisdiction of the National Oceanic & Atmospheric Administration Fisheries Service. Consult with them directly about these species.

Critical Habitat - Area essential to the conservation of a species.

(PX) *Proposed Critical Habitat* - The species is already listed. Critical habitat is being proposed for it.

(C) *Candidate* - Candidate to become a proposed species.

(V) Vacated by a court order. Not currently in effect. Being reviewed by the Service.

(X) *Critical Habitat* designated for this species

Important Information About Your Species List

How We Make Species Lists

We store information about endangered and threatened species lists by U.S. Geological Survey 7½ minute quads. The United States is divided into these quads, which are about the size of San Francisco.

The animals on your species list are ones that occur within, **or may be affected by** projects within, the quads covered by the list.

- Fish and other aquatic species appear on your list if they are in the same watershed as your quad or if water use in your quad might affect them.
- Amphibians will be on the list for a quad or county if pesticides applied in that area may be carried to their habitat by air currents.
- Birds are shown regardless of whether they are resident or migratory. Relevant birds on the county list should be considered regardless of whether they appear on a quad list.

Plants

Any plants on your list are ones that have actually been observed in the area covered by the list. Plants may exist in an area without ever having been detected there. You can find out what's in the surrounding quads through the California Native Plant Society's online Inventory of Rare and Endangered Plants.

Surveying

Some of the species on your list may not be affected by your project. A trained biologist and/or botanist, familiar with the habitat requirements of the species on your list, should determine whether they or habitats suitable for them may be affected by your project. We recommend that your surveys include any proposed and candidate species on your list. See our Protocol and Recovery Permits pages.

For plant surveys, we recommend using the Guidelines for Conducting and Reporting Botanical Inventories. The results of your surveys should be published in any environmental documents prepared for your project.

Your Responsibilities Under the Endangered Species Act

All animals identified as listed above are fully protected under the Endangered Species Act of 1973, as amended. Section 9 of the Act and its implementing regulations prohibit the take of a federally listed wildlife species. Take is defined by the Act as "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect" any such animal.

> Take may include significant habitat modification or degradation where it actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or shelter (50 CFR §17.3).

Take incidental to an otherwise lawful activity may be authorized by one of two procedures:

- If a Federal agency is involved with the permitting, funding, or carrying out of a project that may result in take, then that agency must engage in a formal consultation with the Service.

  During formal consultation, the Federal agency, the applicant and the Service work together to avoid or minimize the impact on listed species and their habitat. Such consultation would result in a biological opinion by the Service addressing the anticipated effect of the project on listed and proposed species. The opinion may authorize a limited level of incidental take.

- If no Federal agency is involved with the project, and federally listed species may be taken as part of the project, then you, the applicant, should apply for an incidental take permit. The Service may issue such a permit if you submit a satisfactory conservation plan for the species that would be affected by your project.

  Should your survey determine that federally listed or proposed species occur in the area and are likely to be affected by the project, we recommend that you work with this office and the California Department of Fish and Game to develop a plan that minimizes the project's direct and indirect impacts to listed species and compensates for project-related loss of habitat. You should include the plan in any environmental documents you file.

Critical Habitat

When a species is listed as endangered or threatened, areas of habitat considered essential to its conservation may be designated as critical habitat. These areas may require special management considerations or protection. They provide needed space for growth and normal behavior; food, water, air, light, other nutritional or physiological requirements; cover or shelter; and sites for breeding, reproduction, rearing of offspring, germination or seed dispersal.

Although critical habitat may be designated on private or State lands, activities on these lands are not restricted unless there is Federal involvement in the activities or direct harm to listed wildlife.

If any species has proposed or designated critical habitat within a quad, there will be a separate line for this on the species list. Boundary descriptions of the critical habitat may be found in the Federal Register. The information is also reprinted in the Code of Federal Regulations (50 CFR 17.95). See our Map Room page.

Candidate Species

We recommend that you address impacts to candidate species. We put plants and animals on our candidate list when we have enough scientific information to eventually propose them for listing as threatened or endangered. By considering these species early in your planning process you may be able to avoid the problems that could develop if one of these candidates was listed before the end of your project.

Species of Concern

The Sacramento Fish & Wildlife Office no longer maintains a list of species of concern. However, various other agencies and organizations maintain lists of at-risk species. These lists provide essential information for land management planning and conservation efforts. More info

Wetlands

If your project will impact wetlands, riparian habitat, or other jurisdictional waters as defined by section 404 of the Clean Water Act and/or section 10 of the Rivers and Harbors Act, you will need to obtain a permit from the U.S. Army Corps of Engineers. Impacts to wetland habitats require site specific mitigation and monitoring. For questions regarding wetlands, please contact Mark Littlefield of this office at (916) 414-6520.

Updates

Our database is constantly updated as species are proposed, listed and delisted. If you address proposed and candidate species in your planning, this should not be a problem. However, we recommend that you get an updated list every 90 days. That would be March 22, 2015.

Appendix B

American River Common Features GRR SAM Analysis

American River Common Features General Reevaluation Report

Standard Assessment Methodology Analysis

July 2015

Contents

1.0 Introduction

This document provides the background data and assumptions for the Standard Assessment Methodology (SAM) effects analysis of the American River Common Features General Reevaluation Report (ARCF GRR) project on the following focus fish species (Table 1).

Table 1. ARCF GRR Project Focus Fish Species.

Species/ESUs	Federal Status
Chinook salmon (*Oncorhynchus tshawytscha*)	
Central Valley spring-run ESU	Threatened
Central Valley fall-run ESU	Species of concern
Central Valley late fall-run ESU	Species of concern
Sacramento River winter-run ESU	Endangered
Central Valley steelhead DPS (*Oncorhynchus mykiss*)	Threatened
green sturgeon (*Acipenser medirostris*)	Threatened

1.1 Background

The U.S. Army Corps of Engineers (Corps) initiated formal Section 7 consultation with the National Marine Fisheries Service (NMFS) for the ARCF GRR on June 27, 2014. The original SAM analysis included in the Section 7 consultation for the ARCF GRR was determined to be insufficient in detail. Through internal discussions and interagency coordination with the NMFS, a revised set of parameters was developed to better assess the project's impact on focus fish species and their habitat. This report documents and provides justification for the revised SAM analysis and should replace the analysis included in the original Biological Assessment (BA) Appendix B.

1.2 SAM Modeling Approach

Long-term effects of the ARCF GRR project on focus fish species and their habitat were estimated using the SAM. The SAM computations were performed using the SAM Electronic Calculation Template (ECT) Version 4.0 (April 2012) developed by the Corps and Stillwater Sciences, in consultation with the National Marine Fisheries Service (NMFS), U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife Service (CDFW), and California Department of Water Resources (DWR), academic contributions from the University of California at Davis and Humboldt State University, and peer reviewed by sixteen professionals in fish biology, river geomorphology, environmental sciences, and engineering (USACE 2012). The SAM allows agencies to quantitatively assess the potential effects of bank protection and stream restoration projects to ensure that these activities do not jeopardize Chinook salmon, steelhead, and green sturgeon, or destroy or adversely modify their critical habitat. The

SAM can also determine suitable compensation for habitat loss, by evaluating the benefits of certain design features (e.g., planted emergent vegetation) to target fish species.

The SAM employs six habitat variables to characterize near-shore and floodplain habitats of listed fish species:

- *bank slope*—average bank slope of each average seasonal water surface elevation;
- *floodplain availability—ratio of wetted channel and floodplain area during the 2-year flood, to the wetted channel area during average winter and spring flows;*
- *bank substrate size—the median particle diameter of the bank (i.e., D50) along each average seasonal water surface elevation;*
- *instream structure*—percent of shoreline coverage of instream woody material along each average seasonal water surface elevation;
- *aquatic vegetation*—percent of shoreline coverage of aquatic or riparian vegetation along each average seasonal water surface elevation; and
- *overhanging shade*—percent of the shoreline coverage of shade along each average seasonal water surface elevation.

The SAM does not directly model changes in the above variables. Instead, habitat changes are estimated separately by the user and entered into an input data file to an electronic calculation template (ECT) developed within an MS Access database to track species responses to project actions over time. Changes in habitat variables may be fixed in time, such as installation of revetment at a particular slope and substrate size. In other circumstances, habitat evolution over time may be represented by more gradual changes in variables such as changes in floodplain inundation due to meander migration or changes in shade due to growth of planted vegetation. Typically, habitat evolution modeling is restricted to shade estimates from riparian growth models, but the SAM accommodates any number of other habitat modeling approaches such as meander migration modeling or large woody debris recruitment modeling.

Once a particular time series of habitat variable estimates is developed and entered into an ECT input file fish responses are calculated using previously developed relationships between habitat variables and species/life stage responses (USACE 2012). The response indices vary from 0 to 1, with 0 representing unsuitable conditions and 1 representing optimal conditions for survival, growth, and/or reproduction. For a given site and scenario (e.g., with- or without-project), the ECT uses these relationships to determine the responses of individual species and life stages to the measured or predicted values of each variable, for each season and target year; the ECT then multiplies these values together to generate an overall species response index. This index is then multiplied by the linear distance or area of bank to which it applies; the product is then integrated through time, generating a weighted species response index (WRI expressed as ft or ft^2) in each year of the analysis. The WRI provides a common metric that can be used to quantify habitat values over time, compare project designs to existing conditions, and evaluate the effectiveness of on-site and off-site habitat compensation actions.

2.0 Habitat Analysis

Following procedures described in the SAM (USACE 2012), construction activities at each site were translated into habitat variables for pre-project and with project conditions in each of four seasons using available data sources. The relevant habitat conditions to encode the conceptual response models for the focus fish species from the present to the future (t = 0, 1, 5, 15, 25, and 50 yrs), and under pre-project and with-project conditions are described below. Revisions to the original SAM analysis are summarized in the discussion.

2.1 Project Description

The ARCF GRR project tentatively selected plan – Alternative 2 – Sacramento Bypass and Improve Levees, involves the construction of fix-in-place levee remediation measures along the Sacramento River, American River, and north side tributaries as well as widening of the Sacramento Weir and Bypass. Proposed repair actions for each waterway are presented below (Table 2). This SDAM analysis groups project actions into 4 SAM reaches based on hydrologic connectivity: American River North (ARN_AB), American River South (ARS_ABC), Sacramento River South (ARS_DEFG), and the Sacramento Bypass (SBP).

2.1.1 Sacramento River

The levees along the Sacramento River under Alternative 2 would be improved to address identified seepage, stability, erosion, and a minimal amount of height concerns. Most height concerns along the Sacramento River would be addressed by a widening of the Sacramento Weir and Bypass to divert more flows into the Yolo Bypass.

2.1.2 American River

Levees along the American River under Alternative 2 require improvements to address erosion. The proposed measures for these levees consist of waterside armoring to prevent erosion to the river bank and levee, which could potentially undermine the levee foundation. There are two measures proposed for the American River levees: (1) bank protection, and (2) launchable rock trench. Both of these measures are described in detail in the BA.

2.1.3 East Side Tributaries

Natomas East Main Drain Canal (NEMDC) requires improvements to address seepage and stability at locations where historic creeks had intersected the current levee alignment. A conventional open trench cutoff wall would be constructed at these locations to address the seepage and stability problems. The NEMDC east levee also has height issues which will be addressed with construction of a new floodwall. The floodwall would be placed at the waterside hinge point of the levee and would be designed to disturb a minimal amount of waterside slope and levee crown for construction.

We will be doing no in-water work on NEMDC under the Alternative 2 scenario and after consultation with NMFS, NEMDC was left out of the SAM analyses.

2.1.4 Sacramento Weir and Bypass

Under Alternative 2, the width of the Sacramento Weir and Bypass would be roughly doubled to accommodate increased bypass flows. The expanded Sacramento Weir and Bypass would generally result in an additional 25,000 cfs flow during high water conditions. The frequency of water diversion is expected to be the same, which is to use the current Sacramento Weir operation based on a stream gage at the I Street Bridge (Schlunegger 2014). Under normal flow conditions the Sacramento Weir and Bypass would be operating at pre-existing conditions described in detail in the ARCF GRR biological assessment (USACE 2014). Implementation of this action would result in the degradation of the existing north levee of the Sacramento Bypass and construction of a new levee approximately 1,500 feet to the north. The existing Sacramento Weir would be expanded to match the wider bypass. At this time, it is not known whether the new segment of weir would be constructed consistent with the 1916 design described above, or whether it would be designed to be a gravity-type weir. The new north levee of the bypass would be designed to be consistent with the existing Sacramento Bypass north levee, however, it would also include a 300-foot-wide seepage berm on the landside with a system of relief wells.

Table 2. ARCF GRR Project Alternative 2 – Proposed Remediation Measures by Waterway.

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[1]	---	---	Bank Protection, Launchable Rock Trench	---
Sacramento River	Cutoff Wall	Cutoff Wall	Bank Protection	Sacramento Bypass and Weir Widening, Levee Raise
NEMDC	Cutoff Wall	Cutoff Wall	---	Floodwall
Arcade Creek	Cutoff Wall	Cutoff Wall	---	Floodwall
Dry/Robla Creeks	---	---	---	Floodwall
Magpie Creek[2]	---	---	---	Floodwall, Levee Raise

[1]American River seepage, stability, and overtopping measures were addressed in the American River Common Features, WRDA 1996 and 1999 construction projects.
[2]In addition to the Floodwall, Magpie Creek will include construction of a new levee along Raley Boulevard south of the creek, and construction of a detention basin on both sides of Raley Boulevard. In addition, some improvements would need to occur on Raley Boulevard, including widening of the Magpie Creek Bridge, raising the elevation of the roadway, and removing the Don Julio Creek culvert.

2.1.5 Construction Schedule

The ARCF GRR project reach will be implemented in increments. The timing of each project reach (Table 3) is based on the proposed schedule provided in the Biological Assessment: American River Common Features General Reevaluation Report (USACE 2014).

Table 3. Tentative Construction Schedule for the Recommended Plan.

PRIORITY	WATERWAY	REACH[1]	YEAR OF PROJECT CONSTRUCTION												
			1	2	3	4	5	6	7	8	9	10	11	12	13
1	Sacramento River	ARS F													
2	Sacramento River	ARS E													
3	American River	ARS A													
4	Sacramento River	ARS G													
5	Sacramento River	ARS D													
6	American River	ARS B													
7	American River	ARN A													
8	American River	ARS C													
9	American River	ARN B													
10	Sacramento Weir & Bypass	--													
11	Arcade Creek	ARN D													
12	NEMDC	ARN F													
13	Arcade Creek	ARN E													
14	NEMDC	ARN C													
15	Dry/Robla Creek	ARN G													
16	Magpie Creek	ARN I													

2.1.6 Vegetation on Levees

Compliance with Engineering Technical Letter 1110-2-571 (ETL) vegetation requires implementation of a vegetation-free zone within 15 ft of the waterside and landside toes of a levee. The levees along the Sacramento and American rivers were often set close to the river which has resulted in limited riparian vegetation in the project reach. The Corps is seeking a variance from the ETL vegetation requirements along the Sacramento River and American River portions of this project. This SAM analysis assumes that a Vegetation Variance Request (VVR) was assumed to be in place for the Sacramento and American River reaches. The Corps will obtain an ETL-approved vegetation variance exempting the Sacramento River sites from vegetation removal in the lower third of the waterside of the levee prior to final construction and design phase. The Corps will be complying with the ETL on the American River via a System Wide Implementation Framework (SWIF). The VVR is not assumed to apply to the SBP.

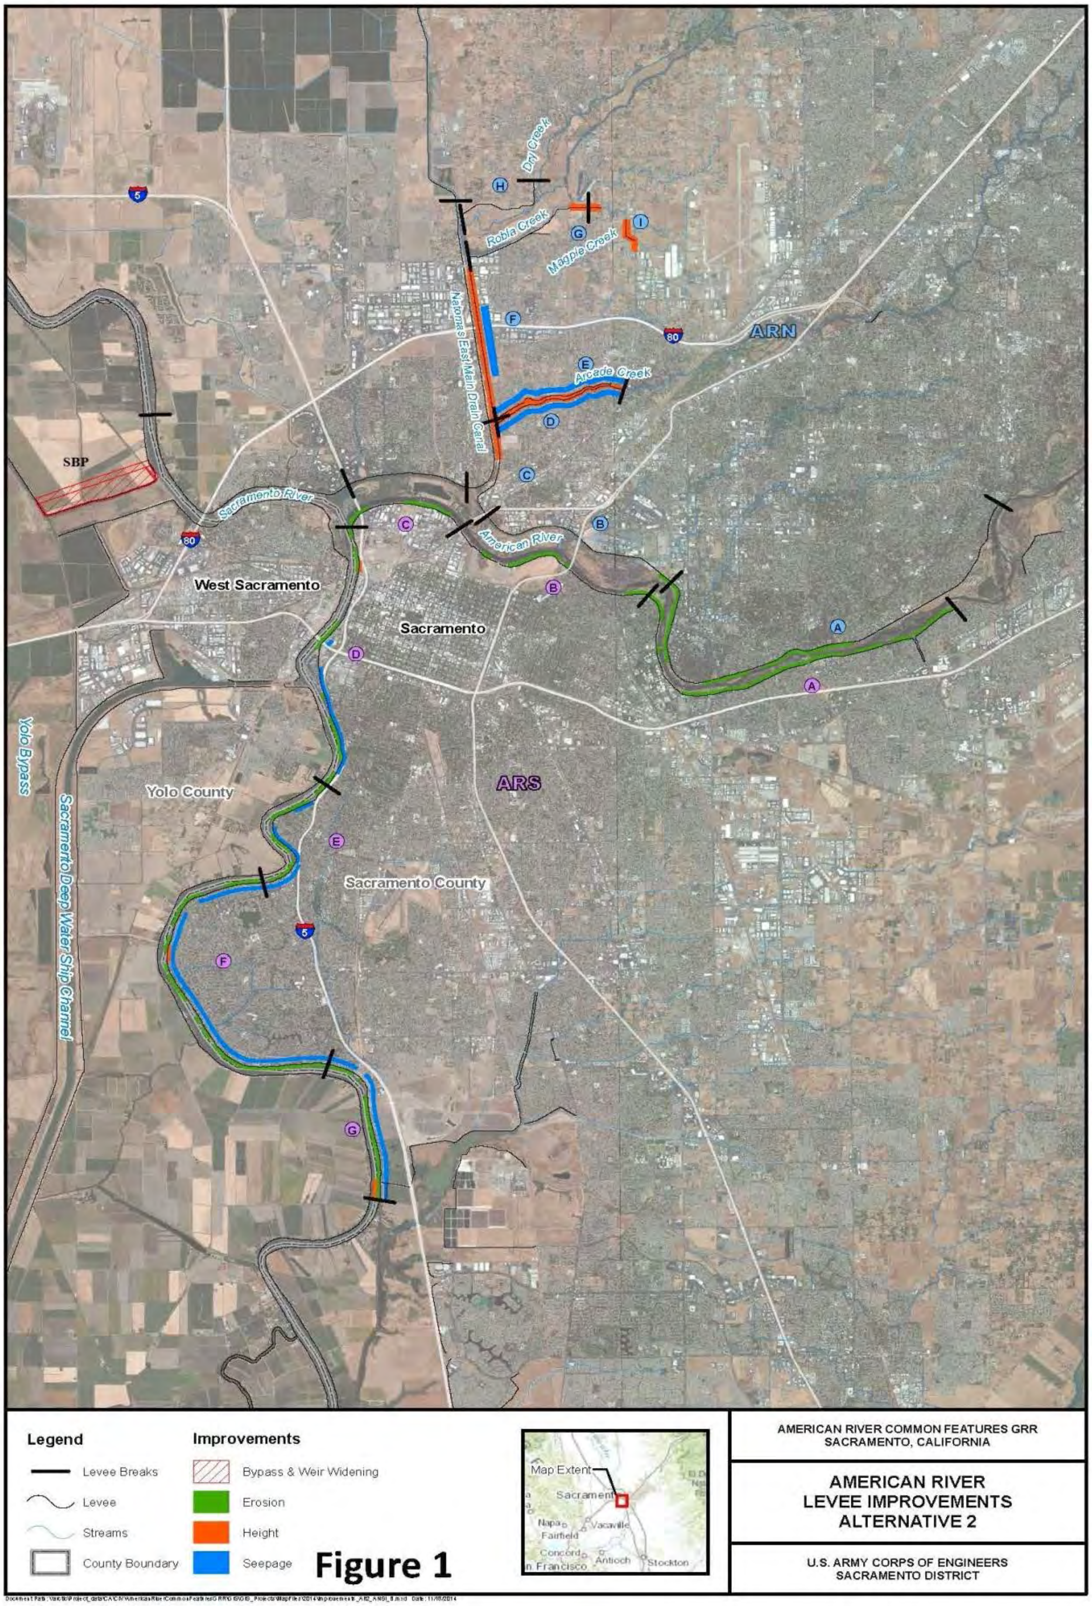

Figure 1. ARCF GRR Study Area with Reach Identification.

2.2 Characterization of Existing Conditions

The following data sources were used to characterize SAM habitat conditions (as defined by bank slope, floodplain availability, substrate size, instream structure, aquatic vegetation, and overhanging shade) within the ARCF GRR project area under existing or pre-project conditions.

Sacramento River Revetment Database – This database was used to stratify the project reach into subreaches that encompass relatively uniform bank conditions based on their general physical characteristics (USACE 2007). This database was used to characterize existing habitat conditions within individual reaches where more recent data were unavailable.

Aerial images of the ARCF GRR project reach (Google™ Earth Pro), provided current and historical images of bank conditions that were used to address gaps or uncertainties related to existing cover characteristics within individual subreaches.

The following describes how input values for each of these attributes were derived for existing conditions in the SAM assessment. Specific input values for each site can be seen below at the end of report in (Tables 6-25).

2.2.1 Bank Slope

In the SAM, bank slope serves as an indicator of the availability of shallow-water habitat and is obtained from point estimates of bank slope (horizontal change to vertical change, dW:dH) along each seasonal shoreline (i.e., the line where the water surface intersects the bank on average fall, winter, spring, and summer) (USACE 2012). Existing bank slopes were extrapolated from cross sections along the Sacramento River, American River, and existing SAM analyses performed on regionally analogous sites. Bank slope along all reaches was assumed to be 2 for existing conditions.

2.2.2 Floodplain Availability

In the SAM, floodplain habitat availability is considered important for juvenile life stages and is defined by areas that are flooded by the 2-year flood event (Q2) and measured by calculating a Floodplain Inundation Ratio (USACE 2012). This ratio is calculated by dividing the wetted channel and inundated floodplain areas during the 2- year flood event (AQ2) by the wetted channel area (AQavg) during average winter and spring flows. The amount of available floodplain habitat is consequently proportional to the ratio’s positive deviation from unity (i.e., values greater than 1) (USACE 2012).

In this SAM analysis, it was assumed that the with-project floodplain inundation ratios would be the same as pre-project values, which is consistent with assumptions made during the pre-construction SAM analyses. As a result, no impacts to habitat quality at the ARCF GRR reaches are expected with respect to this habitat variable.

2.2.3 Bank Substrate Size

The median substrate size (D_{50}) along the summer-fall and winter-spring shorelines of the project reach was determined through by referencing the Revetment Database (USACE 2007) and current and historical aerial images. Based on previous analysis of Sacramento River Bank Protection Project (SRBPP) sites (USACE 2008, USACE 2013) sections of shoreline with natural substrate were assigned a D_{50} of 0.25 inches. Sections of shoreline with rock revetment were assigned a D_{50} of 10 inches.

2.2.4 Instream Structure

The shoreline coverage of Instream Woody Material (IWM) along the average summer-fall and winter-spring shorelines of the ARCF GRR project reach were determined by referencing the revetment database (USACE 2007). The revetment database uses four classes of instream structure, based on ranges of percent shoreline having IWM. Table 4 indicates how these revetment database attribute values were converted to a single value for input to SAM. These values were assumed to be appropriate for both the summer-fall and winter-spring seasons. For sub-reaches without available data, an estimate was based on shoreline conditions assessed from aerial images. Shorelines with dense riparian canopy were assigned 5% shoreline coverage of IWM. Shorelines without dense riparian canopy were assigned 0% shoreline coverage of IWM.

Table 4. Conversion of Revetment Database Instream Woody Material Classes to SAM Attribute Value for Instream Structure.

Revetment Database IWM Class	SAM Input Value
None	0%
1 - 10%	5%
11 - 50%	30%
> 50%	75%

2.2.5 Aquatic Vegetation

The revetment database attribute for Emergent Vegetation was used for summer-fall aquatic vegetation characterization, and the Ground Cover attribute was used for winter-spring characterization. Within the ARCF GRR project reaches, this approach generally gave a vegetation value of zero for summer-fall conditions, which is appropriate given the scarcity of emergent aquatic vegetation. Table 5 summarizes the conversion of revetment database attribute values for input to the SAM analysis.

Table 5. Conversion of Revetment Database Emergent Vegetation and Ground Cover Classes to SAM Attribute Values for Vegetation.

	Revetment Database IWM Class	SAM Input Value
Summer and Fall	False	0%
Revetment Database:	PEM 1 - 5%	3%
“Emergent Vegetation” Attribute	PEM 6 - 25%	15%
	PEM 26 – 75%	50%
	PEM >75%	85%
Winter and Spring	<25%	13%
Revetment Database:	26-50%	38%
“Ground Cover” Attribute	51-75%	63%
	>75%	88%

2.2.6 Overhanging Shade

The extent of overhanging shade along the summer-fall and winter-spring shorelines was determined through analysis of current and historic aerial images. Summer-fall conditions were analyzed using imagery from late summer and early fall months, typically representative of low water conditions. Winter-spring conditions were analyzed using imagery from late winter and early spring months, typically representative of high water conditions. Values for overhanging shade at winter and spring habitat conditions were modified by factors of 0.25 and 0.75 respectively to account for seasonal defoliation.

2.3 Characterization of With-Project Conditions

The with-project conditions were characterized using the project description outlined for Alternative 2 in the ARCF GRR BA. This analysis was conducted at a feasibility level of design; specific project designs will be developed under a Planning and Engineering Design phase. In the absence of more specific designs, this SAM analysis was developed using a set of “reasonable worst-case” parameters. The parameters were developed by evaluating the applicability of past levee repair designs to the project reach. Past levee repairs were conducted under the Sacramento River Bank Protection Project (SRBPP) within each of the sub-reaches (USACE 2008, USACE 2013). Applicability of design features was evaluated using the professional judgment and experience of the project team. In cases where the applicability of a particular design feature for a particular reach was in question, the analysis erred on the side of caution and applied reduced values or omitted the feature from final analysis. The set of reasonable worst-case parameters is designed to provide a maximum estimation of impact for the purpose of consultation at feasibility planning level. A Vegetation Variance Request (VVR) was assumed to be in place for the Sacramento and American River reaches. The Corps will obtain an ETL-approved vegetation variance exempting the Sacramento River sites from vegetation removal in the lower third of the waterside of the levee prior to final construction and design phase. The Corps will be complying with the ETL on the American River via a SWIF. The VVR is not assumed to apply to the SBP. Specific habitat attributes are provided by site in (Tables 6-25) and specific justifications for each variable is also provided in those tables.

The following describes how input values for each of the SAM habitat attributes were derived for with-project conditions:

2.3.1 Bank Slope

In the SAM, bank slope serves as an indicator of the availability of shallow-water habitat and is obtained from point estimates of bank slope (horizontal change to vertical change, dW:dH) along each seasonal shoreline (i.e., the line where the water surface intersects the bank on average fall, winter, spring, and summer) (USACE 2004). With-project bank slopes were based on the description of project actions for each reach. Bank slopes for the Sacramento and American River reaches were assumed to be analogous to associated SRBPP repair sites that were in close proximity to the reach being analyzed. Consequently, bank slopes with a summer-fall slope of 3 and winter-spring slope of 10 were used.

2.3.2 Floodplain Availability

The with-project floodplain inundation ratios used in this SAM analysis remained unchanged from existing conditions. Levee repair and bank stabilization actions typically do not increase floodplain availability (with exception of constructing setback levees). In the absence of levee setback actions, the amount of available floodplain areas and channel cross sections would not be greatly altered during levee repair activities.

In this SAM analysis, it was assumed that the with-project floodplain inundation ratios would be the same as pre-project values. As a result, no impacts to habitat quality at the ARCF GRR reaches are expected with respect to this habitat variable.

2.3.3 Bank Substrate Size

The median substrate size (D_{50}) along the summer-fall and winter-spring shorelines of the project reach were based on the description of project actions for each sub-reach. Bank substrate size along the American River sub-reaches were assumed to be 18 inch rock revetment at summer-fall shoreline and 0.25 inch natural substrate at winter-spring shoreline. Bank substrate size along the Sacramento River sub-reaches were assumed to be 12 inch rock revetment at summer-fall shoreline and 0.25 inch natural substrate at winter-spring shoreline.

2.3.4 Instream Structure

The shoreline coverage of IWM along the average summer-fall and winter-spring shorelines was based on the description of project actions for each reach. In the SAM analysis, IWM coverage along the Sacramento and American River reaches were assumed to include installation of 40% shoreline coverage at summer-fall and winter-spring shoreline conditions.

2.3.5 Aquatic Vegetation

The shoreline coverage of aquatic vegetation along the average summer-fall and winter-spring shorelines was based on the description of project actions for each sub-reach. Aquatic vegetation along the Sacramento and American River sub-reaches were assumed to be analogous to SRBPP repair sites. The vegetation growth models below applied to the Sacramento and American River sub-reaches were taken from previous SAM analysis'. For the American River (ARN_AB, ARS_ABC) four previously constructed SRBPP sites within the ARCF GRR project area were used for analysis (LAR 0.3L, LAR 2.8L, LAR 10.0L, and LAR 10.6L)(USACE, 2013). For the Sacramento River 15 previously constructed SRBPP sites within the ARCF GRR project area were used for analysis (SAC 49.7L, SAC 52.3L, and SAC 53.5R)(USACE 2013) and (RM 47.0L, RM 47.9R, RM 48.2R, RM 49.6R, RM 49.9L, RM 50.2L, RM 50.4L, RM 50.8L, RM 51.5 L, RM 52.4L, RM 53.1L, and RM 56.7L)(USACE 2008). Relevant O&M activities were considered but excluded from this analysis. The assumed vegetation variance would apply to woody vegetation only and O&M activities would be expected to result in the removal of shrubs on the slope of the levee; however, it was assumed that typical SRBPP repair designs would locate the planted riparian bench at appropriate elevations and distance from the levee to allow for revegetation efforts. Any removal of shrubby vegetation as the result of O&M activities would take place on the upper slope of the levee and would not impact the habitat considered in a typical SAM analysis.

2.3.6 Overhanging Shade

The shoreline coverage of overhanging shade along the average summer-fall and winter-spring shorelines was based on the description of project actions for each sub-reach. Overhanging shade along the Sacramento and American River sub-reaches were assumed to be analogous to SRBPP repair sites. It was assumed that a variance would be in place allowing for retention of woody vegetation along the lower 2/3 of the levee slope. As the result of constructing a planted bench, it was assumed that the with-project seasonal shoreline would be shifted away from the existing shade providing canopy. Under this assumption, existing summer-fall values for overhanging shade were taken as the starting point for with-project winter-spring conditions. The with-project winter-spring values were further reduced by 75% (winter) and 25% (spring) to account for defoliation. As a final step, these winter-spring values were reduced by 20% to account for trees removed for construction equipment access. With-project overhanging shade values were expected to start at 0% as the result of a constructed bench shifting the shoreline away from the existing canopy. The shade growth models below were applied to the starting seasonal values for overhanging shade described above along the Sacramento and American River sub-reaches. These shade growth models were taken from previous SRBPP SAM analysis' conducted within the ARCF GRR project area.

3.0 Results

The SAM results are presented as weighted response indices (WRI), that give a relative indication of fish response to a project action over time. A negative WRI can be interpreted as a reduction in habitat value and a positive WRI can be interpreted as a increase in habitat value Although the WRI values are not directly representative of actual lengths or areas, the resource agencies have used those values as proxies in determining mitigative requirements. Appropriate mitigation is typically determined by identifying the maximum negative WRI for critical life stages (spawning and egg incubation, fry and juvenile rearing, and juvenile migration) on a site-by-site basis. Therefore this section will present results with a focus on the identification of maximum negative WRIs.

As described above, the ARCF GRR project reaches were grouped into four SAM analysis reaches based on hydrologic connectivity. Results are presented below by reach and species and are summarized in tables 30-32 and figures 2-22 at the end of the document.

3.1 Sacramento River SAM Analysis (ARS_DEFG)

The Sacramento River SAM analysis reach includes the entire left bank (east side) of the Sacramento River from the American River confluence to approximately 4,020 linear feet (lf) below the Freeport Bridge. The response of all runs of Chinook salmon, steelhead, and green sturgeon to project actions were included in the analysis of this reach. The green sturgeon spawning and egg incubation life stage was excluded from the analysis because spawning does not occur in the project area.

3.1.1 Spring/ Fall/ Late-Fall/ Winter Run Chinook Salmon

Chinook salmon are expected to show a long term positive response to project actions in the Sacramento River SAM analysis reach over the lifetime of the project. Chinook salmon should exhibit a positive response by year 5 in the winter-spring when most juvenile Chinook salmon are expected in the ARCF GRR project area. Short term negative WRI are expected within the recommended recovery period for Chinook salmon. The maximum negative WRI identified is -4,258 ft for the juvenile migration life stage of Chinook salmon in the summer of year 9. Short term negative WRI values will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions. The SAM data iterations for the various life stages for Chinook salmon can be seen in (Table 28). The WRI response curves for juvenile migration and rearing can be located in (Figures 4 and 7). The NMFS SAM effects analysis summary tables can be seen in (Table 32).

3.1.2 Steelhead

Steelhead are expected to show a long term positive response to project actions in the Sacramento River SAM analysis reach over the lifetime of the project. Steelhead should exhibit a positive response by year 4 in the winter-spring when most juvenile steelhead will be migrating and rearing through the project area. The maximum negative WRI identified is -3,985 ft for the juvenile migration life stage of steelhead in the fall of year 10. Short term negative WRI values will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions. The WRI response curves for juvenile migration and rearing can be located in (Figures 10 and 13).

3.1.3 Green Sturgeon

SRBPP onsite mitigative features were designed to maximize habitat response for salmonid species. SAM WRI's for green sturgeon generally indicate a negative response or no response to typical onsite mitigative features. Green sturgeon are expected to show long term negative response to project actions in the Sacramento River SAM analysis reach for several life stages at all seasonal habitat conditions over the lifetime of the project. The maximum negative WRI identified is -5,009 for fry and juvenile rearing in the summer of year 1. Negative WRI displayed a general trend toward decreasing beyond the lifetime of the project for fry and juvenile rearing life stages. Negative WRI values for adult life stages will result from the creation of a 10:1 planted bench at winter/spring habitat conditions. The WRI response curves for juvenile rearing can be located in (Figure 16).

3.2 American River SAM Analysis (ARN_AB and ARS_ABC)

The American River SAM analysis reaches include portions of the right and left bank of the American River from Goethe Park to the confluence of the Sacramento. The response of spring and fall runs of Chinook salmon, steelhead, and green sturgeon were included in the analysis of these reaches. Additional seasonal fall run juvenile migration life stage analysis was conducted after consultation with NMFS. Green sturgeon analysis was also included because of critical habitat in the lowest sub-reach (ARS_C) of the American River project area.

3.2.1 Spring/ Fall Chinook Salmon

Chinook salmon are expected to show a long term positive response to project actions in the American River SAM analysis reaches over the lifetime of the project when both IWM and planted benches are incorporated into the with-project conditions. Chinook salmon should exhibit a positive response by year 5. Short term habitat deficits are expected within the recommended recovery period for Chinook salmon. The maximum negative WRI value identified for the American River SAM ARN_AB and ARS_ABC is -3,129 ft for the juvenile migration life stage of fall-run Chinook salmon in the summer of year 1. Short term negative WRI values will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions. The SAM data iterations for the various life stages for Chinook salmon can be seen in (Tables 26-27). The WRI response curves for juvenile migration and rearing can be located in (Figures 2,3,5,and 6). Additional fall-run Chinook salmon juvenile migration life stages not normally set as default in SAM were included on the American River reaches per NMFS request.

3.2.2 Steelhead

Steelhead are expected to show a long term positive response to project actions in the American River SAM analysis reach over the lifetime of the project. Steelhead should exhibit a positive response by year 4. Short term habitat deficits are expected within the recommended recovery period for steelhead. The maximum negative WRI value identified for the American River SAM analysis is -3,061 ft for the adult residence life stage in the summer of year 1 (Figures 20 and 21). Short term negative WRI values will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions. The WRI response curves for juvenile migration and rearing can be located in (Figures 8,9,11, and 12).

3.2.3 Green Sturgeon

Project actions in the American River SAM analysis reach will mimic SRBPP repair site onsite mitigative features. SRBPP onsite mitigative features were designed to maximize habitat response for salmonid species; green sturgeon will exhibit a negative response for juvenile rearing in the summer/fall to these onsite mitigative features. However, during the winter/spring green sturgeon juvenile rearing life stages will exhibit a positive response to these onsite mitigative features. The maximum negative WRI value identified is -7,118 ft for the fry and juvenile rearing life stage in the summer of year 1. The WRI response curves for juvenile rearing can be located in (Figures 14 and 15).

3.3 Sacramento Bypass and Weir SAM Analysis

The Sacramento Bypass SAM analysis reach includes the right bank (north side) of the Sacramento Bypass levee in its entirety from the confluence of the Sacramento River to its termination at the Yolo Bypass. The response of all runs of Chinook salmon, steelhead, and green sturgeon were included in the analysis of this reach.

3.3.1 Spring/ Fall/ Late-Fall/ Winter Run Chinook Salmon

Chinook salmon are expected to show a small long term negative response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project. Chinook salmon should exhibit a negative response by year 1. The maximum negative WRI value identified is -188 ft for the juvenile migration life stage of Spring and Winter-run Chinook salmon in the spring of year 2. Short term and long term negative WRI values will result from the loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions during and after the construction of the extension to the Sacramento Bypass Weir. The SAM data iterations for the various life stages for Chinook salmon can be seen in (Table 29). The NMFS SAM effects analysis summary tables can be seen in (Table 33).

3.3.2 Steelhead

Steelhead are also expected to show a small long term negative response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project. Steelhead should exhibit a negative response by year 1. The maximum negative WRI value identified is -174 ft for the juvenile migration life stage in the spring of year 2. Short term and long term negative WRI values will result from the loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions during and after the construction of the extension to the Sacramento Bypass Weir. The NMFS SAM effects analysis summary tables can be seen in (Table 33).

3.3.3 Green Sturgeon

Green Sturgeon are expected to show a long term positive response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project for the fry and juvenile rearing life stages in the winter/spring/summer/fall of year 1. The maximum negative WRI value identified is -8 ft for the adult residence life stage of green sturgeon in the winter/spring/summer of year 1 which carries over through the life of the project into year 50. The SAM data iterations for the various life stages for green sturgeon can be seen in (Table 29). The NMFS SAM effects analysis summary tables can be seen in (Table 33).

4.0 Discussion

The SAM analysis indicates that the project actions in the Sacramento River SAM analysis reach, American River SAM analysis reach, and the Sacramento Bypass SAM analysis reach would result in short and longer-term impacts for focus fish species. Impacts to Chinook salmon, Central Valley steelhead, and green sturgeon are generally the result of reduction in the available natural substrate, shade and the alteration of near-shore slope resulting from bank armoring. Long term recovery of onsite vegetation, addition of IWM, and retention of existing vegetation are all expected to minimize impact as well as contribute to long term gains in habitat value.

This SAM analysis employed a set of worst case scenario parameters developed to capture the maximum potential impacts of the project for the Section 7 consultation process. Future implementation of the project is expected to result in significantly lower impacts. Project actions along portions of the American River reach will likely not include bank armoring in their final design, which will significantly reduce estimated impacts to fish species. Additional mitigative design features or improved erosion repair designs may result in reduced impact compared to the legacy designs used for the basis of this analysis. Site specific designs will be implemented on a site by site basis in consultation with resource agencies and project partners to minimize impacts as well as maximize opportunities for implementing onsite mitigative features.

During project implementation, site specific SAM analyses will be run on final designs to better evaluate impact. SAM results will be used by the Corps and NMFS in the negotiation of appropriate mitigation for project actions. Although short term impacts are generally self mitigating through the development of onsite mitigative features, the Corps will compensate for the temporal impacts to habitat through the purchase of offsite mitigative credits. Typically appropriate mitigation will be based on the identification of maximum negative WRI values. By mitigating for the maximum negative WRI, lesser impacts are expected to be appropriately mitigated. As a general rule, the SAM applies any habitat characteristics at summer/fall conditions to winter/spring conditions with the assumption that those characteristics would provide similar value during inundation. Onsite mitigation at summer/fall conditions is expected to provide similar habitat benefit for winter/spring conditions. Offsite mitigation is expected to provide mitigative value at all seasonal habitat conditions. Longer term impacts to habitat may not recover to baseline conditions over the life of the project due to design restrictions. These impacts to habitat will be compensated through the purchase of offsite mitigative credits as well as the incorporation of additional onsite mitigative features (ie. low water plantings, additional IWM, additional revegetation).

Additional mitigative concerns, not considered in a SAM analysis, will be addressed along the Sacramento Bypass reach, including potential adult and juvenile passage issues, loss of shoreline riparian vs. gain in floodplain, and contradicting ESA species habitat requirements. These issues will be considered and appropriate actions will be taken where possible in coordination with other agencies.

4.1 Chinook Salmon

Impacts to Chinook salmon were analyzed for the Sacramento River SAM analysis reach (ARS_DEFG), American River SAM analysis reach (ARN_AB, ARS_ABC) and the Sacramento Bypass SAM analysis reach. In the Sacramento River SAM analysis reach, negative WRI values are due to short term removal of aquatic vegetation and overhanging shade caused by the repair action. The SAM analysis indicates that repair actions would result in a maximum negative WRI value of -4,258 ft. This value is based on the maximum negative WRI value observed for juvenile migration life stage of Chinook salmon in the summer of year 9. USACE will mitigate for -4,258 ft of equivalent habitat as described above in Section 4.0.

In the American River SAM analysis reaches ARN_AB and ARS_ABC negative WRI values are due to short term removal of aquatic vegetation and overhanging shade caused by the repair action. The SAM analysis incorporating planted benches and IWM indicates that repair actions would result in a maximum habitat deficit of -3,129 ft. This value is based on the maximum negative WRI value observed for the juvenile migration life stage of spring and fall-run Chinook salmon in the summer and fall of year 1. USACE will mitigate for -3,129 ft of equivalent habitat as described above in Section 4.0.

There were no initial construction impact negative WRI values for the juvenile rearing life stage of Chinook salmon in the winter and spring water levels on the American and Sacramento River reaches. A possible explanation is that the SAM ECT does not produce an output at Year-0. It does not calculate the difference from the baseline to with-Project results. SAM at Year-0 is zero. The relative response for Year-1 is actually the Year-0 results+Year-1 results divided by 2, see pages 5-29 to 5-31 in the SAM Certification Update for SAM formula detailed explanation. In Year-0 revetment will be added, vegetation will be removed and slope will have a positive change. In Year-1 IWM will be added, soil and planting on the bench will occur, and the VVR will kick in. Year-0 habitat deficits would be more than the Year-1 deficits where the positive and negative deficits are equal.

In the Sacramento Bypass SAM analysis reach negative WRI values are due to short and long term removal of aquatic vegetation and overhanging shade for the upstream extension of the Sacramento Bypass Weir. The SAM analysis indicates that repair and removal actions would result in a maximum negative WRI value of -146 ft. This value is based on the maximum negative WRI value observed for juvenile migration of Chinook salmon in the winter of year 1. USACE will mitigate for -146 ft of equivalent habitat as described above in Section 4.0.

4.2 Steelhead

Impacts to steelhead were analyzed for the Sacramento River SAM analysis reach, American River SAM analysis reach, and the Sacramento Bypass SAM analysis reach. The Sacramento River SAM analysis indicates that repair actions would result in maximum negative WRI values of -3,985 ft. This value is based on the maximum negative WRI value observed for the juvenile migration life stage of steelhead in the fall of year 10.

The American River SAM analysis ARN_AB and ARS_ABC indicates that repair actions would result in negative WRI values of -3,061 ft. This negative WRI is expected to be adequately compensated through mitigation of a greater negative WRI for Chinook salmon.

There were no initial construction impact negative WRI values for the juvenile rearing life stage of steelhead in the winter and spring water levels on the Sacramento River reaches. A possible explanation is that the SAM ECT does not produce an output at Year-0. It does not calculate the difference from the baseline to with-Project results. SAM at Year-0 is zero. The relative response for Year-1 is actually the Year-0 results+Year-1 results divided by 2, see pages 5-29 to 5-31 in the SAM Certification Update for SAM formula detailed explanation. In Year-0 revetment will be added, vegetation will be removed and slope will have a positive change. In Year-1 IWM will be added, soil and planting on the bench will occur, and the VVR will kick in. Year-0 habitat deficits would be more than the Year-1 habitat deficits where the positive and negative deficits are equal.

The Sacramento Bypass SAM analysis indicates that repair actions would result in maximum negative WRI values of -174 ft. This value is based on the maximum negative WRI value observed for the juvenile migration life stage of steelhead in the spring of year 4. This negative WRI is expected to be adequately compensated through mitigation of a greater negative WRI for Chinook salmon.

4.3 Green Sturgeon

Impacts to green sturgeon were analyzed for the Sacramento and American River SAM and Sacramento Bypass analysis reaches. Green sturgeon critical habitat in the American River extends from the confluence of the Sacramento River to the Highway 160 bridge (ARS_C). Additional SAM elements were incorporated to address potential green sturgeon effects in the American River reaches (ARN_AB and ARS_AB), as per NMFS request, even though use of these reaches by green sturgeon has not been documented. Recently a white sturgeon (161mm) was collected in a rotary screw trap (RST) by the U.S. Fish and Wildlife Service (USFWS) at the Watt Avenue bridge, the first such documented catch of a sturgeon since records have been kept dating back to approximately 1996. There have been no green sturgeon collected, and the correlation of green sturgeon presence to white sturgeon presence is not well understood for larval life stages in this region of the river. This additional analysis allowed for a more conservative estimate of impacts and may not necessarily reflect the true impacts from the project.

The habitat requirements of green sturgeon are not well understood; assumptions built into the SAM on fish response to shoreline features were based on limited information. Habitat use of the American River, Sacramento River, and Sacramento Bypass project reaches by green sturgeon are likely limited to use as a migration corridor by adults and potential rearing area by juvenile life stages. Although the SAM indicates negative response to habitat by adult life stages, it is unlikely that shoreline repair activities would significantly impact the river for residence or as a migration corridor. SRBPP style repairs are designed to mimic naturally occurring habitat types and are not expected to significantly alter the width of the river. USACE does not expect any significant impacts to the adult residence or adult migration life stages in the American or Sacramento River and does not propose any additional mitigation.

No suitable spawning habitat exists in the Sacramento River, American River, and Sacramento Bypass project reaches. Green sturgeon spawning with concurrent egg incubation and early life history primarily takes place upriver of Colusa on the Sacramento River and in the lower Feather River outside of the project area. Because no suitable spawning habitat is present in the project reaches under existing conditions, USACE does not expect any significant impacts to the spawning and egg incubation life stage of green sturgeon and does not propose any additional mitigation.

The American River SAM analysis ARN_AB and ARS_ABC indicates that repair actions would result in a maximum negative WRI values of -7,118 ft. for fry and juvenile rearing in the summer of year one. The Sacramento River SAM analysis ARS_DEFG indicates that repair actions would result in a maximum negative WRI values of -5,009 for fry and juvenile rearing in the summer of year one.

The Sacramento Bypass SAM analysis indicates that repair actions would result in maximum negative WRI values of -8 ft in response to the removal of aquatic vegetation and SRA for the expansion of the Sacramento Bypass and Weir. This value is based on the maximum negative WRI values observed for the adult residence life stage of green sturgeon in the winter/spring /summer of year 1 continuing through the life of the project to year 50.

Little is known about the fry and juvenile rearing and juvenile migration life stages of green sturgeon. The SAM does not evaluate response to specific habitat attributes for the juvenile migration life stage. For the purpose of this analysis it is assumed that these life stages exhibit similar responses to analogous life stages of Chinook and steelhead. This approach assumes that fry and juvenile rearing and juvenile migration life stages of green sturgeon will exhibit a positive response to “good riparian habitat” (i.e. increased shoreline coverage of overhanging shade, aquatic vegetation, and IWM). During the planning and design phase of the project, opportunities for the incorporation of additional onsite mitigative features will be evaluated in coordination with resource agencies to ensure the projected longer term impacts are appropriately compensated for green sturgeon. Potential onsite mitigative features include the planting of vegetation at the low water line, the incorporation of additional IWM, and limitations in instream revetment.

Table 6

SAM data summary of existing conditions at site Lower American River RM 10.0L and 10.6L (ARN_AB).

		Seasonal Values			
Habitat Parameter	Water Year	Fall	Winter	Spring	Summer
Shoreline Length (feet) [1]	2024	18,576	18,576	18,576	18,576

-WY = water year; spans fall, winter, spring and summer; rock and soil placement and IWM installation assumed during Winter in the initial WY and revegetation planting assumed during Spring of the initial WY.

[1] Shoreline Length Estimated from Aerial images. Attribute surveyed in the field following the field data collection protocol for the USACE Revetment Database (2007).

[2] Assume no significant change to Bank Slope.

[3] Assume no significant increase in floodplain between seasonal water surface elevations or as a result of project construction.

[4] Assume floodplain inundation ratio of 1 for all seasons in all ARCF GRR Reaches.

[5] Assume installation of rock revetment at summer/fall (D_{50} of 18 in) and natural substrate at winter/spring (D_{50} of 0.25 in).

[6] Assume installation of 40% shoreline coverage of IWM at summer/fall and winter/spring.

[6] Assume a variance in place allowing existing woody vegetation to remain in place on bottom 2/3 of levee

Table 10

SAM data summary of existing conditions at site Lower American River RM 2.8L (ARS_B).

		Seasonal Values

4 Assume floodplain inundation ratio of 1 for all seasons in all ARCF GRR Reaches.
5 Assume installation of rock revetment at summer/fall (D50 of 12 in) and natural substrate at winter/spring (D50 of 0.25 in).
6 Assume installation of 40% shoreline coverage of IWM at summer/fall and winter/spring.
6 Assume a variance in place allowing existing woody vegetation to remain in place on bottom 2/3 of levee

Table 20

SAM data summary of existing conditions at site Sacramento River RM 47.0L and 47.9R (ARS_G).

		Seasonal Values			
Habitat Parameter	Water Year	Fall	Winter	Spring	Summer
Shoreline Length (feet) [1]	2024	11,066	11,066	11,066	11,066
	2074	11,066	11,066	11,066	11,066
Bank Slope (dH:dV) [2]	2024	2	2	2	2
	2074	2	2	2	2
Floodplain Inundation Ratio (AQ2:AQavg) [3]	2024	1	1	1	1
	2074	1	1	1	1
Bank Substrate Size (D50 in inches) [4]	2024	9.40	9.40	9.40	9.40
	2074	9.40	9.40	9.40	9.40
Instream Structure (% shoreline) [5]	2024	5.5	5.5	5.5	5.5
	2074	5.5	5.5	5.5	5.5
Vegetation (% shoreline) [6]	2024	0	88	88	0
	2074	0	88	88	0
Shade (% shoreline) [7]	2024	90	22	67	90
	2074	90	22	67	90

1 Shoreline Length Estimated from Aerial images. Attribute surveyed in the field following the field data collection protocol for the USACE Revetment Database (2007).
2 Existing slopes taken from 2 SRBPP repair sites modeled by SAM.
3 Assume no significant increase in floodplain between seasonal water surface elevations. Assume floodplain inundation ratio of one for all seasons in all ARCF GRR Reaches.
4 Bank substrate data taken from USACE Revetment Database (2007) and confirmed with aerial imagery. Natural substrate assigned a D50 of 0.25 inches. Revetment substrate assigned a D50 of 10 inches.
5 Instream Structure data taken from USACE Revetment Database (2007).
6 Shoreline coverage of Vegetation taken from USACE Revetment Database and evaluated against aerial imagery. Summer/Fall values taken from "Emergent Veg" attribute. Winter/ Spring values taken from "Veg Cover%" attribute.
7 Attribute coverage determined from analysis of aerial imagery. Winter/ Spring values modified by 0.25/ 0.75 respectively to represent seasonal defoliation.

Table 21

	2074	100	25	75	100

-WY = water year; spans fall, winter, spring and summer; rock and soil placement and IWM installation assumed during Winter in the initial WY and revegetation planting assumed during Spring of the initial WY.

1 Shoreline Length Estimated from Aerial images. Attribute surveyed in the field following the field data collection protocol for the USACE Revetment Database (2007).

2 Assume no significant change to Bank Slope.

3 Assume no significant increase in floodplain between seasonal water surface elevations or as a result of project construction.

4 Assume floodplain inundation ratio of 1 for all seasons in all ARCF GRR Reaches.

5 Assume installation of rock revetment at summer/fall (D50 of 12 in) and natural substrate at winter/spring (D50 of 0.25 in).

6 Assume installation of 40% shoreline coverage of IWM at summer/fall and winter/spring.
6 Assume a variance in place allowing existing woody vegetation to remain in place on bottom 2/3 of levee

Appendix A – Exhibits

1.0 INTRODUCTION

The purpose of this preliminary biological evaluation is to support the preparation of a forthcoming biological assessment (BA). The BA would analyze the North Sacramento Streams (NSS) component of the Sacramento Area Flood Control Agency's (SAFCA) proposed Levee Accreditation Project (NSS Levee Improvements Project) in sufficient detail to determine the extent to which the proposed action may affect any of the federally listed species described below under "Species Considered."

A BA is prepared in accordance with requirements set forth under Section 7 of the Federal Endangered Species Act (ESA) (16 United States Code [USC] 1536[c]). It serves to initiate consultation with the U.S. Fish and Wildlife Service (USFWS) and consultation with the National Marine Fisheries Service (NMFS) on effects of the NSS Levee Improvements Project on federally listed species. A BA also serves to initiate consultation with NMFS on essential fish habitat (EFH) conservation recommendations for Pacific salmon (*Oncorhynchus* spp.), as required by the Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801). (See the "Essential Fish Habitat Assessment" section below.)

Section 7(a)(2) of the ESA directs federal agencies to ensure that their activities are not likely to jeopardize the continued existence of any listed species, or to result in the destruction or adverse modification of designated critical habitat. This section of the ESA also requires agencies with regulatory authority over listed species to issue biological opinions evaluating the direct and indirect effects of federal actions, and actions that are interrelated or interdependent with the federal action. The biological opinions must determine whether the actions being evaluated may appreciably reduce the listed species' likelihood of surviving or recovering in the wild by reducing their productivity, numbers, or distribution.

To implement the NSS Levee Improvements Project, SAFCA would request permission from the U.S. Army Corps of Engineers (USACE) for:

- alteration of federal project levees, pursuant to Section 14 of the Rivers and Harbors Act of 1899 (33 USC 408, referred to in this preliminary biological evaluation as "Section 408"); and

- placement of fill in jurisdictional waters of the United States, pursuant to Section 404 of the Clean Water Act (33 USC 1344, referred to in this preliminary biological evaluation as "Section 404").

These activities are described in more detail under "Description of the Proposed Action." Similar to a BA, this preliminary biological evaluation analyzes direct, indirect, interrelated/interdependent, and cumulative effects of the proposed action on federally listed species.

The proposed action described herein is also part of a larger, joint project with USACE and the State of California called the American River Common Features (ARCF) Project. The ARCF Project is currently in the planning phase and therefore detailed design information is not available. Therefore, USACE is consulting with NMFS and USFWS on the ARCF Project using a worst-case approach. Since the NSS Levee Improvements Project is a subset of the ARCF Project, and because detailed design information for SAFCA's NSS Levee Improvements Project is available, consultation for the two projects is being combined. It should be noted that because design for the NSS Levee Improvements Project has progressed further than that for the ARCF Project, some areas (e.g., borrow sites) not identified by USACE are being identified below. SAFCA also anticipates future consultation as part of the ARCF Project consultation for work along the Sacramento River, although this effort is still in the planning phase by SAFCA.

2.0 SPECIES CONSIDERED

This document considers species or designated critical habitat that have been termed “threatened” or “endangered” under the jurisdiction of USFWS and NMFS. On February 22, 2015, biologists consulted the online database maintained by USFWS’s Sacramento Office to conduct a query of the Rio Linda (512B) and Sacramento East (512C) 7.5-minute quadrangles (USFWS 2015). Using the California Department of Fish and Wildlife’s (CDFW’s) California Natural Diversity Database (CNDDB) (2015) and the California Native Plant Society’s database of rare and endangered plant species (CNPS 2014), biologists also conducted a query of the topographic quadrangles in which the action area occurs and the surrounding quadrangles; these database queries were conducted on February 27, 2014, and March 3, 2014, respectively. This query identified all listed species in the area surrounding the action area, which is defined here in accordance with ESA guidelines as “all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action” (50 Code of Federal Regulations [CFR] 402.02).

On June 18, 20, 23, 24, and 25, 2014, AECOM biologists conducted field surveys of Arcade Creek. NEMDC/Steelhead Creek was surveyed by AECOM biologists on September 3 and 8, 2014. A qualitative survey of additional areas where other proposed project elements would occur, including Robla Creek, was conducted by AECOM biologists through interpretation of aerial imagery. The purpose of these surveys was to characterize general biological resources, map vegetation and land covers within the footprints of the various project elements (i.e., levee improvements, encroachment removal, vegetation management, and Conservation Strategy), and assess the potential for the project study area to support special-status species and other sensitive biological resources. Locations of elderberry shrubs within the project study area (including a 100-foot buffer area around the various levee improvement footprints) were mapped, but no protocol-level plant or wildlife surveys were conducted. Tree survey data collected along the project study area levees by MBK Engineers (2014) was reviewed in the field. Vegetation and land cover were mapped onto aerial photographs during field surveys. The polygons were later digitized into a GIS overlay and used to create maps depicting the location and extent of each cover type present in the project study area.

Based on these database queries, field surveys, and the biologists’ familiarity with local flora and fauna, 15 plant and wildlife species that are federally listed as endangered or threatened, or are federally proposed for listing, were considered as part of this assessment (**Table 1**).

Table 1
Fish and Wildlife Species Federally Listed or Proposed for Listing that Were Considered in the Evaluation of the North Sacramento Streams Levee Improvements Project

Species	Status	Habitat	Potential to Occur[1] in the Action Area[2]
Plants			
Slender Orcutt grass *Orcuttia tenuis*	Threatened	Vernal pools, often in gravelly soils; from 114 to 5,774 feet in elevation. Blooms May–October.	No potential to occur. No suitable habitat is present within the action area.[2]
Sacramento Orcutt grass *Orcuttia viscida*	Endangered	Vernal pools; from 98 to 328 feet in elevation. Blooms April–September.	No potential to occur. No suitable habitat is present within the action area.[2]
Invertebrates			
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	Threatened	Closely associated with blue elderberry (*Sambucus* sp.), which is an obligate host for the beetle larvae; CNDDB (2014) occurrences along the Sacramento	Could occur; elderberry shrubs present occasionally along the Arcade Creek; however, no shrubs were observed in NSS Levee Improvements Project area.

Table 1
Fish and Wildlife Species Federally Listed or Proposed for Listing that Were Considered in the Evaluation of the North Sacramento Streams Levee Improvements Project

Species	Status	Habitat	Potential to Occur[1] in the Action Area[2]
		and American Rivers.	
Vernal pool fairy shrimp *Branchinecta lynchii*	Threatened	Vernal pools and other seasonal wetlands, typically small but including a wide range of sizes; scattered CNDDB (2014) occurrences in vicinity of Dry Creek.	Could occur. Potentially suitable habitat is present within the action area.[2]
Vernal pool tadpole shrimp *Lepidurus packardi*	Endangered	Vernal pools and other seasonal wetlands, typically medium to large but including a wide range of sizes with relatively long inundation period; scattered CNDDB (2014) occurrences in vicinity of Dry Creek.	Could occur. Potentially suitable habitat is present within the action area.[2]
Fish			
Central Valley steelhead *Oncorhynchus mykiss*	Threatened	Anadromous. Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta. Adult migration to upstream spawning areas occurs July–March (Hallock 1987). Juveniles typically spend 1–3 years in fresh water before migrating to the ocean, generally in December–August (McEwan 2001).	Likely to occur. Expected to occur in the NEMDC/Steelhead Creek, either as adults migrating to their upstream spawning habitat, or as juveniles and smolts, rearing and migrating towards the ocean. High water temperatures and low flows preclude occurrence in NEMDC/Steelhead Creek in summer. Not expected to occur in Arcade or Robla Creek as these streams lack suitable water quality conditions for spawning. Designated critical habitat is in the action area[2].
Central Valley fall-/late fall-run Chinook salmon *Oncorhynchus tshawytscha*	Species of Concern[2]	Anadromous. Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta. Fall-run adults migrate in June–December, and juveniles migrate downstream and out to the ocean soon after emerging (December–March), rearing in fresh water for only a few months, and migrating to the ocean in March–July (Yoshiyama et al. 1998). Late fall-run adults migrate in October–April, and juveniles rear in their natal stream during summer; in some streams they remain throughout the year. Smolt outmigration can occur in November–May (Yoshiyama et al. 1998).	Likely to occur. Occurs in the Sacramento and San Joaquin Rivers, tributaries, and the Delta. Fall-run could occur in the NEMDC/Steelhead Creek, either as adults migrating upstream to their spawning habitat, spawning in the lower American River, or as juveniles and smolts, rearing and migrating towards the ocean. Not expected to occur in Arcade or Robla Creeks, as these streams regularly lack suitable water quality conditions or access for spawning. Essential fish habitat is in the action area[2].
Delta smelt *Hypomesus*	Threatened	Semi-anadromous. Typically restricted to the Delta and the	Unlikely to occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin

Table 1
Fish and Wildlife Species Federally Listed or Proposed for Listing that Were Considered in the Evaluation of the North Sacramento Streams Levee Improvements Project

Species	Status	Habitat	Potential to Occur[1] in the Action Area[2]
transpacificus		lower Sacramento River downstream of Isleton; juveniles move downstream with the currents (USFWS 1996; Sommer et al. 2001a; Moyle 2002).	Rivers, tributaries, and Delta. No spawning habitat is in the action area.[2]
Sacramento River winter-run Chinook salmon *Oncorhynchus tshawytscha*	Endangered	Anadromous. Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta. Adults migrate upstream in December–July (peak in March) (Moyle 2002), and juveniles migrate downstream soon after fry emerge, typically beginning in August and peaking in September and October (Vogel and Marine 1991).	Unlikely to occur. Occurs in the Sacramento River, tributaries, and the Delta. The Sacramento River channel is the main migration route for winter-run juveniles, and smolts (Yoshiyama et al. 1998). No spawning habitat is in the action area[2].
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	Threatened	Anadromous. Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta. Adults migrate upstream in March–September, (peak May–June) (Yoshiyama et al. 1998), and juveniles and yearlings migrate downstream following the onset of the winter storm season through March (CDFG 1998; Fisher 1994; S. P. Cramer and Associates 1995; Hill and Webber 1999). Adults: July–March (Hallock 1987).	Unlikely to occur. Occurs in the Sacramento River, tributaries, and the Delta. No spawning habitat is in the action area[2].
Green sturgeon *Acipenser medirostris*	Threatened	Anadromous. Requires seasonally inundated floodplains, rivers, tributaries, and the Delta. Adults migrate upstream to their spawning habitat (between late February and late July), and juveniles are reared and migrate to the ocean (year-round).	Unlikely to occur. Occurs in the Sacramento and San Joaquin Rivers, tributaries, and the Delta. No spawning habitat is in the action area[2].
Amphibians and Reptiles			
California red-legged frog *Rana draytonii (=R. aurora draytonii)*	Threatened	Prefers semi-permanent and permanent stream pools, ponds, and creeks with emergent riparian vegetation and typically without predatory fish. Requires adequate hibernacula such as small-mammal burrows and moist leaf litter.	No potential to occur. The action area is outside of the species' extant range.

Table 1
Fish and Wildlife Species Federally Listed or Proposed for Listing that Were Considered in the Evaluation of the North Sacramento Streams Levee Improvements Project

Species	Status	Habitat	Potential to Occur[1] in the Action Area[2]
California tiger salamander *Ambystoma californiense*	Threatened	Vernal pools and other seasonal wetlands with adequate inundation period and adjacent uplands, primarily grasslands, with burrows and other refugia; no known occurrences in the project vicinity.	No potential to occur. No suitable habitat is present within the action area.[2]
Giant garter snake *Thamnophis gigas*	Threatened	Open water associated with marshes, sloughs, and irrigation/drainage ditches within the Central Valley; requires emergent herbaceous wetland vegetation for escape and foraging habitat, grassy banks and openings in waterside vegetation for basking, and higher elevation upland habitat for cover and refuge from flooding. Nearest known extant populations are located in the Natomas Basin, adjacent to and just west of NEMDC/Steelhead Creek (CDFW 2014).	Could occur. In the NSS Levee Improvements Project area, the quality of habitat for giant garter snake is better along the NEDMC/ Steelhead Creek north of Dry Creek; Arcade and Robla Creeks and the NEMDC/Steelhead Creek south of Dry Creek are less suitable for this species. Giant garter snakes are known to occur in rice fields, associated canals, and managed marshes in the Natomas Basin west of the portion of NEMDC/Steelhead Creek that is north of Dry Creek; thus, there is potential for the species to occur, at least occasionally, in this portion of NEMDC/Steelhead Creek.
Birds			
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	Threatened	Riparian forest with dense deciduous trees and shrubs; there are no recent CNDDB occurrences in the vicinity of the program area, but migrant individuals are likely to pass through the area in transit to breeding sites along the Sacramento River north of Colusa.	Unlikely to occur. Although potential dispersal and foraging habitat is in the NSS Levee Improvements Project area, the action area is outside of the species' extant range.

Notes: CNDDB = California Natural Diversity Database; Delta = Sacramento–San Joaquin Delta; NSS = North Sacramento Streams

1 **Potential for Occurrence Definitions:**

No potential to occur: Potentially suitable habitat is not present.

Unlikely to occur: Potentially suitable habitat present but species unlikely to be present because of very restricted distribution.

Could occur: Suitable habitat is available; however, there are few or no other indicators that the species may be present.

Likely to occur: Habitat conditions, behavior of the species, known occurrences in the vicinity, or other factors indicate a relatively high likelihood that the species would occur.

Known to occur: The species, or evidence of its presence, was observed during reconnaissance-level surveys or was reported by others.

2 Action Area: The action area is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the NSS Levee Improvements Project. Areas downstream of the NSS Levee Improvements Project area may also be indirectly affected by the flood risk management component of the project through improved water quality and flood risk management conditions.

Sources: CDFW 2014; CNPS 2014; data collected and compiled by AECOM in 2014 CNDDB 2014, CNPS 2014, USFWS 2014; data compiled by AECOM and Stillwater Sciences in 2014

The following federally proposed and federally listed species are known to occur or have the potential to occur in the NSS Levee Improvements Project area:

- vernal pool fairy shrimp *(Branchinecta lynchi),*
- vernal pool tadpole shrimp *(Lepidurus packardii),*
- valley elderberry longhorn beetle (VELB) (*Desmocerus californicus dimorphus*),
- Central Valley steelhead distinct population segment (DPS) (*Oncorhynchus mykiss*), and
- giant garter snake (*Thamnophis giga*).

Central Valley fall- /late fall-run Chinook salmon ESU (*O. tshawytscha*) is not federally listed; however, EFH is present in the action area.

The other federally listed species identified in **Table 1** were eliminated from further consideration because they are not likely to occur in the NSS Levee Improvements Project area because of a lack of suitable habitat, local range restrictions, regional extirpations, or lack of connectivity between areas of suitable or occupied habitat, or because the action area is located outside of the extant range of the species (see "Action Area" section below). The USFWS-regulated species with the potential to occur on-site are discussed in more detail in this preliminary biological evaluation.

2.1 SPECIES HABITAT AND POTENTIAL FOR OCCURRENCE IN THE AREA

The following is a summary of relevant habitat conditions in the action area for species that could occur, are likely to occur, or are known to occur in the NSS Levee Improvements Project area. Full species accounts for federally listed species addressed in this preliminary biological evaluation are presented in the section titled "Species Accounts."

- **Vernal pool fairy shrimp** and **vernal pool tadpole shrimp:** Seasonal wetlands, which may provide suitable habitat for vernal pool invertebrates, occur at Borrow Site 3/ Robla woodland mitigation site A. There are documented occurrences of vernal pool fairy shrimp north of Dry Creek along the landside of the NEMDC/Steelhead Creek East Levee and there are documented occurrences of vernal pool fairy shrimp and vernal pool tadpole on the former McClellan Air Force Base, northeast of Arcade Creek (CDFW 2014).

- **Valley elderberry longhorn beetle:** Elderberry shrubs were not observed along Arcade Creek or NEMDC/Steelhead Creek during field surveys. Robla Creek has not been surveyed for elderberry shrubs, the obligate host plant for the valley elderberry longhorn beetle, but shrubs may occur amongst vegetation along the creek, adjacent to Borrow Site 3 and the proposed woodland mitigation sites north of Robla Creek. While there are no documented occurrences of valley elderberry longhorn beetle in the NSS Levee Improvements Project area, this species could occur in elderberry shrubs, if present along Robla Creek.

- **Central Valley Steelhead DPS:** Adult and juvenile Central Valley steelhead could occur in the action area during migrations along the Sacramento River and its tributaries. Central Valley steelhead are expected to occur in NEMDC/Steelhead Creek as adults, migrating upstream to their spawning habitat, and as juveniles and smolts, rearing and migrating toward the ocean. Central Valley steelhead would not typically occur in Arcade Creek, as this stream regularly lacks water quality conditions for spawning. There are no known runs within Robla Creek, similar to Arcade Creek. NEMDC/Steelhead Creek includes critical habitat for Central

Valley steelhead, which uses this locations for juvenile rearing, juvenile migration, and adult migration (NMFS 2014). There is no critical fish habitat designation for Arcade and Robla Creeks.

- **Central Valley fall-/late fall-run Chinook salmon:** Adult and juvenile Central Valley fall-run Chinook salmon could occur in the action area during migrations along the Sacramento River and its tributaries. They are not expected to occur in Arcade Creek or other tributaries to NEMDC/Steelhead Creek lacking suitable water quality conditions for spawning and rearing. EFH is also present in both streams for fall-run Chinook, which use these areas for juvenile rearing, juvenile migration, and adult migration. There is no EFH for Arcade and Robla Creeks.

- **Giant garter snake:** There are numerous occurrences of giant garter snake west of NEMDC/Steelhead Creek within the Natomas Basin; these records, which are located between NEMDC/Steelhead Creek and I-5/State Route (SR) 99/70, are all located north of Elkhorn Boulevard (CDFW 2014). The channel, water primrose wetlands, and hardstem bulrush marsh in NEMDC/Steelhead Creek, particularly north of Dry Creek, provide suitable aquatic habitat for giant garter snake; suitable upland habitat for this species is present where annual (wild oats) grasslands are within 200 feet of these aquatic features. However, there are no documented occurrences of this species in NEMDC/Steelhead Creek or in any of its eastside tributaries (CDFW 2014). The historic habitat conditions of NEMDC/Steelhead Creek and particularly its eastside tributaries were likely never suitable for this species (e.g., steeper elevational slope, rapid water runoff, lack of historical marsh [E. Hansen, pers. comm., 2015; B. Halstead, pers. comm., 2015]); a recent analysis suggests that this species' distribution is limited by dispersal distances associated with historic marsh habitats (Halstead et al. 2014). However, the quality of habitat for giant garter snake is better along the NEDMC/Steelhead Creek north of Dry Creek and giant garter snakes are known to occur in rice fields, associated canals, and managed marshes in the Natomas Basin west of this portion of NEMDC/Steelhead Creek; thus, there is potential for the species to occur, at least occasionally, in this portion of NEMDC/Steelhead Creek.

2.2 CRITICAL HABITAT

"Critical habitat" is defined in Section 3(5)A of the ESA as the specific areas in the geographical area occupied by the species where physical or biological features are found that are essential to the conservation of the species and that may require special management considerations or protection. Specific areas outside of the geographical area occupied by the species may also be included in critical-habitat designations, based on a determination that such areas are essential for the conservation of the species.

The proposed action addressed in this preliminary biological evaluation falls within designated critical habitat for Central Valley steelhead DPS. Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the NEMDC/Steelhead Creek in the action area (see "Action Area" section below).

The action area is not within designated critical habitat for the remaining species listed in **Table 1** for which such a designation has been made: Conservancy fairy shrimp, vernal pool fairy shrimp, vernal pool tadpole shrimp, VELB, Sacramento River winter-run Chinook salmon ESU, Central Valley spring-run Chinook salmon ESU, and California red-legged frog. Critical habitat has not been designated for Central Valley fall-/late fall–run Chinook salmon ESU, giant garter snake, or western yellow-billed cuckoo.

3.0 CONSULTATION TO DATE

[No information to input yet.]

4.0 DESCRIPTION OF THE PROPOSED ACTION

4.1 PROJECT LOCATION

The proposed project includes Levee Accreditation improvements that would be implemented in the North Sacramento Streams area. Approximately 4 miles of levee along the Natomas East Main Drainage Canal (NEMDC)/Steelhead Creek East Levee and Arcade Creek North and South Levees would be improved (**Exhibit 1**). These levee reaches require substantial work to mitigate seepage, meet embankment and foundation stability requirements, and remove high-hazard encroachments and vegetation. This work requires use of proposed borrow sites (located along either side of NEMDC/Steelhead Creek, just north of Dry Creek and along the north side of Robla Creek) and staging areas (located along the levee improvement areas).

4.2 PROJECT SCHEDULE

SAFCA's NSS Levee Improvements Project would start construction in 2016. The proposed project is anticipated to take 1 to 2 years to complete.

4.3 DESCRIPTION OF PROPOSED PROJECT ELEMENTS

The NSS Levee Improvements Project consists of four project elements: levee improvements, high-hazard levee encroachment and vegetation removal, and conservation strategy. These four project elements are summarized in **Table 2** below.

Table 2. Summary of Locations of Proposed Project Elements in NSS Levee Improvements Area

Portion of Project Study Area	Levee Improvements	Encroachment Removal	Vegetation Management	Conservation Strategy[1]
Arcade Creek Levees	X	X	X	X
NEMDC/Steelhead Creek East Levee	X	–	–	X
Robla Creek South Levee	–	X	–	X
Borrow Sites	X	–	–	X
Robla Creek Tree Mitigation Sites (A and B)	–	–	–	X

Notes: NEMDC = Natomas East Main Drainage Canal

[1] In addition to providing mitigation for levee improvements, the Conservation Strategy includes an extensive list of avoidance and minimization measures that would be implemented throughout the project study area, where applicable

Source: Data compiled by AECOM in 2014

4.3.1 NORTH SACRAMENTO STREAMS LEVEE IMPROVEMENTS

DESCRIPTION OF THE NORTH SACRAMENTO STREAMS LEVEE IMPROVEMENTS AREA

This section discusses specific levee improvements proposed for each reach along NEMDC/Steelhead Creek and Arcade Creek in the NSS Levee Improvements area. To identify and describe the levee improvements proposed for the NSS Levee Improvements area, the area has been divided into eight levee reaches (**Exhibit 1**): two along the east side of NEMDC/Steelhead Creek and three along each side of Arcade Creek. These levee reaches and associated improvements are described below.

NEMDC A

Reach A of the NEMDC/Steelhead Creek East Levee is about 1,700 feet long and extends from Station 3028+00 to Station 3051+00. The levee height ranges from 22.7–25.7 feet, with a crown width ranging from 14–26 feet. This reach is located along the eastern boundary of the Natomas Basin, just south of the confluence with Arcade Creek. A railroad embankment that pre-dates the construction of the NEMDC/Steelhead Creek East Levee is present along the entirety of the landside embankment slope of this reach and is integral with the NEMDC/ Steelhead Creek levee.

The levee embankment consists of clay materials with a fine-grained blanket layer of clay and silt, and occasional instances of clayey sand at the ground surface. This reach contains riparian habitat, ruderal land, and stream channels within the construction footprint of the proposed improvements. Preliminary analysis indicates that this reach does not meet 100-year water surface elevation (WSE) criteria or Urban Levee Design Criteria (ULDC) for potential underseepage. The underseepage may be due to high hydraulic head in the stormwater collector channel along the landside levee toe that leads to a pump station within the reach.

Construction of a cement-bentonite (CB) slurry cutoff wall at the waterside toe of the levee was selected as the preferred levee improvement.

ACS A

Reach A of the Arcade Creek South (ACS) Levee is about 1,300 feet long and extends from Station 4000+00 to Station 4013+00. This reach was originally constructed in the 1930s, but specific construction details and documentation are unavailable. The levee crest was widened and the waterside slope liner was constructed in the 1950s by USACE. The levee ranges between 19.4 and 22.0 feet high, with a crown width ranging from 10–26 feet. A railroad crossing occurs at the downstream boundary of the levee, with a stoplog structure across the rail used to block this crossing during high-water events.

The levee embankment consists of clay, silt, and sand materials, and contains a fine-grained blanket layer comprised of clay and silt. The reach contains riparian habitat, creek, and ruderal land within the construction footprint of proposed levee improvements. Preliminary analysis indicates that this reach does not meet 100-year WSE criteria or ULDC for potential underseepage and stability.

Construction of a soil-bentonite (SB) cutoff wall at the centerline of the levee was selected as the preferred levee improvement.

ACS B

Reach B of the Arcade Creek South Levee is about 3,727 feet long and extends from Station 4031+18 to Station 4068+45. This reach was originally constructed in the 1930s, but specific construction details and documentation are unavailable. The levee crest was widened and the waterside slope liner was constructed in the 1950s by USACE. The levee ranges between 11 and 17 feet high, with a crown width ranging from 17–28 feet.

The levee embankment consists of clay, silt, and sand materials, and contains a fine-grained blanket layer comprised of clay and silt. This reach contains riparian habitat, creek, and ruderal land within the construction footprint of the proposed levee improvements. Preliminary analysis indicates that this reach does not meet 100-year WSE criteria or ULDC for potential underseepage and stability.

Construction of an SB cutoff wall at the centerline of the levee was selected as the preferred levee improvement.

ACS C

Reach C of the Arcade Creek South Levee is about 4,155 feet long and extends from Station 4068+45 to Station 4110+34. The levee was constructed in the 1930s, but the original construction documentation is unavailable. Subsequent improvements to the levee (i.e., crest raise and floodwall) were completed by SAFCA in the 1990s. The downstream (western) boundary of this reach occurs at the intersection of the levee reach with Rio Linda Boulevard. The upstream (eastern) boundary is located at the intersection of the levee and Marysville Boulevard. The levee ranges between 19.4 and 22.0 feet high, with a crown width ranging from 10–26 feet. A low concrete flood wall curb extends along the waterside of the levee crest from Rio Linda Boulevard to Marysville Boulevard.

The levee embankment consists of clayey and silty sand materials, with a foundation layer comprised of silty and clayey sand over silt. The reach contains riparian habitat, creek, and ruderal land within the construction footprint of proposed levee improvements. Preliminary analysis indicates that this reach does not meet 100-year WSE underseepage and stability criteria, as well as ULDC for underseepage, through-seepage or stability.

Construction of a CB slurry cutoff wall at the waterside toe combined with waterside slope replacement was selected as the preferred levee improvement.

ACN A

Reach A of the Arcade Creek North Levee is about 1,050 feet long and extends from Station 5023+00 to Station 5033+50. This levee reach was originally constructed in the 1950s by USACE. Subsequent improvements to the levee’s landside and waterside slopes, in conjunction with a levee raise, were completed in the 1990s by SAFCA. A concrete-lined ditch owned by the City of Sacramento at Drainage Pumping Plant No. 158 is located approximately 30 feet from the landside toe up to Station 5031+00. From there, this concrete-lined toe ditch descend into the pump station sump. This reach includes the lined channel and the concrete paved pump station sump area. The levee ranges between 15 and 28 feet high, with a crown width ranging from 8–16 feet.

The levee embankment consists of silty and clayey sand materials. Preliminary analysis indicates that this reach does not meet 100-year WSE underseepage and stability criteria, as well as ULDC for underseepage, through-seepage, or stability.

Installation of pressure relief wells along the landside of the levee was selected as the preferred levee improvement.

ACN B

Reach B of the Arcade Creek North Levee is about 3,700 feet long and extends from Station 5038+00 to Station 5075+00. The upstream (eastern) boundary of this reach occurs at the beginning of the concrete floodwall that runs along the levee crest between Stations 5068+10 and Marysville Boulevard. The levee ranges between 10 and 18 feet high, with a crown width ranging from 8–23 feet. This levee reach was originally constructed in the 1950s by USACE. Subsequent improvements to the levee’s landside and waterside slopes, in conjunction with a levee raise, were completed in the 1990s by SAFCA.

The levee embankment consists of silty and clayey sand materials. The downstream blanket layer is comprised of silty and clayey sand, while the upstream blanket layer is comprised of clay and silt. This reach contains riparian habitat, creek, and ruderal land within the construction footprint of proposed levee improvements. Preliminary analysis indicates that this reach does not meet 100-year WSE criteria or ULDC for underseepage and stability.

Construction of an SB cutoff wall at the centerline of the levee was selected as the preferred levee improvement.

ACN C

Reach C of the Arcade Creek South Levee is about 3,743 feet long and extends from Station 5075+00 to Station 5112+3. This levee reach was originally constructed in the 1950s by USACE. The floodwall that runs along the waterside of the levee crest was constructed in the 1990s by SAFCA. The downstream (western) boundary of this reach is located at the beginning of the concrete floodwall that runs along the levee crest between Stations 5075+00 and Marysville Boulevard. The upstream (eastern) boundary of this reach is located at the intersection of the levee and Marysville Boulevard. The levee ranges between 1 and 9 feet high, with a crown width ranging from 5–17 feet.

The levee embankment consists of silty and clayey sand materials, with a coarse-grained blanket layer comprised of silty and clayey sand. This reach contains riparian habitat, creek, and ruderal land within the construction footprint of proposed levee improvements. Preliminary analysis indicates that this reach does not meet 100-year WSE criteria or ULDC for underseepage and stability.

Construction of a CB cutoff wall at the waterside toe combined with waterside slope replacement from Station 5075+00 to Station 5100+00, and construction of a sheet pile cutoff wall at the centerline of the levee from Station 5100+00 to Marysville Boulevard was selected as the preferred levee improvement.

BORROW AREAS AND HAUL ROUTES

Based on proximity to the improvement areas, SAFCA has identified three preferred borrow sites to provide suitable material for levee improvements for the NSS Levee Improvements area. The preferred borrow sources are illustrated in **Exhibit 2** and their locations are briefly described below.

- **Site 1 -** Three soil stockpiles located on the grounds of a new high school, near Sorento Road and East Levee Road.
- **Site 2 -** Site 2K **-** Up to 35,000 cubic yards (cy) available above the water table.
- **Site 3 -** Area north of Robla Creek and the Dry Creek South Levee, east of Rio Linda Boulevard.

The most likely sources for borrow currently under consideration are Sites 1 and 2. While Site 3 is a possible source, the suitability and available quantities of borrow material from each source must be investigated further and confirmed as part of project design.

The goal in selecting haul routes is to use existing levee crowns for hauling wherever possible (**Exhibit 3**). However, there are locations where hauling on paved public roads is the best available option because the levee crown is already paved for public use or because there is inadequate room on the waterside of the levee to develop a temporary toe road without affecting standing water or low flow channels. Final haul routes would be selected based on constraints, the construction schedule, and in coordination with the City.

Borrow site strippings would either be reused as part of post-borrow reclamation or hauled off-site. Borrow sites would be returned to pre-project conditions following construction activities.

POTENTIAL STAGING AREAS

Four potential staging areas have been identified for potential use to support construction of of the NSS Levee Improvements Project (see **Exhibit 3 4**). Several of these areas have been used previously to support levee improvements along Arcade Creek. The areas would require little preparation other than surface stripping, and temporary connection roads and ramps to the levee crown.

The primary use for the staging areas would be for temporary trailers, parking, and material staging and for stockpiling and blending of excavated soils with imported borrow to make the excavated soils suitable for use in levee reconstruction. This would involve stockpiles of material to be processed, a processing area where excavated soils and imported soils would be spread out and processed to mix and moisture condition the material, and stockpiles of processed material. Importing, processing, and exporting material for levee reconstruction would all be continuous activities once the work flow is established during the start of the construction season. Other disturbed areas would be also be stabilized. Staging areas would be returned to pre-project conditions following construction activities unless the owner agrees to some grade raising to help dispose of excess construction soils.

ADDITIONAL LEVEE IMPROVEMENTS COMPONENTS

Erosion Protection

The only erosion protection currently envisioned includes placement of rip rap on waterside benches where waterside toe slurry walls are constructed. Following construction, levee slopes and other areas disturbed by construction would be revegetated and brought back to pre-project conditions.

Locations where erosion is identified along the waterside levee slope and riverbank have been evaluated to determine whether levee integrity or stability may be affected. Insufficient embankment protection may cause a levee to be undermined by erosive forces due to wave action and/or high flow velocities along the levee bank. In many cases, the placement of embankment protection material, such as engineered armoring (rip-rap), would dissipate wave and velocity forces and reduce the potential for erosion to occur. Other factors to be considered prior to installing embankment protection material include grading the levee waterside slope to address stability issues, and environmental impacts within the vicinity of the embankment repair site.

Utility Relocation

SAFCA prepared an inventory and assessment of existing encroachments and penetrations within the NSS Levee Improvements Project area. Known utilities that cross or are adjacent to the levee include gas pipelines; storm drainage and pump station discharge pipes; and numerous water supply mains, culverts, electrical conduits, and sanitary sewers. The construction contractor can work around many of these utilities. However, some utilities may need to be temporarily removed or relocated prior to construction. Temporary bypass pumping may be required for sanitary sewers. SAFCA and the construction contractor would coordinate closely with utility owners to manage the utilities in advance of construction. Disturbed utilities would be restored after construction consistent with CVFPB requirements. Coordination between SAFCA and the utility owner would be required for those utilities that do not currently have CVFPB encroachment permits.

Stormwater Pollution Prevention

Temporary erosion/runoff best management control measures would be implemented during construction to minimize stormwater pollution resulting from erosion and sediment migration from the construction, borrow, and staging areas. These temporary control measures may include implementing construction staging in a manner that minimizes the amount of area disturbed at any one time; secondary containment for storage of fuel and oil; and the management of stockpiles and disturbed areas by means of earth berms, diversion ditches, straw wattles, straw bales, silt fences, gravel filters, mulching, revegetation, and temporary covers as appropriate. Erosion and stormwater pollution control measures would be consistent with National Pollutant Discharge Elimination System (NPDES) permit requirements and would be included in a Stormwater Pollution Prevention Plan (SWPPP).

After completion of construction activities, the temporary facilities (construction trailers and batch plants) would be removed and the site would be restored to pre-project conditions. Site restoration activities for areas disturbed by construction activities, including borrow areas and staging areas, will include a combination of regrading, reseeding, constructing permanent diversion ditches, using straw wattles and bales, and applying straw mulch and other measures deemed appropriate.

PROPOSED SEQUENCE OF PROJECT CONSTRUCTION

It is anticipated that the North Sacramento Streams levee improvements would be implemented in one construction season (2016). The construction season would take place from April 15 to November 1. An approximate construction sequence includes the following:

- **Mobilization:** Mobilization would include setting up construction offices and the slurry batch plant and transporting heavy earthmoving equipment to the site. These activities may take up to 1 month.
- **Vegetation and encroachment removal:** Trees and other encroachments that impact remedial measures would be removed consistent with established SAFCA policies regarding vegetation and encroachments. These activities may take 1–4 weeks depending upon the reach being remediated.
- **Levee degradation for cutoff wall installation:** Beginning of levee degradation would follow vegetation and encroachment removal and precede cutoff wall installation. Degradation would take a total of about 4 months but it would not likely be conducted in one simultaneous operation. Rather, levee reaches would be degraded for specific lengths of cutoff wall to minimize the total length of degraded levee at any one time. Construction would take approximately 3 months.
- **Cutoff wall installation:** This activity would begin with construction of the work pad once a sufficient length of levee was degraded and was available for construction. Assuming four headings, construction would take approximately 4 months.
- **Drainage blanket construction:** Drainage blanket would be constructed prior to placing overlying slope reconstruction fill. Portions of drainage blanket extending up levee cut slopes would be placed as the adjacent slope reconstruction material is placed. Construction would take approximately 1 month since such construction is a small part of the proposed project.
- **Toe cutoff wall erosion protection:** Toe cutoff wall rip rap erosion protection would be placed after the toe cutoff wall bench has been completed to final lines and grades. Construction would take approximately 2 months.
- **Utility relocation:** Any required utility relocation would be conducted concurrent with the levee degradation, toe cutoff wall bench construction, and reconstruction operations. Construction would take approximately 4 months.
- **Levee reconstruction:** Levee reconstruction would begin once there was sufficient length completed cutoff wall to efficiently begin reconstructing the levee embankment. Total time estimated for levee reconstruction is about 6 months.
- **Seepage Wells:** Seepage wells can be installed at any time during the construction season. Installation and development of relief wells and reconstruction of paved channel and basin inverts would likely take about 2 month.

- **Site restoration and demobilization:** Upon completion of the main construction activities, the levee patrol road would be resurfaced, disturbed areas would be revegetated, staging and borrow areas would be restored, and the contractor would demobilize the site(s). These activities are expected to take about 2 months.

Construction would be staged and sequenced with the appropriate stakeholders: the City, County, Reclamation District, utility and service providers, biological resource construction work windows, and other environmental and land use/real estate constraints, to the greatest extent practical to minimize impacts and effects on the community.

4.3.2 HIGH HAZARD LEVEE ENCROACHMENT AND VEGETATION REMOVAL

ENCROACHMENT MANAGEMENT

The National Flood Insurance Program (NFIP) standards for levee accreditation and the State's ULDC both require removal or modification of encroachments that pose an unacceptably high risk to the performance and safety of a levee either by undermining its structural integrity or by interfering with necessary inspection, operation, and maintenance activities. To address this requirement, SAFCA has identified and evaluated all of the encroachments in the NSS Levee Improvements area. Each of these encroachments has been evaluated to determine whether it constitutes an unacceptably high risk to the performance of the levee either by undermining the stability of the levee or by interfering with necessary patrolling, operation, and maintenance activities. Based on this evaluation, the encroachments have been classified as either:

- High-risk – poses a threat to levee integrity, removable prior to the levee being accredited;
- High-risk – impedes operation, maintenance, and inspection, removable within 3 years after the levee is accredited; or
- Low-risk – not identified as high hazard.

In the NSS Levee Improvements area, high-risk encroachments to be removed are limited to residential landscaping located at approximately 10 locations along the landside of the south and north levees of Arcade Creek (mainly between Marysville Boulevard and Rio Linda Boulevard) and along the Robla Creek South Levee, east of Rio Linda Boulevard.

VEGETATION MANAGEMENT

The levee accreditation element of the proposed project also includes a vegetation management component. Although the NFIP does not identify specific standards for managing vegetation on levees, ULDC provides criteria that reflect the underlying risk management objectives of the NFIP. Under these criteria, vegetation on levees must be modified or removed if it presents an unacceptable risk to the structural integrity or impedes operation and maintenance of the levee.

In the NSS Levee Improvements area, approximately 8 high-risk trees along Arcade Creek have been identified for removal. All of the trees are either nonnative (7) or snags (3). Five are located on the waterside of the levees. These trees are in addition to any trees that would be removed as a result of implementation of levee improvements in the NSS Levee Improvements area.

4.3.3 CONSERVATION STRATEGY

Implementation of the NSS Levee Improvements Project would result in impacts on sensitive biological resources such as riparian woodland, near-shore aquatic, and special-status species habitat on the NEMDC/Steelhead Creek and Arcade Creek. The measures outlined in the Conservation Strategy would avoid and reduce some of these impacts. However, even with implementation of avoidance and minimization measures and with self-mitigating projects, impacts on sensitive biological resources would require compensatory mitigation to reduce impacts to less-than-significant levels, and to comply with permit conditions. These compensatory mitigation actions and potential mitigation sites are described below. Mitigation sites would be planned, designed and constructed to avoid impacts to sensitive biological and cultural resources, and if further analysis indicates potential impacts would be unavoidable, the site would be removed from further consideration.

AVOIDANCE AND MINIMIZATION MEASURES

A key element of the Conservation Strategy is to avoid and/or minimize impacts on sensitive habitats and special-status species during implementation of the NSS Levee Improvements Project. The following general and resource-specific conservation measures will be incorporated by SAFCA during construction (which also includes demolition), operation, and maintenance.

General Conservation Measures

- **CM-1: Limit Ground Disturbance to Construction Areas and Avoid and Limit Disturbance to River and Creek Banks and Habitats when Feasible.** Ground disturbance shall be limited to construction areas, including necessary access routes and staging areas. The number of access routes, size of staging areas, and total area of the project activity shall be limited to the minimum necessary. When possible, existing access routes and points shall be used. All roads, staging areas, and other facilities shall be placed to avoid and limit disturbance to river and creek banks and habitat when feasible.

- **CM-2: Clearly Mark Project Construction Limits.** To minimize ground and vegetation disturbance during project construction, project limits shall be clearly marked, including the boundaries of designated equipment staging areas; ingress and egress corridors; stockpile areas for spoils disposal, soil, and materials; and equipment exclusion zones.

- **CM-3: Observe 20-Mile-Per-Hour Speed Limits within Construction Areas on City, Private, and Levee Roads.** Project-related vehicles shall observe a 20-mile-per-hour speed limit within construction areas, except on County roads and on State and Federal highways.

- **CM-4: Avoid Disturbing or Exceeding the Minimum Vegetation Removal Necessary.** Disturbance or removal of vegetation by machinery shall not exceed the minimum necessary to complete project construction and operations.

- **CM-5: Replant or Reseed with Native Species and Monitor and Maintain Growth to Ensure Success for Areas Requiring Vegetation Removal.** When vegetation removal is required, the disturbed areas shall be replanted or reseeded with native species and monitored and maintained to ensure the revegetation effort is successful. If erosion control fabrics are used in revegetated areas, they shall be slit in appropriate locations as necessary to allow for plant root growth.

- **CM-6: Limit Rock Riprap for Erosion Protection.** The amount of rock riprap and other materials used for bank protection shall be limited to the minimum needed for erosion protection and establishment of planting benches.

- **CM-7: Destroy and Dispose of Invasive Species using Approved Protocols and Disposal Sites.** Invasive species that are removed shall be destroyed using approved protocols and disposed of in an appropriate disposal area out of the stream channel.

- **CM-8: Use All Pesticides in Accordance with Laws and Regulations.** All pesticides/herbicides (pesticides) used to control nonnative vegetation shall be used in accordance with label directions. Methods and materials used for herbicide application shall be in accordance with DWR's most current guidelines on herbicide use and with laws and regulations administered by the California Department of Pesticide Regulation.

- **CM-9: Store All Construction Materials at Designated Construction Staging Areas.** Construction materials such as portable equipment, vehicles, and supplies, including chemicals, shall be stored at designated construction staging areas.

- **CM-10: Prepare and Implement a Storm Water Pollution Prevention Plan.** A SWPPP that identifies specific best management practices to avoid and minimize impacts on water quality during construction activities shall be prepared and implemented.

- **CM-11: Install, Monitor, and Maintain Erosion Control Measures that Minimize Soil or Sediment from Entering Waterways or Wetlands.** Erosion control measures that minimize soil or sediment from entering waterways and wetlands shall be installed, monitored for effectiveness, and maintained throughout construction operations.

- **CM-12: Use Acceptable Erosion Control Materials to Minimize Potential for Small Animals to Become Entangled.** If use of erosion control fabrics is necessary, tightly-woven fiber netting (mesh size less than 0.25-inch) or similar material shall be used to minimize potential for small animals to become entangled. Coconut coir matting is an acceptable erosion control material, but no plastic mono-filament matting shall be used. The edge of the material shall be buried in the ground to prevent animals from crawling underneath the material.

- **CM-13: Avoid Use of Materials in Locations Where it can Erode from Normal or Expected High Flows.** No material shall be placed in a manner or location where it can be eroded by normal or expected high flows. Jute netting or another non-monofilament erosion control fabric shall be used to cover soil that is placed over or mixed into riprap or other revetment materials.

- **CM-14: Implement Precautionary Measures to Minimize Turbidity/Siltation during Construction.** Precautions to minimize turbidity/siltation shall be implemented during construction. This may require placing barriers (e.g., silt curtains) to prevent silt and/or other deleterious materials from entering downstream reaches.

- **CM-15: Inspect Sediment and Turbidity Control Barriers Daily during Construction for Proper Function and Replace Immediately if Not Functioning Effectively.** Performance of sediment and turbidity control barriers shall be inspected at least once each day during construction to check that they are functioning properly. Should a control barrier not function effectively, it shall be immediately repaired or replaced. Additional controls shall be installed as necessary.

- **CM-16: Remove Sediment from Sediment Controls and Dispose of Properly.** Sediment shall be removed from sediment controls once the sediment has reached 1/3 of the exposed height of the control. Sediment collected in these devices shall be disposed of away from the collection site at designated upland disposal sites.

- **CM-17: Treat Water with Silt or Mud from Construction Activities to Prevent it from Entering Live Waterways.** Water containing mud or silt from construction activities shall be treated by filtration, or retention in a settling pond, adequate to prevent muddy water from entering live waterways.

- **CM-18: Treat All Disturbed Soils with Appropriate Erosion Control.** All disturbed soils shall undergo appropriate erosion control treatment (e.g., sterile straw mulching, seeding, planting) prior to the end of the construction season, or prior to November 1, whichever comes first.

- **CM-19: Dispose of All Construction Materials at an Approved Disposal Site.** All debris, sediment, rubbish, vegetation, or other material removed from the construction areas shall be disposed of at an approved disposal site.

- **CM-20: Dispose Daily all Construction-related Materials and Equipment that Cannot be Secured at an Appropriate Disposal/Storage Site.** All litter, debris, unused materials, equipment, and supplies that cannot reasonably be secured shall be removed daily from the project work area and deposited at an appropriate disposal or storage site.

- **CM-21: Remove Immediately All Construction-Related Pads/Debris from Work Sites Upon Completion.** All work pads and construction debris shall be removed from work sites immediately when work is completed at each site.

- **CM-22: Use Safer Alternative Products to Protect Streams and Other Waters.** Every reasonable precaution shall be exercised to protect streams and other waters from pollution with fuels, oils, and other harmful materials. Safer alternative products (such as biodegradable hydraulic fluids) shall be used where feasible.

- **CM-23: Prevent Any Contaminated Construction By-Products from Entering Flowing Waters; Collect and Transport Such By-Products to An Authorized Disposal Area.** Petroleum products, chemicals, fresh cement, and construction by-products containing, or water contaminated by, any such materials shall not be allowed to enter flowing waters and shall be collected and transported to an authorized upland disposal area.

- **CM-24: Prevent Hazardous Petroleum or Other Hazardous Substances to Aquatic Life from Contaminating the Soil or Entering Waters of the State or U.S.** Gas, oil, other petroleum products, or any other substances that could be hazardous to aquatic life and resulting from project-related activities, shall be prevented from contaminating the soil and/or entering waters of the State and/or waters of the U.S.

- **CM-25: Prepare and Implement a Spill Prevention and Control Plan.** A written spill prevention and control plan (SPCP) shall be prepared and implemented. The SPCP and all material necessary for its implementation shall be accessible on-site prior to initiation of project construction and throughout the construction period. The SPCP shall include a plan for the emergency cleanup of any spills of fuel or other material. Employees/construction workers shall be provided the necessary information from the SPCP to prevent or reduce the discharge of pollutants from construction activities to waters and to use the appropriate measures should a spill occur. In the event of a spill, work shall stop immediately and the California Department of Fish and Wildlife (CDFW), U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), Central Valley Regional Water Quality Control Board (RWQCB), and USACE shall be notified within 24 hours.

- **CM-26: Properly Maintain All Construction Vehicles and Equipment and Inspect Daily for Leaks; Remove and Repair Equipment/Vehicles with Leaks.** Construction vehicles and equipment shall be properly maintained to prevent contamination of soil or water from external grease and oil or from leaking hydraulic fluid, fuel, oil, and grease. Vehicles and equipment shall be checked daily for leaks. If leaks are found, the equipment shall be removed from the site and shall not be used until the leaks are repaired.

- **CM-27: Refuel and Service Equipment at Designated Refueling and Staging Areas.** Equipment shall be refueled and serviced at designated refueling and staging sites located on the crown or landside of the levee and at least 50 feet from active stream channels or other water bodies. All refueling, maintenance, and staging of equipment and vehicles shall be conducted in a location where a spill shall not drain directly toward aquatic habitat. Appropriate containment materials shall be installed to collect any discharge, and adequate materials for spill cleanup shall be maintained on-site throughout the construction period.

- **CM-28: Store Heavy Equipment, Vehicles, and Supplies at Designated Staging Areas.** All heavy equipment, vehicles, and supplies shall be stored at the designated staging areas at the end of each work period.

- **CM-29: Install an Impermeable Membrane Between the Ground and Any Hazardous Material in Construction Storage Areas.** Storage areas for construction material that contains hazardous or potentially toxic materials shall have an impermeable membrane between the ground and the hazardous material and shall be bermed as necessary to prevent the discharge of pollutants to groundwater and runoff water.

- **CM-30: Use Water Trucks to Control Fugitive Dust during Construction.** Water (e.g., trucks, portable pumps with hoses) shall be used to control fugitive dust during temporary access road construction.

- **CM-31: Use Only Nontoxic Materials and Materials Placed in Any Waters with No Coatings or Treatments Deleterious to Aquatic Organisms.** All materials placed in streams, rivers, or other waters shall be nontoxic and shall not contain coatings or treatments or consist of substances deleterious to aquatic organisms that may leach into the surrounding environment in amounts harmful to aquatic organisms.

- **CM-32: Clean Construction Vehicles and Equipment Used Within the Stream Channel Before Arrival at the Project Construction Areas, and Inspect Vehicles/Equipment to Ensure They Are Free of Soil, Debris, and Nonnative Aquatic Species.** Construction vehicles and equipment operated within the channel margins (high water line) shall be cleaned of mud and other debris with a scrub brush and dry, or pressure-washed with hot (>140°F) water, before arrival at the project construction areas and prior to transporting the equipment to another stream or watershed. All equipment operated within the channel margins shall be carefully inspected for signs of aquatic invasive species (https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=4958&inline), including mussels and plant materials, with special attention paid to shaded, sheltered, and protected areas which might contain standing water and areas that form ‘edges’ or ‘right angles,’ such as tracks, feet, and/or tires. If vehicles or equipment are found to be contaminated with non-native invasive species, vehicles and equipment shall be stored in a dry location for at least one week prior to transport to a different stream or watershed, or alternatively, will be pressure-washed with hot (>140°F) water after each use. All water shall be drained from watercraft, including motor cooling system and bilge, and allow to dry as thoroughly as possible prior to entering a new stream or watershed. Large vessels and barges transported via the stream channel shall be contracted from nearby locations or shall undergo similar hull-cleaning prior to use for the project. Watercraft transported from distant areas, including barges, shall not release bilge water into the project area, unless screened to prohibit fish, plant, or other animal transport.

Resource-Specific Conservation Measures

Sensitive Biological Resources

- **SBR-1: Conduct Environmental Awareness Training.** A qualified biologist shall provide environmental awareness training to workers before project construction activities begin, and as needed when new personnel begin work on the project. The environmental awareness training shall inform all construction personnel about the relevant species and habitats that are known to occur in the project study area and vicinity, the need to avoid damaging these resources and causing mortality, measures to avoid and minimize impacts on the sensitive biological resources, the conditions of relevant regulatory permits, and the possible penalties for not complying with these requirements.

- **SBR-2: Erect High-Visibility Fencing to Protect Sensitive Biological Resource Areas, Inspect Fencing Daily, and Incorporate Sensitive Habitat Information into Bid Specifications.** Before the commencement of construction activities, high-visibility fencing shall be erected to protect areas of sensitive biological resources that are located adjacent to construction areas, but can be avoided, from encroachment of personnel and equipment. The fencing shall be inspected before the start of each work day and shall be removed only when the construction within a given area is completed. Sensitive habitat information shall be incorporated into project bid specifications, along with a requirement for contractors to avoid these areas.

- **SBR-3: Monitor Construction Activities in Sensitive Biological Resource Areas and Stop Work if Unauthorized Project Impacts Occur.** A qualified biologist shall monitor all construction activities in sensitive biological resource areas to ensure that avoidance and minimization measures are being properly implemented and no unauthorized activities occur. The biological monitor shall be empowered to stop construction activities that threaten to cause unanticipated and/or unauthorized project impacts. Project activity shall not resume until the conflict has been resolved.

- **SBR-4: Conduct Vegetation Removal Between September 16 and January 31 to the Extent Feasible.** Vegetation removal, particularly tree removal, shall be conducted between September 16 and January 31, to the extent feasible, to minimize potential loss of active bird nests and bat maternity roosts.

Vernal Pool Crustaceans

- **VPC-1: Provide Suitable Vernal Pool Crustacean Habitat with Protective Buffers, to the Extent Feasible, and Temporarily Fence and Designate the Buffers as Environmental Sensitive Areas.** Suitable habitat for vernal pool crustaceans shall be provided with protective buffers, to the extent feasible. The size and shape of the buffers shall depend on the local topography and potential for project activities to affect hydrology of the habitat. All buffers shall be temporarily fenced and designated as environmentally sensitive areas. These areas shall be avoided by all construction personnel.

- **VPC-2: Monitor All Construction Activities in Sensitive Biological Resources to Ensure that Avoidance and Minimization Measures Are Being Properly Implemented and Stop Construction Activities that Threaten Unauthorized Project Impacts.** A qualified biologist shall monitor all construction activities in sensitive biological resource areas to ensure that avoidance and minimization measures are being properly implemented and no unauthorized activities occur. The biological monitor shall be empowered to stop construction activities that threaten to cause unanticipated and/or unauthorized project impacts. Project activity shall not resume until the conflict has been resolved.

Valley Elderberry Longhorn Beetle

- **VELB-1: Temporarily Fence All Elderberry Shrubs Adjacent to Construction Areas and Designate the Area as Environmentally Sensitive.** All elderberry shrubs that are located adjacent to construction areas, but can be avoided, shall be temporarily fenced and designated as environmentally sensitive areas. These areas shall be avoided by all construction personnel. Fencing shall be placed at least 20 feet from the dripline of each shrub, unless otherwise approved by USFWS.

- **VELB-2: Prohibit Use of Pesticides or Chemicals within 100 Feet of Elderberry Shrubs.** No insecticides, herbicides, or other chemicals that might harm the beetle or its host plant shall be used within 100 feet of the elderberry shrubs.

- **VELB-3: Transplant Elderberry Shrubs Requiring Removal to Riparian Habitat Creation Areas, or Alternative Transplant Areas.** Elderberry shrubs that require removal shall be transplanted to the riparian habitat creation areas. If none of the areas of suitable habitat to be created as part of the proposed project would be available before the impact would occur, alternative transplant locations shall be identified. Transplant activities shall be conducted in accordance with USFWS guidelines.

Special-Status Fish

- **SSF-1: Conduct In-Water Construction Work Within In-Water Work Windows (June-October).** In-water construction activities shall be conducted within in-water work windows to avoid impacts to critical salmonid life stages (juvenile rearing, and juvenile and adult passage), typically from June through October.

- **SSF-2: Avoid SRA Habitat to the Maximum Extent Practicable and Temporarily Fence and Designate SRA Habitat as Environmentally Sensitive.** Natural woody riparian and/or SRA habitat shall be avoided to the maximum extent practicable. Habitat to be avoided shall be temporarily fenced and designated as environmentally sensitive areas. These areas shall be avoided by all construction personnel.

- **SSF-3: Install Screens on Any Construction-Related Water Pump Intakes Located on Waterways with Salmonids.** Screens shall be installed on any construction-related water pump intakes located on waterways with salmonids in accordance with current salmonid screening specifications of NMFS and CDFW.

Giant Garter Snake

- **GGS-1: Avoid Construction Activities within 200 Feet from the Banks of Suitable Giant Garter Snake Habitat and Confine Movement of Heavy Equipment to Existing Roadways, Where Feasible in These Areas.** To the extent possible, construction activities shall be avoided within 200 feet from the banks of suitable giant garter snake habitat. Movement of heavy equipment in these areas shall be confined to existing roadways, where feasible, to minimize habitat disturbance.

- **GGS-2: Temporarily Fence and Designate Suitable Giant Garter Snake Habitat to be Avoided as an Environmentally Sensitive Area.** Suitable giant garter snake habitat to be avoided within or adjacent to construction areas shall be temporarily fenced and designated as environmentally sensitive areas. These areas shall be avoided by all construction personnel.

- **GGS-3: Limit Ground Disturbance within 200 Feet of Suitable Giant Garter Snake Habitat and Conduct Activities Between May 1 and October 1, Unless Authorized by USFWS.** Unless authorized by USFWS, construction and other ground-disturbing activities within 200 feet of suitable aquatic habitat for the giant garter snake shall not commence before May 1, with initial ground disturbance expected to correspond with the snake's active season (as feasible in combination with minimizing disturbance of nesting Swainson's hawks). Initial ground disturbance shall be completed by October 1.

- **GGS-4: Ensure that Suitable Giant Garter Snake Aquatic Habitat that is Dewatered Remains Dry for 15 Consecutive Days after April 15 and if Not Possible, Potential Snake Prey is Removed.** Any suitable giant garter snake aquatic habitat that is dewatered shall remain dry for at least 15 consecutive days after April 15 and before excavating or filling of the dewatered habitat. If complete dewatering is not possible, potential snake prey (e.g., fish and tadpoles) shall be removed so that snakes and other wildlife are not attracted to the construction area.

- **GGS-5: Conduct a Preconstruction Survey within 200 Feet of Suitable Giant Garter Snake Habitat Within 24 Hours Before Commencement of Ground-Disturbing Activities.** Within 24 hours before the commencement of ground-disturbing activities, areas within 200 feet of suitable giant garter snake habitat shall be surveyed for giant garter snakes by a qualified biologist. The biologist shall provide USFWS with written documentation of the monitoring efforts within 48 hours after the survey is completed. The project area shall be reinspected by a qualified biologist whenever a lapse in construction activity of 2 weeks or greater has occurred.

- **GGS-6: Allow Snakes to Leave the Construction Area on Their Own and Notify USFWS and CDFW Immediately if a Giant Garter Snake is Found On Site.** No snakes shall be harassed, harmed, or killed, and they shall be allowed to leave the construction area on their own volition. If any snake is observed retreating into an underground burrow within the project limits, a 50-foot radius nondisturbance buffer zone shall be established until a qualified biologist determines that the snake is not a giant garter snake or the snake has left the area. The biologist shall notify USFWS and CDFW immediately if a giant garter snake is found on-site, and shall submit a report, including date(s), location(s), habitat description, and any corrective measures taken to protect the snake.

- **GGS-7: Restore All Suitable Giant Garter Snake Habitat Subject to Temporary Ground Disturbance to Preproject Conditions.** After construction activities are complete, all suitable giant garter snake habitat subject to temporary ground disturbances, including storage and staging areas and temporary roads, shall be restored to preproject conditions. These areas shall be recontoured, if appropriate, and revegetated with appropriate native plant species to promote restoration of the area to preproject conditions. Appropriate methods and plant species used to revegetate such areas shall be determined on a site-specific basis in consultation with USFWS and CDFW.

- **GGS-8: Maintain and Monitor Temporarily-Disturbed Areas of Suitable Giant Garter Snake Habitat Following Completion of Construction and Restoration Activities.** Temporarily-disturbed areas of suitable giant garter snake habitat shall be maintained and monitored for 1 year following the completion of construction and restoration activities. Monitoring reports documenting restoration of these areas shall be submitted to USFWS and CDFW upon the completion of the restoration implementation and 1 year after the restoration implementation.

COMPENSATION MEASURES

To mitigate for impacts to riparian habitat caused by levee improvements along Arcade Creek, and for removal of high-hazard trees that may affect the performance and reliability of existing levees on the Arcade Creek, SAFCA has identified some locations where native riparian vegetation could be established. Planting locations were selected to increase the patch size, improve habitat connectivity, and expand age class and species diversity of woodland habitat. These improvements would enhance nesting opportunities for native bird species, and, if necessary, could provide opportunities to satisfy VELB compensation.

- **Arcade Creek Habitat Improvements:** Impacts caused by levee improvements and high-hazard tree removal along Arcade Creek would be mitigated on-site to the extent feasible by improving and expanding native wetland and riparian habitat adjacent to the low-flow channel within the reach between Rio Linda Boulevard and Marysville Boulevard, which is currently dominated by nonnative annual grasses and broadleaf weeds. Following construction, native wetland vegetation (e.g., Santa Barbara sedge, Baltic rush) would be planted along the banks of Arcade Creek, and one row of large riparian tree species (e.g., valley oak) would be planted along each bank of the low-flow channel. The tree spacing would be determined by the capacity of the floodplain to accommodate vegetation without impacting the desired flood performance. The dense, high overhead canopy of the trees as they mature would provide important shade to the low-flow channel and bank, cover for small mammals and a connected migration corridor for flying and gliding animals (both vertebrates and invertebrates). The SRA habitat along the active channel would benefit water quality by keeping temperatures lower (cooler water retains higher levels of dissolved oxygen needed to sustain native fish and aquatic invertebrates), and provide leaf drop and other organic material to support aquatic food webs. In addition, shade from streamside trees would help suppress some growth of dense red sesbania and willows in the understory, and prevent new colonization of invasive species.

- **Robla Creek Habitat Improvements:** Replacement riparian woodlands are proposed either on Robla Creek Mitigation Site A (which is also Borrow Site 3, approximately 6 acres north of Rio Linda Boulevard) or on Robla Creek Mitigation Site B (approximately 7.1 acres south of Rio Linda Boulevard). Both sites are adjacent to and west of Robla Creek, (see **Exhibit 5**). Site A is a previous borrow site and is at a lower elevation making this area better suited for wetland mitigation. Site B is connected to the Robla Creek floodplain and is the site of a future multi-use recreational trail. SAFCA would provide right-of-way for future construction of the trail.

5.0 ACTION AREA

The action area is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 Code of Federal Regulations [CFR] 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the NSS Levee Improvements Project. Areas downstream of the NSS Levee Improvements Project area might also be indirectly affected by the flood risk management component of the project through improved water quality and flood risk management conditions. The extent of this potential effect is difficult to quantify.

For the purpose of the proposed project, project activities would occur in the following areas, which collectively comprise the action area:

- The section of NEMDC/Steelhead Creek that extends approximately 0.5-mile south from the confluence of Arcade Creek.
- The section of Arcade Creek between NEMDC/Steelhead Creek and Marysville Boulevard.
- A small section along the Robla Creek south levee, east of Rio Linda Boulevard near Dry Creek Road.
- The 3 borrow sites.
- The 4 potential staging areas.
- The one woodland mitigation site along Robla Creek.

6.0 ENVIRONMENTAL BASELINE

The NSS Levee Improvements Area includes NEMDC/Steelhead Creek and two of its tributaries: Arcade and Robla Creeks, as well as the borrow sites, potential staging areas, and tree mitigation site.

6.1 VEGETATION AND HABITAT

6.1.1 NEMDC/STEELHEAD CREEK

NEMDC/Steelhead Creek is an approximately 13.3-mile, human-made, partially leveed drainage channel that provides drainage from Sankey Road and connects streams of the American Basin (Dry, Robla, and Arcade Creeks) to the American River. The NEMDC/Steelhead Creek forms a portion of the eastern boundary of the Natomas Basin and under high flows connects to the Pleasant Grove Creek Canal which drains into the Natomas Cross Canal and carries flows to the Sacramento River. For the purpose of the proposed project, levee improvements would occur on a portion of the NEMDC/Steelhead Creek levee that extends approximately 0.5-mile south from the confluence of Arcade Creek. The East Levee Road extends along the crown of the west levee, and a levee road and railroad tracks extend along the crown of the east levee.

South of the confluence with Arcade Creek, the east and west levees of NEMDC/Steelhead Creek are dominated by wild oats grasslands, while the channel of NEMDC/Steelhead Creek is characterized by Fremont cottonwood forest, with smaller amounts of valley oak woodland, smart-weed cocklebur patches, and perennial rye grass fields.

6.1.2 ARCADE CREEK

The approximately 16.2-mile-long channel of Arcade Creek extends east-to-west from Orangevale to the American River, via NEMDC/Steelhead Creek. Levee improvements, as well as components of the Conservation Strategy, would occur on the section of Arcade Creek between NEMDC/Steelhead Creek and Marysville Boulevard, and encroachment removal and vegetation management would occur mainly in the section between Rio Linda and Marysville Boulevards.

The north and south levees are dominated by wild oats grasslands, with a paved or gravel road along the levee crowns and the landside levee toe. Developed areas along Arcade Creek include the four bridges that cross the channel; from east to west, these are: Norwood Avenue, the Sacramento Northern Bike Trail, Rio Linda Boulevard, and Marysville Boulevard. Residential developments and Gateway Park, located north of Arcade Creek and respectively east and west of Norwood Avenue, and Hagginwood Park, located north Arcade Creek east of Marysville Boulevard, include landscaped areas. Valley oak woodland is the main riparian vegetation type along Arcade Creek, but Fremont cottonwood forest occurs in small patches along the easternmost reach of Arcade Creek near NEMDC/Steelhead Creek. Hardstem bulrush marsh is found within Arcade Creek near Norwood Avenue while water primrose wetlands are predominant within the channel of Arcade Creek from approximately the confluence with NEMDC/Steelhead Creek to Norwood Avenue. East of Norwood Avenue, the creek channel becomes narrower, and dominated by a shaded canopy of valley oak woodland.

6.1.3 ROBLA CREEK

Robla Creek is a perennial stream located just south of Dry Creek, extending east-to-west from near McClellan Air Force Base to the American River (via NEMDC/Steelhead Creek). In the 1970s, a reach of Robla Creek between Dry Creek Road and the Sacramento Northern Bike Trail was relocated to facilitate the construction of a housing development and recreational lakes. This channelized section of Robla Creek was restricted to a very narrow corridor that contained low-quality habitat and did not provide adequate room for flood flows (SAFCA 2014). In 1993, SAFCA constructed a new Rio Linda Creek channel west of Dry Creek Road. A section of the Robla Creek channel west of Dry Creek Road was filled in 2002 to accommodate the Robla Creek north levee, and a new channel was built to replace it. This new creek section provides a sinuous, meandering channel with improved flood flow capabilities and increased habitat values (SAFCA 2014). The area adjacent to NEMDC/ Steelhead Creek is characterized as seasonal wetlands, while further east, the creek channel is surrounded by, invasive red sesbania, wild oats grasslands with some clusters of valley oak woodland. For the purposes of the proposed project, a limited amount of encroachment removal would occur in a small footprint along the Robla Creek south levee, east of Rio Linda Boulevard near Dry Creek Road.

6.1.4 BORROW AND STAGING AREAS

Three potential borrow sites have been identified to support levee improvements in the North Sacramento Streams Levee Improvements area. The environmental effects that would result from use of borrow materials from Borrow Site 1 were evaluated in the Phase 3 FEIS/FEIR (USACE and SAFCA 2009).

Borrow Site 2 is a narrow site dominated by yellow star thistle and nonnative grasslands, located between the NEMDC/Steelhead Creek levees (East Levee Road and Sorrento Road), immediately east of the channel. Just east of the southern portion of this borrow site is the approximately 60-acre Wolf Ranch Wildlife Sanctuary, on which SAFCA created mitigation wetland and upland habitats after using the site as a borrow source for a previous levee improvement project (SAFCA 2014).

Borrow Site 3 is located north of Robla Creek and the Robla Creek South Levee, east of Rio Linda Boulevard on a site that is comprised of ruderal fields. This site would also serve as a potential tree mitigation site for the North Sacramento Streams Levee Improvements.

Four potential staging areas have been identified to support the levee improvements in the North Sacramento Streams Levee Improvements area. As depicted in **Exhibit 4.6-1**, three of these occur adjacent to, but not within the levee improvement footprint; thus, these areas are considered additional impacts. Staging Area 1 is considered developed. Staging Areas 2 and 4 are primarily wild oats grassland with some developed. Staging Area 3 is primarily developed with some wild oats grasslands. Staging within these areas would be located to avoid the removal of sensitive vegetation and trees. Wild oats grasslands are found in the levee maintenance easements.

6.1.5 WOODLAND MITIGATION SITES

Two areas have been identified where riparian woodlands could replaced as off-site mitigation for tree removal associated with levee improvements along Arcade Creek and NEMDC/Steelhead Creek. These two sites are located north of and immediately adjacent to Robla Creek, distributed along both sides of Rio Linda Boulevard. Both sites are owned by SAFCA and are currently ruderal grassland. The approximately 6-acre Site A is also the potential Borrow Site 3. Site B is an approximately 7.1-acre area.

6.2 WILDLIFE

The NSS Levee Improvements area provides a variety of wildlife habitats associated with the various creeks that are present. The NEMDC/Steelhead Creek habitat corridor and downstream portion of the Arcade Creek corridor generally provide higher-quality wildlife habitat than the upper portions of Arcade Creek, because they are wider and support more diversity of habitat types. A variety of common wildlife species are anticipated to be resident in the North Sacramento Streams Levee Improvements area, and additional species are likely to use the channels on a seasonal or other irregular basis as movement corridors between upstream and downstream areas.

7.0 SPECIES ACCOUNTS

[Refer to the USACE GRR BA.]

8.0 EFFECTS

8.1 DIRECT AND INDIRECT EFFECTS ON SPECIES IN THE ACTION AREA

Under the ESA, direct effects are those that are caused by the project and that occur at the same time as the action (see, e.g., construction-related effects). Indirect effects are those that are caused by the proposed action and are later in time, but are reasonably certain to occur (e.g., operational effects). Avoidance and minimization measures for both direct and indirect effects are presented in the "Conservation Strategy" section above.

8.1.1 VERNAL POOL INVERTEBRATES

Seasonal wetland habitat is present in annual grassland north of Robla Creek, including in the eastern portion of Borrow Site 3/Robla woodland mitigation site A. Although borrow extraction and riparian planting activities associated with levee improvements and the Conservation Strategy in the NSS Levee Improvements area would not directly affect the seasonal wetland habitat, these activities could indirectly affect potentially suitable habitat for vernal pool invertebrates in this area by altering hydrology and/or degrading water quality. These effects could result in temporary loss of individuals, but the population could persist if the habitat is restored to its prior condition.

However, implementation of the Conservation Strategy avoidance and minimization measures, and specifically VPC-1, "Provide Suitable Vernal Pool Crustacean Habitat with Protective Buffers, to the Extent Feasible, and Temporarily Fence and Designate the Buffers as Environmental Sensitive Areas," and VPC-2, "Monitor All Construction Activities in Sensitive Biological Resources to Ensure that Avoidance and Minimization Measures Are Being Properly Implemented and Stop Construction Activities that Threaten Unauthorized Project Impacts," would avoid and minimize the potential for indirect effects on suitable habitat for vernal pool invertebrates through the establishment of appropriate buffers.

8.1.2 VALLEY ELDERBERRY LONGHORN BEETLE

Blue elderberry shrubs (Sambucas mexicana), the host plant for valley elderberry longhorn beetle larvae, are sparsely scattered throughout the action area. There are no known documented occurrences of VELB in the NSS Levee Improvements Project area, but the species could use elderberry shrubs in the action area.

Elderberry shrubs were not observed along Arcade Creek or NEMDC/Steelhead Creek during field surveys and are not expected to occur at Borrow Sites 2 and 3. Encroachment removal along Robla Creek would be limited to trimming back residential landscaping from a fence line and would have no potential for adverse impact to any elderberry shrubs, if present nearby. Elderberry shrubs could be present adjacent to potential woodland mitigation sites, including along Robla Creek. However, the Conservation Strategy would focus tree mitigation efforts on open grassland areas and avoid disturbance of elderberry shrubs that may be nearby. Further, implementation of the Conservation Strategy avoidance and minimization measures, and specifically VELB-1 "Temporarily Fence All Elderberry Shrubs Adjacent to Construction Areas and Designate the Area as Environmentally Sensitive," would avoid the potential for direct and indirect effects on elderberry shrubs through the establishment of appropriate buffers. Other Conservation Strategy avoidance and minimization measures, such as VELB-2, "Prohibit Use of Pesticides or Chemicals within 100 Feet of Elderberry Shrubs,"

8.1.3 SPECIAL-STATUS FISH SPECIES [PLACEHOLDER]

8.1.4 GIANT GARTER SNAKE

Giant garter snakes have not been documented in NEMDC/Steelhead Creek or its eastside tributaries (CDFW 2014), and historical habitat conditions are thought to have limited dispersal of the species east of NEMDC/ Steelhead Creek (Halstead et al. 2014; B. Halstead, pers. comm., 2015; E. Hansen, pers. comm., 2015). Based on these factors and current habitat conditions, such as close proximity to urban development, high levels of human disturbance, scarcity of upland habitat, and riparian vegetation along the banks of most channel reaches, giant garter snakes are unlikely to occur in the eastside tributaries and the southern portion of NEMDC/Steelhead Creek. Therefore, all proposed project elements that would occur in these areas, including encroachment removal and levee improvements along Arcade Creek and levee improvements along the adjacent portion of the NEMDC/ Steelhead Creek east levee, are unlikely to directly or indirectly impact giant garter snakes or adversely affect habitat occupied by the species.

The quality of habitat for giant garter snake improves along NEDMC/Steelhead Creek north of Dry Creek, where aquatic habitat is more extensive, very little riparian vegetation is present, urban development is less extensive, and large areas of open grasslands are present landside of the levees. Giant garter snakes are known to occur in rice fields, associated canals, and managed marshes in the Natomas Basin. An occurrence was documented along Elkhorn Boulevard, approximately 0.7 mile northwest of Borrow Site 2, and the species occurs at the complex of TNBC reserves immediately west of NEMDC/Steelhead Creek, approximately 3.5 miles farther north (CDFW 2014). Based on habitat conditions and known occurrences of giant garter snake, there is potential for the species to occur, at least occasionally, in nearby portions of NEMDC/Steelhead Creek. Borrow Site 2 is located immediately east of NEMDC/Steelhead Creek and may support potentially suitable upland habitat for the species. If giant garter snakes are present during borrow activities, these activities would result in direct and indirect effects to this species.

Ground disturbing activities at Borrow Site 2, where uplands adjacent to suitable aquatic habitat would be disturbed, could result in direct displacement, injury, or death of snakes if the habitat is used for basking, hibernating, or aestivating. Indirect effects could occur if snakes are displaced from occupied habitat or disturbed by nearby construction activities. Displacement and disturbance resulting from human activity, construction noise, and equipment vibrations could affect the ability of snakes to conduct essential life history functions, such as dispersal, movement, or foraging, and could result in increased competition for food and space and vulnerability to predation. Construction activities could temporarily degrade aquatic habitat, but the overall result of implementing the Conservation Strategy would be an enhancement of habitat quality.

All project-related impacts at Borrow Site 2 would occur within one active season and, therefore, are considered temporary. Borrow Site 2 would be restored /enhanced and re-graded to a condition that exceeds the pre-project condition by lowering the land surface closer to the low flow channel elevation and through establishment of a more diverse mosaic of aquatic and wetland habitat components.

9.0 CUMULATIVE EFFECTS

[Refer to the USACE GRR BA.]

10.0 CONCLUSIONS AND DETERMINATION

In conclusion, based on the biology and ecology of the federally listed species that have the potential to occur in the NSS Levee Improvements Project area, the environmental baseline for the action area, and the effects of the proposed action and its cumulative effects, implementing the NSS Levee Improvements Project may affect and is likely to adversely affect giant garter snake and would result in no effect on listed vernal pool invertebrates, valley elderberry longhorn beetle, and Central Valley steelhead. Designated critical habitat in the action area has been designated for Central Valley steelhead; however, none would be adversely modified or destroyed.

- **Vernal pool invertebrates:** The NSS Levee Improvements Project would result in no effect on federally listed vernal pool invertebrates considered in this preliminary biological evaluation. Effects are not expected to occur because of the avoidance and minimization measures incorporated into the NSS Levee Improvements Project. The NSS Levee Improvements Project includes several measures that would avoid potential direct and indirect environmental effects during project construction. The potential indirect effects impacts of altered hydrology or degraded water quality, would be avoided and minimized through the use of best management practices (e.g., establishment and maintenance of appropriate buffers, erosion control, and revegetation).

- **Valley elderberry longhorn beetle:** The NSS Levee Improvements Project would result in no effect to VELB. Any elderberry shrubs located in the NSS Levee Improvements Project area would be avoided (see VELB-1 "Temporarily Fence All Elderberry Shrubs Adjacent to Construction Areas and Designate the Area as Environmentally Sensitive"), thereby avoiding direct effects to VELB. Additional conservation measures (VELB-2, "Prohibit Use of Pesticides or Chemicals within 100 Feet of Elderberry Shrubs.".

- **Federally listed fish species:** [Placeholder]

- **Giant garter snake:** The NSS Levee Improvements Project may affect and is likely to adversely affect giant garter snake through the implementation of activities at Borrow Site 2. Ground disturbing activities at Borrow Site 2 could result in direct displacement, injury, or death of snakes and indirect displacement of snakes. These direct and indirect effects, which could affect the ability of snakes to conduct essential life history functions, such as dispersal, movement, or foraging, would be temporary (occurring during one active season). Construction activities could temporarily degrade aquatic habitat, but the overall result of implementing the Conservation Strategy would be an enhancement of habitat quality.

11.0 ESSENTIAL FISH HABITAT ASSESSMENT

The Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801), requires that EFH be identified and described in federal fishery management plans. Federal agencies must consult with NMFS on any activity that they fund, permit, or carry out that may adversely affect EFH. The EFH regulations require that federal agencies obligated to consult on EFH also provide NMFS with a written assessment of the effects of any action on EFH (50 CFR 600.920). NMFS is required to provide EFH conservation and enhancement recommendations to federal agencies. The statute also requires federal agencies receiving NMFS EFH conservation recommendations to provide a detailed written response to NMFS within 30 days of receipt, detailing how they intend to avoid, mitigate, or offset the impact of activity on EFH (Section 305[b][4][B]).

EFH is defined as those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity. For the purposes of interpreting the definition of EFH, "waters" includes aquatic areas and their associated physical, chemical, and biological properties that are used by fish, and may include areas historically used by fish where appropriate; "substrate" includes sediment, hard bottom, structures underlying the waters, and associated biological communities; "necessary" means habitat required to support a sustainable fishery and a healthy ecosystem; and "spawning, breeding, feeding, or growth to maturity" covers all habitat types used by a species throughout its life cycle.

The Pacific Fishery Management Council has identified and described EFH, adverse impacts, and recommended conservation measures for salmon in Amendment 14 to the *Pacific Coast Salmon Plan* (PFMC 2003). Freshwater EFH for Pacific salmon in the Central Valley includes waters currently or historically accessible to salmon within the Central Valley ecosystem, as described in Myers et al. (1998), and includes the segment of the NEMDC/Steelhead Creek in the action area. Central Valley fall-/late fall–run Chinook salmon is a species managed under the *Pacific Coast Salmon Plan* that occur in the NEMDC/Steelhead Creek.

THE PROPOSED ACTION

The proposed action is described in detail in the "Description of the Proposed Action" section of this preliminary biological evaluation. The action area, environmental baseline, and species accounts, respectively, are described in the "Action Area," "Environmental Baseline," and "Species Accounts" sections of this preliminary biological evaluation.

Subject: Review of the Proposed Magpie Creek Flood Control Project, Sacramento County, California, for Inclusion with the Vernal Pool Crustaceans Programmatic Consultation (File Number 1-1-96-F-0001) and a Separate Formal Consultation for the Giant Garter Snake

Dear Mr. Charlton:

This letter responds to your March 25, 2004, letter requesting formal consultation with the U. S. Fish and Wildlife Service (Service) and concurrence to append the U. S. Army Corps of Engineers' (Corps) proposed Magpie Creek Flood Control Project (project) in Sacramento, California, to the programmatic formal consultations for the threatened giant garter snake (*Thamnophis gigas*), and the endangered vernal pool tadpole shrimp (*Lepidurus packardi*) and the threatened vernal pool fairy shrimp (*Branchinecta lynchi*) (File Numbers 1-1-F-97-149 and 1-1-96-F-1, respectively).

As explained below, we determined during our review of your request that the proposed project qualifies for inclusion under the programmatic consultation for vernal pool crustaceans only. Accordingly, a separate consultation for giant garter snake was deemed necessary and is provided in this letter. The findings in this consultation are based on information provided in your March 25, 2004, letter and attached *Draft Environmental Assessment* (DEA), dated January 2004; your *Draft Detailed Project Report/Environmental Assessment* dated January 14, 2004; a *Second Revised Draft Fish and Wildlife Coordination Act* (FWCA) *Report*, dated May 8, 2003, prepared by the Service; site visits on April 27 and May 20, 2004, with the Corps and Sacramento Area Flood Control Agency (SAFCA), the project local sponsor; electronic mail (e-mail) communications to the Service from the Corps dated May 17 and June 9, 2004, providing project description language pertaining to preservation of purchased land; and our review of earlier FWCA Reports, numerous other file documents, and meeting and site visit notes during the 1993-2004 period of Service coordination and consultation activity on this project.

CONSULTATION HISTORY

In the early 1990s, the Corps investigated flood protection needs in the Magpie Creek area, compared detention basin and channel widening (channel plan) alternatives that included the former McClellan Air Force Base (currently known as McClellan Business Park), and recommended the channel plan. The Service's biological opinion dated September 20, 1995 (File Number 1-1-95-F-30) determined that the channel plan would have direct and indirect effects on vernal pools and other wetlands that would involve significant compensation for impacts. The opinion did not address effects on giant garter snake. The Service met with the local sponsor on November 20, 1997, regarding the potential for use of habitat within the lower Dry Creek corridor for mitigation of project impacts, but did not reach agreement. In late 1999 to early 2000, the channel plan was redesigned with an upstream terminus just east of Raley Boulevard. This plan provided for reduced effects to seasonal wetlands and increased vegetation allowance (with reduced maintenance) within the widened Magpie Creek Diversion Channel (MCDC), with raising of Raley Boulevard and relocation of a portion of Don Julio Creek. On February 27, 2001, Service and Corps staff met and discussed effects of the project on floodplain development. Beginning June 2001, the project was again redesigned based on additional hydraulic analysis and preliminary alternatives developed by David Ford Consulting Engineers (Magpie Creek Floodplain Analysis, dated November 19, 2001). The selected alternative which is described in more detail below, would accomplish flood protection using modest levee and culvert improvements together with purchase of land primarily east of Raley Boulevard for the purpose of peak flood detention, and would not involve widening or other modification of the existing MCDC channel.

Recent consultation activities directly related to this proposed project are as follows:

March 26, 2004: Service received letter from the Corps (Mark Charlton) dated March 25, 2004, and draft Environmental Assessment dated January 2004, requesting appendage of the proposed project to the programmatic biological opinions for giant garter snake and vernal pool crustaceans.

April 29, 2004: Service, Corps, and SAFCA staff met in the field to review proposed project features and confirm type of disturbance associated with Robla Creek bikeway trail culvert.

May 7, 2004: Service staff (Steve Schoenberg) submitted an e-mail request to Corps staff (Ed Stewart) to clarify protective mechanism by which purchased lands would be preserved in perpetuity.

May 17, 2004: Service received an e-mail response from Corps staff (Ed Stewart), forwarding language from SAFCA (Grant Kreinberg) that it would place a flood control easement on the land in addition to purchase and would request purchased land be re-zoned as open space.

May 18, 2004: Service informed Corps by an e-mail of the need for a second site visit to verify vernal pool indirect effects near Kelly-Moore Paint Store, and assess status of vernal pools south of MCDC between Vinci Avenue and Dry Creek Road previously mapped in 1993.

May 19, 2004: Service faxed the Corps additional information on locations of vernal pool crustacean habitat which required confirmation.

May 20, 2004: Service and Corps staff met in field, concluded that pool impacts near the Kelly-Moore Paint Store were at most no greater in size than indicated in the March 25, 2004, biological assessment, and the pool areas between Vinci Avenue and Dry Creek Road were no longer present, possibly due to recent grading from an unrelated project.

May 22, 2004: Service requested via an e-mail to the Corps, clarification as to whether unrelated grading/construction activity between Vinci Avenue and Dry Creek Road would require modification of the proposed flood control project, specifically, the location of the maintenance road.

June 8, 2004: Corps (Charles Rairdan) replied via an e-mail that the Corps had contacted the developer who had conducted subject unrelated grading, and confirmed that the maintenance road element of the proposed flood control project would be constructed in the location as originally planned.

June 9, 2004: Corps (Charles Rairdan) e-mailed Service revisions to proposed project description language.

July 30, 2004: Service requested via an e-mail to the Corps to confirm areas of habitat disturbance and loss.

August 3, 2004: Corps (Ed Stewart) replied via an e-mail to the Service confirming habitat disturbance and loss areas.

PROJECT DESCRIPTION

The proposed project would be located in Sacramento County north of Interstate 80 and west of McClellan Business Park, and would provide for improved flood protection within the historic Magpie Creek floodplain between Raley Boulevard and the Natomas East Main Drainage Canal. Currently, drainage is provided by the MCDC, an existing artificial channel which spans between

Raley Boulevard and the confluence of Robla Creek with the MCDC. The MCDC includes existing sections of levees between Raley Boulevard and Vinci Avenue, and between Dry Creek Road and the Robla Creek confluence. Proposed project features include:

- raising the MCDC levee between Raley Boulevard and Vinci Avenue;
- constructing maintenance roads - for the 2,100 feet between Raley Boulevard and Vinci Avenue, the existing road on top of the levee would be reconstructed and a second new road would be built land side of the levee base; for the 2,700 feet between Vinci Avenue and Dry Creek Road, a new maintenance road would be constructed immediately adjacent to the top of slope of the MCDC;
- constructing a new 1,000-foot-long levee along the west side of Raley Boulevard between the existing MCDC crossing and Santa Ana Avenue to prevent outflanking flows (with floodgates at the entrance to the Kelly-Moore Paint Store);
- excavating a new overflow channel and installing culverts under the bike trail bridge near the Robla Creek confluence with the MCDC;
- relocating and replacing the existing slide gate outlet between the MCDC and historic Magpie Creek;
- disposing of abandoned tanks between the MCDC and Raley Boulevard, and;
- acquiring and preserving in perpetuity 79 acres (76.5 acres excluding roadways and channels) between Raley Boulevard, McClellan Business Park, and Magpie and Don Julio Creeks.

The MCDC levee raise and new Raley Boulevard levee segment are designed to detain the 250 year flood within the 79-acre area which would be acquired (hereafter termed "preservation area"). The raise would range from about five feet at Raley Boulevard and taper to existing ground a short distance south of Vinci Street. The Raley Boulevard levee would be about five feet high where it meets the MCDC levee, tapering to existing ground near Santa Ana Avenue. The bike trail culvert is sized to result in no change in peak flood stage on the MCDC upstream of Dry Creek Road. The maintenance roads allows the full length of proposed project features (both levee and channel) to be maintained. The 20-foot-wide overflow channel near the bike bridge would be above the invert of the MCDC and configured to avoid existing oak trees. The new slide gate outlet to historic Magpie Creek would retain the flexibility to release flows into the historic channel.

Construction will take one season. Two staging areas have been designated, an existing borrow storage and disposal location near Dry Creek Road and Ascot Avenue, and a section of Vinci Avenue just west of the MCDC. The bike trail culvert and overflow channel would be constructed first, and suitable material stockpiled for use in subsequent construction of the new Raley Boulevard levee or MCDC levee raise work described above. Remaining material would be obtained from the existing borrow storage area. After the levee work is completed, the maintenance roads would be built with an aggregate base. All soils exposed by grading would be revegetated by seeding and mulching.

The action area includes the MCDC and adjacent lands where levee, channel, culvert, or road construction would occur, a small area along Raley Boulevard where levee construction would occur, the preservation area, and the historic Magpie Creek floodplain. These areas are dominated by uplands, primarily herbaceous, non-native grasslands, with scattered houses and a few light industries near Raley Boulevard. Most areas are relatively undisturbed, but other areas near residences are more frequently disturbed by tilling, and ongoing activities such as grazing, storage of a variety of items, and off-road vehicle travel. Magpie and Don Julio Creeks, and the MCDC, have both wetland and primarily young woody vegetation within the channel banks. Larger and more dense woody vegetation is present around some sections of Don Julio Creek, and several mature oaks are in the vicinity of the bike trail culvert element. The preservation area as well as portions of the historic Magpie Creek floodplain have a variety of seasonal and permanent wetlands. The MCDC currently is subject to occasional maintenance of vegetation. The proposed work would occur outside of the channels and no change in channel maintenance is proposed. Approximately 0.25 acres of wetland that is potential vernal pool crustacean habitat near the MCDC would be indirectly affected by elimination of outflanking flows. About 6.1 acres of lands adjacent to the MCDC that are potential giant garter snake habitat, would be disturbed by the proposed project (upland plus the existing maintenance road), of which 1.4 acres would be a permanent conversion of upland to additional maintenance road surface.

The Corps has recommended fee title acquisition of the preservation area and SAFCA has indicated it will purchase the property in fee and also place a flood control easement on the title. The intention of these actions is to prohibit construction of any structures on the properties and to permanently prevent the properties from being developed. Although conservation areas in accordance with programmatic formal consultations are typically protected by a conservation easement, the Corps can only require a flowage easement to fulfill the proposed project's flood control purpose. However, the restrictiveness and compensation for such an easement has been determined by the Corps to be tantamount to fee title. Following purchase, SAFCA will request the City of Sacramento to change the land use and zoning designation on the property to reflect the permanent preservation of the properties as open space. SAFCA has further indicated it will develop, separate from the proposed flood control project, a habitat management plan for the properties with a view toward enhancing the habitat, such as by native tree planting adjacent to Magpie and Don Julio Creeks, and has stated its intention to coordinate such enhancement activity with appropriate regulatory agencies, which would include the Service.

Proposed Minimization and Compensation Measures: The Corps has proposed to acquire 0.5 mitigation credits from a Service-approved mitigation bank for preservation of vernal pool habitat. As it concerns measures to protect the giant garter snake, the Corps states that it will limit such construction to between May 1 and October 1, instruct personnel in awareness training by a Service-approved biologist, confine construction equipment to existing roads and levee surfaces, conduct pre-construction surveys and re-surveys between construction lapses, report any giant garter snake sitings and, upon any siting, halt construction until such time avoidance measures are developed in consultation with the Service. These are consistent with the standard avoidance and minimization measures 1-7 of the Service's *Programmatic Formal Consultation for U.S. Army Corps of Engineers 404 Permitted Projects with Relatively Small Effects on the Giant Garter Snake within Butte, Colusa, Glenn, Fresno, Merced, Sacramento, San Joaquin, Solano, Stanislaus, Sutter, and Yolo Counties* (Snake Programmatic Consultation) (Appendix C, attached).

APPENDMENT TO VERNAL POOL FAIRY SHRIMP PROGRAMMATIC OPINION

With respect to listed vernal pool crustaceans, indirect effects of the proposed project could result from elimination of outflanking storm flows to pools within 250 feet of proposed project elements. Two wetlands totaling about 0.25 acre are present west of the Kelly Moore Paint Store. The Corps has proposed to acquire 0.5 mitigation credits from a Service-approved mitigation bank for preservation of vernal pool habitat to offset this impact. The proposed project will also have slight effects on flood depth and duration in the area proposed for purchase and preservation. Increasing the levee height of the MCDC levee would increase the depth of flooding of the area between Magpie and Don Julio Creeks by less than 1 foot for several hours during a 250-year flood event, and by much less (0.01-0.05 feet) during the average annual (2-year) flood event. The hydraulic changes in this area caused by the proposed project are determined by the Service to be of insufficient magnitude, frequency, and duration to cause an adverse effect to listed vernal pool crustaceans or their habitat.

The Service has determined that, based on the effects on listed vernal pool crustaceans described in your March 25, 2004, letter, it is appropriate to append the proposed Magpie Creek Flood Control Project to the Service's *Programmatic Formal Endangered Species Act Consultation on Issuance of 404 Permits for Projects with Relatively Small Effects on Listed Vernal Pool Crustaceans within the Jurisdiction of the Sacramento Field Office, California* (Vernal Pool Programmatic Consultation).

The Service is tracking losses of habitat permitted under the Vernal Pool Programmatic Consultation. We reevaluate the effectiveness of the Vernal Pool Programmatic Consultation at least every six (6) months to ensure that continued implementation will not result in unacceptable effects to the listed species.

The conservation measures identified in the Vernal Pool Programmatic Consultation include the following:

1. <u>Preservation component:</u> For every acre of habitat directly or indirectly affected, at least two vernal pool credits will be dedicated within a Service-approved ecosystem preservation bank or, based on Service evaluation of site-specific conservation values, three acres of vernal pool habitat may be preserved on the project site or another non-bank site as approved by the Service.

2. <u>Creation component:</u> For every acre of habitat directly affected, at least one vernal pool creation credit will be dedicated within a Service-approved habitat creation bank or, based on Service evaluation of site-specific conservation values, two acres of vernal pool habitat will be created and monitored on the project site or another non-bank site as approved by the Service.

3. Listed vernal pool crustacean habitat and associated uplands utilized as on-site compensation will be protected from adverse effects and managed in perpetuity or until the Corps, the applicant, and the Service agree on a process to exchange such areas for credits within a Service-approved conservation banking system. Off-site conservation at a Service-approved non-bank location will be protected and managed in perpetuity through a Service-approved conservation easement, Service-approved management plan, and a sufficient endowment fund to manage the site in perpetuity in accordance with the management plan

4. If habitat is avoided (preserved) on site, then a Service-approved biologist (monitor) will inspect any construction-related activities at the proposed project site to ensure that no unnecessary take of listed species or destruction of their habitat occurs. The biologist will have the authority to stop all activities that may result in such take or destruction until appropriate corrective measures have been completed. The biologist also will be required to immediately report any unauthorized impacts to the Service and the California Department of Fish and Game.

5. Adequate fencing will be placed and maintained around any avoided (preserved) vernal pool habitat to prevent impacts from vehicles.

6. All on-site construction personnel will receive instruction regarding the presence of listed species and the importance of avoiding impacts to these species and their habitat.

7. The applicant will ensure that activities that are inconsistent with the maintenance of the suitability of remaining habitat and associated on-site watershed are prohibited. This includes, but is not limited to: (i) alteration of existing topography or any other alteration or uses for any purposes, including the exploration for or development of mineral extraction; (ii) placement of any new structures on these parcels; (iii) dumping, burning, and/or burying of rubbish, garbage, or any other wastes or fill materials; (iv) building of any new roads or trails; (v) killing, removal, alteration, or replacement of any existing

native vegetation; (vi) placement of storm water drains; (vii) fire protection activities not required to protect existing structures at the project site; and (viii) use of pesticides or other toxic chemicals.

The proposed project will result in 0.25 acre of indirect effects to vernal pools/swales of potentially suitable vernal pool shrimp and vernal pool tadpole shrimp habitat. The applicant has identified and agreed to purchase 0.5 vernal pool preservation credits at a Service-approved conservation bank or Service-approved fund. Credits will be purchased prior to the effect on any vernal pool habitat.

The agreed upon conservation responsibilities of the applicant are as follows:

1. Prior to any earth-moving activities at the proposed project site, the applicant shall purchase at least 0.5 vernal pool preservation credits within a Service-approved ecosystem preservation bank or fund account.

SEPARATE BIOLOGICAL OPINION ON GIANT GARTER SNAKE

With respect to the giant garter snake, certain sections of Magpie and Don Julio Creeks and the MCDC contain suitable habitat for the giant garter snake. The DEA references a professional consultant's opinion that potential presence of giant garter snake cannot be discounted in these sections, and notes the connection between and proximity of the proposed project watercourses to the Natomas drainage system as well as a nearby siting of giant garter snake within McClellan Business Park at Robla Creek. Accordingly, the presence of giant garter snake in the proposed project area is assumed. Although no construction would occur in aquatic habitat, your March 25, 2004, letter which requested formal consultation incorrectly states that there would be no removal of upland habitat during channel modifications. In fact, the DEA states that construction would take place in uplands within 200 feet and/or adjacent to aquatic habitat, in the forms of: (1) 4,800 feet of a new 10-foot-wide maintenance road (and an additional one foot of shoulder on each side); and (2) approximately 200 feet of new 20-foot-wide channel excavation near the bicycle bridge in the vicinity of the Robla Creek Confluence. The total area of upland that would be adversely affected would be 6.1 acres, of which 1.4 acres of impact related to the construction of the new maintenance road would be permanent, as this road would be surfaced with aggregate stone and maintained free of vegetation (areas provided by an e-mail communication from the Corps (Ed Stewart) dated August 3, 2004). Snakes would be able to move across this surface but it would lack the vegetation of typical uplands that provide essential habitat functions. The construction of a culvert and associated channel near the bicycle bridge would be considered a temporary effect, as it would be earth-surfaced, and assumed to be lightly maintained by mowing and debris removal similar to what is currently done on the MCDC. The adjacent upland habitat at the proposed project site represents giant garter snake habitat because snakes prefer upland habitat that consists of grassy banks and openings in waterside vegetation such as occurs in the project site.

Under the Service's Snake Programmatic Consultation, "permanent impacts" are defined as those proposed project activities which result in a loss of essential habitat components, and upland habitat within a 200-foot radius is recognized within that definition of essential habitat and the determination of potential take. Regardless of whether the impact is upland or aquatic in nature, the compensation for all such permanent impact under the guidelines for the Snake Programmatic Consultation is replacement at a 3:1 ratio, with a 2:1 replacement ratio of upland to aquatic area. Applying this guidance to the subject proposed project, 1.40 acres of impact would require 4.20 acres of replacement habitat, which must meet all Terms and Conditions, guidelines, and criteria in Appendices A and C of the Snake Programmatic Consultation (attached).

We have reviewed the Corps' proposed purchase and preservation in perpetuity of 76.5 acres of upland-wetland habitat near the proposed project site. This type of preservation and purchase proposed is not in accordance with Appendix A (replacement guideline #1) and Appendix C (avoidance and minimization measure #8), and is atypical of the protective covenant description in Term and Condition 2D of the Snake Programmatic Consultation. Therefore, the Service has determined that appending this proposed project to the Snake Programmatic Consultation is not appropriate, and a separate biological opinion is required for consultation for this species and consideration of the merits of the proposed preservation area. Despite the inconsistencies with the Snake Programmatic Consultation, the 76.5 acres of habitat that would be protected as part of the proposed project description far exceed the 4.20 acres which would be required if compensation were deemed necessary.

STATUS OF THE SPECIES

The Service published a proposal to list the giant garter snake as an endangered species on December 27, 1991 (56 **FR** 67046). The Service re-evaluated the status of the snake before adopting the final rule. The snake was listed as a threatened species on October 20, 1993 (58 **FR** 54053).

Description. The giant garter snake is one of the largest garter snakes and may reach a total length of at least 64 inches. Females tend to be slightly longer and proportionately heavier than males. The weight of adult female snakes is typically 500-700 grams (1.1-1.5 pounds). Dorsal background coloration varies from brownish to olive with a checkered pattern of black spots, separated by a yellow dorsal stripe and two light-colored lateral stripes. Background coloration and prominence of a black-checkered pattern and the three yellow stripes are geographically and individually variable (Hansen 1980). The ventral surface is cream to olive or brown and sometimes infused with orange, especially in northern populations.

Historical and Current Range. This species formerly occurred throughout the wetlands that were extensive and widely distributed in the Central Valley. Fitch (1941) described the historical range of the snake as extending from the vicinity of Sacramento and Contra Costa Counties southward to Buena Vista Lake, near Bakersfield, in Kern County. Prior to 1970, the snake was recorded historically from 17 localities (Hansen and Brode 1980). Five of these localities were clustered in and around Los Banos, Merced County. The paucity of information makes it difficult to determine precisely the species' former range. Nonetheless, these records coincide with the historical distribution of large flood basins, fresh water marshes, and tributary streams. Destruction of wetlands for agriculture and other purposes apparently extirpated the species from the southern one-third of its range by the 1940s -1950s, including the former Buena Vista Lake and Kern Lake in Kern County, and the historic Tulare Lake and other wetlands in Kings and Tulare Counties (Hansen and Brode 1980, Hansen 1980).

Surveys over the last two decades have found the snake as far north as the Butte Basin in the Sacramento Valley. As recently as the 1970s, the range of the snake extended from near Burrell, Fresno County (Hansen and Brode 1980), northward to the vicinity of Chico, Butte County (Rossman and Stewart 1987). California Department of Fish and Game (CDFG) studies (Hansen 1988) indicate that snake populations currently are distributed in portions of the rice production zones of Sacramento, Sutter, Butte, Colusa, and Glenn Counties; along the western border of the Yolo Bypass in Yolo County; and along the eastern fringes of the Sacramento-San Joaquin River Delta from the Laguna Creek-Elk Grove region of central Sacramento County southward to the Stockton area of San Joaquin County.

Essential Habitat Components. Endemic to wetlands in the Sacramento and San Joaquin valleys, the snake inhabits marshes, sloughs, ponds, small lakes, low gradient streams, and other waterways and agricultural wetlands, such as irrigation and drainage canals and rice fields, and the adjacent uplands. The snake feeds on small fishes, tadpoles, and frogs (Fitch 1941, Hansen 1980, Hansen 1988). Essential habitat components consist of: (1) wetlands with adequate water during the snake's active season (early-spring through mid-fall) to provide food and cover; (2) emergent, herbaceous wetland vegetation, such as cattails and bulrushes, for escape cover and foraging habitat during the active season; (3) upland habitat with grassy banks and openings in waterside vegetation for basking; and (4) higher elevation uplands for escape cover (vegetation, burrows) and underground refugia (crevices and small mammal burrows) (Hansen 1980).

Reproductive Ecology. The breeding season extends through March and April, and females give birth to live young from late July through early September (Hansen and Hansen 1990). Brood size is variable, ranging from 10 to 46 young, with a mean of 23 individuals (Hansen and Hansen 1990). At birth young average about 20.6 cm snout-vent length and 3-5 grams. Young immediately scatter into dense cover and absorb their yolk sacs, after which they begin feeding on their own. Although growth rates are variable, young typically more than double in size by one year of age, and sexual maturity averages three years in males and five years for females (58 **FR** 54053).

Movements and Habitat Use. The giant garter snake typically inhabits small mammal burrows and other soil crevices throughout its winter dormancy period (November to mid-March). Although these areas are generally thought to be above prevailing flood elevations, snakes may not always utilize high ground during their winter dormancy period. The Biological Resources Division (BRD) has documented giant garter snakes at the Colusa National Wildlife Refuge overwintering in areas with few high ground retreat sites (Wylie *et al.* 1997). Snakes in another study population at Gilsizer Slough overwintered in a low elevation wetland area, even though higher ground was present nearby. Both of these populations survived flooding and were not displaced from the area. The snake also uses burrows as refuge from extreme heat during their active period. While the snakes usually remain in close proximity to wetland habitats, the BRD has documented snakes using burrows as much as 165 feet away from the marsh edge to escape extreme heat (Wylie *et al.* 1997). Overwintering snakes have been documented to use burrows as far as 820 feet from the edge of marsh habitat. Snakes typically select south- and west-facing burrows as hibernacula (58 **FR** 54053).

In studies of marked snakes in the Natomas Basin, snakes moved about 0.25 to 0.5 mile per day (Brode and Hansen 1992). However, total activity varies widely between individuals, and individual snakes have been documented moving up to 5 miles over the period of a few days in response to dewatering of habitat (Wylie *et al.* 1997). In agricultural areas, snakes were documented using rice fields in 19-20 percent of the observations, marsh habitat in 20-23 percent of observations, and canal and agricultural waterway habitats in 50-56 percent of the observations (Wylie 1999). Telemetry studies have also shown that active snakes use uplands extensively–more than 31 percent of observations were in uplands (Wylie 1999). Almost all snakes observed in uplands during the active season were near vegetative cover, where cover exceeded 50 percent in the area within 1.6 feet of the snake; less than 1 percent of observations were of snakes in uplands with less than 50 percent cover nearby (Wylie 1999).

Reasons for Decline and Threats to Survival. The current distribution and abundance of the snake is much reduced from former times. Loss of habitat due to agricultural activities and flood control have extirpated the snake from the southern one third of its range in former wetlands associated with the historic Buena Vista, Tulare, and Kern lakebeds. These lakebeds once supported vast expanses of ideal snake habitat, consisting of cattail and bulrush dominated marshes. Vast expanses of bulrush and cattail floodplain habitat also typified much of the Sacramento Valley historically (Hinds 1952). Prior to reclamation activities beginning in the mid to late 1800s, about 60 percent of the Sacramento Valley was subject to seasonal overflow flooding in broad, shallow flood basins that provided expansive areas of snake habitat (Hinds 1952). Valley floor wetlands are subject to the cumulative effects of upstream watershed modifications, water storage and diversion projects, as well as urban and agricultural development; all natural habitats have been lost and an unquantifiable but small percentage of semi-natural wetlands remain extant. Only a small percentage of extant wetlands currently provide habitat suitable for the snake.

Ongoing maintenance of aquatic habitats for flood control and agricultural purposes eliminate or prevent the establishment of habitat characteristics required by snakes and can fragment and isolate available habitat, prevent dispersal of snakes among habitat units, and adversely affect the availability of the garter snake's food items (Hansen 1988, Brode and Hansen 1992). In many areas, the restriction of suitable habitat to water canals bordered by roadways and levee tops renders snakes vulnerable to vehicular mortality. Fluctuation in rice and agricultural production affects stability and availability of habitat. Recreational activities, such as fishing, may disturb snakes and disrupt basking and foraging activities. Nonnative predators, including introduced predatory gamefish, bullfrogs (*Rana catesbiana*), and domestic cats also threaten snake populations. While large areas of seemingly suitable snake habitat exist in the form of duck clubs and waterfowl management areas, water management of these areas typically does not provide the summer water needed by snakes. Although snakes on national wildlife refuges are relatively protected from many of the threats to the species, degraded water quality continues to be a threat to the species both on and off refuges. A number of land use practices and other human activities currently threaten the survival of the snake throughout the remainder of its range. Although some snake populations have persisted at low levels in artificial wetlands associated with agricultural and flood control activities, many of these altered wetlands are now threatened with urban development. Rapidly expanding cities within the current range of the snake include Chico, Yuba City, Sacramento, Galt, Stockton, Gustine, and Los Banos.

Status with Respect to Recovery. Currently, the Service recognizes 13 separate populations of the snake, with each population representing a cluster of discrete locality records (USFWS 1993). The 13 extant population clusters largely coincide with historical riverine flood basins and tributary streams throughout the Central Valley (Hansen 1980; Brode and Hansen 1992): (1) Butte Basin, (2) Colusa Basin, (3) Sutter Basin, (4) American Basin, (5) Yolo Basin-Willow Slough, (6) Yolo Basin-Liberty Farms, (7) Sacramento Basin, (8) Badger Creek-Willow Creek, (9) Caldoni Marsh, (10) East Stockton-Diverting Canal and Duck Creek, (11) North and South Grasslands, (12) Mendota, and (13) Burrell-Lanare. These populations span the Central Valley from just southwest of Fresno (Burrell-Lanare) north to Chico (Hamilton Slough).

The draft recovery plan for the snake subdivided its historic range into four recovery units (Service 1999). These are: (1) the Sacramento Valley unit, extending from the vicinity of Red Bluff south to the confluence of the Sacramento and Feather Rivers; (2) the Mid-Valley unit, extending from the American and Yolo Basins south to Duck Creek near the City of Stockton; (3) the San Joaquin Valley unit, extending south from Duck Creek to the Kings River; and (4) the South Valley unit, extending south of the Kings River to the Kern River Basin. Portions of the Mid-Valley recovery unit are within the action area.

The Sacramento Valley Recovery Unit at the northern end of the species' range is known to support relatively large, stable populations of the snake. This unit contains three populations (Butte Basin, Colusa Basin, and Sutter Basin) and a large amount of suitable habitat, in protected areas on state refuges and refuges of the Sacramento NWR Complex in the Colusa and Sutter Basins, and along waterways associated with rice farming (Service 1999). While populations within this unit have some protection on refuge and other public lands within National Wildlife Refuges, snakes are subjec to flooding and mortality from predatory fish and birds, vehicular traffic agricultural practices, aand maitenance of water channels. The populations within this unit are widely distributed and mostly restricted to unnatural agricultural water delivery and drainage facilities associated with rice fields, and habitat corridors connecting populations and subpopulations are not present and/or protected.

The Mid-Valley Recovery Unit, directly to the south of the Sacramento Valley Recovery Unit, includes seven populations: American Basin, Yolo Basin–Willow Slough, Yolo Basin–Liberty Farms, Sacramento Area, Badger Creek/Willow Creek, Caldoni Marsh, and East Stockton. The status of the seven snake populations in the Mid-Valley Recovery Unit is very uncertain. The East Stockton population may be extirpated, and is not considered recoverable as a result of urban encroachment into habitat (Service 1999). Five of the remaining six populations within the recovery unit are very small, highly fragmented and isolated, and, except for the Badger Creek/Willow Slough population, are also threatened by urbanization. This latter population is within a small isolated area. Within the Mid-Valley unit, only the American Basin population supports a sizeable snake population which is dependent largely upon rice lands. The American Basin population, although threatened by urban development, will receive protection from the approved Metro Air Park Habitat Conservation Plan (HCP) and Natomas Basin HCP (NBHCP), which share a regional strategy to maintain a viable snake population in the basin.

The remaining two recovery units are located to the south in the San Joaquin Valley, where the best available data indicate that the snake's status is precarious. The San Joaquin Valley Recovery Unit contains three historic snake populations: North and South Grasslands; Mendota Area; and Burrell/Lanare Area (Service 1999). This recovery unit formerly supported large snake populations, but numbers have declined severely in recent decades, and recent survey efforts indicate numbers are very low compared to Sacramento Valley populations.

No surviving snake populations are known from the fourth recovery unit, the South Valley Recovery Unit, at the southern end of the snake's historic range; this unit includes only extirpated populations, including the historic but lost Tulare and Buena Visa lakes.

Current Research Related to Recovery Efforts. Since April of 1995, the BRD has further documented occurrences of snakes within some of the known populations. The BRD has studied snake subpopulations at the Sacramento and Colusa NWRs within the Colusa Basin, at Gilsizer Slough within the Sutter Basin, the Badger Creek area of the Cosumnes River Preserve within the Badger Creek-Willow Creek area, and the Natomas area within the American Basin (Wylie *et al.* 1997, Wylie 1999). These subpopulations represent the largest known extant subpopulations. With the exception of the American Basin, these subpopulations are largely protected from many of the threats to the species. Outside of these protected areas, snakes in these populations are still subject to all the threats identified in the final listing rule. The remaining nine populations identified in the final rule are distributed discontinuously in small isolated patches and are vulnerable to extirpation by stochastic environmental, demographic, and genetic processes. The 13 extant populations are largely isolated from each other, with any dispersal corridors between them limited and not protected. When small populations are extirpated, the recolonization is unlikely in most cases, given the isolation from larger populations and the lack of dispersal corridors between them.

ENVIRONMENTAL BASELINE

The action area for the proposed project is included in the American Basin snake population. The American Basin population is within the Mid-Valley Recovery Unit (Service 1999). A description of the recovery unit along with the status of the population is outlined below.

The Mid-Valley Recovery Unit includes seven giant garter snake populations: American Basin, Yolo Basin–Willow Slough, Yolo Basin–Liberty Farms, Sacramento Area, Badger Creek/Willow Creek, Caldoni Marsh, and East Stockton. The status of the seven snake populations in the Mid-Valley Recovery Unit is very uncertain. The East Stockton population may be extirpated, and is not considered recoverable as a result of urban encroachment into habitat (Service 1999). Five of the remaining six populations within the recovery unit are very small, highly fragmented and isolated, and, except for the Badger Creek/Willow Slough population, are also threatened by urbanization. This latter population is within a small isolated area. Within the Mid-Valley unit, only the American Basin population supports a sizeable snake population which is dependent largely upon rice lands. The American Basin population, although threatened by urban development, receives some protection on lands managed by the Natomas Basin Conservancy, which has a goal of maintaining a viable snake population in the basin.

The American Basin has one of the largest and better protected snake poulations, but the unit is subject to the effects of a number of projects. Many development projects have been constructed in or near snake habitat in this rapidly urbanizing area, and snakes are subject to secondary effects of urbanization such as predation by house cats and increased vehicular mortality. Most documented localities have also been adversely impacted by freeway construction, flood control projects, and commercial development. Several former localities are known to have been lost or depleted to the extent that continued viability is in question (Brode and Hansen 1992). The scarcity of remaining suitable habitat, flooding, stochastic processes, and continued threats of habitat loss pose a severe threat to this population.

<u>Factors Affecting the Snake within the Action Area</u>. A number of State, local, private, and unrelated Federal actions have occurred within the action area and adjacent region affecting the environmental baseline of the species. Some of these projects have been subject to prior section 7 consultation. These actions have resulted in both direct and indirect impacts to snake habitat within the region. In addition to projects already discussed, projects affecting the environment in the action area include communication projects (e.g., installation of cable systems) and transportation projects with Federal, county or local involvement. The Corps has consulted the Service on the issuance of wetland fill permits for several bridge replacement projects within the Sacramento Basin that affected snake habitats. The direct effect of these projects is often small and localized, but transportation projects which improve access can indirectly affect snakes by facilitating development of habitat, and by increasing traffic mortality, and these effects are not quantifiable.

Ongoing agricultural activities also affect the environmental baseline for the snake, and are largely not subject to section 7 consultation. Some agriculture, such as rice farming, can provide valuable seasonal foraging and upland habitat for the snake. Although rice fields and agricultural waterways can provide habitat for the snake, agricultural activities such as waterway maintenance, weed abatement, rodent control, and discharge of contaminants into wetlands and waterways can degrade snake habitat and increase the risk of snake mortality (Service 1999). Ongoing maintenance of agricultural waterways can also eliminate or prevent establishment of snake habitat, eliminate food resources for the snake, and can fragment existing habitat and prevent dispersal of snakes (Service 1999). Flood control and maintenance activities which can result in snake mortality and degradation of habitat include levee construction, stream channelization, and the riprapping of streams and canals (Service 1999).

Several flood control programs administered by the Corps are completed or ongoing within the action area. Large completed projects include the Sacramento River Flood Control Project, which constructed and/or improved levees and other flood control features which make up the Federal Sacramento River Flood Control System; this system includes the levee which would receive bank protection under the Corps' proposed action. Subsequent to the 1986 flood events, the Corps initiated the ongoing Sacramento River Flood Control System Evaluation (SRFCSE) to examine the existing flood control system and to develop remedial repair plans to restore the designed level of protection. The Natomas Area Flood Control Project allowed urban development in the Natomas Basin to move forward. The American River Watershed Investigation administered by the Corps will affect snakes in the Natomas and American Basins. A separate recent flood control action in the immediate vicinity of the proposed project area in this consultation is the Lower Dry Creek and Robla Creek Levee Improvement Project (Public Notice 200000541; Service File Number 1-1-01-F-01340), conducted by SAFCA under permit from the Corps. That work involved reconfiguring a section of Robla Creek, and included grading and planting to enhance habitat for the giant garter snake. Other on-going or planned activities include levee raising along the Natomas Cross Canal, modification of the NEMDC Levee, and relocation of canals and stability berms along the various levees. Although the Corps has consulted on previous projects and is expected to continue to do so on future projects, the ongoing nature of these activities and the administration under various programs makes it difficult to determine the continuing and accumulative impacts of these activities.

The Snake in the Proposed Project Area. Numerous California Natural Diversity Database (CNDDB) (CDFG 2001) locality records are known from the Natomas Basin portion of the American Basin and are distributed throughout most of the basin. Robla Creek, Dry Creek, and Magpie Creek all converge with the Natomas East Main Drain Canal east of the Natomas Basin. Recent research efforts by BRD to collect demographic and habitat use data during 1998 and 1999, have further documented occurrences of giant garter snakes within the Natomas Basin (Wylie and Casazza 2000, Wylie *et al.* 2000). BRD surveys have provided significant recent information on the distribution of giant garter snakes within the Basin, and supplements previous research on the snake within Natomas Basin (e.g. Brode and Hansen 1992, Hansen and Brode 1993). BRD capture data and CNDDB records indicate giant garter snakes are distributed throughout the Basin, but relative abundance varies widely across the Basin. Wylie and Cassaza (2000) concluded that habitat within the Natomas Basin has apparently degraded over time, as compared to previous accounts of habitat in the Basin. They also concluded that the quality of habitat within the Natomas Basin is less than that at other geographic locations where giant garter snakes are found. The other localities studied by BRD included more extensive areas of native or restored and/or protected habitat as compared with the Natomas Basin.

EFFECTS OF THE ACTION

The proposed work would affect giant garter snake upland habitat, adjacent to the MCDC. No snake aquatic habitat would be affected. The disturbance would be temporary and occur within the footprint of existing flood control structures, with the exception of a new maintenance road spanning between Raley Boulevard and Dry Creek Road on the outboard side of the levee or adjacent to the existing channel. The Service acknowledges that the levee raise approach obviates the need to disturb giant garter snake habitat in the MCDC, as would have been required by the channel widening approach considered in our previous biological opinion of September 20, 1995 (File Number 1-1-95-F-30). However, construction activities on upland near aquatic habitat may remove vegetative cover and basking sites used for thermoregulation and fill, or crush burrows/crevices needed for hibernation. Construction or maintenance vehicles may harm or crush snakes, or cause snakes to move to other areas at risk. The risk of take of the snake is reduced by restricted road access (i.e, gates) and limitation on road use for the purpose of channel maintenance. The area of uplands in which the maintenance road would be constructed is currently subject to infrequent disturbance by discing or mowing, and infrequent channel maintenance activity with heavy equipment. Due to the presence of uplands on the levee or uplands on the side of the MCDC opposite the maintenance road, uplands would not be entirely eliminated by the proposed action, and snakes would not be required to cross this maintenance road to access essential habitat elements due to the presence of uplands on the opposite side. Although the Service agrees that the protection measures proposed by the Corps would reduce construction-related effects, these measures do not compensate for the loss of upland in association with aquatic habitat.

Although not specifically identified as a compensation measure, the Service evaluated the potential for the preservation area - which functions as an area to detain peak flood flows - to provide for improved habitat and offset impacts to the giant garter snake not identified in the DEA. The habitat which would be acquired and preserved as part of the proposed project is in the vicinity of portions of Magpie and Don Julio Creeks both of which appear to have more consistent, perennial flow than does the MCDC, and possess essential habitat elements for giant garter snake. The preservation area is also adjacent to and serves as an upland buffer to other undeveloped habitat areas in McClellan Business Park with known vernal pool crustacean populations as well as potential suitability for giant garter snake. Due to its proximity to Raley Boulevard and Interstate 80, and current land use designation for light industry, the preservation area would otherwise be considered at a modest risk of development loss over the long- term. However, due to its lower topography and position between two creeks, portions would require either extensive pad construction or additional, upstream flood control measures to avoid flood damage. The acquisition and preservation as provided in the project description allow for future opportunity for habitat enhancement actions as discussed in the Service's December 2003, FWCA report, even though specific enhancements are not proposed as part of the flood control project.

The Service also considered whether the proposed flood control project could have an indirect effect in terms of affecting the rate of development and consequential loss of habitat within the floodplain along portions of historic Magpie Creek that may support giant garter snake or other listed species. In evaluating this influence, we note the floodplain is currently designated FEMA Zone X, a classification which does not require flood insurance for loans, but which may still experience damage during some flood conditions. If the proposed project were not built, earth pads could still be feasibly constructed for individual development actions within the floodplain to reduce flood damage risk to the desired level. Thus, development within the floodplain could occur with or without the project, but at a potentially faster rate (and lower cost) with the project. Loss of habitat due to development near the historic Magpie Creek channel may be limited due to provisions of the *North Sacramento Community Plan Amendment: Magpie Creek Goals and Policies* (approved by City Council July 27, 1993) to establish and enhance a creek right of way, but this policy could be modified over the long-term and would not apply to wetlands outside the right-of-way provision. The largest component of seasonal wetlands is outside the right of way near Sunset Lawn Cemetary, and is currently zoned as agriculture. As reviewed in our May 2003 FWCA report, several recent development actions have already occurred in the floodplain in the absence of the flood control project and, to our knowledge, nearly all have been properly considered and compensated under the Service's Programmatic Consultations. Taken together, the flood zoning, protective local policies, and history of permit actions indicate that the effect of the project in terms of accelerated development is modest if at all, and that any related loss of habitat would likely be detected and compensated under the Corps' 404 permit administration.

We note, however, that this same risk of harm to habitat from development is substantially eliminated from the 76.5 acres of habitat in the preservation area. This preservation area includes a mosaic of two creeks, seasonal and permanent wetland types, and associated upland, and includes numerous vernal pools of which four occurrences of the listed vernal pool fairy shrimp have been documented. It is also adjacent to similar habitat within McClellan Business Park. In the Service's opinion, the preservation element of the proposed project offsets the particular net effect of inducing development growth in the floodplain, and the modest loss of upland near the MCDC. The Service expressly limits this finding to any growth-inducing effect of the flood control project only - not the actual loss of habitat or indirect effect near habitat due to future development action(s). Accordingly, consultation is required for any subsequent action, separate from the proposed project, involving take of a listed species in the historic Magpie Creek floodplain.

CUMULATIVE EFFECTS

Cumulative effects include the effects of future State, local, or private actions that are reasonably certain to occur in the action area considered in this biological opinion. Future Federal actions that are unrelated to the proposed project are not considered in this section because they require separate consultation pursuant to section 7 of the Act, and, therefore, are not considered cumulative to the proposed project.

An undetermined number of future land use conversions and routine agricultural practices that are not subject to Federal authorization or funding may alter the habitat or increase incidental take of giant garter snake, vernal pool fairy shrimp, and vernal pool tadpole shrimp and are, therefore, cumulative to the proposed project.

Cumulative effects that apply to giant garter snake include: (1) unpredictable fluctuations in aquatic habitat due to water management; (2) dredging and clearing vegetation from irrigation canals; (3) discing, mowing, ornamental cultivation, and routine grounds maintenance of upland habitat; (4) increased vehicular traffic on access roads adjacent to aquatic habitat; (5) use of burrow fumigants on levees and other potential upland refugia; (6) contaminated runoff from agriculture and urbanization; (7) predation by feral animals and pets; (8) human intrusion into habitat; (9) diversion of water; and (10) rip-rapping or lining of canals and stream banks.

CONCLUSION

After reviewing the current status of the giant garter snake, the environmental baseline, the effects of the proposed action, and any cumulative effects, it is the Service's biological opinion that the proposed project as described, with the proposed protection measures and habitat preservation/acquisition components, is not likely to jeopardize the continued existence of the giant garter snake. No critical habitat has been designated for this species, therefore, none will be affected.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harass is defined by the Service as an intentional or negligent act or omission which creates the likelihood of injury to a listed species by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding or sheltering. Harm is defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by impairing behavioral patterns including breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking incidental to and not intended as part of the agency action is not considered to be prohibited taking under the Act, provided that such taking is in compliance with this Incidental Take Statement.

The measures described below are nondiscretionary for listed species in this opinion and must be implemented by the Corps so they become binding conditions of any grant or permit issued to the applicant, as appropriate, in order for the exemption in section 7(o)(2) to apply. The Corps has a continuing duty to regulate the activity that is covered by this incidental take statement. If the Federal agency (1) fails to require the applicant to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to the permit or grant document, and/or (2) fails to retain oversight to ensure compliance with these terms and conditions, the protective coverage of section 7(o)(2) may lapse.

AMOUNT OR EXTENT OF INCIDENTAL TAKE

The Service anticipates incidental take of the snake will be difficult to detect or quantify for the following reasons: snakes are cryptically colored, secretive, and known to be sensitive to human activities. Snakes may avoid detection by retreating to burrows, soil crevices, vegetation, and other cover. Individual snakes are difficult to detect unless they are observed, undisturbed at a distance. Most close-range observations represent chance encounters that are difficult to predict. It is not possible to make an accurate estimate of the number of snakes that would be harassed, harmed, or killed during construction activities, including in staging areas, canal banks, soil burrow areas and roads carrying vehicular traffic to borrow areas. In instances where take is difficult to detect, the Service may estimate take in the form of numbers of a species per acre of habitat affected as a result of the action. The Service expects that all snakes in the 6.1 acres of upland habitat on the proposed project site may be harassed, harmed, or killed by loss and disturbance of habitat as a result of the proposed project. The proposed project may result in the death of one snake.

The Service authorizes the following forms of incidental take:

1. The number of giant garter snakes found in 4.7 acres of upland habitat will be disturbed, harassed, harmed, or killed by project activities resulting from temporary impacts due to use of heavy equipment and earthmoving activity near aquatic habitat. No more than one snake will be killed.

2. 1.4 acres of giant garter snake habitat would be permanently lost due to construction of new maintenance road on upland near aquatic habitat.

Upon implementation of the following reasonable and prudent measures, incidental take associated with the proposed project on the snake, in the form of harm, harassment, or death from habitat loss or direct mortality will become exempt from the prohibitions described under section 9 of the Endangered Species Act for direct and indirect effects.

EFFECT OF THE TAKE

In the accompanying biological opinion, the Service has determined that the anticipated take is not likely to jeopardize the giant garter snake or destroy or adversely modify its critical habitat.

REASONABLE AND PRUDENT MEASURES

The Service believes the following reasonable and prudent measures are necessary and appropriate to minimize incidental take of giant garter snakes.

1. The potential effects of the proposed project on the giant garter snake shall be minimized.

TERMS AND CONDITIONS

In order to be exempt from the prohibitions of section 9 of the Act, the Corps must ensure compliance with the following terms and conditions, which implement the reasonable and prudent measures described above. The terms and conditions are non-discretionary.

The following terms and conditions implement the reasonable and prudent measure:

1. Best Management Practices (BMPs) shall be implemented to prevent sediment from entering areas containing giant garter snake habitat including, but not limited to, silt fencing, temporary berms, no cleaning equipment in or near snake habitat, installation of vegetative strips, and temporary sediment disposal.

2. Project-related vehicles shall observe a 20-mph speed limit within construction areas, except on County rods, and State and Federal highways; this is particularly important during periods when the giant garter snake may be sunning or moving on roadways.

3. To eliminate attraction of predators of the snake, all food-related trash items such as wrappers, cans, bottles, and food scraps must be disposed of in closed containers and removed at least every other day from the entire project site.

4. Plastic monofilament netting (erosion control matting) or similar material shall not be used at the project because giant garter snakes may become entangled and trapped in it. Acceptable substitutes include conconut coir matting or takified hydroseeding.

5. After completion of construction activities, any temporary fill and construction debris shall be removed and the 4.7 acres of disturbed areas shall be restored to pre-project conditions. Project proponents will monitor the project site for one year following completion of construction and restoration of habitat. Monitoring

reports documenting the restoration effort shall be submitted to the Service upon completion of the restoration activity, and after one year. The monitoring reports shall include photo-documention when restoration was completed, what materials were used, specified plantings, and justification of any substitution to the Service-recommended guidelines (refer to Appendix A, Snake Programmatic Consultation, Mitigation Criteria for Restoration and/or Replacement of Giant Garter Snake Habitat, attached).

6. The Corps shall ensure compliance with the Reporting Requirements below.

REPORTING REQUIREMENTS

The Service-approved biologist shall notify the Service immediately if giant garter snakes are found on site, and will submit a report including date(s), location(s), habitat description, and any corrective measures taken to protect the snake(s) found. The Service-approved biologist shall submit locality information to the California Department of Fish & Game (CDFG), using completed California Native Species Field Survey Forms or their equivalent, no more than 90 calendar days after completing the last field visit of the project site. Each form shall have an accompanying scale map of the site such as a photocopy of a portion of the appropriate 7.5 minute U.S. Geological Survey map and shall provide at least the following information: township, range, and quarter section; name of the 7.5' or 15' quadrangle; dates (day, month, year) of field work; number of individuals and life stage (where appropriate) encountered; and a description of the habitat by community-vegetation type.

A post-construction compliance report prepared by the Service-approved monitoring biologist shall be forwarded to the Chief, Endangered Species Division, at the Sacramento Fish and Wildlife Office within 60 calendar days of the completion of the project. This report shall detail: (i) dates that construction occurred; (ii) pertinent information concerning the applicant's success in meeting project mitigation measures; (iii) an explanation of failure to meet such measures, if any; (iv) known project effects on federally listed species, if any; (v) occurrences of incidental take of federally listed species, if any; and (vi) other pertinent information.

The Corps shall also monitor specific execution of the proposed measures for protection in perpetuity of the preservation area provided in the project description, and obtain and submit documentation of property purchase, placement of flood easement, request of zoning change, and the decision pertaining to that request, to the Chief, Endangered Species Division, at the Sacramento Fish and Wildlife Office within 60 calendar days of the completion of the project.

The Sacramento Fish and Wildlife Office is to be notified within three working days of the finding of any dead listed species or any unanticipated harm to the species addressed in this biological opinion. The Service contact person for this is the Chief, Endangered Species Division at (916) 414-6600.

CONSERVATION RECOMMENDATIONS

Section 7 (a) (1) of the Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. The recommendations provided here relate only to the proposed action and do not necessarily represent complete fulfillment of the agency's 7(a)(1) responsibilities for these species.

1. As a Recovery Plan for the giant garter snake is developed, the Corps should assist the Service in its implementation.

2. The Corps should incorporate into bidding documents the "Standard Avoidance and Minimization Measures for Construction Activities in Giant Garter Snake Habitat" provided in the Snake Programmatic Opinion, Appendix C, when appropriate.

3. The Corps, in partnership with the Service, should develop maintenance guidelines for the project that will reduce adverse effects of routine maintenance on giant garter snakes and their habitat. Such actions may contribute to the delisting and recovery of the giant garter snake by preventing degradation of existing habitat and increasing the amount and stability of suitable habitat.

4. The Corps should support and assist SAFCA with development of a habitat management plan for the preservation area element of this project with the goal of maximally protecting and enhancing habitat values for listed species, and overall habitat value of the two creeks, associated riparian, seasonal wetland, and upland habitats. Example actions of this type outlined in our May 2003 FWCA report include: a) modest replanting of native trees and shrubs at the top of creek banks, such as oak and elderberry, willow, cottonwood, or box elder; b) management of star thistle in conjunction with reseeding with native grasses and forbs; c) monitoring and management of beaver activity and damage to riparian trees; and d) potential realignment of Don Julio Creek west of Raley Boulevard to a more westerly alignment away from Raley (and with a reconstructed confluence with the MCDC), and revegetation of this reconstructed creek segment. Density and distribution of tree plantings should be such that they would establish with minimal or no irrigation, require no long term irrigation, and would not adversely affect listed vernal pool crustacean habitat.

5. The Corps should support and assist SAFCA with restoration of the historic section of Magpie Creek west of Raley Boulevard including: a) re-establishing flows through the reconstructed low-flow outlet from the MCDC to the historic creek (an element proposed as part of the flood control project action); and b) reconstructing the channel for sections that are now leveled or filled. These actions should be consistent with the North

Sacramento Community Plan Amendment: Magpie Creek Goals and Policies, reference number M92-071, but are recommended to be implemented in advance of that which would be required by the amendment. We especially encourage re-establishing oaks and elderberry, which are largely absent from this drainage, together with more common natives like cottonwood, willow or box elder, and reseeding with native grasses and forbs.

In order for the Service to be kept informed of actions minimizing or avoiding adverse effects or benefitting listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

This concludes formal consultation on the proposed Magpie Creek Flood Control Project. As provided in 50 CFR §402.16, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been maintained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat that was not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation. If you have any questions regarding this biological opinion for the Magpie Creek Flood Control Project, please contact Steven Schoenberg of my staff, at (916) 414-6564.

Sincerely,

Cliff Wagar

APPENDIX A

Guidelines for Restoration and/or Replacement of Giant Garter Snake Habitat

Replacement and Restoration Guidelines are provided together, as the two conservation measures may not be mutually exclusive. Replacement of habitat may also require restoration of some areas. Preserved habitat may additionally be improved for giant garter snake by using some of the restoration guidelines.

Reference sites

A nearby reference site should be chosen both for restoration of giant garter snake habitat and for creation of replacement habitat. The reference site will be used to determine the success of conservation efforts. For restoration of habitat, the pre-project condition may be used as a reference site if adequate documentation exists. For creation of replacement habitat or for restoration where pre-project conditions are not documented, the reference site should be nearby or adjacent and should represent high quality giant garter snake habitat.

Restoration of giant garter snake habitat

Restoration may include incorporating some of the Replacement guidelines to enhance habitat value for giant garter snake. Restoration should follow the guidelines outlined below:

1. Restoring giant garter snake habitat includes minimizing impacts of project activities to the existing habitat, including using silt fencing, designating environmentally sensitive areas, using protective mats, preventing runoff, and providing worker awareness training. Measures to minimize impacts include:

a. Avoid construction activities within 200 feet from the banks of giant garter snake aquatic habitat. Confine movement of heavy equipment to existing roadways to minimize habitat disturbance.

b. Construction activity within habitat should be conducted between May 1 and October 1. This is the active period for giant garter snakes and direct mortality is lessened, because snakes are expected to actively move and avoid danger. Between October 2 and April 30 contact the Service's Sacramento Fish and Wildlife Office to determine if additional measures are necessary to minimize and avoid take.

c. Confine clearing to the minimal area necessary to facilitate construction activities. Flag and designate avoided giant garter snake habitat within or adjacent to the project area as Environmentally Sensitive Areas. This area should be avoided by all construction personnel.

d. Construction personnel should receive Service-approved worker environmental awareness training. This training instructs workers to recognize giant garter snakes and its habitat(s).

e. 24-hours prior to construction activities, the project area should be surveyed for giant garter snakes. Survey of the project area should be repeated if a lapse in construction activity of two weeks or greater has occurred. If a snake is encountered during construction, activities shall cease until appropriate corrective measures have been completed or it has been determined that the snake will not be harmed. Report any sightings and any incidental take to the Service immediately by telephone at (916) 414-6600.

f. Any dewatered habitat should remain dry for at least 15 consecutive days after April 15 and prior to excavating or filling of the dewatered habitat.

2. Remove all construction debris and stockpiled materials.

3. Regrade area to preexisting contour, or a contour that would improve restoration potential of the site.

4. Replant and hydroseed the restoration area. Recommended plantings consist of a) wetland emergents, b) low-growing cover on or adjacent to banks, and c) upland plantings/hydroseeding mix to encourage use by other wildlife. Riparian plantings are not appropriate because shading may result in lack of basking sites. Native plantings are encouraged except where non-natives will provide additional values to wildlife habitat and will not become invasive in native communities. The applicant should obtain cuttings, plantings, plugs, or seeds, from local sources wherever possible. The applicant should attempt to restore conditions similar to that of adjacent or nearby habitats.

a. Emergent wetland plants recommended for giant garter snake habitat are California bulrush (*Scirpus californicus*), cattail (*Typha* spp.), and water primrose (*Ludwigia peploides*). Additional wetland plantings may include common tule (*Scirpus acutus*), Baltic rush (*Juncus balticus*), or duckweed (*Lemna* spp.).

b. Cover species on or adjacent to the bank may include California blackberry (*Rubus vitifolius*) or wild grape (*Vitis californica*), along with the hydroseeding mix recommended below.

c. Upland plantings/hydroseeding mix: Disturbed soil surfaces such as levee slopes should be hydroseeded to prevent erosion. The Service recommends a mix of at least 20-40 percent native grass seeds [such as annual fescue (*Vulpia* spp.), California brome (*Bromus carinatus*), blue wildrye (*Elymus glaucus*), and needle grass (*Nassella* spp.)], 2-10 percent native forb seeds, five percent rose clover (*Trifolium hirtum*), and five percent alfalfa (*Medicago sativa*). Approximately 40-68 percent of the mixture may be non-aggressive European annual grasses [such as wild oats (*Avena sativa*), wheat (*Triticum* ssp.), and barley (*Hordeum vulgare*)]. The Corps will not include aggressive non-native grasses, such as perennial ryegrass (*Lolium perenne*), cheatgrass (*Bromus tectorum*), fescue (*Festuca* spp.), giant reed (*Arundo donax*), medusa-head (*Taeniatherum caput-medusae*), or Pampas grass (*Cortaderia selloana*) in the hydroseed mix. The Corps will not include endophyte-infected grasses in the mix. Mixes of one-hundred percent native grasses and forbs may also be used, and are encouraged.

Replacement of giant garter snake habitat

Location

Replacement location should be within the same population cluster boundaries (population clusters are defined in 58 **FR** 54053) as the habitat lost. For example: The boundaries of the Sacramento Basin population cluster are approximately, Highway 16 to the north, Sacramento River to the west, Twin Cities Road to the south, and the Folsom Aqueduct to the east. Habitat lost within this area must also be replaced within this area.

Habitat components

Giant Garter Snake Habitat. The giant garter snake inhabits marshes, sloughs, ponds, small lakes, low gradient streams, other waterways and agricultural wetlands such as irrigation and drainage canals and rice fields, and the adjacent uplands. Essential habitat components consist of (1) adequate water during the snake's active period, (early spring through mid-fall) to provide a prey base and cover; (2) emergent, herbaceous wetland vegetation, such as cattails and bulrushes, for escape cover and foraging habitat; (3) upland habitat for basking, cover, and retreat sites; and (4) higher elevation uplands for cover and refuge from flood waters. For the purposes of this programmatic opinion, a basic giant garter snake habitat unit will incorporate 2.00 acres (0.81 hectares) of surrounding upland for every 1.00 acre (0.40 hectare) of aquatic habitat. The 2.00 acres (0.81 hectares) of upland also may be defined as 218 linear feet (66 meters) of bankside habitat which incorporates adjacent uplands to a width of 200 feet (61 meters) from the edge of the bank.

Replacement habitat must provide the above mentioned essential habitat components and include the following:

1. All replacement habitat must include both upland and aquatic habitat components. Upland and aquatic habitat components must be included in the replacement habitat at a ratio of 2:1 upland acres to aquatic acres

2. A semi-permanent or permanent aquatic habitat which provides water during the active period for giant garter snakes (April through October) with suitable vegetative cover present. Linear or meandering channels with slow flowing water over mud or silt substrate are preferred.

3. Upland basking and retreat sites with low growing vegetation cover adjacent to aquatic habitat, and upland retreats and flood refugia with partially buried broken concrete or animal burrows.

4. Small fish and amphibian larvae for foraging, but predatory "gamefish" (bass, *Micropterus* spp.; sunfish, *Lepomis* spp.; catfish, *Ictalurus* spp. and *Ameiurus* spp.) absent or controlled.

5. An adequate buffer (at least 200 feet) from roadways to reduce vehicular mortality.

6. Follow planting recommendation provided above under restoration guidelines.

Monitoring

Habitat restoration

Restoration of habitat should be monitored for one year following implementation. Monitoring reports documenting the restoration effort should be submitted to the Service: (1) upon completion of the restoration implementation; and (2) one year from restoration implementation. Monitoring reports should include photo documentation, when restoration was completed, what materials were used, plantings (if specified) and justification of any substitutions to the Service recommended guidelines. Monitoring reports should also include recommendations for remedial actions and approval from the Service, if necessary, and justification from release of any further monitoring, if requested.

Creation of replacement habitat

Replacement habitat should be monitored for 5 years following implementation. Hydrology should be monitored for the first two years after creation of wetlands. The monitoring effort should continue for three additional years to ensure success criteria are met. Monitoring reports documenting implementation of conservation measures should be submitted to the Service: (1) upon completion of wetland creation; (2) yearly for the first two years of monitoring; and (3) 5 years from implementation. Monitoring reports should include photo documentation, when restoration was completed, what materials were used, plantings (if specified) and justification of any substitutions to the Service recommended guidelines. Monitoring reports should also include recommendations for remedial actions and approval from the Service, if necessary, and justification from release of any further monitoring, if requested.

APPENDIX A

Success criteria for replacement habitat:

1. At completion of monitoring, the cover measured on the habitat area should be 90 percent of cover measured on the reference site.

2. At completion of monitoring, the species composition measured on the habitat area should be 90 percent of that measured on the reference site.

3. At completion of monitoring, wetlands created on the site should meet Corps jurisdictional criteria.

Maintenance and management of replacement giant garter snake habitat

1. A final management plan of replacement habitat must be approved by the Service.

2. All maintenance activities should follow Standard Avoidance and Minimization Measures During Construction Activities in Giant Garter Snake Habitat.

3. Additional guidance includes:

   a. Canal Maintenance - Hand clearing of canals is preferred for removal of excessive vegetation or debris. Any equipment should be operated from the bank top. Excavate from only one side of the canal during a given year. Avoid excavating the banks above the high water level. Preferably, one side of the canal should be left undisturbed indefinitely (the preferred side would be the west or north side) so that emergent vegetation and bank side cover is left in place.

   b. Place the spoils from canal clearing in a designated location, rather than along bank tops. This will prevent burying or crushing snakes basking on the banks, or trapping snakes taking cover in burrows or bank-top soil crevices.

   c. Vegetation control - Uplands should not be disced. Leave vegetation on levees and canal sides wherever possible. Mowing to control vegetation should take place July through September and mower blades should be raised at least six inches to avoid injuring snakes and to leave some grassy cover.

   d. Traffic - Control vehicle access to avoid vehicular mortality of giant garter snakes.

4. Use a water maintenance regime that will maintain some open water to provide vegetated edge for giant garter snake to forage along.

5. Eradicate/control non-natives and invasive exotics.

APPENDIX A

Compatible uses of giant garter snake replacement habitat:

Rice farming is a compatible land use for adjacent properties.

Uses of giant garter snake replacement habitat that are incompatible with the habitat of giant garter snake, or represent threats to giant garter snakes include row cropping on uplands, orchards on uplands, OHV (off-highway vehicle) use, and combining with riparian habitat creation which requires dense cover or SRA (shaded riverine aquatic) habitat.

APPENDIX C

Standard Avoidance and Minimization Measures During Construction Activities in Giant Garter Snake (*Thamnophis gigas*) Habitat

HABITAT TYPE:

Marshes, sloughs, ponds, small lakes, low gradient streams, irrigation and drainage canals, and rice fields. Permanent aquatic habitat, or seasonally flooded during the snake's active season (early-spring through mid-fall), with herbaceous wetland vegetation, such as cattails and bulrushes, grassy banks (often salt grass), and uplands for cover and retreat sites during the snake's active season and for refuge from flood waters during the dormant season (winter). Giant garter snakes are typically absent from larger rivers because of lack of suitable habitat, and from wetlands with sand, gravel, or rock substrates. Some riparian woodlands may not provide suitable habitat because of excessive shade, lack of basking sites, and absence of giant garter snake prey.

AVOIDANCE AND MINIMIZATION MEASURES:

1. Avoid construction activities within 200 feet from the banks of giant garter snake aquatic habitat. Confine movement of heavy equipment to existing roadways to minimize habitat disturbance.

2. Construction activity within habitat should be conducted between May 1 and October 1. This is the active period for giant garter snakes and direct mortality is lessened, because snakes are expected to actively move and avoid danger. Between October 2 and April 30 contact the Service's Sacramento Fish and Wildlife Office to determine if additional measures are necessary to minimize and avoid take.

3. Confine clearing to the minimal area necessary to facilitate construction activities. Flag and designate avoided giant garter snake habitat within or adjacent to the project area as Environmentally Sensitive Areas. This area should be avoided by all construction personnel.

4. Construction personnel should receive Service-approved worker environmental awareness training. This training instructs workers to recognize giant garter snakes and their habitat(s).

5. 24-hours prior to construction activities, the project area should be surveyed for giant garter snakes. Survey of the project area should be repeated if a lapse in construction activity of two weeks or greater has occurred. If a snake is encountered during construction, activities shall cease until appropriate corrective measures have been

completed or it has been determined that the snake will not be harmed. Report any sightings and any incidental take to the Service immediately by telephone at (916) 414-6600.

6. Any dewatered habitat should remain dry for at least 15 consecutive days after April 15 and prior to excavating or filling of the dewatered habitat.

7. After completion of construction activities, remove any temporary fill and construction debris and, wherever feasible, restore disturbed areas to pre-project conditions. Restoration work may include such activities as replanting species removed from banks or replanting emergent vegetation in the active channel.

8. Follow the conservation measures in Table 1 to minimize the effects of loss and disturbance of habitat on giant garter snakes. Replacement ratios are based on the acreage and on the duration of disturbance.

TABLE 1 - SUMMARY OF GIANT GARTER SNAKE CONSERVATION MEASURES

	IMPACTS: DURATION	**IMPACTS:** ACRES	**CONSERVATION MEASURE:** COMPENSATION
LEVEL 1	1 season	Less than 20 and temporary	Restoration
LEVEL 2	2 seasons	Less than 20 and temporary	Restoration plus 1:1 replacement
LEVEL 3	More than 2 seasons and temporary	Less than 20 and temporary	3:1 Replacement (or restoration plus 2:1 replacement)
	Permanent loss	Less than 3 acres total giant garter snake habitat AND Less than 1 acre aquatic habitat; OR Less than 218 linear feet bank habitat	3:1 Replacement

Giant garter snake habitat includes 2.0 acres of surrounding upland habitat for every 1.0 acre of aquatic habitat. The 2.0 acres of upland habitat also may be defined as 218 linear feet of bankside habitat which incorporates adjacent uplands to a width of 200 feet from the edge of each bank. Each acre of created aquatic habitat should be supported by two acres of surrounding upland habitat. Compensation may include creating upland refuges and hibernacula for the giant garter snake that are above the 100-year flood plain.

A season is defined as the calendar year period between May 1 and October 1, the active period for giant garter snake when mortality is less likely to occur.

EXECUTIVE SUMMARY

The American River Common Features General Reevaluation Report (GRR) project is currently performing a study along approximately 40 miles of the levee system that surround the American River, Natomas Basin and the Sacramento Bypass.

The GRR is in the Feasibility Study phase of the Civil Works process, which requires a Phase 1 Environmental Site Assessment (ESA) to be performed to identify environmental contamination at or near the project construction site. Contaminated sites have the potential to significantly impact future construction activities and need to be identified as early as possible.

Records review identified 491 environmental sites including 7 sites that have the Hazardous, Toxic, Radiologic Waster (HTRW) concerns with the potential to affect future construction activities and 45 sites with HTRW concerns that should not affect future construction activities. Regional contaminants from historic agriculture and mining sources are likely present and should be considered on a site-specific basis if future construction activity generates soil for reuse or disposal.

This Phase 1 ESA identifies and generally describes locations where environmental conditions exist in proximity to the project levee. The purpose of the GRR is to identify deficiencies in the levee system and perform feasibility analysis on potential remedies for these deficiencies. Separate reports and construction plans will be developed for the chosen remedial alternatives. As the American River Common Features GRR project schedule approaches actual construction, an additional Phase 1 ESA may be necessary to provide up-to-date information necessary to comply with the USACE Civil Works process.

The presence of the Old Bryte Landfill adjacent to the Sacramento Bypass may influence alternative selection, as may the presence of the old Southern Pacific rail yard in downtown Sacramento. The bulk fuel facility at Broadway and Front Street near downtown Sacramento is a petroleum release site on both sides of the levee with fuel pipelines going through the levee and may be unavoidable; but non-hazardous waste under CERCLA.

Further investigation of these sites as they may affect the cost of levee relocation or rehabilitation for seepage, stability and erosion is recommended.

1.0 Introduction

1.1 Purpose

The purpose of this Phase 1 ESA is to identify recognized HTRW environmental conditions, including the presence or likely presence of any hazardous substances or petroleum products under conditions that indicate an existing release, a past release, or the material threat of a release into structures, the ground, and groundwater or surface waters of the project site.
A Phase 1 ESA is required by the United States Army Corps of Engineers (USACE) *Engineering Regulation (ER) 1165-2-132; HAZARDOUS, TOXIC AND RADIOACTIVE (HTRW) GUIDANCE FOR CIVIL WORKS PROJECTS. , Policy Guidance Letter 34 Non-CERCLA Regulated Contaminated Materials at Civil Works Projects* and *ASTM 1527-05 – Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process* is widely used in the environmental industry and will be followed as applicable in this report.

The American River Common Features GRR will analyze the levee system surrounding the American River, Sacramento Bypass, and east bank of the Sacramento River downstream of the American River. These areas will be addressed in the future by using three alternatives developed from past levee construction and repair. The range of possible future construction activities may use techniques and methods that require soil and/or groundwater disturbance, thereby creating possible contaminant exposure concerns.

1.2 Detailed Scope of Services

The scope of this ESA is limited to assessing the environmental condition of the property associated with the levees under study in the American River Common Features General Reevaluation. It also is concerned with identifying HTRW sites within the project boundaries and the surrounding area using commonly known and reasonably ascertainable information.

1.3 Limitations and Exceptions

The Phase I ESA does not include any sampling or testing of soil, air, water or building materials.

1.4 Special Terms and Conditions

The current American River Common Features GRR project does not involve purchase of property for commercial purposes, and as such, the conditions for the ASTM specifications are not completely applicable. The ASTM standard is used as a guide and sections that are not applicable are deleted or modified to meet the requirements of the project. Where applicable, the format and guidance recommended by ASTM is followed as stated in standard E 1527-05. The ASTM post-dates the Regulation, and there is no requirement to follow it, but the ASTM is the industry standard and a convenient guide to follow in performing the environmental site assessment.

1.5 Site Definition

The approach of this report is to search environmental databases and produce a list of sites that have recognized environmental concerns in proximity to the project levee. Sites identified from the environmental database search are classified using the following criteria. The criteria are based on site characteristics that affect the potential of the site to impact future levee construction and repair activities.

Table 1 - Site Characterization Definitions

Type	Definition
1	Site with significant HTRW concerns that may impact future construction activities
2	Site with HTRW concerns that are not likely to have an impact on future construction activities, but warrant mention due to close proximity
3	Site with no apparent HTRW concerns or concerns that have been remediated and closed in the past, or sufficiently removed from the levees so as to have no possible impact.

Type 1 sites have current, significant HTRW concerns that may impact future construction activities. A significant HTRW concern for the American River GRR study and future levee construction projects include soil contamination within the footprint of levee construction activities, or groundwater contamination present on the site that extends to areas of levee construction. Sites with currently undefined or ill-defined contaminant plumes that have the possibility to affect future activities are also included in this category. Most of these sites are currently undergoing assessment, active remediation, or monitoring activities that are under the regulation of the California State Water Resources Control Board (SWCRB), or the California Department of Toxic Substances Control (DTSC).

Type 2 sites have identified HTRW concerns that present a low potential to impact future construction activities. These sites are removed from the levee centerline and will not be included in future areas of construction activity. Current remediation measures on these sites have stabilized a groundwater contaminant plume, remediated or removed a significant amount of the soil contamination present on the site. The combination of remediation measures and distance from the project centerline lead to the lower risk categorization of the site. Also included are contaminated properties that warrant mention simply due to close proximity (generally immediately adjacent to the levee) but pose no apparent problem for work on the levee unless the property must be used, such as a levee setback or staging area.

Type 3 sites have either been closed by a regulatory agency or have no historical evidence of potential HTRW problems. Sites located outside of the “Approximate Minimum Search Distance” defined in ASTM section 8.2.1 but included in the EDR records report are included in this site category as well. Sites with HTRW problems that are sufficiently removed from the levees, such as a site with a 300 foot petroleum groundwater plume located a half mile away, are included.

The best reasonably ascertainable data available to evaluate potential impacts of surface water on the project sites or other regional contaminant considerations comes from California Regional Water Quality Control Boards. Review of the most recent water quality information showed that COCs in the American River / Sacramento River included PCBs, mercury, and other agricultural related chemicals. Environmental impacts from PCBs was observed in fish tissue and seems to be a river wide problem that is regional (agriculture and mining) and best represented as area sources. Mercury contamination originates from the historic uses of the river basin for mining purposes. The levees themselves may be a source of these contaminants as historical records indicate that they were dredged from the riverbed and constructed after hydraulic mining was banned in the Sierra foothills and long after commencement of agricultural use.

1.6 Guidance

This report was prepared in accordance with ASTM E 1527-05, Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process; ER 1165-2-132, HTRW Guidance for Civil Works Projects and Policy Guidance Letter 34: Non-CERCLA Regulated Contaminated Materials at Civil Works Projects. Deviations from the approved guidance procedures are noted where appropriate in the report. Reasons for the deviations generally include the unavailability of required information and feasibility concerns associated with the study. All reasonably ascertainable information has been reviewed in the preparation of this report.

An electronic database search and field observations were conducted in order to compile information for this Phase 1 ESA. This assessment did not include sampling or analysis of environmental media.

ER 11165-2-132 requires that the project avoid hazardous waste as defined by CERCLA. If it cannot be avoided, it must be cleanup at the 100% non-federal sponsor expense. Policy Guidance Letter 34 states that non-hazardous waste (such as State Special or Designated Waste) may be cleaned up as part of the Project; however it is the District’s policy that the non-federal sponsor performs the cleanup. Paragraph 8 of the regulation requires that a site investigation and HTRW feasibility study or “ESA Phase 2” should be performed during the flood risk management feasibility study where waste is unavoidable.

HTRW assessments during the feasibility phase will determine the type and extent of HTRW contamination, if any, and how HTRW considerations will impact on the alternative project plans. A preliminary cost estimate of required HTRW response actions will be needed for each project alternative in order to be able to make a reasoned choice among alternative project plans. Alternative project plans may consider avoidance of HTRW as well as possible responses. At least one alternative plan should be formulated to avoid HTRW sites to the maximum extent possible, consistent with project objectives. These assessments, conducted during the feasibility stage, are shared with the local sponsor for cost-shared studies.

2.0 Site Description

The Project incorporates all or part of the following areas:

- Sacramento Area Flood Control Agency
- American River Flood Control District
- Reclamation District 1000 (Natomas Basin)
- Reclamation District 900 (West Sacramento)
- West Sacramento Area Flood Control Agency

2.1 Location and Legal Description

The American River Levee system is a levee system that divides Sacramento County and joins the Sacramento River on the western boundary of the County. The entire flood-prone area was once called Natomas Basin but has since been sub-divided into Reclamation District 1000 (Natomas Basin) north of the River and American River Flood Control District mostly south of the River, and north of the River east of the Natomas main drainage canal. One alternative considers diverting more of the Sacramento River flow into the Yolo Bypass at the Sacramento Bypass and therefore some of the levee system in Yolo County across the Sacramento River is considered. A separate project to raise the height of the levees on the American River is ongoing.

Levees "reaches" have been assigned to segments of the levee to assist with identification of specific locations (see Figure 1). The Project has divided levee reaches into American River North (ARN) including Dry Creek, Magpie Creek and Arcade Creek, American River South (ARS) including the Sacramento River south of the American River confluence, and Natomas (NAT).

2.2 Site Vicinity General Characteristics

The City of Sacramento is in Sacramento Valley located immediately east of the City of West Sacramento at the confluence of the American River and Sacramento River. The two cities are separated by the Sacramento River, which flows from north to south. The City and County contains a mix of residential, commercial, agricultural and industrial properties. Approximately 500,000 people reside in the City and 1,500,000 reside in the County. The City is the Capital of the State of California. It is considered to be at the highest risk of flooding of any major city in the nation. Most of Reclamation District 1000 is included in a separate flood risk management project. The study area includes

• **Natomas Main Drainage Canal South and East Levee** from the confluence of Dry Creek, Magpie Creek and Arcade Creek to the Sacramento River is included.

• **American River North and South Leve**es from Carmichael through the City of Sacramento to the Sacramento River are included.

• **Sacramento River East Levee** from the American River south to Clarksburg, Freeport and Elk Grove/Laguna Creek is included

• **Sacramento Bypass Levee** extends for approximately 1.1 miles along the Sacramento Bypass left bank from the Sacramento Weir west to the Yolo Bypass Levee.

2.3 Current Use of Property

The American River Common Features Levee system property is a currently used a flood protection levee for the City of Sacramento and Sacramento County.

2.4 Descriptions of Structures, Roads, and Other Improvements on the Site

Roads along the levee system are a mix of gravel and paved roads, railroads and bike trails that can be found along the levee crest and at the base of the levee. The levee system is crossed by numerous bridges. There are numerous residences, businesses and landfills built on the project site (levee) within the developed areas of the City.

2.5 Current Uses of Adjoining Properties

Landside adjacent properties are a mix of light industrial, commercial properties, and residential subdivisions and agricultural lands. Waterside adjacent property is the American River Parkway, the undeveloped Sacramento River; the Yolo Bypass, which is a diversionary floodwater channel used during periods of high water. There are several parks and recreational areas located between portions of the levee and the Sacramento River.

2.6 Completed Study Work

Several earlier feasibility studies to include environmental impact statements and environmental site assessments for the American River (USACE, 1991, 1996, 2004) and Magpie Creek (USACE, 1995) were completed by the Sacramento District. This environmental site assessment is an update to previous assessments.

2.7 Possible Project Alternatives

All alternatives include adding erosion control to the American River levees.

One alternative adds measures for levee stability and seepage control to the levees on the east bank of the Sacramento River south of the American River.

Another alternative avoids improvement of Sacramento River levees by widening the Sacramento Bypass north of West Sacramento to divert more water from the Sacramento River into the Yolo Bypass.

The Project has not fully defined all alternatives but they have defined the project area.

3.0 User Provided Information

3.1 Title Records

Title records are not provided because the project site, including the levees and waterways, is essentially public land, easement or right-of-way.

3.2 Environmental Liens or Activity and Use Limitations

There are no NPL or proposed NPL sites located within the study area. There is one delisted NPL site, Jibboom Junkyard. Three CERCLIS sites are located within the study area including: La Quinta Inn and Jibboom Junkyard Super Fund Site. There are no DoD sites within the study area. One FUDS sites, the Sacramento District Engineer Yard is included in the study area. There are no tribal lands included in the search area. No sites with state environmental liens are located within the study area.

3.3 Reason for Performing Phase 1

A Phase 1 ESA for HTRW is required by USACE ER 1165-2-132 for all civil works projects during the reconnaissance or feasibility study phase. A Phase 1 ESA is also required by National Environmental Protection Act (NEPA) for all construction activities.

3.4 Other

This ESA will follow the environmental industry practice of using the guidelines set forth in the USEPA rule concerning “All Appropriate Inquiries,” the *ASTM E 1527-05* standard, USACE *Engineering Regulation (ER) 1162-2-132* and *Policy Guidance Letter 34, Non-CERCLA Regulated Contaminated Materials at Civil Works Projects. ASTM E 1527-05* was designed to protect persons purchasing property from liability arising from adverse environmental conditions, but also may be used for other situations per section 4.2.1 of the standard.

4.0 Records Review

4.1 Standard Environmental Record Sources

Environmental Data Resources (EDR) conducted a records research of the study area consisting of 71 federal, state, public, and proprietary available data bases.

Figure 2 shows the EDR map used with the one mile buffer around the project levee. A complete copy of the EDR Report is included as Appendix A. Standard "point" searches apply different levels of scrutiny at the ¼ mile, ½ mile and 1 mile search radius per the ASTM. This "corridor" search applies the same level of scrutiny to the entire one mile search radius.

The report generated by EDR searched the following Federal environmental record sources:

- National Priority List (NPL), including current, proposed, de-listed, liens
- Comprehensive Environmental Response, Compensation and Liability Information System (CERCLIS), including archived sites (CERC-NFRAP) and CERCLA Lien Information (LIENS 2)
- Resource Conservation and Recovery Act (RCRA), including transporters, storage and disposal (TSDF), large quantity generators (LQG), small quantity generators (SQG), conditionally exempt small quantity generators (CESQG), non-generators (NonGen) and the RCRA Administration Action Tracking System (RAATS)
- The Emergency Response Notification System (ERNS)
- The Hazardous Materials Incident Report System (HMIRS)
- The EPA's listing of Brownfield properties (US BROWNFIELDS)
- Department of Defense sites (DOD) and Formerly Used Defense Sites (FUDS)
- The Toxic Chemical Release Inventory (TRIS)
- Integrated Compliance Information System (ICIS)
- PCB Activity Database (PADS)

The following State and Local environmental record sources were searched:

- California Department of Health Services (CA BOND EXP. PLAN)
- Solid Waste Facilities/Landfill Sites (SWF/LF)
- California Water Resources Control Board Waste Discharge System (CA WDS)
- Water Management Database System (WMUDS/SWAT)
- Leaking Underground Storage Tank Incident Reports (LUST), Facility Inventory Database (CA FID UST), Underground Storage Tank Database (UST), Historical Underground Storage Tank Database (HIST UST) and the Aboveground Storage Tank Database (AST)
- California Regional Water Quality Control Board (SLIC)
- DTSC Liens (LIENS)

- California Hazardous Material Incident Report System (CHMIRS)
- Confirmed release sites involving DTSC (RESPONSE)
- Pollutant emissions data (AIRS)
- The DTSC database that identifies sites that have known contamination or sites that require further investigation (ENVIROSTOR)

There were no tribal records found that applied to the area in question

4.2 Additional Environmental Record Sources

Federal Sources:

- Corrective Action Report (CORRACTS)
- A listing of sites with engineering controls in place (USENG CONTROLS)
- A listing of sites with institutional controls in place (US INST CONTROL)
- Department of Transportation Office of Pipeline Safety incident and accident data (DOT OPS)
- A listing of clandestine drug lab locations (US CDL)
- Land Use Control Information System (LUCIS)
- A listing of sites that cleanup responsibility and standards have been established by U.S. District Courts (CONSENT)
- Uranium Mill Tailings sites (UMTRA)
- Open Dump Inventory (ODI)
- Torres Martinez Reservation Illegal Dump Site Locations (DEBRIS REGON 9)
- Mines Master Index File (MINES)
- Administrative cases and pesticide enforcement actions (FTTS) and (HIST FTTS)
- FIFRA-related reporting (SSTS)
- Material Licensing Tracking System (MLTS) and Radiation Information Database (RADINFO)
- Facility Index System (FINDS)

State and Local Sources:

- Known and potential hazardous substance sites (HIST Cal-Sites, formerly ASPIS and replaced by ENVIROSTOR)
- School Property Evaluation Program (SCH)
- Toxic Pits CEANUP Act Sites (Toxic Pits)
- Sites designated by LUST, SWF/LS and Cal-Sites (Cortese)
- Recycling facilities (SWRCY)
- Statewide Environmental Evaluation and Planning System (SWEEPS UST)
- Proposition 65 Database (Notify 65)
- Recorder Land Use Restrictions (DEED)
- DTSC low threat level properties (VCP)
- Dry cleaning-related facilities with EPA ID numbers (DRYCLEANERS)
- Clandestine Drug Labs (CDL)

- Well Investigation Program Case List (WIP)
- Extracts from hazardous waste manifests (HAZNET)
- List of waste tire haulers (HAULERS)

4.3 Historical Record Review

Historic aerial, topographic, and fire maps were not obtained for this search due to the cost for a search of this magnitude. Instead the assessment reviewed these historical records obtained for a previous assessment (USACE, 2008) which covered most of the same area, with the assumption that the historic records haven't changed significantly since 2008.

4.4 Regional Contaminant Considerations During Future Construction

Environmental records searches are efficient ways to identify and track sites where past releases have occurred. Other types of contaminants unlikely to be picked up in an environmental records database search are considered in this report because they are associated with significant industries that were historically active in the region. Gold mining and large-scale agricultural activities are two historic activities that have produced regional contaminants in the project area and should be considered when future levee construction occurs.

The levee system around the American River and Natomas Basin lies in a region that has a history of gold mining. The regional history of gold mining coupled with the regional agriculture land use and the historic use of dredge material from the rivers as levee construction material, suggests there are some chemicals for which data collection would be useful to confirm if contaminants from these historic process are present. These include arsenic, mercury, pesticides and herbicides.

Additionally, based on the vehicular use of the existing levee crown, lead and petroleum hydrocarbons may have been released to the upper 3 feet of the roadway shoulder on the existing levee, especially at bridge locations where old corrosion-resistant lead paint would be present. Herbicides are sometimes used for weed abatement on the levees.

Railroad tracks are located on the levee on the Sacramento River west of the downtown area. Old railroad ties were preserved with creosote. Newer wooden ties are probably preserved with copper arsenate. If the railroad road bed must be disturbed for the project, further investigation for these contaminants will be warranted.

Sacramento Regional County Sanitation District has regionalized its wastewater treatment system (SRCSD, 20007). Most or all wastewater is collected and pumped to the regional wastewater treatment plant in Elk Grove. Treated wastewater is discharged just south of the Freeport Bridge in the project area. Wastewater from Natomas is moved south to the west of the Sacramento River and now crosses to Elk Grove at the Freeport bridge. There were wastewater treatments plants located between Exposition Park and Howe Avenue (the "Arden Station") and on River Walk Road (the "Northeast Facility") along the north bank of the American River. These old wastewater treatment plants have been converted to pumping and flow equalization stations that today move wastewater through force mains across the American River. The

Sacramento City Interceptor parallels the Sacramento River south of the Sacramento Marina for several miles. The Dry Creek Interceptor crosses Dry Creek and Magpie Creek between Rio Linda Blvd and Dry Creek Road near the Sacramento Northern Bike Trail, and crosses Arcade Creek at Rio Linda Boulevard. There is no record of overflows but the wastewater pipelines are to be avoided and special personal protective equipment for biological hazards may be required when working in close proximity to present and former treated wastewater discharge locations.

5.0 Site Reconnaissance

5.1 Methodology and Limiting Conditions

The study area site visit was conducted for the Phase 1 ESA by staff from the Environmental Engineering and Geology Sections of the United States Army Corps of Engineers, Sacramento District.

The objective of the site visit was to identify recognizable environmental concerns in connection with the property. Common environmental concerns that were looked for include the following: asbestos; construction and demolition debris; drums; landfill or solid waste disposal sites; pits, ponds or lagoons; wastewater; fill dirt, depressions, mounds, or any artificial structures; PCB containing transformers; monitoring wells, and the presence or likely presence of any hazardous substance or petroleum products on the property under conditions that indicate an existing release, a past release, or a material threat of a release on the property or into the ground, groundwater, or surface water of the property.

The mere presence of a contaminated property on the dry side of the levee was generally considered to be avoidable. The presence of contaminated properties on the “wet” side of the levee or features on or inside the levee such as monitoring wells, drains and pipelines were generally assumed to be unavoidable.

5.2 Observations

Site visits to properties screened as likely affecting the Project were conducted on August 2, 2012. Photographs are included in Appendix D. Findings are incorporated in Chapter 8.

6.0 Historical Records

The 2008 assessment consulted Sanborn Fire Insurance records to glean any information about sites along the rivers that was not presented elsewhere. Basically, the maps confirmed the other sources that most of the industrial sites were located at or near the confluence of the American and Sacramento Rivers. Searching the Internet yielded a few aerial and historical photographs, and maps which confirmed earlier findings about the locations of various industrial sites.

6.1 Aerial Photo Review

EDR provided an Aerial Photo Decade Package (EDR, 2008) for the previous environmental site assessment (USACE, 2008). "Birdseye" view drawings, aerial and other historical photographs were obtained from the EDR report, and from the California State Library in Sacramento, California.

It is unlikely any additional historical air photos have been found in the last four years. Therefore this assessment used the 2008 historical record search from the previous study. It is included in Appendix E.

Several industrial sites were noted, especially along the confluence of the American and Sacramento Rivers. Water-borne shipping was more in evidence in the past than it is today, although the modem ships, while fewer in number carry much larger payloads.

6.2 Topographic Maps

The search also consisted of reviewing historical topographic maps (Appendix F):

- Sacramento East Maps
    - From the edition of 1949, six specific crossings of the Sacramento River were noted, Highway 99, H Street, a footbridge south of Arden Town and three railroads, Southern Pacific, Sacramento Northern and Western Pacific. In addition, there are power line crossings.
    - There are several pumps related to miscellaneous water uses associated with the levees.
    - The edition of 1954 showed the same features, except that the footbridge had become the Watts Avenue crossing.
    - The map of 1967 added a golf course east of the highway 80 and south of Cal Expo, a sewage disposal plant east of mile 5 and west of Howe Avenue, a filtration plant east of the Sacramento State University campus and a fire station, presumably associated with the Sacramento State campus.
    - The Sacramento East map of 1975 was a photo revision of the 1967 edition and added a crossing at Howe Road.

- The editions of 1980 and 1992 did not show any significant additions.

• Sacramento West Maps

- The map of 1949 noted an intake tower and filtration plant south of the confluence of the American River, a pumping plant at the end of the Natomas Canal, a boat launching ways near the confluence of the American River and a clay pit and stack near Clay Bank Bend. Crossings include the Tower Bridge, the I Street Bridge and the Jibboom Street Bridge.
- There are several pumps related to miscellaneous water uses associated with the levees.
- In the 1967 edition, the clay pit has become Lake Greenhaven and the stack is gone. The Sacramento Deep Water Ship Channel is added. There is a new filtration plant south of the end of 10th Avenue, a new sewage disposal plant at the confluence of the barge canal leading to the deep water ship channel, a new marina at Miller Park and borrow pits across the river from the old intake tower. Highway 80, 5 and a proposed crossing for highway 880 are added.
- The photo revision of the 1967 edition shows the actual location of the 880 bridge.

• Clarksburg Maps

- The 1952 edition of the Clarksburg map shows a sugar beet plant located north of Clarksburg on the west side of the Sacramento River and the Borges-Clarksburg Airport at benchmark 13. There are several pumps related to miscellaneous water uses associated with the levees. Crossings include several power lines and a drawbridge south of Freeport.
- The version of 1967 shows three industrial waste ponds in or on the location of the sugar beet plant, just north of Willow Point Road. There is a new water tank and sewage disposal plant at Freeport Bend on the east side of the Sacramento River
- The1975 photo revision of the 1967 edition adds a small waste pond at the old sugar beet plant.
- The 1980 photo revision of the 1967 edition shows a new waste pond at the sugar beet plant.

6.3 Commercial Environmental Database Report

The EDR “Environmental Records Database Search is in Appendix A. Due to the size of the document (over 2,000 pages), the Appendix contains only an extract. The entire document is included in PDF file format on CD.

7.0 Interviews

Six interviews were conducted in the 2008 assessment. One new interview was conducted for this assessment.

7.1 Interviews with Owners/Occupants

Individual Contacted	Date	Title/Organization	Contact Information	Page Number (USACE, 2008)
Mr. Joe Borges	10/23/2008	Owner Borges-Clarksburg Airport	N/A	5

7.2 Interviews with State and Local Government Officials

Tim Kerr, the President of the American River Flood Control Agency (ARFCA) was interviewed. His response is in Appendix C.

Previous interviews included

Individual Contacted	Date	Title/Organization	Contact Information	Page Number (USACE, 2008)
Ms. Mary Perlea	8/31/2007	US Army Corps of Engineers	(916) 557-7185	1
Mr. Terrie Figueroa	9/13/2007	Secretary/ RD1000	(916) 922-1449	2
Mr. Richard Payan	9/13/2007	Battalion Chief/City of Sacramento Fire Department	(916) 216-0311	3
Mr. Paul Devereaux	9/20/2007	General Manager/RD1000	(916) 922-1449	4
Lt(jg) Simone Moss	9/25/2008	Waterways Officer, USCG	(510) 437-2975	6

The interviewees had very limited knowledge of HTRW contaminated properties located along the levees. It is recommended that public officials at the California Department of Toxic Substances Control and Central Valley Regional Water Quality Control Board involved in cleanup of contaminated sites that may affect the Project be interviewed to help define how the Type 1 sites affect project alternatives.

8.0 Findings

The EDR search identified over 600 records of possible HTRW concerns within the study area. All of these sites were identified in the EDR search by a site identification-focus map number identifier. Many of the Site ID's had multiple records of possible HTRW associated with them so the total number of identified sites in the EDR report was 491. Of these, 7 sites were considered to be Type 1 and 45 were found to be Type 2.

Appendix B provides a summary of each site including its levee station and reach, whether or not the site may affect future construction, and links to regulatory information. This information was used to focus the Phase 1 ESA to the potential effects of the identified HTRW sites on future construction activities. Further investigation of potentially hazardous sites included review of available site information in the EnviroStor and GeoTracker databases maintained by the California Department of Toxic Substance Control (DTSC) and California State Water Resources Control Board (SWRCB) respectively. Reports from these databases were used to determine the possible impact identified sites may have on future construction activities. Characteristics used to classify the site included the suspected mass and volume of contaminants, their mobility within the soil-groundwater-air matrix, and the likelihood of traditional levee remediation measures impacting contaminated media.

As previously discussed, sites were classified in one of three types according to the potential for harmful impacts on future construction activities. Tables 2 & 3 below provide a listing of all the Type 1 and Type 2 sites, respectively. Figure 3 provides a map showing the location of all Type 1 and 2 HTRW sites. The remaining Type 3 sites are identified in Appendix A and B.

Whether a contaminated site adjacent to the levee is avoidable depends in part on what work is proposed to be done on the levee; erosion control, stability, seepage control, relocation or raise in elevation. Justification for classification as a Type 1 or Type 2 site is further discussed in Chapter 9, Findings.

Table 2 – Type 1 HTRW Sites

Type 1 Sites – HTRW concerns that may impact future activities					
Site Name	**EDR ID#**	**Assessor Parcel Number**	**Levee Reach**	**Address**	**Summary**
Full Stop Mini Mart	41-5	251-0292-016	ARN_D	3200 Rio Linda Blvd, Sacramento, CA 95815	Gasoline plume at gasoline station adjacent to the levee at a bridge crossing. Active remediation by soil vapor extraction and air sparging is occurring. The oxidizer is immediately adjacent to the levee. http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=T0606701131
Old Bryte Landfill	79-6	042-280-011	WS*	50035 County Rd 126, West Sacramento, CA 95691	Old unregulated landfill, uncapped, is immediately adjacent to the Sacramento Bypass levee. Waste from a car battery lead recycling company in West Sacramento was dumped here. http://www.envirostor.dtsc.ca.gov/public/profile_report.asp?global_id=60001146 http://www.calrecycle.ca.gov/SWFacilities/Directory/57-CR-0002/Detail/
CA State Railroad Museum Unit SHO	120-7	No parcel number, public land	ARS_D	501 Jibboom ST, Sacramento, CA 95814	Union Pacific Railroad (old Southern Pacific) railyard. The museum appears to be a surrogate for the historic locomotive repair shops being preserved here for reevelopment. There are monitoring wells in the levee and in the waterfront park at this location. http://www.envirostor.dtsc.ca.gov/public/profile_report.asp?global_id=80001665
TOSCO Corporation/ ConocoPhillips Sacramento Terminal	174-11	009-0030-054	ARS_D	76 Broadway, Sacramento, CA 95818	Bulk fuel terminal used by ConocoPhillips. Soil and groundwater beneath the site have been impacted by petroleum hydrocarbons, specifically from active gasolines and diesel fuels. http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=SL0606742138
TOSCO Corp. – Sacramento Terminal	174-11	009-0020-001	ARS_D	66 Broadway, Sacramento, CA 95818	Wet side of major petroleum release above still undergoing cleanup. http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=SL372513618
Chevron Sacramento Terminal 1001620	178-11	009-0012-072 009-0012-071	ARS_D	2420 Front St, Sacramento, CA 95818	More dry-side petroleum bulk handling facility. Petroleum pipelines pass through the levee at all properties. http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=T0606700657
Harbor Sand & Gravel/Bell Marine Co Inc.	128-8	001-0160-011	ARS_B	200 28th St, Sacramento, CA	Release was reported in 1994. The property is now occupied by an asphalt concrete recycling company. The new business has fenced off the levee road and its operation is encroaching on the levee.

Table 3 Type 2 HTRW Sites

Type 2 Sites – HTRW concerns that are not likely to impact future activities					
Site Name	**EDR ID#**	**Distance from Centerline (miles)**	**Levee Reach**	**Address**	**Summary**
PG&E – Sacramento Site	156-11	009-0012-003	ARS_D	2000 Front St, Sacramento, CA 95818	Former manufactured gas plant that produced gas from raw materials such as coal and petroleum from 1873 to 1930. Primary COCs in both soil and groundwater are BTEX, and PAHs including naphthalene. http://www.envirostor.dtsc.ca.gov/public/profile_report.asp?global_id=34490048
Shell #204-6678-9003	98-7	001-0011-003	ARS_D	225 Jibboom, Sacramento, CA 95814	Gasoline plume in groundwater. Two gasoline stations, one adjacent to the levee. This waterfront area was a Superfund site that has been redeveloped. http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=T0606700500
Continental Chemical Company	69-8	275-0111-006	ARN_C	2175 Acoma St Sacramento, CA 95815	LUST, SLIC site http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=SL185472918
Micheletti Property	69-8	275-0112-005	ARN_C	2147 Barstow St Sacramento, CA 95815	SLIC site,CVOCs http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=SL0606762702
Martin Sprocket & Gear Inc.	99-8	001-0070-036	ARS_C	1199 Vine St STE 204, Sacramento, CA 95814	Small quantity hazardous waste generator with a diesel tank on-site. No record of releases. A cluster of three monitoring wells was found in the levee near this property, probably associated with Lovotti Bros. at 1275Vine St. http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=T0606793627
Petro-Speed	123-8	001-0142-010 001-0142-011 001-0142-012	ARS_B	324 N 16th St Sacramento, CA	Old gasoline station that has been closed. Petroleum plume being monitoring. Sufficiently removed from the River. http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=T0606700184
Sacramento City Landfill	128-8	001-0170-018	ARS_B	20 28th and A St, Sacramento, CA	Now known as “Sutter’s Landing Regional Park”. Closed Sacramento public solid waste landfill. The landfill is built right up against the levee so that the levee crown road is downhill from the landfill cap. Stormwater drains on the

					landfill cap go through the levee to the River. Landfill gas collection wells are close to the levee. A Kinder Morgan petroleum pipeline is buried under the water-side toe of the levee. http://www.calrecycle.ca.gov/SWFacilities/Directory/34-AA-0018/Detail/
Scollan (Old Sac City Landfill)	133-8	001-0160-013	ARS_B	24th and A St, Sacramento, CA	Old dump site along the AR between railyard and Sac City landfill http://www.calrecycle.ca.gov/SWFacilities/Directory/34-CR-5005/Detail/
Sacramento Housing & Redevelopment Agency	149-11	009-0012-002	ARS_D	1920 Front St, Sacramento, CA 95814	http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=T0606700254 http://www.envirostor.dtsc.ca.gov/public/profile_report.asp?global_id=34240036
Sacramento Municipal Utility District (SMUD)	158-11		ARS_D	Front & T St, Sacramento, CA 95814	Across the street from the PG&E site. Historical uses include vehicle maintenance, fueling, and storage. The potential site contaminants of concern are polynuclear aromatic hydrocarbons (PAHs), total petroleum hydrocarbons as gasoline (TPH-Gas), and volatile organics (VOCs). All remedial activities were completed in 2008, however, DTSC required the continued operation and maintenance of the GWETs and associated monitoring wells and prohibited certain uses of the site. http://www.envirostor.dtsc.ca.gov/public/profile_report.asp?global_id=34490057
Delta Shores	243-20		ARS_G	8145 Freeport Blvd Sacramento CA 95832	http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=T10000000566

9.0 Opinions

All information used to form the following opinions was gathered from the most recent reporting information available in the EnviroStor or GeoTracker databases, site reconnaissance and interviews. If no citation is given, general information on the website or the site details from the EDR report were used.

9.1 Type 1 Sites

76/66 Broadway & 2420 Front St EDR Site 174-11 is a bulk fuel terminal now used by ConocoPhillips. The site is located within an industrial area of Sacramento, north and east of the Sacramento Marina at the intersection of Front and Broadway Streets. Twelve aboveground storage tanks associated above- and below- ground piping, a loading rack, and several buildings are present at the site. Previous site investigations have revealed that the soil and groundwater beneath the site have been impacted by petroleum hydrocarbons, specifically from active gasoline and diesel fuels. Previous remedial activities include a soil vapor extraction system set up in 1991 that removed 26,000 pounds of petroleum hydrocarbons after two months; an expanded soil vapor extraction system. The site is located on both sides of the levee. Pipelines run through the levee from 2420 Front Street to 66 Broadway and from 76 Broadway to the Sacramento Marina. Pipelines also run parallel to the levee from 76 Broadway to 2420 Front Street. 66 Broadway St is on the water side of the levee while 76 Broadway is on the dry side of the levee making this site unavoidable. 2420 Front Street is on the dry side of the levee.

EDR Site 79-6, Yolo County Assessor Parcel Number (APN) 042-280-011 is the Old Bryte Landfill. The landfill was an old unregulated dump site. DTSC has found lead above risk level. The source of the lead is probably scrap from an old car battery lead recycling operation in West Sacramento which is now the site of Sacramento Stucco. The waste would probably classify as CERCLA hazardous waste based on toxicity and leachability. Very likely the north levee for the Sacramento Bypass cannot be moved without dumpsite removal by the non-federal sponsor at 100% non-federal expense.

EDR Site 41-5, Sacramento County APN 251-0292-016 Full Stop Mini Mart in ARN Reach N on Arcade Creek is a leaking underground storage tank adjacent to the Arcade Creek levee adjacent to a bridge. The site is being actively remediated with soil vapor extraction and air sparging and it is possible but not probable that some vapor-laden air from the air sparging escapes the soil vapor extraction system into the levee. The thermal/catalytic oxidizer is trailer-mounted and located at the dry side toe of the levee. The site is included here as it is an actively remediated groundwater contamination site on a parcel adjacent to the levee.

EDR Site Number 120-7 in ARS Reach D is the old Southern Pacific rail yard with engine houses. It has no assessor parcel number as it is now public land for historic preservation and redevelopment. This was a major cleanup site. Monitoring wells are found in and on the west (wet) side of the levee along the Sacramento River. Land use controls are in place. It is probably possible to avoid contamination at this site but the project will need to work around monitoring wells that will be in the way and will need to avoid digging or pile-driving.

EDR Site 128-8 APN 001-0160-011 "Harbor Sand & Gravel" in ARS Reach B is now the site of an asphalt concrete recycling company. The company has blocked the levee road with a gate and is encroaching on the levee including the wet side with piles of recyclable pavement materials and structures (see photo in Appendix D).

EDR Site 156-11 is a former manufactured gas plant, Pacific Gas & Electric Sacramento Site, which produced gas from raw materials such as coal and petroleum from 1873 to 1930 and was demolished in 1961 (there is a second such site located "south of the western end of Broadway"). The site is located between the Sacramento River levee and Front Street. Residuals of the manufactured gas process include lampblack, tar, total petroleum hydrocarbons (TPH), and spent oxides. Contaminants associated with these residues have been detected in soil and groundwater beneath the Site. The primary COCs in both soil and groundwater are benzene, toluene, ethylbenzene and total xylenes (BTEX), and polycyclic aromatic hydrocarbons (PAHs) including naphthalene. The major benzene plume is located in the north eastern area of the site, while a small separate plume exists at the foot of the levee in the central western part of the site based on monitoring results from May 2008 (DTSC 2011).

Numerous remedial investigations, soil removal actions, and many years of groundwater extraction and treatment have been conducted at the Site. Remedial activities to date include: capping of the PG&E property with a geosynthetic clay liner, soil excavations, operation of a soil vapor extraction treatment system, and operation of a groundwater evapotranspiration system (GWETs). Currently, the site is paved to control soil migration and exposure. The Ranney Collector was decommissioned in 2009, thus necessitating a remedy modification. Soil stabilization/solidification, by the addition of Portland Cement and Activated carbon to the areas where the highest contamination is found in the vadose zone, has been selected as the remedial action. Any future construction work would be impacted by the presence of this plume and monitoring system.

9.2 Type 2 Sites

Several sites were visited during site reconnaissance and downgraded from a preliminary classification as "Type 1" to a final classification of Type 2 or 3 based on avoidability. They are discussed here. ***Sites determined from map reconnaissance and records review to be Type 2 and Type 3 sites without site reconnaissance are not discussed***. Most of the sites discussed here are contaminated properties adjacent to or near to the levee that are unlikely to affect levee improvements so long as the properties are avoided.

EDR Site 158-11 is a vacant parcel owned by the Sacramento Municipal Utility District that is located at the intersection of Front and T Streets with the Sacramento River and levee to the west and the Interstate 5 Highway to the east. EDR 158-11 is located on the other side of Front Street, across from EDR 156-11. The site's historical uses include vehicle maintenance, fueling, and storage. This site was discovered during the groundwater investigation of EDR Site 156-11. The investigation revealed that the site consisted of a source of contaminants that were migrating to the groundwater. The potential site contaminants of concern are polynuclear aromatic hydrocarbons (PAHs) from diesel fuel, total petroleum hydrocarbons as gasoline (TPH-Gas), and volatile organics (VOCs). The source of contamination was removed in 1999 by excavating 4,290 tons of contaminated soil and disposing of it off-site. A seasonal soil vapor extraction system (SVETs) operated at the site from November 1999 to May 2007. The SVETs is estimated to have captured and treated 34 pounds of reactive organic compounds and 13 pounds of benzene from the vadose zone. Groundwater monitoring continues to occur on site. The site relies on the EDR Site 156-11 GWETs to remove residual amounts of site contaminants. The California Department of Toxic Substances Control (DTSC) certified that all appropriate remedial actions have been completed in April 2008. However, DTSC also recorded land use controls requiring that the operation and maintenance of the GWETs and associated monitoring wells continue and prohibiting certain uses of the site. Any future construction work should avoid this area (DTSC 2010a).

EDR Site 98-7 Sacramento APN 001-011-003 Shell station in ARS Reach C/D on the Sacramento River south of the American River is a monitored leaking UST across the street from another gasoline station that abuts the levee but does not reach it.

EDR Site 99-8 APN 001-0070-036 in ARS Reach C, Martin Sprocket & Gear. The site is adjacent to the levee along with a few other such properties. The presence of a cluster of three monitoring wells in the levee, probably due to a petroleum release at the Lovotti Brothers site at 1275Vine St, is noted here but unlikely to affect erosion control measures.

EDR Site 128-8 Sacramento APN 001-0170-018 in ARS Reach B is the Sacramento City Landfill, now known as the Sutter's Landing Regional Park (Appendix D). This will have a minor impact on erosion control measures for the Project. The landfill uses the levee as a cap so that the landfill crown is topographically above the road on the levee crown. Stormwater drains from the landfill cap penetrate the levee that will need to be avoided. Landfill gas extraction wells are in or next to the levee but if working properly present no problem. The Kinder Morgan petroleum pipeline parallels the Union Pacific Tracks through most of Placer and Sacramento Counties, but the presence of the landfill between the levee and the tracks at this location means they have buried the pipeline at the toe of the levee on the water side at this location. There is no documented petroleum release from the pipeline in this location, but there is such a site in old North Sacramento across the river. It should be feasible to place riprap on the levee at this location, but care must be taken to avoid landfill features such as the storm water drains and the buried pipeline.

EDR Site 133-8 APN 001-0160-013 the Scollan or "Old Sac Landfill" in ARS Reach B is mentioned here because it is an old, unregulated and un-engineered landfill abutting the levee. An on-line aerial photo in Google Map™ appears to show a cap being placed on the landfill. No leachate collection system or landfill gas collection system are visible.

EDR Site 69-8 Sacramento APN 275-0111-006 Continental Chemical and EDR Site APN 275-0112-005 Micheletti Property in ARN Reach B/N along the Natomas Main Drainage Canal are minor groundwater release sites with petroleum and chlorinated solvents. The issue is that there are several more such documented and monitored release sites in close proximity in this old industrial area in old North Sacramento. There is also a release site immediately adjacent to the levee at EDR Site 69-8, APN 275-0111-001. Due to the close proximity of many contaminated industrial sites and two such properties adjacent to the levee, the project would likely need to ensure that levee improvements would not adversely impact groundwater contaminant plume migration at this location.

1920 Front St - Sacramento Housing and Redevelopment Agency Site: The site was once a lumberyard. A leaking UST and waste from the adjacent manufactured gas plant were found on the property. The property was razed to create a parking lot that caps residual soil waste and has land use controls. A concrete wall 3 feet high separates the parking lot from the levee. A few empty waste drums remain on site. The State of California had a Ranney Well by the river used by the California Department of General Services to provide cooling water for downtown State office buildings. The well was destroyed in 2009.

2000 Front St – PG&E Former Manufactured Gas Plant Site: The site has been razed and paved over. It is located on the dry side of the levee. Land use restrictions are in place. The site is fenced and requires permission from PG&E to access. 40 hour OSHA Hazwoper training is required for access. The site is being remediated by Arcadis with deep soil mixing for soil stabilization/solidification. Remediation may be complete by November. The site is adjacent to the “Boat Section” of Interstate 5 which is lower than the River and actively de-watered. The property must be avoided.

Additional sites were categorized as Type 2 based on record screening without site visit. A summary can be found in Table 3. Type 3 sites are found in Appendix B.

10.0 Conclusions

A Phase 1 Environmental Site Assessment was performed in accordance with the scope and limitations of ASTM E 1527-05 and USACE ER 1165-2-132 for the American River Common Features GRR project. Any exceptions to, or deletions from, these practices have been outlined within the report. There are many contaminated properties adjacent to the levees on the dry side that are considered to be avoidable due to the nature of the contamination or the nature of the work proposed on the levees. This assessment has identified sites with recognized and probably unavoidable environmental conditions at the locations shown in Table 4 below.

Table 4 - Sites with Recognized Environmental Conditions

Site Name	Reach	EDR #	APN	Issue
Old Bryte Landfill	Sacramento Bypass	79-6	042-280-011	Lead in soil,
Southern Pacific Rail Yard	ARS Reach D Sacramento River	120-7	002-0010-049 002-0010-023 002-0010-054	CVOC, TPH Groundwater Plume, land use restrictions
Full Stop Mini Mart	ARN Reach N Arcade Creek	41-5	251-0292-016	TPHg plume at levee bridge crossing with air sparging
Robertson/Harbor Sand & Gravel	ARS Reach B American River	92-8 128-8	001-0160-011	Levee Encroachment, recycled pavement
Old North Sacramento	ARN Reach B/N Natomas Main Drainage Canal	69-8	275-0111-001	CVOC, TPH Groundwater Plumes adjacent to levee, multiple properties
TOSCO Corp./ Conoco-Phillips Sacramento Terminal	ARS_D	174-11	009-0030-054 009-0012-071 009-0012-072	Petroleum release site on dry side of the levee. Petroleum pipelines pass through the levee.
TOSCO Corp. Conoco-Phillips Sacramento Terminal	ARS_D	174-11	009-0020-001	Petroleum release site on wet side of the levee

The historical land uses of the region may also contribute to residual contamination of the entire project area with agricultural fertilizers, herbicides, and pesticides as well as arsenic and mercury from mining operations in the region. Additional sampling will be required during subsequent investigations to determine if project areas have been impacted by these historical contaminants.

On-line records are limited. For contaminated sites identified as unavoidable under the alternatives considered by the American River Common Features GRR, a public records review is recommended at the Central Valley Regional Water Quality Control Board office and the Sacramento Regional Office of the Department of Toxic Substances Control as the next step to determine if additional investigation is required to determine the impact of these sites on the project. Current groundwater plume maps and environmental liens / deed restrictions incorporating land use controls are particularly needed. Emphasis is needed on the Sacramento

Terminal bulk fuel handling facility, the old Southern Pacific rail yard, and the old Bryte landfill as these may affect alternative selection.

Due to the GRR process being a parent project that identifies the need for future actions, a Phase 1 ESA will need to be performed again, either at the appropriate GRR phase planning milestone, or at the beginning of actual construction activity. The subsequent Phase 1 ESA(s) will investigate if new sites have emerged and if existing sites still pose a threat to planned construction.

1.0 INTRODUCTION

1.1 Purpose and Goals

Mitigation for habitat loss is a requirement to compensate for the loss of habitat due to a Federal action. Section 906(d) of the Water Resources Development Act of 1986 states that project alternatives must support recommendations with a specific plan to mitigate fish and wildlife losses. Additionally, the Endangered Species Act states that the purpose of compensatory mitigation is to offset environmental losses resulting from unavoidable impacts.

The primary purpose of vegetation and habitat monitoring is to determine the level of ecological function at each mitigation site as a part of an overall plan to create sites that offset the loss of habitat affected by construction of the proposed project. This Habitat Mitigation Monitoring and Adaptive Management Plan (HMMAMP) describes the types of habitats that will be impacted, the potential impacts caused by the project, and describes the types and amounts of mitigation that would be established in order to compensate for habitat losses. This plan also establishes a framework for the creation of mitigation sites and methods to evaluate the success of these sites in order to ensure that the goals and requirements of the project's required mitigation are accomplished.

The goal of the HMMAMP is to ensure that the conservation values of the mitigation sites are maintained in good condition in perpetuity. The plan's biological goals are to: (1) preserve the abundance and diversity of native species (particularly special status species) in the established habitats; (2) protect the habitat features from the effects of indiscriminate land use that may adversely impact mitigation habitats; and (3) restore any adverse condition within the mitigation habitat areas that may affect or potentially affect these areas. Monitoring would be conducted in a manner compatible with the type of mitigation site. Mitigation requirements are provided by the U.S. Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NMFS) through biological opinions (BOs) received through the Endangered Species Act Section 7 consultation process.

The HMMAMP would be implemented by U.S. Army Corps of Engineers (Corps) staff through coordination with USFWS and NMFS. Monitoring would be conducted by qualified biologists from the Corps, USFWS, the Department of Water Resources (DWR), and the Sacramento Area Flood Control Agency (SAFCA) as necessary. Upon completion of the monitoring term as established by USFWS and NMFS, the land would be turned over to the non-Federal sponsor to be maintained in perpetuity.

1.2 Project Description

The Environmental Impact Statement/Environmental Impact Report (EIS/EIR) prepared for the American River Common Features General Reevaluation Report (ARCF GRR) describes the environmental resources in the project area; evaluates the direct, indirect, and cumulative environmental effects of the three alternative plans; and identifies avoidance, minimization, and mitigation measures. Most potential adverse effects would be either short term or would be avoided or reduced using best management practices.

The proposed project is located in and around the city of Sacramento, California. Sacramento is the state capital of California, located at the confluence of the Sacramento and American Rivers in the northern portion of California's Central Valley. The Sacramento Metropolitan area is the fourth largest in California, and includes seven counties and seven incorporated cities.

The purpose of the ARCF GRR is to evaluate alternatives to reduce the flood risk in the greater Sacramento area. The Sacramento Metropolitan area is one of the most at risk areas for flooding in the United States. There is a high probability that flows in either the American or Sacramento Rivers would stress the network of levees protecting the study area to the point that levees could fail. The consequences of such a levee failure would be catastrophic since the inundated area is highly urbanized and the flooding could be up to 20 feet deep.

The ARFC GRR study area includes: (1) approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; (2) the east bank of the Natomas East Main Drainage Canal (NEMDC), Arcade Creek, and the Magpie Creek Diversion Canal (collectively referred to as the East Side Tributaries); (3) the east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee, the southern defense for Sacramento; and (4) the Sacramento Weir and Bypass, located along the north edge of the city of West Sacramento. A vegetation variance is being sought to allow for vegetation to remain on the lower portion of the waterside levee slope. A complete summary of the proposed measures is shown on Table 1.

Table 1. Proposed Measures for the ARCF Project.

Waterway/Location	Extent of Action	Proposed Measures
American River	North and south levees from the Sacramento River upstream for approximately 12 miles.	Construct bank protection or launchable rock trenches
Sacramento River	East levee from the American River to the North Beach Lake levee.	Install cutoff walls Construct bank protection Construct levee raise (Alternative 1 – 7 miles Alternative 2 – 1 mile) Construct geotextile reinforced soil embankment levee near the town of Freeport
NEMDC	East levee from Dry/Robla Creek to the American River.	Install cutoff walls Construct floodwalls
Arcade Creek	North and south levees from NEMDC to Marysville Boulevard.	Install cutoff walls Raise floodwalls Construct geotextile reinforced soil embankment levee in steep areas on the south levee
Magpie Creek Diversion Canal	Downstream of Raley Boulevard	Raise levees
Magpie Creek area	West side of Raley Boulevard	Construct new levee Install floodgates at two properties
Magpie Creek area	East of Raley Boulevard	Acquire property to create a flood detention basin Widen the Raley Boulevard/Magpie Creek bridge and raise the elevation of the roadway Remove the Don Julio Creek culvert
Magpie Creek area	Sacramento Northern Bike Trail	Install culvert beneath bike trail embankment Excavate new channel connecting culvert to Robla Creek Install stone erosion protection in new channel
Sacramento Weir and Bypass	North bypass levee to 1,500 feet north.	Widen the Sacramento Weir and Bypass by approximately 1,500 feet Construct a new section of weir and levee remove the existing Sacramento Bypass north levee

The Recommended Plan for the ARCF project is to Improve Levees and Widen the Sacramento Weir and Bypass. This alternative would include widening the Sacramento Weir and Bypass to divert more flows into the Yolo Bypass and alleviate the need for most of the raises along the Sacramento River downstream of the bypass. This alternative would also include minimal levee raises along the Sacramento River. In order to reduce the extent of levee raises, the Sacramento Weir and Bypass would be widened to divert more flows into the Yolo Bypass. The levees along the American River, NEMDC, Arcade, and Magpie Creeks, would be improved to address identified seepage, stability, erosion, and height concerns. The levees along the Sacramento River would be improved to address identified seepage, stability, erosion, and a small amount of levee raising. Due to hydraulic, real estate, and environmental constraints within the study area, the majority of the levees would be fixed in place.

The Recommended Plan is the least environmentally damaging practicable alternative under the Clean Water Act and the environmentally preferable alternative under NEPA. This is mainly because it results in less riparian habitat removal along the Sacramento River.

1.3 Proposed Flood Risk Management Measures

1.3.1 Bank Protection

This measure consists of placing rock revetment on the river's bank, and in some locations on the levee slope, to prevent erosion (Figure 1). When necessary, the eroded portion of the bank would be filled and compacted prior to the rock placement. The sites would be prepared by clearing and stripping the site prior to construction. Small vegetation and loose materials would be removed. In most cases, large vegetation would be permitted to remain at these sites. Temporary access ramps would be constructed, if needed, using imported borrow material that would be trucked on site.

1.3.2 Launchable Rock Trench

This measure includes construction of a launchable rock filled trench, designed to deploy once erosion has removed the bank material beneath it (Figure 1). All launchable rock trenches would be constructed outside of the natural river channel. The vegetation would be removed from the footprint of the trench and the levee slope prior to excavation of the trench. The trench would be excavated at the toe of the existing levee. The bottom of the trench would be constructed close to the summer mean water surface elevation in order to reduce the rock launching distance and amount of rock required.

After excavation, the trench would be filled with revetment that would be imported from an offsite location. After rock placement the trench would be covered with a minimum of 3 feet of the stockpiled soil to allow for planting over the trench. Some vegetation could be permitted over the trench if planted outside the specified vegetation free zone required by the Engineering Technical Letter (ETL) 1110-2-583. This vegetation would likely be limited to native grasses, shrubs, and trees with shallow root systems to ensure that they do not limit the functionality of the trench during a flood event.

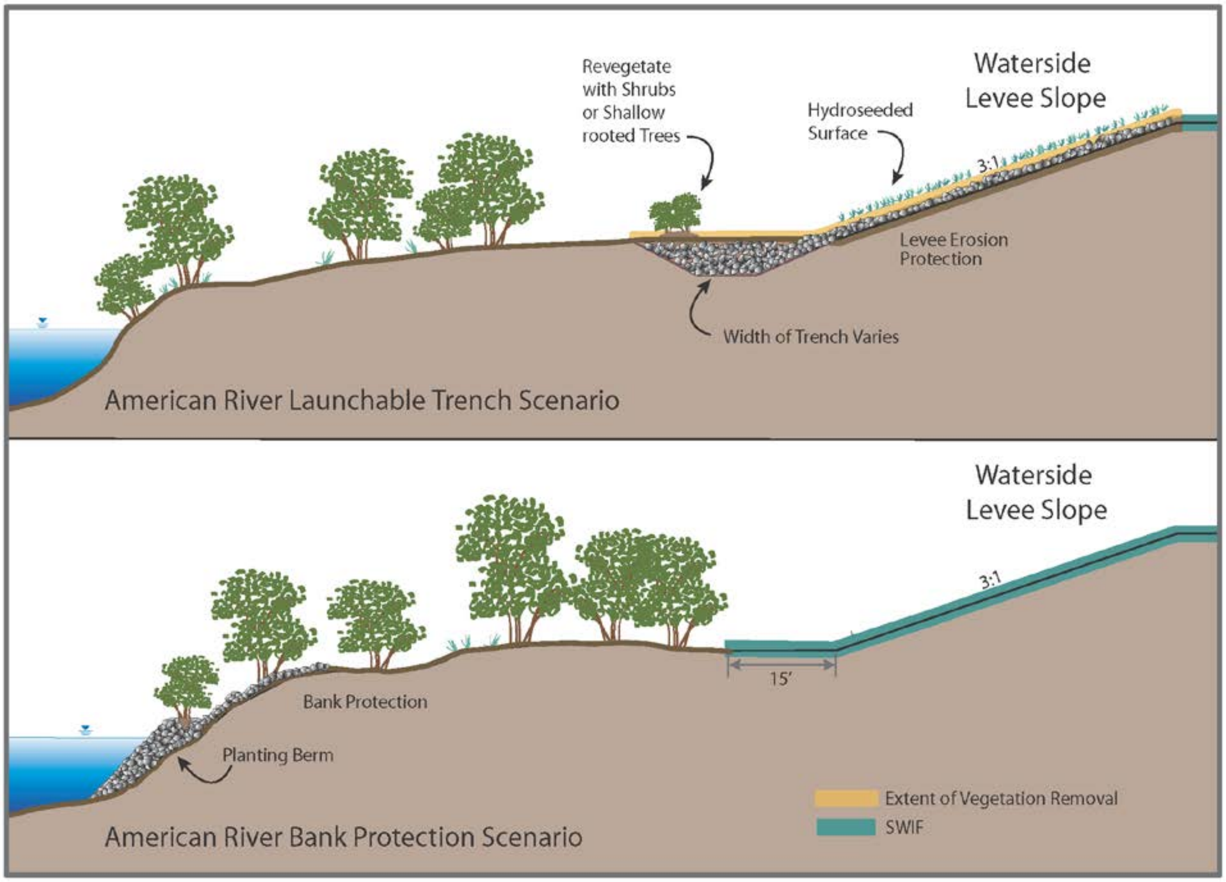

Figure 1. Bank Protection and Launchable Rock Trench Typical Design for American River.

1.3.3 Levee Geometry

Where the existing levee cross section does not meet the levee design requirements, slope flattening, crown widening, and/or a levee raise is required. This improvement measure addresses problems with slope stability, geometry, overtopping, and levee toe and crest access and maintenance. To begin levee embankment grading, the area would be cleared, grubbed, stripped, and, where necessary, portions of the existing embankment would be excavated to allow for bench cuts and keyways to tie in additional embankment fill. The existing levee centerline would be shifted landward where necessary in order to meet Corps standard levee footprint requirements. The levee crown patrol road would be re-established and a new toe access corridor would be added 10 feet landward of the levee toe in areas where levee raises are required.

1.3.4 Cutoff Walls

To address seepage concerns, a cutoff wall would be constructed through the levee crown (Figure 2). A cutoff wall is a water resistant barrier that is constructed vertically into the levee and is designed to prevent through and underseepage in the levee. The cutoff wall would be installed by one of two methods: (1) conventional open trench cutoff walls, or (2) deep soil mixing (DSM) cutoff walls. The method of cutoff wall selected for each reach would depend on the depth of the cutoff wall needed to address the seepage. The open trench method can be used to install a cutoff wall to a depth of approximately 80 feet. For cutoff walls of greater depth, the DSM method would be utilized.

Prior to construction of either method of cutoff wall, the construction site and any staging areas would be cleared, grubbed, and stripped. The levee crown would be degraded up to half the levee height to create a large enough working platform (approximately 30 feet) and to reduce the risk of hydraulically fracturing the levee embankment from the insertion of slurry fluids.

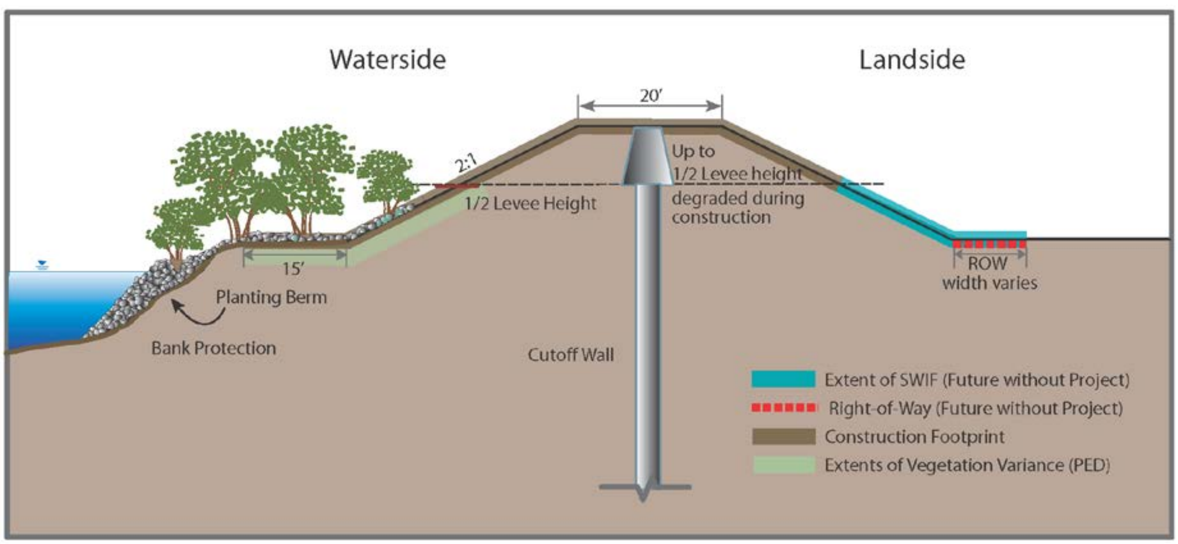

Figure 2. Fix-in-place with Cutoff Wall and No Levee Raise on the Sacramento River.

1.4 Types of Habitats Impacted

A variety of different habitat types occur within the study area including riparian habitat, shaded riverine aquatic habitat, oak woodland, ruderal herbaceous grasslands, and wetlands. These habitats are briefly described below.

1.4.1 Giant Garter Snake Upland Habitat

The giant garter snake inhabits marshes, sloughs, ponds, small lakes, low gradient streams, other waterways and agricultural wetlands such as irrigation and drainage canals and rice fields, and the adjacent uplands. Essential habitat components consist of: (1) adequate water during the snake's active period, (early spring through mid-fall) to provide a prey base and cover; (2) emergent, herbaceous wetland vegetation, such as cattails and bulrushes, for escape cover and foraging habitat; (3) upland habitat for basking, cover, and retreat sites; and (4) higher elevation uplands for cover and refuge from flood waters.

Disturbed soil surfaces such as levee slopes should be hydroseeded to prevent erosion and restore upland habitat for giant garter snake. USFWS recommends a mix of at least 20 to 40 percent native grasses such as annual fescue (*Vulpia* spp.), California brome (*Bromus carinatus*), blue wildrye (*Elymus glaucus*), and needle grass (*Nassella* spp.); 2 to 10 percent native forbs; 5 percent rose clover (*Trifolium hirtum*); and 5 percent alfalfa (*Medicago sativa*). Approximately 40 to 68 percent of the mixture may be non-aggressive European annual grasses such as wild oats (*Avena sativa*), wheat (*Triticum* ssp.), and barley (*Hordeum vulgare*). The Corps will not include aggressive non-native grasses, such as perennial ryegrass (*Lolium perenne*), cheatgrass (*Bromus tectorum*), fescue (*Festuca* spp.), giant reed (*Arundo donax*), medusa-head (*Taeniatherum caput-medusae*), or Pampas grass (*Cortaderia selloana*) in the hydroseed mix.

1.4.2 Shaded Riverine Aquatic Habitat

Shaded Riverine Aquatic (SRA) habitat is defined as the near shore aquatic area occurring at the interface between a river and adjacent woody riparian habitat. The principal attributes of this valuable cover type include: (1) the adjacent bank being composed of natural, eroding substrates supporting riparian vegetation that either overhangs or protrudes into the water; and (2) the water containing variable amounts of woody debris, such as leaves, logs, branches and roots, as well as variable depths, velocities, and currents. SRA occurs throughout the study area along the riverbanks and levees and is contained within the other identified habitat types in these areas.

1.4.3 Valley Foothill Riparian Habitat

Most valley foothill riparian habitat in the study area (hereafter referred to as “riparian habitat”) occurs along the American and Sacramento Rivers, but smaller riparian areas are found at all of the levees in the study area. The overstory of the riparian habitat consists of mature, well-established trees: Fremont cottonwood (*Populus fremontii)*, valley oak (*Quercus lobata*), black willow (*Salix gooddingii*), and box elder (*Acer negundo var. californicum*). During the surveys, Oregon ash (*Fraxinus latifolia*), western sycamore (*Platanus racemosa*), and white alder (*Alnus rhombifolia*) were also observed. The shrub layer consists of smaller trees and shrubs; representative species observed were poison oak

(*Toxicodendron diversilobum*), sandbar willow (*Salix exigua*), and California blackberry (*Rubus ursinus*). Elderberry shrubs (*Sambucus mexicana*), the host plant of the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*), which is Federally listed as threatened, were observed in the riparian habitat along the American and Sacramento Rivers.

1.4.4 Valley Elderberry Longhorn Beetle Habitat

The valley elderberry longhorn beetle (beetle) is completely dependent on its host plant, elderberry (*Sambucus* spp.), which is a common component of the remaining riparian forests and adjacent upland habitats of California's Central Valley. These forests consist of several canopy layers with a dense undergrowth (Katibah, 1983). Fremont cottonwood (*Populus fremontii*), California sycamore (*Platanus racemosa*), willows (Salix spp.), and valley oak (*Quercus lobata*) are common upper canopy species. The shrub layer consists of smaller trees and shrubs; representative species observed were poison oak (*Toxicodendron diversilobum*), sandbar willow (*Salix exigua*), and California blackberry (*Rubus ursinus*). Studies have found that the beetle is more abundant in dense native plant communities with a mature overstory and a mixed understory.

1.4.5 Oak Woodland

Valley oak woodland is dominated with valley oak, interior live oak, box elder, white alder, Oregon ash, and black walnut. Shrubs in this habitat type include California grape (*Vitis californica*), California blackberry (*Rubus ursinus*), and blue elderberry (*Sambucus cerulea*). Oak woodlands are typically found on higher or upland portions of the study area than the riparian habitat discussed above.

1.4.6 Green Sturgeon Benthic Habitat

Little is known about juvenile green sturgeon freshwater rearing. Green sturgeon are presumed to be generalist, opportunistic benthic feeders. Benthic substrate needs to include abundant prey items within estuarine habitats and soft bottom substrates for juvenile, subadult, and adult life stages. Prey species for juvenile, subadult, and adult green sturgeon within bays and estuaries primarily consist of benthic invertebrates and fishes, including crangonid shrimp, burrowing thalassinidean shrimp (particularly the burrowing ghost shrimp), amphipods, isopods, clams, annelid worms, crabs, sand lances, and anchovies. These prey species are critical for the rearing, foraging, growth, and development of juvenile, subadult, and adult green sturgeon within the bays and estuaries. The benthic substrate should include sediment quality (i.e., chemical characteristics) necessary for normal behavior, growth, and viability of all life stages. This includes sediments free of elevated levels of contaminants (e.g., selenium, PAHs, and pesticides) that can cause adverse effects on all life stages of green sturgeon.

1.5 Environmental Baseline

The ARCF action area includes the mainstem Sacramento River from Freeport (river mile [RM] 46) in the Delta upstream to the American River confluence (RM 60). The region also includes the lower American River from the confluence with the Sacramento River upstream to RM 11, NEMDC, Arcade Creek, Dry/Robla Creeks and Magpie Creek.

Downstream from the American River confluence, the Sacramento River is moderately sinuous (average sinuosity of 1.3), with the channel confined on both sides by man-made levees enhanced by decades of man-made additions. The channel in this reach is of uniform width, is not able to migrate, and is typically narrower and deeper relative to the upstream reach due to scour caused by the concentration of shear forces acting against the channel bed (Brice 1977). Channel migration is similarly limited along the lower American River because of man-made levees and regulated flows from Folsom Dam.

The natural banks and adjacent floodplains of both rivers are composed of silt- to gravel-sized particles with poor to high permeability. Historically, the flow regimes caused the deposition of a gradient of coarser to finer material, and longitudinal fining directed downstream (sand to bay muds). The deposition of these alluvial soils historically accumulated to form extensive natural levees and splays along the rivers, 5 to 20 feet above the floodplain for as far as 10 miles from the channel (Thompson 1961). The present day channels consist of fine-grained cohesive banks that erode due to natural processes as well as high flow events (Corps 2012).

Seasonal high flows enter the adjacent Yolo Bypass from this reach of the Sacramento River via the Sacramento Bypass (RM 63). Tidal influence emanating from Suisun Bay extends up the Sacramento River for 80 miles to Verona, with greater tidal variations occurring downstream during low river stages in summer and fall.

NEMDC is an approximately 13.3-mile, human-made, partially leveed drainage channel that provides drainage from Sankey Road and connects streams of the American Basin (Dry, Robla, and Arcade Creeks) to the American River. South of the confluence with Arcade Creek, the east and west levees of NEMDC are dominated by wild oats grasslands while the channel is characterized by Fremont cottonwood forest, with smaller amounts of valley oak woodland, smart-weed cocklebur patches, and perennial rye grass fields.

The approximately 16.2-mile-long channel of Arcade Creek extends east-to-west from Orangevale to the American River, via NEMDC. The north and south levees are dominated by wild oats grasslands. Valley oak woodland is the main riparian vegetation type along Arcade Creek, but Fremont cottonwood forest occurs in small patches along the easternmost reach of Arcade Creek near NEMDC. Hardstem bulrush marsh is found within Arcade Creek near Norwood Avenue while water primrose wetlands are predominant within the channel of Arcade Creek from approximately the confluence with NEMDC to Norwood Avenue. East of Norwood Avenue, the creek channel becomes narrower, and dominated by a shaded canopy of valley oak woodland.

The environmental baseline in the ARCF GRR action area includes the sites completed under the Water Resources Development Act (WRDA) 1996 and WRDA 1999 authorizations. The WRDA 1996 construction included installing slurry walls in the American River levees to address seepage and slope stability concerns. The WRDA 1999 construction included shape and slope improvements to specific reaches of the American River levee system and some segments of the Sacramento River levees.

1.6 Potential Project Impacts

A vegetation variance is being sought by the Sacramento District to comply with ETL 1110-2-583 on the waterside of the levee. The vegetation variance request requires the Corps to show that the safety, structural integrity, and functionality of the levee would be retained if the vegetation were to remain in place. This would allow most of the trees on the lower one half of the waterside slope to remain in place, reducing the impacts to vegetation and wildlife. In addition, a System Wide Improvement Framework (SWIF) agreement with the non-Federal sponsor would allow vegetation and encroachment compliance on the landside of the levee to be deferred and addressed by the local maintaining agency at a later time. This would be a beneficial effect to vegetation and wildlife, as standard long-term Operations and Maintenance (O&M) of the levee system in the study area would otherwise require the immediate removal of all vegetation. Vegetation impacts throughout the project area would occur in the proposed construction footprint.

Infestation of invasive weeds has an influence on hydraulic roughness during high-flow events, decreases the capacity of the floodway, and adversely affects bank erosion and sedimentation processes. The Corps would remove the noxious weeds from the various plant communities prior to construction. For each of the action alternatives, direct effects to stands of grassland habitat with invasive plants would result from clearing and grubbing and rock placement activities once levee improvements and construction begin. The total number of acres of grassland affected would be refined during the design phase.

The estimated impacts for the habitats discussed above and special-status species impacts as established in the BOs are shown below on Table 2.

Table 2. Impacts for ARCF GRR Recommended Plan.

	GGS Upland ***	GGS Aquatic ***	Riparian/ Western Yellow-billed Cuckoo **	SRA Habitat ***	Elderberry Shrubs **	Vernal Pools **	Delta Smelt Spawning **	Shallow Water **	Oak Woodland *	Wetlands

1.7 Habitat Evaluation

For the purposes of evaluating the impacts of the ARCF GRR on fish and wildlife resources in the project area, with a reliance on existing information in the spirit of SMART Planning, the Habitat Evaluation Procedures (HEP) for the *American River Watershed Investigation, Common Features Modifications, Mayhew Drain Site Project* were relied upon as a reference baseline. The HEP for the Mayhew Drain Site Project was conducted in 2005 to quantify anticipated impacts to fish and wildlife and their habitats, and to determine mitigation needs for the project. This HEP was selected for the ARCF GRR because the Mayhew Drain Site is located within the overall study area for the ARCF GRR, and the habitat type and value at the Mayhew site is consistent with the habitat that occurs throughout the ARCF GRR project area.

The HEP provided information for two general types of wildlife habitat comparisons: 1) the relative value of different areas at the same point in time; and 2) the relative value of the same areas at future points in time. By combining the two types of comparisons, the impacts of proposed project on wildlife habitat were quantified and compensation needs (in terms of acreage) for the project were determined. The assumption that habitat for selected wildlife species or communities can be numerically described by a model produces a Habitat Suitability Index (HSI). The HSI, a value from 0.0 to 1.0, provides a measure of habitat quality for a sample area in terms of suitability for the particular species or community being evaluated.

For the Mayhew Drain project, the Northern oriole Riparian woodland model was used because it best suited the habitat type in the project area. The quantity part of the formula is any measure of area which is appropriately sized for the study. The product of these two measures is comparable to "habitat value" which equals habitat quantity multiplied by habitat quality. This formula is expressed as a Habitat Unit (HU).

Habitat Type x Habitat Area = Habitat Value

The Average Annual Habitat Units (AAHUs) over the life of the project can then used to determine mitigation needs. The model, variables measured and data collection methods used for the Mayhew Drain Project are shown below in Table 3. For the ARCF GRR, data was estimated visually and using google earth.

Table 3. HSI model, Variables, and Data Collection Methods.

HSI Model and Cover-Type	HSI Model Variables	Data Collection Method
Northern oriole Riparian Woodland	V1 – Average height of deciduous tree canopy	Visual estimation
	V2- Percent deciduous tree crown cover	Densiometer along belt transects
	V3 – Stand width	Estimated using aerial photos

Since it is not possible to empirically determine habitat quality and quantity for future years, future HSI values were projected. This was accomplished by increasing or decreasing specific baseline variables and/or HSI values for each evaluation element for the Northern oriole based on best professional knowledge of performance at other mitigation sites, literature on plant growth, and conditions at reference sites. To predict changes in the HSI for each future scenario, it was necessary to make assumptions regarding baseline and future values within project impact and compensation areas. The assumptions made for the ARCF GRR with project can be seen in Table 4 and without project can be seen in Table 5 below.

Table 4. HSI Variables for the ARCF GRR Based on Habitat Values.

HEP - FUTURE WITH-PROJECT							
Time	**Variables**			**Suitability Index**			**Output**
	V1	**V2**	**V3**	**SI-V1**	**SI-V2**	**SI-V3**	**HSI**
TY1	20	25%	2	0.60	1.00	1.00	0.84
TY2	10	25%	2	0.30	1.00	1.00	0.67
TY25	20	75%	2	0.60	0.75	1.00	0.77
TY50	35	75%	2	1.00	0.75	1.00	0.91
HSI = (V1*V2*V3)^1/3						Average	0.80

Table 5. HSI Variables for the ARCF Without Project Based on Habitat Values.

HEP - FUTURE WITHOUT-PROJECT							
Time	**Variables**			**Suitability Index**			**Output**
	V1	**V2**	**V3**	**SI-V1**	**SI-V2**	**SI-V3**	**HSI**
TY1	35	75%	2	1.00	0.75	1.00	0.91
TY2	35	75%	2	1.00	0.75	1.00	0.91
TY25	35	75%	2	1.00	0.75	1.00	0.91
TY50	35	75%	2	1.00	0.75	1.00	0.91
HSI = (V1*V2*V3)^1/3						Average	0.91

The HSI value of 0.80 in Table 4 results from a temporal loss of habitat value and function from the removal of existing mature riparian habitat. This is due to the lower values given to mitigation plantings during the establishment period. The ARCF GRR proposes to implement riparian habitat mitigation at a 2:1 ratio. A 2:1 mitigation ratio is a reasonable requirement for implementation of mitigation for this habitat type, because the proposed project will decrease the connectivity of existing habitat along the Sacramento River system. Additionally, temporal loss of onsite habitat results in a reduction in value and function of the new vegetation within the mitigation areas as it grows to maturity. This also accounts for the loss of other services that riparian vegetation provides, including:

- An essential food source for fish and wildlife, including ESA species;

- Aquatic resting and refugia for resident and migratory fish species;
- Large woody debris recruitment;
- Nesting and rearing habitat for terrestrial wildlife species;
- Nutrients for the ecological system;
- Shade for the river which maintains water temperatures and dissolved oxygen concentrations; and,
- Increased habitat value for VELB.

The above-listed functions and services associated with a newly created acre of habitat are usually expected to be less than those associated with natural habitat. As a result the 2:1 mitigation ratio is appropriate to compensate for the loss of mature riparian habitats.

To determine whether the proposed mitigation amounts were cost effective, a Cost Effective /Incremental Cost Analysis (CE/ICA) was conducted. The CE/ICA report is included with this document as Appendix A. The Mayhew HEP and the Northern oriole HSI model variables were referenced to establish habitat values for the CE/ICA. The cost for mitigation was estimated for five scenarios for the purposes of the CE/ICA for both alternatives. These scenarios included: (1) maximized on- and off-site habitat creation; (2) maximizing the use of credits at a local mitigation bank; (3) a combination of on-site, off-site, and a mitigation bank at a 2:1 ratio; (4) a combination of on-site, off-site, and a mitigation bank at a 1:1 ratio; and (5) a combination of on-site, off-site, and a mitigation bank at a 3:1 ratio. Per the discussion above and the results shown in Table 4, the loss in ecological value associated with on-/off-site mitigation was reduced to an overall 0.8 habitat value. The Recommended Plan is the Alternative 2 Combination Plan with a 2:1 ratio, because it is the smallest mitigation proposal that accomplishes the terms and conditions of the Biological Opinions, and the CE/ICA determined that it was a cost effective plan.

1.8 Proposed Mitigation Measures

The preparation of mitigation plans, including objectives, plan design, determination of success criteria, and monitoring needs would be coordinated with Federal and State resource agencies to the greatest extent practicable. Mitigation objectives are specific actions to be taken to avoid and minimize adverse effects, such as Best Management Practices, compliance with Federal and State regulatory laws, and environmental commitments. Mitigation objectives include the identification of specific amounts of mitigation required to compensate for remaining unavoidable losses.

Items below present a summary of environmental commitments that the Corps would implement as part of the ARCF project to mitigate by avoiding and minimizing impacts and to meet the requirements, terms and conditions specified in the BOs.

- A vegetation variance is being sought by the Sacramento District to comply with ETL 1110-2-583 in order to exempting the Sacramento River and East Side Tributaries from vegetation removal in the lower third of the waterside of the levee prior to final construction and design phase. The ARCF GRR will be complying with the ETL on landside of the levee under a SWIF. This approval process is in alignment with the Corps' Levee Safety Program's goal of maintaining public safety as the primary objective and assuring application of consistent and well documented approaches. As a result, vegetation removed under the ARCF GRR would be limited to the footprint necessary in order to construct the proposed measures. Disturbance or removal of trees or larger woody vegetation would be replaced with native riparian species, outside of the vegetation free zone, as established in the ETL.
- The Corps would use a rock soil mixture to facilitate re-vegetation of the proposed project area. A (70:30) rock to soil ratio would be implemented. The soil-rock mixture would be placed on top of the of the rock revetment to allow native riparian vegetation to be planted to ensure that SRA habitat lost is replaced or enhanced. Alternatively, a rock lined soil trench approach could be taken.
- Vegetation removal, particularly tree removal, would be conducted between September 16 and January 31, to the extent feasible, to minimize potential loss of active bird nests and bat maternity roosts.
- Construction would be scheduled when listed terrestrial and aquatic species would be least likely to occur in the project area, approximately May or June through October, depending on the species present on a site-specific basis. If construction needs to extend into the timeframe that species are present, the Corps would coordinate with the resource agencies.

In addition to the mitigation measures described above, the Corps would implement compensatory mitigation, as described below.

The mitigation acreages for ARCF GRR were calculated using a combination of site surveys and aerial photography from Google Earth to determine where the project footprint impacted different habitat types. The habitat types included: riparian, SRA, giant garter snake (GGS), valley elderberry longhorn beetle (VELB), vernal pools, and Delta smelt shallow water. The acreages of each impacted habitat type were then broken up by reach.

Table 7 describes the types and amounts of habitat that would be potentially impacted by the project, the duration of the impacts, the amount of mitigation in total acreage per the USFWS and NMFS BOs and the recommendations of the USFWS Coordination Act Report, and projected costs as estimated according to existing mitigation prices.

Costs are displayed showing the difference between the estimate for on site mitigation or mitigation at a bank. Currently, permanent impacts to GGS uplands and aquatic habitat, vernal pools, Delta smelt spawning and shallow water habitat, and wetlands are proposed to occur at a mitigation bank. Riparian, SRA, elderberry, oak woodland, and green sturgeon are proposed to occur on site.

Table 7. Environmental Effects and Proposed Mitigation for the Recommended Plan.

Habitat Type	Potential Impacts	Duration of Impact	Mitigation (Acres/Linear Feet)	Cost at Mitigation Bank	Cost On- or Off-Site within Study Area
GGS Uplands	30 acres 75 acres	Permanent Temporary	90 acres 75 acres	$4,500,000	N/A*
GGS Aquatic	15 acres	Permanent	45 acres	$2,250,000	
Riparian	150.6 acres	Permanent	301.2 acres		$16,566,000
Shaded Riverine Aquatic Habitat	82,325 lf	Permanent	82,325 lf		$19,020,000**
Elderberry Shrubs	3,292 stems	Permanent	1,715.6 credits 70.89 acres		$6,026,000
Vernal Pools	0.25 acre	Permanent	0.5 acre	$138,000	---
Green Sturgeon	20 acres	Permanent	Restore acres, monitoring, and fish passage features		$16,259,000
Delta Smelt Spawning Habitat	34 acres	Permanent	34 acres	$4,160,000	
Shallow Water Habitat (Delta Smelt)	14 acres	Permanent	42 acres	$5,460,000	
Oak Woodland	2 acres	Permanent	4 acres		$200,000
Wetlands	0.4 acres	Permanent	0.8 acres	$130,000	---
Sub-Total				**$16,775,000**	**$58,341,000**

* 75 acres of temporary effects to GGS habitat from the relocation of the Sacramento Bypass toe drain would consist of standard site restoration erosion control features such as hydroseeding. This is contained within construction costs and is not considered a mitigation cost. It is presented in this plan due to monitoring requirements, as described in Section 2.1 below.
** SRA habitat mitigation is provided in the project's cost estimate as a separate construction cost rather than a mitigation cost, since it is a feature of the bank protection designs and would be included as a part of the construction contract. The cost is displayed under the Fish and Wildlife Facilities account as "Construction" costs and is estimated to be approximately $231 per linear foot.

1.9 Location of Mitigation and Compensation Sites

WRDA 2007 Section 2036(c) directs the Corps to, where appropriate, first consider the use of an approved mitigation bank to compensate for wetland impacts. Credits for additional habitat types, including riparian zones, is also permitted, if credits are available and the use of them is deemed appropriate. As discussed above, the Corps proposes to purchase credits at a mitigation bank for permanent impacts to GGS uplands and aquatic habitat, vernal pools, Delta smelt spawning and shallow water habitat, and wetlands. As a result, these habitat types are not discussed further in this document, because the mitigation bank would be responsible for all site establishment, monitoring, adaptive management measures, and for achieving mitigation success.

The onsite mitigation proposed for the ARCF GRR consists of riparian, SRA, oak woodland, elderberry habitats, all of which are components of the riparian habitat corridor along the Sacramento River. Section 4.a.3 of WRDA 2007 Section 2036(c) implementation guidance states that credits for riparian habitat may be purchased at a mitigation bank, but are not required to be as a first order preference. All of these habitats contribute to the riparian corridor of the Sacramento and American Rivers. As described in Section 1.7 above, the removal of 268 acres of riparian, SRA, oak woodland, and elderberry habitat under the ARCF GRR could adversely affect ESA species within the project area if the function and services provided by riparian habitat is relocated away from the Sacramento River and American River riparian corridors. Additionally, credits are not available for the quantity of riparian habitat being removed for the ARCF project and mitigation requirements would likely increase if the projects proposed all mitigation offsite. As a result, it is appropriate to select on- and off-site mitigation within the study area for these habitat types rather than purchasing credits at a mitigation bank.

Upon completion of construction, sites with preexisting habitat would be restored to pre-construction conditions, where feasible. Sites compatible with on-site mitigation such as the 75 acres of upland GGS habitat and 82,325 linear feet of SRA habitat would be restored in place. Riparian habitat, elderberry compensation, and oak woodland habitat would be mitigated on-and off-site within the project area to the greatest extent practicable. The specific locations for offsite mitigation along the American River would be coordinated with the Sacramento County Department of Parks and Recreation (County Parks) during the design phase of the project.

On-site mitigative features are proposed as part of the bank protection construction to mitigate for impacts to SRA habitat. These features would be designed on a site-specific basis during the design phase and would include a planting berm as shown on Figure 1 above. Riparian vegetation installed on the planting berm would include large woody species such as Fremont cottonwood (*Populus fremontii*), California sycamore (*Platanus racemosa*), and valley oak (*Quercus lobata*), white alder (*Alnus rhombifolia*), and box elder (*Acer negundo var. californicum*); shrub-scrub species such as elderberry (*Sambucus* spp.), redbud (*Cercis canadensis*), and coyote brush (*Baccharis pilularis*); and understory species such as California rose (*Rosa californica*), California blackberry (*Rubus ursinus*), and wild grape (*Vitus californica*); and native grasses such as annual fescue (*Vulpia* spp.), California brome (*Bromus* *carinatus*), blue wildrye (*Elymus glaucus*), and needle grass (*Nassella* spp.).

The Corps is committed to implementing project conservation and mitigation as detailed in the BOs, however site selection and real estate coordination has not occurred at this time for onsite and offsite mitigation and would be determined during the design phase of the project. This HMMAMP will accompany the final EIS/EIR, and will be updated throughout the design phase as detailed design efforts allow for finalizing the mitigation plans. The HMMAMP will be coordinated with the Services during the design phase and updated as needed. The Corps would go through the following process in order to determine sites for implementing compensation for impacts to riparian habitat, including VELB compensation sites:

- The Corps would assess opportunities to purchase credits at a mitigation bank as a first option.
- The Corps would assess opportunities for on-site compensation to replace the habitat function and services that would be impacted within the study area. This assessment would include considering site-specific conditions, including whether the site is protected from future erosion by bank protection, or remains at risk of berm and vegetation loss due to the launchable rock trench.
- If on-site compensation is not possible, the Corps would evaluate opportunities to expand existing Corps mitigation sites within the American River Parkway, such as the River Bend Park mitigation site.
- If the Corps requires additional lands for compensation, other opportunities within the American River Parkway would be assessed in coordination with County Parks, USFWS, NMFS, and the American River Flood Control District.

Although much of the mitigation would occur on-site, for riparian, SRA, elderberries, oak woodland, and green sturgeon benthic habitat, some mitigation would be compensated for through the purchase of credits from approved mitigation or conservation banks. Mitigation bank credits are available within the project watershed for riparian habitat, elderberry shrubs, and oak woodland on the Sacramento River.

1.10 Compensation Timing

Compensation timing refers to the time between the initiation of construction at a particular site and the attainment of the habitat benefits to targeted species from designated compensation sites. For example, compensation time would be the time required for on-site plantings to provide significant amounts of shade or structural complexity from instream woody material recruitment to provide habitat for fish species. Significant long-term benefits have often been considered as appropriate to offset small short-term losses in habitat for listed species in the past, as long as the overall action contributes to recovery of the listed species. The authority to compensate prior to or concurrent with project construction is given under WRDA 1986 (33 United States Code [USC] § 2283). Additionally, ER 1105-2-100, Appendix C states that authorized ecological resource mitigation activities and features should occur before construction of the project, concurrent with the acquisition of lands, or concurrent with the physical construction of the project.

2.0 Mitigation and Management Strategy

The purpose of this HMMAMP is to present conceptual mitigation proposals, establish performance standards, and outline adaptive management tasks and costs. Conceptual mitigation proposals are based on the habitat impacts described above. Performance standards are established below for each habitat type, and monitoring would be conducted with the intent of meeting those standards. Over the 3 to 5 year site establishment period, improvements in field and analytic techniques may lead to changes in the monitoring methodology. While this vegetation and habitat monitoring methodology protocol builds on past years' experiences, it is likely that other opportunities for improvement will be identified in the future that should be incorporated into the protocol. In the future, there may be a determination that specific performance standards have been met and that associated monitoring tasks could cease. Similarly, it could be determined that a monitoring task was not returning useful information, and therefore not worth the expense of continuation.

Monitoring must be closely integrated with adaptive management. The application of adaptive management principles to mitigation projects by modifying mitigation objectives during the monitoring period is a reasonable and foreseeable alternative. Unrealistic expectations or inaccurate assumptions can lead to the establishment of inappropriate project objectives. It is possible that a decision to modify success criteria might be reached based on results after several years of monitoring. In addition to modifying project objectives, there is a potential for changes to or adaptation of management actions based on monitoring results. The purpose of adaptive management is to enable strategic changes to improve the mitigation sites to functioning habitat.

Vegetation and habitat variable monitoring and data collection would occur annually by a qualified biologist, botanist, or habitat restoration specialist using the protocol described below and shown in Table 8 to determine the success of riparian revegetation plantings and overall habitat development.

The project's compensation objective is to directly mitigate for the loss of habitat value that results from construction impacts. This plan focuses on establishing successful and diverse habitats that provide an ecological value consistent with mature existing habitat conditions in the study area. The specific habitats focused on within the sections below are the habitats that would be created by the Corps on-site or off-site, including GGS upland habitat, habitat for VELB, and habitat for green sturgeon. In addition, mitigation sites would be created which present a combination of riparian, oak woodland, and SRA habitats, which are highly related and provide value to a number of listed species, including VELB, Western yellow-billed cuckoo, and fish species.

Table 8. Summary of On-site Habitat Types and Monitoring Recommendations.

Habitat	Monitoring Variable	Method to be Used	Spacing/number of Samples	Data to be Collected	Success Criteria
GGS Upland	Total Herbaceous Species Cover	Visual estimates of cover within 1 square meter (m^2) sampling quadrats	One quadrat randomly located in each planting zone	Herbaceous species composition, total cover, and observation of GGS	Meeting 75% native species present and 95% overall cover onsite within 1 year
Riparian Habitat	Vegetation Species Cover (Ground and Canopy)	Line-intercept estimates of ground and overhead canopy cover with visual estimates of vigor	Monitoring transects; number of transects and spacing dependent on site length	Woody species composition, growth, and natural recruitment	75% vegetative cover after 5 years
SRA Habitat	Shaded Riverine Aquatic (SRA) Cover	Line-intercept estimates of canopy cover overhanging the river	Transect parallel to the shoreline along summer mean water surface elevation (SMWSE); length of transect dependent on site length	Woody species composition and percentage of canopy cover overhanging river (shade)	75% vegetative cover after 5 years
Elderberry	Elderberry and Native Vegetation Health and Vigor (VELB habitat)	Visual assessment of vegetation health and vigor; census of VELB and exit holes	Total census of elderberry shrubs and native vegetation, census of VELB and exit holes	Total survival of elderberry and native vegetation, census of VELB and exit holes	Survivability of 60% shrubs*; 75% vegetative cover after 5 years
Oak Woodland Habitat	Woody Species Overhead Canopy Cover	Line-intercept estimates of overhead canopy cover and visual estimates of vigor	Monitoring transects; number of transects and spacing dependent on site length	Woody species composition, growth, and natural recruitment	75% vegetative cover after 5 years
Green Sturgeon Benthic Habitat	In-water slope and substrate	Substrate sampling and visual assessment of slope/substrate conditions.	Monitoring the width and depth of the river at regular intervals throughout the project area.	Substrate content, percentage of fines, slope defining measurements.	Slope (H:V) of 2:1 with substrate at average of 0-10 inches.

*60% survivability is the established survival criteria for elderberry shrubs in the USFWS Conservation Guidelines for the Valley Elderberry Longhorn Beetle (1999).

2.1 GGS Uplands Mitigation

2.1.1 Objectives and Implementation Strategy

The primary objective of upland habitat mitigation is to restore upland refugia habitat for the giant garter snake (*Thamnophis gigas*) (GGS) in a manner consistent with adjacent equitable habitat. Upland refugia habitat is generally considered native grasslands with space appropriate for basking, cover, and retreat sites for GGS. Upland refugia is also considered higher elevation areas for cover and refuge from flood waters. Upland refugia restoration would take place on grasslands adjacent to GGS wetland habitat as well as levee slopes for higher elevation refuge. These conservation and restoration measures are taken from the Guidelines for Restoration and/or Replacement of Giant Garter Snake Habitat (USFWS, 1997).

Restoring GGS habitat includes minimizing the potential impacts of project activities to the existing habitat. Use of silt fencing and protective mats to prevent runoff and reduce the possibility of individual GGS from entering the project area is recommended. Designation of environmentally sensitive areas and providing worker awareness training is also recommended. Construction activities should be 200 feet from GGS aquatic habitat, and should occur between May 1 and October 1. Project areas should be surveyed for GGS 24 hours prior to ground disturbing activities, and surveys should be repeated if a lapse in construction activity of two weeks or greater has occurred. If aquatic habitat must be removed as part of the construction activities, any dewatering would occur after April 15 and dewatered habitat would be left dry for at least 15 consecutive days.

Upon the completion of construction, the area would be regraded to the preexisting contour. Upland refugia would be hydroseeded with native grasses. USFWS recommends a mix of native grass seeds such as annual fescue (*Vulpia* spp.), California brome (*Bromus carinatus*), blue wildrye (*Elymus glaucus*), and needle grass (*Nassella* spp.). Additional native plant seeds consistent with adjacent habitat may be used at the discretion of USFWS. Permanent irrigation would not need to be established for this habitat type, however the site would require periodic watering in drought conditions.

2.1.2 Success Criteria

Monitoring of GGS upland habitat would focus on: (1) the percentage cover of native species, and (2) the percentage of overall vegetative cover. The restored habitat would be considered successful if 75 percent of the vegetation on site consists of native species. Additionally, the overall vegetative cover on site must be 95 percent.

2.1.3 Mitigation Monitoring Strategy

Restored habitat should be monitored for one year following implementation. Surveys would involve a general overview of the condition of the site, an estimate of ground cover, and a passive (observation only) GGS survey to determine potential habitat use. A ground cover survey would occur to determine the ground cover percent of native and non-native species. Ground cover surveys, if determined by the Corps to be needed to evaluate the success of the mitigation area, would involve the use of a one square meter quadrat placed haphazardly in the restored areas. Once placed, all herbaceous vegetation within the quadrat would be recorded to species level. The percent of cover by native and non-native species would be determined in addition to the percent of total cover.

Monitoring reports documenting the restoration effort would be submitted to USFWS upon completion of the restoration implementation and one year from restoration implementation. Monitoring reports would include photos, the timing of the completion of the restoration, what materials were used in the restoration, plantings (if specified), and justification of any substitutions to USFWS recommended guidelines. Monitoring reports would also include recommendations for additional remedial actions, if necessary.

2.1.4 Adaptive Management Strategy

If the habitat is not meeting the success criteria established above, then adaptive management would be implemented in order to ensure that the habitat establishment is successful. The following subsections identify triggers that would indicate the need to implement adaptive management measures and the measures that would be implemented accordingly.

Adaptive Management Triggers

- Desired Outcome: Increase percent cover of GGS upland habitat.

  Trigger: 95% cover is not achieved within one year.

- Desired Outcome: Decrease percent of non-native invasive species that outcompete natives.

  Trigger: Non-native percent cover of more than 25% within one year.

Adaptive Management Measures

If the triggers established above occur, the following measures would be implemented for GGS upland habitat in order to adaptively manage the site for success.

- If the performance criteria are not met within one year, additional monitoring would be implemented in order to ensure that the site is successful.
- If non-native species are outcompeting the native species, measures would be implemented to manage presence of invasive species, including mowing and selective removal of non-native species at optimal times for native growth.
- If non-native species are outcompeting the native species and targets for overall cover are not being met, then revegetation of native species would occur.
- Supplemental watering if targets for overall cover are not being met.

2.2 Riparian, Oak Woodland, and Shaded Riverine Aquatic Habitat

2.2.1 Objectives and Implementation Strategy

The primary objective of riparian habitat mitigation is to compensate for impacted habitat types and community types, and reduce erosion rates within the alluvial floodplain. Native plant communities and streambank vegetation would be represented in species density appropriate to the surrounding area. As native vegetation matures, it helps to stabilize stream banks and shorelines; provides food, shelter, shade, and access to adjacent habitats; nursery habitat; pathways for movement by resident and nonresident aquatic, semi-aquatic, and terrestrial organisms; and improves and protects water quality by reducing the amount of sediment and other pollutants such as pesticides, organic materials, and nutrients in surface runoff. The long term goal of riparian mitigation is to provide habitat similar to the habitat that was impacted by project construction. These improvements would enhance nesting opportunities for native bird species, and provides opportunities to satisfy VELB compensation. Oak woodland and SRA habitat are considered components of riparian habitat with specific functions within the ecosystem.

Riparian vegetation would include large woody species such as Fremont cottonwood (*Populus fremontii*), California sycamore (*Platanus racemosa*), valley oak (*Quercus lobata*), white alder (*Alnus rhombifolia*), and box elder (*Acer negundo var. californicum*); shrub-scrub species such as elderberry (*Sambucus spp.*), redbud (*Cercis Canadensis*), and coyote brush (*Baccharis pilularis*); and understory species such as California rose (*Rosa californica*), California blackberry (*Rubus ursinus*), and wild grape (*Vitus californica*); and native grasses such as annual fescue (*Vulpia* spp.), California brome (*Bromus carinatus*), blue wildrye (*Elymus glaucus*), and needle grass (*Nassella* spp.). Native trees and shrubs provide a buffer to adjacent urban and industrial land uses, and provide habitat structure for wildlife. Leaf litter and large organic debris would create a variety of microhabitats, increasing species diversity and potentially creating a prey base for larger predators.

SRA habitat consists of riparian trees and shrubs growing on the bank and over-hanging the channel that provide instream shade for the water column adjacent to the bank and deposit insects, organic matter, and nutrients into the river. Shade from the vegetation helps to cool water temperatures in the river. SRA is especially important to juvenile salmonids as they migrate down the river to the sea. Terrestrial insects that live on riparian vegetation fall into the river and provide an important food source for fish. Proposed SRA mitigation would occur on the planting berms designed into the bank protection sites along the American and Sacramento Rivers, as shown in Figures 1 and 2 above. Riparian trees and shrubs would be installed in the planting berms, and existing large trees would be protected in place on the lower waterside slope of the levee. Implementation of this SRA habitat mitigation, including protecting large trees in place, is part of the recommended plan and is reliant on the approval of a vegetation variance, which will be sought during the design phase of the project.

The primary objective of oak woodland mitigation, which would occur in the upland zone of the riparian habitat, is the establishment of mature valley oaks and savannah. Planting would generally occur during the late fall when the plants are dormant and soils are moist. Establishment of woody vegetation would likely require multiple techniques including transplants, cuttings, acorn plantings, and seedlings.

Riparian and oak woodland mitigation sites would likely require fencing to protect establishing habitats from recreation, wildlife, and other potential damages. Sites would have irrigation during the establishment period, and would be watered as needed until the vegetation is established and self-sustaining. Mowing would occur periodically to ensure that weed species do not shade out new plantings.

SRA habitat would be established in planting berms along the river. These sites could require beaver fencing. Sites would have temporary irrigation during the summer, and would be watered as needed until the vegetation is established and self-sustaining. A weed eater would be used to ensure that weed species do not shade out new plantings.

2.2.2 Success Criteria

Monitoring of riparian, oak woodland, and SRA habitats would focus on: (1) the percent cover of native plant species; (2) presence of at least five native species contributing to structural diversity; (3) percentage of canopy cover over water; and (4) decrease percent cover of non-native invasive species that out-compete natives. Additionally, an inventory of wildlife species would be recorded during annual monitoring. Table 9 establishes the percentages required to meet these performance standards. If the habitat is meeting these performance standards, conditions should be consistent enough to estimate community composition and general success of planting efforts. Table XX establishes the percentages required to meet these performance standards.

Table 9. Riparian, Oak Woodland, and SRA Habitat Performance Standards.

Performance Standard	Quantitative Measure
Percent cover of native plant species	75%
Structural diversity	At least five native species contributing to 75% canopy and 50% shrub cover
Percent of canopy cover over water per LF	75%
Percent cover of non-native species	Less than 15%

2.2.3 Mitigation Monitoring Strategy

The following monitoring procedures will provide the information necessary to evaluate the success of riparian, oak woodland, and SRA habitat mitigation. Vegetation sampling will occur annually for the duration of the monitoring period. Sampling will occur during spring months, at the peak of growing season, and will consist of permanent field monitoring plots along one or more transects either perpendicular to the river or parallel to the floodplain slope. Plots will be located randomly within each site, and the distance between plots and along transects will be site specific. Woody species with overhead canopy cover that falls along the vegetation monitoring transect, including those that were planted, have recruited naturally to the site, or were existing at the site prior to planting efforts would be recorded. Monitoring will measure percent cover of native and non-native plant species, structural diversity, and percent cover over water. Photograph stations are also important for documenting vegetation conditions. All plots and photograph stations will be documented via Global Positioning System (GPS) coordinates to maintain consistency throughout the monitoring period.

Additionally, field personnel would visually estimate the height (+/- 2 feet) of each tree and shrub that provides overhead canopy cover. Exact heights are not necessary, since there is no tree height criterion included in this protocol. Rather, approximate tree heights would be visually assessed to monitor tree growth over time. Data collected would include species name, location (feet) along the vegetation monitoring transect (upper extent of canopy and lower extent of canopy), whether the tree or shrub is planted (P), recruited (R), or existing (E), height (feet), and vigor as determined using the metric outlined in Table 10, below.

Table 10. Estimation of General Health and Vigor for Plant Species.

Visual Estimate of Foliage	Vigor Category	Value
81 percent (or greater) of foliage appears to be healthy	Excellent	4
51 to 80 percent of foliage appears to be healthy	Good	3
25 to 50 percent of foliage appears to be healthy	Fair	2
Less than 25 percent of foliage appears to be healthy	Poor	1
Dead	Dead	0

General observations, such as fitness and health of plantings, native plant species recruitment, and signs of drought stress would be noted during the surveys. Additionally, potential soil erosion, flood damage, vandalism and intrusion, trampling, and pest problems would be qualitatively identified. A visual check of irrigation infrastructure and fencing would also be conducted. A general inventory of all wildlife species observed and detected using the mitigation site would be documented. Nesting sites and other signs of wildlife use of the newly created habitat would be recorded.

Monitoring reports documenting the restoration effort would be prepared following the first monitoring period and would continue annually until the site has met the success criteria. Monitoring reports would include photos, the timing of the completion of the restoration, what materials were used in the restoration, and plantings (if specified). Monitoring reports would also include recommendations for additional adaptive management measures, if necessary. Following this initial establishment period, any subsequent monitoring activities would be the responsibility of the local maintaining agency, and would focus primarily on general and biological inspections for the purposes of fire management and habitat evaluation.

2.2.4 Adaptive Management Strategy

If the habitat is not meeting the success criteria established above, then adaptive management would be implemented in order to ensure that the habitat establishment is successful. The following subsections identify triggers that would indicate the need to implement adaptive management measures and the measures that would be implemented accordingly.

Adaptive Management Triggers

- Desired Outcome: Increase percent cover of native riparian habitat.

  Triggers: If 50% cover of native riparian habitat is not achieved within 3 years, or 75% cover of native riparian habitat is not achieved within 5 years.

- Desired Outcome: Maintain appropriate structural diversity of native riparian habitats.

  Trigger: Suitable structural diversity is not achieved, if canopy cover and/or shrub cover does not achieve 50% within 5 years.

- Desired Outcome: Increase percent vegetative cover over water per linear foot to support native fish.

  Trigger: If percent cover over water is not 30% within 3 years, and 50% within 5 years.

- Desired Outcome: Decrease percent cover of non-native invasive species that outcompete natives.

  Trigger: If non-native percent cover is greater than 15% during the monitoring period.

Adaptive Management Measures

If the triggers established above occur, the following measures would be implemented for riparian, oak woodland, and SRA habitat in order to adaptively manage the site for success.

- Replanting may be needed if triggers for vegetative cover, vegetative cover over water, and/or structural diversity are being met. Monitoring results should be used to assess the underlying cause of inadequate cover, which may require that additional adaptive management actions be implemented to support successful replanting. Adaptive management actions could include targeted revegetation, such as replanting varieties of species that are exhibiting the greatest growth and survival, or planting at elevations that are exhibiting the greatest growth and survival.
- Nonnative species management may be needed if monitoring results show that the triggers for nonnative species present are met, or if nonnative species are impacting the survival of native species. Adaptive management measures may include adjustments to nonnative control methods, such as plant removal, grading of site to remove nonnative roots, or mowing and selective removal of non-native species at optimal times for native growth.
- Irrigation and/or supplemental water may be needed if vegetation is not meeting success criteria, or if species are exhibiting signs of water stress. Assessment of monitoring results may show that drought conditions are causing poor establishment or die off of planted vegetation. Adaptive management actions would include supplemental water to support achievement of percent cover criteria and structural diversity.
- Plant protection may be needed if triggers for vegetative cover and/or structural diversity are being met. If monitoring results show that plantings are failing due to predation or trampling from human use, then adaptive management actions would include plant cages or protective fencing that could be installed to protect plantings.

2.3 Elderberry Shrubs

2.3.1 Objectives and Implementation Strategy

The primary objective of elderberry shrub mitigation is to compensate for the adverse effects of the project on habitat important to the Federally listed valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) (VELB). Where possible, conservation areas would connect with adjacent habitat in order to prevent isolation of beetle populations. Removal, transplanting, and establishment of elderberry shrubs would be coordinated with USFWS and would follow the USFWS Conservation Guidelines for the valley elderberry longhorn beetle (USFWS, 1999).

Elderberry shrubs with one or more stems measuring one inch or greater in diameter at ground level must be transplanted if they cannot be avoided by the proposed project. Elderberry shrubs should be transplanted when they are dormant, typically from November to the first two weeks in February. Transplanting during the non-growing season would reduce shock to the plant and increase transplantation success. Most transplants require watering through the first summer.

Elderberry stems measuring greater than one inch in diameter are considered habitat for the VELB and trimming or removal of stems would require coordination and mitigation. Each elderberry stem that is adversely affected must be replaced in the conservation area with elderberry seedlings or cuttings as specified by USFWS. Seedlings and cuttings should be obtained from local sources. If the project site is in the vicinity of the conservation area, cuttings may be obtained from elderberry shrubs to be transplanted

Mitigation site planting areas must be at least 1,800 square feet for each elderberry transplant. As many as five additional elderberry plantings (cuttings or seedlings) and up to five associated native species plantings may also be planted within the 1,800 square foot area with the transplant. Studies have found that the VELB is more abundant in dense native plant communities with a mature overstory and a mixed understory. Therefore, a mix of native riparian species such as Fremont cottonwood (*Populus fremontii*), California sycamore (*Platanus racemosa*), valley oak (*Quercus lobata*), box elder (*Acer negundo*), white alder (*Alnus rhombifolia*), and California button willow (*Cephalanthus occidentalis californica*) would be planted along with the elderberry shrubs. Stock of saplings, cuttings, and seedlings would be obtained from local sources. Planting or seeding the area with native herbaceous species is also encouraged. Weeds and other non-native plants would be removed by mechanical means at least once a year or at the discretion of USFWS.

No pesticides, herbicides, fertilizers, or other chemical agents would be used in or within 100 feet of the conservation area. Fencing would be placed around the conservation area during the establishment period of the elderberry shrubs. Signs would be posted on the fence stating the status of the VELB and the purpose of the habitat. The conservation area would be protected in perpetuity as habitat for the VELB. Conservation areas may be transferred to resource agencies or appropriate private organizations for long term management. Biologists and law enforcement personnel from the California Department of Fish and Wildlife and USFWS must be given complete access to the project site to monitor transplanting activities. Personnel from these agencies must also be given complete access to the conservation area to monitor the beetle and its habitat in perpetuity.

2.3.2 Success Criteria

After the first year, it is anticipated that the sites would be evaluated to determine the level of project success and apply adaptive management, if necessary. If the habitat meets the below performance standards for three consecutive years, depending on physical site characteristics, conditions should be consistent enough to estimate community composition and general success of planting efforts. Three consecutive years of success should indicate that the project sites are self-sustaining and should not require supplemental irrigation or intensive weed control. Following this initial establishment period, any subsequent monitoring activities would be the responsibility of the local maintaining agency, and would focus primarily on general and biological inspections for the purposes of fire management and habitat evaluation.

Monitoring of elderberry habitats would focus on a minimum survival rate of at least 60 percent of the elderberry shrubs. Within one year of discovery that survival has dropped below 60 percent, additional plantings would be installed to bring survival above this level. Monitoring of associated riparian habitat would focus on: (1) the percent cover of native plant species; (2) presence of at least five native species contributing to structural diversity; and (3) decrease percent cover of non-native invasive species that out-compete natives. Additionally, an inventory of wildlife species would be recorded during annual monitoring. Table 11 establishes the percentages required to meet these performance standards. If the habitat is meeting these performance standards, conditions should be consistent enough to estimate community composition and general success of planting efforts.

Table 11. Elderberry and Associated Riparian Habitat Performance Standards.

Performance Standard	Quantitative Measure
Percent survivability of elderberry shrubs	60%
Percent cover of native riparian species	75%
Structural diversity	At least 5 native species contributing to 75% canopy and 50% shrub cover
Percent cover of non-native species	Less than 15%

2.3.3 Mitigation and Monitoring Strategy

Monitoring would be conducted annually per the USFWS Conservation Guidelines for the valley elderberry longhorn beetle (USFWS, 1999). Two surveys would be conducted by qualified biologists between February 14 and June 30 of each year until the mitigation has met the success criteria. Surveys would include:

1. An evaluation of the elderberry plants and associated native plants on the site, including the number of plants, their size and condition.
2. Presence of the adult beetles, including the number of beetles observed, their condition, behavior, and their precise locations.
3. Presence of beetle exit holes in elderberry stems, noting their locations and estimated ages.
4. An evaluation of the adequacy of the fencing, signs, and weed control efforts in the avoidance and conservation areas.
5. A general assessment of the habitat, including any real or potential threats to the beetle and its host plants, such as erosion, fire, excessive grazing, off-road vehicle use, vandalism, excessive weed growth, etc.

A written report presenting and analyzing the data from the project monitoring would be prepared following the surveys, and would be submitted by December 31 of the same year to USFWS. The report would address the status and progress of the transplanted and planted elderberry shrubs, associated native plants and trees, and any failings of the conservation plan and the steps taken to correct them. Any observations of beetles or fresh exit holes must be noted. Copies of original field notes, raw data, and photographs of the conservation area would be included with the report. A vicinity map of the site and maps showing where the individual adult beetles and exit holes were observed would also be included. The survival rate, condition, and size of the elderberry and associated native plants would be analyzed in the report. Real and likely future threats would be addressed along with suggested remedies and preventative measures (such as limiting public access, more frequent removal of invasive non-native vegetation, etc.).

2.3.4 Adaptive Management Strategy

If the habitat is not meeting the success criteria established above, then adaptive management would be implemented in order to ensure that the habitat establishment is successful. The following subsections identify triggers that would indicate the need to implement adaptive management measures and the measures that would be implemented accordingly.

<u>Adaptive Management Triggers</u>

- Desired Outcome: Increase percent survivability of elderberry shrubs.

  Triggers: If 60% survivability is not achieved during the monitoring period.

- Desired Outcome: Increase percent cover of native riparian habitat.

  Triggers: If 50% cover of native riparian habitat is not achieved within 3 years, or 75% cover of native riparian habitat is not achieved within 5 years.

- Desired Outcome: Maintain appropriate structural diversity of native riparian habitats.

  Trigger: Suitable structural diversity is not achieved, if canopy cover and/or shrub cover does not achieve 50% within 5 years.

- Desired Outcome: Decrease percent cover of non-native invasive species that outcompete natives including elderberry shrubs.

  Trigger: If non-native percent cover is greater than 15% during the monitoring period.

Adaptive Management Measures

If the triggers established above occur, the following measures would be implemented for VELB habitat in order to adaptively manage the site for success.

- Replanting may be needed if triggers for vegetative cover and/or survivability are being met. Monitoring results should be used to assess the underlying cause of inadequate cover or survival, which may require that additional adaptive management actions be implemented to support successful replanting. Adaptive management actions could include targeted revegetation, such as replanting at elevations that are exhibiting the greatest growth and survival.
- Nonnative species management may be needed if monitoring results show that the triggers for nonnative species present are met, or if nonnative species are impacting the survival of native species including elderberry shrubs. Adaptive management measures may include adjustments to nonnative control methods, such as plant removal, grading of site to remove nonnative roots, or mowing and selective removal of non-native species at optimal times for native growth.
- Irrigation and/or supplemental water may be needed if vegetation is not meeting success criteria, or if species are exhibiting signs of water stress. Assessment of monitoring results may show that drought conditions are causing poor establishment or die off of planted vegetation. Adaptive management actions would include supplemental water to support achievement of percent cover criteria and structural diversity.
- Plant protection may be needed if triggers for vegetative cover and/or survivability are being met. If monitoring results show that plantings are failing due to predation or trampling from human use, then adaptive management actions would include plant cages or protective fencing that could be installed to protect plantings.

2.4 Green Sturgeon

2.4.1 Objectives and Implementation Strategy

The ARCF GRR project will restore existing or create new habitat to compensate for the quality and quantity of green sturgeon habitat (including soft bottom benthic substrate) permanently impacted by project construction. If possible, this would occur at a mitigation bank, however currently no mitigation banks in the Sacramento area provide credits for green sturgeon habitat.

If onsite mitigation is not possible, and there are no mitigation banks available, then compensation for green sturgeon habitat would occur within the north Delta in as close of a proximity to the study area as possible. The non-Federal sponsor supports green sturgeon mitigation, has the capability to implement the mitigation, and would participate in implementation of this mitigation in coordination with the Corps. Based on current best available science, there are limited opportunities for habitat creation within the study area. Created or restored habitat would be designed in coordination with NMFS and would be based on the primary constituent elements (PCEs) of critical habitat such as food availability, water flow, water quality, migration corridors, and sediment quality. Successful establishment of onsite mitigation or creation of offsite habitat will be determined through the success criteria in Section 2.6.3 below.

2.4.2 Success Criteria

The overall performance standard for green sturgeon habitat is based on the establishment of slope and substrate, with a focus on a suitable range of conditions for rearing juvenile green sturgeon developed from SAM. Slope and substrate are critical components of habitat for rearing juvenile green sturgeon. Slope is used as an indicator of shallow water refuge for juveniles as well as food and resting areas. Substrate size is used as an indicator of juvenile refuge from predators, suitable predator habitat, and food availability for juvenile and adult life stages of focus fish. Table 12 below establishes the suitable range of substrate and slope that must be met for each year of monitoring. Slope and substrate would be monitored yearly along with other potential variables discussed below. The monitoring will continue until all performance standards have been achieved for three consecutive years.

Table 12. Green Sturgeon Habitat Performance Standards.

	Acceptable Range
Slope (H:V)	>2:1
Substrate (average size, inches)	0 – 10

Note: Based on outputs from the SAM model. The Corps, in coordination with NMFS, determined that these outputs from the SAM model are the most likely outputs that would remain relevant to sturgeon with improved baseline condition data.

As stated previously, there is insufficient knowledge of the species' relationship to many habitat attributes; however, there may be opportunities to incorporate additional habitat attributes into the evaluation process. Experts at the Corps Engineering Research and Design Center would be engaged in order to develop a post-construction sampling and monitoring plan that would be refined during PED based on any improvements in the understanding of the species at that time. Potential habitat attributes that could be incorporated into success criteria following preconstruction monitoring and the development of the EFM model include:

- Food Resources – Benthic invertebrates and fishes (various species of shrimp, amphipods, isopods, clams, annelid worms, crabs, sand lances, and anchovies) can be measured in terms of biomass loss, gain, or recovery rate. The impact on the benthic environment can be quantified within the footprint and adjacent to the footprint. Grab samples would be collected at various points of the river. These samples would be analyzed in order to determine the bed material and any change in presence of benthic food sources (clams, invertebrates, etc.) that resulted from construction.
- Water Flow – Although levee improvement projects are unlikely to impact water flow, there may be some localized increase in flow over revetment that could affect the swimming or foraging habits of green sturgeon. These changes can be assessed through a physical or hydraulic model. This monitoring should be paired with a fish tracking study to assess the species presence/ association with habitat/project features in the project area.
- Water Depth – A diversity of water depth is necessary for shelter, foraging, and migration of juvenile, subadult, and adult life stages of green sturgeon and salmonids. Water depth impacted by levee construction or bank armoring can be measured impact through a direct physical quantification of changes to shallow and deep water habitat.
- Water Quality –Although levee improvement projects are unlikely to impact long term water quality, sediment quality, or migratory corridors, baseline conditions of these resources could be determined in order to develop a greater understanding of how these resources could impact normal behavior, growth, and viability of all life stages of green sturgeon and other fish species. Water Quality monitoring would involve testing water temperature, salinity, oxygen content, and other chemical characteristics within the project reach.

2.4.3 Mitigation Monitoring Strategy

The mitigation monitoring strategy will focus on the successful establishment of critical habitat elements, including slope and substrate. Post-construction monitoring would continue until the mitigation site has met the success criteria for three consecutive years. Slope would be monitored on an annual basis using range finding technologies. Slope will be sampled in varying distances perpendicular to the shoreline to assess slope ratio and depth. Substrate can vary seasonally and therefore will be monitored bi-annually before and after high flows. Substrate would be evaluated through direct physical samples. Substrate will be sampled in varying distances perpendicular to the shoreline to assess the content of benthic material.

A post-construction monitoring report would be produced annually following monitoring. The report would summarize and analyze all monitoring activities with overall evaluation of the performance of the success criteria. Additional results, analysis, proposed adaptive management measures, and associated costs would be incorporated into the monitoring report.

2.4.4 Adaptive Management Strategy

If the habitat is not meeting the success criteria established above, then adaptive management would be implemented in order to ensure that the habitat establishment is successful. The following subsections identify triggers that would indicate the need to implement adaptive management measures and the measures that would be implemented accordingly.

Adaptive Management Triggers

- Desired Outcome: Maintain slope gradient of greater than 2H:1V.

  Triggers: If slope is less than 2H:1V during the monitoring period.

- Desired Outcome: Maintain acceptable range of substrate conditions to provide benthic habitat.

  Triggers: If average substrate sizes are composed of cobbles larger than 10 inches during the monitoring period.

Adaptive Management Measures

If the triggers established above occur, the following measures would be implemented for green sturgeon benthic habitat in order to adaptively manage the site for success.

- Slope regrading may be needed if monitoring results show that the trigger for slope angle is met. Adaptive management measures may include grading to recontour slope angle to 2H:1V or greater.
- Sediment management measures may be needed if the trigger for substrate is met. If monitoring results show that average substrate composition is larger than 10 inches, then the following measures may be implemented. Measures may include gravel augmentation, sediment catching measures, and/or introduction of fines.

3.0 Adaptive Management Costs

This section outlines the feasibility level adaptive management costs for the American River Common Features (ARCF) General Reevaluation Report (GRR) study. The adaptive management plan for this project reflects a level of detail consistent with the project Feasibility Study. The primary intent is to develop adaptive management costs appropriate for and specific to the project's adaptive management measures and monitoring strategies, as described in Section 2.0 of this document. The specified management actions allow estimation of the adaptive management program costs for the project.

The cost for implementation of this plan are provided at October 2015 price levels and prior to contingency. The cost for implementing the monitoring plan proposed above is approximately $5.05 million and is shown on Table 13 below.

Table 13. Monitoring Costs for the ARCF GRR.

Monitoring	Assumed Tasks for Monitoring	Frequency	Cost Assumptions	Total Cost for 5 Years
Vegetation Monitoring	Assume monitoring of mitigation sites, including transects for percent cover of natives and non-natives, structural diversity, and canopy cover over water using transect/plot monitoring. Assume vegetation mapping, inventories of general wildlife, and observations of damage to habitat would be recorded. Assume monitoring of all parameters would be done concurrently during each monitoring event.	Annually for 5 Years	Monitoring: Cost estimate based on standard establishment contract, including monitoring cost and annual report from contractor. Assume $50,000 per year for 4 biologists to survey mitigation sites	$1,296,000
Green Sturgeon Habitat Monitoring	Assume monitoring of slope and in-channel habitat elements including substrates (i.e., composition and percentage of fines)	Annually for 5 Years	Monitoring: Assume monitoring of 8 reaches for 5 years	$3,750,000
			TOTAL MONITORING	**$5,050,000**

The cost for the adaptive management plan is approximately $5.15 million and is shown on Table 14 below.

Table 14. Adaptive Management Costs for the ARCF GRR.

Adaptive Management Measures	Assumed Tasks for Adaptive Management	Cost Assumptions	Total Cost for 5 Years
Irrigation/Supplemental Water	Apply supplemental irrigation to water stressed plants	Assuming $900 per acre per year for 5 years	$900,000
Re-planting	Assume that assume 25% of vegetation may require replanting over 5 years.	Cost of vegetation was estimated at $5,000 per planted acre	$2,220,000
Plant Protection & Fencing	Assume 10,000 plant cages and 10,000 feet of fencing may be needed.	Assume $10/plant cage; $3/linear foot for fencing; plus $50,000 installation. Costs referenced from existing restoration contracts.	$280,000
Slope Regrading and Sediment Management	Recontouring or existing slopes and gravel augmentation	Assume regarding and gravel augmentation at 25% of mitigation site at $35 per CY	$1,560,000
Annual Report	Produce annual report	Assume $37,500 per report, annually for 5 years	$190,000
		TOTAL ADAPTIVE MANAGEMENT	**$5,150,000**
		TOTAL MONITORING AND ADAPTIVE MANAGEMENT	**$10,200,000**

The combined monitoring and adaptive management costs at October 2015 price levels, as included in the certified total project cost summary under the 06 “fish and wildlife facilities” account, total $10.2 million for the Recommended Plan.

Appendix A

Cost Effectiveness/Incremental Cost Analysis

Mitigation for ARCF GRR

Development of Compensatory Mitigation Acreages for Alternatives 1 and 2

Mitigation for habitat loss is a requirement to compensate for the loss of habitat due to a Federal action. Section 2036(a) of the Water Resources Development Act of 2007 states that project alternatives must support recommendations with a specific plan to mitigate fish and wildlife losses. Additionally, the Endangered Species Act states that the purpose of compensatory mitigation is to offset environmental losses resulting from unavoidable impacts.

The ARFC GRR study area includes: (1) approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; (2) the east bank of the Natomas East Main Drainage Canal (NEMDC), Arcade Creek, and the Magpie Creek Diversion Canal (collectively referred to as the East Side Tributaries); (3) the east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee, the southern defense for Sacramento; and (4) the Sacramento Weir and Bypass, located along the north edge of the city of West Sacramento.

The mitigation acreages for ARCF GRR were calculated using a combination of site surveys and aerial photography from Google Earth to determine where the project footprint impacted different habitat types. The habitat types included: riparian, shaded riverine aquatic (SRA), oak woodland, wetlands, GGS uplands and aquatic, elderberry shrubs, vernal pools, green sturgeon benthic habitat, and Delta smelt spawning and shallow water. The acreages of each impacted habitat type were then broken up by reach in order to show differences between the two Alternatives. Impacts caused by the construction of this project are shown in Tables 1 and 2.

Table 1: Impacts for ARCF GRR – Alternative 1

	GGS Upland ***	GGS Aquatic ***	Riparian/ Western Yellow-billed Cuckoo **	SRA Habitat ***	Elderberry Shrubs (VELB) **	Vernal Pools **	Delta Smelt Spawning	Shallow Water **	Green Sturgeon Benthic **	Oak Woodland *	Wetlands
American River North											
Reach A (American River)			22 acres	19,000 LF	284 stems						
Reach B (American River)			0.5 acre		183 stems						0.05 acre
Reach C (American River & NEMDC)										1 acre	
Reach D (Arcade Creek)			6 acres

	GGS Upland ***	GGS Aquatic ***	Riparian	SRA Habitat***	Elderberry Shrubs (VELB)**	Vernal Pools **	Oak Woodland *	Delta Smelt Spawning	Shallow Water **	Green Sturgeon Benthic **	Wetlands
Mitigation Cost at a Bank per acre	$50,000	$50,000	$75,000	$75/LF	$4,500/ credit	$275,000	$75,000	$130,000	$130,000	----	$130,000
Mitigation Created per acre	----	----	$55,000	$231/LF	$85,000	----	$50,000	$55,000	$55,000	$150,000	----

The cost for mitigation was estimated for five scenarios for the purposes of the CE/ICA for both alternatives. These scenarios included: (1) maximized on- and off-site habitat creation; (2) maximizing the use of credits at a local mitigation bank; (3) a combination of on-site, off-site, and a mitigation bank at a 2:1 ratio; (4) a combination of on-site, off-site, and a mitigation bank at a 1:1 ratio; and (5) a combination of on-site, off-site, and a mitigation bank at a 3:1 ratio. The estimated acreage for the first scenario takes into account the feasibility of being able to do this mitigation on-site. For example, Delta smelt mitigation is not likely to be feasible on site due to the limitations of the waterways in the study area and the lack of real estate area to be able to create newly flooded habitat. As a result, Delta smelt mitigation is not assessed under this scenario since it is not implementable. However, it is a requirement of the project's biological opinion; therefore this alternative does not consider all required mitigation. Similarly, the mitigation bank only scenario also does not consider all required mitigation, because some habitat types must occur on-site due to limitations in available mitigation bank credits, and ESA requirements. Projected mitigation costs for both habitat creation and mitigation bank credits are shown in Table 3, above.

The cost for credits at a mitigation bank were obtained by contacting local mitigation banks to determine their prices per acre or credit for each of the habitat types needed for the GRR. These costs were then combined for each reach and Alternative to determine and overall mitigation cost per Alternative. These mitigation costs were included in the overall project cost for each alternative.

The combination alternative is likely the most implementable solution. It takes into account all required mitigation for the project per the NMFS and USFWS Biological Opinions, and assesses the implementation based on a reasonable estimate of on site mitigation, combined with using a mitigation bank. However, due to the temporal loss of habitat while new on site habitat is growing, the ecological value associated with onsite mitigation was reduced to an overall 80% habitat value for all scenarios based on the results of the associated HEP analysis, which was relied on for the purposes of this analysis.

For the purposes of evaluating the impacts of the ARCF GRR on fish and wildlife resources in the project area, with a reliance on existing information in the spirit of SMART Planning, the Habitat Evaluation Procedures (HEP) for the *American River Watershed Investigation, Common Features Modifications, Mayhew Drain Site Project* were relied upon as a reference baseline. The HEP for the Mayhew Drain Site Project was conducted in 2005 to quantify anticipated impacts to fish and wildlife and their habitats, and to determine mitigation needs for the project. This HEP was selected for the ARCF GRR because the Mayhew Drain Site is located within the overall study area for the ARCF GRR, and the habitat type and value at the Mayhew site is consistent with the habitat that occurs throughout the ARCF GRR project area.

The HEP provided information for two general types of wildlife habitat comparisons: 1) the relative value of different areas at the same point in time; and 2) the relative value of the same areas at future points in time. By combining the two types of comparisons, the impacts of proposed project on wildlife habitat were quantified and compensation needs (in terms of acreage) for the project were determined. The assumption that habitat for selected wildlife species or communities can be numerically described by a model produces a Habitat Suitability Index (HSI). The HSI, a value from 0.0 to 1.0, provides a measure of habitat quality for a sample area in terms of suitability for the particular species or community being evaluated.

For the Mayhew Drain project, the Northern oriole Riparian woodland model was used because it best suited the habitat type in the project area. The quantity part of the formula is any measure of area which is appropriately sized for the study. The product of these two measures is comparable to "habitat value" which equals habitat quantity multiplied by habitat quality. This formula is expressed as a Habitat Unit (HU).

Habitat Type x Habitat Area = Habitat Value

The Average Annual Habitat Units (AAHUs) over the life of the project can then used to determine mitigation needs. The model, variables measured and data collection methods used for the Mayhew Drain Project are shown below in Table 4. For the ARCF GRR, data was estimated visually and using google earth.

Table 4. HSI model, Variables, and Data Collection Methods.

HSI Model and Cover-Type	HSI Model Variables	Data Collection Method
Northern oriole Riparian Woodland	V1 – Average height of deciduous tree canopy	Visual estimation
	V2- Percent deciduous tree crown cover	Densiometer along belt transects
	V3 – Stand width	Estimated using aerial photos

Since it is not possible to empirically determine habitat quality and quantity for future years, future HSI values were projected. This was accomplished by increasing or decreasing specific baseline variables and/or HSI values for each evaluation element for the Northern oriole based on best professional knowledge of performance at other mitigation sites, literature on plant growth, and conditions at reference sites. To predict changes in the HSI for each future scenario, it was necessary to make assumptions regarding baseline and future values within project impact and compensation areas. The assumptions made for the ARCF GRR with project can be seen in Table 5.

Table 5. HSI Variables for the ARCF GRR Based on Habitat Values.

HEP - FUTURE WITH-PROJECT							
Time	**Variables**			**Suitability Index**			**Output**
	V1	**V2**	**V3**	**SI-V1**	**SI-V2**	**SI-V3**	**HSI**
TY1	20	25%	2	0.60	1.00	1.00	0.84
TY2	10	25%	2	0.30	1.00	1.00	0.67
TY25	20	75%	2	0.60	0.75	1.00	0.77
TY50	35	75%	2	1.00	0.75	1.00	0.91
HSI = (V1*V2*V3)^1/3						Average	0.80

The HSI value of 0.80 in Table 5 results from a temporal loss of habitat value and function from the removal of existing mature riparian habitat. This is due to the lower values given to mitigation plantings during the establishment period. The recommended plan for mitigation associated with the ARCF GRR is the Alternative 2 combination plan at a 2:1 ratio (the third scenario discussed above). A 2:1 mitigation ratio is a reasonable requirement for implementation of mitigation for this already scarce habitat type, because the proposed project will decrease the connectivity of existing habitat along the Sacramento River system. Additionally, temporal loss of onsite habitat results in a reduction in value and function of the new vegetation within the mitigation areas as it grows to maturity. This also accounts for the loss of other services that riparian vegetation provides, including:

- An essential food source for fish and wildlife, including ESA species;
- Aquatic resting and refugia for resident and migratory fish species;
- Large woody debris recruitment;
- Nesting and rearing habitat for terrestrial wildlife species;

- Nutrients for the ecological system;
- Shade for the river which maintains water temperatures and dissolved oxygen concentrations; and,
- Increased habitat value for VELB.

The above-listed functions and services associated with a newly created acre of habitat are usually expected to be less than those associated with natural habitat. As a result the 2:1 mitigation ratio is appropriate to compensate for the loss of mature riparian habitats.

Tables 6 and 7 below show the environmental effects and proposed mitigation for each of the two alternatives under the recommended plan. Note that some habitat types are adjusted to 1:1 and 3:1 to comply with the terms and conditions of the Biological Opinions.

Table 6. Environmental Effects of and Proposed Mitigation for Alternative 1.

Habitat Type	Potential Impacts	Duration of Impact	Mitigation (Acres/Linear Feet)	Cost at Mitigation Bank	Cost On- or Off-Site within Study Area
GGS Uplands	None	None	None	None	None
GGS Aquatic	None	None	None	None	None
Riparian	184.3 acres	Permanent	368.6 acres		20,273,000
Shaded Riverine Aquatic Habitat	82,325 lf	Permanent	82,325 lf		$19,020,000**
Elderberry Shrubs	3,292 stems	Permanent	1,715.6 credits 70.89 acres		$6,026,000
Vernal Pools	0.25 acre	Permanent	1 acre	$275,000	---
Green Sturgeon	20 acres	Permanent	Restore acres, monitoring, and fish passage features		$16,259,000
Delta Smelt Spawning Habitat	32 acres	Permanent	34 acres	$4,160,000	
Shallow Water Habitat (Delta Smelt)	14 acres	Permanent	42 acres	$5,460,000	
Oak Woodland	2 acres	Permanent	4 acres		$200,000
Wetlands	0.4 acres	Permanent	0.8 acres	$130,000	---
Sub-Total				**$10,025,000**	**$61,778,000**

** SRA habitat mitigation is provided in the project's cost estimate as a separate construction cost rather than a mitigation cost, since it is a feature of the bank protection designs and would be included as a part of the construction contract. The cost is displayed under the Fish and Wildlife Facilities account as "Construction" costs and is estimated to be approximately $231 per linear foot.

Table 7. Environmental Effects and Proposed Mitigation for Alternative 2, the Recommended Plan.

Habitat Type	Potential Impacts	Duration of Impact	Mitigation (Acres/Linear Feet)	Cost at Mitigation Bank	Cost On- or Off-Site within Study Area
GGS Uplands	30 acres 75 acres	Permanent Temporary	90 acres 75 acres	$4,500,000	N/A*
GGS Aquatic	15 acres	Permanent	45 acres	$2,250,000	
Riparian	150.6 acres	Permanent	301.2 acres		$16,566,000
Shaded Riverine Aquatic Habitat	82,325 lf	Permanent	82,325 lf		$19,020,000**
Elderberry Shrubs	3,292 stems	Permanent	1,715.6 credits 70.89 acres		$6,026,000
Vernal Pools	1 acre	Permanent	1 acre	$275,000	---
Green Sturgeon	20 acres	Permanent	Restore acres, monitoring, and fish passage features		$16,259,000
Delta Smelt Spawning Habitat	34 acres	Permanent	34 acres	$4,160,000	
Shallow Water Habitat (Delta Smelt)	14 acres	Permanent	42 acres	$5,460,000	
Oak Woodland	2 acres	Permanent	4 acres		$200,000
Wetlands	0.4 acres	Permanent	0.8 acres	$130,000	---
Sub-Total				**$16,775,000**	**$58,341,000**

* 75 acres of temporary effects to GGS habitat from the relocation of the Sacramento Bypass toe drain would consist of standard site restoration erosion control features such as hydroseeding. This is contained within construction costs and is not considered a mitigation cost. It is presented in this plan due to monitoring requirements, as described in Section 2.1 below.
** SRA habitat mitigation is provided in the project's cost estimate as a separate construction cost rather than a mitigation cost, since it is a feature of the bank protection designs and would be included as a part of the construction contract. The cost is displayed under the Fish and Wildlife Facilities account as "Construction" costs and is estimated to be approximately $231 per linear foot.

In order to establish a basis of comparison for this Cost Estimate, the "Without Project Condition" is assumed to be of such low habitat value that there would be 0 AAHU's without implementing compensatory mitigation. The "With Project Condition" is the completed mitigation as designed. On site costs were estimated using the average of costs for other onsite mitigation the District has constructed for projects in the region. Due to the temporal loss of habitat while new on site habitat is growing, the ecological value associated with onsite mitigation was reduced to an overall 80% habitat value.

The Mitigation Outputs and Cost tables below compare the Average Annual Habitat Units (AAHU's) and costs between the five scenarios.

The following pages include the outputs from the CE/ICA IWR Plan software. The Best Buy plans were shown to be the No Action Plan, the Alternative 1 Combination Plan with a 1:1 ratio, and the Alternative 2 Combination Plan with a 1:1 ratio. However, none of these plans accomplish the terms and conditions of the Biological Opinions and thus cannot be implemented and remain in compliance with the Endangered Species Act. As a result, the Recommended Plan remains the Alternative 2 Combination Plan with a 2:1 ratio, because it accomplishes the terms and conditions of the Biological Opinions, and the CE/ICA did determine that it was a cost effective plan.

Chart of Alternatives:

This chart provides an illustration of costs and benefits associated with alternatives generated during development of the American River Common Features GRR. Alternatives are charted based on their benefit (x-axis) and cost (y-axis) coordinates.

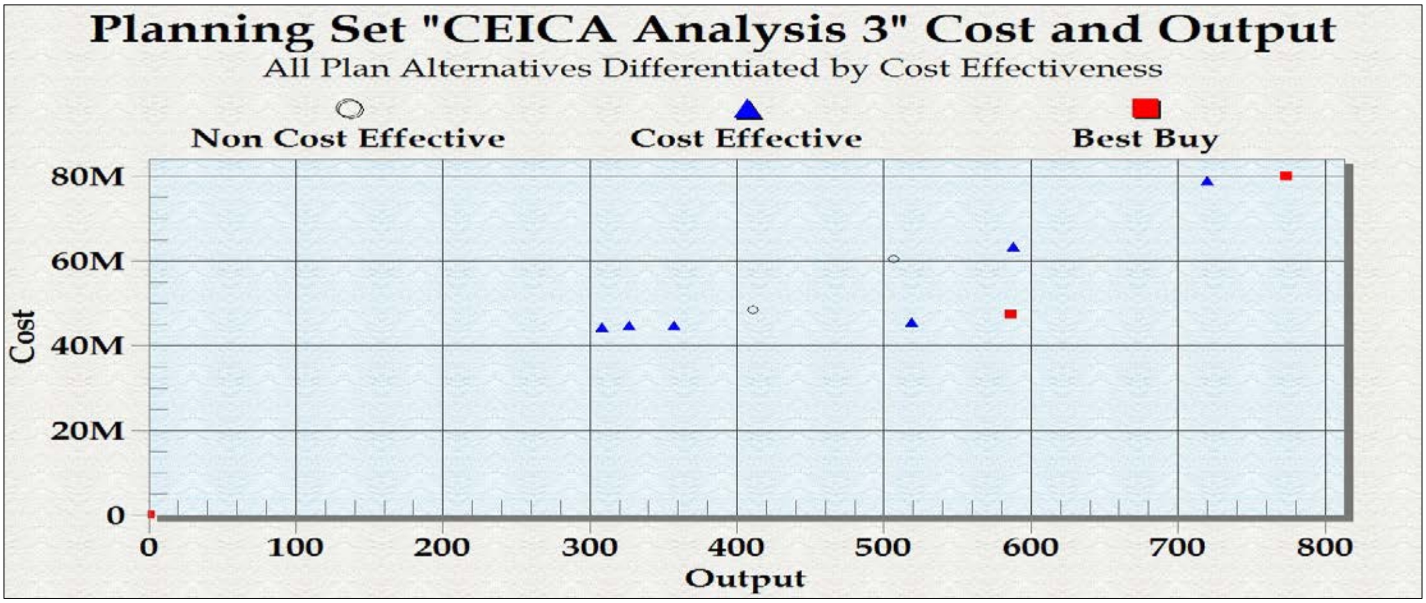

Chart of Cost-Effective Alternatives:

This chart provides an illustration of costs and benefits associated with cost-effective alternatives considered during development of the American River Common Features GRR. Alternatives are charted based on their benefit (x-axis) and cost (y-axis) coordinates. The depicted alternatives have been identified among the most cost-effective of the alternatives considered during development of the study.

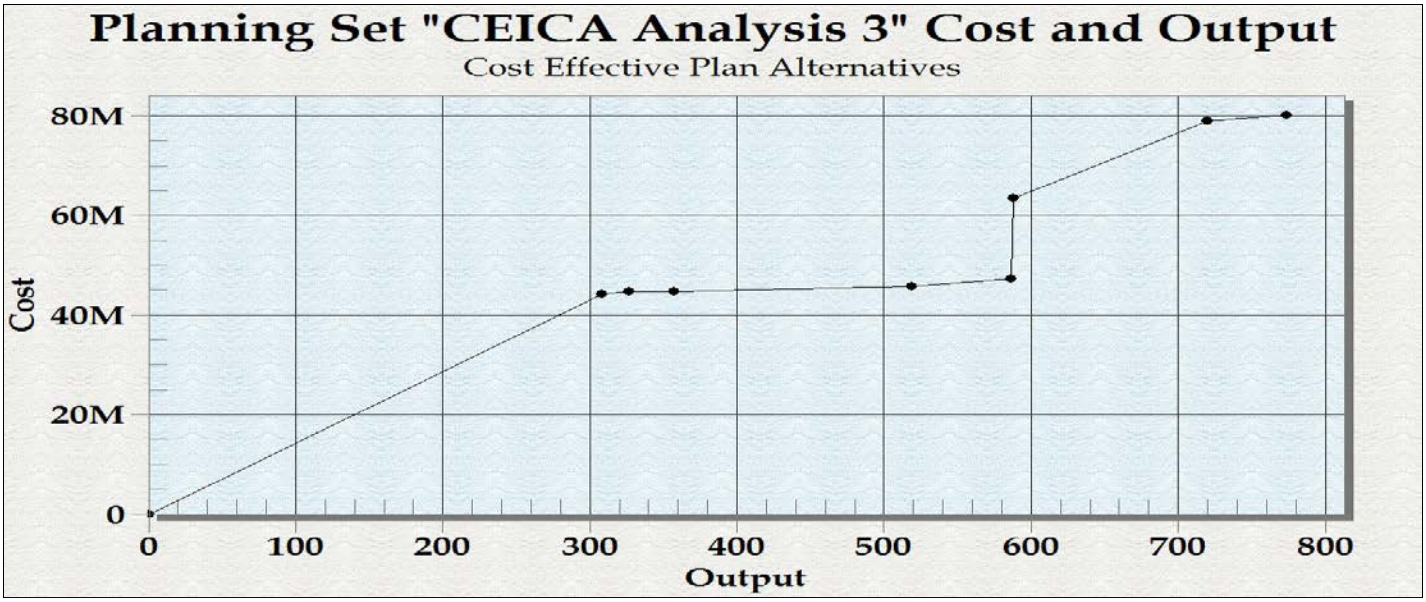

Chart of Incremental Costs and Benefits of Alternatives:

This chart provides an illustration of costs and benefits associated with alternatives considered during development of the American River Common Features GRR. The magnitudes of incremental benefits (width of rectangle) and incremental costs (height of rectangle) are represented to illustrate the relative magnitudes of each alternative's "added" costs associated with benefits exceeding the "next-best" cost-effective alternative.

Subject: Formal Consultation on the American River Common Features (AFRC) Project, Sacramento County, California

Dear Ms. Kirchner:

This letter is in response to the U.S. Army Corps of Engineers (Corps) April 3, 2015, request for consultation with the U.S. Fish and Wildlife Service (Service) on the proposed American River Common Features General Reevaluation Report (ARCF GRR) project in Sacramento County, California. You request was received by the Service on April 7, 2015. The Corps originally initiated consultation on June 30, 2014; however, the Service responded on July 23, 2014, with a request for additional information regarding the project description and the effects analysis the Corps had completed. The April 3, 2015, letter and biological assessment began the formal consultation period. This response is provided under the authority of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*) (Act).

The Federal action on which we are consulting is the ARCF GRR, which includes levee improvements and bank protection along the Sacramento River, levee improvements along Arcade, Magpie, and Dry/Robla Creeks, widening the Sacramento Bypass and Weir, and bank protection along the lower American River. Pursuant to 50 CFR 402.12(j), you submitted a biological assessment for our review and requested concurrence with the findings presented therein. These findings conclude that the proposed project may affect and is not likely to adversely affect the vernal pool fairy shrimp (*Branchinecta lynchi*) and vernal pool tadpole shrimp (*Lepidurus packardi*); may affect likely to adversely affect the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*), delta smelt (*Hypomesus transpacificus)* (smelt) and its critical habitat; the giant garter snake (*Thamnophis gigas*); and the yellow-billed cuckoo (*Coccyzus americanus occidentalis*). The project is outside of critical habitat designated for the valley elderberry longhorn beetle and critical habitat proposed for the yellow-billed cuckoo.

The Corps previously consulted with the Service on the Magpie Creek Flood Control Project and on September 15, 2004 a biological opinion regarding effects to the vernal pool fairy shrimp, vernal pool tadpole shrimp, and giant garter snake (File # 1-1-04-F-0132) was provided. The project described in the 2004 biological opinion is exactly the same as the Magpie Creek portion of the project description in the Common Features biological assessment. Because the environmental baseline for vernal pool fairy shrimp and vernal pool tadpole shrimp has not changed from the baseline that was analyzed in the 2004 biological opinion and the project description remains the same, effects to and take of vernal pool fairy shrimp and vernal pool tadpole shrimp are addressed in the September 15, 2004, biological opinion. More recent information regarding the status of the habitat along Magpie Creek for giant garter snake has changed from the 2004 biological opinion. This opinion addresses those changes and any potential effects to the giant garter snake.

Seasonal wetlands, which may provide suitable habitat for vernal pool fairy shrimp and vernal pool tadpole shrimp, occur in the vicinity of the Robla Creek woodland mitigation site A, however any vernal pools in this area would be avoided by these activities. The Corps will implement a 250-foot buffer between vernal pools and vegetation planting. Planting activities will be done in the fall when the wetlands are dry and will use best management practices to ensure that sediment does not enter the seasonal wetlands. The Service concurs that with your determination of may affect, not likely to adversely affect vernal pool fairy shrimp and vernal pool tadpole shrimp at the Robla Creek woodland mitigation site A.

This biological opinion is based on information provided in the Corps' letter requesting consultation and the biological assessment. A complete administrative record is on file at the Service's Sacramento Fish and Wildlife Office.

CONSULTATION HISTORY

September 4, 2013: The Service commented on the April 2013 draft biological assessment.

April 8, 2014: The Service commented on the October 2013 draft biological assessment.

June 30, 2014: The Corps initiated section 7 consultation with the Service.

July 23, 2014: The Service sent a letter in response to the Corps initiation requesting additional information.

April 3, 2015: The Corps provided an updated biological assessment with responses to the Service's July 23, 2014, request for additional information.

August 31, 2015: The Corps provided a revised biological assessment that addressed questions the Service had regarding the project description.

BIOLOGICAL OPINION

Description of the Action

Congress directed the Corps to investigate the feasibility of reducing flood risk of the city of Sacramento. The Corps completed feasibility studies in 1991 and 1996, recommending a concrete gravity flood detention dam on the north fork of the American River at the Auburn site along with levee improvements downstream of Folsom Dam. Other plans evaluated in the report were Folsom Dam improvements and a stepped release plan for Folsom Dam releases. These additional plans also included levee improvements downstream of Folsom Dam. Congress recognized that levee improvements were "common" to all candidate plans in the report and that there was a Federal interest in participating in these "common features." Thus, the ARCF Project was authorized in the Water Resources Development Act (WRDA) of 1996 and a decision on Auburn Dam was deferred to a later date. Major construction components of ARCF in the WRDA 1996 authorization included construction of seepage remediation along about 22 miles of American River levees and construction of levee strengthening and raising of 12 miles of Sacramento River levee in Natomas.

Following the 1986 flood, significant seepage was experienced on the Sacramento River from Verona (upstream end of Natomas) at River Mile (RM) 79 to Freeport at RM 45.5. In addition, both the north and south bank of the American River from RM 0 to about RM 11.4 experienced seepage. Seepage on the Sacramento River was so extensive that Congress, soon after the 1986 flood event, funded remediation in the Sacramento Urban Levee Improvement Project (Sac Urban). The Sac Urban Project constructed shallow seepage cutoff walls from Powerline Road in Natomas at approximately RM 64 down to Freeport.

Shortly thereafter, the Sacramento Valley experienced a flood event in 1997. Considerable seepage occurred on the Sacramento River as well as on the American River. Seepage on the American River was expected because remediation measures had yet to be constructed, but the occurrence of significant seepage on the Sacramento River in the reach remediated as part of the Sac Urban Project was alarming and confirmed that deep underseepage was also of significant concern. As a result, seepage remediation on the American River (then in the late 1990s in the design phase) would need to be designed to remediate both through- and deep underseepage.

In 1999, Congress decided not to authorize Auburn Dam, but instead authorized improvements for Folsom Dam. By doing this, improvements to levees downstream of Folsom Dam could be fine-tuned to work closely with the Folsom improvements being discussed by Congress. Therefore, the ARCF project was modified by WRDA 1999 to include additional necessary features for the American River so that it could safely convey the proposed emergency release of 160,000 cubic feet per second (cfs) from Folsom Dam. Major construction components for the ARCF project in the WRDA 1999 authorization include construction of seepage remediation and levee raise along four stretches of the American River, and construction of levee strengthening and raising of 5.5 miles of Natomas Cross Canal levee in Natomas. All American River features authorized in WRDA 1996 and 1999 have been constructed or are in design analysis for construction within a year or two.

The purpose of the ARCF project is to reduce the flood risk for the city of Sacramento. The following problems were identified within the Sacramento levee system:

- Seepage and underseepage;
- Levee erosion;
- Levee stability;
- Levee overtopping;
- Access for maintenance and flood fighting;
- Vegetation and encroachments;
- Releases from Folsom Dam;
- Floodplain management; and
- Additional upstream storage from existing reservoirs.

In order to evaluate the effects to listed species, the Corps looked at the largest foreseeable footprint. As the Corps moves into the design phase of the project, footprint changes will likely reduce the effects to listed species.

The project is designed to allow for the release of 160,000 cubic feet per second (cfs) from Folsom Dam. The levees along the American River are unable to withstand these maximum flows for extended periods of time without increased risk of erosion and potential failure. The exact location where erosion will occur and to what extent erosion will occur during any given event is unknown. Erosion within the American River Parkway will be addressed as part of the Folsom Dam Water Control Manual Update currently under evaluation and a biological assessment is being prepared to initiate section 7 consultation with both the Service and National Marine Fisheries Service (NMFS). Therefore, the effects of erosion along the lower American River and effects of increased Yolo Bypass flooding frequency due to changes in operations from Folsom Dam are not analyzed in this project description. This is because construction of the American River and Sacramento Bypass measures, which are dependent on releases from Folsom Dam, will not occur until after a biological opinion is received for the Water Control Manual Update. Sacramento River and East Side Tributaries measures are necessary to improve the flood risk management system in the Sacramento area regardless of the change in operation at Folsom Dam and are not dependent on Folsom Dam operations for their implementation. As a result, construction in these areas could occur regardless of the Folsom Dam Water Control Manual Update schedule.

The Corps' project involves the construction of fix-in-place levee remediation measures to address seepage, stability, erosion, and height concerns identified for the Sacramento River and American River levees, Natomas East Main Drainage Canal (NEMDC), Arcade, Dry/Robla, and Magpie Creeks (Figure 1). Most height concerns along the Sacramento River will be addressed by a widening of the Sacramento Weir and Bypass to divert more flows into the Yolo Bypass. Due to the urban nature and proximity of existing development within the American River North and South basins the Corps is planning fix in place remediation. This would improve the flood damage reduction system to safely convey flows to a level that maximizes net benefits. Table 1 summarizes the levee problems discussed above and the proposed measure for each waterway.

Sacramento Area Flood Control Agency (SAFCA), the project's local sponsor, will complete some portions of the Federal project. SAFCA is seeking permission from the Corps pursuant to 33 USC §408 (Section 408) for alteration of the Federal levees along the NEMDC and Arcade Creek.

In addition to the proposed levee improvements measures shown in Table 1, the following measures and policies would be addressed during construction:

- The non-Federal (Department of Water Resources (DWR)) will bring the levees into compliance with the Corps' standard levee footprint using a System Wide Implementation Framework (SWIF) process. A SWIF is a plan developed by the levee sponsor(s) and accepted by the Corps to implement system-wide improvements to a levee system (or multiple levee systems within a watershed) to address system-wide issues, including correction of unacceptable inspection items, in a prioritized way to optimize flood risk reduction. The standard levee footprint consists of a 20 foot crown width, 3:1 waterside

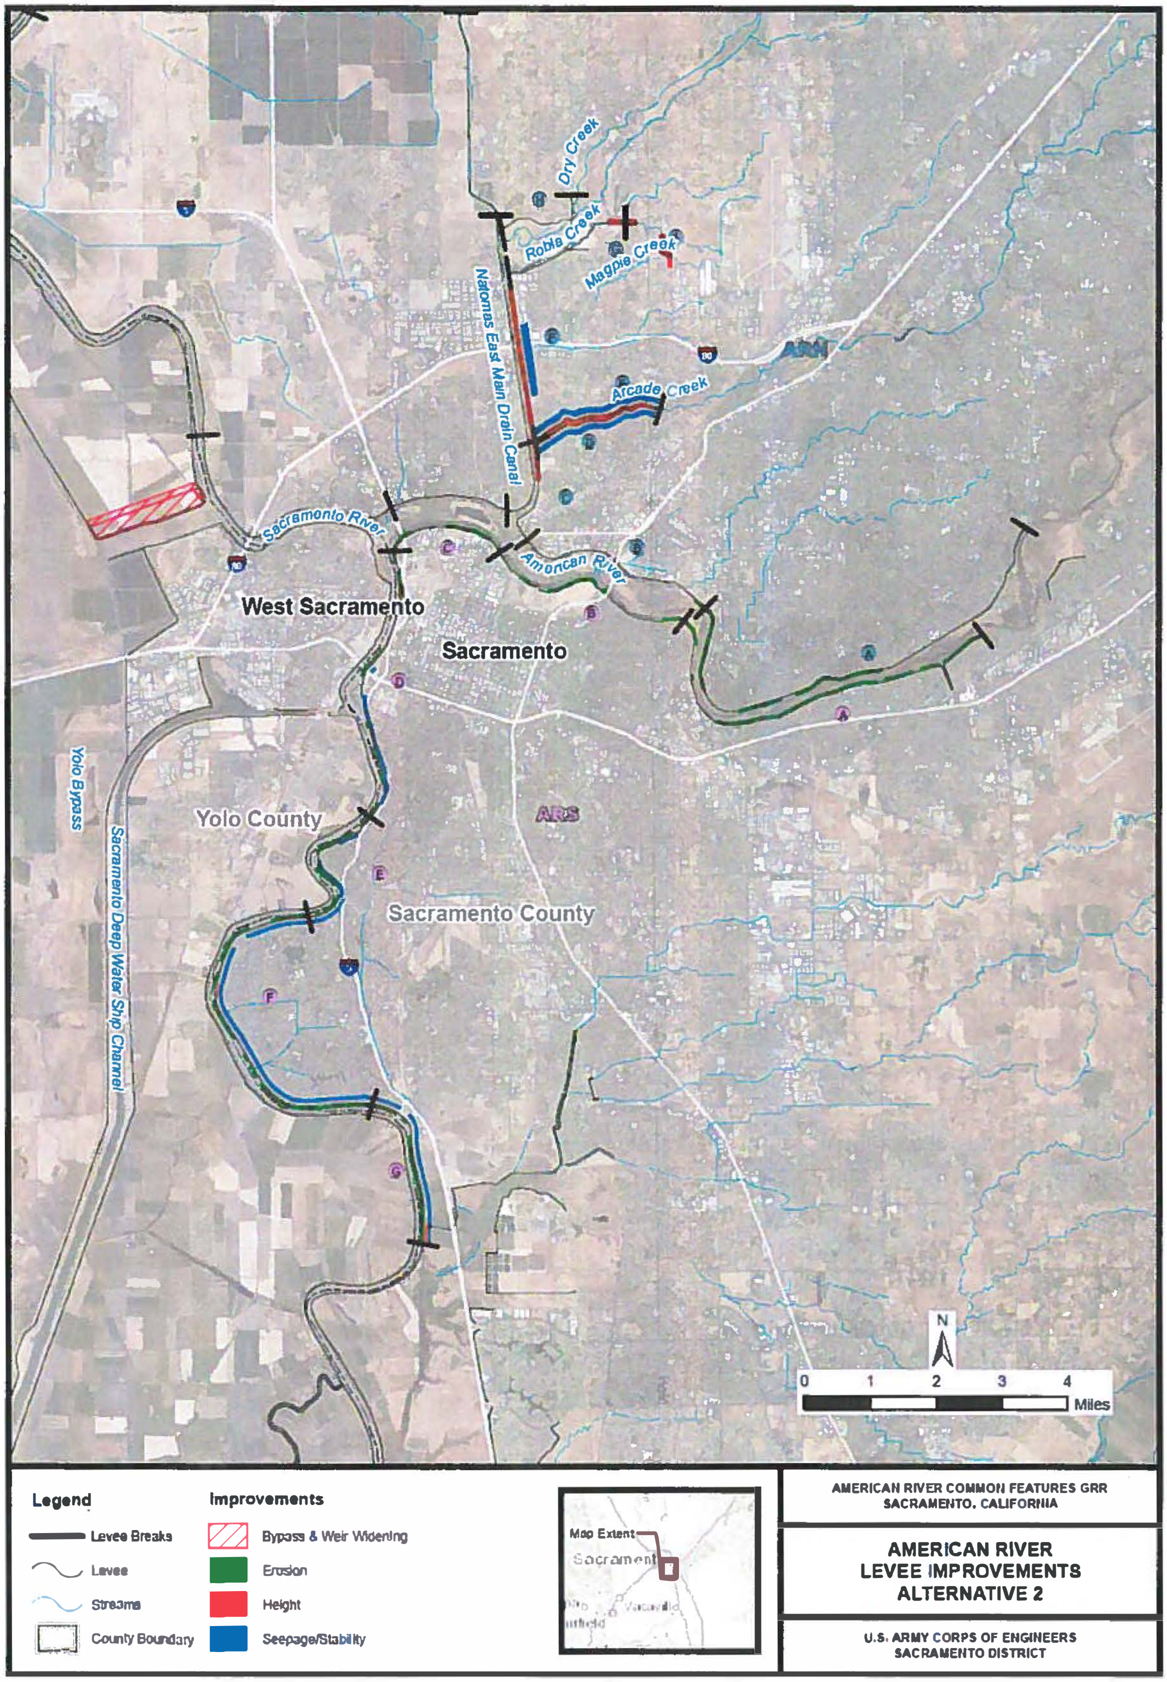

Figure 1. American River Common Features Project Area

Table 1. Remediation by Waterway.

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[1]	---	---	Bank Protection, Launchable Rock Trench (31,000 linear feet)	---
Sacramento River	Cutoff Wall (50,300 linear feet)	Cutoff Wall (50,300 linear feet)	Bank Protection (50,300 linear feet)	Sacramento Bypass and Weir Widening, Levee Raise (1,500 feet)
NEMDC	Cutoff Wall (6,000 linear feet)	Cutoff Wall	---	Floodwall (15,600 linear feet)
Arcade Creek	Cutoff Wall (22,000 linear feet)	Cutoff Wall	---	Floodwall (22,000 linear feet)
Dry/Robla Creeks	---	---	---	Floodwall (2,500 linear feet)
Magpie Creek[2]	---	---	---	Floodwall, Levee Raise

[1]American River seepage, stability, and overtopping measures were addressed in a previous construction project.
[2]In addition to the floodwall, Magpie Creek will include construction of a new levee (3,100 linear feet) along Raley Boulevard south of the creek, and construction of a detention basin on both sides of Raley Boulevard (79 acres). In addition, some improvements would need to occur on Raley Boulevard, including widening of the Magpie Creek Bridge, raising the elevation of the roadway, and removing the Don Julio Creek culvert.

slope and 2:1 landside slope, when possible. If the 3:1 waterside slope is not possible, then a minimum 2:1 waterside slope would be established instead.

- Engineering Technical Letter 1110-2-583 (ETL) vegetation compliance would occur under a SWIF by the local maintaining agency (LMA). The intent of the SWIF is to collaboratively work with the resource agencies and levee sponsors to transition existing levees to Corps standards while maintaining Public Law (PL) 84-99 rehabilitation assistance and adhering to the Act and other environmental laws. The SWIF is a two-step process completed by the applicant that is composed of a letter of intent, which is followed by submission of a SWIF plan. The SWIF process allows eligible local sponsors to implement levee improvements in a prioritized "worst first" way to optimize the achievement of risk reduction. The Corps acknowledges that implementing system-wide improvements will need to be done within a collaborative intergovernmental framework and that it will take time to develop and implement improvements in complex situations. Challenges including ensuring that both environmental and levee safety considerations are adequately served.
- The vegetation requirements for the SWIF include a 15-foot waterside, landside, and vertical vegetation-free zone. Trees that pose an unacceptable risk to levee integrity will be removed and the root balls and roots will be remediated. Trees that do not pose a threat will not be removed. Vegetation on the landside slope would only be removed within the construction

footprint (up to ½ levee degrade) and the remaining vegetation would be dealt with under the SWIF process.

- Utility encroachments will be brought into compliance with Corps policy. Utilities that penetrate the levee would be removed and replaced with one of two fixes: (1) a surface line over the levee prism, or (2) a through-levee line equipped with positive closure devices.
- Private encroachments shall be removed by the non-Federal sponsor prior to construction.
- The Sacramento District of the Corps will pursue a vegetation variance which will allow vegetation on the lower ½ of the levee slope to 15 feet waterward of the waterside levee toe to remain in place. The Sacramento District has conducted an evaluation which examined the safety, structural integrity, and functionality of the levees that will be retained and not compromised if a tree were to fall and result in scouring of the root ball area. The results show that the tree fall and scour did not significantly affect levee performance, and the levee meets Corps seepage and slope stability criteria assuming the entire project is constructed.

American River

Levees along the American River require improvements to address erosion. The proposed measures for these levees consist of waterside armoring to prevent erosion to the river bank and levee, which could potentially undermine the levee foundation. There are two measures proposed for the American River levees: (1) a maximum of 31,000 linear feet (LF) of bank protection, and (2) a maximum of 65 acres/45,000 LF of launchable rock trench. Both of these measures are described in detail in the subsections below. These numbers are maximized because there is some overlap identified to account for the uncertainty of site-specific conditions. For example, for some reaches both bank protection and launchable rock trench impacts were estimated even though both measures will not be constructed in the same reach.

<u>Bank Protection</u>

This measure consists of placing rock revetment on the river's bank to prevent erosion. It entails installing revetment along the stream bank based on site-specific analysis (Figure 2). When necessary, the eroded portion of the bank will be filled and compacted prior to the rock placement. The sites will be prepared by clearing and stripping of loose material and understory growth prior to construction. In most cases, large vegetation will be permitted to remain at these sites. Temporary access ramps will be constructed, if needed, using imported borrow material that would be trucked on site.

The placement of rock onto the bank will occur from a land based staging area using long reach excavators and loader. The loader brings rock from a permitted source and stockpiles it near the levee in the construction area. The excavator then moves the rock from the stockpile to the waterside of the levee.

The revetment will be placed on the existing bank at a slope varying from 2V:1H to 3V:1H depending on site specific conditions. After revetment placement has been completed, a planting berm will be constructed in the rock to allow for revegetation of the site. The planting berm varies in width from 5 to 15 feet. In all cases the planting will occur outside the vegetation free zone as required by the ETL.

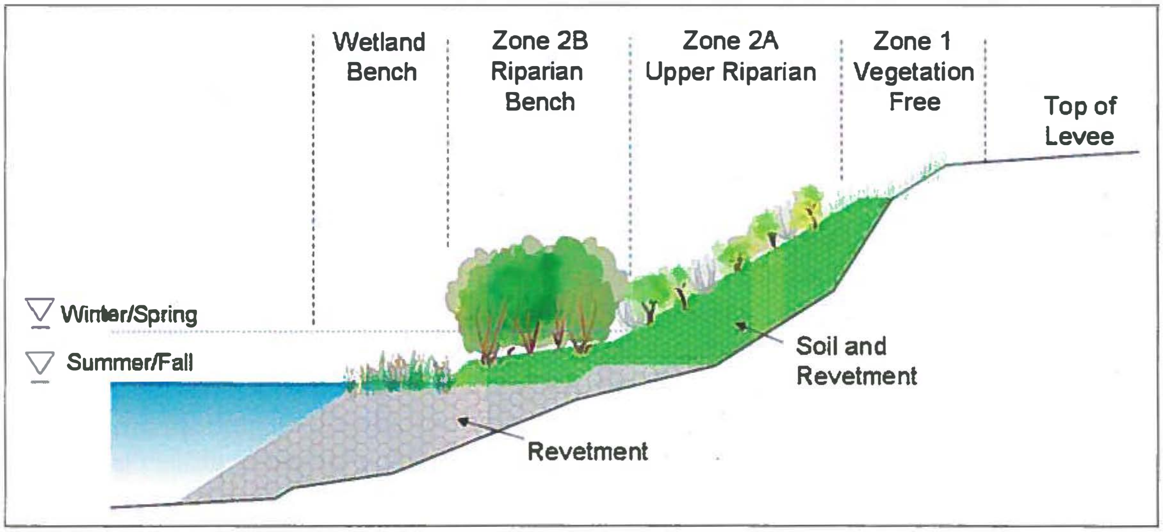

Figure 2. Bank Protection with Planting Bench.

<u>Launchable Rock Trench</u>

For the purposes of this project description, it is assumed that 65 acres of the lower American River will have a launchable rock trench fix. The remainder will be the bank protection described above. This measure includes construction of a launchable rock filled trench, designed to deploy once erosion has removed the bank material beneath it (Figure 3). All launchable rock trenches will be constructed outside of the natural river channel. The vegetation will be removed from the footprint of the trench and the levee slope prior to excavation of the trench. The trench configuration will include a 2:1 landside slope and 1:1 waterside slope and will be excavated at the toe of the existing levee. All soil removed during trench excavation will be stockpiled for potential reuse. The bottom of the trench will be constructed close to the summer mean water surface elevation in order to reduce the rock launching distance and amount of rock required.

After excavation, the trench will be filled with revetment that will be imported from an offsite commercial location. After rock placement the trench will be covered with a minimum of 3 feet of the stockpiled soil for a planting berm. Rock placed on the levee slope will be covered with 2 feet of stockpiled soil. All disturbed areas will be reseeded with native grasses and small shrubs where appropriate. Trees and shrubs could be permitted on the trench if planted outside the specified vegetation free zone as required by the ETL.

Sacramento River

Levees along the Sacramento River require improvements to address seepage, stability, and erosion. About 50,300 LF of bank protection and cutoff wall or slope stability work is proposed for the Sacramento River. In addition, these levees require a total of one mile of intermittent height improvements in order to convey additional flows that exceed current design levels.

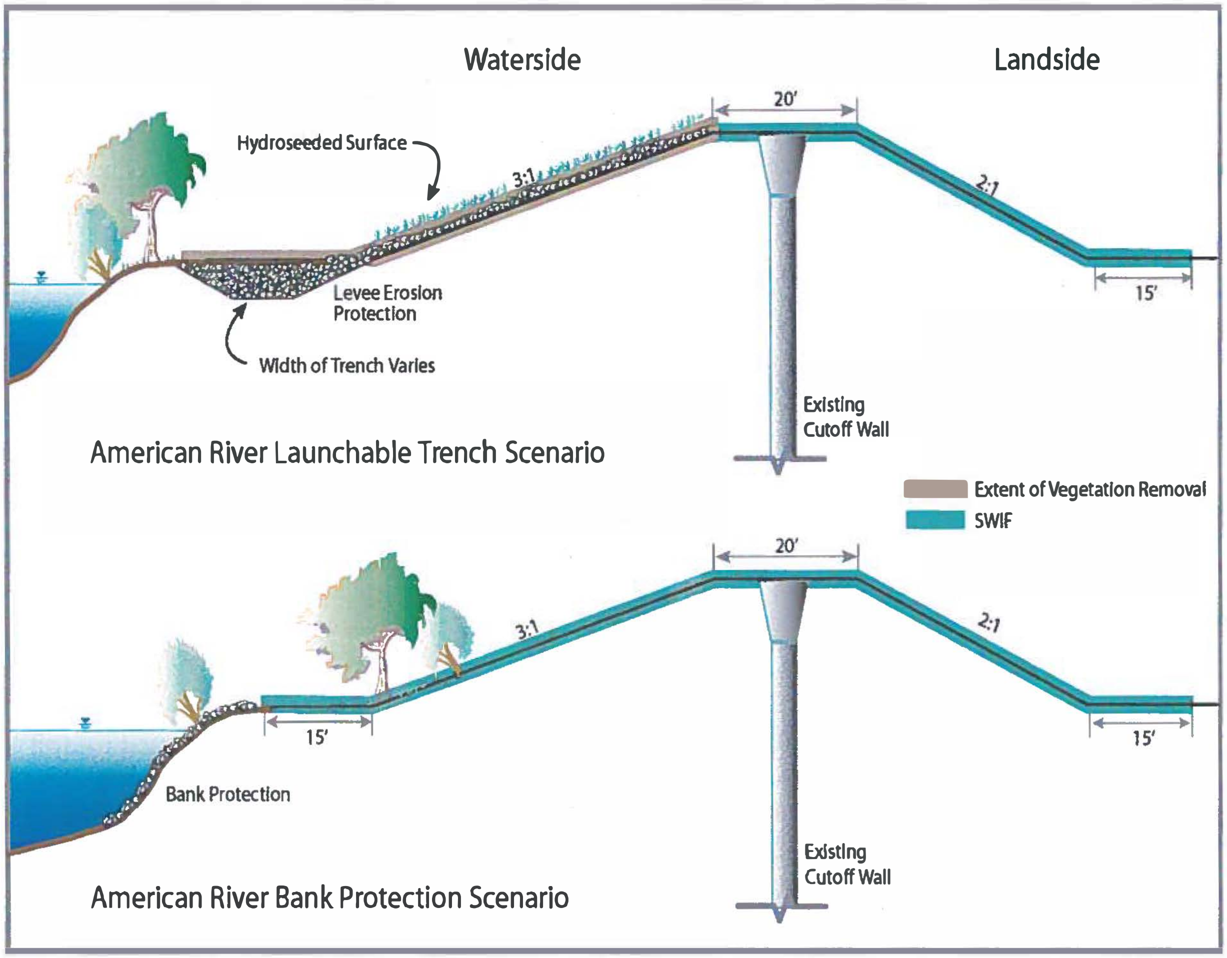

Figure 3. Launchable Rock Trench and Bank Protection.

Where the existing levee does not meet the levee design requirements, as discussed above, slope flattening, crown widening, and/or a minimal amount of levee raise is required. This improvement measure addresses problems with slope stability, geometry, height and levee crest access and maintenance. To begin levee embankment grading, loose material and vegetation understory will be cleared, grubbed, stripped, and where necessary, portions of the existing embankment will be excavated to allow for bench cuts and keyways to tie in additional embankment fill. Excavated and borrow material (from nearby borrow sites) will be stockpiled at staging areas. Haul trucks and front end loaders will bring borrow materials to the site, which will then be spread evenly and compacted according to levee design plans.

The levee will be raised about 1 to 2 feet resulting in the levee footprint extending out a maximum of 5 feet on the landside from the existing levee. The levee crown patrol road will be re-established at the completion of construction.

Cutoff Walls

To address seepage concerns, a cutoff wall will be constructed through the levee crown. The cutoff wall will be installed by one of two methods: (1) conventional open trench cutoff walls, or (2) deep soil mixing (DSM) cutoff walls. The method of cutoff wall selected for each reach will depend on the depth of the cutoff wall needed to address the seepage. The open trench method can be used to install a cutoff wall to a depth of about 85 feet. For cutoff walls of greater depth the DSM method will be utilized.

Prior to any cutoff wall construction method, the construction site and any staging areas will be cleared, grubbed, and stripped. The levee crown will be degraded up to half the levee height to create a large enough working platform (about 30 feet) and to reduce the risk of hydraulically fracturing the levee embankment from the insertion of slurry fluids. This method of slurry wall installation will also reduce the risk of slurry mixture following seepage paths and leaking into the river or into landside properties.

Open Trench Cutoff Wall

Under the open trench method, a trench about 3 feet wide will be excavated at the top of levee centerline and into the subsurface materials up to 85 feet deep with a long boom excavator. As the trench is excavated, it is filled with low density temporary bentonite water slurry to prevent cave in. The soil from the excavated trench is mixed nearby with hydrated bentonite, and in some applications cement. The soil bentonite mixture is backfilled into the trench, displacing the temporary slurry. Once the slurry was hardened, it will be capped and the levee embankment will be reconstructed with impervious or semi-impervious soil.

DSM Cutoff Wall

The DSM method involves a crane supported set of two to four mixing augers used to drill through the levee crown and subsurface to a maximum depth of about 140 feet. As the augers are inserted and withdrawn, a cement bentonite grout will be injected through the augers and mixed with the native soils. An overlapping series of mixed columns will be drilled to create a continuous seepage cutoff barrier. A degrade of up to one half the levee height will be required for construction of the DSM wall. For both methods, once the slurry has hardened it will be capped and the levee embankment will be reconstructed with impervious or semi-impervious soil.

Bank Protection

Proposed bank protection along the Sacramento River will address erosion concerns. Studies have shown that the Sacramento River levees have a medium to high risk of breach due to erosion. Bank protection will be addressed by standard bank protection with planting berm. The standard bank protection measure for the Sacramento River consists of placing rock protection on the bank to prevent erosion. This measure entails filling the eroded portion of the bank, where necessary, and installing revetment along the waterside levee slope and streambank from streambed to a height determined by site-specific analysis. Large trees on the lower half of the waterside slope will be protected in place to retain shaded riverine aquatic (SRA) habitat. The sites will be prepared by removing vegetation along the levee slopes at either end of the site for construction of a temporary access ramp, if needed. The ramp will then be constructed using imported commercial borrow material that will be trucked on site.

The placement of rock onto the levee slope will occur from atop the levee and/or from the waterside by means of barges. Rock required within the channel, both below and slightly above the water line at the time of placement, will be placed by an excavator located on a barge. Construction will require two barges: one barge would carry the excavator, while the other barge will hold the stockpile of rock to be placed on the channel slopes. Rock required on the upper portions of the slopes will be placed by an excavator located on top of the levee. Rock placement from atop the levee will require one excavator and one loader for each potential placement site. The loader brings the rock from a permitted source and stockpiles it near the levee in the construction area. The excavator then moves the rock from the stockpile to the waterside of the levee.

The revetment will be placed via the methods discussed above on existing bank at a slope varying from 2V:1H to 3V:1H depending on site specific conditions. After revetment placement has been completed, a small planting berm will be constructed in the rock to allow for some revegetation of the site.

Natomas East Main Drain Canal

The east levee of the NEMDC requires 6,000 LF of improvements to address seepage and stability at locations where historic creeks had intersected the current levee alignment. A cutoff wall will be constructed at this location to address the seepage and stability problems. The cutoff wall will be constructed by one of the methods described in the Sacramento River section above. SAFCA is proposing to construct 1,700 LF of cutoff wall beginning just south of the confluence of Arcade Creek and extending south along the NEMDC. The Corps will construct the remaining 4,300 LF of cutoff wall.

Arcade Creek

The Arcade Creek levees require improvements to address seepage, slope stability, and overtopping when the event exceeds the current design. A centerline cutoff wall will be constructed to address seepage along 22,000 LF of the Arcade Creek levees. Levees from Rio Linda Boulevard to Marysville Boulevard will have a cutoff wall constructed at the waterside toe of the levee. Construction of the waterside toe cutoff wall will require constructing a work bench along the toe of the levee. Excavation for the bench will extend deep enough below existing grade to remove organic material and soft, unsuitable foundation soils. Bench excavation will also extend into the existing waterside slope of the levee as needed. Riprap will be placed on the waterside benches after construction of the waterside toe cutoff wall. Some portions of the Arcade Creek north levee will require more substantial excavation and reconstruction of the waterside slope to provide a low permeable seepage levee slope barrier. Bench fill material will be integrated with the slope reconstruction fill to provide an integral seepage barrier with the cutoff wall over the full height of the levee slope. A small section of levee will have a sheet pile cutoff wall at the centerline of the levee, rather than the waterside toe cutoff wall.

There is a ditch adjacent to the north levee at the landside toe which provides a shortened seepage path, and could affect the stability of the levee. The ditch will be replaced with a conduit or box culvert and then backfilled. This will lengthen the seepage path and improve the stability of the levee. Additionally, pressure relief wells will be installed along the landside toe of the levee along the north levee west of Norwood Avenue.

The majority of the Arcade Creek levees have existing floodwalls, however there remains a height issue in this reach. A 1 to 4-foot floodwall will allow the levees to pass flood events greater than the current design level. The floodwall will be placed on the waterside hinge point of the levee and will be designed to disturb a minimal amount of waterside slope and levee crown for construction. The waterside slope will be re-established to its existing slope and the levee crown will grade away from the wall and be surfaced with aggregate base.

Dry and Robla Creeks

The Dry and Robla Creeks levees require improvements to address overtopping when flood events exceed the design level. Height improvements will be made with a new floodwall constructed to a height of 4 to 6 feet along 2,500 LF of the south levee. The floodwall will be placed at the waterside hinge point of the levee and will be designed to disturb a minimal amount of waterside slope and levee crown for construction. Construction of the floodwall will be consistent with the description for Arcade Creek above. The waterside slope will be re-established to its existing slope and the levee crown will grade away from the wall and be surfaced with aggregate base.

Magpie Creek Diversion Canal

The Magpie Creek Diversion Canal project description is the same as was described in the September 15, 2004 biological opinion.

Sacramento Weir and Bypass

The Sacramento Weir was completed in 1916. It is the only weir in the Sacramento River Flood Control Project that is manually operated; all others overflow by gravity on their own. It is located along the right bank of the Sacramento River about 4 miles upstream of the Tower Bridge, and about 2 miles upstream from the confluence with the American River. Its primary purpose is to protect the city of Sacramento from excessive flood stages in the Sacramento River channel downstream of the American River. The weir limits flood stages (water surface elevations) in the Sacramento River to project design levels through the Sacramento/West Sacramento area. Downstream of the Sacramento Weir, the design flood capacity of the American River is 5,000 cfs higher than that of the Sacramento River. Flows from the American River channel during a major flood event often exceed the capacity of the Sacramento River downstream of the confluence. When this occurs, floodwaters flow upstream from the mouth of the American River to the Sacramento Weir.

The project design capacity of the weir is 112,000 cfs. It is currently 1,920 feet long and consists of 48 gates to divert floodwaters to the west through the mile-long Sacramento Bypass to the Yolo Bypass. Each gate has 38 vertical wooden plank "needles" (4 inches thick by 1 foot wide by 6 feet long).

Though the weir crest elevation is 24.75 feet, the weir gates are not opened until the river reaches 27.5 feet at the I Street gage with a forecast to continue rising. This gage is about 1,000 feet upstream from the I Street Bridge and about 3,500 feet upstream from the mouth of the American River. The number of gates to be opened is determined by the National Weather Service/DWR river forecasting team to meet either of two criteria: (1) to prevent the stage at the I Street gage from exceeding 29 feet, or (2) to hold the stage at the downstream end of the weir to 27.5 feet (DWR 2010). The weir gates are then closed as rapidly as practicable once the stage at the weir drops below 25 feet. This provides "flushing" flows to re-suspend sediment deposited in the Sacramento River between the Sacramento Weir and the American River during the low flow periods when the weir is open during the peak of the flood event (DWR 2010).

The Sacramento Weir and Bypass will be expanded to roughly twice their current width to accommodate increased bypass flows. The existing north levee of the Sacramento Bypass will be degraded and a new levee would be constructed 1,500 feet to the north. The existing Sacramento Weir will be expanded to match the wider bypass. At this time, it is not known whether the new segment of weir will be constructed consistent with the 1916 design described above, or whether it will be designed to be a gravity-type weir. The new north levee of the bypass will be designed to be consistent with the existing Sacramento Bypass north levee; however, it will also include a 300-foot-wide seepage berm on the landside with a system of relief wells. A hazardous, toxic, and radiological waste site near the existing north levee will be remediated by the non-Federal sponsor prior to construction.

Operation of the new segment of the Sacramento Weir will occur during high water situations only, when the American River flows exceed 115,000 cfs. The existing Sacramento Weir will be operating at the pre-existing conditions described above. There are not expected to be any water quality impacts, though this has not been specifically modeled. The approximate change in water diversions, which are shown in Table 2, will vary based on the size of the flood event. The frequency of water diversion is expected to be the same, dependent on the stream gage at the I Street Bridge reaching 27.5 feet.

The widened portion of the Sacramento Weir will only be operated when the release from Folsom Dam is above 115,000 cfs. With the Folsom Dam improvements in place, releases from Folsom Dam will be above 115,000 cfs for flood events greater than the 100-year event. Therefore, for events up to and including the 100-year event, only the existing weir will be operated per the criteria previously established. For events greater than the 100-year event, when the release from Folsom Dam will go above 115,000 cfs, the new weir will be opened. Therefore, for events up to the 100-year event there will be no change in flow conditions in the Sacramento and Yolo Bypasses.

Table 2. Comparison of 10-, 100-, and 200-year Frequency Flows under Various Conditions

10-Year Event	Existing Condition	Future Without Project Condition	Future With Project Condition
American River	43,000 cfs	72,000 cfs	72,000 cfs
Sacramento Bypass	50,000 cfs	66,000 cfs	66,000 cfs
Yolo Bypass below Sacramento Bypass	270,000 cfs	296,000 cfs	296,000 cfs
100-Year Event	**Existing Condition**	**Future Without Project Condition**	**Future With Project Condition**
American River	145,000 cfs	115,000 cfs	115,000 cfs
Sacramento Bypass	131,000 cfs	115,000 cfs	115,000 cfs
Yolo Bypass below Sacramento Bypass	555,000 cfs	535,000 cfs	535,000 cfs
200-Year Event	**Existing Condition**	**Future Without Project Condition**	**Future With Project Condition**
American River	320,000 cfs	160,000 cfs	160,000 cfs
Sacramento Bypass	183,000 cfs	149,000 cfs	164,000 cfs
Yolo Bypass below Sacramento Bypass	656,000 cfs	631,000 cfs	643,000 cfs

For the 200-year event, there will be an increase in flows in the Sacramento Bypass of about 15,000 cfs. In the Yolo Bypass, this equates to an increase of about 0.10-foot of water surface elevation. During the 200-year event, the Yolo Bypass is already flooded from levee to levee. The addition of these flows will equate to about 0.5-foot of additional width on the Yolo Bypass levee slopes.

High Hazard Levee Encroachment and Vegetation Removal

The National Flood Insurance Program (NFIP) standards for levee accreditation and the State's ULDC both require removal or modification of encroachments that pose an unacceptably high risk to the performance and safety of a levee either by undermining its structural integrity or by interfering with necessary inspection, operation, and maintenance activities. To address this requirement, SAFCA has identified and evaluated all of the encroachments in the NEMDC, Robla Creek, and Arcade Creek area. Each of these encroachments has been evaluated and based on this evaluation the encroachments have been classified as either:

- High-risk – poses a threat to levee integrity, removable prior to the levee being accredited;
- High-risk – impedes operation, maintenance, and inspection, removable within 3 years after the levee is accredited; or
- Low-risk – not identified as high hazard.

High-risk encroachments to be removed are limited to residential landscaping located at 10 locations along the landside of the south and north levees of Arcade Creek and along the Robla Creek south levee.

Vegetation on levees must be modified or removed if it presents an unacceptable risk to the structural integrity or impedes operation and maintenance of the levee. Eight high-risk trees along Arcade Creek have been identified for removal. All of the trees are either nonnative (7) or snags (1). Five are located on the waterside of the levees. These trees are in addition to any trees that will be removed as a result of implementation of levee improvements in the Arcade Creek area.

Utility Relocation

Existing encroachments and penetrations within the NEMDC and Arcade Creek have been inventoried by SAFCA. Many utilities will be avoided, however some utilities may need to be temporarily removed or relocated prior to construction. Temporary bypass pumping may be required for sanitary sewers. SAFCA and the construction contractors will coordinate with utility owners to manage the utilities in advance of construction. Disturbed utilities will be restored after construction consistent with Central Valley Flood Protection Board requirements.

Stormwater Pollution Prevention

Temporary erosion/runoff best management control measures would be implemented during construction to minimize stormwater pollution resulting from erosion and sediment migration from the construction, borrow, and staging areas. These temporary control measures may include implementing construction staging in a manner that minimizes the amount of area disturbed at any one time; secondary containment for storage of fuel and oil; and the management of stockpiles and disturbed areas by means of earth berms, diversion ditches, straw wattles, straw bales, silt fences, gravel filters, mulching, revegetation, and temporary covers as appropriate. Erosion and stormwater pollution control measures will be consistent with National Pollutant Discharge Elimination System (NPDES) permit requirements and included in a Stormwater Pollution Prevention Plan (SWPPP).

After completion of construction activities, the temporary facilities (construction trailers and batch plants) will be removed and the site would be restored to pre-project conditions. Site restoration activities for areas disturbed by construction activities, including borrow areas and staging areas, will include a combination of regrading, reseeding, constructing permanent diversion ditches, using straw wattles and bales, and applying straw mulch and other measures deemed appropriate.

Borrow Sites, Haul Routes, and Staging Areas

Borrow Sites - It is estimated that a maximum of 1 million cubic yards (cy) of borrow material will be needed to construct the project. Detailed studies of the borrow needs have not been completed. Actual volumes exported from any single borrow site will be adjusted to match demands for fill. Borrow sites will be selected that avoid effects to endangered species or their habitat.

To identify potential locations for borrow material soil maps and land use maps were obtained for a 20-mile radius surrounding the project area. Except as discussed below for Arcade Creek and NEMDC, eventual borrow site selection will include the following criteria: avoid threatened and endangered species effects and habitat, current land use patterns, and soil types.

Excavation limits on the borrow sites will provide a minimum buffer of 50 feet from the edge of the borrow site boundary. From this setback, the slope from existing grade down to the bottom of the excavation will be no steeper than 3:1. Excavation depths from the borrow sites will be determined based on available suitable material. The borrow sites will be stripped of top material and excavated to appropriate depths. Once material is extracted, borrow sites will be returned to their existing use whenever possible, or these lands could be used to mitigate for project effects, if appropriate.

Because SAFCA has completed more detailed design and studies for work along NEMDC and Arcade Creek the borrow site has been selected. Borrow site 2 is located along the east side of the NEMDC north of where the levee repairs will occur. About 27,000 cubic yards of material will be excavated from the 5.5-acre borrow site in order to construct levee improvements along the NEMDC and Arcade Creek. Following borrow activities the site will be contoured to create about 0.5 acre of tule bench, set an elevation the will provide aquatic habitat all year, 1.0 acre of higher bench with seasonal wetlands, that will flood in the winter and spring, and 3.5 acres of native grassland.

Clean rock will be commercially acquired in order to construct the American and Sacramento River bank protection sites. For the Sacramento River, rock will be acquired from a commercial source in the Bay Area and barged up the Sacramento River to the construction sites. Rock for the American river sites will be acquired from a commercial source within a 50-mile radius and will be hauled in trucks to the construction sites.

Haul Routes – Haul routes will be determined during the design phase and will depend on what borrow sites and staging areas are selected. Haul routes will be selected based on existing commercial routes and levee roads. Haul routes will be selected that avoid effects to federally listed species.

For Arcade Creek and NEMDC, haul trucks will leave borrow site 2 and use East Levee Road from the borrow site down to a point just north of the existing Del Paso/Main Avenue Bridge over NEMDC. Temporary bridges crossing the NEMDC and Arcade Creek will be used to allow haul trucks to reach repair sites. Railroad car undercarriages on temporary abutment supports will be one option for temporary bridge crossings.

Staging Areas – Staging areas will be selected that do not require the removal of vegetation or habitat that is used by threatened or endangered species or effect threatened or endangered species. Four potential staging areas have been identified for improvements along Arcade Creek. All four areas will require little preparation other than surface striping and temporary connection roads and ramps to the levee crown. The primary use of staging areas will be for temporary trailers, parking, and material staging. Additionally, there will need to be space to process material and an area where excavated soils and imported soils will be spread out and processed material. Importing, processing, and exporting material for levee reconstruction will be continuous activities once the work flow is established during the start of the construction season. Staging areas will be returned to pre-project conditions following construction activities unless the owner agrees to some grade raising to help dispose of excess construction soils.

Operation and Maintenance

Operation and maintenance (O&M) of the levees in the Sacramento area are the responsibility of the local maintaining agencies, including the American River Flood Control District, the DWR, and the City of Sacramento. The applicable O&M Manual for the Sacramento area levees is the Standard Operation and Maintenance Manual for the Sacramento Flood Control Project. Typical levee O&M in the Sacramento in the Sacramento area currently includes the following actions:

- Vegetation maintenance up to four times a year by mowing or applying herbicide.
- Control of burrowing rodent activity monthly by baiting with pesticide.
- Slope repair, site-specific and as needed, by re-sloping and compacting.
- Patrol road reconditioning up to once a year by placing, spreading, grading, and compacting aggregate base or substrate.
- Visual inspection at least monthly, by driving on the patrol road on the crown and maintenance roads at the base of the levee.
- Post-construction, groundwater levels will be monitored using the piezometers.

The Corps will work with local maintaining agencies to develop the maintenance activities necessary for long-term operations and maintenance. This will occur during the preconstruction engineering and design phase of the project. The Corps will evaluate if these maintenance activities will affect any Federally-listed species and reinitiate section 7 consultation if there will be adverse effects to listed species. Currently, the Corps only has a project description for activities that will affect valley elderberry longhorn beetle habitat. This is included below.

Following construction, the O&M manual for these reaches will be adjusted to reflect the vegetation variance and the SWIF plan. Under the adjusted O&M manual, large trees that are protected in place under the variance will be allowed to remain on the waterside slopes and additional vegetation will be planted on the planting benches.

Vegetation maintenance includes keeping maintenance roads clear of overhanging branches. Some of the vegetation along the levees includes elderberry shrubs. As part of long-term O&M, elderberry shrubs will be trimmed by the three levee maintenance districts. Table 3 describes the maximum amount of elderberry acreage that will be trimmed each year as a result of O&M. Trimming consists of cutting overhanging branches along the levee slopes on both the landside and waterside. Some shrubs may be located adjacent to the levee with branches hanging over the levee maintenance road. Up to a third of a shrub will be trimmed in a single season. Trimming will occur between November 1 and March 15. Loss of habitat will be offset through the development of a conservation area as described in the conservation measures below. Each year the local maintaining agency will document the amount of valley elderberry longhorn beetle habitat that they have trimmed and report that number to the Corps to ensure compliance with this biological opinion. If the local maintaining agency has a need to exceed the amount of valley elderberry longhorn beetle habitat which needs to be trimmed or affected due to routine maintenance, then they will request the Corps reinitiate consultation on this biological opinion for those actions.

Table 3. O&M by Maintaining Agency

Local Maintaining Agency	Levee Systems Covered	Annual Acreage of Trimmed Elderberry Shrubs*	Total Acreage of Elderberry Shrubs Trimmed over the 50 Year Life of the Project
American River Flood Control District	Lower American River, Dry/Robla Creek, Arcade Creek, NEMDC	0.5	25
Maintenance Area 9	Sacramento River east levee between Sutterville Road and the Beach Lake Levee	0.2	10
City of Sacramento	Sacramento River East Levee between the confluence of the American River and Sutterville Road	0.1	5

*acreage based on an estimated average shrub of 0.027 acre and no more than 1/3 of a shrub trimmed any given year.

Valley Elderberry Longhorn Beetle Habitat

Valley elderberry longhorn beetles are closely associated with elderberry shrubs. In 2011, the Corps conducted surveys and mapped all of the elderberry shrubs on the levees and 15 feet on either side of the levee. Elderberry shrubs were located along the American River and Sacramento River. The Corps counted shrub clusters and used elderberry stem counts from previous projects in the area to estimate a standard number and size of elderberry stems per shrub cluster. Tables 4 and 5 list the stem counts for shrubs along the American River and Sacramento River respectively. While shrubs exist along Arcade Creek or Magpie Creek, the Corps and SAFCA will avoid effects to the beetle by following the conservation measures below.

Table 4. American River Elderberry Shrub Effects and Compensation

Location	Stems	Exit Holes	No. of Stems	Elderberry Ratios	Elderberry Plantings	Associated Native Planting	Associated Native Ratios
riparian	> or = 1" & < or = 3"	no	1,998	2	3,996	3,996	1
		yes	0	4	0	0	2
riparian	> 3" & < 5"	no	790	3	2,370	2,370	1

				total basins or credits=	85		
				total acres need for compensation	3.51		

Delta Smelt Habitat

The American River lacks suitable turbidity making it unsuitable for delta smelt. Due to the higher temperatures within Arcade Creek, Magpie Creek, and NEMDC it is also unlikely that delta smelt will use these tributaries. Therefore, suitable delta smelt habitat occurs within the Sacramento River in the reach where erosion protection will occur. The Corps has calculated that there will be a complete loss of 14 acres of shallow water habitat due to the placement of riprap and a change of substrate from natural soil to riprap on 32 acres.

Giant Garter Snake Habitat

Giant garter snakes are not known to use large rivers such as the American and Sacramento Rivers. Given the close proximity to urban development, high level of human disturbance, presence of riparian vegetation along the banks of most channel reaches, and lack of extensive marsh or rice to the east, giant garter snakes are unlikely to occur in Arcade Creek, Dry Creek, Robla Creek, Magpie Creek, or the southern section of the NEMDC (south of where Dry Creek enters). North of Dry Creek, the NEMDC has less woody vegetation, less urban development, and large areas of open grassland along the landside of the levee with rice farming occurring to the west of the grasslands. Therefore, there is potential for the snake to occur either in the upland or within the NEMDC north of where Dry Creek enters. Work in this location will involve removal of borrow material at borrow site 2 (5.5 acres of upland habitat).

Habitat for the giant garter snake also exists north of the existing Sacramento Bypass north levee. The land north of the Sacramento Bypass is currently agricultural fields producing row crops and nut orchards. Existing giant garter snake aquatic habitat occurs in drainage ditches and farm canals and the surrounding upland habitat. About 15 acres of aquatic habitat will be filled making it and the associated 30 acres of upland habitat unavailable to the giant garter snake. The Sacramento Bypass also has a toe drain along the levee with 25 acres of aquatic and 50 acres of upland habitat that will be relocated to the toe of the new Sacramento Bypass levee.

Yellow-billed Cuckoo Habitat

Yellow-billed cuckoos use riparian habitat for foraging and nesting. Suitable habitat occurs within the lower American River. The project will affect 65 acres of riparian habitat that could be used by the yellow-billed cuckoo. While riparian habitat occurs along Arcade Creek, Magpie Creek, and NEMDC it is very narrow and cuckoos are not likely to use these areas. Riparian habitat occurs along the Sacramento River and in some areas may be of such a width that a cuckoo could stop and use it during migration, but it is not wide enough to support a nesting pair of cuckoos. The Corps will remove 110 acres of riparian habitat along the Sacramento River and disturb an additional 50 acres of riparian habitat by removing the understory and placing rock around the large trees. The Sacramento Bypass does not have suitable habitat for the yellow-billed cuckoo. But riparian habitat does exist north of the existing Sacramento Weir along the Sacramento River (8 acres). Cuckoos have been observed in the Yolo Bypass in recent years (Ebird 2015).

Conservation Measures

Valley Elderberry Longhorn Beetle

- The Corps assumes complete avoidance of the valley elderberry longhorn beetle when a 100-foot (or wider) buffer is established and maintained around elderberry shrubs.
- When work will occur within the 100-foot buffer, a setback of 20 feet from the dripline of each elderberry shrub will be maintained whenever possible.
- During construction activities, all areas to be avoided will be fenced and flagged.
- Contractors will be briefed on the need to avoid damaging elderberry shrubs and the possible penalties for not complying with these requirements.
- Signs will be erected every 50 feet along the edge of the avoidance area, identifying the area as an environmentally sensitive area.
- Any damage done to the buffer area will be restored.
- Buffer areas will continue to be protected after construction.
- No insecticides, herbicides, fertilizers, or other chemicals that might harm the beetle or its host plant will be used in the buffer areas.
- Elderberry shrubs that cannot be avoided would be transplanted to an appropriate riparian area at least 100 feet from construction activities.
- Elderberry shrubs will be surveyed prior to construction to ensure that the actual effects match the estimated effects of this biological opinion. If the Corps will effect more valley elderberry longhorn beetle habitat than estimated than they will reinitiate consultation with the Service.
- If possible, elderberry shrubs would be transplanted during their dormant season (November through the first two weeks in February). If transplantation occurs during the growing season, increased mitigation will apply.
- Elderberry compensation will be planted in the American River Parkway. The Corps has six existing sites which are offsetting previous Corps flood control projects along the lower American River and near Folsom Dam. The Corps will find areas within the lower American River parkway which will either expand existing compensation areas or provide for connectivity between conserved valley elderberry longhorn beetle habitat. Sites within the lower American River parkway will be coordinated with Sacramento County Parks and the Service during the design phase of the project. Sites will be designed and developed prior to any effects to valley elderberry

longhorn beetle habitat. The Corps will create 69.91 acres of riparian habitat which supports valley elderberry longhorn beetle within the lower American River parkway for the transplantation of elderberry shrubs. In addition, the local sponsors will create an additional 40 acres of land to benefit the valley elderberry longhorn beetle or purchase 40 acres of credits at a Service approved conservation bank to offset the loss of habitat due to trimming of elderberry shrubs along the lower American River, Sacramento River, Dry/Robla Creeks, Arcade Creek, Magpie Creek, and NEMDC.

- Management of these lands will include all measures specified in the Service's conservation guidelines (1999a) related to weed and litter control, fencing, and the placement of signs.
- Monitoring will occur for 10 consecutive years or for 7 non-consecutive years over a 15-year period. Annual monitoring reports will be submitted to the Service.
- Compensation areas will be protected in perpetuity and have a funding source for maintenance (endowment).

Giant Garter Snake

- Unless approved otherwise by the Service, construction will be initiated only during the giant garter snakes' active period (May 1–October 1, when they are able to move away from disturbance).
- Construction personnel will be given a Service-approved worker environmental awareness program.
- A survey for giant garter snakes will be conducted within 24 hours prior to construction beginning in potential giant garter snake habitat. Should there be any interruption in work for greater than 2 weeks, a biologist will resurvey the area within 24 hours prior to the restart of construction.
- Giant garter snakes encountered during construction will be allowed to move away from construction activities on their own.
- Movement of heavy equipment to and from the construction site will be restricted to established roadways. Stockpiling of construction materials will be restricted to designated staging areas, which will be located more than 200 feet away from giant garter snake aquatic habitat.
- Giant garter snake habitat within 200 feet of construction activities will be designated as an environmentally sensitive area and delineated with signs or fencing. This area will be avoided by all construction personnel.
- Habitat temporarily affected for one season (the 5.5 acre borrow site along the NEMDC and the 75 acres along the toe drain of the Sacramento Bypass levee) will be restored after construction by applying appropriate erosion control techniques and replanting/seeding with appropriate native plants. If for any reason construction extends into another active season the Corps will replace the habitat on-site and purchase credits at a ratio of 1:1 at a Service approved conservation bank.
- Habitat temporarily affected for more than three or more seasons will be restored and twice as much habitat will be created.
- Habitat permanently affected in the Sacramento Bypass in the form of drainage ditches and irrigation canals will be compensated for through the purchase of 135 acres of credits at a Service approved conservation bank.
- One year of monitoring will be conducted for the 80.5 acres that are temporarily affected.

- The Corps will purchase credits at a conservation bank prior to any permanent disturbance of giant garter snake habitat.
- A biological monitor will be on-site during all ground disturbing activities at borrow site 2.
- Exclusionary fencing will be placed, at least 10 days prior to the beginning of ground disturbing activities after May 1, to exclude giant garter snakes from entering areas where upland disturbance (borrow site 2 and Sacramento Bypass) will occur during the active season (May 1 to October 1). Prior to fencing installation, the fence line will be mowed (with a minimum height of 6 inches) in order to conduct a surface survey of potential burrows. Fencing will be installed with a minimum of 6 inches buried in the ground and a minimum of 24 inches above ground. Fence staking will be installed on the inside of the exclusion area. One-way escape funnels will be installed every 50 to 100 feet and sealed along the fence line to provide an escape for any giant garter snake that may be within the exclusion area. The fencing will enclose the entirety of the site, or additional exclusionary fencing can be extended 200 to 400 feet beyond the proposed entrance area. The fencing will be inspected before the start of each work day and maintained by the contractor until completion of the project. The fencing will be removed only when project activities are completed.

Yellow-Billed Cuckoo

- Prior to construction, surveys will be conducted to determine the presence of yellow-billed cuckoos within the project area in accordance with any required Service survey protocols and permits at the time of construction.
- If surveys find cuckoos in the area, vegetation removal will be done outside of the cuckoo nesting season.
- Riparian habitat that is removed due to project construction along the American River will be replanted within the American River parkway. The Corps intends to expand existing conserved riparian lands within the parkway that could support the yellow-billed cuckoo. The design of replacement riparian areas will be coordinated with the Service to ensure that the habitat benefits both valley elderberry longhorn beetles and yellow-billed cuckoos.

Fisheries Conservation Measures

- In-water construction activities (e.g., placement of rock revetment) will be limited to the work window of August 1 through November 30. If the Corps wants to work outside of this window they will consult with National Marine Fisheries Service (NMFS) and/or the Service.
- The Corps will purchase 42 acres of delta smelt credits from a Service-approved conservation bank to off-set the loss of 14 acres of shallow water habitat.
- The Corps will purchase an additional 32 acres of delta smelt credits from a Service-approved conservation bank to off-set the loss of spawning habitat due to the placement of riprap on the river bed.
- Erosion control measures (BMPs), including Storm Water Pollution Prevention Program and Water Pollution Control Program, that minimize soil or sediment from entering the river shall be installed, monitored for effectiveness, and maintained

throughout construction operations to minimize effects to federally listed fish and their designated critical habitat.

- Screen any water pump intakes, as specified by NMFS and the Service screening specifications. Water pumps will maintain an approach velocity of 0.2 feet per second or less when working in areas that may support delta smelt.
- The Corps shall include as part of the project, a Riparian Corridor Improvement Plan with the overall goal of maximizing the ecological function and value of the existing levee system within the Sacramento Metropolitan area.

Additional Minimization and Conservation Measures

- Obtain an ETL approved vegetation variance exempting sites from vegetation removal prior to final design and construction phase for the Sacramento River.
- Construction will be scheduled when listed terrestrial and aquatic species will be least likely to occur in the project area. If construction needs to extend into the timeframe that species are present, then coordination/reinitiation with the Service will occur.
- Compensation for impacts to native riparian habitat will occur on a 2:1 basis on-site or in close proximity to the impact area. Riparian vegetation impacted under the SAFCA 408/404 actions will be replaced on a 3:1 canopy cover acreage basis.
- Stockpile all liquid chemicals and supplies at a designated impermeable membrane fuel and refueling station with a 110% containment system.
- Stockpile construction materials such as portable equipment, vehicles, and supplies, at designated construction staging areas and barges, exclusive of any riparian and wetland areas.
- Implement BMPs to prevent slurry from seeping out to the river and require piping systems on the landside of the levee.
- Project related vehicles will observe a 20-mile-per-hour speed limit within construction areas, except on County roads and on State and federal highways.
- Site access will be limited to the smallest area possible in order to minimize disturbance. Litter, debris, unused materials, equipment, and supplies will be removed from the project area daily. Such materials or waste will be deposited at an appropriate disposal or storage site.
- Immediately (within 24 hours) cleanup and report any spills of hazardous materials to the resource agencies. Any such spills, and the success of the efforts to clean them up, shall also be reported in post-construction compliance reports.
- Designating a Service approved biologist as a point-of-contact for any contractor who might incidentally take a living, or find a dead, injured, or entrapped threatened or endangered species. This representative shall be identified to the employees and contractors during an all employee education program conducted by the Corps.

Action Area

The action area is defined in 50 CFR § 402.02, as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action." For the purposes of the effects assessment, the action area encompasses the Sacramento River from the Sacramento Bypass downstream to River Mile 45, the Yolo Bypass south the confluence of the Sacramento Bypass, the lower American River from Arden Way to the confluence of the Sacramento River, Arcade Creek from Marysville Boulevard to the confluence of the NEMDC, the NEMDC from the south Dry

Creek levee to just south of the NEMDC Arcade Creek confluence, the southern Dry Creek levee between Dry Creek Road and Rose Street, the borrow site along the NEMDC, and any borrow sites. Additionally, we are including a buffer of 300 feet from construction to account for effects to listed species due to dust and noise.

Analytical Framework for the Jeopardy Analysis

The following analysis relies on four components to support the jeopardy determination for the giant garter snake, valley elderberry longhorn beetle, yellow-billed cuckoo, and delta smelt: (1) the *Status of the Species*, which evaluates the species' range-wide condition, the factors responsible for that condition, and their survival and recovery needs; (2) the *Environmental Baseline*, which evaluates the condition of the species in the action area, the factors responsible for that condition, and the role of the action area in the species' survival and recovery; (3) the *Effects of the Action*, which determines the direct and indirect impacts of the proposed Federal action and the effects of any interrelated or interdependent activities on these species; and (4) the *Cumulative Effects*, which evaluates the effects of future, non-Federal activities in the action area on these species.

In accordance with the implementing regulations for section 7 and Service policy, the jeopardy determination is made in the following manner: the effects of the proposed Federal action are evaluated in the context of the aggregate effects of all factors that have contributed to the current status of the delta smelt, valley elderberry longhorn beetle, giant garter snake, and yellow-billed cuckoo. Additionally, for non-Federal activities in the action area, we will evaluate those actions likely to affect the species in the future, to determine if implementation of the proposed action is likely to cause an appreciable reduction in the likelihood of both its survival and recovery in the wild.

The following analysis places an emphasis on using the rang-wide survival and recovery needs of the delta smelt, valley elderberry longhorn beetle, giant garter snake, and yellow-billed cuckoo, and the role of the action area in providing for those needs as the context for evaluating the significance of the effects of the proposed Federal action, taken together with cumulative effects, for purposes of making the jeopardy determination.

Analytical Framework Adverse Modification

This biological opinion does not rely on the regulatory definition of "destruction or adverse modification" of critical habitat at 50 CFR 402.2. Instead, we have relied upon the statutory provisions of the Act to complete the following analysis with respect to critical habitat.

In accordance with policy and regulation, the adverse modification analysis in this biological opinion relies on four components: (1) the *Status of the Critical Habitat*, which evaluates the range-wide condition of critical habitat for the delta smelt in terms of primary constituent elements (PCE)s, the factors responsible for that condition, and the intended recovery function of the critical habitat at the provincial and range-wide scale; (2) the *Environmental Baseline*, which evaluates the condition of the critical habitat in the action area, the factors responsible for that condition, and the recovery role of the critical habitat in the action area; (3) the *Effects of the Action*, which determines the direct and indirect impacts of the proposed Federal action and the effects of any interrelated or interdependent activities on the PCEs and how that will influence the recovery role of affected critical habitat units and; (4) *Cummulative Effects*, which evaluates the effects of future, non-Federal activities in the action area on the PCEs and how that will influence the recovery role of affected critical habitat units.

For purposes of the adverse modification determination, the effects of the proposed Federal action on the delta smelt critical habitat are evaluated in the context of the range-wide condition of the critical habitat at the provincial and range-wide scales, taking into account any cumulative effects, to determine if the critical habitat range-wide would remain functional (or would retain the current ability for the PCEs to be functionally established in areas of currently unsuitable but capable habitat) to serve its intended recovery role for the delta smelt.

The analysis in this biological opinion places an emphasis on using the intended range-wide recovery function of delta smelt critical habitat and the role of the action area relative to that intended function as the context for evaluating the significance of the effects of the proposed Federal action, taken together with cumulative effects, for purposes of making the adverse modification determination.

Status of the Species and Environmental Baseline

Valley Elderberry Longhorn Beetle Status of the Species

Please refer to the *Withdrawl of the Proposed Rule to Remove the Valley Elderberry Longhorn Beetle from the Federal List of Endangered and Threatened Wildlife* (Service 2014) for the current status of the species. Ongoing threats to the valley elderberry longhorn beetle include habitat loss due to flood control projects, development projects, and invasive species. While these threats continue to affect the valley elderberry longhorn beetle throughout its range, to date no project has proposed a level of effect for which the Service has issued a biological opinion of jeopardy for the valley elderberry longhorn beetle.

Valley Elderberry Longhorn Beetle Environmental Baseline

The project footprint along both the Sacramento River and the American River contain riparian vegetation. The beetle is known in numerous locations along the American River parkway (CNDD 2015). Suitable habitat for the beetle in the form of elderberry shrubs occurs within the action area along the Sacramento River, the American River, and Arcade Creek.

Sacramento River - Riparian habitat along the Sacramento River, south of the city of Sacramento, occurs in narrow bands along the riverbank and levee. Generally an overstory layer is present composed of cottonwood, sycamore, and oak trees. Shrubs occur as a mid-story layer including buttonbush, blue elderberry, white alder, and Oregon ash. Elderberry shrubs occur randomly along the reach of river proposed for improvements. The Corps has documented at least 73 elderberry shrubs along the Sacramento River reach where construction is proposed. Natural river processes of erosion and accretion effect elderberry shrubs which is the host plant of the valley elderberry longhorn beetle by eroding away bank and potentially elderberry shrubs. Levee maintenance can adversely affect elderberries within this stretch of the Sacramento River either by pruning or drift of herbicides used along the levee slope.

American River – The valley elderberry longhorn beetles have been identfied along the lower American River Parkway in the CNDDB (2015). Additionally, the Corps has designed and built six sites along the lower American River as habitat for the valley elderberry longhorn beetle. These sites extend from RM 0.9 up to RM 21. Levee maintenance can adversely affect elderberry shrubs, though the largest threat to valley elderberry longhorn beetle is fires that have been started in the parkway and burned habitat that supports valley elderberry longhorn beetles.

Delta Smelt Status of Species

Listing Status: The Service proposed to list the delta smelt as threatened with proposed critical habitat on October 3, 1991 (56 FR 50075). The Service listed the delta smelt as threatened on March 5, 1993 (58 FR 12854), and designated critical habitat for this species on December 19, 1994 (59 FR 65256). The delta smelt was one of eight fish species addressed in the *Recovery Plan for the Sacramento–San Joaquin Delta Native Fishes* (Service 1996). This recovery plan is currently under revision. A 5-year status review of the delta smelt was completed on March 31, 2004 (Service 2004). The 2004 review affirmed the need to retain the delta smelt as a threatened species. A 12-month finding on a petition to reclassify the delta smelt was completed on April 7, 2010 (75 FR 17667). After reviewing all available scientific and commercial information, the Service determined that re-classifying the delta smelt from a threatened to an endangered species was warranted, but precluded by other higher priority listing actions (Service 2010).

Distribution: The delta smelt is endemic to the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (Bay-Delta) in California, and is restricted to the area from San Pablo Bay upstream through the Delta in Contra Costa, Sacramento, San Joaquin, Solano, and Yolo counties (Moyle 2002). Their range extends from San Pablo Bay upstream to Verona on the Sacramento River and Mossdale on the San Joaquin River. The delta smelt was formerly considered to be one of the most common pelagic fish in the upper Sacramento-San Joaquin Estuary.

Description: Live delta smelt are nearly translucent with a steely-blue sheen to their sides and have been characterized to have a pronounced odor reminiscent of cucumber (Moyle 2002). Although delta smelt have been recorded to reach lengths of up to 120 millimeters (mm) (4.7 in) (Moyle 2002), mean fork length of the delta smelt from 1974 to 1991 was measured to be 64.1 ± 0.1 mm. Since then, catch data from 1992 - 2004 showed mean fork length decreased to 54.1 ± .01 mm (Bennett 2005; Sweetnam 1999). Delta smelt are also identifiable by their relatively large eye to head size (Moyle 2002). Delta smelt have a small, translucent adipose fin located between the dorsal and caudal fins.

The delta smelt is one of six species currently recognized in the *Hypomesus* genus (Bennet 2005). Genetic analyses have confirmed that *H. transpacificus* presently exists as a single intermixing population (Stanley *et al.* 1995; Trenham *et al.* 1998; Fisch *et al.* 2011). Within the genus, delta smelt is most closely related to surf smelt (*H. pretiosis*), a species common along the western coast of North America. Despite morphological similarities, the delta smelt is less-closely related to the wakasagi (*H. nipponensis*), an andadromous western Pacific species introduced to Central Valley reservoirs in 1959, and may be seasonally sympatric with delta smelt in the estuary (Trenham *et al.* 1998). Allozyme studies have demonstrated that wakasagi and delta smelt are genetically distinct and presumably derived from different marine ancestors (Stanley *et al.* 1995).

Life History and Biology

Adult-Spawning: Adult delta smelt spawn during the late winter and spring months, with most spawning occurring during April through mid-May (Moyle 2002). Spawning occurs primarily in sloughs and shallow edge areas in the Delta. Delta smelt spawning has also been recorded in Suisun Marsh and the Napa River (Moyle 2002). Most spawning occurs at temperatures between 12-18°C. Although spawning may occur at temperatures up to 22°C, hatching success of the larvae is very low (Bennett 2005).

Fecundity of females ranges from about 1,200 to 2,600 eggs, and is correlated with female size (Moyle 2002). Moyle *et al.* (1992) considered delta smelt fecundity to be "relatively low." However, based on Winemiller and Rose (1992), delta smelt fecundity is fairly haigh for a fish its size. Captive delta smelt can spawn up to 4-5 times. While most adults do not survive to spawn a second season, a few (<5 percent) do (Moyle 2002; Bennett 2005). Those that do survive are typically larger (90-110 mm Standard Length[sdl]) females that may contribute disproportionately to the population's egg supply (Moyle 2002 and references therein). Two-year-old females may have 3-6 times as many ova as first year spawners.

Most of what is known about delta smelt spawning habitat in the wild is inferred from the location of spent females and young larvae captured in the California Department of Fish and Wildlife Spring Kodiak Trawl (SKT) and 20-mm Survey, respectively. In the laboratory, delta smelt spawned at night (Baskerville-Bridges *et al.* 2000; Mager *et al.* 2004). Other smelts, including marine beach spawning species and estuarine populations and the landlocked Lake Washington longfin smelt, are secretive spawners, entering spawning areas during the night and leaving before dawn. If this behavior is exhibited by delta smelt, then delta smelt distribution based on the SKT, which is conducted during daylight hours in offshore habitats, may reflect general regions of spawning activity, but not actual spawning sites.

Delta smelt spawning has only been directly observed in the laboratory and eggs have not been found in the wild. Consequently, what is known about the mechanics of delta smelt spawning is derived from laboratory observations and observations of related smelt species. Delta smelt eggs are 1 mm diameter and are adhesive and negatively buoyant (Moyle 1976, 2002; Mager *et al.* 2004; Wang 1986, 2007). Laboratory observations indicate that delta smelt are broadcast spawners, discharging eggs and milt close to the bottom over substrates of sand and/or pebble in current (DWR and Reclamation 1994; Brown and Kimmerer 2002; Lindberg *et al.* 2003; Wang 2007). Spawning over gravel or sand can also aid in the oxygenation of delta smelt eggs. Eggs that may have been laid in silt or muddy substrates might get buried or smothered, preventing their oxygenation from water flow (Lindberg pers. comm. 2011). The eggs of surf smelts and other beach spawning smelts adhere to sand particles, which keeps them negatively buoyant but not immobile, as the sand may move ("tumble") with water currents and turbulence (Hay 2007). It is not known whether delta smelt eggs "tumble incubate" in the wild, but tumbling of eggs may moderately disperse them, which might induce predation risk within a localized area.

The locations in the Delta where newly hatched larvae are present, most likely indicates spawning occurrence. The 20-mm trawl has captured small (~5 mm sdl) larvae in Cache Slough, the lower Sacramento River, San Joaquin River, and at the confluence of these two rivers (e.g., 20-mm trawl survey 1 in 2005). Larger larvae and juveniles (size > 23 mm sdl), which are more efficintly sampled by the 20-mm trawl gear, have been captured in Cache Slough and the Sacramento Deep Water Ship Channel in July (e.g. 20-mm trawl survey 9 in 2008). Because they are small fish inhabiting pelagic habitats with strong tidal and river currents, delta smelt larval distribution depends on both the spawning area from which they originate and the effect of transport processes caused by flows. Larval distribution is further affected by water salinity and temperature. Hydrodynamic simulations reveal that tidal action and other factors may cause substantial mixing of water with variable salinity and temperature among regions of the Delta (Monson *et al.* 2007). This could result in rapid dispersion of larvae away from spawning sites.

The timing of spawning may affect delta smelt population dynamics. Lindberg (2011) has suggested that smelt larvae that hatch early, around late February, have an advantage over larvae hatched during late spawning in May. Early season larvae have a longer growing season and may be able to grow larger faster during more favorable habitat conditions in the late winter and early spring. An early growing season may result in higher survivorship and a stronger spawning capability for that generation. Larvae hatched later in the season have a shorter growing season which effectively reduces survivorship and spawning success for the following spawning season.

Larval Development: Mager *et al.* (2004) reported that embryonic development to hatching takes 11-13 days at 14-16° C for delta smelt, and Baskerville-Bridges *et al.* (2000) reported hatching of delta smelt eggs after 8-10 days at temperatures between 15-17° C. Lindberg *et al.* (2003) reported high hatching rates of delta smelt eggs in the laboratory at 15° C, and Wang (2007) reported high hatching rates at temperatures between 14-17° C. Hatching success peaks near 15°C (Bennett 2005) and swim bladder inflation occurring at 60-70 days post hatch at 16-17°C (Mager *et al.* 2004). At hatching and during the succeeding three days, larvae are buoyant, swim actively near the water surface, and do not react to bright direct light (Mager *et al.* 2004). As development continues, newly hatched delta smelt become semi-buoyant and sink in stagnant water. However, larvae are unlikely to encounter stagnant water in the wild.

Growth rates of wild-caught delta smelt larvae are faster than laboratory-cultured individuals. Mager *et al.* (2004) reported growth rates of captive-raised delta smelt reared at near-optimum temperatrues (16-17°C). Their fish were about 12 mm long after 40 days and about 20 mm long after 70 days. In contrast, analyses of otoliths indicated that wild delta smelt larvae were 15-25 mm, or nearly twice as long at 40 days of age (Bennett 2005). By 70 days, most wild fish were 30-40 mm long and beyond the larval stage. This suggests there is a strong selective pressure for rapid larval growth in nature, a situation that is typical for fish in general (Houde 1987). Successful feeding seems to depend on a high density of food organisms and turbidity, and increases with stronger light conditions (Baskerville-Bridges *et al.* 2000; Mager *et al.* 2004; Baskerville-Bridges *et al.* 2004). The food available to larval fishes is constrained by mouth gape and status of fin development. Larval delta smelt cannot capture as many kinds of prey as larger individuals, but all life stages have small gapes that limit their range of potential prey. Prey availability is also constrained by habitat use, which affects what types of prey are encountered. Larval delta smelt are visual feeders. They find and select individual prey organisms and their ability to see prey in the water is enhanced by turbidity (Baskerville-Bridges *et al.* 2004). Thus, delta smelt diets are largely comprised of small crustacea that inhabit the estuary's turbid, low-salinity, open-water habitats (i.e., zooplankton). Larval delta smelt have particularly restricted diets (Nobriga 2002). They do not feed on the full array of zooplankton with which they co-occur; they mainly consume three copepods, *Eurytemora affinis*, *Pseudodiaptomus forbesi*, and freshwater species of the family Cyclopidae. Further, the diets of first-feeding delta smelt larvae are largely restricted to the larval stages of these copepods; older, larger life stages of the copepods are increasingly targeted as the delta smelt larvae grow, their gape increases, and they become stronger swimmers.

The triggers for and duration of delta smelt larval movement from spawning areas to rearing areas are not known. Hay (2007) noted that eulachon larvae are probably flushed into estuaries from upstream spawning areas within the first day after hatching, but downstream movement of delta smelt larvae occurs much later. Most larvae gradually move downstream toward the two parts per thousand (ppt) isohaline (X2). X2 is scaled as the distance in kilometers from the Golden Gate Bridge (Jassby *et al.* 1995).

At all life stages, delta smelt are found in greatest abundance in the water column and usually not in close association with the shoreline. They inhabit open, surface waters of the Delta and Suisun Bay, where they presumably aggregate in loose schools where conditions are favorable (Moyle 2002). In years of moderate to high Delta outflow (above normal to wet water years), delta smelt larvae are abundant in the Napa River, Suisun Bay and Montezuma Slough, but the degree to which these larvae are produced by locally spawning fish versus the degree to which they originate upstream and are transported by tidal currents to the bay and marsh is uncertain.

Juveniles: Young-of-the-year delta smelt rear in the low-salinity zone (LSZ) from late spring through fall and early winter. Once in the rearing area growth is rapid, and juvenile fish are 40-50 mm sdl long by early August (Erkkila *et al.* 1950; Ganssle 1966; Radtke 1966). They reach adult size (55-70 mm sdl) by early fall (Moyle 2002). Delta smelt growth during the fall months slows considerably (only 3-9 mm total), presumably because most of the energy ingested is being directed towards gonadal development (Erkkila *et al.* 1950; Radtke 1966).

Delta Smelt Population Dynamics and Abundance Trends

As a consequence of channelization, water operations, and agriculture in the Delta there has been a change to the physical appearance, water salinity, water clarity, and hydrology in the Delta such that most life stages of the delta smelt are now distributed across a smaller area than historically (Arthur *et al.* 1996; Feyrer *et al.* 2007). Wang (1991) noted in a 1989 and 1990 study of delta smelt larval distribution that, in general, the San Joaquin River was used more intensively for spawning than the Sacramento River. Nobriga *et al.* (2008) found that delta smelt capture probabilities in the Summer Townet Survey (TNS) are highest at specific conductance levels of 1,000 to 5,000 $\mu S\ cm^{-1}$ (approximately 0.6 to 3.0 practical salinity unit [psu]). Similarly, Feyrer *et al.* (2007) found a decreasing relationship between abundance of delta smelt in the Fall Midwater Trawl (FMWT) and specific conductance during September through December. The location of the low salinity zone (LSZ) and changes in delta smelt habitat quality in the San Francisco Estuary can be indexed by changes in X2. The LSZ historically had the highest primary productivity and is where zooplankton populations (on which delta smelt feed) were historically most dense (Knutson and Orsi 1983; Orsi and Mecum 1986). However, this has not always been true since the invasion of the overbite clam (Kimmerer and Orsi 1996). The abundance of many local aquatic species has tended to increase in years when winter-spring outflow has high and Z2 was pushed seaward (Jassby *et al.* 1995), implying that the quantity and quality (overall suitability) of estuarine habitat increases in years when outflows are high. However, delta smelt is not one of the species whose abundance has statistically covaried with winter-spring freshwater flows (Stevens and Miller 1983; Moyle *et al.* 1992; Kimmerer 2002a; Bennett 2005).

The distribution of juvenile delta smelt has also changed over the last several decades. During the years 1970 through 1978, delta smelt catches in the TNS survey declined rapidly to zero in the Central and South Delta and have remained near zero since. A similar shift in FMWT catches occurred after 1981 (Arthur *et al.* 1996). This portion of the Delta has also had a long-term trend increase in water clarity during July through December (Arthur *et al.* 1996; Feyrer *et al.* 2007; Nobriga *et al.* 2008).

The CDFW has conducted several long-term monitoring surveys that have been used to index the relative abundance of delta smelt. The 20-mm Survey has been conducted every year since 1995. This survey targets late-stage delta smelt larvae. Most sampling has occurred April-June. The TNS has been conducted nearly every year since 1959. This survey targets 38-mm striped bass, but collects similar-sized juvenile delta smelt. Most sampling has occurred June-August. The Fall Midwater Trawl Survey has been conducted nearly every year since 1967. This survey also targets age-0 striped bass, but collects delta smelt > 40 mm in length. The FMWT samples monthly, September-December. The relative abundance index data and maps of the sampling stations used in these surveys are available at http://www.CDFW.ca.gov/delta/. The methods that underlie the surveys have been described previously (Stevens and Miller 1983; Moyle *et al.* 1992; Dege and Brown 2004). The delta smelt catch data and relative abundance indices derived from these sampling programs have been used in numerous publications (e.g., Stevens and Miller 1983; Moyle *et al.* 1992; Jassby *et al.* 1995; Kimmerer 2002b; Dege and Brown 2004; Bennett 2005; Feyrer *et al.* 2007; Sommer *et al.* 2007; Kimmerer 2008; Newman 2008; Nobriga *et al.* 2008; Kimmerer *et al.* 2009; Mac

Nally *et al.* 2010; Thomson *et al.* 2010; Feyrer *et al.* 2011; Maunder and Deriso 2011). These abundance index time series document the long-term decline of the delta smelt.

Early statistical assessments of delta smelt population dynamics concluded that at best, the relative abundance of the adult delta smelt population had only a very weak influence on subsequent juvenile abundance (Sweetnam and Stevens 1993). Thus, early attempts to describe abundance variation in delta smelt ignored stock-recruit effects and researchers looked for environmental variables that were directly correlated with interannual abundance variation (e.g., Stevens and Miller 1983; Moyle *et al.* 1992; Sweetnam and Stevens 1993; Herbold 1994; Jassby *et al.* 1995). Because delta smelt live in a habitat that varies in size and quality with Delta outflow, the authors cited above searched for a linkage between Delta outflow (or X2) and the TNS and FMWT indices. Generally, these analyses did not find strong support for an outflow-abundance linkage. These analyses led to a prevailing conceptual model that multiple interacting factors had caused the delta smelt decline (Moyle *et al.* 1992; Bennett and Moyle 1996; Bennett 2005). It has also recently been noted that delta smelt's FMWT index is partly influenced by explanation for why few analyses could consistently link springtime environmental conditions to delta smelt's fall index.

One published exception to the multi-factor hypothesis was proposed by Gilbert (2010), who posited that nutrient pollution was the root cause of all the food web and fish assemblage changes that caused the decline of delta smelt and other pelagic fishes. However, the statistical approach she used to support her hypothesis was not appropriate and the untransformed data sets do not support this hypothesized chain of consequences stemming solely from wastewater inputs to the Delta (Jassby *et al.* in press). It is now recognized that delta smelt abundance plays an important role in subsequent abundance (Bennett 2005; Maunder and Deriso 2011). Bennett (2005) assessed (1) the influence of adult stock as indexed by the FMWT versus the next generation of juveniles indexed by the following calendar year's TNS; (2) the influence of the juvenile stock indexed by the TNS versus the subsequent adult stock indexed a few months later in the FMWT; (3) the influence of the FMWT on the following year's FMWT and on the FMWT two years later, and (4) he did the same for the TNS data. He concluded that (1) two-year-old delta smelt might play an important role in delta smelt population dynamics, (2) it was not clear wheter juvenile production was a density-independent or density-dependent function of adult abundance, and (3) adult production was a density-dependent function of juvenile abundance and the carrying capacity of the estuary to support this life-stage transition had declined over time. These conclusions are also supported by Maunder and Deriso (2011).

The concept of density-dependence and how it has affected the delta smelt is important because it may be used as a reason not to protect particular life stages from sources of mortality. Bennet (2005) concluded it was (statistically) unclear whether density-dependence occurs between generations. He also noted that the delta smelt indices strongly suggest that density-dependence has occurred, at least over the long-term, during the juvenile stage. The uncertainty about density-dependence between generations results because statistical assessments of the relationship between the adult stock and the next generation of recruits (juveniles_ result in similar fits for linear (density-independent) and nonlinear (density-dependent) relationships (Bennett 2005; Maunder and Deriso 2011).

One reason for this is that delta smelt population dynamics may have changed over time. Previous papers have reported a delta smelt step-decline during 1981-1982 (Kimmerer 2002a; Thomson *et al.* 2010). Prior to this decline, the stock-recruit data are consistent with "Ricker" type density-dependence where increasing adult abundance resulted in decreased juvenile abundance. Since the decline, recruitment has been positively and essentially linearly related to prior adult abundance, suggesting that reproduction has been basically density-independent for about the past 30 years.

This means that since the early 1980s, more adults translates into more juveniles and fewer adults translates into fewer juveniles without being 'compensated for' by density-dependence. In contrast to the transition among generations, the weight of scientific evidence strongly supports the hypothesis that, at least over the history of Interagency Ecological Program (IEP) fish monitoring, delta smelt has experienced density-dependence during the juvenile stage of its life cycle, i.e., between the summer and fall (Bennett 2005; Maunder and Deriso 2011). This has been inferred because, statistically, the FMWT index does not increase linearly with increases in the summer townet index. Rather, the best-fitting relationships between the summer townet index and the FMWT index show that the FMWT indices approach an asymptote as the summer townet increases or possibly even declines at the highest summer townet indices.

From a species conservation perspective, the most relevant aspect of this juvenile density dependence is that the carrying capacity of the estuary for delta smelt has declined (Bennett 2005). Thus, the delta smelt population decline has occurred for two basic reasons. First, the compensatory density-dependence that historically enabled juvenile abundance to rebound from low adult numbers stopped happening. This change had occurred by the early 1980s as described above. The reason is still not known, but the consequence of the change is that for the past several decades, adult abundance drives juvenile production in a largely density-independent manner. Thus, if numbers of adults or adult fecundity decline, juvenile production will also decline (Kimmerer 2011). Second, because juvenile carrying capacity has declined, juvenile production hits a 'ceiling' at a lower abundance than it once did. This limits adult abundance and possibly per capita fecundity, which cycles around and limits the abundance of the next generation of juveniles. The mechanism causing carrying capacity to decline is likely due to the long-term accumulation of deleterious habitat changes, both physical and biological, during the summer-fall (Bennett *et al.* 2008; Feyrer *et al.* 2007; 2011; Maunder and Deriso 2011).

Habitat

The existing physical appearance and hydrodynamics of the Delta have changed substantially from the environment in which native fish species like delta smelt evolved. The Delta once consisted of tidal marshes with networks of diffuse dendritic channels connected to floodplains of wetlands and upland areas (Moyle 2002). The in-Delta channels were further connected to drainages of larger and smaller rivers and creeks entering the Delta from the upland areas. In the absence of upstream reservoirs, freshwater inflow from smaller rivers and creeks and the Sacramento and San Joaquin Rivers were highly seasonal and more strongly and reliably affected by precipitation patterns than they are today. Consequently, variation in hydrology, salinity, turbidity, and other characteristics of the Delta aquatic ecosystem was greater in the past than it is today (Kimmerer 2002a). For instance, in the early 1900s, the location of maximum salinity intrusion into the Delta during dry periods varied from Chipps Island in the lower Delta to Stockton along the San Joaquin River and Merritt Island in the Sacramento River. Operations of upstream reservoirs have reduced spring flows while releases of water for Delta water export and increased flood control storage have increased late summer and fall inflows (Knowles 2002), though Delta outflows have been tightly constrained during late summer-fall for several decades. The following is a brief description of the changes that have occurred to delta smelt's habitat that are relevant to the environmental baseline for this consultation.

Changes to the LSZ: There have been documented changes to the delta smelt's LSZ habitat that have led to present-day, baseline habitat conditions. The close association of delta smelt with the San Francisco estuary LSZ has been known for many years (Stevens and Miller 1983; Moyle *et al.* 1992). Peterson (2003) developed a conceptual model that hypothesized how, "stationary and dynamic components of estuarine habitats" interacted to influence fisheries production in tidal river estuaries.

Peterson's model suggests that when the dynamic and static aspects of estuarine habitat sufficiently overlap, foraging, growth, density, and survival are all high, and that enables fish production to outpace losses to predators. The result is high levels of successful recruitment of new individuals. The model also hypothesizes that when the dynamic and static aspects of an estuarine habitat do not sufficiently overlap, foraging, growth, density, and survival are impaired such that losses to predators increase and recruitment of new individuals decreases. This model was developed specifically for species spawned in marine environments that were subsequently transported into estuaries. However, the concept of X2, which was developed in the San Francisco estuary to describe how freshwater flow affected estuarine habitat (Jassby *et al.* 1995), played a role in the intellectual development of Peterson's model. The Peterson model also provides a useful framework to conceptualize delta smelt's LSZ habitat.

Currently available information indicates that delta smelt habitat is most suitable for the fish when low-salinity water is near 20°C, highly turbid, oxygen saturated, low in contaminants, supports high densities of calanoid copepods and mysid shrimp (Moyle *et al.* 1992; Lott 1998; Nobriga 2002), and occurs over comparatively static 'landscapes' that support sandy beaches and bathymetric variation that enables the fish and their prey to aggregate (Kimmerer *et al.* 2002a; Bennett *et al.* 2002; Hobbs *et al.* 2006). Almost every component listed above has been degraded over time (see below). The Service has determined that this accumulation of habitat change is the fundamental reason or mechanism that has caused delta smelt to decline.

Alterations to estuarine bathymetry and salinity distribution (~ 1850-present): The position of the LSZ, where delta smelt rear, has changed over the years. The first major change in the LSZ was the conversion of the landscape over which tides oscillate and river flows vary (Moyle *et al.* 2010). The ancestral Delta was a large tidal marsh-floodplain habitat totaling approximately 700,000 acres. Most of the historic wetlands within the system were diked and reclaimed for agriculture or other human uses by 1920 (Atwater *et al.* 1979). Channels were dredged deep (~12 meters[m]) to accommodate shipping traffic from the Pacific Ocean and San Francisco Bay to ports in Sacramento and Stockton. These changes left Suisun Bay and the confluence of the Sacramento-San Joaquin Rivers as the largest and most bathymetrically variable places in the LSZ. This region remained a highly productive nursery for many decades (Stevens and Miller 1983; Moyle *et al.* 1992; Jassby *et al.* 1995). However, the deepened channels created to support shipping and flood control, requires more freshwater outflow to maintain the LSZ in the large Suisun Bay and River confluence than was once required (Gartrell 2010). The construction of the CVP and SWP not only provided water supply for urban, agricultural and industrial users, but also provided water needed to combat salinity intrusion into the Delta, which was observed by the early 20th century. California's demand for freshwater (keeps) continues to increase, thus seasonal salinity intrusion perpetually reduces the temporal overlap of the LSZ (indexed by X2) within the Suisun Bay (region), especially in the fall (Feyrer *et al.* 2007; 2011). Consequently, the second major habitat change in the Delta has been in the frequency with which the LSZ is maintained in Suisun Bay for any given amount of precipitation. There was a step-decline in the LSZ in 1977 from which it has never recovered for more than a few years at a time. Based on model forecasts of climate change and water demand, this trend is expected to continue (Feyrer *et al.* 2011).

Summer and fall environmental quality has decreased overall in the Delta because outflows are lower and water transparency is higher. These changes may be due to increased upstream water diversions for flooding rice fields (Kawakami *et al.* 2008). The confluence of the Sacramento and San Joaquin Rivers has, as a result, become increasingly important as a rearing location for delta smelt, with physical environmental conditions constricting the species range to a relatively narrow area (Feyrer *et al.* 2007; Nobriga *et al.* 2008). This has increased the likelihood that most of the juvenile population is exposed to chronic and cyclic environmental stressors, or catastrophic events. For instance, all seven delta smelt collected during the September 2007 FMWT survey were captured at statistically significantly higher salinities than what would be expected based upon historical distribution data generated by Feyrer *et al.* (2007). During the same year, the annual bloom of toxic cyanobacteria (Microcystis aeruginosa) spread far downstream to the west Delta and beyond during the summer (Peggy Lehman, pers comm). This has been suggested as an explanation for the anomaly in the distribution of delta smelt relative to water salinity levels (US Bureau of Reclamation 2008).

Bank Protection (Levees): The placement of riprap bank protection has led to the loss of riparian habitat, large woody debris, shallow water habitat, and natural channel migration. Bank stabilization and riprapping has been shown to change natural river processes such as erosion and accretion which reduces habitat complexity; creates a smooth, hydraulically enhanced surface that is not conducive to the habitat requirements of fish including delta smelt; stops woody vegetation from entering the river and reduces the long-term recruitment of large woody debris; inhibits plant growth through a change is substrate; lowers the amount of outside food sources because of the lack of riparian and wetland vegetation for aquatic invertebrates; and increases stream edge velocities which decreases available refuge areas for fish (Service 2000). More than half of the Sacramento River's lower 194 miles have been riprapped, mostly under the Corps Sacramento River bank Protection Project. Today most of the riparian forests and wetlands have been removed and the Sacramento River has been constrained to not allow natural erosion and accretion to occur.

Turbidity: From 1999 to present, the Delta experienced a change in estuarine turbidity that culminated in an estuary-wide step-decline in 1999 (Schoellhamer 2011). For decades, the turbidity of the modified estuary had been sustained by very large sediment deposits resulting mainly from gold mining in the latter 19th century. Sediments continued to accumulate into the mid-20th century, keeping the water relatively turbid even as sediment loads from the Sacramento River basin declined due to dam and levee construction (Wright and Schoellhamer 2005). The flushing of the sediment deposits may also have made the estuary deeper overall and thus a less suitable nursery from the 'static' bathymetric perspective (Schroeter 2008).

Delta smelt are associated with highly turbid waters; there is a negative correlation between the frequency of delta smelt occurrence in survey trawls during the summer, fall and early winter and water clarity. For example, the likelihood of delta smelt occurrence in trawls at a given sampling station decreases with increasing Secchi depth at the stations (Feyrer *et al.* 2007, Nobriga *et al.* 2008). This is very consistent with behavioral observations of captive delta smelt (Nobriga and Herbold 2008). Few daylight trawls catch delta smelt at Secchi depths over 0.5 m and capture probabilities for delta smelt are highest at 0.40 m depth or less. First-feeding delta smelt larvae require relatively turbid (muddy) waters to capture prey, but older fish do not require turbidity to capture prey and very high turbidity may even have some inhibitory effect on prey consumption (Hasenbein *et al.* 2013). Delta smelt may also use turbidity as cover from predators; this was hypothesized based on long-term monitoring of the distribution of fish in the wild (e.g., Feyrer *et al.* 2007) and recently supported by a laboratory experiment (Ferrari *et al.* 2014).

Temperature: Temperature also affects delta smelt distribution. Swanson and Cech (1995) and Swanson *et al.* (2000) indicate delta smelt tolerate temperatures (<8° C to >25° C), however warmer water temperatures >25° C restrict their distribution more than colder water temperatures (Nobriga and Herbold 2008). Delta smelt of all sizes are found in the main channels of the Delta and Suisun Marsh and the open waters of Suisun Bay where the water is well oxygenated and temperatures are usually less than 25° C in summer (Nobriga *et al.* 2008). Currently, delta smelt are subjected to thermally stressful temperatures every summer, and all available regional climate change projections predict central California will be warmer still in the coming decades (Dettinger 2005). We expect warmer estuary temperatures to be yet another significant conservation challenge based on climate change models. Warmer water temperatures would increase delta smelt mortality and constrict suitable habitat throughout the Delta during the summer months. Higher temperatures would shrink delta smelt distribution into the fall, limiting their presence to Suisun Bay and in waters with less than optimal salinities (Brown *et al.* 2013). Water temperatures are presently above 20°C for most of the summer in core habitat areas, sometimes even exceeding the nominal lethal limit of 25°C for short periods. Coldwater fishes begin to have behavioral impairments (Marine and Cech 2004) and lose competitive abilities (Taniguchi *et al.* 1998) prior to reaching their thermal tolerance limits. Thus, the estuary can already be considered thermally stressful to delta smelt and can only become more so if temperatures warm in the coming decades.

Foraging Ecology: Delta smelt feed primarily on small planktonic crustaceans, and occasionally on insect larvae (Moyle 2002). Juvenile-stage delta smelt prey upon copepods, cladocerans, amphipods, and insect larvae (Moyle 2002). Historically, the main prey of delta smelt was the euryhaline copepod *Eurytemora affinis* and the euryhaline mysid *Neomysis mercedis.* The slightly larger *Pseudodiaptomus forbesi* has replaced *E. affinis* as a major prey source of delta smelt since its introduction into the Bay-Delta, especially in summer, when it replaces *E. affinis* in the plankton community (Baxter *et al.* 2008; Moyle 2002). The most common copepod in the estuary now is a small nonnative species, *Limnoithona tetraspina.* It has been suggested that *L. tetraspina* may be an inferior food for pelagic fishes including delta smelt because of its small size and generally sedentary behavior (Bouley and Kimmerer 2006). Experimental studies addressing this issue have suggested that smelt larvae will attack *L. tetraspina* until they grow large enough to successfully capture larger copepods; also, growth rate of delta smelt fed *L. tetraspina* was lower than that of smelt fed the larger copepods (Sullivan *et al.*, unpublished). *L. tetraspina* is sometimes consumed in large numbers by juvenile delta smelt during late summer when this copepod is abundant in the LSZ (Slater and Baxter 2014). *Acartiella sinensis*, a calanoid copepod species that invaded the Delta at the same time as *L. tetraspina*, also occurs at high densities in Suisun Bay and in the western Delta over the last decade. Delta smelt eat these newer copepods, but *Pseudodiaptomus* remains their dominant prey (Baxter *et al.* 2008).

River flows influence estuarine salinity gradients and water residence times and thereby affect both habitat suitability for benthos and the transport of pelagic plankton upon which delta smelt feed. High tributary flow leads to lower residence time of water in the Delta, which generally results in lower plankton biomass (Kimmerer 2004). In contrast, higher residence times, which result from low tributary flows, can result in higher plankton biomass but water diversions, overbite clam grazing (Jassby *et al.* 2002) and possibly contaminants (Baxter *et al.* 2008) remove a lot of plankton biomass when residence times are high. These factors all affect food availability for planktivorous fishes that utilize the zooplankton in Delta channels. Delta smelt cannot occupy much of the Delta anymore during the summer (Nobriga *et al.* 2008). Thus, there is the potential for mismatches between regions of high zooplankton abundance in the Delta and delta smelt distribution now that the overbite clam has decimated LSZ zooplankton densities.

The delta smelt compete with and are prey for several native and introduced fish species in the Delta. The introduced Mississippi silverside may prey on delta smelt eggs and/or larvae and compete for copepod prey (Bennett and Moyle 1996; Bennett 2005). Young striped bass also use the LSZ for rearing and may compete for copepod prey and eat delta smelt. Centrarchid fishes and coded wire tagged Chinook salmon smolts released in the Delta for survival experiments since the early 1980s may potentially also prey on larval delta smelt (Brandes and McLain 2001; Nobriga and Chotkowski 2000). Studies during the early 1960s found delta smelt were only an occasional prey fish for striped bass, black crappie and white catfish (Turner and Kelley 1966). However, delta smelt were a comparatively rare fish even then, so it is not surprising they were a rare prey. Striped bass appear to have switched to piscivorous feeding habits at smaller sizes than they historically did, following severe declines in the abundance of mysid shrimp (Feyrer *et al.* 2003). Nobriga and Feyrer (2008) showed that Mississippi silverside, which is similar in size to delta smelt, was only eaten by subadult striped bass less than 400-mm fork length. While largemouth bass are not pelagic, they have been shown to consume some pelagic fishes (Nobriga and Feyrer 2007).

Other Stressors

Aquatic Macrophytes: For many decades, the Delta's waterways were turbid and growth of submerged plants was apparently unremarkable. That began to change in the mid-1980s, when the Delta was invaded by the non-native plant, *Egeria densa*, a fast-growing aquatic macrophyte that has now taken hold in many shallow habitats throughout the Delta (Brown and Michnuik 2007; Hestir 2010). *Egeria densa* and other non-native species of submerged aquatic vegetation (SAV) grow most rapidly in the summer and late fall when water temperatures are warm (> 20°C) and outflow is relatively low (Hestir 2010). The large canopies formed by these plants have physical and biological consequences for the ecosystem (Kimmerer *et al.* 2008). First, the dense nature of SAV promotes sedimentation of particulate matter from the water column, which increases water transparency that then limits the amount of habitat available for delta smelt (Feyrer *et al.* 2007; Nobriga *et al.* 2008). Second, dense SAV canopies provide habitat for a suite of non-native fishes that occupy the littoral and shallow habitats of the Delta, displacing native fishes (Nobriga *et al.* 2005; Brown and Michniuk 2007). Finally, the rise in SAV colonization over the last three decades has led to a shift in the dominant trophic pathways that fuel fish production in the Delta. Until the latter 1980s, the food web of most fishes was often dominated by mysid shrimp (Feyrer *et al.* 2003) that were subsidized by phytoplankton food sources (Rast and Sutton 1989). Now, most littoral and demeral fishes of the Delta have diets dominated by the epibenthic amphipods that eat SAV detritus or the epiphytic algae attached to SAV (Grimaldo *et al.* 2009).

E. densa and other non-native submerged aquatic vegetation (e.g., *Myriophyllum spicatum*) can affect delta smelt in direct and indirect ways. Directly, submerged aquatic vegetation can over whelm littoral habitats (inter-tidal shoals and beaches) where delta smelt may spawn making them unsuitable for spawning. Indirectly, submerged aquatic vegetation decreases turbidity (by trapping suspended sediment) which has contributed to a decrease in both juvenile and adult smelt habitat (Feyrer *et al.* 2007; Nobriga *et al.* 2008). Increased water transparency may delay feeding and may also make delta smelt more susceptible to predation pressure.

Predators: Delta smelt is a rare fish and has been a rare fish (compared to other species) for at least the past several decades (Nobriga and Herbold 2008). Therefore, it has also been rare in examinations of predator stomach contents. Delta smelt were occasional prey fish for striped bass, black crappie, and white catfish in the early 1960s (Turner and Kelly 1966) but went undetected in a recent study of predator stomach contents (Nobriga and Feyrer 2007). The predator with the highest historical documentation of predation on delta smelt is striped bass (*Morone saxatilis*; Stevens 1963; 1966; Thomas 1967). In these studies, striped bass were confirmed to prey on both juvenile and adult delta smelt. Striped bass are widely distributed in pelagic areas of the San Francisco Bay-Delta and parts of its watershed, and thus striped bass distribution fully encompasses the distribution of delta smelt juveniles and adults (Nobriga *et al.* 2013). Striped bass also tend to aggregate in the vicinity of water diversion structures, where delta smelt are frequently entrained (Nobriga and Feyrer 2007). No inverse correlations between the abundance of striped bass and the relative abundance of delta smelt have been found to date using a variety of statistical approaches (Mac Nally et al 2010; Thomson *et al.* 2010; Maunder and Deriso 2011; Miller *et al.* 2012; Nobriga et al 2013). Although the relative rarity of delta smelt in the estuary food web would presumably make them an incidental prey item for striped bass, it is possible that striped bass abundance and demand for prey are always high enough to limit delta smelt population growth rate (Nobriga *et al.* 2013).

Fish eggs and larvae can be opportunistically preyed upon by many invertebrate and vertebrate animals. There has always been a very long list of potential predators of delta smelt's eggs and larvae. One of these is the nonnative Mississippi silverside (*Menidia audens*), which like delta smelt is and annual fish with a maximum length near 100 mm (4 inches). Mississippi silversides may be both predators and competitors of delta smelt (Bennett 2005). Mississippi silversides were first introduced to the San Francisco Bay-Delta in the mid-1970s, and have increased dramatically in numbers since the mid-1980s. They forage in schools around the shoreline habitats and tidal marsh channels of the San Francisco Bay-Delta, where they are exceptionally common (Matern *et al.* 2002); Nobriga *et al.* 2005; Gewant and Bollens 2012). They readily consume delta smelt larvae in aquarium tests Bennett (20025_ concluded that "delta smelt are at high risk of eggs or larvae co-occur with schools of foraging silversides."

Another known predator is the largemouth bass are freshwater fish that prefer clear waters along shorelines (littoral habitat) with relatively dense water plants (Nobriga and Feyrer 2007; Brown and Michniuk 2007; Baxter *et al.* 2008). This is a suite of habitat characteristics that is distinctly different from those described above for delta smelt. Thus, unlike delta smelt and striped bass, delta smelt and largemouth bass have different habitat requirements (e.g., Nobriga *et al.* 2005) and their distributions do not strongly overlap. However, there has been a major increase in the Delta's largemouth bass population since the early 1990's that is believed to have been facilitated by the spread of the introduced plant *Egeria densa*, which provides rearing habitat for the bass (Baxter *et al.* 2008). Despite increases in largemouth bass populations and habitat, Nobriga and Feyrer (2007) did not find delta smelt as largemouth bass prey. Nor have more recent and extensive surveys of largemouth bass stomach contents. In captivity however, even young juvenile largemouth bass will attempt to consume delta smelt (Ferrari *et al.* 2014) so they presumably represent a predation threat when the species closely co-occur in the wild. In contrast to the situation for striped bass, several researchers have found inverse correlations between the relative abundance of largemouth bass or multi-species indices that included largemouth bass and the relative abundance of delta smelt (MacNally *et al.* 2010; Thomson *et al.* 2010; Maunder and Deriso 2011). At this time however, there is no way to determine whether these correlations are causative (predation by largemouth bass caused delta smelt to decline) or not (delta smelt simply use different habitats than largemouth bass and delta smelt habitat has decreased whil largemouth bass habitat has increased).

Other potential predators of eggs and larvae of smelt in littoral habitats are yelllowfin goby, entrarchids, and Chinook salmon. Potential native predators of juvenile and adult delta smelt would also have included numerous bird and fish species and this may be reflected in delta smelt's annual life-history. Annual fish species, also known as "opportunistic strategists", are adapted to high mortality rates in the adult stage (Winemiller and Rose 1992). This high mortality is usually due to predation or highly unpredictable environmental conditions, both of which could have characterized the ancestral niche of delta smelt.

Predation is a common source of density-dependent mortality in fish populations (Rose *et al.* 2001). Thus, it is possible that predation was a mechanism that historically generated the density-dependence observable in delta smelt population dynamics that has been noted by Bennett (2005) and Maunder and Deriso (2011). As is the case with other fishes, the vulnerability of delta smelt to predators may be influence primarily by habitat suitability. It is widely documented that pelagic fishes, including many smelt species, experience lower predation risks under turbid water conditions (Thetmeyer and Kils 1995; Utne-Palm 2002; Horpilla *et al.* 2004). Growth rates, a result of feeding success plus water temperature, are also well known to affect fishes' cumulative vulnerability to predation (Sogard 1997).

Competition: It has been hypothesized that delta smelt are adversely affected by competition from other introduced fish species that use overlapping habitats, including Mississippi silversides, (Bennett and Moyle 1995) striped bass, and wakasagi (Sweetnam 1999). Laboratory studies show that delta smelt growth is inhibited when reared with Mississippi silversides (Bennett 2005) but there is no empirical evidence to support the conclusion that competition between these species is a factor that influences the abundance of delta smelt in the wild. There is some speculation that the overbite clam competes with delta smelt for copepod nauplii (Nobriga and Herbold 2008). It is unknown how intensively overbite clam grazing and delta smelt directly compete for food, but overbite clam consumption of shared prey resources does have other ecosystem consequences that appear to have affected delta smelt indirectly.

Microcystis: Large blooms of toxic blue-green algae, *Microcystis aeruginosa*, were first detected in the Delta during the summer of 1999 (Lehman *et al.* 2005). Since then *M. aeruginosa* has bloomed each year, forming large colonies throughout most of the Delta and increasingly down into eastern Suisun Bay. Blooms typically occur between late spring and early fall (peak in the summer) when temperatures are above 20°C. *M. aeruginosa* can produce natural toxins that pose animal and human health risks if contacted or ingested directly. It is unclear whether microcystins and other toxins produced by local blooms are acutely toxic to fishes at current concentrations; however, the toxins accumulate in fish and their prey. During the summer of 2005, Age-0 striped bass and Mississippi silversides that were co-occurring with the *Microcystis* bloom showed various forms of liver damage (Lehman *et al.* 2010). When ingested with food, microcystins have been experimentally shown to cause substantial impairment of health in threadfin shad (Acuna *et al.* 2012). In addition, the copepods that delta smelt eat are particularly susceptible to these toxins (Ger 2008; Ger *et al.* 2010). An investigation of food web effects and fish toxicity concluded that even at low abundances, *M. aeruginosa* may impact estuarine fish productivity through both toxicity and food web impacts (Lehman *et al.* 2010). *M. aeruginosa* is most likely to affect juvenile delta smelt during summer blooms. Microcystis blooms may also decrease dissolved oxygen to lethal levels for fish (Saiki *et al.* 1998), although delta smelt do not strongly overlap the densest *Microcystis* concentrations, so dissolved oxygen is not likely a problem. *Microcystis* blooms are a symptom of eutrophication and high ammonia to nitrate ratios in the water.

Contaminants: Contaminants can change ecosystem functions and productivity through numerous pathways. However, contaminant loading and its ecosystem effects within the Delta are not well understood. Although a number of contaminant issues were first investigated during the Pelagic Organism Decline (POD) years, concern over contaminants in the Delta is not new. There are long-standing concerns related to mercury and selenium levels in the watershed, Delta, and San Francisco Bay (Linville *et al.* 2002; Davis *et al.* 2003). Phytoplankton growth rate may, at times, be inhibited by high concentrations of herbicides (Edmunds *et al.* 1999). New evidence indicates that phytoplankton growth rate is chronically inhibited by ammonium concentrations in and upstream of Suisun Bay (Wilkerson *et al.* 2006, Dugdale *et al.* 2007). Contaminant-related toxicity to invertebrates has been noted in water and sediments from the Delta and associated watersheds (e.g., Kuivila and Foe 1995, Giddings 2000, Werner *et al.* 2000, Weston *et al.* 2004). Undiluted drain water from agricultural drains in the San Joaquin River watershed can be acutely toxic (quickly lethal) to fish and have chronic effects on growth (Saiki *et al.* 1992).

Evidence for mortality of young striped bass due to discharge of agricultural drainage water containing rice herbicides into the Sacramento River (Bailey *et al.* 1994) led to new regulations for

water discharges. Bio assays using caged Sacramento sucker (Catostomus occidentalis) have revealed deoxyribonucleic acid strand breakage associated with runoff events in the watershed and Delta (Whitehead *et al.* 2004). Kuivila and Moon (2004) found that peak desities of larval and juvenile delta smelt sometimes coincided in time and space with elevated concentrations of dissolved pesticides in the spring. These periods of co-occurrence lasted for up to 2-3 weeks, but concentrations of individual pesticides were low and much less than would be expected to cause acute mortality. However, the effects of exposure to the complex mixtures of pesticides actually present are unknown.
Current science suggests the possible link between contaminants and the POD may be the effects of contaminant exposure on prey items, resulting in an indirect effect on the survival of POD species (Johnson *et al.* 2010). The POD investigators initiated several studies beginning in 2005 to address the possible role of contaminants and disease in the declines of Delta fish and other aquatic species. Their primary study consists of twice-monthly monitoring of ambient water toxicity at fifteen sites in the Delta and Suisun Bay. In 2005 and 2006, standard bioassays using the amphipod *Hyalella azteca* had low (<5 percent) frequency of occurrence of toxicity (Werner *et al.* 2008). The results indicated that 2007, a dry year, showed a higher incidence of toxic events than in the previous (wetter) year, 2006 (Werner *et al.* 2010). Parallel testing with the addition of piperonyl butoxide, an enzyme inhibitor, indicated that both organophosphate and pyrethroid pesticides may have contributed to the pulses of toxicity. Most of the tests that were positive for *H. azteca* toxicity have come from water samples from the lower Sacramento River.

Pyrethroids are of particular concern because of their widespread use, and their tendency to be genotoxic (DNA damaging) to fishes at low doses (in the range of micrograms per liter) (Campana *et al.* 1999). The pyrethroid esfenvalerate is associated with delayed spawning and reduced larval survival of bluegill sunfish (*Lepomis macrochirus*) (Tanner and Knuth 1996) and increased susceptibility of juvenile Chinook salmon (*Oncorhynchus tshawytscha*) to disease (Clifford *et al.* 2005). In addition, synthetic pyrethroids may interfere with nerve cell function, which could eventually result in paralysis (Bradbury and Coats 1989; Shafer and Meyer 2004). Weston and Lydy (2010) found the largest source of pyrethroids flowing into the Delta to be coming from the Sacramento Regional Waste water Treatment Plant, where only secondary treatment occurs. Their data not only indicate the presence of these contaminants, but the concentrations found exceeded acute toxicity thresholds for the amphipod *Hyalella azteca.* This is of substantial concern because the use of insecticides flowing into the Delta. Furthermore, this was not the case for the Stockton Wastewater Treatment facility, where tertiary treatment occurs, suggesting that different treatment methods may remove or etain pyretroids differently (Baxter *et al.* 2010).

In conjunction with the POD investigation, larval delta smelt bioassays were conducted simultaneously with a subset of the invertebrate bioassays. The water samples for these tests were collected from six sites within the Delta during May-August of 2006 and 2007. Results from 2006 indicated that delta smelt are highly sensitive to high levels of ammonia, low turbidity, and low salinity. There is some preliminary indication that reduced survival may be due to disease organisms (Werner *et al.* 2008). No significant mortality of larval delta smelt was found in the 2006 bioassays, but there were two instances of significant mortality in June and July of 2007. In both cases, the water samples were collected from sites along the Sacramento River and had relatively low turbidity and salinity levels and moderate levels of ammonia. It is also important to note that no significant *H. azteca* mortality was detected in these water samples. While H. Azteca tests are very useful for detecting biologically relevant levels of water column toxicity for zooplankton, interpretation of the *H. azteca* test results with respect to fish should proceed with great caution. The relevance of the bioassay results to field conditions remains to be determined. Werner *et al.* (2010b) conducted *in situ* testing in the laboratory and compared contaminant sensitivity of delta smelt to common bioassay organisms, including *H. azteca*. The investigations included contaminants commonly observed in the

Delta, such as organophosphate and pyrethroid insecticides, copper, and total ammonia. In the laboratory, delta smelt were 1.8 to >11 times more sensitive thatn fathead minnow to ammonia, copper and all insecticides tested (except permethrin). The invertebrates tested were more sensitive to contaminants than delta smelt or fathead minnows. *Eurytemora affinis* and *Ceriodaphnia dubia* were the most sensitive to total ammonia. *C. dubia* was the most sensitive to copper and organophosphates pesticides. *H. azteca* was the most sensitive test organism to pyrethroids. Toxicity was not detected for the Sacramento River at Hood or the San Joaquin River at Rough and Ready Island during the 2009 in situ testing period. Delta smelt survival was low in treatment and control waters. Werner *et al.* (2010b) concluded that larval smelt may be too sensitive to salinity, temperature and transport stress for *in situ* exposures and recommended using surrogate species in future tests.

Persistent confinement of the spawning population of delta smelt to the Sacramento River increases the likelihood that a substantial portion of the spawners will be affected by a catastrophic event or localized chronic threat. For instance, large volumes of highly concentrated ammonia released into the Sacramento River from the Sacramento Regional County Sanitation District may affect embryo survival or inhibit prey production. Further, agricultural field in the Yolo Bypass and surrounding areas are regularly sprayed by pesticides, and water samples taken from Cache Slough sometimes exhibited toxicity to *H. azteca* (Werner *et al.* 2008; 2010). The thresholds of toxicity for delta smelt for most of the known contaminants have not been determined, but the exposure to a combination of different compounds increases the likelihood of adverse effects. The extent to which delta smelt larvae are exposed to contaminants varies with flow entering the Delta. Flow pulses during spawning increase exposure to many pesticides (Kuivila and Moon 2004) but decrease ammonia concentrations from wastewater treatment plants.

The POD investigations into potential contaminant effects also include the use of biomarkers that have been used previously to evaluate toxic effects on POD fishes (Bennett and Moyle 1996, Bennett 2005). The results to date have been mixed. A pathogen survey of 105 adult delta smelt, sampled from January through May, at several sites in the Delta, found that disease did not appear to overtly influence the health of the surveyed population for that year (Foott and Bigelow 2010). Histopathological and viral evaluation of young longfin smelt collected in 2006 indicated no histological abnormalities associated with exposure to toxics or disease (Foott *et al.* 2006). There was also no evidence of viral infection or high parasite loads. Similarly, young threadfin shad showed no histological evidence of contaminant effects or of viral infections (Foott *et al.* 2006). Parasites were noted in threadfin shad gills at a high frequency but the infections were not considered severe. Both longfin smelt and threadfin shad were considered healthy in 2006. Adult delta smelt collected from the Delta during the winter of 2005 also were considered healthy, showing little histopathological evidence for starvation or disease (Teh 2007). However, there was some evidence of low frequency endocrine disruption. In 2005, nine of 144 (six percent) of adult delta smelt males sampled were intersex, having immature oocytes in their testes (Teh 2007). Bennett (2005) reported that about 10 percent of the delta smelt analyzed for histopathological anomalies in 1999-2000 showed evidence of deleterious contaminant exposure. In contrast, 30-60 percent of these fish had liver glycogen depletion consistent with food limitation.

In contrast, preliminary histopathological analyses have found evidence of significant disease in other species and for POD species collected from other areas of the estuary. Massive intestinal infections with an unidentified myxosporean were found in yellowfin goby (*Acanthogobius flavimanus*) collected from Suisun Marsh. Severe viral infection was also found in Mississippi silverside and juvenile delta smelt collected from Suisun Bay during summer 2005. Lastly, preliminary evidence suggests that contaminants and disease may impair survival of age-0 striped bass. Baxter *et al.* 2008 found high occurrence and severity of parasitic infections, inflammatory conditions, and muscle degeneration in young striped bass collected in 2005; levels were lower in 2006. Several biomarkers of contaminant exposure including P450 activity (i.e., detoxification enzymes in liver), acetylcholinesterase activity (i.e., enzyme activity in brain), and vitellogenin induction (i.e., presence of egg yolk protein in blood of males) were also reported from striped bass collected in 2006 (Ostrach 2008).

Delta smelt can also be exposed to other toxic substances. Recent toxicological research has provided dose-response curves for several contaminants (Connon *et al.* 2009; 2011). This research has also shown that gene expression changes and impairment of delta smelt swimming performance occur at contaminant concentrations lower than levels that cause mortality.

Climate Change: Climate change is likely already impacting the delta smelt. Climate change may affect the delta smelt directly by creating physiological stress, the primary impacts of climate change on the species are expected to be through changes in the availability and distribution of delta smelt habitat.

The terms "climate" and "climate change" are defined by the Intergovernmental Panel on Climate Change (IPCC). The term "climate" refers to the mean and variability of different types of weather conditions over time, with 30 years of being a typical period for such measurements (IPCC 2013a). The term "climate change" thus refers to a change in the mean or variability of one or more measures of climate (for example, temperature or precipitation) that persists for an extended period, whether the change is due to natural variability or human activity (IPCC 2013a). Scientific measurements spanning several decades demonstrate that changes in climate are occurring, and that the rate of change has increased since the 1950s. Examples include warming of the global climate system, and substantial increases in precipitation in some regions of the world and decreases in other regions.

Scientific measurements spanning several decades demonstrate that changes in climate are occurring, and that the rate of change has increased since the 1950s. Examples include warming of the global climate system, and substantial increases in precipitation in some regions of the world and decreases in other regions (for these and other examples, see Solomon *et al.* 2007;; IPCC 2013b;; IPCC 2014). Results of scientific analyses presented by the IPCC show that most of the observed increase in global average temperature since the mid-20th century cannot be explained by natural variability in climate and is "very likely" (defined by the IPCC as 90 percent or higher probability) due to the observed increase in greenhouse gas (GHG) concentrations in the atmosphere as a result of human activities, particularly carbon dioxide emissions from use of fossil fuels (Solomon *et al.* 2007; IPCC 2013b). Further confirmation of the role of GHGs comes from analyses by Huber and Knutti (2011), whom concluded it is extremely likely that approximately 75 percent of global warming since 1950 has been caused by human activities.

Scientists use a variety of climate models, which include consideration of natural processes and variability, as well as various scenarios of potential levels and timing of GHG emissions, to evaluate the causes of changes already observed and to project future changes in temperature and other climate conditions (Meehl *et al.* 2007, entire; Ganguly *et al.* 2009; Prinn *et al.* 2011). All combinations of models and emissions scenarios yield very similar projections of increases in the most common measure of climate change, average global surface temperature (commonly known as global warming), until about 2030. Although projections of the magnitude and rate of warming differ after about 2030, the overall trajectory of all the projections is one of increasing global warming through the end of this century, even for the projections based on scenarios that assume that GHG emissions will stabilize or decline. Thus, there is strong scientific support for projections that warming will continue through the 21st century, and that the magnitude and rate of change will be influenced substantially by the extent of GHG emissions (Meehl *et al.* 2007; Ganguly *et al.* 2009; Prinn *et al.* 2011; IPCC 2013b). See IPCC 2013b (entire), for a summary of other global projections of climate-related changes, such as frequency of heat waves and changes in precipitation.

Current Drought Conditions and Relative Abundance: California is experiencing its fourth consecutive dry water-year due to low rainfall and low snowpack. On January 17, 2014, the Governor of California declared a State of Emergency due to the drought and directed state officials to take all necessary actions to make water immediately available (Office of the Governor 2014). As of June 2015, the Governor's drought declaration remains in place and the current drought conditions are comparable to the driest years on record in California. The severity of California's drought has been exacerbated by record warm temperatures and below-normal precipitation in 2015, resulting in a severely reduced snowpack. During the last two years, Federal and state governments (Bureau of Reclamation and California Department of Water Resources) have taken actions to ensure the reduced water quality and supply does not reach a level of concern for human health and safety, while complying with biological opinions. The actions taken include the 2015 placement of a salinity rock barrier on West False River and numerous Temporary Urgency Change Orders to modify requirements under Decision 1641 to meet certain water quality objectives, reduction of river flows caused by low reservoir storage, and river temperature requirements.

Drought conditions and some drought management actions have decreased suitable and available aquatic habitat in the Delta for delta smelt breeding and survival, thereby reducing the overall population in the Delta. Fish surveys indicate that the relative abundance of delta smelt is very low. In the last five years, the FMWT, TNS, and 20mm survey results have produced some of the lowest adult and larval delta smelt abundance indexes on record (CDFW 2013, 2014, 2015). The 2014 FMWT abundance index which determines the relative population status for the delta smelt was set at 9, which is the lowest index on record. The low index numbers and relatively few occurrences represent the additive impact of drought to the delta smelt and its habitat.

Status of the Delta Smelt Critical Habitat

The Service designated critical habitat for the delta smelt on December 19, 1994 (Service 1994). The geographic area encompassed by the designation includes all water and all submerged lands below ordinary high water and the entire water column bounded by and contained in Suisun Bay (including the contiguous Grizzly and Honker Bays); the length of Goodyear, Suisun, Cutoff, First Mallard (Spring Branch), and Montezuma sloughs; and the existing contiguous waters contained within the legal Delta (as defined in section 12220 of the California Water Code) (Service 1994).

Conservation Role of Delta Smelt Critical Habitat

The Service's primary objective in designating critical habitat was to identify the key components of delta smelt habitat that support successful spawning, larval and juvenile transport, rearing, and adult migration. Delta smelt are endemic to the Bay-Delta and the vast majority only live one year. Thus, regardless of annual hydrology, the Delta must provide suitable habitat all year, every year. Different regions of the Delta provide different habitat conditions for different life stages, but those habitat conditions must be present when needed, and have sufficient connectivity to provide migratory pathways and the flow of energy, materials and organisms among the habitat components. The entire Delta and Suisun Bay are designated as critical habitat; over the course of a year, the entire habitat is occupied.

Description of the Primary Constituent Elements

In designating critical habitat for the delta smelt, the Service identified the following primary constituent elements (PCEs) essential to the conservation of the species:

Primary Constituent Element 1: "Physical habitat" is defined as the structural components of habitat. Because delta smelt is a pelagic fish, spawning substrate is the only known important structural component of habitat. It is possible that depth variation is an important structural characteristic of pelagic habitat that helps fish maintain position within the estuary's low-salinity zone (LSZ) (Bennett *et al.* 2002, Hobbs *et al.* 2006).

Primary Constituent Element 2: "Water" is defined as water of suitable quality to support various delta smelt life stages with the abiotic elements that allow for survival and reproduction. Delta smelt inhabit open waters of the Delta and Suisun Bay. Certain conditions of temperature, turbidity, and food availability characterize suitable pelagic habitat for delta smelt. Factors such as high entrainment risk and contaminant exposure can degrade this PCE even when the basic water quality is consistent with suitable habitat.

Primary Constituent Element 3: "River flow" is defined as transport flow to facilitate spawning migrations and transport of offspring to LSZ rearing habitats. River flow includes both inflow to and outflow from the Delta, both of which influence the movement of migrating adult, larval, and juvenile delta smelt. Inflow, outflow, and Old and Middle Rivers flow influence the vulnerability of delta smelt larvae, juveniles, and adults to entrainment at Banks and Jones. River flow interacts with the fourth primary constituent element, salinity, by influencing the extent and location of the highly productive LSZ where delta smelt rear.

Primary Constituent Element 4: "Salinity" is defined as the LSZ nursery habitat. The LSZ is where freshwater transitions into brackish water; the LSZ is defined as 0.5-6.0 psu (parts per thousand salinity) (Kimmerer 2004). The 2 psu isohaline is a specific point within the LSZ where the average daily salinity at the bottom of the water is 2 psu (Jassby *et al.* 1995). By local convention the location of the LSZ is described in terms of the distance from the 2 psu isohaline to the Golden Gate Bridge (X2); X2 is an indicator of habitat suitability for many San Francisco Estuary organisms and is associated with variance in abundance of diverse components of the ecosystem (Jassby *et al.* 1995, Kimmerer 2002a). The LSZ expands and moves downstream when river flows into the estuary are high. Similarly, it contracts and moves upstream when river flows are low. During the past 40 years, monthly average X2 has varied from San Pablo Bay (45 kilometers) to as far upstream as Rio Vista on the Sacramento River (95 kilometers). At all times of year, the location of X2 influences both the area and quality of habitat available for delta smelt to successfully complete their life cycle. In general, delta smelt habitat quality and surface area are greater when X2 is located in Suisun Bay. Both habitat quality and quantity diminish the more frequently and further the LSZ moves upstream, toward the confluence.

Overview of Delta Smelt Habitat Requirements and the Primary Constituent Elements

Delta smelt live their entire lives in the tidally-influenced fresh- and brackish waters of the San Francisco Estuary (Moyle 2002). Delta smelt are an open-water, or pelagic, species. They do not associate strongly with structure. They may use nearshore habitats for spawning (PCE #1), but free-swimming life stages mainly occupy offshore waters (PCE #2). Thus, the distribution of the population is strongly influenced by river flows through the estuary (PCE #3) because the quantity of fresh water flowing through the estuary changes the amount and location of suitable low-salinity, open-water habitat (PCE #4). This is true for all life stages. During periods of high river flow into the estuary, delta smelt distribution can transiently extend as far west as the Napa River and San Pablo Bay. Delta smelt distribution is highly constricted near the Sacramento-San Joaquin river confluence during periods of low river flow into the estuary (Feyrer *et al.* 2007). In the 1994 designation of critical habitat, the best available science held that the delta smelt population was responding to variation in spring X2.

Alterations to Estuarine Bathymetry (PCE # 1) (~ 1850-present)

The first major change in the LSZ was the conversion of the landscape over which tides oscillate and river flows vary (Nichols *et al.* 1986). The ancestral Delta was a large tidal marsh-floodplain habitat totaling approximately 300,000 acres. Most of the wetlands were diked and reclaimed for agriculture or other human use by the 1920s. The physical habitat modifications of the Delta and Suisun Bay were mostly due to land reclamation and urbanization. Water conveyance projects and river channelization have had some influence on the regional physical habitat by armoring levees with riprap, building conveyance channels like the Delta Cross Channel, storage reservoirs like Clifton Court Forebay, and by building and operating temporary barriers in the south Delta and permanent gates and water distribution systems in Suisun Marsh.

In the 1930s to 1960s, the shipping channels were dredged deeper (~12 m) to accommodate shipping traffic from the Pacific Ocean and San Francisco Bay to ports in Sacramento and Stockton. These changes left Suisun Bay and the Sacramento-San Joaquin river confluence region as the largest and most bathymetrically variable places in the LSZ. This region remained a highly productive nursery for many decades (Stevens and Miller 1983; Moyle *et al.* 1992; Jassby *et al.* 1995). However, the deeper landscape created to support shipping and flood control requires more freshwater outflow to maintain the LSZ in the large Suisun Bay/river confluence region than was once required (Gartrell 2010).

Seasonal salinity intrusion reduces the temporal overlap of the LSZ (indexed by X2) with the Suisun Bay region, especially in the fall (Feyrer *et al.* 2007, 2010). Thus, the second major change has been in the frequency with which the LSZ is maintained in Suisun Bay for any given amount of precipitation. This metric showed a step-decline in 1977 from which it has never recovered for more than a few years at a time. Based on model forecasts of climate change and water demand, this trend is expected to continue (Feyrer *et al.* 2011). As such this alteration of PCE # 1 also affects the other PCEs, particularly PCE # 4. The major landscape factor affecting this interaction was the dredging of shipping channels.

Spawning delta smelt require all four PCEs, but spawners and embryos are the life stage that is believed to most require a specific structural component of habitat. Spawning delta smelt require sandy or small gravel substrates for egg deposition (Bennett 2005). The major invasive species effect on physical habitat is the dense growth of submerged aquatic vegetation in the Delta. These plants carpet large areas in parts of the Delta such as Frank's Tract. The vegetation beds act as mechanical filters removing turbidity and possibly other water quality components as the tides and river flows move water over them (Hestir 2010). Thus, the proliferation of submerged aquatic plants has likely also reduced the area of nearshore habitat suitable for delta smelt spawning.

Alterations to Water (PCE # 2)

PCE # 2 is primarily referring to a few key water quality components (other than salinity) that influence spawning and rearing habitat suitability for delta smelt. Research to date indicates that water quality conditions are more important than physical habitat conditions for predicting where delta smelt occur (Feyrer *et al.* 2007; Nobriga *et al.* 2008) probably because delta smelt is a pelagic fish except during its egg/embryo stage. However, the interaction of water quality and bathymetry is thought to generally affect estuarine habitat suitability (Peterson 2003) and there is evidence that delta smelt habitat is optimized when appropriate water quality conditions overlap the Suisun Bay region (Moyle *et al.* 1992; Hobbs *et al.* 2006; Feyrer *et al.* 2011). This is discussed further in the section about PCE # 4 (salinity).

Changing predation pressure (1879 to present): Noting is known about the historical predators of delta smelt or their possible influence on delta smelt. Fish eggs and larvae can be opportunistically preyed upon by many invertebrate and vertebrate animals so there has always been a very long list of potential predators of delta smelt's eggs and larvae. Potential native predators of juvenile and adult delta smelt would also have included numerous bird and fish species and this may be reflected in delta smelt's annual life-history. Annual fish species, also known as "opportunistic strategists", are adapted to high mortality rates in the adult stage (Winemiller and Rose 1992). This high mortality is usually due to predation or highly unpredictable environmental conditions, both of which could have characterized the ancestral niche of delta smelt.

The introduction of striped bass into the San Francisco Estuary in 1879 added a permanently resident, large piscivorous fish to the low-salinity zone: a habitat that is not known to have had an equivalent predator prior to the establishment of striped bass (Moyle 2002). This likely changed predation rates on delta smelt, but there are no data available to confirm this hypothesis. For many decades the estuary supported higher striped bass and delta smelt numbers than it does currently. This is evidence that delta smelt is able to successfully coexist with striped bass.

The current influence of striped bass and other predators on delta smelt population dynamics is also not known mainly because quantitative descriptions of predator impacts on rare prey are extremely difficult to generate. Delta smelt were observed in the stomach contents of striped bass and other fishes in the 1960s (Stevens 1963; Turner and Kelley 1966), but have not been observed in more recent studies (Feyrer *et al.* 2003; Nobriga and Feyrer 2007). Predation is a common source of density-dependent mortality in fish populations (Rose *et al.* 2001). Thus, it is possible that predation was a mechanism that historically generated the density-dependence observed in delta smelt population dynamics (Bennett 2005; Maunder and Deriso 2011). Because it is generally true for fishes, the vulnerability of delta smelt to predators is influenced primarily by habitat conditions. Turbidity may be a key mediatory of delta smelt's vulnerability to predators (Nobriga *et al.* 2005; 2008). Growth rates, an interactive outcome of feeding success and water temperature, are also well known to affect fishes' cumulative vulnerability to predation (Sogard 1997). Thus, predation rate is best characterized as an aspect food web function linked to PCE # 2.

Food web alterations attributable to the overbite clam (1987-present): The next major change to PCE #2 occurred following the invasion of the estuary by overbite clam (*Corbula amurensis*). The overbite clam was first detected in 1986 and from 1987-1990 its influence on the ecosystem became evident. Since 1987, there has been a step-decline in phytoplankton biomass (Alpine and Cloern 1992; Jassby *et al.* 2002). Phytoplankton in the LSZ is an important component of the pelagic food web that delta smelt are a part of because a key part of the diet of delta smelt's prey is phytoplankton. Not only does the overbite clam reduce food for delta smelt's prey, it can also graze directly on the larval stages of the copepods eaten by delta smelt (e.g., Kimmerer *et al.* 1994). The grazing pressure applied by the overbite clam rippled through the historical zooplankton community that fueled fishery production in the LSZ (Kimmerer and Orsi 1996; Orsi and Mecum 1996; Kimmerer 2002b; Feyrer *et al.* 2003). This major change in the way energy moved through the ecosystem has likely facilitated the numerous invasions of the estuary by suppressing the production of historically dominant zooplankton, which increases the opportunity for invasion by other species that are less dependent on high densities of LSZ phytoplankton.

The distribution and abundance of several LSZ fishes have changed since 1987 (Kimmerer 2002b; Kimmereer 2006; Rosenfield and Baxter 2007; Mac Nally *et al.* 2010). Surprisingly, the changes in phytoplankton and zooplankton production have not been as evident for delta smelt as for other organisms (Kimmer 2002b; Kimmerer 2006; Sommer *et al.* 2007; Mac Nally *et al.* 2010). Nonetheless, delta smelt collected in the FMWT have been persistently smaller since the overbite clam invasion (Sweetnam 1999; Bennett 2005). This is evidence for reduced growth rates that could have been caused by food web changes stemming from overbite clam grazing. The Service considers the prey density aspect of the estuarine food web to be a component of PCE #3 ("Water"). The Central Valley Project and State Water Project entrain some food web production (about 4.5 percent on a daily average basis was attributed to all water diversions in the Delta; Jassby *et al.* 2002). However, prey densities have been most strongly affected by clam grazing (Kimmerer *et al.* 1994; Jassby *et al.* 2002). Urban wastewater input, *Microcystis* blooms, and pesticide loads may also impair the production of zooplankton eaten by delta smelt or eaten by delta smelt's prey (Wilkerson *et al.* 2006; Dugdale *et al.* 2007; Jassby 2008; Ger *et al.* 2009; Werner *et al.* 2010).

Proliferation of submerged aquatic vegetation (1980s to present): For many decades, the Delta's waterways were turbid and the growth of submerged plants was apparently unremarkable. That began to change in the mid-1980s, when the Delta was invaded by non-native plant *Egeria densa*, a fast-growing aquarium plant that has taken hold in many shallow habitats (Brown and Michnuik 2007; Hestir 2010). *Egeria densa* and other non-native species of submerged aquatic vegetation (SAV) grow most rapidly in the summer and late fall when water temperatures are warm (>20°C) and outflow is relatively low (Hestir 2010). The large canopies formed by these plants have physical and biological consequences for the ecosystem (Kimmerer *et al.* 2008). First, dense SAV promotes water transparency. Increased water transparency leads to a loss of habitat for delta smelt (Feyrer *et al.* 2007; Nobriga *et al.* 2008). Second, dense SAV canopies provide habitat for a suite of non-native fishes, including largemouth bass, which now dominate many shallow habitats of the Delta and displace native fishes (Nobriga *et al.* 2005; Brown and Michniuk 2007). Finally, SAV colonization over the last three decades has led to a shift in the dominant freshwater food web pathways and that fuel fish production (Grimaldo *et al.* 2009b). It is noteworthy that SAV-dominated habitats are comparatively productive (Nobriga *et al.* 2005; Grimaldo *et al.* 2009b), but most of the productivity they generate remains in the nearshore environment and therefore does not contribute much to pelagic fish production (Grimaldo *et al.* 2009b).

Reduced turbidity (1999-present): The next major change was a change in estuarine turbidity that culminated in an estuary-wide step-decline in 1999 (Schoellhamer 2011). For decades, the turbidity of the modified estuary had been sustained by very large sediment deposits resulting mainly from gold mining in the latter 19th century. The sediments continued to accumulate into the mid-20th century, keeping the water relatively turbid even as sediment loads from the Sacramento River basin declined due to dam and levee construction (Wright and Schoellhamer 2004). The flushing of the sediment deposits may also have made the estuary deeper overall and thus a less suitable nursery from the 'static' bathymetric perspective (Schroeter 2008). Delta smelt larvae require turbidity to initiate feeding (Baskerville-Bridges *et al.* 2004), and as explained above, older fish are thought to use turbidity as cover from predators. Thus, turbidity is an aspect of PCE # 2 which is a necessary water quality aspect of delta smelt's critical habitat.

Dams and armored levees have contributed to the long-term decline in sediment load to the estuary (Wright and Schoellhamer 2004) and to the clearing of estuary water. This is a long-term effect that stemmed from building and maintaining infrastructure. Opportunities to substantively address this change are limited due to the extreme Central Valley flood and water supply risks that will result from decommissioning dams or removing levees.

Changing water temperature (present through long-term climate forecasts): Delta smelt is already subjected to thermally stressful temperatures every summer in the Delta. Water temperatures are presently above 20°C for most of the summer in core habitat areas, sometimes even exceeding the nominal lethal limit of 25°C for short periods. Coldwater fishes begin to have behavioral impairments (Marine and Cech 2004) and lose competitive abilities (Taniguchi *et al.* 1998) prior to reaching their thermal tolerance limits. Thus, the estuary can already be considered thermally stressful to delta smelt and can only become more so if temperatures warm in the coming decades.

All available regional climate change projections predict central California will be warmer still in the coming decades (Dettinger 2005). It is expected that warmer estuary temperatures will be yet another significant conservation challenge (Brown *et al.* 2013; Cloern *et al.* 2011). This is true because they will limit abiotic habitat suitability further than indicated by flow-based projection (e.g., Feyrer *et al.* 2011). In addition, warmer water temperatures mean that higher prey densities will be required just to maintain present-day growth rates, which are already lower than they once were (Sweetnam 1999; Bennett 2005). Water temperature is mainly affected by climate variation, both as air temperature and as flood and drought scale flow variation (Kimmer 2004; Wagner *et al.* 2011).

Sensitivities to contaminants (ongoing): Delta smelt's spawning migration coincides with early winter rains (Sommer *et al.* 2011). This 'first-flush' of inflow to the Delta brings sediment-bound pesticides with it (Bergamaschi *et al.* 2001), and peak densities of larvae and juveniles can co-occur with numerous pesticides (Kuivila and Moon 2004). Bennett (2005) reported that about 10 percent of the delta smelt analyzed for histopathological anomalies in 1999-2000 showed evidence of deleterious contaminant exposure, but this was low compared to the 30-60 percent of these fish that appeared to be food-limited.

Delta smelt can also be exposed to other toxic substances. Recent toxicological research has provided dose-response curves for several contaminants (Connon *et al.* 2009; 2011). This research has also shown the gene expression changes and impairment of delta smelt swimming performance occur at contaminant concentrations lower than levels that cause mortality. Climate scale flow variation (e.g., flood versus drought scale variation) affects the amount of methyl mercury (Darryl Slotton presentation) entering the ecosystem and may have some influence on the meaningful dilution of ammonium from urban wastewater inputs (Dick Dugdale presentation).

Invasive species may also affect PCE #2 by changing contaminant dynamics. For instance, *Microcystis* blooms generate toxic compounds that can kill delta smelt prey (Ger *et al.* 2009) and accumulate in the estuarine food web (Lehman *et al.* 2010). A second example is the biomagnification of selenium in the food web by *Corbula* (Stewart *et al.* 2004). This has been considered a potential issue for the clam's predators – namely sturgeon, splittail, and diving ducks (Richman and Lovvorn 2004; Stewart *et al.* 2004). However, it is not known whether this change in selenium dynamics negatively affects delta smelt and other fishes that do not directly prey on the clams.

Alterations of River Flows (PCE # 3)

This PCE refers to the transport flows that help guide young delta smelt from spawning habitats to rearing habitats, and to flows that guide adult delta smelt from rearing habitats to spawning habitats. Delta outflow also has some influence on delta smelt's supporting food web (Jassby *et al.* 2002; Kimmerer 2002a) and it affects abiotic habitat suitability as well (Feyrer *et al.* 2007; 2011). The latter is expanded upon in the discussion of PCE # 4. The environmental driver with the strongest influence on PCE # 3 is highly dependent on the time-scale being considered. The tide has the largest influence on flow velocities and directions in delta smelt's critical habitat at very short timescales (minutes to days), whereas interannual variation in precipitation and runoff has the largest influence on flows into and through the Delta at very long timescales (years to decades), and sometimes at shorter time scales (days to weeks) during major storm events. Changes to flow regimes can have the largest influence on PCE #3 at timescales of weeks to seasons. This is particularly true during periods of low natural inflow, for instance during the fall and during droughts, and in the south Delta where Old and Middle River flows are often managed using changes in export flow rates.

Entrainment into water export diversions (1951 to present): The amount of water diverted from the estuary has generally increased over time, and most of the increase during the 1950s and 1960s was due to CVP exports and since the latter 1960s, SWP exports. There are two basic potential fishery impacts that result from water diversion from the Delta: ecosystemic impacts and direct entrainment. From the ecosystemic perspective, water diversions are unnatural 'predators' because they 'consume' organisms at every trophic level in the ecosystem from phytoplankton (Jassby *et al.* 2002) to fish (Kimmerer 2008). Unlike natural predators which typically shift their prey use over time in association with changes in prey fish density (Nobriga and Feyrer 2008), fractional entrainment losses of fishes to diversions are functions of water and demand (e.g., Grimaldo *et al.* 2009). Thus, water diversions not only elevate 'predation' mortality in an aquatic system, but they can do so in an atypical, density-independent manner. Diversions and fish collection facilities in the south Delta are very large structures which attract large aggregations of actual predatory fish and prey on smaller species like delta smelt before they reach the fish salvage facilities and within these facilities (Gingras 1997).

Estimated entrainment losses of delta smelt to SWP and CVP diversions can be substantial in some years (Kimmerer 2008). Given the delta smelt's current density-independent population dynamics, even a statistically indiscernible entrainment effect on the population is likely to cause the species to continue to decline (Kimmerer 2011). The entrainment losses of delta smelt are not generally observed until they reach the early juvenile stage (~20-30 mm in length), but combinations of 20-mm Survey distribution data and hydrodynamic modeling provide evidence that their risk of entrainment into the CVP and SWP diversions can be described by any of several indices that integrate Delta inflow and export flow (Kimmerer and Nobriga 2008; Kimmerer 2008; Service 2008; Grimaldo *et al.* 2009).

Delta smelt entrainment losses estimated from survey data and hydrodynamics can also be substantial in some years (Kimmerer 2008), though it is possible that Kimmerer may have overestimated them (Miller 2011). Nonetheless, increasing higher outflow (or lower X2) moves the bulk of the larval population increasingly west, which results in fewer larvae distributed in the south Delta where they are at highest risk of entrainment. At the same time, indices like the export to inflow ratio or Old and Middle river flow are useful metrics for gauging the effect of exports on the south Delta.

The risk of delta smelt entrainment into smaller agricultural irrigation diversions used mainly to irrigate crops within the Delta is also related to flow conditions. These in-Delta irrigation diversions generally have mean flow rates less than 1 cubic meter per second (Nobriga *et al.* 2004). The lower the Delta outflow, the higher the proportion of the young delta smelt population that overlaps the array of irrigation diversions in the Delta (Kimmerer and Nobriga 2008). However, the irrigation diversions are not currently considered to represent a substantial source of mortality because they individually draw small quantities of water relative to channel volumes (Nobriga *et al.* 2004).

In Suisun Marsh, water diversions are largely made to support waterfowl production. Some Suisun Marsh diversions are larger for the size of channels they are in than most of the agricultural irrigation diversions in the Delta. Based on hydrodynamic simulations, proximity to water diversions in the marsh is expected to correlate strongly with entrainment (Culberson *et al.* 2004), and substantial delta smelt losses have been reported when these diversions are not screened (Pickard *et al.* 1982). Entrainment risk for delta smelt in western Suisun Marsh is considered low because the habitat surrounding the diversions is often too saline (Enos *et al.* 2007).
Salinity PCE # 4

The core delta smelt habitat, is the LSZ (Moyle *et al.* 1992; Bennett 2005). The LSZ is where freshwater transitions into brackish water; the LSZ is defined as the area of the estuary where salinity ranges from 0.5-6.0 psu (Kimmerer 2004). This area is always moving due to tidal and river flow variation. The 2 psu isohaline is a specific location within the LSZ where the average daily salinity at the bottom of the water is 2 psu (Jassby *et al.* 1995). By local convention, changes in the location of the LSZ are described in terms of the distance from the Golden Gate Bridge to the 2 psu isohaline (X2); X2 is an indicator of habitat suitability for many of the estuary's organisms and it is associated with variance in abundance of diverse components of the ecosystem (Jassby *et al.* 1995; Kimmerer 2002b; Kimmerer *et al.* 2009). The LSZ expands and moves downstream when river flows into the estuary are high (Kimmerer *et al.* 2009). Similarly, it contracts and moves upstream when river flows are low. During the past 40 years, monthly average X2 has varied from as far downstream of San Pablo Bay (45 km) to as far upstream as Rio Vista on the Sacramento River (95 km).

Larval delta smelt tend to reside somewhat landward (upstream) of X2 (Dege and Brown 2004), but the center of juvenile distribution tends to be very near X2 until the fish start making spawning migrations in the winter (Feyrer *et al.* 2011; Sommer *et al.* 2011). Because of this association between the distribution of salinity in the estuary and the distribution of the delta smelt population, the tidal and river flows that comprise PCE # 3 affect PCE # 4.

The expansion and contraction of the LSZ affects the areal extent of abiotic habitat for delta smelt, both during spring (Kimmerer *et al.* 2009) and fall (Feyrer *et al.* 2007; 2011). In the spring, most delta smelt are larvae or young juveniles and the LSZ is typically maintained over the expansive Suisun Bay region. Thus, abiotic habitat "limitation" is unlikely and no consistent influence of spring X2 variation on later stage abundance estimates has been reported to date (Jassby *et al.* 1995; Bennett 2005; Kimmerer *et al.* 2009). In fact, historical maxima in juvenile abundance according to CDFW's TNS occurred in low outflow years when abiotic habitat area was comparatively low (Kimmerer 2002a; Kimmerer *et al.* 2009).

In contrast, during fall delta smelt are late stage juveniles and for the past decade or more, the LSZ has been persistently constricted by low Delta outflow. Fall habitat conditions affect delta smelt distribution and the concurrent FMWT abundance index (Feyrer *et al.* 2007; 2011). However, the quantitative life cycle models developed to date have not found evidence for a year over year effect of fall LSZ location on delta smelt population dynamics (Mac Nally *et al.* 2010; Thompson *et al.* 2010; Maunder and Deriso 2011).

It is now recognized that some delta smelt occur year-round in the Cache Slough region including the Sacramento Deep Water Shipping Channel and Liberty Island (Kimmerer 2011; Miller 2011; Sommer *et al.* 2011). The latter has been a consistently available habitat only since 1997. This region is often lower in salinity than 0.6 psu, the lower formal limit of the LSZ as defined by Kimmerer (2004). Delta smelt likely use it because it is one of the most turbid habitats remaining in the Delta (Nobriga *et al.* 2005). A recent population genetic study found no evidence that delta smelt inhabiting this region are unique compared to delta smelt using the LSZ-proper (Fisch *et al.*

2011), therefore it is likely that individual delta smelt migrate between the LSZ and the Cache Slough region. This is consistent with the high summer water temperatures observed there, which might compel individual delta smelt to seek out cooler habitats within and outside the Cache Slough region.

Delta Smelt Environmental Baseline

The portions of the Action Area that fall within the range of delta smelt include the Sacramento River east levee, south of Sacramento and the Sacramento Weir. Delta smelt typically migrate up into this area as early as December and move out in the spring and summer. The proposed project contains habitat components that can be used for feeding, spawning, rearing, and movement. Some amount of erosion protection has already occurred within the action area. Additionally, the Corps has a project which will place rock along 31,000 linear feet of the right bank of the Sacramento River immediately across the river and extending upstream from the proposed project footprint. Compensation for the placement of this rock will be through the development of a setback levee that will provide 118 acres of newly created shallow water habitat.

Giant Garter Snake Status of the Species

For the most recent assessment of the species' range-wide status please refer to the *Giant Garter Snake (Thamnophis gigas) 5-year Review: Summary and Evaluation* (Service 2012) for the current status of the species. Ongoing threats to giant garter snake include habitat loss from water transfers, rice fallowing due to drought conditions, habitat disturbance and loss from irrigation and drainage ditch maintenance, climate change, and invasive species. While these threats continue to effect the giant garter snake throughout its range, to date no project has proposed a level of effect for which the Service has issued a biological opinion of jeopardy for the giant garter snake.

Giant Garter Snake Environmental Baseline

The *Draft Recovery Plan for the Giant Garter Snake* (Service 1999b) subdivides the range of the species into four recovery units. Each recovery unit includes populations. The action area for the proposed project is located within the Yolo Basin-Willow Slough unit and the American Basin unit. According to the 2012, 5-year review (Service 2012) the abundance and distribution of giant garter snakes has not changed significantly. Within the Action Area habitat loss and fragmentation is the most significant threat to the giant garter snake. Urbanizing areas within the Action Area include Sacramento and West Sacramento. Habitat loss through water transfers and rice fallowing also negatively affects giant garter snakes. In the Sacramento Valley, rice has served as a substitute for the large amounts of historical wetlands that used to exist in the Central Valley. Loss of this habitat has been shown to reduce or exclude giant garter snakes compared to areas which are actively irrigated in rice (Wylie *et al.* 2002a, b, 2004).

Flood control maintenance and agricultural activities can reduce and prevent the establishment of vegetation and burrows needed by the giant garter snake for cover and shelter on canals, levees, and agricultural ditches. This can also reduce the prey base for giant garter snake, affecting their feeding. Additionally, clearing, scraping and/or re-contouring canals, ditches, and levees, destroys burrows and crevices that are used as over-wintering habitat and during the summer for thermoregulation, shedding, and giving birth. These activities are being conducted by local maintaining agencies throughout the Action Area.

Other factors which effect the giant garter snake population in the Action Area include vehicular mortality particularly where canals or aquatic habitat are bordered by roads such as the crown of the levees. Non-native predators such as game fish, bull frogs (*Rana catesbiana*), and domestic cats can affect giant garter snake populations (Service 1999b). This can be particularly detrimental to young and juvenile giant garter snakes. All of the Action Area has non-native predators occurring in it.

Snakes have been located within the Yolo Bypass within 2 miles of the Sacramento Bypass. Numerous irrigation and drainage canals exist which provide connectivity from the Sacramento Bypass and areas that are known to support snakes in the Yolo Bypass. A snake observed 0.5 mile to the west of the NEMDC along Elkhorn Boulevard in 1996 (CNDDB 2015). Borrow site 2's northern boundary is Elkhorn Boulevard on the east side of the NEMDC. Giant garter snakes could be using the NEMDC for aquatic habitat and the surrounding grasslands for uplands.

Western Yellow-Billed Cuckoo Status of the Species

For the most recent assessment of the species range-wide status please refer to the October 3, 2014, *Determination of Threatened Status for the Western Distinct Population Segment of the Yellow-billed Cuckoo (Coccyzus americanus occidentalis)* (79 FR 59991). Ongoing threats to the yellow-billed cuckoo include habitat loss from flood control projects and maintenance, alterations to hydrology, climate change, and invasive species. While these threats continue to affect the yellow-billed cuckoo throughout its range, no project, to date, has proposed a level of effect for which the Service has issued a biological opinion of jeopardy for the yellow-billed cuckoo.

Western Yellow-Billed Cuckoo Baseline

Yellow-billed cuckoo detections have occurred most frequently in the upper Sacramento River where levees are setback from the river or do not exist. Additionally, the last 20 years has seen a large amount of riparian restoration occur in the upper Sacramento River. Habitat in the action area tends to be more narrow and linear than in the upper Sacramento River. Levees were constructed close to the bank of the Sacramento River leaving narrow bands of small patch sizes. Construction of the setback levee along the right bank of the Sacramento River as part of the West Sacramento Flood Control Project will provide some wider patches of riparian habitat that will benefit the yellow-billed cuckoo. The American River has a wider floodplain due to levees being setback from the channel. There are some patches large enough to support nesting yellow-billed cuckoos, though cuckoos have not been observed nesting along the American River.

Effects of the Proposed Action

Valley Elderberry Longhorn Beetle

Vegetation removal, including elderberries could cause mortality of any beetle larvae within the elderberry shrub. Transplanting the shrubs between November 1 and February 15, when the shrubs are dormant, will minimize the likelihood of killing larvae within the shrub. Transplanting the shrub could still result in mortality to larvae within the shrub, particularly if the shrub does not survive transplantation. Proper care of the transplants through watering in the initial years can minimize this loss and increase the likelihood that the shrub will survive and provide continued habitat for the valley elderberry longhorn beetle.

Construction that occurs near elderberry shrubs that will be protected in place can kill adult beetles if construction equipment is operating between the months of March and June when valley elderberry longhorn beetles have emerged from the elderberry shrubs and are locating mates for reproduction. Fencing the area which contains riparian habitat, specifically elderberry shrubs, and keeping a minimum of a 20 foot buffer from the dripline of the elderberry shrub will keep construction equipment from driving too close to the shrubs and minimize the number of beetles that might be struck or run over by equipment.

Transplanting elderberry shrubs out of the construction footprint has the potential to affect valley elderberry longhorn beetle dispersal if there is potential to remove large areas of elderberry shrubs. The Corps has provided maps of where existing valley elderberry longhorn beetle habitat exists and where shrubs will be removed due to the project. Along the Sacramento River, 13 elderberry shrubs distributed within 70 acres of riparian habitat will be transplanted as part of the project, however during surveys the Corps has documented an additional 60 elderberry shrubs that will be protected in place along the Sacramento River. The Corps has also proposed to include elderberry shrub plantings along the bank repair footprint where the elevation is suitable so the shrubs are not inundated too frequently. Along the American River, 250 elderberry shrubs distributed within 65 acres of riparian habitat will be transplanted as part of the project. The American River has many conservation sites and the Corps has proposed to offset the removal of elderberry shrubs through development of additional sites and enlargement of existing sites in the lower American River Parkway. The Corps is proposing to create an additional 69.91 acres of habitat for the valley elderberry longhorn beetle in the lower American River Parkway.

Trimming of elderberry shrubs can result in the loss of some habitat for the valley elderberry longhorn beetle. Unlike transplantation however, the shrub remains within the riparian corridor and can provide habitat for the beetle during dispersal. There is potential for one of the pruned stems to contain the larvae of the valley elderberry longhorn beetle. While elderberry shrubs do resprout readily, there is a temporal loss of habitat for the beetle and as part of the maintenance any resprouted stems will be removed in order to provide maintenance equipment access. To offset these effects the local maintaining agencies have proposed to create a 40-acre conservation area for the valley elderberry longhorn beetle. This area will be selected as described in the preceding paragraph. This will ensure habitat connectivity and help with long-term maintenance and monitoring of these lands.

Delta Smelt

Construction along the Sacramento River will place bank protection along a 50,300 linear foot section of the left bank of the Sacramento River. Delta smelt are a pelagic species that is typically found in the center of the channel. However, as described in the status of the species they do spawn on sandy beaches in shallow water habitat (0 to 3 meters) and in this portion of the Sacramento River are found close to the banks. The rock footprint will change the substrate along the 50,300 linear feet of 33 acres of shallow water habitat. Additionally 13 acres are being converted from riverine bank edge to a rock wedge. Construction related effects to individual delta smelt will be avoided because construction is occurring between August 1 and November 30, a time when delta smelt are located further downstream in the Delta and Suisun Bay. Effects due to increasing sediment downstream of the work area will be minimized through the conservation measures involving monitoring water quality during construction to ensure that effects do not extend into the portion of the Delta that delta smelt occupies during the late summer/fall period. Construction to widen the Sacramento Weir will occur on the landside of the existing Sacramento River right bank levee. Upon completion of the weir extension the levee removed between August 1 and November 30 avoiding effects to delta smelt habitat.

The primary negative effect of the project on potential spawning habitat is the change of substrate from sand to riprap. Rock used for bank protection is large enough to retard erosional forces of the river and therefore has interstitial spaces. Should delta smelt spawn over this riprap substrate, it is very likely that any eggs will fall into these interstitial spaces resulting in the loss of eggs and potentially causing fertilization to not occur if the eggs fall into the interstitial spaces. The Corps has proposed to offset this loss of spawning potential in these areas through the purchase of 33 acres of credits at a Service-approved delta smelt conservation bank. The placement of rock will permanently narrow the channel by 13 acres through the change of riverine edge to rock wedge. Rock slope protection limits the lateral mobility of a river channel, increases flow velocities (Sedell *et al.* 1990), limit sediment transport, and eliminates bankside refugia areas (Gregory *et al.* 1991). Rock placement can also affect primary productivity through the loss of vegetation. The Corps will protect large trees in place and plant riparian benches at the conclusion of the rock placement to replace the loss of vegetation. Planting benches and vegetation planting will also help to offset the increased velocities that the bank protection sites will experience due to the smoother rock surface. To offset the complete loss of riverine edge habitat the Corps has proposed to purchase 39 acres of credits at a Service-approved delta smelt conservation bank for a total of 72 acres of credits.

The Corps has proposed to evaluate effects to listed species including delta smelt when long-term maintenance activities for the Sacramento River can be described. If maintenance activities will affect delta smelt the Corps will reinitiate consultation with the Service. Therefore, this biological opinion does not address effects to the delta smelt from any long-term levee maintenance activities.

Delta Smelt Critical Habitat

This opinion on the critical habitat for the delta smelt does not rely on the regulatory definition of "destruction or adverse modification" of critical habitat at 50 CFR § 402.02. Instead, we have relied upon the statute and the August 6, 2004, Ninth Circuit Court of Appeals decision in *Gifford Pinchot Task Force v. U. S. Fish and Wildlife Service* (No. 03-35279) to complete the following analysis with respect to the proposed critical habitat.

Implementation of the proposed project will affect PCE #1 Physical Habitat as described under the environmental baseline section above. The placement of rock will change the substrate of shallow water habitat for 46 acres. Any loss of shallow water habitat will be compensated through the purchase of credits at a delta smelt conservation bank. It is expected that planting the sites post-construction will replace any loss of primary productivity within the Sacramento River water column.

Giant Garter Snake

Borrow Site 2 – Upland habitat will be disturbed at borrow site 2 (5.5 acres) when heavy equipment is brought in to remove soil for the Arcade Creek levee repair. Removal of soil from the site will result in the crushing of burrows that snakes use for aestivating and thermoregulation. Fencing the borrow site prior to borrow excavation will minimize the likelihood that snakes will be in the borrow site when construction equipment begins to mobilize. Fencing the site will temporarily (one active season) exclude the use of the area for giant garter snake. This could result in snakes having to move further distances to find upland refugia in the summer months and expose them to predation or other sources of mortality such as being run over by a vehicle on the levee road on the opposite side of the NEMDC. Because the aquatic habitat will not be disturbed by the project, there will not be any effects on the snake's ability to forage.

Upon completion of the project, the site will restored and re-graded to create three habitat types. The creation of additional tule marsh along the edge of the canal will benefit giant garter snakes that may be using the NEMDC as it will provide cover, an area for prey production, and refugia from predators. Additionally, the seasonal wetland bench will only provide aquatic habitat in the winter months when the snake is typically in burrows. The wetland bench will provide some upland habitat for the giant garter snake during the summer when the snake is active in the form of basking habitat and if dried wetland vegetation remains some refugia from predators; however, because the site will be flooded in the winter it will not serve as overwintering habitat for the snake. The remaining 3.5 acres of the borrow site will be restored to native grassland and will function as summer upland refugia and basking and in the winter serve as overwintering habitat for the snake.

Sacramento Bypass – Enlarging the Sacramento Bypass and Weir will result in both permanent and temporary effects to giant garter snake habitat. Construction of the widened bypass will have similar effects to giant garter snake as the work along borrow site 2. Snakes could be crushed by heavy equipment, entombed in refugia when burrows collapse, and exposed to increased predation because they may have to travel further to find habitat that is unavailable to them due to the project. The 25 acres of aquatic habitat and 50 acres of upland habitat that will be temporarily affected because of the relocation of a levee toe drain will be replaced within one year of construction. The Corps has committed to creating a toe drain that closely mimics the existing aquatic and upland habitat along the northern levee of the Sacramento Bypass. The effects of crushing snakes and exposing them to increased predation will be minimized through the use of the conservation measures described in the project description above.

Permanently, 15 acres of aquatic and 30 acres of upland habitat will be lost through the removal of drainage ditches and farm canals in the area that is currently outside of the bypass footprint. The Corps has committed to offsetting the loss of this habitat through the purchase of 135 acres of giant garter snake credits at a Service-approved conservation bank. Conservation banks provide protection, conservation easement, and funding, endowment, in perpetuity for the giant garter snake. These long-term protections and location of the conservation banks all contribute to the long-term recovery of the giant garter snake.

Operation of the expanded Sacramento Weir and Bypass will result in an increase of water surface elevation of approximately 0.5-foot on the levee slopes on either side of the Yolo Bypass. However, when this increase occurs, during a 200-year flood event, the Yolo Bypass levees already contain water up to 21 feet deep. As a result, giant garter snake burrows would likely already be saturated before the additional water associated with the widened Sacramento Bypass is a factor. The additional 0.5-foot resulting from this action would not significantly change the timing or duration of this flooding and would not result in further impacts to giant garter snake habitat.

The Corps has proposed to evaluate effects to listed species including giant garter snake when long-term maintenance activities for the Sacramento Bypass can be described. If maintenance activities will affect giant garter snakes the Corps will reinitiate consultation with the Service. Therefore, this biological opinion does not address effects to the giant garter snake from any long-term levee maintenance activities.

Yellow-Billed Cuckoo

Sacramento River – The Corps is planning on removing 70 acres of riparian habitat along the Sacramento River. The riparian corridor in this section of the Sacramento River is narrow (about 100 feet wide) because the levees were constructed so close to the edge of the channel bank. This is too narrow for the yellow-billed cuckoo to nest, however it is possible for the yellow-billed cuckoo to use this as a stopover when migrating to the Central Valley to breed. Vegetation removal will reduce the width of the riparian corridor from 100 feet to 40 feet on average. The Corps proposal to plant the bank protection sites will create a 25-foot wide planting berm leaving a loss of about 35 feet of riparian corridor. The Corps proposes to offset the loss of the 70 acres of riparian through the creation of 140 acres of riparian habitat along the lower American River.

American River – The construction of launchable rock trench will remove 65 acres of riparian habitat along the lower American River. The lower American River does have habitat patches large enough to support nesting yellow-billed cuckoos. Large patches of habitat will not be removed; rather a strip will be removed adjacent to the levee which could reduce the size of some of the potential nesting areas. To compensate for this the Corps is proposing to plant 130 acres along the lower American River. As described in the conservation measures, the Corps will develop a Riparian Conservation Plan that will determine the best locations to develop additional riparian habitat. The conservation areas will provide both habitat for yellow-billed cuckoo and valley elderberry longhorn. The areas will also ensure that there is a net increase of potential yellow-billed cuckoo nesting habitat along the lower American River Parkway. There will be a temporal loss of habitat because riparian habitat can take up to 20 years to develop.

In addition to the habitat loss for both the Sacramento and American Rivers, construction itself has the potential to adversely affect yellow-billed cuckoos. Construction that occurs when the cuckoo is in the Sacramento Valley has the potential to harass the bird due to noise. To minimize effects to the cuckoo due to construction noise the Corps conservation measure to do protocol level surveys prior to beginning construction will enable the Corps to determine if yellow-billed cuckoos are nesting near the construction footprint. The Corps has committed to avoid construction near an active yellow-billed cuckoo nest. However, cuckoos that could be foraging in the area could be harassed due to construction activities and noise and move to other locations in the lower American River parkway which could expose individual cuckoos to increased predation.

The Corps has proposed to evaluate effects to listed species including yellow-billed cuckoo when long-term maintenance activities for the Sacramento River and American River can be described. If maintenance activities will affect yellow-billed cuckoos the Corps will reinitiate consultation with the Service. Therefore, this biological opinion does not address effects to the yellow-billed cuckoo from any long-term levee maintenance activities.

Cumulative Effects

Cumulative effects include the effects of future State, Tribal, local, or private actions that are reasonably certain to occur in the action area considered in this biological opinion. Future federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Act.

Valley Elderberry Longhorn Beetle

Non-Federal adverse effects to the valley elderberry longhorn beetle include effects from nearby pesticide spraying drifting into valley elderberry longhorn beetle habitat and levee and channel maintenance. In the areas of the urbanized areas of the American and Sacramento Rivers human started fires is by far the largest effect to valley elderberry longhorn beetles. Over the last several years numerous fires have burned portions of the American River Parkway.

Delta Smelt

Adverse effects to delta smelt may result from point and non-point source chemical contaminant discharges within the action area. These contaminants include but are not limited to ammonia and free ammonium ion, numerous pesticides and herbicides from agricultural activities, and oil and gasoline product discharges. Oil and gasoline product discharges may be introduced into the Sacramento River from shipping and boating activities and from urban activities and runoff. Other future, non-Federal actions within the action area that are likely to occur and may adversely affect delta smelt include: the dumping of domestic and industrial garbage that decreases water quality; oil and gas development and production that may affect aquatic habitat and may introduce pollutants into the water; agricultural activities, including burning or removal of vegetation on levees that reduce riparian and wetland habitats that contribute to the quality of habitat used by delta smelt; and livestock grazing activities that may degrade or reduce riparian and wetland habitats that contribute to the quantity and quality of habitat used by delta smelt.

San Francisco Bay-Delta Climate Change

The effects of climate change do not act in isolation; they are anticipated to exacerbate existing threats to delta smelt. We considered the potential effects of climate change on the delta smelt based on projections derived from various modeling scenarios. A series of publications (Feyrer *et al.* 2011; Cloern *et al.* 2011; Brown *et al.* 2013) have modeled future impacts of climate change in the Delta and projected how this will affect delta smelt. These models used the B1 and A2 scenarios from the 2007 IPCC report. Each scenario included both a warmer-wetter and warmer-dryer sub scenario. Modeled predictions presented in these publications are based on current baseline conditions (no increased outflow, no breeching of levees) which may or may not change in the future. Temperature increases are likely to lead to a continued rise in sea level, further increasing salinity which will increasingly restrict delta smelt's already limited geographic range (Feyrer *et al.* 2011; Cloern *et al.* 2011; Brown *et al.* 2013). Higher air temperatures will reduce snowpacks, melt snow earlier in the winter or spring, and increase water temperatures. These changes will likely alter freshwater flows, possibly shifting and condensing the timing and location of delta smelt reproduction (Brown *et al.* 2013).

Projections indicate that temperature and precipitation changes will diminish snowpack, changing the availability of natural water supplies (Reclamation 2011). Warming may result in more precipitation falling as rain and less storage as snow. This would result in increased rain on snow events and increase winter runoff with an associated decrease in runoff for the remainder of the year (Reclamation 2011). Sacramento Valley Ecoregion projections include a 27 percent decrease in annual freshwater flows and earlier snowmelts, with increased freshwater flows in January and February but reduced throughout the rest of the year (PRBO Conservation Science 2011). Earlier seasonal warming increases the likelihood of rain-on-snow events, which are associated with mid-winter floods. Smaller snowpacks that melt earlier in the year may result in increased drought frequency and severity (Rieman and Isaak 2010). Thus overall, these changes may lead to increased frequency of flood and drought cycles during the 21st century (Reclamation 2011).

Sea level rise is likely to increase the frequency and range of saltwater intrusion. Salinity within the northern San Francisco Bay is projected to rise by 4.5 by the end of the century (Cloern *et al.* 2011). Elevated salinity levels could push the position of X2 farther up the estuary if outflows were not increased to compensate for it. Fall X2 mean values are projected to increase by a mean of about 7 km to the area of Antioch for a distance of about 90 km from the Golden Gate Bridge by 2100 (Brown *et al.* 2013). This increase in the position of X2 in the fall is expected to result in a decrease in suitable physical habitat (Brown *et al.* 2013) if current levees and channel structures are maintained. A decrease in spring habitat due to the movement of X2 upstream due to sea level rise is also expected to result from climate change.

We expect warmer estuary temperatures to be yet another significant conservation challenge based on climate change models. Mean annual water temperatures within the upper Sacramento River portion of the Bay-Delta estuary are expected to approach or exceed 14 °C during the second half of this century (Cloern *et al.* 2011). Warmer water temperatures could reduce delta smelt growth, increase delta smelt mortality and constrict suitable habitat within the estuary during the summer months. Due to warming temperatures, delta smelt are projected to spawn an average of 10 to 25 days earlier in the season depending on the location (Brown *et al.* 2013). Also due to expected temperature increases, total number of high mortality days is expected to increase for all IPCC climate change scenarios (Brown *et al.* 2013). The number of stress days is expected to be stable or decrease partly because many stress days will become high mortality days. This could lead to delta smelt being forced to grow under highly stressful conditions during summer and fall with less time to mature because of advanced spawning (Brown *et al.* 2013). Growth rates have been shown to slow as water temperatures increase therefore requiring delta smelt to consume more food to reach growth rates that are normal at lower water temperatures (Rose *et al.* 2013a). Delta smelt are already often smaller than they used to be (Sweetnam 1999; Bennett 2005) and expected temperature increases due to climate change will likely further slow growth rates.

At the same time, warmer water will tend to move the spawning season earlier in the year (Brown *et al.* 2013). That means the fish will have to grow faster still to compensate for that shorter growing season to produce even as many eggs as they do now – and that may already be a serious limitation on their population fecundity (Rose *et al.* 2013b). Higher temperatures may restrict delta smelt distribution into the fall, limiting their presence in Suisun Bay for more than just salinity reasons and force greater inhabitation of cooler high salinity waters (Brown *et al.* 2013). Water temperatures are already presently above 20°C for most of the summer in core habitat areas, sometimes even exceeding 25 °C for short periods.

The delta smelt is currently at the southern limit of the inland distribution of the family Osmeridae along the eastern Pacific coast. That indicates that this region was already about as warm as that fish family can handle. Increased temperatures associated with climate change may result in a habitat in the Bay-Delta that is outside of the species ecological tolerance limits.

Giant Garter Snake

The Service is aware of other projects currently under review by the State, county, and local authorities where biological surveys have documented the occurrence of federally-listed species. These projects include such actions as urban expansion, water transfer projects that may not have a Federal nexus, and continued agricultural development. The cumulative effects of these known actions pose a significant threat to the eventual recovery of the species. Additionally, an undetermined number of future land use conversions and routine agricultural practices are not subject to Federal permitting processes and may alter the habitat or increase incidental take of snakes, and are, therefore, cumulative to the proposed project. For example other cumulative effects include: (1) unpredictable fluctuations in aquatic habitat due to water management and diversions; (2) dredging and clearing of vegetation from irrigation canals; (3) discing or mowing upland habitat; (4) increased vehicular traffic on access roads adjacent to aquatic habitat; (5) use of burrow fumigants on levees and other potential upland refugia; (6) human intrusion into habitat; (7) use of inappropriate plastic erosion control netting (Stuart *et al.* 2001); (8) riprapping or lining of canals and stream banks; (9) fluctuations in acreages of rice production due to market conditions or water availability; (10) ornamental cultivation; (11) routine grounds maintenance of upland habitat; (12) contaminated runoff from agriculture and urbanization; (13) maintenance of non-Federal flood control structures; and (14) predation by feral animals and pets. Specific cumulative effects related to the proposed project include maintenance activities and/or an increased potential for vandalism, which may degrade or destroy habitat or cause unpredictable fluctuations in habitat.

Yellow-Billed Cuckoo

Habitat that is currently occupied by the yellow-billed cuckoo occurs on public and privately owned lands. Activities on non-Federal lands that may affect the yellow-billed cuckoo include the construction and maintenance of recreational hiking and bicycle trails; restoration of native riparian habitat; transportation related projects like construction and maintenance of State, county, and private roads and bridges; flood channel maintenance by the State water resources agencies, and conversion of riparian habitat to agriculture on private lands.

Conclusion

After reviewing the current status of the valley elderberry longhorn beetle, delta smelt, giant garter snake and yellow-billed cuckoo, the environmental baseline for the action area, the effects of the proposed ARFC project, and the cumulative effects on these species, it is the Service's biological opinion that the proposed AFRC project, is not likely to jeopardize the continued existence of these species. The Service reached this conclusion because the project-related effects to the species, when added to the environmental baseline and analyzed in consideration of all potential cumulative effects, will not rise to the level of precluding recovery or reducing the likelihood of survival of the species based on the conservation measures proposed by the Corps including: creating additional riparian habitat for the valley elderberry longhorn beetle and the yellow-billed cuckoo; purchasing credits at conservation banks for giant garter snake and delta smelt; and restoring any temporarily affected habitat to pre-project conditions.

After reviewing the current status of designated critical habitat for delta smelt, the environmental baseline of critical habitat in the action area, the effects of the proposed ARFC project, and the cumulative effects, it is the Service's biological opinion that the proposed ARFC project, as proposed, is not likely to destroy or adversely modify designated critical habitat. The Service reached this conclusion because the project-related effects to the designated critical habitat, when added to the environmental baseline and analyzed in consideration of all potential cumulative effects, will not rise to the level of precluding the function of the delta smelt critical habitat, to serve its intended conservation role for the species based on the Corps proposal to purchase credits at a conservation bank for permanent effects to the substrate of the Sacramento River. The effects to delta smelt critical habitat are small and discrete, relative to the entire area designated, and are not expected to appreciably diminish the value of the critical habitat or prevent it from sustaining its role in the conservation of the delta smelt.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harass is defined by Service regulations at 50 CFR 17.3 as an intentional or negligent act or omission which creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding or sheltering. Harm is defined by the same regulations as an act which actually kills or injures wildlife. Harm is further defined to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavior patterns, including breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered to be prohibited taking under the Act provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are nondiscretionary, and must be undertaken by the Corps and SAFCA so that become binding conditions of any contract issued for the exemption in section 7(o)(2) to apply. The Corps has a continuing duty to regulate the activity that is covered by this incidental take statement. If the Corps (1) fails to assume and implement the terms and conditions, or (2) fails to require their contractor or SAFCA or to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to the contract, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the Corps must report the progress of the action and its impact on the species to the Service as specified in the incidental take statement [50 CFR §402.14(i)(3)].

Amount or Extent of Take

Valley Elderberry Longhorn Beetle

The Service anticipates that incidental take of valley elderberry longhorn beetle will be difficult to detect due to its life history and ecology. Specifically, valley elderberry longhorn beetles can be difficult to locate due to the fact that a majority of their life cycle is spent in the elderberry shrub and finding a dead or injured individual is unlikely due to their relatively small size. There is a risk of harm, harassment, injury and mortality as a result of the proposed construction activities; therefore, the Service is authorizing take incidental to the proposed action as harm, harassment, injury, and mortality of all valley elderberry longhorn beetles within 263 shrubs that will be transplanted as a result of construction and 40 acres of elderberry shrubs that will be trimmed for maintenance purposes over the project's 50 year life.

Delta Smelt

The Service expects that incidental take of delta smelt will be difficult to detect or quantify for the following reasons: the small size of adults, their occurrence in turbid aquatic habitat makes them difficult to detect, and the low likelihood of finding dead or impaired specimens. The Service anticipates that the extent of incidental take will be minimized due to the proposed conservation measures and low relative abundance. Due to the difficulty in quantifying the number of delta smelt that will be taken as a result of the proposed action, the number of acres of affected habitat becomes a surrogate for the species that will be taken. The Service anticipates that all individual adult delta smelt in the 46 acres of the action area may be subject to incidental take in the form of harm as described in this biological opinion. Incidental take of delta smelt for maintenance activities is not covered in this biological opinion.

Giant Garter Snake

The Service anticipates that incidental take of the snake will be difficult to detect or quantify for the following reasons: snakes are cryptically colored, secretive, and known to be sensitive to human activities. Snakes may avoid detection by retreating to burrows, soil crevices, vegetation, and other cover. Individual snakes are difficult to detect unless they are observed, undisturbed, at a distance. Most close-range observations represent chance encounters that are difficult to predict. It is not possible to make an accurate estimate of the number of snakes that will be harassed during construction activities, including in staging areas and roads carrying vehicular traffic. In instances when take is difficult to detect, the Service may estimate take in numbers of species per acre of habitat lost or degraded as a result of the action as a surrogate measure for quantifying individuals.

Therefore, the Service anticipates the number of giant garter snakes that may be found in 125.5 acres of aquatic and upland habitat will be harmed or killed as a result of habitat modification due to the proposed project. Incidental take of giant garter snake for maintenance activities is not covered in this biological opinion.

Yellow-Billed Cuckoo

The Service anticipates that incidental take of yellow-billed cuckoo will be difficult to detect due to its life history and ecology. Specifically, yellow-billed cuckoos can be difficult to locate due to their cryptic appearance and behavior and finding a dead or injured individual is unlikely. There is a risk of harm and harassment as a result of proposed construction activities and operations and maintenance of the restoration plantings; therefore, the Service is authorizing take incidental to the proposed action as harm of all yellow-billed cuckoos within 135 acres. Incidental take of yellow-billed cuckoo for maintenance activities is not covered in this biological opinion.

Effect of the Take

In the accompanying biological opinion, the Service determined that this level of anticipated take is not likely to result in jeopardy to the species or destruction or adverse modification of critical habitat.

Reasonable and Prudent Measures

All necessary and appropriate measure to avoid or minimize effects on the species resulting from implementation of this project have been incorporated into the project's proposed conservation measures. Therefore, the Service believes the following reasonable and prudent measure is necessary and appropriate to minimize incidental take of the species.

1. All conservation measures, as described in the biological assessment and restated here in the Project Description section of this biological opinion, shall be fully implemented and adhered to. Further, this reasonable and prudent measure shall be supplemented by the terms and conditions below.

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the Act, the Corps must ensure compliance with the following terms and conditions, which implement the reasonable and prudent measure described above. These terms and conditions are nondiscretionary.

1. The Corps shall include full implementation and adherence to the conservation measures as a condition of any permit or contract issued for the project.

2. The Corps will develop a Riparian Planting Plan. The plan will evaluate locations for riparian vegetation planting based on land use in the lower American River Parkway, effects from future projects, such as the reoperation of Folsom Dam, where existing riparian and valley elderberry longhorn beetle habitat exists, creating and maintaining connectivity between large riparian patches, and coordination with Sacramento County Parks. The plan will maximize habitat quality for both the valley elderberry longhorn beetle and the yellow-billed cuckoo.

3. In order to monitor whether the amount or extent of incidental take anticipated from implementation of the project is approached or exceeded, the Corps shall adhere to the following reporting requirements. Should this anticipated amount or extent of incidental take be exceeded, the Corps must immediately reinitiate formal consultation as per 50 CFR 402.16.

   (a) For those components of the action that will result in habitat degradation or modification whereby incidental take in the form of harm is anticipated, the Corps will provide monthly updates to the Service with a precise accounting of the total acreage of habitat impacted. Updates shall also include any information about changes in project implementation that result in habitat disturbance not described in the Project Description and not analyzed in this biological opinion.

   (b) For those components of the action that may result in direct encounters between listed species and project workers and their equipment whereby incidental take in the form of harassment, harm, injury, or death is anticipated, the Corps shall immediately contact the Service's Sacramento Fish and Wildlife Office (SFWO) at (916) 414-6600 to report the encounter. If the encounter occurs after normal working hours, the Corps shall contact the SFWO at the earliest possible opportunity the next working day. When injured or killed individuals of the listed species are found, the Corps shall follow the steps outlined in the Salvage and Disposition of Individuals section below.

   (c) Injured listed species must be cared for by a licensed veterinarian or other qualified person(s), such as a Service-approved biologist. Dead individuals must be sealed in a resealable plastic bag containing a paper with the date and time when the animal was found, the location where it was found, and the name of the person who found it. The bag containing the specimen must be frozen in a freezer located in a secure site, until instructions are received from the Service regarding the disposition of the dead specimen. The Service contact persons are the Habitat Conservation Division Chief at the Sacramento Fish and Wildlife Office at (916) 414-6600; the Assistant Field Supervisor of ESA/Regulatory Division at the Bay Delta Fish and Wildlife Office at (916) 930-5603; and the Resident Agent-in-Charge of the Service's Office of Law Enforcement at (916) 569-8444.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. The Service recommends the following actions:

1. The Service recommends the Corps develop and implement restoration measures in areas designated in the Delta Fishes Recovery Plan (Service 1996) the Giant Garter Snake Recovery Plan (1999) and the Valley Elderberry Longhorn Beetle Recovery Plan (1984).

2. The Corps and SAFCA should develop and implement projects that support DWR's Central Valley Flood System Conservation Strategy. This document provides goals and measurable objectives and potential projects which could be implemented in a manner that while improving the riverine ecosystem also will improve the flood system.

In order for the Service to be kept informed of actions minimizing or avoiding adverse effects or benefiting listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

REINITIATION - CLOSING STATEMENT

This concludes formal consultation with the Corps on the American River Common Features GRR Project. As provided in 50 CFR §402.16, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been retained or is authorized by law and:

(a) If the amount or extent of taking specified in the incidental take statement is exceeded;

(b) If new information reveals effects of the action that may affect listed species or critical habitat in a manner or to an extent not previously considered;

(c) If the identified action is subsequently modified in a manner that causes an effect to the listed species or critical habitat that was not considered in the biological opinion; or

(d) If a new species is listed or critical habitat designated that may be affected by the identified action.

If you have any questions regarding this biological opinion, please contact Jennifer Hobbs (jennifer_hobbs@fws.gov or (916) 414-6541) or Doug Weinrich, Assistant Field Supervisor at the letterhead address, (916) 414-6600.

Sincerely,

Jennifer M. Norris
Field Supervisor

Re: Endangered Species Act Section 7(a)(2) Biological Opinion, and Magnuson-Stevens Fishery Conservation and Management Act Essential Fish Habitat Response, for the American River Common Features General Reevaluation Report (Common Features GRR)

Dear Ms. Kirchner:

Thank you for your letter of April 3, 2015, providing an updated biological assessment and requesting initiation of consultation with NOAA's National Marine Fisheries Service (NMFS) pursuant to section 7 of the Endangered Species Act of 1973 (ESA) (16 U.S.C. 1531 *et seq.*) for the Common Features GRR.

This letter also transmits NMFS's essential fish habitat (EFH) conservation recommendations for Pacific salmon as required by the Magnuson-Stevens Fishery Conservation and Management Act (MSA) as amended (16 U.S.C. 1801 *et seq.*).

Based on the best available scientific and commercial information, the Biological Opinion (BO) concludes that the Common Features GRR is not likely to jeopardize the continued existence of the federally listed threatened Central Valley (CV) spring-run Chinook salmon evolutionarily significant unit (ESU) (*Oncorhynchus tshawytscha*), endangered Sacramento River winter-run Chinook salmon ESU (*O. tshawytscha*), threatened California CV steelhead distinct population segment (DPS) (*O. mykiss*), or the threatened Southern DPS (sDPS) of North American green sturgeon (*Acipenser medirostris*) and is not likely to destroy or adversely modify their designated critical habitats. For the above species, NMFS has included an incidental take statement with reasonable and prudent measures and non-discretionary terms and conditions that are necessary and appropriate to avoid, minimize, or monitor incidental take of listed species associated with the project.

The EFH consultation concludes that the proposed action would adversely affect the EFH of Pacific salmon in the action area. The EFH consultation adopts the ESA reasonable and prudent measures and associated terms and conditions from the BO and includes additional conservation recommendations specific to the adverse effects to fall- and late fall-run Chinook salmon (*O. tshawytscha*) EFH.

The U.S. Army Corps of Engineers (Corps) has a statutory requirement under section 305(b)(4)(B) of the MSA to submit a detailed written response to NMFS within 30 days of receipt of these conservation recommendations, and 10 days in advance of any action, that includes a description of measures adopted by the Corps for avoiding, minimizing, or mitigating the impact of the project on EFH (50 CFR 600.920(j)). If unable to complete a final response within 30 days, the Corps should provide an interim written response within 30 days before submitting its final response. In the case of a response that is inconsistent with our recommendations, the Corps must explain its reasons for not following the recommendations, including the scientific justification for any disagreements with NMFS over the anticipated effects of the Common Features GRR and the measures needed to avoid, minimize, or mitigate (also referred to as compensate by NMFS) such effects.

Please contact Howard Brown at the NMFS California Central Valley Office, 916-930-3608, or at Howard.Brown@noaa.gov, if you have any questions concerning this section 7 consultation, or if you require additional information.

Sincerely,

for Maria Rea

INTRODUCTION

The U.S. Army Corps of Engineers (Corps) proposes to implement flood risk management improvements under the American River Common Features General Reevaluation Report (Common Features GRR). The purpose of this Biological Opinion (BO) is to analyze the potential effects of repairing the levees in the Sacramento Metropolitan area (including both the Sacramento and American Rivers), widening the Sacramento Weir and Bypass, and diverting more flows into the Yolo Bypass on listed threatened or endangered species and on designated critical habitat, within the project's area of effect (action area).

1.1 Common Features GRR Project Study Area

The Common Features GRR project study area is located within the Sacramento and American River Watersheds. The Sacramento River watershed covers approximately 26,000 square miles in central and northern California. Major tributaries of the Sacramento River include the Feather, Yuba, and American Rivers. The American River Watershed covers about 2,100 square miles northeast of the city of Sacramento and includes portions of Placer, El Dorado, Alpine, and Sacramento counties. The American River watershed includes Folsom Dam and Reservoir; inflowing rivers and streams, including the North, South, and Middle forks of the American River; and the lower American River downstream of Folsom Dam to its confluence with the Sacramento River in the city of Sacramento. The Sacramento and American Rivers, in the Sacramento area, form a flood plain covering roughly 110,000 acres at their confluence. The flood plain includes most of the developed portions of the city of Sacramento. Figure 1 shows the study area.

The Common Features GRR study area includes:

1. Approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River.
2. The east bank of the Dry, and Robla Creeks and the Magpie Creek Diversion Channel (collectively referred to as the East Side Tributaries).
3. The east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee.
4. The Sacramento Weir and Bypass, located along the north edge of the city of West Sacramento (Figure 1).

The action area for the ARCF GRR project includes the American River from below Folsom Dam to the confluence with the Sacramento River and the Sacramento River from the Sacramento Bypass down to below Freeport. In addition the action area includes the East Side Tributaries: Dry and Robla Creeks, and the Magpie Creek Diversion Channel.

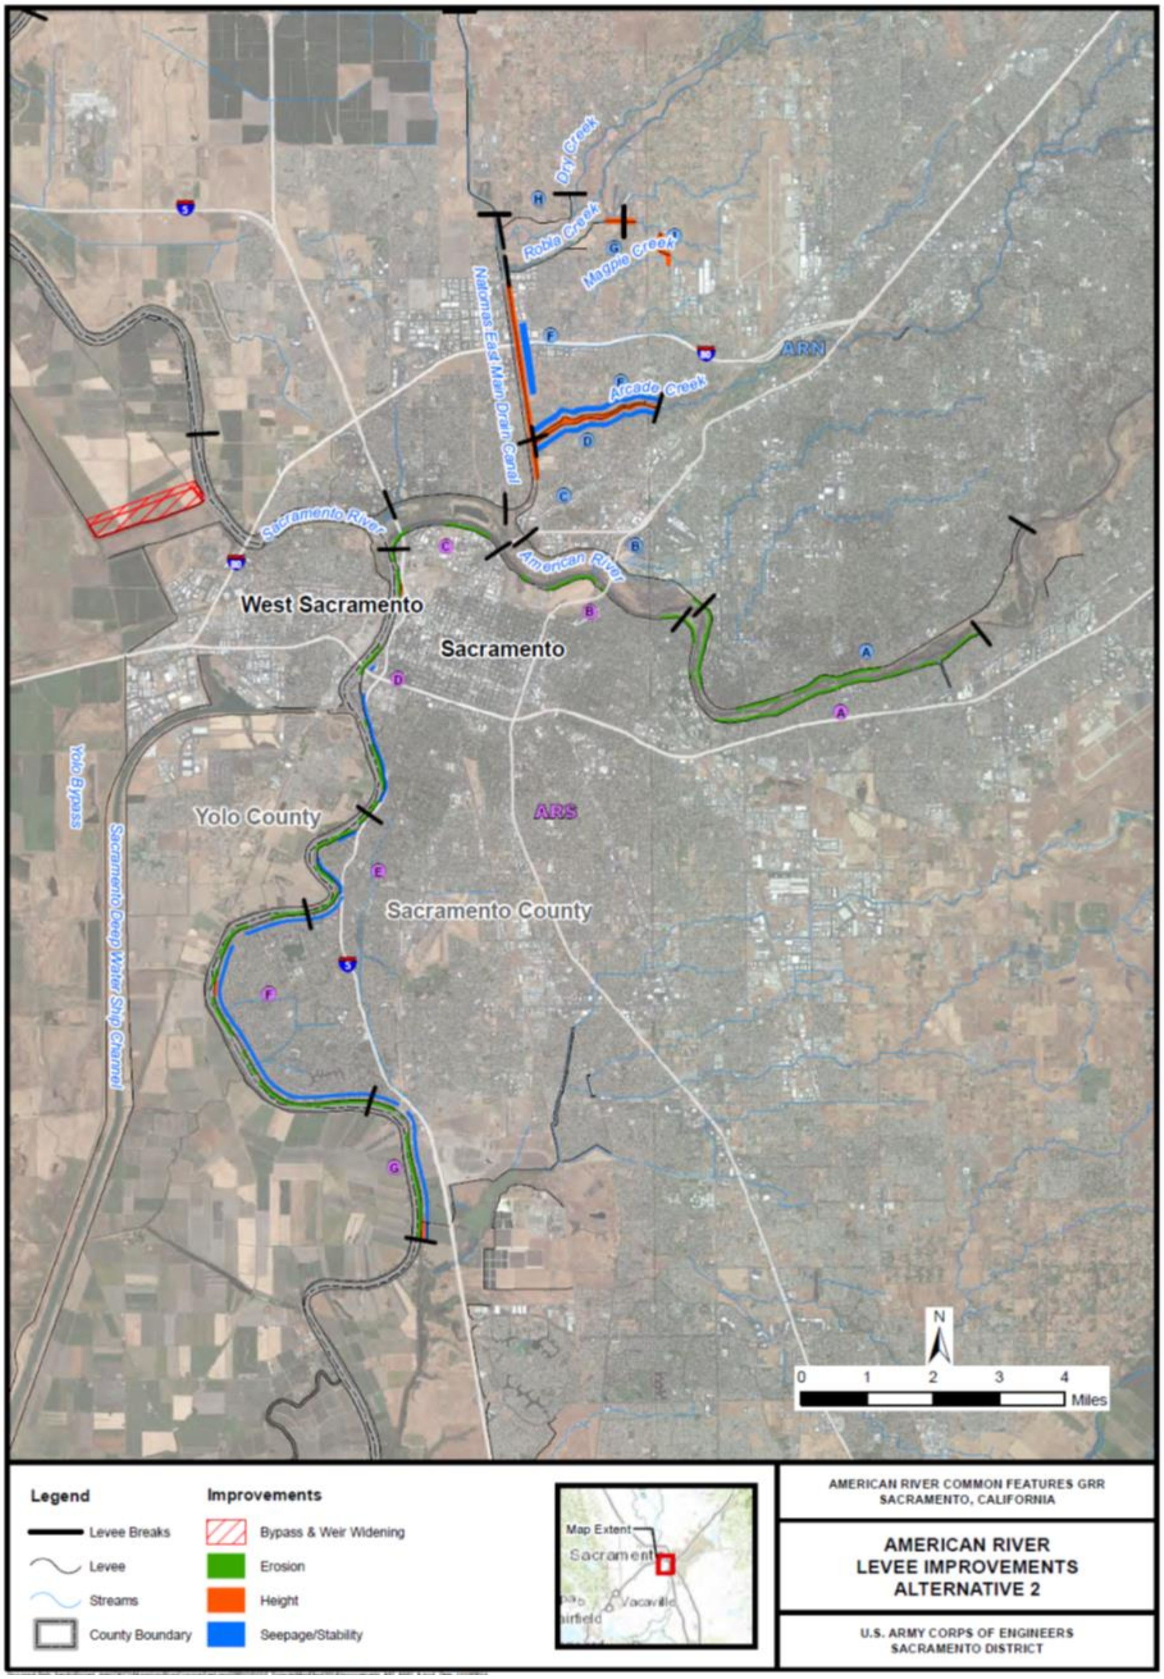

Figure 1. Common Features GRR Study Area (Corps 2014).

1.2 Background, Authority and Policy

The National Marine Fisheries Service (NMFS) prepared the BO and incidental take statement (ITS) portions of this document in accordance with section 7(b) of the Endangered Species Act (ESA) of 1973 (16 USC 1531 *et seq*.), and implementing regulations at 50 CFR part 402.

We also completed an essential fish habitat (EFH) consultation on the proposed action, in accordance with section 305(b)(2) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA) (16 U.S.C. 1801 *et seq*.) and implementing regulations at 50 CFR 600.

We completed pre-dissemination review of this document using standards for utility, integrity, and objectivity in compliance with applicable guidelines issued under the Data Quality Act (section 515 of the Treasury and General Government Appropriations Act for Fiscal Year 2001, Public Law 106-554). The document will be available through NMFS' Public Consultation Tracking System, https://pcts.nmfs.noaa.gov/pcts-web/homepage.pcts. A complete record of this consultation is on file at the NMFS California Central Valley Office.

1.2.1 Background

After the flood of 1986, Congress directed the Corps to investigate the feasibility of reducing flood risk to the city of Sacramento. The Corps completed feasibility studies in 1991 and 1996, recommending a concrete gravity flood detention dam on the north fork of the American River at the Auburn site along with levee improvements downstream of Folsom Dam. Other plans evaluated in the report were Folsom Dam improvements and a stepped release plan for Folsom Dam releases. These additional plans also included levee improvements downstream of Folsom Dam. Congress recognized that levee improvements were "common" to all candidate plans in the report and that there was a Federal interest in participating in these "common features." Thus, the ARCF Project was authorized in WRDA 1996 and a decision on Auburn Dam was deferred to a later date. Major construction components for ARCF in the WRDA 1996 authorization include construction of seepage remediation along approximately 22 miles of American River levees and construction of levee strengthening and raising of 12 miles of Sacramento River levee in Natomas.

Following the flood of 1986, significant seepage was experienced on the Sacramento River from Verona (upstream end of Natomas) at River Mile (RM) 79 to Freeport at RM 45.5. In addition, both the north and south bank of the American River from RM 0 to approximately RM 11.4 experienced seepage. Seepage on the Sacramento River was so extensive that Congress, soon after the 1986 flood event, funded remediation in the Sacramento Urban Levee Improvement Project (Sac Urban). The Sac Urban Project constructed shallow seepage cutoff walls from Powerline Road in Natomas at approximately RM 64 down to Freeport.

In 1999, Congress decided not to authorize Auburn Dam but instead to authorize improvements for Folsom Dam. By doing this, improvements to levees downstream of Folsom Dam could be fine-tuned to work closely with the Folsom Dam improvements being discussed by Congress. Therefore, the Common Features project was modified by WRDA 1999 to include additional necessary features for the American River so that it could safely convey the proposed emergency release of 160,000 cfs from Folsom Dam. Major construction components for the Common Features project in the WRDA 1999 authorization include construction of seepage remediation and levee raises along four stretches of the American River, and construction of levee strengthening and raising of 5.5 miles of Natomas Cross Canal levee in Natomas. All American River features authorized in WRDA 1996 and 1999 have been constructed or are in design analysis for construction within a year or two.

Because of the considerable cost increase of seepage remediation on the American River, all funds appropriated by Congress throughout the late 1990s and the early part of the 2000s were used for construction activities on the American River instead of for design efforts in the Natomas Basin. Combining this with the recognition that all work in the Natomas Basin would also require significantly more effort than was anticipated at the time of authorization, it was decided in 2002 that a general reevaluation study would be required for at least the Natomas Basin portion of the ARCF project. This general reevaluation started in 2006.

At approximately the same time that the reevaluation study was beginning, the Folsom Dam Post Authorization Change report (PAC) was being completed by the Sacramento District. Results of this study showed that additional levee improvements were needed on the American River and on the Sacramento River below the American River in order to truly capture the benefits of the Folsom Dam projects. These levee improvements consisted primarily of addressing erosion concerns on the American River and seepage, stability, erosion, and height concerns on the Sacramento River below the American River.

There are three additional flood management Corps projects related to the Common Features GRR that provide additional context. The Corps initiated consultation for the West Sacramento GRS project in early 2015. Many of the proposed elements associated with the West Sacramento GRS are anticipated to be similar in nature to proposed elements with the Common Features GRR. The project area will include the opposite bank (west bank) of the Sacramento River from the West Sacramento GRS. Potential impacts associated with vegetation removal and bank armoring associated with the West Sacramento GRS could further degrade this area of the Sacramento River watershed. These potential impacts in combination with potential impacts associated with the West Sacramento GRR could degrade the overall health of the lower Sacramento River watershed.

The Corps has initiated consultation for the Sacramento Bank Protection Project Phase II project. Sacramento Bank Protection Project Phase II will cover up to 80,000 lf of bank protection as part of the SRFCP. A number of the potential bank protection sites are located in the general vicinity of the Common Features GRR.

Under the Water Resources Development Act of 1999, Pub. L. No. 106-53, § 366, 113 Stat. 269, 319-320 (1999) (WRDA 1999), Congress authorized improvements to Folsom Dam to control a 200-year flood event with a peak release of 160,000 cfs. WRDA 1999 also authorized the Folsom Dam Modification Project to modify the existing outlets to allow for higher releases earlier in flood events. At the same time, Congress also directed the Corps to review additional modifications to the flood storage of Folsom Dam, indicating that Congress was looking at maximizing the use of Folsom Dam to reduce flood risk prior to consideration of any additional upstream storage on the American River. The Folsom Dam Raise Project was subsequently authorized by Congress in 2004. The project is designed to allow for the release of 160,000 cubic feet per second (cfs) from Folsom Dam. The levees along the American River are unable to withstand these maximum flows for extended periods of time without increased risk of erosion and potential failure. Erosion within the American River Parkway is being addressed as part of the Folsom Reoperation project currently under evaluation and a biological assessment is being prepared to initiate Section 7 consultation with both USFWS and NMFS. These projects have the potential to increase the bank armoring and could exacerbate any impacts associated with the Common Features GRR.

1.2.2 Authority and Policy

According to the Corps' BA, they have no discretion in regards to the continuing existence and operation of the flood control structures of the SRFCP. They assert to have responsibility to maintain Civil Works structures so that they continue to serve their congressionally authorized purposes is inherent in the authority to construct them and is, according to the Corps, non-discretionary. The Corps also asserts that only Congressional actions to de-authorize the structures can alter or terminate this responsibility and thereby allow the maintenance of the structures to cease.

The Corps BA also claims that it has a non-discretionary duty to maintain the SRFCP and the fact the Corps perpetuates the projects existence is not an action subject to consultation. The Federal government maintains oversight but has no ownership of or direct responsibilities for performing maintenance of the Federal levee system, except for few select features that continue to be owned and operated by the Corps. However, the Corps asserts they do have discretion in regard to how and where maintenance actions are performed. The discretion lies within the authorities of the SRBPP and section 408 of the Rivers and Harbors Act. The Corps is seeking additional authorities that will include discretion over future flood risk reduction projects associated with the West Sacramento GRS and the Common Features GRR.

Considering these exceptions, the Corps maintains that the majority of levees, channels, and related flood risk management structures are owned, operated, and maintained by the State of California and local levee and reclamation districts as governed by Corps Operations and Maintenance (O&M) manuals. The Corps points to the May 1955 Standard O&M manual for the SRFCP as the primary O&M manual for the area. The levees of the West Sacramento and Common Features Projects are part of the SRFCP and therefore covered in the 1955 O&M manual.

The BA states that following completion of construction, the Corps will prepare a supplement to the 1955 O&M manual which will specify maintenance requirements for these projects. Because the Corps does have discretion in how and when levee maintenance activities are performed (as opposed to the results of maintenance), maintenance is a discretionary activity that is part of the proposed action subject to consultation.

Typical maintenance activities would include vegetation control through mowing, herbicide application, and/or slope dragging; rodent control; patrol road maintenance; and erosion control and repair. Vegetation control typically would be performed twice a year. Herbicide and bait station application would be conducted under county permit by experts licensed by the state for pest control. Erosion control and slope repair activities would include re-sloping and compacting; fill and repair of damage from rodent burrows would be treated similarly.

To meet Federal Flood Control Regulations (33 CFR 208.10) and state requirements (California Water Code Section 8370), the Federal Flood Risk Management facilities are inspected four times annually, at intervals not exceeding 90 days. The California Department of Water Resources (DWR) would inspect the system twice a year, and the local maintaining authorities would inspect it twice a year and immediately following major high water events. The findings of these inspections would be reported to the Central Valley Flood Protection Board's (CVFPB) Chief Engineer through DWR's Flood Project Integrity and Inspection Branch.

Each federal agency has an obligation to insure that any discretionary action it authorizes, funds, or carries out is not likely to jeopardize the continued existence of any endangered or threatened species or destroy or adversely modify its critical habitat. Furthermore, under Section 2 of the ESA, it is declared that all Federal agencies shall seek to conserve endangered species and threatened species and shall utilize their authorities in furtherance of the purposes of the ESA. In regards to species and critical habitat compensation, the Corps has the authority to compensate prior to or concurrent with project construction impacts. This authority is given under WRDA 1986 (33 USC §§ 2201–2330).

The Common Features Project is being proposed in accordance with the principles that have been outlined in the Corps' SMART Planning Guide (Corps 2013). SMART Planning requires that all feasibility studies should be completed within a target of 18 months (to no more than three years at the greatest), at a cost of no more than $3 million, utilizing 3 levels of vertical team coordination, and of a "reasonable" report size. All designs associated with the Common Features GRR use the largest footprint to evaluate affects to listed species. The larger footprint will look at the maximum extent the project could affect species in the action area.

The Corps proposes to construct the Common Features Project levee improvement measures to comply with the Engineering Technical Letter (ETL) 1110-2-571 Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures. The vegetation requirements include a vegetation-free zone on the levee slopes and crown, 15 feet from both landside and waterside levee toes, and 8 feet vertically.

The levees within the study area require seepage, slope stability, height, and erosion improvements in order to meet Corps levee safety criteria. In order to protect existing vegetation and allow for revegetation to occur, the Corps must apply for and issue itself with a vegetation variance. The vegetation variance will be sought during the preconstruction engineering and design phase to allow vegetation to remain on the lower 2/3 of the waterside slope and out 15 feet from the waterside toe. If the Corps grants itself a variance, the variance would allow for vegetation to remain in these areas. No vegetation would be permitted on the landside slope or within 15 feet of the landside toe. To show that the safety, structural integrity, and functionality of the levee would be retained with a variance, an evaluation of underseepage and waterside embankment slope stability was completed by Corps engineers.

The Corps' preliminary analysis for the vegetation variance was conducted by analyzing two index points. These two index points were chosen for the vegetation variance analyses because they were considered to be representative of the most critical channel and levee geometry, underseepage, slope stability conditions, and vegetation conditions of the respective basins. The analysis incorporated tree fall and scour on the cross-section geometry of the index points by using a maximum depth of scour for cottonwoods as approximately 11.0 feet; the associated soil removed was projected at a 2:1 slope from the base of the scour toward both the landside, and waterside slopes. The base scour width was equal to the maximum potential diameter at breast height (dbh) of cottonwoods (12.0 feet) projected horizontally at a depth of 11.0 feet below the existing ground profile. The results show that the tree fall and scour did not significantly affect levee performance and that the levee would meet Corps seepage and slope stability criteria when the seepage and slope stability improvement measures are in place ("with-project" conditions). Therefore, it is a reasonable conclusion that allowing vegetation to remain on the lower waterside levee slope would not affect the safety, structural integrity, and functionality of the Sacramento River levee.

As a result of the geotechnical analysis, the Corps would request a vegetation variance of themselves for the Sacramento River, Dry/Robala Creeks, Arcade Creek, and Magpie Creek portions of the project. In many cases along the American River levees, the levee is far enough back from the water's edge to allow vegetation providing shaded riverine aquatic cover to remain on the bank with no vegetation variance necessary. However, the Sacramento Weir and Bypass levees would be constructed in compliance with the Corps ETL as these would be new levees. No vegetation removal would be required within the existing or expanded Sacramento Bypass. There will be no Vegetation Variance requested for the American River sites and will require removal of vegetation and will therefore comply with the ETL. Refer to Table 1 for reach specific information regarding presence or absence of a vegetation variance.

Table 1: Summary of ETL compliance Method by Waterway.

	Vegetation Variance	**SWIF**
Sacramento River (lower ½ of levee slope which is outside construction footprint)		
Waterside	X	
Landside		X
American River		
Trench Landside[1]		X
Bank Protection		X
North Area Tributaries[2]		
NEMDC	X	X
Dry/Robla Creeks	X	X
Arcade Creek	X	X
Magpie Creek[3]	X	X

1 The waterside footprint for the trench construction would require removal of vegetation and therefore compliance with the ETL.
2 A variance is included for these tributaries waterside slopes outside of the construction footprint, and a SWIF would be prepared by the non-Federal partners for the landside slopes and access.
3 The new levee constructed along Raley Boulevard would be constructed in compliance with the ETL.

In addition to the Vegetation variance, this project will implement the System Wide Improvement Framework (SWIF). The SWIF is an agreement between the Corps and the non-Federal sponsor that allows the local maintain agency (LMA) to defer compliance with ETL 1110-2-583. In an effort to modernize the levee system to meet current engineering standards, vegetation and encroachment issues (including landside levee access) in the study area will be resolved through a combination of construction actions associated with implementation of the recommended plan and formal agreements. The formal agreements involve the integrated use of a SWIF agreement with the LMA and a variance from vegetation standards in ETL 1110-2-583, Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures.

Under the SWIF agreement, the LMA would address landside vegetation and encroachment issues (including landside levee access) through the implementation of their standard operation and maintenance (O&M) actions over time. Therefore, vegetation not impacted by project construction would be addressed by the LMA in accordance with the State's Levee Vegetation Management Strategy in the Central Valley Flood Protection Plan (CVFPP) over the next 20 to 40 years. The SWIF will be planned and implemented by the non-Federal sponsor and includes the following criteria:

- An engineering inspection and evaluation shall be conducted to identify trees and other woody vegetation (alive or dead) on the levee and within 15 feet of the levee toe that pose an unacceptable threat to the integrity of the levee. Identified trees shall be removed and associated root balls and roots shall be appropriately remediated. Based on the engineering inspection and evaluation, trees and other woody vegetation that do not pose an unacceptable threat need not be removed.

- In cases of levee repair or improvement projects, vegetation within the project footprint shall be removed as part of construction activities.

- Trees and other woody vegetation that are not removed must be monitored as part of routine levee maintenance to identify changed conditions that cause any of these remaining trees and other woody vegetation to pose an unacceptable threat to levee integrity. Otherwise, such trees and woody vegetation are to be maintained according to the levee vegetation management criteria included in the CVFPP which establish a vegetation management zone (including the landside levee slope, crown and upper 1/3 of the waterside slope) in which trees are trimmed up to 5 feet above the ground (12-foot clearance above the crown road) and thinned for visibility and access while brush, trees and other woody vegetation less than four inches in diameter at breast height, weeds or other such vegetation over 12 inches high are to be removed in an authorized manner.

The standard O&M activities will be adjusted to reflect any vegetation variance. Under the adjusted O&M manual, large trees that were protected in place under the variance will be allowed to remain on the waterside slopes, but smaller shrubs will be removed and grasses will be regularly mowed to allow for inspection and access.

The ARCF project was authorized by Section 106(a)(1) of the Water Resources Development Act (WRDA) of 1996, (Public Law [PL] 104-303) (110 Stat. 3658, 3662-3663), as amended by Section 130 of the Energy and Water Development and Related Agencies Appropriations Act of 2008, (PL 110-161) (121 Stat. 1844, 1947). Additional authority was provided in Sections 366 and 566 of WRDA 1999, (PL 106-53), (113 Stat. 269, 319-20. The current estimated cost of the authorized project is $274,100,000. In accordance with Section 902 of WRDA 1986 (Pub. L. 99-662, § 902, Nov. 17, 1986, 100 Stat. 4183), the allowable cost limit is $284,000,000.

1.3 Consultation History

NMFS received a request for initiation of consultation on July 1, 2014. However, the initial request did not contain an appropriate effects determination. The Biological Assessment (BA) was missing necessary information to perform a species impact analysis. NMFS reviewed the biological assessment provided with the initiation letter and concluded it lacked sufficient detail to determine the extent to which the proposed project may affect federally listed species and their designated critical habitats. In addition, NMFS found that the information provided with the letter was incomplete and lacked all the information necessary to initiate section 7 consultation on the proposed project, as outlined in the regulations governing interagency consultation (50 CFR §402.12). On September 9th, 2014 NMFS sent an insufficiency letter outlining the information needs to initiate consultation.

On April 3, 2015 NMFS received a new request for initiation of consultation. The request included the North Sacramento Streams projects that were to be conducted by SAFCA. In the April 3, 2015 letter the Corps requested concurrence from NMFS that the Common Features GRR will adversely affect threatened Central Valley (CV) spring-run Chinook salmon evolutionarily significant unit (ESU) (*Oncorhynchus tshawytscha*), endangered Sacramento River winter-run Chinook salmon ESU (*O. tshawytscha*), threatened California CV (CCV) steelhead distinct population segment (DPS) (*O. mykiss*), and threatened Southern DPS (sDPS) of North American green sturgeon (*Acipenser medirostris*), and their designated critical habitats. Additionally, the Corps has determined that the Common Features Project may adversely affect Essential Fish Habitat (EFH) pursuant to the Magnuson-Stevens Fishery Management Act. The Corps also states that there is an expectation that the Common Features GRR may benefit long-term EFH quality in the action area.

After phone conversations, emails, and an inter-agency meeting on April 21, 2015 the Corps agreed to send a letter advising that the North Sacramento Streams projects would be separated from the Common Features GRR for a separate consultation, and that new SAM analysis models needed to be run. NMFS informed the Corps that consultation could not begin until the letter was received and SAM analysis completed.

May 14, 2015 another interagency meeting that included the Corps and NMFS occurred for the revised SAM analysis. NMFS again informed the Corps that consultation could not begin until the letter was received and SAM analysis completed. NMFS and the Corps agreed that the following information should be included in the letter transmitting the new Standard Assessment Methodology (SAM) analysis Memo:

1. Establish that for all of the three reaches what Sac Bank approximation was used for all SAM runs. Meaning the sites constructed near to the sites to be constructed, those specifications were used for the with-construction conditions, remember to add to the SAM analysis memo we are working on.

2. Add all green sturgeon life stages to the SAM analysis for site C since it is in Green Sturgeon Critical habitat.

3. Add green sturgeon juvenile rearing habitat SAM analysis for all America River sites.

4. Add justification for not including certain life history stages to the SAM analysis.

5. Addition of a discussion for the purchase of mitigation credits appropriate for each site.

6. Addition of numbers for fall-run juvenile migration all water levels for EFH.

7. Incorporate 60% IWM into the SAM analysis.

8. Incorporate a discussion of possibly incorporating 80% IWM.

9. Incorporation of plantings (*i.e.* button bush) at the lowest/Fall water line to increase the value.

June 11, 2015 NMFS received email with Draft memo of new Sam analysis information which included a new reach of the Sacramento bypass and weir and NMFS initiated consultation.

August 24, 2015 NMFS met with the Corps and received new conservation measures to add to the project description.

August 28, 2015. NMFS received a letter from the Corps officially providing the revised project description and new Green Sturgeon conservation measures.

1.4 Proposed Action

"Action" means all activities or programs of any kind authorized, funded, or carried out, in whole or in part, by Federal agencies (50 CFR 402.02).

The Corps has identified a number of problems associated with the flood risk management system protecting the city of West Sacramento and surrounding areas. There is a high probability that flows in the American and Sacramento Rivers will stress the network of levees protecting Sacramento to the point that levees could fail. Such a levee failure would flood a highly urbanized area.

Levees in the Common Features GRR action area require improvements to address seepage, stability, erosion, and height concerns identified for the American River levees, Dry/Robla, and Magpie Creeks. The levees along the Sacramento River would be improved to address identified seepage, stability, erosion, and a minimal amount of height concerns. Most height concerns along the Sacramento River would be addressed by a widening of the Sacramento Weir and Bypass to divert more flows into the Yolo Bypass. The measures proposed to improve the levees consist of: (1) bank protection or launchable rock trenches, (2) install cutoff walls, (3) levee raise, (4) construct floodwalls, (5) raise floodwalls, (6) construct new levee, (7) acquire property to create a flood detention basin, (8) widen and raise a bridge crossing, (9) remove a culvert, (10) widen the Sacramento Weir and Bypass, (11) construction of a new weir, and 12) removal of existing levee. The above measures will be implemented by fixing levees in place or constructing adjacent levees. It is possible that sheet pile walls, jet grouting, and relief wells will be used at various locations so they are also described below. Once a levee is modified, regardless of the measure implemented for the alternative, the levee will be brought into compliance with Corps levee design criteria.

For more details on the potential levee repairs listed above and in Table 2, refer to the American River Common Features General Reevaluation Report North Sacramento Streams Levee Improvement Project, specifically Chapter 2 (Corps 2015a).

In addition to the proposed levee improvements measures, the following measures and policies will apply to all of the levee repair alternatives, and will be addressed during construction:

1. Utility encroachments such as structures, certain vegetation, power poles, pump stations, and levee penetrations (*e.g.*, pipes, conduits, cables) will be brought into compliance with applicable Corps policy or removed depending on type and location. This measure will include the demolition of such features and relocation or reconstruction as appropriate on a case-by-case basis (or retrofit to comply with standards). Utilities replacements will occur via one of two methods: (1) a surface line over the levee prism, or (2) a through-levee line equipped with positive closure devices.

2. Private encroachments shall be removed by the non-federal sponsor prior or property owner prior to construction.

The O&M of the levees in the Sacramento area are the responsibility of the local maintaining agencies, including the American River Flood Control District, Maintenance Area 9, The California Department of Water Resources (DWR), and the City of Sacramento. The applicable O&M Manual for the Sacramento levees is the Standard O&M Manual for the Sacramento River Flood Control Project. Typical levee O&M in the Sacramento area includes the following actions:

1. Vegetation maintenance up to four times a year by mowing or applying herbicide.

2. Control of burrowing rodent activity monthly by baiting with pesticide.

3. Slope repair, site-specific and as needed, by re-sloping and compacting.

4. Patrol road reconditioning up to once a year by placing, spreading, grading, and compacting aggregate base or substrate.

5. Visual inspection at least monthly, by driving on the patrol road on the crown and maintenance roads at the base of the levee.

6. Post-construction, groundwater levels would be monitored using the piezometers.

Flood risk reduction construction activities will primarily occur during the April 15 to October 31 time frame, although extension of the CVFPB encroachment permit may be sought if weather conditions permit. However, construction activities, including, but not limited to, structure and vegetation removal, roadway removal and replacement, revegetation, and utility removal and replacement, regardless of the construction season will be subject to the conditions of environmental and encroachment permits and authorizations to be issued by the California Department of Fish and Wildlife (CDFW), CV Regional Water Quality Control Board (RWQCB), CVFPB, the Corps, US Fish and Wildlife Service (USFWS), NMFS, Yolo County, City of West Sacramento, and others.

Construction of the Common Features Project is proposed to take approximately 13 years if each reach is constructed sequentially. The construction reaches have been prioritized based on a variety of factors, including the condition of the levee, the potential damages that will occur due to levee failure, and construction feasibility considerations, such as the availability of equipment at any given time. A summary of the flood risk reduction measures proposed as part of this study are included in Table 2.

Table 2. Proposed Measures for the Common Features GRR Project.

Waterway/Location	Extent of Action	Proposed Measure
American River	North and south levees from the confluence with the Sacramento River upstream for approximately 12 miles.	• Construct bank protection or launchable rock trenches
Sacramento River	East levee from the American River to Morrison Creek.	• Install cutoff walls • Construct bank protection • Construct levee raise
Dry/Robla Creek		• Raise floodwalls
Magpie Creek Diversion Canal	Upstream of Raley Boulevard	• Construct floodwalls
Magpie Creek area	South of Raley Boulevard	• Construct new levee
Magpie Creek area	East of Raley Boulevard	• Acquire property to create a flood detention basin • Widen the Raley Boulevard/Magpie Creek bridge and raise the elevation of the roadway • Remove the Don Julio Creek culvert
Sacramento Weir and Bypass	North bypass levee to 1,500 feet north.	• Widen the Sacramento Weir and Bypass by approximately 1,500 feet • Construct a new section of weir and levee • Remove the existing Sacramento Bypass north levee

The tentative schedule of construction is shown in Table 3. The durations are for construction activities only, and do not include the time needed for design, right-of-way, utility relocation, *etc*.

Table 3. Common Features GRR Project Construction Schedule.

PRIORITY	WATERWAY	REACH	YEAR OF PROJECT CONSTRUCTION												
			1	2	3	4	5	6	7	8	9	10	11	12	13
1	Sacramento River	ARS F													
2	Sacramento River	ARS E													
3	American River	ARS A													
4	Sacramento River	ARS G													
5	Sacramento River	ARS D													
6	American River	ARS B													
7	American River	ARN A													
8	American River	ARS C													
9	American River	ARN B													
10	Sacramento Weir & Bypass	--													
11	Dry/Robla Creek	ARN G													
12	Magpie Creek	ARN I													

Analysis of total linear feet (lf) of shaded riverine aquatic (SRA) habitat was conducted using Google Earth Pro for the reaches only associated with bank protection on the American and Sacramento Rivers in the Common Features GRR action area (Table 4). However, site specific conditions at proposed bank protection sites will evaluate SRA habitat values using the SAM method of analysis to determine impacts and onsite compensation value based on actual designs. The East Side Tributaries were not evaluated because no bank erosion protection is planned. It should be noted however that there is minimal, if any, SRA associated with the tributaries in the reaches where construction is proposed, except Arcade Creek. It is not anticipated that trees would need to be removed within the Sacramento Bypass as a result of the levee relocation effort, since the footprint of the expanded Bypass area is open farmland with no trees present. However, trees along the Sacramento River would be removed to construct the new 1,500 foot Sacramento Weir.

Identification of individual reaches in the Common Features GRR action area can be seen in Figure 1. American River North (ARN) reaches A through I includes the north side of the American River and the East Side Tributaries. American River South (ARS) reaches A through G includes the south side of the American River and the east side of the Sacramento River.

Table 4. SRA Reach Specific Summary

AMERICAN RIVER		SACRAMENTO RIVER	
REACH	**LINEAR FEET (lf) of SRA**	**REACH**	**LINEAR FEET (lf) of SRA**
A	31,174	D	9,643
B	7,259	E	7,709
C	6,934	F	21,263
		G	11,689
		Sac Weir	1,500
Total	**45,367**	**Total**	**51,804**

1.11 Vegetation Policy Compliance

Vegetation removal under the Common Features GRR project would be limited to no more than the upper one-half of the waterside of the levees therefore leaving the lower one-half or more of the trees in place on the Sacramento River within the study area. SRA would not be compromised, thus maximizing existing SRA values in the study area. No vegetation removal would be required within the existing or expanded Sacramento Bypass. New levees (such as setback levees) would be designed to be compliant with Corps levee vegetation policy. Consistent with the Central Valley Flood Protection Plan (CVFPP) guidance. Any vegetation removed as part of direct construction activities would not be replaced onsite if possible.

1.12 Interrelated and Interdependent Actions

"Interrelated actions" are those that are part of a larger action and depend on the larger action for their justification. "Interdependent actions" are those that have no independent utility apart from the action under consideration (50 CFR 402.02). In this case, there are no interrelated or interdependent actions.

The Folsom Dam Raise Project and subsequent Folsom Reoperation Project have the potential to increase the bank armoring and could exacerbate any impacts associated with the common Features GRR, but are not interrelated or interdependent actions because neither project depends on the other for their justification and they both have independent utility. The erosion issues within the American River Parkway is being addressed as part of the Folsom Reoperation Project currently under evaluation and a biological assessment is being prepared to initiate Section 7 consultation with both USFWS and NMFS.

1.13 Conservation Actions

The Corps will seek to avoid and minimize construction effects on listed species and their critical habitat to the extent feasible, and will implement on-site, and off-site compensation actions as necessary. Compensation time is the time required for on-site plantings to provide significant amounts of shade or structural complexity. Depending on project impacts, a project may incorporate various habitat and species benefits to compensate for short-term losses in habitat for listed species. Long-term compensation to offset short-term losses is generally not an option for the loss of critical habitats under the ESA (USFWS 1998a). The Corps uses the following compensation time periods (based loosely on life expectancy) as guidelines for compensation:

- Green sturgeon, 15 years;
- Chinook salmon, 5 years; and
- Central Valley steelhead, 4 years (Corps 2012).

1. Obtain an ETL approved vegetation variance exempting sites from vegetation removal prior to final design and construction phase for the Sacramento River.
2. Minimize the removal of existing vegetation in the proposed project area. Any disturbance or removal of vegetation will be replaced with native riparian vegetation, outside of the vegetation-free zone, as established in the ETL.
3. Implement best management practices (BMPs) to prevent slurry seeping out to river and require piping system on land side only.
4. The Corps will incorporate compensation for SRA habitat losses either by project constructed compensation sites or in combination with purchase of credits at a NMFS approved conservation bank where appropriate.
5. The Corps will seek an ETL-approved vegetation variance exempting the Sacramento River sites from vegetation removal in the lower one-third of the waterside of the levee prior to final construction and design phase. Construction may require removal of vegetation on the upper two-thirds of the waterside and landside slope. Full ETL compliance will occur on some of the American River reaches.
6. The Corps will use a rock soil mixture to facilitate re-vegetation of the project sites that require bank protection work. A (70:30) rock to soil ratio will be implemented. The soil-rock mixture will be placed on top of the of the rock revetment along the Sacramento River levees to allow native riparian vegetation to be planted to insure that SRA habitat lost is replaced or enhanced.
7. In addition to an approved vegetation variance, the Corps will minimize the removal of existing vegetation in the proposed project area. Disturbance or removal of trees or larger woody vegetation will be replaced with native riparian species, outside of the vegetation-free zone, as established in the ETL.
8. Levee repair designs will be analogous to those developed for an SRBPP repair site. These levee repair designs include installation of IWM, native vegetation planting, incorporation of soil with the rock, *etc*.
9. Construction will be scheduled when listed terrestrial and aquatic species will be least likely to occur in the project area. If construction needs to extend into the timeframe that species are present coordination with the resource agencies will occur.

10. Stockpile construction materials such as portable equipment, vehicles, and supplies, at designated construction staging areas and barges, exclusive of any riparian and wetlands areas.
11. Stockpile all liquid chemicals and supplies at a designated impermeable membrane fuel and refueling station with a containment system.
12. Erosion control measures including Storm Water Pollution Prevention Program (SWPPP) and Water Pollution Control Program that minimize soil or sediment from entering the river. BMPs shall be installed, monitored for effectiveness, and maintained throughout construction operations to minimize effects to Federally listed fish and their designated critical habitat.
13. Site access will be limited to the smallest area possible in order to minimize disturbance.
14. Litter, debris, unused materials, equipment, and supplies will be removed from the project area daily. Such materials or waste will be deposited at an appropriate disposal or storage site.
15. Immediately (within 24 hours) cleanup and report any spills of hazardous materials to the resource agencies. Any such spills, and the success of the efforts to clean them up, shall also be reported in post-construction compliance reports.
16. Designating a Corps-appointed representative as the point-of-contact for any contractor who might incidentally take a living, or find a dead, injured, or entrapped threatened or endangered species. This representative shall be identified to the employees and contractors during an all employee education program conducted by the Corps.
17. Vegetation removed as a part of ETL compliance will be compensated on site, outside of the vegetation-free zone, to the extent feasible. When on-site compensation is not feasible, compensation is proposed at local conservation banks with available credits. If credits are not available locally, then compensation is proposed to occur within the West Sacramento city limits.
18. The Corps will compensate for any short and longer term impacts through additional onsite compensation, purchase of compensatory conservation credits, or development of suitable created aquatic habitat.
19. Screen any water pump intakes.
20. The Corps will work with local cost share sponsors to ensure GRR-related future flood risk reduction actions related to widening the Sacramento Weir shall fully mitigate upstream and downstream fish passage effects at the weir and within the spillway basin.
21. The goal is to ensure that adult CV spring-run and Sacramento River inter-run Chinook salmon, CCV steelhead, and sDPS green sturgeon are able to migrate upstream while the weir is spilling into the bypass and that juvenile stranding in the spillway basin is minimized to the maximum extent possible.
22. The Corps shall ensure the widening of the Sacramento Bypass is designed and constructed to minimize stranding of fish in the depressions wound within the bypass though grading or construction of drainage channels.
23. The goal is to ensure that the bypass is designed and constructed in a manner that reduces adult and juvenile stranding to the maximum extent possible.

A number of measures will be applied to the entire Common Features Project or specific actions, and other measures may be appropriate at specific locations within the Common Features Project study area. Avoidance activities to be implemented during final design and construction may include, but are not limited to, the following:

1. Identifying all habitats utilized by listed terrestrial, wetland, and plant species in the potentially affected project areas. To the extent practicable efforts will be made to minimize effects by modifying engineering design to avoid potential direct and indirect effects.
2. Incorporating sensitive habitat information into project bid specifications.
3. Incorporating requirements for contractors to avoid identified sensitive habitats into project bid specifications.
4. Minimizing vegetation removal to the extent feasible.
5. Minimizing, to the extent possible, grubbing and contouring activities.
6. Where feasible compensating for impacts close to where impacts have occurred.

1.14 Additional Conservation Measures for sDPS Green Sturgeon

Through collaboration with NMFS, the Corps has updated the project description in the Environmental Impact Statement/Environmental Impact Report (EIS/EIR) and will implement the following additional measures that have been coordinated with NMFS to reduce impacts to green sturgeon habitat.

1. The Corp's final Environmental Impact Statement/Environmental Impact Report for the American River Common Features GRR shall include a proposal to develop a green sturgeon habitat, mitigation, and monitoring plan (HMMP) with the specific elements that are described below.

   The goal of the developing the HMMP is to ensure that adverse impacts of future American River Common Features GRR projects on sDPS green sturgeon are fully mitigated in order to maintain the growth, survival and recovery of the species in the study area.

2. The green sturgeon HMMP shall be developed in coordination with the IEP green sturgeon project work team and consulted on with NMFS prior to the construction of any work within the designated critical habitat of sDPS green sturgeon related to the American River Common Features GRR. The HMMP should focus on filling important data gaps on green sturgeon life history and micro and macro habitat ecology in both the Sacramento River and the north Delta within the project impact area, in regard to how bank stabilization measures proposed in the American River Common Features GRR affect sturgeon ecology and survival, particularly in regard to juvenile rearing and survival.

   The goal of this conservation measure is to leverage the resources of the IEP to develop an HMMP that utilizes and applies the best available scientific expertise and information available.

3. The Corps shall either refine the SAM or develop an alternative green sturgeon survival and growth response model based on using and updating the existing Hydrologic Engineering Center Ecosystem Function Model (HEC-EFM) that reflects green sturgeon's preference for benthic habitat and that accounts for the physical loss of habitat from revetment footprints instead of the convention used by the SAM where the fish response is evaluated at the intersect of seasonal water surface elevations. The new modeling may include hydraulic modeling, but must be capable of evaluating green sturgeon survival in response to levee repair projects in the project impact area and their effects on all habitat conditions, not exclusively flow changes. Development of the model shall be initiated at the start of the preconstruction engineering and design (PED) phase of the American River Common Features GRS and shall be peer reviewed by sturgeon experts on the IEP, other academia with sturgeon expertise and be consulted on with NMFS.

   The goal of this measure is to develop a functional assessment methodology using the best available scientific expertise and information available to model the effects of future American River Common Features GRR actions and evaluate the performance of mitigation actions relative to the survival and growth of sDPS green sturgeon that are exposed to such actions.

4. The HMMP shall also, restore or compensate for the number of acres and ecological function of soft bottom benthic substrate for sDPS green sturgeon permanently lost to project construction. This mitigation shall be coordinated with the Interagency Working Group (IWG) or a Bank Protection Working Group (BPWG) and must be carried out within the lower Sacramento River/North Delta in order to offset the adverse modification to designated critical habitat. The restored habitat must be capable of providing abundant benthic prey freshwater or estuarine areas; with adequate water quality, including temperature, salinity, oxygen content, and other chemical characteristics, is necessary for normal behavior, growth and viability of all life stages; and provide safe and unobstructed migratory pathways are necessary for timely passage of adult, sub-adult, and juvenile fish within the region's different estuarine habitats and between the upstream riverine habitat and the marine habitats. The restoration/mitigation shall be initiated prior to commencement of construction within the designated critical habitat of sDPS green sturgeon for the American River Common Features GRR and the updated model should be used to validate performance. The restoration site and plan shall be developed in coordination with the IEP and be consulted on with NMFS.

   The goal is to ensure the spatial and temporal ecological impacts from project-related permanent loss of critical habitat for green sturgeon critical for juvenile green sturgeon are fully compensated.

5. The green sturgeon HMMP shall also be developed with measurable objectives for completely offsetting all adverse impacts to all life stages of sDPS green sturgeon (as modeled using refined approaches described in RPA action 3, above, and considering design refinements that occur in the PED phase of project implementation).

The goal of this measure is to develop "SMART" objectives for mitigation. "SMART" objectives are specific (target a specific area for improvement), measurable (quantify or suggest an indicator of progress), attainable (specify who will do the work and if possible how), realistic (state what results can realistically be achieved, given available resources) and timely (specify when the results can be achieved) habitat performance objectives for green sturgeon mitigation.

6. Mitigation actions shall be initiated prior to the construction activities affecting sDPS green sturgeon and their critical habitat. Specific mitigation plans may be developed during project design engineering to reduce the specific impacts of levee construction actions.

   The goal of this measure is to ensure that mitigation coincides with project implementation and to minimize, to the maximum extent possible, extended temporal effects.

7. The sDPS green sturgeon HMMP will include measurable performance standards at agreed upon intervals and will be monitored for a period of at least ten years following construction. If additional monitoring is necessary, the monitoring shall be included in the project O&M plan and carried out by the local sponsor. The HMMP will include adaptive management strategies for correcting any mitigation measures that do not meet performance standards.

   The goal of this measure it to provide a reasonable amount of time to measure performance standards after mitigation occurs to ensure that it meets the objectives of the HMMP.

1.5 Action Area

"Action area" means all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action (50 CFR 402.02).

The action area for the Common Features GRR includes: (1) approximately 12 miles of the north and south banks of the American River immediately upstream from the confluence with the Sacramento River; (2) the east bank of the Natomas East Main Drainage Canal (NEMDC), Dry, Robla, and Arcade Creeks and the Magpie Creek Diversion Channel (collectively referred to as the East Side Tributaries); (3) the east bank of the Sacramento River downstream from the American River to Freeport, where the levee ties into Beach Lake Levee, the southern defense for Sacramento; and (4) the Sacramento Weir and Bypass, located along the north edge of the city of West Sacramento (Figure 1).

The action area includes perennial waters of the Sacramento River extending 200 feet perpendicular from the average summer-fall shoreline and 1,000 feet downstream from proposed in-water construction areas. This represents the potential area of turbidity and sedimentation effects based on the reported limits of visible turbidity plumes in the Sacramento River during similar construction activities (NMFS 2008).

ENDANGERED SPECIES ACT: BIOLOGICAL OPINION AND INCIDENTAL TAKE STATEMENT

The ESA establishes a national program for conserving threatened and endangered species of fish, wildlife, plants, and the habitat upon which they depend. As required by section 7(a)(2) of the ESA, Federal agencies must ensure that their actions are not likely to jeopardize the continued existence of endangered or threatened species, or adversely modify or destroy their designated critical habitat. Per the requirements of the ESA, Federal action agencies consult with NMFS and section 7(b)(3) requires that, at the conclusion of consultation, NMFS provides an opinion stating how the agency's actions will affect listed species and their critical habitat. If incidental take is expected, section 7(b)(4) requires NMFS to provide an ITS that specifies the impact of any incidental taking and includes non-discretionary reasonable and prudent measures and terms and conditions to minimize such impacts.

2.1 Analytical Approach

This BO includes both a jeopardy analysis and an adverse modification analysis. The jeopardy analysis relies upon the regulatory definition of "to jeopardize the continued existence of a listed species," which is "to engage in an action that will be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species" (50 CFR 402.02). Therefore, the jeopardy analysis considers both survival and recovery of the species.

The adverse modification analysis considers the impacts of the Federal action on the conservation value of designated critical habitat. This BO does not rely on the regulatory definition of "destruction or adverse modification" of critical habitat at 50 CFR 402.02. Instead, we have relied upon the statutory provisions of the ESA to complete the following analysis with respect to critical habitat.[1]

We use the following approach to determine whether a proposed action is likely to jeopardize listed species or destroy or adversely modify critical habitat:

1. Identify the rangewide status of the species and critical habitat likely to be adversely affected by the proposed action.
2. Describe the environmental baseline in the action area.
3. Analyze the effects of the proposed action on both species and their habitat using an "exposure-response-risk" approach.
4. Describe any cumulative effects in the action area.
5. Integrate and synthesize the above factors to assess the risk that the proposed action poses to species and critical habitat.
6. Reach jeopardy and adverse modification conclusions.
7. If necessary, define a reasonable and prudent alternative to the proposed action.

[1] Memorandum from William T. Hogarth to Regional Administrators, Office of Protected Resources, NMFS (Application of the "Destruction or Adverse Modification" Standard Under Section 7(a)(2) of the Endangered Species Act) (November 7, 2005).

2.1.1 Use of Analytical Surrogates

The effects of the Common Features GRR are primarily analyzed using Standard Assessment Methodology (SAM). The Corps provided the background data, assumptions, analyses, and assessment of habitat compensation requirements for the federally protected fish species relevant to this consultation.

The SAM was designed to address a number of limitations associated with previous habitat assessment approaches and provide a tool to systematically evaluate the impacts and compensation requirements of bank protection projects based on the needs of listed fish species.

It is a computational modeling and tracking tool that evaluates bank protection alternatives by taking into account several key factors affecting threatened and endangered fish species. By identifying and then quantifying the response of focal species to changing habitat conditions over time, project managers, biologists and design engineers can make changes to project design to avoid, minimize, or compensate for impacts to habitat parameters that influence the growth and survival of target fish species by life stage and season. The model is used to assess species responses as a result of changes to habitat conditions, either by direct quantification of bank stabilization design parameters (*e.g.,* bank slope, substrate).

In 2003, the Corps established a program to carry out "a process to review, improve, and validate analytical tools and models for USACE Civil Works business programs". Reviews are conducted to ensure that planning models used by the Corps are technically and theoretically sound, computationally accurate, and in compliance with the Corps planning policy. As such, all existing and new planning models developed by the Corps are required to be certified through the appropriate Planning Center of Expertise and Headquarters in accordance with Corps rules and procedures.

The assumptions, model variables, and modeling approaches used in the SAM have been developed to be adapted and validated through knowledge gained from monitoring and experimentation within the SRBPP while retaining the original overall assessment method and framework. The first update to the SAM included the addition of sDPS green sturgeon as well as a number of modifications to modeled-species responses based upon updated literature reviews and recent monitoring efforts at completed bank protection sites (Stillwater Sciences 2009, USACE 2009).

In late 2010, the certification process for the SAM was initiated by the Corps, Sacramento District in coordination with the Ecosystem Planning Center of Expertise. The process entailed charging a panel of six experts to review the SAM, along with the SAM (version 3.0). The Review Panel was composed of a plan formulation expert, fisheries biologist, aquatic ecologist, geomorphologist/geologist, population biologist/modeling expert, and software programmer.
A major advantage of the SAM is that it integrates species life history and seasonal flow-related variability in habitat quality and availability to generate species responses to project actions over time. The SAM systematically evaluates the response of each life stage to habitat features affected by bank protection projects.

The SAM quantifies habitat values in terms of a weighted species response index (WRI) that is calculated by combining habitat quality (*i.e.*, fish response indices) with quantity (*i.e.*, bank length or wetted area) for each season, target year, and relevant species/life stage. The fish response indices are derived from hypothesized relationships between key habitat attributes (described below) and the species and life stage responses. Species response indices vary from 0 to 1, with 0 representing unsuitable conditions and 1 representing optimal conditions for survival, growth, and/or reproduction. For a given site and scenario (*i.e.*, with or without project), the SAM uses these relationships to determine the response of individual species and life stages to the measured or predicted values of each habitat attribute for each season and target year, and then multiplies these values together to generate an overall species response index. This index is then multiplied by the linear feet or area of shoreline to which it applies to generate a weighted species response index expressed in feet or square feet. The species WRI provides a common metric that can be used to quantify habitat values over time, compare project conditions to existing conditions, and evaluate the effectiveness of on-site and off-site compensation actions.

The WRI represent an index of a species growth and survival based on a 30-day exposure to post project conditions over the life of the project. As such, negative SAM values can be used as a surrogate to quantify harm to a target fish species by life stage and season. Also, although SAM values represent and index of harm to a species, since the values are expressed as "weighted bankline feet" or "weighted area", these values can be used to help quantify compensatory conservation actions such as habitat restoration, and are used for that purpose in this BO.

During the process of this consultation, the Corps and NMFS identified several short comings with the SAM as a tool for reliably forecasting the growth and survival of green sturgeon. The primary short coming is that the SAM evaluates habitat conditions at the seasonal water surface intersect with the river bank. While this is considered an effective point for measuring salmon and steelhead habitat, green sturgeon have a greater affinity for benthic habitat than shoreline habitat. Further, during discussions between the Corps and NMFS, it was widely agreed upon that levee repair actions in the West Sacramento Study Area are likely to only affect the juvenile rearing life stage and probably have little to no adverse impacts on the adult life stages of green sturgeon because spawning habitat is not present and adults that are migrating upstream are probably more influenced by impacts that affect swimming speed and upstream passage than shoreline habitat manipulations. Because of this, NMFS has decided to use the SAM as a proxy for quantifying habitat disturbance and harm and use as an ecological surrogate for quantifying the amount and extent of take for juvenile rearing and migrating green sturgeon, but the precision is not as sharp as for salmon and steelhead. Therefore, a new model will be developed to determine compensatory mitigation actions and tracking performance.

2.1.2 Compensation Timing

As described in the proposed action, projects such as this often propose compensation for unavoidable short-term effects to species and impacts to habitat. These compensation timeframes are generally based on anticipated SAM response time. Under the Corps BA, compensation timing is defined and in practice adopts an approach that the SAM modeled impact at the proposed timing (Green sturgeon: 15 years: Chinook salmon, 5 years: Central Valley steelhead, 4 years) is sufficient to compensate for project effects. NMFS adopts a slightly different approach to the analysis of the BO in that the compensation time should be a target for avoiding exposure of more than one generation of a population with a multiple age class structure. Negative SAM-modeled values beyond those years, especially at winter and spring water surface elevations, may have significant effects to the species and impacts to critical habitat that would reduce the species survival and recovery in the wild or substantially reduce the conservation value of the species because the adverse effects (reduced growth and survival of individuals) would begin to reduce the number of reproducing individuals across multiple generations. In some cases, negative SAM values extend beyond these compensation periods, in which case offsite compensatory mitigation can reduce the long-term effects to a species survival and recovery by creating high quality habitat conditions in areas that provide high ecological value for the species. Because we have determined the SAM model is not a strong representation of green sturgeon growth and survival response, we are applying the implementation of the USACE Green Sturgeon Conservation Measures As key actions necessary to both avoid reducing the survival and recovery of the species in the wild and reducing the conservation value of critical habitat, instead of applying a specific compensation time period for green sturgeon. As such, this BO applies the following compensation timing as general targets for avoiding such long-term effects to salmon and steelhead:

1. Chinook salmon, 5 years;
2. Central Valley steelhead, 4 years

2.2 Rangewide Status of the Species and Critical Habitat

This BO examines the status of each species that will be adversely affected by the proposed action. The status is determined by the level of extinction risk that the listed species face, based on parameters considered in documents such as recovery plans, status reviews, and listing decisions. This informs the description of the species' likelihood of both survival and recovery. The species status section also helps to inform the description of the species' current "reproduction, numbers, or distribution" as described in 50 CFR 402.02. The BO also examines the condition of critical habitat throughout the designated area, evaluates the conservation value of the various watersheds and coastal and marine environments that make up the designated area, and discusses the current function of the essential physical and biological features that help to form that conservation value.

One factor affecting the rangewide status of the CV spring-run Chinook salmon, Sacramento River winter-run Chinook salmon, CCV steelhead, and the sDPS green sturgeon, and aquatic habitat at large is climate change.

The following federally listed species and designated critical habitats occur in the action area and may be affected by the proposed action:

Sacramento River winter-run Chinook salmon ESU (*Oncorhynchu tshawytscha*) Listed as endangered (70 FR 37160, June 28, 2005)

Sacramento River winter-run Chinook salmon designated critical habitat (June 16, 1993, 58 FR 33212)

CV spring-run Chinook salmon ESU (*O. tshawytscha*)
Listed as threatened (70 FR 37160, June 28, 2005)

CV spring-run Chinook salmon designated critical habitat (70 FR 52488, September 2, 2005)

CCV steelhead DPS (*O. mykiss*)
Listed as threatened (71 FR 834, January 5, 2006)

CCV steelhead designated critical habitat
(70 FR 52488, September 2, 2005)

Southern DPS of North American green sturgeon (*Acipenser medirostris*)
Listed as threatened (71 FR 17757, April 7, 2006)

Southern DPS of North American green sturgeon designated critical habitat (74 FR 52300, October 9, 2009)

Critical habitat designations identify those physical and biological features of the habitat that are essential to the conservation of the species and that may require special management consideration or protection. Within the Common Features GRR this includes the river water, river bottom, and the lateral extent as defined by the ordinary high-water line. In areas where the ordinary high-water line has not been defined, the lateral extent is defined by the bankfull elevation (defined as the level at which water begins to leave the channel and move into the floodplain; it is reached at a discharge that generally has a recurrence interval of one to two years on the annual flood series) used by listed salmonids and sturgeon.

NMFS has recently completed an updated status review of five Pacific salmon ESUs and one steelhead DPS, including Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon and CCV steelhead, and concluded that the species' status should remain as previously listed (76 FR 50447; August 15, 2011). The 2011 status reviews (NMFS 2011a, 2011b, 2011c) additionally stated that, although the listings should remain unchanged, the status of these populations have worsened over the past five years since the 2005/2006 reviews and recommended that status be reassessed in two to three years as opposed to waiting another five years.

2.2.1 Sacramento River Winter-run Chinook salmon

The Sacramento River winter-run Chinook salmon (winter-run *Oncorhynchus tshawytscha*) ESU, currently listed as endangered, was listed as a threatened species under emergency provisions of the ESA on August 4, 1989 (54 FR 32085) and formally listed as a threatened species in November 1990 (55 FR 46515). On January 4, 1994 (59 FR 440), NMFS re-classified winter-run as an endangered species. NMFS concluded that winter-run in the Sacramento River warranted listing as an endangered species due to several factors, including: (1) the continued decline and increased variability of run sizes since its first listing as a threatened species in 1989;

(2) the expectation of weak returns in future years as the result of two small year classes (1991 and 1993); and (3) continued threats to the "take" of winter-run (August 15, 2011, 76 FR 50447).

On June 28, 2005, NMFS concluded that the winter-run ESU was "in danger of extinction" due to risks to the ESU's diversity and spatial structure and, therefore, continues to warrant listing as an endangered species under the ESA (70 FR 37160). In August 2011, NMFS completed a 5-year status review of five Pacific salmon ESUs, including the winter-run ESU, and again determined that the species' status should remain as "endangered" (August 15, 2011, 76 FR 50447). The 2011 review concluded that although the listing remained unchanged since the 2005 review, the status of the population had declined over the past five years (2005–2010).

The winter-run ESU currently consists of only one population that is confined to the upper Sacramento River (spawning downstream of Shasta and Keswick dams) in California's CV. In addition, an artificial propagation program at the Livingston Stone National Fish Hatchery (LSNFH) produces winter-run that are considered to be part of this ESU (June 28, 2005, 70 FR 37160). Most components of the winter-run life history (*e.g.*, spawning, incubation, freshwater rearing) have been compromised by the habitat blockage in the upper Sacramento River. All historical spawning and rearing habitats have been blocked since the construction of Shasta Dam in 1943. Remaining spawning and rearing areas are completely dependent on cold water releases from Shasta Dam in order to sustain the remnant population.

Life History

1. <u>Adult Migration and Spawning</u>

Winter-run exhibit a unique life history pattern (Healey 1994) compared to other salmon populations in the CV (*i.e.*, spring-run, fall-run, and late-fall run), in that they spawn in the summer, and the juveniles are the first to enter the ocean the following winter and spring. Adults first enter San Francisco Bay from November through June (Hallock and Fisher 1985) and migrate up the Sacramento River, past the RBDD from mid-December through early August (NMFS 1997). The majority of the run passes RBDD from January through May, with the peak passage occurring in mid-March (Hallock and Fisher 1985). The timing of migration may vary somewhat due to changes in river flows, dam operations, and water year type (Table 5; Yoshiyama *et al.* 1998, Moyle 2002).

Winter-run tend to enter freshwater while still immature and travel far upriver and delay spawning for weeks or months upon arrival at their spawning grounds (Healey 1991). Spawning occurs primarily from mid-May to mid-August, with the peak activity occurring in June and July in the upper Sacramento River reach (50 miles) between Keswick Dam and RBDD (Vogel and Marine 1991). Winter-run deposit and fertilize eggs in gravel beds known as redds excavated by the female that then dies following spawning. Average fecundity was 5,192 eggs/female for the 2006–2013 returns to LSNFH, which is similar to other Chinook salmon runs [*e.g.*, 5,401 average for Pacific Northwest (Quinn 2005)]. Chinook salmon spawning requirements for depth and velocities are broad, and the upper preferred water temperature is between 55–57°F (13–14°C) degrees (Snider *et al.* 2001). The majority of winter-run adults return after three years.

Table 5. The temporal occurrence of adult (a) and juvenile (b) winter-run in the Sacramento River. Darker shades indicate months of greatest relative abundance.

2. <u>Eggs/Fry Emergence</u>

Winter-run incubating eggs are vulnerable to adverse effects from floods, flow fluctuations, siltation, desiccation, disease, predation during spawning, poor gravel percolation, and poor water quality. The optimal water temperature for egg incubation ranges from 46–56°F (7.8–13.3°C) and a significant reduction in egg viability occurs in mean daily water temperatures above 57.5°F (14.2°C; Seymour 1956, Boles 1988, USFWS 1998, EPA 2003, Richter and Kolmes 2005, Geist *et al.* 2006). Total embryo mortality can occur at temperatures above 62°F (16.7°C; NMFS 1997). Depending on ambient water temperature, embryos hatch within 40-60 days and alevin (yolk-sac fry) remain in the gravel beds for an additional 4–6 weeks. As their yolk-sacs become depleted, fry begin to emerge from the gravel and start exogenous feeding in their natal stream, typically in late July to early August and continuing through October (Fisher 1994).

3. <u>Juvenile/Outmigration</u>

Juvenile winter-run have been found to exhibit variability in their life history dependent on emergence timing and growth rates (Beckman *et al.* 2007). Following spawning, egg incubation, and fry emergence from the gravel, juveniles begin to emigrate in the fall. Some juvenile winter-run migrate to sea after only 4 to 7 months of river life, while others hold and rear upstream and spend 9 to 10 months in freshwater. Emigration of juvenile winter-run fry and pre-smolts past RBDD (RM 242) may begin as early as mid-July, but typically peaks at the end of September (Table 5), and can continue through March in dry years (Vogel and Marine 1991, NMFS 1997).

4. Estuarine/Delta Rearing

Juvenile winter-run emigration into the estuary/Delta occurs primarily from November through early May based on data collected from trawls in the Sacramento River at Sherwood Harbor (West Sacramento), RM 57 (USFWS 2001). The timing of emigration may vary somewhat due to changes in river flows, Shasta Dam operations, and water year type, but has been correlated with the first storm event when flows exceed 14,000 cfs at Knights Landing, RM 90, which trigger abrupt emigration towards the Delta (del Rosario *et al.* 2013). Residence time in the Delta for juvenile winter-run averages approximately 3 months based on median seasonal catch between Knights Landing and Chipps Island. In general, the earlier juvenile winter-run arrive in the Delta, the longer they stay and rear, as peak departure at Chipps Island regularly occurs in March (del Rosario *et al.* 2013). The Delta serves as an important rearing and transition zone for juvenile winter-run as they feed and physiologically adapt to marine waters (smoltification). The majority of juvenile winter-run in the Delta are 104 to 128 millimeters (mm) in size based on USFWS trawl data (1995-2012), and from 5 to 10 months of age, by the time they depart the Delta (Fisher 1994, Myers *et al.* 1998).

5. Ocean Rearing

Winter-run smolts enter the Pacific Ocean mainly in spring (March–April), and grow rapidly on a diet of small fishes, crustaceans, and squid. Salmon runs that migrate to sea at a larger size tend to have higher marine survival rates (Quinn 2005). The diet composition of Chinook salmon from California consist of anchovy, rockfish, herring, and other invertebrates (in order of preference, Healey 1991). Most Chinook from the Central Valley move northward into Oregon and Washington, where herring make up the majority of their diet. However winter-run, upon entering the ocean, tend to stay near the California coast and distribute from Point Arena southward to Monterey Bay. Winter-run have high metabolic rates, feed heavily, and grow fast, compared to other fishes in their range. They can double their length and increase their weight more than ten-fold in the first summer at sea (Quinn 2005). Mortality is typically highest in the first summer at sea, but can depend on ocean conditions. Winter-run abundance has been correlated with ocean conditions, such as periods of strong up-welling, cooler temperatures, and El Nino events (Lindley *et al.* 2009). Winter-run spend approximately 1-2 years rearing in the ocean before returning to the Sacramento River as 2-3 year old adults. Very few winter-run Chinook salmon reach age 4. Once they reach age 3, they are large enough to become vulnerable to commercial and sport fisheries.

Description of Viable Salmonid Population (VSP) Parameters

1. Abundance

Historically, winter-run population estimates were as high as 120,000 fish in the 1960s, but declined to less than 200 fish by the 1990s (NMFS 2011). In recent years, since carcass surveys began in 2001 (Figure 3), the highest adult escapement occurred in 2005 and 2006 with 15,839 and 17,296, respectively. However, from 2007 to 2012, the population has shown a precipitous decline, averaging 2,486 during this period, with a low of 827 adults in 2011 (Figure 3). This recent declining trend is likely due to a combination of factors such as poor ocean productivity (Lindley *et al.* 2009), drought conditions from 2007-2009, and low in-river survival (NMFS 2011a). In 2013, the population increased to 6,075 adults, well above the 2007–2012 average, but below the high for the last ten years.

Although impacts from hatchery fish (*i.e.*, reduced fitness, weaker genetics, smaller size, less ability to avoid predators) are often cited as having deleterious impacts on natural in-river populations (Matala *et al.* 2012), the winter-run conservation program at LSNFH is strictly controlled by the USFWS to reduce such impacts. The average annual hatchery production at LSNFH is approximately 176,348 per year (2001–2010 average) compared to the estimated natural production that passes RBDD, approximately 4.7 million (2002–2010 average, Poytress and Carrillo 2011). Therefore, hatchery production typically represents approximately 3-4 percent of the total in-river juvenile production in any given year.

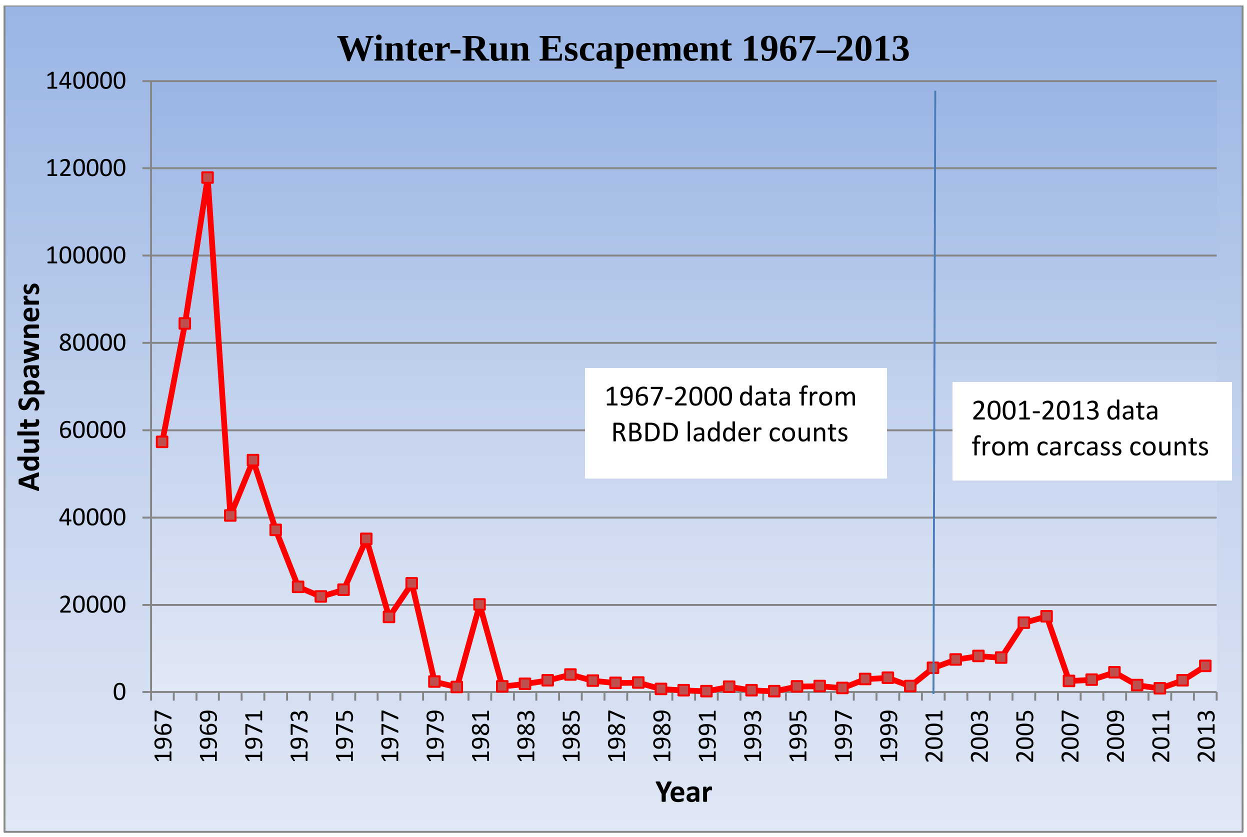

Figure 2. Winter-run Chinook salmon escapement numbers 1970-2013, includes hatchery broodstock and tributaries, but excludes sport catch. RBDD later counts used pre-2000, carcass surverys post 2001(3).

2. Productivity

ESU productivity was positive over the period 1998–2006, and adult escapement and juvenile production had been increasing annually until 2007, when productivity became negative (Figure 4) with declining escapement estimates. The long-term trend for the ESU, therefore, remains negative, as the productivity is subject to impacts from environmental and artificial conditions. The population growth rate based on cohort replacement rate (CRR) for the period 2007–2012 suggests a reduction in productivity (Figure 4), and indicates that the winter-run population is not replacing itself. In 2013, winter-run experienced a positive CRR, possibly due to favorable in-river conditions in 2011 (a wet year), which increased juvenile survival to the ocean.

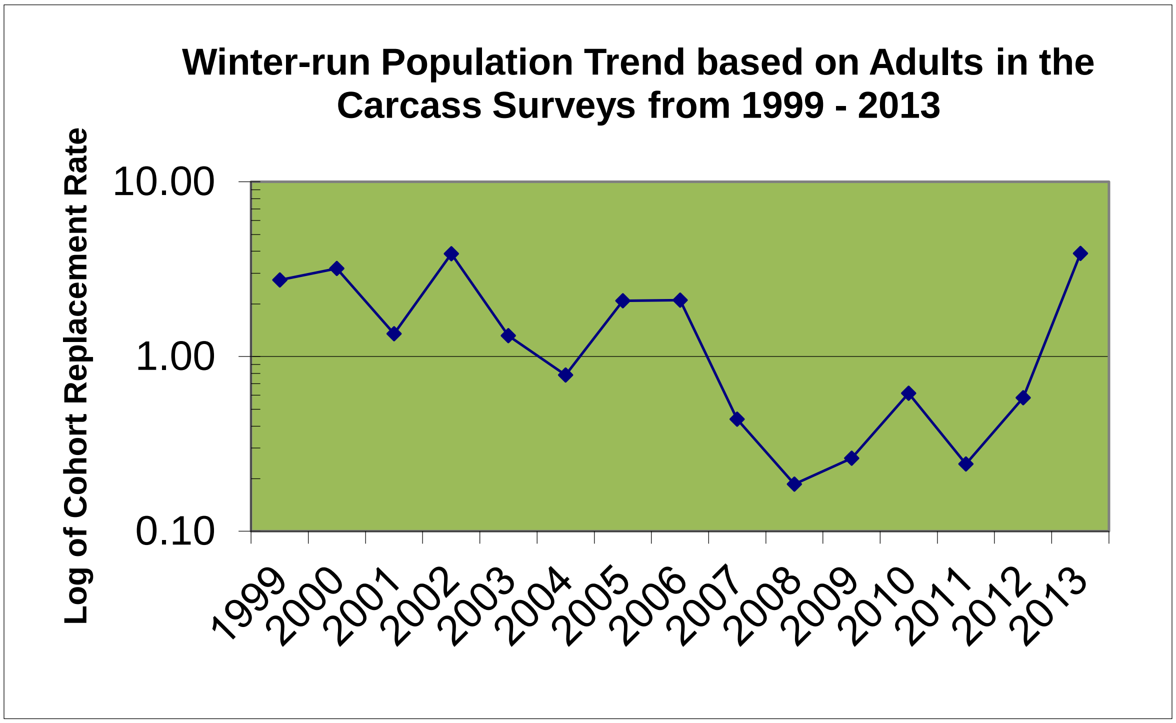

Figure 3. Winter-run population trend using cohort replacement rate derived from adult escapement, including hatchery fish, 1986–2013.

An age-structured density-independent model of spawning escapement by Botsford and Brittnacher (1998) assessing the viability of winter-run found the species was certain to fall below the quasi-extinction threshold of three consecutive spawning runs with fewer than 50 females (Good *et al.* 2005). Lindley and Mohr (2003) assessed the viability of the population using a Bayesian model based on spawning escapement that allowed for density dependence and a change in population growth rate in response to conservation measures found a biologically significant expected quasi-extinction probability of 28 percent. Although the growth rate for the winter-run population improved up until 2006, it exhibits the typical variability found in most endangered species populations. The fact that there is only one population, dependent upon cold-water releases from Shasta Dam, makes it vulnerable to periods of prolonged drought (NMFS 2011). Productivity, as measured by the number of juveniles entering the Delta, or juvenile production estimate (JPE), has declined in recent years from a high of 3.8 million in 2007 to 1.1 million in 2013 (Table 6). Due to uncertainties in the various factors, the JPE was updated in

2010 with the addition of confidence intervals (Cramer Fish Sciences model), and again in 2013 with a change in survival based on acoustic tag data (NMFS 2014). However, juvenile winter-run productivity is still much lower than other Chinook salmon runs in the Central Valley and in the Pacific Northwest (Michel 2010).

Table 6. Winter-run adult and juvenile population estimates based on RBDD counts (1986–2001) and carcass counts (2001–2013), with corresponding 3-year-cohort replacement rates

Return Year	**Adult Population Estimate[a]**	**Cohort Replacement Rate[b]**	**NMFS-calculated Juvenile Production**
1986	2596		
1987	2185		
1988	2878		
1989	696	0.27	
1990	430	0.20	
1991	211	0.07	
1992	1240	1.78	40,100
1993	387	0.90	273,100
1994	186	0.88	90,500
1995	1297	1.05	74,500
1996	1337	3.45	338,107
1997	880	4.73	165,069
1998	2992	2.31	138,316
1999	3288	2.46	454,792
2000	1352	1.54	289,724
2001	8224	2.75	370,221
2002	7441	2.26	1,864,802

2008	2830	0.18	1,100,067
2009	4537	0.26	1,152,043
2010	1,596	0.63	1,144,860
2011	827	0.29	332,012
2012	2,674	0.59	162,051
2013	6,075	3.88	1,196,387
median	2,542	0.95	412,507

[a] Population estimates include adults taken into the hatchery and were based on ladder counts at RBDD until 2001, after which the methodology changed to carcass surveys (CDFG 2012).

[b] Assumes all adults return after three years. NMFS calculated a CRR using the adult spawning population, divided by the spawning population three years prior. Two year old returns were not used.

[c] JPE estimates include survival estimates from the spawning gravel to the point where they enter the Delta (Sacramento I St Bridge), but does not include through-Delta survival.

3. Spatial Structure

The distribution of winter-run spawning and initial rearing historically was limited to the upper Sacramento River (upstream of Shasta Dam), McCloud River, Pitt River, and Battle Creek, where springs provided cold water throughout the summer, allowing for spawning, egg incubation, and rearing during the mid-summer period (Slater 1963 *op. cit.* Yoshiyama et al. 1998). The construction of Shasta Dam in 1943 blocked access to all of these waters except Battle Creek, which currently has its own impediments to upstream migration (*i.e.*, a number of small hydroelectric dams situated upstream of the Coleman Fish Hatchery weir). The Battle Creek Salmon and Steelhead Restoration Project (BCSSRP) is currently removing these impediments, which should restore spawning and rearing habitat for winter-run in the future. Approximately 299 miles of former tributary spawning habitat upstream of Shasta Dam is inaccessible to winter-run. Yoshiyama *et al.* (2001) estimated that in 1938, the upper Sacramento River had a "potential spawning capacity" of approximately 14,000 redds equal to 28,000 spawners. Since 2001, the majority of winter-run redds have occurred in the first 10 miles downstream of Keswick Dam. Most components of the winter-run life history (*e.g.*, spawning, incubation, freshwater rearing) have been compromised by the construction of Shasta Dam.

The greatest risk factor for winter-run lies within its spatial structure (NMFS 2011). The remnant and remaining population cannot access 95% of their historical spawning habitat, and must therefore be artificially maintained in the Sacramento River by: (1) spawning gravel augmentation, (2) hatchery supplementation, and, (3) regulating the finite cold-water pool behind Shasta Dam to reduce water temperatures. Winter-run require cold water temperatures in the summer that simulate their upper basin habitat, and they are more likely to be exposed to the impacts of drought in a lower basin environment. Battle Creek is currently the most feasible opportunity for the ESU to expand its spatial structure, but restoration is not scheduled to be completed until 2017 (BCSSRP). The draft CV Salmon and Steelhead Recovery Plan includes criteria for recovering the winter-run Chinook salmon ESU, including re-establishing a population into historical habitats upstream of Shasta Dam (NMFS 2009b). Additionally, NMFS (2009a) included a requirement for a pilot fish passage program upstream of Shasta Dam.

4. Diversity

The current winter-run population is the result of the introgression of several stocks (*e.g.*, spring-run and fall-run Chinook) that occurred when Shasta Dam blocked access to the upper watershed. A second genetic bottleneck occurred with the construction of Keswick Dam which blocked access and did not allow spatial separation of the different runs (Good *et al.* 2005). Lindley *et al.* (2007) recommended reclassifying the winter-run population extinction risk from low to moderate, if the proportion of hatchery origin fish from the LSNFH exceeded 15 percent due to the impacts of hatchery fish over multiple generations of spawners. Since 2005, the percentage of hatchery winter-run recovered in the Sacramento River has only been above 15 percent in two years, 2005 and 2012 (Figure 5).

Concern over genetic introgression within the winter-run population led to a conservation program at LSNFH that encompasses best management practices such as: (1) genetic confirmation of each adult prior to spawning, (2) a limited number of spawners based on the effective population size, and (3) use of only natural-origin spawners since 2009. These practices reduce the risk of hatchery impacts on the wild population. Hatchery-origin winter-run have made up more than 5 percent of the natural spawning run in recent years and in 2012, it exceeded 30 percent of the natural run (Figure 5). However, the average over the last 16 years (approximately 5 generations) has been 8 percent, still below the low-risk threshold (15%) used for hatchery influence (Lindley *et al.* 2007).

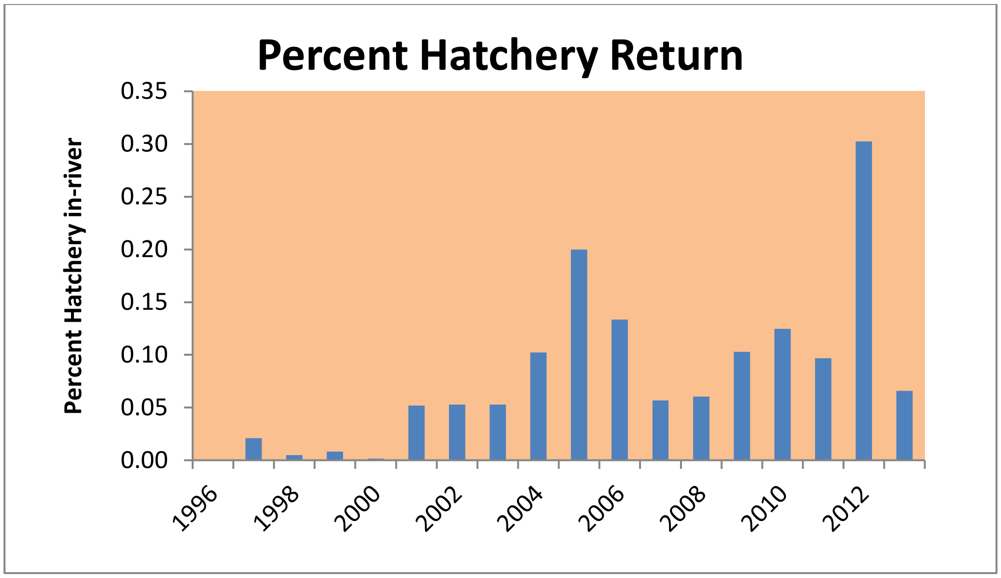

Figure 4. Percentage of hatchery-origin winter-run Chinook salmon naturally spawning in the Sacramento River (1996–2013). Source: CDFW carcass surveys, 2013.

Summary of Sacramento River Winter-run Chinook Salomon ESU Viability

There are several criteria (only one is required) that would qualify the winter-run ESU at moderate risk of extinction, and since there is still only one population that spawns downstream of Keswick Dam, that population would be at high risk of extinction in the long-term according the criteria in Lindley *et al.* (2007). Recent trends in those criteria are: (1) continued low abundance (Figure 3); (2) a negative growth rate over 6 years (2006–2012), which is two complete generations (Figure 4); (3) a significant rate of decline since 2006; and (4) increased risk of catastrophe from oil spills, wild fires, or extended drought (climate change). The most recent 5-year status review (NMFS 2011) on winter-run concluded that the ESU had increased to a high risk of extinction. In summary, the most recent biological information suggests that the extinction risk for the winter-run ESU has increased from moderate risk to high risk of extinction since 2005, and that several listing factors have contributed to the recent decline, including drought and poor ocean conditions (NMFS 2011).

Critical Habitat: Essential Features for Sacramento River Winter-run Chinook Salmon

NMFS designated critical habitat for winter-run Chinook salmon on June 16, 1993 (58 FR 33212). Critical habitat was delineated as the Sacramento River from Keswick Dam at river mile (RM) 302 to Chipps Island, RM 0, at the westward margin of the Sacramento-San Joaquin Delta (Delta), including Kimball Island, Winter Island, and Brown's Island; all waters from Chipps Island westward to the Carquinez Bridge, including Honker Bay, Grizzly Bay, Suisun Bay, and the Carquinez Strait; all waters of San Pablo Bay westward of the Carquinez Bridge, and all waters of San Francisco Bay north of the San Francisco-Oakland Bay Bridge from San Pablo Bay to the Golden Gate Bridge. In the Sacramento River, critical habitat includes the river water, river bottom, and the adjacent riparian zone.

Critical habitat for winter-run is defined as specific areas (listed below) that contain the physical and biological features considered essential to the conservation of the species. This designation includes the river water, river bottom (including those areas and associated gravel used by winter-run as spawning substrate), and adjacent riparian zone used by fry and juveniles for rearing (June 16, 1993, 58 FR 33212). NMFS limits "adjacent riparian zones" to only those areas above a stream bank that provide cover and shade to the near shore aquatic areas. Although the bypasses (*e.g.,* Yolo, Sutter, and Colusa) are not currently designated critical habitat for winter-run, NMFS recognizes that they may be utilized when inundated with Sacramento River flood flows and are important rearing habitats for juvenile winter-run. Also, juvenile winter-run may use tributaries of the Sacramento River for non-natal rearing. Critical habitat also includes the estuarine water column and essential foraging habitat and food resources used by winter-run as part of their juvenile outmigration or adult spawning migration.

The following is the status of the physical and biological habitat features that are considered to be essential for the conservation of winter-run (June 16, 1993, 58 FR 33212):

1. <u>Access from the Pacific Ocean to Appropriate Spawning Areas</u>

Adult migration corridors should provide satisfactory water quality, water quantity, water temperature, water velocity, cover, shelter and safe passage conditions in order for adults to reach spawning areas. Adult winter-run generally migrate to spawning areas during the winter and spring. At that time of year, the migration route is accessible to the appropriate spawning grounds on the upper 60 miles of the Sacramento River, however much of this migratory habitat is degraded and they must pass through a fish ladder at the Anderson-Cottonwood Irrigation Dam (ACID). In addition, the many flood bypasses are known to strand adults in agricultural drains due to inadequate screening (Vincik and Johnson 2013). Since the primary migration corridors are essential for connecting early rearing habitat with the ocean, even the degraded reaches are considered to have a high intrinsic conservation value to the species.

2. <u>The Availability of Clean Gravel for Spawning Substrate</u>

Suitable spawning habitat for winter-run exists in the upper 60 miles of the Sacramento River between Keswick Dam and Red Bluff Diversion Dam (RBDD). However, the majority of spawning habitat currently being used occurs in the first 10 miles downstream of Keswick Dam.

The available spawning habit is completely outside the historical range utilized by winter-run upstream of Keswick Dam. Because Shasta and Keswick dams block gravel recruitment, the U.S. Bureau of Reclamation (Reclamation) annually injects spawning gravel into various areas of the upper Sacramento River. With the supplemented gravel injections, the upper Sacramento River reach continues to support a small naturally-spawning winter-run Chinook salmon population. Even in degraded reaches, spawning habitat has a high conservation value as its function directly affects the spawning success and reproductive potential of listed salmonids.

3. Adequate River Flows for Successful Spawning, Incubation of Eggs, Fry Development and Emergence, and Downstream Transport of Juveniles

An April 5, 1960, Memorandum of Agreement between Reclamation and the CDFW originally established flow objectives in the Sacramento River for the protection and preservation of fish and wildlife resources. In addition, Reclamation complies with the 1990 flow releases required in State Water Resource Control Board (SWRCB) Water Rights Order (WRO) 90-05 for the protection of Chinook salmon. This order includes a minimum flow release of 3,250 cubic feet per second (cfs) from Keswick Dam downstream to RBDD from September through February during all water year types, except critically dry.

4. Water Temperatures at 5.8–14.1°C (42.5–57.5°F) for Successful Spawning, Egg Incubation, and Fry Development

Summer flow releases from Shasta Reservoir for agriculture and other consumptive uses drive operations of Shasta and Keswick dam water releases during the period of winter-run migration, spawning, egg incubation, fry development, and emergence. This pattern, the opposite of the pre-dam hydrograph, benefits winter-run by providing cold water for miles downstream during the hottest part of the year. The extent to which winter-run habitat needs are met depends on Reclamation's other operational commitments, including those to water contractors, Delta requirements pursuant to State Water Rights Decision 1641 (D-1641), and Shasta Reservoir end of September storage levels required in the NMFS 2009 biological opinion on the long-term operations of the CV Project and State Water Project (CVP/SWP, NMFS 2009a). WRO 90-05 and 91-1 require Reclamation to operate Shasta, Keswick, and Spring Creek Powerhouse to meet a daily average water temperature of 13.3°C (56°F) at RBDD. They also provide the exception that the water temperature compliance point (TCP) may be modified when the objective cannot be met at RBDD. Based on these requirements, Reclamation models monthly forecasts and determines how far downstream 13.3°C (56°F) can be maintained throughout the winter-run spawning, egg incubation, and fry development stages.

In every year since WRO 90-05 and 91-1were issued, operation plans have included modifying the TCP to make the best use of the cold water available based on water temperature modeling and current spawning distribution. Once a TCP has been identified and established in May, it generally does not change, and therefore, water temperatures are typically adequate through the summer for successful winter-run egg incubation and fry development for those redds constructed upstream of the TCP (except for in some critically dry and drought years). However, by continually moving the TCP upstream, the value of that habitat is degraded by reducing the spawning area in size and imprinting upon the next generation to return further upstream.

5. Habitat and Adequate Prey Free of Contaminants

Water quality conditions have improved since the 1980s due to stricter standards and Environmental Protection Agency (EPA) Superfund site cleanups (see Iron Mountain Mine remediation under Factors). No longer are there fish kills in the Sacramento River caused by the heavy metals (*e.g.*, lead, zinc and copper) found in the Spring Creek runoff. However, legacy contaminants such as mercury (and methyl mercury), polychlorinated biphenyls (PCB), heavy metals and persistent organochlorine pesticides continue to be found in watersheds throughout the CV. In 2010, the EPA, listed the Sacramento River as impaired under the Clean Water Act, section 303(d), due to high levels of pesticides, herbicides, and heavy metals (http://www.waterboards.ca.gov/water_issues/programs/tmdl/2010state_ir_reports/category5_report.shtml). Although most of these contaminants are at low concentrations in the food chain, they continue to work their way into the base of the food web, particularly when sediments are disturbed and previously entombed compounds are released into the water column.

Adequate prey for juvenile salmon to survive and grow consists of abundant aquatic and terrestrial invertebrates that make up the majority of their diet before entering the ocean. Exposure to these contaminated food sources such as invertebrates may create delayed sublethal effects that reduce fitness and survival (Laetz *et al*. 2009). Contaminants are typically associated with areas of urban development, agriculture, or other anthropogenic activities (*e.g.*, mercury contamination as a result of gold mining or processing). Areas with low human impacts frequently have low contaminant burdens, and therefore lower levels of potentially harmful toxicants in the aquatic system. Freshwater rearing habitat has a high intrinsic conservation value even if the current conditions are significantly degraded from their natural state.

6. Riparian and Floodplain Habitat that Provides for Successful Juvenile Development and Survival

The channelized, leveed, and riprapped river reaches and sloughs that are common in the Sacramento River system typically have low habitat complexity, low abundance of food organisms, and offer little protection from predators. Juvenile life stages of salmonids are dependent on the natural functioning of this habitat for successful survival and recruitment. Ideal habitat contains natural cover, such as riparian canopy structure, submerged and overhanging large woody material (LWM), aquatic vegetation, large rocks and boulders, side channels, and undercut banks which augment juvenile and adult mobility, survival, and food supply. Riparian recruitment is prevented from becoming established due to the reversed hydrology (*i.e*., high summer time flows and low winter flows prevent tree seedlings from establishing). However, there are some complex, productive habitats within historical floodplains [*e.g.*, Sacramento River reaches with setback levees (*i.e.*, primarily located upstream of the City of Colusa)] and flood bypasses (*i.e.*, fish in Yolo and Sutter bypasses experience rapid growth and higher survival due to abundant food resources) seasonally available that remain in the system. Nevertheless, the current condition of degraded riparian habitat along the mainstem Sacramento River restricts juvenile growth and survival (Michel 2010, Michel *et al.* 2012).

7. Access Downstream so that Juveniles Can Migrate from the Spawning Grounds to San Francisco Bay and the Pacific Ocean

Freshwater emigration corridors should be free of migratory obstructions, with water quantity and quality conditions that enhance migratory movements. Migratory corridors are downstream of the Keswick Dam spawning areas and include the mainstem of the Sacramento River to the Delta, as well as non-natal rearing areas near the confluence of some tributary streams.

Migratory habitat condition is strongly affected by the presence of barriers, which can include dams (*i.e.*, hydropower, flood control, and irrigation flashboard dams), unscreened or poorly screened diversions, degraded water quality, or behavioral impediments to migration. For successful survival and recruitment of salmonids, freshwater migration corridors must function sufficiently to provide adequate passage. Unscreened diversions that entrain juvenile salmonids are prevalent throughout the mainstem Sacramento River and in the Delta. Predators such as striped bass (*Morone saxatilis*) and Sacramento pikeminnow (*Ptychocheilus grandis*) tend to concentrate immediately downstream of diversions, resulting in increased mortality of juvenile Chinook salmon.

Water pumping at the CVP/SWP export facilities in the South Delta at times causes the flow in the river to move back upstream (reverse flow), further disrupting the emigration of juvenile winter-run by attracting and diverting them to the interior Delta, where they are exposed to increased rates of predation, other stressors in the Delta, and entrainment at pumping stations. NMFS' biological opinion on the long-term operations of the CVP/SWP (NMFS 2009a) sets limits to the strength of reverse flows in the Old and Middle Rivers, thereby keeping salmon away from areas of highest mortality. Regardless of the condition, the remaining estuarine areas are of high conservation value because they provide factors which function as rearing habitat and as an area of transition to the ocean environment.

2.2.2 Central Valley Spring-run Chinook salmon

In August 2011, NMFS completed an updated status review of five Pacific Salmon ESUs, including CV spring-run Chinook salmon, and concluded that the species' status should remain as previously listed (76 FR 50447). The 2011 Status Review (NMFS 2011b) additionally stated that although the listings will remain unchanged since the 2005 review, and the original 1999 listing (64 FR 50394), the status of these populations has worsened over the past five years and recommended that the status be reassessed in two to three years as opposed to waiting another five years.

CV spring-run Chinook salmon were listed as threatened on September 16, 1999, (64 FR 50394). This ESU consists of spring-run Chinook salmon occurring in the Sacramento River basin. The Feather River Fish Hatchery (FRFH) spring-run Chinook salmon population has been included as part of the CV spring-run Chinook salmon ESU in the most recent modification of the CV spring-run Chinook salmon listing status (70 FR 37160). Critical habitat was designated for CV spring-run Chinook salmon on September 2, 2005, (70 FR 52488), and includes the action area for the Proposed Action. It includes stream reaches of the Feather and Yuba rivers, Big Chico, Butte, Deer, Mill, Battle, Antelope, and Clear creeks, the main stem of the Sacramento River from Keswick Dam through the Delta; and portions of the network of channels in the northern Delta.

Historically spring-run Chinook salmon were the second most abundant salmon run in the CV and one of the largest on the west coast (CDFG 1990, 1998). These fish occupied the upper and middle reaches (1,000 to 6,000 feet elevation) of the San Joaquin, American, Yuba, Feather, Sacramento, McCloud and Pit rivers, with smaller populations in most tributaries with sufficient habitat for over-summering adults (Stone 1874, Rutter 1904, Clark 1929). The CV Technical Review Team (TRT) estimated that historically there were 18 or 19 independent populations of CV spring-run Chinook salmon, along with a number of dependent populations, all within four distinct geographic regions (diversity groups) (Lindley *et al.* 2004). Of these 18 populations, only 3 extant populations currently exist (Mill, Deer, and Butte creeks on the upper Sacramento River) and they represent only the northern Sierra Nevada diversity group. All populations in the basalt and porous lava diversity group and the southern Sierra Nevada diversity group have been extirpated. The northwestern California diversity group did not historically contain independent populations, and currently contains two or three populations that are likely dependent on the northern Sierra Nevada diversity group populations for their continued existence.

Construction of low elevation dams in the foothills of the Sierras on the Mokelumne, Stanislaus, Tuolumne, and Merced rivers, was thought to have extirpated CV spring-run Chinook salmon from these watersheds of the San Joaquin River, as well as on the American and Yuba rivers of the Sacramento River basin. However, observations in the last decade suggest that perhaps a naturally occurring population may still persist in the Stanislaus and Tuolumne rivers (Franks, personal communication, 2012), as well as in the Yuba River. Documented naturally-spawning populations of CV spring-run Chinook salmon are currently restricted to accessible reaches of the upper Sacramento River, Antelope Creek, Battle Creek, Beegum Creek, Big Chico Creek, Butte Creek, Clear Creek, Deer Creek, Feather River, Mill Creek, and the Yuba River (CDFG 1998).

Life History

Adult CV spring-run Chinook salmon leave the ocean to begin their upstream migration in late January and early February (CDFG 1998) and enter the Sacramento River beginning in March (Yoshiyama 1998). Spring-run Chinook salmon move into tributaries of the Sacramento River (*e.g.* Butte, Mill, Deer creeks) beginning as early as February in Butte Creek and typically mid-March in Mill and Deer creeks (Lindley *et al.* 2004). Adult migration peaks around mid-April in Butte Creek, and mid-to end of May in Mill and Deer creeks, and is complete by the end of July in all three tributaries (Lindley *et al.* 2004) (Table 7). Typically, spring-run Chinook salmon utilize mid- to high-elevation streams that provide appropriate temperatures and sufficient flow, cover, and pool depth to allow over-summering while conserving energy and allowing their gonadal tissue to mature (Yoshiyama *et al.* 1998).

Spring-run Chinook salmon spawning occurs between September and October (Moyle 2002). Between 56 and 87 percent of adult spring-run Chinook salmon that enter the Sacramento River basin to spawn are 3 years old (Calkins *et al.* 1940, Fisher 1994).

Spring-run Chinook salmon fry emerge from the gravel from November to March (Moyle 2002) and the emigration timing is highly variable, as they may migrate downstream as young-of-the-year or as juveniles or yearlings. The model size of fry migrants at approximately 40 millimeters (mm) between December and April in Mill, Butte, and Deer creeks reflects a prolonged emergence of fry from the gravel (Lindley *et al.* 2004). Studies in Butte Creek, (Ward *et al.* 2003, McReynolds *et al.* 2007) found the majority of CV spring-run Chinook salmon migrants to be fry, which occurred primarily during December, January, and February; and that these movements appeared to be influenced by increased flow. Small numbers of CV spring-run Chinook salmon were observed to remain in Butte Creek to rear and migrated as yearlings later in the spring. Juvenile emigration patterns in Mill and Deer creeks are very similar to patterns observed in Butte Creek, with the exception that Mill and Deer creek juveniles typically exhibit a later young-of-the-year migration and an earlier yearling migration (Lindley *et al.* 2004). CDFW (CDFG 1998) observed the emigration period for spring-run Chinook salmon extending from November to early May, with up to 69 percent of the young-of-the-year fish outmigrating through the lower Sacramento River and Delta during this period. Peak movement of juvenile CV spring-run Chinook salmon in the Sacramento River at Knights Landing occurs in December, and again in March and April. However, juveniles also are observed between November and the end of May (Snider and Titus 2000).

Once juveniles emerge from the gravel they initially seek areas of shallow water and low velocities while they finish absorbing the yolk sac and transition to exogenous feeding (Moyle 2002). Many also would disperse downstream during high-flow events. As is the case in other salmonids, there is a shift in microhabitat use by juveniles to deeper faster water as they grow larger. Microhabitat use can be influenced by the presence of predators which can force fish to select areas of heavy cover and suppress foraging in open areas (Moyle 2002).

Description of VSP Parameters

Like the winter-run Chinook salmon population, the CV spring-run Chinook salmon population fails to meet the “representation and redundancy rule” since there are only one demonstrably viable populations in one diversity group (northern Sierra Nevada) out of the three diversity groups that historically contained them. Over the long term, these remaining populations are considered to be vulnerable to catastrophic events, such as volcanic eruptions from Mount

Lassen or large forest fires due to the close proximity of their headwaters to each other. Drought is also considered to pose a significant threat to the viability of the spring-run Chinook salmon populations in these three watersheds due to their close proximity to each other.

1. Abundance

The CV drainage as a whole is estimated to have supported spring-run Chinook salmon runs as large as 600,000 fish between the late 1880s and 1940s (CDFG 1998). The San Joaquin River historically supported large runs of spring-run Chinook salmon, suggested to be one of the largest runs of any Chinook salmon on the West Coast with estimates averaging 200,000 – 500,000 adults returning annually (CDFG 1990). Construction of Friant Dam began in 1939 and was completed in 1942, which blocked access to upstream habitat.

The FRFH spring-run Chinook salmon population has been included in the ESU based on its genetic linkage to the natural population and the potential development of a conservation strategy for the hatchery program. On the Feather River, significant numbers of spring-run Chinook salmon, as identified by run timing, return to the FRFH. Since 1954, spawning escapement has been estimated using combinations of in-river estimates and hatchery counts, with estimates ranging from 2,908 in 1964 to 2 fish in 1978 (DWR 2001). Spring-run estimates after 1981 have been based solely on salmon entering the hatchery during the month of September. The 5-year moving averages from 1997 to 2006 had been more than 4,000 fish, but from 2007 to 2011, the 5-year moving averages have declined each year to a low of 1,783 fish in 2011 (CDFG 2012). However, coded wire tag (CWT) information from these hatchery returns has indicated that fall-run and spring-run Chinook salmon have overlap (DWR 2001). In addition, genetic testing has indicated substantial introgression has occurred between fall-run and spring-run Chinook salmon populations within the Feather River system due to temporal overlap and hatchery practices (DWR 2001). Because Chinook salmon have not always been spatially separated in the FRFH, spring-run and fall-run Chinook salmon have been spawned together, thus compromising the genetic integrity of the spring-run Chinook salmon stock (Good *et al.* 2005; DWR draft Hatchery Genetic Management Plan 2010). For the reasons discussed above, the Feather River spring-run Chinook salmon population numbers are not included in the following discussion of ESU abundance.

In addition, monitoring of the Sacramento River mainstem during spring-run Chinook salmon spawning timing indicates some spawning occurs in the river. Here, the lack of physical separation of spring-run Chinook salmon from fall-run Chinook salmon is complicated by overlapping migration and spawning periods. Significant hybridization with fall-run Chinook salmon makes identification of spring-run Chinook salmon in the mainstem very difficult to determine, but counts of early spawning Chinook salmon redds are typically used as an indicator of abundance. Less than 15 redds per year were observed in the Sacramento River from 1989 to 1993, during September aerial redd counts (USFWS 2003). Redd surveys conducted in September between 2001 and 2011 have observed an average of 36 salmon redds from Keswick Dam downstream to the RBDD, ranging from three to 105 redds (CDFG, unpublished data, 2011). Therefore, even though physical habitat conditions can support spawning and incubation, spring-run Chinook salmon depend on spatial segregation and geographic isolation from fall-run Chinook salmon to maintain genetic diversity. With the onset of fall-run Chinook salmon spawning occurring in the same time and place as potential spring-run Chinook salmon spawning, it is likely to have caused extensive introgression between the populations (CDFG 1998). For these reasons, Sacramento River mainstem spring-run Chinook salmon are not included in the following discussion of ESU abundance trends.

Sacramento River tributary populations in Mill, Deer, and Butte creeks are likely the best trend indicators for the CV spring-run Chinook salmon ESU as a whole because these streams contain the primary independent populations within the ESU. Generally, these streams have shown a positive escapement trend since 1991, displaying broad fluctuations in adult abundance, ranging from 1,013 in 1993 to 23,788 in 1998. Tributary numbers during 2005 to 2011 showed a downturn; however, 2012 and 2013 showed an increase to 10,810 and 18,499 fish, respectively. Escapement numbers for 2013 increased in most tributary populations, which resulted in the second highest number of spring-run Chinook salmon returning to the tributaries since 1960. Escapement numbers are dominated by Butte Creek returns, which have averaged over 7,000 fish from 1995 to 2005. During this same period, adult returns on Mill and Deer creeks have averaged 780 fish, and 1,464 fish respectively. From 2001 to 2005, the CV spring-run Chinook salmon ESU has experienced a trend of increasing abundance in some natural populations, most dramatically in the Butte Creek population (Good *et al.* 2005). Although trends were generally positive during this time, annual abundance estimates display a high level of fluctuation, and the overall number of CV spring-run Chinook salmon remains well below estimates of historic abundance.

In 2002 and 2003, mean water temperatures in Butte Creek exceeded 21^{o}C for 10 or more days in July (Williams 2006). These persistent high water temperatures, coupled with high fish densities, precipitated an outbreak of Columnaris Disease (*Flexibacter columnaris*) and Ichthyophthiriasis (*Ichthyophthirius multifiis*) in the adult spring-run Chinook salmon over-summering in Butte Creek. In 2002, this contributed to the pre-spawning mortality of approximately 20 to 30 percent of the adults. In 2003, approximately 65 percent of the adults succumbed, resulting in a loss of an estimated 11,231 adult spring-run Chinook salmon in Butte Creek due to the disease. Since 2005, abundance numbers in most of the tributaries have declined. From 2006 to 2009, adult returns indicate that population abundance is declining from the peaks seen in the 5 years prior for the entire Sacramento River basin.

For Mill Creek the 2009, return of 220 spring-run Chinook salmon was the lowest return since 1997. Assuming the 2012, spring-run Chinook salmon return was primarily of three year old fish, then those 768 Chinook salmon represent a significant increase over the 2009, parent year. The 2013 estimate was 644, which was an increase from 2010 estimate of 482. The Mill Creek population of spring-run Chinook salmon is currently at a moderate risk of extinction, due to the significant decline in abundance from prior to 2008 through 2011. However, with the increase in abundance in 2012 and 2013, this trend may be improving. The Deer Creek abundance of spring-run Chinook salmon experienced a significant decline starting in 2008, with an increase in 2012 and 2013.

The abundance of spring-run Chinook salmon in Clear Creek was lower in 2010, 2011, and from 2005 through 2011, abundance numbers in most of the tributaries declined. Adult returns from 2006 to 2009, indicate that population abundance for the entire Sacramento River basin was declining from the peaks seen in the five years prior to 2006. Declines in abundance from 2005 to 2011, placed the Mill Creek and Deer Creek populations in the high extinction risk category due to the rates of decline, and in the case of Deer Creek, also the level of escapement (NMFS 2011). Butte Creek had sufficient abundance to retain its low extinction risk classification, but the rate of population decline in years 2006 through 2011 was nearly sufficient to classify it as a high extinction risk based on this criteria. Nonetheless, the watersheds identified as having the highest likelihood of success for achieving viability/low risk of extinction include, Butte, Deer and Mill creeks (NMFS 2011). Some other tributaries to the Sacramento River, such as Clear Creek and Battle Creek have seen population gains in the years from 2001 to 2009, but the overall abundance numbers have remained low. Year 2012 appeared to be a good return year for most of the tributaries with some, such as Battle Creek, having the highest return on record (799). Additionally, 2013 adult escapement numbers combined for Butte, Mill and Deer creeks increased (over 17,000), which resulted in the second highest number of spring-run Chinook salmon returning to the tributaries since 1998. 2014 adult escapement was lower than 2013 to be lower, with an adult escapement of just over 5,000 fish, which indicates a highly fluctuating and unstable ESU.

1. Productivity

The 5-year geometric mean for the extant Butte, Deer, and Mill creek spring-run Chinook salmon populations ranged from 491 to 4,513 fish, indicating increasing productivity over the short-term and was projected to likely continue into the future (Good *et al.* 2005). However, as mentioned in the previous paragraph, the next five years of adult escapement to these tributaries has seen a cumulative decline in fish numbers and the CRR has declined in concert with the population declines. The productivity of the Feather River and Yuba River populations and contribution to the CV spring-run ESU currently is unknown.

2. Spatial Structure

With only one of four diversity groups currently containing viable populations, the spatial structure of CV spring-run Chinook salmon is severely reduced. Butte Creek spring-run Chinook salmon cohorts have recently utilized all currently available habitat in the creek; and it is unknown if individuals have opportunistically migrated to other systems. The persistent populations in Clear Creek and Battle Creek, with habitat restoration completed and underway are anticipated to add to the spatial structure of the CV spring-run Chinook salmon ESU if they can reach viable status in the basalt and porous lava and northwestern California diversity group areas. The spatial structure of the spring-run Chinook salmon ESU would still be lacking with the extirpation of all San Joaquin River basin spring-run Chinook salmon populations. Plans are underway to re-establish a spring-run Chinook salmon experimental population downstream of Friant Dam in the San Joaquin River, as part of the San Joaquin River Settlement Agreement. This would be done with Feather River Hatchery stock. Interim flows for this began in 2009. Its long-term contribution to the CV spring-run Chinook salmon ESU is uncertain. It is clear that further efforts would need to involve more than restoration of currently accessible watersheds to make the ESU viable. The draft CV Recovery Plan calls for reestablishing populations into historical habitats currently blocked by large dams, such as a population upstream of Shasta Dam. It also calls to facilitate passage of fish upstream and downstream of Englebright Dam on the Yuba River (NMFS 2009b).

3. Diversity

The CV spring-run Chinook salmon ESU is comprised of two genetic complexes. Analysis of natural and hatchery spring-run Chinook salmon stocks in the CV indicates that the northern Sierra Nevada diversity group spring-run Chinook salmon populations in Mill, Deer, and Butte creeks retains genetic integrity as opposed to the genetic integrity of the Feather River population, which has been somewhat compromised. The Feather River spring-run Chinook salmon have introgressed with the fall-run Chinook salmon, and it appears that the Yuba River population may have been impacted by FRFH fish straying into the Yuba River. Additionally, the diversity of the spring-run Chinook salmon ESU has been further reduced with the loss of the majority, if not all, of the San Joaquin River basin spring-run Chinook salmon populations. Efforts underway, like the San Joaquin Restoration Project, are needed to improve the diversity of the CV spring-run Chinook salmon ESU.

Summary of CV Spring-run Chinook salmon DPS Viability

Lindley et al. (2007) indicated that the spring-run Chinook salmon populations in the CV had a low risk of extinction in Butte and Deer creeks, according to their population viability analysis (PVA) model and other population viability criteria (*i.e.*, population size, population decline, catastrophic events, and hatchery influence, which correlate with VSP parameters abundance, productivity, spatial structure, and diversity). The Mill Creek population of spring-run Chinook salmon was at moderate extinction risk according to the PVA model, but appeared to satisfy the other viability criteria for low-risk status. However, the CV spring-run Chinook salmon population failed to meet the "representation and redundancy rule" since there are only demonstrably viable populations in one diversity group (northern Sierra Nevada) out of the three diversity groups that historically contained them. Over the long term, these remaining populations are considered to be vulnerable to catastrophic events, such as volcanic eruptions from Mount Lassen or large forest fires due to the close proximity of their headwaters to each other. Drought is also considered to pose a significant threat to the viability of the spring-run Chinook salmon populations in these three watersheds due to their close proximity to each other. One large event could eliminate all three populations.

In the 2011 California CV status review for spring-run Chinook salmon, NMFS identified the status of CV spring-run Chinook salmon ESU as having probably deteriorated since the 2005 status review and Lindley et al.'s (2007) assessment, with two of the three extant independent populations (Deer and Mill creeks) of spring-run Chinook salmon slipping from low or moderate extinction risk to high extinction risk. Since the abundance of some populations is improving, though this is based on only two years (2012 and 2013), the extinction risk of Sacramento tributary populations generally has improved from high to moderate.

Critical Habitat and Primary Constituent Elements for CV Spring-Run Chinook Salmon

Critical habitat was designated for CV spring-run Chinook salmon on September 2, 2005, (70 FR 52488). Critical habitat for CV spring-run Chinook salmon includes stream reaches of the Feather, Yuba and American rivers, Big Chico, Butte, Deer, Mill, Battle, Antelope, and Clear creeks, the Sacramento River, as well as portions of the northern Delta. Critical habitat includes the stream channels in the designated stream reaches and the lateral extent as defined by the ordinary high-water line. In areas where the ordinary high-water line has not been defined, the lateral extent will be defined by the bankfull elevation (defined as the level at which water begins to leave the channel and move into the floodplain; it is reached at a discharge that generally has a recurrence interval of one to two years on the annual flood series) (Bain and Stevenson 1999; 70 FR 52488). Critical habitat for CV spring-run Chinook salmon is defined as specific areas that contain the primary constituent elements (PCEs) essential to the conservation of the species. Following are the inland habitat types used as PCEs for CV spring-run Chinook salmon.

1. Spawning Habitat

Freshwater spawning sites are those with water quantity and quality conditions and substrate supporting spawning, incubation, and larval development. Most spawning habitat in the CV for Chinook salmon is located in areas directly downstream of dams containing suitable environmental conditions for spawning and incubation. Spawning habitat for CV spring-run Chinook salmon occurs on the mainstem Sacramento River between RBDD and Keswick Dam and in tributaries such as Mill, Deer, and Butte creeks; as well as the Feather and Yuba rivers, Big Chico, Battle, Antelope, and Clear creeks. However, little spawning activity has been recorded in recent years on the Sacramento River mainstem for spring-run Chinook salmon. Even in degraded reaches, spawning habitat has a high conservation value as its function directly affects the spawning success and reproductive potential of listed salmonids.

2. Freshwater Rearing Habitat

Freshwater rearing sites are those with water quantity and floodplain connectivity to form and maintain physical habitat conditions and support juvenile growth and mobility; water quality and forage supporting juvenile salmonid development; and natural cover such as shade, submerged and overhanging large woody material, log jams and beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks. Both spawning areas and migratory corridors comprise rearing habitat for juveniles, which feed and grow before and during their outmigration. Non-natal, intermittent tributaries also may be used for juvenile rearing. Rearing habitat condition is strongly affected by habitat complexity, food supply, and the presence of predators of juvenile salmonids. Some complex, productive habitats with floodplains remain in the system (*e.g.*, the lower Cosumnes River, Sacramento River reaches with setback levees [*i.e.*, primarily located upstream of the City of Colusa]) and flood bypasses (*i.e.*, Yolo and Sutter bypasses). However, the channelized, leveed, and riprapped river reaches and sloughs that are common in the Sacramento-San Joaquin system typically have low habitat complexity, low abundance of food organisms, and offer little protection from piscivorous fish and birds.

Freshwater rearing habitat also has a high intrinsic conservation value even if the current conditions are significantly degraded from their natural state. Juvenile life stages of salmonids are dependent on the function of this habitat for successful survival and recruitment.

3. Freshwater Migration Corridors

Ideal freshwater migration corridors are free of migratory obstructions, with water quantity and quality conditions that enhance migratory movements. They contain natural cover such as riparian canopy structure, submerged and overhanging large woody objects, aquatic vegetation, large rocks, and boulders, side channels, and undercut banks which augment juvenile and adult mobility, survival, and food supply. Migratory corridors are downstream of the spawning areas and include the lower mainstems of the Sacramento and San Joaquin rivers and the Delta. These corridors allow the upstream passage of adults, and the downstream emigration of juveniles. Migratory habitat condition is strongly affected by the presence of barriers, which can include dams (*i.e.*, hydropower, flood control, and irrigation flashboard dams), unscreened or poorly screened diversions, degraded water quality, or behavioral impediments to migration. For successful survival and recruitment of salmonids, freshwater migration corridors must function sufficiently to provide adequate passage. For adults, upstream passage through the Delta and much of the Sacramento River is not a problem, yet a number of challenges exist on many tributary streams. For juveniles, unscreened or inadequately screened water diversions throughout their migration corridors and a scarcity of complex in-river cover have degraded this PCE. However, since the primary migration corridors are used by numerous populations, and are essential for connecting early rearing habitat with the ocean, even the degraded reaches are considered to have a high intrinsic conservation value to the species.

4. Estuarine Areas

Estuarine areas free of migratory obstructions with water quality, water quantity, and salinity conditions supporting juvenile and adult physiological transitions between fresh and salt water are included as a PCE. Natural cover such as submerged and overhanging large woody material, aquatic vegetation, and side channels, are suitable for juvenile and adult foraging.

The remaining estuarine habitat for these species is severely degraded by altered hydrologic regimes, poor water quality, reductions in habitat complexity, and competition for food and space with exotic species. Regardless of the condition, the remaining estuarine areas are of high conservation value because they provide factors which function to provide predator avoidance, as rearing habitat and as an area of transition to the ocean environment.

2.2.3 California Central Valley steelhead

CCV steelhead were listed as threatened on March 19, 1998, (63 FR 13347). Following a new status review (Good *et al.* 2005) and after application of the agency's hatchery listing policy, the NMFS reaffirmed its status as threatened and also listed several hatchery stocks as part of the DPS in 2006 (71 FR 834). In June 2004, after a complete status review of 27 west coast salmonid ESUs, the NMFS proposed that CCV steelhead remain listed as threatened (69 FR 33102). On January 5, 2006, NMFS reaffirmed the threatened status of the CCV steelhead and applied the

DPS policy to the listed steelhead ESUs because the resident and anadromous life forms of *O. mykiss* remain “markedly separated” as a consequence of physical, ecological and behavioral factors, and therefore warranted delineation as a separate DPS (71 FR 834). On August 15, 2011, the NMFS completed another 5-year status review of CCV steelhead and recommended that the CCV steelhead DPS remain classified as a threatened species (NMFS 2011a).

Critical habitat was designated for CCV steelhead on September 2, 2005, (70 FR 52488). Critical habitat includes the stream channels to the ordinary high water line within designated stream reaches such as those of the American, Feather, and Yuba rivers, and Deer, Mill, Battle, Antelope, and Clear creeks in the Sacramento River basin; the Mokelumne, Calaveras, Stanislaus, Tuolumne, and Merced rivers in the San Joaquin River basin; and the Sacramento and San Joaquin rivers and Delta. Currently the CCV steelhead DPS and its designated critical habitat extends up the San Joaquin River upstream to the confluence with the Merced River.

Life History

1. Migratory Forms Present in CV

Steelhead in the CV historically consisted of both summer-run and winter-run migratory forms, based on their state of sexual maturity at the time of river entry and the duration of their time in freshwater before spawning. Between 1944 and 1947, annual counts of summer-run steelhead passing through the Old Folsom Dam fish ladder during May, June, and July ranged from 400 to 1,246 fish (Gerstung 1971). After 1950, when the fish ladder at Old Folsom Dam was destroyed by flood flows, summer-run steelhead were no longer able to access their historic spawning areas, and either perished in the warm water downstream of Old Folsom Dam or hybridized with winter-run steelhead. Only winter-run (ocean maturing) steelhead currently are found in California CV rivers and streams (Moyle 2002; McEwan and Jackson 1996). Summer-run steelhead have been extirpated due to a lack of access to suitable holding and staging habitat, such as coldwater pools in the headwaters of CV streams, presently located upstream of impassible dams (Lindley *et al.* 2006).

2. Age Structure

Juvenile steelhead (parr) rear in freshwater for one to three years before outmigrating to the ocean as smolts (Moyle 2002). The time that parr spend in freshwater is related to their growth rate, with larger, faster-growing members of a cohort smolting at an earlier age (Peven *et al.* 1994; Seelbach 1993). Hallock *et al.* (1961) aged 100 adult steelhead caught in the Sacramento River upstream of the Feather River confluence in 1954, and found that 70 had smolted at age-2, 29 at age-1, and one at age-3. Seventeen of the adults were repeat spawners, with three fish on their third spawning migration, and one on its fifth. Age at first maturity varies among populations. In the CV, most steelhead return to their natal streams as adults at a total age of two to four years (Hallock 1961, McEwan and Jackson 1996).

3. Egg to Parr Stages

Steelhead eggs hatch in three to four weeks at 10°C to 15°C (Moyle 2002). The length of time it takes for eggs to hatch depends mostly on water temperature. After hatching, alevins remain in the gravel for an additional two to five weeks while absorbing their yolk sacs, and emerge in spring or early summer (Barnhart 1986). Fry emerge from the gravel usually about four to six weeks after hatching, but factors such as redd depth, gravel size, siltation, and temperature can speed or retard this time (Shapovalov and Taft 1954). Upon emergence, fry inhale air at the stream surface to fill their air bladders, absorb the remains of their yolks in the course of a few days, and start to feed actively, often in schools (Barnhart 1986; NMFS 1996).

The newly emerged juveniles move to shallow, protected areas associated within the stream margin (McEwan and Jackson 1996). As steelhead parr increase in size and their swimming abilities improve, they increasingly exhibit a preference for higher velocity and deeper mid-channel areas (Hartman 1965; Everest and Chapman 1972; Fontaine 1988).

4. Preferred Juvenile Habitat

Productive juvenile rearing habitat is characterized by complexity, primarily in the form of cover, which can be deep pools, woody debris, aquatic vegetation, or bolders. Cover is an important habitat component for juvenile steelhead both as velocity refugia and as a means of avoiding predation (Meehan and Bjornn 1991). Optimal water temperatures for growth range from 15°C to 20°C (McCullough *et al.* 2001, Spina 2006).

5. Smolt Migration

Juvenile steelhead will often migrate downstream as parr in the summer or fall of their first year of life (USFWS 2002), but this is not a true smolt migration (Loch *et al.* 1988). Smolt migrations occur in the late winter through spring, when juveniles have undergone a physiological transformation to survive in the ocean, and become slender in shape, bright silvery in coloration, with no visible parr marks. Emigrating steelhead smolts use the lower reaches of the Sacramento River and the Delta primarily as a migration corridor to the ocean. There is little evidence that they rear in the Delta or on floodplains, though there are few behavioral studies of this life-stage in the CV.

6. Ocean Behavior

Unlike Pacific salmon, steelhead do not appear to form schools in the ocean (Behnke 1992). Steelhead in the southern part of their range appear to migrate close to the continental shelf, while more northern populations may migrate throughout the northern Pacific Ocean (Barnhart 1986).

7. Adult Run-Timing and Spawning Habitat

CCV steelhead generally leave the ocean from August through April (Busby *et al.* 1996), enter freshwater from August to November with a peak in September (Hallock 1961), and spawn from

December to April, with a peak in January through March, in rivers and streams where cold, well oxygenated water is available (Table 8; Williams 2006; Hallock *et al.* 1961; McEwan and Jackson 1996). Timing of upstream migration is correlated with higher flow events, such as freshets, and the associated change in water temperatures (Workman *et al.* 2002). Adults typically spend a few months in freshwater before spawning (Williams 2006). Female steelhead construct redds in suitable gravel and cobble substrate, primarily in pool tailouts and heads of riffles.

8. Fecundity

The number of eggs laid per female is highly correlated with adult size, though the strain of the fish can also play a role. Adult steelhead size depends on the duration of and growth rate during their ocean residency (Meehan and Bjornn 1991). CCV steelhead generally return to freshwater after one to two years at sea (Hallock *et al.* 1961), and adults typically range in size from two to twelve pounds (Reynolds *et al.* 1993). Steelhead about 55 cm long may have fewer than 2,000 eggs, whereas steelhead 85 cm long can have 5,000 to 10,000 eggs, depending on the stock (Meehan and Bjornn 1991). The average for Coleman National Fish Hatchery (CNFH) since 1999 is about 3,900 eggs per female (USFWS 2011).

9. Iteroparity

Unlike Pacific salmon, steelhead are iteroparous, meaning they are capable of spawning multiple times before death (Busby *et al.* 1996). However, it is rare for steelhead to spawn more than twice before dying; and repeat spawners tend to be biased towards females (Busby *et al.* 1996). Iteroparity is more common among southern steelhead populations than northern populations (Busby *et al.* 1996). Although one-time spawners are the great majority, Shapovalov and Taft (1954) reported that repeat spawners were relatively numerous (17.2 percent) in Waddell Creek. Null *et al.* (2013) found between 36 percent and 48 percent of kelts released from CNFH in 2005 and 2006 survived to spawn the following spring, which is in sharp contrast to what Hallock (1989) reported for CNFH in the 1971 season, where only 1.1 percent of adults were fish that had been tagged the previous year. Most populations have never been studied to determine the percentage of repeat spawners. Hatchery steelhead are typically less likely than wild fish to survive to spawn a second time (Leider *et al.* 1986).

10. Kelts

Post-spawning steelhead (kelts) may migrate downstream to the ocean immediately after spawning, or they may spend several weeks holding in pools before outmigrating (Shapovalov and Taft 1954). Recent studies have shown that kelts may remain in freshwater for an entire year after spawning (Teo *et al.* 2011), but that most return to the ocean (Null *et al.* 2013).

11. Population Dynamics

Historic CCV steelhead run sizes are difficult to estimate given the paucity of data, but may have approached one to two million adults annually (McEwan 2001). By the early 1960s the steelhead run size had declined to about 40,000 adults (McEwan 2001). Hallock *et al.* (1961) estimated an average of 20,540 adult steelhead through the 1960s in the Sacramento River upstream of the Feather River. Steelhead counts at the RBDD declined from an average of 11,187 for the period from 1967 to 1977, to an average of approximately 2,000 through the early 1990's, with an estimated total annual run size for the entire Sacramento-San Joaquin system, based on RBDD counts, to be no more than 10,000 adults (McEwan and Jackson 1996, McEwan 2001). Steelhead escapement surveys at RBDD ended in 1993 due to changes in dam operations.

About 80 percent of the historical spawning and rearing habitat once used by anadromous *O. mykiss* in the CV is now upstream of impassable dams (Lindley *et al.* 2006). The extent of habitat loss for steelhead most likely was much higher than that for salmon because steelhead were undoubtedly more extensively distributed. Due to their superior jumping ability, the timing of their upstream migration which coincided with the winter rainy season, and their less restrictive preferences for spawning gravels, steelhead could have utilized at least hundreds of miles of smaller tributaries not accessible to the earlier-spawning salmon (Yoshiyama *et al.* 1996). Steelhead were found as far south as the Kings River (and possibly Kern river systems in wet years) (McEwan 2001). Native American groups such as the Chunut people have had accounts of steelhead in the Tulare Basin (Latta 1977).

Nobriga and Cadrett (2003) compared CWT and untagged (wild) steelhead smolt catch ratios at Chipps Island trawl from 1998 through 2001 to estimate that about 100,000 to 300,000 steelhead smolts are produced naturally each year in the CV. Good *et al.* (2005) made the following conclusion based on the Chipps Island data:

> *"If we make the fairly generous assumptions (in the sense of generating large estimates of spawners) that average fecundity is 5,000 eggs per female, 1 percent of eggs survive to reach Chipps Island, and 181,000 smolts are produced (the 1998-2000 average), about 3,628 female steelhead spawn naturally in the entire CV. This can be compared with McEwan's (2001) estimate of 1 million to 2 million spawners before 1850, and 40,000 spawners in the 1960s."*

Existing naturally produced steelhead stocks in the CV are mostly confined to the upper Sacramento River and its tributaries, including Antelope, Deer, and Mill creeks and the Yuba River. Populations may exist in Big Chico and Butte creeks and a few wild steelhead are produced in the American and Feather rivers (McEwan and Jackson 1996). Clear Creek steelhead spawner abundance has not been estimated.

Until recently, CCV steelhead were thought to be extirpated from the San Joaquin River system. Monitoring has detected small numbers of steelhead in the Stanislaus, Mokelumne, and Calaveras rivers, and other streams previously thought to be devoid of steelhead (McEwan 2001). On the Stanislaus River, steelhead smolts have been captured in rotary screw traps at Caswell State Park and Oakdale each year since 1995. A counting weir has been in place in the Stanislaus River since 2002 and in the Tuolumne River since 2009 to detect adult salmon, and have also detected *O. mykiss* passage. In 2012, 15 adult *O. mykiss* were detected passing the Tuolumne River weir and 82 adult *O. mykiss* were detected at the Stanislaus River weir (FishBio 2012a,b). In addition, rotary screw trap sampling has occurred since 1995 in the Tuolumne River, but only one juvenile *O. mykiss* was caught during the 2012 season (FishBio 2012b).

Rotary screw traps are well known to be very inefficient at catching steelhead smolts, so the actual numbers of smolts could be much higher. Rotary screw trapping on the Merced River has occurred since 1999. A fish counting weir was installed on this river in 2012. Since installation, one adult *O. mykiss* has been reported passing the weir. Juvenile *O. mykiss* were not reported captured in the rotary screw traps on the Merced River until 2012, when a total of 381 were caught (FishBio 2013). The unusually high number of *O. mykiss* captured may be attributed to a flashy storm event that rapidly increased flows over a 24 hour period. Zimmerman *et al.* (2009) has documented CCV steelhead in the Stanislaus, Tuolumne, and Merced rivers based on otolith microchemistry.

CDFW conducts annual Kodiak trawl sampling on the San Joaquin River near Mossdale. Based on these catches, as well as rotary screw trap efforts in all three tributaries, Marston (2004) stated that it is “clear from this data that *O. mykiss* do occur in all the tributaries as migrants and that the vast majority of them occur on the Stanislaus River.” Mossdale Kodiak trawl catches continue to occur and are still being conducted by CDFW. The low adult returns to these tributaries and the low numbers of juvenile emigrants captured suggest that existing populations of CCV steelhead on the Tuolumne, Merced, and lower San Joaquin rivers are severely depressed. The loss of these populations would severely impact CCV steelhead spatial structure and further challenge the viability of the CCV steelhead DPS.

In the Mokelumne River, East Bay Municipal Utilities District has included steelhead in their redd surveys on the Lower Mokelumne River since the 1999-2000 spawning season (NMFS 2011a). Based on data from these surveys, the overall trend suggests that redd numbers have slightly increased over the years (2000-2010). However, according to Satterthwaite *et al.* (2010), it is likely that most of the *O. mykiss* spawning in the Mokelumne River are non-anadromous (or resident) fish rather than steelhead. The Mokelumne River steelhead population is supplemented by Mokelumne River Hatchery production. In the past, this hatchery received fish imported from the Feather River and Nimbus hatcheries (Merz 2002). However, this practice was discontinued 11 years ago for Nimbus stock, and 3 years ago for Feather River stock. Recent results show that the Mokelumne River Hatchery steelhead are closely related to Feather River fish, suggesting that there has been little carry-over of genes from the Nimbus stock.

Although there have been recent restoration efforts in the San Joaquin River tributaries, CCV steelhead populations in the San Joaquin Basin continue to show a decline, an overall low abundance, and fluctuating return rates. Lindley *et al.* (2007) developed viability criteria for CV salmonids. Using data through 2005, Lindley *et al.* (2007) found that data were insufficient to determine the status of any of the naturally-spawning populations of CCV steelhead, except for those spawning in rivers adjacent to hatcheries, which were likely to be at high risk of extinction due to extensive spawning of hatchery-origin fish in natural areas.

The most recent status review of the CCV steelhead DPS (NMFS 2011a) found that the status of the population appears to have worsened since the 2005 status review (Good *et al.* 2005), when it was considered to be in danger of extinction. Analysis of data from the Chipps Island monitoring program indicates that natural steelhead production has continued to decline and that hatchery origin fish represent an increasing fraction of the juvenile production in the CV. Since 1998, all hatchery produced steelhead in the CV have been adipose fin clipped (ad-clipped). Since that time, the trawl data indicates that the proportion of ad-clip steelhead juveniles captured in the Chipps Island monitoring trawls has increased relative to wild juveniles, indicating a decline in natural production of juvenile steelhead. In recent years, the proportion of hatchery produced juvenile steelhead in the catch has exceeded 90 percent and in 2010 was 95 percent of the catch. Because hatchery releases have been fairly consistent through the years, this data suggests that the natural production of steelhead has been declining in the CV.

Salvage of juvenile steelhead at the CVP and SWP fish collection facilities has also shown a shift towards reduced natural production. In the past decade, there has been a decline in the percentage of salvaged juvenile steelhead that are naturally produced from 55 percent in 1998 down to 22 percent in 2010 (NMFS 2011a).

In contrast to the data from Chipps Island and the CVP and SWP fish collection facilities, some populations of wild CCV steelhead appear to be improving (Clear Creek) while others (Battle Creek) appear to be better able to tolerate the recent poor ocean conditions and dry hydrology in the CV compared to hatchery produced fish (NMFS 2011a). Since 2003, fish returning to the CNFH have been identified as wild (adipose fin intact) or hatchery produced (Ad-clipped). Returns of wild fish to the hatchery have remained fairly steady at 200-300 fish per year, but represent a small fraction of the overall hatchery returns. Numbers of hatchery origin fish returning to the hatchery have fluctuated much more widely; ranging from 624 to 2,968 fish per year. The returns of wild fish remained steady, even during the recent poor ocean conditions and the 3-year drought in the CV, while hatchery produced fish showed a decline in the numbers returning to the hatchery (NMFS 2011a). Furthermore, the continuing widespread distribution of wild steelhead in the CV provides the spatial distribution necessary for the DPS to survive and avoid localized catastrophes. However, these populations are frequently very small, and lack the resiliency to persist for protracted periods if subjected to additional stressors, particularly widespread stressors such as climate change (NMFS 2011a).

Description of VSP Parameters

1. Abundance

All indications are that natural CCV steelhead have continued to decrease in abundance and in the proportion of natural fish over the past 25 years (Good *et al.* 2005; NMFS 2011a); the long-term trend remains negative. Comprehensive steelhead population monitoring has not taken place in the CV, despite 100 percent marking of hatchery steelhead since 1998. Efforts are underway to improve this deficiency, and a long term adult escapement monitoring plan is being considered (Eilers *et al.* 2010). Hatchery production and returns are dominant over natural fish and include significant numbers of non-DPS-origin Eel/Mad River steelhead stock. Continued decline in the ratio between naturally produced juvenile steelhead to hatchery juvenile steelhead in fish monitoring efforts indicates that the wild population abundance is declining. Hatchery releases (100 percent adipose fin clipped fish since 1998) have remained relatively constant over the past decade, yet the proportion of adipose fin-clipped hatchery smolts to unclipped naturally produced smolts has steadily increased over the past several years.

2. Productivity

An estimated 100,000 to 300,000 naturally produced juvenile steelhead are estimated to leave the CV annually, based on rough calculations from sporadic catches in trawl gear (Good *et al.* 2005). The Mossdale trawls on the San Joaquin River conducted annually by CDFW and USFWS capture steelhead smolts, although usually in very small numbers. These steelhead recoveries which represent migrants from the Stanislaus, Tuolumne, and Merced rivers suggest that existing populations of CCV steelhead on these tributaries are severely depressed. In addition, the Chipps Island midwater trawl dataset from the USFWS provides information on the trend (Williams *et al.* 2011).

3. Spatial Structure

Steelhead appear to be well-distributed throughout the CV (Good *et al.* 2005; NMFS 2011a). In the San Joaquin River Basin, steelhead have been confirmed in all of the tributaries: Mokelumne, Calaveras, Stanislaus, Tuolumne, and Merced rivers. Zimmerman *et al.* (2009) used otolith microchemistry to show that *O. mykiss* of anadromous parentage occur in all three major San Joaquin River tributaries, but at low levels, and that these tributaries have a higher percentage of resident *O. mykiss* compared to the Sacramento River and its tributaries. The efforts to provide passage of salmonids over impassable dams may increase the spatial diversity of CCV steelhead populations if the passage programs are implemented for steelhead. In addition, the San Joaquin River Restoration Program (SJRRP) calls for a combination of channel and structural modifications along the San Joaquin River downstream of Friant Dam, releases of water from Friant Dam to the confluence of the Merced River, and the reintroduction of spring-run and fall-run Chinook salmon. If the SJRRP is successful, habitat improved for spring-run Chinook salmon could also benefit CCV steelhead (NMFS 2011a).

4. Diversity

CCV steelhead abundance and growth rate continue to decline, largely the result of a significant reduction in the diversity of habitats available to CCV steelhead (Lindley *et al.* 2006). Recent reductions in population size are also supported by genetic analysis (Nielsen *et al.* 2003). Garza and Pearse (2008) analyzed the genetic relationships among CCV steelhead populations and found that unlike the situation in coastal California watersheds, fish downstream of barriers in the CV were more closely related to downstream of barrier fish from other watersheds than to *O. mykiss* upstream of barriers in the same watershed. This pattern suggests the ancestral genetic structure is still relatively intact upstream of barriers, but may have been altered below barriers by stock transfers. The genetic diversity of CCV steelhead is also compromised by hatchery origin fish, which likely comprise the majority of the spawning run, placing the natural population at a high risk of extinction (Lindley *et al.* 2007). There are four hatcheries (CNFH, FRFH, Nimbus Fish Hatchery, and Mokelumne River Fish Hatchery) in the CV which combined release approximately 600,000 yearling steelhead smolts each year. These programs are intended to compensate for the loss of steelhead habitat caused by dam construction, but hatchery origin fish now appear to constitute a major proportion of the total abundance in the DPS. Two of these hatchery stocks (Nimbus and Mokelumne River hatcheries) originated from outside the DPS (from the Eel and Mad rivers) and are not presently considered part of the DPS.

Summary of CCV Steelhead DPS Viability

All indications are that natural CCV steelhead have continued to decrease in abundance over the past 25 years (Good et al. 2005; NMFS 2011a). The long-term trend remains negative. Hatchery production and returns are dominant over natural fish. Continued decline in the ratio between naturally produced juvenile steelhead to hatchery juvenile steelhead in fish monitoring efforts indicates that the wild population abundance is declining. Hatchery releases (100 percent adipose fin clipped fish since 1998) have remained relatively constant over the past decade, yet the proportion of adipose fin-clipped hatchery smolts to unclipped naturally produced smolts has steadily increased over the past several years.

Although there have been recent restoration efforts in the San Joaquin River tributaries, CCV steelhead populations in the San Joaquin Basin continue to show a decline, an overall low abundance, and fluctuating return rates. Lindley et al. (2007) developed viability criteria for CV salmonids. Using data through 2005, Lindley et al. (2007) found that data were insufficient to determine the status of any of the naturally-spawning populations of CCV steelhead, except for those spawning in rivers adjacent to hatcheries, which were likely to be at high risk of extinction due to extensive spawning of hatchery-origin fish in natural areas.

The widespread distribution of wild steelhead in the CV provides the spatial distribution necessary for the DPS to survive and avoid localized catastrophes. However, these populations are frequently very small, and lack the resiliency to persist for protracted periods if subjected to additional stressors, particularly widespread stressors such as climate change (NMFS 2011a). The most recent status review of the CCV steelhead DPS (NMFS 2011a) found that the status of the population appears to have worsened since the 2005 status review (Good et al. 2005), when it was considered to be in danger of extinction.

Critical Habitat and Primary Constituent Elements for CCV Steelhead

Critical habitat was designated for CCV steelhead on September 2, 2005 (70 FR 52488). Critical habitat for CCV steelhead includes stream reaches such as those of the Sacramento, Feather, and Yuba Rivers, and Deer, Mill, Battle, and Antelope creeks in the Sacramento River basin; the San Joaquin River, including its tributaries, and the waterways of the Delta. Critical habitat includes the stream channels in the designated stream reaches and the lateral extent as defined by the ordinary high-water line. In areas where the ordinary high-water line has not been defined, the lateral extent will be defined by the bankfull elevation (defined as the level at which water begins to leave the channel and move into the floodplain; it is reached at a discharge that generally has a recurrence interval of 1 to 2 years on the annual flood series) (Bain and Stevenson 1999; 70 FR

52488). Critical habitat for CCV steelhead is defined as specific areas that contain the PCE and physical habitat elements essential to the conservation of the species. Following are the inland habitat types used as PCEs for CCV steelhead. PCEs for CCV steelhead include:

1. Freshwater Spawning Habitat

Freshwater spawning sites are those with water quantity and quality conditions and substrate supporting spawning, incubation, and larval development. Most of the available spawning habitat for steelhead in the CV is located in areas directly downstream of dams due to inaccessibility to historical spawning areas upstream and the fact that dams are typically built at high gradient locations. These reaches are often impacted by the upstream impoundments, particularly over the summer months, when high temperatures can have adverse effects upon salmonids spawning and rearing downstream of the dams. Even in degraded reaches, spawning habitat has a high conservation value as its function directly affects the spawning success and reproductive potential of listed salmonids.

2. Freshwater Rearing Habitat

Freshwater rearing sites are those with water quantity and floodplain connectivity to form and maintain physical habitat conditions and support juvenile growth and survival; water quality and forage supporting juvenile development; and natural cover such as shade, submerged and overhanging LWM, log jams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks. Both spawning areas and migratory corridors comprise rearing habitat for juveniles, which feed and grow before and during their outmigration. Non-natal, intermittent tributaries also may be used for juvenile rearing. Rearing habitat condition is strongly affected by habitat complexity, food supply, and the presence of predators of juvenile salmonids. Some complex, productive habitats with floodplains remain in the system (*e.g.*, the lower Cosumnes River, Sacramento River reaches with setback levees [*i.e.*, primarily located upstream of the City of Colusa]) and flood bypasses (*i.e.*, Yolo and Sutter bypasses). However, the channelized, leveed, and riprapped river reaches and sloughs that are common in the Sacramento-San Joaquin system typically have low habitat complexity, low abundance of food organisms, and offer little protection from either fish or avian predators. Freshwater rearing habitat also has a high conservation value even if the current conditions are significantly degraded from their natural state. Juvenile life stages of salmonids are dependent on the function of this habitat for successful survival and recruitment.

3. Freshwater Migration Corridors

Ideal freshwater migration corridors are free of migratory obstructions, with water quantity and quality conditions that enhance migratory movements. They contain natural cover such as riparian canopy structure, submerged and overhanging large woody objects, aquatic vegetation, large rocks, and boulders, side channels, and undercut banks which augment juvenile and adult mobility, survival, and food supply. Migratory corridors are downstream of the spawning areas and include the lower mainstems of the Sacramento and San Joaquin rivers and the Delta. These corridors allow the upstream and downstream passage of adults, and the emigration of smolts. Migratory habitat condition is strongly affected by the presence of barriers, which can include dams (*i.e.*, hydropower, flood control, and irrigation flashboard dams), unscreened or poorly screened diversions, degraded water quality, or behavioral impediments to migration. For successful survival and recruitment of salmonids, freshwater migration corridors must function sufficiently to provide adequate passage. For this reason, freshwater migration corridors are considered to have a high conservation value even if the migration corridors are significantly degraded compared to their natural state.

4. Estuarine Areas

Estuarine areas free of migratory obstructions with water quality, water quantity, and salinity conditions supporting juvenile and adult physiological transitions between fresh and salt water are included as a PCE. Natural cover such as submerged and overhanging LWM, aquatic vegetation, and side channels, are suitable for juvenile and adult foraging. Estuarine areas are considered to have a high conservation value as they provide factors which function to provide predator avoidance and as a transitional zone to the ocean environment.

2.2.4 Southern DPS of North American Green Sturgeon

The following section entails the status of the species for the Southern distinct population segment of SDPS green sturgeon (sDPS green sturgeon). This section establishes the life history and viability for sDPS green sturgeon, and discusses their critical habitat. The critical habitat analysis is approached by examining the PCEs of that critical habitat, and this analysis considers separately freshwater and estuarine environments. Throughout this analysis of life history, viability, and critical habitat, the focus is upon the CV of California. Therefore, not all aspects of sDPS green sturgeon are presented; for example, the PCEs for the critical habitat in the marine environment are not included.

1. Listed as threatened on June 6, 2006 (71 FR 17757)
2. Critical habitat designated October 9, 2009 (74 FR 52300)

Life History

Our understanding of the biology of the sDPS of green sturgeon is evolving. In areas where information is lacking, inferences are sometimes made from what is known about the Northern distinct population segment (nDPS) green sturgeon and, to a lesser extent, from other sturgeon species, especially the sympatric white sturgeon (*Acipenser transmontanus*). Green sturgeon are long lived, iteroperous, anadromous fish. They may live up to 60-70 years; green sturgeon captured in Oregon have been age-estimated using a fin-spine analysis up to 52 years (Farr and Kern 2005). The green sturgeon sDPS includes those that spawn south of the Eel River. Until recently, it was believed that the green sturgeon sDPS was composed of a single spawning population on the Sacramento River. However, recent research conducted by DWR has revealed spawning activity in the Feather River (Seesholtz, A. M., M. J. Manuel, and J. P. Van Eenennaam). 2015. First documented spawning and associated habitat conditions for green sturgeon in the Feather River, California. Environmental Biology of Fishes 98:905-912. Additionally, there is some evidence of spawning in the Yuba River downstream of Daguerre Point Dam (Cramer Fish Sciences 2013).

Laboratory studies have provided some important information about about larval sturgeon diet and habitat use. Green sturgeon larvae hatch from fertilized eggs after approximately 169 hours at a water temperature of 15º C (59º F) (Van Eenennaam *et al.* 2001, Deng *et al.* 2002). Studies conducted at the University of California, Davis by Van Eenennaam *et al.* (2005) using nDPS juveniles indicated that an optimum range of water temperature for egg development ranged between 14º C (57.2ºF) and 17º C (62.6ºF). Temperatures over 23 ºC (73.4ºF) resulted in 100 percent mortality of fertilized eggs before hatching. Eggs incubated at water temperatures between 17.5º C (63.5ºF) and 22º C (71.6ºF) resulted in elevated mortalities and an increased occurrence of morphological abnormalities in those eggs that did hatch. At incubation temperatures below 14º C (57.2ºF), hatching mortality also increased significantly, and morphological abnormalities increased slightly, but not statistically so (Van Eenennaam *et al.* 2005).

Young green sturgeon appear to rear for the first one to two months in the Sacramento River between Keswick Dam and Hamilton City (CDFG 2002). Juvenile green sturgeon first appear in USFWS sampling efforts at RBDD in June and July at lengths ranging from 24 to 31 mm fork length, indicating they are approximately two weeks old (CDFG 2002, USFWS 2002). Growth is rapid as juveniles reach up to 300 mm the first year and over 600 mm in the first 2 to 3 years (Nakamoto *et al.* 1995). Juvenile green sturgeon have been salvaged at the Federal and State pumping facilities (which are located in the southern region of the Delta), and sampled in trawling studies by the CDFW during all months of the year (CDFG 2002). The majority of these fish that were captured in the Delta were between 200 and 500 mm indicating they were from 2 to 3 years of age, based on Klamath River age distribution work by Nakamoto *et al.* (1995). The lack of a significant proportion of juveniles smaller than approximately 200 mm in Delta captures indicates juvenile sDPS green sturgeon likely hold in the mainstem Sacramento River for up to 10 months, as suggested by Kynard *et al.* (2005). Both nDPS and sDPS green sturgeon juveniles tested under laboratory conditions, with either full or reduced rations, had optimal bioenergetic performance (*i.e.,* growth, food conversion, swimming ability) between 15ºC (59º F) and 19º C (66.2º F), thus providing a temperature related habitat target for conservation of this rare species (Mayfield and Cech 2004). This temperature range overlaps the egg incubation temperature range for peak hatching success previously discussed.

Radtke (1966) inspected the stomach contents of juvenile green sturgeon in the Delta and found food items to include a mysid shrimp (*Neomysis awatschensis),* amphipods (*Corophium* spp.*)*, and other unidentified shrimp. No additional information is available regarding the diet of sDPS green sturgeon in the wild, but they are presumed to be generalist, opportunistic benthic feeders.

There is a fair amount of variability (1.5 – 4 years) in the estimates of the time spent by juvenile green sturgeon in freshwater before making their first migration to sea. Nakamoto *et al.* (1995) found that nDPS green sturgeon on the Klamath River migrated to sea, on average by age three and no later than by age four. Moyle (2002) suggests juveniles migrate out to sea before the end of their second year, and perhaps as yearlings. Laboratory experiments indicate that both nDPS and sDPS green sturgeon juveniles may occupy fresh to brackish water at any age, but they are physiologically able to completely transition to saltwater at around 1.5 years in age (Allen and Cech 2007). In studying nDPS green sturgeon on the Klamath River, Allen *et al.* (2009) devised a technique to estimate the timing of transition from fresh water to brackish water to seawater by taking a bone sample from the leading edge of the pectoral fin and anlyzing the ratios of stontium and barium to calcium. The results of this study indicate that green sturgeon move from freshwater to brackish water (such as the estuary) at ages 0.5–1.5 years and then move into seawater at ages 2.5-3.5 years. Table 9 shows the migration timing of various life stages throughout the CV, Delta, San Francisco Bay, and into the Pacific Ocean.

In the summer months, multiple rivers and estuaries throughout the sDPS range are visited by dense aggregations of green sturgeon (Moser and Lindley 2007, Lindley *et al.* 2011). Capture of green sturgeon as well as tag detections in tagging studies have shown that green sturgeon are present in San Pablo Bay and San Francisco Bay at all months of the year (Kelly *et al.* 2007, Heublein *et al.* 2009, Lindley *et al.* 2011). An increasing amount of information is becoming available regarding green sturgeon habitat use in estuaries and coastal ocean, and why they aggregate episodically (Lindley *et al.* 2008, Lindley *et al.* 2011). Genetic studies on green sturgeon stocks indicate that almost all of the green sturgeon in the San Francisco Bay ecosystem belong to the sDPS (Israel and Klimley 2008).

Green sturgeon do not mature until they are at least 15–17 years of age (Beamesderfer *et al.* 2007). Therefore, it would not be expected that a green sturgeon returning to freshwater would be younger than this. However, once mature, green sturgeon appear to make spawning runs once every few years. Erickson and Hightower (2007) found that nDPS green sturgeon returned to the Rogue River 2–4 years after leaving; it is presumed that sDPS green sturgeon display similar behavior and return to the Sacramento River or Feather River system to spawn every 2–5 years. Adult sDPS green sturgeon begin their upstream spawning migrations into freshwater as early as late February with spawning occuring between March and July (CDFG 2002, Heublein 2006, Heublein *et al.* 2009, Vogel 2008). Peak spawning is believed to occur between April and June in deep, turbulent, mainstem channels over large cobble and rocky substrates featuring crevices and interstices (Van Eenennaam *et al.* 2001). Poytress *et al.* (2012) conducted spawning site and larval sampling in the upper Sacramento River from 2008–2012 and has identified a number of confirmed spawning locations (Figure 6). Green sturgeon fecundity is approximately 50,000 to 80,000 eggs per adult female (Van Eenennaam *et al.* 2001). They have the largest egg size of any sturgeon. The outside of the eggs are mildly adhesive, and are more dense than than those of white sturgeon (Kynard *et al.* 2005, Van Eenennaam *et al.* 2009).

Post spawning, green sturgeon may exhibit a variety of behaviors. Ultimately they will return to the ocean, but how long they take to do this and what they do along the way are open questions. Illustrating the spectrum of behavioral choices, Benson *et al.* (2007) conducted a study in which 49 nDPS green sturgeon were tagged with radio and/or sonic telemetry tags and tracked manually or with receiver arrays from 2002 to 2004. Tagged individuals exhibited four movement patterns: upstream spawning migration, spring outmigration to the ocean, or summer holding, and outmigration after summer holding.

Threats and Stressors

Green sturgeon are long lived, and thus face environmental and anthropocentric stressors that may affect the probability that they reach reproductive maturity. Males are observed to reproduce as early as 14 years old, while females grow older prior to maturing as early as 16 years old (Van Eenennaam et al. 2005). Both males and females occupy all types of aquatic environments- freshwater, estuarine, and marine. Numerous environmental factors potentially limit green sturgeon survival during the earliest stages of their life cycle while in freshwater. This period is called the "critical age" in fishes due to its relevance in survival and recruitment of individuals into the adult population (Hardy and Litvak 2004). Recruitment failure of the earliest life history stages may be a significant bottleneck for other North American acipenserids such as Pallid sturgeon and the white sturgeon in Upper Columbia and Kootenai rivers, the populations of which have numerous reproductive adults, but few recently surviving wild juveniles (Duke et al. 1999, Hildebrand et al. 1999, Korman and Walters 2001) .

There are many potential limiting factors during this early life period. They are the following: 1) warm water temperatures, 2) insufficient flows, 3) decreased dissolved oxygen, 4) lack of rearing habitat, and 5) increased predation. Water is released from Shasta Dam to maintain daily temperatures below 18º C downstream to a temperature compliance point, which in 2007 was maintained at Jellys Ferry and Balls Ferry to facilitate the incubation of eggs of spawning winter-run Chinook. This maintenance of cool water temperatures benefits green sturgeon spawning upstream of Red Bluff Diversion Dam. Temperature records from acoustic telemetry receivers along the mainstem have not been analyzed, but may provide data for assessing whether temperatures are limiting survival of embryos, larvae or juveniles downstream of RBDD. Once larvae grow into juveniles, their survival may be limited by lack of habitat, insufficient food, and possibly contaminants. Juveniles are fairly tolerant of variable temperature and dissolved oxygen, and are likely mobile enough to select favorable habitats (see Ecology sections). It is possible that juveniles can also be entrained in water diversions for farmland irrigation, although their benthic behavior likely limits this impact, and this is not well understood.

The members of the older age classes principally face anthropocentric threats to their survival in estuarine and marine environments. Once within the estuary, juveniles might accumulate pollutants such as methyl-mercury and pyrethroids, whose uptake is enhanced by the benthic feeding orientation of green sturgeon. Pyrethroids also may limit the availability of prey for young green sturgeon due to their effect of very low dosages on zooplankton and bottom-dwelling organisms. The size of the populations of subadults and adults have been potentially limited by human fisheries and barriers to spawning areas which may prevent them from racing the most optimal spawning habitats. Harvest can cause abrupt declines in green sturgeon adult abundance. Even an amount as small as 10% additional mortality over the green sturgeon's life-span can reduce population abundance by 50% and adult abundance by 90% (Beamesderfer et al. 2007). An additional simulated increase in mortality of 20% over natural mortality resulted in no green sturgeon surviving to adulthood. These forms of mortality could include human and nonhuman sources of direct mortality, and are not well quantified for the Southern DPS. Of greater concern, might be even much smaller additional mortality rates' influence on green sturgeon's reproductive potential. Additional rates of only 2-3% annual mortality over green sturgeon's life cycle reduced egg production to levels making sturgeon stocks extremely susceptible to overfishing (Beamesderfer et al. 2007).

Modification of the riverscape has resulted in loss of spawning habitat, rearing habitat, and increased barriers to migration. Larvae, juveniles, and adults life history stages are all benthic in orientation and all require deep habitats for dispersal, holding, and spawning. Successful fertilization and survival of embryos seems to require spawning habitats reflecting specific water quality and quantity parameters, which have been negatively impacted by construction of dams and channelization of the river. Riparian habitats provide allochthonous contributions to the river food web that indirectly support juvenile prey items. It is possible that modifications in temperature regime controlled by the Shasta Dam temperature control device may benefit green sturgeon spawning above Red Bluff Diversion Dam, but more research is necessary to understand the impacts of temperature on the distribution and success of green sturgeon spawning.

Channelization of the estuary has likely negative impacted the amount of subtidal and intertidal habitat available for green sturgeon foraging. These habitats have been lost along San Pablo and Suisun bays, where subadult and adult green sturgeon are commonly found. These estuarine habitats are likely important for growth during the juvenile, coastal migrant, and adults life stages. Invasive plant species in the estuary have likely impacted the quantity of shallow habitat available to coastal migrant and adult green sturgeon, and alterations of the food web due to invasive species have also likely shifted green sturgeon estuarine diet.

Future Research

One conclusion of the NMFS BRT assessing the status of green sturgeon was that “it is essential that immediate efforts be undertaken to implement population monitoring for the DPS using methods that directly assess population status” (NMFS 2005). Although laboratory studies have yielded much information on the physiological needs of the species, field studies have yet to be completed applying this information to identifying adult spawning, larval survival, juvenile rearing, and juvenile smoltification. Information is necessary about the life history diversity, abundance, population growth rate, foraging behavior and temporal presence of Sacramento River green sturgeon.

Managers should develop research and monitoring to estimate the riverine larval and juvenile populations for a period of time reflecting the potential variation in physical and biological processes influencing recruitment. These results will give managers an idea for the effect of management on critical habitats, influence of adult demography on recruitment dynamics, and the actual production of green sturgeon in younger cohorts. Estimates derived from these types of studies may be a good indication for spawning and abundance, which are not negatively influenced by the impact of entrainment, operations, and harvest. If estimates of young riverine fish are known, then adaptive research evaluating the impacts of anthropocentric stressors on older life history stages will allow managers to assess the actual effects of these anthropocentric stressors. Currently, abundance derived from harvest or operational entrainment data does not allow managers to determine if these impacts are causing declines in abundance or just reflect the natural production of spawning adults.

The distribution of spawning adults as well as a characterization of their spawning habitat within the Sacramento River should be completed. This will provide insight into the density of spawning adults and influence spawning aggregation have to the juvenile population, the rates of egg and larval mortality, and the potential loss of this spawning habitat by flow and temperature modification in the system. In 2008, UCD, BOR, and FWS initiated tracking green sturgeon as they move within the upper mainstem and collected eggs at spawning sites. Additional funding is necessary to adequately monitor spawning movements and increased egg and larval collection sites along the Sacramento riverscape to evaluate green sturgeon habitat relationships.

Little is known about green sturgeon food selection and foraging behavior making the predictability of where preferred food is available low. As green sturgeon move into lower riverine reaches, the estuary and marine environments, food resources are not well understood (Israel and Klimley 2008). If native food sources have declined due to invasive species occupying their habitat or pollutants reducing available food, finding sufficient food may be problematic for juvenile green sturgeon. There is a need to investigate further the effects of selenium and other contaminants on green sturgeon and to find ways to reduce sources. Recent evidence indicates adult white sturgeon may be accumulating selenium in concentrations detrimental to reproduction, presumably by consuming the introduced overbite clam (Linville 2006).

Support should be provided for priority research guided by the Interagency Ecological Program Sturgeon Work Team. This conceptual model should indicate that much is already known about the basic biology of green sturgeon from laboratory studies and can serve as the basis for developing hypotheses for testing in field studies. The next research step should be to discern the importance of this biology on population viability within the watershed. A systematically applied research program attempting to study the critical periods and habitats of green sturgeon in riverine and estuarine environments will provide managers with information on the actual utilization, status, and abundance of different life history stages of green sturgeon in the Sacramento River. Once these field observations are completed, our larger and more comprehensive understanding for the basic ecology of the species will permit the development of a population viability model, which could prioritize the above-mentioned risks to the population and guide management decisions (Israel and Klimley 2008).

Description of Viability Parameters for sDPS Green Sturgeon

As an approach to determining the conservation status of salmonids, NMFS has developed a framework for identifying attributes of a VSP. The intent of this framework is to provide parties with the ability to assess the effects of management and conservation actions and ensure their actions promote the listed species' survival and recovery. This framework is known as the VSP concept (McElhany *et al.* 2000). The VSP concept measures population performance in term of four key parameters: abundance, population growth rate, spatial structure, and diversity. Although the VSP concept was developed for Pacific salmonids, the underlying parameters are general principles of conservation biology and can therefore be applied more broadly; here we adopt the VSP concept for sDPS green sturgeon.

1. Abundance

Abundance is one of the most basic principles of conservation biology, and from this measurement other parameters can be related. In applying the VSP concept, abundance is examined at the population level, and therefore population size is perhaps a more appropriate term. Population estimates of the green sturgeon sDPS are in development. A decrease in sDPS green sturgeon abundance has been inferred from the amount of take observed at the south Delta pumping facilities; the Skinner Delta Fish Protection Facility (SDFPF) and the Tracy Fish Collection Facility (TFCF) (Figure 7). There are, however, uncertainties with the data in figure 7. Adams et al. (2007) describe that while the numbers of green sturgeon still were higher in the pre 1986 period, it appears that the expansion procedure exaggerated that difference. These entrainment estimates suffer from problems of species identification (green sturgeon were not identified until 1981 at the federal facility), and the estimates are expanded catches from brief sampling periods.

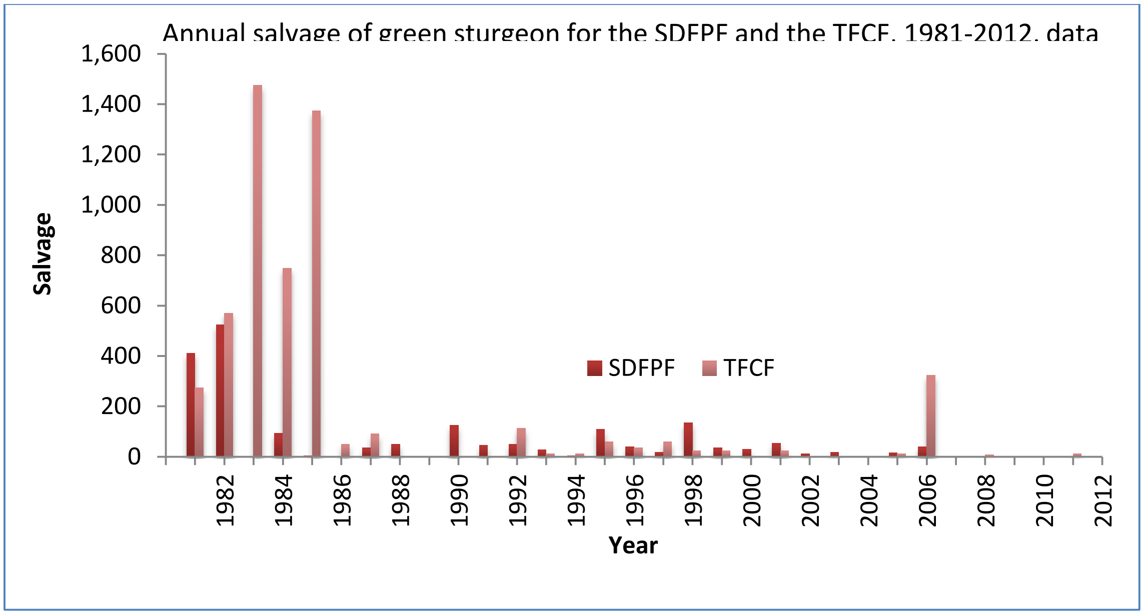

Figure 7. Annual salvage of green sturgeon for the SDFPF and the TFCF from 1981 to 2012. Data source: ftp://ftp.delta.dfg.ca.gov/salvage

Adult spawning population estimates in the upper Sacramento River (above RBDD*)*, using sibling based genetics, indicates 10-28 spawners contributed to juvenile production per year between 2002-2006 (Israel and May 2010). This is a minimum estimate of the effective adult spawning population because sampling was limited, may have preferentially selected for larvae spawning immediately above RBDD, and did not include animals spawning downstream of the RBDD. Fish monitoring efforts at RBDD and Glen Colusa Irrigation District (GCID) on the upper Sacramento River have captured anywhere between 0 and 2,068 juvenile green sturgeon per year, between 1986 and 2000 (Adams *et al.* 2002).

In determining the conservation status of sDPS green sturgeon, a few notes with regards to population size are crucial. Population(s) should be large enough to survive environmental variations, catastrophes, and anthropogenic perturbations. Also, the population(s) should be sufficiently large to maintain long term genetic diversity (McElhany *et al.* 2000). Our understanding of the status of sDPS green sturgeon towards these concerns is developing.

Because of their long life span, green sturgeon abundance is particularly sensitive to increased mortality. Even relatively small increases in annual mortality can substantially reduce adult abundance due to cumulative effects accruing over a number of years. Because of their delayed age of maturation, cumulative impacts may severely reduce the population's reproduction potential.

Beamesderfer *et al*. (2007) used the life table model to evaluate the sensitivity of the population to additional mortality rates when applied to different life stages. The analyses showed that low rates of additional mortality (2% to 5%), when applied across multiple life stages, can result in abrupt declines in green sturgeon population numbers and reproductive potential.

2. <u>Productivity</u>

For long-lived species such as sturgeon, abundance, age structure, and sex ratios are particularly powerful indicators of long-term productivity patterns. Viable sturgeon populations are characterized by a broad distribution of size classes and ages. In order for sDPS green sturgeon to rebound from being threatened to a viable status, its population growth rate will need to be positive until some equilibrium population size is reached, at which point the growth rate should stabilize.

Productivity and recruitment information for sDPS green sturgeon is an area that requires additional research; existing data is too limited to be presented as robust estimates. Incidental catches of larval green sturgeon in the mainstem Sacramento River and of juvenile green sturgeon at the south Delta pumping facilities suggest that green sturgeon are successful at spawning, but that annual year class strength may be highly variable (Beamesderfer *et al.* 2007, Lindley *et al.* 2007). In general, sturgeon year class strength appears to be episodic with overall abundance dependent upon a few successful spawning events (NMFS 2010). It is unclear if the population is able to consistently replace itself. This is significant because the VSP concept requires that a population meeting or exceeding the abundance criteria for viability should, on average, be able to replace itself (McElhany *et al*. 2000). More research is needed to establish green sturgeon sDPS productivity.

3. <u>Spatial Structure</u>

Green sturgeon, as a species, are known to range from Baja California to the Bering Sea along the North American continental shelf. During the late summer and early fall, subadults and nonspawning adult green sturgeon frequently can be found aggregating in estuaries along the Pacific coast (Emmett 1991, Moser and Lindley 2007). Based on genetic analyses and spawning site fidelity (Adams *et al.* 2002, Israel *et al.* 2004), green sturgeon are comprised of at least two DPSs.

1. A nDPS consisting of populations originating from coastal watersheds northward of and including the Eel River (*i.e.* Klamath, Rogue, and Umpqua rivers), and
2. A sDPS consisting of populations originating from coastal watersheds south of the Eel River.

Throughout much of their range, sDPS and nDPS green sturgeon are known to co-occur, especially in northern estuaries and over-wintering grounds. However, those green sturgeon that are found within the inland waters of the Central Valley, California are almost entirely sDPS green sturgeon (Israel and Klimley 2008).

Adams *et al.* (2007) summarizes information that suggests green sturgeon may have been distributed upstream of the locations of present-day dams on the Sacramento and Feather rivers. In the California CV, sDPS green sturgeon are known to range from the Delta to the Sacramento River up to Keswick Dam, the Feather River up to the fish barrier structure downstream of Oroville Dam, and the Yuba River up to Daguerre Point Dam. Additional habitat may have historically existed in the San Joaquin River basin. Anecdotal evidence from anglers suggest sDPS green sturgeon presence in the San Joaquin River. Since implementation of the Sturgeon Report Card in 2007, anglers have reported catching 177 white sturgeon and 7 green sturgeon on the San Joaquin River upstream from Stockton (Dubois, J., M. D. Harris, and J. Mauldin. 2014. 2013 Sturgeon Fishing Report Card: Preliminary Data Report. CDFW Bay Delta Region, Stockton, CA, May 8, 2014).

In applying the VSP concept to sDPS green sturgeon, it is important to look at the within-population spatial diversity. Ongoing research is being conducted to determine if the green sturgeon sDPS is composed of a single population, or perhaps several populations. It is known that sDPS green sturgeon spawn in the mainstem Sacramento River, the Feather River, and the Yuba River; but it is not yet known if these spawning areas represent individual populations, sub-populations, or if they are all part of one single population. However, it is encouraging to note that at least this level of spatial diversity exists; when sDPS green sturgeon were originally listed as threatened under the ESA, the only known spawning locations at the time were those on the mainstem Sacramento River.

4. Diversity

The VSP concept identifies a variety of traits that exhibit diversity within and among populations, and this variation has important effects on population viability (McElhany *et al.* 2000). For sDPS green sturgeon, such traits include, but are not limited to fecundity, age at maturity, physiology, and genetic characteristics. On a species-wide scale, studies have examined the genetic differentiation between sDPS and nDPS green sturgeon (Israel *et al.* 2004).

Although the population structure of sDPS green sturgeon is still being refined, it may be the case that only a single population exists. This may have the effect of providing for lower diversity than if two or more populations existed. Lindley *et al.* (2007), in discussing winter-run Chinook salmon, states that an ESU represented by a single population at moderate risk of extinction is at high risk of extinction over the long run. This concern applies to any DPS or ESU represented by a single population.

Summary of sDPS Green Sturgeon Viability

The viability of sDPS green sturgeon is constrained by factors such as a small population size, lack of multiple populations, and concentration of spawning sites into just a few locations. The risk of extinction is believed to be moderate because, although threats due to habitat alteration are thought to be high and indirect evidence suggests a decline in abundance, there is much uncertainty regarding the scope of threats and the viability of population abundance indices (NMFS 2010a). Viability is defined as an independent population having a negligible risk of extinction due to threats from demographic variation, local environmental variation, and genetic diversity changes over a 100-year timeframe (McElhany et al. 2000). The best available scientific information does not indicate that the extinction risk facing sDPS green sturgeon is negligible over a long term (~100 year) time horizon; therefore the sDPS is not believed to be viable. To support this statement, the population viability analysis (PVA) that was done for sDPS green sturgeon in relation to stranding events (Thomas et al. 2013) may provide some insight. While this PVA model made many assumptions that need to be verified as new information becomes available, it was alarming to note that over a 50-year time period the DPS declined under all scenarios where stranding events were recurrent over the lifespan of a green sturgeon.

Although the population structure of sDPS green sturgeon is still being refined, it is currently believed that only one population of sDPS green sturgeon exists. Lindley et al. (2007), in discussing winter-run Chinook salmon, states that an ESU represented by a single population at moderate risk of extinction is at high risk of extinction over the long run. This concern applies to any DPS or ESU represented by a single population, and if this were to be applied to sDPS green sturgeon directly, it could be said that sDPS green sturgeon face a high extinction risk. However, the position of NMFS, upon weighing all available information (and lack of information) has stated the extinction risk to be moderate (NMFS 2010a).

There is a strong need for additional information about sDPS green sturgeon, especially with regards to a robust abundance estimate, a greater understanding of their biology, and further information about their habitat needs.

Southern DPS of North American Green Sturgeon Critical Habitat

Critical habitat was designated for the sDPS green sturgeon on October 9, 2009 (74 FR 52300). A full and exact description of all sDPS green sturgeon critical habitat, including excluded areas, can be found at 50 CFR 226.219. Critical habitat includes the stream channels and waterways in the Delta to the ordinary high water line. Critical habitat also includes the main stem Sacramento River upstream from the I Street Bridge to Keswick Dam, the Feather River upstream to the fish barrier dam adjacent to the Feather River Fish Hatchery, and the Yuba River upstream to Daguerre Dam. Coastal marine areas include waters out to a depth of 60 fathoms, from Monterey Bay in California, to the Strait of Juan de Fuca in Washington. Coastal estuaries designated as critical habitat include San Francisco Bay, Suisun Bay, San Pablo Bay, and the lower Columbia River estuary. Certain coastal bays and estuaries in California (Humboldt Bay), Oregon (Coos Bay, Winchester Bay, Yaquina Bay, and Nehalem Bay), and Washington (Willapa Bay and Grays Harbor) are also included as critical habitat for sDPS green sturgeon.

Critical habitat for sDPS green sturgeon includes principal biological or physical constituent elements within the defined area that are essential to the conservation of the species. PCEs for sDPS green sturgeon have been designated for freshwater riverine systems, estuarine habitats, and nearshore coastal areas. In keeping with the focus on the California CV, we will limit our discussion to freshwater riverine systems and estuarine habitats.

Freshwater Riverine Systems

1. Food Resources

Abundant food items for larval, juvenile, subadult, and adult life stages for sDPS green sturgeon should be present in sufficient amounts to sustain growth, development, and support basic metabolism. Although specific information on food resources for green sturgeon within freshwater riverine systems is lacking, they are presumed to be generalists and opportunists that feed on similar prey as other sturgeons (Israel and Klimley 2008). Seasonally abundant drifting and benthic invertebrates have been shown to be the major food items of shovelnose and pallid sturgeon in the Missouri River (Wanner *et al.* 2007), lake sturgeon in the St. Lawrence River (Nilo *et al.* 2006), and white sturgeon in the lower Columbia River (Muir *et al.* 2000). As sturgeons grow, they begin to feed on oligochaetes, amphipods, smaller fish, and fish eggs as represented in the diets of lake sturgeon (Nilo *et al.* 2006), pallid sturgeon (Gerrity *et al.* 2006), and white sturgeon (Muir *et al.* 2000).

2. Substrate Type or Size

Critical habitat in the freshwater riverine system should include substrate suitable for egg deposition and development, larval development, subadults, and adult life stages. For example, spawning is believed to occur over substrates ranging from clean sand to bedrock, with preferences for cobble (Emmett *et al.* 1991, Moyle *et al.* 1995). Eggs are likely to adhere to substrates, or settle into crevices between substrates (Van Eenennaam *et al.* 2001, Deng *et al.* 2002). Larvae exhibited a preference for benthic structure during laboratory studies (Van Eenennaam *et al.* 2001, Deng *et al.* 2002, Kynard *et al.* 2005), and may seek refuge within crevices, but use flat-surfaced substrates for foraging (Nguyen and Crocker 2006).

3. Water Flow

An adequate flow regime is necessary for normal behavior, growth, and survival of all life stages in the upper Sacramento River. Such a flow regime should include stable and sufficient water flow rates in spawning and rearing reaches to maintain water temperatures within the optimal range for egg, larval, and juvenile survival and development (11°C - 19°C) (Mayfield and Cech 2004, Van Eenennaam *et al.* 2005, Allen *et al.* 2006). Sufficient flow is also needed to reduce the incidence of fungal infestations of the eggs, and to flush silt and debris from cobble, gravel, and other substrate surfaces to prevent crevices from being filled in and to maintain surfaces for feeding. Successful migration of adult green sturgeon to and from spawning grounds is also dependent on sufficient water flow. Spawning in the Sacramento River is believed to be triggered by increases in water flow to about 14,000 cfs [average daily water flow during spawning months: 6,900 – 10,800 cfs; Brown (2007)]. In Oregon's Rogue River, nDPS green sturgeon have been shown to emigrate to sea during the autumn and winter when water temperatures dropped below 10° C and flows increased (Erickson *et al.* 2002). On the Klamath

River, the fall outmigration of nDPS green sturgeon has been shown to coincide with a significant increase in discharge resulting from the onset of the rainy season (Benson *et al* 2007). On the Sacramento River, flow regimes are largely dependent on releases from Shasta Dam, thus the operation of this dam could have profound effects upon sDPS green sturgeon habitat.

4. Water Quality

Adequate water quality, including temperature, salinity, oxygen content, and other chemical characteristics are necessary for normal behavior, growth, and viability of all life stages. Suitable water temperatures would include: stable water temperatures within spawning reaches; temperatures within 11°C - 17°C (optimal range = 14°C - 16°C) in spawning reaches for egg incubation (March-August) (Van Eenennaam *et al.* 2005); temperatures below 20°C for larval development (Werner *et al.* 2007); and temperatures below 24°C for juveniles (Mayfield and Cech 2004, Allen *et al.* 2006). Suitable salinity levels range from fresh water (< 3 ppt) for larvae and early juveniles to brackish water (10 ppt) for juveniles prior to their transition to salt water. Prolonged exposure to higher salinities may result in decreased growth and activity levels and even mortality (Allen and Cech 2007). Adequate levels of dissolved oxygen (DO) are needed to support oxygen consumption by early life stages (ranging from 61.78 to 76.06 mg O_2 hr^{-1} kg^{-1} for juveniles, Allen and Cech (2007). Suitable water quality would also include water with acceptably low levels of contaminants (*i.e*., pesticides, organochlorines, selenium, elevated levels of heavy metals, *etc*.) that may disrupt normal development of embryonic, larval, and juvenile stages of green sturgeon. Poor water quality can have adverse effects on growth, reproductive development, and reproductive success. Studies on effect of water contaminants upon green sturgeon are needed; studies performed upon white sturgeon have clearly demonstrated the negative impacts contaminants can have upon white sturgeon biology (Foster *et al.* 2001a, 2001b, Feist *et al.* 2005, Fairey *et al.* 1997, Kruse and Scarnecchia 2002). Legacy contaminants such as mercury still persist in the watershed and pulses of pesticides have been identified in winter storm discharges throughout the Sacramento River basin, and the CV and Delta.

5. Migratory Corridor

Safe and unobstructed migratory pathways are necessary for adult green sturgeon to migrate to and from spawning habitats, and for larval and juvenile green sturgeon to migrate downstream from spawning and rearing habitats within freshwater rivers to rearing habitats within the estuaries. Unobstructed passage throughout the Sacramento River up to Keswick Dam (RM 302) is important, because optimal spawning habitats for green sturgeon are believed to be located upstream of the RBDD (RM 242).

6. Depth

Deep pools of ≥ 5 m depth are critical for adult green sturgeon spawning and for summer holding within the Sacramento River. Summer aggregations of green sturgeon are observed in these pools in the upper Sacramento River upstream of GCID. The significance and purpose of these aggregations are unknown at the present time, but may be a behavioral characteristic of green sturgeon. Adult green sturgeon in the Klamath and Rogue rivers also occupy deep holding pools for extended periods of time, presumably for feeding, energy conservation, and/or refuge from high water temperatures (Erickson *et al.* 2002, Benson *et al.* 2007). As described above approximately 54 pools with adequate depth have been identified in the Sacramento River upstream of the GCID location.

7. Sediment Quality

Sediment should be of the appropriate quality and characteristics necessary for normal behavior, growth, and viability of all life stages. This includes sediments free of contaminants [*e.g.*, elevated levels of heavy metals (*e.g.*, mercury, copper, zinc, cadmium, and chromium), polycyclic aromatic hydrocarbons (PAHs), and organochlorine pesticides] that can result in negative effects on any life stage of green sturgeon or their prey. Based on studies of white sturgeon, bioaccumulation of contaminants from feeding on benthic species may negatively affect the growth, reproductive development, and reproductive success of green sturgeon. The Sacramento River and its tributaries have a long history of contaminant exposure from abandoned mines, separation of gold ore from mine tailings using mercury, and agricultural practices with pesticides and fertilizers which result in deposition of these materials in the sediment horizons in the river channel. The San Joaquin River is a source for many of these same contaminants, although pollution and runoff from agriculture are the predominant driving force. Disturbance of these sediment horizons by natural or anthropogenic actions can liberate he sequestered contaminants into the river. This is a continuing concern throughout the watershed.

For Estuarine Habitats

1. Food Resources

Abundant food items within estuarine habitats and substrates for juvenile, subadult, and adult life stages are required for the proper functioning of this PCE for green sturgeon. Green sturgeon feed primarily on worms, mollusks, and crustaceans (Moyle 2002). Radtke (1966) studied the diet of juvenile sDPS green sturgeon and found their stomach contents to include a mysid shrimp, amphipods, and other unidentified shrimp. These prey species are critical for the rearing, foraging, growth, and development of juvenile, subadult, and adult green sturgeon within the bays and estuaries. Currently, the estuary provides these food resources, although annual fluctuations in the population levels of these food resources may diminish the contribution of one group to the diet of green sturgeon relative to another food source.

Invasive species are a concern because they may replace the natural food items consumed by green sturgeon. The Asian overbite clam (*Corbula amurensis*) is one example of a prolific invasive clam species in the Delta. It has been observed to pass through white sturgeon undigested (Kogut 2008).

2. Water Flow

Within bays and estuaries adjacent to the Sacramento River (*i.e.*, the Delta and the Suisun, San Pablo, and San Francisco bays), sufficient flow into the bay and estuary to allow adults to successfully orient to the incoming flow and migrate upstream to spawning grounds is required. Sufficient flows are needed to attract adult green sturgeon to the Sacramento River from the bay and to initiate the upstream spawning migration into the upper river. The specific quantity of flow required is a topic of ongoing research.

3. Water Quality

Adequate water quality, including temperature, salinity, oxygen content, and other chemical characteristics, is necessary for normal behavior, growth and viability of all life stages. Suitable water temperatures for juvenile green sturgeon should be below 24°C (75ºF). At temperatures above 24°C, juvenile green sturgeon exhibit decreased swimming performance (Mayfield and Cech 2004) and increased cellular stress (Allen *et al.* 2006). Suitable salinities in the estuary range from brackish water (10 ppt) to salt water (33 ppt). Juveniles transitioning from brackish to salt water can tolerate prolonged exposure to salt water salinities, but may exhibit decreased growth and activity levels (Allen and Cech 2007), whereas subadults and adults tolerate a wide range of salinities (Kelly *et al.* 2007). Subadult and adult green sturgeon occupy a wide range of DO levels, but may need a minimum DO level of at least 6.54 mg O_2/l (Kelly *et al.* 2007, Moser and Lindley 2007).

Suitable water quality also includes water free of contaminants (*e.g.*, pesticides, organochlorines, elevated levels of heavy metals) that may disrupt the normal development of juvenile life stages, or the growth, survival, or reproduction of subadult or adult stages. In general, water quality in the Delta and estuary meets these criteria, but local areas of the Delta and downstream bays have been identified as having deficiencies. Discharges of agricultural drain water have also been implicated in local elevations of pesticides and other related agricultural compounds within the Delta and the tributaries and sloughs feeding into the Delta. Discharges from petroleum refineries in Suisun and San Pablo bay have been identified as sources of selenium to the local aquatic ecosystem (Linville *et al.* 2002).

4. Migratory Corridor

Safe and unobstructed migratory pathways are necessary for timely passage of adult, sub-adult, and juvenile fish within the region's different estuarine habitats and between the upstream riverine habitat and the marine habitats. Within the waterways comprising the Delta, and bays downstream of the Sacramento River, safe and unobstructed passage is needed for juvenile green sturgeon during the rearing phase of their life cycle. Passage within the bays and the Delta is also critical for adults and subadults for feeding and summer holding, as well as to access the Sacramento River for their upstream spawning migrations and to make their outmigration back into the ocean. Within bays and estuaries outside of the Delta and the areas comprised by Suisun, San Pablo, and San Francisco bays, safe and unobstructed passage is necessary for adult and subadult green sturgeon to access feeding areas, holding areas, and thermal refugia, and to ensure passage back out into the ocean. Currently, safe and unobstructed passage has been diminished by human actions in the Delta and bays. The CVP and SWP, responsible for large volumes of water diversions, alter flow patterns in the Delta due to export pumping and create entrainment issues in the Delta at the pumping and Fish Facilities. Power generation facilities in Suisun Bay create risks of entrainment and thermal barriers through their operations of cooling water diversions and discharges. Installation of seasonal barriers in the South Delta and operations of the radial gates in the Delta Cross Channel (DCC) facilities alter migration corridors available to green sturgeon. Actions such as the hydraulic dredging of ship channels and operations of large ocean going vessels create additional sources of risk to green sturgeon within the estuary. Commercial shipping traffic can result in the loss of fish, particularly adult fish, through ship and propeller strikes.

5. Water Depth

A diversity of depths is necessary for shelter, foraging, and migration of juvenile, subadult, and adult life stages. Subadult and adult green sturgeon occupy deep (≥ 5 m) holding pools within bays, estuaries, and freshwater rivers. These deep holding pools may be important for feeding and energy conservation, or may serve as thermal refugia (Benson *et al.* 2007). Tagged adults and subadults within the San Francisco Bay estuary primarily occupied waters with depths of less than 10 meters, either swimming near the surface or foraging along the bottom (Kelly *et al.* 2007). In a study of juvenile green sturgeon in the Delta, relatively large numbers of juveniles were captured primarily in shallow waters from 3 – 8 feet deep, indicating juveniles may require shallower depths for rearing and foraging (Radtke 1966).

Currently, there is a diversity of water depths found throughout the San Francisco Bay estuary and Delta waterways. Most of the deeper waters, however, are composed of artificially maintained shipping channels, which do not migrate or fluctuate in response to the hydrology in the estuary in a natural manner. Shallow waters occur throughout the Delta and San Francisco Bay. Extensive "flats" occur in the lower reaches of the Sacramento and San Joaquin river systems as they leave the Delta region and are even more extensive in Suisun and San Pablo bays. In most of the region, variations in water depth in these shallow water areas occur due to natural processes, with only localized navigation channels being dredged (*e.g.*, the Napa River and Petaluma River channels in San Pablo Bay).

6. Sediment Quality

Sediment quality (*i.e.*, chemical characteristics) is necessary for normal behavior, growth, and viability of all life stages. This includes sediments free of contaminants (*e.g.*, elevated levels of selenium, PAHs, and organochlorine pesticides) that can cause negative effects on all life stages of green sturgeon (see description of *sediment quality* for riverine habitats above).

Summary of the Conservation Value of Green Sturgeon Critical Habitat

The current condition of critical habitat for the green sturgeon sDPS is degraded over its historical conditions. It does not provide the full extent of conservation values necessary for the survival and recovery of the species, especially in the upstream riverine habitat. In particular, passage and water flow PCEs have been impacted by human actions, substantially altering the historical river characteristics in which the green sturgeon sDPS evolved. The habitat values proposed for green sturgeon critical habitat have suffered similar types of degradation as described for winter-run Chinook salmon critical habitat. In addition, the alterations to the lower Sacramento River and delta may have a particularly strong impact on the survival and recruitment of juvenile green sturgeon due to the protracted rearing time in the delta and estuary. Loss of individuals during this phase of the life history of green sturgeon represents losses to multiple year classes, which can ultimately impact the potential population structure for decades.

2.3 Environmental Baseline

The "environmental baseline" includes the past and present impacts of all Federal, state, or private actions and other human activities in the action area, the anticipated impacts of all proposed Federal projects in the action area that have already undergone formal or early section 7 consultation, and the impact of state or private actions which are contemporaneous with the consultation in process (50 CFR 402.02).

The environmental baseline describes the status of listed species and critical habitat in the action area, to which we add the effects of the Common Features GRR, to consider the effects of the proposed Federal actions within the context of other factors that impact the listed species. The effects of the proposed Federal action are evaluated in the context of the aggregate effects of all factors that have contributed to the status of listed species and, for non-Federal activities in the action area, those actions that are likely to affect listed species in the future, to determine if implementation of the Common Features GRR is likely to cause an appreciable reduction in the likelihood of both survival and recovery or result in destruction or adverse modification of critical habitat.

Reaches throughout the Common Features GRR planning area historically provided both shallow and deeper water habitat. Channel confining levees and upstream reservoirs that maintain year-round outflow have eliminated much of the adjacent shallow water floodplain habitat. Many native fish species are adapted to rear in flooded, shallow water areas that provide abundant cover and prey. As a consequence of habitat alterations, and the introduction of non-native species and pollutants, some native fish species are now extinct while most others are reduced in numbers (Moyle 2002).

The Sacramento River watershed receives winter/early spring precipitation in the form of rain and snow (at higher elevations). Prior to the construction and operation of any reservoirs, winter rainfall events caused extensive flooding and spring snowmelt resulted in high flows during spring and early summer. Summer and fall flows were historically low. Currently, much of the total runoff is captured and stored in reservoirs for gradual release during the summer and fall months. High river flows occur during the winter and spring, but these are usually lower than during pre-European settlement times; summer and fall low flows are sustained by releases from upstream reservoirs.

The flood risk management system protecting the City of Sacramento has been identified as insufficient by the Corps. According to the Corps, there is a high probability that flows in the American and Sacramento Rivers will stress the network of levees protecting Sacramento to the point that levees could fail. Failure of these levees could inundate highly urbanized areas up to 20 feet deep.

Sixteen land cover types were identified in the Common Features GRR project area. Nine of the land cover types are considered natural communities: all four riparian habitats, emergent marsh, valley oak woodland, walnut woodland, nonnative annual grassland, pond, and perennial drainage. The other cover types are associated with human activities: all three agricultural field types, walnut orchard, agricultural ditch, and developed/landscaped.

Despite the impaired status of the Sacramento and American Rivers in the proposed project action area, the value of the lower Sacramento River as a migratory corridor for CV spring-run Chinook salmon, CCV steelhead, Sacramento River winter-run Chinook salmon, and sDPS green sturgeon is high primarily because it contains habitat elements that support the rearing and growth of juveniles and the successful upstream migration of adults. The same high value can be attributed to the American River for both CV spring-run and sDPS green sturgeon. The Common Features GRR will occur downstream of the confluence of major watersheds, including the American, Yuba, and Feather river and watersheds further upstream such as Butte Creek and Battle Creek. Thus, the action area is also within the migratory corridor for the fish that utilize all the aforementioned watersheds.

Anticipated climate change may affect spatial and temporal precipitation patterns along with the intensity and duration of precipitation within the Sacramento and American River watersheds. The effect of climate change is anticipated to be more winter and less spring and summer run-off within the watershed. In addition, expected run-off is anticipated to be warmer, possibly affecting the ability to meet downstream water temperature objectives to protect salmon, steelhead, and green sturgeon. This combined with more precipitation as rain will affect future operations of all reservoirs within the California CV. A change in the run-off pattern within the Sacramento and American River watersheds will likely affect reservoir storage and downstream river flows due to more frequent spillway releases.

This same flood management system impacts the natural meander and ecosystem of the Sacramento and American Rivers. The Common Features Project study area includes the mainstem The Common Features GRR action area includes the mainstem Sacramento River from Freeport (RM 46) in the Delta upstream to the American River confluence (RM 60). The region also includes the lower American River from the confluence with the Sacramento River upstream to RM 11, NEMDC, Arcade Creek, Dry/Robla Creeks and Magpie Creek.

Downstream from the American River confluence, the Sacramento River is moderately sinuous, with the channel confined on both sides by man-made levees enhanced by decades of man-made additions. The channel in this reach is of uniform width, is not able to migrate, and is typically narrower and deeper relative to the upstream reach due to scour caused by the concentration of shear forces acting against the channel bed (Brice 1977). Channel migration is similarly limited along the lower American River because of man-made levees and regulated flows from Folsom and Nimbus Dams.

The natural banks and adjacent floodplains of both rivers are composed of silt- to gravel-sized particles with poor to high permeability. Historically, the flow regimes caused the deposition of a gradient of coarser to finer material, and longitudinal fining directed downstream (sand to bay muds). The deposition of these alluvial soils historically accumulated to form extensive natural levees and splays along the rivers, 5 to 20 feet above the floodplain for as far as 10 miles from the channel (Thompson 1961). The present day channels consist of fine-grained cohesive banks that erode due to natural processes as well as high flow events (Corps 2012).

Seasonal high flows enter the adjacent Yolo Bypass from this reach of the Sacramento River via the Sacramento Bypass (RM 63). Tidal influence emanating from Suisun Bay extends up the Sacramento River for 80 miles to Verona, with greater tidal variations occurring downstream during low river stages in summer and fall.

NEMDC is an approximately 13.3-mile, human-made, partially leveed drainage channel that provides drainage from Sankey Road and connects streams of the American Basin (Dry, Robla, and Arcade Creeks) to the American River. South of the confluence with Arcade Creek, the east and west levees of NEMDC are dominated by wild oats grasslands, while the channel is characterized by Fremont cottonwood forest, with smaller amounts of valley oak woodland, smart-weed cocklebur patches, and perennial rye grass fields.

The approximately 16.2-mile-long channel of Arcade Creek extends east-to-west from Orangevale to the American River, via NEMDC. The north and south levees are dominated by wild oats grasslands. Valley oak woodland is the main riparian vegetation type along Arcade Creek, but Fremont cottonwood forest occurs in small patches along the easternmost reach of Arcade Creek near NEMDC. Hardstem bulrush marsh is found within Arcade Creek near Norwood Avenue while water primrose wetlands are predominant within the channel of Arcade Creek from approximately the confluence with NEMDC to Norwood Avenue. East of Norwood Avenue, the creek channel becomes narrower, and dominated by a shaded canopy of valley oak woodland.

The environmental baseline in the Common Features GRR action area also includes the sites completed under the WRDA 1996 and WRDA 1999 authorizations for the project. The WRDA 1996 construction included installing slurry walls in the American River levees to address seepage and slope stability concerns. The WRDA 1999 construction included shape and slope improvements to specific reaches of the American River levee system, and some segments of the Sacramento River levees.

The Common Features Project study area consists of primarily riparian forest, valley oak woodland, riparian scrub-shrub habitat, and typically non-native annual grassland. Early riparian habitat may be called scrub-shrub. Scrub-shrub generally refers to areas where the woody riparian canopy is composed of trees or shrubs approximately 20 feet high. Species that are typically found in these habitats include young cottonwood (*Populus trichocarpa*), willow (*Salix spp.*), elderberry (*Sambucus spp.*), buttonbush (*Cephalanthus occidentalis*), Himalaya blackberry (*Rubus armeniacus*), wild grape (*Vitis vinifera*), and poison oak (*Toxicodendron spp.*).

Riparian forest typically has a dominant overstory of cottonwood, California sycamore (*Platanus racemosa*), or valley oak (*Quercus lobata*). Species found in the scrub-shrub will make up the sub canopy and could also include white alder and box elder. Layers of climbing vegetation make up part of the subcanopy, with wild grape being a major component, but wild cucumber and clematis are also found in riparian communities.

The herbaceous ruderal habitat is found on most levees along the Sacramento River. It occurs on the levees and also within gaps in the riparian habitats. Plant species include wild oats (*Avena spp.*), soft chess (*Bromus hordeaceus*), ripgut brome (*Bromus hordeaceus*), red brome (*Bromus madritensis*), wild barley (*Bromus hordeaceus)*, and foxtail fescue (*Festuca megalura*). Common forbs include broadleaf filaree (*Erodium spp.*), red stem filaree (*Erodium spp.*), turkey mullein (*Eremocarpus setigerus*), clovers (*Trifolium spp.*), and many others. The majority of these plants are not native to the project area.

Riparian recruitment and establishment models (Mahoney and Rood 1998; Bradley and Smith 1986) and empirical field studies (Scott et al. 1997, 1999) emphasize that hydrologic and fluvial processes play a central role in controlling the elevational and lateral extent of riparian plant species. These processes are especially important for pioneer species that establish in elevations close to the active channel, such as cottonwood and willows (*Salix* spp.). Failure of cottonwood recruitment and establishment is attributed to flow alterations by upstream dams (Roberts et al. 2001) and to isolation of the historic floodplain from the river channel. In addition, many of these formerly wide riparian corridors are now narrow and interrupted by levees and weirs. Finally, draining of wetlands, conversion of floodplains to agricultural fields, and intentional and unplanned introduction of exotic plant species have altered the composition and associated habitat functions of many of the riparian communities that are able to survive under current conditions.

2.3.1 Status of the Species in the Action Area

The action area, which encompasses portions of the lower Sacramento River and lower American River, and associated floodplains and riparian areas at and adjacent to the proposed construction sites functions as a migratory corridor for CV spring-run Chinook salmon, Sacramento River winter-run Chinook salmon, CCV steelhead, and sDPS green sturgeon. The action area is also used for rearing and adult feeding.

1. <u>Presence of CCV Steelhead in the Action Area</u>

The CCV steelhead DPS final listing determination was published on January 5, 2006 (71 FR 834) and included all naturally spawned populations of steelhead (and their progeny) downstream of natural and manmade barriers in the Sacramento and San Joaquin rivers and their tributaries. FRFH steelhead are also included in this designation. All adult CCV steelhead originating in the Sacramento River watershed will have to migrate through the action area in order to reach their spawning grounds and to return to the ocean following spawning. Likewise, all CCV steelhead smolts originating in the Sacramento River watershed will also have to pass through the action area during their emigration to the ocean. The waterways in the action area also are expected to provide some rearing benefit to emigrating steelhead smolts. The CCV steelhead DPS occurs in both the Sacramento River and the San Joaquin River watersheds. However the spawning population of fish is much greater in the Sacramento River watershed and accounts for nearly all of the DPS' population.

CCV steelhead smolts will first start to appear in the action area in November. This is based on the records from the CVP and SWP fish salvage facilities, as well as the fish monitoring program in the northern and central Delta. Their presence increases through December and January, peaks in February and March, and declines in April. By June, the emigration has essentially ended, with only a small number of fish being salvaged through the summer at the CVP and SWP. Adult steelhead are expected to move through the action area throughout the year with the peak of upriver immigration expected to occur August through November. There is potential exposure to adult steelhead moving back downstream in a post-spawn condition (kelts) through the action area during the February to May period. It is expected that more kelts will be observed earlier in the period (February) due to the timing of spawning in the Sacramento River basin.

Based on the temporal presence of adult and juvenile steelhead in the lower Sacramento and American Rivers, the timing of the proposed project, and the location of the action area, it is likely that adult steelhead will be using the action area as a migration corridor during construction. Additionally, it is likely that juvenile steelhead may be emigrating through the action area during construction. Depending on the water year type and the timing of high flows in the Sacramento River basin, adult and/or juvenile CCV steelhead may be present in the Yolo Bypass and the Sacramento Bypass.

2. Presence of CV spring-run Chinook salmon in the Action Area

A similar application of the CVP and SWP salvage records and the northern and Central Delta fish monitoring data to the presence of CV spring-run Chinook salmon indicates that juvenile spring-run Chinook salmon first begin to appear in the action area in December and January, but that a significant presence does not occur until March and peaks in April. By May, the salvage of juvenile CV spring-run Chinook salmon declines sharply and essentially ends by the end of June. The data from the northern and central Delta fish monitoring programs indicate that a small proportion of the annual juvenile spring-run emigration occurs in January and is considered to be mainly composed of older yearling spring-run juveniles based on their size at date. Adult spring-run Chinook salmon are expected to start entering the action area in approximately January. Low levels of adult migration are expected through early March. The peak of adult spring-run Chinook salmon movement through the action area is expected to occur between April and June with adults continuing to enter the system through the summer. Currently, all known populations of CV spring-run Chinook salmon inhabit the Sacramento River watershed.

Based on the temporal presence of CV spring-run Chinook salmon in the lower Sacramento and American River, the timing of the proposed project, and the location of the action area, it is likely that adult and juvenile CV spring-run Chinook salmon will be using the action area. Depending on the water year type and the timing of high flows in the Sacramento River basin, adult and/or juvenile CV spring-run Chinook salmon may be present in the Yolo Bypass and the Sacramento Bypass. It is possible that any CV spring-run Chinook salmon (particularly adults) that arein the lower Sacramento River may enter into the American River.

3. Presence of Sacramento River winter-run Chinook salmon in the Action Area

The temporal occurrence of Sacramento River winter-run Chinook salmon smolts and juveniles within the action area are best described by a combination of the salvage records of the CVP and SWP fish collection facilities and the fish monitoring programs conducted in the northern and central Delta. Based on salvage records at the CVP and SWP fish collection facilities, juvenile Sacramento River winter-run Chinook salmon are expected in the actions area starting in December. Their presence peaks in March and then rapidly declines from April through June. The majority of winter-run juveniles will enter the action area during February through June. Presence of adult Chinook salmon is interpolated from historical data. Adult winter-run Chinook salmon are expected to enter the action area starting in January, with the majority of adults passing through the action area between February and April.

Based on the temporal presence of Sacramento River winter-run Chinook salmon in the lower Sacramento River, the timing of the proposed project, and the location of the action area, it is likely that adult and juvenile Sacramento River winter-run Chinook salmon will be using the action area. Depending on the water year type and the timing of high flows in the Sacramento River basin, adult and/or juvenile Sacramento River winter-run Chinook salmon may be present in the Yolo Bypass and the Sacramento Bypass. It is possible that any Sacramento River winter-run Chinook salmon (particularly adults) that are in lower Sacramento River may enter into the American River.

4. Presence of sDPS green sturgeon in the Action Area

The Sacramento River and a portion of the American River serve as an important migratory corridor for larval and juvenile sturgeon during their downstream migration to the San Francisco Bay Delta and Estuary. The San Francisco Bay Delta and Estuary provides year-round rearing habitat for juveniles, as well as foraging habitat for non-spawning adults and subadults in the summer months (NMFS 2008).

Detailed information regarding historic and current abundance, distribution and seasonal occurrence of SDPS green sturgeon in the action area is limited due to a general dearth of green sturgeon monitoring. The action area is located on the main migratory route for adults moving upstream to spawn, post spawn adults migrating back to the ocean, juvenile outmigrants, and rearing subadults. Juvenile green sturgeon from the sDPS are routinely collected at the SWP and CVP salvage facilities throughout the year. Based on the salvage records, green sturgeon may be present during any month of the year, and have been particularly prevalent during July and August. Adult green sturgeon begin to enter the Delta in late February and early March during the initiation of their upstream spawning run. The peak of adult entrance into the Delta appears to occur in late February through early April with fish arriving upstream in April and May. Adults continue to enter the Delta until early summer (June-July) as they move upriver to spawn. It is also possible that some adult green sturgeon will be moving back downstream in April and May through the action area, either as early post spawners or as unsuccessful spawners. Some adult green sturgeon have been observed to rapidly move back downstream following spawning, while others linger in the upper river until the following fall. It is possible that any of the adult or sub-adult sturgeon that inhabit the lower Sacramento River may swim into the American River. Similar to the salmonid species, depending on the water year type, it is possible that sturgeon will enter the Sacramento and Yolo bypass.

2.3.2 Status of Critical Habitat within the Action Area

The action area occurs within the USGC Hydrologic Unit Code (HUC) Lake Greenhaven-Sacramento River subbasin designated HUC 180201630701. Designated critical habitat for Sacramento River winter-run Chinook salmon (June 16, 1993, 58 FR 33212), CV spring-run Chinook salmon (September 2, 2005, 70 FR 52488), CCV steelhead (September 2, 2005, 70 FR 52488) and the sDPS of green sturgeon (October 9, 2009, 74 FR 52300) occur in this hydrologic unit. The HUC includes portions of the Sacramento and American Rivers. The critical habitat analytical review team (CHART) concluded that it contained one or more PCEs for both the CCV steelhead DPS and CV spring-run Chinook salmon ESU (NMFS 2005). The PCEs for steelhead and spring-run Chinook salmon habitat within the action area include freshwater rearing habitat and freshwater migration corridors. The features of the PCEs included essential to the conservation of the CCV steelhead DPS and CV spring-run Chinook salmon include the following: sufficient water quantity and floodplain connectivity to form and maintain physical habitat conditions necessary for salmonid development and mobility, sufficient water quality, food and nutrients sources, natural cover and shelter, migration routes free from obstructions, no excessive predation, holding areas for juveniles and adults, and shallow water areas and wetlands. Habitat within the action area is primarily utilized for freshwater rearing and migration by CCV steelhead and CV spring-run Chinook salmon juveniles and smolts and for adult freshwater migration. CCV steelhead also utilize the American River for spawning habitat.

Critical habitat for winter-run Chinook salmon includes the Sacramento River reach within the action area. Critical habitat elements include the river water, river bottom, and adjacent riparian zone used by fry and juveniles for rearing. Downstream migration of juveniles and upstream migration of adults should not be impeded or blocked. Adequate forage base is required to provide food for emigrating juvenile winter-run.

In regards to the designated critical habitat for the sDPS of green sturgeon, the action area includes PCEs concerned with: adequate food resources for all life stages; water flows sufficient to allow adults, subadults, and juveniles to orient to flows for migration and normal behavioral responses; water quality sufficient to allow normal physiological and behavioral responses; unobstructed migratory corridors for all life stages; a broad spectrum of water depths to satisfy the needs of the different life stages present in the estuary; and sediment with sufficiently low contaminant burdens to allow for normal physiological and behavioral responses to the environment.

The general condition and function of the aquatic habitat has already been described in the *Status of the Species and Critical Habitat* section of this BO. The substantial degradation over time of several of the essential critical elements has diminished the function and condition of the freshwater rearing and migration habitats in the action area. It has only rudimentary functions compared to its historical status. The channels of the lower Sacramento and American Rivers have been riprapped with coarse stone slope protection on artificial levee banks and these channels have been straightened to enhance water conveyance through the system. The extensive riprapping and levee construction has precluded natural river channel migrations. The natural floodplains have essentially been eliminated, and the once extensive wetlands and riparian zones have been "reclaimed" and subsequently drained and cleared for farming.

Even though the habitat has been substantially altered and its quality diminished through years of human actions, its conservation value remains high for Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon. CCV steelhead adults migrate into the lower American River to spawn, which is within the Lake Greenhaven-Sacramento River HUC, and the resulting fry rear and hold over within the American river until they are ready to migrate out to the ocean. All juvenile winter-run and spring-run Chinook salmon, sDPS green sturgeon, as well as those CCV steelhead smolts originating in the Sacramento River basin must pass into and through the Lake Greenhaven-Sacramento River HUC to reach the lower Delta and the ocean. A large fraction of these fish will likely pass downstream through the action area within the Sacramento River channel. Likewise, adults migrating upstream to spawn must pass through Lake Greenhaven-Sacramento River HUC to reach their upstream spawning areas on the tributary watersheds or main stem Sacramento River. A large proportion of the population is expected to move through the action area within the main channel of the Sacramento River. Therefore, it is of critical importance to the long-term viability of the Sacramento River winter-run Chinook salmon and CV spring-run Chinook salmon ESUs, the sDPS of green sturgeon, and the Sacramento River basin portion of the CCV steelhead DPS to maintain a functional migratory corridor and freshwater rearing habitat through the action area and the Lake Greenhaven-Sacramento River HUC in general.

2.3.4 Factors Affecting the Species and Habitat in the Action Area

The action area encompasses a small portion of the area utilized by the Sacramento River winter-run and CV spring-run Chinook salmon ESUs, and the CCV steelhead DPS as well as the sDPS green sturgeon. Many of the factors affecting these species throughout their range are discussed in the *Rangewide Status of the Species and Critical Habitat* section of this BO, and are considered the same in the action area. This section will focus on the specific factors in the action area that are most relevant to the proposed project.

The magnitude and duration of peak flows during the winter and spring are reduced by water impoundment in upstream reservoirs affecting listed salmonids in the action area. Instream flows during the summer and early fall months have increased over historic levels for deliveries of municipal and agricultural water supplies. Overall, water management now reduces natural variability by creating more uniform flows year-round. Current flood control practices require peak flood discharges to be held back and released over a period of weeks to avoid overwhelming the flood control structures downstream of the reservoirs (*i.e.* levees and bypasses). Consequently, managed flows in the main stem of the river often truncate the peak of the flood hydrograph and extended the reservoir releases over a protracted period. These actions reduce or eliminate the scouring flows necessary to mobilize gravel and clean sediment from the spawning reaches of the river channel.

High water temperatures also limit habitat availability for listed salmonids in the lower Sacramento River. High summer water temperatures in the lower Sacramento River can exceed 72ºF (22.2ºC), and create a thermal barrier to the migration of adult and juvenile salmonids (Kjelson *et al*. 1982). In addition, water diversions at the dams (*i.e.* Friant, Goodwin, La Grange, Folsom, Nimbus, and other dams) for agricultural and municipal purposes have reduced in-river flows below the dams. These reduced flows frequently result in increased temperatures during the critical summer months which potentially limit the survival of juvenile salmonids in these tailwater sections (Reynolds *et al*. 1993). The elevated water temperatures compel many salmon juveniles to migrate out of the valley floor systems before summer heat makes the tailwaters unsuitable for salmonids. Those fish that remain either succumb to the elevated water temperatures or are crowded into river reaches with suitable environmental conditions.

Levee construction and bank protection have affected salmonid habitat availability and the processes that develop and maintain preferred habitat by reducing floodplain connectivity, changing riverbank substrate size, and decreasing riparian habitat and shaded riverine aquatic (SRA) cover. Individual bank protection sites typically range from a few hundred to a few thousand linear feet in length. Such bank protection generally results in two levels of impacts to the environment: (1) site-level impacts which affect the basic physical habitat structure at individual bank protection sites; and (2) reach-level impacts which are the accumulative impacts to ecosystem functions and processes that accrue from multiple bank protection sites within a given river reach. Revetted embankments result in loss of sinuosity and braiding and reduce the amount of aquatic habitat. Impacts at the reach level result primarily from halting erosion and controlling riparian vegetation. Reach-level impacts which cause significant impacts to fish are reductions in new habitats of various kinds, changes to sediment and organic material storage and transport, reductions of lower food-chain production, and reduction in large woody debris (LWD).

The use of rock armoring limits recruitment of LWD (*i.e.*, from non-riprapped areas), and greatly reduces, if not eliminates, the retention of LWD once it enters the river channel. Riprapping creates a relatively clean, smooth surface which diminishes the ability of LWD to become securely snagged and anchored by sediment. LWD tends to become only temporarily snagged along riprap, and generally moves downstream with subsequent high flows. Habitat value and ecological functioning aspects are thus greatly reduced, because wood needs to remain in place to generate maximum values to fish and wildlife. Recruitment of LWD is limited to any eventual, long-term tree mortality and whatever abrasion and breakage may occur during high flows. Juvenile salmonids are likely being impacted by reductions, fragmentation, and general lack of connectedness of remaining near shore refuge areas.

Point and non-point sources of pollution resulting from agricultural discharge and urban and industrial development occur upstream of, and within the action area. The effects of these impacts are discussed in detail in the *Rangewide Status of the Species and Critical Habitat* section. Environmental stressors as a result of low water quality can lower reproductive success and may account for low productivity rates in fish (*e.g.* green sturgeon, Klimley 2002). Organic contaminants from agricultural drain water, urban and agricultural runoff from storm events, and high trace element (*i.e.* heavy metals) concentrations may deleteriously affect early life-stage survival of fish in the Sacramento River (USFWS 1995). Principle sources of organic contamination in the Sacramento River are rice field discharges from Butte Slough, Reclamation District 108, Colusa Basin Drain, Sacramento Slough, and Jack Slough (USFWS 1995). Other impacts to adult migration present in the action area, such as migration barriers, water conveyance factors, water quality, NIS, *etc.*, are discussed in the *Rangewide Status of the Species and Critical Habitat* section.

As previously stated in the *Rangewide Status of the Species and Critical Habitat* section, the transformation of the Sacramento River from a meandering waterway lined with a dense riparian corridor, to a highly leveed system under varying degrees of control over riverine erosional processes resulted in homogenization of the river, including effects to the rivers sinuosity. These impacts likely included the removal of valuable pools and holding habitat for SDPS green sturgeon. In addition, the change in the ecosystem as a result of the removal of riparian vegetation and LWD likely reduce access to floodplain and offchannel rearing habitat, reduced the quantity and quality of benthic habitat and reduced the abundance prey items rearing, foraging and holding habitat. A major factor in the decline of sDPS green sturgeon, and the primary reason for listing this species, was the alteration of its adult spawning and larval rearing habitat in California's Sacramento River Basin (71 FR 17757, April 7, 2006).

2.4 Effects of the Action

Under the ESA, "effects of the action" means the direct and indirect effects of an action on the species or critical habitat, together with the effects of other activities that are interrelated or interdependent with that action (in this case there are no interrelated or interdependent actions), that will be added to the environmental baseline (50 CFR 402.02). Indirect effects are those that are caused by the proposed action and are later in time, but still are reasonably certain to occur.

To evaluate the effects of the Common Features GRR, NMFS examined the potential proposed actions in the designated action areas. We analyzed construction-related impacts and the expected short- and long-term fish response to habitat modifications using the SAM. We also reviewed and considered the Corps proposed conservation measures. This assessment relied heavily on the information from the Corps BA developed for the Common Features GRR, and available monitoring data from other CV fish studies.

In general, the footprint for the Common Features Project consists of the flood risk management system protecting the city of Sacramento and surrounding areas. This will include structure upgrades, levee deconstruction, and adjacent staging areas. The continued existence of any new or improved flood management structures, associated critical habitat disturbance, vegetation removal, and operational aspects may adversely affect several life stages of CV spring-run Chinook salmon, CCV steelhead, Sacramento River winter-run Chinook salmon, and the sDPS of SDPS green sturgeon in the action area.

The assessment will consider the nature, duration, and extent of the potential actions relative to the migration timing, behavior, and habitat requirements of federally listed CV spring-run Chinook salmon, CCV steelhead, Sacramento River winter-run Chinook salmon, and sDPS of SDPS green sturgeon. Specifically, this assessment will consider the potential impacts resulting from the construction and subsequent O&M activites. Effects of the Common Features Project on aquatic resources include both short- and long-term impacts. Short-term effects, which are related primarily to construction activities (*i.e.*, increased suspended sediment and turbidity), may last several hours to several weeks. Long-term impacts may last months or years and generally involve physical alteration of the river bank and riparian vegetation adjacent to the water's edge.

The Common Features Project construction activities may increase noise, turbidity, suspended sediment, and sediment deposition that may disrupt feeding or temporarily displace fish from preferred habitat or impair normal behavior. Construction activities will also introduce rip rap material into the water column that may injure, harm, or kill listed fish. Some of these effects may occur downstream of the construction activities because noise and sediment may be propagated downstream. Substantial increases in suspended sediment could temporarily bury substrates and submerged aquatic vegetation that supports invertebrates for feeding juvenile fish.

The bank armoring and some of the levee repairs will also contribute to the continued confinement of the riverine system that in turn negatively impacts listed fish species and their designated critical habitat. Even with an ETL variance in place, adopting the ETL as part of the proposed project may have long-term impacts to critical habitat and listed species. Additionally, despite the assumption of a variance, there are uncertainties as to the subsequent O&M activities and their impacts.

Since specific project designs were not available at the time of this analysis, impacts are characterized using "worst case scenario" assumptions. With-project conditions were assumed to be analogous a typical SRBPP repair site (bank armoring paired with onsite restoration features including a planted riparian bench and installed IWM). A Vegetation Variance Request (VVR) was assumed to be in place. Project actions along the Sacramento Bypass and weir reaches, including slurry wall construction, slope stabilization, and levee raises, weir repair, and levee construction were assumed to result in removal of all woody and herbaceous vegetation and armoring of both summer-fall and winter-spring shorelines.

The Common Features project reach will be implemented in increments. The timing of each project sub-reach (Table 4) is based on the proposed schedule provided in the BA (USACE 2015). Some of the project increments will be of varying length, thereby impacting the subsequent analysis.

2.4.1 Construction Related Effects

NMFS expects that adult and juvenile CCV steelhead, adult winter-run Chinook salmon, adult spring-run Chinook salmon, and adult and juvenile green sturgeon may be present in the action area (although in low numbers because the construction window avoids periods of peak abundance) during construction activities. Only those fish that are holding adjacent to or migrating past the project sites will be directly exposed or affected by construction activities. Those fish that are exposed to the effects of construction activities will encounter short-term (*i.e.*, minutes to hours) construction-related noise, physical disturbance, and water quality changes that may cause injury or harm by increasing the susceptibility of some individuals to predation by temporarily disrupting normal behaviors, and affecting sheltering abilities. If an adult salmonid were to enter the action area, they will likely exhibit avoidance behavior in response to construction and associated activities.

Larger fish will likely respond to construction activities by quickly swimming away from the construction sites, and will escape injury. Toxic substances used at construction sites, including gasoline, lubricants, and other petroleum-based products could enter the waterway as a result of spills or leakage from machinery and injure listed salmonids, and green sturgeon. Petroleum products also tend to form oily films on the water surface that can reduce DO available to aquatic organisms. NMFS expects that adherence to BMPs that dictate the use, containment, and cleanup of contaminants will minimize the risk of introducing such products to the waterway.

Green sturgeon move to estuaries and the lower reaches of rivers between late winter and early summer, and ascend rivers to spawn in the spring and early summer. Adult green sturgeon may leave the rivers soon after spawning or hold in the river through the fall or winter (Heublein et al. 2009). Movement and foraging during downstream migration occurs at night for both larvae (approximately 10 days post-hatch) and juveniles (73 FR 52084; Cech *et al*. 2000, as cited in Reclamation 2008). Juvenile emigration reportedly occurs from May through September. Juveniles will experience the greatest exposure to construction activities.

Direct effects are defined as "the direct or immediate effects of the Proposed Action on the species or its habitat" (USFWS and NMFS, March 1998). Direct effects associated with in-river construction work will involve equipment and activities that will produce pressure waves, and create underwater noise and vibration, thereby temporarily altering in-river conditions.

Any increases in turbidity will most likely disrupt feeding and migratory behavior activities of juvenile salmonids (which CCV juvenile Steelhead have a high likely hood of being present).though their abundance is expected to be low). Turbidity and sedimentation events are not expected to affect visual feeding success of green sturgeon, as they are not believed to utilize visual cues (Sillman *et al.* 2005). Green sturgeon, which can occupy waters containing variable levels of suspended sediment and thus turbidity, are not expected to be impacted by the slight increase in the turbidity levels anticipated from the pile driving action as explained above. The construction activities are unlikely to impact any deepwater areas where the species spawn and hold.

NMFS expects that actual physical damage or harassment to listed fish species will be low during the months of construction. Adults will not sustain any physical damage due to construction because their size, preference for deep water, and their crepuscular migratory behavior will enable them to avoid most temporary, nearshore disturbance that occurs during typical daylight construction hours.

2.4.2 Standard Assessment Methodology Analysis

Common Features Project impacts were analyzed using SAM. The Corps provided the background data, assumptions, analyses, and assessment of habitat compensation requirements for the federally protected fish species relevant to this consultation. The Corps also included analysis for fall-run and late-fall run Chinook salmon.

The Sacramento River SAM analysis reach includes the entire left bank (east side) of the Sacramento River from the American River confluence to approximately 4,020 linear feet (lf) below the Freeport Bridge. The American River SAM analysis (ARN A-B and ARS A-C) reaches include portions of the right and left bank of the American River from Goethe Park to the confluence of the Sacramento. It also includes portions of NEMDC, Arcade Creek, Magpie Creek, and Dry/Robla Creek.

As described in the *Analytical* Approach section of the BO, during the process of this consultation, the Corps and NMFS identified several short comings with the SAM as a tool for reliably forecasting the growth and survival of green sturgeon. The primary short coming is that the SAM evaluates habitat conditions at the seasonal water surface intersect with the river bank. While this is considered an effective point for measuring salmon and steelhead habitat, green sturgeon have a greater affinity for benthic habitat than shoreline habitat. Further, during discussions between the Corps and NMFS, it was widely agreed upon that levee repair actions in the West Sacramento Study Area are likely to only affect the juvenile rearing life stage and probably have little to no adverse impacts on the adult life stages of green sturgeon because spawning habitat is not present and adults that are migrating upstream are probably more influenced by impacts that affect swimming speed and upstream passage than shoreline habitat manipulations. Because of this, NMFS has decided to use the SAM as a temporary proxy for quantifying habitat disturbance and harm that will ultimately be replaced by a more precise model as proposed by the Corps in the *Proposed Action* section of this BO.

The following data sources were used to characterize SAM habitat conditions (as defined by bank slope, floodplain availability, substrate size, instream structure, aquatic vegetation, and overhanging shade) within the Common Features Project area under baseline conditions:

1. The Corps' Sacramento River revetment database.
2. Aerial images of the Common Features Project reach (Google™ Earth).

The SAM employs six habitat variables to characterize near-shore and floodplain habitats of listed fish species:

1. Bank slope;
2. Floodplain availability;
3. Bank substrate size;
4. Instream structure;
5. Aquatic vegetation; and
6. Overhanging shade.

The following describes how input values for each of these attributes were derived for existing conditions in the SAM assessment.

1. **Bank Slope:** Existing bank slopes (rise-over-run ratio) were extrapolated from cross sections along the Sacramento River and existing SAM analyses performed on regionally analogous sites. Bank slope along all sub-reaches was assumed to be 2.5 for existing conditions.

2. **Floodplain Availability:** The SAM attribute of floodplain inundation ratio, which represents floodplain availability, was assumed to have a value of 1, reflecting the absence of significant floodplain habitat above the winter-spring shoreline under existing conditions.

3. **Bank Substrate Size:** The median substrate size along the summer-fall and winter-spring shorelines of the project reach was determined by referencing the Revetment Database (USACE 2004) and current and historical aerial images.

4. **Instream Structure:** The shoreline coverage of IWM along the average summer-fall and winter-spring shorelines of the Common Features project reach were determined by referencing the revetment database (USACE 2004). The revetment database uses four classes of instream structure, based on ranges of percent shoreline having IWM.

5. **Overhanging Shade:** The extent of overhanging shade along the summer-fall and winter-spring shorelines was determined through analysis of current and historic aerial images. Summer-fall conditions were analyzed using imagery from late summer and early fall months, typically representative of low water conditions. Winter-spring conditions were analyzes using imagery from late winter and early spring months, typically representative of high water conditions.

The following describes how input values for each of the SAM habitat attributes were derived for with-project conditions:

1. **Bank Slope:** With-project bank slopes (rise-over-run ratio) were based on the description of project actions for each sub-reach. Bank slopes for the SAC sub-reach were assumed to be analogous to SRBPP repair sites.

2. **Floodplain Availability:** Levee repair and bank stabilization actions typically do not increase floodplain availability (with exception of constructing setback levees). The Common Features project reaches being analyzed under this SAM do not include construction of any setback levees; therefore, the SAM attribute of floodplain inundation ratio, which represents floodplain availability, was assumed to lack significant floodplain habitat above the winter-spring shoreline under existing conditions.

3. **Bank Substrate Size:** The median substrate size along the summer-fall and winter-spring shorelines of the project reach were based on the description of project actions

for each reach. Bank substrate size along the Sacramento River reach was assumed to be analogous to SRBPP repair sites. Project actions at all other sub-reaches were expected to result in placement of 10 inch rock revetment along both summer-fall and winter-spring shorelines.

4. **Instream Structure:** The shoreline coverage of IWM along the average summer-fall and winter-spring shorelines was based on the description of project actions for each sub-reach. IWM coverage along the SAC sub-reach was assumed to be analogous to SRBPP repair sites (installation of 40 percent shoreline coverage at summer-fall shoreline). Project actions at all other sub-reaches were not expected to result in a change in available IWM along both summer-fall and winter-spring shorelines; IWM values for these sub-reaches will mirror existing condition values.

5. **Aquatic Vegetation:** The shoreline coverage of aquatic vegetation along the average summer-fall and winter-spring shorelines was based on the description of project actions for each sub-reach. Aquatic vegetation along the Sacramento River was assumed to be analogous to SRBPP repair sites. The vegetation growth model below that was applied to the Sacramento River was taken from a previous SAM analysis conducted for Sacramento RM 62.5R (USACE 2008).

6. **Overhanging Shade:** The shoreline coverage of overhanging shade along the average summer-fall and winter-spring shorelines was based on the description of project actions for each sub-reach. Overhanging shade along the Sacramento River was assumed to be analogous to SRBPP repair sites. It was assumed that a variance will be in place allowing for retention of woody vegetation along the lower 2/3 of the levee slope (applies to Sacramento River only). As the result of constructing a planted bench, it was assumed that the with-project seasonal shoreline will be shifted away from the existing shade providing canopy. Under this assumption, existing summer-fall values for overhanging shade were taken as the starting point for with-project winter-spring conditions. The with-project winter-spring values were further reduced by 75 percent (winter) and 25 percent (spring) to account for defoliation. As a final step, these winter-spring values were reduced by 20 percent to account for trees removed for construction equipment access. With-project overhanging shade values were expected to start at 0 percent as the result of a constructed bench shifting the shoreline away from the existing canopy. The shade growth model used was taken from a previous SAM analysis conducted for Sacramento RM 62.5R (USACE 2008).

Project actions at all other sub-reaches were expected to result in a complete removal of woody vegetation without revegetation efforts. For these sub-reaches, a value of 0 percent shoreline coverage of overhanging shade was applied throughout the life of the project along both summer-fall and winter-spring shorelines.

For more information on the SAM analysis and inputs, refer to the Appendix A.

2.4.3 SAM Results

The SAM results presented below and in Table 10, 11, and 12 are based on a "worst case scenario" analysis, as developed by the Corps. Table 10 and 11 show negative WRI values, but there are several areas where the action will result in improved conditions for salmon and steelhead. These are discussed below, and are summarized in Appendix A table 26, 27, and 28. The with-project conditions for the focus fish species and life stages were evaluated over a 50-year assessment timeline with baseline habitat values for each species and life stage described by pre-project conditions. Biological responses of each focus fish species life stage and average seasonal water surface elevation were predicted within each habitat unit and for each time step, based on habitat variable values and fish residency determined from region-specific timing tables (USACE 2012b). This analysis automatically includes or excludes particular life stages of the focus fish by assessing the river mile locations of each bank repair site, with the encoded timing tables. In general, as calculated, positive differences between the existing and with-project responses are considered to result in improved growth and survival for the focus fish species (*i.e.*, the bank repair action produced superior conditions than pre-project conditions). Negative values indicate the bank repair actions produced inferior conditions when compared with pre-project conditions and reduced growth and survival over a 30 day exposure period. In almost all cases, regardless of the integrated conservation and compensation measures (*i.e.*, installation of IWM, planting riparian habitat, and construction of engineered floodplain) there is a short-term temporal negative habitat impact associated with many of the bank repair activities, mainly because new levee configurations move the river bank away from existing, protected riparian vegetation and because it takes several years for newly planted riparian vegetation to growth out over the river channel and create overhanging shade and other benefits to aquatic habitat such as a source of macroinvertebrate production.

American River

NMFS reviewed the SAM results provided by the Corps. Details of the SAM results can be found Appendix A of this document. This includes tables and graphs of the SAM results from year 0 (beginning of construction) to year 50. Tables 10, 11, and 12 summarize all negative Common Features Project SAM WRI values for Chinook salmon, steelhead, and green sturgeon. It is important to note that when interpreting SAM results, year 0 refers to the year of construction.

Summary of CV spring-run Chinook salmon, Sacramento River winter-run Chinook salmon, CCV steelhead and sDPS green sturgeon effects by water surface elevation per location:

Common Features American River North Reaches A and B:

At fall water surface elevations:

Reduced growth and survival of fry and juvenile rearing CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon are expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The adverse effects are greatest in the first 3 to 5 years for each species at -366 WRI, -712, and -5577, respectively.

Reduced growth and survival of juvenile migrating (smolts) CV spring-run Chinook salmon is expected to extend past 50 years after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this adverse effect is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The adverse effect is greatest at -2303 WRI.

The SAM displays reduced survival of adult migrating CCV steelhead is expected for up to 48 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this potential effect is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The adverse effect is greatest at -1554 WRI and exceeds baseline following year 48 to a maximum increase benefit of 8 WRI.

At winter surface elevations:

Increased growth and survival of fry and juvenile rearing CV spring-run Chinook salmon is expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size reaching a maximum of 1,102 WRI. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO.

Reduced growth and survival of fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The adverse effects are greatest at -36 WRI for steelhead in the first year and the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival is expected. After year one, survival and growth values improve to 1507 for CCV steelhead. The adverse effects to sDPS green sturgeon are greatest at -5020 and are expected to extend past 50 years.

Reduced growth and survival of migrating (smolts) CV spring-run Chinook salmon is expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The adverse effects are greatest at -3,002 WRI. At year 2, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching 1,699 WRI.

The SAM displays reduced survival of adult migrating CCV steelhead for up to 5 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this potential effect is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The adverse effect is greatest at -1554 WRI. At year 5, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching 460 WRI.

Reduced survival of adult residence CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The adverse effect is greatest at -1,558 and -3,621 WRI, respectively. At year 5 for CCV steelhead, the SAM modeled habitat conditions exceed baseline conditions and improves growth and survival conditions are expected, reaching 460 WRI.

At spring water surface elevations:

Increased growth and survival of fry and juvenile rearing CV spring-run Chinook salmon occurs after any construction activities by the first year and reaching a maximum of 1354 WRI. Increased growth and survival of fry and juvenile are expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO.

Reduced growth and survival of fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction due to impacts to riparian habitat IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The adverse effects are greatest at -2681 and -5020, respectively. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1418 WRI. The adverse effects to sDPS green sturgeon are greatest at -5020 WRI and are expected to extend past 50 years.

Reduced growth and survival of juvenile migrating (smolts) CV spring-run Chinook salmon and CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The adverse effects are greatest at -3129 and -2096 WRI, respectively. At year 4, for CV spring-run Chinook salmon, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching 1,699 WRI. At year 2, for CCV steelhead, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching 1173 WRI.

The SAM displays reduced survival of adult migrating CCV steelhead after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this potential effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The adverse effect is greatest at -1635 WRI. At year 6, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching 407 WRI.

Reduced survival of adult resident CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO.

The adverse effects are greatest at -1635 WRI for CCV steelhead in the first six years and the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival is expected. After six years, survival and growth values improve to 407 for CCV steelhead.

At summer surface elevations:

Reduced growth and survival of fry and juvenile rearing CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon are expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The adverse effects are greatest for each species at -421 WRI, -833, and -7118, respectively.

Reduced growth and survival of juvenile migrating (smolts) of CV spring-run Chinook salmon and CCV steelhead are expected to extend past 50 years after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of these adverse effects are quantified in the SAM in table 26 in Appendix A and summarized in table 10 of this BO. The adverse effects are greatest at -3,129 and -3013 WRI, respectively.

Reduced survival of adult resident CV steelhead is expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM and, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The adverse effects on the species are greatest at -3061 WRI, and -942, respectively.

American River South Bank sites A, B, and C

At fall surface elevations:

Reduced growth and survival of fry and juvenile rearing CV spring run Chinook salmon, CCV steelhead, and sDPS green sturgeon are expected after any construction activities due to impacts riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The adverse effects are greatest for each species at -229 WRI, -489, and -2154, respectively. At year 26 for CV spring run Chinook salmon and year 36 for CCV steelhead, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 112 WRI and 88, respectively. The adverse effects to sDPS green sturgeon are greatest at -2154 and are expected to extend past 50 years.

Reduced growth and survival of juvenile migrating (smolts) CV spring run Chinook salmon is expected after any construction due to impacts riparian habitat, IWM, and bank substrate size. The amount and extent of this adverse effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The adverse effect is greatest at -620 WRI. After year 21, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected reaching a maximum of 526 WRI.

The SAM displays increased survival of adult migrating CV steelhead after construction activities due to impacts), IWM, and bank substrate size. The amount and extent of this potential effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The increased benefit maximizes at 3696 of WRI.

Increased survival of adult resident CCV steelhead is expected after construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The maximum increase benefit is for the species is 3696 and WRI and 1548, respectively.

At winter water surface elevations:

Increased growth and survival of fry and juvenile rearing CV spring run Chinook salmon occurs after any construction activities by the first year and reaching a maximum of 1578 WRI. The amount and extent of this effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO.

Reduced growth and survival of fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction due to impacts to riparian habitat IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The adverse effects are greatest at – 489 WRI and – 876, respectively. At year 36, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 88 WRI. At year one, the SAM modeled habitat conditions for sDPS green sturgeon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 2941 WRI.

Increased growth and survival of juvenile migrating (smolts) CV spring run Chinook salmon is expected to occur after construction activities due to impacts on riparian habitat, IWM and, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The maximum increase benefit for this species is 5377 WRI.

The SAM displays increased survival of adult migrating CCV steelhead after construction activities due to impacts on riparian habitat, IWM and, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The increased benefit maximizes at 4015.

Increased survival of adult resident CV steelhead is expected to occur after construction activities, the maximum increase benefit for this species is 4015 WRI.

At spring water surface elevations:

Increased growth and survival of fry and juvenile rearing CV spring run Chinook salmon and CCV steelhead occurs starting at year 0 and increased to the maximum above baseline scores of 2,100 and 2,601 WRI, respectively. Reduced growth and survival of fry and juvenile rearing sDPS green sturgeon is expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of these effects are quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The greatest adverse effect is at -876 WRI. At year 1, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 2,941 WRI.

Increased growth and survival of juvenile migrating (smolts) CV spring run Chinook salmon and CV steelhead is expected due to impacts on riparian habitat, IWM, and bank substrate size. The greatest effects for each species is 5123 WRI and 4061 WRI respectively. The amount and extent of this potential effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO.

The SAM displays increased survival of adult migrating CCV steelhead after the first year of construction due to impacts on riparian habitat, IWM, and bank substrate size the amount and extent of this potential effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The maximum benefit is 4164 WRI.

Increased survival of resident CCV steelhead occurs starting at year 0 and increased to above baseline 4164 WRI due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of these effects are quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO.

Increased survival of adult resident CV steelhead is expected to occur after construction activities, the maximum increase benefit for this species is 4015 WRI.

At summer water surface elevations:

Reduced growth and survival of fry and juvenile rearing CV spring run Chinook salmon, CCV steelhead, and sDPS green sturgeon are expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The adverse effects are greatest at – 239, -512, and – 2496 WRI, respectively. At year 26, the SAM modeled habitat conditions for CV spring run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 111 WRI. At approximately year 6, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 64 WRI. The adverse effects to sDPS green sturgeon are expected to extend past 50 years.

Reduced growth and survival of juvenile migrating (smolts) CV spring run Chinook salmon and CCV steelhead are expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of these effects are quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The adverse effects are greatest at -967 and -722 WRI, respectively. At year 22, the SAM modeled habitat conditions for CV spring run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 510 WRI. At year 25, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 583 WRI.

Increased survival of adult resident CCV steelhead is expected after construction activities due to impacts on riparian habitat, IWM, and bank substrate size, with maximum benefits of 3616 and 1537 WRI, respectively. The amount and extent of this effect is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO.

Project actions along portions of the American River reach will likely not include bank armoring in their final design, which will significantly reduce estimated impacts to fish species. Additional compensatory mitigation design features or improved erosion repair designs may result in reduced impact compared to the legacy designs used for the basis of this analysis. Site specific designs will be implemented on a site by site basis in consultation with resource agencies and project partners to minimize impacts as well as maximize opportunities for implementing onsite compensatory mitigation features.

The Corps has proposed to offset the effects with onsite and offsite compensation. During project implementation, site specific SAM analyses will be run on final designs to better evaluate these effects. These offsets are likely to improve growth and survival of Chinook salmon and steelhead at higher value habitats in the Delta and along their primary migration corridor of the Sacramento and American Rivers, and spawning and rearing areas along the American River.

Sacramento River Sites D,E,F, and G

At fall water surface elevations:

Reduced growth and survival of fry and juvenile rearing CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. Reduced growth and survival of fry and juvenile rearing sDPS green sturgeon is expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of these effects are quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The greatest adverse effects for the salmonids are -558 WRI, -1156, and -558 WRI respectively. The SAM modeled habitat conditions exceed baseline conditions and improve growth and survival is expected in year 35, 44, and 35, respectively with maximum values reaching 116, 99, and 116 WRI, respectively. The adverse effects to sDPS green sturgeon are greatest at -4674 WRI and are expected to extend past 50 years.

Reduced growth and survival of juvenile migrating (smolts) CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon is expected to extend past 50 years after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of these adverse effects are quantified in the SAM analysis table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest at -3845 WRI, -3985, and -3845, respectively.

The SAM displays reduced survival of adult migrating CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and the extent of these potential effects is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The greatest adverse effects for the salmonids are -1394 WRI, -2053, and 1394, respectively. The SAM modeled habitat conditions exceed baseline conditions and improved growth and survival is expected at years 35, 29, and 35 respectively. After these years, survival and growth values improve to 362, WRI, 832, and 362 WRI, respectively.

Reduced survival of adult resident CCV steelhead after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this potential effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effect is greatest at -2053 WRI and exceeds baseline following year 29, where adult resident survival increases to a maximum value of 832 WRI.

At winter surface elevations:

Increased growth and survival of fry and juvenile rearing CV spring run Chinook salmon and Sacramento River winter-run Chinook salmon occurs after any construction activities by the first year and reaching a maximum of 2390 WRI for both species. The amount and extent of this effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO.

Reduced growth and survival of fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction due to impacts on riparian habitat, IWM and, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest at -77 and -4397, respectively. At year 1, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 3234 WRI. The adverse effects to sDPS green sturgeon are expected to extend past 50 years.

Reduced growth and survival of juvenile migrating (smolts) CCV spring run Chinook salmon, CCV steelhead, and CV winter run is expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this adverse effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest for the species at -3451 WRI, -3044, and -3451, respectively. At year two, the SAM modeled habitat conditions for CV spring run Chinook salmon and Sacramento River winter-run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 4794 WRI for both species. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 3355 WRI.

The SAM displays reduced survival of adult migrating CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon are expected to occur after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this potential effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest for the species at -892 WRI, -1747, and -892 WRI, respectively. At year 4, the SAM modeled habitat conditions for CV spring run Chinook salmon and CV winter run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 643 WRI. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1455 WRI.

Reduced survival of adult residence CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest for the species at -1801 WRI, and -3068, respectively. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1757 WRI.

At spring water surface elevations:

Increased growth and survival of fry and juvenile rearing CV spring run and winter-run Chinook salmon occurs after any construction activities by the first year and reaching a maximum of 3445 WRI. The amount and extent of this effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO.

Reduced growth and survival of fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest at -36 WRI and -4397, respectively. At year 1, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 4317 WRI. The adverse effects to sDPS green sturgeon are expected to extend past 50 years.

Reduced growth and survival of juvenile migrating (smolts) CCV spring run Chinook salmon, CCV steelhead, and CV winter run is expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this adverse effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest for the species at -3484 WRI, -3082, and -3484, respectively. At year 2, the SAM modeled habitat conditions for CV spring run Chinook salmon and Sacramento River winter-run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 4862 WRI for both species. At year three, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 3474 WRI.

The SAM displays reduced survival of adult migrating CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon are expected to occur after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this potential effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest for the species at -946 WRI, -1801, and -

946 WRI, respectively. At year 4, the SAM modeled habitat conditions for CV spring run Chinook salmon and CV winter run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 931 WRI. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1757 WRI.

Reduced survival of adult residence CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest for the species at -1801 WRI, and -3068, respectively. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1757 WRI.

At summer water surface elevations:

Reduced growth and survival of fry and juvenile rearing CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. Reduced growth and survival of fry and juvenile rearing sDPS green sturgeon is expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of these effects are quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest for the salmonids are -578 WRI, -1206, and -578 WRI respectively. The SAM modeled habitat conditions exceed baseline conditions and improve growth and survival is expected in years 36, 45, and 36, respectively, with maximum increased WRI values of 113, 92, and 113. The adverse effects to sDPS green sturgeon are greatest at -5009 WRI and are expected to extend past 50 years.

Reduced growth and survival of juvenile migrating (smolts) CCV spring run Chinook is expected to extend past 50 years after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this adverse of these adverse effects are quantified in the SAM analysis table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest at -4258 WRI.

The SAM displays reduced survival of adult migrating CV spring run Chinook salmon, CV steelhead, and Sacramento River winter-run Chinook salmon after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and the extent of these potential effects is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The greatest adverse effects for these species are -2136 WRI, -3793, and -2136 WRI, respectively. The SAM modeled habitat conditions exceed baseline conditions and improved growth and survival is expected at years 37, 32, and 37 respectively. After these years, survival and growth values improve to 319 WRI, 748, and 319 WRI, respectively.

Reduced survival of adult residence CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this effect is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The adverse effects are greatest for the species at -3793 WRI, and -1298, respectively. At year

32, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 748 WRI.

Effects at the Sacramento Weir and Bypass

Bypass flooding may affect juvenile fish in two different manners: (1) stranding (and killing) of juvenile fish in the widened bypass is possible on the declining limb of flood flows when weir operations cease after a flood event, and (2) increasing floodplain inundation area and increasing juvenile growth and survival. Sommer *et. al.* (2001), have demonstrated that the Yolo Bypass, the primary floodplain of the lower Sacramento River, provides better rearing and migration habitat for juvenile chinook salmon (*Oncorhynchus tshawytscha*) than adjacent river channels. We expect that due to the proximity of the Sacramento Bypass to the Yolo Bypass, the fact that the Sacramento Bypass flows into the Yolo Bypass and similar floodplain conditions in both bypasses, that similar growth and survival conditions would be expected. Both effects are expected to occur approximately once every ten years when the river reaches an elevation of 27.5 feet at the I Street gage with a forecast to continue rising. The duration of bypass inundation is highly variable depending of the magnitude and duration of flood events. After a flood event, weir gates are typically closed as rapidly as practicable once the stage at the weir drops below 25 feet. This provides "flushing" flows to re-suspend sediment deposited in the Sacramento River between the Sacramento Weir and the American River during the low flow periods when the weir is open during the peak of the flood event Baseline stranding and growth levels are not known and it is difficult to predict specific stranding rates with a widened bypass, however, the Corps proposes to grade new and existing bypass features to drain in a manner that reduce juvenile stranding.

Interruption of upstream passage of adult salmonids and sturgeon along the Sacramento weir and stranding within the bypass may occur due to the declining hydrograph as a result of the widening of the bypass. This is also expected to occur once every ten years following the spilling of river water and as the flood flows recede. Stranding in the Sacramento Bypass and blocked upstream passage may not occur however, with the implemented conservation measures as outlined in the project description and may in fact improve passage conditions currently found at the Sacramento weir and bypass and reduce current stranding rates.

Migrating green sturgeon in the lower portion of the Sacramento River become stranded during high flow events in flood control weirs and bypasses. In April 2011, 24 threatened green sturgeon were stranded in two flood diversions along the Sacramento River. Modeling and research suggests that recurrent stranding of a similar magnitude without rescue could affect the long-term viability of Green Sturgeon (Thomas et. al., 2013). With the widening of the Sacramento Weir for increased flow capacity during high flow events, there is a potential to maintain or increase stranding of adults behind the weir individuals if no passage criteria are included within the weir design. However, as stated in the conservation measures as outlines in the Proposed Action section of this BO, the Corps also will work with local cost share sponsors to ensure GRR-related future flood risk reduction actions related to widening the Sacramento Weir shall fully mitigate upstream and downstream fish passage effects at the weir and within the spillway basin. The goal is to ensure that adult CV spring-run and Sacramento River inter-run Chinook salmon, CCV steelhead, and sDPS green sturgeon are able to migrate upstream while the weir is spilling into the bypass and that juvenile stranding in the spillway basin is minimized to the maximum extent possible. These measures are expected to reduce juvenile and adult stranding in the bypass and provide long-term benefits through improved growth and survival of juveniles and improved survival of adults.

Implementation of the Corps proposed Green Sturgeon Conservation Measures

The implementation of the Corp's Green Sturgeon Conservation Measures will serve several purposes to address scientific uncertainty about the species in the study area and to provide compensatory mitigation for the adverse effects related to shoreline and benthic habitat impacts. The HMMP with ensure that adverse impacts of future West Sacramento projects are sufficiently compensated in order to allow for the growth, survival and recovery of the species in the study area. Coordination of the HMMP with the IEP will leverage green sturgeon scientific expertise to ensure selected mitigation actions fully address the micro- and macro-ecological and survival needs of the species in the study area. Refinement of the SAM or development of alternative green sturgeon survival and response model using the Corps' Hydrologic Ecosystem Function Model, in consultation with NMFS and the IEP, will result in new modeling capacity that more accurately evaluates adverse project actions and the beneficial effects of mitigation actions relative to the growth and survival of green sturgeon in the study area. Restoring and compensating for the number of acres and ecological function of impacted benthic habitat and the initiation of this compensatory mitigation in the study area prior to the commencement of levee construction will reduce the impact of levee construction actions. The development of SMART compensatory mitigation objectives will ensure that all of the ecological impacts of levee construction actions are fully addressed.

2.4.4 Project Effects on Critical Habitat

For CV spring-run Chinook salmon and steelhead, the project generally will have short term impacts on the freshwater rearing and freshwater rearing PCEs of critical habitat. For winter-run Chinook salmon, and for winter-run Chinook salmon impacted essential features of critical habitat that will be affect include the river water, river bottom, and adjacent riparian zone used by fry and juveniles for rearing. The SAM model, which models fish response, also serves as a good proxy for measuring impact to these species critical habitat because it the model evaluates changes to important attributes of PCEs and essential features including overhanging shade, substrate size, instream woody material, bank slope and instream aquatic vegetation. The changes to these features are recognized in Table 10, 11 and 12 below. In general, impacts to critical habitat will generally last between 1 and 10 years, and in almost all cases they improve each year and eventually exceed baseline conditions over the life of the project. For these reasons, we do not expect the proposed action to reduce the conservation value of the critical habitat.

Because the proposed action occurs along the lower Sacramento River at the convergence of the north Delta, the action area includes both freshwater and estuarine habitat types. For green sturgeon, this means there are freshwater and estuarine including:

Freshwater

a) Food resources. Abundant prey items for larval, juvenile, subadult, and adult life stages.
b) Substrate type or size (*i.e*., structural features of substrates). Substrates suitable for egg deposition and development (*e.g.*, bedrock sills and shelves, cobble and gravel, or hard clean sand, with interstices or irregular surfaces to "collect" eggs and provide protection from predators, and free of excessive silt and debris that could smother eggs during incubation), larval development (*e.g.*, substrates with interstices or voids providing refuge from predators and from high flow conditions), and feeding of juveniles, subadults, and adults (*e.g.*, sand/mud substrates).

Estuarine

a) Food resources. Abundant prey items within estuarine habitats and substrates for juvenile, subadult, and adult life stages.

NMFS estimates that approximately 20 acres of soft substrate habitat below the ordinary high water mark will be permanently lost to rock revetment. This number was calculated by using the provided linear feet in reaches C, D, E, F, and G in Table 4 and multiplying it by 15 feet which is the length of the distance revetment is placed from the bank into the river. This is a conceptual estimate that will be further refined during the preliminary engineering design (PED) phase before construction begins. This loss of habitat is expected to adversely affect benthic substrate and impair food resources for all life stages; and the quantity of sediment to allow for normal physiological and behavioral responses to the environment. Similar to salmon and steelhead, the SAM serves as a reasonable proxy for measuring impacts to critical habitat. For most life stages and season water surface elevations, the SAM show immediate adverse effects that continue to decline for the life of the project. However, the Corps' Green Sturgeon Conservation Measures will reduce the impact on critical habitat by providing compensatory mitigation within the action area. Specifically, the HMMP shall also restore or compensate for the number of acres and ecological function of soft bottom benthic substrate for sDPS green sturgeon permanently lost to project construction. This compensation will be carried out within the lower Sacramento River/North Delta in order to offset the adverse modification to designated critical habitat. The restored habitat will be capable of providing abundant benthic prey, freshwater or estuarine areas with adequate water quality, temperature, salinity, oxygen content, and other chemical characteristics, necessary for normal behavior, growth and viability of all life stages. It will also provide safe and unobstructed migratory pathways necessary for timely passage of adult, sub-adult, and juvenile fish within the region's different estuarine habitats and between the upstream riverine habitat and the marine habitats.

2.5 Cumulative Effects

"Cumulative effects" are those effects of future state or private activities, not involving Federal activities, that are reasonably certain to occur within the action area of the Federal action subject to consultation (50 CFR 402.02). Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the ESA.

2.5.1 Water Diversions and Agricultural Practices

Water diversions for irrigated agriculture, municipal and industrial use, and managed wetlands are found along the Common Features GRR action area. Depending on the size, location, and season of operation, these unscreened diversions entrain and kill many life stages of aquatic species, including juvenile listed anadromous species. For example, as of 1997, 98.5 percent of the 3,356 diversions included in a CV database were either unscreened or screened insufficiently to prevent fish entrainment (Herren and Kawasaki 2001).

Agricultural practices in the action area may adversely affect riparian and wetland habitats through upland modifications of the watershed that lead to increased siltation or reductions in water flow. Grazing activities from cattle operations can degrade or reduce suitable critical habitat for listed salmonids by increasing erosion and sedimentation as well as introducing nitrogen, ammonia, and other nutrients into the watershed, which then flow into the receiving waters of the associated watersheds. Stormwater and irrigation discharges related to both agricultural and urban activities contain numerous pesticides and herbicides that may adversely affect listed salmonid and sDPS green sturgeon reproductive success and survival rates (Dubrovsky *et al.* 1998, 2000; Daughton 2003).

2.5.2 Aquaculture and Fish Hatcheries

More than 32-million fall-run Chinook salmon, 2-million spring-run Chinook salmon, 1-million late fall-run Chinook salmon, 0.25-million winter-run Chinook salmon, and 2-million steelhead are released annually from six hatcheries producing anadromous salmonids in the CV. All of these facilities are currently operated to mitigate for natural habits that have already been permanently lost as a result of dam construction. The loss of this available habitat results in dramatic reductions in natural population abundance which is mitigated for through the operation of hatcheries. Salmonid hatcheries can, however, have additional negative effects on ESA-listed salmonid populations. The high level of hatchery production in the CV can result in high harvest-to-escapements ratios for natural stocks. California salmon fishing regulations are set according to the combined abundance of hatchery and natural stocks, which can lead to over-exploitation and reduction in the abundance of wild populations that are indistinguishable and exist in the same system as hatchery populations. Releasing large numbers of hatchery fish can also pose a threat to wild Chinook salmon and steelhead stocks through the spread of disease, genetic impacts, competition for food and other resources between hatchery and wild fish, predation of hatchery fish on wild fish, and increased fishing pressure on wild stocks as a result of hatchery production. Impacts of hatchery fish can occur in both freshwater and the marine ecosystems. Limited marine carrying capacity has implications for naturally produced fish experiencing competition with hatchery production. Increased salmonid abundance in the marine environment may also decrease growth and size at maturity, and reduce fecundity, egg size, age at maturity, and survival (Bigler *et al.* 1996). Ocean events cannot be predicted with a high degree of certainty at this time. Until good predictive models are developed, there will be years when hatchery production may be in excess of the marine carrying capacity, placing depressed natural fish at a disadvantage by directly inhibiting their opportunity to recover (NPCC 2003).

2.5.3 Increased Urbanization

Increases in urbanization and housing developments can impact habitat by altering watershed characteristics, and changing both water use and stormwater runoff patterns. Increased growth will place additional burdens on resource allocations, including natural gas, electricity, and water, as well as on infrastructure such as wastewater sanitation plants, roads and highways, and public utilities. Some of these actions, particularly those which are situated away from waterbodies, will not require Federal permits, and thus will not undergo review through the ESA section 7 consultation process with NMFS.

Increased urbanization also is expected to result in increased recreational activities in the region. Among the activities expected to increase in volume and frequency is recreational boating. Boating activities typically result in increased wave action and propeller wash in waterways. This potentially will degrade riparian and wetland habitat by eroding channel banks and mid-channel islands, thereby causing an increase in siltation and turbidity. Wakes and propeller wash also churn up benthic sediments thereby potentially re-suspending contaminated sediments and degrading areas of submerged vegetation. This in turn will reduce habitat quality for the invertebrate forage base required for the survival of juvenile salmonids and green sturgeon moving through the system. Increased recreational boat operation is anticipated to result in more contamination from the operation of gasoline and diesel powered engines on watercraft entering the associated water bodies.

2.5.4 Global Climate Change

The world is about 1.3°F warmer today than a century ago and the latest computer models predict that, without drastic cutbacks in emissions of carbon dioxide and other gases released by the burning of fossil fuels, the average global surface temperature may rise by two or more degrees in the 21st century (IPCC 2001). Much of that increase likely will occur in the oceans, and evidence suggests that the most dramatic changes in ocean temperature are now occurring in the Pacific (Noakes 1998). Using objectively analyzed data Huang and Liu (2000) estimated a warming of about 0.9°F per century in the Northern Pacific Ocean.

Sea levels are expected to rise by 0.5 to 1.0 meters in the northeastern Pacific coasts in the next century, mainly due to warmer ocean temperatures, which lead to thermal expansion much the same way that hot air expands. This will cause increased sedimentation, erosion, coastal flooding, and permanent inundation of low-lying natural ecosystems (*e.g.*, salt marsh, riverine, mud flats) affecting listed salmonid and green sturgeon PCEs. Increased winter precipitation, decreased snow pack, permafrost degradation, and glacier retreat due to warmer temperatures will cause landslides in unstable mountainous regions, and destroy fish and wildlife habitat, including salmon-spawning streams. Glacier reduction could affect the flow and temperature of rivers and streams that depend on glacier water, with negative impacts on fish populations and the habitat that supports them.

Summer droughts along the South Coast and in the interior of the northwest Pacific coastlines will mean decreased stream flow in those areas, decreasing salmonid survival and reducing water supplies in the dry summer season when irrigation and domestic water use are greatest. Global warming may also change the chemical composition of the water that fish inhabit: the amount of oxygen in the water may decline, while pollution, acidity, and salinity levels may increase. This will allow for more invasive species to overtake native fish species and impact predator-prey relationships (Peterson and Kitchell 2001, Stachowicz *et al.* 2002).

In light of the predicted impacts of global warming, the CV has been modeled to have an increase of between +2^{o}C and +7^{o}C by 2100 (Dettinger *et al.* 2004, Hayhoe *et al.* 2004, Van Rheenen *et al.* 2004, Stewart 2005), with a drier hydrology predominated by rainfall rather than snowfall. This will alter river runoff patterns and transform the tributaries that feed the CV from a spring and summer snowmelt dominated system to a winter rain dominated system. It can be hypothesized that summer temperatures and flow levels will become unsuitable for salmonid survival. The cold snowmelt that furnishes the late spring and early summer runoff will be replaced by warmer precipitation runoff. This will truncate the period of time that suitable cold-water conditions exist downstream of existing reservoirs and dams due to the warmer inflow temperatures to the reservoir from rain runoff. Without the necessary cold water pool developed from melting snow pack filling reservoirs in the spring and early summer, late summer and fall temperatures downstream of reservoirs, such as Lake Shasta, could potentially rise above thermal tolerances for juvenile and adult salmonids (*i.e.* Sacramento River winter-run Chinook salmon and CCV steelhead) that must hold and/or rear downstream of the dam over the summer and fall periods.

2.5.5 Rock Revetment and Levee Repair Projects

Cumulative effects include non-Federal riprap projects. Depending on the scope of the action, some non-Federal riprap projects carried out by state or local agencies do not require Federal permits. These types of actions and illegal placement of riprap occur within the Sacramento River watershed. For example, most of the levees have roads on top of the levees which are either maintained by the county, reclamation district, owner, or by the state. Landowners may utilize roads at the top of the levees to access part of their agricultural land. The effects of such actions result in continued fragmentation of existing high-quality habitat, and conversion of complex nearshore aquatic to simplified habitats that affect salmonids in ways similar to the adverse effects associated with the Common Features Project.

2.6 Integration and Synthesis

The *Integration and Synthesis* section is the final step of NMFS' assessment of the risk posed to species and critical habitat as a result of the proposed action. In this section, NMFS performs two evaluations: whether, given the environmental baseline and status of the species and critical habitat, as well as future cumulative effects, it is reasonable to expect the proposed action is not likely to: (1) reduce the likelihood of both survival and recovery of the species in the wild; and (2) result in the destruction or adverse modification of designated critical habitat (as determined by whether the critical habitat will remain functional to serve the intended conservation role for the listed anadromous species or retain its current ability to establish those features and functions essential to the conservation of the species).

The *Analytical Approach* described the analyses and tools we have used to complete this analysis. This section is based on analyses provided in the *Status of the Species*, the *Environmental Baseline*, and the *Effects of the Proposed Action*.

In our *Status of the Species* section, NMFS summarized the current likelihood of extinction of each of the listed species. We described the factors that have led to the current listing of each species under the ESA across their ranges. These factors include past and present human activities and climatological trends and ocean conditions that have been identified as influential to the survival and recovery of the listed species. Beyond the continuation of the human activities affecting the species, we also expect that ocean condition cycles and climatic shifts will continue to have both positive and negative effects on the species' ability to survive and recover. The *Environmental Baseline* reviewed the status of the species and the factors that are affecting their survival and recovery in the action area. The *Effects of the Proposed Action* reviewed the exposure of the species and critical habitat to the proposed action and cumulative effects. NMFS then evaluated the likely responses of individuals, populations, and critical habitat. The

Integration and Synthesis will consider all of these factors to determine the proposed action's influence on the likelihood of both the survival and recovery of the species, and on the conservation value of designated critical habitat.

The criteria recommended for low risk of extinction for Pacific salmonids are intended to represent a species and populations that are able to respond to environmental changes and withstand adverse environmental conditions. Thus, when our assessments indicate that a species or population has a moderate or high likelihood of extinction, we also understand that future adverse environmental changes could have significant consequences on the ability of the species to survive and recover. Also, it is important to note that an assessment of a species having a moderate or high likelihood of extinction does not mean that the species has little or no chance to survive and recover, but that the species faces moderate to high risks from various processes that can drive a species to extinction. With this understanding of both the current likelihood of extinction of the species and the potential future consequences for species survival and recovery, NMFS will analyze whether the effects of the proposed action are likely to in some way increase the extinction risk each of the species faces.

In order to estimate the risk to CV spring-run Chinook salmon, Sacramento River winter-run Chinook salmon, CCV steelhead, and green sturgeon as a result of the proposed action, NMFS uses a hierarchical approach. The condition of the ESU or DPS is reiterated from the *Status of the Species* section of this BO. We then consider how the status of populations in the action area, as described in the *Environmental Baseline*, is affected by the proposed action. Effects to individuals is summarized, and to the consequence of those effects is applied to establish risk to the diversity group, ESU, or DPS.

In designating critical habitat, NMFS considers the physical and biological features (essential features) within the designated areas that are essential to the conservation of the species and that may require special management considerations or protection. Such requirements of the species include, but are not limited to: (1) space for individual and population growth, and for normal behavior; (2) food, water, air, light, minerals, or other nutritional or physiological requirements; (3) cover or shelter; (4) sites for breeding, reproduction, or rearing offspring, and generally; and (5) habitats that are protected from disturbance or are representative of the historic geographical and ecological distributions of this species [see 50 CFR § 424.12(b)]. In addition to these factors, NMFS also focuses on the principal biological or physical constituent elements within the defined area that are essential to the conservation of the species. Primary constituent elements may include, but are not limited to, spawning sites, food resources, water quality and quantity, and riparian vegetation.

The basis of the "destruction or adverse modification" analysis is to evaluate whether the proposed action results in negative changes in the function and role of the critical habitat in the conservation of the species. As a result, NMFS bases the critical habitat analysis on the affected areas and functions of critical habitat essential to the conservation of the species, and not on how individuals of the species will respond to changes in habitat quantity and quality.

2.6.1 Status of the CV Spring-Run Chinook Salmon ESU

The CV spring-run Chinook salmon ESU is at moderate risk of extinction (Lindley *et al.* 2007). The most recent viability assessment of CV spring-run Chinook salmon was conducted during NMFS' 2011 status review (NMFS 2011b). This review found that the biological status of the ESU has worsened since the last status review. In the 2011, the ESU as a whole could not be considered viable because there were no extant viable populations in the three other diversity groups. In addition, Mill, Deer, and Butte creeks are close together geographically, decreasing the independence of their extinction risks due to catastrophic disturbance. These and other conditions covered in the 2011 status review have not changed since 2011. While the abundance for some populations appears to be slightly improving, the ESU is still demonstrating a high variability in adult abundance (especially in Butte Creek), we cannot say based on the trend over the past three years that the risk of extinction for the ESU has improved.

2.6.2 Summary of the Status of the CCV Steelhead DPS

All indications are that natural Central Valley steelhead have continued to decrease in abundance and in the proportion of natural fish over the past 25 years (Good et al. 2005; NMFS 2011); the long-term trend remains negative. Hatchery production and returns are dominant over natural fish, and one of the four hatcheries is dominated by Eel/Mad River origin steelhead stock. Continued decline in the ratio between naturally produced juvenile steelhead to hatchery juvenile steelhead in fish monitoring efforts indicates that the wild population abundance is declining. Hatchery releases (100 percent adipose fin-clipped fish since 1998) have remained relatively constant over the past decade, yet the proportion of adipose fin-clipped hatchery smolts to unclipped naturally produced smolts has steadily increased over the past several years.

Although there have been recent restoration efforts in the San Joaquin River tributaries, CCV steelhead populations in the San Joaquin Basin continue to show an overall very low abundance, and fluctuating return rates. Lindley et al. (2007) developed viability criteria for Central Valley salmonids. Using data through 2005, Lindley et al. (2007) found that data were insufficient to determine the status of any of the naturally-spawning populations of CCV steelhead, except for those spawning in rivers adjacent to hatcheries, which were likely to be at high risk of extinction due to extensive spawning of hatchery-origin fish in natural areas.

The widespread distribution of wild steelhead in the Central Valley provides the spatial structure necessary for the DPS to survive and avoid localized catastrophes. However, most wild CCV populations are very small, are not monitored, and may lack the resiliency to persist for protracted periods if subjected to additional stressors, particularly widespread stressors such as climate change (NMFS 2011). The genetic diversity of CCV steelhead has likely been impacted by low population sizes and high numbers of hatchery fish relative to wild fish. The life-history diversity of the DPS is mostly unknown, as very few studies have been published on traits such as age structure, size at age, or growth rates in CCV steelhead.

The CCV steelhead DPS is at high risk of extinction (NMFS 2011c), and the extinction risk is increasing. The most recent viability assessment of CCV steelhead was conducted during NMFS' 2011 status review (NMFS 2011c). This review found that the biological status of the ESU has worsened since the last status review recommend that its status be reassessed in two to three years as opposed to waiting another five years, if it does not respond positively to improvements in environmental conditions and management actions.

2.6.3 Summary of the Status of the Green Sturgeon southern DPS

The viability of sDPS green sturgeon is constrained by factors such as a small population size, lack of multiple populations, and concentration of spawning sites into just a few locations. The risk of extinction is believed to be moderate because, although threats due to habitat alteration are thought to be high and indirect evidence suggests a decline in abundance, there is much uncertainty regarding the scope of threats and the viability of population abundance indices (NMFS 2010a).

Although the population structure of sDPS green sturgeon is still being refined, it is currently believed that only one population of sDPS green sturgeon exists. Lindley et al. (2007), in discussing winter-run Chinook salmon, states that an ESU represented by a single population at moderate risk of extinction is at high risk of extinction over the long run. This concern applies to any DPS or ESU represented by a single population, and if this were to be applied to sDPS green sturgeon directly, it could be said that sDPS green sturgeon face a high extinction risk. However, the position of NMFS, upon weighing all available information (and lack of information) has stated the extinction risk to be moderate (NMFS 2010a).

Adult green sturgeon migrate through the action area to reach upstream spawning habitat. Early larval drift and rearing is also likely to occur upstream from the action area near spawning sites. As juveniles migrate downstream toward the ocean, they become more oriented to benthic environments. Juvenile green sturgeon migrate toward seawater portions of natal estuaries as early as one and a half years old (75cm TL, Allen and Cech 2007). Juvenile and subadult green sturgeon may rear in freshwater and brackish water for up to three years. During laboratory experiments, juvenile green sturgeon select low light habitats and are primarily inactive during daylight hours, while they seemed to forage actively during night (Kynard et al. 2005). Juvenile green sturgeon were captured during the summer in shallow shoals (1-3 m deep) in the lower San Joaquin River (Radtke 1966), and are assumed to occupy similar habitats along the lower Sacramento River.

There is a strong need for additional information about sDPS green sturgeon, especially with regards to a robust abundance estimate, a greater understanding of their biology, and further information about their micro- and macro-habitat ecology.

2.6.4 Summary of Status of the Environmental Baseline and Cumulative Effects in the Action Area

The action area is used by most diversity groups and populations of the salmon, steelhead and green sturgeon ESUs and DPSs that are the subject of this BO. Salmon, steelhead and green sturgeon use the action area as an upstream and downstream migration corridor and for rearing.

Within the action area, the essential features of freshwater rearing and migration habitats for salmon, steelhead and green sturgeon have been transformed from a meandering waterway lined with a dense riparian vegetation, to a highly leveed system under varying degrees of constraint of riverine erosional processes and flooding. Levees have been constructed near the edge of the river and most floodplains have been completely separated and isolated from the Sacramento and American Rivers (USFWS 2000). Severe long-term riparian vegetation losses have occurred in this part of the Sacramento and American Rivers, and there are large open gaps without the presence of these essential features due to the high amount of riprap (USFWS 2000). The change in the ecosystem as a result of halting the lateral migration of the river channel, the loss of floodplains, the removal of riparian vegetation and IWM have likely affected the functional ecological processes that are essential for growth and survival of salmon, steelhead and green sturgeon in the action area.

The *Cumulative Effects* section of this BO describe how continuing or future effects such as non-Federal water diversions, the discharge of point and non-point source chemical contaminant discharges, and climate change affect the species in the action area. These actions typically result in habitat fragmentation, and conversion of complex nearshore aquatic habitat to simplified habitats that reduce the carrying capacity of the rearing and migratory corridors.

2.6.5 Summary of Project Effects on Sacramento River Winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead and sDPS Green Sturgeon Individuals

1. <u>Construction and O&M-related Effects</u>

During construction and O&M, some injury or death to individual fish could result from rock placement (crushing), or predation related to displacement of individuals away from the shoreline or at the margins or turbidity plumes. These construction type actions will occur during summer and early fall months, when the abundance of individual salmon and steelhead is low and should result in correspondingly low levels of injury or death.

Green sturgeon adults may be migrating downstream through the area during construction (Heublein et al. 2009) and juveniles may be in the area May through September (noted in section 2.4.1, pg. 83). Adults and subadults would likely respond to construction activities by quickly swimming away, escaping injury, but juveniles are not strong swimmers and will experience the greatest exposure and may encounter short-term construction-related noise, physical disturbance, and water quality changes that may cause injury or harm by increasing the susceptibility of some individuals to predation by temporarily disrupting normal behaviors and affecting sheltering abilities.

2. <u>Long-term Effects Related to the Presence of Project Features</u>

For juvenile and outmigrating salmon and steelhead, the proposed action will result in short- and long-term adverse effects to individual salmon and steelhead that are exposed to the project features along the Sacramento and American Rivers. These adverse effects are indexed by SAM model results and expressed as WRI deficits. The long term WRI deficits are highest at fall and summer water surface elevations. We interpret those flow conditions to be consistent with summer and fall months, which are seasons during which individual Sacramento River winter-run, CV spring-run and CCV steelhead is low (fall), or they are absent. For other seasonal water surface elevations, there will be short term reductions in survival and growth as indicated by WRI values, but these values will increase above baseline and result in beneficial conditions that exceed baseline values.

NMFS expects that the most significant habitat deficits will occur at summer and fall flows due to the inherent difficulty of successfully establishing riparian vegetation in a zone that is impacted by boat wake erosion, and variable flow conditions typical of a regulated river system. The modeled summer and fall habitat deficits are expected to affect relatively few fish, since the majority of adult migration and juvenile rearing and emigration within the action area does not occur during these periods. Instead, a significant majority of Chinook salmon and steelhead adult migration and juvenile rearing and emigration occurs during periods of higher flow that are more accurately represented by conditions at average winter and spring WSELs. Long-term effects at the winter and spring WSELs will be substantially positive, with conditions improving beyond existing conditions through year 50.

SAM modeled WRI values for adult salmon and steelhead migration and steelhead residence (outmigrating post spawning adults) are deficits at winter, spring and summer water surface elevations. These effects are considered to be *de minimus* because, although modeled as a result of a reduction in IWM and riparian habitat, the actual survival of adults is unlikely to be affected because there will be no increase in predation, and the upstream migration will not be impeded by any structural features that influence upstream migration.

Project actions along portions of the American River reach will likely not include bank armoring in their final design, which will significantly reduce estimated impacts to fish species. Additional compensatory mitigation design features or improved erosion repair designs may result in reduced impact compared to the legacy designs used for the basis of this analysis. Site specific designs will be implemented on a site by site basis in consultation with resource agencies and project partners to minimize impacts as well as maximize opportunities for implementing onsite compensatory mitigation features.

During project implementation, site specific SAM analyses will be run on final designs to better evaluate impact. SAM results will be used by the Corps and NMFS in the negotiation of appropriate mitigation for project actions. Although short term impacts are expected to be self-mitigating through the development of onsite compensatory mitigation features, the Corps will compensate for the temporal impacts to habitat through the purchase of offsite compensatory mitigation credits. Typically appropriate mitigation will be based on the identification of maximum negative WRI values. Offsite mitigation is expected to provide compensatory mitigation value at all seasonal habitat conditions. Longer term impacts to habitat may not recover to baseline conditions over the life of the project due to design restrictions. These impacts to habitat will be compensated through the purchase of offsite compensatory mitigation credits as well as the incorporation of additional onsite compensatory mitigation features (*i.e.* low water plantings, additional IWM, additional revegetation).

Details regarding the extent of juvenile green sturgeon rear in this reach of the river is not clear, but all juvenile sDPS must pass through the area on their migration to the estuary and ocean. Levee repair actions in the Common Features Study Area are likely to only affect the juvenile rearing life stage and probably have little to no adverse impacts on the adult life stages of green sturgeon because spawning habitat is not present in the action area and upstream migrating adults are probably more influenced by impacts that affect swimming speed and upstream passage than shoreline habitat manipulations. The levee repair actions will cause long-term reductions in shoreline habitat features for juvenile rearing and migrating green sturgeon and a loss of several acres of benthic habitat that is most likely used for foraging.

The implementation of the Corp's Green Sturgeon Conservation Measures will serve several purposes to address scientific uncertainty about the species in the study area and to provide compensatory mitigation for the adverse effects related to shoreline and benthic habitat impacts. The HMMP with ensure that adverse impacts of future Common Features GRR projects are sufficiently compensated in order to allow for the growth, survival and recovery of the species in the study area. Coordination of the HMMP with the IEP will leverage green sturgeon scientific expertise to ensure selected mitigation actions fully address the micro- and macro-ecological and survival needs of the species in the study area. Refinement of the SAM or development of alternative green sturgeon survival and response model using the Corps' Hydrologic Ecosystem Function Model, in consultation with NMFS and the IEP, will result in new modeling capacity that more accurately evaluates adverse project actions and the beneficial effects of mitigation actions relative to the growth and survival of green sturgeon in the study area. Restoring and compensating for the number of acres and ecological function of impacted benthic habitat and the initiation of this compensatory mitigation in the study area prior to the commencement of levee construction will reduce the impact of levee construction actions. The development of SMART compensatory mitigation objectives will ensure that all of the ecological impacts of levee construction actions are fully addressed.

The Corps also will work with local cost share sponsors to ensure GRR-related future flood risk reduction actions related to widening the Sacramento Weir shall fully mitigate upstream and downstream fish passage effects at the weir and within the spillway basin. The goal is to ensure that adult CV spring-run and Sacramento River inter-run Chinook salmon, CCV steelhead, and sDPS green sturgeon are able to migrate upstream while the weir is spilling into the bypass and that juvenile stranding in the spillway basin is minimized to the maximum extent possible. Long-term, and once implemented, this measure would be expected to improve the growth and survival of all affected salmon, steelhead and green sturgeon.

2.6.6 Summary of Project Effects on Sacramento River Winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead and sDPS Green Sturgeon Critical Habitat

Within the action area, the relevant PCEs of the designated critical habitat for listed salmonids are migratory corridors and rearing habitat, and for green sturgeon the six PCEs include food resources, water flow, water quality, migratory corridors, water depth, and sediment quality.

Based on SAM modeled WRIs, we expect small reductions in the value of PCEs for salmon and steelhead freshwater rearing due to the temporary loss of riparian habitat, the conversion of natural substrate river banks with revetment and the short term loss of IWM, but these reductions are at fall and summer water surface elevations and not at water surface elevations when the habitat use is the highest and most significant. Additionally, as planted vegetation begins to grow, the quality of rearing habitat will improve over baseline. There will also be SAM modeled WRI deficits for adult migration-related PCEs for all species. These deficits are temporary and eventually increase over baseline, so over time we do not expect these effects to reduce the conservation value of critical habitat.

The current condition of critical habitat for the green sturgeon sDPS in the action area is degraded over its historical conditions. It does not provide the full extent of conservation values necessary for the survival and recovery of the species. In particular, passage and water flow PCEs have been impacted by human actions, substantially altering the historical river characteristics in which the green sturgeon sDPS evolved.

The Corps estimates that approximately 20 acres of soft substrate habitat below the ordinary high water mark will be permanently lost to rock revetment. This is a conceptual estimate that will be further refined during the PED phase before construction begins. This loss of habitat is expected to adversely affect benthic substrate and impair food resources for all life stages; and the quantity of sediment to allow for normal physiological and behavioral responses to the environment. Similar to salmon and steelhead, the SAM serves as a reasonable proxy for measuring impacts to critical habitat. For most life stages and season water surface elevations, the SAM show immediate adverse effects that continue to decline for the life of the project. However, the Corps' Green Sturgeon Conservation Measures will reduce the impact on critical habitat by providing compensatory mitigation within the action area. Specifically, the HMMP shall also restore or compensate for the number of acres and ecological function of soft bottom benthic substrate for sDPS green sturgeon permanently lost to project construction. This compensation will be carried out within the lower Sacramento River/North Delta in order to offset the adverse modification to designated critical habitat. The restored habitat will be capable of providing abundant benthic prey, freshwater or estuarine areas with adequate water quality, temperature, salinity, oxygen content, and other chemical characteristics, necessary for normal behavior, growth and viability of all life stages. It will also provide safe and unobstructed migratory pathways necessary for timely passage of adult, sub-adult, and juvenile fish within the region's different estuarine habitats and between the upstream riverine habitat and the marine habitats.

The proposed action will permanently destroy up to 20 acres of critical habitat but also includes implementation of a comprehensive suite of conservation measures that will fill important data gaps, address existing modeling insufficiencies and implement compensatory measures with the goal of maintaining green sturgeon growth, survival and recovery in the action area through measures that will be developed in coordination with the IEP's green sturgeon project work team and in consultation with NMFS. The measures will be undertaken prior to or concurrent with project implementation. For these reasons, we expect the proposed action will not reduce the conservation value of critical habitat for sDPS green sturgeon.

2.6.7 Summary

Although there are some short-term and SAM modeled WRI deficits for salmon and steelhead, the effects of these deficits, when added to the environmental baseline and cumulative effects in the action area are small, occur during seasons when fish abundance is low or they are not present at all, and is of short duration. In the case of fry and juvenile rearing and migration for all species, the SAM modeled WRI values show significant increases in the growth and survival of individuals over baseline conditions between years 0 and 13, especially at winter spring water surface elevations, which represent a shoreline area where most emigrating salmon and steelhead would be exposed. Because the WRI measure growth and survival values recover rather quickly and generally exceed baseline conditions, the incremental effects of the action are not expected to increase the extinction risk of the Sacramento River winter-run Chinook salmon and CV spring-run Chinook salmon and ESU CCV steelhead and or reduce the conservation value of their designated critical habitat.

Furthermore, the anticipated growth and survival of salmon, steelhead rearing and juvenile migration are substantially positive and demonstrate how integrating NMFS high priority recovery actions, such as setback levee construction and restoration of floodplain habitat can contribute to an increase in the production and abundance of the Sacramento River winter-run Chinook salmon and CV spring-run Chinook salmon and ESU CCV steelhead.

The project will result in unavoidable impacts to the shoreline and benthic habitat of green sturgeon. However, the Corps' proposed Green Sturgeon Conservation Measures are expected to make significant contributions to monitor the species, address important data gaps in the action area, improve species growth and survival modeling and use the modeling to develop and track the performance of compensatory mitigation with the goal of fully addressing the loss of micro and macro-ecological impacts of the levee construction work in a manner that maintains the growth, survival and recovery of the species. The measures also address critical habitat PCEs and will ensure the conservation value of critical habitat is not reduced.

2.7 Conclusion

After reviewing and analyzing the current status of the listed species and critical habitat, the environmental baseline within the action area, the effects of the proposed action, any effects of interrelated and interdependent activities, and cumulative effects, it is NMFS' biological opinion that the proposed action is not likely to jeopardize the continued existence of Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead and sDPS green sturgeon or destroy or adversely modify their designated critical habitat.

2.8 Incidental Take Statement

Section 9 of the ESA and Federal regulations pursuant to section 4(d) of the ESA prohibit the take of endangered and threatened species, respectively, without a special exemption. "Take" is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. "Harm" is further defined by regulation to include significant habitat modification or degradation that actually kills or injures fish or wildlife by significantly impairing essential behavioral patterns, including breeding, spawning, rearing, migrating, feeding, or sheltering (50 CFR 222.102). "Incidental take" is defined by regulation as takings that result from, but are not the purpose of, carrying out an otherwise lawful activity conducted by the Federal agency or applicant (50 CFR 402.02). Section 7(b)(4) and section 7(o)(2) provide that taking that is incidental to an otherwise lawful agency action is not considered to be prohibited taking under the ESA if that action is performed in compliance with the terms and conditions of this ITS.

The measures described below are non-discretionary, and must be undertaken by the Corps so that they become binding conditions of any grant, contract or permit, as appropriate, for the exemption in section 7(o)(2) to apply. The Corps has a continuing duty to regulate the activity covered by this incidental take statement. If the Corps: (1) fails to assume and implement the terms and conditions, or (2) fails to require the permittee, contractor, or grantee to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to the permit, contract or grant document, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the Corps must report the progress of the action and its impact on the species to NMFS as specified in the incidental take statement (50 CFR §402.14(i)(3)).

2.8.1 Amount or Extent of Take

NMFS anticipates incidental take of adult and juvenile listed CV spring-run Chinook salmon, CCV steelhead, and juvenile sDPS green sturgeon and juvenile Sacramento River winter-run Chinook salmon in the action area through the implementation of the proposed action.

NMFS cannot, using the best available information, quantify the anticipated incidental take of individual Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead, and the sDPS green sturgeon because of the variability and uncertainty associated with the population size of each species, annual variations in the timing of migration, and uncertainties regarding individual habitat use of the project area. However, it is possible to describe the general programmatic conditions and ecological surrogates using negative SAM WRI values.

Accordingly, NMFS is quantifying take of Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead, and the sDPS green sturgeon incidental to the action resulting from short-term construction impacts, as well as long-term impacts as indexed by the SAM model.

The amount and extent of take described below is in the form of harm due to habitat impacts that will reduce the growth and survival of individuals from predation, or by causing fish to relocate and rear in other locations and reduce the carrying capacity of the existing habitat. This SAM values represent the extent of habitat impacts that will harm fish. As described in the *Analytical Approach* and the *Effects Analysis Sections* of this BO, the SAM values represent an index of fish response to habitat variables to which fish respond including bank slope, bank substrate size, instream structure, overhanging shade, aquatic vegetation and floodplain availability. Positive SAM values represent a positive growth and survival response and negative values index negative growth and survival. There is not a stronger ecological surrogate based on the information available. Due to a lack of site-specific fish data, the exact number of fish that will be affected is not known. The following level of incidental take from program activities is anticipated:

Incidental Take Associated with Construction:

1. Take of Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon in the form of injury and death from predation caused by construction-related turbidity that extends up to 100 feet from the shoreline, and 1,000 feet downstream, along all project reaches for levee construction activities.

2. Take of juvenile and smolt Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead, and the sDPS green sturgeon, in the form of harm or injury of fish from O&M actions is expected from habitat-related disturbances from the annual placement of up to 600 cubic yards of material per site for the extent of the project life (*i.e.*, 50 years). Approximately 60 percent of the 600 cubic yards will be at or below the ordinary high water mark, or approximately 360 cubic yards. Take will be in the form of harm to the species through modification or degradation of the PCEs for rearing and migration that reduces the carrying capacity of habitat.

Incidental Take Associated with Exposure to Project Facilities along the Sacramento and American Rivers

Common Features American River North Reaches A and B:

At fall water surface elevations:

1. Take in the form of harm to fry and juvenile rearing CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon are expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The amount and extent of harm is greatest in the first 3 to 5 years for each species at -366 WRI, -712, and -5577, respectively.

2. Take in the form of harm to juvenile migrating (smolts) CV spring-run Chinook salmon is expected to extend past 50 years after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The amount and extent of harm is greatest at -2303 WRI.

3. Take in the form of harm to adult migrating CCV steelhead for up to 48 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The amount and extent of harm is greatest at -1554 WRI and exceeds baseline following year 48 to a maximum increase benefit of 8 WRI.

At winter surface elevations:

1. Take in the form of harm to fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction activities due to impacts on riparian habitat,

IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The amount and extent of harm is greatest at -36 WRI for steelhead in the first year and the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival is expected. After year one, survival and growth values improve to 1507 for CCV steelhead. The amount and extent of harm to sDPS green sturgeon are greatest at -5020 and are expected to extend past 50 years.

2. Take in the form of harm to juvenile migrating (smolts) CV spring-run Chinook salmon are expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO, harm is greatest in approximately year 3 at -2303 WRI.

3. Take in the form of harm to adult migrating CCV steelhead for up to 48 after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in Table 10 of this BO. The amount and extent of harm is greatest at -1554 WRI. At year 48, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching 8 WRI.

At spring water surface elevations:

1. Take in the form of harm to fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction due to impacts to riparian habitat IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The amount and extent of harm is greatest at -2681 and -5020, respectively. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1418 WRI. The extent and amount of harm to sDPS green sturgeon are greatest at -5020 WRI and are expected to extend past 50 years.

2. Take in the form of harm to juvenile migrating (smolts) CV spring-run Chinook salmon and CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The amount and extent of harm is greatest at -3129 for CV spring-run Chinook salmon and is expected to extend past 50 years. The greatest amount and extent of harm for CCV steelhead is greatest at -2096 WRI. At year 2, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching 1173 WRI.

3. Take in the form of harm to adult migrating CCV steelhead after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this harm is quantified in the SAM table 26 in Appendix A and summarized

in table 10 of this BO. The amount and extent of harm is greatest at -1635 WRI. At year 6, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching 407 WRI.

4. Take in the form of harm to adult resident CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The amount and extent of harm is greatest at -1635 WRI for CCV steelhead in the first six years and the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival is expected. After six years, survival and growth values improve to 407 for CCV steelhead.

At summer surface elevations:

1. Take in the form of harm to fry and juvenile rearing CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon are expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The amount and extent of harm is greatest for each species at -421 WRI, -833, and -7118, respectively.

2. Take in the form of harm to juvenile migrating (smolts) of CCV steelhead is expected to extend past 50 years after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM in table 26 in Appendix A and summarized in table 10 of this BO. The amount and extent of harm is greatest at -3013 WRI.

3. Take in the form of harm to adult resident CV steelhead is expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM and, and bank substrate size. The amount and extent of harm is quantified in the SAM table 26 in Appendix A and summarized in table 10 of this BO. The amount and extent of harm on the species is greatest at -3061 WRI.

American River North, South Bank sites A, B, and C

***At fall surface elevations*:**

1. Take in the form of harm to fry and juvenile rearing CV spring run Chinook salmon, CCV steelhead, and S DPS green sturgeon are expected after any construction activities due to impacts riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The amount and extent of harm is greatest for each species at -229 WRI, -489, and -2154, respectively. At year 26 for CV spring run Chinook salmon and year 36 for CCV steelhead, the SAM modeled habitat conditions exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 112 WRI and 88,

respectively. The amount and extent of harm to sDPS green sturgeon are greatest at -2154 and are expected to extend past 50 years.

2. Take in the form of harm to juvenile migrating (smolts) CV spring run Chinook salmon is expected after any construction due to impacts riparian habitat, IWM, and bank substrate size. The amount and extent of this amount and extent of harm is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The amount and extent of harm is greater greatest at -620 WRI and exceed baseline conditions and improved growth and survival conditions are expected following year 2 with the maximum increase benefit of 526 WRI.

3. The SAM displays increased survival of adult migrating CV steelhead after construction activities due to impacts), IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 27and summarized in table 11 of this BO. The increased benefit maximizes at 3696 of WRI.

At winter water surface elevations:

1. Take in the form of harm to fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction due to impacts to riparian habitat IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The amount and extent of harm is greatest at – 489 WRI and – 876, respectively. At year 36, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 88 WRI. At year one, the SAM modeled habitat conditions for sDPS green sturgeon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 2941 WRI.

At summer water surface elevations:

1. Take in the form of harm to fry and juvenile rearing CV spring run Chinook salmon and sDPS green sturgeon are expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The amount and extent of harm is greatest at – 239 WRI and – 2496, respectively. At year 26, the SAM modeled habitat conditions for CV spring run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 111 WRI. The amount and extent of harm to sDPS green sturgeon are expected to extend past 50 years.

2. Take in the form of harm to juvenile migrating (smolts) CV spring run Chinook salmon is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 27 in Appendix A and summarized in table 11 of this BO. The amount and extent of harm is greatest at -967 WRI. At year 22, the SAM modeled habitat conditions for CV spring run

Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 510 WRI.

Sacramento River Sites D, E, F, and G

At fall water surface elevations:

1. Take in the form of harm to fry and juvenile rearing CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. Take in the form of harm to fry and juvenile rearing sDPS green sturgeon is expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The greatest amount and extent of harm for the salmonids is -558 WRI, -1156, and -558 WRI respectively. The SAM modeled habitat conditions exceed baseline conditions and improve growth and survival is expected in year 35, 44, and 35, respectively. The amount and extent of harm to sDPS green sturgeon is greatest at -4674 WRI and are expected to extend past 50 years.

2. Take in the form of harm to juvenile migrating (smolts) CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon is expected to extend past 50 years after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM analysis table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest at -3845 WRI, -3985, and -3845, respectively.

3. Take in the form of harm to adult migrating CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and the extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The greatest amount and extent of harm for the salmonids are -1394 WRI, -2053, and 1394, respectively. The SAM modeled habitat conditions exceed baseline conditions and improved growth and survival is expected at years 35, 29, and 35 respectively. After these years, survival and growth values improve to 362, WRI, 832, and 362 WRI, respectively.

4. Take in the form of harm to adult resident CCV steelhead after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest at -2053 WRI and exceeds baseline following year 29, where adult resident survival increases to a maximum value of 837 WRI.

At winter surface elevations:

1. Take in the form of harm to fry and juvenile rearing CCV steelhead, CV winter run Chinook salmon, and sDPS green sturgeon are expected after any construction due to impacts on riparian habitat, IWM and, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest at -77 WRI, -4397, and -558, respectively. At year 1, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 3234 WRI. At year 35, the SAM modeled habitat conditions for CV winter run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 116 WRI. The amount and extent of harm to sDPS green sturgeon are expected to extend past 50 years.

2. Take in the form of harm to juvenile migrating (smolts) CCV spring run Chinook salmon, CCV steelhead, and CV winter run is expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest for the species at -3451 WRI, -3044, and -3085, respectively. At year two, the SAM modeled habitat conditions for CV spring run Chinook salmon and Sacramento River winter-run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 4794 WRI for both species. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 3355 WRI.

3. Take in the form of harm to adult migrating CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon are expected to occur after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest for the species at -892 WRI, -1801, and -892 WRI, respectively. At year 4, the SAM modeled habitat conditions for CV spring run Chinook salmon and CV winter run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 643 WRI. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1757 WRI.

4. Take in the form of harm to adult residence CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest for the species at -1801 WRI. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1757 WRI.

At spring water surface elevations:

1. Take in the form of harm to fry and juvenile rearing CCV steelhead and sDPS green sturgeon are expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest at -36 WRI and -4397, respectively. At year 1, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 4317 WRI. The amount and extent of harm to sDPS green sturgeon are expected to extend past 50 years.

2. Take in the form of harm to juvenile migrating (smolts) CCV spring run Chinook salmon, CCV steelhead, and CV winter run is expected after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest for the species at -3484 WRI, -3082, and -3484, respectively. At year 2, the SAM modeled habitat conditions for CV spring run Chinook salmon and Sacramento River winter-run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 4862 WRI for both species. At year three, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1757 WRI.

3. Take in the form of harm to adult migrating CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon are expected to occur after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest for the species at -946 WRI, -1801, and -946 WRI, respectively. At year 4, the SAM modeled habitat conditions for CV spring run Chinook salmon and CV winter run Chinook salmon exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 931 WRI. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1757 WRI.

4. Take in the form of harm to adult residence CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest for the species at -1801 WRI. At year 3, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 1757 WRI.

At summer water surface elevations:

1. Take in the form of harm to fry and juvenile rearing CV spring run Chinook salmon, CCV steelhead, and CV winter run Chinook salmon after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. Take in the form of harm to fry and juvenile rearing sDPS green sturgeon is expected to extend past 50 years after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of these effects are quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest for the salmonids are -578 WRI, -1206, and -578 WRI respectively. The SAM modeled habitat conditions exceed baseline conditions and improve growth and survival is expected in years 36, 45, and 36, respectively, with maximum increased WRI values of 113, 92, and 113. The amount and extent of harm to sDPS green sturgeon are greatest at -5009 WRI and are expected to extend past 50 years.

2. Take in the form of harm to juvenile migrating (smolts) CCV spring run Chinook is expected to extend past 50 years after any construction due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of this adverse of these amount and extent of harm is quantified in the SAM analysis table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest at -4258 WRI.

3. Take in the form of harm to adult migrating CV spring run Chinook salmon, CV steelhead, and Sacramento River winter-run Chinook salmon after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and the extent of these potential effects is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The greatest amount and extent of harm for these species are -2136 WRI, -3793, and -2136 WRI, respectively. The SAM modeled habitat conditions exceed baseline conditions and improved growth and survival is expected at years 37, 32, and 37 respectively. After these years, survival and growth values improve to 319 WRI, 748, and 319 WRI, respectively.

4. Take in the form of harm to adult residence CCV steelhead is expected after any construction activities due to impacts on riparian habitat, IWM, and bank substrate size. The amount and extent of harm is quantified in the SAM table 28 in Appendix A and summarized in table 12 of this BO. The amount and extent of harm is greatest for the species at -3793 WRI. At year 32, the SAM modeled habitat conditions for CCV steelhead exceed baseline conditions and improved growth and survival conditions are expected, reaching a maximum of 748 WRI.

Take along and within the Sacramento Bypass and Weir

1. Take in the form of injury or death to adult and juvenile CV spring-run Chinook salmon, Sacramento River winter-run Chinook salmon, CCV steelhead, and sDPS green sturgeon as a result of stranding in the spillway basin along 3425 linear feet of the expanded Sacramento Weir as a result of impaired upstream or downstream migrations. This take

is expected to occur once every 10 years following the spilling of river water and as the flood flows recede standing these species in the spillway basin.

2. Take in the form of injury or death to adults and juvenile CV spring-run, Sacramento River winter-run Chinook salmon, CCV steelhead, and sDPS green sturgeon due to stranding on the declining hydrograph within 660 acres (Personal Communication, Anne Baker, Army Corps of Engineers) as a result of the widening of the bypass. This take is expected to occur once every ten years following the spilling of river water and as the flood flows recede stranding these species in the Sacramento Bypass.

2.9.2 Effect of the Take

In the BO, NMFS determined that the amount or extent of anticipated take is not likely to result in jeopardy to the Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead and sDPS green sturgeon or destruction or adverse modification of their critical habitat.

2.8.3 Reasonable and Prudent Measures

"Reasonable and prudent measures" are nondiscretionary measures that are necessary or appropriate to minimize the impact of the amount or extent of incidental take (50 CFR 402.02).

1. Measures shall be taken to ensure that future flood risk reduction projects related to the American River Common Features GRR minimize, to the maximum extent practicable, any adverse effects on federally listed salmon, steelhead and green sturgeon that are subject to this consultation.

2. Measures shall be taken to maintain, monitor, and adaptively manage all conservation measures through the HMMP to ensure their effectiveness.

3. Measures shall be taken to minimize the impacts of bank protection and setback levee construction by implementing integrated conservation measures that provide beneficial growth and survival conditions for salmonids, and the sDPS of North American green sturgeon.

4. Measures shall be taken to insure that contractors, construction workers, and all other parties involved with these projects implement the projects as proposed in the biological assessment and this BO.

5. Measures shall be taken to ensure that riparian habitat within the study area is preserved and protected to the maximum extent feasible for protection of fish habitat features that are the subject of this BO.

2.9.4 Terms and Conditions

The terms and conditions described below are non-discretionary, and the Corps or any applicant must comply with them in order to implement the reasonable and prudent measures (50 CFR 402.14). The Corps or any applicant has a continuing duty to monitor the impacts of incidental take and must report the progress of the action and its impact on the species as specified in this incidental take statement (50 CFR 402.14). If the entity to whom a term and condition is directed does not comply with the following terms and conditions, protective coverage for the proposed action would likely lapse.

1. The following terms and conditions implement reasonable and prudent measure 1: "*Measures shall be taken to ensure that future flood risk reduction projects related to the American River Common Features GRR minimize, to the maximum extent practicable, any adverse effects on federally listed salmon, steelhead and green sturgeon that are subject to this consultation.*"

    a. The Corps shall participate in an existing IWG or work with other agencies to participate in a new BPWG to coordinate stakeholder input into future flood risk reduction actions associated with the American River Common Features GRR. The BPWG will hold technical deliberations over proposed bank protection, including the need (basis of/for design), purpose and proposed designs (emphasis on avoidance and fish-friendly designs). Membership in the BPWG will be subject to agency decisions to participate, but should at a minimum include participation from resource agency staff (USFWS, NMFS, CDFW), CVFPB and SAFCA (local sponsors).
    b. The Corps shall coordinate with NMFS during PED as future flood risk reduction actions are designed to ensure conservation measures are incorporated to the extent practicable and feasible and projects are designed to maximize ecological benefits.
    c. The Corps shall include as part of the HMMP, a Riparian Corridor Improvement Plan with the overall goal of mitigating for the impacts to the ecological function and value of the existing levee system within the GRR study area. The Corps shall coordinate this plan with NMFS prior to the construction of any projects related to the GRS.
    d. The Corps shall ensure the widening of the Sacramento Bypass is designed and constructed to minimize stranding of fish at facilities of the weir and in the depressions of the bypass though grading or construction of drainage channels or other mechanisms as applicable.
    e. During Preconstruction Engineering and Design, the Corps, in coordination with the local sponsor, shall coordinate with NMFS to provide an operation of the Sacramento Weir to allow, without detrimental effects to flood management operations, for controlled ramp down rates of water into the Sacramento Bypass following peak flows.
    f. The Corps, in coordination with the local sponsors, shall compensate for fish passage impacts that result from the widening of the Sacramento Weir by including an adult fish passage facility associated with flood operations at the new weir. The fish passage facility would be designed with NMFS technical experts as part of the design team. Measures also shall be taken to modify the downstream side of the Weir to prevent adult and juvenile green sturgeon from stranding in the spillway basin.

g. The Corps shall update the O&M manual to incorporate, without detrimental effects to flood operations, the following measures: (1) an adaptive management plan for operations of the Sacramento Weir that allows for ramp down flows in a manner that minimize juvenile fish stranding in the Sacramento Bypass, (2) integration of Sacramento Weir operations with the Yolo Bypass.

2. The following terms and conditions implement reasonable and prudent measure 2: "*Measures shall be taken to maintain, monitor, and adaptively manage all conservation measures through the HMMP to ensure their effectiveness*."

    a. The Corps shall develop a HMMP with an overall goal of ensuring the conservation measures achieve a high level of ecological function and value. The HMMP shall include specific goals and objectives and a clear strategy for maintaining all of the project conservation elements for the life of the project. The HMMP shall be consulted on with NMFS prior to the onset of any riverside construction, including the placement of in-water revetment or removal of riparian vegetation.
    b. The HMMP measures shall be monitored by the Corps for 10 years following construction and shall update their O&M manual to ensure the HMMP is adopted by the local sponsor to ensure the goals and objectives of the conservation measures are met for the life of the project.
    c. The HMMP shall include specific goals and objectives and a clear strategy for achieving full compensation for all project-related impacts on the affected species described above.
    d. The HMMP shall include a compensatory mitigation accounting plan to ensure the tracking of compensatory measures associated with future American River Common Features GRR projects as described in the proposed action.
    e. The Corps shall continue to coordinate with NMFS during all phases of construction, implementation, and monitoring by hosting annual meetings and issuing annual reports throughout the construction period as described in the HMMP.
    f. The Corps shall host an annual meeting and issue annual reports for five years following completion of project construction. The purpose is to ensure that conservation features of the project are developing consistent with the MMP.
    g. The Corps shall update their O&M Manual to ensure that the self-mitigating elements are meeting the criteria established in the HMMP with the goal of meeting SAM values.
    h. The Corps, in coordination with the local sponsor, shall ensure that the mitigation and monitoring plan for the Sacramento Bypass includes baseline post-project monitoring of fish stranding. The monitoring plan shall be developed in coordination with NMFS.

3. The following terms and conditions implement reasonable and prudent measure 3: "*Measures shall be taken to minimize the impacts of bank protection and setback levee construction by implementing integrated conservation measures that provide beneficial growth and survival conditions for salmonids, and the sDPS of North American green sturgeon*."

a. The Corps shall ensure that, for salmon and steelhead, the maximum SAM WRI deficits for each seasonal water surface elevation as determined appropriate with input from the IWG or the BPWG are fully offset through habitat improvements along the future American River Common Features GRR project or through the purchase of credits at a NMFS approved conservation bank (as described in the BA).
b. The Corps shall minimize the removal of existing riparian vegetation and IWM to the maximum extent practicable, and where appropriate, removed IWM will be anchored back into place or if not feasible, new IWM will be anchored in place.
c. The Corps shall ensure that the planting of native vegetation will occur as described in the Corps 2014 BA and within this BO. All plantings must be provided with the appropriate amount of water to ensure successful establishment.
d. The Corps shall compensate for lost habitat using NMFS approved mitigation actions at a 1:1 ratio prior to construction, 2:1 ratio during construction, or a 3:1 ratio if mitigation actions occur after construction. This includes habitat improvements adjacent to the project area, or through conservation bank credit purchase as described in the Corps revised, American River Common Features GRR SAM Analysis as received by email on June 18, 2015 and included in this document in Appendix A.

4. The following terms and conditions implement reasonable and prudent measure 4: "*Measures shall be taken to insure that contractors, construction workers, and all other parties involved with these projects implement the projects as proposed in the biological assessment and this BO*."

a. The Corps shall provide a copy of this BO, or similar documentation, to the prime contractor, making the prime contractor responsible for implementing all requirements and obligations included in these documents and to educate and inform all other contractors involved in the project as to the requirements of this BO. A notification that contractors have been supplied with this information will be provided to the reporting address below.
b. A NMFS-approved Worker Environmental Awareness Training Program for construction personnel shall be conducted by the NMFS-approved biologist for all construction workers prior to the commencement of construction activities. The program shall provide workers with information on their responsibilities with regard to Federally-listed fish, their critical habitat, an overview of the life-history of all the species, information on take prohibitions, protections afforded these animals under the ESA, and an explanation of the relevant terms and conditions of this BO. Written documentation of the training must be submitted to NMFS within 30 days of the completion of training.
c. The Corps shall consider installing IWM along future flood risk reduction projects associated with the American River Common Features GRR at 40 to 80 percent shoreline coverage at all seasonal water surface elevations in coordination with the IWG or the BPWG. The purpose is to maximize the refugia and rearing habitats for juvenile fish.

5. The following terms and conditions implement reasonable and prudent measure 5: "*Measures shall be taken to ensure that riparian habitat within the study area is preserved and protected to the maximum extent feasible for protection of fish habitat features that are the subject of this BO*."

    a. The Corps shall develop a vegetation variance in consultation with NMFS to allow for the protection of existing vegetation in place and the planting of new low-risk vegetation on the lower 1/3 slope of the levee system.

2.10 Conservation Recommendations

Section 7(a)(1) of the ESA directs Federal agencies to use their authorities to further the purposes of the ESA by carrying out conservation programs for the benefit of the threatened and endangered species. Specifically, conservation recommendations are suggestions regarding discretionary measures to minimize or avoid adverse effects of a proposed action on listed species or critical habitat or regarding the development of information (50 CFR 402.02).

1. The Corps should integrate the 2017 California Central Valley Flood Protection Plan's Conservation Strategy into all flood risk reduction projects they authorize, fund, or carry out.
2. The Corps should prioritize and continue to support flood management actions that set levees back from rivers and in places where this is not technically feasible, repair in place actions should pursue land-side levee repairs instead of waterside repairs.
3. The Corps should consult with NMFS in the review of ETL variances for future projects that require ETL compliance.
4. The Corps should develop ETL vegetation variances for all flood management actions that are adjacent to any anadromous fish habitat.
5. The Corps should use all of their authorities, to the maximum extent feasible to implement high priority actions in the NMFS Central Valley Salmon and Steelhead Recovery Plan. High priority actions related to flood management include setting levees back from river banks, increasing the amount and extent of riparian vegetation along reaches of the Sacramento River Flood Control Project.
6. The Corps should encourage cost share sponsors and applicants to develop floodplain and riparian corridor enhancement plans as part of their projects.
7. The Corps should seek out opportunities for setback levee and other flood management activities that promote overall riverine system restoration.
8. The Corps should support and promote aquatic and riparian habitat restoration within the Sacramento River and other watersheds, especially those with listed aquatic species. Practices that avoid or minimize negative impacts to listed species should be encouraged.
9. The Corps should continue to work cooperatively with other State and Federal agencies, private landowners, governments, and local watershed groups to identify opportunities for cooperative analysis and funding to support salmonid habitat restoration projects.

10. The Corps should continue to work with NMFS and other agencies and interests to restore fish passage to support the improved growth, survival and recovery of native fish species in the Yolo Bypass and other bypasses within the Sacramento River Flood Control Project.

In order for NMFS to be kept informed of actions minimizing or avoiding adverse effects or benefitting listed species or their habitats, NMFS requests notification of the implementation of any conservation recommendations.

2.10 Reinitiation of Consultation

This concludes formal consultation for the West Sacramento River GRS. As 50 CFR 402.16 states, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been retained or is authorized by law and if: (1) the amount or extent of incidental taking specified in the incidental take statement is exceeded, (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion, (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat that was not considered in this opinion, or (4) a new species is listed or critical habitat designated that may be affected by the action.

MAGNUSON-STEVENS FISHERY CONSERVATION AND MANAGEMENT ACT ESSENTIAL FISH HABITAT CONSULTATION

Section 305(b) of the MSA directs Federal agencies to consult with NMFS on all actions or proposed actions that may adversely affect EFH. The MSA (section 3) defines EFH as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." Adverse effect means any impact that reduces quality or quantity of EFH, and may include direct or indirect physical, chemical, or biological alteration of the waters or substrate and loss of (or injury to) benthic organisms, prey species and their habitat, and other ecosystem components, if such modifications reduce the quality or quantity of EFH. Adverse effects on EFH may result from actions occurring within EFH or outside of it and may include site-specific or EFH-wide impacts, including individual, cumulative, or synergistic consequences of actions (50 CFR 600.810). Section 305(b) also requires NMFS to recommend measures that can be taken by the action agency to conserve EFH.

This analysis is based, in part, on the EFH assessment provided by the Corps and descriptions of EFH for Pacific coast salmon (PFMC 1999) contained in the fishery management plans developed by the Pacific Fishery Management Council and approved by the Secretary of Commerce.

The proposed action is described in detail in Section 1.4 of the Common Features GRR BO.

3.1 Essential Fish Habitat Affected by the Project

The action area for the Common Features GRR has been identified as EFH for Pacific coast salmon. Sacramento River winter-run Chinook salmon (*Oncorhynchus tshawytscha*), CV spring-run Chinook salmon (*O. tshawytscha*), and CV fall-/late fall-run Chinook salmon (*O. tshawytscha*) are species managed under the Pacific coast salmon fishery management plan that occur within the proposed action area.
This BO addresses Sacramento River winter-run and CV spring-run Chinook salmon (*O. tshawytscha*). The Sacramento River winter-run and CV spring-run Chinook salmon are listed under both ESA and the MSA and potentially will be affected by the Common Features GRR. This EFH consultation will concentrate on CV fall-/late fall-run Chinook salmon (*O. tshawytscha*) because their habitat is covered under the MSA but not covered in subject BO.

The Habitat Areas of Particular Concern (HAPCs) in the action area include complex channels, floodplain habitats and constrained channels with large woody debris.

3.2 Adverse Effects on Essential Fish Habitat

The effects of the proposed action on Pacific Coast salmon EFH will be similar to those discussed in the *Effects of the Action* section (2.4) for Sacramento River winter-run and CV spring-run Chinook salmon. Based on the information provided, NMFS concludes that the proposed action would adversely affect EFH for federally managed Pacific salmon. A summary of the effects of the proposed action on EFH for Chinook salmon are discussed below.

Adverse effects to the HAPCs of Pacific salmon EFH resulting from the proposed action construction activities may contribute sediment, increase turbidity, and increase localized sound levels, including areas downstream and upstream of the construction site. These impacts will occur only during the time when construction is occurring in or adjacent to the water column. There is potential for toxic compounds to be introduced into EFH during construction. This could occur at any time during the construction, both during in-water and out-of-water phases. All of the above impacts will be short-term. Construction activities may also eliminate or alter habitat that is essential to the life-cycle of Pacific salmon. For example, the addition of rock revetment to a previously vegetated bank may eliminate juvenile rearing habitat. These habitat impacts are better illustrated in Tables 10, 11, and 12 of the BO associated with this EFH consultation and Tables 26, 27 and 28 in Appendix A that summarizes SAM deficits for the Common Features GRR.

3.3 Essential Fish Habitat Conservation Recommendations

Fully implementing these EFH conservation recommendations will protect, by avoiding or minimizing the adverse short-term habitat effects described in section 3.2. The Corps should mitigate for WRI deficits by offsetting the maximum deficits. Below is a summary of WRI that should be mitigated to minimize the adverse effects of the Common Features GRR to Pacific coast salmon species. The Corps should offset deficits either onsite or at a NMFS approved conservation bank. The mitigation should be at a 1:1 ratio if conducted prior to the compensation timing schedule described in the *Analytical Approach* section of the BO, or at a 3:1 ratio if carried out any later.

Common Features American River North Reaches A and B:

At fall water surface elevations:

1. The maximum impact from the Common Features GRR to adult fall-run Chinook salmon migrating habitat is -877 WRI for 39 years.

2. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon rearing habitat is -366 WRI for 50 years.

3. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon migration habitat is -2,303 WRI for 50 years.

At winter surface elevations:

1. The maximum impact from the Common Features GRR to adult fall-run Chinook salmon migrating habitat is -759 WRI for 5 years.

2. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon migration habitat is –3,002 WRI for 4 years.

At spring water surface elevations:

1. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon migration habitat is -2,681 WRI for 3 years.

2. The maximum impact from the Common Features GRR to adult fall-run Chinook salmon habitat is -773 WRI for 4 years.

At summer surface elevations:

1. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon rearing habitat is -421 WRI for 50 years.

2. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon migration habitat is -3,129 WRI for 50 years.

American River North, South Bank sites A, B, and C

At fall water surface elevations:

1. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon rearing habitat is -229 WRI for 26 years.

2. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon migration habitat is -620 WRI for 21 years.

At winter surface elevations:

1. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon migration habitat is -333 WRI for 1 years.

At summer surface elevations:

1. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon rearing habitat is -239 WRI for 26 years.

2. The maximum impact from the Common Features GRR to juvenile fall- run Chinook salmon migration habitat is -697 WRI for 22 years.

Sacramento River Sites D, E, F, and G

At fall water surface elevations:

1. The maximum impact from the Common Features GRR to adult fall-run and late-fall run Chinook salmon migration habitat is -1,394 WRI for 35 years.

2. The maximum impact from the Common Features GRR to juvenile fall-run and late-fall run Chinook salmon rearing habitat is -558 WRI for 35 years.

3. The maximum impact from the Common Features GRR to juvenile fall-run and late-fall run Chinook salmon migration habitat is -3,845 WRI for 50 years.

At winter surface elevations:

1. The maximum impact from the Common Features GRR to adult fall-run and late-fall run Chinook salmon migration habitat is -892 WRI for 4 years.

2. The maximum impact from the Common Features GRR to juvenile fall-run and late-fall run Chinook salmon migration habitat is -3,451 WRI for 2 years.

At spring water surface elevations:

1. The maximum impact from the Common Features GRR to adult late-fall run Chinook salmon migration habitat is -946 WRI for 4 years.

2. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon migration habitat is -3,484 WRI for 2 years.

At summer surface elevations:

1. The maximum impact from the Common Features GRR to juvenile fall-run and late-fall run Chinook salmon rearing habitat is -578 WRI for 36 years.

2. The maximum impact from the Common Features GRR to juvenile fall-run Chinook salmon migration habitat is -4,258 WRI for 50 years.

3.4 Statutory Response Requirement

As required by section 305(b)(4)(B) of the MSA, the Corps must provide a detailed response in writing to NMFS within 30 days after receiving an EFH Conservation Recommendation. Such a response must be provided at least 10 days prior to final approval of the action if the response is inconsistent with any of NMFS' EFH Conservation Recommendations unless NMFS and the Federal agency have agreed to use alternative time frames for the Federal agency response. The response must include a description of measures proposed by the agency for avoiding, mitigating, or offsetting the impact of the activity on EFH. In the case of a response that is inconsistent with the Conservation Recommendations, the Federal agency must explain its reasons for not following the recommendations, including the scientific justification for any disagreements with NMFS over the anticipated effects of the action and the measures needed to avoid, minimize, compensate, or offset such effects (50 CFR 600.920(k)(1)).

In response to increased oversight of overall EFH program effectiveness by the Office of Management and Budget, NMFS established a quarterly reporting requirement to determine how many conservation recommendations are provided as part of each EFH consultation and how many are adopted by the action agency. Therefore, we ask that in your statutory reply to the EFH portion of this consultation, you clearly identify the number of conservation recommendations accepted.

3.5 Supplemental Consultation

The Corps must reinitiate EFH consultation with NMFS if the proposed action is substantially revised in a way that may adversely affect EFH, or if new information becomes available that affects the basis for NMFS' EFH Conservation Recommendations (50 CFR 600.920(l)).

DATA QUALITY ACT DOCUMENTATION AND PRE-DISSEMINATION REVIEW

The Data Quality Act (DQA) specifies three components contributing to the quality of a document. They are utility, integrity, and objectivity. This section of the opinion addresses these DQA components, documents compliance with the DQA, and certifies that this opinion has undergone pre-dissemination review.

4.1 Utility

Utility principally refers to ensuring that the information contained in this consultation is helpful, serviceable, and beneficial to the intended users. The intended users of this opinion are the Corps. Other interested users could include SAFCA, USFWS, CDFW, or DWR. Individual copies of this opinion were provided to the Corps. This opinion will be posted on the Public Consultation Tracking System web site (https://pcts.nmfs.noaa.gov/pcts-web/homepage.pcts). The format and naming adheres to conventional standards for style.

4.2 Integrity

This consultation was completed on a computer system managed by NMFS in accordance with relevant information technology security policies and standards set out in Appendix III, 'Security of Automated Information Resources,' Office of Management and Budget Circular A-130; the Computer Security Act; and the Government Information Security Reform Act.

4.3 Objectivity

Information Product Category: Natural Resource Plan

Standards: This consultation and supporting documents are clear, concise, complete, and unbiased; and were developed using commonly accepted scientific research methods. They adhere to published standards including the NMFS ESA Consultation Handbook, ESA regulations, 50 CFR 402.01 *et seq*., and the MSA implementing regulations regarding EFH, 50 CFR 600.

Best Available Information: This consultation and supporting documents use the best available information, as referenced in the References section. The analyses in this opinion and the EFH consultation contain more background on information sources and quality.

Referencing: All supporting materials, information, data and analyses are properly referenced, consistent with standard scientific referencing style.

Review Process: This consultation was drafted by NMFS staff with training in ESA and MSA implementation, and reviewed in accordance with West Coast Region ESA quality control and assurance processes.

APPENDIX A.

Appendix A comprises the updated SAM analysis report emailed to NMFS from the USACE on JUNE 11, 2015. This represents the final SAM run agreed upon jointly.

Appendix A
American River Common Features GRR SAM Analysis

ARCF GRR Project Reach SAM Analysis

1.0 Introduction

This document provides the background data and assumptions for the Standard Assessment Methodology (SAM) effects analysis of the American River Common Features General Reevaluation Report (ARCF GRR) project on the following focus fish species (Table 1).

Table 1. ARCF GRR Project Focus Fish Species

Species/ESUs	Federal Status
Chinook salmon (*Oncorhynchus tshawytscha*)	
Central Valley spring-run ESU	Threatened
Central Valley fall-run ESU	Species of concern
Central Valley late fall-run ESU	Species of concern
Sacramento River winter-run ESU	Endangered
Central Valley steelhead DPS (*Oncorhynchus mykiss*)	Threatened
green sturgeon (*Acipenser medirostris*)	Threatened

1.1 Background

The US Army Corps of Engineers (Corps) initiated formal Section 7 consultation with the National Marine Fisheries Service (NMFS) for the ARCF GRR on June 27, 2014. The original SAM analysis included in the Section 7 consultation for the ARCF GRR was determined to be insufficient in detail. Through internal discussions and interagency coordination with the NMFS, a revised set of parameters was developed to better assess the project's impact on focus fish species and their habitat. This report documents and provides justification for the revised SAM analysis and should replace the analysis included in the original Biological Assessment (BA) Appendix B.

1.2 SAM Modeling Approach

Long-term effects of the ARCF GRR project on focus fish species and their habitat were estimated using the SAM. The SAM computations were performed using the SAM Electronic Calculation Template (ECT) Version 4.0 (April 2012) developed by the Corps and Stillwater Sciences, in consultation with the National Marine Fisheries Service (NMFS), U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife Service (CDFW), and California Department of Water Resources (DWR), academic contributions from the University of California at Davis and Humboldt State University, and peer reviewed by sixteen professionals in fish biology, river geomorphology, environmental sciences, and engineering (USACE 2012). The SAM allows agencies to quantitatively assess the potential effects of bank protection and stream restoration projects to ensure that these activities do not jeopardize Chinook salmon, steelhead, and green sturgeon, or destroy or adversely modify their critical habitat. The SAM can also determine suitable compensation for habitat loss, by evaluating the benefits of certain design features (*e.g*., planted emergent vegetation) to target fish species.

The SAM employs six habitat variables to characterize near-shore and floodplain habitats of listed fish species:

- *bank slope*—average bank slope of each average seasonal water surface elevation;
- *floodplain availability*—ratio of wetted channel and floodplain area during the 2-year flood, to the wetted channel area during average winter and spring flows;
- *bank substrate size*—the median particle diameter of the bank (*i.e.*, D50) along each average seasonal water surface elevation;
- *instream structure*—percent of shoreline coverage of instream woody material along each average seasonal water surface elevation;
- *aquatic vegetation*—percent of shoreline coverage of aquatic or riparian vegetation along each average seasonal water surface elevation; and
- *overhanging shade*—percent of the shoreline coverage of shade along each average seasonal water surface elevation.

The SAM does not directly model changes in the above variables. Instead, habitat changes are estimated separately by the user and entered into an input data file to an electronic calculation template (ECT) developed within an MS Access database to track species responses to project actions over time. Changes in habitat variables may be fixed in time, such as installation of revetment at a particular slope and substrate size. In other circumstances, habitat evolution over time may be represented by more gradual changes in variables such as changes in floodplain inundation due to meander migration or changes in shade due to growth of planted vegetation. Typically, habitat evolution modeling is restricted to shade estimates from riparian growth models, but the SAM accommodates any number of other habitat modeling approaches such as meander migration modeling or large woody debris recruitment modeling.

Once a particular time series of habitat variable estimates is developed and entered into an ECT input file fish responses are calculated using previously developed relationships between habitat variables and species/life stage responses (USACE 2012). The response indices vary from 0 to 1, with 0 representing unsuitable conditions and 1 representing optimal conditions for survival, growth, and/or reproduction. For a given site and scenario (*e.g*., with- or without-project), the ECT uses these relationships to determine the responses of individual species and life stages to the measured or predicted values of each variable, for each season and target year; the ECT then multiplies these values together to generate an overall species response index. This index is then multiplied by the linear distance or area of bank to which it applies; the product is then integrated through time, generating a weighted species response index (WRI expressed as ft or ft^2) in each year of the analysis. The WRI provides a common metric that can be used to quantify habitat values over time, compare project designs to existing conditions, and evaluate the effectiveness of on-site and off-site habitat compensation actions.

2.0 Habitat Analysis

Following procedures described in the SAM (USACE 2012), construction activities at each site were translated into habitat variables for pre-project and with project conditions in each of four seasons using available data sources. The relevant habitat conditions to encode the conceptual response models for the focus fish species from the present to the future (t = 0, 1, 5, 15, 25, and 50 yrs), and under pre-project and with-project conditions are described below. Revisions to the original SAM analysis are summarized in the discussion.

2.1 Project Description

The ARCF GRR project tentatively selected plan – Alternative 2 – Sacramento Bypass and Improve Levees, involves the construction of fix-in-place levee remediation measures along the Sacramento River, American River, and north side tributaries as well as widening of the Sacramento Weir and Bypass. Proposed repair actions for each waterway are presented below (Table 2). This SDAM analysis groups project actions into 4 SAM reaches based on hydrologic connectivity: American River North (ARN_AB), American River South (ARS_ABC), Sacramento River South (ARS_DEFG), and the Sacramento Bypass (SBP).

2.1.1 Sacramento River

The levees along the Sacramento River under Alternative 2 would be improved to address identified seepage, stability, erosion, and a minimal amount of height concerns. Most height concerns along the Sacramento River would be addressed by a widening of the Sacramento Weir and Bypass to divert more flows into the Yolo Bypass.

2.1.2 American River

Levees along the American River under Alternative 2 require improvements to address erosion. The proposed measures for these levees consist of waterside armoring to prevent erosion to the river bank and levee, which could potentially undermine the levee foundation. There are two measures proposed for the American River levees: (1) bank protection, and (2) launchable rock trench. Both of these measures are described in detail in the BA.

2.1.3 East Side Tributaries

Natomas East Main Drain Canal (NEMDC) requires improvements to address seepage and stability at locations where historic creeks had intersected the current levee alignment. A conventional open trench cutoff wall would be constructed at these locations to address the seepage and stability problems. The NEMDC east levee also has height issues which will be addressed with construction of a new floodwall. The floodwall would be placed at the waterside hinge point of the levee and would be designed to disturb a minimal amount of waterside slope and levee crown for construction.

We will be doing no in-water work on NEMDC under the Alternative 2 scenario and after consultation with NMFS, NEMDC was left out of the SAM analyses.

2.1.4 Sacramento Weir and Bypass

Under Alternative 2, the width of the Sacramento Weir and Bypass would be roughly doubled to accommodate increased bypass flows. The expanded Sacramento Weir and Bypass would generally result in an additional 25,000 cfs flow during high water conditions. The frequency of water diversion is expected to be the same, which is to to use the current Sacramento Weir operation based on a stream gage at the I Street Bridge (Schlunegger 2014). Under normal flow conditions the Sacramento Weir and Bypass would be operating at pre-existing conditions described in detail in the ARCF GRR biological assessment (USACE 2014). Implementation of this action would result in the degradation of the existing north levee of the Sacramento Bypass and construction of a new levee approximately 1,500 feet to the north. The existing Sacramento Weir would be expanded to match the wider bypass. At this time, it is not known whether the new segment of weir would be constructed consistent with the 1916 design described above, or whether it would be designed to be a gravity-type weir. The new north levee of the bypass would be designed to be consistent with the existing Sacramento Bypass north levee, however, it would also include a 300-foot-wide seepage berm on the landside with a system of relief wells.

Table 2. ARCF GRR Project Alternative 2 – Proposed Remediation Measures by Waterway.

Waterway	Seepage Measures	Stability Measures	Erosion Protection Measures	Overtopping Measures
American River[1]	---	---	Bank Protection, Launchable Rock Trench	---
Sacramento River	Cutoff Wall	Cutoff Wall	Bank Protection	Sacramento Bypass and Weir Widening, Levee Raise
NEMDC	Cutoff Wall	Cutoff Wall	---	Floodwall
Arcade Creek	Cutoff Wall	Cutoff Wall	---	Floodwall
Dry/Robla Creeks	---	---	---	Floodwall
Magpie Creek[2]	---	---	---	Floodwall, Levee Raise

[1]American River seepage, stability, and overtopping measures were addressed in the American River Common Features, WRDA 1996 and 1999 construction projects.
[2]In addition to the Floodwall, Magpie Creek will include construction of a new levee along Raley Boulevard south of the creek, and construction of a detention basin on both sides of Raley Boulevard. In addition, some improvements would need to occur on Raley Boulevard, including widening of the Magpie Creek Bridge, raising the elevation of the roadway, and removing the Don Julio Creek culvert.

2.1.5 Construction Schedule

The ARCF GRR project reach will be implemented in increments. The timing of each project reach (Table 3) is based on the proposed schedule provided in the Biological Assessment: American River Common Features General Reevaluation Report (USACE 2014).

Table 3. ARCF GRR Project Alternative 2 – Construction Sequence and Duration

Priority	Construction Sequence	Reach	Construction Duration
1	Sacramento River	ARS F	5 years
2	Sacramento River	ARS E	3 years
3	American River	ARS A	4 years
4	Sacramento River	ARS G	3 years
5	Sacramento River	ARS D	3 years
6	American River	ARS B	2 years
7	American River	ARN A	4 years
8	American River	ARS C	3 years
9	American River	ARN B	2 years
10	Sacramento Weir & Bypass		4 years
11	Arcade Creek	ARN D	2 years
12	NEMDC	ARN F	2 years
13	Arcade Creek	ARN E	2 years
14	NEMDC	ARN C	2 years
15	Dry/Robla Creek	ARN G	3 years
16	Magpie Creek	ARN I	3 years

2.1.6 Vegetation on Levees

Compliance with Engineering Technical Letter 1110-2-571 (ETL) vegetation requires implementation of a vegetation-free zone within 15 ft of the waterside and landside toes of a levee. The levees along the Sacramento and American rivers were often set close to the river which has resulted in limited riparian vegetation in the project reach. The Corps is seeking a variance from the ETL vegetation requirements along the Sacramento River and American River portions of this project. This SAM analysis assumes that a Vegetation Variance Request (VVR) was assumed to be in place for the Sacramento and American River reaches. The Corps will obtain an ETL-approved vegetation variance exempting the Sacramento River sites from vegetation removal in the lower third of the waterside of the levee prior to final construction and design phase. The Corps will be complying with the ETL on the American River via a System Wide Implementation Framework (SWIF). The VVR is not assumed to apply to the SBP.

2.2 Characterization of Existing Conditions

The following data sources were used to characterize SAM habitat conditions (as defined by bank slope, floodplain availability, substrate size, instream structure, aquatic vegetation, and overhanging shade) within the ARCF GRR project area under existing or pre-project conditions.

Sacramento River Revetment Database – This database was used to stratify the project reach into subreaches that encompass relatively uniform bank conditions based on their general physical characteristics (USACE 2007). This database was used to characterize existing habitat conditions within individual reaches where more recent data were unavailable.

Aerial images of the ARCF GRR project reach (Google™ Earth Pro), provided current and historical images of bank conditions that were used to address gaps or uncertainties related to existing cover characteristics within individual subreaches.

The following describes how input values for each of these attributes were derived for existing conditions in the SAM assessment. Specific input values for each site can be seen below at the end of report in (Tables 6-25).

2.2.1 Bank Slope

In the SAM, bank slope serves as an indicator of the availability of shallow-water habitat and is obtained from point estimates of bank slope (horizontal change to vertical change, dW:dH) along each seasonal shoreline (*i.e.*, the line where the water surface intersects the bank on average fall, winter, spring, and summer) (USACE 2012). Existing bank slopes were extrapolated from cross sections along the Sacramento River, American River, and existing SAM analyses performed on regionally analogous sites. Bank slope along all reaches was assumed to be 2 for existing conditions.

2.2.2 Floodplain Availability

In the SAM, floodplain habitat availability is considered important for juvenile life stages and is defined by areas that are flooded by the 2-year flood event (Q2) and measured by calculating a Floodplain Inundation Ratio (USACE 2012). This ratio is calculated by dividing the wetted channel and inundated floodplain areas during the 2-year flood event (AQ2) by the wetted channel area (AQavg) during average winter and spring flows. The amount of available floodplain habitat is consequently proportional to the ratio's positive deviation from unity (*i.e.*, values greater than 1) (USACE 2012).

In this SAM analysis, it was assumed that the with-project floodplain inundation ratios would be the same as pre-project values, which is consistent with assumptions made during the pre-construction SAM analyses. As a result, no impacts to habitat quality at the ARCF GRR reaches are expected with respect to this habitat variable.

2.2.3 Bank Substrate Size

The median substrate size (D_{50}) along the summer-fall and winter-spring shorelines of the project reach was determined through by referencing the Revetment Database (USACE 2007) and current and historical aerial images. Based on previous analysis of Sacramento River Bank Protection Project (SRBPP) sites (USACE 2008, USACE 2013) sections of shoreline with natural substrate were assigned a D_{50} of 0.25 inches. Sections of shoreline with rock revetment were assigned a D_{50} of 10 inches.

2.2.4 Instream Structure

The shoreline coverage of Instream Woody Material (IWM) along the average summer-fall and winter-spring shorelines of the ARCF GRR project reach were determined by referencing the revetment database (USACE 2007). The revetment database uses four classes of instream structure, based on ranges of percent shoreline having IWM. Table 4 indicates how these revetment database attribute values were converted to a single value for input to SAM. These values were assumed to be appropriate for both the summer-fall and winter-spring seasons. For sub-reaches without available data, an estimate was based on shoreline conditions assessed from aerial images. Shorelines with dense riparian canopy were assigned 5% shoreline coverage of IWM. Shorelines without dense riparian canopy were assigned 0% shoreline coverage of IWM.

Table 4. Conversion of Revetment Database Instream Woody Material Classes to SAM Attribute Value for Instream Structure

Revetment Database IWM Class	SAM Input Value
None	0%
1 - 10%	5%
11 - 50%	30%
> 50%	75%

2.2.5 Aquatic Vegetation

The revetment database attribute for Emergent Vegetation was used for summer-fall aquatic vegetation characterization, and the Ground Cover attribute was used for winter-spring characterization. Within the ARCF GRR project reaches, this approach generally gave a vegetation value of zero for summer-fall conditions, which is appropriate given the scarcity of emergent aquatic vegetation. Table 5 summarizes the conversion of revetment database attribute values for input to the SAM analysis.

Table 5. Conversion of Revetment Database Emergent Vegetation and Ground Cover Classes to SAM Attribute Values for Vegetation.

	Revetment Database IWM Class	SAM Input Value
Summer and Fall Revetment Database: “Emergent Vegetation” Attribute	False	0%
	PEM 1 - 5%	3%
	PEM 6 - 25%	15%
	PEM 26 – 75%	50%
	PEM >75%	85%
Winter and Spring Revetment Database: “Ground Cover” Attribute	<25%	13%
	26-50%	38%
	51-75%	63%
	>75%	88%

2.2.6 Overhanging Shade

The extent of overhanging shade along the summer-fall and winter-spring shorelines was determined through analysis of current and historic aerial images. Summer-fall conditions were analyzed using imagery from late summer and early fall months, typically representative of low water conditions. Winter-spring conditions were analyzed using imagery from late winter and early spring months, typically representative of high water conditions. Values for overhanging shade at winter and spring habitat conditions were modified by factors of 0.25 and 0.75 respectively to account for seasonal defoliation.

2.3 Characterization of With-Project Conditions

The with-project conditions were characterized using the project description outlined for Alternative 2 in the ARCF GRR BA. This analysis was conducted at a feasibility level of design; specific project designs will be developed under a Planning and Engineering Design phase. In the absence of more specific designs, this SAM analysis was developed using a set of “reasonable worst-case” parameters. The parameters were developed by evaluating the applicability of past levee repair designs to the project reach. Past levee repairs were conducted under the Sacramento River Bank Protection Project (SRBPP) within each of the sub-reaches (USACE 2008, USACE 2013). Applicability of design features was evaluated using the professional judgment and experience of the project team. In cases where the applicability of a particular design feature for a particular reach was in question, the analysis erred on the side of caution and applied reduced values or omitted the feature from final analysis. The set of reasonable worst-case parameters is designed to provide a maximum estimation of impact for the purpose of consultation at feasibility planning level. A Vegetation Variance Request (VVR) was assumed to be in place for the Sacramento and American River reaches. The Corps will obtain an ETL-approved vegetation variance exempting the Sacramento River sites from vegetation removal in the lower third of the waterside of the levee prior to final construction and design phase. The

Corps will be complying with the ETL on the American River via a SWIF. The VVR is not assumed to apply to the SBP. Specific habitat attributes are provided by site in (Tables 6-25) and specific justifications for each variable is also provided in those tables.

The following describes how input values for each of the SAM habitat attributes were derived for with-project conditions:

2.3.1 Bank Slope

In the SAM, bank slope serves as an indicator of the availability of shallow-water habitat and is obtained from point estimates of bank slope (horizontal change to vertical change, dW:dH) along each seasonal shoreline (*i.e.*, the line where the water surface intersects the bank on average fall, winter, spring, and summer) (USACE 2004). With-project bank slopes were based on the description of project actions for each reach. Bank slopes for the Sacramento and American River reaches were assumed to be analogous to associated SRBPP repair sites that were in close proximity to the reach being analyzed. Consequently, bank slopes with a summer-fall slope of 3 and winter-spring slope of 10 were used.

2.3.2 Floodplain Availability

The with-project floodplain inundation ratios used in this SAM analysis remained unchanged from existing conditions. Levee repair and bank stabilization actions typically do not increase floodplain availability (with exception of constructing setback levees). In the absence of levee setback actions, the amount of available floodplain areas and channel cross sections would not be greatly altered during levee repair activities.

In this SAM analysis, it was assumed that the with-project floodplain inundation ratios would be the same as pre-project values. As a result, no impacts to habitat quality at the ARCF GRR reaches are expected with respect to this habitat variable.

2.3.3 Bank Substrate Size

The median substrate size (D_{50}) along the summer-fall and winter-spring shorelines of the project reach were based on the description of project actions for each sub-reach. Bank substrate size along the American River sub-reaches were assumed to be 18 inch rock revetment at summer-fall shoreline and 0.25 inch natural substrate at winter-spring shoreline. Bank substrate size along the Sacramento River sub-reaches were assumed to be 12 inch rock revetment at summer-fall shoreline and 0.25 inch natural substrate at winter-spring shoreline.

2.3.4 Instream Structure

The shoreline coverage of IWM along the average summer-fall and winter-spring shorelines was based on the description of project actions for each reach. In the SAM analysis, IWM coverage along the Sacramento and American River reaches were assumed to include installation of 40% shoreline coverage at summer-fall and winter-spring shoreline conditions.

2.3.5 Aquatic Vegetation

The shoreline coverage of aquatic vegetation along the average summer-fall and winter-spring shorelines was based on the description of project actions for each sub-reach. Aquatic vegetation along the Sacramento and American River sub-reaches were assumed to be analogous to SRBPP repair sites. The vegetation growth models below applied to the Sacramento and American River sub-reaches were taken from previous SAM analysis'. For the American River (ARN_AB, ARS_ABC) four previously constructed SRBPP sites within the ARCF GRR project area were used for analysis (LAR 0.3L, LAR 2.8L, LAR 10.0L, and LAR 10.6L)(USACE, 2013). For the Sacramento River 15 previously constructed SRBPP sites within the ARCF GRR project area were used for analysis (SAC 49.7L, SAC 52.3L, and SAC 53.5R)(USACE 2013) and (RM 47.0L, RM 47.9R, RM 48.2R, RM 49.6R, RM 49.9L, RM 50.2L, RM 50.4L, RM 50.8L, RM 51.5 L, RM 52.4L, RM 53.1L, and RM 56.7L)(USACE 2008). Relevant O&M activities were considered but excluded from this analysis. The assumed vegetation variance would apply to woody vegetation only and O&M activities would be expected to result in the removal of shrubs on the slope of the levee; however, it was assumed that typical SRBPP repair designs would locate the planted riparian bench at appropriate elevations and distance from the levee to allow for revegetation efforts. Any removal of shrubby vegetation as the result of O&M activities would take place on the upper slope of the levee and would not impact the habitat considered in a typical SAM analysis.

2.3.6 Overhanging Shade

The shoreline coverage of overhanging shade along the average summer-fall and winter-spring shorelines was based on the description of project actions for each sub-reach. Overhanging shade along the Sacramento and American River sub-reaches were assumed to be analogous to SRBPP repair sites. It was assumed that a variance would be in place allowing for retention of woody vegetation along the lower 2/3 of the levee slope. As the result of constructing a planted bench, it was assumed that the with-project seasonal shoreline would be shifted away from the existing shade providing canopy. Under this assumption, existing summer-fall values for overhanging shade were taken as the starting point for with-project winter-spring conditions. The with-project winter-spring values were further reduced by 75% (winter) and 25% (spring) to account for defoliation. As a final step, these winter-spring values were reduced by 20% to account for trees removed for construction equipment access. With-project overhanging shade values were expected to start at 0% as the result of a constructed bench shifting the shoreline away from the existing canopy. The shade growth models below were applied to the starting seasonal values for overhanging shade described above along the Sacramento and American River sub-reaches. These shade growth models were taken from previous SRBPP SAM analysis' conducted within the ARCF GRR project area.

3.0 Results

The SAM results are presented as weighted response indices (WRI), that give a relative indication of fish response to a project action over time. A negative WRI can be interpreted as a reduction in habitat value and a positive WRI can be interpreted as a increase in habitat value Although the WRI values are not directly representative of actual lengths or areas, the resource agencies have used those values as proxies in determining determine mitigative requirements. Appropriate mitigation is typically determined by identifying the maximum negative WRI for critical life stages (spawning and egg incubation, fry and juvenile rearing, and juvenile migration) on a site-by-site basis. Therefore this section will present results with a focus on the identification of maximum negative WRIs.

As described above, the ARCF GRR project reaches were grouped into four SAM analysis reaches based on hydrologic connectivity. Results are presented below by reach and species and are summarized in tables 30-32 and figures 2-22 at the end of the document.

3.1 Sacramento River SAM Analysis (ARS_DEFG)

The Sacramento River SAM analysis reach includes the entire left bank (east side) of the Sacramento River from the American River confluence to approximately 4,020 linear feet (lf) below the Freeport Bridge. The response of all runs of Chinook salmon, steelhead, and green sturgeon to project actions were included in the analysis of this reach. The green sturgeon spawning and egg incubation life stage was excluded from the analysis because spawning does not occur in the project area.

3.1.1 Spring/ Fall/ Late-Fall/ Winter Run Chinook Salmon

Chinook salmon are expected to show a long term positive response to project actions in the Sacramento River SAM analysis reach over the lifetime of the project. Chinook salmon should exhibit a positive response by year 5 in the winter-spring when most juvenile Chinook salmon are expected in the ARCF GRR project area. Short term negative WRI are expected within the recommended recovery period for Chinook salmon. The maximum negative WRI identified is -4,258 ft for the juvenile migration life stage of Chinook salmon in the summer of year 9. Short term negative WRI values will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions. The SAM data iterations for the various life stages for Chinook salmon can be seen in (Table 28). The WRI response curves for juvenile migration and rearing can be located in (Figures 4 and 7). The NMFS SAM effects analysis summary tables can be seen in (Table 32).

3.1.2 Steelhead

Steelhead are expected to show a long term positive response to project actions in the Sacramento River SAM analysis reach over the lifetime of the project. Steelhead should exhibit a positive response by year 4 in the winter-spring when most juvenile steelhead will be migrating and rearing through the project area. The maximum negative WRI identified is -3,985 ft for the juvenile migration life stage of steelhead in the fall of year 10. Short term negative WRI values will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer habitat conditions. The WRI response curves for juvenile migration and rearing can be located in (Figures 10 and 13).

3.1.3 Green Sturgeon

SRBPP onsite mitigative features were designed to maximize habitat response for salmonid species. SAM WRI's for green sturgeon generally indicate a negative response or no response to typical onsite mitigative features. Green sturgeon are expected to show long term negative response to project actions in the Sacramento River SAM analysis reach for several life stages at all seasonal habitat conditions over the lifetime of the project. The maximum negative WRI identified is -5,009 for fry and juvenile rearing in the summer of year 1. Negative WRI displayed a general trend toward decreasing beyond the lifetime of the project for fry and juvenile rearing life stages. Negative WRI values for adult life stages will result from the creation of a 10:1 planted bench at winter/spring habitat conditions. The WRI response curves for juvenile rearing can be located in (Figure 16).

3.2 American River SAM Analysis (ARN_AB and ARS_ABC)

The American River SAM analysis reaches include portions of the right and left bank of the American River from Goethe Park to the confluence of the Sacramento. The response of spring and fall runs of Chinook salmon, steelhead, and green sturgeon were included in the analysis of these reaches. Additional seasonal fall run juvenile migration life stage analysis was conducted after consultation with NMFS. Green sturgeon analysis was also included because of critical habitat in the lowest sub-reach (ARS_C) of the American River project area.

3.2.1 Spring/ Fall Chinook Salmon

Chinook salmon are expected to show a long term positive response to project actions in the American River SAM analysis reaches over the lifetime of the project when both IWM and planted benches are incorporated into the with-project conditions. Chinook salmon should exhibit a positive response by year 5. Short term habitat deficits are expected within the recommended recovery period for Chinook salmon. The maximum negative WRI value identified for the American River SAM ARN_AB and ARS_ABC is -3,129 ft for the juvenile migration life stage of fall-run Chinook salmon in the summer of year 1. Short term negative WRI values will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions. The SAM data iterations for the various life stages for Chinook salmon can be seen in (Tables 26-27). The WRI response curves for juvenile migration and rearing can be located in (Figures 2,3,5,and 6). Additional fall-run Chinook salmon juvenile migration life stages not normally set as default in SAM were included on the American River reaches per NMFS request.

3.2.2 Steelhead

Steelhead are expected to show a long term positive response to project actions in the American River SAM analysis reach over the lifetime of the project. Steelhead should exhibit a positive response by year 4. Short term habitat deficits are expected within the recommended recovery period for steelhead. The maximum negative WRI value identified for the American River SAM analysis is -3,061 ft for the adult residence life stage in the summer of year 1 (Figures 20 and 21). Short term negative WRI values will result from the initial loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions. The WRI response curves for juvenile migration and rearing can be located in (Figures 8,9,11, and 12).

3.2.3 Green Sturgeon

Project actions in the American River SAM analysis reach will mimic SRBPP repair site onsite mitigative features. SRBPP onsite mitigative features were designed to maximize habitat response for salmonid species; green sturgeon will exhibit a negative response for juvenile rearing in the summer/fall to these onsite mitigative features. However, during the winter/spring green sturgeon juvenile rearing life stages will exhibit a positive response to these onsite mitigative features. The maximum negative WRI value identified is -7,118 ft for the fry and juvenile rearing life stage in the summer of year 1. The WRI response curves for juvenile rearing can be located in (Figures 14 and 15).

3.3 Sacramento Bypass and Weir SAM Analysis

The Sacramento Bypass SAM analysis reach includes the right bank (north side) of the Sacramento Bypass levee in its entirety from the confluence of the Sacramento River to its termination at the Yolo Bypass. The response of all runs of Chinook salmon, steelhead, and green sturgeon were included in the analysis of this reach.

3.3.1 Spring/ Fall/ Late-Fall/ Winter Run Chinook Salmon

Chinook salmon are expected to show a small long term negative response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project. Chinook salmon should exhibit a negative response by year 1. The maximum negative WRI value identified is -188 ft for the juvenile migration life stage of Spring and Winter-run Chinook salmon in the spring of year 2. Short term and long term negative WRI values will result from the loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions during and after the construction of the extension to the Sacramento Bypass Weir. The SAM data iterations for the various life stages for Chinook salmon can be seen in (Table 29). The NMFS SAM effects analysis summary tables can be seen in (Table 33).

3.3.2 Steelhead

Steelhead are also expected to show a small long term negative response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project. Steelhead should exhibit a negative response by year 1. The maximum negative WRI value identified is -174 ft for the juvenile migration life stage in the spring of year 2. Short term and long term negative WRI values will result from the loss of aquatic vegetation and over hanging shade at fall/summer/winter/spring habitat conditions during and after the construction of the extension to the Sacramento Bypass Weir. The NMFS SAM effects analysis summary tables can be seen in (Table 33).

3.3.3 Green Sturgeon

Green Sturgeon are expected to show a long term positive response to project actions in the Sacramento Bypass SAM analysis reach over the lifetime of the project for the fry and juvenile rearing life stages in the winter/spring/summer/fall of year 1. The maximum negative WRI value identified is -8 ft for the adult residence life stage of green sturgeon in the winter/spring/summer of year 1 which carries over through the life of the project into year 50. The SAM data iterations for the various life stages for green sturgeon can be seen in (Table 29). The NMFS SAM effects analysis summary tables can be seen in (Table 33).

4.0 Discussion

The SAM analysis indicates that the project actions in the Sacramento River SAM analysis reach, American River SAM analysis reach, and the Sacramento Bypass SAM analysis reach would result in short and longer-term impacts for focus fish species. Impacts to Chinook salmon, Central Valley steelhead, and green sturgeon are generally the result of reduction in the available natural substrate, shade and the alteration of near-shore slope resulting from bank armoring. Long term recovery of onsite vegetation, addition of IWM, and retention of existing vegetation are all expected to minimize impact as well as contribute to long term gains in habitat value.

This SAM analysis employed a set of worst case scenario parameters developed to capture the maximum potential impacts of the project for the Section 7 consultation process. Future implementation of the project is expected to result in significantly lower impacts. Project actions along portions of the American River reach will likely not include bank armoring in their final design, which will significantly reduce estimated impacts to fish species. Additional mitigative design features or improved erosion repair designs may result in reduced impact compared to the legacy designs used for the basis of this analysis. Site specific designs will be implemented on a site by site basis in consultation with resource agencies and project partners to minimize impacts as well as maximize opportunities for implementing onsite mitigative features.

During project implementation, site specific SAM analyses will be run on final designs to better evaluate impact. SAM results will be used by the Corps and NMFS in the negotiation of appropriate mitigation for project actions. Although short term impacts are generally self mitigating through the development of onsite mitigative features, the Corps will compensate for the temporal impacts to habitat through the purchase of offsite mitigative credits. Typically appropriate mitigation will be based on the identification of maximum negative WRI values. By mitigating for the maximum negative WRI, lesser impacts are expected to be appropriately mitigated. As a general rule, the SAM applies any habitat characteristics at summer/fall conditions to winter/spring conditions with the assumption that those characteristics would provide similar value during inundation. Onsite mitigation at summer/fall conditions is expected to provide similar habitat benefit for winter/spring conditions. Offsite mitigation is expected to provide mitigative value at all seasonal habitat conditions. Longer term impacts to habitat may not recover to baseline conditions over the life of the project due to design restrictions. These impacts to habitat will be compensated through the purchase of offsite mitigative credits as well as the incorporation of additional onsite mitigative features (ie. low water plantings, additional IWM, additional revegetation).

Additional mitigative concerns, not considered in a SAM analysis, will be addressed along the Sacramento Bypass reach, including potential adult and juvenile passage issues, loss of shoreline riparian vs. gain in floodplain, and contradicting ESA species habitat requirements. These issues will be considered and appropriate actions will be taken where possible in coordination with other agencies.

4.1 Chinook Salmon

Impacts to Chinook salmon were analyzed for the Sacramento River SAM analysis reach (ARS_DEFG), American River SAM analysis reach (ARN_AB, ARS_ABC) and the Sacramento Bypass SAM analysis reach. In the Sacramento River SAM analysis reach, negative WRI values are due to short term removal of aquatic vegetation and overhanging shade caused by the repair action. The SAM analysis indicates that repair actions would result in a maximum negative WRI value of -4,258 ft. This value is based on the maximum negative WRI value observed for juvenile migration life stage of Chinook salmon in the summer of year 9. USACE will mitigate for -4,258 ft of equivalent habitat as described above in Section 4.0.

In the American River SAM analysis reaches ARN_AB and ARS_ABC negative WRI values are due to short term removal of aquatic vegetation and overhanging shade caused by the repair action. The SAM analysis incorporating planted benches and IWM indicates that repair actions would result in a maximum habitat deficit of -3,129 ft. This value is based on the maximum negative WRI value observed for the juvenile migration life stage of spring and fall-run Chinook salmon in the summer and fall of year 1. USACE will mitigate for -3,129 ft of equivalent habitat as described above in Section 4.0.

There were no initial construction impact negative WRI values for the juvenile rearing life stage of Chinook salmon in the winter and spring water levels on the American and Sacramento River reaches. A possible explanation is that the SAM ECT does not produce an output at Year-0. It does not calculate the difference from the baseline to with-Project results. SAM at Year-0 is zero. The relative response for Year-1 is actually the Year-0 results+Year-1 results divided by 2, see pages 5-29 to 5-31 in the SAM Certification Update for SAM formula detailed explanation. In Year-0 revetment will be added, vegetation will be removed and slope will have a positive change. In Year-1 IWM will be added, soil and planting on the bench will occur, and the VVR will kick in. Year-0 habitat deficits would be more than the Year-1 deficits where the positive and negative deficits are equal.

In the Sacramento Bypass SAM analysis reach negative WRI values are due to short and long term removal of aquatic vegetation and overhanging shade for the upstream extension of the Sacramento Bypass Weir. The SAM analysis indicates that repair and removal actions would result in a maximum negative WRI value of -146 ft. This value is based on the maximum negative WRI value observed for juvenile migration of Chinook salmon in the winter of year 1. USACE will mitigate for -146 ft of equivalent habitat as described above in Section 4.0.

4.2 Steelhead

Impacts to steelhead were analyzed for the Sacramento River SAM analysis reach, American River SAM analysis reach, and the Sacramento Bypass SAM analysis reach. The Sacramento River SAM analysis indicates that repair actions would result in maximum negative WRI values of -3,985 ft. This value is based on the maximum negative WRI value observed for the juvenile migration life stage of steelhead in the fall of year 10.

The American River SAM analysis ARN_AB and ARS_ABC indicates that repair actions would result in negative WRI values of -3,061 ft. This negative WRI is expected to be adequately compensated through mitigation of a greater negative WRI for Chinook salmon.

There were no initial construction impact negative WRI values for the juvenile rearing life stage of steelhead in the winter and spring water levels on the Sacramento River reaches. A possible explanation is that the SAM ECT does not produce an output at Year-0. It does not calculate the difference from the baseline to with-Project results. SAM at Year-0 is zero. The relative response for Year-1 is actually the Year-0 results+Year-1 results divided by 2, see pages 5-29 to 5-31 in the SAM Certification Update for SAM formula detailed explanation. In Year-0 revetment will be added, vegetation will be removed and slope will have a positive change. In Year-1 IWM will be added, soil and planting on the bench will occur, and the VVR will kick in. Year-0 habitat deficits would be more than the Year-1 habitat deficits where the positive and negative deficits are equal.

The Sacramento Bypass SAM analysis indicates that repair actions would result in maximum negative WRI values of -174 ft. This value is based on the maximum

\negative WRI value observed for the juvenile migration life stage of steelhead in the spring of year 4. This negative WRI is expected to be adequately compensated through mitigation of a greater negative WRI for Chinook salmon.

4.3 Green Sturgeon

Impacts to green sturgeon were analyzed for the Sacramento and American River SAM and Sacramento Bypass analysis reaches. Green sturgeon critical habitat in the American River extends from the confluence of the Sacramento River to the Highway 160 bridge (ARS_C). Additional SAM elements were incorporated to address potential green sturgeon effects in the American River reaches (ARN_AB and ARS_AB), as per NMFS request, even though use of these reaches by green sturgeon has not been documented. Recently a white sturgeon (161mm) was collected in a rotary screw trap (RST) by the U.S. Fish and Wildlife Service (USFWS) at the Watt Avenue bridge, the first such documented catch of a sturgeon since records have been kept dating back to approximately 1996. There have been no green sturgeon collected, and the correlation of green sturgeon presence to white sturgeon presence is not well understood for larval life stages in this region of the river. This additional analysis allowed for a more conservative estimate of impacts and may not necessarily reflect the true impacts from the project.

The habitat requirements of green sturgeon are not well understood; assumptions built into the SAM on fish response to shoreline features were based on limited information. Habitat use of the American River, Sacramento River, and Sacramento Bypass project reaches by green sturgeon are likely limited to use as a migration corridor by adults and potential rearing area by juvenile life stages. Although the SAM indicates negative response to habitat by adult life stages, it is unlikely that shoreline repair activities would significantly impact the river for residence or as a migration corridor. SRBPP style repairs are designed to mimic naturally occurring habitat types and are not expected to significantly alter the width of the river. USACE does not expect any significant impacts to the adult residence or adult migration life stages in the American or Sacramento River and does not propose any additional mitigation.

No suitable spawning habitat exists in the Sacramento River, American River, and Sacramento Bypass project reaches. Green sturgeon spawning with concurrent egg incubation and early life history primarily takes place upriver of Colusa on the Sacramento River and in the lower Feather River outside of the project area. Because no suitable spawning habitat is present in the project reaches under existing conditions, USACE does not expect any significant impacts to the spawning and egg incubation life stage of green sturgeon and does not propose any additional mitigation.

The American River SAM analysis ARN_AB and ARS_ABC indicates that repair actions would result in a maximum negative WRI values of -7,118 ft. for fry and juvenile rearing in the summer of year one. The Sacramento River SAM analysis ARS_DEFG indicates that repair actions would result in a maximum negative WRI values of -5,009 for fry and juvenile rearing in the summer of year one.

The Sacramento Bypass SAM analysis indicates that repair actions would result in maximum negative WRI values of -8 ft in response to the removal of aquatic vegetation and SRA for the expansion of the Sacramento Bypass and Weir. This value is based on the maximum negative WRI values observed for the adult residence life stage of green sturgeon in the winter/spring /summer of year 1 continuing through the life of the project to year 50.

Little is known about the fry and juvenile rearing and juvenile migration life stages of green sturgeon. The SAM does not evaluate response to specific habitat attributes for the juvenile migration life stage. For the purpose of this analysis it is assumed that these life stages exhibit similar responses to analogous life stages of Chinook and steelhead. This approach assumes that fry and juvenile rearing and juvenile migration life stages of green sturgeon will exhibit a positive response to “good riparian habitat” (*i.e.* increased shoreline coverage of overhanging shade, aquatic vegetation, and IWM). During the planning and design phase of the project, opportunities for the incorporation of additional onsite mitigative features will be evaluated in coordination with resource agencies to ensure the projected longer term impacts are appropriately compensated for green sturgeon. Potential onsite mitigative features include the planting of vegetation at the low water line, the incorporation of additional IWM, and limitations in instream revetment.

Table 6
SAM data summary of existing conditions at site Lower American River RM 10.0L and 10.6L (ARN_AB).

Habitat Parameter	Water Year	Seasonal Values Fall	Winter	Spring	Summer

	2073	30	7	22	30

[1] Shoreline Length Estimated from Aerial images. Attribute surveyed in the field following the field data collection protocol for the USACE Revetment Database (2007).
[2] Existing slopes taken from 1 SRBPP repair site modeled by SAM.
[3] Assume no significant increase in floodplain between seasonal water surface elevations. Assume floodplain inundation ratio of one for all seasons in all ARCF GRR Reaches.
[4] Bank substrate data taken from USACE Revetment Database (2007) and confirmed with aerial imagery. Natural substrate assigned a D50 of 0.25 inches. Revetment substrate assigned a D_{50} of 10 inches.
[5] Instream Structure data taken from USACE Revetment Database (2007).
[6] Shoreline coverage of Vegetation taken from USACE Revetment Database and evaluated against aerial imagery. Summer/Fall values taken from "Emergent Veg" attribute. Winter/ Spring values taken from "Veg Cover%" attribute.
[7] Attribute coverage determined from analysis of aerial imagery. Winter/ Spring values modified by 0.25/ 0.75 respectively to represent seasonal defoliation.

-WY = water year; spans fall, winter, spring and summer; rock and soil placement and IWM installation assumed during Winter in the initial WY and revegetation planting assumed during Spring of the initial WY.

[1] Shoreline Length Estimated from Aerial images. Attribute surveyed in the field following the field data collection protocol for the USACE Revetment Database (2007).

[2] Assume no significant change to Bank Slope.

[3] Assume no significant increase in floodplain between seasonal water surface elevations or as a result of project construction.

[4] Assume floodplain inundation ratio of 1 for all seasons in all ARCF GRR Reaches.

[5] Assume installation of rock revetment at summer/fall (D_{50} of 12 in) and natural substrate at winter/spring (D_{50} of 0.25 in).

[6] Assume installation of 40% shoreline coverage of IWM at summer/fall and winter/spring.

[6] Assume a variance in place allowing existing woody vegetation to remain in place on bottom 2/3 of levee

Table 22

SAM data summary of existing conditions at site Sacramento River 50.0L (SBP Levee).

Habitat Parameter	Water Year	Seasonal Values

	2062	48	12	36	48

[1] Wetted area estimated from aerial images in Google Earth Pro. Length x Width

[2] USACE Revetment Database (2007) and Google Earth Pro.

[3] Repairs not expected to affect slope, assume slope of 2 for consistency with USACE standards.

[4] Assume no significant increase in floodplain between seasonal water surface elevations. Assume floodplain inundation ratio of 1 for all seasons in all ARCF GRR Reaches.

[5] Bank substrate data taken from USACE Revetment Database (2007) and confirmed with aerial imagery. Natural substrate assigned a D50 of 0.25 inches. Revetment substrate assigned a D_{50} of 10 inches.

[6] Instream Structure data taken from USACE Revetment Database (2007).

[7] Shoreline coverage of Vegetation taken from USACE Revetment Database and evaluated against aerial imagery. Summer/Fall values taken from "Emergent Veg" attribute. Winter/ Spring values taken from "Veg Cover%" attribute.

[8] Attribute coverage determined from analysis of aerial imagery. Winter/ Spring values modified by 0.25/ 0.75 respectively to represent seasonal defoliation.

Site Selected:	Date Of Selection	Was A Local Site Assessment Used? YES ☐ NO ☐

Reason For Selection:

Name of Federal agency representative completing this form: U.S. Army Corps of Engineers	Date: 9/9/15

(See Instructions on reverse side) **Form AD-1006 (03-02)**

STEPS IN THE PROCESSING THE FARMLAND AND CONVERSION IMPACT RATING FORM

Step 1 - Federal agencies (or Federally funded projects) involved in proposed projects that may convert farmland, as defined in the Farmland Protection Policy Act (FPPA) to nonagricultural uses, will initially complete Parts I and III of the form. For Corridor type projects, the Federal agency shall use form NRCS-CPA-106 in place of form AD-1006. The Land Evaluation and Site Assessment (LESA) process may also be accessed by visiting the FPPA website, http://fppa.nrcs.usda.gov/lesa/.

Step 2 - Originator (Federal Agency) will send one original copy of the form together with appropriate scaled maps indicating location(s)of project site(s), to the Natural Resources Conservation Service (NRCS) local Field Office or USDA Service Center and retain a copy for their files. (NRCS has offices in most counties in the U.S. The USDA Office Information Locator may be found at http://offices.usda.gov/scripts/ndISAPI.dll/oip_public/USA_map**,** or the offices can usually be found in the Phone Book under U.S. Government, Department of Agriculture. A list of field offices is available from the NRCS State Conservationist and State Office in each State.)

Step 3 - NRCS will, within 10 working days after receipt of the completed form, make a determination as to whether the site(s) of the proposed project contains prime, unique, statewide or local important farmland. (When a site visit or land evaluation system design is needed, NRCS will respond within 30 working days.

Step 4 - For sites where farmland covered by the FPPA will be converted by the proposed project, NRCS will complete Parts II, IV and V of the form.

Step 5 - NRCS will return the original copy of the form to the Federal agency involved in the project, and retain a file copy for NRCS records.

Step 6 - The Federal agency involved in the proposed project will complete Parts VI and VII of the form and return the form with the final selected site to the servicing NRCS office.

Step 7 - The Federal agency providing financial or technical assistance to the proposed project will make a determination as to whether the proposed conversion is consistent with the FPPA.

INSTRUCTIONS FOR COMPLETING THE FARMLAND CONVERSION IMPACT RATING FORM

(For Federal Agency)

Part I: When completing the "County and State" questions, list all the local governments that are responsible for local land use controls where site(s) are to be evaluated.

Part III: When completing item B (Total Acres To Be Converted Indirectly), include the following:

1. Acres not being directly converted but that would no longer be capable of being farmed after the conversion, because the conversion would restrict access to them or other major change in the ability to use the land for agriculture.
2. Acres planned to receive services from an infrastructure project as indicated in the project justification (e.g. highways, utilities planned build out capacity) that will cause a direct conversion.

Part VI: Do not complete Part VI using the standard format if a State or Local site assessment is used. With local and NRCS assistance, use the local Land Evaluation and Site Assessment (LESA).

1. Assign the maximum points for each site assessment criterion as shown in § 658.5(b) of CFR. In cases of corridor-type project such as transportation, power line and flood control, criteria #5 and #6 will not apply and will, be weighted zero, however, criterion #8 will be weighed a maximum of 25 points and criterion #11 a maximum of 25 points.

2. Federal agencies may assign relative weights among the 12 site assessment criteria other than those shown on the FPPA rule after submitting individual agency FPPA policy for review and comment to NRCS. In all cases where other weights are assigned, relative adjustments must be made to maintain the maximum total points at 160. For project sites where the total points equal or exceed 160, consider alternative actions, as appropriate, that could reduce adverse impacts (e.g. Alternative Sites, Modifications or Mitigation).

Part VII: In computing the "Total Site Assessment Points" where a State or local site assessment is used and the total maximum number of points is other than 160, convert the site assessment points to a base of 160.
Example: if the Site Assessment maximum is 200 points, and the alternative Site "A" is rated 180 points:

$$\frac{\text{Total points assigned Site A}}{\text{Maximum points possible}} = \frac{180}{200} \times 160 = 144 \text{ points for Site A}$$

For assistance in completing this form or FPPA process, contact the local NRCS Field Office or USDA Service Center.

NRCS employees, consult the FPPA Manual and/or policy for additional instructions to complete the AD-1006 form.

MITIGATION, MONITORING, AND REPORTING PLAN

AMERICAN RIVER WATERSHED COMMON FEATURES

GENERAL REEVALUATION REPORT

SACRAMENTO COUNTY, CALIFORNIA

This mitigation monitoring or reporting plan (MMRP) is designed to fulfill Section 21081.6 (a) of the California Environmental Quality Act (CEQA). Which requires public agencies to adopt a reporting or monitoring program whenever a project or program is approved that includes mitigation measures identified in an environmental document for which the agency makes a finding pursuant to CEQA Section 21081 (a) (1). The mitigation measures and strategies described below and in the attached table are to be used to avoid, minimize, or reduce any potentially significant environmental impacts.

The MMRP table includes the following:

- Section and Impacts – identifies the issue area section of the EIR/EIS and corresponding impact.
- Mitigation Measures – lists the adopted mitigation measures from the EIR/EIS.
- Implementation Timing – identifies the timing of implementation of the action described in the mitigation measures.
- Responsible for Implementation – identifies the agency/party responsible for implementing the actions described in the mitigation measures.
- Responsible for Monitoring/Reporting Action – identifies the agency/party responsible for monitoring implementation of the actions described in the mitigation measures. Verification will be carried-out during the project and an MMRP completion report will be submitted to the CVFPB staff upon completion of the project.

Section and Impacts	Mitigation Measures	Implementation Timing	Responsible for Mitigation	Responsible for Monitoring/ Reporting Action
3.2 Geologic Resources Alternative 1 Excavation for borrow material or during construction could increase soil erosion or permanent loss of topsoil. Alternative 2 Similar impact as alternative 1, but a greater magnitude.	Both Alternatives Prior to construction, USACE or its contractor would be required to acquire all applicable permits for construction. Prior to construction, a Stormwater Pollution Protection Plan (SWPPP) would be prepared, and best management practices (BMPs) would be proposed to reduce potential erosion and runoff during rain events. Minimize ground and vegetation disturbance during project construction by establishing designated equipment staging areas, ingress and egress corridors, spoils disposal and soil stockpile areas, and equipment exclusion zones prior to the commencement of any grading operations. Stockpile soil on the landside of the levee reaches, and install sediment barriers (e.g., silt fences, fiber rolls, and straw bales) around the base of stockpiles to intercept runoff and sediment during storm events. If necessary, cover stockpiles with geotextile fabric to provide further protection against wind and water erosion.	D,P,C	USACE	CVFPB Monitor measures applicable to site: Verify that all required permits have been acquired. Verify that SWPPP and BMP's have been prepared. Review plans to see that stockpiles will be on landside. Monitor construction periodically to assure ground and vegetation

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	Install sediment barriers on graded or otherwise disturbed slopes as needed to prevent sediment from leaving the project site and entering nearby surface waters. Install plant materials to stabilize cut and fill slopes and other disturbed areas once construction is complete. Temporary structural BMPs, such as sediment barriers, erosion control blankets, mulch, and mulch tackifier, could be installed as needed to stabilize disturbed areas until vegetation becomes established.			disturbance is minimal. Verify use of sediment barriers and instillation of stabilizing plant materials. Verify establishment of vegetation.
3.3 Land Use Alternative 1 Acquisition of properties for levee easements along the Sacramento River and Arcade Creek. Alternative 2 Acquisition of properties for levee easements along the Sacramento River and Arcade Creek (fewer properties impacted than Alternative 1). Conversion of agricultural lands to floodway.	Coordination with Sacramento County Department of Parks and Recreation, the National Park Service, the other Federal and State agencies responsible for managing the resources of the Parkway, and non-governmental stakeholders will ensure consistency with existing plans. All property acquisitions would be conducted in compliance with Federal and State relocation law, and relocation services would be accomplished in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1960. Mitigation for the lands converted from parkway land to flood control uses will be mitigated by paying fees to the County under the Habitat Restoration Program Fees (HRP).	D	USACE	CVFPB Coordinate with stakeholders to ensure consistency. Verify that acquisitions are conducted in accordance with Uniform Relocation Act. Verify payment of fees.
3.4 Hydrology and Hydraulics				

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

Alternative 1 No impact Alternative 2 Reduce water surface elevation in the Sacramento River downstream of the confluence of the American River without significantly increasing water surface elevation in the Yolo Bypass downstream of the confluence of the Sacramento Bypass.	None required.	D	USACE	CVFPB
3.5 Water Quality and Groundwater Resources Alternative 1 Increased turbidity during bank protection construction, runoff of exposed soils, and cement, slurry, or fuel spills during construction. Rock revetment placement in open water would result in significant indirect effects as the sediment and turbidity plume drifts further downstream and later effect the water qualify in those areas found further downstream of the project area. Alternative 2 Same impacts as alternative 1 plus, a potential for water quality impacts to occur if the weir is constructed in a way that debris or other construction materials could enter the Sacramento River.	Monitor turbidity in the adjacent water bodies, where applicable criteria apply, to determine whether turbidity is being affected by construction and to ensure that construction does not result in a rise in turbidity levels above ambient conditions, in accordance with the Central Valley RWQCB Basin Plan turbidity objectives Prepare a SWPPP, Spill Prevention Control and Countermeasures Plan (SPCCP), and a bentonite slurry spill contingency plan (BSSCP) • Conduct earthwork during low flow periods (July 1 through November 30). • To the extent possible, stage construction equipment and materials on the landside of the subject levee reaches in areas that have already been disturbed.	P, C	USACE	CVFPB Verify coordination with RWQCB. Review SWPPP, SPCCP, and BSSCP. Verify measures are in place during construction.

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	• Minimize ground and vegetation disturbance during project construction by establishing designated equipment staging areas, ingress and egress corridors, spoils disposal and soil stockpile areas, and equipment exclusion zones prior to the commencement of any grading operations. • Stockpile soil on the landside of the levee reaches, and install sediment barriers (e.g., silt fences, fiber rolls, and straw bales) around the base of stockpiles to intercept runoff and sediment during storm events • Install sediment barriers on graded or otherwise disturbed slopes as needed to prevent sediment from leaving the project site and entering nearby surface waters. • Install plant materials to stabilize cut and fill slopes and other disturbed areas once construction is complete. Plant materials could include an erosion control seed mixture or shrub and tree container stock. Temporary structural BMPs, such as sediment barriers, erosion control blankets, mulch, and mulch tackifier, could be installed as needed to stabilize disturbed areas until vegetation becomes established. • Conduct water quality tests specifically for increases in turbidity and sedimentation caused by construction activities.			

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	• Water samples for determining background levels shall be collected in the adjacent water body for each erosion construction site. • During working hours, the construction activity shall not cause the turbidity in the adjacent water body down current from the construction sites to exceed the Basin Plan turbidity objectives.			
3.6 Vegetation and Wildlife Alternative 1 The launchable rock trenches would result in the removal of a maximum of 65 acres of riparian habitats within the American River Parkway. Bank protection measure would result in impacts to a maximum of 31,000 linear feet of SRA habitat. The existing levee structure would be degraded by one half to create a working platform for slurry wall installation. As the levee is degraded, all vegetation located in the degraded area would be removed. The maximum degraded area (the upper one half of the levee) is approximately 110 acres and contains about 750 trees of various sizes and species. On the landside of the levee, where levee raises are required, all trees would	During the design refinement phase, plans will be evaluated to reduce the impact on vegetation and wildlife to the extent practicable. Refinements that could be implemented to reduce the loss of riparian habitat include: reduced footprint, constructing bank protection rather than launchable rock trench whenever feasible, and designing planting berms in areas where significant riparian habitat exists adjacent to the levee toe. To compensate for the removal of a maximum of 65 acres of riparian habitat, approximately 130 acres of replacement habitat would be created to account for the temporal loss of habitat while newly created habitat is growing. Surveys would be conducted prior to construction to determine if any birds are nesting within 0.5 miles of the construction activities. If nests are located within the vicinity of construction for any given year, coordination with the appropriate resource agencies would occur to determine what	D, P, C	USACE	CVFPB Verify impact refinement for smaller footprint. Verify replacement habitat creation. Verify and participate in nesting bird surveys. Verify that tree removal occurs outside of nesting season. Verify vegetation

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

be removed from the levee slope and within 15 feet of the levee toe to construct the levee raise. A landside maintenance easement would be required along the levee toe within the 8 miles of levee raise. This easement will be left in place after construction as access. There are approximately 1,300 trees of various species and size within this landside easement that once removed would not be replaced on-site. There would be a maximum of 200 trees removed from both the landside and waterside to construct the project. These trees compose approximately 2 acres of oak woodland habitat on NEMDC, and approximately 10.5 acres of riparian on Arcade Creek. Alternative2 Because the amount of levee raising is significantly reduced under Alternative 2 due to the widening of the Sacramento Weir and Bypass, effects to the landside vegetation on the levees would be less than under implementation of Alternative 1. This would result in the removal of approximately 750 trees of various species	action should be taken to reduce impacts. Trees would not be removed if an active nest is found; however, once the young have fledged, the tree can be removed for construction. If survey results determine that no nests are in the vicinity of construction scheduled for that year, construction may commence without further coordination on this issue. Avoidance and minimization measures incorporated as part of the Sacramento River design include: compliance with the USACE vegetation policy through a vegetation variance, installation of a planting berm where erosion protection is required, and narrowing of the levee footprint by construction of a retaining wall, when feasible. The vegetation variance would allow waterside trees on the lower half of the slope to remain in place. This would allow approximately 930 trees along 10 miles of the Sacramento River to continue to provide habitat for fish and wildlife species. Along with retaining the trees, additional plantings of small vegetation would be done on the newly constructed berm. Species of plants would be coordinated with NMFS, USFWS, and State and local partners. Off-Site mitigation for the removal of 50 trees in the Arcade Creek area would be done in compliance with the Sacramento City tree ordinance. It is estimated that 2 acres would be required to accommodate the planting of			variance is in place to minimize tree removal. Verify mitigation area for trees planted off-site.

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

	approximately 450 trees. Alternative 2 Compensation was determined by evaluating other projects with similar impacts in the Central Valley, coordination with resource agencies, and evaluation of compensation plantings' ability to provide similar wildlife habitat. A total of 16 acres would be needed to compensate for the removal of the vegetation along the Sacramento River and within the new weir footprint, due to the temporal loss of habitat while the new habitat is establishing. Plantings could be accomplished within the expanded bypass, other nearby available lands, or through the purchase of credits at an approved mitigation bank.			
3.7 Fisheries Alternative 1 Rock placement would most likely disturb the native resident fish by increasing noise, water turbulence, and turbidity, causing them to move away from the area of placement. In some pelagic native juvenile species utilizing the near shore habitat for cover, moving away from that cover could put them at a slight risk of predation. Construction during the project may disturb soils and the nearshore	Mitigation measures for vegetation and wildlife, and water quality will also apply for fisheries. Additionally; • In-water construction would be restricted to the general estimated work window of August 1 through November 30. For the purpose of this study however, during PED, the work window will be adjusted on a site specific basis taking into account periods of low fish abundance, and in-water construction outside the principal spawning and migration season. Typical construction season generally corresponds to the dry	D, P, C	USACE	CVFPB Verify implementation of vegetation and wildlife mitigation measures. Verify implementation of water quality mitigation measures.

Notes:

O: To be implemented as an operational practice after construction is complete

environment, leading to increases in sediment in the nearshore aquatic habitat. This in turn may increase sedimentation (i.e., deposition of sediment on the substrate), suspended sediments, and turbidity. Alternative 2 By widening the Sacramento Weir and Bypass, the project would create additional floodplain habitat within the Sacramento Bypass, which could benefit native fish.	season, but construction may occur outside the limits of the dry season, only as allowed by applicable permit conditions. • Due to the deleterious effects of numerous chemicals on native resident fish used in construction, if a hazardous materials spill does occur, a detailed analysis will be performed immediately by a registered environmental assessor or professional engineer to identify the likely cause and extent of contamination. This analysis will conform to American Society for Testing and Materials standards, and will include recommendations for reducing or eliminating the source or mechanisms of contamination. Based on this analysis, the USACE and its contractors will select and implement measures to control contamination, with a performance standard that surface water quality and groundwater quality must be returned to baseline conditions. • If mitigation or compensation sites are planned within the Sacramento Bypass for the overall ARCF project, information gained from the 2013 Knaggs Ranch Pilot Study would be reviewed for potential beneficial habitat for native fish species to be

	incorporated into the sites.			
3.8 Special Status Species Alternative 1 <u>Valley Elderberry Longhorn Beetle</u> Within the surveyed study area, approximately 250 shrubs were located along the American River Parkway and 50 shrubs were located along the Sacramento River. Prior to project construction, a qualified biologist would conduct focused surveys of elderberry shrubs within 100 feet of the project area for construction in accordance with the USFWS guidelines.	Mitigation measures are similar for both Alternatives 1 and 2 <u>Valley Elderberry Longhorn Beetle</u> The following is a summary of measures that would be implemented during construction based on the *Conservation Guidelines for the Valley Elderberry Longhorn Beetle* (USFWS 1999a). These measures will be implemented to minimize any potential effects on valley elderberry longhorn beetles or their habitat, including restoration and maintenance activities, long-term, protection, and compensation if shrubs cannot be avoided: • When a 100-foot (or wider) buffer is established and maintained around elderberry shrubs, complete avoidance (i.e., no adverse effects) will be assumed. • Where encroachment on the 100-foot buffer has been approved by the USFWS, a setback of 20 feet from the dripline of each elderberry shrub will be maintained whenever possible. • During construction activities, all areas to be avoided will be fenced and flagged. • Contractors will be briefed on the need to avoid damaging elderberry shrubs and the possible penalties for not complying with	D, P, C , M	USACE	CVFPB Verify that all BMP's and mitigation measures are followed during construction. Verify setback distances Verify that environmental awareness training has been implemented

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

VELB continued	these requirements. • Signs will be erected every 50 feet along the edge of the avoidance area, identifying the area as an environmentally sensitive area. • Any damage done to the buffer area will be restored. • Buffer areas will continue to be protected after construction. • No insecticides, herbicides, fertilizers, or other chemicals that might harm the beetle or its host plant will be used in the buffer areas. • Trimming of elderberry plants will be subject to mitigation measures. • Elderberry compensation would be planted in the American River Parkway. The USACE has six existing sites which are offsetting previous USACE flood control projects along the lower American River and near Folsom Dam. The USACE will find areas within the lower American River parkway which will either expand existing compensation areas or provide for connectivity between conserved valley elderberry longhorn beetle habitat. Sites within the Parkway will be coordinated with County Parks and the Service during the design phase of the project. Sites will be designed and developed prior to any effects to valley elderberry longhorn beetle habitat. The USACE will create 69.91 acres of riparian habitat which supports valley elderberry longhorn beetle within the lower American			Verify sign placement.

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

VELB continued Vernal Pool Fairy Shrimp and Vernal Pool Tadpole Shrimp There is approximately 0.25 acre of land within the construction footprint of the new levee and floodwall that could potentially include vernal pool habitat. This 0.25 acre could be adversely affected from ground disturbing activities, operation of construction	River parkway. • If possible, elderberry shrubs would be transplanted during their dormant season (approximately November, after they have lost their leaves, through the first two weeks in February). If transplantation occurs during the growing season, increased mitigation ratios will apply. • Any areas that receive transplanted elderberry shrubs and elderberry cuttings will be protected in perpetuity. • The USACE will work to develop off-site compensation areas prior to or concurrent with any take of valley elderberry longhorn beetle habitat. • Management of these lands will include all measures specified in USFWS's conservation guidelines (1999a) related to weed and litter control, fencing, and the placement of signs. • Monitoring will occur for ten consecutive years or for seven non-consecutive years over a 15-year period. Annual monitoring reports will be submitted to USFWS. Vernal Pool Fairy Shrimp and Tadpole Shrimp The following measures from the 2004 Biological Opinion from the Magpie Creek Flood Control Project would be implemented to avoid and minimize impacts to potential vernal pools in the vicinity of the Magpie Creek construction area: • Preservation component: For every acre of

O: To be implemented as an operational practice after construction is complete

<u>Vernal Pool Fairy Shrimp and Vernal Pool Tadpole Shrimp continued</u> <u>Giant Garter Snake (GGS)</u> The East Side Tributaries (NEMDC, Magpie Creek, and Arcade Creek) have some potential GGS habitat, however, the creeks in this area lack year round water and connectivity to rice fields, a major component of GGS habitat. The closest rice fields are about 5 miles away up the NEMDC and above a pump plant	water drains; (vii) fire protection activities not required to protect existing structures at the project site; and (viii) use of pesticides or other toxic chemicals. The proposed project will result in 0.25 acre of indirect effects to vernal pools/swales of potentially suitable vernal pool shrimp and vernal pool tadpole shrimp habitat. The applicant has identified and agreed to purchase 0.5 vernal pool preservation credits at a Service-approved conservation bank or Service-approved fund. Credits will be purchased prior to the effect on any vernal pool habitat. The agreed upon conservation responsibilities of the applicant are as follows: • Prior to any earth-moving activities at the proposed project site, the applicant shall purchase at least 0.5 vernal pool preservation credits within a Service-approved ecosystem preservation bank or fund account. <u>Giant Garter Snake</u> The following measures will be implemented to minimize effects on giant garter snake habitat that occurs within 200 feet of any construction activity. These measures are based on USFWS guidelines for restoration and standard avoidance measures included as appendices in USFWS (1997).			

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

located on the NEMDC just above Dry/Robla Creek. Additionally, Arcade Creek and NEMDC both have segments that include large cover vegetation that would make them undesirable for GGS.	• Unless approved otherwise by USFWS, construction will be initiated only during the giant garter snakes' active period (May 1 to October 1, when they are able to move away from disturbance). • Construction personnel will participate in USFWS-approved worker environmental awareness program. • A giant garter snake survey would be conducted 24 hours prior to construction in potential habitat. Should there be any interruption in work for greater than two weeks, a biologist would survey the project area again no later than 24 hours prior to the restart of work. • Giant garter snakes encountered during construction activities will be allowed to move away from construction activities on their own. • Movement of heavy equipment to and from the construction site will be restricted to established roadways. Stockpiling of construction materials will be restricted to designated staging areas, which will be located more than 200 feet away from giant garter snake aquatic habitat.

O: To be implemented as an operational practice after construction is complete

GGS continued	• Giant garter snake habitat within 200 feet of construction activities will be designated as an environmentally sensitive area and delineated with signs or fencing. This area will be avoided by all construction personnel. • Habitat temporarily affected for more than three or more seasons will be restored and twice as much habitat will be created. • The USACE has estimated that approximately 15 acres of aquatic habitat (drainage ditches and irrigation canals) and 30 acres of associated upland habitat would be permanently affected due to the widening of the Sacramento Weir and Bypass. Habitat permanently affected in the Sacramento Bypass will be compensated for through the purchase of 135 acres of credits at a USFWS-approved conservation bank. Due to the spatial and temporal loss of habitat, and the lack of permanent on-site replacement, the ecological value associated with doing all mitigation at an off-site location was reduced to an overall 70% habitat value. This reduction is offset by the increase of mitigation credits at ratios specified by USFWS in the Biological Opinion included as Appendix J.

O: To be implemented as an operational practice after construction is complete

<u>GGS continued</u> <u>Western Yellow-Billed Cuckoo</u> The project area is unlikely to support western yellow-billed cuckoo nesting habitat due to the narrow riparian corridors along the waterways, with the exception of the American River Parkway. However, migrant individuals are likely to pass through the area in transit to breeding sites along the Sacramento River north of Colusa. Potential long-term effects to the cuckoo could result from the loss of 65 acres of riparian habitat in the footprint of the rock trench sites within the American River Parkway. For the American River, impacts to trees would be the width of the launchable rock trenches (currently proposed at approximately 40-feet wide) for a total of approximately 65 acres. Additionally, approximately 110 acres of riparian habitat would be impacted along the Sacramento River. <u>Swainson's Hawks</u>	• One year of monitoring will be conducted for the 80.5 acres that are temporarily affected. • The USACE will purchase credits at a conservation bank prior to any permanent disturbance of giant garter snake habitat. <u>Western Yellow-Billed Cuckoo, Swainson's Hawk, White-Tailed Kite, and Purple Martin</u> The following BMPs will be implemented: • Before ground disturbance, all construction personnel would participate in a CDFW-approved worker environmental awareness program. A qualified biologist would inform all construction personnel about the life history of Swainson's hawk and the importance of nest sites and foraging habitat. • A breeding season survey for nesting birds would be conducted for all trees and shrubs that would be removed or disturbed which are located within 500 feet (0.5 mile for Swainson's hawk) of construction activities, including grading. Swainson's hawk surveys would be completed during at least two of the following survey periods: January 1 to March 20, March 20 to April 5, April 5 to April 20, and June 10 to July 30 with no fewer than three surveys completed in at least two survey periods, and with at least one of these surveys occurring immediately prior to project initiation (Swainson's Hawk Technical Advisory Committee 2000). Other			

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

Approximately 175 acres of riparian habitat used by Swainson's hawk for roosting and nesting could be affected by project construction. Additionally, approximately 2.5 acres of non-native grassland intermixed with barren ground would be removed or disturbed as a result of construction activities at levees. Much of this habitat is within the Sacramento urban area, where Swainson's hawks nest and forage along the American and Sacramento Rivers. <u>White-Tailed Kite</u> Construction activities conducted during nesting season, including vegetation removal, could significantly impact the white-tailed kite by removing nesting habitat or causing the species to abandon any active nests. In addition, the short-term loss of approximately 175 acres of riparian habitat on the landside of the levees that could support white-tailed kite nesting and foraging could result in significant effects to this species. <u>Purple Martin</u> Construction activities conducted during	migratory bird nest surveys could be conducted concurrent with Swainson's hawk surveys with at least one survey to be conducted no more than 48 hours from the initiation of project activities to confirm the absence of nesting. If the biologist determines that the area surveyed does not contain any active nests, construction activities, including removal or pruning of trees and shrubs, could commence without any further mitigation. • If active nests are found, the USACE would maintain a 0.25-mile buffer between construction activities and the active nest(s). In addition, a qualified biologist would be present on-site during construction activities to ensure the buffer distance is adequate and the birds are not showing any signs of stress. If signs of stress that could cause nest abandonment are noted, construction activities would cease until a qualified biologist determines that fledglings have left an active nest. • Tree and shrub removal, and other areas scheduled for vegetation clearing, grading, or other construction activities would not be conducted during the nesting season (generally February 15 through August 31 depending on the species and environmental conditions for any given year) . These construction activities could affect them by removing or causing abandonment of active nests of migratory birds protected under the Migratory Bird Treaty Act and California Fish

nesting season, including vegetation removal, could significantly impact the purple martin by removing nesting habitat or causing the species to abandon any active nests. In addition, the short-term loss of approximately 175 acres of riparian habitat on the landside of the levees that could support purple martin nesting and foraging could result in significant effects to this species. <u>Burrowing Owl</u> Construction activities, including grading and clearing activities within or adjacent to potential burrowing owl habitat, could result in nesting failure, death of nestlings, or loss of eggs. In addition, the short-term loss of approximately 175 acres of riparian habitat on the landside of the levees that could support burrowing owl nesting and foraging could result in significant effects to this species.	and Game Code To reduce the impact on migratory birds habitat the USACE will seek a vegetation variance on lower half of the waterside levee slope. Additionally, where bank protection work is performed the sites would be planted with vegetation and trees that over time will provide habitat for the hawks. To compensate for the removal of 134 acres of riparian habitat supporting Western yellow-billed cuckoos, Swainson's hawks, and other migratory birds approximately 268 acres of replacement habitat will be created, as discussed in the vegetation and wildlife section. <u>Burrowing Owl</u> • Prior to the implementation of construction, surveys will be conducted to determine the presence of burrows or signs of burrowing owl presence within the project area. The survey would be conducted in accordance with Appendix D of CDFW's Staff Report on Burrowing Owl Mitigation (CDFG 2012). • If burrowing owls are observed, coordination would occur with CDFW to determine the appropriate actions to take or any additional avoidance and minimization measures that may need to occur. These measures may include creating a protective buffer around occupied burrows during the duration of the breeding season and biological monitoring of

Listed Fish Species: Winter-Run Chinook Salmon Implementation of the bank erosion protection measures may result in adverse effects to juvenile and smolt winter-run Chinook salmon, their critical habitat, and EFH. Construction activities that increase noise, turbidity, and suspended sediment may disrupt feeding or temporarily displace fish from preferred habitat. Physical damage or harassment to listed fish species would be low during the months of construction. Winter-run Chinook salmon are expected to show a long term positive response to project actions in the Sacramento River and American River SAM analysis reaches over the lifetime of the project when both IWM and planted benches are incorporated into the with-project conditions. Chinook	active burrows to ensure that construction activities do not result in adverse effects on nesting burrowing owls. • If potential burrows are present, all on-site construction personnel shall be instructed regarded the potential presence of burrowing owls, identification of these owls and their habitat, and the importance of minimizing impacts on burrowing owls and their habitat. Listed Fish Species USACE proposes to develop a green sturgeon habitat, mitigation, and monitoring plan (HMMP) (Appendix I) to address the long-term negative impacts to green sturgeon designated critical habitat with the specific elements that are described below: • The green sturgeon HMMP shall be developed in coordination with the Interagency Ecological Program (IEP) green sturgeon project work team and consulted on with NMFS prior to the construction of any work within the designated critical habitat of sDPS green sturgeon related to the ARCF GRR. • The USACE shall either refine the SAM or develop an alternative green sturgeon survival and growth response model based on using and updating the existing Hydrologic Engineering Center Ecosystem Function Model (HEC-EFM) that reflects			

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

salmon should exhibit a positive response by year 5 in the winter-spring when most juvenile Chinook salmon are expected in the ARCF GRR project area. Spring-run Chinook Salmon Adult spring-run Chinook salmon migrate up the Sacramento River from March through September although most individuals have entered tributary streams by mid-June and will not be affected by construction activities. Therefore, potential for construction-related ARCF GRR project effects will be similar to that described for winter-run Chinook salmon. Central Valley Fall-/Late Fall–Run Chinook Salmon Fall-/Late Fall-Run Chinook salmon are expected to show a long term positive response to project actions in the Sacramento River and American River SAM analysis reaches over the lifetime of the project when both IWM and planted benches are incorporated into the with-project conditions. Chinook salmon should exhibit a positive response by year 5 in the winter-spring	green sturgeon's preference for benthic habitat. • The green sturgeon HMMP shall also be developed with measurable objectives for completely offsetting all adverse impacts to all life stages of sDPS green sturgeon (as modeled using refined approaches described above and considering design refinements that occur in the PED phase of project implementation. • The HMMP shall also, restore or compensate for the number of acres of soft bottom benthic substrate for sDPS green sturgeon permanently lost to project construction. This mitigation shall be coordinated with the Interagency Working Group (IWG) or a Bank Protection Working Group (BPWG) and must be carried out within the lower Sacramento River/North Delta in order to offset the adverse modification to designated critical habitat. • Mitigation actions shall be initiated prior to the construction activities affecting sDPS green sturgeon and their critical habitat. • The sDPS green sturgeon HMMP will include measurable performance standards at agreed upon intervals and will be monitored for a period of at least ten years following construction. The following additional conservation measures would be implemented to reduce the adverse effects to listed Chinook, steelhead, delta smelt, and green sturgeon:			

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

when most juvenile Chinook salmon are expected in the ARCF GRR project area. <u>Central Valley Steelhead</u> Steelhead are expected to show a long term positive response to project actions in the Sacramento River and American River SAM analysis reaches over the lifetime of the project. Steelhead should exhibit a positive response by year 4 in the winter-spring when most juvenile steelhead will be migrating and rearing through the project area. <u>Green Sturgeon</u> If larvae or juveniles are present during construction, in-water activities could result in localized displacement and possible injury or mortality to individuals that do not readily move away from the channel or nearshore areas. Project actions associated with bank protection measures may increase sediment, silt, and pollutants, which could adversely affect rearing habitat or reduce food production, such as aquatic invertebrates, for larval and juvenile green sturgeon.	• In-water construction activities (e.g., placement of rock revetment) will be limited to the work window of August 1 through November 30. If the USACE wants to work outside of this window they will consult with USFWS and NMFS. • The USACE will purchase delta smelt credits from a USFWS-approved conservation bank to off-set the loss of 14 acres of shallow water habitat, and 13 acres of spawning habitat. This mitigation is assumed to occur through the purchase of credits at a mitigation bank due to the lack of available real estate in the study area for on-site mitigation. Due to the spatial and temporal loss of habitat, the ecological value associated with doing all mitigation at an off site location was reduced to an overall 70% habitat value. This reduction is offset by the increase of mitigation credits at ratios specified by USFWS and NMFS in the Biological Opinions. The USACE proposes to purchase a total of 72 credits to ensure that impacts to Delta smelt are fully mitigated. • Erosion control measures will be implemented (BMPs), including Storm Water Pollution Prevention Program and Water Pollution Control Program, that minimize soil or sediment from entering the river. BMPs shall be followed, monitored for effectiveness, and maintained throughout construction operations to minimize effects to Federally listed fish and their designated			

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

Due to these adverse effects to juvenile green sturgeon, USACE is proposing to adaptively manage the project in a number of ways in order to minimize impacts to this species. In particular, preconstruction physical modeling is proposed to assist in determining potential methods of implementing the proposed measures to minimize impacts to salmon. Additionally, new habitat modeling is proposed to better define what those impacts may be. Monitoring would be conducted during and post-construction in order to confirm the impacts estimated to result from the project, and to allow for improvement in minimizing impacts for future construction throughout the estimated 10 year construction period. <u>Delta Smelt</u> Potential spawning habitat includes shallow channel edge waters in the Delta and Sacramento River. Construction-related effects include disruption of spawning activities, disturbance or mortality of eggs and newly hatched larvae, and alteration of spawning and incubation habitat. As a result, potential construction-related effects to delta smelt physical habitat would include disruption of spawning activities, disturbance or mortality of	critical habitat. • Screen any water pump intakes, as specified by NMFS and USFWS screening specifications. Water pumps will maintain an approach velocity of 0.2 feet per second or less when working in areas that may support delta smelt. • No grading or altering of the lands within the existing Sacramento Bypass will occur as part of the project. • The USACE shall participate in an existing IWG or work with other agencies to participate in a new BPWG to coordinate stakeholder input into future flood risk reduction actions associated with the ARCF GRR. • The USACE shall coordinate with NMFS during PED as future flood risk reduction actions are designed to ensure conservation measures are incorporated to the extent practicable and feasible and projects are designed to maximize ecological benefits. • The USACE shall include as part of the Project, a Riparian Corridor Improvement Plan with the overall goal of maximizing the ecological function and value of the existing levee system within the Sacramento Metropolitan Area. • The USACE shall develop a HMMP with an overall goal of ensuring the conservation measures achieve a high level of ecological function and value. The HMMP shall include:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

eggs and newly hatched larvae, alteration of spawning and incubation habitat, and loss of shallow water habitat for spawning. Juvenile delta smelt may be subject to disturbance or displacement caused by construction activities that increase noise, turbidity, and suspended sediment. Delta smelt may not be readily able to move away from channel or nearshore areas that are directly affected by construction activities (i.e., placement of rock revetment). Larvae may be disrupted during summer months as they migrate downstream to rear in the Delta. Incidental take of delta smelt may occur from direct mortality or injury during a construction activity, or by the impairment of essential behavior patterns (i.e., feeding, escape from predators). In addition, physiological impairment could be caused by toxic substances (i.e., gasoline, lubricants, oil) entering the water. Construction related effects on delta smelt rearing and migration will be minimized by restricting in-water construction activities on the Sacramento River to a general estimated work window between August 1 and November 30. For the purpose of this study however, during PED, the work window will be adjusted on a site specific basis taking into account presence of juvenile and	▪ Specific goals and objectives and a clear strategy for maintaining all of the project conservation elements for the life of the project. ▪ Measures to be monitored by the USACE for 10 years following construction and shall update their O&M manual to ensure the HMMP is adopted by the local sponsor to ensure the goals and objectives of the conservation measures are met for the life of the project. ▪ Include specific goals and objectives and a clear strategy for achieving full compensation for all project-related impacts to listed fish species. ▪ The USACE shall continue to coordinate with NMFS during all phases of construction, implementation, and monitoring by hosting annual meetings and issuing annual reports throughout the construction period as described in the HMMP. ▪ The USACE shall host an annual meeting and issue annual reports for five years following completion of project construction. • The USACE shall ensure that, for salmon and

Listed Fish Species continued	completion of training. • The USACE shall consider installing IWM along future flood risk reduction projects associated with the ARCF GRR at 40 to 80 percent shoreline coverage at all seasonal water surface elevations in coordination with the IWG or the BPWG. The purpose is to maximize the refugia and rearing habitats for juvenile fish. • The USACE shall protect in place all riparian vegetation on the lower waterside slope of any levee unless removal is specifically approved by NMFS. • The USACE shall develop a Vegetation Variance for all elements of the ARCF GRR that are adjacent to habitat that is occupied by federally listed salmon, steelhead and green sturgeon, including the main channel of the Sacramento River (as proposed) and the Sacramento Bypass. • The USACE shall ensure the widening of the Sacramento Bypass is designed and constructed to minimize stranding of fish in the depressions wound within the bypass though grading or construction of drainage channels. • The USACE, in coordination with the local sponsor, shall ensure that the Habitat Mitigation and Monitoring Plan for the Sacramento Bypass includes baseline post-project monitoring of fish stranding. The monitoring plan shall be developed in coordination with NMFS.			

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

Listed Fish Species continued	• The USACE shall update the O&M manual to incorporate without detrimental effects to flood operations 1) operations of the Sacramento Weir include a plan that allows for ramp down flows in a manner that minimize juvenile fish stranding in the Sacramento Bypass, (2) integration of Sacramento Weir operations with the Yolo Bypass. • During Preconstruction Engineering and Design, the USACE, in coordination with the local sponsor, shall coordinate with NMFS to provide an operation of the Sacramento Weir to allow without detrimental effects to flood management operations, for controlled ramp down rates of water into the Sacramento Bypass following peak flows. • Additional concerns about mitigation, not considered in a SAM analysis, will be included in the MMP (See Appendix I) along the Sacramento Bypass reach, including potential adult and juvenile passage issues, loss of shoreline riparian vs. gain in floodplain, and contradicting ESA species habitat requirements. These issues will be considered and appropriate actions will be taken where possible in coordination with other agencies. For SRA habitat impacted by construction, the following measures would be implemented to compensate for the habitat loss:			

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

Listed Fish Species continued	• Compensation timing refers to the time between the initiation of construction at a particular site and the attainment of the habitat benefits to protected species from designated compensation sites. In general, compensation time is the time required for on-site plantings to provide significant amounts of shade or structural complexity from instream woody material recruitment. Significant long-term benefits have often been considered as appropriate to offset small short-term losses in habitat for listed species in the past, as long as the overall action contributes to recovery of the listed species. The authority to compensate prior to or concurrent with project construction is given under WRDA 1986 (33 United States Code [USC] §§ 2201–2330). • For identified designated critical habitat, where feasible all efforts will be made to compensate for impacts where they have occurred or in close proximity. Impacts to designated critical habitat, SRA and instream components combined and the compensation value of replacement habitat will be based on the interagency approved Standard Assessment Model (SAM) used throughout the Sacramento River basin and Delta flood control system. • Compensation sites would be monitored and vegetation would be replaced as necessary based on performance standards in the Mitigation Monitoring Plan (MMP) as detailed in Appendix I of the EIS/EIR.

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

                  Special Status Plant Species: Sanford's Arrowhead Sanford's arrowhead is known to occur in the Arcade Creek and NEMDC channels. Levee work in these reaches is proposed to remain within the levee prism and would not encroach into the channel; therefore, construction activities in this reach would not result in direct impacts to Sanford's arrowhead. Indirect effects to Sanford's arrowhead could occur during construction due to dust disturbance. However, the mitigation measures proposed in the air quality section.	Depending on the species of interest (e.g., delta smelt), the severity of the short-term habitat losses due to bank erosion repair actions may not be compensated by long-term gains, whereas longer lived species (e.g., steelhead, Chinook) have longer periods for compensation to be provided. The following compensation time periods (based loosely on life expectancy) should be considered as guidelines for compensation: • Green sturgeon, 15 years; • Chinook salmon, 5 years; • Central Valley steelhead, 4 years; and • Delta smelt, 1 year. Special Status Plant Species The following avoidance and minimization measures would be implemented during construction to reduce potentially significant effects to Sanford's arrowhead and wooly rose-mallow to less than significant. Additionally, the avoidance and minimization measures to address invasive plant species in Section 3.6.6 would also reduce potential impacts to special status plant species. • Preconstruction surveys would be conducted by a qualified botanist in suitable habitat to determine the presence of any special status plants. Surveys would be conducted at an			

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

Wooly Rose-Mallow There are no known populations of wooly rose-mallow in the study area, however since they are known to occur on levee banks with riprap, they could potentially be adversely impacted by construction of the proposed project. Clearing and grubbing of the levee slopes, and some long-term O&M activities, such as mowing of the levees, could also remove populations of this plant, if present. **Alternative 2** A maximum of 15 acres of aquatic GGS habitat (drainage ditches and farm canals) would be permanently removed and incorporated into the Sacramento Bypass. To the east of the bypass, there are approximately 8 acres of riparian vegetation growing along the Sacramento River that would be removed to construct the new weir structure. The 8-acre area contains both the Old River Road and Union Pacific Railroad (UPRR) tracks. Prior to construction this area would be surveyed to determine if any avian species have nested in the area. If there is nesting Swainson's Hawks	appropriate time of year during which the species are likely to be detected, which would likely be during the blooming period. • If special status plant species are found during preconstruction surveys, the habitat would be marked or fenced as an avoidance area during construction. A buffer of 25 feet would be established. If a buffer of 25 feet is not possible, the next maximum possible distance would be fenced off as a buffer. • If special status plant species cannot be avoided during construction, the USACE would coordinate with the resource agencies to determine additional appropriate mitigation measures. **Alternative 2** Same mitigation ratios and BMPs as alternative 1			

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

construction would be delayed until fledglings have left the nest. Fish in the area would likely disperse with the disturbance to the water. The expansion of the Sacramento Weir and Bypass could have a positive beneficial effect on special status wildlife such as the giant garter snake and its riparian vegetation once construction is complete and lands are converted from farming activities to open space where wetlands and shrubby riparian habitat is expected to naturally regenerate with the increased area that is periodically inundated from flooding during the rainy season. Widening of the weir and bypass will increase the entrainment and stranding exposure and rates of juvenile green sturgeon. When the weir is overtopping and water is flowing down the bypass, adult fish are attracted to the flow and follow it upstream in an attempt to reach their holding and spawning habitat. Widening the weir and bypass would increase the amount of water going over the weir and increase the attraction rate of sturgeon, salmon and steelhead.				
3.9 Cultural Resources The effects of the erosion repair on the	Avoidance of adverse effects to historic properties is the preferred treatment approach.	D, P, C	USACE	CVFPB

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

American River, levee geometry measures, cutoff walls, and bank protection on the Sacramento River and construction of cutoff walls, correction of the levee geometry, installation of floodwalls, installation of a conduit or box culvert, raising of floodwalls and existing levees, construction of maintenance roads, installation of floodgates, and creation of a detention basin on the East Side Tributaries would likely result in an adverse effect to some historic properties located within the APE for the project. The records and literature search conducted for the project identified 69 known prehistoric and historic resources in the total project APE. For the purposes of this EIS/EIR, the USACE assumes that all of these resources would be impacted by the levee improvement alternatives. Site specific determinations of effect and impact cannot be made at this time because each site within the APE would need to be field checked, the previous recordation (included site boundary, associated features, integrity) verified, and each site would need to be considered for eligibility for listing in the NRHP. The process for field checking cultural resources sites and making determinations of eligibility for listing in	The USACE will consider design refinements of project elements in order to avoid historic properties and project effects that may be adverse. Avoidance of adverse effects to historic properties is a significant part of the USACE planning and cultural resources management for this project as described in the PA. The PA includes a framework to identify historic properties, evaluate NRHP eligibility, and assess effects. Although specific effects to historic properties cannot be determined at this time, effects could include, but is not limited to, the following: temporary visual and auditory effects caused by construction activities, temporary lack of access and/or privacy to areas traditionally used by Native American tribes for ceremonies, temporary and/or permanent effects to the viewshed of TCPs caused by construction activities and associated noise levels, vibration or compression effects caused by construction activities to historic properties located in proximity to construction activities, alteration or destruction of built environment resources, removal of trees and vegetation that may represent plants significant to Native American tribes and used in ceremonies or for other traditional uses.			Verify that the PA is in place

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

the NRHP are outlined in the Programmatic Agreement (PA). Specific individual determinations of effect for historic properties that may be affected by Alternative 1 would be completed under the stipulations of the PA, which includes a framework to identify historic properties, evaluate NRHP eligibility, and assess effects. Although specific effects to historic properties cannot be determined at this time, effects could include, but is not limited to, the following: temporary visual and auditory effects caused by construction activities, temporary lack of access and/or privacy to areas traditionally used by Native American tribes for ceremonies, temporary and/or permanent effects to the viewshed of TCPs caused by construction activities and associated noise levels, vibration or compression effects caused by construction activities to historic properties located in proximity to construction activities, alteration or destruction of built environment resources, removal of trees and vegetation that may represent plants significant to Native American tribes and used in ceremonies or for other traditional uses. Alternative 2				

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

Effects to cultural resources from the construction of levee improvements under Alternative 2 would be consistent with those analyzed for Alternative 1 with the addition of effects resulting from construction of the Sacramento Weir and Bypass widening. Effects to historic properties may also result from disturbance of cultural resources sites due to remediation of a hazardous, toxic, and radiological waste (HTRW) site near the existing north levee, which may consist of historic era debris.				
3.10 Transportation and Circulation Increased traffic on public roadways.	Preparation of a traffic control and Road Management Plan BMP's below will be implemented to reduce the impacts from traffic: • The contractor would be required to prepare a Traffic Control and Road Maintenance Plan. A traffic control plan describes the methods of traffic control to be used during construction. All on-street construction traffic would be required to comply with the local jurisdiction's standard construction specifications. The plan would reduce the effects of construction on the roadway system in the project area throughout the construction period.	P, C	USACE	CVFPB Verify traffic plan

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	• Construction contractors would follow the standard construction specifications of affected jurisdictions and obtain the appropriate encroachment permits, if required. The conditions of the encroachment permit would be incorporated into the construction contract and would be enforced by the agency that issues the encroachment permit. • If rock or other materials are transported by barge on the Sacramento River, appropriate water safety measures would be utilized in order to reduce impacts to recreational boaters. • The construction contractor would provide adequate parking for construction trucks, equipment, and construction workers within the designated staging areas throughout the construction period. If inadequate space for parking is available at a given work site, the construction contractor would provide an off-site staging area and, as needed, coordinate the daily transport of construction vehicles, equipment, and personnel to and from the work site. • Proposed lane closures would be coordinated with the appropriate jurisdiction and would be minimized to the extent possible during the morning and evening peak traffic periods. Standard construction specifications also typically limit lane closures during commuting hours. Lane closures will be kept as short as possible. If a road must be closed, detour routes and/or			Verify barge usage when appropriate.

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

	temporary roads would be made to accommodate traffic flows. Detour signs would be provided to direct traffic through detours. Advance notice signs of upcoming construction activities would be posted at least 1 week in advance so that motorists are able to avoid traveling through the study area during these times. Within the Parkway, detours would be used to allow for continued use by bicycle commuters. • Safe pedestrian and bicyclist access would be maintained in or around the construction areas at all times. Construction areas would be secured as required by the applicable jurisdiction to prevent pedestrians and bicyclists from entering the work site, and all stationary equipment would be located as far away as possible from areas where bicyclists and pedestrians are present. • The construction contractor would notify and consult with emergency service providers to maintain emergency access and facilitate the passage of emergency vehicles on city streets. • Emergency vehicle access would be made available at all times. Coordination with local emergency responders by the contractor to inform them of the construction activities would be required by the contractor. • The construction contractor would assess damage to roadways used during construction and will repair all potholes, fractures, or other damages.			Verify pedestrian and cyclist detour routes.

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

	• Trains utilizing the Yolo Shortline Railroad would be detoured to a different rail line during construction. If an alternative rail line is not available, railroad services would be continued by transporting goods on public roads using cargo trucks during the extent of closures required by the construction and realignment of the railroad on the new portion of the Sacramento Weir.			
<u>3.11 Air Quality</u> Emissions of criteria pollutants from construction equipment, haul trucks, and barges. Construction of the proposed project would result in short-term dust emissions from grading and earth moving activities at the project construction sites and the soil borrow sites. Construction of the proposed project would result in short-term diesel particulate emissions from onsite heavy duty equipment and on-road haul trucks. DPM, which is classified as a carcinogenic TAC by CARB, is the primary pollutant of concern with regard to indirect health risks to sensitive receptors. Nearby land uses, especially those residences and schools located downwind of the project sites could be exposed to DPM generated during construction activities, indirectly	SMAQMD's Basic Construction Emissions Control Practices The SMAQMD requires construction projects to implement basic construction emission control practices to control fugitive dust and diesel exhaust emissions (SMAQMD 2015). The USACE would comply with the following control measures for the project: • Water all exposed surfaces twice daily. Exposed surfaces include but are not limited to: soil piles, graded areas, unpaved parking areas, staging areas, and access roads. • Cover or maintain at least two feet of free board space on haul trucks transporting soil, sand, or other loose material on the site. Any haul trucks that would travel along freeways or major roadways should be covered. • Use wet power vacuum street sweepers to remove any visible trackout mud or dirt from adjacent public roads at least once a day.	D, P, C	USACE	CVFPB Verify that emissions control guidance is followed. Verify that dust control measures are in place.

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

resulting in potential adverse health effects. The proposed project would not result in any major sources of odor, and the project would not involve operation of any of the common types of facilities that are known to produce odors (e.g., landfill, wastewater treatment facility). Odors associated with diesel exhaust emissions from the use of onsite construction equipment may be noticeable from time to time by adjacent receptors. Alternative 2 Construction of the Sacramento Weir and Bypass Widening would occur in YSAQMD and include clearing of trees and vegetation, construction of the new levee, construction of the new portion of the weir, construction of new sections of road and railroad on the top of the new portion of the weir and the new levee, relocation of utilities, degrading and excavating the existing levee, and delivery and installation of rip-rap on the waterside slope of the new levee. Materials for the construction of the new levee would be reused from the existing levee to the greatest extent possible.	Use of dry power sweeping is prohibited. • Complete all roadways, driveways, sidewalks, or parking lots to be paved as soon as possible. In addition, building pads should be laid as soon as possible after grading unless seeding or soil binders are used. • Minimize idling time either by shutting equipment off when not in use or reducing the time of idling to 5 minutes [required by California Code of Regulations, Title 13, sections 2449(d)(3) and 2485]. Provide clear signage that posts this requirement for workers at the site entrances. • Maintain all construction equipment in proper working condition according to the manufacturer’s specifications. The equipment must be checked by a certified mechanic and determined to be running in proper condition before it is operated. <u>Fugitive Dust Emission Mitigation Measures</u> Fugitive dust mitigation would require the use of adequate measures during each construction activity and would include frequent water applications or application of soil additives, control of vehicle access, and vehicle speed restrictions. The USACE would implement the dust mitigation measures listed below. • Water exposed soil with adequate frequency for continued moist soil. • Suspend excavation, grading, and/or			

Notes:

D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination

O: To be implemented as an operational practice after construction is complete

	demolition activity when wind speeds exceed 20 mph. • Install wind breaks (e.g., plant trees, solid fencing) on windward side(s) of construction areas. • Plant vegetative ground cover (fast-germinating native grass seed) in disturbed areas as soon as possible. • Install wheel washers for all exiting trucks, or wash off all trucks and equipment leaving the site. • Treat site accesses to a distance of 100 feet from the paved road with a 6 to 12-inch layer of wood chips, mulch, or gravel to reduce generation of road dust and road dust carryout onto public roads. • Post a publicly visible sign with the telephone number and person to contact at the lead agency regarding dust complaints. This person shall respond and take corrective action within 48 hours. The phone number of the District shall also be visible to ensure compliance. The project will ensure that emissions from all off-road diesel powered equipment used on the project site do not exceed 40 percent opacity for more than three minutes in any one hour. The use of USEPA adopted Tier 3 and Tier 4 standards for newly-built marine engines in 2008 would be encouraged under the barge delivery scenario. The Tier 3 standards reflect the			

Notes:

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	application of technologies to reduce engine PM and NO_X emission rates. Tier 4 standards reflect application of high-efficiency catalytic after-treatment technology enabled by the availability of ultra-low sulfur diesel. These Tier 4 standards would be phased in over time for marine engines beginning in 2014 (USEPA 2008). The USACE will require that all off-road construction equipment comply with SMAQMD's enhanced exhaust controls (20% NO_X and 45% PM reductions). The USACE will encourage their construction contractors to use off-road diesel-powered construction equipment greater than 50 horsepower that meets Tier-4 off-road emission standards under the barge delivery scenario. As of July 1, 2015, the mitigation fee rate is $18,030 per ton of emissions. The Contractor would provide payment of the appropriate SMAQMD-required NO_x mitigation fee to offset the project's NO_x emissions when they exceed SMAQMD's threshold of 85 lbs/day. The USACE would consult with the BAAQMD in good faith to enter into a mitigation contract for an emission reduction incentive program (e.g., TFCA or Carl Moyer Program). The current emissions limit is $17,080/weighted ton of criteria pollutants (NO_X + ROG + [20*PM]). An administrative fee of 5 percent would be paid to the BAAQMD to implement the program. The contractor would conduct daily and annual emissions monitoring to ensure onsite emissions

O: To be implemented as an operational practice after construction is complete

	reductions are achieved and no additional mitigation payments are required. The contractor would be required to ensure the requirement is met. This requirement would be incorporated into the construction contracts as part of the project's specifications.			
3.12 Climate Change Increased GHG emissions from construction equipment, haul trucks, and barges.	The following measures may be considered to lower GHG emissions during the construction: • Encourage and provide carpools, shuttle vans, transit passes and/or secure bicycle parking for construction worker commutes. • Recycle at least 75% of construction waste and demolition debris. • Purchase at least 20% of the building materials and imported soil from sources within 100 miles of the project site. • Minimize idling time either by shutting equipment off when not in use or reducing the time of idling to no more than 3 minutes (5 minute limit is required by the state airborne toxics control measure [Title 13, sections 2449(d)(3) and 2485 of the California Code of Regulations]). Provide clear signage that posts this requirement for workers at the entrances to the site. • Maintain all construction equipment in proper working condition according to manufacturer's specifications. The equipment must be checked by a certified	P, C	USACE	CVFPB Verify mitigation measures are being implemented.

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	mechanic and determined to be running in proper condition before it is operated. • Use equipment with new technologies (repowered engines, electric drive trains). • Perform on-site material hauling with trucks equipped with on-road engines (if determined to be less emissive than the off-road engines). • Use a CARB approved low carbon fuel for construction equipment. (NO_x emissions from the use of low carbon fuel must be reviewed and increases mitigated.) • Purchase GHG offset for program-wide GHG emissions (direct emissions plus indirect emissions from on-road haul trucks plus commute vehicles) exceeding SMAQMD or CEQ's significance thresholds applicable at the time of construction. Carbon offset credits shall be purchased from programs that have been approved by SMAQMD.			
3.13 Noise Construction activities in the American River Parkway, Sacramento River, East Side Tributaries and Sacramento Bypass could result in temporary significant impacts on residents, recreationists, and other noise sensitive groups.	During construction, noise-reduction measures would be employed in order to ensure that construction noise complies with local ordinances. Prior to the start of construction, a noise control plan would be prepared that would identify feasible measures to reduce construction noise, when necessary. The following measures would apply to construction activities within 500 feet of a sensitive receptor, including, but not limited to, residences. These measures may include, but are not limited to, the following:	P, C	USACE	CVFPB Verify noise control plan. Verify that residents have been notified in writing. Verify signage.

P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting

C: To be implemented during project construction

M: To be implemented as ongoing maintenance after construction is complete

O: To be implemented as an operational practice after construction is complete

	• Provide written notice to residents within 1,000 feet of the construction zone, advising them of the estimated construction schedule. This written notice would be provided within one week to one month of the start of construction at that location. • Display notices with information including, but not limited to, contractor contact telephone number(s) and proposed construction dates and times in a conspicuous manner, such as on construction site fences. • Schedule the loudest and most intrusive construction activities during daytime hours (7:00 a.m. to 7:00 p.m.), when feasible. • Require that construction equipment be equipped with factory-installed muffling devices, and that all equipment be operated and maintained in good working order to minimize noise generation. • Locate stationary noise-generating equipment as far as practicable from sensitive receptors. • Limit unnecessary engine idling (i.e., more than 5 minutes) as required by State air quality regulations. • Employ equipment that is specifically designed for low noise emission levels, when feasible. • Employ equipment that is powered by electric or natural gas engines, as opposed to those powered by gasoline fuel or diesel, when feasible.			

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	• If the construction zone is within 500 feet of a sensitive receptor, place temporary barriers between stationary noise equipment and noise sensitive receptors to block noise transmission, when feasible, or take advantage of existing barrier features, such as existing terrain or structures, when feasible. • If the construction zone is within 500 feet of a sensitive receptor, prohibit use of backup alarms and provide an alternate warning system, such as a flagman or radar-based alarm that is compliant with State and Federal worker safety regulations. • Locate construction staging areas as far as practicable from sensitive receptors. • Design haul routes to avoid sensitive receptors, to the extent practical. • If there are any occupied buildings with plaster or wallboard construction within 40 feet of construction equipment, a vibration control plan would be prepared prior to construction.			
3.14 Recreation Site-specific designs have not been conducted to determine which erosion protection measure is appropriate along each reach of the Parkway, certain assumptions can be made: • Access to the American River for	The following measures would be implemented to keep the public informed of construction activities to mitigate for effects to bike trail/recreation trail access: • Coordination with recreation user groups would occur prior to and during construction for input into mitigation measures that would reduce affects to the maximum extent practicable.	P,C	USACE	CVFPB Verify that notice is given about recreational impacts prior to closure.

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

the purposes of erosion control construction would require some temporary closures of portions of the recreation trail during construction activities. • Haul trucks would use portions of the recreational trail to bring materials to the construction sites, reducing accessibility to recreationists. • Some areas within the Parkway itself would be construction staging areas. • The presence of construction equipment and haul trucks would reduce the quality of recreational experiences. Alternative 2 Possible closure of the Sacramento Bypass during portions of the hunting season.	• Advance notice would be given to recreation users informing them of anticipated activities and detours to reduce the effects. To ensure public safety: • Flaggers, • Signs restricting access would be posted before and during construction • Detour routes would be clearly marked, • Fences would be erected in order to prevent access to the project area. • In areas where recreational traffic intersects with construction vehicles, traffic control will be utilized in order to maintain public safety. • The public will have continued access to the Parkway and recreation facilities during construction, but bike and running trail users would likely be required to detour onto public roads or alternative trails. • If any access point needs to be closed during construction, notices will be posted providing alternative access routes.			Verify use of flaggers. Verify use of detour signs.
3.15 Visual Resources Vegetation loss and construction activities would disrupt the existing visual conditions in the Parkway and along the Sacramento River.	American River Trees will be planted along the outer portion of the rock trench where there is sufficient space. Sacramento River Trees will remain on the waterside lower third of the levee. The understory vegetation will be removed in order to place rock.	P, C, M	USACE	CVFPB Verify replanting of trees. Verify that lower one third of trees are not removed.

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	Sacramento Weir and Bypass Native trees and shrubs within the existing bypass would be avoided during construction as much as practicable to help minimize visual impacts. The loss of ground cover in the existing and expanded bypass would be mitigated by planting native grasses and forbs in areas disturbed by construction, except within the footprint of the extended weir. The loss of existing native trees and shrubs within the existing bypass, along the bank of the Sacramento River, and within small portions of the agricultural lands directly impacted by the project would be mitigated by planting native trees and shrubs within certain portions of the expanded bypass.			Verify tree mitigation.
3.16 Public Utilities and Services Temporary disruptions to utility services are possible particularly during relocation of utilities that penetrate the levee.	Consultation with all known service providers would take place prior to construction to identify specific infrastructure locations and appropriate protection measures. Consultation would continue during construction to ensure avoidance/protection of facilities to minimize service disruptions. Where feasible, replacement utility structures would be completed before demolition of existing facilities. Mitigation measures would include the following: • Notification of any potential interruptions in service shall be provided to the appropriate agencies and affected landowners. • Before the start of construction, utility locations shall be verified through field surveys and the use of the Underground Service Alert services. Any buried utility lines	D, P, C	USACE	CVFPB Verify coordination with appropriate service providers.

Notes:
D: To be implemented or included as part of project design. Includes pre-project permitting and agency coordination
P: To be implemented prior to construction being initiated prior (pre-construction), but not part of project design or permitting
C: To be implemented during project construction
M: To be implemented as ongoing maintenance after construction is complete
O: To be implemented as an operational practice after construction is complete

	shall be clearly marked in the area of construction on the construction specifications in advance of any earthmoving activities. • Before the start of construction, a response plan shall be prepared to address potential accidental damage to a utility line. The plan shall identify chain of command rules for notification of authorities and appropriate actions and responsibilities to ensure the safety of the public and workers. Worker education training in response to such situations shall be conducted by the contractor. The response plan shall be implemented by the project proponent(s) and its contractors during construction activities. • Utility relocations shall be staged to minimize interruptions in service. • Construction activities will be coordinated with first responders within the study area so plans can be implemented to avoid response delays due to construction detours.			
3.17 Hazardous, Toxic, and Radiological Wastes No effect from construction activities. HTRW sites encountered would be removed and properly disposed of prior to construction.	Borrow material would be tested prior to use to ensure that no contaminated soils are used in project.	P, C	USACE	CVFPB Verify that import soils are tested prior to use in project.
3.18 Socioeconomics, Population, and Environmental Justice Disruption to residents alongside	Mitigation for relocation of people and their homes would be compensated under the Federal Relocation Act.	D,P	USACE	CVFPB Verify that Federal

CENTRAL VALLEY
FLOOD MANAGEMENT
PLANNING PROGRAM

FloodSAFE
CALIFORNIA

July 2012

2012 Central Valley Flood Protection Plan

Consolidated Final Program Environmental Impact Report

PUBLIC SAFETY ENVIRONMENTAL STEWARDSHIP ECONOMIC STABILITY

Cover Photo: Feather River near Yuba City (December 1955)

The flood of December 1955 was one of the most widespread and destructive floods in Central Valley history. A levee break on the Feather River at Yuba City (shown) flooded about 6,000 homes and resulted in 38 confirmed deaths and millions in property damage.

Executive Summary

Table of Contents

Figures

Tables

EXECUTIVE SUMMARY

ES.1 Introduction

Historically, the Central Valley has experienced some of California's largest and most damaging floods. Floods have had devastating effects on life and property in the Central Valley and on the state's economic prosperity. The most recent large floods in the Central Valley, in 1986 and 1997, together caused more than $1 billion in damage (USACE 1997).

Despite the current flood management system in the Central Valley, the valley's residual flood risk remains among the highest in the country. Currently, even small flood events with a 5 percent chance of occurring annually can stress parts of the flood system.

"Residual Flood Risk" Residual risk is the portion of flood risk that remains after a flood control structure or works has been built. Risk remains because the likelihood exists for the design of the completed works to be surpassed by a flood event of sufficient intensity, resulting in structural failure.

Public awareness of flood risks was heightened by the catastrophic flooding in New Orleans associated with Hurricane Katrina in August 2005. That event caused estimated property damage exceeding $80 billion and took more than 1,800 lives.

In 2006, the California Department of Water Resources (DWR) launched FloodSAFE California, a multifaceted initiative to improve integrated flood management. In November of that year, the state's voters passed two important bond measures, Propositions 84 and 1E, which included approximately $3.3 billion in funds that could be used to support flood risk reduction efforts in the Central Valley.

In 2007, the California Legislature passed a package of several related flood bills, which included a requirement to prepare a Central Valley Flood Protection Plan (CVFPP). Additional requirements for the CVFPP were added in the Central Valley Flood Protection Act of 2008 (Senate Bill 5). That same year, DWR embarked on the Central Valley Flood Management Planning Program, which addresses flood management planning activities in the Central Valley that require leadership and participation by the State of California (State). The Central Valley Flood Management Planning Program is one of several programs managed by DWR under FloodSAFE California.

The CVFPP is a critical document intended to guide California's participation (and to influence federal and local participation) in managing flood risk along the Sacramento River and San Joaquin River systems. The CVFPP proposes a State Systemwide Investment Approach (SSIA) as its proposed program for sustainable, integrated flood management in areas currently protected by facilities of the State Plan of Flood Control (SPFC). The CVFPP is a program-level, rather than project-level, document. It articulates programs to further flood risk reduction in the Central Valley and suggests a range of potential future projects that could help meet that goal. The CVFPP will be updated every 5 years, with each update providing the opportunity to update existing policies, programs, and suggested projects, or to add new ones.

After extensive outreach to stakeholders and the public, a draft of the CVFPP was released to the public on December 30, 2011. Pursuant to Section 9612 of the California Water Code, the Central Valley Flood Protection Board (Board) shall adopt the CVFPP by July 1, 2012.

This CVFPP program environmental impact report (PEIR) was developed to inform DWR, which is developing the CVFPP, and the Board, which will consider adopting the CVFPP, about potential program-level environmental effects and mitigation measures related to the components of the CVFPP. The PEIR is written so that DWR and the Board will be able to rely on this PEIR for future planning and feasibility studies pertinent to implementation.

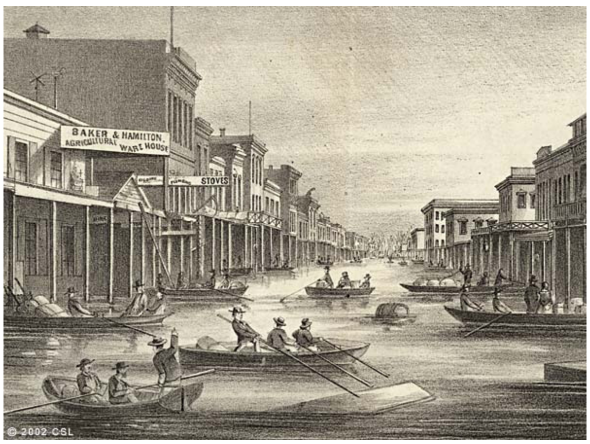
This executive summary provides an overview of the CVFPP PEIR consistent with Section 15123(a) of the California Environmental Quality Act Guidelines (CEQA Guidelines), which states that an EIR "shall contain a brief summary of the proposed action and its consequences." As explained in Section 15123(b), the summary shall identify (1) each significant impact, with proposed mitigation measures and alternatives; (2) areas of controversy known to the lead agency; and (3) issues to be resolved in the EIR.

This draft PEIR (DPEIR) is being circulated for public review. Comments received during the public review will be considered by DWR and the Board, and responses to comments will be included in the final PEIR. Continued public outreach, including public hearings, will be conducted before the final PEIR is completed. See Section ES.9, "Next Steps for the PEIR," below, for additional information.

ES.2 History and Background of Flood Protection in the Central Valley

Before settlement associated with the Gold Rush began, the Central Valley routinely flooded, forming a vast inland sea. Flood management efforts in the Central Valley began toward the middle of the 19th century, when major settlement and land reclamation and cultivation began in California's two largest valleys. The drainage and levee construction originally undertaken by individual farmers shifted in the 1880s to collective efforts and financing by newly authorized levee and reclamation districts in both the Sacramento and San Joaquin valleys. Because individual public levee and reclamation districts were formed by landowners, flood control efforts were fundamentally local and uncoordinated. The system proved inadequate, especially for the Sacramento River system.

In lieu of building river levees to make the Sacramento River a single, ever-wider flood channel, a weir and bypass system known as the "Jackson Plan" was conceived and formally adopted by the California Debris Commission in 1911. The Debris Commission was a federal body that had been created to address the effects of the deposition of mining debris on navigation. The bypass system proposed in the Jackson Plan consisted of weirs built to divert portions of the high Sacramento River flows from the river at different points into specially constructed, large-capacity flood channels to reduce flood stages in the river, and thereby to move floodwaters safely to the ocean. In 1911, the State authorized a means of funding the plan by creating a regional assessment district, the Sacramento–San Joaquin Drainage District, and a governing body for it, the State Reclamation Board. (The State Reclamation Board is now known as the Central Valley Flood Protection Board.) The plan, which became known as the Sacramento River Flood Control Project, was completed in 1960 by the U.S. Army Corps of Engineers (USACE).



1862 Flooding in Sacramento

The structures, such as levees and bypasses and other flood structures designed and primarily built by USACE in the watershed of the Sacramento and San Joaquin rivers, are known as the federal flood control facilities for the Central Valley. The levees that are part of federal flood control facilities are known as "project levees," which distinguishes them from levees that are not part of USACE's federal system of levees and other flood facilities in the Central Valley. These project levees are now called facilities of the SPFC. Construction of these facilities contributed to the loss of floodplain habitats and marshes over time.

About 45 percent of the levees in the Sacramento–San Joaquin Delta (Delta) are not project levees. The nonproject levees are maintained by local reclamation districts and are generally eligible for financial assistance from the State through the Delta Levees Subventions Program. The Delta Flood Protection Fund Act of 1988 substantially increased reimbursement opportunities for the local reclamation districts and added environmental mitigation and protection requirements for grant recipients. Multipurpose storage reservoirs on both the San Joaquin and Sacramento rivers that are not part of the federal flood control facilities also protect the valley from flooding.

Today, the Central Valley flood management system includes levees along the major rivers and streams of the valley floor and around the islands of the Delta, a major bypass system for the Sacramento River and its tributaries, several bypass segments along the San Joaquin River, and numerous reservoirs on almost all major rivers and streams draining to the Central Valley.

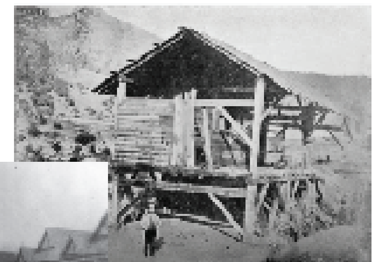
During major flood events, State, federal, and local agencies work together closely to forecast weather and runoff conditions, manage and coordinate flood releases from the reservoir system, patrol and conduct flood fights along the levee and bypass system, and operate the Sacramento Weir, drainage pumps, and other flood control structures.

Figure ES. 2-1 provides a chronology depicting the history of Central Valley flood management.

Figure ES. 2-1. Chronology of Flood Management–Related Actions in the Central Valley

Significant Flood Management Events

1849	California Gold Rush
1850	Federal Arkansas Act giving away "California Swamplands"
1850	California Statehood
1861	State Flood Control Act
	Reclamation District Act
1883	Federal Anti-Debris Act ends hydraulic mining
1911	State Reclamation Board Created
1933	Central Valley Project Authorized
2003	Paterno Decision
2005	DWR Flood Warning White Paper
2006	Propositions 1E and 84 Passed
2007	Flood Management Reform Legislation

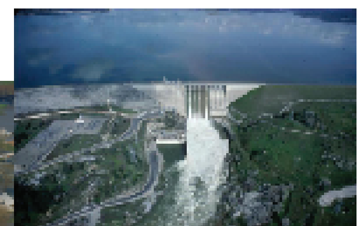


1849 Sutter's Mill

1907 Flood in West Sacramento

Sacramento River Basin

1850	First Levee built in Sacramento
1917	Sacramento River Flood Control Project Authorized
1944	Shasta Dam was built
1955	Folsom Dam was built
1967	Oroville Dam was built
1969	New Bullards Bar Dam was built



1955 Folsom Dam was built

1997 Flood in Central Valley

San Joaquin River Basin

1944	Lower San Joaquin River and Tributaries Project
1949	Friant Dam Completed
1955	Bypasses and Levees authorized on the San Joaquin River above Merced River
1963	Camanche Dam was built
1964	New Hogan Dam was built
1967	New Exchequer Dam was built
1971	New Don Pedro Dam was built
1978	New Melones Dam was built
1993	Redbank/Fancher Creeks Project

1949 Friant Dam was built

1955 Flood in Visalia

1978 New Melones Dam was built

Over the past 150 years, funding levels for flood risk reduction activities in the Central Valley have varied considerably. Those funds have come from a variety of sources at the federal, State, and local levels, and have fluctuated as a result of factors such as competing priorities, changing levels of concern about flood risks, and economic concerns.

Geotechnical improvements to levees in the Pocket Area of Sacramento

As indicated above, in November 2006 California's voters passed two important general obligation bond measures, Propositions 84 and 1E, which provided approximately $3.3 billion for flood risk reduction activities in the Central Valley. Since the passage of Propositions 84 and 1E, DWR has been working with USACE and local agencies to improve flood management within areas protected by SPFC facilities. In the 5 years since these funds first became available, approximately $1.5 billion has been spent on a range of activities, the most important of which are summarized below.

A top priority was to repair portions of the levee system at critical risk of failure as a result of erosion or other factors. Since 2006, more than 120 critical levee erosion sites have been repaired, and a variety of conditions have been repaired at more than 220 other sites. DWR also undertook several major maintenance projects, including the removal of 3 million cubic yards of sediment from the bypasses, and rehabilitated seven flood system structures. More than 240,000 tons of rock have been stockpiled in the Delta to allow faster response to flood emergencies.

DWR also began extensive evaluations of the status of the flood system to provide the necessary factual support for flood planning efforts. To date, the department has collected topographic data and light detection and ranging (or LiDAR) data for 9,000 square miles along the flood system, conducted engineering and geotechnical evaluations for urban and nonurban levees, and developed a comprehensive medium-scale GIS data set of riparian vegetation for the Central Valley. DWR has also added about 50 flood forecasting and water supply gauging sites, developed the Flood Emergency Response Information System, developed a forecast coordinated operations program for the Yuba-Feather River system, and updated hydrology information for Central Valley streams. Major products of these efforts include the *State Plan of Flood Control Descriptive Document* in 2009 and the *Flood Control System Status Report in 2011.*

These activities have included an increased understanding of and emphasis on habitat and other environmental factors in the management of the flood risk reduction system. DWR has assessed major fish passage barriers within the flood protection system, evaluated potential floodplain restoration opportunity areas, catalogued and summarized conservation objectives from 30 conservation planning efforts, prepared a public draft Conservation Framework, and implemented 12 Flood Corridor Program projects in the Central Valley, providing habitat conservation on more than 4,000 acres and agricultural land conservation on more than 500 acres. There has been enhanced environmental integration of emergency response activities, including an emergency response exercise conducted with environmental resource and regulatory agencies.

DWR has also taken steps to improve its planning processes and coordinate those activities with other maintaining and regulatory agencies. In 2005, DWR initiated and coordinated the Interagency Flood Management Collaborative Program, a working group of federal, State, and local officials from key regulatory and maintaining agencies that meets monthly to address issues of mutual concern. The department is developing several integrated flood management and environmental initiatives in partnership with resource and regulatory agencies, including a Corridor Management Strategy and the Small Erosion Repair Program (SERP). SERP will streamline the permitting process for small erosion repair projects, so that the repairs can be undertaken before further erosion occurs and requires a larger, more costly repair with greater impacts on the riverine habitat and the environment. SERP will help avoid duplicative permitting efforts that can delay repairs and divert resources from more pressing environmental issues. DWR is taking the lead in developing a statewide policy framework and draft approach for Regional Advance Mitigation Planning.

To assist local planning entities, DWR has prepared voluntary flood-related Building Standards Code specifications (California Code of Regulations, Title 24, Parts 2 and 2.5) for single-family residential occupancy groups R-3 and R-3.1, for adoption by cities and counties. It has initiated mapping of the Central Valley Levee Flood Protection Zones and sent flood-risk notification letters to 300,000 affected property owners in the Central Valley in 2010 and 2011.

During the past 5 years, the State, USACE, and local agencies have also been working on major projects to upgrade the State-federal flood management system in the Central Valley. These projects include the American River Common Features Project, to provide improved flood protection to areas protected by levees along the following reaches: the American River downstream from Folsom Dam; the Sacramento River downstream from the American River; and the Natomas Basin. Other important projects include the following:

- Folsom Dam Modifications (as part of the Folsom Dam Joint Federal Project)
- Marysville Ring Levee Improvement Project
- Geotechnical improvements to levees in the Pocket Area of Sacramento
- Mid-Valley Area Levee Reconstruction Project
- South Sacramento Streams Project
- Three Rivers Levee Improvement Authority, Feather River Levee Improvement Project, Yuba County
- Three Rivers Levee Improvement Authority, Upper Yuba River Levee Improvement Project, Yuba County
- Levee District 1, Star Bend levee setback on the Feather River, Sutter County
- Reclamation District 2103, Bear River North Levee Rehabilitation Project, Sutter, Yuba, and Placer counties
- Reclamation District 17, 100-Year Seepage Area Project, San Joaquin River, San Joaquin County
- West Sacramento Area Flood Control Agency, Capital Outlay, City of West Sacramento
- West Sacramento Project, repair of two Yolo Bypass east bank levee slips in West Sacramento (under way)
- West Sacramento Setback Levee and Slurry Wall at River Mile 57.2 right bank constructed under the Sacramento River Bank Protection Project (under way)

These activities during the past 5 years have provided DWR with enhanced interagency relationships, improved planning and project implementation capabilities, and the information necessary to support the preparation of the CVFPP and this PEIR.

ES.3 Description of the Proposed Program

The SSIA is DWR's proposed program for sustainable, integrated flood management in areas currently protected by SPFC facilities. The SSIA described in the CVFPP is the proposed program evaluated in this PEIR. The proposed program includes broad management actions to improve the flood management system, policies, and institutions at a systemwide level, while enabling flexibility in addressing changing needs and funding scenarios. The program also integrates environmental conservation strategies and actions to improve the flood management system's long-term sustainability while improving ecosystem function. At the same time, it provides additional options for addressing compliance with environmental regulations related to long-term operation and maintenance.

"Sustainable" A project is considered sustainable when it is socially, environmentally, and financially feasible for an enduring period. For the CVFPP, a sustainable project will also have the flexibility to adapt to potential future changes such as climate change.

Flooding poses different threats to the people, critical infrastructure, and properties within the valley's varied land uses. Consequently, the proposed program provides different approaches to improve flood protection depending on the land use and its requirements. These land use areas have been delineated in the proposed program as urban areas, small communities, and rural-agricultural areas. Briefly, the key features of the proposed program can be characterized as follows:

- Improve levees that protect existing urban and urbanizing areas (populations greater than 10,000) to achieve an urban level of flood protection (protection against a 0.5-percent-chance event), at minimum.
- Reduce flood risk in existing small communities (with populations less than 10,000), where feasible.
- Improve rural-agricultural area levees included in the proposed program to reflect the lower levels of development within these floodplains.
- Improve the overall ability of the SPFC to convey large flood events through modified (or potentially new) weirs, bypass systems, hydraulic structures, and easements.
- Improve ecological conditions on a systemwide basis, using integrated policies, programs, and projects.

Implementation of the proposed program would depend on both the collaboration and independent decision-making of federal, State, and local cooperating and regulatory agencies. Follow-on feasibility studies and CVFPP updates are expected to refine the proposed program and assess the potential costs, benefits, and impacts of site-specific implementation projects.

ES.3.1 Near-Term and Long-Term Management Activities

For purposes of the PEIR, proposed activities that are part of the proposed program are divided into near-term management activities (NTMAs) and long-term management activities (LTMAs). NTMAs are those management activities that would be initiated during the first 5 years after approval of the CVFPP, with many having the potential to be completed during that initial period; LTMAs are management activities that would be initiated at any time beyond 5 years after adoption of the CVFPP. In the PEIR, NTMAs are evaluated at a greater level of specificity than LTMAs for the following reasons:

- NTMAs are better defined and less conceptual than LTMAs, are more likely to be implemented in the short term (within the first 5 years after approval of the CVFPP), and are generally less complex.
- NTMAs have more secure funding sources than LTMAs.
- Environmental impacts of NTMAs can generally be evaluated more accurately than impacts of LTMAs.

NTMAs can consist of any of the following types of activities:

- Conveyance management activities:
    - » Sediment removal
    - » Levee repair, reconstruction, and/or improvements:
        - ◦ Raise levees by adding earthen material or constructing floodwalls.
        - ◦ Strengthen levees to enhance their integrity by improving the properties and geometry of embankment soils to resist slope and seepage failures.
        - ◦ Address seepage with seepage berms, stability berms, impermeable barrier curtains (slurry cutoff walls) in the levee and/or its foundation, and relief wells and toe drains.
        - ◦ Armor the landside of the levees to improve levee resiliency during overtopping episodes.
        - ◦ Construct small setback levees (generally less than 0.75 mile long).

San Joaquin River at Friant Dam

- Storage management activities:
  - » Change reservoir operations criteria to alter the timing, magnitude, and frequency of flood releases to downstream channels, providing reductions in river flood stage and volume.
    - ◦ Coordinate operation among different reservoirs to increase objective releases from reservoirs.
    - ◦ More effectively use weather forecasting in conjunction with reservoir operations.
    - ◦ Use weather forecasting to support more flexibility in short-term allocations of available storage space between water supply and flood control.
- Other management activities:
  - » Implement a vegetation management strategy.
  - » Purchase floodplain easements and/or other interests in land.
  - » Integrate conservation strategies to improve the overall sustainability of and ecosystem benefits provided by the flood management system.
  - » Refine flood emergency response, improve flood system operations and maintenance, continue floodplain risk management, conduct feasibility studies, and implement flood risk reduction projects in coordination and partnership with local and federal agencies.

All other types of CVFPP activities fall within the LTMA category and consist of the following types of activities:

Construction of a new levee in the Natomas Basin of Sacramento

- Widening floodways (through setback levees and/or purchase of easements)
- Constructing or modifying weirs and bypasses
- Improving and remediating levees
- Constructing new levees
- Removing some facilities from the SPFC
- Using long-term forecasts to improve operation of existing reservoirs
- Achieving protection of urban areas from a flood event with 0.5 percent risk of occurrence in any given year
- Achieving protection of small communities from a flood event with 1 percent risk of occurrence in any given year
- Protecting rural-agricultural area against floods by facilitating inspection and flood fighting, improving levee performance, and purchasing agricultural easements
- Changing policies, guidance, standards, and institutional structures
- Implementing additional and ongoing conservation elements

However, because NTMA-type activities would continue to be implemented in the CVFPP study area into the longer term time frame of the LTMAs (e.g., remediation of existing levees), LTMAs include a continuation of activities described as part of the NTMAs.

ES.3.2 Purpose of the Proposed Program

The broad purpose of the proposed program is to respond to the California Legislature's direction in Senate Bill 5 to develop and implement a sustainable, integrated flood management plan for the Central Valley. In taking an integrated flood management approach, the proposed program recognizes that flood management is connected to water resource management; land use planning; environmental stewardship; and long-term economic, environmental, and social sustainability. Integrated flood management also recognizes the importance of evaluating opportunities and potential impacts from a systemwide perspective, and the importance of coordinating across geographic and agency boundaries to effectively manage flood flows in any given hydrologic unit.

Much of the legacy flood management system is characterized by aging infrastructure, making it increasingly difficult for DWR and local maintaining agencies to carry out maintenance programs. The proposed program reflects the State's vision for modernizing the SPFC to address current challenges and future trends and to meet the proposed program's objectives.

The proposed program would be implemented over time by the State, federal agencies, and local agencies such as reclamation districts, municipal and regional flood management agencies, and cities and counties.

The CVFPP is part of a long-term planning effort and is to be updated every 5 years. As the first edition of the plan, the 2012 CVFPP does the following:

- Describes a broadly supported vision for improving flood management in the Central Valley
- Recommends initial management actions to reduce flood risks
- Identifies potential modifications to the flood management system for further study
- Describes a framework for implementing future improvements
- Describes a framework for developing a conservation strategy for the flood system

ES.3.3 Objectives of the Proposed Program

Eight program objectives were formulated to guide development of this PEIR and a reasonable range of alternatives to be evaluated in the PEIR. Five of these objectives address the underlying goals of the proposed program: a primary objective to improve flood risk management and supporting objectives to improve operations and maintenance, promote ecosystem functions, improve institutional support, and promote multi-benefit projects. The remaining three program objectives guiding this PEIR reflect direction provided in the authorizing legislation: maximize flood-risk reduction benefits within the practical constraints of available funds; adopt the CVFPP by July 1, 2012; and promote as feasible the multiple objectives provided in Section 9616 of the California Water Code. These objectives are presented below.

Primary Objective

- **Improve Flood Risk Management**—Reduce the chance of flooding and damages, once flooding occurs, and improve public safety, preparedness, and emergency response through the following:
  - Identifying, recommending, and implementing structural and nonstructural projects and actions that benefit lands currently receiving protection from facilities of the SPFC.
  - Formulating standards, criteria, and guidelines to facilitate implementation of structural and nonstructural actions for protecting urban areas and other lands of the Sacramento and San Joaquin river basins and the Delta.

Supporting Objectives

- **Improve Operations and Maintenance**—Reduce systemwide maintenance and repair requirements by modifying the flood management systems in ways that are compatible with natural processes, and adjust, coordinate, and streamline regulatory and institutional standards, funding, and practices for operations and maintenance, including significant repairs.
- **Promote Ecosystem Functions**—Integrate the recovery and restoration of key physical processes, self-sustaining ecological functions, native habitats, and species into flood management system improvements.
- **Improve Institutional Support**—Develop stable institutional structures, coordination protocols, and financial frameworks that enable effective and adaptive integrated flood management (designs, operations and maintenance, permitting, preparedness, response, recovery, and land use and development planning).
- **Promote Multi-Benefit Projects**—Describe flood management projects and actions that also contribute to broader integrated water management objectives identified through other programs.

Statutory Objectives

- **Maximize Flood Risk Reduction Benefits within the Practical Constraints of Available Funds**—Ensure that technically feasible and cost-effective solutions are implemented to maximize the flood risk reduction benefits given the practical limitations of available funding, and provide a feasible, comprehensive, and long-term financing plan for implementing the plan.
- **Adopt the CVFPP by July 1, 2012**—Complete all steps necessary to develop and adopt the CVFPP by July 1, 2012, or such other date as may be provided by the Legislature.
- **Meet Multiple Objectives Established in Section 9616 of the California Water Code, Wherever Feasible:**
    - » *Reduce the risk to human life, health, and safety from flooding, including protection of public safety infrastructure.*
    - » *Expand the capacity of the flood management system in the Sacramento–San Joaquin Valley to either reduce flood flows or convey floodwaters away from urban areas.*
    - » *Link the flood protection system with the water supply system.*
    - » *Reduce flood risks in currently nonurbanized areas.*
    - » *Increase the engagement of local agencies willing to participate in improving flood protection, ensuring a better connection between State flood protection decisions and local land use decisions.*

- *Improve flood protection for urban areas to the urban level of flood protection.*
- *Promote natural dynamic hydrologic and geomorphic processes.*
- *Reduce damage from flooding.*
- *Increase and improve the quantity, diversity, and connectivity of riparian, wetland, floodplain, and shaded riverine aquatic habitats, including the agricultural and ecological values of these lands.*
- *Minimize flood management system operations and maintenance requirements.*
- *Promote the recovery and stability of native species' populations and overall biotic community diversity.*
- *Identify opportunities and incentives for expanding or increasing use of floodway corridors.*
- *Provide a feasible, comprehensive, and long-term financing plan for implementing the CVFPP.*
- *Identify opportunities for reservoir reoperation in conjunction with groundwater flood storage.*

ES.4 Study Area

The proposed program would be implemented primarily in the Systemwide Planning Area (SPA) of the CVFPP. The SPA includes lands that receive protection from the SPFC and are subject to flooding under the current facilities and operation of the Sacramento–San Joaquin River Flood Management System, including lands with facilities that provide substantial systemwide benefits or that protect urban areas in the Sacramento–San Joaquin Valley. The SPA also includes lands with facilities that are not part of the SPFC, including federal and local reservoirs that have allocated flood storage.

Effects of management actions implemented in the SPA may extend beyond this area. Therefore, the PEIR study area is divided into three regions for describing the environmental setting and potential environmental effects of implementing the CVFPP. These areas are described below and illustrated in Figure ES. 4-1.

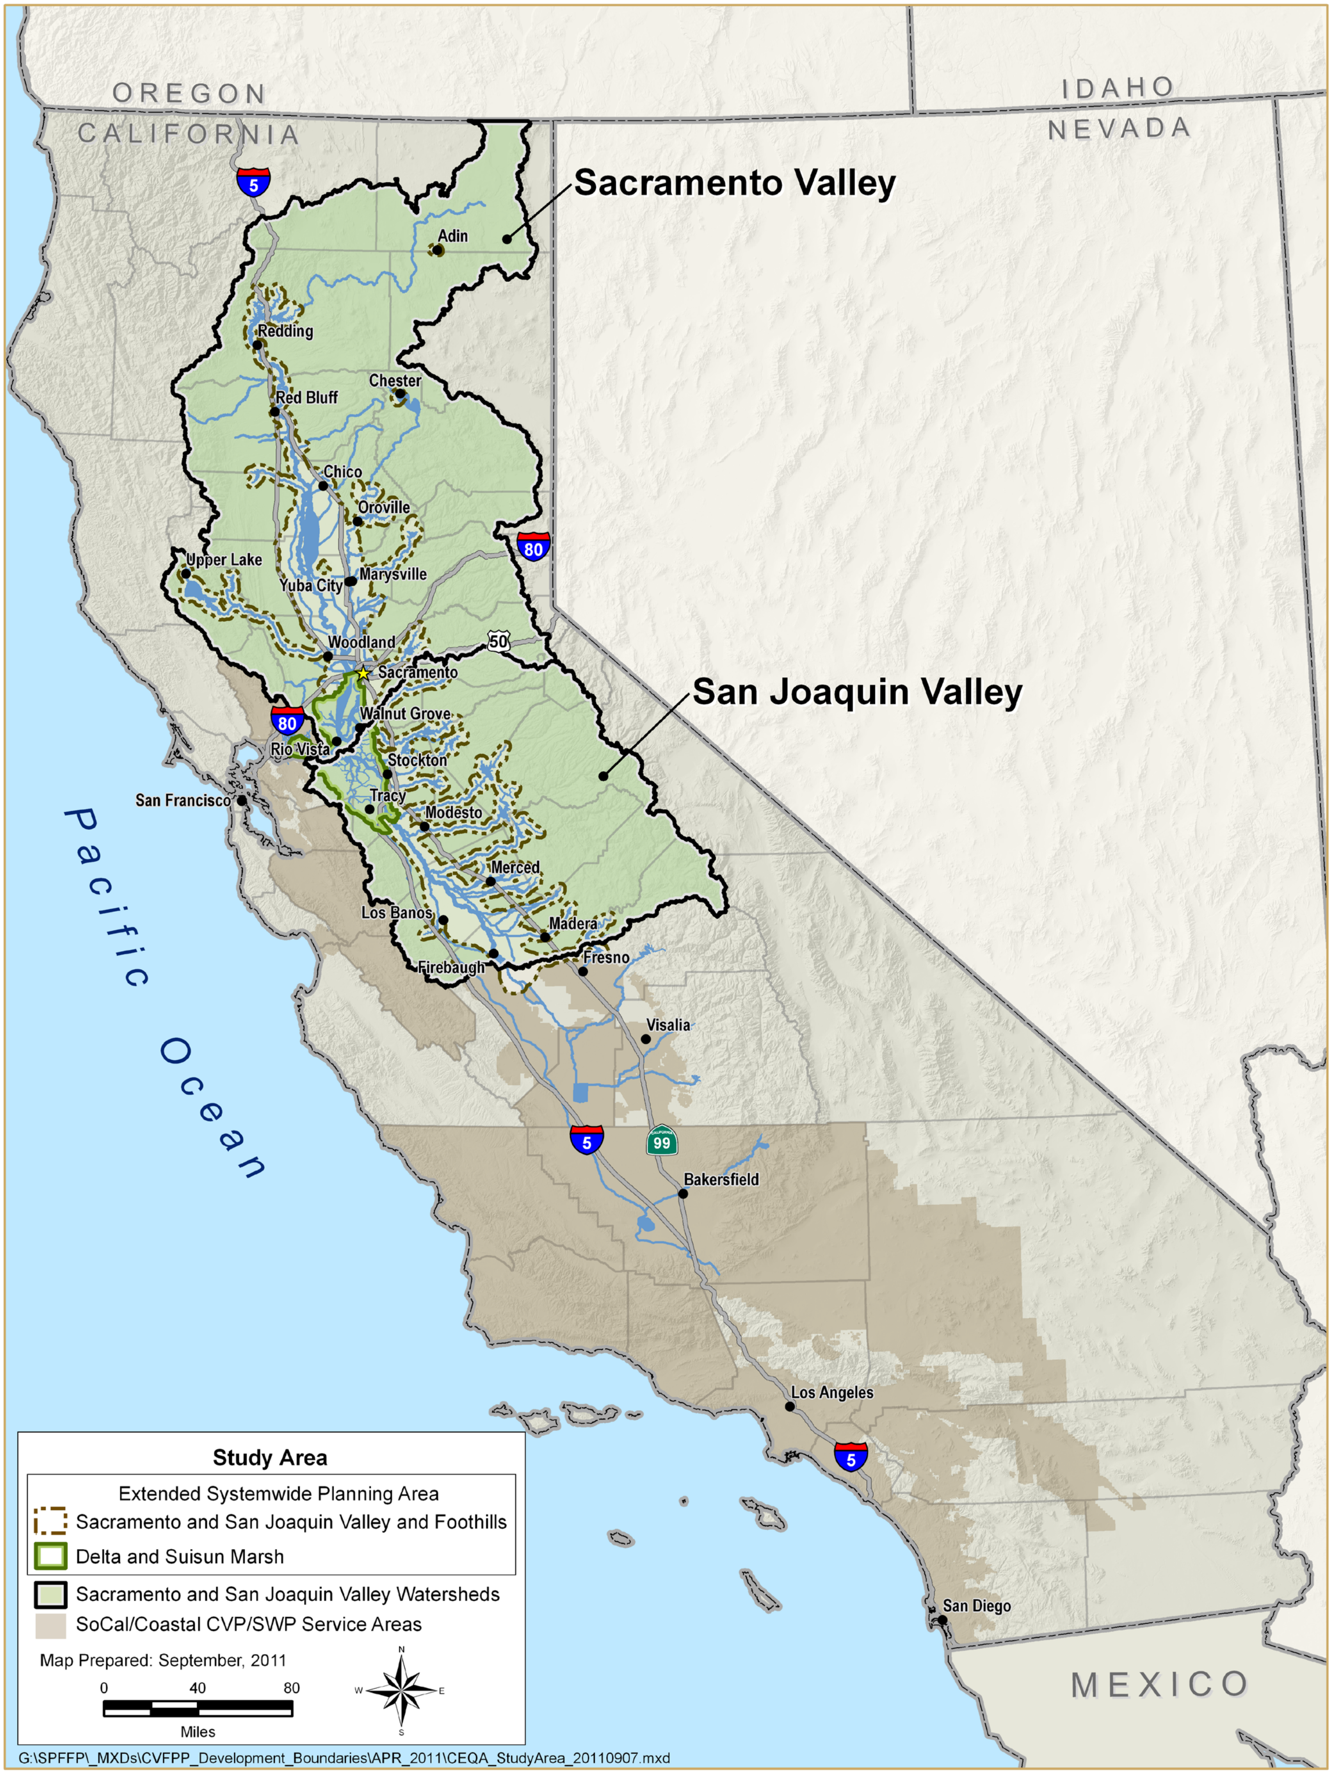


Figure ES. 4-1. PEIR Study Area

ES.4.1 Systemwide Planning Area Plus 2-Mile Buffer and Suisun Extension (Extended Systemwide Planning Area)

The Extended SPA includes a 2-mile-wide buffer around the SPA to provide the environmental context for direct and indirect impacts on areas adjacent to the SPA. Because of topographical and land use considerations, the buffer is 1 mile wide in urban areas and does not extend beyond the adjacent ridgeline along foothill waterways. The buffer is wider than 2 miles in the Suisun Marsh area so that the Extended SPA encompasses the hydrologically influenced areas. The Extended SPA is divided into two subregions:

- **Sacramento and San Joaquin Valley and Foothills**—This area consists of the Sacramento and San Joaquin valleys and the surrounding foothills along several major waterways. Most of the management actions would be implemented in this area.
- **Delta and Suisun Marsh**—This area encompasses the Delta and portions of Suisun Marsh where upstream management actions may affect water flows or quality. At Suisun Marsh, the boundary is at the west end of Montezuma Slough.

ES.4.2 Sacramento and San Joaquin Valley Watersheds

The Sacramento and San Joaquin Valley watersheds are the portions of the watershed upstream from the Extended SPA that may be affected by the management actions employed in these watersheds. These watersheds are discussed in less detail in this PEIR than the Extended SPA.

ES.4.3 SoCal/Coastal CVP/SWP Service Areas

The Southern California and coastal service areas of the Central Valley Project (CVP) and State Water Project (SWP) (referred to in this document as the "SoCal/coastal CVP/SWP service areas") consist of those portions of the CVP/SWP service areas that are not in the Extended SPA. These CVP/SWP service areas are located primarily in Southern California and the Central Coast areas and include CVP/SWP service areas in the Tulare Lake Basin. There are only limited mechanisms by which the SSIA might affect the environment in the SoCal/coastal CVP/SWP service areas, and these areas are discussed in less detail in this PEIR than are the Extended SPA and the Sacramento and San Joaquin Valley watersheds.

ES.5 Areas of Known Controversy and Issues To Be Resolved

Overcoming challenges to improving flood management in the Central Valley will require diligent collaboration, effective partnerships, and public outreach and participation. The CVFPP reflects the State's effort to take a balanced approach to achieving the objectives established in the Central Valley Flood Protection Act of 2008 and the primary and supporting goals defined in the initial phase of CVFPP formulation. Various areas of controversy and challenges associated with implementation of the CVFPP have been identified and are described briefly below.

- **Determining the appropriate level of public investment in flood protection.** Although $3.3 billion of funds were provided by Propositions 84 and 1E, substantial additional funds will be required to implement the proposed program. The State has a fundamental interest in promoting the safety of its people, sustainable economic growth, and a healthy ecosystem; however, all levels of government share the responsibility for managing flood risks. The allocation of finite public resources raises questions related to the level at which the State should invest in flood management and related activities, the degree to which such investments can and should maximize local and federal cost-sharing, and the extent to which State investments should accommodate local objectives. The amount of State funding available and the timing of the funding are also uncertain. Ultimately, although DWR has recommended a level of public investment reflected in the proposed program, the California Legislature and voters will make the final decisions regarding the amounts of State funds to be invested. Federal appropriations and local financial inputs will also be needed.
- **Relative level of expenditures in urban versus rural/agricultural areas.** Controversy exists regarding the focus and/or geographic distribution of flood management project expenditures within the program area. For example, if expenditures were to be allocated solely based on maximizing public safety, then a larger proportion of funding would be allocated to urban areas with concentrated populations. Similarly, if funding were to be allocated to multi-purpose projects that serve multiple needs (e.g., local flood protection, regional system improvements, ecosystem enhancement), then a wider variety of projects in geographically diverse areas would receive funding. Generally, local interests support investments in their local facilities. DWR, however, is required to take a broader statewide perspective and make difficult decisions to resolve these often-competing interests.
- **Financial responsibility for public investments.** Opinions differ regarding the financial responsibility for improving and maintaining the flood management system in the Central Valley. The "beneficiary pays" approach (i.e., only those with property in the specific flood protected area pay for system improvements) can be challenging, particu-

larly when the beneficiaries' capacity to fund improvements is limited. Debate continues regarding the responsibility of the State as a whole (including taxpayers residing outside the Central Valley) to contribute to improved flood management, when local areas primarily benefit from improved flood protection, which in turn supports the State and regional economy and infrastructure.

- **Requirements imposed on local planning entities by the 2007 California flood risk management legislation.** The 2007 flood legislation states that after the adoption of the CVFPP, local agencies within the Sacramento–San Joaquin Valley must amend their general plans and zoning ordinances, and must make certain findings related to the appropriate level of flood protection (200-year protection in urban and urbanizing areas and 100-year protection in nonurbanized areas) before making certain land use decisions. To make these findings, cities and counties will need information on floodplain extent (floodplain mapping) and frequency, which may not be readily available in all areas. Concern also has been raised about the financial burden placed on local cities and counties by these legislative requirements and the feasibility of the legislative timetable.
- **Issues raised by proposals to develop in floodplains.** There is controversy about the extent to which the State should discourage new development in floodplains, without infringing on the land use authority of local jurisdictions. Efforts by the State to effectively manage flood risks and associated liabilities in areas protected by the SPFC, especially in deep floodplains, may influence land uses and subsequently affect landowners, local governments, and developers.
- **Serving multiple benefits with flood system improvements.** Allocating investments to serve the State's interest in public safety while also accommodating other interests and needs, such as ecosystem sustainability and habitat enhancement, are not without challenges and controversy. Continued coordination with all affected stakeholders and agencies is necessary to implement flood management improvements that will serve multiple interests and achieve a balanced use of public funds, while meeting legislative requirements.
- **The appropriate level of vegetation management on levees.** In the wake of Hurricane Katrina, USACE has revisited its nationwide policies regarding vegetation management. USACE currently requires that all woody vegetation be removed from levees in the absence of a USACE-issued variance, if maintaining agencies such as DWR wish to retain eligibility for federal emergency repair funding under Public Law 84-99. This policy is memorialized in USACE's Engineering Technical Letter 1110-2-571 (ETL), *Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures,* adopted April 10, 2009. (All references to the "ETL" in this chapter are specifically to ETL 1110-2-571.)

DWR does not believe that the science supports USACE's underlying assumption that all woody vegetation increases risks to public safety. In fact, in most circumstances, vegetation helps protect levees from erosion and other risk factors, while also providing important habitat values. Moreover, DWR has estimated that strict compliance with USACE's policy in the Central Valley could cost in excess of $10 billion, and would result in massive and likely unmitigable habitat losses. As a result, DWR has proposed a vegetation management strategy (VMS) that would retain all vegetation on the waterside slope of levees up to a line 20 feet below the levee crown (other than vegetation presenting a demonstrable risk, which would be removed); the VMS would limit vegetation management elsewhere to measures necessary for visibility and access. To further accommodate USACE's new policy, however, DWR is also proposing a life-cycle management (LCM) component of the VMS that would limit the recruitment of replacement trees on the upper waterside slope, crown, and landside of levees, which over time would reduce the amount of woody vegetation in those areas. Resource management agencies and environmental interests have expressed concerns about this LCM component.

- **Coordination with other collaborative processes and local planning efforts.** Multiple ongoing planning efforts in the Central Valley (e.g., the CALFED Bay-Delta Program, Bay Delta Conservation Plan, habitat conservation plans/natural communities conservation plans) overlap with the CVFPP in both geography and scope. Challenges exist when balancing the needs of these many efforts where jurisdictions and project timing overlap, and where the actions of one program may preclude (or limit) the actions of another.
- **Differing policies and guidance from permitting and implementing agencies.** Several agencies inform or oversee project permitting and implementation: DWR, the Board, USACE, local maintaining agencies, the California Department of Fish and Game, cities and counties, the State Water Resources Control Board, the regional water quality control boards, and the U.S. Fish and Wildlife Service and National Marine Fisheries Service. Each agency has its own requirements, guidance, and role in project implementation, and there are challenges associated with meeting the requirements of State and federal laws under the jurisdiction of these agencies.

ES.6 Alternatives to the Proposed Program

Development of the CVFPP involved formulating and evaluating substantially different preliminary alternatives to address CVFPP goals. The preliminary alternatives were used primarily to explore different potential physical changes to the existing flood management system and to assist in highlighting the need for policy changes or other management actions.

As described below, seven alternatives were considered for analysis in this PEIR:

- No-Project Alternative—Continued Operations Scenario
- No-Project Alternative—No Additional Activities Scenario
- Modified SSIA Alternative
- Achieve SPFC Design Flow Capacity Alternative
- Achieve SPFC Design Flow Capacity with Strict ETL Compliance Alternative
- Protect High-Risk Communities Alternative
- Enhance Flood System Capacity Alternative

ES.6.1 No Project Alternative—Continued Operations Scenario

Under the No-Project Alternative—Continued Operations Scenario, and without a systemwide flood management plan such as the CVFPP, current flood management trends in the Central Valley would likely continue. Projects that are planned or under way and supported by reasonably anticipated funds would commence and/or continue to completion. The Federal Emergency Management Agency would continue to remap the floodplains protected by the SPFC with less than 100-year flood protection. Existing partnerships among the federal government, the State, and local entities to implement flood risk reduction projects would continue. However, this alternative assumes that funding beyond that currently authorized under Propositions 84 and 1E would not be available, substantially constraining the scale of construction and other activities under this alternative. Local agencies' planning obligations that would be triggered by adoption of the CVFPP would not be triggered under this alternative, and system maintenance would still be challenged by the need to complete annual maintenance activities. The VMS, including the LCM component, would be implemented with or without the adoption of the CVFPP.

"100-Year Flood" is a shorthand expression for a flood that has a 1-in-100 chance of being exceeded in any given year. This may also be expressed as the 1-percent-annual-chance-of-exceedence flood, or "1-percent-annual-chance flood" for short. Similarly, a 200-year flood has a 1-in-200 (or 0.5-percent) chance of being exceeded in any given year.

ES.6.2 No-Project Alternative—No Additional Activities Scenario

The No-Project Alternative—No Additional Activities Scenario is similar to the No-Project Alternative—Continued Operations Scenario, except that this scenario does not assume that projects not already under way will be commenced, and further does not assume that funding will be forthcoming for projects other than those already commenced. This scenario also assumes that the component of the VMS reflected in *California's Central Valley Flood System Improvement Framework*, signed on February 27, 2009—vegetation management in the vegetation management zone for purposes of visibility and access—will continue to be implemented by maintaining agencies. However, it assumes that the LCM component—long-term elimination of trees in the vegetation management zone—will not be adopted or applied. Under this scenario, some recruitment of new trees on SPFC levees will incidentally be prevented by maintenance undertaken for purposes of visibility and access, but less thoroughly and at a slower rate than would be the case with LCM, so that some trees likely would remain.

ES.6.3 Modified State Systemwide Investment Approach Alternative

The Modified SSIA Alternative is similar to the proposed program in that it is based on the urban protection provided by the Protect High-Risk Communities Alternative and adds some small-community protection, but with more limited construction activities than for other alternatives. The alternative also includes expanding the Yolo Bypass and widening Fremont Weir, but does not include any of the other bypass expansions and related improvements contained in the proposed program. This alternative presents a less construction-intensive alternative that addresses only the most critical stressors on public safety, operations and maintenance, and ecosystem function, while minimizing potential adverse environmental effects. Work would focus on repairing and improving existing levees in urban areas with only limited work on expanding floodways.

ES.5.4 Achieve SPFC Design Flow Capacity Alternative

The Achieve SPFC Design Flow Capacity Alternative focuses on addressing the condition of existing SPFC levees so that the channels convey their design flows with a high degree of reliability based on current engineering criteria. The system was largely constructed based on geometric criteria using available soil materials without extensive investigation of foundation conditions. The majority of SPFC levees do not meet current engineering criteria. This alternative addresses an element of the authorizing legislation (California Water Code, Section 9614(g)), which requires that DWR evaluate structural projects that could be undertaken to reconstruct SPFC facilities to bring each of the facilities of the SPFC to within its design standard. This alternative involves addressing levee conditions primarily in place, without making major changes to the footprint or operation of those facilities. Levee improvements would be made regardless of the areas they protect or the level of protection they provide. This alternative would provide little opportunity to incorporate benefits beyond flood management.

ES.6.5 Achieve SPFC Design Flow Capacity with Strict ETL Compliance Alternative

The Achieve SPFC Design Flow Capacity with Strict ETL Compliance Alternative is the same as the Achieve SPFC Design Flow Capacity Alternative but presents a different method of addressing the issue of vegetation on levees. The Achieve SPFC Design Flow Capacity with Strict ETL Compliance Alternative involves meeting two goals simultaneously:

1. Improve existing SPFC levees so that they convey their design flow capacities.
2. Ensure the strictest compliance with USACE guidance provided in the ETL.

This alternative assumes that DWR would not use USACE's associated draft policy guidance letter, *Process for Requesting a Variance from Vegetation Standards for Levees and Floodwalls; Additional Findings* (77 *Federal Register* 9637–9650, February 17, 2012). The variance process allows for retention of some woody vegetation on or near levees under certain very specific circumstances.

ES.6.6 Protect High-Risk Communities Alternative

The Protect High-Risk Communities Alternative evaluates improvements to levees to protect life safety and property for high-risk population centers, including urban and small communities. Most levees in rural-agricultural areas would remain in their existing configurations; however, new training levees, ring levees, or floodwalls immediately adjacent to the communities may be constructed. This alternative would provide a minor opportunity to incorporate benefits beyond flood management.

ES.6.7 Enhance Flood System Capacity Alternative

The Enhance Flood System Capacity Alternative involves seeking opportunities to achieve multiple benefits by enhancing the flood system's storage and conveyance capacity, protecting high-risk communities, and fixing levees in place in rural-agricultural areas. This alternative combines the features of other alternatives and provides greater capacity within flood conveyance channels to lower flood stages in most of the system.

ES.6.8 Alternatives Carried Forward for Evaluation

Two alternatives described above—the Achieve SPFC Design Flow Capacity with Strict ETL Compliance and Protect High-Risk Communities alternatives—were considered for further evaluation in the PEIR but were rejected. These alternatives were rejected because they failed to meet most of the basic program objectives, were determined to be infeasible, would not avoid or substantially lessen significant environmental impacts, and/or would be so similar to another alternative that they would not add to expand the range of alternatives evaluated in this PEIR.

The other five alternatives were carried forward for further analysis and evaluation in this PEIR. These alternatives were determined to meet most of the program objectives, were found to be feasible, would avoid or substantially lessen significant environmental impacts, would collectively provide a reasonable range of feasible alternatives to evaluate in this PEIR, and/or were specifically included in the CVFPP planning process by the California Legislature. These alternatives carried forward are the No-Project Alternative—Continued Operations Scenario, No-Project Alternative—No Additional Activities Scenario, Modified SSIA Alternative, Achieve SPFC Design Flow Capacities Alternative, and Enhance Flood System Capacity Alternative. See Section ES.8, "Comparison of Environmental Impacts of the Proposed Program and Alternatives," below.

ES.7 Summary of Environmental Impacts of the Proposed Program

The PEIR impact analysis examines all potentially significant impacts that would occur with implementation of the CVFPP. Impacts and mitigation measures are described for NTMAs and LTMAs.

The impact analysis addresses construction, operations and maintenance, and policy actions for both activity categories. Construction-related, operational, and maintenance-related impacts would result in direct and indirect impacts, while policy actions would result only in indirect impacts.

Potential environmental impacts of the proposed program and associated mitigation measures are summarized in Table ES-1 at the end of this Executive Summary.

ES.8 Comparison of Environmental Impacts of the Proposed Program and Alternatives

This section compares the environmental impacts of each of the five retained alternatives (described above) with the impacts of the proposed program.

The CEQA Guidelines (Section 15126.6(d)) permit evaluation of the alternatives in less detail than for a proposed project. Consistent with Section 15126.6(d) of the CEQA Guidelines, the analysis below generally compares the environmental effects of the alternatives against the effects of the proposed program, focusing on whether the alternative would result in effects greater than, less than, or similar to those identified for the proposed program.

Table ES.8-1 provides a summary comparison of the impact levels of the proposed program, and alternatives when compared to the proposed program. The impact levels listed for the proposed program in Table ES.8-1 reflect the most substantial environmental effects identified for each environmental resource area.

Table ES. 8-1. Comparison of Impact Levels of the Proposed Program and the Alternatives

ENVIRONMENTAL RESOURCE	PROPOSED PROGRAM[1]	NO-PROJECT—CONTINUED OPERATIONS SCENARIO	NO-PROJECT—NO ADDITIONAL ACTIVITIES SCENARIO	MODIFIED SSIA	ACHIEVE SPFC DESIGN FLOW CAPACITIES	ENHANCE FLOOD SYSTEM CAPACITY

Source: Data compiled by AECOM in 2012

Notes:
[1] Impact categories listed for the proposed program provide the most severe impact category identified for the environmental issue area. If there are one or more significant and unavoidable impacts, then "Significant and unavoidable" or "Potentially significant and unavoidable" is placed in the column. If the most severe impact within the environmental issue area is "Less than significant after mitigation," then this designation is placed in the column. If every impact for the environmental issue area is less than significant, then "Less than significant" is placed in the column.

Key:
SPFC = State Plan of Flood Control
SSIA = State Systemwide Investment Approach

ES.9 Next Steps for the PEIR

The DPEIR is available for public review and comment for 45 days. Written comments must be received at the physical or e-mail address below no later than the close of business (5 p.m. Pacific time) on Friday, April 20, 2012:

Mary Ann Hadden, Staff Environmental Scientist
DWR, DFM
c/o MWH
3321 Power Inn Road, Suite 300
Sacramento, CA 95826
(916) 574-1431
DPEIRcomments@water.ca.gov

Please include "Comments on the March 2012 CVFPP DPEIR" in the subject line of e-mail or paper comments submitted.

All documents referenced in the DPEIR are available at MWH, 3321 Power Inn Road, Suite 300, Sacramento, California. The DPEIR is available on the following Web site where it may be viewed or downloaded: http://www.water.ca.gov/cvfmp/documents.cfm.

The DPEIR schedule is presented below, with public hearings indicated in italics.

Public Release Date of DPEIR	March 6, 2012
Public Hearing—Sacramento, Resources Building, Auditorium, 1416 Ninth Street	April 5, 2012 – 2 p.m.
Public Hearing—Marysville, Yuba County Government Office, Board of Supervisors Boardroom, 915 8th Street	April 6, 2012 – 2 p.m.
Public Hearing—Stockton, San Joaquin County Robert J. Cabral Agricultural Center, 2101 E. Earhart Avenue	April 9, 2012 – 2 p.m.
Public Hearing—Woodland, Yolo County Board of Supervisors Building, 625 Court Street	April 11, 2012 – 2 p.m.
End of 45-day DPEIR Public Comment Period	April 20, 2012 – 5 p.m.

Impact VIS-1 (NTMA & LTMA): *Temporary, Short-Term Construction-Related Changes in Scenic Vistas, Scenic Resources, and Existing Visual Character*	LTS		N/A	LTS	
Impact VIS-2 (NTMA & LTMA): *Degradation of Scenic Vistas, Scenic Resources, and Existing Visual Character Resulting from Conveyance-Related Management Activities*	LTS		N/A	LTS	
Impact VIS-3 (NTMA & LTMA): *Degradation of Scenic Vistas, Scenic Resources, and Existing Visual Character Resulting from Storage-Related Management Activities*	LTS		N/A	LTS	
Impact VIS-4 (NTMA & LTMA): *New Sources of Substantial Light and Glare*	PS		Mitigation Measure VIS-4 (NTMA & LTMA): *Establish and Require Conformance to Lighting Standards, and Prepare and Implement a Lighting Plan* Not all measures listed below may be applicable to each management action. Rather, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action. The project proponent will ensure that the following measures are implemented where project activities occur in the vicinity of sensitive light receptors to reduce potentially significant adverse effects associated with light and glare: • If construction lighting is needed, contractors will be required to shield or screen lighting fixtures and direct lights downward onto the work site and prevent significant light spill onto adjacent properties. • Contractors will place and direct flood or area lighting needed for construction activities or for security so as not to significantly disturb adjacent residential areas, passing motorists, or other light-sensitive receptors. • The use of harsh mercury vapor, low-pressure sodium, or fluorescent bulbs or light fixtures that are of unusually high intensity or brightness will be prohibited unless there is no practicable alternative. • Where applicable and practicable, lighting fixtures will meet lighting standards of the local jurisdiction. Design features that will reduce the effects of nighttime lighting, namely directional shielding for all substantial light sources, will be included in the project designs. In addition, the use of automatic shutoffs or motion sensors for lighting features will be considered in the project designs to further reduce excess nighttime lighting. All nighttime lighting will be shielded to prevent the light from shining off the surface intended to be illuminated. • Materials with natural colors and low-reflection materials will be used on all new or replacement structures to the extent feasible so that the facilities appear more consistent with the existing character of the area and do not generate excessive glare. 3.3 Agriculture and Forestland Resources					

Impact AG-1 (NTMA & LTMA): *Conversion of Substantial Amounts of Important Farmland to Nonagricultural Uses and Conversion of Land under Williamson Act Contracts to an Inconsistent Use Resulting from Conveyance-Related Management Activities*	PS		Mitigation Measure AG-1a (NTMA & LTMA): *Preserve Agricultural Productivity of Important Farmland to the Extent Feasible*
			
			In a May 4, 2005, memorandum to California Resources Agency departments, boards, and commissions, the Secretary stated that "in selecting and developing resource-related projects, departments under the Resources Agency should consider ways to reduce effects on productive agricultural lands" and encouraged departments to incorporate, where appropriate, the strategies identified in the CALFED Bay-Delta Program (CALFED) EIR to reduce the impact of the CALFED Ecosystem Restoration Program on agricultural land and water use.
			
			The measures listed below include the applicable strategies identified in the CALFED EIR and some additional measures. Not all measures listed below may be applicable to each management action. Rather, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action.
			
			The project proponent will ensure that the following measures are implemented as applicable to reduce effects and preserve agricultural productivity on Important Farmland:
			• Site projects and project footprints to minimize the permanent conversion of Important Farmland to nonagricultural uses.
			• Identify and implement project design features that will benefit flood management, agriculture, and natural resources.
			• When selecting sites and methods for repair, reconstruction, and improvement of flood control facilities, minimize the splitting or fragmentation of parcels that are to remain in agricultural use.
			• Maximize contiguous parcels of agricultural land of a size sufficient to support their efficient use for continued agricultural production.
			• Where the construction or operation of a facility could limit access to ongoing agricultural operations, maintain a means of reasonably convenient access to these agricultural properties as part of project design, construction, and implementation.
			• At borrow sites to be returned to agricultural production, remove and stockpile, at a minimum, the upper 2 feet of topsoil and replace the topsoil after project completion as part of borrow site reclamation. Borrow site reclamation for agricultural production will also take into account the potential unique characteristics of soils for production of certain crops (e.g. clay pan soils for rice).
			• In areas permanently disturbed by program activities, and where topsoil is removed as part of project construction (e.g., stripping topsoil under a levee foundation) and not reused as part of the project, make the topsoil available to less productive agricultural lands that could benefit from the introduction of good-quality soil. By agreement between the project proponent or landowners of affected properties and the recipient(s) of the topsoil, the recipient(s) would use the topsoil for agricultural purposes.
			• Relocate and/or replace wells, pipelines, power lines, drainage systems, and other infrastructure that are needed for ongoing agricultural uses and would be affected by project construction or operation.
			• Minimize disturbance of Important Farmland and continuing agricultural operations during construction by implementing the following measures:
			   ◆ To the extent possible, locate construction laydown and staging areas on sites that are fallow, already developed or disturbed, or to be discontinued for use as agricultural land.
			   ◆ Use existing roads to access construction areas to the extent possible.
			• Coordinate with growers to develop appropriate construction practices to minimize construction-related impairment of agricultural productivity. Practices may include coordinating the movement of heavy equipment and implementing traffic control measures.
			• Support the testing and application of alternative crops (i.e., agroforestry or energy crops) on idle farmland.
			• Before an NTMA [or LTMA] is implemented, search the CNDDB to determine whether sensitive communities, habitats, and species observation records may be present in or near the project area. These communities, habitats, and species occurrences will be identified, mapped, and quantified as deemed appropriate. The project proponent, assisted by the primary engineering and construction contractors, will coordinate with a qualified biologist to ensure that implementation of NTMAs [or LTMAs] minimizes direct and indirect disturbance of sensitive communities, habitats, and species to the extent feasible. In consultation with USFWS and DFG, the project proponent will develop measures to minimize and, where appropriate, compensate for construction-related effects on sensitive communities, habitats, and species.

	NTMAs	LTMAs		NTMAs	LTMAs

			Mitigation Measure AG-1b (NTMA & LTMA): *Minimize Impacts on Williamson Act–Contracted Lands, Comply with Government Code Sections 51290–51293, and Coordinate with Landowners and Agricultural Operators*
			
			The project proponent will consider the following mitigation measures and implement them, as applicable, to reduce effects on lands under Williamson Act contracts:
			• The project proponent will comply with applicable provisions of California Government Code Sections 51290–51295 with regard to acquiring lands under Williamson Act contract. Sections 51290(a) and 51290(b) specify that State policy, consistent with the purpose of the Williamson Act to preserve and protect agricultural land, is to avoid locating public improvements and any public utilities improvements in agricultural preserves, whenever practicable. If such improvements must be located within a preserve, they will be located on land that is not under contract, if practicable.
			• More specifically, the project proponent will comply with the following basic requirements stated in the California Government Code:
			  ◆ Whenever it appears that land within a preserve or under contract may be required for a public improvement, DOC and the city or county responsible for administering the preserve must be notified (Section 51291(b)).
			  ◆ Within 30 days of being notified, DOC and the city or county must forward comments, which will be considered by the proponent of the public improvement (Section 51291(b)).
			  ◆ A public improvement may not be located within an agricultural preserve unless findings are made that (1) the location is not based primarily on the lower cost of acquiring land in an agricultural preserve and (2) for agricultural land covered under a contract for any public improvement, no other land exists within or outside the preserve where it is reasonably feasible to locate the public improvement (Sections 51291(a) and 51291(b)). If the land is acquired for the purpose of flood damage reduction measures, the project proponent(s) is exempt from the findings required in California Government Code Section 51292 (Section 51293(e)(1)).
			  ◆ The contract is normally terminated for lands acquired by eminent domain or in lieu of eminent domain (Section 51295).
			  ◆ DOC must be notified within 10 working days upon completion of the acquisition (Section 51291(c)).
			  ◆ DOC and the city or county must be notified before completion of any proposed work of any significant changes related to the public improvement (Section 51291(d)).
			  ◆ If, after acquisition, the acquiring public agency determines that the property would not be used for the proposed public improvement, DOC and the city or county administering the involved preserve must be notified before the land is returned to private ownership. The land will be reenrolled in a new contract or encumbered by an enforceable restriction at least as restrictive as that provided by the Williamson Act (Section 51295).
			• The project proponent will coordinate with landowners and agricultural operators to sustain existing agricultural operations, at the landowners' discretion, until the individual agricultural parcels are needed for project construction.		

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
			Mitigation Measure AG-1c (NTMA & LTMA): *Establish Conservation Easements Where Potentially Significant Agricultural Land Use Impacts Remain after Implementation of Mitigation Measures AG-1a (NTMA) and AG-1b (NTMA)* As discussed in Mitigation Measures AG-1a (NTMA) and AG-1b (NTMA), in general, where there is a reduction or termination of agricultural activities to undertake flood protection, environmental protection, or other conservation measures, project proponents should consider other measures before considering purchasing easements or other measures of compensation (collectively referred to as "easements" below). If after implementing all other applicable measures, the proposed project could still result in a potentially significant environmental impact, easements should be considered. Easements are most likely appropriate where there would be serious degradation or elimination of the physical conditions or natural processes that provide the land's resource qualities for agriculture. In this situation, there would normally also be other impacts on the environment. Where easements are applicable, the following factors will be considered: • Where easements are considered for other resources such as terrestrial biological resources, purchase of easements should be coordinated where possible so that agricultural resources are also addressed. For example, if it were determined that a project would permanently terminate agricultural activities on a piece of land that served as Swainson's hawk foraging habitat, if an easement on another property were determined appropriate to address losses of Swainson's hawk foraging habitat, the replacement land could also support the same kind of agricultural activity as the original converted property. • Applicable methods established in the area of the specific project activity will be considered. Methods for compensation may include but are not limited to establishing agricultural conservation easements, paying in-lieu fees toward agricultural conservation easements, supporting agricultural land trusts, and participating in habitat conservation plans or natural communities conservation plans that include conservation of agricultural lands. The appropriate ratio of purchase or establishment of agricultural conservation easements relative to conversion of Important Farmland will be established on a case-by-case basis for each project. Depending on the specifics of the impact, available agricultural conservation programs in various locations, and local or regional regulatory standards, there are some circumstances where less than a 1-to-1 compensation ratio may be appropriate, and other circumstances where greater ratios may be required. Where conservation easements are established by the project proponent, they may be held by land trusts, local governments, or other appropriate agencies that are responsible for ensuring that these lands are maintained in agricultural use. When determining whether effects on agricultural land warrant purchase of an easement, the following factors should be considered: • Whether the change would affect the use of the land for agricultural purposes (i.e., ceasing agricultural activities and allowing land to be fallowed or be used for resource restoration in such a way that land could be returned to agricultural production) • Whether the change would permanently take land out of production (i.e., depositing sediment on agricultural lands) • Whether the land could be used for agricultural production but has not been or is not likely to be able to be used for such purposes because of flooding, bad soils, lack of dependable water supplies, or other reasons • Whether the land is currently being used for agricultural production and would not be able to be used for similar purposes in the future because of the project, but the project would provide benefits to nearby or other land that could be or is being used for agricultural purposes • Whether the land is currently being used for agricultural production and would not be able to be used for similar purposes in the future because of the project, but the land is not Prime Farmland, Unique Farmland, or Farmland of Statewide Importance • Whether the land is currently being used for agricultural production and would not be able to be used for similar purposes in the future because of physical changes brought about by the project, and the land is Prime Farmland, Unique Farmland, or Farmland of Statewide Importance • Whether thse land would be converted to a use that would reduce ancillary environmental benefits

3.4 Air Quality					

Impact AQ-1 (NTMA & LTMA): *Construction-Related Emissions of Criteria Air Pollutants and Ozone Precursors Resulting from Conveyance and Other Components that Could Exceed Local CEQA Thresholds of Significance*	PS		Mitigation Measure AQ-1 (NTMA & LTMA): *Implement Measures to Reduce Construction-Related Emissions*
			
			The following measures will be considered during project-level evaluation of specific management actions. Not all measures listed below may be applicable to each management action. Rather, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action.
			
			The mitigation measures described below are grouped according to whether they address construction in general, fugitive dust emissions, or exhaust emissions.
			
			GENERAL CONSTRUCTION MITIGATION
			The following measures are designed to reduce all construction-related emissions:
			• Comply with and implement applicable air district rules and regulations that pertain to construction activities (e.g., asphalt ROG requirements, administrative requirements, fugitive dust management practices). As applicable, implement construction-related requirements from air districts or local governments with authority over the project at the commencement of and during each construction activity.
			• Do not use open burning to dispose of any excess materials generated during site preparation or other project activities.
			
			FUGITIVE DUST EMISSIONS
			The following measures may be used to reduce fugitive dust emissions:
			• Submit a dust control plan to the local air district, and obtain approval of the plan before the grading permit is issued. Implement the plan during construction. The dust control plan will specifically identify measures that would demonstrate that earth-moving activities in areas of the site would comply with applicable requirements of the local air district.
			• Phase long-duration construction activities to reduce the size of the disturbed area at any given time.
			• Water all exposed surfaces three times a day or sufficiently to prevent visible dust emissions from exceeding 20 percent opacity beyond the construction boundaries.
			• Apply water, nontoxic chemical stabilizers, or dust suppressants or use tarps or other suitable material (e.g., vegetative ground cover) in all disturbed areas that will not be used for 10 days or more.
			• Suspend excavation and grading activities when winds exceed 15 mph.
			• Restrict the speed of construction vehicles to 15 mph on any unpaved surface.
			• Prevent carryout and trackout of fugitive dust on construction vehicles. Methods to limit carryout and trackout include using wheel washers; sweeping any trackout on adjacent public streets at the end of each workday; and lining access points with gravel, mulch, or wood chips.
			• Cover access roads within 100 feet of paved roads with a 6- to 12-inch layer of wood chips or mulch or a 6-inch layer of gravel to reduce the generation of road dust and road dust carryout onto public roads.
			• Clean up carryout and trackout using any of the following methods:
			  ◆ Manually sweeping and picking up
			  ◆ Operating a rotary brush or broom accompanied or preceded by sufficient wetting to limit visible dust emissions to 20 percent opacity
			  ◆ Operating a PM_{10}-efficient street sweeper that has a pickup efficiency of at least 80 percent
			  ◆ Flushing with water if curbs or gutters are not present and if using water would not either result in a source of trackout material, result in adverse impacts on stormwater drainage systems, or violate any National Pollutant Discharge Elimination System permit program
			• Cover or wet the filled cargo compartment of material transport trucks to limit visible dust emissions during transport, and maintain at least 2 feet of freeboard from the top of the container.
			• Clean or cover the cargo compartment of empty material transport trucks before they leave the site.
			• Install sandbags or other erosion control measures on sites with a slope greater than 1 percent to prevent runoff of silt to public roadways.
			• Limit the number of areas subject to excavation, grading, and other ground-disturbing activities at any given time.
				PSU	

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
			EXHAUST EMISSIONS The following measures may be used to reduce exhaust emissions: • Develop a comprehensive construction-activity management plan to minimize the amount of large construction equipment operating at any given time. • Implement a shuttle service to and from retail services and food establishments during lunch hours, or employ a catering service to bring lunch to the project site. • Use diesel-powered construction equipment that meets CARB's 1996 or newer certification standard for off-road heavy-duty diesel engines. • Schedule construction truck trips during nonpeak traffic hours to reduce peak-hour emissions and traffic congestion to the extent feasible. • Use alternative-fueled (e.g., compressed natural gas (CNG), liquefied natural gas (LNG), propane, biodiesel) or electricity-powered construction equipment, where feasible. Project-specific analysis should confirm that using any alternative fuel would not increase NO_x emissions. • Install diesel oxidation catalysts, catalyzed diesel particulate filters, or other applicable air district–approved emission reduction retrofit devices where feasible. • Use the newest equipment available to try to maintain a Tier 1 fleet equipment average. The following measures from Mitigation Measure CLM-1a (NTMA) in Section 3.7, "Climate Change and Greenhouse Gas Emissions," could help to further reduce exhaust emissions of criteria air pollutants and ozone precursors: • *BMP 6.* Minimize idling time by requiring that equipment be shut off after 5 minutes when not in use (as required by the State airborne toxics control measure (Title 13, Section 2485 of the California Code of Regulations)). Provide clear signage that posts this requirement for workers at the entrances to the site and provide a plan for the enforcement of this requirement. • *BMP 7.* Maintain all construction equipment in proper working condition and perform all preventative maintenance. Required maintenance includes compliance with all manufacturer's recommendations, proper upkeep and replacement of filters and mufflers, and maintenance of all engine and emissions systems in proper operating condition. Maintenance schedules shall be detailed in an air quality control plan prior to commencement of construction. • *BMP 8.* Implement a tire inflation program on jobsite to ensure that equipment tires are correctly inflated. Check tire inflation when equipment arrives on-site and every 2 weeks for equipment that remains on-site. Check vehicles used for hauling materials off-site weekly for correct tire inflation. Procedures for the tire inflation program shall be documented in an air quality management plan prior to commencement of construction. • *BMP 9.* Develop a project-specific ride share program to encourage carpools, shuttle vans, transit passes, and/or secure bicycle parking for construction worker commutes.		
Impact AQ-2 (NTMA & LTMA): *Potential for Construction-Related Emissions of Criteria Air Pollutants and Ozone Precursors Resulting from Storage-Related NTMAs [& LTMAs] to Exceed Local CEQA Thresholds of Significance*	LTS		N/A	LTS

Impact AQ-3 (NTMA & LTMA): *Potential for Long-Term Operational and Maintenance-Related Emissions of Criteria Air Pollutants and Ozone Precursors to Exceed Local CEQA Thresholds of Significance*	LTS	PS	**Mitigation Measure AQ-3 (LTMA):** *Implement Measures to Reduce Operational Emissions* The following measures will be considered during project-level evaluation of specific management actions. Not all measures would be applicable to each management activity. Rather, these measures serve as an overlying mitigation framework to be used when individual projects are evaluated. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action. The following measures may be implemented to reduce exhaust emissions from vehicles and equipment where operations and maintenance activities for specific projects exceed applicable emissions thresholds: • Develop and implement a comprehensive maintenance-activity management plan to miniize the amount of vehicle travel associated with maintenance actions. • Develop and implement a worker trip reduction plan to achieve average vehicle ridership of 1.5 persons or greater where applicable. • Maintain all equipment (including maintenance trucks) to the manufacturers' specifications. The equipment should be checked by a certified mechanic on a regular basis. • Minimize idling time either by shutting off equipment when it is not in use or by reducing the time of idling to no more than 5 minutes. Provide clear signage regarding idling at locations visible to maintenance staff. • Schedule maintenance trips during nonpeak traffic hours to reduce peak-hour emissions and traffic congestion to the extent feasible. • Use alternative-fueled (e.g., CNG, LNG, propane), electricity-powered, or catalyst-equipped diesel vehicles where feasible. The following measures from Mitigation Measure CLM-1b (NTMA) in Section 3.7, "Climate Change and Greenhouse Gas Emissions," could help to further reduce operational emissions of criteria air pollutants and ozone precursors: • Implement all current standards and/or requirements as part of any DWR sustainability plan or guidelines. • Use renewable energy generated on site (i.e., solar, wind, hydroelectric) where feasible. • Use alternative fuels for maintenance vehicles and equipment. • Use energy-efficient equipment for operation and maintenance of proposed facilities (e.g., pumps, hydraulic equipment, maintenance equipment). Equipment and operation of equipment will conform to U.S. Department of Energy best practices, Consortium for Energy Efficiency initiatives and guidance, and National Electrical Manufacturers Association standards where feasible. • Require proposed buildings to exceed California Building Standards Code Title 24 energy efficiency standards by 20 percent or more. <tr><td>Impact AQ-6 (NTMA & LTMA): Potential Construction-Related Exposure of Sensitive Receptors to Substantial Pollutant Concentrations through Diesel PM and Naturally Occurring Asbestos or Potential Generation of Substantial Concentrations of TACs during Operations</td><td colspan="2">PS</td><td>Mitigation Measure AQ-6 (NTMA & LTMA): Implement Strategies to Protect Sensitive Receptors from Substantial Construction-Related Emissions of Naturally Occurring Asbestos

Not all measures listed below may be applicable to each management action. Rather, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action.

It will be assumed that any construction within one-half mile of State-identified NOA areas is operating in serpentine or ultramafic rock and will comply with all requirements outlined in CARB's Asbestos Air Toxic Control Measures for Construction, Grading, Quarrying, and Surface Mining Operations. These requirements include all of the following:
Prepare and implement an asbestos dust mitigation plan, which must be approved by the local air district before construction begins and must be implemented at the commencement and maintained throughout the duration of construction and grading activities in known NOA areas.
Prepare and implement an asbestos health and safety program in known NOA areas, if required under California Code of Regulations Title 8, Section 1529(4), Asbestos.
The asbestos dust mitigation plan, as required by Title 17, Sections 93105(e)(2) and 93105(e)(4) of the California Code of Regulations, will identify dust mitigation practices that are sufficient to ensure that no equipment or operations emit dust that is visible and crossing property lines. The plan will also identify trackout prevention and control measures, control measures for disturbed surface areas and storage piles that would remain inactive for more than 7 days, postconstruction stabilization measures, and asbestos monitoring measures, if required. Examples of these measures include wetting, covering, or crusting the surface; applying chemical dust suppressants or stabilizers; installing wind barriers; enforcing speed limits in construction areas; controlling truck spillage; and establishing vegetative covers. In addition, the asbestos dust mitigation plan will include recordkeeping and reporting requirements that will be used to document the results of any air monitoring, geologic evaluation, and asbestos bulk sampling.

The asbestos health and safety program will be implemented if permissible exposure limits for airborne asbestos are found to be exceeded within the study area. Implementation will include applicable measures to protect construction employees as defined under Title 8, Section 1529(g) of the California Code of Regulations, and any additional measures required by the California Occupational Safety and Health Administration to reduce exposure of construction employees to airborne asbestos.</td><td colspan="2">LTS</td></tr>

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
Impact BIO-A-2 (NTMA & LTMA): *Effects on Special-Status Fish, Fish Movement, Nursery Ground Usage, Riparian Habitat, Designated Critical Habitat, and Essential Fish Habitat Caused by Loss of Overhead Cover and Instream Woody Material as Part of the Vegetation Management Strategy*	PS		**Mitigation Measure BIO-A-2a (NTMA & LTMA):** *Secure Applicable State and/or Federal Permits and Implement Permit Requirements* Not all measures listed below may be applicable to each management action. Rather, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action. The project proponent will ensure that the following measures are implemented to reduce the effects of repairing, reconstructing, and improving levees on trees within stream zones, shaded riverine aquatic habitat, IWM, listed fish species, and designated critical habitat: • A Section 1602 streambed alteration agreement will be obtained from DFG before any trees are removed from a stream zone that is under DFG jurisdiction unless the activity is implemented by USACE. The project proponent will comply with all terms and conditions of the streambed alteration agreement, including measures to protect habitat or to restore, replace, or rehabilitate any habitat. • The project proponent will consult or coordinate with USFWS and NMFS as required under the federal ESA, and with DFG as required under the CESA, regarding potential impacts on listed fish species, including the loss of habitat. The project proponent will implement any additional measures developed through the ESA and CESA consultation processes, including the conditions of Section 7 biological opinions, Section 10 HCPs, and Section 2081 permits. Where an existing approved HCP, NCCP, or similar plan covers an NTMA [or LTMA] and provides for compliance with applicable State or federal regulations, the project proponent may participate in and comply with the terms of such a plan to achieve the permit compliance measures listed above. Any mitigation plantings in the floodway will not be permitted if they would result in substantial increases in flood stage elevations, or alter flows in a manner that would have a substantial adverse effect on the opposite bank. **Mitigation Measure BIO-A-2b (NTMA & LTMA):** *Ensure Full Compensation for Losses of Riparian Habitat Functions and Values Caused by Implementing the Vegetation Management Strategy Along Levees* DWR will coordinate with the Board and levee maintenance agencies tasked with implementing the vegetation management strategy to develop and implement a plan to record data on riparian vegetation lost or removed due to implementation of the vegetation management strategy, and to ensure adequate compensation for losses of riparian habitat functions and values. Although this mitigation measure is written as if a single plan is prepared, multiple plans addressing individual regions, watersheds, river corridors, or other geographic subdivisions are also acceptable. The plan will be completed and suitable for implementation before the start of riparian habitat removal under the vegetation management strategy. The plan will include mechanisms to, at a minimum, record and track the acreage, type, and location of riparian habitat to be removed through implementation of the vegetation management strategy or lost over time through LCM. The plan will also address compensation for the loss and degradation of riparian habitat through the enhancement, restoration, or creation of riparian habitat in other locations. Assessment of the value of lost or degraded habitat and of compensation habitat will take into account issues such as the differing functions of waterside and landside riparian habitat, continuity and connectivity of habitat, types of riparian habitat removed vs. type of compensation habitat (e.g., riparian scrub vs. cottonwood riparian forest), and ability of habitat to support special-status species. DWR will track habitat compensation efforts and only authorize implementation of vegetation removal under the vegetation management strategy at a rate and in locations consistent with the volume and type of compensation habitat that has been established. This habitat compensation tracking program will be included in the program MMRP prepared to support this PEIR. The plan must, at a minimum, meet the following basic performance standard: • Authorized losses of habitat do not exceed the function and value of available compensation habitat. DWR will coordinate with USFWS, NMFS, and DFG during preparation and implementation of the plan to incorporate into the plan appropriate compensation for effects on special-status species from vegetation management along the levee system. Various mechanisms may be employed to provide compensation habitat under the plan, as long as the performance standard identified above is met. The mechanisms include but are not limited to the following: • Implementation of the CVFPP Conservation Strategy Framework • Participation in existing NCCPs, HCPs, or other conservation plans • Purchase of habitat credits at an established mitigation bank • Habitat restoration implemented by a levee maintenance agency or other entity Any mitigation plantings in the floodway will not be permitted if they would result in substantial increases in flood stage elevations, or alter flows in a manner that would have a substantial adverse effect on the opposite bank	PSU	

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
Impact BIO-A-3 (NTMA & LTMA): *Effects on Special-Status Fish, Fish Movement, Nursery Ground Usage, Riparian Habitat, Designated Critical Habitat, and Essential Fish Habitat Caused by Loss of Overhead Cover and Instream Woody Material during Construction*	S		**Mitigation Measure BIO-A-3 (NTMA & LTMA):** *Inventory and Replace Shaded Riverine Aquatic Habitat* The project proponent will require that the following measures be implemented to reduce the effects of program construction activities on special-status fish, fish movement, nursery sites, riparian habitat, designated critical habitat, and EFH. These measures may already be incorporated into the conditions of permits identified above in Mitigation Measure BIO-A-2a. • An inventory of shaded riverine aquatic habitat will be conducted before construction activities begin. Any shaded riverine aquatic habitat that is removed will be replaced, with replacement to occur on site when feasible. This includes IWM and other instream structures, overhead shade, and shallow-water habitat. • Mitigation credits may be purchased from a public or private mitigation bank approved by DFG, USFWS, and/or NMFS. The final number of credits to be purchased will be determined by agency staff. • A mitigation and monitoring plan will be developed and implemented to ensure that the proposed bank treatments and any off-site mitigation treatments fully compensate for losses of shaded riverine aquatic habitat. On-site revegetation is the preferred method of compensation, and could reduce the impact to a less-than-significant level, and even potentially to a beneficial level. If on-site compensation is not feasible, off-site mitigation will be established either before or as soon as feasible after existing vegetation is removed, or mitigation bank credits will be purchased before existing vegetation is removed. As much of the mitigation habitat as feasible will be created at or near the project site. If off-site mitigation is necessary, a location that does not currently support riparian vegetation and is capable of supporting riparian habitats will be preferred. Revegetation requirements may be accomplished as part of implementation of the CVFPP Conservation Framework. Any mitigation plantings in the floodway will not be permitted if they would result in substantial increases in flood stage elevations, or alter flows in a manner that would have a substantial adverse effect on the opposite bank.	LTS	SU
Impact BIO-A-4 (NTMA & LTMA): *Effects on Special-Status Fish, Fish Movement, Nursery Ground Usage, Designated Critical Habitat, and Essential Fish Habitat Caused by an Increase in Hydrostatic Pressure, Underwater Noise, and Vibrations during Construction*	PS		**Mitigation Measure BIO-A-4 (NTMA & LTMA):** *Conform to NMFS Guidelines for Pile-Driving Activities* Several measures may be effective in reducing potential impacts on listed fish species, either by decreasing the level of underwater sound or by decreasing the number of fish exposed to the sound. The project proponent and construction contractors will implement the following measures to the extent feasible, as construction activities and site-specific conditions allow: • Use fewer piles, smaller piles, or a different type of pile to minimize the number and/or intensity of pile hammer impacts. • Drive piles when species of concern are not present, as determined either from surveys or by known migration and use patterns for species occurring in the project area. • Use a vibratory hammer rather than an impact hammer. • Use a cushioning block between the hammer and pile. • Use a confined or unconfined air bubble curtain. • Drive piles during periods of reduced currents. Pile-driving activities at project sites will be monitored to ensure that the effects of pile driving on listed fish species are minimized. If any injury or mortality to fish is observed, DFG, NMFS and/or USFWS will be immediately notified and in-water pile driving will cease.	LTS	
Impact BIO-A-5 (NTMA & LTMA): *Effects on Special-Status Fish, Fish Movement, Nursery Ground Usage, Riparian Habitat, Designated Critical Habitat, and Essential Fish Habitat Caused by Rock Placement*	PS		**Mitigation Measure BIO-A-5 (NTMA & LTMA):** *Implement Mitigation Measures BIO-A-2a (NTMA) and BIO-A-2b (NTMA)*	PSU	
Impact BIO-A-6 (NTMA & LTMA): *Effects on Special-Status Fish, Fish Movement, Nursery Ground Usage, Riparian Habitat, Designated Critical Habitat, and Essential Fish Habitat Caused by the Increased Availability of Floodplain Habitat Generated by Setback Levees*	PS		**Mitigation Measure BIO-A-6 (NTMA & LTMA):** *Design and Implement Floodplain Habitat to Minimize Stranding* To avoid or minimize the potential for fish stranding associated with the creation of new floodplain habitat, the existing topographic and hydrologic characteristics of the floodplain will be examined to define the flooding regime, drainage patterns, water depths, and potential risks of fish stranding. Potential floodplain habitat will slope to a main channel or slough to facilitate complete drainage and avoid depressions or other low-lying floodplain features that may strand fish. Periodic recontouring (e.g., filling and excavation) of floodplain surfaces may be required to avoid stranding fish.	LTS	
Impact BIO-A-7 (LTMA): *Effects on Passage by Special-Status Fish and Fish Movement*	N/A	B	N/A	N/A	B

	NTMAs	LTMAs		NTMAs	LTMAs
3.6 Biological Resources–Terrestrial					
Impact BIO-T-1 (NTMA & LTMA): *Construction-Related Effects on Sensitive Natural Communities and Habitats*	S		Mitigation Measure BIO-T-1a (NTMA & LTMA): *Conduct Biological Resources Surveys to Quantify Sensitive Natural Communities in Project Areas, and Avoid, Minimize, and, Where Appropriate, Compensate for Construction-Related Effects* Not all measures listed below may be applicable to each management action. Rather, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action. The project proponent will ensure that applicable elements of the following measures are implemented to reduce construction-related effects of proposed NTMAs [or LTMAs] on sensitive natural communities. Where measures below call for field surveys, the project proponent may be able to rely on previous surveys that were conducted for the project area if these surveys meet the applicable agency guidelines. • Before an NTMA [or LTMA] is implemented, the CNDDB will be searched and other sources (which may include species experts, species recovery plans, and other monitoring or research studies) will be consulted to determine whether sensitive communities, habitats, and species observation records may be present in or near the project area. These communities, habitats, and species occurrences will be identified, mapped, and quantified as deemed appropriate. The project proponent, assisted by the primary engineering and construction contractors, will coordinate with a qualified biologist to ensure that implementation of NTMAs [or LTMAs minimizes direct and indirect disturbance of sensitive communities, habitats, and species to the extent feasible. In consultation with USFWS and DFG, the project proponent will develop measures to minimize and, where appropriate, compensate for construction-related effects on sensitive communities, habitats, and species. • Before an NTMA [or LTMA] is implemented and if the project so warrants, waters of the United States will be delineated according to methods established in the USACE wetlands delineation manual and Arid West Supplement (Environmental Laboratory 1987, 2008). The delineation will map and quantify the acreage of wetland habitats in the area, and will be submitted to USACE for verification. Not all projects involving construction activities may require a delineation of waters. • If wetlands are found within the proposed construction site or any other area to be disturbed, a wetland delineation report will be prepared and submitted to USACE. After USACE verifies the acreage of waters and wetlands, the project proponent will determine how many acres of waters of the United States and waters of the State would be affected by the NTMA [or LTMA]. The verified wetland delineation, field observation, and as needed, hydraulic modeling will be used to make this determination. Where feasible, impacts will be avoided and minimized by establishing a buffer around wetlands and waterways. • The project proponent will replace, restore, or enhance the acreage of all wetlands, other waters of the United States, and waters of the State that cannot be avoided and will be removed and/or degraded. Thus, the project will achieve "no net loss" of wetland functions and values, in accordance with the requirements of USACE and the Central Valley RWQCB. Wetland habitat will be restored, enhanced, and/or replaced at an acreage and location agreed upon by the project proponent, USACE, and the Central Valley RWQCB, as appropriate. The acreage, location, and methods will be determined during the Section 401 and Section 404 permitting processes, and will be based on a USACE-verified wetland delineation. Methods to be used will be approved by the agency with jurisdiction over the area. • In consultation with the appropriate resource agency (typically DFG), native woodland areas will be identified, mapped, and quantified as deemed appropriate. The project proponent, assisted by the primary engineering and construction contractors, will coordinate with a qualified biologist to ensure that construction activities of NTMAs [& LTMAs] minimize disturbance of native woodlands, including riparian habitats, to the extent feasible. Temporary fencing will be installed during construction to prevent avoidable disturbance of native trees that are located adjacent to construction areas. In consultation with DFG, the project proponent will develop measures to minimize and, where appropriate, compensate for effects on native woodlands. • Protected areas that are managed by federal, State, and local governments or agencies and private entities will be identified, mapped, and quantified as deemed appropriate. The project proponent will coordinate with the appropriate government or agency manager to minimize disturbance of the protected habitats, to the extent feasible.	LTS	

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
			Mitigation Measure BIO-T-1b (NTMA & LTMA): *Minimize Construction-Related Effects on Critical Habitat and Compensate for Unavoidable Adverse Effects* Before an NTMA [or LTMA] is implemented, USFWS-designated critical habitat in the project area will be identified, mapped, and quantified by a qualified biologist. The project proponent will consult with USFWS to develop and implement measures to avoid, minimize, and, where necessary, compensate for construction-related effects on primary constituent elements and potential adverse modification of critical habitat. Compensation would likely consist of enhancement, restoration, and/or creation of habitat types and vegetation communities that serve as primary constituent elements for the critical habitat affected. Compensation habitat would be enhanced/restored/created within the geographic range of critical habitat for the species in question.		
Impact BIO-T-2 (NTMA & LTMA): *Construction-Related Effects on Water Quality in Sensitive Natural Communities and Special-Status Species' Habitats*	LTS		N/A	LTS	
Impact BIO-T-3 (NTMA & LTMA): *Construction-Related Effects on Special-Status Plants and Wildlife*	S		**Mitigation Measure BIO-T-3a (NTMA & LTMA):** *Conduct Focused Surveys for Special-Status Plants and Wildlife, and Avoid Impacts* Not all measures listed below may be applicable to each management action. Rather, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action. The project proponent will verify whether species survey and avoidance protocols have been established for species that might be affected by the specific project, or will coordinate with the appropriate regulatory agency (e.g., USFWS or DFG) to determine an acceptable alternative method for surveying and avoiding effects on a species. To avoid effects of proposed construction activities on special-status plants and wildlife, the project proponent will ensure that the following measures are implemented before commencement of ground-disturbing activities. Where measures below call for field surveys, the project proponent may rely on previous surveys that were conducted for the project area if these surveys meet the applicable agency guidelines. If avoidance consistent with these measures cannot be achieved, the project proponent will implement the minimization and compensation measures included in Mitigation Measure BIO-T-3b described below. Where surveys for special-status species may be necessary, the project proponent may be able to rely on previous surveys that were conducted for the project area if these surveys meet the applicable agency guidelines. • The CNNDB will be searched to determine whether any records describe species observations and indicate the presence of habitat for those species in or near the project area. These habitats and species occurrences will be identified, mapped, and quantified as deemed appropriate. The project proponent, assisted by the primary engineering and construction contractors, will coordinate with a qualified biologist to ensure that disturbance of sensitive communities, habitats, and species is minimized during construction to the extent feasible. In consultation with USFWS and DFG, the project proponent will develop measures to minimize and, where appropriate, compensate for construction-related effects on sensitive habitats and special-status species. • A qualified botanist will conduct surveys for special-status plants (as listed in Table 3.6-3) with potential to occur in appropriate habitat within the project area. The surveys will follow applicable guidelines established by USFWS and/or DFG, and will be conducted at the appropriate time of year when the target species would be clearly identifiable. If no special-status plants have the potential to occur in the project area or none are found during focused surveys, no further action is required. If special-status plants are found, areas of occupied habitat will be identified. The construction contractor will avoid these areas where feasible. Temporary fencing will be installed to protect all occupied habitat that is located adjacent to construction areas but can be avoided. • A qualified biologist will conduct a survey in areas where elderberry shrubs could occur within 100 feet of construction and inundation areas. Surveys and stem counts will follow the USFWS conservation guidelines for the valley elderberry longhorn beetle (USFWS 1999). If elderberry shrubs are found, the project proponent will implement avoidance measures that are consistent with the USFWS conservation guidelines for this species (USFWS 1999). Where feasible, effects will be avoided by establishing and maintaining a 100-foot-wide buffer around elderberry plants. Where a 100-foot buffer is not feasible, effects may be minimized by providing a minimum setback, with a buffer around elderberry plants measuring at least 20 feet wide.	LTS	

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
			• Protocol surveys of all potential nesting trees and habitat in the area will be completed during the raptor nesting season (generally February 15–September 15 but may be adjusted for individual species), particularly if any construction activity is to occur during that season. Potential nesting trees and other nesting habitats (e.g., grasslands for northern harriers and burrowing owls) that are within one-half mile of proposed activity will be surveyed. To avoid the loss of active raptor nests, if the project proponent elects to remove trees suitable for nesting, the trees will be removed during the non-nesting season (generally between September 15 and February 15), to the extent practicable. Where feasible and depending on the species (particularly for Swainson's hawk), construction activities within one-quarter mile of active nests will be avoided during the raptor nesting season. Other nesting raptors may tolerate a much smaller buffer (e.g., one-tenth mile). • Surveys for other special-status wildlife listed in Table 3.6-4 with potential to occur in the project area will be conducted by a qualified biologist at the appropriate time of year when the target species would be clearly identifiable. Not all wildlife species require surveys, because their presence may be assumed based on habitat components and known locality records or they clearly will not be present in the area. USFWS and DFG will be consulted to determine for which species surveys should be conducted; appropriate species protocols will be followed. Occupied and potentially suitable habitat will be avoided where feasible by installing temporary exclusionary fencing. • If potentially suitable aquatic habitat for giant garter snake is identified, a buffer area of 200 feet will be established around the aquatic habitat, where feasible. These buffers will be indicated by temporary fencing, high-visibility flagging, or other equally effective means. • If nesting areas for pond turtles are identified, a buffer area of 300 feet will be established between the nesting site and nearby wetlands, where feasible. (The nesting site may be adjacent to wetlands or extend up to 400 feet away from wetland areas in uplands.) These buffers will be indicated by temporary fencing if construction has begun or will be established before nesting periods are ended (the period from egg laying to emergence of hatchlings is normally April to November). • Preconstruction surveys for special-status bat species will be conducted to determine the presence of roosts. When colonial roosting sites located in trees or structures must be removed, removal will occur outside of the nursery and/or hibernation seasons. Unless otherwise approved by DFG, such removal will occur during dusk and/or evening hours after bats have left the roosting site. When hibernation sites are identified on the project site, nursery and hibernation sites will be sealed before the hibernation season (November–March). Additional measures, such as monitoring and on-site mitigation roosts, will be implemented, as feasible (see H.T. Harvey & Associates 2004). • Participation in and compliance with an existing approved HCP, NCCP, or similar plan applicable to an NTMA [or LTMA] may replace the specific survey and avoidance actions listed above if all of the following conditions are met: • The existing approved HCP, NCCP, or similar plan is applicable to the NTMA [or LTMA]. • The NTMA [or LTMA] is within the permit area. • The NTMA [or LTMA] is a covered activity under the existing plan. • The plan addresses methods to identify, avoid, minimize, and compensate for effects on special-status species. Mitigation Measure BIO-T-3b (NTMA & LTMA): *If Avoiding Construction-Related Effects on Special-Status Plants and Wildlife is Infeasible, Minimize and, Where Appropriate, Compensate for Effects on Special-Status Species and Loss of Habitat* If the focused surveys described above in Mitigation Measure BIO-T-3a have been completed and avoiding effects on special-status species is infeasible, the project proponent will coordinate with the appropriate regulatory agency (e.g., USFWS or DFG) to determine acceptable methods for minimizing or compensating for effects on a species. Various minimization and compensation measures are described below. The CVFPP Conservation Strategy Framework may be a suitable source of compensation habitat. The project proponent will ensure that the following measures are implemented to minimize and compensate for effects of proposed levee improvements on special-status plants and wildlife: • If special-status plants cannot be avoided, the project proponent will coordinate with USFWS and/or DFG (depending on which agency has jurisdiction over the particular species) to determine appropriate minimization and compensation measures. Some local plans and policies, if applicable to the project being implemented, may require that the project proponent completely avoid effects on a special-status plant species or pay a fee to mitigate impacts. Where feasible and applicable, the project proponent will consult and/or coordinate with local agencies on these plans and policies. In some instances, sensitive plants may be relocated to an area approved by DFG or USFWS.		

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
			• If ground-disturbing activities are to occur within 20 feet of the dripline of an elderberry shrub, minimization and compensation measures consistent with the USFWS conservation guidelines (USFWS 1999) will be implemented. These measures include transplanting elderberry shrubs and planting compensatory elderberry seedlings and associated native plantings. • If an active raptor nest is found, a biologist, in coordination with DFG, will determine an appropriate buffer that minimizes the potential for disturbing the nest. Setbacks will be marked by brightly colored temporary fencing. Based on the coordination with DFG, no construction activities will begin in the buffer area until a qualified biologist has confirmed that the nest is no longer active or that the birds are not dependent on it. A qualified biologist will monitor construction to ensure that project activities will not substantially adversely affect the nesting pair or their young. The size of the buffer may vary, depending on the nest location, nest stage, construction activity, and monitoring results. If establishing the buffer becomes infeasible or construction activities result in an unanticipated nest disturbance, DFG will be consulted to determine the appropriate course of action. • Minimization and compensation measures for other special-status wildlife species will be developed in consultation with DFG and/or USFWS. DFG and USFWS provide standardized minimization measures for several species; for example, the giant garter snake has specific minimization measures, such as restrictions on the construction season and a requirement for biological surveys and monitoring. Participation in and compliance with an existing approved HCP, NCCP, or similar plan applicable to an NTMA [or LTMA] may replace the specific minimization and compensation actions listed above if all of the following conditions are met: • The existing approved HCP, NCCP, or similar plan is applicable to the NTMA [or LTMA]. • The NTMA [or LTMA] is within the permit area. • The NTMA [or LTMA] is a covered activity under the existing plan. • The plan addresses methods to identify, avoid, minimize, and compensate for effects on special-status species. All construction-related activities will be subject to all applicable permitting requirements. The mitigation measures described above, when combined with applicable permit requirements, must, at a minimum, meet the following basic performance standard: • Authorized losses of habitat will not exceed the function and value of available compensation habitat. DWR will also track these habitat compensation efforts as part of the MMRP for this PEIR. These measures will be designed to ensure that construction activities will not result in a substantial reduction in the population size or range of any special-status plants or wildlife. Mitigation Measure BIO-T-3c (NTMA & LTMA): *Secure Applicable State and/or Federal Permits and Implement Permit Requirements* The project proponent will ensure that the following measures are implemented to reduce construction-related effects of proposed levee or other repairs, remediation, and improvements on trees and shrubs within stream zones, listed plant and wildlife species, and wetlands: • A streambed alteration agreement, as required under Section 1602 of the California Fish and Game Code, will be obtained from DFG before any vegetation is removed from a stream zone under DFG jurisdiction unless the activity is being implemented by USACE. The project proponent will comply with all terms and conditions of the streambed alteration agreement, including measures to protect habitat or to restore, replace, or rehabilitate any habitat. • The project proponent will consult or coordinate with USFWS under the federal ESA and DFG under the CESA regarding potential impacts on listed plant and wildlife species and associated critical habitat. The project proponent will implement any additional measures developed through the ESA and CESA consultation processes, including conditions of Section 7 biological opinions and Section 2081 permits. • Before ground-disturbing activities begin on a project reach that contains waters of the United States, authorization for fill of such waters will be secured from USACE through the Section 404 permitting process. This permitting process will include providing compensatory mitigation for affected wetlands to ensure no net loss of wetland functions and values. Participation in and compliance with an existing approved HCP, NCCP, or similar plan applicable to an NTMA [or LTMA] may be used to achieve the permit compliance measures listed above if all of the following conditions are met: • The existing approved HCP, NCCP, or similar plan is applicable to the NTMA [or LTMA]. • The NTMA [or LTMA] is within the permit area. • The NTMA [or LTMA] is a covered activity under the existing plan. • The plan provides for compliance with applicable State or federal regulations.

3.7 Climate Change and Greenhouse Gas Emissions					
Impact CLM-1 (NTMA & LTMA): *Net Construction-Related and Operational Greenhouse Gas Emissions*	LTS		Mitigation Measure CLM-1a (NTMA & LTMA): *Implement Greenhouse Gas–Reducing Construction BMPs* DWR has developed preconstruction, construction, and final design BMPs for reduction of GHG emissions. These preconstruction and final design and construction BMPs are designed to ensure that individual projects are evaluated and their unique characteristics taken into consideration when determining if specific equipment, procedures, and or material requirements are feasible and efficacious for reducing GHG emissions from the project. As applicable and appropriate, the following BMPs would be applied: • *BMP 1*. Evaluate project characteristics, including location, project work flow, site locations, and equipment performance requirements, to determine whether specifications of the use of equipment with repowered engines, electric drive trains, or other high-efficiency technologies are appropriate and feasible for the project or specific elements of the project. • *BMP 2*. Evaluate the feasibility and efficacy of performing on-site material hauling with trucks equipped with on-road engines. • *BMP 3*. Ensure that all feasible avenues have been explored for providing an electrical server drop to the construction site for temporary construction power. When generators must be used, use alternative fuels, such as propane or solar, to power generators to the maximum extent feasible. • *BMP 4*. Evaluate the feasibility and efficacy of producing concrete on-site and specify that batch plants be set up on-site or as close to the site as possible. • *BMP 5*. Evaluate the performance requirements for concrete used on the project, and specify concrete mix designs that minimize GHG emissions from cement production and curing while preserving all required performance characteristics. • *BMP 6*. Minimize idling time by requiring that equipment be shut off after 5 minutes when not in use (as required by the State airborne toxics control measure, Title 13, Section 2485 of the California Code of Regulations). Provide clear signage that posts this requirement for workers at the entrances to the site and provide a plan for the enforcement of this requirement. • *BMP 7*. Maintain all construction equipment in proper working condition and perform all preventative maintenance. Required maintenance includes compliance with all manufacturer's recommendations, proper upkeep and replacement of filters and mufflers, and maintenance of all engine and emissions systems in proper operating condition. Maintenance schedules shall be detailed in an air quality control plan prior to commencement of construction.	LTS	N/A/TS

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
			• *BMP 8.* Implement a tire inflation program on jobsite to ensure that equipment tires are correctly inflated. Check tire inflation when equipment arrives on-site and every 2 weeks for equipment that remains on-site. Check vehicles used for hauling materials off-site weekly for correct tire inflation. Procedures for the tire inflation program shall be documented in an air quality management plan prior to commencement of construction. • *BMP 9.* Develop a project-specific rideshare program to encourage carpools, shuttle vans, transit passes, and/or secure bicycle parking for construction worker commutes. • *BMP 10.* Reduce electricity use in temporary construction offices by using high-efficiency lighting and requiring that heating and cooling units be Energy Star compliant. Require that all contractors develop and implement procedures for turning off computers, lights, air conditioners, heaters, and other equipment each day at close of business. • *BMP 11.* For deliveries to project sites where the haul distance exceeds 100 miles and a heavy-duty class 7 or class 8 semi-truck or 53-foot or longer box-type trailer is used for hauling, a SmartWay certified truck will be used to the maximum extent feasible. • *BMP 12.* Minimize the amount of cement in concrete by specifying higher levels of cementitious material alternatives, larger aggregate, longer final set times, or lower maximum strength where appropriate and while preserving all required performance characteristics. • *BMP 13.* Develop a project-specific construction debris recycling and diversion program to achieve a documented 50 percent diversion of construction waste. Mitigation Measure CLM-1b (NTMA & LTMA): *Implement Greenhouse Gas–Reducing Operational Practices* Incremental operational GHG emissions would likely be reduced in the near term relative to existing conditions through the replacement of older equipment, buildings, and vehicles. Even so, although Impact CLM-1 (NTMA [or LTMA]) would be less than significant, the project proponent will implement the measures listed below—where needed, feasible, and appropriate—to minimize operational GHG emissions for replacement and new CVFPP facilities associated with NTMAs [or LTMAs]. Not all mitigation measures listed below may be applicable to each management action. Rather, these mitigation measures serve as an overlying mitigation framework to be utilized for specific management actions. The applicability of mitigation measures would vary based on the lead agency, location, timing, and nature of each management action. • Implement all current standards and/or requirements as part of any DWR sustainability plan or guidelines. • Use renewable energy generated on site (i.e., solar, wind, hydroelectric). • Use alternative fuels for maintenance vehicles and equipment. • Use energy-efficient equipment for operation and maintenance of proposed facilities (e.g., pumps, hydraulic equipment, maintenance equipment). Equipment and operation of equipment will conform to U.S. Department of Energy best practices, Consortium for Energy Efficiency initiatives and guidance, and National Electrical Manufacturers Association standards where possible. • Require proposed buildings to exceed California Building Standards Code Title 24 energy efficiency standards by 20 percent or more.		
3.8 Cultural and Historic Resources					
Impact CUL-1 (NTMA & LTMA): *Potential Damage to or Destruction of Known Archaeological Resources from Ground Disturbance or Other Construction-Related Activities*	PS		Mitigation Measure CUL-1a (NTMA & LTMA): *Conduct Cultural Resource Studies and Avoid Effects on Known Archaeological Resources* To minimize potential adverse effects on prehistoric and historic-era archaeological resources, the project proponent will conduct cultural resource studies before project approval (where feasible and appropriate) to identify the presence of such resources at all project sites. Where field surveys cannot be completed before project approval, such as in locations where access permission has not been received, field surveys will be completed before ground disturbance begins. These archaeological studies and surveys will be conducted by professionals who meet the Secretary of the Interior's standards for archaeology professionals. Should resources eligible for listing in the NRHP and CRHR be identified within the study area, effects on those resources resulting from any NTMA [or LTMA] will be avoided, if feasible. Methods of avoidance may include redesigning or relocating the project, such as moving an access road around an archaeological site instead of through it. Where avoidance is not feasible, see Mitigation Measure CUL-1b (NTMA [& LTMA]) below.	LTS	

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
			Mitigation Measure CUL-1b (NTMA & LTMA): *Conduct Additional Evaluations and Recover Sufficient Data to Compensate for Damage to or Destruction of Known Archaeological Sites* If a substantial adverse change to an archaeological resource that has been determined as eligible for listing in the NRHP or the CRHR cannot be avoided, the project proponent will deploy a qualified archaeologist to conduct additional research and other tasks. These tasks will include preparing a research design; conducting additional archival and historical research, when appropriate; conducting an archaeological excavation; analyzing artifacts, features, and other attributes of the resource; and preparing a technical report documenting the methods and results of the investigation in accordance with the California Office of Historic Preservation's Guidelines for Archaeological Research Design (1991). The purpose of this work will be to recover a sufficient quantity of data to compensate for damage to or destruction of the resource. The procedures to be employed in this data recovery program will be determined in consultation with responsible agencies and interested parties, such as Native American tribes, as identified by the Native American Heritage Commission, as appropriate. The approved measures must be implemented before construction activities occur at the archaeological site. An alternative method to mitigate impacts on archaeological sites considered eligible for listing in the NRHP and CRHR is to have the primary construction contractor for the project proponent cap the site with soil, gravels, rock, or appropriate vegetation to protect the deposit. For example, sites subject to inundation and water-level fluctuations may be protected from erosion by application of a layer of gravel/rock or soil, or both. A layer of soil (i.e., sterile fill) may also be placed over a site where construction of a building is planned, such that all construction activities will occur in the fill material. For sites located in areas subject to looting, vegetation such as blackberry brambles or wild rose may be planted over the site as a useful deterrent, but only in areas where operations and maintenance of facilities would not be impaired by the deterrent vegetation. If capping an archaeological site proves necessary, the project proponent will provide the materials and labor, regularly monitor and evaluate the efficacy of the mitigation, and refresh the protection, when necessary.		
Impact CUL-2 (NTMA & LTMA): *Potential Damage to or Destruction of Previously Undiscovered Buried Archaeological Resources from Ground Disturbance or Other Construction-Related Activities*	PS		Mitigation Measure CUL-2 (NTMA & LTMA): *If Cultural Resources Are Discovered, Immediately Halt Construction and Implement an Accidental-Discovery Plan* Should cultural resources such as structural features, unusual amounts of bone or shell, artifacts, human remains, or architectural remains be encountered during construction activities, work will be suspended immediately at the location of the find and within a 50-foot radius. A qualified archaeologist will conduct a field investigation of the specific site and recommend mitigation necessary to protect or recover any cultural resource determined by the archaeologist to represent a historical resource or unique archaeological resource. Based on the archaeologist's recommendations, the project proponent will develop measures in consultation with responsible agencies and, as appropriate, interested parties such as Native American tribes. The approved mitigation must be implemented before construction activities resume at the archaeological site, as identified by the Native American Heritage Commission. All of the steps identified above will be detailed in an accidental-discovery plan developed before construction so that all parties are aware of the process that must be implemented should buried archaeological resources be uncovered during construction. Construction monitoring by a qualified archaeologist in areas determined particularly sensitive for buried archaeological remains will be implemented by project proponents when warranted, as recommended by the archaeological professional. Reasons for providing an archaeological monitor may include but are not limited to the previous identification of buried cultural deposits in the project vicinity or the previous recordation of an archaeological site that could not be recently identified on the ground surface. Furthermore, some landforms, such as mounded areas in floodplains adjacent to water courses, are more likely to be sensitive for buried resources. Large-scale projects involving a great deal of ground disturbance (e.g., lengthy levee construction) could benefit from geoarchaeological studies to determine those areas most likely to contain buried cultural deposits. Discoveries of human remains will be treated as described in Mitigation Measure CUL-5c (NTMA [& LTMA]), below.	LTS	
Impact CUL-3 (NTMA & LTMA): *Potential Damage or Disturbance to or Change in Significance of Built-Environment Resources*	PS		Mitigation Measure CUL-3a (NTMA & LTMA): *Conduct Cultural Resources Studies and Avoid Effects on Built-Environment Resources* In areas potentially containing historic resources, the project proponent will ensure that architectural history studies and surveys will be conducted by professionals who meet the Secretary of the Interior's professional standards, to identify the presence of built-environment resources within a particular project location. Should buildings or structures that are eligible for listing in the NRHP or CRHR be identified within the study area, impacts on those resources resulting from any NTMA [or LTMA] will be avoided, if feasible. Project relocation and redesign are appropriate avoidance measures. For example, should constructing a new levee require removal of a historic farmhouse, realigning the levee away from the structure would avoid a significant adverse change to the structure. If avoidance is not feasible, see Mitigation Measure CUL-3b (NTMA [& LTMA]) below.	LTS	

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
			Mitigation Measure CUL-3b (NTMA & LTMA): *Follow the Secretary of the Interior's Standards for the Treatment of Historic Properties* In some cases, completely avoiding an element of the built environment that qualifies as a historical resource or historic property may not be feasible, and the feature must be altered as part of project implementation. In such a scenario, any program-related alterations to historic-era buildings or structures, including relocations, will conform to the Secretary of the Interior's Standards for the Treatment of Historic Properties and Guidelines for Preserving, Rehabilitating, Restoring, and Reconstructing Historic Buildings (1995). The project proponent will develop and implement any plans necessary to mitigate alterations to historic properties in accordance with these standards. The plans will be submitted to the SHPO for approval before project implementation. If these standards cannot be met, see Mitigation Measure CUL-3c (NTMA) below.		
	PS		Mitigation Measure CUL-3c (NTMA & NTMA): *Record Built-Environment Resources to Historic American Buildings Survey and Historic American Engineering Record Standards* In some cases, avoiding or relocating a building or structure considered eligible for the NRHP or CRHR may not be feasible, and that resource must be demolished. These situations are expected to be rare occurrences. However, in such a scenario, the project proponent will retain a qualified architectural historian to document the affected historical built-environment resource according to Historic American Buildings Survey (HABS) or Historic American Engineering Record (HAER) standards, as appropriate. HABS and HAER documentation packages will be entered into the Library of Congress, as well as the appropriate Information Center of the California Historical Resources Information System.	PSU	
Impact CUL-4 (NTMA & LTMA): *Potential Damage or Disturbance to Traditional Cultural Properties during Ground Disturbance or Other Construction-Related Activities*	PS		Mitigation Measure CUL-4a (NTMA & LTMA): *Conduct Cultural Resources Studies and Avoid Effects on TCPs* In areas potentially containing traditional cultural properties, an ethnographer or archaeologist who meets the Secretary of the Interior's standards as a professional cultural resource specialist will consult with appropriate populations (Native Americans or otherwise) before approval of any project and identify the presence of any TCPs at the project location. Native American TCPs may be identified by an ethnographer who has worked intensively with community members (often, but not always, elders) possessed of considerable knowledge about places important to the community. Should TCPs be identified in the project area, they will be avoided by project redesign or relocation, if feasible. As an example, the proposed location of a water-monitoring device may be moved to another, still appropriate, place along a stream bed to avoid a section of the creek bank that is a TCP for medicinal plants, thereby avoiding a substantial adverse change to the resource. If avoidance is not feasible, see Mitigation Measure CUL-4b (NTMA [& LTMA]) below.	LTS	
			Mitigation Measure CUL-4b (NTMA & LTMA): *Consult with Native American Communities and Implement Appropriate Measures to Mitigate Effects on TCPs* Effects to TCPs are expected to be rare occurrences. However, where an identified TCP cannot be fully avoided by a proposed project, the project proponent will engage in early, meaningful consultation with Native American communities, as identified by the Native American Heritage Commission, to identify ways to mitigate impacts on TCPs. For example, if TCP locations that presently support plant species cultivated and harvested by Native American communities for traditional medicines and foods, or for uses such as basketry, are slated for destruction to make way for planned construction, the project proponent may work with the Native American community associated with the TCP to identify other nearby locations that can support these same plants. The project proponent can then take steps to enhance existing plant populations at those locations or provide materials and labor to cultivate new plants, with assistance from the Native American community. Working with local Native American communities to develop interpretive programs is another measure to mitigate impacts on TCPs. Programs may include developing signage, constructing visitor centers describing locations that have sacred or other special meaning to Native Americans, developing and implementing management plans for important cultural resources, or establishing conservation easements to protect culturally important places.	PSU	

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
Impact CUL-5 (NTMA & LTMA): *Potential Damage or Disturbance to Human Remains, Including Those Interred Outside of Formal Cemeteries, during Ground Disturbance or Other Construction-Related Activities*	PS		**Mitigation Measure CUL-5a (NTMA & LTMA):** *Conduct Cultural Resources Studies and Avoid Effects on Human Remains* The project proponent will ensure that archaeological and historical studies and surveys will be conducted by professionals who meet the Secretary of the Interior's standards, to identify the presence of human remains within a particular project location. Should human remains be identified within the study area, impacts on those remains resulting from any NTMA [or LTMA] will be avoided, if feasible. Project relocation and redesign are appropriate avoidance measures. For example, should construction of a new maintenance facility be proposed at a place known to contain human remains, relocation of the facility would avoid disturbing the burials. However, if avoidance is not feasible, see Mitigation Measures CUL-5b (NTMA [& LTMA]) and/or CUL-5c (NTMA [& LTMA]) below, as applicable. **Mitigation Measure CUL-5b (NTMA & LTMA):** *Relocate Known Cemeteries* The project proponent will consult with the entity (county, city, or private) that has jurisdiction over the cemetery, and with interested parties as appropriate, to identify a satisfactory place to relocate human remains that would provide protection from future disturbance. Similarly, if Native American burials are known to exist in an archaeological site, the project proponent will work with the appropriate tribe, as identified by the Native American Heritage Commission, to identify a satisfactory location for reinterment of burials in a protected location. **Mitigation Measure CUL-5c (NTMA & LTMA):** *Immediately Halt Construction If Human Remains Are Discovered and Implement a Burial Treatment Plan* Construction activities have the potential to result in unanticipated effects on buried human remains where there is no surface indication of their presence. Under these circumstances, the project proponent will adhere to the requirements described in Section 7050.5 of the California Health and Safety Code and PRC Section 5097.98: • If human remains are uncovered during ground-disturbing activities, potentially damaging excavation must halt in the area of the remains and the local county coroner must be notified. The coroner is required to examine all discoveries of human remains within 48 hours of receiving notice of a discovery on private or state lands (Health and Safety Code, Section 7050.5(b)). • If the coroner determines that the remains are those of a Native American, he or she must contact the NAHC by phone within 24 hours of making that determination (Health and Safety Code, Section 7050(c)). • In turn, under the provisions of PRC Section 5097.98, NAHC will identify a Most Likely Descendant (MLD). The MLD designated by the NAHC will have at least 48 hours to inspect the site and propose treatment and disposition of the remains and any associated grave goods. For large projects (e.g., new levee construction) or projects where a high probability of encountering human remains exists, a burial treatment plan will be developed by the project proponent in consultation with local Native American tribes before construction. During this process, all parties will be made aware of the actions required should buried Native American human remains be uncovered during construction. The plan will detail all of the activities identified above and include treatment preferences identified by the MLD. Smaller, localized projects do not require a burial treatment plan. Examples of such projects are modifications of existing facilities and projects that do not involve ground disturbance (e.g., purchases of easements, structure modifications). However, should human remains be uncovered during these project activities, treatment of the remains will strictly follow the requirements in Section 7050.5 of the California Health and Safety Code and PRC Section 5097.98. Impact GEO-3 (NTMA & LTMA): *Potential risks of Damage to Infrastructure Associated with Expansive Soils*	LTS		N/A	LTS	
Impact GEO-4 (NTMA & LTMA): *Potential Use of Septic Tanks or Alternative Wastewater Disposal Systems in Areas with Unfavorable Soils*	NI		N/A	LTS	
Impact GEO-5 (NTMA & LTMA): *Potential Loss of Availability of a Known Mineral Resource of Value*	LTS		Mitigation Measure GEO-5 (LTMA): *Minimize Loss of Mineral Resources through Siting and Design* When designing bypasses or setback levees or purchasing easements, the project proponent will consider a range of locations and configurations to minimize the potential to eliminate access to locally valuable mineral resources.	LTS	PSU
Impact GEO-6 (NTMA & LTMA): *Possible Damage to or Destruction of Unique Paleontological Resources*	PS		Mitigation Measure GEO-6 (NTMA & LTMA): *Prepare a Paleontological Resources Assessment and, If Necessary, Conduct Construction Worker Personnel Education, Stop Work If Paleontological Resources Are Encountered during Earthmoving Activities, and Implement Recovery Plan* If an NTMA [or LTMA] involves excavation in native soil (e.g., not imported fill) that has the potential to contain fossils (e.g., greater than 11,000 years old), an assessment of the paleontological sensitivity of rock formations in the excavation area will be conducted. The project proponent will retain the services of a paleontologist to perform an evaluation that includes all of the following: • A determination of the specific rock formations present at the project site • A records search of the applicable paleontological resources database to identify past fossil finds in the area • A field visit (if necessary as determined by the paleontologist) • A determination as to the paleontological sensitivity of the rock formations in areas proposed for excavation using SVP (1995) guidelines Studies conducted for past projects in the same area that meet these criteria may be used to fulfill this requirement. No further mitigation will be required for excavation activities in rock formations that are determined to be of low paleontological sensitivity. Before earthmoving activities begin for any project phase in rock units that have moderate to high paleontological sensitivity, the project proponent will retain a qualified paleontologist or archaeologist to train all construction personnel involved in earthmoving activities, including the site superintendent, regarding the following: • The possibility of encountering fossils • The appearance and types of fossils likely to be seen during construction • The proper notification procedures to follow if fossils are encountered In addition, as determined by the paleontologist in consultation with the project proponent, full-time monitoring during earthmoving activities may be required in areas of high paleontological sensitivity. If a paleontological resource potentially qualifying as unique or significant (as defined above in "Thresholds of Significance") is discovered during earthmoving activities, the construction crew will immediately cease work in the vicinity of the find and notify the project proponent. The project proponent will retain a qualified paleontologist to evaluate the resource, and if it is confirmed to qualify as a unique or significant resource, a qualified paleontologist will prepare a recovery plan in accordance with SVP guidelines (1995). The recovery plan may include but will not be limited to further field surveys in the vicinity of the find, sampling and data recovery procedures, museum storage coordination for any specimen recovered, further monitoring of earthmoving activities, and a report of findings. The project proponent will ensure implementation of the recovery plan. Construction activities can resume at locations where unique or significant paleontological resource are discovered after the resource has been recovered and moved from the work site.	LTS

Impact GRW-4 (NTMA & LTMA): *Modification of Groundwater Flows Resulting in Decreased Natural Recharge to Regional or Local Groundwater Supplies or Reduced or Delayed Local Drainage*	LTS		N/A	LTS	
Impact GRW-5 (LTMA): *Degradation of Water Quality or Adverse Rise in Groundwater Elevation as a Result of Groundwater Banking*	N/A	PS	Mitigation Measure GRW-5a (LTMA): *Develop and Implement Groundwater Management Plans or Expand Existing Groundwater Management Plans, Including Defining Basin Management Objectives, Groundwater Monitoring Plans, and Conditions under Which Corrective Actions Are Taken* Formalized groundwater management plans will be developed or expanded by the project proponent to guide management of groundwater basins where managed groundwater recharge and/or groundwater banking projects are to occur. These plans will include quantifiable basin-management objectives and groundwater monitoring plans to allow for management of the basin in a manner that minimizes adverse effects on groundwater. The plans will identify conditions to be evaluated using groundwater monitoring data and will describe corrective actions that may be taken, such as modifications to groundwater banking operations. Mitigation Measure GRW-5b (LTMA): *Conduct Phase I Environmental Site Assessments* Phase I Environmental Site Assessments will be conducted by the project proponent at all sites before groundwater banking activities begin to prevent the degradation of water quality associated with recharging water in a potentially contaminated aquifer or exposing rising groundwater to contaminated soils.	N/A	LTS
3.12 Hazards and Hazardous Materials					
Impact HHM-1 (NTMA & LTMA): *Hazards from Routine Transport, Use, or Disposal and Reasonably Foreseeable Accidental Release of Hazardous Materials*	LTS		N/A	LTS	
Impact HHM-2 (NTMA & LTMA): *Accidental Release and Use of Hazardous Materials within One-Quarter Mile of an Existing or Proposed School*	PS		Mitigation Measure HHM-2 (NTMA & LTMA): *Conduct a Site-Specific Analysis to Determine the Proximity of School Sites, Notify and Consult with Affected Schools, and Implement Storm Water Pollution Prevention Plan and Best Management Practices as Required* The project proponent will determine whether the site of any existing or proposed school is located within one-quarter mile of each site-specific NTMA or LTMA that would require construction activities. If no school sites are located within this distance, no further mitigation is required. If existing or proposed schools are located within one-quarter mile, the project proponent will notify each affected school (or the school district in which the school is located) in writing, and will consult with appropriate school or district personnel about the types of activities that would occur and their estimated timing. The project proponent will provide examples of the types of hazardous materials that could be used during proposed activities. The written notification will be provided at least 30 days before the commencement of any construction activities within one-quarter mile of the school or at least 30 days before any future project-specific CEQA document is certified or adopted, whichever is earlier. The project proponent will also be required by law to design and implement spill prevention and cleanup measures (i.e., best management practices (BMPs)) as part of the storm water pollution prevention plan (SWPPP) prepared for each site-specific NTMA or LTMA (see Section 3.13, "Hydrology," for a discussion of relevant BMPs and the SWPPP process), which would help to reduce the potential for adverse impacts during project construction.	LTS	

EIR SECTION AND IMPACT(S)	LEVELS OF SIGNIFICANCE BEFORE MITIGATION[a]		MITIGATION MEASURE	LEVELS OF SIGNIFICANCE AFTER MITIGATION[b]	
	NTMAs	LTMAs		NTMAs	LTMAs
Impact HHM-3 (NTMA & LTMA): *Exposure of People and the Environment to Existing Hazardous Materials, Including Sites on the Cortese List*	PS		Mitigation Measure HHM-3a (NTMA & LTMA): *Search for Contaminated Sites Potentially Affected by Site-Specific Projects and Avoid Contact with or Clean Up Contaminated Areas* Before construction begins on any site-specific project that involves earth-moving activities, a Phase I Environmental Site Assessment (ESA) will be completed. An existing Phase I ESA can be used to complete this requirement if it covers the project area and has been completed within 5 years of initiation of the project's environmental analysis, and land uses on the project site have not changed since completion of the Phase I ESA that would alter the potential for contamination to be present. The Phase I ESA will include a database search to determine whether site-specific work would take place within the boundary of any facilities included on the Cortese List or other recorded contaminated or potentially contaminated sites. If so, the project proponent will do one of the following: 1. Coordinate with the appropriate federal, State, or local agency to determine whether the contamination issue has been resolved by the responsible party. OR 2. Determine whether a qualified hazardous materials specialist has found, through soil and groundwater testing, that previously documented contamination would be sufficiently distant from project construction areas to ensure that the site's known hazardous materials would not be encountered or threaten the safety of construction workers, the public, or the environment. However, if evidence of existing contamination is found on the site, the nature of this contamination will be evaluated in the Phase I ESA and appropriate action will be recommended. Such action may involve further study through completion of a Phase II ESA. If the contamination is sufficient to exceed applicable regulatory thresholds, then the project proponent will ensure cleanup of the site, consistent with regulatory requirement. Cleanup of contaminated sites will be completed before construction is initiated in the contaminated location. In the case of projects that could put the contaminated site in contact with surface waters, cleanup will be completed before levees or other features are modified in a manner that would allow surface waters to reach the contaminated site. Mitigation Measure HHM-3b (NTMA & LTMA): *Locate Oil and Gas Wells and Transmission Lines Potentially Affected by Site-Specific Projects, and Coordinate with Owner/Operators to Avoid Disturbance* Before construction begins on any site-specific project, the project proponent will search appropriate State and local databases to determine whether any oil or natural gas wells or transmission pipelines are located within the specific project site. If any wells or pipelines are found, the project proponent will notify and coordinate with the owner/operators of the wells and pipelines to ensure that such facilities are properly flagged in the field and avoided during construction. Mitigation Measure HHM-3c (NTMA & LTMA): *Train Construction Workers on Hazardous Materials, Stop Work Near Contaminated Soils, and Determine and Implement an Avoidance or Cleanup Strategy* Before construction begins on any site-specific project, the project proponent will train construction workers on the potential to encounter hazardous materials and proper notification procedures. Such training will specify that work in the vicinity must cease and a qualified hazardous materials specialist must be consulted if stained or odorous soils; underground storage tanks; or abandoned or closed wells, mines, or septic systems are encountered. The project proponent will also notify the appropriate federal, State, and/or local agencies. A variety of steps may be taken at the discretion of the project proponent. Among those steps are the following: • Avoid the area containing the stained/odorous soils or infrastructure. • Perform a Phase I ESA to determine the nature, extent, and level of hazard to the public and construction workers if construction needs to occur in the exact location of the soils or infrastructure. • Clean up the area or coordinate with the owner of the affected parcel to perform cleanup activities. Should the project proponent elect to clean up activities on its own, all hazardous substances encountered will be removed and properly disposed of by a licensed contractor in accordance with federal and State regulations.	LTS

	NTMAs	LTMAs		NTMAs	LTMAs
Impact HHM-4 (NTMA & LTMA): *Creation of Safety Hazards, Including Bird Strike, in the Vicinity of a Public or Private Airstrip*	PS		Mitigation Measure HHM-4 (NTMA & LTMA): *Prepare Site-Specific Impact Assessments and, If Necessary, Coordinate with Affected Airport(s) to Prepare and Implement Wildlife Hazard Management Plan(s)* Future CEQA documents related to the proposed program will include analyses of bird strike hazards in those situations where NTMAs or LTMAs would increase the amount of bird habitat or the amount of inundated floodplain within the following distances: • 5,000 feet from airports serving piston-powered aircraft • 10,000 feet from airports serving turbine-powered aircraft • 5 statute miles from airports where the wildlife attractant may cause hazardous wildlife movement into or across the approach or departure airspace Each analysis will consider the size of the airport, the species of birds likely to be present near the proposed improvements, the proximity to any known migratory bird corridors (e.g., the Pacific Flyway), and the number of previously documented bird-strike incidents at the airport (if any). The analysis will determine whether the project-related increase in bird habitat would be substantial compared to existing bird habitat that is already present in the airport vicinity. If the results of the site-specific analysis determine that the impact would be significant, the project proponent will consult and coordinate with the affected airport operator to determine whether a wildlife hazard management plan is required. If required, the project proponent will coordinate with the affected airport to prepare and implement such a plan pursuant to 14 CFR Part 139. The wildlife hazard management plan will identify the hazardous wildlife attractants on or near the airport, the appropriate damage management techniques to minimize the wildlife hazard, and prioritize the management measures. The plan will be prepared in consultation with a wildlife biologist. Bird control techniques may include but are not limited to maintaining grass at a height of less than 8 inches, preventing growth of large emergent plants (e.g., cattails), installing barriers between water features and nearby vegetated areas, installing signs prohibiting feeding of birds, removing nesting materials, and hazing birds to discourage them from using water features.	LTS	
Impact HHM-5 (NTMA & LTMA): *Exposure to Substantial Hazard from Wildland Fires*	LTS		N/A	LTS	
Impact HHM-6 (NTMA & LTMA): *Increased Human Health Hazards Associated with Vector-Borne Diseases*	PS		Mitigation Measure HHM-6 (NTMA & LTMA): *Implement Workplace Precautions against Vector-Borne Diseases and Coordinate with and Support Local Vector Control District Programs* The project proponent will implement the following workplace precautions against vector-borne diseases at the construction sites of future site-specific projects: • Conduct construction worker personnel training that covers the potential hazards and risks associated with exposure to and protection from vector-borne diseases such as West Nile virus. Instruct personnel in the use of proper construction apparel and warn them against handling any dead animals (particularly birds) with bare hands. • Inspect work areas and eliminate sources of standing water that could provide breeding habitat for mosquitoes. For example, eliminate uncovered, upright containers that could accumulate water, and fill or drain potholes or other areas where water is likely to accumulate. • Provide insect repellent for worker use at construction sites. As recommended by the Centers for Disease Control and Prevention (CDC), the insect repellent should contain active ingredients that have been registered with EPA for use as insect repellents on skin or clothing such as diethyl(meta)toluamide (DEET) or picaridin (KBR 3023) (CDC 2010). • Notify the appropriate city or county health department about dead birds found at any project site. In addition, the project proponent will coordinate with and support local vector control districts in implementing their vector control activities at the time of future site-specific projects, as appropriate and feasible. Support will include but will not be limited to the following actions: • Inform the appropriate vector control district about implementation of site-specific projects. Provide information requested to support vector control activities along waterways affected by those site-specific projects in a manner that could increase exposure to vector-borne diseases. • Implement applicable BMPs from the DPH publication entitled *Best Management Practices for Mosquito Control on California State Properties* (DPH 2008). Impact HYD-1 (NTMA & LTMA): *Increased Erosion and Siltation from Modifying the Flood Conveyance System*	LTS		Mitigation Measure HYD-1 (LTMA): *Identify and Implement Measures to Minimize Downstream Erosion and Siltation* Before a project is approved and implemented, the project proponent will perform an analysis of the new facilities to determine whether the facility will experience or cause elsewhere an erosion or siltation problem. To the extent possible, the facility will be designed to avoid or minimize these effects. Where avoidance is not feasible, the project proponent will address any erosion or siltation impacts through bank protection measures on- or off-site depending on where the increase erosion or siltation may occur. Measures could include moving levee foundations landward away from the eroding bank, maintaining waterside vegetation, dredging to remove siltation, or installing rock revetments, riprap, or other engineered structures along the eroding banks to reduce further erosion and protect the foundation of the levee. These measures will be implemented or funded by the project proponent.	LTS

<tr><td rowspan="2">Impact NOI-1 (NTMA & LTMA): Exposure of Sensitive Receptors to Temporary and Short-Term Construction-Related Noise</td><td colspan="2">PS

(construction noise)</td><td>Mitigation Measure NOI-1 (NTMA & LTMA): Implement Noise-Reducing Construction Practices

Not all measures listed below may be applicable to each management action. Instead, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action.

The project proponent will implement the following measures during construction activities when noise-sensitive receptors are located nearby and could be subject to substantial construction noise in excess of applicable standards or substantially greater than existing conditions.
• Equipment will be operated, stored, and/or maintained as far away as practical from sensitive noise receptors.
• Construction equipment will be properly maintained per manufacturers' specifications and fitted with the best available noise suppression devices (e.g., mufflers, silencers, wraps). All impact tools will be shrouded or shielded, and all intake and exhaust ports on power equipment will be muffled or shielded.
• Equipment that is quieter than standard equipment will be used in the vicinity of sensitive noise receptors. For example, electrically powered equipment will be used instead of internal combustion equipment where use of such equipment is a readily available substitute that accomplishes program tasks in the same manner as internal combustion equipment.
• Construction equipment operating in the vicinity of sensitive noise receptors will not be left idling for extended periods between construction activities.
• To the greatest extent feasible, construction activities will limit the use of "alarms" (e.g., backup indicators) on construction equipment in the vicinity of sensitive noise receptors. One mechanism to achieve this objective is by providing adequate turning movement distance such that construction and delivery vehicles can turn around without having to operate in reverse.
• Construction equipment will be inspected before first use at a project site located near sensitive noise receptors and at least once during construction for compliance with noise reduction measures.
• To the greatest extent feasible, construction outside of normal construction hours will be minimized or avoided completely when located in the vicinity of sensitive noise receptors. Except under extreme circumstances (as in the case of construction of a slurry cutoff wall, which must be in continuous operation), construction activities will be limited to normal construction hours or hours identified in applicable local noise regulations.
• Where stationary construction equipment would result in exceedence of noise standards at a nearby sensitive receptor, temporary noise barriers will be installed where feasible between the stationary construction operation and the sensitive receptor.
• Speed limits will be established and enforced for construction traffic.</td><td colspan="2" rowspan="2">LTS</td></tr>
<tr><td colspan="2">LTS
(construction traffic noise)</td><td>Mitigation Measure NOI-1b (LTMA): Minimize Construction-Related Traffic Noise

Where the project-specific noise analysis conducted as part of CEQA review for a project indicates that noise from construction traffic could exceed applicable standards at a sensitive receptor, an additional individual traffic noise analysis will be prepared. The individual traffic noise analysis will be conducted as haul routes are determined to establish existing average noise conditions and model the noise contribution from project construction. The traffic noise analysis will take into account daily traffic volumes, fleet mixes (percentages of automobiles, medium-duty trucks, and heavy-duty trucks during daytime, evening, and nighttime hours), and vehicle speeds along designated haul-route roadways. If the individual traffic noise analysis also concludes that applicable noise standards are exceeded at a sensitive receptor, the analysis will identify additional measures to reduce noise levels at sensitive receptors and these measures will be implemented by the project proponent. Measures could include (but would not be limited to) using alternative traffic routes, splitting trips among multiple routes, or directing noisier vehicles to use less noisesensitive routes.</td></tr>

Impact NOI-2 (NTMA & LTMA): *Exposure of Sensitive Receptors to, or Generation of, Excessive Groundborne Vibration*	PS		Mitigation Measure NOI-2 (NTMA & LTMA): *Implement Vibration-Reducing Construction Practices* Not all measures listed below may be applicable to each management action. Instead, these measures serve as an overlying mitigation framework to be used for specific management actions. The applicability of measures listed below would vary based on the lead agency, location, timing, and nature of each management action. The project proponent will implement the following measures before and during construction activities that occur within 300 feet of a receptor sensitive to vibration disturbance: • A disturbance coordinator will be designated, and this person's contact information will be posted in a location near the construction site that is clearly visible to the nearby receptors most likely to be disturbed. The disturbance coordinator will manage complaints and concerns resulting from activities that cause vibrations. The severity of the vibration concern will be assessed by the disturbance coordinator and, if necessary, evaluated by a qualified noise and vibration control consultant. • Vibration monitoring will be conducted before and during construction-generated vibration activities occurring within 100 feet of historic structures. Every attempt will be made to limit construction-generated vibration levels in accordance with Caltrans's recommendations during pile driving and other groundborne noise- and vibration-generating activities in the vicinity of historic structures. • If estimated or recorded vibration levels meet or exceed levels that could damage an adjacent historic feature, the adjacent historic features will be covered or temporarily shored, as necessary, to protect them from vibrations. • For pile driving required within 100 feet of residences or other occupied structures, alternative installation methods (e.g., pile cushioning, jetting, predrilling, cast-in-place systems, resonance-free vibratory pile drivers) will be used where feasible to reduce the number and amplitude of blows required to seat the pile. If the estimated vibration levels exceed levels that could damage the structures, they will be covered or temporarily shored, as necessary, to protect them from vibrations. • Pile-driving activities conducted within 300 feet of sensitive receptors will occur during daytime hours to avoid causing sleep disturbance during evening and nighttime hours.	LTS

<tr><td>Impact REC-1 (NTMA & LTMA): Substantial Permanent Displacement of or Decreased Access to Recreational Facilities Caused by Levee Reconstruction, Improvements, or Setbacks</td><td colspan="2">PS</td><td>Mitigation Measure REC-1 (NTMA & LTMA): Replace Displaced Recreational Facilities and Access

Where recreational facilities or access must be displaced by levee reconstruction or improvements, facilities and access will be restored on site as part of the project design. If the facilities or access cannot be replaced at the project site, they will be replaced as close as possible to the original project site. Alternatively, existing facilities could be expanded to meet the demand for recreational opportunities lost with the removal of the facility at the project site, or to compensate for the loss of access resulting from project implementation. Where new facilities must be constructed or existing facilities are expanded, these actions will undergo necessary environmental review and mitigation will be implemented as appropriate. Please also see Impact Rec-6 (NTMA) below regarding environmental effects of new facilities.</td><td colspan="2">LTS</td></tr>
<tr><td>Impact REC-2 (NTMA & LTMA): Temporary Decrease in Opportunities for Recreation or Access to Recreational Facilities during Construction of Conveyance or Storage Improvements</td><td colspan="2">LTS</td><td>Mitigation Measure REC-2 (NTMA & LTMA): Minimize Construction Activities and Staging near Recreational Facilities and Time Such Activities to Avoid the High-Use Recreation Season

Where feasible, the project proponent will avoid placing construction staging areas or borrow areas near recreational facilities or popular use areas, and will avoid using key recreation access routes as access and haul routes for construction. Where avoiding facilities is not possible, construction will be scheduled to minimize temporary closure or access restrictions or other temporary adverse effects on recreation facilities. Numerous factors must be considered in the siting and timing of construction activities and selection of access and haul routes; for some projects, however, opportunities may exist to select from among several options those that would have the smallest effect on recreation
Where feasible, the project proponent will schedule construction activities to avoid the high-use recreation season for the potentially affected areas. This frequently will not be possible for major repairs or upgrades because those major construction activities typically occur during the dry season (May through October). However, in some cases it may be possible to focus construction activity during the months when recreational activity would be least affected. In addition, the project proponent will avoid scheduling construction activities on weekend days, where feasible, to help minimize effects on recreational activities.</td><td colspan="2">LTS</td></tr>

Impact REC-4 (NTMA & LTMA): *Boat Navigation Hazards and Passage Restrictions for Recreational Boat Traffic Resulting from Construction Activities Conducted from Barges in Waterways*	PS		Mitigation Measure REC-4 (NTMA & LTMA): *Maintain Safe Boat Passage and Provide Appropriate Safety Measures to Minimize Navigation Hazards Associated with Construction Equipment and Activity in Waterways* The project proponent will establish construction exclusion zones around barges and other equipment in waterways to keep boats from approaching too closely. The project proponent will follow all standard U.S. Coast Guard practices for navigation safety and communications, and will ensure that barges and other construction equipment are lit at night to avoid potential boat collisions. The objectives of this mitigation measure are to maintain safe boat passage in affected waterways to the maximum extent possible, and to minimize boat traffic delays, particularly in high-traffic areas. Stopping boat traffic may be necessary for brief periods (for example, while material or equipment is being transferred to or from a barge); however, the expectation is that with appropriate caution, boat traffic will be able to navigate past construction sites at most times. Boats may be required to reduce speeds in the vicinity of the barge for safe passage. The period of time when boat traffic must be restricted will be minimized to the extent feasible.	LTS

Impact REC-6 (NTMA & LTMA): *Environmental Effects Associated with Construction of Recreational Facilities and Access to Replace Facilities Displaced by Management Activities*	LTS		N/A	LTS	
Impact REC-7 (LTMA): *Substantial Displacement of or Decreased Access to Recreational Facilities Caused by Conveyance-Related and Other Management Activities*	N/A	PS	Mitigation Measure REC-7 (LTMA): *Replace Displaced Recreational Facilities* This mitigation measure would be similar to Measure REC-1 (NTMA) as described above, but mitigation would be required at a broader range of recreational facilities and sites, beyond those associated with levees. Specifically, mitigation would be required at reservoirs, within bypasses, and at areas outside the present flood control system (for example, where a new bypass is constructed).	N/A	LTS
3.19 Transportation and Traffic					
Impact TRN-1 (NTMA & LTMA): *Temporary Increases in Traffic from Construction Activities*	PS		Mitigation Measure TRN-1 (NTMA & LTMA): *Implement Measures to Reduce Construction Traffic* To minimize impacts on traffic circulation and roadway capacity, including emergency vehicle access, the project proponent will implement the following measures: • Require construction contractors to limit truck trips to less than 50 trips per hour on any affected roadway during the morning and afternoon or evening peak-hour periods, if feasible. • Before construction of major projects that could exceed this threshold, prepare a traffic management plan that identifies the number of truck trips, time of day for truck arrivals and departures, limits on the number of truck trips, and traffic circulation control measures. Control measures typically include advertising planned lane closures, installing warning signage, providing a flagperson to direct traffic flows when needed, and implementing methods to maintain continued access by emergency vehicles. During project construction, access to existing land uses will be maintained at all times where feasible, with detours used as necessary during road closures. • Submit the traffic management plan to the appropriate city or county public works, fire, police, and sheriff's departments for comments. • Implement the traffic management plan and feasible recommendations by the appropriate departments.	LTS	PSU
Impact TRN-2 (NTMA & LTMA): *Removal or Temporary Disruption of Current Transportation Infrastructure*	PS		Mitigation Measure TRN-2 (NTMA & LTMA): *Provide Detours for Closed or Disrupted Routes* If the effects of a project on roadways will be temporary, the project proponent will provide easily recognizable detour signs and prepare and implement a traffic management plan to minimize traffic, including bicycle, impacts, in consultation with the local transportation agency. If management actions require removal of transportation infrastructure, efforts will be undertaken to make sure that a convenient transportation alternative option is available for travel. For effects on rail lines, the project proponent will work with the respective rail owner to maintain maximum use of the line.	LTS	PSU

3.20 Utilities and Service Systems					
Impact UTL-1 (NTMA & LTMA): *Potential Disruption of Utility Service and Modification or Relocation of Utility Infrastructure from Project Construction Activities*	PS		Mitigation Measure UTL-1 (NTMA & LTMA): *Verify Utility Locations, Coordinate with Utility Providers, Prepare and Implement a Response Plan, and Conduct Worker Training with Respect to Accidental Utility Damage* Before construction begins, the project proponent and its primary contractors will coordinate with applicable regulatory agencies and utility providers to implement orderly relocation of utilities that need to be removed or relocated. The project proponent and its primary contractors will implement all of the following measures: • The appropriate agencies and affected landowners will be notified of any potential interruptions in service. • Before the start of construction, the locations of utilities will be verified through field surveys and the use of Underground Service Alert services. Any buried utility lines will be clearly marked in areas where construction activities would take place and on the construction specifications before any earth-moving activities begin. • Many of the Board's encroachment permits for utility facilities contain clauses requiring the owner to remove and/or relocate the facility at the owner's expense. If necessary, infrastructure will be removed, relocated to safer locations, or made flood resistant in coordination with all potential service providers known to have, or potentially having, utility infrastructure in the project area. • If necessary, infrastructure will be flood-proofed (e.g., raised on piers) in coordination with all transmission providers known to have infrastructure in the project area. • Before the start of construction, a response plan will be prepared to address the potential for accidental damage to a utility. The plan will identify chain-of-command rules for notifying authorities and appropriate actions and responsibilities to ensure the safety of the public and workers. The construction contractor will conduct worker education training on responding to situations when utility lines are accidentally damaged. The project proponent and its contractors will implement the response plan during construction activities. • Utility relocations will be staged to minimize interruptions in service.	LTS	
Impact UTL-2 (NTMA & LTMA): *Potential Disruption of Utility Service and Modification or Relocation of Utility Infrastructure from Project Operation*	B		N/A	B	
Impact UTL-3 (NTMA & LTMA): *Increased Generation of Solid Waste during Project Construction*	LTS		N/A	LTS	
3.21 Water Quality					
Impact SWQ-1 (NTMA & LTMA): *Temporary Construction-Related Effects on Water Quality that Would Not Cause Violations of Existing Water Quality Standards or Otherwise Substantially Degrade Water Quality*	LTS		N/A	LTS	
Impact SWQ-2 (NTMA & LTMA): *Modification of Reservoir Operations that Would Not Cause Violations of Existing Water Quality Standards or Otherwise Substantially Degrade Water Quality*	LTS		N/A	LTS	
Impact SWQ-3 (NTMA & LTMA): *Alteration of Floodplain Inundation Patterns that Could Result in Substantial Erosion and Adversely Affect Water Quality*	PS		Mitigation Measure SWQ-3 (NTMA & LTMA): *Conduct and Comply with Phase I Environmental Site Assessments* The project proponent will conduct a Phase I Environmental Site Assessment to determine the presence of any hazardous materials at all sites where new floodplain would be exposed to inundation. Project proponents of subsequent site-specific projects will implement all the recommended actions and measures identified in the Phase I Environmental Site Assessment. In addition, the project proponent will be required to comply with the federal and California endangered species acts and incorporate associated measures into the project design/planning features.	LTS	

Notes:

N/A Either impact mechanism, need for mitigation, and/or determination of significance after mitigation is not applicable

[a] Impact Significance before Mitigation
B Beneficial
NI No impact
LTS Less than significant
PS Potentially significant
S Significant
TS The impact is too speculative to make a significance determination

[b] Impact Significance after Mitigation
B The impact would be beneficial and no mitigation is required; therefore, the impact would remain beneficial.
LTS The impact would be less than significant and no mitigation is required; therefore, the impact would remain less than significant, whether or not mitigation has been provided to further reduce the impact.
SU Significant and unavoidable
PSU Potentially significant and unavoidable
TS The impact is too speculative to make a significance determination

Although some impacts are identified as significant and unavoidable or potentially significant and unavoidable in Table ES-1, these impact conclusions may or may not apply to any given project, as most projects would result in less-than-significant impacts after mitigation, but some projects may not, as described in Chapter 3.0 and summarized in Section 6.3 "Significant and Unavoidable Impacts."
